The objective of this study was to investigate effects of starter crude protein (CP) level and weaning regimen on metabolic hormone and glucose concentrations in neonatal dairy calves through 10 weeks of age. Twenty four Holstein ($n = 12$ male and 12 female) calves were assigned to one of four treatments in a 2×2 factorial arrangement consisting of 2 calf starters (16% vs. 22% CP, as-fed basis) and 2 weaning ages (4 or 8 weeks). Calves received colostrum for 3 days and then milk replacer (22% CP, 15% fat) until weaning. Milk replacer was fed at 10% of birth weight divided into 2 feedings daily until 2 weeks prior to weaning. Then replacer was reduced to 75% of original amount and fed once daily and further reduced to 50% of original amount one week prior to weaning. Beginning on day 4 calves were allowed free access to calf starter. Blood samples were collected weekly from weeks 1 through 10 prior to and 2 hours after the morning feeding. Pre-feeding samples were analyzed for insulin-like growth factor-I (IGF-I), insulin, glucagon, and glucose, while post-feeding samples were analyzed for insulin and glucose. At 2 week intervals, blood samples were collected every 15 minutes for 7.5 hours for determination of growth hormone (GH). Concentrations of plasma GH, IGF-I, insulin, glucagon, and glucose were not affected by starter CP level ($P > 0.05$). Mean plasma GH concentrations tended to be greater ($P = 0.09$) in calves weaned at 8 weeks. Plasma IGF-I concentrations increased with age ($P < 0.01$) but were not influenced by weaning regimen ($P > 0.05$). Plasma glucagon concentrations decreased with age ($P < 0.01$) and were lower in calves weaned at 8 weeks ($P < 0.05$). Glucose concentrations were greater in calves weaned at 8 weeks ($P < 0.01$). There was an interaction of weaning age by week by time relative to feeding for concentrations of insulin ($P < 0.01$) and glucose ($P < 0.05$). Post-feeding concentrations of insulin and glucose increased weekly until weaning. After weaning, concentrations of insulin and glucose, regardless of sampling time, decreased until the end of the 10 week study. While starter crude protein level did not affect hormone or metabolite concentrations, age related changes were evident in these metabolic parameters in developing neonatal calves.

Key Words: Dairy calves, Hormones, Metabolites

936 Thyrotropin releasing hormone (TRH) mediates serotonin-induced release of growth hormone. R. P. Radcliff^{*}, L. T. Chapin, K. J. Lookingland, and H. A. Tucker, Michigan State University, East Lansing, MI.

The serotonin receptor agonist, quipazine, induces secretion of growth hormone (GH) in cattle, but the mediator of this response is not known. We hypothesize that TRH mediates serotonin-induced secretion of GH. Holstein steers were injected daily with 3,3',5-triiodo-L-thyronine (T_3) dissolved in corn oil ($n=8$) to induce negative feedback on the thyrotropic axis, thereby decreasing TRH receptor expression on the anterior pituitary gland and/or TRH synthesis in the hypothalamus. Controls ($n=8$) received corn oil. Blood was collected at 20-min intervals for 6 h on days -1, 5 and 10 relative to initiation of injections to quantify basal secretion of GH. After 20 d of injections, steers were challenged every other day with an i.v. injection of growth hormone-releasing hormone (GHRH), TRH, quipazine or vehicle. Blood was collected at -60, -40, -20, 0, 5, 10, 15, 20, 30, 40 and 60 min relative to i.v. challenge and serum assayed for GH. Compared with corn oil, T_3 did not affect basal concentrations of GH in serum. As expected, GHRH increased area under the response curve (AUC) of GH similarly in corn oil- and T_3 -treated steers. Compared with vehicle, TRH increased AUC of GH in corn oil-treated (386 vs 873 \pm 95 ng \cdot ml⁻¹ min; $P > 0.01$) but not T_3 -treated steers (294 vs 609 \pm 101; ng \cdot ml⁻¹ min; $P > 0.1$). However, TRH induced AUC of GH in T_3 -treated steers was intermediate between T_3 -treated steers that received vehicle and corn oil-treated steers that received TRH. Similarly, compared with vehicle, quipazine increased AUC of GH in corn oil-treated 413 vs 1169 \pm 181 ng \cdot ml⁻¹ min; $P < 0.01$) but not T_3 -treated steers (340 vs 601 \pm 198 ng \cdot ml⁻¹ min; $P > 0.5$). Like TRH, quipazine induced AUC of GH in T_3 -treated steers was intermediate between T_3 -treated steers that received vehicle and corn oil-treated steers that received quipazine. Thus, injections of T_3 reduce but do not completely block TRH- and serotonin receptor agonist-induced secretion of GH. In conclusion, TRH mediates, in part, serotonin-induced secretion of GH in cattle.

Key Words: Cattle, Hyperthyroidism, Serotonin, Growth hormone

937 The effect of photoperiod on hepatic Growth Hormone receptor (GHR) expression in steer calves. P. E. Kendall^{*1}, T. L. Auchtung¹, K. S. Swanson¹, M. L. Bode², M. C. Lucy², J. K. Drackley¹, and G. E. Dahl¹, ¹University of Illinois, Urbana, IL, ²University of Missouri, Columbia, MO.

Photoperiod manipulation, specifically long days (LDPP), increases milk production in lactating cattle. We have previously reported that the galactopoietic effect of LDPP is associated with an increase in circulating insulin-like growth factor-I (IGF-I), which occurs independent of changes in IGF binding proteins and GH concentrations. This study tests the hypothesis that LDPP increases the expression of GHR 1A mRNA in the liver. Two groups of Holstein steers (98 \pm 4 days old) were maintained indoors and exposed to LDPP (16L:8D; $n=6$) or short day photoperiod (SDPP) (8L:16D; $n=6$) for a total of 9 weeks. The calves were fed individual rations of a grain- and alfalfa-based diet, which were adjusted for live weight. Jugular blood samples were collected at weekly intervals to determine changes in serum IGF-I by radioimmunoassay. Liver biopsies were obtained at 3-week intervals to quantify changes in hepatic GHR 1A mRNA using real time polymerase chain reaction on an ABI PRISM 7700[®] Sequence Detection System. Steer live weight increased during the study but did not differ between treatments, nor were differences in feed consumption found. Despite the variation within treatments, there was a tendency for the amount of GHR 1A mRNA to be higher ($P=0.08$) in LDPP steers on day 39 relative to SDPP steers. This would be consistent with the hypothesis that liver GHR 1A mRNA is correlated with circulating IGF-I concentrations. We conclude that changes in IGF-I secretion in LDPP cattle could be regulated by an increase in GHR 1A, but that the endocrine pathway whereby LDPP influences GHR expression remains to be elucidated.

Key Words: Cattle, Photoperiod, Growth Hormone receptor

938 Constraints on reproductive performance of indigenous cows under small holder village farming system in Bangladesh. M. Samad Khan*, *Bangladesh Agricultural University, Mymensingh.*

Indigenous cows were studied to find out the reproductive constraints under village condition of Bangladesh. Sixty seven postpartum cows were taken from 65 small holder farmers. Selected animals were used for dairy/draught purpose. Cows were supplied with rice straw based diet. Calves were allowed to free access for suckling cows during day and were tied up at night. Cows were milked once a day in the morning. Metabolic kits supplied by the Food and Agriculture Organization of the United Nations/ International Atomic Energy Agency (FAO/IAEA) were used for metabolic profile study and FAO/IAEA Radioimmunoassay (RIA) kits were used for progesterone (P4) measurement. Calving to first ovulation were calculated on the basis of first P4 rise in milk. Reproductive events were measured. Data were analyzed by 4 seasons to find out the reproductive constraints of indigenous cows. The plasma urea values (mmol/L) of the cows were 4.5, 7.2, 5.5 and 3.2 for the seasons Summer, Autumn, Winter and Spring respectively. The calving to first ovulation were 66, 67, 187 and 51 days; to first service were 272, 120, 191 and 216 days; to first conception were 263, 136, 197 and 223 days; and calving interval were 544, 419, 489 and 501 days for the seasons Summer, Autumn, Winter and Spring respectively. Among the blood metabolites studied, a considerable change in urea values were noticed. It represents an important nutritional constraints on reproduction. The Spring values were lower enough to suggest a shortage of Rumen Degradable Protein (RDP) in the ration. The calving to first service was higher than that of calving to first ovulation, that means farmers were unable to detect heat of their cows. So, heat detection was a constraint to the reproduction of indigenous cows. The calving to first service in the Autumn was much better than that in the other 3 seasons. It would be tempting to relate to the urea levels that were the highest in the Autumn. From this study two important constraints of reproduction has been identified for the indigenous cows where interventions are needed, (1) Nutritional constraints in general, mainly protein, during the Spring season and (2) Lack of knowledge of estrus detection by the farmers during the early part of lactation.

Key Words: Indigenous, Progesterone, Protein

939 True estrus determination through evaluation of serum-progesterone levels at the time of insemination of dairy cows from semi-intensive dairies in north-central Mexico. EF Ricoy¹, C Acua, RM Rincon, DF Cortes, R Bauelos-Valenzuela, and CF Arechiga*, ¹*Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

The purpose of this study was to determine which proportion of cows bred by artificial insemination (n=103), at semi-intensive dairies from north-central Mexico (La Fresnille, Zacatecas, Mexico), presented a true estrus at the time of insemination. Criteria for detection of a true estrus was based on serum-progesterone levels measured by radioimmunoassay. A blood sample was collected from tail-vein via venipuncture and serum was separated. Serum-progesterone levels lower than 1 ng/ml indicated the presence of the follicular phase of the estrous cycle and possibly the presence of a true estrus (i.e., heat); and, serum-progesterone levels greater than 1 ng/ml confirmed the presence of a luteal phase of the estrous cycle and a total absence of estrus. Results have shown that 23.3% (24/103) of inseminated cows had serum-progesterone levels above 1 ng/ml indicating the total absence of estrus (P<0.001). Thus, only 76.7% (79/103) had a chance to be in estrus or around it. Cows with serum-progesterone levels above 1 ng/ml (follicular phase) had an average of 0.092 ng/ml; whereas, cows with serum-progesterone levels above 1 ng/ml (luteal phase) had an average of 1.070 ng/ml. These results confirmed serious management problems at those dairies on estrous detection and insemination criteria that could compromise fertility, semen costs, and genetic improvement at the dairy.

Key Words: estrus, dairy cow, Mexico

940 Effect of a reduced dose of GnRH (50 µg) in a timed AI protocol used for Holstein cows from an intensive dairy at north-central Mexico. OI Gutierrez¹, RD Gonzalez¹, RR Lozano², F de la Colina¹, R Bauelos¹, E Gonzalez-Padilla², and CF Arechiga*¹, ¹*Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*, ²*Universidad Nacional Autonoma de Mexico, Mexico.*

Present study try to determine whether a reduced dose of GnRH (i.e., 50 vs. 100 µg) in a timed AI protocol (TAI) [d 0, GnRH; d 7, PGF2α; d 9, GnRH; d 10, TAI] was effective increasing pregnancy rates of dairy cows (Aguascalientes, Mexico). Dairy cows (n=120), 45 to 90 d postpartum (PP), from 1 to 7 parities, an average body condition score of 3.28, an milk yield of 25-28 kg/d (3x), were randomly assigned into two groups: 1) Control (100 µg GnRH in a TAI protocol). 2) Treated (50 µg GnRH in a TAI protocol). There were no differences in pregnancy rates to first service [19.17% (23/120) vs. 25.00% (30/120)], neither at 150 d PP [28.33% (34/120) vs. 27.50% (33/120)] or intermediate periods (60, 90, 120 d PP). There were no differences in the intervals from calving to first service and to conception; neither in services per conception. A greater proportion of cows tended to become pregnant when a medium or large follicle (10 and 15 mm, respectively), was present in the ovary at the beginning of the TAI protocol or with cows of lower milk yield (3,500-7,500 kg). A reduced dose of GnRH, reduces cost of TAI by \$5.3 dollars, and cost of TAI for pregnant cows at first service by \$17.1 dollars. In conclusion, a reduced dose of GnRH was effective to synchronize ovulation without affecting reproductive parameters. Such a lower input will allow to disseminate the use of timed AI protocols in dairy cows from developing countries.

Key Words: dairy cow, timed AI, Mexico

941 Serum-progesterone measurements to determine age at puberty and luteal function in hair sheep from a semi-arid region in north-central Mexico. A Gutierrez, W Gonzalez, RM Rincon, O Perez-Veyna, R Bauelos-Valenzuela, and CF Arechiga*, ¹*Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

Serum-progesterone measurements were performed by radioimmunoassay to determine luteal activity (i.e., greater than 1 ng/ml), maintenance of luteal function and age at the onset of puberty in hair sheep (n=17; Pelibuey Sheep) exposed to a semi-arid environment. Ewes had an average weight of 1.98 ± 0.03 at birth, and just before the six-months of age (175-185 d), they were transported to a semi-arid environment where the experiment took place, which included twice weekly determinations of serum-progesterone levels throughout 110 d. By the end of the experiment when ewes had 285 d of age and an average body-weight of 18.87 ± 0.17 kg, results have shown that 53% (i.e., 9 of 17 ewes) had serum-progesterone levels greater than 1 ng/ml at least once throughout the experimental period. But only 29% (i.e., 5 of 17 ewes) maintained luteal activity similar to an estrous-cycle pattern of progesterone secretion. Serum-progesterone levels increased significantly by the end of the experiment (P<0.05) and were correlated with body-weight increases throughout the experiment and decreased light-hours during the day (P<0.05). Average progesterone levels were 0.29 ± 0.05 ng/ml. Average daily gain was 0.080-0.150 kg/d from 0 to 285 d of age; and 0.050-0.057 kg/d from 175 to 285 d of age. In conclusion, onset of puberty in hair sheep at semi-arid regions seems to be influenced by increases in body weight and a reduction in light-hours during the day (i.e., below 12 light-hours during the day).

Key Words: Hair Sheep, Photoperiod, Mexico

942 Nutrient digestibility and nitrogen balance of growing Zimbabwean Mukota, Large White and their F1 crosses fed on diets containing graded levels of maize cobs. A.T. Kanengoni, K. Dzama*, M. Chimonyo, J. Kusina, and E. Bhebhe, *University of Zimbabwe, Harare, Zimbabwe.*

A study was conducted to compare the digestibility of organic matter (OM), neutral detergent fibre (NDF), acid detergent fibre (ADF), nitrogen (N) and hemicellulose and nitrogen balance in Zimbabwean Mukota, Large White (LW) and their F1 crosses. Four male pigs of each breed, selected at 30 percent of their mature live weights, were sequentially allocated to each of four diets. The diets, which were formulated to contain similar levels of protein (ca. 160g CP/kg) and energy (ca. 9MJ ME/kg),

contained 0, 100, 200 and 300g maize cobs/kg. There was a negative correlation ($P < 0.001$) between the digestibility of the nutrients and the level of NDF in the diet. There was a linear decrease ($P < 0.05$) in the digestibility of OM, ADF and hemicellulose with increase in the level of fibre among all the breeds. The OM, ADF and hemicellulose digestibilities, however, decreased faster ($P < 0.05$) in the LW than in the Mukota and F1 crosses as the level of maize cobs increased. Both breed and level of maize cobs had no effect on N digestibility, N retained per metabolic body weight and N retained per nitrogen intake ($P > 0.05$). The findings showed that the Mukota and the F1 crosses were better able to digest the fibrous components than the LW. In addition, the Mukota and F1 crosses displayed an ability to retain protein to the same extent as the LW.

Key Words: Zimbabwean Mukota, Nitrogen balance, Digestibility

943 Present Status of the Heifer Project International-Cameroon Rabbit Program. S. D. Lukefahr*¹, H. I. Nkwocha², H. Njaki², E. Tawah², J. M. Akob², F. A. Kongyu², and D. Gudahl³, ¹Texas A&M Univ.-Kingsville, ²Heifer Project International, Bamenda, Cameroon, ³Heifer Project International, Little Rock, AR.

In the past five years, Heifer Project International (HPI) has distributed a minimum of 2,119 rabbits to 1,410 limited-resource families in 66 villages primarily located in the northwest province of Cameroon. However, these figures exclude thousands of additional farmers who received either direct or indirect assistance by HPI since project inception in 1982. HPI's approach towards poverty alleviation is to financially support a new rabbit project for farm families in a selected village for a period of three years. Technical follow-up support is then extended for an additional two years, after which time the anticipated self-sufficient project is formally phased-out. In 1999, accompanied by HPI field staff, the consultant (the first author of this abstract) visited a total of 48 farmers from 9 villages in the northwest province. On each farm, notes were taken which identified poor to good management-level practices, housing and feeding systems, as well as socio-economic aspects of the project. HPI progress reports and case studies conducted by student interns from University of Dschang were made available to supplement the consultant's notes in developing an evaluation report. Overall, production level of rabbit fryers presently appears to be low on farms (approximately 2.45 fryers are consumed and 2.61 fryers are sold per month). Further, income generation is a critical determinant of whether rabbits will continue to be regarded by farmers as a backyard livestock species for domestic use or as a commodity species for supplemental income. HPI could play a pivotal role in developing either local or formal market outlets for their surplus fryers. To date, the HPI-CAM rabbit program has improved family nutrition, enhanced community development and gender status in villages.

Key Words: Rabbits, International Programs, Development

944 Effects of World Bank prescribed economic structural adjustment on poultry production in Nigeria and policy suggestions for the improvement of the sector. A. A. Onifade*¹, F. A. Nasiru², O.T.F. Abanikanda¹, and F. Kudah², ¹Department of Animal Science, University of Ibadan, ²Michael Stevens & Associates, 1 Tokan Street, Western Avenue, Surulere, P. O. Box 528, Apapa, Lagos.

The World Bank advised the Nigerian Government to undertake structural adjustment (SAP) of the economy, and this was commenced in June 1986 and remained until early 1990. The economic reforms involved policy reforms such as exchange rate deregulation, trade reforms, tariffs restructuring, all of which affected the macroeconomic variables such

as inflation, interest rate, employment. A nationwide study was carried out to obtain primary data using stratified random questionnaire administration and structured interviews of small-scale and organized poultry farmers, and officials of Government livestock Departments. Additional data were sourced from secondary sources. The depreciation of the Nigerian currency caused spiraling inflation and volatile interest rates, which made cost of livestock inputs especially the imported components such as feed ingredients and medicaments to soar, access to credits became difficult, producer prices rose significantly, capacity utilization and demand for animal products fell drastically, and a general decline in poultry production was noticed from 1986. The ban on importation of corn and barley caused distortion in animal feed production and led to widespread closures of poultry production facilities. There was intra-sectoral shift with more farmers moved into egg production and meat-type poultry production was targeted at festivals. There was increased utilization of alternative feedstuffs especially by-products of oil mills and tuber processing. The establishment of private veterinary services increased, but farmers complained of low-quality services and products. Quality of feedstuffs and finished feeds in the market decreased forcing most medium producers to integrate feedmilling into their production. In conclusion, the economic adjustment in the main negatively impacts on poultry production, there was policy misjudgment in banning of corn, but increased utilization of alternative feedstuffs; increased custom feedmilling, vertical integration and intra-sectoral shifts and increased accessibility to veterinary services were recorded. Policy suggestions favored concretization of national policies on poultry production, nutrition, health, research and extension.

Key Words: Economic Adjustment Program, Poultry Production, Policy Suggestions

945 Comparing the economic power of the populations of European Community (EC) and North American Treaty Countries (NAT)-1999-2010, using per adult human unit (PAHU) versus per capita (PC). S. Hasimoglu*¹, ¹Continental Analytical Services Inc., Salina, KS.

At the beginning of the new millennium EC and NAT countries became strong economic competitors. As the 15-nation EC expands during the next 10 years, competition will continue to increase. The data gathered to evaluate food production and consumption has traditionally been presented on PC basis. The use of "per capita" rarely has been challenged. Presentation of the alternative PAHU system will, however, show "per capita" as inherently erroneous. The PAHU calculation method and obtained conversion factors for the age groups showed a 21.76 percentage units (PU) difference from PC calculations in the under 20-year-old age group in equally populated developed and developing countries. PC evaluation disregards not only the younger, but also the older portions of populations. The calculated, unintended, fault level is not less than 15.86 PU when compared to PAHU. In 1999, three NAT countries had 405 million PC population, calculated as 329 million PAHU. These three countries will reach 451 million PC, or 374 million PAHU in the year 2010. In 1999 NAT had 31 and 12 million higher PC and PAHU than EC countries respectively. EC (15-nation) during same time of period will have 374 million PC, or 317 million PAHU. Since EC going to expand in the next ten years to include 11 new applicant countries (an addition of 159 million PC, or 134 million PAHU), it will reach 533 million PC, or 445 million PAHU inhabitants. Planned as an integrated economic area with a single currency, it will be the largest organized agricultural trading, production and consumption power in the world. Since PAHU replaces the word "predict" with "measure", it will not only help better redesign economic relationships throughout the world, it will influence national and international direction of obtaining precise food consumption/production measurements aimed to create a nutrition monitoring system that will standardize all nutrition intake reporting done by various agencies of both developed and developing countries.

ASAS/ADSA Physiology: Male Physiology/Conceptus Development and Survival

946 The History of Artificial Insemination: Founders and Facts. R.H. Foote*, Cornell University.

This overview will cover briefly the relevant knowledge existing when intensive studies on artificial insemination (AI) began, the problems faced, and how these were overcome. Also, some of the people who made it happen will be identified. Emphasis will be on dairy cattle, but also

beef cattle, swine, horses, sheep, goats, poultry, laboratory animals, and endangered species will be included. There are many steps that are important in AI so that maximal fertility will result when sperm are transferred from the male at one time and place to a female in estrus elsewhere. These steps include: 1) understanding and exploiting each bull's sexual behavior; 2) providing an optimal schedule and place

for semen collection; 3) using the most reliable equipment for collecting and processing semen; 4) using objective methods for evaluating semen; 5) providing optimal semen extenders and procedures for sperm preservation; 6) adopting procedures to insure protected distribution and storage of semen in the field; 7) and skillful insemination of cows properly selected for the right time to inseminate. With modification of these procedures the principles apply to all species. New methods for accurate evaluation of the genetic worth of the males selected for use in AI were needed and developed. Resistance by elements of the public to "meddling with nature", and by cattle breeders in competition for the sale of bulls, had to be overcome. But eventually AI was accepted as the greatest biotechnology ever developed and applied for the control of venereal diseases and the genetic improvement of dairy cattle. The acceptance of AI laid the foundation and opened opportunities for subsequent development of synchronized estrus, embryo transfer, sexed semen, and even cloning. Conventional AI will continue to benefit animal agriculture and human welfare as it moves into the 21st century of genomics, with marker assisted selection and genetic engineering.

Key Words: Artificial Insemination, Domestic Animals, Biotechnology

947 Effect of capacitation environment of spermatozoa on fertilization of porcine oocytes in vitro. J.M. Popwell¹ and W.L. Flowers*¹, ¹North Carolina State University.

The objective of this study was to examine the effect of the capacitation environment of porcine spermatozoa on their ability to fertilize oocytes in vitro. Semen was collected from 4 boars and processed for either in vivo or in vitro capacitation. For in vivo capacitation, 50 mL of neat semen containing 20 billion spermatozoa was used for insemination (n=18 gilts/boar). Between 6 and 16 h after insemination, uterine horns and oviducts were flushed and spermatozoa recovered from each location were classified as being exposed to a unique capacitation environment. For in vitro capacitation, the remainder of each ejaculate was washed and incubated in media for an equivalent length of time. Spermatozoa (200/oocyte) from each environment (oviduct, uterus, and in vitro) were used to fertilize oocytes (n=200/environment) in vitro. Chlortetracycline staining also was used to assess the capacitation status of spermatozoa at the time of fertilization. Boar A (15.3+/-4.7%) had fewer (P<.05) capacitated spermatozoa than boars C (32.7+/-6.7%) and D (42.1+/-6.8%). The capacitation status of sperm cells from boar B (28.1+/-9.2%) was similar (P>.15) to that observed for the other boars. In contrast, boar B (14.7+/-1.4%) produced higher (P<.05) monospermic fertilization rates in vitro than boars A (10.0+/-1.5%) and C (6.2+/-2.1%). Sperm cells from boar D (12.3+/-1.7%) fertilized more (P<.05) oocytes than those from boar C. A greater proportion (P<.05) of capacitated spermatozoa were present in vitro (40.7+/-7.1%) and in the oviducts (52.2+/-7.1%) than in the uterus (18.3+/-6.2%). However, there was no difference (P=.27) in the ability of spermatozoa from the oviductal (12.3+/-2.0%), uterine (8.7+/-2.1%), or in vitro (9.8+/-1.8%) environments to fertilize oocytes. In summary, capacitation environments of spermatozoa did not influence monospermic fertilization in vitro even though significant differences were present for the proportion of capacitated sperm cells in each environment.

Key Words: Spermatozoa, Fertilization, Swine

948 Apoptosis as a Mechanism of Germ Cell Loss in Yearling Stallions. N.L. Heninger*¹, C.L. Donnelly¹, C. Staub³, T.L. Blanchard², D.D. Varner², D.W. Forrest¹, and L. Johnson³, ¹Texas A&M Dept. of Animal Science, ²Texas A&M Dept of Veterinary Large Animal Medicine and Surgery, ³Texas A&M Dept of Veterinary Anatomy and Public Health.

In an effort to determine whether germ cell loss occurs via apoptotic mechanisms during the development of spermatogenesis, 22 testicles from 17 yearling stallions with normally developing testes (ages 11-15 mo) were weighed, cross-sectioned, fixed in 4 % paraformaldehyde, and set in paraffin. Immunohistochemical apoptotic detection was performed on 5mm sections mounted on glass slides using Apoptag peroxidase detection kit S7100 (Intergen, Purchase, NY). Tissue sections were deparaffinized and free 3-OH ends labeled (TUNEL) in situ by direct immunoperoxidase detection of digoxigenin labeled DNA. Sections were counterstained with methyl green. Two evaluators counted the total number of apoptotic cells in 50 round seminiferous tubules from both light and dark parenchyma within a single section. The frequency of tubules containing at least one apoptotic cell, as well as tubule diameter were also recorded. Light and dark tissue was classified according to

lumen score (1-5) as described in previous research. Lumen scores of 1-2 were obtained for dark parenchyma, and 3-4 for light parenchyma. No stage 5 tubules (the most mature) were seen for these young animals. More apoptotic cells per tubule were detected (P < 0.001) in light tissue (0.5 ± 0.01) when compared to dark tissue (0.06 ± 0.01). As tubule diameter increased, total number of apoptotic cells increased (r²= 0.70, P < 0.001). Light parenchyma contained a greater (P < 0.001) proportion of tubules with at least 1 apoptotic cell (23% ± 3%) when compared to dark parenchyma (5% ± 1%). It is clear that apoptosis is involved in normal progression of spermatogenesis as a means of removing germ cells from the seminiferous epithelium in pubertal stallions. Further research is needed to determine cell types typically undergoing apoptosis, as well as topographical trends in development of apoptosis during initiation of spermatogenesis.

Key Words: Apoptosis, Spermatogenesis, Stallion

949 Comparison of traits at sexual maturity of recently introduced breeds to Angus and Brahman bulls. S.R. Tatman*¹, C.C. Chase², D.A. Neuendorff¹, A.W. Lewis¹, T.W. Wilson¹, C.G. Brown¹, and R.D. Randel¹, ¹Texas Agricultural Research and Extension Center, Overton, TX 75684-0290, ²Subtropical Research Station, ARS, USDA, Brooksville, FL 34601-4672.

Reproductive development of Angus (A; n=7), Brahman (BR; n=10), Bonsmara (BO; n=8), Romosinuano (R; n=10), Tuli (T; n=14), and Wagyu (W; n=10) bulls was studied. All bulls were maintained together and fed a 3:1 (corn: soybean meal) supplement containing lasalocid. The supplement was fed at 1.5% BW with free access to coastal bermuda grass hay, water, and a salt/mineral mix. Measurements of reproductive development were taken at 14-d intervals until each bull reached sexual maturity (SM; ejaculate with at least 500 million sperm with at least 50% motility). Measurements included BW, body condition score (BCS), scrotal circumference (SC), and individual testis length. After reaching 21 cm SC, ejaculates were collected at 14-d intervals through SM via electroejaculation. Age at SM differed among breeds (P < 0.05) with BR the oldest (453±11 d), followed by A (417±13 d) and R (414±11 d) which did not differ (P > 0.10), and T (377±9 d), W (359±11 d), and BO (335±12 d). Age at SM in W and BO bulls did not differ (P > 0.10). BW at SM was greatest for BR (418±14 kg) and differed (P < 0.01) followed by A (350±16 kg), BO (336±15 kg), and R (330±13 kg). A vs T (308±11 kg) BW at SM was similar (P > 0.10) while W bulls were lightest (281±13 kg), yet similar (P > 0.10) to T. SC at SM was similar for (P > 0.10) BR (30.2±.9 cm), BO (30±.9cm), A (29.9±1 cm), R (28.5±.8 cm), and T (28.4±.7cm) while W bulls had the smallest (P < 0.05) SC at 25.9±.8 cm. A, BO and BR bulls had the greatest PTV at SM (448±36 cc, 426±33 cc, and 405±31 cc) and were similar (P > 0.10), followed by T (370±25 cc), R (351±30 cc), and W (286±30 cc). BR bulls were oldest and heaviest at SM followed by A in both categories. W bulls had the least BW, SC, and PTV at SM. Newly introduced breeds in this study performed competitively with A bulls in a subtropical environment and may play an important role in crossbreeding.

950 Comparison of adrenal and testis content of the steroidogenic acute regulatory (StAR) and P450 side-chain cleavage enzyme proteins in Angus, Brahman and Romosinuano bulls. J.W. Koch*^{1,2}, K.N. Livingston¹, S.R. Tatman², D. Alberts³, D.M. Stocco³, C.C. Chase, Jr.⁴, R.D. Randel², and T.H. Welsh, Jr.¹, ¹Texas Agricultural Experiment Station, College Station, TX, ²Overton, TX, ³Texas Tech University Health Sciences Center, Lubbock, TX, ⁴ARS, USDA, Brooksville, FL.

Whether breed influences adrenal and testis content of StAR and P450 proteins was studied by use of Angus (n=7; A), Brahman (n=8; B) and Romosinuano (n=10; R) bulls. Bulls were slaughtered 69-111 d after reaching sexual maturity. Adrenals and testes were collected at slaughter, trimmed and weighed. Western blot analyses were performed to compare StAR and P450 content based on integrated optical density units (IOD). B and R had similar adrenal gland weights (14.8±0.8; 14.9±0.7 g, respectively) which were less (P<.02) than A adrenal weight (17.7±0.7). Plasma cortisol was similar among breeds at slaughter (A, 11.9±2.9; B, 16.5±2.7; R, 18.3±2.6 ng/ml). Adrenal StAR protein was similar in A and R (.209±.010; .199±.008, respectively). B adrenal StAR (.0177±.009) was lower than A but not R adrenal StAR. Adrenal P450 did not differ among breeds. Adrenal StAR and P450 proteins

were not significantly correlated. Testis weight was greater ($P < .02$) in B (642.7 ± 32.6 g) than A (417.7 ± 34.8 g) and R (379.1 ± 29.2 g). Plasma testosterone at slaughter was similar among breeds (A, 3.0 ± 2.2 ; B, 2.5 ± 2.1 ; R, 6.7 ± 1.9 ng/ml). Testis StAR was lower ($P < .006$) in B ($.079 \pm .016$) than A ($.154 \pm .017$) and R ($.155 \pm .014$) bulls which did not differ from each other. Testis P450 was lower ($P < .02$) in B ($.012 \pm .006$) versus A ($.036 \pm .006$) bulls. Testis P450 in R ($.028 \pm .005$) did not differ from A or B bulls. Testis StAR was positively correlated with testis P450 ($r = .6$, $P < .003$) and testosterone at slaughter ($r = .4$, $P < .03$) but negatively correlated with testis weight ($r = -.6$, $P < .005$). Breedtype appeared to influence expression of proteins involved in adrenal and testicular steroidogenesis.

Key Words: Adrenal, Testis, StAR

951 Effects of castration on patterns of LH and testosterone and reproductive behavior in bulls. D.B. Imwalle and K.K. Schillo*, *University of Kentucky, Lexington KY.*

We tested the hypothesis that testosterone is required for maintaining reproductive behavior in sexually experienced bulls. Eighteen yearling bulls were divided randomly into three treatment groups: intact (I); castrated (C); castrated + testosterone (T). All bulls were subjected to libido tests one week before and weekly for four weeks after castration to quantify mounting activity and flehmen responses. Patterns of LH and testosterone were also assessed at these times. One week before castration, concentrations of testosterone, concentrations of LH and frequencies of LH pulses were not different among treatment groups. In the C group, concentrations of testosterone decreased ($P = .01$) to non-detectable levels by one week following castration. During this time, concentrations of testosterone did not change in the I group and increased ($P = .003$) in the T group. Throughout the post-castration period, concentrations of testosterone were higher ($P = .001$) in T bulls than in I or C bulls, and concentrations of testosterone in I bulls were higher ($P = .02$) than in C bulls. Mean concentrations of LH and LH pulse frequencies increased ($P < .001$) between one week before and one week after castration in C animals, but did not change in I or T animals during this time. During the post-castration period, LH concentrations and LH pulse frequencies were higher ($P < .001$) in C bulls than in the I and T bulls, but neither of these variables differed between the I and T groups. Mounting activity decreased ($P = .05$) in all groups between one week before and one week after castration. Thereafter, mounting activity increased ($P = .001$) in each group and reached pre-castration levels by the end of the experiment. At no time during the post-castration period did mounting activity differ among treatment groups. Number of flehmen responses did not differ among groups before castration. However, after castration, C bulls consistently showed fewer ($P = .04$) flehmen responses than I and T bulls. In conclusion, testosterone does not appear to be required to maintain mounting activity in adult bulls. However, testosterone may be important in regulating flehmen responses.

Key Words: LH, Testosterone, Masculine behavior

952 Evaluation of somatotrophic axis gene expression and function in Angus, Romosinuano, and Brahman bulls. T. A. Strauch*^{1,2}, J. W. Koch^{1,2}, S. R. Tatman^{1,2}, C. C. Chase, Jr.³, C. A. Abbey¹, T. M. Bryan¹, R. D. Randel², and T. H. Welsh, Jr.¹, ¹Texas Agricultural Experiment Station, College Station, ²and Overton, TX, ³Subtropical Agricultural Research Station, ARS, USDA, Brooksville, FL.

Whether genotype influences somatotrophic gene expression and function in temperate *Bos taurus* (Angus; A), tropically adapted *Bos taurus* (Romosinuano; R), and tropically adapted *Bos indicus* (Brahman; B) bulls was evaluated. Growth rate, anterior pituitary expression of growth hormone (GH) mRNA, liver expression of mRNA for exon 1A of the GH receptor (GH1A) and IGF-I, and plasma IGF-I concentrations in postpuberal A ($n = 10$), R ($n = 10$), and B ($n = 8$) bulls were determined. Pituitary and liver tissues were collected for mRNA analysis and blood was collected for analysis of plasma IGF-I concentrations by IRMA. GH mRNA expression in the anterior pituitary gland, and GH1A and IGF-I mRNA expression in the liver were determined via ribonuclease protection assays and quantified via integrated optical density units (IOD). There was a difference ($P < .008$) among breeds in ADG with A bulls having increased ADG as compared to B and R bulls (.98, .83, and .82 kg/d; A, R, and B, respectively; $SE = .04$). There was no difference ($P = .45$) in mRNA expression of GH among breeds; however, GH1A

mRNA expression did differ among bull breeds with B bulls having the lowest expression ($P < .006$; $.0002 \pm .05$, $.195 \pm .04$, and $.24 \pm .04$ IOD; B, R, and A, respectively). B bulls had higher IGF-I mRNA expression than R or A bulls ($P < .0001$; $2.11 \pm .22$, $1.1 \pm .18$, and $.66 \pm .18$, and IOD; B, R, and A, respectively). Plasma IGF-I concentrations were highest in R bulls both preslaughter ($P < .001$; 380.2 ± 26.3 , 277.1 ± 29.9 , and 212.2 ± 29.9 ng/ml; R, B, and A, respectively) and postslaughter ($P < .0001$; 433.6 ± 28.6 , 365.8 ± 30.3 , and 178.4 ± 27.1 ng/ml; R, B, and A). This suggests that breeds differ in somatotrophic gene expression and function, with tropically-adapted *Bos taurus* bulls being more similar to *Bos indicus* bulls than to temperate *Bos taurus* bulls.

Key Words: Somatotrophic axis, *Bos taurus*, *Bos indicus*

953 Embryonic mortality from the embryo's perspective. PJ Hansen, *University of Florida.*

For the embryo to successfully complete the preimplantation period, it must be capable of executing its developmental program within a microenvironment largely established by the mother. Mortality results either because of intrinsic defects within the embryo, an inadequate maternal environment, asynchrony between embryo and mother, or failure of the mother to respond appropriately to embryonic signals. To some extent, the embryo's fate is dictated by events before fertilization since embryos formed from incompetent oocytes have a low probability of successful development. For example, embryos have reduced developmental competence when formed from oocytes from persistent ovarian follicles or from cows in the summer in Florida. Chromosomal abnormalities, caused by incompetent oocytes or other causes, represent additional types of intrinsic errors responsible for embryonic loss. Alterations in the maternal environment can cause embryonic mortality as has been shown for heat stress, low maternal progesterone secretion, and feeding diets high in degradable protein. The preimplantation embryo is most susceptible to certain types of stresses (for example, heat shock and arsenic exposure) very early in development. At the earliest stages of development, the embryo is distinct from most cells in that its genome is largely repressed. Thus, the cellular adjustments the early embryo can make in response to perturbations in its environment are limited. Some genes related to resistance to cellular stress can become activated very early in development while other molecular responses to stress are absent. For example, heat shock can induce transcription of the heat shock protein 70 gene in the bovine embryo at the 2-cell stage even though general embryonic genome activation occurs at the late 4-cell and 8-cell stage. In contrast, the early bovine embryo cannot undergo apoptosis in response to cellular stresses that ordinarily activate this process. One possibility is that the acquisition of the capacity for apoptosis represents an important mechanism by which an embryo acquires the ability to survive cellular stress.

Key Words: Embryonic mortality, Embryo

954 The influence of uterine function on embryonic and fetal survival. J. L. Vallet*, *USDA, ARS, RLH US Meat Animal Research Center, Clay Center, NE, USA.*

The secretion rate of growth factors and the delivery rate of nutrients by the uterus affects the growth rate, development and survival of the conceptus. For most growth factors and nutrients, passage into the uterus is not simply controlled by diffusion. Many growth factors are products of uterine tissue. Transport of some nutrients is aided by specific transporter molecules on the uterine endometrial epithelial cell, while others (e.g., retinol, iron, folate) are incorporated into uterine secreted proteins (e.g., retinol binding protein, uteroferrin, folate binding protein). The rate of production of these proteins during pregnancy profoundly affects pregnancy outcome. Uterine gland knockout experiments in sheep demonstrate that pregnancy fails in the absence of uterine glands. In pigs, both global and specific effects of uterine products on aspects of conceptus development can influence litter size. The provision of growth factors and nutrients by the uterus plays a role in entraining conceptus development, so that the uterine environment and the developmental stage of the conceptus match. This uterine dependent control of conceptus development influences pregnancy success. For example, the uterus of the Meishan pig secretes less protein prior to elongation, which slows conceptus development, results in smaller placentas and smaller fetuses, and allows for greater litter size. Furthermore, in Occidental pig breeds, an earlier rise in progesterone at the beginning of pregnancy accelerates

the onset of protein secretion, increases estrogen secretion by the conceptus, increases the size of the fetus in later pregnancy, and decreases litter size. Studies of fetal erythropoiesis also indicate that specific uterine products (uteroferrin, folate binding protein) are required for this important aspect of fetal development and that greater litter size is associated with improved erythropoiesis. Thus, manipulation of uterine function can modify conceptus development and impact pregnancy success in domestic livestock.

Key Words: Pregnancy, Uterus, Conceptus

955 Role of placental function in mediating conceptus growth and survival. M. E. Wilson*, *West Virginia University.*

Conceptus mortality is a significant factor limiting reproductive efficiency of livestock. In both singlet (i.e., cattle) and litter (i.e., pigs and sheep) bearing species, investigations of conceptus mortality have traditionally focused on the period immediately preceding and throughout the attachment phase, around the time of maternal recognition of pregnancy. Recently, data has emerged leading to the suggestion that conceptus loss later in gestation is also significant and that variation in placental size and function may play a very important part in determining whether or not a conceptus survives. In the pig, the number of

conceptuses present after the initial period of loss that survive to term appears to be influenced by the total amount of placental mass present, such that litters containing individuals with relatively small placentae have a greater potential for a large litter size when compared to litters containing similar numbers of individuals with relatively large placentae. In ruminants, recent evidence supports the time of placental development and initial vascularization (between d 28 and 40) as a second period of significant loss, particularly in situations involving manipulation (ovulation synchronization for timed AI in cattle and out-of-season breeding in sheep). In the pig, not only does placental size vary, but the efficiency (as measured by the fetal wt to placental wt ratio) can vary as much as 3-fold within a litter, leading to the suggestion that selection for small very efficient placentae may provide a mechanism for increasing litter size. In ruminants, there are obvious cases where placental growth has been markedly altered (i.e., large offspring syndrome or heat stress) and a subsequent deviation from 'normal' placental efficiency occurs. Less information is available on normal variation in placental size and efficiency; however, the timing of the secondary period of loss supports a role for events during placental development and vascularization being critical to survival and potentially contributing to the observed loss.

Key Words: Conceptus survival, Placental function, Reproductive efficiency

956 Factors affecting profitability of the cow-calf enterprise. B.H. Dunn*, R.J. Pruitt, and E.D. Hamilton, *South Dakota State University.*

The cow-calf enterprise (CCE) was analyzed for factors affecting profitability with production and financial data from 148 individual CCE enterprises from the states of SD, MT, NE, IA, MN, WY, ND, and KS from 1991-1999. Data were collected at the herd level according to Standardized Performance Analysis (SPA) guidelines. SPA financial measurements are reported on a per 100 kg weaned calf (CALF), per beginning year breeding female (FEMALE), and a per hectare used by the CCE (HA). Profit is defined as return on assets (ROA). Mean separation was used to describe the relationships between levels of profit and SPA measurements. Enterprises were divided into three profit groups based on ROA. High Profit (HP) is defined as those CCE with a ROA > 1 SD above the mean ROA. Low Profit (LP) are those CCE with a ROA < 1 SD below the mean. Medium Profit (MP) are CCE with ROA of -6.7 to 12.9%. Of the 23 SPA production measurements used to describe the CCE by size, reproductive performance, and the production of weaned weight, the only variable for which HP enterprises were higher ($P < 0.10$) than MP and LP enterprises was weaning percentage. The weaning percentages were 90.2, 86.6 and 83.4 for HP, MP, and LP. The same was not the case for the comparisons of SPA financial measurements. On a CALF basis, HP had fewer total dollars invested than did MP ($P < 0.05$), lower depreciation expenses ($P < 0.10$), and lower total expenditures ($P < 0.05$) than both MP and LP enterprises. By all three units of measure, HP had lower breakevens ($P < 0.05$), and higher net income and ROA ($P < 0.01$) than MP and LP. Factors affecting ROA were determined with multiple regression. A predictive equation with an R^2 of 0.813 included the independent variables net income, owners equity, pregnancy percentage, and the interaction of net income and owners equity ($P < 0.05$). These analyzes of the CCE indicate that high ROA is not a function of size, but low levels of investment, average levels of weaned weight, high reproduction, high net income, and low total expenditures.

Key Words: Cow-calf, Profit, SPA

957 Characterization of the production and financial performance of the cow-calf enterprise using Standardized Performance Analysis. B.H. Dunn*, E.D. Hamilton, and R.J. Pruitt, *South Dakota State University.*

The cow-calf enterprise (CCE) was described with production data from 185 individual CCEs with 148 providing financial data. Data were compiled over nine years (1991-1999) from CCEs located in the states of SD, MT, NE, IA, MN, WY, ND, and KS. Data were collected at the herd level according to the guidelines of Standardized Performance Analysis

(SPA). The SPA financial measurements are reported on a per 100 kg weaned calf (CALF), per beginning year breeding female (FEMALE), and a per ha used by the CCE (HA). The average CCE consisted of 508 ± 723 beginning year breeding females and $5,067 \pm 9,106$ ha. Hectares per exposed female averaged 9.7 ± 4.7 . The mean beginning Gregorian calving date was 59.4 ± 26.6 . Reproductive performance was measured by mean pregnancy, calving, and weaning percentage which were 93.0 ± 4.6 , 91.4 ± 7.3 and 86.7 ± 7.8 respectively. The percentage of calves born from d 1 - 21, 1 - 42, 1 - 63, and calves born after d 63 were 56.8 ± 5.5 , 84.1 ± 11.6 , 96.0 ± 4.8 , 4.0 ± 4.91 . The average herd replacement rate was $19.7 \pm 19.4\%$. The calves averaged 199.0 ± 28.0 d at weaning. Mean calf weaning weight, kg of weaned calf per cow exposed, and kg of weaned calf per ha utilized by the CCE was 235.9 ± 27.3 kg, 205.0 ± 32.3 , and 44.8 ± 26.7 respectively. The CCEs had an average investment of $\$970.97 \pm 664.91$, $\$2,087 \pm 1473$, $\$473.79 \pm 435.71$ per CALF, FEMALE, and HA respectively. The total annual expenditure was $\$189.55 \pm 98.3$, $\$397 \pm 217$, $\$82.03 \pm 86.52$ per CALF, FEMALE, and HA respectively. Total revenue was $\$206.62 \pm 79.60$, $\$430 \pm 159$, $\$89.27 \pm 71.25$ per CALF, FEMALE, and HA respectively. Net income was $\$17.09 \pm 84.17$, $\$33 \pm 175$, and $\$16.92 \pm 41.49$ CALF, FEMALE, and HA respectively. The mean breakeven was $\$154.11 \pm 97.75$, 331 ± 217 , and 69.21 ± 80.20 per CALF, FEMALE, and HA respectively. The mean return on assets was 3.1%. CCEs in this sample were large, productive, required a large capital investment, and had low levels of profitability.

Key Words: Cow-calf, Profit, SPA

958 Management factors affecting selling prices of beef calves. T. R. Troxel*, M. S. Gadberry, S. Cline, J. Foley, G. Ford, D. Urell, and R. Wiedower, *University of Arkansas Cooperative Extension Service, Little Rock, AR.*

The objective of this study was to determine how management factors affected selling price of beef calves. Data were collected from January 1 to December 31, 2000 at seventeen Arkansas livestock auctions. The database consisted of 81,703 head of cattle representing 15.3% of the total calves sold. Information was collected by experienced livestock market news reporters and included body condition, time of sale, castration, horn status, fill, health, and individual or group selling. Each factor was analyzed using GLM procedures using month, weight and nearby feeder cattle future prices as covariates and least-squared means were generated. All prices are based upon dollars per 45.45 kg of live weight. Body condition affected selling price ($P < 0.0001$) with very thin, thin, average, fleshy and fat calves selling for $\$85.94$, $\$96.03$, $\$93.63$, $\$91.76$ and $\$88.94$, respectively. The selling price of calves sold during the second third ($\$93.90$) of the sale was higher ($P < 0.02$) than cattle sold during the first ($\$93.64$) and third third ($\93.55). Steers sold for $\$4.63$

more ($P < 0.001$) than bulls and polled calves sold for \$1.49 more ($P < 0.001$) than horned calves. Fill affected selling price ($P < 0.0001$) with gaunt, shrunk, average, full and tanked calves selling for \$97.12, \$95.47, \$93.26, \$88.53, and \$82.16, respectively. Healthy calves sold for \$94.07, which was higher ($P < 0.001$) than dead hair (\$83.37), stale (\$82.49), sick (\$68.27), bad eye(s) (\$81.57) or lame (\$66.67) calves. Calves sold in groups of 2 to 5 head (\$95.14) and groups greater than six (\$94.61) received a higher ($P < 0.04$) selling price than calves sold as individuals (\$93.90). Beef cattle producers can greatly influence the selling prices of their calves through managing calf body condition, castration, horns, fill, health and group selling.

Key Words: Selling price, Beef calves, Auctions

959 Impact of the phenotypic expression of calf genetics on the selling price of beef calves. M. S. Gadberry*, T. R. Troxel, S. Cline, J. Foley, G. Ford, D. Urell, and R. Wiedower, *University of Arkansas Cooperative Extension Service, Little Rock, AR.*

A study was conducted to evaluate the impact of genetic factors on the selling price of beef calves marketed through Arkansas auction barns. Data was collected on 65,743 individually sold calves, marketed through 17 auction barns in y 2000. Data collection was conducted by experienced livestock market news reporters. Information pertaining to the phenotypic expression of calf genetics included subjective identification of breed, color, and USDA frame and muscle scores. Due to the unbalanced nature of the dataset, variables were analyzed individually with month, calf weight, and nearby feeder cattle futures as covariates, and least-square means were generated. All prices are based upon dollars per 45.45 kg of live weight. Breed, color (independent of breed), frame and muscle impacted ($P < 0.01$) feeder calf price. Twenty breed or breed groupings were evaluated. Charolais by Limousin cross calves (\$97.96) brought a higher selling price ($P < 0.001$) than all other breeds whereas Hereford (\$83.37), Brahman (\$80.94), and Longhorn/Longhorn cross calves (\$74.52) were lower in price ($P < 0.001$) compared to other breeds. Yellow-colored calves (\$96.47) brought a higher selling price ($P < 0.001$) compared to all other calf colors. Spotted calves (\$83.84) received the lowest price ($P < 0.001$). Yellow-white face (\$95.65) and black-white face calves (\$95.23) tended to be similar in value ($P = 0.07$), but the price for black-white face calves did not differ from the price of whites (\$94.93; $P = 0.14$). Price due to frame size differed ($P < 0.001$) for all three frame sizes. The selling price for large, medium and small-framed calves was \$94.34, \$93.38, and \$74.81, respectively. Price also differed ($P < 0.001$) for muscle scores 1, 2, and 3 (\$95.02, \$85.35 and \$70.51, respectively). Beef cattle producers can influence the calf-selling price through genetic selection.

Key Words: Feeder calves, Market price, Genetic factors

960 Evaluation of stocking rate and breed type on cattle feedlot production costs and carcass value. J. J. Cleere*¹, A. D. Herring¹, J. W. Holloway², H. Lippke², C. R. Long³, F. M. Rouquette³, and B. G. Warrington², ¹Texas Tech University, Lubbock, ²Texas Agricultural Experiment Station, Uvalde, ³Texas Agricultural Experiment Station, Overton.

Spring born steers ($n = 89$) and heifers ($n = 36$) were assigned to two stocking rates in December 1999 at the Texas Agricultural Experiment Stations in Overton (OVT) and Uvalde (UVL) to create different growth rates. Animals were either 100% Angus (A) or Angus cross (AC) at UVL and were either 75% Angus (A75), 50% Angus (A50) or Brahman (B) at OVT. UVL animals and the OVT B animals were steers, whereas the OVT A75 and A50 were a combination of heifers and steers. Animals grazed TAM 90 (RG) annual ryegrass (*Lolium multiflorum*) in UVL at 2.5 to 4.0 animals/ha (LO) or 4.2 to 6.7 animals/ha (HI). Calves grazed 'Maton' rye (*Secale cereale*) and (RG) in OVT at 3.0 animals/ha (LO) or 6.2 animals/ha (HI). Cattle were placed at the Texas Tech Alltech Research feedlot in May 2000 to determine the influence of stocking rate (SR) and breed type (BT) on feedlot performance and carcass traits. Cattle were randomly assigned to pens by LOC, BT, SR, sex and weight with 4 to 7 animals per pen. Traits on cattle from OVT and UVL were analyzed separately with pen as the experimental unit for all analyses. The statistical model for the UVL cattle included SR, BT and initial feedlot weight as a covariate, whereas the model for the OVT cattle included the same variables plus sex and BT x SR. Among the OVT cattle, SR did not affect carcass value (CARC), feed cost of gain (COG), daily DMI or average daily gain (ADG) ($P > .05$). SR did not affect CARC,

COG or ADG among the UVL animals ($P > .05$). However, the HI animals had a higher daily DMI ($9.57 \pm .12$ kg) than the LO animals ($9.16 \pm .18$ kg) ($P < .10$). BT did not affect CARC, COG or ADG among the OVT animals ($P > .05$). However, the B cattle consumed less feed ($7.49 \pm .39$ kg/d) in comparison to the A50 ($10.28 \pm .20$ kg/d) and the A75 ($11.14 \pm .38$ kg/d) ($P < .05$). There was also a potential BT x SR interaction among the OVT animals for daily DMI ($P = .11$). Among the UVL animals, BT did not affect CARC, COG, or ADG ($P > .05$). The A animals had a higher DMI ($9.81 \pm .10$ kg) than the AC animals ($8.92 \pm .21$ kg) ($P < .05$). Previous management should be considered in marketing feedlot cattle.

Key Words: Beef cattle, Feedlot costs, Carcass value

961 Phenotypic relationships between serial ultrasound measures of body composition in commercial beef feedlot animals determined with a random regression model. T.L. Fernandes*¹, S.P. Miller¹, and C.J.B. Devitt², ¹University of Guelph, Guelph, Ontario, Canada, ²Beef Improvement Ontario, Guelph, Ontario, Canada.

Objective was to determine the relationship between serial ultrasound measurements within an animal (rib-eye area-REA, backfat-BF, and intra-muscular fat-IMF) in relation to body weights and days on feed. Serial ultrasound measurements were obtained from 165 feedlot cattle in Ontario over 7 months (from entry into the feedlot until slaughter). Number of scans per animal ranged from 3 to 6. For each animal, univariate, random linear regressions of REA, BF and IMF on body weight (261-708 kg) or days on feed (30-205 days) were fit. (Co)variance components for intercept, slope and residual were estimated by Restricted Maximum Likelihood (REML), implementing an average information algorithm in the Statistical package ASreml. The estimated covariance function was expanded to determine the (co)variance between any weight or days within the recorded range. For regression on weight, correlations of ultrasound measures within animal ranged from 0.26-0.55, 0.29-0.94, and 0.24-0.75 for REA, BF, and IMF respectively, between measures at 50kg intervals and measure at 600 kg. For regression on days on feed, correlations between measures within an animal ranged from 0.42-0.55, 0.69-0.92, and 0.46-0.66 for measures at 30-day intervals, with 120 days on feed for REA, BF, and IMF, respectively. (Co)variances estimated form a basis for further studies investigating predictions of carcass merit with early ultrasound measures.

Key Words: Cattle, Ultrasound, Predictions

962 Effect of different implant regimes on the accuracy of ultrasound for prediction of body composition characteristics in beef cattle. T.L. Perkins and B.L. Frieden*, *Southwest Missouri State University.*

The objective of this study was to examine the effect of different implant regimes on the accuracy of ultrasound for the estimation of body composition characteristics in beef cattle. Ultrasonic measurements of longissimus muscle area (LMAU), 12th-rib fat thickness (FTU), and percent intramuscular fat (PFATU) were taken by one technician. Cattle were harvested at 110 d ($n=21$), 141 d ($n=3$), 160 d ($n=25$), 180 d ($n=23$), 201 d ($n=25$), 208 d ($n=20$) and 258 d ($n=24$) after being scanned. Carcass measurements included: hot carcass weight (HCW), longissimus muscle area (LMAC), fat thickness at the 12th rib (FTC), preliminary yield grade (PYG), kidney, pelvic, and heart fat (KPH), marbling score (MS), final yield grade (YG), and final quality grade (QG). All crossbred steers ($n=141$) were scanned ultrasonically and implanted on the same day. One of four implant regimes were administered in a completely randomized design as follows: control ($n=36$) with no implant (TRT1); Ralgron® ($n=31$) (zeranol, 36 mg; Schering-Plough, Union, NJ) (TRT2); Revalor® ($n=35$) (24 mg estradiol, 120 mg trenbolone acetate; Hoechst Roussel Vet., Warren, NJ) (TRT3); and double Revalor® ($n=39$) (TRT4) implant. Means by treatment for FTC, REAC, MS, FTU, LMAU, PFATU, and HCW were 1.05 cm, 94.29 cm², 5.3, .65 cm, 65 cm², 3.6% (TRT1); 1.09 cm, 93.69 cm², 5.2, .57 cm, 64 cm², 3.4% (TRT2); 1.02 cm, 94.63 cm², 5.1, .49 cm, 63 cm², 3.3% (TRT3); .84 cm, 96.83 cm², 5.0, .53 cm, 63.2 cm², 3.3% (TRT4) respectively. Correlations between FTU and FTC by treatment were .71; .73; .60; and .61 for each implant regime. Correlations between LMAU and LMAC by treatment were .40; .57; .43 and .58 for each implant regime. Correlations between PFATU and MS by treatment were .27; -.08; .47;

and .37 for each implant regime. These data suggest that ultrasound accuracy was affected by different implant regimes. Implant treatment affected accuracy of fat prediction less than it did accuracy of muscle area or marbling.

Key Words: Ultrasound, Implant, Accuracy

963 Effects of anabolic implants on intramuscular lipid deposition. K. R. Smith^{*1}, J. R. Sackmann¹, S. K. Duckett¹, and T. D. Pringle¹, ¹University of Georgia, Athens, GA.

Ten Angus heifers (386 kg) sired by high marbling EPD bulls were used in a 108 d finishing trial to determine effects of anabolic implants on i.m. lipid deposition. Five randomly selected heifers were implanted with Synovex-Plus (SP; 28 mg estradiol benzoate containing 200 mg of trenbolone acetate) at d 0 and 55. The remaining five heifers were not implanted and served as controls (N). Real-time ultrasound measurements of ribeye area (UREA), fat thickness (UFT) and intramuscular lipid (UIMF) percentage were recorded at 28 d intervals throughout the finishing period. At 108 d, all heifers were harvested and carcass data recorded. One steak (2.54 cm thick) was removed from the 12/13th rib, trimmed of all subcutaneous fat and connective tissue, and pulverized in liquid nitrogen to obtain total lipid content. Ultrasound and performance data were analyzed using the GLM procedure of SAS with time, treatment and two-way interaction in the model. Carcass and lipid data were analyzed using GLM with treatment in the model. Average daily gain was 36% greater ($P < 0.01$) for SP than N. UREA increased ($P < 0.05$) over time for both treatments; however, SP increased at a faster rate than N (0.31 vs 0.23 cm²/d). UFT and UIMF increased ($P < 0.001$) across time-on-feed but were similar between treatments. Implantation altered ($P < 0.06$) the magnitude of change in UIMF over time during finishing, with 82% of the total UIMF deposited between d 27 to 55 in SP and 48% of the total UIMF deposited between d 55 to 80 in N. Final live weight and hot carcass weight were 11% greater ($P < 0.07$) for SP than N. Ribeye area was larger ($P < 0.01$) by 23% for SP than N. SP had 10% greater ($P < 0.05$) overall maturity scores than N. Other carcass measures including marbling score and quality grade were similar ($P > 0.05$) between treatments. Total lipid content of the longissimus was similar ($P > 0.05$) between SP and N. Use of anabolic implants in heifers with the genetic potential to marble did not alter ultimate i.m. lipid content of longissimus; however, pattern of i.m. lipid deposition was altered by implantation.

Key Words: Beef, Implant, Lipid

964 Effects of Implants on Growth Performance of Steers Wintered on Dormant Native Tallgrass Prairie, Subsequent Performance, and Carcass Merit. G.W. Horn^{*}, C.J. Ackerman, S.I. Paisley, and B.A. Gardner, Oklahoma Agricultural Experiment Station, Stillwater, OK/USA.

Three hundred, twenty fall-weaned crossbred steer calves (214 ± 21.9 kg) received either no implant (Control), or were implanted with Synovex-C[®] (SC = 10 mg estradiol benzoate + 100 mg progesterone), Synovex-S[®] (SS = 20 mg estradiol benzoate + 200 mg progesterone), or Revalor-G[®] (RG = 8 mg estradiol-17β + 40 mg trenbolone acetate) to determine the effects of implants on weight gain during winter grazing on dormant tallgrass prairie, subsequent grazing and finishing performance, and carcass merit. Steers grazed two dormant tallgrass prairie pastures from October 23, 1998 until April 5, 1999 (164 d) and received 1.82 kg/d of a cottonseed meal and wheat middling-based 20% CP supplement. Following winter grazing, all steers were implanted with Ralgro[®] (36 mg zeranol) and grazed a common tallgrass prairie pasture until July 15 (101 d). After summer grazing, all steers were implanted with Revalor-S[®] (24 mg estradiol-17β + 120 mg trenbolone acetate) and winter implant treatment groups were equally allotted to two pens in a commercial feedlot. Steers were harvested November 19, 1999 after a 127 d finishing period. Data were analyzed by least squares analysis, and treatment sums of squares were separated using nonorthogonal contrasts that compared Control vs implanted, RG vs SC (i.e., similar amounts of estrogenic activity), and RG vs SS. Mean daily gains (kg) of all cattle during the winter, summer, and feedlot phases were 0.16 ± .009, 1.05 ± .016, and 1.62 ± .029, respectively, and were not influenced by implanting. Steers implanted during the wintering phase had increased ($P < 0.05$) skeletal maturities. "B" maturity carcasses were increased 5.1, 8.8, and 2.4 percentage units by SC, SS, and RG implants. This is consistent with

our previously reported results, and brings to question the efficacy of continuous use of growth-promoting implants in coordinated beef cattle production systems and effects on carcass value.

Key Words: Growing Steers, Implants, Carcass Merit

965 Effect of Feed Intake Restriction on Animal Performance and Carcass Characteristics. C.D. Drager^{*}, M.S. Brown, M. Jeter, P. Dew, and E. Cochran, West Texas A&M University.

An experiment was conducted to study the effect of the severity of DMI restriction on performance and carcass characteristics of feedlot cattle. Crossbred steers (n = 256, 311 ± 1.6 kg initial BW) were block by BW, randomly assigned to one of four treatments (28 pens, 7 pens/treatment), and fed a common 90% concentrate diet. Treatments were: 1) 75% of DMI of steers allowed ad libitum access (AL) for 65 d, 95% of AL for 65 d, and AL for 21d (AL85); 2) 80% of AL for 65 d, 100% of AL for 65 d, and AL for 21 d (AL90); 3) 85% of AL for 65 d, 105% of AL for 65 d, and AL for 21d (AL95), and 4) AL for 151 d (AL100). Feed was offered at approximately 110% of appetite for steers allowed ad libitum access. Feed refused was weighed, and ingredient and diet DM were determined weekly. Feed was offered for AL85, AL90, AL95 based on DMI by AL100 the previous week. All steers were fed a similar quantity of DM for 3 d prior to initial, interim, and final BW determination. Overall DMI was increased ($P < 0.01$) for AL100 compared to the average of restricted steers and increased linearly ($P < 0.01$) with increasing DMI of restricted steers (8.92, 9.13, 9.36, 9.74 ± 0.08 kg/d for AL85, AL90, AL95, and AL100, respectively). Overall ADG (carcass-adjusted) was decreased ($P < 0.01$) for restricted steers compared to AL100 (1.46, 1.60, 1.57, 1.67 ± 0.03 kg/d). Overall ADG and ADG:DMI (carcass-adjusted) responded quadratically ($P < 0.04$) with increasing DMI of restricted steers. Hot carcass weight, ribeye area, and kidney, pelvic, and heart fat percentage were increased ($P < 0.03$) for AL100 compared to restricted steers, and responded quadratically ($P < 0.07$) with increasing DMI of restricted steers. The number of carcasses grading Choice, Select, ≥ low Choice, or Select + Standard did not differ ($P > 0.14$). The severity of restriction and pattern of increasing feed intake resulted in 17, 12.7, and 8 kg/steer less total DM consumed, decreased average daily gain, and decreased gross carcass value an average of \$25 for restricted steers.

Key Words: Feed Restriction, Caloric Restriction, Feedlot Cattle

966 Feedlot performance and carcass characteristics of Mashona-sired steers. G. C. Duff^{*}, D. A. Walker, K. J. Malcolm-Callis, J. E. Sawyer, J. Weaver, and M. G. Thomas, Clayton Livestock Research Center, New Mexico State University, Clayton.

Seventy-one Mashona (Sanga-type cattle indigenous to Zimbabwe)-sired Brangus or Angus crossed steers (191 kg initial BW) were used to evaluate CP concentration (phase 1; 84 d) and protein source (phase 2; 126 d) on finishing performance and carcass characteristics. During phase 1, treatments were no added CP (3 pens; 12 steers/pen) or a diet containing 14% CP (DM basis; 3 pens; 11 or 12 steers/pen). Steers fed 14% CP diets had greater ($P < 0.01$) ADG, daily DMI, and gain:feed (G:F) than steers fed diets with no added CP during the first 84-d. After 84-d, steers fed diets with no added CP during phase 1 were allotted to 14% CP treatment diets (two pens/treatment; nine steers/pen) containing either soybean meal (SBM) or urea as CP sources; steers fed 14% CP in phase 1 served as controls (diets contained 4.5% SBM and 1% urea). During the final 126 d finishing phase ADG was greater ($P < 0.01$), daily DMI was decreased ($P < 0.05$) and G:F was increased ($P < 0.01$) for the average of SBM and urea diets vs controls. Likewise, final BW was increased ($P < 0.01$) for controls vs the average of SBM and urea diets (490, 462, and 468 kg for controls, SBM, and urea diets). No differences ($P > 0.10$) in performance were detected between SBM or urea as CP sources. Hot carcass wt (303.6, 282.4, and 284.6 kg) and longissimus muscle area (76.7, 72.2, and 72.9 cm² for control, SBM, and urea diets, respectively) were increased ($P < 0.05$) for controls relative to the average of SBM and urea diets. Dressing percent (62.0, 61.3, 61.0), marbling score (53.7, 48.7, 51.7), fat thickness (1.36, 1.11, 1.12 cm), internal fat (2.1, 2.1, 2.0) and percentage carcasses grading choice + prime (88.6, 88.2, 94.4% for controls, SBM, and urea, respectively) did not differ ($P > 0.10$) between treatments. Results suggest that Mashona-sired steers perform best with 14% CP concentrations typical of commercial feedlot

diets. Likewise, either SBM or urea can be fed to Mashona-sired steers after feeding low CP diets.

Key Words: Mashona, Performance, Carcass Characteristics

967 Effect of two weaning systems on milk composition, storage, and ejection in dairy ewes. B. C. McKusick*¹, Y. M. Berger¹, P. G. Marnet², and D. L. Thomas¹, ¹University of Wisconsin-Madison, Madison, WI, ²Institut National de la Recherche Agronomique, Rennes, France.

In small dairy ruminants, a mixed weaning system (MIX) of suckling and machine milking is commonly used during the first 30 d of lactation. The main disadvantage of the MIX system is the markedly low fat content in the machine milk. We hypothesize that the inhibition of milk ejection during machine milking along with alteration in storage of milk fat between milkings is responsible. Twenty-six East Friesian crossbred dairy ewes were used to study the effects of two weaning systems on milk composition, storage, and ejection during the first 4 wk of lactation. At parturition, ewes were randomly assigned to two weaning system groups: no suckling and exclusive twice daily machine milking (DY1, n = 10), or the MIX system of once daily machine milking in the morning and then suckling for 10 hr per day (n = 16). Ewes were injected with saline (control), oxytocin (OT), or an oxytocin-receptor blocking agent (AT) prior to a morning milking once weekly, and machine milk was sampled to evaluate milk storage within the udder. Milk and milk protein yields ($1.15 \pm .10$ kg and 58.4 ± 4.7 g, respectively) were similar for DY1/AT, MIX/control, and MIX/AT ewes, and less ($P < .05$) than DY1/controls ($1.49 \pm .10$ kg and 77.4 ± 5.1 g, respectively). This observation confirms inhibition of the milk ejection reflex during machine milking of MIX/control ewes, as only 75% of total machine milk and milk protein is recuperated (cisternal milk). MIX/control and MIX/AT ewes yielded less ($P < .001$) milk fat (28.8 ± 4.3 g) compared to DY1/AT ewes (57.2 ± 6.1 g). When OT was injected to remove all of the milk within the udder, MIX/OT ewes had similar milk and milk protein yield, but 34% less ($P < .001$) milk fat yield than DY1/OT ewes. These results demonstrate that yield and storage of milk and milk protein within the udder is similar for MIX and DY1 ewes, however, there appears to be proportionally less cisternal storage of milk fat in MIX ewes. The present experiment raises further questions concerning the alveolar transfer, stasis and inhibition of milk fat synthesis in ewes managed within the MIX system.

Key Words: Dairy Ewe, Milk Fat, Milk Ejection

968 Supplementing ewe diets with a microbial enzyme preparation (Fibrozyme). I. Effects on production characteristics during lactation. D. K. Aaron*¹, D. G. Ely¹, W. P. Deweese¹, E. Fink¹, B. T. Burden¹, and K. A. Dawson², ¹University of Kentucky, Lexington, KY, ²Alltech Biotechnology Center, Nicholasville, KY.

Twenty-four Polypay ewes (70 kg), with twin lambs, were used to determine effects of dietary supplementation with a microbial enzyme preparation (Fibrozyme, Alltech Biotechnology Center, Nicholasville, KY) on production characteristics. Each ewe and her lambs were placed in individual pens, at 8 d postpartum, and randomly assigned to one of two treatments: F (2 g Fibrozyme, topdressed, 2x/d, n = 12) or C (no Fibrozyme, n = 12). The daily basal diet consisted of 1.0 kg grain,

0.9 kg alfalfa cubes, and corn silage fed to appetite. Ewes, separated from lambs, had access to diets from 0800 to 0930 and 1600 to 1730 daily. Lambs had continual access to a creep diet beginning on d 26. Ewes and lambs were individually weighed and ewes body condition-scored and machine-milked every 7 d from d 15 through 64 of lactation. Weekly feed and creep intakes were recorded. By d 29, estimated 24-h milk production was higher for F than for C ewes (3.17 vs 2.80 kg; $P < .05$), and F ewes continued to produce more milk ($P < 0.05$) on each of the remaining collection days (d 36: 3.08 vs 2.66 ; d 43: 3.00 vs 2.58 ; d 50: 3.00 vs 2.48 ; d 57: 2.70 vs 2.23 ; d 64: 2.33 vs 1.70 kg). Overall, F ewes produced 18 kg more milk (144 vs 126 ; $P < .01$), consumed slightly more feed (275 vs 269 kg), and produced milk more efficiently (0.52 vs 0.47 ; $P < 0.10$). Ewes in both groups tended to gain weight and condition, but no significant differences were found between treatments. Lamb pairs nursing F ewes consumed less creep feed from d 26 through 64 than those nursing C ewes (37.6 vs 45.6 kg; $P < .05$), but twin lamb weaning weights were similar (52.8 vs 53.4 kg) and lamb production efficiencies were equal (0.12). These results indicate Fibrozyme can have a positive effect on milk production, but its effects on lamb growth may be offset by lower creep feed intake.

Key Words: Ewes, Lactation, Enzyme Supplement

969 Supplementing ewe diets with a microbial enzyme preparation (Fibrozyme). II. Effects on nutrient utilization during lactation. D. G. Ely*¹, D. K. Aaron¹, W. P. Deweese¹, E. Fink¹, B. T. Burden¹, and K. A. Dawson², ¹University of Kentucky, Lexington, KY, ²Alltech Biotechnology Center, Nicholasville, KY.

Twenty-four Polypay ewes (70 kg), with twin lambs, were used to determine effects of dietary supplementation with a microbial enzyme preparation (Fibrozyme, Alltech Biotechnology Center, Nicholasville, KY) on total GI tract nutrient digestibility and ruminal metabolism. Each ewe and her lambs were placed in individual pens, at 8 d postpartum, and randomly assigned to treatment: F (2 g Fibrozyme, topdressed, 2x/d, n = 12) or C (no Fibrozyme, n = 12). The daily basal diet contained 1.0 kg grain mix, 0.9 kg alfalfa cubes, and corn silage fed to appetite (3.9 kg av.) from d 8 through 64 postpartum. Ewes, separated from lambs, had access to diets from 0800 to 0930 and 1600 to 1730 daily. Fecal grab samples were taken at 12-h intervals, advanced 2 h daily, from d 33 to 39. Samples were dried, composited by ewe, and analyzed for DM, N, ADF, and NDF. Acid-insoluble ash was used as an internal indicator. After the last fecal sampling at 0800 on d 39, ruminal fluid was obtained from each ewe with a stomach tube (0 h). Ewes were fed immediately after this sampling. Ruminal fluid was also collected 2, 4, 6, and 8 h post-feeding. The pH was determined as samples were collected. Samples were subsequently analyzed for VFA. Digestibilities (%) of DM, CP, ADF, and NDF were 62, 58 ($P < 0.05$); 61, 59 ($P < 0.05$); 32, 27 ($P < 0.05$); and 30, 25 (ns) for F and C, respectively. Ruminal fluid pH was not affected by diet. Total VFA, acetate, butyrate, and valerate concentrations were greater ($P < 0.05$) with F at 8 h post-feeding. Propionate, isobutyrate, and isovalerate were unaffected by diet. Acetate to propionate ratios were greater ($P < 0.05$) for F at 6 and 8 h after feeding. These results indicate Fibrozyme can increase nutrient utilization, by altering ruminal metabolism, in ewes fed high roughage lactation diets.

ASAS/ADSA Ruminant Nutrition: Growing Cattle

970 Influence of mass of ruminal contents on voluntary intake of steers fed concentrate and forage diets. Marcela A. Schettini*, Edward C. Prigge, and Eric L. Nestor, West Virginia University.

Five ruminally cannulated steers (590 kg) were fed a high concentrate (C) or a hay (H) diet in a 5×5 Latin square experiment to evaluate the influence of mass of rumen contents on voluntary intake and rumen function. Mass of ruminal contents was altered by adding varying weights of modified tennis balls (6.7-cm diameter) to the rumen before the initiation of each experimental period. Treatments consisted of 0 balls added to the rumen and fed 70 % C (control), 75 balls with a specific gravity (SG) of 1.1 fed C, 75 balls with SG 1.4 fed C, 75 balls with SG 1.1 fed H, and 75 balls with SG 1.4 fed H. Total weight of the balls

was 12.75 and 16.35 kg for 1.1 and 1.4 SG, respectively. Daily DMI was 15.11, 11.93, 10.65, 6.09, and 5.10 for control, 1.1 SG balls fed C diet, 1.4 SG balls fed C diet, 1.1 SG balls fed H diet, and 1.4 SG balls fed H diet, respectively. Addition of balls into the rumen of steers fed the C diet decreased DMI ($P < 0.01$), and increasing SG of balls in the C and H diet decreased DMI ($P < 0.05$) further. Digestibility of NDF, ADF, and CP, and DM were not influenced by the addition of balls nor by increasing SG of the balls for steers fed C and H diet. Adding balls to the rumen of steers fed the C diet decreased particle passage rate (PR) ($P < .05$), while increasing SG of balls decreased particle PR for C and H diet. Liquid dilution rate (LDR) was decreased by the addition of balls in the rumen of the steers ($P < 0.05$) fed the C diet and increasing SG of the balls decreased LDR ($P < 0.01$) for both H and C diets.

Addition of balls in the rumen of steers fed the C diet decreased ($P < 0.01$) the proportion of medium (1.1-1.4) and increased ($P < 0.01$) the proportion of low (<1.1) functional SG digesta particles. Balls added to the rumen of steers fed C diet increased ($P < 0.05$) digesta particle size. Ruminant NH₄ levels of steers fed the C diet were decreased ($P < .01$) with addition of balls. These results suggest that physical factors in the rumen have an influence on voluntary intake of both forage and concentrate diets.

Key Words: Beef Cattle, Voluntary Intake, Concentrate

971 Intake characteristics of beef steers consuming hay ad libitum. E.E.D. Felton* and M.S. Kerley, *University of Missouri, Columbia Missouri.*

Chopped alfalfa and big bluestem (early(EC) & late cut(LC)) hay were used in two 4X4 Latin square experiments (Exp.1 & Exp.2) to investigate the decrease in forage intake associated with decreasing forage quality. Treatments consisted of 100%EC or LC and 67%EC 33%LC or 33%EC 67%LC fed at 110% of ad-libitum intake. Dual-cannulated beef steers (Exp.1 & Exp.2 average BW = 298 & 321 kg, respectively) were used in both experiments. Diet and refusal samples were separated by particle size (fractions: (A) particles > 19mm, (B) between 19 and 8mm, & (C) < 8mm) using the Penn State particle separator and analyzed for fiber and CP. In both experiments, quality of the diets decreased (increased ADF & NDF, decreased CP) linearly ($P < .01$) which resulted in a linear reduction in intake in Exp.1 ($P = .08$) and in Exp.2 ($P < .01$). In neither experiment were the proportions of particles within each diet or refusals affected by treatment (Diet-Exp.1 fraction A=8.24%, B=20.18%, C=71.58% & Exp.2 fraction A=21.56%, B=20.74%, C=57.70% and Refusal-Exp.1 fraction A=37.62%, B=33.64%, C=28.74% & Exp.2 fraction A=28.49%, B=24.89%, C=46.62%). From particle analysis of feed and refusals, animals in both experiments consumed a greater percentage of fraction C than of B or A. Fraction C of feed and refusals for both experiments had a higher ($P < .05$) concentration of protein and less ($P < .05$) fiber than fraction B or A. Correlation analysis of DMI to forage NDF, ADF and CP, were different between Exp.1 and Exp.2. Dry matter intake in Exp.1 appeared only marginally correlated with NDF (-.43, $P = .09$) and CP (.41, $P = .10$) and was not correlated with ADF. In Exp.2, DMI was highly correlated with ADF (-.90, $P < .01$) and CP (.84, $P < .01$) and had a moderate correlation with NDF (-.65, $P < .01$). These results indicated that NDF from lower fiber forages does not have the same effect on DMI intake as does the NDF from higher fiber forages and may not be a good indicator of bulk fill.

Key Words: Intake, Forage, Steers

972 Effect of rate of liveweight gain during winter grazing on blood constituents during adaptation of cattle in the feedlot. M. J. Hersom, R. P. Wettemann, G. W. Horn, and C. R. Krehbiel, *Oklahoma Agricultural Experiment Station, Stillwater, OK.*

Forty-eight fall-weaned Angus x Hereford steer calves (244 ± 23 kg) were used in a completely random design to determine the effect of rate of liveweight gain during winter grazing and subsequent feedlot gain on serum and plasma hormones and metabolites. During the 120-d grazing period, the three treatments were: high (HGW, 1.28 kg/d) and low (LGW, 0.48 kg/d) gain on wheat pasture, and winter grazing of dormant tallgrass native range (NR, 0.21 kg/d). Prior to the feedlot phase (wk 0), jugular blood (venipuncture) was collected from all steers. Thirty-six steers were placed into three pens/treatment and fed a whole-shelled corn finishing diet. Blood was also collected weekly six times beginning 2 wk after arrival in the feedlot. Concentrations of insulin in serum on wk 0 were influenced by treatment ($P < 0.05$; 2.56 ± 0.42, 1.18 ± 0.40, and .92 ± 0.44 ng/mL for HGW, LGW, and NR respectively) and insulin was greater in HGW steers than LGW or NR steers during wk 4 through wk 7. Concentrations of glucose in plasma were not influenced by treatments after wk 0. Serum triiodothyronine (T₃) concentrations were greater ($P < 0.05$) in HGW than LGW and NR steers on wk 0 (1.6 ± .1, 1.4 ± .1, and 1.2 ± .1 ng/mL) through wk 5. Similarly, thyroxine (T₄) concentrations in HGW steers were greater ($P < 0.05$), than in LGW or NR steers on wk 0 (71.7 ± 3.9, 54.2 ± 3.7, and 49.5 ± 4.0 ng/mL) through wk 5. Concentrations of NEFA in serum were greater ($P < 0.05$) in LGW (500 ± 20 ng/mL) and NR (530 ± 22 ng/mL) steers on wk 0 than HGW steers (286 ± 21 ng/mL). Thereafter, NEFA concentrations were greater ($P < 0.05$) in HGW steers than LGW and NR steers until wk 5. Greater feed intake and/or daily gain before steers

were fed a high-energy diet increased serum concentrations of insulin and increased T₃ and T₄ during the first 5 to 7 wk of the feedlot phase.

Key Words: Growing Cattle, Winter Weight Gains, Hormones

973 Coastal and Tifton 85 hay digestion by steers: I. Cultivar and maturity effects. G. M. Hill*¹, R. N. Gates², J. W. West¹, R. S. Watson¹, and B. G. Mullinix¹, ¹University of Georgia, Tifton, GA/USA, ²USDA-ARS, Tifton, GA/USA.

Bermudagrass hay cultivar [Coastal (C) or Tifton 85 (T85)] and hay maturity (5-wk or 7-wk (7-wk)), effects on growing beef steer intake and digestion were determined. Steers (n=24; 255.2 ± 10.7 kg BW) were ranked by BW and randomly assigned to four hay treatments (TRT) in a 2 X 2 factorial with six steers per TRT. Steers were individually-fed T85 hay from a different source for 10 d, followed by free-choice feeding of TRT hays for 21 d. Fresh water and a free-choice mineral supplement (12.5% Ca, 4% P, 19% NaCl, with trace minerals) were available at all times. Steers received Cr₂O₃ (10 g/steer daily) in gelatin capsules from d 10 to d 20, and 12 fecal samples/steer were collected (d 17 to d 21), dried, composited, and analyzed for Cr, and nutrients. In hay analyses (4 samples/hay) the DM, ash, CP, ADF, and NDF (% DM basis), respectively, were: C-5-wk= 92.0, 7.1, 14.4, 36.8, 75.3; C-7-wk=93.2, 6.7, 10.2, 38.9, 70.3; T85-5-wk=94.2, 6.9, 13.6, 39.0, 78.4; T85-7-wk=94.4, 6.3, 9.9, 40.6, 79.0. Hay cultivar and maturity main effects for DMI (kg/d) and digestibility (%) of OM, CP, ADF, and NDF, respectively, were: Cultivar, C=4.19, 61.6b, 67.1, 59.3b, 61.8b; T85=4.25, 67.7a, 66.0, 69.2a, 71.9a; Maturity, 5-wk=4.25, 65.8, 70.6a, 66.3c, 69.5a, 7-wk=4.18, 63.6, 62.5b, 62.2d, 64.2b; within main effect, for each component (a,b $P < 0.01$; c,d $P < 0.05$). There were no cultivar X maturity interactions ($P > 0.10$) for these variables. Although T85 hays had comparatively high concentrations of ADF and NDF, DMI was not affected ($P > 0.10$), and digestion of OM, ADF and NDF were higher for T85 than C. Maturity of the forage when harvested for hay did not affect DMI, but it decreased CP content and digestion of CP, ADF and NDF.

Key Words: Hay, Steer, Digestion

974 Coastal and Tifton 85 hay digestion by steers: II. Cultivar, maturity and energy effects. G. M. Hill*¹, R. N. Gates², J. W. West¹, R. S. Watson¹, and B. G. Mullinix¹, ¹University of Georgia, Tifton, GA/USA, ²USDA-ARS, Tifton, GA/USA.

Bermudagrass hay cultivar [Coastal (C) or Tifton 85 (T85)], hay maturity [5-wk (5wk) or 7-wk (7wk)], and energy supplementation [None (NE) or added corn (E)] effects on beef steer intake and apparent digestion were determined. Steers (n=36; 261.8 ± 12.9 kg BW) were randomly assigned to treatments (TRT) in a 2 X 2 X 2 factorial arrangement (4 steers/ TRT for hay; 5 steers/TRT for hay and energy). After feeding T85 hay from another source for 10 d, steers were individually-fed TRT diets for 21 d. Gelatin capsules with Cr₂O₃ (10 g/steer daily) were given from d 10 to d 20. Fecal samples (12/steer; d 17 to d 21) were dried, composited, and analyzed for Cr, and nutrients. The DM, ash, CP, ADF, and NDF (% DM basis), respectively, in four samples/hay were: C-5wk= 93.4, 7.7, 14.1, 36.2, 73.0; C-7wk=94.1, 6.4, 9.8, 36.8, 71.4; T85-5wk=94.6, 6.9, 13.3, 38.0, 77.3; T85-7wk=94.6, 6.7, 9.9, 40.0, 78.5. Total DMI was restricted to 90% of hay DMI by similar steers in a companion study. Four TRT were fed hay only, and four TRT were fed rolled corn (89.7% DM, 10.2% CP) at 33% of total DMI. Hay DMI, corn DMI, and total DMI (kg), respectively, were: C-5wk-NE=3.76, 0, 3.76; C-5wk-E=2.51, 1.30, 3.81; C-7wk-NE=3.76, 0, 3.76; C-7wk-E=2.51, 1.29, 3.80; T85-5wk-NE=3.9, 0, 3.90; T85-5wk-E=2.61, 1.33, 3.94; T85-7wk-NE=3.70, 0, 3.70; T-85-7wk-E=2.46, 1.29, 3.76. Cultivar X energy interactions for digestibility (%) of OM and ADF were: OM= C-NE, 46.5, C-E, 56.9, T85-NE, 58.4, T85-E, 59.8 [SE=1.63, F=7.7 ($P < 0.01$)]; ADF= C-NE, 40.9, C-E, 43.7, T85-NE, 60.9, T85-E, 57.0 [SE=1.75, F=3.6 ($P < 0.07$)]. Cultivar, maturity and added energy digestibility (%) for CP and NDF, respectively, were: CP=C, 50.3a, T85, 50.5a; NDF=C 46.4b, T85, 61.1a; CP=5wk, 54.1a, 7wk, 46.7b; NDF=5wk, 57.2a, 7wk, 50.2b; CP=NE, 55.9a, E, 44.9b; NDF=NE, 55.5a, E, 52.0b; within nutrient (a,b, $P < 0.05$). Hay digestibility was greater for T85 than C, and increased hay maturity decreased nutrient digestion. Added energy increased OM digestibility of C hay diets to the level of T85 hay without added energy, but added energy did not increase OM digestion of T85 hays.

Key Words: hay, steer, *Cynodon dactylon*

975 Effect of intake level on the body composition and net energy requirement of Nellore steers and bulls for maintenance and growth. L.O. Tedeschi*¹, D.G. Fox¹, C. Boin², P.R. Leme³, and G.F. Alleoni⁴, ¹Cornell University, Ithaca, NY, USA, ²ESALQ-USP, Piracicaba, SP, Brazil, ³FZEA-USP, Pirassununga, SP, Brazil, ⁴Instituto de Zootecnia, Nova Odessa, SP, Brazil.

Three comparative slaughter experiments with individually fed Nellore bulls (31 animals) and steers (66 animals) were used to determine their NEm and NEg and the effect of level of intake on their composition of gain. Bulls (experiment 1) were divided into two intake levels (60 g DM/kg^{0.75} of shrunk body weight (SBW) and ad libitum of a diet containing 2.3 Mcal ME/kg) and three slaughter groups, which were based on days on treatment (100, 150, and 190 days, and 130, 180, and 200 days, respectively for older and younger animal subgroups). For experiments 2 and 3, steers were allocated to three intake levels (55 and 70 g DM/kg^{0.75} SBW, and ad libitum of a diet containing 2.2 Mcal ME/kg). In both trials, three slaughter groups within each intake level were set as when animals of the ad libitum treatment reached 400, 440, and 480 kg SBW on average for the first, second, and third group, respectively. For all experiments, initial body composition was determined with equations developed from a base line slaughter group, using SBW, empty body weight (EBW), fat (EBF), and protein (EBP) as variables. For bulls, there were no differences ($P > 0.05$) between treatments in EBW percentage of protein and water, and fat and protein in the gain (FIG and PIG, respectively). In contrast, in steers level of intake affected EBW percentage of protein and fat ($P < 0.05$), but FIG and PIG were not different ($P > 0.05$). A nonlinear equation with the pooled data was developed to predict retained energy (RE) using maturity degree ($u = \text{actual/mature weight}$, which was estimated to be 350 and 550 kg of SBW at 25% EBF for steers and bulls, respectively); $RE = 0.00949 * EWG^{0.9425} * EBW^{exp(0.0924 * u)}$. The NEm was similar for bulls and steers, and averaged 76 kcal/kg^{0.75} EBW. However, the efficiency of conversion of metabolizable to NEm was greater for steers than bulls (70.6 and 65.2%, respectively), indicating that bulls had an 8.6% greater ME requirement for maintenance than steers ($P < 0.05$). Our analyses do not support the hypothesis that Nellore, a *Bos indicus* species, has a lower net energy requirement for maintenance than *Bos taurus* breeds.

Key Words: body composition, net energy requirement, Nellore

PSA Pathology: Session II

977 Pathogenesis of ascites syndrome in broiler chicken in relation to combined E. coli and infectious bronchitis virus (IBV) infection. M.S. Youssef*, A.H. Bayoumi, A.Z. Mahmoud, S. Mousa, and M. Mubarak, *Veterinary Medicine, Assiut University, Assiut, Egypt.*

Forty white leghorn chicks (one day old and specific pathogen free) were used in this study. Chicks were inoculated via nares with 0.1 ml E. coli (O : 115 serotype O) at the titre of 106.7 colony forming units/ml, and 0.1 ml IBV (Massachusetts serotype M41) at the titre of 105.5 ciliostatic dose 50 (CD 50). The experimental period was 7 weeks. The incidence of ascites was 20%. Tissues from inoculated birds were examined using light and electron microscopes. Immunohistochemistry was also conducted to detect IBV antigen in pulmonary tissue of inoculated birds. Pulmonary lesions were fibrinopurulent pneumonia at early stage followed by late granulomatous reaction. It was concluded that the development of ascites in IBV-E. coli infected birds is attributed to the induced pulmonary lesions which led to a state of pulmonary hypertension.

Key Words: Ascites, broiler chickens, E. coli, IBV

978 Clinicopathological studies on ascites syndrome in broiler chickens with special reference to the role of hypoxia. A.Z. Mahmoud*, A.H. Bayoumi, S. Mousa, M.S. Youssef, and M. Mubarak, *Veterinary Medicine, Assiut Univ., Assiut, Egypt.*

Forty-nine ascitic broiler chickens from 7 different flocks were used in this study. An experimental investigation was also conducted to induce ascites in broiler chickens by creating a hypoxic condition. In the first trial 32 birds were exposed to periodic hypoxia (6 and 12 hrs/day) and in the second trial 24 birds were exposed to periodic hypoxia (6 hrs/day) and fed on pelleted feed. The experimental period was 4 weeks. All

976 Monitoring energy expenditure in sheep from daily heart rate measurement. A Arieli*¹, A Kalouti², Y Aharoni³, and A Brosh³, ¹Hebrew University of Jerusalem, Israel, ²Wageningen Agricultural University, Netherlands, ³Agricultural Research Organization, Ramat Yishay, Israel.

A trial was conducted in sheep to validate the usage of continuous heart rate (HR) monitoring for the prediction of energy expenditure (EE) in free-living animals. Sixteen Assaff lambs (BW 50 kg) were used. Four lambs were slaughtered at the beginning of the experiment, and the others at the end of the experiment. Carcass body composition was analysed and energy retention was calculated. The 12 lambs were kept on metabolic crates for 84 d. Lambs were blocked into 3 dietary treatments: Group HH was fed a 75:25 concentrates: alfalfa hay (C:A) diet during the entire experiment. Group LH were fed 25C:75A diet during the first 42 d, and then switched into a 75C:25A diet. Group LL received 25C:75A diet during the entire experimental period. Feed was given ad libitum. The experimental period was divided into 4 sub-periods of 21 d. During each sub-period, body weight change, daily intake and feces output was measured. Intake of ME was calculated from NRC (1989). HR was recorded by data loggers during 15 to 17 d. On 18 d oxygen consumption (VO₂), using an open circuit mask system, and HR were measured for a period of 15 min, from which oxygen pulse (OP = VO₂:HR ratio) was determined. For each sub-period EE was estimated from daily HR measurements and oxygen consumption, calibrated against OP. Direct measurement of EE could thus be compared with the prediction obtained from the difference between ME intake (MEI) and measured energy retention. Average (and SE) intakes of ME were 857 (33), 854 (39), and 805 (42) kJ/metabolic body weight (MBW)-d in HH, LH, and LL, respectively. The respective energy retentions were 194 (23), 233 (27) and 141 (22) kJ/MBW-d ($P = 0.06$). Overall energy predictability (MEI/(energy retention + EE estimated by the HR method) was 0.957 ($n = 12$; SE 0.024), and was not affected by dietary energy concentration. It is concluded that the HR technique can be used for the estimation of long-term energy expenditure in growing animals.

Key Words: Energy expenditure, Heart rate, Oxygen pulse

exposed birds were investigated for haematological, histopathological, immunohistochemical, and ultrastructural studies. Pathomorphological examination revealed degenerative myocarditis, granulomatous and fibrinopurulent pneumonia, 25% of experimental birds developed ascites, and haematological and pulmonary changes were prominent in them. It was concluded that ascites syndrome in broiler chickens is multifactorial in origin, and heart and lungs are central organs in the pathogenesis of ascites. The development of ascites in hypoxic birds is mediated through haematological and pulmonary changes.

Key Words: Ascites, broiler chicken, Hypoxia

979 Experimental study on sodium intoxication in relation to ascites syndrome in broiler chickens. M. Mubarak*, A.H. Bayoumi, A.Z. Mahmoud, M.S. Youssef, and S. Mousa, *Vet. Med., Assiut Univ., Assiut, Egypt.*

This work was designed to induce ascites in broiler chickens by sodium chloride intoxication. Three experiments were conducted using 40, 40, and 50 chickens, respectively, which received high doses (1.5%) and low doses (0.75%) of sodium chloride (SC), sodium bicarbonate (SB), and sodium phosphate (SP) in their drinking water for 4 weeks. Haematologic parameters, serum level of sodium, creatine kinase and lactate dehydrogenase were estimated. Histopathological and ultrastructural studies were also performed. Ascites was not recorded in high dosed birds. Low dosed birds manifested ascites at the incidence of 40% (SB), 35% (SC), and 10% (SP). Cardiac and pulmonary lesions were observed in ascitic birds. It was concluded that pathogenesis of ascites in sodium intoxicated birds is mediated through pulmonary hypertension induced right sided heart failure.

Key Words: Ascites, broiler chicken, sodium chloride toxicity

980 Detection of experimental *Salmonella enteritidis* and *S. typhimurium* infections in laying hens by fluorescence polarization assay for egg yolk antibodies. R. K. Gast*¹, M. S. Nasir², M. E. Jolley², P. S. Holt¹, and H. D. Stone¹, ¹USDA-ARS Southeast Poultry Research Laboratory, Athens, GA, ²Diachemix Corporation, Grayslake, IL.

The effectiveness of risk reduction programs for controlling egg-borne transmission of *Salmonella* infections to humans depends on accurate detection of infected commercial laying flocks. Although most *S. enteritidis* (SE) control programs in the U.S. have emphasized bacteriological detection of the pathogen in laying house environments and eggs, antibody detection methods have been used successfully elsewhere and are of particular interest in application to egg yolks (which can be collected more conveniently than serum samples). Fluorescence polarization (FP) technology offers advantages over traditional enzyme immunoassays in terms of both speed and methodological simplicity. This study evaluated the sensitivity and specificity of detection of antibodies in the yolks of eggs laid by experimentally infected chickens by FP assays using tracers prepared from the O-polysaccharides of SE and *S. typhimurium* (ST) and an ELISA using an SE flagellin antigen. In 2 trials, groups of specific-pathogen-free laying hens were infected orally with either 10⁶ or 10⁸ cfu of SE (phage type 13a) or with 10⁸ cfu of ST. Egg yolks were obtained at 5 weekly intervals from infected and uninfected negative control hens. Both ELISA and FP (using SE tracers) detected a high percentage of hens infected with SE, although both assays also detected antibodies in eggs from some hens infected with ST. The FP assay for SE was both more sensitive and more specific than the ELISA. Two different SE tracers for FP displayed different sensitivities and specificities of detection. FP using an ST tracer likewise detected ST infection but cross-reacted with antibodies to SE.

Key Words: *Salmonella enteritidis*, Fluorescence polarization, Egg yolk antibodies

981 The role of intracellular sodium in skeletal muscle damage: effects on muscles from two broiler genotypes. D. A. Sandercock* and M. A. Mitchell, *Roslin Institute, Roslin, Midlothian, UK*.

The incidence of idiopathic myopathy is increasing in poultry lines selected for high growth rates and muscle yields. The condition has been linked with impaired muscle intracellular calcium (Ca²⁺_i) homeostasis. Elevations in Ca²⁺_i are known to be associated with the development of myopathy. These increases may be mediated by initial changes in other ions, such as sodium (Na⁺). This study examines the role of Na⁺_i on Ca²⁺_i and muscle damage and compares its effects on these parameters in muscles from two broiler genotypes. The study employed an isolated in vitro chicken skeletal muscle preparation. Alterations in Na⁺_i were induced using the Na⁺ ionophore monensin and Na⁺/K⁺ exchange inhibitor ouabain. In a parallel experiment, muscles from fast (FG) and slow (SG) growing broiler lines were similarly treated. Muscle damage was determined from creatine kinase (CK) loss into the incubation medium. Muscle calcium accumulation was estimated by ⁴⁵Ca²⁺ uptake. Monensin and ouabain treatments both caused similar elevations in ⁴⁵Ca²⁺ uptake (p<0.05) and were associated with increases in CK loss (p<0.001). Effects of simultaneous incubation with both agents were additive. In studies on muscles from FG and SG lines, ⁴⁵Ca²⁺ uptakes and CK losses were not different under control conditions. Treatment with monensin produced differential increases in ⁴⁵Ca²⁺ uptake (p<0.01) and CK loss (p<0.001) in muscles from the two lines. Absolute uptakes of ⁴⁵Ca²⁺ (p<0.05) and CK losses (p<0.001) were greater in muscles from the FG line as were their relative increases (p<0.05). The results suggest initial increases in Na⁺_i can produce elevations in Ca²⁺_i and muscle injury. FG and SG lines exhibit differences in the extent of Na⁺-mediated alterations in muscle Ca²⁺_i and CK loss. It is proposed that subjecting birds to situations which may cause changes in muscle Na⁺_i (e.g. raised muscle activity and stress) should be avoided, especially in current broiler lines, in which sensitivity to Na⁺-induced changes in myopathology appears to be increased.

Key Words: Sodium, Muscle damage, Broiler

982 Idiopathic myopathy in commercial turkeys: a relationship with muscle fiber diameter? M.A. Mitchell*¹, L.J. Mills¹, M. Mahon², and S. Gilpin², ¹Roslin Institute, Roslin, Midlothian, UK, ²Manchester University, Manchester, UK.

Previous studies in this laboratory have described an age dependent, idiopathic or spontaneous myopathy in rapidly growing commercial turkeys associated with an exponential rise in plasma creatine kinase (CK) activity. These effects were not found in an unimproved strain. Growth restriction in commercial turkeys reduced plasma CK, suggesting a link between growth rate, bodyweight and myopathy. The aim of this experiment was to correlate the incidence and extent of this pathology with morphometric characteristics of the muscle fibers. Large, white commercial male-line stags were reared to two weeks of age and split into 2 treatment groups. One group was fed ad libitum (AL) throughout the experiment and the other treatment group was restricted from 5 weeks of age (R), receiving 70% of the reported ad lib food intakes. Every four weeks up to 20 weeks of age 8 birds per treatment were weighed and blood sampled. Plasmas were analyzed for CK activities. Histological analyses were performed upon muscle samples from leg and breast. Bodyweights, fiber diameters and plasma CK activities increased significantly with age in both treatments and were significantly greater in the AL treatment (p<0.001). At 8 weeks body weight and CK activities were significantly higher (p<0.001) in the AL treatment and by 12 weeks fiber diameter was also significantly increased (p<0.001). Regression analysis highlighted almost identical exponential relationships between CK and bodyweight and between CK and fiber diameter for both treatment groups (p<0.001). The take-off point for CK corresponded to approximately 10kg bodyweight and 65mm fiber diameter in both treatments. It is suggested that myopathy is linked to muscles fiber size rather than the rate of growth. Selection in commercial turkeys has achieved greater muscle weights mainly through fiber hypertrophy. The resulting large diameter fibers may exceed a size threshold at which normal function is compromised and pathology occurs. Future selection programs may benefit by concentrating on selection for smaller fiber sizes and greater fiber numbers (hyperplasia) to achieve high muscle yield, good meat quality and muscle health.

Key Words: Turkey, Muscle, Myopathy

983 Bacteriophage prevents *Escherichia coli* respiratory infection in broiler chickens. W. E. Huff*, G. R. Huff, N. C. Rath, J. M. Balog, H. Xie, P. A. Moore, Jr., and A. M. Donoghue, *PPPSRU/ARS/USDA Fayetteville, AR*.

Bacteriophage are viruses that infect and can kill bacteria. A study was conducted to determine if bacteriophage could protect broiler chickens challenged with *E. coli*. There were 13 treatments with 2 replicate pens of 10 chicks. Two treatments consisted of birds challenged at 3 days of age with either 10³ or 10⁴ cfu *E. coli* injected into the thoracic airsac. There were 4 phage treatments that consisted of mixing a bacteriophage isolated from a municipal sewer treatment plant with *E. coli* 24 hours prior to challenging the birds. The 10³ *E. coli* culture was mixed with either 10³ or 10⁶ phage, and the 10⁴ *E. coli* culture was mixed with either 10⁴ or 10⁸ phage. Four treatments consisted of challenging the birds with only 10³, 10⁴, 10⁶, or 10⁸ phage. Three control treatments consisted of unchallenged birds, birds challenged with the culture broth, or birds challenged with phosphate buffered saline. The birds were necropsied at 3 weeks of age. At 1 and 2 weeks of age birds challenged with either 10³ or 10⁴ cfu of *E. coli* had significantly decreased body weights from controls. At 2 weeks of age the birds that received 10⁴ cfu of *E. coli* mixed with 10⁴ bacteriophage had significantly decreased body weights from the controls. Mortality in the birds that received 10³ or 10⁴ cfu of *E. coli* was 80 and 85%, respectively. Mortality of birds that were challenged with either 10³ or 10⁴ cfu of *E. coli* mixed with equal amounts of bacteriophage was 25 and 45%, respectively. Mortality of birds challenged with 10³ or 10⁴ cfu of *E. coli* mixed with 10⁶ or 10⁸ bacteriophage was 5 and 0%, respectively. Based on mortality there was essentially complete protection of the birds given either 10³ or 10⁴ cfu *E. coli* mixed with either 10⁶ or 10⁸ bacteriophage, and partial protection when equal amounts of *E. coli* and bacteriophage were mixed prior to challenge. These data suggest that bacteriophage may have efficacy to prevent *E. coli* respiratory infections in broiler chickens.

Key Words: Bacteriophage, Broiler chickens, *Escherichia coli*

984 Efficacy of bacteriophage to prevent *Escherichia coli* respiratory infection in broiler chickens when administered in the drinking water prior to challenge. W. E. Huff*, G. R. Huff, N. C. Rath, J. M. Balog, H. Xie, P. A. Moore, Jr., and A. M. Donoghue, *PPPSRU/ARS/USDA Fayetteville, AR.*

Bacteriophage are viruses that can infect and kill bacteria. A study was conducted to determine if bacteriophage added to drinking water for 1 wk prior to respiratory challenge of broiler chickens with *E. coli* would provide protection. There were 12 treatments with 2 replicate pens of 10 chicks. The treatments consisted of birds on normal water challenged at 1 wk with either 10^3 or 10^4 cfu *E. coli* injected into the thoracic air sac, or with either 10^3 , 10^6 , or 10^4 , 10^6 phage/ml in their water, respectively. Unchallenged birds were given either 10^3 , 10^4 , or 10^6 phage/ml in their water, and birds on normal water were unchallenged, challenged with the culture broth, or with phosphate buffered saline. The birds were necropsied at 3 wks of age. At 2 wks, birds challenged with 10^4 *E. coli* regardless of water treatment, and birds challenged with 10^3 *E. coli* on normal water had decreased BW, however, birds challenged with 10^3 *E. coli* and given water treated with either 10^3 or 10^6 phage/ml had higher BW than birds challenged with 10^3 *E. coli* on normal water. At 3 wks, unchallenged birds that received 10^3 phage, and birds that received 10^4 phage and challenged with 10^4 *E. coli* had decreased BW. At 1 wk, treatment of water with 10^6 phage/ml decreased mortality by 50% in birds challenged with 10^3 *E. coli*. Total mortality was 55% in the birds that received 10^4 *E. coli* alone, 35% when treated with 10^4 phage, and 40% when treated with 10^6 phage. These data indicate that treating the water of broiler chickens prior to a respiratory challenge with *E. coli* may have provided some protection immediately after challenge.

Key Words: Bacteriophage, Broiler chickens, *Escherichia coli*

985 Effect of feed supplementation with vitamin D metabolites in a dexamethasone-*Escherichia coli* challenge model of turkey osteomyelitis complex. G. R. Huff*, W. E. Huff, N. C. Rath, and J. M. Balog, *PPPSRU/ARS/USDA, Fayetteville AR.*

Supplementation with vitamin D₃ was previously shown to protect *E. coli* challenged birds which were immunosuppressed with dexamethasone (DEX) at 5 wk and at 12 wk of age. The purpose of this study was to determine the effects of continual dietary supplementation with either 10 g/kg 1,25 dihydroxyvitamin D₃ (1,25) or 99 g/kg 25-hydroxyvitamin D₃ (Hy-D) on disease resistance. Seven hundred twenty turkey poults were placed into 24 duplicated floor pens in a 3 X 2 X 2 design comparing each metabolite treatment to controls. At 5 wk of age half of the birds were treated with DEX and half of the DEX-treated birds were challenged with *E. coli*. All mortalities and lame birds were necropsied. At 9 wk all DEX-treated birds were treated with another series of DEX injections. At this time, the birds which had only been challenged with *E. coli* were also treated with DEX. Two weeks later 10 birds/pen were necropsied. After the first series of DEX injections, there was an increase in mortality in the Hy-D supplemented birds which were given both the DEX treatment and the *E. coli* challenge. After the second series of DEX injections the main effect mean body weights were lower in birds given 1,25 as compared to both controls and Hy-D supplemented birds. Mortality was higher in 1,25 supplemented birds which were challenged with *E. coli* at 5 wk and treated with DEX at 9 wk as compared to Hy-D supplemented birds. The 1,25-treated birds which were treated with DEX at both 5 wk and 9 wk and challenged with *E. coli* at 5 wk had higher mortality as compared to both controls and Hy-D birds. The main effect mean mortality was higher in birds given 1,25 as compared to controls and Hy-D birds. The percentage of birds with lesions of turkey osteomyelitis complex (TOC) was decreased from 27% to 0 by both Hy-D and 1,25 in the groups given 2 DEX treatments and *E. coli* challenge. This study suggests that continual supplementation with vitamin D metabolites at these levels can decrease TOC incidence, however this result may be related to a concomitant increase in mortality.

Key Words: vitamin D, turkeys, *Escherichia coli*

Ractopamine at One Year of Commercial Application

986 Biological basis of the ractopamine response. S.E. Mills*, *Purdue University.*

Ractopamine belongs to a class of compounds that binds beta-adrenergic receptors (β AR) and promotes the accretion of muscle protein while reducing body fat. The growth response is observed across many species and with a variety of structurally related compounds, suggesting that a common regulatory pathway is involved. The β AR-selective agonist isoproterenol also stimulates muscle growth in rodents suggesting that β AR, and not other receptors, mediate the hypertrophic response. Three β AR subtypes have been cloned from several mammalian species and specie differences in the relative distribution and pharmacology of subtypes have been demonstrated. These specie differences likely account for the lesser or greater efficacy of specific compounds in specific species. In the pig, the β 1AR is the predominant subtype expressed in the adipocyte (75%) and skeletal muscle (60%), followed by the β 2AR (18 and 39%) and β 3AR (7 and 1%). Ractopamine binds the porcine β 1AR and β 2AR with similar high affinity ($K_d = 25$ to 100 nM). Intracellular signaling through the β AR is achieved via activation of adenylyl cyclase and generation of cAMP. Ractopamine activates adenylyl cyclase but is only 20 to 40% as effective as isoproterenol and may more effectively signal through the β 2AR than the β 1AR. Ractopamine would be considered a partial agonist at both β AR subtypes. In adipose tissue, ractopamine stimulates triglyceride hydrolysis in vivo and in vitro through activation of adenylyl cyclase. Absolute rates of fat accretion are not consistently observed in feeding studies however, likely due to the combination of β AR down regulation with chronic feeding and the partial agonist activity. Ractopamine consistently increases the rate of skeletal muscle protein accretion in pigs, although the response is diminished with time. Down regulation of β AR is less evident in skeletal muscle, which may prolong the positive effect. It is not clear which β AR subtype(s) are linked to protein accretion and what intracellular path-

ways are involved. Answers to these questions may provide insights for the next generation of β AR agonist.

Key Words: pig, adrenergic, receptor

987 Impact of nutrition on the ractopamine response. W. C. Weldon* and T. A. Armstrong, *Elanco Animal Health, Greenfield Indiana.*

Proper nutrition is critical to effective implementation of ractopamine (Paylean[®]) in commercial swine production facilities. There is only a limited response to ractopamine if it is included in diets with limited amino acid fortification. Very simply, the ability of ractopamine to increase lean growth is limited by the availability of nutrients. To make an accurate estimate of the optimal nutrient concentration, it is critical to understand the potential lean growth response to ractopamine. The growth response to ractopamine is dramatic. Several studies have shown that the inclusion of ractopamine in the diet will increase ADG by as much as 275 g/d during the early weeks of ractopamine feeding. The improvements in growth performance decrease over time. Current recommendations are to feed ractopamine so that the majority of the pigs are marketed within four weeks of the initiation of ractopamine feeding. Practically, the primary adjustment necessary in diets containing ractopamine is to increase the amino acid concentration. A summary of four historical data sets indicates that the increased lean growth requires 3.6 to 7.5 g/d more true ileal digestible lysine during 28 d of ractopamine feeding (based on NRC 1998). If the increased lysine needs are distributed based on the relative response in ADG, the lysine requirement is greatest during the first few weeks of ractopamine feeding. The average increase in lysine requirements for the first 21 d of ractopamine feeding (based on historical lean growth data using NRC (1998) calculations) is 6.5 g/d of true ileal digestible lysine. Therefore, if pigs consume 2.5 kg of feed/d, the concentration of true ileal digestible lysine in the diet would need to be increased 0.26%. The results from ongoing studies will further define the interactions between dose and feeding duration

and allow for more specific nutritional recommendations. Feeding ractopamine in diets that are not adequately fortified, may severely limit the improvements in growth performance and carcass composition.

Key Words: Ractopamine, Swine, Nutrition

988 Genetic variation in the response to ractopamine. A.P. Schinckel*¹, B.T. Richert¹, and C.T. Herr¹, ¹*Purdue University.*

Several research trials have evaluated the impact of ractopamine (RAC, Paylean[®], Elanco Animal Health) on barrows and gilts of various genetic populations (GP). Overall, the desirable response of RAC to increase daily carcass lean gain, improve feed efficiency, and increase carcass lean percentage has been observed in GP of substantially different lean growth rates and carcass lean percentages. Three trials have evaluated the magnitude of GP × RAC interactions. Carcass muscle accretion (g/d) increased with RAC to a greater extent in high lean gain (HL) barrows than low lean gain (LL) barrows ($P < .02$, Bark et al., 1992, *J. Anim. Sci.* 70:3391). Dissected fat accretion (g/d) was reduced by a greater magnitude in the HL than the LL barrows ($P < .04$). Gu et al. (1991, *J. Anim. Sci.* 69:2694) evaluated the RAC response in five GP of barrows and found significant RAC by GP interactions ($P < .05$) for daily carcass lean gain. Regression of GP means for carcass lean gain with RAC on the carcass lean gain of the control for the five GP indicated that the RAC response was best described as a constant percentage (25%) increase in daily lean gain above the controls. The third trial (Herr et al., 2001) evaluated the response of Paylean in 300 gilts in a 3 × 4 factorial with three GP (commercial terminal crosses) and four RAC levels (0, 5, 10, and 20 ppm). The GP had similar carcass lean percentage. No GP by RAC interactions were found ($P > .10$). Overall, the research indicates that RAC has a positive impact on barrows and gilts with substantially different genetic potentials for lean growth and carcass lean percentage. The RAC response to increase lean growth has been found to be proportional to the genetic potential of the GP. Recent research has found significant GP by environmental interactions for pigs reared in different health status environments. Environment by RAC and environment by RAC by GP interactions for compositional growth in pigs need to be evaluated.

Key Words: Ractopamine, Swine genetics, Lean Growth

989 Effects of ractopamine on meat quality. F. K. McKeith* and M. Ellis, *University of Illinois, Champaign-Urbana, IL.*

Ractopamine has been approved for use in pigs in the United States. Previous work on this compound has carefully characterized its effects on carcass growth and composition and some classical evaluations of fresh meat quality (color, firmness, and marbling) and palatability. The majority of the information available is a decade or more old. Results from these studies suggested that ractopamine had no effect on visual color, firmness, or marbling. Instrumental color was evaluated in one study and no effect was observed in L* value (lightness) but a* value

(redness) was reduced. Water holding capacity (drip loss) and ultimate pH were not affected by ractopamine; however, ham curing yields were improved in two studies. The impact of ractopamine was inconsistent for Warner-Bratzler shear force (some studies reported an increase and other studies observed no difference). Sensory tenderness, juiciness, and flavor were not affected. Since its approval, several studies have been conducted using contemporary genotypes to help characterize the fresh meat quality attributes. Preliminary results from these studies are consistent with previous research. Detailed fresh meat quality evaluations suggest that visual color, firmness, and marbling were not affected. Instrumental L* was not affected; however, a* was reduced. Ultimate pH was significantly higher in ractopamine fed animals, but, drip loss and purge loss were not affected. Results from current studies and previous work suggest that ractopamine does not affect pork quality.

Key Words: Pork, Quality, Ractopamine

990 Potential impact of ractopamine on environmental stewardship. A.L. Sutton*, B.T. Richert, S.L. Hankins, S.A. DeCamp, and A.L. Carroll, *Purdue University.*

Numerous studies have shown that ractopamine hydrochloride (RAC) used in finisher swine diets increases the amount of lean tissue in pork carcasses and improves production efficiency (G:F and ADG). With increased body N retention, less feed consumed per unit of lean tissue gain and 4 to 6 d less to market weight, the use of RAC may lead to environmental benefits by reducing manure volume and N excretion. Theoretically, if the same total amount of US lean pork is maintained but with 12.7% improvement in G:F and 9.8% increased ADG due to feeding RAC, then fewer pigs would be required to generate this amount of lean. Consequently, significantly less feed resources (land required for crop production), fertilizer, chemicals, water usage and energy would be required. Little research has directly measured manure volume, nutrient excretion and odors from feeding RAC in commercial diets. A metabolism trial with 84-kg pigs and a 64-d manure incubation study were conducted to determine the effect of RAC on N excretion and odors in stored manure. A 13.8% CP, 0.80% Lys diet representing the industry standard diet for high lean gain pigs was compared to a current approved diet with 16.1% CP, 1.10% Lys + 20 ppm RAC. RAC decreased urine volume (12.6%) and tended to decrease total manure output (7.9%). Pigs fed the RAC diet excreted 14.9% less total N compared to the 13.8% CP standard non-RAC diet due to reduced urinary N excretion. In a 30-d feeding period and 4 less days to market, N excretion would be reduced 206 g per pig marketed. Slurry pH was reduced 0.5 units and ammonia was reduced 8-21% from pigs fed RAC. In an attempt to maximize N utilization and minimize N excretion, a 13.8% CP, 1.10% Lys + 20 ppm RAC diet was fed. The 13.8% CP + RAC diet reduced N excretion by 35.7% and decreased slurry ammonia and VFA production in stored manure to help reduce odors. The utilization of RAC in swine diets could result in additional environmental benefits and improved environmental stewardship.

Key Words: Pigs, Ractopamine, Nitrogen excretion

Teaching Techniques for Meat Judging Coaches

991 Preparing animal science graduates to think critically, compare logically, decide independently, solve problems rationally, communicate effectively and lead decisively. Gary C. Smith*, *Colorado State University.*

If the animal science curriculum is appropriately crafted and structured, undergraduate student majors can develop abilities to think critically, compare logically, decide independently, solve problems rationally and to communicate effectively in the formal course-work offerings. Additionally, though, livestock, meat and wool judging/grading/evaluation experiences provide opportunities for students to develop further those skill-sets, while simultaneously developing leadership skills. To qualify as an "educated" baccalaureate degree graduate, is it really important that a person be able to judge a class of stallions, assign Quality/Yield Grades to a beef carcass, grade a fleece or determine IMPS compliance of a pork loin? Yes, because those who pursue a career in animal agriculture will then be able to describe/discuss intelligently the industry's products and endproducts. But even if a person never intends to, and

does not, pursue a career related to animal agriculture, there are huge personal benefits which accrue from learning the principles involved in mastering the generalities, concepts and specifics of the art and science of judging, grading and evaluation. Development of skills in comparative reasoning, application of memory standards, mental gymnastics, independent problem-solving, knowledge integration, written/oral communication and leadership will prove useful irrespective of one's career path. Animal science department administrators must insist that, within the B.S. curricula, there are opportunities for students to participate in clubs and intercollegiate competitions to serve as an integral part of the process of developing leadership skills.

Key Words: Leadership, Curriculum, Judging teams

992 Techniques and philosophy for training students to grade carcass beef. J.W. Wise*¹ and H.G. Dolezal², ¹USDA, Agricultural Marketing Service, ²Excel Corporation.

Students who are effective in grading beef carcasses for quality grade and yield grade are often successful in overall judging because the skills needed to evaluate grade traits are relevant across species and product lines. Initially, the basics of beef grading should be presented to students with visual aids and actual carcasses to demonstrate the range and variation in skeletal and lean maturity, marbling, lean firmness, internal and external fatness with and without adjustments, and longissimus muscle (LM) size across a range of carcass weights. Once students understand the key factors and the necessary calculations to combine these factors for both quality and yield grading then a session with probes, grids, and marbling cards may be used to test their ability to physically measure or evaluate each factor. Early training for students to call the factors without the use of mechanical aids is best accomplished concentrating on one trait at a time (i.e., call LM area on 15 carcasses and review; then actual preliminary yield grade (PYG) and review, then adjusted PYG, etc.). Encourage students to develop a sequence of practices that work for them to avoid oversights during appraisal. Key factors to consider include the amount of light available and the distance for eye contact they may have for evaluating individual traits. Quality grade training should focus on the lines of transition for each of the factors (marbling score, skeletal maturity, and lean maturity). Students should be trained as individuals to refine their skills for problem traits or ranges within a trait. At each grading exercise, students should be encouraged to begin their evaluation using a carcass with traits that they are most confident in estimating (i.e., small00 marbling. 80.6 sq cm LM area, etc.). Repetition is critical to instill the self-confidence needed by students to grade beef. Instructors are encouraged to involve students in obtaining individual measurements, computing official results, to discuss results while viewing carcasses and to encourage discussion.

Key Words: Beef, Carcass, Education

993 Effectively teaching meat judging specifications. Duane Wulf*¹ and Gretchen Hilton², ¹South Dakota State University, ²Texas Tech University.

The specifications used in Intercollegiate Meat Judging are based on the IMPS specifications. However, these specifications have been modified slightly from the official IMPS specifications to make them more usable in the competitive environment of a meat judging contest. In preparing students to be proficient in a specifications class in a meat judging contest, you should teach them the following steps: 1) memorization, 2) interpretation, 3) application. The specifications class can be the most frustrating aspect of meat judging to a beginning meat judge because of the vast amount of information that must be memorized; however, the class can be one of the most rewarding aspects of meat judging to an experienced meat judge because a perfect score of 100 is a challenging, yet attainable, goal. The first step in mastering the specifications class is to memorize them. A student must not only memorize the specifications but must also memorize the corresponding defect codes on the answer card. This memorization is easier and much more effective if the student has seen the actual meat cuts and understands how the cuts are fabricated from the carcass. The second step in mastering the specifications class is being able to interpret the specifications as they relate to acceptable and unacceptable meat cuts. A student must know specifically where to look on a certain cut to ascertain the adherence to a certain specification. A student must be aware of the different situations that are acceptable and those that are unacceptable. Lastly, a student must learn how to apply the specifications in a contest setting. In a contest setting, a student cannot use any measurement tools, cannot touch any of the meat cuts and has no help from anyone else. Therefore, a student must be confident about their knowledge of the specifications and must rely on that confidence and previous training in order to be successful in a contest specifications class. This confidence comes from being prepared and from practicing. Students who study and practice to prepare themselves for the specifications class will not only learn much about the skeletal and muscular anatomy of meat animal carcasses, but will also learn a great deal about a very important every-day aspect of the meat industry.

Key Words: Meat evaluation

994 Coaching to Succeed: Effective Strategies for Answering Questions in Meat Evaluation. R M Harp*¹, R C Hines¹, and R D Stites², ¹Tarleton State University, ²Eastern Oklahoma State College.

It has been said that there is no substitute for hard work. The ability to think critically and discern differences in meat judging gives the student a definite edge when the decision-making processes occur in real-world situations. Many hours should be spent recruiting and informing the administration of the benefits of an activity such as meat judging. Yet, after this task has been accomplished, we can get into the nuts and bolts of teaching and preparing students to perform at a high level of answering questions. The key factors that must be completed with this high level of precision are understanding proper terminology, understanding the concepts of quality and cutability, possess a competitive nature, be willing to give the proper time on task, concentration (focus). Many coaches recruit good students and teach the fundamentals, yet students fail to fully concentrate 100 %, and follow a methodical procedure. Furthermore, the successful coach needs to understand that students have various learning styles. Let us note at the onset that note-taking for questions is different than that for reasons in most cases. Reasons are comparative with each of the three pairs and is descriptive for the last carcass or cut, whereas, questions are more holistic in that they are descriptive for the entire class. Notes for questions are to observe and identify the major points for placing the entire class according to quality and cutability as well as understand the reasoning for placing the class. Secondly, organize the notes in a manner in which the student can read the notes and make a mental picture of the class. In preparing for questions, remember take notes on the big differences first and work your way down. We should aim for one hundred percent, but at least 75-80% of the questions will pertain to the distinguishable differences that was used to place the class. As in both reasons and questions the student's notes should "Paint the picture of the class". This is a critical part of answering questions. Lastly, it is imperative that team members are involved each week throughout the year in preparing for questions. Repetition and concentration are the vital determinants for success and consistency in answering questions.

Key Words: Note-taking, Terminology, Time-on-task

995 Team behavior; at home, on the road, in the plant, at the contest and after the contest. P.T. Berg*, North Dakota State Univ..

The key to student conduct (behavior) can be summarized in a single word: RESPECT. North Dakota State University, College of Agriculture installed an "honor code" system in the late 1950's. Faculty involved with the judging teams try to use the ethical basis for this code in all aspects of student teaching. The intent of the honor code is to place the responsibility for the demonstration of individual effort directly on the student (and their peers) rather than be monitored by an authority figure. The coaches introduce the concept of individual responsibility early and often. It is an easy, logical step to ingrain both the meaning and the philosophy of respect into student thinking. In order to be used for behavioral modulation in team members, five levels of respect, in rank order of importance, are addressed: (Respect) 1. for themselves; 2. for their teammates; 3. for the judging program, (a. at the individual university; b. judging in general); 4. for our hosts; and 5. for the coach. If, through training (and insistence of the coach), respect at all levels is part of the team philosophy, behavior problems are minimal. Discipline of an individual's behavioral breaches are first through peer oriented loss of respect from teammates and contemporaries, which at this age for the average team member, is a powerful motivation. If the coach has clearly established the program's expectations, is fair and consistent in dealing with all aspects of the judging team experience, there need be no role as a fear generating, rule-book adhering disciplinarian.

Key Words: Judging team behavior

The Role of Forages in Enhancing Food Safety and Quality and a Clean Environment

996 Forage feeding to reduce pre-harvest *E. coli* populations in cattle, a review. T. R. Callaway*¹, R. O. Elder¹, J. E. Keen², R. C. Anderson¹, and D. J. Nisbet¹, ¹USDA/ARS-Southern Plains Agricultural Research Center, College Station, TX, ²USDA/ARS-Meat Animal Research Center, Clay Center, NE.

Although *E. coli* are commensal organisms that reside within the host gut, some enteropathogenic strains of *E. coli* can cause hemorrhagic colitis in humans. The most notable enterohemorrhagic *E. coli* (EHEC) strain is O157:H7. Cattle are asymptomatic natural reservoirs of *E. coli* O157:H7; and it has been reported that as many as 30% of all cattle are carriers of this pathogen, and in some circumstances this can be as high as 80%. Feedlot and high-producing dairy cattle are fed high grain rations in order to increase feed efficiency. Because cattle have low amylase activity, much of the starch passes to the hindgut where it is fermented. EHEC are capable of fermenting sugars released from starch breakdown in the colon, and populations of *E. coli* have been shown to be higher in grain fed cattle, and this has been correlated with *E. coli* O157:H7 shedding in barley fed cattle. When cattle were abruptly switched from a high grain (corn) diet to a forage diet, generic *E. coli* populations declined 1000-fold within 5 days and the ability of the fecal generic *E. coli* population to survive an acid shock similar to the human gastric stomach decreased. Other researchers have shown that a switch from grain to hay caused a smaller decrease in *E. coli* populations, but did not observe the same effect on gastric shock survivability. In a study that used cattle naturally infected with *E. coli* O157:H7, fewer cattle shed *E. coli* O157:H7 when switched from a feedlot ration to a forage-based diet compared to cattle continuously fed a feedlot ration. Results indicate that switching cattle from grain to forage could potentially reduce EHEC populations in cattle prior to slaughter; however the economic impact of this needs to be examined.

Key Words: Forage, Cattle, *E. coli*

997 Keeping *Escherichia coli* O157:H7 Down on the Farm. M. P. Doyle*¹, ¹University of Georgia.

E. coli O157:H7 is responsible for an estimated 73,500 cases of infection in the U.S. annually, with principal vehicles of transmission being beef, produce, water (both drinking and recreational), and cattle (handling). *E. coli* O157:H7 is carried in the intestinal tract of cattle and the pathogen's most frequent origin is direct or indirect contact with cow manure. Manure can contaminate food when used as a soil fertilizer, when it pollutes irrigation water, when cattle defecate near produce or foods of animal origin, and when intestinal contents or manure-laden hides contact carcasses during slaughter and processing. Case-control studies of patients with *E. coli* O157:H7 infections revealed that eating undercooked ground beef, living on or visiting a farm, and contact with farm animals, especially cattle, are major risk factors associated with acquiring *E. coli* O157:H7 infections. An estimated 1.36 billion tons of animal manure is produced in the U.S. annually, with greater than 90% attributed to cattle. An effective control program to substantially reduce *E. coli* O157:H7 infections will require the implementation of intervention strategies throughout the food continuum, from farm to table. Promising intervention measures at the farm include competitive exclusion bacteria, bacteriophage, innovative vaccines, and targeted animal management practices addressing common points of contamination. Most promising of these to date is competitive exclusion bacteria of which 80 to 90 percent of cattle administered probiotic *E. coli* was rid of *E. coli* O157:H7 within ca. 2 weeks posttreatment.

Key Words: *E. coli*, beef, contamination

998 Role of diet on conjugated linoleic acid content of milk and meat. T. R. Dhiman*¹, ¹Department of Animal, Dairy and Veterinary Sciences, Utah State University, UT 84322-4815.

Conjugated linoleic acid (CLA) occurs naturally in many foods. However, the principal dietary sources are meat, dairy products and other foods derived from ruminants. Research studies with animal models suggest that CLA reduces the risk of cancers at several sites (mammary tissue, prostate, gastrointestinal tract, lung, and skin), reduces body fat and enhances growth of lean body mass. Current knowledge suggests that the *cis*-9, *trans*-11 CLA isomer is probably responsible for anticancer effects, while the *trans*-10, *cis*-12 CLA isomer induces body

composition changes. Milk fat CLA is 92% *cis*-9, *trans*-11 and contains no detectable *trans*-10, *cis*-12 CLA. However, beef fat has an average 78% of the total CLA as *cis*-9, *trans*-11 and 22% *trans*-10, *cis*-12 CLA. Fat from milk and beef contains an average 4.0 and 3.5 mg CLA/g of fat, respectively. Current research suggests that CLA in meat and milk fat of ruminants originates from two sources: 1. From incomplete ruminal biohydrogenation of lipids, 2. Endogenous synthesis from *trans*-11 C18:1 fatty acid. The delta-9 desaturase enzyme is responsible for the conversion of *trans*-11 C18:1 in the mammary gland. Research review shows that diet and management practices can influence the CLA content of milk and meat. Cows grazing on pasture had 500% more CLA content in milk compared with cows fed typical dairy cow diets containing conserved forage and grain in a 50:50 ratio. Feeding oils such as soybean, sunflower, peanut, linseed and fish oil to dairy cows can increase the CLA content of milk. Feeding full fat extruded soybeans and cottonseed to dairy cows doubled the CLA content of milk and cheese compared with feeding normal diet. Other factors such as feeding high grain diets and reducing the forage particle size will decrease milk fat CLA. Feeding up to 5% soybean oil to feedlot beef cattle during finishing period resulted in a small increase in CLA content of beef. Beef from steers raised on forages had 550% more CLA *cis*-9, *trans*-11 isomer, whereas steers receiving grain in back-grounding and grazed on pasture with no grain supplementation during finishing period had only 300% more CLA compared with beef from steers fed typical feedlot high grain diet. Raising beef cattle on forages and pasture with no grain supplementation can enhance the CLA content of beef.

Key Words: CLA, Milk, Meat

999 Physiological and productive responses of dairy cows to intake and characteristics of fiber. D. Savant*¹ and D.R. Mertens², ¹INRA-Institut National Agronomique, Paris-Grignon, ²US Dairy Forage Research Center, Madison, WI.

Numerous studies have dealt with the influence of chemical and physical fiber in the diet on intake, chewing activities, digestion, metabolism and milk secretion. A database compiled from these experiments was analyzed statistically to extract multiple marginal responses of cattle to dietary fiber. The database consisted of 179 experiments (446 treatments) related to NDF or concentrate proportion in dietary DM and 53 experiments (82 treatments) dealing with the influence of dietary mean particle size (MPS). Data were analyzed with the GLM procedure to investigate relationships across and within experiments. Intake was significantly depressed as dietary NDF increased. Chewing activities decreased as dietary NDF and MPS decreased. Rumen contents were influenced by NDF intake, but not by MPS. Ruminant parameters (pH, VFA contents and profile, microbial growth, etc.) were affected in a similar manner by both NDF and MPS. These responses were consistent with data on chewing activities. Organic matter digestibility and net energy concentration were altered by dietary NDF and DMI. Raw milk yield was depressed as dietary NDF increased. Milk protein and lactose percentages were decreased at a similar rate when dietary NDF increased while the opposite occurred for milk fat percentage. Milk fat was also highly dependent on MPS. In the total database, there was consistency between milk fat percentage and parameters of digestion in the rumen, particularly pH and acetate/propionate ratio. The responses of milk secretion to dietary energy supply were studied in experiments where OM digestibility was measured. It appeared that responses of milk protein, lactose and raw yield were linear functions of energy supply, whereas the response of fat secretion was curvilinear. These responses to dietary fiber contribute quantitatively to the current debate about the concept of effective fiber in dairy cows. Meta-analysis can be used to indicate threshold values for dietary characteristics that can maintain animal health and product quality.

Key Words: Ruminant pH, Fiber, Particle size

1000 Impacts of livestock forage and pasture use on carbon sequestration and greenhouse gas emissions. D.E. Johnson*, H.W. Phetteplace, A.F. Seidl, and R. Conant, *Colorado State University, Ft Collins, CO.*

Representative models of U.S. dairy (WI, CA) and beef (AL, TX, UT, VA, WI) production systems were constructed to sum the land use requirements, greenhouse gas (GHG) emissions and product outputs. Total GHG emissions expressed, as CO₂ equivalents per unit of milk were 1.4 and 1.5 kg/kg, while the production of beef as live weight at the farm gate resulted in from 13.8 to 18.2 kg/kg. The 2 dairy systems utilized 0.6 (CA) and 1.1(WI) ha of land per mature cow unit. Beef systems', including stocker and feedlot, land use was projected to range from 1 to 3.7 ha per mature cow unit. Best management practices applied to all land used in these operations is expected to store .12 and .22 Mg/cow unit for dairy systems and from .2 to .7 Mg of carbon/beef cow unit, anywhere from 4 to 50% of total system GHGs. Twenty-yr

simulations of soil C were run using the Century model for 7 to 10 soil types in 3 locations assuming normal tillage operations. Changing from pasture to either hay or various grain cropping regimens generally decreased soil-C (av. -0.25 Mg/ha/yr), however, the changes were quite variable by soil type. The reverse simulation, change from grains or hay to pasture, at the third location showed wide variations also but averaged +0.28 Mg/ha/yr. Thus changing to increased pasture usage could yield additive C sequestrations above those realized from BMP's. Potential grazing land C-sequestration in the U.S. has been estimated at 4 fold the total agricultural grazing land GHG emissions. Caution must be exercised since tradeoffs, as will be discussed, can occur e.g., if reduced rate of production increases CH₄/product or excess forage N enhances N₂O emissions. Also, long term measurements of soil C in intensively managed pastures can show C losses as noted for a location in NZ.

Key Words: Pasture and forage, Carbon sequestration, Greenhouse gases

ASAS/ADSA Breeding and Genetics: Genetic Parameters of Beef Cattle

1001 Development and use of genetic markers to predict marbling and tenderness in beef cattle. F. L. Fluharty* and D. J. Jackwood, *The Ohio State University, Wooster, OH.*

Detecting animals with the genetic potential for superior performance or meat characteristics requires identifying those genes controlling the desired traits. Since identifying the genes controlling performance and meat characteristics is not practical at this time, genetic markers are used. These markers are used to identify a specific location, or loci, on an animal's chromosome. The key to developing a useful genetic marker is to find one that identifies the specific loci of genes responsible for the trait of interest. We have used the random amplified polymorphic DNA (RAPD) assay to identify two markers that correlate highly with marbling and four markers that correlate highly with tenderness in crossbred beef cattle. Diagnostic tests for these markers that are ultimately developed for commercial use must be relatively low cost, extremely reliable, and logistically appropriate to allow for large numbers of samples to be analyzed in a short period of time. Once an animal's genetic potential is known, management and nutritional strategies must be developed to target the animal toward a known outcome or consumer group. From the standpoint of the seedstock sector, knowing the genetic result of a planned mating shortly after the calf's birth could enhance genetic selection. Feeder calves could be sold in genetically similar groups that are targeted toward a specific consumer group and managed in the feedlot to achieve their potential. The widespread use of genetic technology could lead to a formalized market system in the cattle industry.

Key Words: genetics, markers, beef

1002 Evidence for an association between a *Hind III* PCR-RFLP of the bovine insulin-like growth factor binding protein-2 (IGFBP-2) locus and growth and carcass traits in beef cattle. M. Pagan*, J. Cowley, N.E. Raney, and C.W. Ernst, *Michigan State University, East Lansing.*

Insulin-like growth factor binding protein-2 (IGFBP-2) was selected as a candidate gene for growth and carcass merit in beef cattle. Simmental (n = 21), Shorthorn (n = 13), Tarantaise (n = 7), Angus (n = 17), Hereford (n = 17), Salers (n = 5), Red Angus (n = 1), MARC II (n = 8), and Maine Anjou (n = 11) sired cattle were genotyped for an IGFBP-2 *Hind III* RFLP that was previously identified in our laboratory. Two alleles were found to be segregating in all breeds with frequencies of 0.14 A/0.86 B for Simmental, 0.59 A/0.41 B for Hereford, 0.15 A/0.85 B for Angus, 0.3 A/0.7 B for Salers, 0.31 A/0.69 B for Shorthorn, 0.5 A/0.5 B for MARC II, 0.54 A/0.46 B for Maine Anjou, 0.5 A/0.5 B for Red Angus and 0.07 A/0.93 B for Tarantaise sired cattle. Data from the Hereford, Shorthorn and Maine Anjou breeds (AA, AB, BB genotypes represented) was analyzed for possible associations between IGFBP-2 genotypes and growth and carcass traits. A statistically significant effect of genotype (P < 0.05) was found for days on feed, hot carcass weight, dressing percentage, trimmed hot carcass weight, cold carcass weight, ribeye area and USDA yield grade. Animals with the BB genotype had fewer days on feed, higher hot carcass weight and higher dressing percentage than those with the AB genotype (P < 0.05). No significant differences were observed between AA and BB individuals or

between AA and AB individuals for these traits (P > 0.05). For trimmed hot carcass weight and cold carcass weight, the AA and BB genotypes represented the animals with higher weights in relation to the heterozygous (AB) animals (P < 0.05). The BB individuals had higher ribeye areas and better USDA yield grades than the AA and AB animals (P < 0.05). Therefore, animals with the BB genotype appear to have more desirable growth and carcass characteristics. Results of this study indicate that an association may exist between alleles of the IGFBP-2 gene and growth and carcass traits in beef cattle. Validation of these results in additional populations is warranted.

Key Words: PCR-RFLP, IGFBP-2, Growth

1003 Effects of selection for yearling ultrasound intramuscular fat percentage in Angus bulls on carcass traits of progeny. R. L. Sapp*, J. K. Bertrand, and T. D. Pringle, *University of Georgia, Athens.*

Twenty-one Angus bulls from three purebred farms were used to determine the effects of selection for phenotypic yearling ultrasound intramuscular fat percentage (USIMF) on the carcass traits of steer progeny managed for commercial slaughter. Bulls were selected based on their high or low phenotypic USIMF within a contemporary group. Average USIMF was 4.01% (SD = 1.07, n = 10) and 1.59% (SD = 0.53, n = 11) for high USIMF (HU) and low USIMF (LU) line bulls, respectively. Each bull was randomly mated to a group of 14 to 30 purebred Angus females for 1 to 5 years. One bull from the HU and one bull from the LU were used throughout the project. Birth weight, weaning weight, yearling and carcass weight, fat thickness at the 12th rib (FAT), longissimus muscle area at the 12th rib (REA), and marbling score (MB) measurements were taken on 196 steer progeny. Carcass data were linearly adjusted to 480 d of age at slaughter. Fixed effects for all traits were birth year of calf, phenotypic USIMF line of sire, and interaction between year and line. Sire, nested within year and line, was included as a random effect. Progeny data were analyzed using the MIXED procedure of SAS. Least squares means of progeny sired by HU (LU) bulls for MB and quality grade (QG) were 447.16 ± 10.13 (408.19 ± 10.09) and 606.23 ± 5.30 (585.09 ± 5.29), respectively, where MB of 400 = small and QG of 500 - 599 = Select, 600 - 699 = Choice. Birth weight (P < 0.05), MB (P < 0.02), and QG (P < 0.02) were found to be larger in steers sired by HU bulls. Longissimus muscle area was larger (P < 0.02) for steers sired by LU bulls. Sire selection based on USIMF was effective in increasing MB and QG in steer progeny. These results suggest that yearling bull ultrasound measurements can be used as selection criteria for genetic improvement of steer carcass traits, and selection for higher levels of marbling can be obtained without increasing fat thickness.

Key Words: Ultrasound, Intramuscular Fat, Selection Response

1004 Estimation of heritability for serially measured ultrasound fat thickness and percentage of intramuscular fat in Angus cattle using random regression models. A. Hassen*, D. E. Wilson, and G. H. Rouse, *Iowa State University, Ames, IA, USA.*

The present study included serially measured ultrasound fat thickness (FTK) and percentage of intramuscular fat (PIMF) measures from 423 purebred Angus bulls and heifers. Cattle were born during the spring of 1998 and 1999 at Rhodes beef research farm. Each year, bulls and heifers were scanned four to six times for FTK and PIMF starting at an age of 180 to 269 days, with 30 to 40 days interval between scans. The objective of this study was to evaluate the general trend in heritability and variance component estimates for FTK and PIMF measures spanning ages at measurements. Initially, FTK and PIMF observations from each scan session were analyzed using single-trait animal model. In further evaluation, data were subjected to random regression (RR) models that included fixed effects of contemporary group as well as a linear and quadratic regression on orthogonal polynomials of age. Random effects considered were RR coefficients on orthogonal polynomials of age for each of animal direct genetic and permanent environmental effects. For both traits measurement error variances were assumed independent and homogeneous across ages. Heritability of FTK increased from 0.16 at 196 days age to 0.45 at ages 413 to 441 days. Similarly, heritability of PIMF increased from a minimum of 0.39 at 217 to 266 days of age to a maximum of .58 at 441 days of age. Heritability and repeatability of FTK at one year of age were 0.41 and 0.79, respectively. The corresponding values for PIMF were 0.49 and 0.70, respectively. Heritability estimates from single trait analysis were similar when compared at measurement ages of the respective sessions. Permanent environmental variance contributed to a relatively large proportion of the phenotypic variance for FTK measures ranging from 22.1% to 47.3%, as compared to 21% to 27.7% for PIMF measures. The results suggest that individual selection based on FTK at earlier ages may not be effective due to a large contribution of non-genetic effects to the total phenotypic variance.

Key Words: Composition, Ultrasound, Heritability

1005 Use of repeatedly measured ultrasound percentage of intramuscular fat data to evaluate individual animal rankings. A. Hassen*, D. E. Wilson, and G. H. Rouse, *Iowa State University, Ames, Iowa, USA.*

This study used serially measured percentage of intramuscular fat (PIMF) measures of 82 purebred Angus bulls born in the spring of 1999 at Rhodes beef research farm. Bulls were serially scanned six times for PIMF by a certified technician starting at an age of 180 to 254 days. Intervals between scans ranged from 27 to 40 days and at each session all cattle were scanned twice at two consecutive days (day-I and II). The objective of the study was to compare overall and individual animal ranking for PIMF based on day I and II measurements at each session. The overall mean PIMF values for scans one to six were 3.01, 3.65, 4.10, 4.25, 4.47, and 4.96%, respectively. The absolute difference between day I and II for scan sessions one to six were 0.47, 0.67, 0.62, 0.66, 0.62, and 0.63%, respectively. Repeatability of PIMF values increased with scan session ranging from 0.41 at the second scan to 0.72 at the sixth. A similar analysis of pooled data using random regression model showed a general increase in repeatability values with age ranging from 0.63 at ages 252 to 287 days to a maximum of 0.79 at ages 427 to 441 days. Individual animal curves based on mean values of day I and II of each session often provided a clear view of changes in PIMF than separate plots from the respective days. When PIMF values were compared to carcass intramuscular values, day II measures showed less bias (0.55% vs. 0.58%), absolute difference (0.90% vs 1.00%), and a better rank correlation (0.75 vs. 0.66) and root mean square error (0.96% vs. 1.09%) than measurements taken on day I. In trials involving evaluation of individual animal body composition in young cattle using relatively small sample size, taking PIMF measurements from each animal at two consecutive times (days) for each session may provide a better view of trends.

Key Words: Ultrasound, Intramuscular fat, Beef Cattle

1006 Heritability estimates of visceral fat weight. L. S. Gould*¹, J. A. Marchello², and S. K. DeNise², ¹*Red Angus Association of America, Denton, Texas,* ²*University of Arizona, Tucson, Arizona.*

Heritabilities were evaluated for body composition traits on calves sired by two different groups of bulls. One group of bulls (AHA) were registered with the American Hereford Association and were representative of the Hereford breed in the U.S. The other group of bulls (SCA) came from a closed herd on the San Carlos Apache Reservation in central Arizona that has been selected for 34 years to perform in a nutritionally stressful environment with no supplemental feed. Over a period of three breeding/calving seasons, 127 calves were produced from artificial matings with these sires and raised in adequate nutritional environments. Calves were fed, post weaning, to maximize gain and were slaughtered at constant weight: 520 kg for bulls, 450 kg for heifers. Bull calves remained intact the first season, but were castrated subsequently. Traits analyzed included rib eye area (RE), 12th rib back fat (BF) and visceral fat weight (VF). Differences in VF have been hypothesized to indicate differences in energy requirements for maintenance and/or growth. Because of limited data, genetic correlations and maternal effects were not estimated. All traits were analyzed using the derivative free restricted maximum likelihood procedure. Models to evaluate heritability of RE and BF included sex, and season as fixed effects. Random components included additive genetic and residual effects. Age at slaughter (SLA) for these traits was used as a covariate due to common industry practice. Heritabilities for RE and BF were .39 and .29 respectively. Because BF and RE heritability estimates are similar to estimates from other sources, the data structure of this study, although small, may be appropriate for estimating heritability of VF. Three models, differing only by which covariate was included, were used to evaluate VF. Covariates included SLA, 12th rib back fat and none. Using SLA or no covariate produced similar results with $h^2 = .10$. Using a BF covariate, $h^2 = .35$. Heritability estimates indicate that differences in VF are likely to be heritable and could enhance future predictions of genetic merit for energy requirements in beef cattle.

Key Words: Heritability, Body composition, Energy utilization

1007 Simulation of economic responses to simulated selection for increased conception rate in beef cattle. Lowell Gould*¹ and Dale VanVleck², ¹*Red Angus Association of America, Denton, Texas,* ²*USDA, ARS, MARC, Lincoln, NE.*

A stochastic simulation program was developed to quantify differences in herds of commercial beef cattle using bulls from sire lines with different genetic trends for conception rate. Breeding values were simulated for 15 traits. Conception rate (CR) and calving difficulty were modeled as threshold traits. All genetic change in commercial herds came through selection of male seed stock from sire lines with either positive conception rate (genetic) trends or no trend (NT). Income was derived from sales of weaned steer calves and cull animals. All heifer calves were retained through winter. Herds that utilized bulls from positive CR trend, had breakeven prices that were smaller by \$0.30/kg ($P < .01$). Selection for increased conception rate increased pregnancy rate by 8.0% ($P < .01$) after 25 years of selection. Increased pregnancy rate directly affected subsequent weaning rates by 9.3% ($P < .01$) between the two herds, making that herd more biologically efficient on the basis of calves weaned per cow exposed basis. However, cows were culled before calving only if they were not pregnant. Therefore, the higher pregnancy rate caused more mature cows to be retained over winter. Total body weight of all cows wintered was 161,529 kg for 350 cows in the high fertility herd and 150,558 kg in the commercial herd with no increase in conception rate ($P < .01$). Because feed consumption was based on weight of each animal, more feed was required in the high conception rate herd causing increased feed costs. Although pounds per calf weaned did not differ between the herds, the additional calves gained from increased conception rates were significant enough to overcome increased feed costs by \$12 per cow ($P < .01$). Birth weight per calf was not significantly different between the two herds, but number of assisted calvings was greater by 1.6% ($P < .01$) in the NT herd due to the different age distributions. The simulation model successfully predicted differences between selection strategies which may allow improved management decisions.

Key Words: Economics, Fertility, Management

1008 Genetic correlations between mature and birth or weaning weights of Hereford cattle. J. M. Rumph*¹, R. M. Koch¹, K. E. Gregory², L. V. Cundiff², and L. D. Van Vleck^{2,3}, ¹University of Nebraska, Lincoln, NE, ²USDA, ARS, USMARC, ³Clay Center, NE, ³Lincoln, NE.

The genetic correlations between mature weight (MW) measured at three different times per year and birth (BW) or weaning weight (WW) were estimated. The data were from a control and three selection lines, selected for weaning weight, yearling weight, and an index of yearling weight and muscle score. Weights available were taken at brand clipping (generally before calving, 1123), at breeding (1537), and when calves were weaned and when cows were pregnancy checked (573). Bivariate analyses of data from all lines were performed that paired a single seasonal MW with one of the immature weights. The one MW was taken when the cow was 6-, 7-, 5-, or 8-years-old. For MW, the model included fixed effects of year by age by line, age of dam by line (DAXL), pregnancy status by line, and birth and method of rearing of calf by line. A covariate for the interval between when the weight was measured and when the cow calved was also fit to the data. For BW (11,313 records) and WW (10,011 records), the model included fixed effects of DAXL, birth and method of rearing by age of dam by year of birth, and sex by age of dam by year of birth. A covariate for Julian birth date was also used. Random direct genetic, maternal genetic, and maternal permanent environmental effects were included in the model. Estimates of correlations between MW and BW ranged from .56 to .69 for direct and -.05 to .84 for maternal genetic effects. Estimated correlations between MW and WW ranged from .64 to .73 for direct and .50 to .91 for maternal genetic effects. Estimated correlations between maternal permanent environmental effects were from .00 to .53 between MW and BW and from .78 to .99 for MW and WW. Selection to reduce BW would be expected to decrease MW and selection to increase WW would be expected to increase MW. An index including BW, WW, and MW would be needed to optimize total productivity.

Key Words: Growth, Weight, Beef Cattle

1009 Effect of separating contemporary group by age of dam in Simmental genetic evaluation. Z. Zhang*, E.J. Pollak, and R.L. Quaas, Cornell University.

Young cows are frequently managed differently than older cows. If progeny records of heifers and cows are improperly assigned to the same contemporary group (CG) this can create a CG by age of dam interaction that is not modeled. To ensure that this does not happen, age of dam is made part of the CG definition. This will eliminate potential bias but at the expense of increased variance due to many more contemporary effects and fewer data (loosing connection). A comparison study was done with 3,337,268 records extracted from American Simmental Association (ASA) database on calves born between 1968 and 1999. The CG in 'combined' CG model was defined as in current genetic evaluation of ASA. For 'split' CG model these were separated by age of dam: greater (less) than 990 days. There were 20.3% of the calves out of young cows. Separating CG by age of dam increased number of CG (22.3%, 26.3% and 18.7 for BWT, WWT, and YWT respectively), and decreased numbers of records accepted (4.0%, 4.4% and 5.2% for BWT, WWT, and YWT, respectively). Numbers of sires, dams and nonparents decreased 4.1%, 2.9% and 2.7%, respectively. The EPD differences (combined minus split) were investigated for 10027 bulls with at least ten calves. The correlation between EPD differences and the percentage of calves out of two year old dam were negative for BWT, WWT and YWT (-0.08, -0.11 and -0.11), and positive for milk (0.05).

P	N	Mean difference ± Se (Kg)			
		BWT	WWT	YWT	Milk
0.0-0.2	3041	-0.01±0.00	+0.01±0.02	+0.07±0.03	0.15±0.02
0.2-0.4	3501	-0.01±0.00	-0.04±0.02	+0.00±0.03	0.23±0.02
0.4-0.6	1451	-0.04±0.01	-0.15±0.05	-0.19±0.07	0.21±0.02
0.6-0.8	800	-0.05±0.02	-0.33±0.08	-0.50±0.11	0.23±0.03
0.8-1.0	1234	-0.08±0.02	-0.56±0.08	-0.75±0.11	0.32±0.03
Total	10027	-0.02±0.01	-0.13±0.02	-0.14±0.03	0.21±0.01

P is percentage of calves out of two year old dams; N is number of bulls in each category.

Key Words: Age of dam, Contemporary group, Simmental

1010 Experimental selection for reduced calving difficulty: estimated breeding value trends. G. L. Bennett*, USDA, ARS, US Meat Animal Research Center.

Heifer calving difficulty is heritable but unfavorably correlated with growth. The objective of this experiment was to evaluate multiple-trait genetic evaluation as a tool for simultaneously reducing calving difficulty and maintaining growth. Select and control lines were established in four purebred (Angus, Charolais, Gelbvieh, and Hereford) and three composite (MARC I, MARC II, and MARC III) populations. The select line goals were reduced heifer calving difficulty and average yearling weights. Control line goals were average birth and yearling weights. Average weights for purebreds were defined as industry average EPD. Selection was based on EPD for heifer calving difficulty score and yearling weight EPD in select lines, and birth and yearling weight EPD in control lines. Four phenotypes (heifer calving difficulty score, birth weight, weaning weight, and yearling weight) were used to compute the multiple-trait EPD. During seven years of selection, 6,888 calves were born to 353 select sires and 2,033 calves were born to 237 control sires. Calving difficulty scores were recorded on 1,807 select and 560 control calves born to 2-yr-old dams. Estimated breeding values (EBV) in the table below show strong trends for improved direct calving difficulty score and lower direct genetic birth weight and no trend in yearling weight. For calves born in 1998 and 1999, more control calves (36%) than select calves (15%) born to heifers required assistance ($P \leq .01$). Results show that substantial genetic change in heifer calving difficulty can be made while maintaining growth to yearling age.

EBV	1993	1994	1995	1996	1997	1998	1999
Calving Difficulty Score							
Direct	-0.33	-0.65	-0.74	-0.83	-0.99	-1.06	-1.03
Maternal	0.04	0.08	-0.02	0.09	0.00	-0.08	0.01

Key Words: Calving difficulty, Selection, Breeding value

1011 Nonlinear relationship between birth weight and calving ease determined with ecological analysis in a multi-breed commercial beef herd. Y. Wang*, S.P. Miller, J.W. Wilton, P. Sullivan, and L.R. Banks, University of Guelph, Guelph, Ontario, Canada.

Ecological analysis were applied to a multi-breed commercial beef herd to examine the non-linear relationship between birth weight (BW) and calving ease (CE). Data included 133,280 records on both BW and CE for calves born between 1986 and 2000. Based on the assumption of normality and homogenous residual variances, Snell Scores were calculated by combining individual CE, age of the dam, sex of calf and mating liability (ML) of parents. ML of parents involved five categories with thresholds -1.0, -0.2, 0.2 and 1.0 based on the standardized difference between standardized sire BW ABC (Across Breed Comparison) and standardized dam yearling weight ABC. Ecological correlations, as a correlation of averages, between BW and percent of un-assisted calving and between BW and Snell Score were -0.7399 and -0.7611, respectively. A quadratic regression model described the relationship between BW (independent) and percent of un-assisted calving (dependent) explaining 87% of the variation in CE. It was evident that BW is a major indicator of CE. Snell Scores retained the nature of CE while converting the categorical record to a continuous variable. At a given BW, age of the dam was a larger source of variation for CE than sex of calf and ML of parents. For a 2-year-old dam, 90% or more calving would be expected to be un-assisted in calf weighing 22-35 kg. With age of the dam increased to 3 years and more, the same level of CE can be achieved with a broader range of BW (20-45 kg). However, Pearson correlation of -0.1930 between BW and Snell Score indicated ecological correlations cannot be extrapolated to individuals due to variation in CE with a BW category. Regression coefficients calculated enable more accurate prediction of calving difficulty with changing BW across age of dam and sex categories.

Key Words: birth weight, calving ease, beef cattle

1012 Genotype by country interactions for growth traits in Charolais populations across four countries. K. A. Donoghue* and J. K. Bertrand, *University of Georgia, Athens GA.*

The importance of genotype by country interactions was evaluated for data from Charolais associations in Australia (AUS), Canada (CAN), USA and New Zealand (NZ). Data were composed of edited birth and weaning weight and postweaning gain records from the four countries. Only herds with more than 500 trait records, with an average contemporary group size greater than 9 animals, and that had trait records from progeny of 66 international sires were used in this study. Pairwise country samples were created that ranged from 20000 to 30000 trait records and a multiple trait animal model that considered each trait as a different trait in each country was used to estimate parameters in each pairwise analysis. Direct and maternal (in parentheses) estimated genetic correlations for birth weight for AUS vs. CAN, AUS vs. USA, USA vs. CAN, NZ vs. CAN and NZ vs. USA were 0.88 (0.86), 0.85 (0.82), 0.88 (0.82), 0.85 (0.83), and 0.84 (0.80), respectively. Direct and maternal (in parentheses) estimated genetic correlations for weaning weight for AUS vs. CAN, AUS vs. USA, USA vs. CAN, NZ vs. CAN and NZ vs. USA were 0.96 (0.91), 0.95 (0.90), 0.95 (0.91), 0.95 (0.92), and 0.95 (0.92), respectively. Direct estimated genetic correlations for postweaning gain for AUS vs. CAN, AUS vs. USA, USA vs. CAN, NZ vs. CAN and NZ vs. USA were 0.89, 0.91, 0.94, 0.90, and 0.91, respectively. Direct and maternal heritabilities were similar across all countries for birth and weaning weight, while direct heritabilities for postweaning gain in AUS and NZ were slightly lower than those in CAN and USA. The absence of genotype by country interactions observed in this study strongly indicates that a joint genetic evaluation for growth traits for Charolais populations could be conducted. A model that treated information from AUS, CAN, USA and NZ as one population, while adjusting for possible heterogeneous variances, could be implemented for this purpose.

Key Words: Genotype by Country Interaction, International Evaluation, Beef Cattle

1013 Evaluation of milk yield and udder characteristics in beef cows sired by high or low Milk EPD bulls. K. J. Stutts* and D. S. Buchanan, *Oklahoma Agricultural Experiment Station, Stillwater, OK.*

Maternal milk is an important influence on weaning weight that affects production efficiency in beef herds. The objective of this study was to evaluate High and Low Milk EPD sires for milk production and udder characteristics of their daughters. Cows used in this study were produced through the mating of Angus and Hereford bulls that differed in Milk EPD level to Hereford-Angus and Hereford-Angus-Brahman cows. They ranged in age from 7 to 11 yr old. All cows were bred by artificial insemination to South Devon bulls and calves were born in the spring from early February to early April. Milk production data were collected 7 times prior to weaning at 28 d intervals using the weigh-suckle-weigh method. The final milk production data corresponded to a 205-d weaning age for all calves. Udder measurements and scores were taken during periods 3 and 6 after complete removal of milk from the udder by suckling. Cows were restrained in a squeeze chute and visual conformation scores were given to each teat and the udder. Linear measurements were taken on the length of each teat, distance between the front teats, distance between the rear teats, and the diagonal distance from the left front to the right rear teat. Data were analyzed using least squares. Factors included in the model were breed, Milk EPD level, sex of calf, age of dam, and all two-way interactions. Age of calf was included as a covariate. High Milk EPD cows produced more milk than Low ($P < .05$), but there was not a difference ($P = .71$) in milk production between breeds. The interaction between breed and Milk EPD level was approaching significance ($P = .15$). Hereford sired cows had longer teat length ($P < .02$) and higher (more pendulous) udder scores ($P < .05$) than Angus. Low Milk EPD cows had slightly lower udder scores than High ($P < .10$). These results further confirm the utility of Milk EPD to predict milk production differences and provide only small evidence that there may be a negative effect on udder conformation for older High Milk EPD cows.

Key Words: Beef Cattle, Milk Production, Udder Characteristics

ASAS/ADSA Breeding and Genetics: Genetic Parameters of Dairy Cattle

1014 Possibilities for genetic improvement of fertility in US dairy cattle. K. A. Weigel*¹ and J. S. Clay², ¹*University of Wisconsin, Madison*, ²*Dairy Records Management Systems, Raleigh, North Carolina.*

Interest in improving conception rates has skyrocketed in recent years. Direct costs of poor fertility include increased semen costs, veterinary costs, days open, and involuntary culling. Indirect costs include reduced genetic progress due to a larger number of repeat inseminations and an increased proportion of pregnancies to genetically inferior natural service bulls. Selection for male (service bull) fertility is possible using Estimated Relative Conception Rate data from Dairy Records Management Systems. Service bulls are evaluated for 70-day non-return rate on first inseminations. Evaluations for all bulls with at least 300 inseminations in the past three years are published. Sire evaluations for female (daughter) fertility are not yet available, but a system is under development. Female fertility can also be measured as 70-day non-return rate; in this case male and female fertility can be analyzed jointly using a maternal effects model. Days to first insemination can also be evaluated, but measurements may be biased by the use of heat synchronization products. In a pilot study, male and female fertility were evaluated as 70-day non-return rate using 8.03 million insemination records from 1995 to present. The range in daughter fertility PTA for Holstein sires was roughly 10%, similar to the range in service bull fertility solutions. The correlation between male and female fertility solutions of Holstein sires was 0.02, and the correlation between female fertility and PTA milk was 0.09. Therefore, it will be possible to improve conception rates with little or no loss in genetic merit for milk yield by practicing secondary selection for male and female fertility. Fertility evaluations can be improved by increasing the quantity and quality of DHI insemination data, by utilizing repeat service data, and by considering models that account for the binary nature of the data.

Key Words: genetic selection, fertility, dairy cattle

1015 Effect of heat stress on Non-Return rate in Holstein cattle. O Ravagnolo and I Misztal*, *The University of Georgia, Athens, GA.*

The objective of this study was to examine the relationship between reproductive traits and heat stress. Non-return rate at 45 days (NR45) was analyzed in a fixed effect model that included Temperature Humidity Index from a nearby weather station as a measurement of heat stress. Data consisted of 150,200 first inseminations at first and later parities of 110,860 Holstein cows from 550 herds in Georgia, Tennessee and Florida with weather information from 16 weather stations. THI on the day of the insemination, 2 days prior, 5 days prior, 10, 20 and 30 days after insemination were studied as independent variables. THI on the day of insemination showed the highest effect on NR45, followed by 2 days prior, 5 days prior and 5 days after insemination, but no relationship was found with THI at 10, 20 and 30 days after insemination. NR45 showed a decrease of 0.005 per unit increase in THI on the day of insemination for THI > 68. First and later parities presented similar thresholds but responded differently to increase in THI, with NR45 being significantly lower and more susceptible to increases of THI in cows in their first parity than in later parities (0.008 vs. 0.005 decrease per unit THI). Threshold for sensitivity to heat stress changed with the states, with FL, GA, TN having thresholds of 66, 70 and 70 respectively. The decrease in NR45 per unit increase of THI was 0.006, 0.005 and 0.007 for FL, GA and TN respectively (or a total of 0.07, 0.07 and 0.10). On the TN data only, the final fixed effect model used was $NR45 = \text{Herd}(\text{Year}) + \text{Month}(\text{Year}) + \text{age}(\text{parity}) + \text{days in milk} + 100\text{d milk} + \text{THI} + \text{error}$. Animals with more than 150 DIM had a 0.16 lower NR45 than animals with less than 60 days in milk at insemination. Lower milk producing animals showed 0.08 higher NR45 than higher producing animals. A difference of 0.10 in NR45 was observed between THI lower than 70 and THI 84. This variation in NR45 due to THI changes is sufficient to merit further studies to examine genetic components for heat tolerance for this trait.

Key Words: Heat Stress, Non-return rate, Holstein

1016 Analysing survival score and calving interval as a measure of fertility in Holstein Friesian cows in seasonal calving herds. V.E. Olori*¹, T.H.E. Meuwissen², and R.F. Veerkamp², ¹*Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland*, ²*Institute for Animal Science and Health, ID-Lelystad, Lelystad, The Netherlands*.

In a grass-based production system with seasonal calving, fertility is of major economic importance especially as a delay in conception can lead to culling and a shift in calving pattern. Calving interval (CI) information is readily available from milk records, analysing it presents a problem however as it can only be derived for cows that conceive and calve again. Therefore, calving interval should be treated as a censored trait, with survival to the next lactation (SU) being the censoring variable. These two traits are analysed in this study with a multivariate model to account for the non-random scoring of the CI. Genetic parameters and breeding values (EBVs) for CI and SU were estimated with a sire model for 1st lactation Holstein Friesian cows in Ireland. SU was pre-adjusted for milk yield within HYS. Milk yield was included as a third trait in the analysis because of the large effect it has on both CI and SU. The residual covariance could not be estimated because CI was only known for cows with a SU score of 1 thus this covariance was assumed to be 0. The h^2 was 0.04 for CI and 0.01 for SU with a genetic correlation of -0.28. Genetic standard deviation was 4% for SU and 7 days for CI. EBVs for about 1000 bulls with at least 20 daughters, ranged between -3.28% and 4.22% for survival rate and between -8 and 15 days for CI indicating a difference of about 8% and 23 days between the best and worst bulls. Inter-quartile range was 1.4% and 3.3 days for SU and CI respectively. The current model is expected to recover most of the genetic variation in fertility that can be recovered from calving dates, and future extensions, i.e. use of linear type trait or additional lactations for survival, appear straightforward. These traits now form part of the national index for selecting dairy cows and bulls in Ireland.

Key Words: Cow Fertility, Calving Interval, Survival rate

1017 Correlations among body condition score change, body condition score, production and reproductive performance. C. D. Dechow*¹, G. W. Rogers¹, and J. S. Clay², ¹*Pennsylvania State University*, ²*Dairy Records Management Systems*.

The objectives of this study were to estimate correlations among body condition score change (BCSCH), body condition score (BCS), production and reproductive performance. Producer-recorded BCS were obtained from Dairy Records Management Systems in Raleigh, NC through the PCDART program. Body condition scores were available at both calving (C) and postpartum (PP) for 7,424 cows in first lactation and 6,092 cows in second lactation. An additional 13,196 cows in first lactation and 10,053 cows in second lactation had BCS at C or PP only. Body condition score change was defined as BCS at C minus BCS at PP. Mature equivalents (ME) for milk, fat and protein, days to first service (DFS) and services per conception (SPC) were available. Heritabilities and correlations were estimated assuming bi-variate animal models using Average Information REML. Models included herd-year-season, age at calving, prior calving interval and random animal effect. Non-productive traits were analyzed with and without ME milk as a covariable. Initial correlations between BCS and BCSCH were obtained using all available observations. Additional estimates were obtained through pedigree linkages only by not allowing cows with BCSCH information to contribute BCS observations. Heritabilities estimates for BCSCH ranged from 0.02 to 0.07. Genetic correlation estimates between BCSCH and BCS at C ranged from -0.11 to -0.48. Genetic correlation estimates between BCSCH and BCS at PP ranged from -0.56 to -0.99. Phenotypic correlations between BCSCH and BCS were near 0.54 at C and -0.65 at PP. Genetic correlations between BCSCH and production traits ranged from 0.17 to 0.50. Genetic correlations between BCSCH and DFS ranged from 0.29 to 0.68. Selection for yield appears to increase BCS loss in early lactation by reducing BCS PP. More loss in BCS was correlated with an increase in DFS.

Key Words: Body Condition Score Change, Heritability

1018 Calving disorders of Holstein cows selected for large versus small body size. B.J. Heins*, L.B. Hansen, A.J. Seykora, and G.D. Marx, *University of Minnesota, St. Paul*.

Holsteins selected for large versus small body size since 1966 were evaluated for edema, retained placenta, dystocia, and stillbirths from the Northwest Outreach and Research Center, Crookston, of the University of Minnesota. Edema scores (1 as none to 5 as severe), placental scores (1 as cleaned normally to 5 as prolapsed), dystocia scores (1 as no assistance to 5 as pulled), and stillbirths (0 for alive or 1 for dead) were recorded for 1228 Holstein cows from 1985 to 2000 (born from 1983 to 1999). Records were for 542 first lactations, 320 second lactations, and 366 third or later lactations, and the three lactation groupings were analyzed separately. Investigated were effects of body size line, year of calving, body weight within line, age, sex of calf, and time of calving on the dependent variables: edema score, placenta score, dystocia score, and stillbirths. The large versus small size lines did not differ significantly for edema, retained placenta, or dystocia. However, there was a tendency for edema to increase with body weight within size line. Mean scores were 2.5 for edema, 1.3 for placenta, and 2.2 for dystocia. For dystocia, only sex of calf was significant ($P < .001$) for all lactation groupings. For first calving, the least squares mean for calf sex was 3.4 for males and 2.8 for females. Mean score for dystocia for the entire herd (both body size lines) tended to run higher than the national average and this might have resulted in higher stillbirth rates of calves. The correlation of dystocia and stillbirths was .32 and was highest for first calving. The unadjusted mean for stillbirth rate across all parities and both body size lines (14% for the large line and 10% for the small line) was 12%. The greatest incidence of stillbirths was for first-lactation cows at 23%. Incidence of stillbirth was 3% for second parity and 6% for third and higher parities. For first calving, the body size lines differed significantly ($P < .05$) for stillbirths, with least squares means of 29% for the large line and 22% for the small line. There was no significant trend with time for any of the four traits across the 16 years.

Key Words: body size, dystocia, stillbirths

1019 Genetic parameters for stillbirth in Dutch Black-and-White dairy cattle. A. Harbers*, L. Segeren, and G. De Jong, *CR Delta, Arnhem, The Netherlands*.

Data on stillbirth are recorded in the Netherlands but are not used for a genetic evaluation. Aim of this study was to estimate genetic parameters for stillbirth as a prerequisite for a genetic evaluation. Data included 1 million records of first parity (PAR 1) and 2.8 million records of higher parity (PAR ≥ 2) cows from 1994 onwards. Four different traits (first vs. higher parities and stillbirth as a direct vs. indirect effect) were considered. Heritabilities were estimated using a model with age at calving, parity, year of birth, month of birth, and herd by 2-year period as fixed effects. Random effects were included for sire (direct effect) or maternal grandsire (maternal effect) and residual. Breeding values for indirect effects were computed as maternal effect - 0.5 × direct effect. Genetic correlations were derived from breeding values of bulls adjusted for reliability. Unadjusted means are higher for first parities than for higher (11.4% vs. 5.3%). No phenotypic trend in stillbirth over time was found. Heritabilities range from 0.01 to 0.05. Stillbirth in PAR 1 has only a moderate correlation with stillbirth in PAR ≥ 2 (0.52-0.73), especially for the direct effect. The correlation between direct and indirect effects are -0.07 and -0.02 for PAR 1 and PAR ≥ 2 , respectively. Predicted transmitting abilities (PTA) of bulls range from -7% to +7% for both direct and indirect effects in PAR 1. In PAR ≥ 2 , PTA's range from -3% to +3% for direct and indirect effects. The results indicate that genetic variability for stillbirth exists, but heritabilities are low. Genetic correlations indicate that stillbirth in PAR 1 differ from stillbirth in PAR ≥ 2 . Genetic correlations between direct and indirect effect indicate that both traits can be improved independently. Based on these results a routine genetic evaluation of stillbirth in the Netherlands will be implemented in 2001.

Key Words: Stillbirth, Genetic parameters, Dairy cattle

1020 Timeliness of progeny testing through artificial insemination and percentage of bulls returned to service. H.D. Norman*¹, R.L. Powell¹, J.R. Wright¹, and C.G. Sattler², ¹Agricultural Research Service, USDA, Beltsville, MD, ²National Association of Animal Breeders, Columbia, MO.

Progeny-test (PT) programs of US artificial-insemination (AI) organizations were examined to determine timeliness, PT daughter distribution, and future use of PT bulls. Means, standard deviations (SD), and deciles for bull age at semen distribution, PT daughter birth, and PT daughter calving were calculated by breed (Ayrshire, Brown Swiss, Guernsey, Holstein, and Jersey) for bulls entering AI service since 1959. Mean Holstein bull age at semen distribution (16 mo) changed little over time, but SD decreased from 4 mo in the 1960s to 2.4 mo in the 1990s. Most bulls (80%) had semen released by 18 mo. Mean Holstein bull age at PT daughter birth and calving declined by 4 mo from the 1960s to the 1990s to 29 mo and 56 mo; SD decreased from 6 to 3 mo. Usually for other breeds, bulls were older at PT daughter birth and calving, and SD were larger. Mean Holstein bull age when 80% of PT daughters had been born declined from 36 mo in the 1960s to 31 mo in the early 1990s; for other breeds, bulls were older (36 to 41 mo). Mean Holstein bull age when 80% of PT daughters had calved declined from 65 mo in the 1960s to 59 mo in the 1990s; for other breeds, bulls were older (62 to 70 mo). Percentage of first-lactation Holstein cows that were PT daughters increased over time to 14%. For Holsteins, percentage of herds with five first-lactation records or more that were usable for evaluation but with no usable PT records decreased from 85% in 1965 to 39% in 1998, whereas percentages increased from 11 to 38% for herds with from 1 to 19% PT records and from 1 to 5% for herds with >50% PT records. Percentage of Holstein PT bulls returned to AI service declined from >50% for bulls with PT entry in 1965 to about 15% for bulls with PT entry around 1990; for other breeds, about 20% of recent bulls returned to service. More rapid sampling and increased selection intensity of PT programs have lead to more rapid genetic progress.

Key Words: Artificial insemination, Progeny test

1021 Adjustment for heterogeneity of genetic variance across herds in the Italian Holstein Friesian. F. Canavesi*¹, M. del P. Schneider¹, M. Cassandro², A. Bagnato³, and A. B. Samore¹, ¹ANAFI, Italy, ²University of Padova, Italy, ³University of Milan, Italy.

Heterogeneity of genetic and residual variances exists across herds in the Italian Holstein Friesian population. Residual standard deviations varied from 30 to 35 kg for protein yield and genetic standard deviations across classes varied from 20 to 24 kg. Consequently, heterogeneity of heritability (.30-.34) was observed. The official procedure for genetic evaluation in Italy pre-adjusts for phenotypic within herd variability. This procedure standardizes the residual variance but not the genetic, leaving unchanged the difference in heritability across herds and leading to possible bias in genetic evaluations if daughters of bulls are not randomly distributed across herds. Two methods to account for heterogeneity were tested: a multiple trait approach and a pre-adjustment that takes into account increase of heritability according to herd variability. Methods were compared in terms of sire rankings with the official genetic evaluation. Data used were from the February 1999 official evaluation. The multiple trait approach classified herds into categories of variability and lactations from different categories were considered as different traits. The genetic pre-adjustment of data followed the approach currently applied in the US for its official genetic evaluation. Heritability was assumed to increase with increased within herd variability. Both methods led to a greater representation of bulls in the top list from herds with lower genetic variability (+2/3 bulls) and the difference in kg of protein decreased by 1 kg on average. The multiple trait approach produced a less accurate comparison between generations of bulls, by overestimating older bulls. This result had also an impact on international comparison. Pre-adjustment of genetic variance heterogeneity across herds is now being considered to improve the quality of genetic evaluation procedures in Italy.

1022 Simultaneous accounting for heterogeneity of (co)variance components in genetic evaluation of type traits. N. Gengler^{1,2}, G. R. Wiggans*³, J. R. Wright³, and T. Druet^{1,2}, ¹Gembloux Agricultural University, Gembloux, ²and National Fund for Scientific Research, Brussels, Belgium, ³Agricultural Research Service, USDA, Beltsville, MD.

The multi-trait canonical transformation genetic evaluation system for type traits was modified to estimate adjustments for heterogeneous variance (HV) simultaneously with estimated breeding values (EBV) for final score and linear traits. Heterogeneity, estimated for transformed traits, was regressed within parity toward population mean by fitting a model with fixed effects of mean final score for herd, size of contemporary group, appraisal month, and year-season and a random effect for interaction between herd and appraisal date. Method R was used to estimate variances for the heterogeneity model within each EBV iteration. For 2497 bulls that had been used for artificial insemination, correlations between HV-adjusted and February 2001 official evaluations ranged from 0.981 for suspensory ligament to 0.996 for dairy form. Annual trend for bull EBV was lower with HV adjustment than for official evaluations for all traits except teat length (0.073 points less for dairy form to 0.020 points more for teat length) with the largest percentage reduction (26.4%) for front teat placement. Mean absolute values of differences between HV-adjusted and official evaluations and standard deviations (SD) of those differences generally increased as reliabilities increased to about 80% but decreased slightly for reliabilities of >90%. Mean differences were largest for bulls born from 1985 through 1994 and bulls with daughters with lowest mean final scores. Mendelian sampling (evaluation minus mean of parent evaluations) was calculated for cows born from 1984 through 1998. Mendelian-sampling SD with HV analysis declined less over time than for official evaluations. For regression of SD on birth year, slope from the HV analysis ranged from 21% of slope for official evaluations for rear udder height to 76% for rump angle. Type evaluations of Ayrshires, Brown Swiss, Guerneys, Jerseys, and Milking Shorthorns will be adjusted for HV to enable more accurate selection decisions.

Key Words: heterogeneous variance adjustment, type evaluation

1023 Evaluation of classifiers that score type traits and body condition score using common sires. R. F. Veerkamp¹, C. L. M. Gerritsen¹, E. P. C. Koenen², A. Hamoen², and G. De Jong*², ¹Institute of Animal Science and Health, ID-Lelystad, The Netherlands, ²NRS, Arnhem, The Netherlands.

Subjective visual assessment of animals by classifiers is undertaken for several different traits in farm livestock, e.g. linear type classification, body condition score, or carcass conformation. One of the difficulties is the effect of an individual classifier. To ensure that classifiers rank animals consistently, i.e. the repeatability between classifiers and within classifier, training sessions are required. In this study genetic links across routinely scored records are used to validate scoring of individual classifiers. Absence of a unity correlation between classifiers might be due to poor repeatability between classifiers. Eighteen classifiers of the NRS scored 18 traits, and body condition for 91,589 first lactation heifers, daughters of 601 sires. Genetic correlation of each individual classifiers with all other classifiers grouped where estimated in a series of bivariate analysis. Likelihoods were compared between two models with the genetic correlation either estimated or fixed at unity. Classifiers that scored a large number of animals (ca. 7,500) had a relative large part of the genetic correlation significantly different from unity as these were estimated with large precision. Estimates from classifiers that scored a few animals (ca. 1000) were sometimes low due to sampling. Therefore, a genetic correlation ≤ 0.90 that was significantly different from unity was used as criteria to mark traits for individual classifiers. On average each classifier had 3.3 traits marked, ranging from 0 to 9. Overall feet and legs, rump width, central ligament, and foot angle received most marks (12 to 6 classifiers), but there was agreement (i.e. no mark) for body condition score, stature, rump angle, teat length, overall udder, and teat placement. It is concluded that these simply and cheaply to obtain marks can be used in training sessions to improve the quality of the scoring system.

Key Words: Genetic correlations, Body condition score, Type classification

1024 Evaluations for final score at different ages. L. Klei^{*1}, S. Tsuruta², I. Misztal², and T. J. Lawlor¹, ¹Holstein Association USA, Inc., Brattleboro, VT, ²University of Georgia, Athens, GA.

The objective of this study was to investigate genetic evaluations for final score (PTAT) at different ages. Breeding values were predicted with a random regression model (RRM) and with the current national genetic evaluation model (NE), a repeatability model. RRM included fixed effects for management group and stage of lactation; fixed regressions on age at classification; additive genetic and permanent environmental effects with random regressions on age; and random residual effects. Correlations between PTATs from RRM at various ages and NE ranged from 0.89 to 0.99. PTAT genetic trends for sires and registered cows from RRM at 24 and 60 months of age were similar to those obtained from NE. Trend for grade cows from RRM was lower at 60 month of age than NE trend. The correlation between PTAT of sires and the average age of daughters tended to be positive indicating that daughters of high type bulls are scored more often. Bulls whose genetic evaluation improves as the age of daughters increases tend to have higher genetic evaluations for traits associated with increased longevity. For example, sires with the largest positive difference between PTAT at 60 and 24 months of age had an udder composite evaluation that was 2.7 points higher than those with the largest negative difference in PTAT at the two ages. Proportion of registered cows in the data set decreased from over 80% for cows born in 1981 to 55% for cows born in 1997. Registered cows have mostly two or more scores while grade cows tend to have only a single score at an early age. Declining numbers of scores at later ages may result in selection of sires whose daughters are superior at an early age but age poorly. Evaluation for final score by the random regression model allows identifying bulls whose daughters are superior at an early age and mature gracefully.

Key Words: Holstein, Final Score, Random Regression

1025 Genetic correlations of pathogen-specific clinical mastitis with milk yield and somatic cell score. Y. de Haas^{*1}, H.W. Barkema², and R.F. Veerkamp¹, ¹Institute for Animal Science and Health, ID-Lelystad, The Netherlands, ²Animal Health Service, Drachten, The Netherlands.

Several pathogens play a crucial role in the type of clinical mastitis (CM), and since the etiology of each mastitis-causing pathogen is different the question can be raised whether selection for yields affects all pathogens equally, and if selection for lower somatic cell counts improves resistance to all pathogens equally. Therefore, the objective of this study was to quantify genetic variation for overall and pathogen-specific CM and to estimate genetic correlations with milk yield and somatic cell score. Data from 274 Dutch herds recording clinical mastitis over an 18-months period were used. Analyzed pathogens were *Staphylococcus aureus*, coagulase negative staphylococci, *Escherichia coli*, *Streptococcus dysgalactiae*, *Streptococcus uberis* and other streptococci. The data set contained 47,563 lactations of 28,695 cows of different parities. Cases of overall and pathogen-specific CM were treated as binary traits

in AS-REML. In total, 5,950 lactations with at least one case of CM were included, and in 5,780 cases the mastitis-causing pathogen was classified. Variance components for the sire, maternal grandsire, and permanent environmental effect were estimated using generalized linear mixed models with a logit-link function. Heritabilities ranged from 0.02 to 0.10 for pathogen-specific CM. Genetic correlations of overall CM with milk yield and somatic cell score at 150 days were 0.69 and 0.63, respectively. However, these genetic correlations differed per mastitis-causing pathogen. For instance, the incidence rate of clinical *E. coli* mastitis was slightly unfavorably correlated with 150d milk yield (0.13), but stronger with 150d SCS (0.74). Whereas the genetic correlations with clinical *Str. dysgalactiae* mastitis were 0.70 and 0.16, respectively. Therefore, current selection practices (using milk yield and somatic cell count) will have different effects on the incidence rates of each pathogen.

Key Words: Genetic correlations, Clinical mastitis, Pathogens

1026 Genetic evaluation of episodes of short and long duration of elevated somatic cell scores. X. Li, M. M. Schutz^{*}, A. P. Schinckel, and D. L. Lofgren, Purdue University.

Long or short episodes of elevated somatic cell scores (SCS) may indicate different causes of mastitis and may be under different levels of genetic control. The objectives of this study were to estimate genetic and phenotypic parameters of short and long episodes of elevated SCS, and to compare preliminary Predicted Transmitting Abilities (PTA) of sires for lactation means of SCS and short and long episodes. Two random subsets of Holstein Dairy Herd Improvement Association test-day records represented 70,369 lactations of 51,433 cows and 79,890 lactations of 57,357 cows, respectively. Occurrence of short and long episodes of elevated SCS within a lactation were binomial traits defined by two methods. Method 1 defined short episodes (S1) as test-day SCS increasing by 2 or more units to above 5 and then declining by 2 or more units to below 5 on consecutive test days. Long episodes (L1) were defined when no decrease of 2 occurred for the subsequent test day. Method 2 defined short (S2) and long episodes (L2) similarly, but used the within-herd residual standard deviation of a lactation curve for 30 stage of lactation classes in place of the constant threshold of 5. Genetic components of variation for lactation means of SCS and the incidence of short and long episodes were analyzed using single- and multiple-trait animal models. Heritabilities of lactation SCS (LSCS) and adjusted lactation SCS after removing episodes of short duration (ALSCS) were around 0.10. Heritability estimates were near 0 for S1 and S2, and near 0.04 for L1 and L2. Genetic correlation of LSCS with S1 and S2 averaged 0.902 and 0.945, respectively. Phenotypic correlations were low, about 0.197 and 0.239 for S1 and S2, respectively. Current selection for decreased SCS appears to be consistent with genetic improvement for lower incidence of short episodes of elevated SCS. Low heritability of short episodes may preclude genetic progress from direct selection. The PTA for LSCS and ALSCS were similar giving further evidence that episodes of short duration may be under little genetic control.

Key Words: Mastitis, Somatic Cell Scores, Genetics

ASAS/ADSA Physiology: Estrous Synchronization

1027 Use of ECP in a presynchronized timed artificial insemination protocol for lactating dairy cows. E. R. Jordan^{*1}, S. M. Pancarci², M. J. Schouten³, and W. W. Thatcher², ¹Texas A and M University, ²University of Florida, ³Schouten Dairy, Hico, TX.

To test whether ECP could replace the final GnRH in a timed artificial insemination (TAI) protocol, lactating dairy cows were grouped by week of calving and assigned to treatments on alternating weeks. All cows were presynchronized using two PGF_{2α} (Lutalyse[®]; Pharmacia Corp., Kalamazoo, MI; 25 mg, im) treatments 14d apart (35±3 and 49±3d postpartum). Cows in both groups received a treatment of GnRH (Cystorelin[®]; Merial Ltd., Iselin, NJ; 100µg, im) on d0 (63±3d postpartum). Seven days later (70±3d postpartum) PGF_{2α} was administered. Cows assigned to TAI (n=157) received a second GnRH at experimental d9 (72±3d postpartum) and were artificially inseminated 24 hr later (73±3d postpartum). Cows in the ECPsynch group (n=164) received ECP (ECP[®]; Pharmacia Corp., Kalamazoo, MI; 1 mg, im) on experimental d8 (71±3d postpartum) and were artificially inseminated 48 hr later (73±3d postpartum). Pregnancy was verified 37-44d after insemination

by rectal palpation. Health records of cows were recorded and included in the data analysis. Stage of the estrous cycle at initiation of the treatment protocol and prior cyclicity was determined based on previous observed estrus. Statistical analyses included stepwise logistic regression analysis to determine significant variables and the general linear model of SAS. The treatment by estrus interaction was significant (P<.01). The pregnancy rate for the cows in estrus was 32.8±8.2% (n=28) for TAI and 40.4±4.1% (n=107) for ECPsynch, but 26.8±3.8% (n=129) and 6.6±5.7% (n=57), respectively for cows not observed in estrus. Fewer cows on TAI than ECPsynch expressed visual signs of estrus (P<.01). The pregnancy rate for cows initiating the synchronized regime between d5 and 12 of the estrous cycle was higher than for cows at other stages of the cycle or at an unknown stage (P<.02). Based on these results, pregnancy rates at first synchronized insemination after the voluntary waiting period will be similar for cows receiving either ECP or GnRH as the ovulatory hormone for timed insemination.

Key Words: Timed artificial insemination, ECP, ECPsynch

1028 Presynchronization of estrous cycles in lactating dairy cows with Ovsynch + CIDR and resynchronization of repeat estrus using the CIDR. S.Z. El-Zarkouny*, J.A. Cartmill, A.M. Richardson, M.A. Medina-Britos, B.A. Hensley, and J.S. Stevenson, *Kansas State University, Manhattan.*

Our objectives were to determine if presynchronized estrous cycles and the addition of progesterone (P4) to the Ovsynch (OVS) protocol would improve pregnancy rates (PR) on d 29 and whether a repeat estrus could be resynchronized with P4 after timed AI (TAI). A total of 630 cows in two cooperating herds were assigned to eight treatments (A, B, C, D, E, F, G, and H). All cows received the OVS protocol: 100 µg of GnRH on d -10 and d -1; 25 mg of PGF_{2α} on d -7; and TAI on d 0. Estrus in cows was presynchronized with two injections of PGF_{2α} 14 d apart (Presynch; A, B, C, and D) with the second injection given 12 d before the OVS protocol, whereas cows in E, F, G, and H received no PGF_{2α} before OVS. Cows in C, D, G, and H received (d -7) a P4-releasing intravaginal insert (CIDR) for 7 d (d -10 to -3). Repeat estrus in cows was resynchronized (Resynch; B, D, F, and H) with a used CIDR for 7 d starting on d 13 after TAI, whereas cows in A, C, E, and G were controls. Blood samples were collected before each hormonal injection for determination of P4 (d -36, -22, -10, -3, -1, +13, and +20). On d 29 and 57, PR was diagnosed by ultrasonography after TAI and embryo survival (ES) was calculated. A three-way interaction occurred (P=0.07), indicating that Presynch increased PR (46 vs. 37%), but without Presynch, the CIDR + Resynch reduced and no CIDR + Resynch increased PR. Because of a Presynch × CIDR interaction (P<0.05), AI submission rate for 2nd AI (AISR; first eligible estrus 20-25 d after TAI) was greater (P<0.05) for Presynch cows treated with vs. without the CIDR (38 vs. 18%), whereas in no Presynch cows, the CIDR had no effect (23 vs. 27%). Resynch decreased (P=0.08) 2nd CR (first eligible estrus 20-25 d after TAI) compared to controls (18 vs. 33%). An interaction (P=0.07) of Presynch × CIDR decreased 2nd CR for Presynch cows with vs. without CIDR (15 vs. 29%), but increased 2nd CR for no Presynch cows with vs. without CIDR (38 vs. 20%). We concluded that Presynch + OVS increased PR above OVS alone. Resynch did not increase AISR, decreased 2nd CR, and tended to increase ES.

1029 Characteristics of estrus before and after insemination and fertility after estrus synchronization with GnRH, PGF_{2α}, and progesterone in dairy heifers. A.M. Richardson*, B.A. Hensley, and J.S. Stevenson, *Kansas State University, Manhattan.*

Our objectives were to determine whether estrus activity was diminished after AI and possible pregnancy initiation compared to before AI and whether conception was reduced when a progestin treatment was used without turning over the dominant follicle at the time of progestin initiation. Pubertal Holstein heifers were assigned randomly to three treatments: 1) 100 µg of GnRH given 6 d before 25 mg of PGF_{2α} (d -1) plus a used intravaginal progesterone-releasing (CIDR-B, InterAg) insert (d -7 to 0; CIDR+GnRH); 2) same as CIDR+GnRH without GnRH (CIDR); and 3) same as CIDR+GnRH without used CIDR (GnRH). All heifers were fitted with HeatWatch® patches and characteristics of estrus examined before and after AI included duration of estrus (DUR), number of standing events (STD), and total duration of standing events (DURSTD). Heifers were inseminated 10-12 h after the onset of estrus. Blood samples were collected on d -7, -1, and 0 for determination of progesterone. Pregnancy was diagnosed by ultrasonography 28-30 d after AI. Estrus-detection rates (EDR) and pregnancy rates (PR) tended (P<0.10) to be less for heifers treated with GnRH. Heifers in their luteal phase (d 5-18; n=102) on d -7 had greater (P<0.05) EDR (86 vs. 59%) and greater (P<0.05) PR (50 vs. 29%) than heifers in their follicular phase (d 19-21; n=17). Luteal-phase heifers had shorter (P<0.05) DUR (11.5 ± 0.5 vs. 14 ± 1 h), fewer (P<0.05) STD (34 ± 3 vs. 51 ± 6), and shorter (P<0.05) DURSTD (89 ± 9 vs. 137 ± 17 s) than those in

metestrus (d 1-4; n=35). Heifers (59/69; 87%) not conceiving after the synchronized estrus were detected in estrus 18 to 26 d later. Comparing characteristics of estrus before and after the synchronized estrus in these 59 heifers, STD (36 ± 3 vs. 23 ± 3) and DURSTD (94 ± 7 vs. 60 ± 7 s) were greater (P<0.01) before than after AI, whereas DUR (11.8 ± 0.6 vs. 10.6 ± 0.6 h) and individual DURSTD (2.6 ± 0.1 vs. 2.7 ± 0.1 s) were not different. Conception at this first eligible repeat estrus was 46% (27/59). We concluded that conception rates were not reduced after estrus synchronization with CIDR + PGF_{2α} and estrus activity (STD and DURSTD) was reduced after once inseminated.

Trait	CIDR+GnRH	CIDR	GnRH

Key Words: Estrus, Conception, Progesterin

1030 Time of ovulation and follicular development in estrus synchronized Brahman females. S.R. Tatman¹, D.A. Neuendorff^{*1}, A.W. Lewis¹, T.W. Wilson¹, C.R. Looney², and R.D. Randel¹, ¹Texas A&M Research Center, Overton, TX, ²Ovagenix, LP, Bryan, TX.

Dry, multiparous, Brahman cows were used to determine the effect of PG (25 mg Lutalyse®, Upjohn) injection or an intravaginal progesterone releasing device (CIDR) combined with PG on follicular development from estrus to ovulation and ovulation time. Based on 2 mo of daily estrus detection, cows with normal estrus cycles were selected for the trial. Three treatments (control [CO], PG, CIDR + PG (CP), n=12 per treatment) were used. PG cows received PG on d 14 of an induced cycle. CIDRs were inserted in CP cows and removed after 7 d when PG was injected. Estrus was detected using 4 sterile bulls and constant estrus detection. The dominant follicle was measured by ultrasonography at 2-hr intervals from estrus to ovulation. Follicle size at estrus did not differ among treatments (CO: 17.3±1 mm; PG: 16.6±.9 mm; CP: 18.2±1 mm). Follicle diameter at ovulation was similar (P > 0.10) in CP (18.8±.9 mm) and CO (18.3±.7 mm), but both were greater (P < 0.05) than PG (16.2±.7 mm). No differences were detected (P > 0.10) for change in follicle diameter or change in follicular size/hr from estrus to ovulation (CP: .59±1.3 mm and .019±.04 mm/hr; CO: .94±1.1 mm and .04±.04 mm/hr; and PG: -.43±1 mm and -.011±.03 mm/hr; respectively). Interval from estrus to ovulation was similar (P > 0.10) for CP (27.7±2 hr), CO (27.1±2 hr), and PG (27.4±2 hr). Neither interval from PG injection to ovulation nor PG injection to estrus was different (P > 0.10) between CP (101±9 hr, 74±10 hr; respectively) and PG (118±7 hr, 92±7 hr; respectively). Follicle sizes at CIDR insertion and removal were similar (P > 0.10) in synchronized vs. non-synchronized cows. A lower proportion of CP cows (50%) showed normal estrus compared to PG (83%). In this protocol, the CIDR may have been detrimental for estrus synchronization of Brahman cows.

Key Words: Brahman female, Synchronization, Ovulation

1031 Ovulation synchronization using progestins, GnRH, and PGF_{2α} before timed AI (TAI) and resetting follicular waves for resynchronization of repeat inseminations of suckled beef cattle. M.A. Medina-Britos^{*1}, A.M. Richardson¹, G.C. Lamb², C.R. Dahlen², S.K. Johnson¹, S.Z. El-Zarkouny¹, B.A. Hensley¹, and J.S. Stevenson¹, ¹Kansas State University, ²University of Minnesota.

We determined if there was an advantage to providing progestin before or concurrent with ovulation synchronization prior to TAI. Secondly, we determined whether resynchronization of follicular waves would synchronize repeat estrus after TAI and increase return rates to estrus and 23-d pregnancy rates (23-d PR). Suckled beef cows (n=609) were used at four locations in KS and MN. Cows were assigned to a 2 × 3 factorial experiment with five treatments. Two prebreeding treatments: 1) CIDR: 100 µg of GnRH on d -9 and a progesterone (P4)-releasing intravaginal insert (CIDR, InterAg) for 7 d; 25 mg of PGF_{2α} on d -2;

100 µg of GnRH and TAI on d 0 and 2) MGA: same protocol without CIDR but cows were fed 0.5 mg of MGA for 14 d beginning 26 d before the first GnRH injection. Three postbreeding treatments were: 1) control; 2) 1 mg of estradiol benzoate (EB) + CIDR; or 3) 1 mg of estradiol cypionate (ECP) + CIDR. Estrogen injections were given on d 13 and 20 and a used CIDR was inserted between d 13 and 20 after TAI. Upon removal of CIDR, cows were reseeded after twice daily detection of estrus until d 23. Blood samples were collected on d -35, -21, -9, -2, 0, +13, and +20 for later measurement of P4 and cycling status. Body condition was assessed on d -2. Pregnancy was diagnosed by ultrasonography at 28-33 and 56-61 d after TAI. Variables were calculated: pregnancy rate after TAI (PR); % returned to estrus 20-23 d after TAI (% RET); average interval to estrus after TAI (INT); conception rate after second AI (CR); and embryo survival (ES) from d 28-33 to 56-61. We concluded that a concurrent source of P4 with ovulation synchronization increased PR compared to using MGA. Use of estrogen + CIDR increased return rate to estrus without affecting conception at the previous TAI and increased the 23-d PR.

1032 Addition of GnRH to a melengestrol acetate (MGA)-prostaglandin F_{2α} (PG) estrus synchronization protocol in postpartum beef cows. D. J. Patterson*, J. F. Bader, K. K. Graham, F. N. Kojima, G. A. Perry, M. S. Kerley, and M. F. Smith, *University of Missouri, Columbia, MO.*

This experiment was conducted to determine whether addition of GnRH to a MGA-PG protocol would improve synchrony of estrus and maintain high fertility in postpartum beef cows. Primi- and multiparous crossbred cows were assigned by age, body condition score (BCS) and days postpartum (dpp) to one of two treatments. Cows were fed MGA (.5mg·hd⁻¹·d⁻¹) for 14 d followed by an injection of PG (25 mg Lutalyse) 19 d after MGA withdrawal. GnRH (100 µg Cystorelin) was administered to 103 of the cows 12 d after MGA withdrawal and 7 d before PG. Control cows (n=106) received only MGA-PG. Average BCS and dpp for GnRH-treated and control cows were 5.0 and 5.0; 44 and 46 d, respectively. Blood samples were collected from all cows 10 d before and on the first day of MGA, and 7 d before and on the day PG was administered. Progesterone in serum was elevated (> 1 ng/ml) in 40 % of GnRH-treated and 33 % of control cows prior to treatment, respectively (P > .1). Cows were observed for signs of behavioral estrus for 7 d after PG and AI was performed 12 h after observed estrus. Estrus response did not differ (P > .1) between treatments (GnRH: 83 %, 86/103; control: 80 %, 85/106). The mean interval to estrus after PG was 72.0 and 74.7 h for GnRH-treated and control cows, respectively (P > .1). The peak synchronized period for both treatments occurred between 72 and 96 h after PG and did not differ (P > .1) between treatments. Estrus response after PG ranged from 36 to 132 h for GnRH-treated, and from 36 to 120 h for control cows. Synchronized conception (SCR) and pregnancy rate (SPR) did not differ (P > .1) between treatments [SCR: 78 % (67/86), 85 % (72/85); SPR: 65 % (67/103), 68 % (72/106) for GnRH-treated and control cows, respectively]. This study demonstrates similarities in response to a 14-19 d MGA-PG estrus synchronization protocol in postpartum beef cows with or without the addition of GnRH. (Supported by grants from Select Sires, Inc., and USDA-NRI 2000-02163)

Key Words: Estrus synchronization, Progestin, Beef cows

1033 Comparison of melengestrol acetate (MGA)-based estrus synchronization protocols in yearling beef heifers. F. N. Kojima*, J. F. Bader, J. E. Stegner, B. E. Salfen, S. L. Wood, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia, MO.*

The objective of this study was to identify estrus synchronization protocols that offer potential for use in fixed-time AI programs for replacement beef heifers. Three MGA-based protocols were compared in yearling Angus heifers (n = 345: n = 115/treatment). Heifers were assigned to one of three treatments by reproductive tract score (RTS) and BW 2 wk prior to the initiation of treatments. Treatments were: 1) MGA (.5mg·hd⁻¹·d⁻¹) for 14 d followed by prostaglandin F_{2α} (PG; 25 mg Lutalyse[®]) 19 d after MGA withdrawal (MGA-PG); 2) addition of GnRH (100 µg Cystorelin[®]) on d 26 of the MGA-PG protocol (MGA-GnRH-PG); and 3) MGA for 7 d, PG on the last day of MGA, GnRH 4 d after PG, and a second injection of PG 11 d after the last day of MGA (7-11 Synch). Heifers were monitored for signs of behavioral estrus for 7 d beginning on the day PG was administered. AI was performed 12 h after onset of estrus. Estrus response (ER), synchronized conception rate (SCR), and synchronized pregnancy rate (SPR) were analyzed by Chi-square analysis. Synchrony of estrus was analyzed by ratio of variance (F-test) for mean time interval to onset of estrus. ER did not differ (P > .10) among treatments. Estrus synchrony was greater (P < .05) for 7-11 Synch treated heifers (331.9) than for MGA-PG (667.1) or MGA-GnRH-PG treated heifers (539.3). SCR and SPR were greater (P < .05) for MGA-PG (63 % and 54 %) than MGA-GnRH-PG (45 % and 39 %) or 7-11 Synch (47 % and 37 %) treated heifers. There was an effect of reproductive maturity/cycling status of heifers, indicated by RTS, on ER, SCR, and SPR regardless of treatment. ER (93 % and 81 %), SCR (66 % and 46 %), and SPR (62 % and 37 %) were all greater (P < .01) in cycling compared to non-cycling heifers. Reproductive maturity/cycling status significantly influenced response to synchronization treatment and subsequent conception and pregnancy rate in yearling beef heifers. (Supported by USDA-NRI grant 2000-02163)

Key Words: Estrus synchronization, Artificial insemination, Yearling beef heifers

1034 Effects of a progestin on ovulation, accessory CL formation and follicular development during GnRH and PGF_{2α} treatment in beef cattle. M.L. Mussard*, C.R. Burke, D.E. Grum, and M.L. Day, *Ohio State University, Columbus, OH/USA.*

The improvements in pregnancy rates expected to result from addition of a progestin during a GnRH-PGF_{2α} synchrony system have not been consistently realized in recent field studies. The objectives of this experiment were to determine the effects of a progestin on follicular dynamics and accessory CL formation following treatment with GnRH-PGF_{2α}. Randomly cycling, postpartum beef cows (n=67) received 100 g GnRH on d 0 and 25 mg PGF_{2α} on d 7. Daily transrectal ultrasonography was used to monitor ovarian structures from d -4 to 12. Cows received either melengestrol acetate (.5 mg/hd) daily from d 0 to 6 (MGA; n=33) or the grain carrier for MGA (non-MGA; n=34). Blood samples were collected on d -2, 0, 4, 6, 7, and 9 for progesterone analysis. On d 9, a second injection of GnRH (100 g) was administered to approximately 50% of the animals in the MGA (n=15) and non-MGA (n=16) treatments. Animals that did not receive the second GnRH injection were observed for estrus every 8 h from d 5 to 12. The incidence of ovulation in response to GnRH on d 0, accessory CL formation, diameter of the dominant ovarian follicle on d 7 and 9, and time of ovulation following PGF_{2α} were compared. On d 7, animals in the MGA treatment tended (P < 0.10) to have dominant follicles of greater diameter (12.7 ± .40 mm) and fewer accessory CL (36%) than in the non-MGA treatment (11.8 ± .35 mm and 59%, respectively). Regardless of whether a second GnRH injection was given on d 9, the interval to ovulation following PGF_{2α} was later (P < 0.05) in the MGA than non-MGA treatment (4.2 ± .17 d vs. 3.7 ± .15 d, respectively). In conclusion, treatment with MGA tended to decrease the incidence of accessory CL formation following GnRH, disrupt follicular growth and delay timing of ovulation following PGF_{2α}. Results from this study suggest that inclusion of MGA in a GnRH-PGF_{2α} based synchrony system may alter typical ovarian responses observed in cyclic cows.

1035 Estradiol Enhances Synchrony and Fertility to Artificial Insemination (AI) or Embryo Transfer (ET) in Brangus Females. J.A. Meyer^{*1}, C.R. Looney², C.R. Long², J.A. Thompson¹, M.L. Day³, H.D. Hafs⁴, and D.W. Forrest¹, ¹Texas A&M University, College Station, TX, ²Ovagenix, Bryan, TX, ³The Ohio State University, Columbus, OH, ⁴Rutgers University, New Brunswick, NJ.

Two trials were conducted to quantify effects of estradiol benzoate (EB) administration on fertility after removal of a controlled internal drug release (CIDR)[®] insert. Lactating, primi- and multiparous Brangus females were administered a CIDR (1.38g Progesterone) for 7 or 8 d with prostaglandin F_{2α} (25 mg, im) administered upon removal of the CIDR (control group). Females allotted to the treatment group were administered estradiol benzoate (EB, 1 mg,im) at 24 h post-CIDR removal. Females were observed twice daily for signs of estrus behavior for 5 d after CIDR removal. In Trial 1, females were inseminated 12 h post-onset of estrus. The synchrony rate (SR; 93.9%) in EB treated (n = 82)

females was higher (P < 0.01) than the SR (80.0%) in the control group (n = 230). First service conception rate (FSCR) was not affected (P > 0.1) by EB treatment (50.6 and 46.4% for treatment and control groups, respectively). However, females in the treatment group had a higher (P = 0.08) first service pregnancy rate (FSPR) than females in the control group (47.6 vs. 36.7%, respectively). In Trial 2, recipient cows received a single embryo 6.5 to 7.5 d post-onset of estrus. SR was higher (P < 0.01) in EB treated (n = 886) females compared to control (n = 457) females (93.0 and 73.5%, respectively). FSCR did not differ (P > 0.1) between control and treatment groups (54.4 and 55.7%, respectively). FSPR was higher (P < 0.01) in EB females (46.1%) compared to females in the control group (38.1%). In conclusion, the addition of an injection of 1 mg EB administered 24 h after a conventional CIDR synchronization treatment regimen increased both SR and FSPR following either AI or ET, in Brangus females.

1036 Decreasing nitrogen losses from open-dirt feedlot pens by manipulation of organic matter excretion. G. E. Erickson^{*}, T. J. Klopfenstein, and C. T. Milton, ¹University of Nebraska-Lincoln.

Three experiments with yearling steers (404 ± 15 kg) evaluated adding either 15 (15bran) or 30% (30bran) corn bran to a 15% corn silage, corn based diet (0bran). Experiments were conducted from October to February (128 d), February to June (105 d), and June to September (110 d) in eastern Nebraska. Performance and mass-balance of nitrogen were assessed for each pen (8 steers/pen; 4 pens/treatment) in each experiment. No experiment by treatment interactions were detected (P > .10), so performance data were pooled. Increasing dietary corn bran from 0 to 30% increased (P < .01) DM intake and decreased (P < .05) ADG, leading to depressed (P < .01) feed efficiency. Compared to the 0bran diet, feed efficiency was depressed by 7.8 and 10.4% for 15bran and 30bran, respectively, suggesting that organic matter (OM) excretion was increased. For the winter/spring months, increasing dietary corn bran increased manure N and decreased N losses (primarily volatilization) expressed as either kg/steer or percentage of N excretion. During the summer experiment, increasing dietary corn bran did not significantly influence either manure N or N losses. Increasing OM excretion of feedlot cattle may increase manure N thereby decreasing volatilization losses but will also depress feed efficiency.

Item	0bran	15bran	30bran	SE	Linear	Quadratic
ADG, kg/d	1.82	1.81	1.74	.03	.05	.58

1037 Validation of the nitrogen balance in a whole system feedlot model. H. Fairweather, K. A. Beauchemin, and K. M. Koenig, *Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

FeedNuts is a stochastic daily time step simulation of a feedlot system model and predicts the nutrient flow (N, P) from feed inputs to the manure and effluent storage systems. Inputs (CP, P, UIP, DM and TDN, % dietary DM) into the FeedNuts model are stochastic and the mass balance is calculated initially for a single animal, which is then aggregated

to the whole system. Data from Bierman et al. (1999; J. Anim. Sci. 77:1295-1305), which evaluated the N balance in a feedlot, were used to verify the model calculations and validate the N balance predicted by the FeedNuts model. The N balance experiments consisted of a digestibility trial and a feedlot trial (87 d) in which cattle were fed one of three corn grain based diets. The diets were: wet corn gluten feed (WCGF, 41.5% of DM), 10% forage (10F) and all concentrate (CONC). Total tract N digestibility of the diets was 65.2, 74.7 and 76.9% for the WCGF, 10F and CONC diets, respectively. The FeedNuts model predicts the total N excreted as the difference between N intake and N retained (calculated using the net protein gain equation, NRC (1996)). A rumen sub-model that accounts for microbial protein synthesis and the degradability of feed protein sources is used to determine N output in urine and feces. Using a daily time step to predict N retention predicted a higher amount of N retained (approximately 0.5 kg over the 87 d) compared with the estimated retention in the feedlot study. However, that calculation used only the final weight. The N digestibility and predicted fecal and urinary N, as a percentage of N intake, were within 10% of the measured values for each diet. Furthermore the predicted relative ranking of diets in terms of fecal and urinary N agreed with the observed. This verification and validation exercise demonstrates the capability of the FeedNuts model for predicting the N balance in the feedlot system at any point in time as a function of ration inputs.

1038 Digestibility of several known dietary manipulations used in combination to reduce nutrient excretion in pigs. S.L. Hankins^{*}, D.C. Kendall, B.E. Hill, and B.T. Richert, *Purdue University, West Lafayette, IN.*

Twelve crossbred barrows (Initial BW=96kg) were blocked by weight and randomly assigned to one of three diets. All diets were formulated to provide 0.48% digestible Lys and were: 1) Standard 13.1% CP corn-soy diet, 0.23% available P (0.50% total P) (STD), 2) 11.5% CP corn-soy diet, 0.15% Lys-HCl, 0.26% available P (0.50% total P) (RCP), and 3) 8.25% CP diet with 5% soybean hulls, high-available P corn, 0.05% phytase and reduced mineral sulfates, 0.40% Lys-HCl, 0.16% available P (0.26% total P) (HRP) to evaluate the effect of several known dietary manipulations in combination on nutrient excretion compared to standard diets. Pigs were adapted to metabolism stalls and dietary treatments for 7 d followed by a 3 d total feces and urine collection. Feces and acidified urine were collected twice daily and frozen until analysis. Pigs were fed at 3X maintenance levels (NRC, 1988) with ad-libitum access to water. Feces and urine were analyzed for DM, nitrogen (N), ammonium N (AMM) and total P (TP). DM digestibility was 88.8%, 88.3% and 87.9% for the STD, RCP and HRP diets, respectively. N and P digestibility were 82.8%, 81.4%, 75.2% and 45.9%, 48.3%, 56.1% for the STD, RCP and HRP diets, respectively. Urine N was 41% and 66% lower (P<.05) from pigs fed the RCP and HRP diets, respectively, compared to the STD diet. Total N excretion was reduced (P<.05) 37% and 55% when the RCP (20.3 g/d) and HRP (14.6 g/d) diets were fed respectively when compared to the STD (32.2 g/d) diet. N retention as a percent of total N absorbed was 30% higher (P<.05) for pigs on

the HRP diet and 16% higher for pigs fed the RCP diet compared to the STD diet. Pigs fed the HRP diet had 55% and 62% lower ($P < .05$) total P excretion (4.0 g/d) than pigs fed the RCP (8.8 g/d) and STD (10.7 g/d) diets, respectively. P retention as a percent of that absorbed tended to be higher for pigs fed the HRP diet compared to the STD diet. Nitrogen and P excretion can be effectively reduced when a combination of synthetic amino acids, high-available P corn, phytase and 5% soybean hulls are fed to finishing pigs.

Key Words: Pigs, Digestibility, Excretion

1039 Effects of soybean hulls in a commercial diet on pig performance, manure composition, and selected air quality parameters in swine facilities. S.A. DeCamp¹, B.E. Hill¹, S.L. Hankins¹, D.C. Kendall¹, B.T. Richert¹, A.L. Sutton¹, D.T. Kelly¹, M.L. Cobb¹, D.W. Bundy², and W.J. Powers², ¹Purdue University, Lafayette, IN, ²Iowa State University, Ames, IA.

Grow-finish pigs ($n=150$) were used to evaluate the inclusion of soybean hulls in swine diets to reduce aerial pollutants and alter manure composition. The pigs (initial BW=85.3 kg) were placed in two identical, environmentally controlled rooms (5 pigs/pen, 5 pens/room; 50 pigs/rep) with 3 replications and treatments rotating between rooms. Diets were split-sex fed and consisted of either a corn-soybean meal based control (C) or the control diet with the addition of 10% soybean hulls and 3.4% supplemental fat (SH) (all diets=3370 Kcal ME/kg; barrows 12.0% CP, 0.53% dLys; gilts 12.7% CP, 0.57% dLys). Pigs and feeders were weighed at 0, 3, and 6 wks to calculate ADG, ADFI, and G:F. Aerial ammonia concentration (AAC), hydrogen sulfide (HS), detection threshold (DT) of odor samples, and pit manure samples were taken at wk 0, 3, and 6. Pigs fed SH diets had greater overall ADG (905 vs 859 g/d; $P < .03$) and tended to have higher G:F (0.326 vs 0.310; $P < .09$) with no difference in ADFI. Pigs fed SH had greater adjusted backfat (113 kg BW) at wk 6 (15.8 vs 14.7 mm; $P < .001$) than C pigs. At wk 6, there was a 20% reduction in AAC ($P < .02$), a 32% reduction in HS ($P < .003$) and an 11% reduction in DT when pigs were fed SH diets. There was a decrease in wk 6 manure pH (7.12 vs 7.26; $P < .03$) and an increase in all individual manure VFA concentrations, with total manure VFA concentrations increasing by 32% ($P < .001$) when pigs were fed SH. At wk 6, the stored manure from pigs fed SH diets had 21% greater total nitrogen accumulation (22.5 vs 18.6 kg; $P < .02$) and an 8% increase in ammonium N accumulation (18.3 vs 16.9 kg; $P < .05$), with no difference in phosphorus. The addition of 10% SH to a commercial type diet can enhance environmental stewardship, without hindering pig growth performance and carcass characteristics. The addition of SH lowered AAC and HS in room air and increased manure N content, indicating greater retention of N in the manure and less N volatilization. This increased manure N reflects a more stable microbial protein form and provides a reduced environmental runoff potential.

Key Words: pigs, odor, manure composition

1040 Effects of dietary phytase and aluminum chloride manure amendments on phosphorus in swine manure. D.R. Smith^{*1}, P.A. Moore, Jr.², C.V. Maxwell¹, and T.C. Daniel¹, ¹University of Arkansas, Fayetteville, ²USDA-ARS, Fayetteville.

Phosphorus (P) runoff from animal manure applied to pastures has been implicated in eutrophication of lakes and rivers. Two technologies that have been proposed to reduce P in manure are the addition of dietary phytase, which allows lower total P to be fed, or addition of aluminum compounds to the manure, which precipitates soluble P. The objectives of this study were (1) to evaluate the effects of dietary phytase, and aluminum chloride ($AlCl_3$) added to swine (*Sus scrofa domestica*) manure, on P in manure and runoff, and (2) to study the effects of $AlCl_3$ amended manure on ammonia volatilization from swine manure. A 2 X 4 factorial design was applied to twenty-four pens of nursery pigs, using two levels of phytase (500 IU phytase kg^{-1} and no phytase), and four levels of $AlCl_3$ (0, 0.25, 0.50 and 0.75% of final manure volume). Each pen was fitted with an individual manure collection pit. A pull/plug manure management system was simulated by flushing pits bi-weekly and recharging with simulated lagoon water, at which time $AlCl_3$ amendments were made. A three phase diet was used with the control diet based on NRC available P (aP) and phytase diets based on NRC -0.1% aP. Ammonia fluxes were measured in-situ twice weekly. Manure was collected at the end of each phase, and analyzed for total and soluble reactive P (SRP). Manure was also collected and applied to 1.96 X 5.96

m plots cropped to tall fescue (*Festuca arundinacea* Shreb.) at a rate of 150 kg N ha^{-1} for rainfall simulations. A simulated 5 cm hr^{-1} rainfall event was conducted on each plot, and runoff samples collected. Phytase reduced SRP in manure by 15% (89.6 mg P L^{-1} for no phytase and 76 mg P L^{-1} for phytase diet, $P < .01$). A 78% reduction in SRP ($P < .001$) in manure was noted in high $AlCl_3$ (34 mg P L^{-1}) pits compared to controls (154 mg P L^{-1}). Ammonia fluxes were reduced ($P < .001$) by 51% for high $AlCl_3$ treatments compared to controls. These two technologies could be employed by production facilities to reduce risk of P losses from swine manure.

Key Words: Phosphorus, Phytase, Aluminum Chloride

1041 Effects of monensin on microbial activity in in vitro swine manure slurries. M.A. Cotta^{*}, R.L. Zeltwanger, and T.R. Whitehead, USDA/ARS/Natl. Cent. for Agricul. Utilizn. Res..

Storage of swine waste is associated with the microbiological production of a variety of odorous compounds, including ammonia, organic acids and alcohols, and sulfides. These compounds can contribute to health problems for swine facility workers and animals, as well as odors that affect local human populations. Previous research in our laboratories has demonstrated that the primary microbial populations in stored swine waste are low (G+C), Gram-positive anaerobic bacteria. Monensin has been used to alter the bacterial population and metabolic end-products in the rumen of domestic animals for improved animal performance, largely through its effect on Gram-positive bacteria. Therefore, it was decided to test the effects of monensin on stored swine waste slurry. Fecal and manure storage pit slurry were collected from a local swine production facility. Manure slurry was combined with 20%(w/v) feces and mixed under gas. The mixture was aliquoted into glass bottles under gas, stoppered and maintained under anaerobic conditions. Monensin (10 μM) was added to two bottles, and two bottles without monensin were used as controls. Gas production was measured over time, and aliquots were removed for chemical analyses and determination of viable bacterial numbers. Gas production in the monensin samples were greatly reduced within 24 hr (<10% of controls), and this reduction was maintained over a 28 day test period. Methane production was also reduced (<5% of controls). However, no detectable hydrogen was observed in any sample. Volatile fatty acid production was only slightly decreased in the monensin samples, while butyrate production increased 3-fold. These results are quite different from those observed in the rumen. Viable bacterial levels as determined by anaerobic agar plating were consistent between the treatments over the test period. Since a shift in bacterial populations was probably occurring during incubations with monensin, total DNA was isolated from the samples. The DNA will be used to assess changes in bacterial populations by 16S rDNA Amplified Ribosomal DNA Restriction Analysis (ARDRA). The results of this study suggests that addition of antimicrobial compounds may prove useful for reducing gaseous, odorous emissions from swine facilities, although monensin may not be the correct one.

Key Words: Swine, Manure, Monensin

1042 Factors influencing estrus and ovulation in weaned sows as determined by transrectal ultrasound. R. Knox^{*1} and S. Rodriguez-Zas, ¹University of Illinois, Urbana IL.

Characterization of factors influencing estrus and ovulation in sows may facilitate development of procedures for improving reproductive performance. The experiment was conducted in confinement during 1997-1999 using 174 Large White x Landrace sows. After weaning, sows were checked for estrus twice daily. In the first year transrectal ultrasound was performed once daily and in the second year twice daily at estrus, and on every day until ovulation. The effects of lactation length (≤ 16 d, 17-24 d, 25-31 d or ≥ 32 d), parity (1, 2 or ≥ 3), season (winter, spring, summer or fall) and weaning to estrus interval (3 d, 4 d, 5 d, or 6-8 d) and their interactions on estrual and ovulatory responses were studied. There was no effect of frequency of ultrasound on any measures so data across years were pooled. Estrus was influenced by lactation length ($P < .001$), with sows lactating ≤ 16 d (35.2%) less likely to express estrus than sows lactating ≥ 17 d (94%). A parity by season interaction effect was observed ($P < .001$) for estrus with lowest expression in parity 1 sows in fall (73.0%) and winter (86.4%), parity 2 sows in fall (67.2%), and \geq parity 3 sows in summer (84.6%). No explanatory variable had a significant effect on wean to estrus interval (4.4 d) or on follicle size at estrus (8.1 mm). Ovulation hour after onset of estrus was affected by

wean to estrus interval ($P < .01$) with sows returning in 3 d ovulating at 46.2 h, and between 6-8 d at 30.2 h. The percentage of sows ovulating was influenced by lactation length ($P < .001$) and wean to estrus interval ($P < .001$). Sows that lactated ≤ 16 d were less likely to ovulate (78.0%) than those lactating ≥ 17 d ($> 92\%$). Sows that returned to estrus in 3 d were also less likely to ovulate (79.5%) than sows returning ≥ 4 d after weaning ($> 92\%$). A parity by season interaction effect was also observed on ovulation ($P < .001$). The data suggest that parity, lactation length and early return to estrus and parity by season effects are associated with risk of failure to express estrus and ovulate.

Key Words: sows, estrus, ovulation

1043 Use of CowTempTM temperature monitoring system for prediction of calving onset in beef cows. J. N. Nielsen^{*1}, S. S. Donkin¹, K. Vanzant¹, P. A. McAfee², and S. A. Brune², ¹Purdue University, West Lafayette, IN, ²Innotek, Inc., Garrett, IN.

The ability to identify cows that will calve within 24 hours would enhance the herd manager's provision of appropriate peripartum care. Previous studies using surgically implanted temperature monitors identified a drop in body temperature from 48-8 hours prior to calving. This study tested the calving predictive value of the CowTempTM, a telemetric system in development that measures and transmits the temperature within the reticulum on a periodic basis. Nine pregnant multiparous beef cows were orally administered a reticular bolus containing a temperature sensor, microprocessor and transmitter 7-41 days prior to calving. Each bolus was programmed with a unique ID number, which was transmitted with temperature via a receiver to a computer that averaged the temperature over a 24-hour period and graphically displayed the results. A computer program was designed to compare the rolling 24-hour temperature average with the previous 5 days' average. The mean temperature nadir and standard deviation (SD) prior to calving was $-0.69 \pm 0.18^\circ\text{C}$ (reduction from rolling average). The nadir temperature was recorded 3.1 ± 2.4 hours prior to parturition. Using a critical temperature from 1 to 2 standard deviations above the nadir (0.39°C), all cows were identified 9-23 hours prior to calving. At 1 SD above the nadir, one of the 9 cows would have been missed, since her temperature drop was not great enough to trigger the alarm. At 2 SD above the nadir this same cow had multiple false alarms for impending calving. Although this is a small sampling of animals, it demonstrates the value of remotely monitoring temperature within the reticulum to predict calving within a 9-23 hour window.

Key Words: Temperature, Calving, Radiotelemetry

1044 Optimal days in period to detect a change in estrus detection. A. de Vries^{*} and B.J. Conlin, University of Minnesota, St. Paul, Minnesota.

The objective was to determine the optimal number of days in a period (DIP) to detect a change in average estrus detection index (EDI) with a Shewhart control chart. EDI is defined as the number of observed estruses over the number of expected estruses in a period. Shewhart charts are tools in statistical process control and distinguish between true changes and normal variation in EDI. A signal is triggered when EDI value falls outside a control limit. Control limits are based on the desired rate of false alarms and a measure of the standard error in EDI from period to period. Typically, EDI is calculated monthly (DIP = 30 or 31). Long periods imply large sample sizes and therefore EDI has more power ($1 - \beta$) to signal a true change. On the other hand, short periods take less time to complete and may signal larger changes faster. Thus, the DIP should be chosen such that the average time to signal (ATS) given a true change is as short as possible. Assuming that the distribution of EDI can be modeled by a normal distribution, then the optimal DIP can be found by minimizing $\text{DIP} / (1 - \beta) = \text{DIP} / [1 - (\text{Pr}(X < \text{EDI}0 - Z * \sigma / \sqrt{\text{DIP}}) + \text{Pr}(X > \text{EDI}0 + Z * \sigma / \sqrt{\text{DIP}}))]$ where X is the EDI random variable, EDI0 is the average EDI before a change, sigma is the standard deviation of EDI with periods of 1 day. The constant Z depends on the desired average days between false alarms (ATS0) and the change of most interest (EDI1): $Z = \Phi^{-1}(\text{DIP} / \text{ATS}0 / 2) - (\text{EDI}0 - \text{EDI}1) / \sigma * \sqrt{\text{DIP}}$ where $\Phi^{-1}()$ is the inverse of the standard normal distribution. Then $\text{ATS}1 = \text{optimal DIP} / (1 - \beta)$ is the average days to signal after the change to EDI1. For example, assume $\text{ATS}0 = 730$ and $\sigma = 0.25$ for a 1000 cow herd. A change from $\text{EDI}0 = 0.6$ to $\text{EDI}1 = 0.4$ is the fastest

detected with $\text{DIP} = 12$ ($\text{ATS}1 = 18.6$). A period length of $\text{DIP} = 31$ would result in $\text{ATS}1 = 31.2$. Similarly, a 100 cow herd with $\sigma = 0.79$ would have optimal $\text{DIP} = 57$ ($\text{ATS}1 = 102.0$). For $\text{DIP} = 31$, $\text{ATS}1 = 115.8$. The conclusion is that optimal period length decreases with larger herd size, larger change of interest, and higher false alarm rate.

Key Words: Estrus detection, Statistical process control, Sample size

1045 The effect of days open on milk produced per day across sequential lactations. J.D. Ferguson^{*1}, D.T. Galligan¹, G. Atzaro², S. Ventura², and G. Licitra², ¹University of Pennsylvania, ²Consorzio-Ricerca Fileria Lattiero-Caesaria.

The objective of this study was to calculate the effect of days open on milk produced per day across sequential lactations in Holstein-Friesian cows. Records (39,929) were collected from the Ragusa, Italy DHIA organization from 263 herds for the years 1995-1999. Each record included herd ID, cow ID, date of parturition, lactation number, total cumulative milk production, and total days in milk at last test record. Cumulative milk production (CUMMILK) was calculated from monthly test records. Calving interval (CI) was determined by the interval between sequential calvings for each cow. The CI was associated with the next lactation record for that cow, as was previous lactation cumulative milk yield (PREVMILK) and previous total lactation days (PREVDIM). Days open (DOPEN) was calculated as $(\text{CI} - 280)$. Total milk produced (TOTMILK) in sequential lactations was $(\text{CUMMILK} + \text{PREVMILK})$. Total days (TOTDIM) was $(\text{CI} + \text{DIM})$ in the subsequent lactation. Milk produced per day (MPD) was calculated as $\text{TOTMILK} / \text{TOTDIM}$. To index production, the 305 milk yield (M305) was calculated based on production curves for each cow-lactation generated from monthly milk records. Data was edited to exclude extreme PREVDIM and DIM records. Final analysis was on 8331 records. MPD was influenced by M305 of cow, lactation number, month of parturition, and DOPEN. The relationship of MPD to DOPEN was nonlinear and fit the following model $(\text{SE}): \text{MPD} = .00341(.00014) * \text{M}305 * \text{DOPEN}^{-.0383(.0111)} * \exp(\text{DOPEN} * -.00014(.0001))$. Selective culling may have resulted in the nonlinear relationship of MPD and DOPEN.

Key Words: days open, milk produced per day, reproductive efficiency

1046 Conception rates of sequential inseminations after batch-thawing multiple straws of semen: A professional technician case study. M. J. Sprenger¹, J. M. DeJarnette^{*2}, and C. E. Marshall², ¹Paddocks Breeding Service, Warsaw, NY, ²Select Sires, Inc., Plain City, OH.

Although standard recommendations for thawing cryopreserved bovine semen are to thaw no more straws than can be deposited in the female within 10 to 15 minutes and to maintain thermal homeostasis during this interval, recent studies suggest thawing more than two straws at once results in compromised fertility of the third or greater sequential insemination number (SIN). This study evaluated the effects of SIN on conception rates (CR) after batch-thawing of straws by a professional AI technician (PAIT). The study was conducted in western NY from June 1999 through May 2000. As efficiency dictated that multiple straws should be thawed ($n = 2$ to 11), the PAIT recorded herd, cow ID, bull ID, AI date, and SIN. Pregnancy data ($n = 6122$) were obtained by cross-referencing the recorded events with each herd#s ($n = 28$) reproductive database subsequent to pregnancy diagnosis. To increase sample size for statistical analyses, $\text{SIN} \geq 7$ were combined and data from 16 small herds ($n < 80/\text{herd}$) were combined as one. Data were evaluated in logistic regression models that included the main effects of herd ($n=13$), SIN, season, service (first or repeat), and all two-way interactions. The herd by SIN interaction tended ($P = 0.07$) to influence CR. In herd E, CR of SIN 5 was lower ($P < 0.01$; 10%, 11/108) than SIN 1 to 4 or 6 and ≥ 7 (28% for each). In herd M, CR of SIN 6 (0%, 0/11) and ≥ 7 (7%, 1/14) were lower than SIN 1 to 5 (32% for each). SIN had no effect ($P > 0.10$) on CR in the other 11 herds nor across all herds (1 = 32%, 397/1260; 2 = 33%, 411/1250; 3 = 34%, 386/1129; 4 = 33%, 300/917; 5 = 32%, 219/696; 6 = 29%; 133/464; $\geq 7 = 35\%$, 142/406). Additionally, CR evaluated by the total number of straws in each thaw revealed no decline in fertility due to batch-thawing. These

data suggest that PAITs and herdsman inseminators who follow recommended semen handling procedures can thaw more than two straws at once without compromising conception rates.

1047 Results of Breeding Soundness Evaluations performed on Senepol bulls in the US Virgin Islands. R.W. Godfrey* and R.E. Dodson, ¹University of the Virgin Islands, Agricultural Experiment Station, St. Croix.

The Breeding Soundness Evaluation (BSE) was used to evaluate Senepol bulls on 3 farms on St. Croix over a 2-yr period. One set of bulls (SELECT; n = 75) was tested prior to sale or use in the breeding herd. The second group of bulls (UNSELECT; n = 440) was tested at 4-mo intervals without any prior selection. Bulls in the SELECT and UNSELECT groups ranged in age from 12.7 to 89.3 mo and 6.5 to 101 mo, respectively. Bulls were given a rating of satisfactory or unsatisfactory based the BSE guidelines. Data were analyzed using GLM and chi-squared procedures of SAS. In the UNSELECT group the percentage of bulls passing the BSE increased (P < .0001) with age. In the SELECT group the percentage of bulls passing the BSE decreased (P < .02) with age. In the UNSELECT group, bulls that passed the BSE had larger SC (P < .0001), greater sperm motility (P < .0001) and a higher percentage of normal sperm (P < .03) than bulls that failed. In the SELECT group, bulls that passed the BSE had a higher percentage of normal sperm (P < .0001) but there was no difference (P > .10) in SC or sperm motility. Of the SELECT bulls that failed the BSE, a higher percentage (P < .0001) received passing scores for sperm motility and SC than they did for sperm morphology (92, 94.4 and 1.1 %, respectively). Of the UNSELECT bulls that failed the BSE, there was no difference (P > .10) in the percentage that received passing scores for SC, sperm motility or morphology (7.2, 7.7 and 9.7 %, respectively). In the SELECT and UNSELECT groups, 28 and 197 bulls were tested more than once, respectively. In the UNSELECT bulls that were tested more than once, there were increases in SC (P < .0001) and sperm motility (P < .01), but not sperm morphology (P > .10) over time. In the SELECT bulls that were tested more than once there was no effect of time on SC, sperm motility or morphology (P > .10). These results indicate that sperm morphology had a greater impact on the proportion of Senepol bulls passing the BSE than did testicular size or sperm motility.

Key Words: Bull, Scrotal Circumference, Semen Quality

1048 Effects of GnRH-PGF based estrus synchronization with or without short-term progestin exposure on reproductive performance of postpartum suckled beef cows. J. M. DeJarnette, R. A. Wallace, and C. E. Marshall, *Select Sires, Inc., Plain City, OH.*

This study evaluated the effects of short-term progestin exposure on synchrony of estrus and reproductive performance of postpartum beef cows synchronized to estrus using GnRH and PGF. Postpartum (80 2.2 d) Angus cows were injected (im) with 100 mg of GnRH on d #7 and PGF (0.5 mg cloprostenol) on d 0. Animals were randomly allotted by parity and calving date to receive either: 1) no further treatment (GP; n = 45) or 2) 0.5 mg/hd/d of melengestrol acetate (MGA) from d #6 through d #1 (GMP; n = 54). Unbalanced sample size is due to herd-owner decision (subsequent to treatment allocation) to bred animals to randomly detected natural heats during the 2 week prior to treatment, however, postpartum interval and parity distribution remained balanced across treatments. Twice daily observation for estrus began on d #3 and continued until 72 h post-PGF. Cows detected in estrus were bred by AI 8 to 12 h later (EAI). Cows not detected in estrus by 72 h post-PGF were fixed-time inseminated and concurrently injected (im) with 100 mg of GnRH (TAI). Cows were exposed to herd bulls on d 13 and ultrasonographic pregnancy diagnosis was performed on d 38. Data were analyzed in logistic regression models that included the effects of treatment, parity, postpartum interval, body condition score, and all two-way interactions. Although fewer (P = 0.08) GMP than GP-treated cows were detected in estrus (59 vs. 76%, respectively), the numerical difference (P = 0.30) in conception rate at TAI (56 vs. 36%, respectively) and the absence of estrus by 24 h post-PGF (0 vs. 9%, respectively) suggests a greater degree of ovulatory synchrony was established by GMP treatment. Conception rates to EAI (GP vs. GMP; 75 vs. 69%) and synchronized AI pregnancy rates (GP vs. GMP; 67 vs. 63%) were not affected (P > 0.10) by treatment. These data suggest

MGA can be used to prevent premature estrus in GnRH-PGF treated cows without compromising AI pregnancy rate.

Key Words: Estrus synchronization, Melengestrol acetate, Progestin

1049 Effectiveness of a stand-alone electronic estrus detection device - MountCount. H. K. Baitis*, J. B. Hall, D. E. Eversole, and D. Cuddy, *Virginia Polytechnic Institute and State University, Blacksburg, Virginia.*

An electronic estrus detection (EED) system, HeatWatch® (DDx, Inc., Boulder, CO), increases estrus detection efficiency in cattle, but requires receivers, repeaters, and a computer. MountCount® (DDx, Inc., Boulder, CO) is a stand-alone EED unit that indicates estrus status by lights. Information on the effectiveness of MountCount® (MC) compared to other estrus detection systems is limited. The objective of this study was to compare the efficiency and accuracy of visual estrus detection (VIS) or MC to HeatWatch® (HW). In trial 1, dry open cows (n=50) were fitted with both MC and HW. Cows were observed for estrus for 10 d and then synchronized with prostaglandin. In trial 2, lactating postpartum cows (n=136) were randomly fitted with either MC or HW. Cattle were synchronized with either 7-11 or CO-Synch protocol. Cattle were observed 2x/d (trial 1; VIS-2) or 5x/d (trial 2; VIS-5) for visual signs of estrus, MC status and condition of MC and HW. In trial 1, either MC or HW detected more (P<.001) cows in estrus than VIS-2. VIS-2 and MC agreed with HW 43.0% and 93.3%, respectively, when HW indicated cows were in estrus. MC more often indicated (P<.02) that cows were in estrus when HW did not indicate estrus. Agreement with HW was 85.0% and 70.0% for VIS-2 and MC, when HW indicated no estrus activity. In trial 2, for HW cows, VIS-5 identified fewer (P<.03) cows in estrus than HW. Estrus detection rates were 86.7% and 100% for VIS-5 and HW, respectively. For MC cows, VIS-5 identified more (P<.02) cows in estrus than MC with estrus detection rates of 96.0% and 78.0% for VIS-5 and MC, respectively. Pregnancy rates to artificial insemination were not different (P>.15) for MC cows (47.8%) compared to HW cows (30.4%). Observers indicated that MC was difficult to visualize in daylight. We conclude that MC is superior to twice-daily visual estrus detection, but appears less effective than intensive visual estrus detection or HW.

Key Words: Estrus Detection, Cows, Electronic

1050 Lowering dietary P in dairy rations reduces the vulnerable P fraction in manure. Z. Dou*¹, K. Knowlton², G. Zhang¹, Z. Wu³, and R. Kohn⁴, ¹University of Pennsylvania, ²Virginia Tech, ³Penn State University, ⁴University of Maryland.

Phosphorus (P) accumulation on livestock farms contributes to elevated P runoff loss and accelerated eutrophication of surface waters. Recent studies strongly suggest that the amount and concentration of P in dairy manure can be substantially reduced by lowering dietary P levels in lactating cow rations while maintaining cow performance. Yet, little is known concerning the effect of dietary manipulation on the forms and relative solubility of manure P. The objective of this study was to characterize P in dairy feces collected from several feeding trials, each comparing two or three dietary P concentrations in lactating dairy cows. Fecal samples, collected during various stages of lactation, dried and ground, were measured for readily soluble P by extracting in deionized water with 1 hr shaking. Selected fecal samples were used to determine P fraction distributions using a sequential extraction procedure. Lowering dietary P levels dramatically reduced the amount of readily soluble P in fecal materials. For example, decreasing dietary P from 0.47% to 0.39% of feed DM resulted in a reduction of readily soluble P from 4.33 to 2.82 g/kg fecal DM. In another trial, decreasing dietary P from 0.52% to 0.34% reduced readily soluble P from 4.40 to 1.82 g/kg DM. The same pattern was observed throughout the sampling periods covering up to 11 wks in lactation. Results from the sequential extractions indicate that dietary P levels not only affected the quantities but also the relative proportions of P fractions in feces. For instance, cumulative P released in repeated water extraction accounted for 88%, 84%, and 76% of the total P extracted through the sequential extractions corresponding to dietary P levels of 0.67%, 0.52%, and 0.34% DM. Reducing excessive P in diets may lead to a substantial decrease in the potential runoff loss of manure P from fields.

Key Words: Dietary P, Manure, P fraction

1051 Reducing phosphorus solubility in animal manures using chemical amendments. J. D. Toth*¹, G. Zhang¹, Z. Dou¹, and J. D. Ferguson¹, ¹*University of Pennsylvania*.

Controlling nutrient losses from animal manures when they are land-applied is a critical factor in nutrient management, promoting environmental health and maintaining the sustainability of animal agriculture. Phosphorus is of particular concern due to its implication in eutrophication of surface waters and declines in water quality. We conducted a laboratory experiment to test the effect of several chemical amendments on reducing P solubility of animal manure. Freshly excreted swine or dairy manure samples were treated with aluminum sulfate (alum) or coal combustion byproducts: fluidized bed combustion flyash (FBC), flue gas desulfurization product (FGD), or anthracite refuse flyash (ANT). After incubation at ambient temperature for 3 d, subsamples were dried and ground. Samples were extracted with shaking for 1 hr in deionized water and the pH and inorganic and total P concentrations measured. Selected samples were extracted using a sequential procedure developed in our laboratory to identify the changes in soluble P forms as a function of amendment type and rate. Compared to untreated controls,

alum, FBC and FGD substantially reduced water soluble inorganic P in the 1 hr extract in fresh swine manure (by 80, 60 and 77%, at 250, 400 and 250 g amendment per kg DM manure, respectively). The 1 hr water extractable inorganic and total P in dairy manure were reduced by an average of 65 (alum at the 50 g rate) and 50% (FBC at the 400 g rate). The ANT amendment was ineffective in reducing water soluble P in swine manure, and both ANT and FGD ineffective in dairy manure. In the sequential, repeated extraction trial, addition of the amendments alum, FBC or FGD to swine manure reduced the total water soluble inorganic P concentration and increased the concentrations of bicarbonate, hydroxide and acid-soluble P by 11-21% compared to the control, demonstrating effectiveness in shifting inorganic P from the most vulnerable, water-soluble fraction to less soluble forms. The alum and FBC amendments had a similar effect on the dairy manure samples. Additional trials are planned to examine the amendments for other manure types and to refine effective rates of addition to reduce soluble P.

Key Words: Phosphorus Solubility, Nutrient Management, Manure Nutrients

Beyond pH: Metabolic Factors Affecting Pork Quality

1052 The Effect of the RN⁻ Allele on Meat Quality and how the Gene was Discovered. K. Lundstrom* and L. Andersson, *Swedish University of Agricultural Sciences, Uppsala, Sweden*.

The RN⁻ allele was first identified in France as causing a reduction in the yield of cured cooked ham from composite lines containing the Hampshire breed. The effect was determined by "Napole yield" (Rendement Napole in France), a standardized method for estimating yield. The dominant allele decreasing the yield was called RN⁻ and was due to an increase in muscle glycogen content. The RN locus has been mapped to chromosome 15, and has recently been identified as a mutation in the PRKAG3 gene, which encodes a muscle-specific isoform of the regulatory λ subunit of adenosine monophosphate-activated protein kinase (AMPK).

The RN⁻ allele has a great effect on technological meat quality, leading to a decrease in ultimate pH and water holding capacity, and an increase in reflectance value. The chemical composition of meat is also altered with an increase of glycogen and water content and a reduction of pro-

tein content. These changes lead to a reduction in the yield of cooked cured ham. On the other hand, the eating quality is enhanced. In several Swedish studies, pork from animals carrying the gene had higher juiciness, meat taste and acidulous taste and usually a higher tenderness. Also Swedish consumers preferred pork from carriers of the RN⁻ allele in comparison with non-carriers. Processed meat from RN⁻ carriers also showed a higher juiciness and tenderness in sensory tests with a trained panel. In contrast, French results showed a negative effect on eating quality. Also, the production traits are altered as an effect of the RN⁻ allele, leading to a higher growth rate and a higher proportion of lean meat in the carcass.

The gene frequency of the RN⁻ allele has been around 0.6 in Swedish Hampshire. Due to the negative effect of the RN⁻ allele on technological meat quality, most countries and breeding companies would like to eliminate the mutation. With the mutation identified, this could be easily achieved. However, the positive effects of the RN⁻ allele on eating quality should be taken into consideration.

Key Words: RN⁻ allele, Meat Quality, Napole Yield

ASAS/ADSA Food Safety and PSA Pathology

1053 Effect of dietary fiber on enterohemorrhagic *Escherichia coli* O157:H7 shedding in lambs. M. Lema* and L. Williams, Alabama A & M University.

E. coli O157:H7 is an emerging food-borne pathogen implicated in several outbreaks. Fecal shedding of the pathogen constitutes the mode of entry into the human food chain. We compared the influence of dietary acid-detergent fiber (ADF) concentration on fecal shedding of the pathogen and meat production efficiency of lambs. Fourteen growing-finishing Suffolk ram lambs averaging 28.13 kg in body weight were arranged in two 7 x 7 Latin squares with 1-week adaptation and 2-weeks of fecal sample collection and fed diets with 5, 10, 15, 20, 25, or 35 % ADF content, ranging from all-concentrate (5 % ADF) to all-forage diet (35 % ADF). Diets were fed daily at the rate of 1.4 kg/head. Fecal samples were collected weekly and analyzed for *E. coli* O157:H7 using modified tryptic soy broth with novobiocin as a pre-enrichment broth and cefixim-tellurite sorbitol MacConkey agar (CT-SMAC) as a selective media. *E. coli* O157:H7 was confirmed by its reaction with O157 and H7 antisera. Lamb growth rate and daily dry matter intake were determined and composite feed samples analyzed for nutrient content. When fed 10, 15, 20, 25, 30 and 35 % ADF in the diet, *E. coli* O157:H7 shedding was comparable among treatments suggesting that within 10 to 35 % ADF range dietary fiber does not impact *E. coli* O157:H7 shedding. However, lamb growth rate and feed efficiency were significantly lower ($P < 0.05$) for the 25, 30 and 35 % ADF diets. The 5 % ADF (100 % concentrate) diet resulted in significantly higher ($P < 0.05$) shedding of the pathogen (6.09 versus 5.12, 4.82, 5.21, 5.05 and 5.04 log₁₀ CFU/g of feces for the 10, 15, 20, 25, 30, and 35 % ADF diets, respectively) than the other treatments. The results suggests that increasing the ADF content of the concentrate ration between 10 and 20 % ADF results in significant reduction in the shedding of *E. coli* O157:H7 as compared to 5, 25, 30, and 35 % ADF diets without adversely affecting animal meat production efficiency.

Key Words: *E. coli* O157:H7, Fecal shedding, Dietary fiber

1054 Simultaneous detection of *Salmonella* sp. and *E. coli* O157:H7 using PCR on beef carcasses from a slaughterhouse in Mexico City. E Lopez, R Alonso, MS Rubio*, F Nuez, M Nicoli, and P Miranda, Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autonoma de Mexico.

The aim of this work was to develop a multiplex PCR assay to detect simultaneously *Salmonella* (S) and *E. coli* O157:H7 (Ec) on beef carcasses. Shiga like toxin I, II, eaeA gene and uidA primers were used to detect Ec. The invA gene was used to detect S. In order to have an internal control to distinguish between negative and false negatives results, we incorporated to the PCR mix pBR322 plasmid DNA and primers specific to amplify a characteristic fragment. PCR reaction conditions, which amplify DNA from both bacteria, and control plasmid, were as follow: a denaturalization step at 94C by 3 min followed by 30 cycles consisting of 94C during 30 s, 50C for 30 s and 72C by 30 s and finally a step of 72C for 3 min. Experimentally infected meat was used to evaluate the assay. Individual strains and the mixture of both (meat was previously washed using a physiological salt solution) were used. Non-infected washed pieces of meat were used as negative controls. The assay was evaluated in field specimens. Sixty beef carcasses from slaughterhouses were sampled on the shoulder region with sterile cotton swap on a delimited surface of 17x17 cm². To transport, the swap was kept in a plastic bag containing a peptone broth. Before DNA extraction, samples were cultivated in an enriched broth and incubated for 24 h. Results indicated that the positive experimental controls (individual strain and mixture) showed the expected amplified bands. Washed meat showed no band. Field results showed that none of the carcasses were contaminated with Ec, and only 10% of the carcasses were positive to S. Standards microbiology procedures of the samples showed a higher percentage of samples with S, which in comparison with the PCR results indicates that no all the S found were invasive.

1055 Simple and Rapid Method for Screening Antimicrobial Activities of *Bifidobacterium* Species of Human Isolates. S.A. Ibrahim* and M.M. Salameh, North Carolina Agricultural and Technical State University.

Bifidobacteria constitute a major part of the human intestinal microflora. Many health benefits are associated with bifidobacteria including their antimicrobial activities. For this reason, there has been increased interest in the development of a rapid method for screening antimicrobial activities of *Bifidobacterium* isolates from human fecal samples. The objective of this research was to develop a rapid procedure for the screening antimicrobial activities of *Bifidobacterium* species of human isolates. A Bifidobacteria selective medium BIM-25 agar was modified by adding of 0.5g/l cysteine-hydrochloride, 1.5g/l lithium Chloride, 1.5g/l beef extract, and 5ml/l Tween 20. This medium was inoculated (45C) with diluted fecal material from 5 subjects and overlaid into 0.1% Tween 20 BHI agar plates. Plates were incubated in anaerobic chamber at 37C for 48 hours. Plates were then inverted to allow the two layers of agar to fall into the petri lid. BHI soft agar (0.45%) containing *Micrococcus luteus* (as indicator) was overlaid onto the other layers in the petri dish. Plates were incubated at 37C overnight and zone of growth inhibition was observed. This method is simple and rapid whereas the original method for screening of antimicrobial activities of bifidobacteria is a more time consuming and cumbersome procedure.

Key Words: Rapid Method, *Bifidobacterium* species

1056 D-value Determination of *Listeria monocytogenes* and *Salmonella typhimurium* in low fat ready-to-eat processed meat. Kevin McCormick*, Inyee Y. Han, and Paul L. Dawson, Clemson University, Clemson, South Carolina/US.

The research was conducted to determine the best processing temperature for inactivating *Listeria monocytogenes* and *Salmonella typhimurium* on packaged turkey bologna. To determine the best treatment temperature, the D-values of *L. monocytogenes* and *S. typhimurium* at various temperatures were tested. A low-fat turkey bologna was cut into 3cm² squares and irradiated to ensure that the sample was sterile before being inoculated. Each sterile sample was inoculated with approximately 10⁸ CFU/ml inoculum and aseptically placed into a LLDPE pouch and vacuum-sealed. Then, the samples were submerged in a water bath held at constant temperature, and removed at timed intervals. Different water bath temperatures between 60° and 85° C were used with processing temperatures measured and recorded using a CALPlex datalogger and Calsoft software. The number of cells on each sample was determined by plating on appropriate growth media after making serial dilutions. The plates were incubated for 48 hours, and the counts were used along with time and temperature data to determine the D-values at 60°C, 65°C, and 70°C. At 85°C water temperature, no *L. monocytogenes* cells were detected (< 10²) after 10 seconds submersion, while at 60°C cells were detected (> 10²) up to 10 minutes after submersion of the packaged meat in the heated water bath. Similar results were found for *S. typhimurium*. The data shows that significant reductions in bacterial counts can be achieved with these temperatures and that only a small increase in temperature greatly affects the D-values for both bacteria examined.

Key Words: D-value, *Listeria monocytogenes*, *Salmonella typhimurium*

1057 Molecular Subtyping and Tracking of *Listeria monocytogenes* in Hispanic Cheese Factories. D.Y. Kabuki¹, A.Y. Kuaye¹, M. Wiedmann², and K.J. Boor², ¹Faculdade de Engenharia de Alimentos-UNICAMP-Brazil, ²Food Safety Laboratory - Department of Food Science-Cornell University.

This research focused on identifying *L. monocytogenes* prevalence patterns to track sources of bacterial contamination in Hispanic-style fresh cheese manufacture, which represents a growing sector of the New York State dairy processing industry. A total of 357 samples were collected from three Hispanic cheese factories in New York City during 4 visits in a 6-month period. *L. monocytogenes* was found in 6.3% (7/111) of finished fresh cheeses and 11.0% (27/246) of environmental samples (food contact surfaces, floor drains, floors, walls and miscellaneous). Among

the environmental samples, 30% of drain and 20.6% of floor samples were positive for *L. monocytogenes*. A total of 80 representative isolates from all positive samples were subtyped for allelic polymorphisms using PCR-RFLP for virulence genes encoding listeriolysin O (*hlyA*) and ActA (*actA*). Allelic type 4 for *actA* and allelic type 1 for *hlyA* (lineage I) were predominant among the isolates. Isolates were classified to lineage I (80.0%) more frequently than to lineage II (20.0%) or III (0.0%). 23 *L. monocytogenes* isolates from the factory with positive cheeses and food contact surfaces were ribotyped using EcoRI with the Qualicon RiboPrinter. Ribotypes DUP-1044 (82.6%), DUP-1045 (13.0%) and DUP-1039 (4.4%) were identified among the isolates tested. A unique *L. monocytogenes* subtype (*actA* type 4, *hlyA* type 1, and ribotype DUP-1044) was isolated from finished products, drains, floors, a plastic connecting tube, and a polytetrafluorethylene table in one plant. This subtype was found during all 4 visits to this plant. Our subtyping data indicate persistent environmental contamination as a primary source of finished product contamination. Although the prevalence of *L. monocytogenes* positive samples decreased following some modifications in the plant's sanitation program during the sampling period, the unique, persistent *L. monocytogenes* strain still remained in the factory. We conclude that focused measures will be required to eliminate persistent *L. monocytogenes*, which are a likely cause of finished product contamination.

Key Words: *Listeria monocytogenes*, cheese, subtyping

1058 Characterization of isolated bacterial strains with antagonistic properties against food-borne pathogen *Listeria monocytogenes*. H. Roman*, E. T. Ryser, S. Rust, and M. T. Yokoyama, *Michigan State University, East Lansing, MI/United States*.

Listeriosis in ruminants is most frequently implicated with improperly fermented silage. The causative agent is *Listeria monocytogenes*. We hypothesize that bacterial strains, antagonistic against this foodborne pathogen, can be isolated directly from the farm environment. Three wild bacteria strains (designated Ba-E, Bs-3 and Bs-13) antagonistic towards strains of this pathogen (CWD246 Brick silage and DGallup CWD95), were isolated from fresh corn silage and rumen fluid. Isolates were identified as *Bacillus* spp. according to the API system, FAME and 16S rRNA. Ammonium sulfate precipitation of these isolates revealed the presence of bioactive protein factors. SDS-PAGE analysis of two of these preparations (Bs-3 and Bs-13) showed that only one peptide band displayed antimicrobial activity. These peptides were sensitive to protease and gastric peptidases (protease, proteinase K, chymotrypsin and lipase) tolerant of changes in heat (30-100C), organic solvents (acetone, acetonitrile, ethyl alcohol, methanol, chloroform and toluene) and pH (4 # 8). We speculate that at least one of these bioactive peptides may be a new bacteriocin which can potentially be used as a probiotic for silage and other feeds to control *Listeria monocytogenes*. These isolates survived and grew in TSB with yeast extract, containing either rumen fluid (50% v/v) or bile (0.3% w/v). An *in vitro* challenge study using co-cultures of *Listeria monocytogenes* CWD246 Brick Silage and strains of *Bacillus* spp (either wild type or ATCC 6633 strains) was conducted. Both the optical density (OD_{600nm}) and the viable counts (log cfu/0.1ml) of *Listeria monocytogenes* were monitored during a 24-h period. The treatment containing a mix of two wild type strains of *Bacillus* spp. (Bs-3 and Bs-13) was more effective in decreasing the viable counts of *Listeria monocytogenes*. We conclude that this combination might be a better treatment for controlling *Listeria monocytogenes* than either the ATCC6633 strain or the Ba-E wild strain. This research was partially supported by the National Food Safety & Toxicology Center, MSU.

Key Words: Listeriosis, Bacteriocin, Probiotic

1059 The effect of environmental and substrate factors on the growth and survival of *Salmonella agona*. S.A. Ibrahim*, T.A. Lloyd, M.M. Salameh, A. Shahbazi, R. Purcell, and C.W. Seo, *North Carolina Agricultural and Technical State University*.

Salmonella agona (*S. agona*) is one of approximately 2000 *Salmonella* serotypes that can cause illness in humans. *S. agona* has been linked to cereal food outbreak. This is the first time a commercial cereal product has been implicated in a *Salmonella* outbreak. *S. agona* is an uncommon serotype of *Salmonella*, it is found in a variety of animal reservoirs including poultry, cattle, pigs, and animal feed. Little information is

available about the physiology, growth and survival of this pathogen in foods. Therefore, the objective of this research was to determine factors affecting the growth and survival of *S. agona* in foods. Two strains obtained from the Center for Disease Control (CDC); *S. agona* H6115 and F 5567 were used in this study. Results indicated that 30C is optimum growth temperature for *S. agona*. Acetic acid is most inhibitory organic acid at pH value of 5.5. The addition of 3% sodium acetate or 3% sodium chloride showed significant reduction (P < 0.05) in microbial growth. Heat treatment at 55C for 20 min, 57.5C for 14 min, or 60C for 5 min was needed to achieve 5-log reduction in microbial populations. Thermal resistant of *S. agona* can be lowered by combining extrinsic factors such as pH, sodium chloride or sodium acetate. Cold shock at 2C for 25 min, prior to heat treatment, increased the thermal sensitivity of *S. agona*. In a model broth system, thermal death time at 57.5C was reduced by up to 1.5 log after the pathogen was cold shocked for 25 min. This indicates that cold shock has a potential to become a practical method to control pathogens in foods.

Key Words: *Salmonella agona*, Thermal

1060 Effects of Tasco® 14 on Prevalence Levels of Enterohemorrhagic *Escherichia coli* and *Salmonella* spp. in Feedlot Steers. A.R. Barham¹, B.L. Barham*¹, J.R. Blanton, Jr.¹, V.G. Allen¹, K.R. Pond¹, and M.F. Miller¹, ¹*Texas Tech University*.

The purpose of the study was to determine the effects of Tasco® 14 supplementation at 2% of a commercial grain based diet on *Salmonella* spp. (SAL) and Enterohemorrhagic *E. coli* (EHEC). Sixteen pens from a large commercial feedlot in West Texas were fed Tasco® 14 supplementation for 14 days starting at day forty-five of the feeding period and received a second supplementation for 14 days prior to shipment to slaughter facilities. Fecal and hide samples were collected from 13 animals in each pen for USDA approved microbiological assays prior to feeding Tasco® 14, prior to shipment for slaughter, and immediately following exsanguination. Prevalence levels were generated using the frequency procedures in SAS (1995). Changes in prevalence levels from the three sample times were analyzed using the T-test procedure in SAS (1995). Prior to Tasco® 14 supplementation, prevalence of EHEC and SAL was 18% and 39% respectively on hides and 34% and 30% in fecal samples. After the 14d feeding period prevalence of EHEC and SAL were 5% and 34% respectively on hides and 0% and 30% in fecal samples. Data reveals that at the packing facility, prevalence of EHEC and SAL were 0% and 70% respectively on hides and 2% and 57% in fecal samples. A significant reduction in EHEC on both hides and fecal samples occurred after the first feeding of Tasco® 14 compared to the pre-feeding samples (P < .05). The first Tasco® 14 supplementation did not significantly reduce SAL on hides but did significantly reduce prevalence of SAL in fecal samples. The second feeding period of Tasco® 14 significantly reduced EHEC in fecal samples when compared to both the pre-feeding and the first Tasco® 14 supplementation sample times. Samples taken at the packing plant indicated significantly lower prevalence levels of EHEC when compared to pre-feeding samples. SAL prevalence was reduced in fecal and hide samples at the packing plant when compared to samples taken after the second supplementation of Tasco® 14.

Key Words: Beef Cattle, *E. coli*, *Salmonella*

1061 A challenge trial testing the effects of Acid Pak 4-Way on *Salmonella* cecal colonization in broiler chicks. J.W. Evans* and M.S. Plunkett, *Alltech Biotechnology, Inc., Nicholasville, KY*.

An experiment was conducted to evaluate the effectiveness of a product containing a combination of organic acids, electrolytes, bacteria and enzymes (Acid-Pak 4-Way, Alltech, Inc.) at reducing cecal colonization in day-old chicks challenged with *Salmonella typhimurium* 29E (1 x 10⁶ CFU/g). Day-old chicks were randomly assigned to a control chamber with an untreated water supply or to a chamber supplied with water containing 1g/L Acid-Pak 4-Way. The experiment consisted of five control groups and five treatment groups with ten chicks in each group. Each chick was inoculated by oral gavage with a standard inoculum to provide similar microflora at the beginning of the experiment. On d3, each chick received 0.25ml *S. typhimurium* (4 x 10⁶/ml) by oral gavage. On d10 chicks were sacrificed and both ceca removed. The content of one cecum was diluted and plated on Brilliant Green Agar (BGA) to determine salmonella concentrations. The content of the other cecum

was placed in deionized water to measure pH levels and to determine VFA concentrations. The cecum was then placed in lactose broth to be used as a confirmation in samples that did not grow on the BGA. Cecal VFA concentrations and pH in the treatment group were not different from those in the control group. However, salmonella concentrations were lower ($P < 0.01$) in the treatment group ($6.87 \log_{10} \text{CFU/g}$) than in the control ($7.5 \log_{10} \text{CFU/g}$). The results from this experiment indicate that adding Acid-Pak 4-Way to the drinking water of young chicks reduces the cecal colonization of chicks exposed to salmonella.

Key Words: Water acidification, Challenge trials, Salmonella

1062 Effect of an essential oil blend on coccidiosis in broiler chicks. J.W. Evans*, M.S. Plunkett, and M.J. Banfield, *Alltech Biotechnology, Inc., Nicholasville, KY.*

The effects of a dietary essential oil blend on an *Eimeria acervulina* and *Clostridium perfringens* infection was investigated in broiler chicks. Two hundred, day-old chicks were housed in ten isolation chambers. At 15d old, one hundred and fifty were allotted to ten isolation chambers with 15 chicks per chamber. Chicks in five chambers received a starter poultry diet as a control. The chicks in the remaining five chambers received the same diet containing an essential oil blend (1.0% clove oil, 0.1% thyme oil, 0.1% peppermint oil, and 0.1% lemon oil). All chicks received 0.25ml *Cl. Perfringens* ($4 \times 10^8 \text{CFU/ml}$) for three days by oral gavage on d19-21. They received 0.25ml oral gavage of 2.5×10^5 *E. acervulina* oocysts on d22. Five chicks per chamber were sacrificed on d15, 22 and 36, and the entire gastrointestinal tract (GIT) was removed for *Cl. perfringens* enumeration. The chicks were housed on raised wire mesh floors in isolation chambers. From d21-35 feces were analyzed for oocysts. Performance parameters were measured on d15, 22, 29 and 36. The control chicks live weight was greater than the live weight of the treatment chicks on d36 (1575 vs. 1429g, $P < 0.05$). Feed intake was lower in the treatment chicks than in the control chicks from d15-21 (80 vs. 75g/bird/d, $P < 0.01$). FCR was not affected by treatment. Fecal oocyst yields were lower in the treatment chicks than in the control chicks at the peak of the infection (d26) (5.24×10^8 vs. 6.86×10^8 oocysts/bird/d, $P = 0.028$). The average of the total oocyst yields were also lower over the whole infection (9.94×10^8 vs. 1.17×10^8 oocysts/bird/d, $P = 0.032$). No differences in GIT *Cl. perfringens* populations were observed between treatments. The results of this trial indicate that the addition of essential oils to a normal poultry diet reduced the oocysts excreted at peak infection, however the addition of the oils also appeared to reduce the overall performance of the birds.

Key Words: Coccidiosis, Essential oils, *Eimeria acervulina*

1063 Apramycin resistance of *E. coli* isolated from cold-stressed swine. D.B. Arnett*, P. Cullen, P.D. Ebner, and A.G. Mathew, *University of Tennessee, Knoxville, TN.*

To determine if the development of resistance to apramycin in *E. coli* isolated from cold-stressed swine could be linked to plasmids, six weaned pigs were administered apramycin in the feed (150 g/ton for 14 d) and was exposed to cold stress in the form of an 8C reduction in recommended daily temperature throughout the wean-to-finish period. Fecal swabs were taken on days 0, 2, 7, 14, 28, 64, 148, and 149 for recovery of *E. coli*, and isolates were tested for sensitivity to apramycin using microdilution minimum inhibitory concentration (MIC) analysis. One resistant and one sensitive isolate were randomly chosen from each sampling day, and plasmids separated from each isolate. Plasmid profiles of resistant and sensitive isolates were compared based on plasmid number and size. Arbitrarily primed PCR (AP PCR) was used to identify resistant plasmids. PCR fingerprints were made of all plasmids using primers 23L and OPB-17. Pulsed-field gel electrophoresis (PFGE) was performed on chromosomal DNA using *SpeI* and *XbaI* restriction endonucleases. Profiles from AP PCR and PFGE were compared separately for similarity by eye and by using a molecular analyst fingerprinting software that created dendrograms for comparisons. Resistant plasmids were not identified, and the source of resistance could not be linked to plasmids by these methods. Other methods, including southern blot analysis, may be needed to identify resistance plasmids.

Key Words: swine, antibiotic resistance, plasmids

1064 The effect of antibiotics on broiler body weight, feed conversion and tibial dyschondroplasia scores. T.L. Peters*, K.D. Roberson, R.M. Fulton, and M.W. Orth, *Michigan State University, East Lansing, MI/USA.*

One of the major metabolic skeletal disorders that effect the long bones of fast growing birds is tibial dyschondroplasia (TD). Disrupted bone metabolism allows an avascular plug of cartilage to accumulate in the metaphyseal region of tibiae, which can weaken bones. The etiology of TD remains unclear. Recently, we found that doxycycline, oxytetracycline, enrofloxacin, ceftiofur, and salinomycin inhibited in vitro cartilage degradation of embryonic chick tibiae. Therefore, the objective of this study was to determine if these five antibiotics inhibited cartilage degradation and induced TD in growing broilers. Day-old male broiler chicks were randomly assigned to a treatment group and placed in a heated wire-floored battery brooder at 8 birds per pen with 3 pens per treatment. Chicks had ad libitum access to feed and water and were raised under continuous fluorescent light. Oxytetracycline, chlortetracycline, doxycycline, salinomycin, enrofloxacin, and ceftiofur were administered appropriately to chicks. A non-antibiotic control and thiram (a fungicide known to induce TD) group were also included in the experiment. Weekly growth rates and feed consumption were measured. Both proximal tibiotarsi were visually inspected for TD lesions at 22 days of age. Oxytetracycline, chlortetracycline, doxycycline, and ceftiofur did not differ from the control for any parameter tested. All salinomycin treated birds were lighter than controls; however, feed conversion only differed at the highest dose and TD incidence was not different for any dose tested. The lowest dose of enrofloxacin treated birds were heavier, but there was no difference for any dose in feed conversion or TD incidence. Control birds had a 15% incidence of TD while the 20 ppm thiram treated birds had a 92% incidence rate. Body weight and feed conversion were not different for thiram treated birds. Therefore, the results of this study show that the antibiotics tested are likely not involved in the etiology of TD in broilers.

Key Words: Tibial dyschondroplasia, Cartilage degradation, Antibiotic

1065 Haematological and histological findings in experimental Newcastle disease. F Galindo¹, N Calderon¹, M Charles¹, G Tellez¹, and T Fortoul², ¹*Departamento de Produccion Animal Aves, FMVZ, UNAM*, ²*Departamento de Biologia Celular y Tisular, Facultad de Medicina, UNAM.*

In an attempt to obtain more information about the pathogenesis of haemorrhages in Newcastle disease, blood cells counts with special emphasis on thrombocytes were performed in 25 specific pathogen-free chickens experimentally infected by ocular instillation of 10^6 embryolethal doses 50% of a velogenic viscerotropic strain of Newcastle disease virus (Chimalhuacan strain); five control chickens were also included. Birds were killed at 24 hours followed by 12 hours intervals. Whole blood and tissue samples were collected. The previous studies were complemented with the histological evaluation of bone marrow, brain, kidney, lung and proventriculus of the same animals. In this study a significant reduction of thrombocyte counts was detected within 72 hours post infection (hpi). A typical lymphopenia was detected; also an increase in heterophils and a decrease in monocytes at 60 hpi was observed. The histological findings consisted in swelling and vacuolization of capillary endothelial cells, mainly in the bone marrow and lung at 60 hpi. In the bone marrow early necrosis of haematopoietic islands was noted within 48 hpi. At 72 hpi there was a multifocal necrosis with the loss of cellular details and abundant debris. The thromboplasts at 60 hpi showed cytoplasmic vacuolation, nuclear vacuolation and basophilia. The thrombocytopenia and the endothelial damage are considered the main causes of haemorrhages. In this study, it is presumed by our findings that thrombocytopenia resulted from a direct mononuclear precursor cell viral damage of the thrombocytes in bone marrow.

Key Words: Newcastle disease, haemorrhages, vascular endothelium, thrombocyte, bone marrow

1066 Pathogenesis of thrombocytopenia in Newcastle disease: ultrastructural study. F Galindo¹, N Calderon*¹, G Tellez¹, and T Fortoul², ¹*Departamento de Produccion Animal Aves, FMVZ, UNAM*, ²*Departamento de Biología Celular y Tissular, Facultad de Medicina, UNAM.*

The ultrastructure of the bone marrow in 25 chickens experimentally infected with the Newcastle disease virus, Chimalhuacan strain and five control chickens were studied in order to determine if the virus caused direct damage to thrombocytes or their precursors. Light microscopy observations of semithin sections in the bone marrow revealed cell depletion and marked cell degeneration, principally of granulocytes and erythrocytes. At 24 hours post infection (hpi) electron microscopy showed cells with dense cytoplasm and chromatin associated with cellular death. At 36 hpi, decreases in erythrocytes and in some granulocytic cells were observed, and spherical electron-dense structures like viral particles were detected in dilated vesicles, as well as dilation of Golgi complex and endoplasmic reticulum. At 48 and 60 hpi an important depletion of hematopoietic cells was found and several cells presented perinuclear edema with necrosis or cytoplasmic degeneration. Apoptotic cells also were observed. At 72 hpi in the hematopoietic islands, few cells were found which showed necrosis and numerous cellular debris. Our results indicate that the depletion and necrosis of hematopoietic cells, including thrombocyte precursors, were responsible for thrombocytopenia detected in the early stage of the disease.

Key Words: Newcastle disease, pathogenesis, thrombocytopenia, thromboplast, electron microscopy, chickens

1067 Organochlorine pesticide residues in cow's milk from tropical region of Veracruz (Mexico). V.T. Pardo*¹, K.N. Waliszewski², and A. Ramirez¹, ¹*Universidad Veracruzana, Veracruz, Veracruz/Mexico*, ²*Instituto Tecnológico de Veracruz, Veracruz, Veracruz/Mexico.*

The purpose of the study was to assess the organochlorine pesticide levels in cow's milk produced in the central agricultural region of Veracruz State. These pesticides are intensively used in Mexico, causing exposure to significant levels of contamination to consumers and livestock. A hundred and twenty milk samples were collected bi-weekly at random during six weeks from farms located in three areas. Samples were cooled down, the fat layer was separated by centrifugation and stored in glass vials at -25°C until analysis. Organochlorine pesticide levels were determined by GLC/ μ ECD according to USEPA Method 608. A recovery study was performed on ten replicate spiked blank milk fat samples. Analyses were conducted for α -, β -, and γ -HCH, pp'-DDT, op'-DDT, pp'-DDD and pp'-DDE. The residue levels were reported as ng/g on lipid basis and the estimated dietary exposure as ng/day. Results were analyzed by analysis of variance with Minitab 10.5. Milk samples from Tlalixcoyan area showed a mean level of γ -HCH 128 ng/g which was significantly higher than Lindane residues in Jamapa (49 ng/g) and Paso San Juan (22 ng/g) milk samples. The mean value of Σ -HCH 230 ng/g was two times the FAO/WHO tolerance level of 100 ng/g. Concerning to DDT, mean levels of op'-DDT 26 ng/g, 39 ng/g of pp'-DDE, and 89 ng/g of pp'-DDT were found in milk samples collected from Jamapa area. The mean value of pp'-DDT was significantly higher than the levels detected in samples collected in the other two areas and four times the FAO/WHO tolerance level of 20 ng/g. For all chlorinated pesticide residues the estimated mean daily intake was 6.9 ng/d. Results indicate direct cattle exposure to HCH and DDT due to the fact that Lindane is still used to a limited extent for animal husbandry and the spray of DDT in vector control programs against malaria in Veracruz. This fact causes special concern since milk plays a central role in human nutrition and these pesticides have provided compelling evidence of hormone disruption activity in humans and lipid profile-disrupting activity in laboratory animals.

Key Words: Organochlorine pesticides, cow's milk, dietary exposure

1068 Detection of ochratoxin A in sorghum grain using various methods. J.H. Franco de la Torre*, W.P. Reyes, R. Nuo, and A. Taylor, *Centro Univ. de Los Altos, Universidad de Guadalajara.*

Ochratoxin A (OA) is a secondary metabolite, produced by *Aspergillus ochraceus* and *Penicillium viridicatum*. It is found as a frequent contaminant in various grains, cereals and animal feeds. The purpose of this

trial was to compare the efficiency of three immunoassay techniques (Veratox, Ridascreen, and Agraquant), and two immunoaffinity techniques (Afinitest and Ochratest), with HPLC in the detection of OA in sorghum grain, artificially and natural contaminated. Also two extraction methods (acetonitrile 60% and methanol 70%) were validated for the OA determinations with HPLC. The OA data were analyzed with a random and an angular transformation for arcsine of the CV for precision, the exactitude with the quadratic error, and the linearity with simple lineal correlation. The results showed that Agraquant gave a high linearity, precision, and exactitude, similar to the HPLC ($P > 0.05$), while Veratox, Ridascreen, Afinitest, and Ochratest; overestimate the detected levels of OA ($P < 0.05$). The extraction methods were similar ($P > 0.05$) in detecting OA, giving an additive constant of recuperation with acetonitrile, while the methanol has given a proportional recuperation (85%) as a multiplicative constant. Therefore, the immunoassay are a choice compare to HPLC in the detection of Ochratoxin A in animal feedstuffs.

Key Words: Ochratoxin A, Immunoassay, Immunoaffinity, HPLC

1069 Interaction between ochratoxin and aluminosilicate on the histopathologic aspect of organs and the humoral immunity against Newcastle disease virus in broilers. Elizabeth Santin*, A.C. Paulillo, A.C., Alessi, E.L. Krabbe, and A. Maiorka, *Faculdade de Ciências Agrárias e Veterinárias - UNESP, Jaboticabal, SP, Brasil.*

This study aimed at evaluating the effect of ochratoxin in the diet, in the presence or absence of aluminosilicate, on the histopathological aspect of the liver and the kidneys and the humoral immune response of broilers vaccinated against Newcastle disease virus (NDV). The exposure of 200 broilers to 2 ppm of ochratoxin, either in the presence or absence of aluminosilicate, reduced their humoral immune response and the number of mitotic cells in the bursa, but aluminosilicate did not influence ($P > 0.05$) these parameters. All groups reacted to antigenic stimulation by NDV at 11 days of age, but the best ($P < 0.05$) hemagglutination-inhibiting antibody titers were obtained in birds not exposed to ochratoxin (GMT 8.04, 8.24, 6.59 and 6.89 to group without ochratoxin and aluminosilicate, group with aluminosilicate, group with ochratoxin, and group with ochratoxin and aluminosilicate, respectively), which demonstrated the interference of this mycotoxin in the humoral immune response of broilers vaccinated against Newcastle disease. The liver of the birds exposed to this toxin showed an increase in its relative weight, and histopathological lesions of vacuolisation, megalocytosis in hepatocytes and proliferation of bile duct cells, whereas the kidneys had hypertrophy of proximal tubule cells and megalocytosis, with thickening of the glomerule membrane. The presence of aluminosilicate did not reduce the deleterious effects promoted by ochratoxin in broilers. Although several prior studies showed the efficacy of aluminosilicates in cases of aflatoxicosis, recent research demonstrated that these minerals do not inactivate other types of mycotoxins. This is probably due to the variation in the structure of adsorbent substances, as the adsorption is a function of ion and/or molecule exchange between these compounds and mycotoxins.

Key Words: Ochratoxin, Aluminosilicate, Immunity

1070 Surveillance programme of the microbiological safety and hygiene of meat in South Africa. AE de Jesus¹, EM Buys*¹, RP Greebe¹, J Kruger¹, L Kgosana¹, and WH Giesicke², ¹*Animal Nutrition and Animal Products Institute, Agricultural Research Council, Irene 0062, South Af.*, ²*Department of Agriculture North West Province, Mmabatho 2735, South Africa.*

The Directorate of Veterinary Services (DVS) of the Department of Agriculture in the North West Province recognised the need for information on the microbiological status of the meat supply as an essential supplement to veterinary efforts of improving hygiene management during the harvesting and post-harvesting stages of the meat supply chain. The Animal Nutrition and Animal Products Institute (ARC-ANPI) was contracted to design and implement a surveillance scheme to monitor the microbiological quality of meat after the final stages of slaughtering and at the retailer. The present project was not just to establish the microbiological quality of meat in the NWP. It was also designed as a model to be used to improve meat quality and safety in the whole of the RSA. From a practical point of view, the "bacterial scores" generated by the MeatStats programme developed show how each abattoir performed while the "abattoir ranking system" shows where abattoirs

stand compared to other abattoirs. A particularly attractive feature of the bacterial score and rating systems is that the scoring is entirely based on sample data and that subjective scoring is eliminated. With such systems and assistance at hand, the present surveillance system can only benefit the whole meat industry for many years to come.

Key Words: Base line study, Microbiological safety, Meat

1071 Fermentation of whey permeate to lactic acid by *Lactobacillus helveticus* in a spiral-sheet bioreactor. M.M. Salameh*, A. Shahbazi, S.A. Ibrahim, M. Mims, and V. Shirley, *North Carolina Agricultural and Technical State University.*

The United States generates nearly 325 billion gallons of wastes and by-products during the processing of foods. Whey is a by-product produced in cheese industry and it is estimated that as much as 40-50% of the whey produced is disposed of as sewage or applied to agricultural lands. The remaining 50-60% is being used primarily for animal feed or for human food. Whey contains high quantity of lactose and other nutrients, which can be easily utilized by lactic acid bacteria to produce organic acids and value added products. The objectives of this work were to determine the ability of spiral-sheet to immobilize *Lactobacillus helveticus* (*L. helveticus*) and to determine the performance membrane for the continuous production of lactic acids using cheese whey as by-product. Active culture of *L. helveticus* (ATCC15009) was weekly transferred into fresh MRS and maintained at 4C. This culture was inoculated into 9 liters of MRS and incubated at 37 C for 16-18 hours. Fermented broth was transferred into the spiral-sheet bioreactor and was allowed to immobilize for 24 hours. After successful immobilization, MRS broth was withdrawn and replaced by fresh 4.8% lactose-MRS broth under aseptic conditions. Bioreactor was connected to Bioflo III (2-liter fermentor which has a control loop for temperature and pH) with continuous medium circulation at 37 C and agitation rate at 100rpm. Samples were withdrawn every 6 hours for lactose and lactic acid analysis using HPLC. Changes in pH were monitored during fermentation process. During fermentation the pH value was dropped from 6.2 to 3.8, which inhibited the bacterial activity. During the following experiments, we adjusted the pH to 6.50 by neutralizing the acid with 5-N ammonium hydroxide. Under the controlled pH condition, lactose conversion rate was 59.00%. These results showed that immobilization of *L. helveticus* on spiral-sheet reactor was a successful operation for the continuous production of lactic acid.

Key Words: spiral-sheet bioreactor, *Lactobacillus helveticus*, immobilization

1072 Molecular certification in chicken meat channel. V. Haezebroeck¹, R. Renaville*¹, I. Parmentier¹, S. Fontaine¹, S. Hetzel¹, and D. Portetelle¹, ¹*Animal and microbial biology Unit, Gembloux Agricultural University, Gembloux, Belgium.*

Adulteration of meat products is prohibited for fair trading, consumer protection, religious reasons or public health. As DNA can be extract from many different sources (blood, raw or cooked meat, milk,), DNA fingerprinting methods find an interesting applicability in species identification and meat traceability. Microsatellites markers are very polymorphic loci constituted by a variable number of a tandemly repeated motif of 1 to 6 base pairs, more commonly (CA)_n/(TG)_n. There are

abundant, multi-allelic, codominant and uniformly distributed throughout the genome of numerous species. The aim of this study was to find specific chicken microsatellites markers and to verify their ability to authenticate chicken products from other major meats. Nine microsatellites markers (MCW180, MCW135, MCW68, LEI161, MCW239, MCW264, LEI162, HUJ2, LEI78) were selected in the chicken genome and were combined in three triplex reactions. No cross-amplification were observed with bovine and pig DNA. All the nine microsatellites were also tested for cross-species amplification with other avian genomes. We observed that the microsatellite LEI161 give amplification product only for chicken. LEI161 is associated in a triplex PCR reaction with the markers MCW239 and MCW264. These three markers were revealed to easily distinguish chicken or turkey meat products. In conclusion, this triplex could be used to authenticate chicken or turkey in food and to detect falsification. Such a mean of analysis give new and alternative approaches of animal and species characterisation in meat products (Grant S-5876, Belgian Ministry of Small Enterprises, Traders and Agriculture DG4 and DG6 / and Belgian Public Health Ministry).

1073 Nutritional evaluation of Bt-corn in pigs . Tim Reuter, Karen Aulrich*, Andreas Berk, and Gerhard Flachowsky, *Institute of Animal Nutrition, Federal Agricultural Research Centre .*

The increasing cultivation of genetically modified plants opens new questions to animal nutritionists. One of them is to compare the nutritional value from parental and transgenic plants, another one is consumer safety. Analytical investigations to check the nutritional value are in progress at our institute, also investigations on the fate of "foreign"-DNA. The present project deals with a balance study to check the substantial equivalence, a grower-finisher trial to measure the pig performances and the fate of foreign-DNA in different tissues of pigs. The pigs were supplied with a 70% corn of the parental or the Bt-line containing diet. In a three collection period containing trial with twelve pigs we compared the feeding value of the Bt and the parental corn. All measured parameters were similar for both corn lines as shown in Table 1 (p > 0.05). The pig performances were measured with 48 pigs in a second trial. 12 pigs were fed a diet containing the parental corn, 36 pigs a diet containing the Bt corn. There were no significant differences (parental vs. Bt) in daily weight gain g/d (81593 vs. 80464), feed consumption kg/d (2.060.10 vs. 2.040.16) and Feed:gain kg/kg (2.550.27 vs. 2.590.18) between both groups (p > 0.05). The calculated results base on a growing period of 91 days. To investigate the fate of foreign DNA pigs were divided into different groups of six pigs each and slaughtered on different times after feeding. Samples were taken after slaughtering from different tissues.

Table 1. Digestibility of crude protein (dP), N-free extracts (dX) and metabolizable energy (ME) of diets

	1.period (grower)		2.period (finisher)		3.period (finisher)

PSA Environment and Management

1074 The Effect of Lighting Program and Light Intensity on the Performance and the Incidence of Leg Abnormalities of Broiler Chickens . A. Kamyab*¹, S. Raja-Abadi², K. Yousefi³, and A. Taghipour Farshi⁴, ¹*University of Tehran, Animal Sci. Dept.*, ²*University of Mazandaran*, ³*Mobark Andish, Co.*, ⁴*Telavang, Co.*

This experiment was conducted in a 2x2x2 factorial arrangement, using two different lighting regimens, continuous (23L:1D) vs. intermittent (1L: 3D), two light intensities, high (30 Lx) vs. low (8 Lx) and two sexes. Some 864-day old chicks were randomly distributed by sex among 24 pens of 36 chicks each. In the first 2 days, all birds received 23 hours of light per day with 20 Lx intensity. After that chicks were subjected to an intermittent or continuous lighting program, combined

with two different intensities. At the end of study, day 42, body weight gain was affected by lighting treatments (P<0.05), but feed intake was not affected by lighting programs and intensities, and the only difference was found among males and females which had reflected the sex effect (P<0.05). Cumulative feed conversion among lighting programs, intensities and genders was significant (P<0.05). Comparison of feed conversions revealed the superiority of the intermittent lighting program relative to continuous one, low intensity compared to that of high intensity and males in comparison with females (P<0.05). The interactions of lighting programXintensity, lighting program x sex and intensity x sex were significant in some cases (P<0.05). Abdominal fat was affected by lighting treatment and was much lower in broilers reared under the intermittent lighting regimen than that of the broilers reared under the continuous one. Also males deposited less fat than that of the fe-

males ($P < 0.05$). Comparison the effects of high and low intensity on abdominal fat showed no discrepancy ($P > 0.05$). The lighting programs, intensities and sexes interactions, in most cases, had a significant effect on abdominal fat ($P < 0.05$). When comparing the effects of treatments on mortality, no significant differences were found. Meanwhile, the difference of bone ash percentage was not statistically significant among the different treatments.

Key Words: Light, Intensity, Leg abnormality

1075 Effect of a subtherapeutic level of virginiamycin on the clearance of *E. coli* O157:H7 from an anaerobic continuous-flow culture of chicken microflora. Toni Poole*, Kenneth Bischoff, Todd Callaway, and David Nisbet, *USDA,ARS, College Station, TX 77845.*

Antibiotics are used in food animal production for growth promotion; these drugs typically target Gram-positive microorganisms. An anaerobic continuous-flow fermentation culture of chicken gastrointestinal microorganisms has been used as a model of the chicken ceca to study interactions between normal avian gut microflora and enteropathogens. Previous studies have shown that such a culture clears *E. coli* O157:H7 at a rate of one log/CFU/day. The purpose of this study was to determine if virginiamycin, an antibiotic used for growth promotion that targets Gram-positive microorganisms and anaerobes, would provide a selective growth advantage for *E. coli* O157:H7; thus preventing clearance from the continuous-flow culture. Two of three identical chicken continuous-flow cultures were treated with 1.0 $\mu\text{g/ml}$ virginiamycin, a concentration considered to be subtherapeutic. After one week of virginiamycin treatment, 1.0×10^7 CFU/ml *E. coli* O157:H7 was added to all three cultures. For the duration of the experiment the endogenous bacteroides, veillonella, lactic acid bacteria and enterococci in the virginiamycin treated cultures remained at the same concentration as those in the untreated control culture. The *E. coli* O157:H7 population dropped at a rate of one log/CFU/day until it reached a concentration of approximately 10^3 CFU/ml in all three cultures. The *E. coli* O157:H7 population remained at approximately 10^2 - 10^3 CFU/ml in the two virginiamycin treated cultures and at 10^1 - 10^2 CFU/ml in the untreated control. The results of this study suggest that a subtherapeutic level of 1.0 $\mu\text{g/ml}$ virginiamycin was not sufficient to perturb the microbial ecology of the culture such that *E. coli* O157:H7 was provided with a competitive advantage.

Key Words: Growth promotion, Competitive exclusion, *E. coli* O157:H7

1076 Effect of Organic Acids and Formaldehyde on Pellet Quality and Pellet Process Efficiencies. S. Moore, M. Neill, P. Bentley, R. Odgaard, and P. A. Welch*, *Kemin Americas, Inc.*

An organic acid containing compound (K-One brand Feed Treatment) and a 30% formaldehyde based compound were evaluated for their effects on pellet quality and pelleting efficiencies. Control elements, i.e., mash temperature, run time (min), pellet mill volts, and production rate per hour (2.9 MT/hr.) in the pelleting process were maintained constant. Percent pellets, Pellet Durability Index (PDI), amperage, motor load, horsepower, and relative electrical energy per ton (kWh/MT) were measured. A commercial broiler grower ration containing 65% corn, 27% soybean meal, and 3% meat and bone meal was used as a basal diet, to which the various chemical treatments were applied. Treatment inclusion rates of organic acids was 0.4%, and the 30% formaldehyde based compound was added at a rate of 0.3% (0.09% formaldehyde). No significant differences were observed in percent pellets or PDI values between the control and organic acid treatment; however, incorporating formaldehyde into the basal diet resulted in a significant decrease in percent pellets (3.14%) and PDI (4.87%). Motor load was similar for the control and the organic acid treatment, but increased significantly with the inclusion of formaldehyde into the basal diet. Organic acid treatment resulted in lower amperage and horsepower requirement as compared to the control and the formaldehyde treatment. Although relative electrical energy per ton values appeared to be numerically higher for formaldehyde treated feed, statistically all treatments were similar. In conclusion, it appears that the use of organic acids improve pellet quality when compared to formaldehyde, and organic acids reduced amperage, and horsepower requirements for pelleting broiler feed. Formaldehyde

in this study appears to have had a negative impact on pelleting process dynamics.

Key Words: Pellet Quality, Pelleting Efficiencies, Broiler Ration

1077 Phylogenetic analysis of cecum mucosal bacteria in broiler chickens. J. Gong¹, J.R. Chambers*¹, R.J. Forster², H. Yu¹, P. Sabour¹, R. Wheatcroft¹, and S. Chen³, ¹*Food Research Program, Agriculture & Agri-Food Canada*, ²*Lethbridge Research Center, Agriculture & Agri-Food Canada*, ³*Laboratory Service, University of Guelph, Guelph.*

The community structures of bacterial populations associated with cecal surface of broiler chickens were investigated by comparative DNA sequence analysis of 16S rRNA genes. Total DNA was extracted from bacteria collected from the cecal surface of ten 6-week-old chickens that were fed with standard commercial diets containing no antibiotics. One hundred and fifteen random clones of 16S rRNA genes were isolated for sequence analysis after PCR amplification with eubacterial primers. Phylogenetic analysis indicated that all cloned sequences were similar to low G + C Gram-positive bacteria. The cloned sequences showed large phylogenetic diversity within this group, with many sequences being related to cloned sequences from the human gut or from the rumen. There were 11 groups of sequences comprised of 4 or more closely related clones, and the largest group of sequences (34) were closely or distantly related to *Fusobacterium prausnitzii*. Of all the clones, at least 29% were related to butyrate-producing bacteria. The ecological/physiological significance of the predominant bacteria remains to be determined.

Key Words: Chicken, Bacteria, 16S rRNA

1078 Bioprocessing of poultry feather wastes using three feather-degrading microorganisms: fermentation characteristics, keratinases activities and biochemical properties. A. A. Onifade*¹ and N.A. Al-Sane¹, ¹*Department of Biological Sciences, Kuwait University, P.O. Box 5969, Safat 13060, Kuwait.*

Poultry feather accumulates as waste after slaughtering of the chicken; however, there exists the potential for its bioprocessing prior to recycling as animal feedstuff using feather-degrading microorganisms. Bioprocessing is environmentally friendly, low-energy consuming and an alternative to hydro-thermal processing, which appears not completely satisfactory. Three feather-degrading microorganisms: *C. zonatum*, *C. pannicola* and the *Streptomyces* (K) were used for bioprocessing of feather. *In vitro* biodegradation of poultry feather obtained from slaughtered 7-week old white-feathered broilers was carried out by inoculating the spore suspension of feather-degrading microbes in Keratin Salt Medium containing $g\ l^{-1}$: 20 partially milled feather; 0.5 $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$; 0.46 KH_2PO_4 and 1.0 K_2HPO_4 followed by incubation at 28 °C for 9 days at 200 rpm until the feather was completely degraded. The extracellular keratinases were separately recovered from a cell-free extract of the growth media of the three microbes by 80% $(\text{NH}_4)_2\text{SO}_4$ saturation and further subjected to biochemical assays. Results showed that the three fermentation media became alkaline terminally and highest substrate consumption of 75.6% was by *Streptomyces* (K) achieved because of its highest proteolytic activity. The three microbes synthesized *de novo* and export considerably active keratinases into the culture media, which were recoverable. Production of keratinase by *Streptomyces* (K) tended to decrease with time, whereas both *Chrysosporium* species demonstrated increasing production, but *C. zonatum* produced greater amount of keratinase than *C. pannicola*. The data obtained suggest that the major keratinases produced by *C. zonatum* and *Streptomyces* (K) are metalloproteases while a mixture of serine and metalloprotease are produced by *C. pannicola*. The optimal pH and temperature were: 8.0; 9.0; 8; 50 °C; 65 °C and 40 °C for *C. zonatum*, *Streptomyces* (K) and *C. pannicola*, respectively. The biochemical adjuncts added to the keratinase assay milieu elicited improved activities especially organic detergents, sulfurhydryl group protectors and reducing agents and the keratinase tolerated some common organic solvents. In conclusion, poultry feather wastes were bioprocessed and microbially digested, multi-component, relatively thermostable keratinases were produced and both products are amenable to animal feeding operations.

Key Words: Bioprocessing of poultry feather, Feather-degrading microorganisms, Fermentation and keratinases characteristics

1079 Effect of timing of hypobaric exposure on the incidence of ascites syndrome in broilers. J. M. Balog*¹, N. B. Anthony², M. A. Cooper², B. D. Kidd^{1,2}, G. R. Huff¹, W. E. Huff¹, N. C. Rath¹, and Y. K. Kirby¹, ¹PP&PSR/ARS/USDA, Fayetteville, AR, ²University of Arkansas, Fayetteville, AR.

Ascites is a metabolic disease of fast growing meat-type birds, that can be induced by rearing birds in a hypobaric chamber. The hypobaric chamber simulates high altitude by operating under a partial vacuum, leaving the birds with less available oxygen. A study was conducted to determine if birds exposed to simulated altitude for varying amounts of time would, when moved to local altitude, still develop ascites and if the reverse was true for birds moved from local altitude to high altitude. Three replicate trials were conducted utilizing 480 male broilers for each trial. Half the birds were assigned to the hypobaric chamber and the other 240 were placed in an environmentally matched local altitude chamber. Within each chamber, birds were randomly assigned to one of four treatments. The control birds remained at their initial altitude for the entire 6 wk trial. Birds in Treatment 2 remained at their initial altitude for 2 wk, and were then moved to the other chamber. Treatment 3 birds remained for 3 wk, and Treatment 4 birds remained for 4 wk at their initial altitude before being moved. All birds and feed were weighed weekly. Necropsies were conducted daily to determine cause of death. At the end of 6 wks, blood samples and organ weights were collected and all birds were examined for signs of ascites. In all three trials, time spent at simulated high altitude significantly affected ascites mortality and body weight. Birds that remained at high altitude for the duration experienced the highest ascites mortality while birds that were never placed at high altitude had the least ascites. As the amount of time that a group spent at high altitude increased, so did their ascites mortality. Body weights were negatively correlated with the amount of time spent at high altitude. In general, when birds were moved to high altitude, it took 2 wks of exposure before a significant increase in ascites incidence was noted. Conversely, when birds were moved from high altitude to low, it took 2 wks before ascites mortality significantly declined.

Key Words: Ascites, Hypobaric, Broilers

1080 Campylobacter jejuni Isolation Trends of Broilers Reared on Different Bedding Materials. W Willis*, C Murray, and W Willis, *North Carolina A&T State University.*

An experiment was conducted to evaluate different bedding materials on *Campylobacter jejuni* isolation with broiler chickens. Five bedding types were utilized in floor pens: (1) pine wood shaving; (2) sand; (3) corn-cob; (4) red cedar shaving and (5) wheatstraw. Each treatment was replicated three times with five birds placed on day 0, 3, and 6-d in each pen. Samples were taken 3, 6, 9, 12 and 15-d post placement in each treatment. All litter treatments had been previous utilized by a *Campylobacter jejuni* experimental infected flock. No chicks tested positive in any of the treatments at 0, 3 and 6-d placement for 3-d cloaca sampling. The longest time that chicks tested negative was 12-d at the 0, 3, and 6-d placements. Chicks placed on the pine and corn-cob bedding generally were the first to test positive, whereas, the cedar and sand were the last to test positive for *C. jejuni* at all placement times. All chicks crop tested for *C. jejuni* at 49-d of age were 100% positive for all treatments. Carcass yields varied for each treatment with 71.6, 75.1, 73.9, 73.8 and 71.2, respectively. The results from this study indicates that bedding materials can influence or delay the isolation of *C. jejuni* but not totally inhibit it.

Key Words: *Campylobacter jejuni*, Broilers, Bedding

1081 Multi-Phase Versus Single-Phase Feeding During the Broiler Starter Period; Effects on Performance and Nitrogen Excretion. N. Nasril*, C. Zhang, A.U. Haq, J. Carey, and C.A. Bailey, *Texas Agricultural Experiment Station.*

Two experiments were conducted to evaluate the effects of a multi-phase feeding program in which the nutrient content of the diet was changed every 24 hours versus a single-phase feeding program in which a single diet was fed over a 21-day growing period. In Experiment 1, 144 day-old straight run broiler chicks were randomly placed in 24 separate battery brooder pens and fed either a broiler starter diet containing 22% protein (3146 kcal ME/kg) or a linear blend of two diets so that birds received a diet containing 24% protein (3124 kcal ME/kg) on Day 1 and 20% protein (3168 kcal ME/kg) by Day 21. Experiment 2 was similar to Experiment 1 with the exception that 24 day-old straight run broilers were

individually caged and the control diet contained 23% protein while the blended diet ranged from 26 to 20% protein. Poultry metabolizable energy was maintained at 3200 kcal ME/kg. Multi-phase feeding had no significant influence on feed consumption, daily gain, feed conversion or net fecal nitrogen in either experiment.

Key Words: Multi-phase feeding, Broilers, Nitrogen excretion

1082 Limitation of *Salmonella enteritidis* colonization by diets containing low calcium and low zinc. S.C. Ricke*¹, Y.M. Kwon², C.L. Woodward¹, J.A. Byrd², D.J. Nisbet², and L.F. Kubena², ¹Texas A&M University, College Station, Texas/USA, ²USDA-ARS, SPARC, College Station, Texas/USA.

The use of feed deprivation to induce molting and stimulate multiple egg-laying cycles in laying hens is a common practice in commercial egg production. An increased susceptibility to *Salmonella enteritidis* (SE) and an increased risk of SE positive eggs and internal organs has been observed under laboratory conditions, probably due to the stress involved in feed deprivation. There is the need to test other methods that stimulate multiple egg-laying cycles without the increased risk of SE. Leghorn hens over 50 wk of age were divided into treatment groups of 12 hens each and placed in individual laying hen cages. One wk prior to dietary changes, hens were exposed to an 8-h light and 16 h-dark photoperiod that was continued throughout the 9-day experiment. Individual hens in all treatments were challenged orally with 10⁴ cfu of SE on the fourth day. Treatments consisted of full-fed hens (non-molt, NM), non-fed hens (molt, M), hens fed a low calcium diet (LC), and hens fed the low LC diet supplemented with 110 mg zinc/kg of diet (LC-ZN). When compared with the NM treatment, weight losses were higher and water consumption was increased in hens fed the LC and LC-ZN diets. The number of crop and ceca culture positive hens and the numbers of SE per crop and per gram of cecal contents were lower in the LC and LC-ZN treatments than in the M treatment, and were comparable to the NM treatment. Invasion of the liver, spleen, and ovary by SE was similar to the NM treatment, which was significantly lower (P < 0.05) than the M treatment. These dietary regimens may prove to be useful for reducing the incidence of SE in eggs and internal organs during and following molting of laying hens.

Key Words: *Salmonella enteritidis*, Laying hens-Molting, Diets-zinc-calcium

1083 *Salmonella* Typhimurium Virulence Response to Poultry House Water as Measured by *hilA:lacZY* Fusion. J. D. Nutt*, K. L. Medvedev, C. L. Woodward, S. D. Pillai, and S. C. Ricke, *Texas A&M University, College Station, TX, USA.*

Salmonella is regarded as a primary foodborne pathogen commonly found in the gastrointestinal tract and internal organs of poultry. Recent studies have shown *Salmonella* to be capable of surviving in several types of aquatic habitats. Depending on environmental factors of the aquatic habitat, the bacteria cells may be induced to express virulence genes. Our objective in this study was to determine virulence expression in a strain of *Salmonella* Typhimurium when exposed to fresh versus standing water samples taken from the drinking containers of commercial laying hens. The caging facility contained two rows of 30 cages placed back to back for a total of 60 cages housing 58 hens. Water was supplied to each cage by a U-shaped pipe with individual outlets to each cage. The 60 cages were divided into four quadrants. Quadrant one was the closest to the initial water source while quadrant four was the greatest distance from the origin of the water source. Water from the containers were sampled, refilled and sampled again. Each water sample (1.5ml) was inoculated with 0.120ml of a *hilA:lacZY* fusion strain of *S. Typhimurium* inoculum and incubated for two hours. After incubation, β -galactosidase assays were performed on the samples to determine virulence expression with brain heart infusion (BHI) broth serving as a control. BHI values ranged from 40-45 Miller units while water samples displayed Miller units in the range of 300-500. Results showed that there was a significant difference (p<0.05) in virulence expression between the four quadrants in the fresh water samples. However, no significant difference was observed between quadrants for the standing water samples. Both standing and fresh water samples gave a 5-10 fold increase of virulence expression as compared to BHI.

Key Words: *Salmonella*, poultry water, virulence

1084 Differential response in fertility of broiler breeder males selected for the sperm quality index prior to heat exposure. A. G. Karaca*, H. M. Parker, J. B. Yeatman, and C. D. McDaniel, *Mississippi State University, Mississippi State, MS.*

Heat stress (H) is deleterious to broiler breeder reproductive performance. The present study was undertaken to determine if fertility of males with a higher sperm quality index (SQI), prior to exposure to H, is more susceptible to high ambient temperatures than that of males with a lower SQI. Cobb males (108) were individually caged in six temperature controlled rooms. Males were tested twice for the SQI and then placed into four SQI treatment groups as follows: best (B), good (G), fair (F), and poor (P). The SQI groups represented the four SQI population quartiles. Four or five males from each SQI group were placed in every room. After a 29 wk acclimation period, three rooms were heated to 35°C, and the other three rooms were maintained at a constant 22°C as controls (C). For each SQI group in each room, 15 Leghorn hens were artificially inseminated (50 million sperm/hen) once a week for 8 wk for fertility observations. Sperm concentration, sperm viability, and the SQI were evaluated for each male on a weekly basis. Linear contrasts were used to compare males in the top 75% of the SQI population (B+G+F) to males in the lowest 25% of the SQI population (P). Body weight, sperm concentration, SQI, and fertility of the P males was lower than that of the other three SQI groups. Body temperature of the top three SQI groups was increased by exposure to heat stress, but body temperature was not altered by H in the P group. Also, mortality was elevated and feed consumption was decreased by exposure of males to high ambient temperature. Fertility, sperm viability, and SQI of the top three SQI groups was decreased by exposure to high ambient temperature; however, the same characteristics of the P males were not affected by heat exposure. In conclusion, high ambient temperatures had a more dramatic impact on the semen quality and fertility of males with a higher SQI as compared to those with a lower SQI prior to heat exposure.

Key Words: fertility, sperm quality index, heat stress

1085 Employing Ultrasound Technology to Measure Testicular Development in Broiler Breeder Roosters. L. J. Richardson*¹, A. B. Caudle¹, and J. L. Wilson¹, ¹*The University of Georgia.*

An ultrasound (Aloka SSD-500V) fitted with a linear prostate probe (UST-660 7.5MHz-16mm) was used to access testicular development in broiler breeder males. The objective was to characterize the size of the testes without killing or harming the birds. In order to obtain diagnostic images, bird position, probe placement, lubricant mixture, and feeding schedule had to be determined. The birds were fed one hour prior to the ultrasound procedure to reduce intestinal fragility and the presence of lower gastrointestinal feces. A lubricant (J-Lube) was used to ease probe insertion, decrease the possibility of intestinal tract damage, while increasing ultrasound image quality.

The trial was completed with twelve, 65 wk old broiler breeder males. Five ultrasound images were attempted of each rooster over a four wk period. Several problems were identified to interfere with probe placement and image quality: limited abdominal cavity space to maneuver probe, close proximity of abdominal air sacs and abdominal aorta to testes, and narrowing of large intestine at the branch of the ceca. Roosters were held in a dorsal position by an assistant to reduce bird stress and allow for easy probe insertion through the cloaca to a depth of 12 cm. The longitudinal scanning face of the probe was inserted parallel with the spinal column and came to rest between the testes. In this position, the scanning face of the probe was rotated 30-40 degrees in either direction to obtain an ultrasound image of each testis. Semen collection was attempted from the roosters before ultrasound images were obtained (semen collected from 8 of the 12 roosters). A similar number of males ejaculated semen 3-7 days after the ultrasound procedures indicating no long term detrimental effect of probe insertion.

Key Words: Ultrasound, Testes, Broiler breeder males

1086 The Effects of Chlorine and Hydrogen Peroxide at Various Concentrations on Total Bacteria and Coliform Counts in Poultry Drinking Water. J Zhang*, D McGhee, and S VanBoekel, *Cold Springs Farm Ltd. Thamesford, Ontario, Canada.*

Water samples were collected from the drinkers in the poultry barns on four farms and were cultured on petrifilm plates for the total aerobic bacteria and coliform counts. Water in the poultry barns on all farms was treated either with chlorine (Cl₂) or with hydrogen peroxide (H₂O₂). The Cl₂ levels in the water were about 3-4 ppm and the H₂O₂ levels were about 40-50 ppm. All the levels were measured at the beginning points of water lines, however, both Cl₂ and H₂O₂ concentrations were much lower in the water samples collected from the drinkers (below 0.5 ppm for Cl₂ and below 30 ppm for H₂O₂). After 24 hour incubation at 37 °C, the total aerobic bacteria counts were too numerous to count (TNTC) for all samples and coliforms were recovered for these samples in which H₂O₂ levels were below 30 ppm and Cl₂ level was not detected. However, there was no coliform count from the samples in which Cl₂ levels were discovered (> 0 ppm). To continue this investigation, water sample contaminated with bacteria was used. One sample was untreated as control and some samples were treated either with Cl₂ at 0.5, 1, 1.5, 2, 2.5, 4, and 6 ppm or with H₂O₂ at 20, 40, and 60 ppm as in final solutions in the laboratory. From the control sample, the total aerobic bacteria count was TNTC and coliform count was 69/mL. From the samples treated with Cl₂, the aerobic bacteria counts were 2400, 3, and 2/mL when Cl₂ concentrations were at 0.5, 1 and 1.5 ppm, respectively. There was no bacteria count in all samples when Cl₂ concentrations were at 2 ppm and higher levels. While, the coliform count was zero in each sample treated with Cl₂ at all concentrations. From the samples treated with H₂O₂, the total aerobic bacteria were TNTC and there were countable numbers of coliforms in all samples. However, the coliform counts were decreased when the H₂O₂ concentrations were increased from 20 to 60 ppm. From these investigations, the results indicate that when Cl₂ is used as a disinfectant in the poultry drinking water, it plays a better role in the deductions for total bacteria counts, especially for coliform counts over H₂O₂. Further study may be required to investigate H₂O₂ effect on bacteria deduction in poultry drinking water at higher concentration.

Key Words: Chlorine, Hydrogen Peroxide, Bacteria

1087 Prevalence of *Campylobacter* in a Turkey Production Facility. A. S. Kiess* and P. B. Kenney, *West Virginia University.*

Campylobacter ingestion may cause campylobacteriosis in humans with most cases being linked to poultry products. In order to reduce *Campylobacter* in turkey products, frequency of *Campylobacter* colonization in live turkeys must be reduced. One turkey flock, with two genetic lines, was sampled for *Campylobacter*. Gastrointestinal tracts and box liners were collected when poult were placed, and water and fecal samples were taken at specified times throughout a 20-week production cycle. Each GI tract and box liner sample, a 5.2-cm square, was removed and placed in a sterile stomacher bag containing 100 or 25-mL nutrient broth (#2), respectively. A 100-mL water sample was transferred from each drinker to a sterile 250-mL bottle, and fecal droppings were placed in sterile plastic bags. All samples were packed on ice and transported to the microbiology lab for *Campylobacter* isolation. Following mixture of feces with nutrient broth, a sample was directly plated onto a Campy-Cefex agar plate. Water samples were filtered through a 0.4-micron filter; the filter was then placed face down onto a Campy-Cefex agar plate. Twelve plates were placed in a gallon, ziplock bag, flushed (85% N₂, 10% CO₂ and 5% O₂) sealed, and incubated at 40 to 42 °C for 36h. Presumptive positives were confirmed by latex agglutination. *Campylobacter* was present in 59.7% of all samples by week three of production, and it remained at this level throughout production. Frequency of detection was higher in females (63.1%) than males (56.3%). The higher frequency in females may be the influence of the males on female behavior in adjacent pens. The high prevalence of *Campylobacter* in this flock supports the need for implementation of preharvest practices to reduce this food borne pathogen in turkeys at harvest.

Key Words: Turkeys, *Campylobacter*, Preharvest

1088 Does genetic selection for contrasting adrenocortical responsiveness influence underlying sociality in Japanese quail? R. H. Marin^{*1}, R. B. Jones², D. G. Satterlee¹, and G. G. Cadd¹, ¹Dept. of Poultry Science, Louisiana State University Agricultural Center, Baton Rouge, LA 70803, US, ²Roslin Institute (Edinburgh), Midlothian EH25 9PS, Scotland.

Inappropriate levels of sociality (motivation to be near conspecifics) may engender fear and distress, high levels of which can seriously damage poultry productivity and well-being. Thus, low sociality birds may be ill-suited to housing in very large groups. Genetic selection of Japanese quail for a dampened (LS, low stress) rather than exaggerated (HS, high stress) adrenocortical response to brief restraint is associated with decreased fearfulness and a non-specific reduction in stress responsiveness. Because sociality and fear may be linked in certain circumstances, the present study compared underlying sociality in chicks of the LS and HS lines in two test situations. In Experiment 1, social proximity was evaluated by filming undisturbed same-line groups of LS and HS chicks in their home cages; during subsequent analysis of the videotapes we then measured clumping and the distance between the two furthest birds at regular intervals. In Experiment 2, the responses of individually-tested chicks were measured in a runway when the goal box at the opposite end contained two other chicks (1 LS, 1 HS). Social proximity was greater ($P < 0.03$) in LS than HS quail and the LS birds tended to segregate more ($P < 0.10$). Similarly, once the quail had reached the runway zone nearest the goal box, LS birds spent a greater proportion of the remaining time in close proximity to the stimulus birds ($P = 0.04$) than did HS ones. Social proximity in the home cage and affiliation responses in a runway are widely considered to be positively related to underlying sociality. Therefore, the present findings clearly suggest that underlying sociality is greater in quail selected for low rather than high adrenocortical stress responsiveness

Key Words: Adrenocortical responsiveness, Japanese quail, Genetic selection, Sociality

1089 Early T-maze behavior, puberty and egg production in Japanese quail selected for contrasting adrenocortical responsiveness. R. H. Marin^{*1}, D. G. Satterlee¹, G. G. Cadd¹, and R. B. Jones², ¹Dept. of Poultry Science, Louisiana State University Agricultural Center, Baton Rouge, LA 70803, ²Roslin Institute (Edinburgh), Midlothian EH25 9PS, Scotland.

Broiler chicks that traversed a T-maze quickly to reinstate contact with their companions (HP, high performance) then grew faster, showed greater sociality and lower plasma corticosterone (C) responses to an acute stressor than did slower (LP, low performance) chicks. Genetic lines differing in adrenocortical responsiveness are powerful tools for studying the relationships between behavior, stress and performance. Herein we asked if early T-maze behavior is related to the attainment of puberty and to egg production in Japanese quail selected for low (LS) or high (HS) plasma C response to restraint. At 3 d of age, 196 HS and 189 LS quails were tested in a T-maze and categorized as HP or LP if running times were < 25 s or > 100 s, respectively. They were housed in mixed-category, mixed-line groups in brooder batteries until 4 weeks when they were caged in same-line, same-category pairs of 1 male and 1 female until 14 weeks. Thus, there were 4 treatment combinations, i.e., 19 HP-LS, 21 HP-HS, 23 LP-LS and 24 LP-HS pairs. Egg records were kept from the first oviposition for the next 8 weeks. HP birds reached puberty sooner than LP ones as shown by reductions in age at first egg and at 25% egg production (ANOVA, $P < 0.02$). Post-hoc tests showed that age at first egg and at 25% egg production were lower ($P < 0.05$) in HP-LS than LP-HS pairs. Overall hen-day egg production (HDEP) was greater (repeated measures ANOVA, $P < 0.04$) in HP than LP quail. A numerical trend towards greater overall HDEP (+5%) in LS than HS quail failed to reach significance ($P < 0.34$). Our results suggest that rapid negotiation of the T-maze was associated with accelerated puberty and an associated increase in HDEP in quail of two genetically diverse lines. These findings strengthen our proposal that this simple, non-invasive test could be a useful selection criterion for breeding programs to improve productivity

Key Words: Japanese quail, T-maze behavior, puberty

1090 Effect of age, body weight, and sex ratio on fertility and hatchability in the Japanese quail (*Coturnix coturnix japonica*) under subtropical conditions. Gehan Ragheb^{*}, H. El-Hammady, and M. Abdelnabi, Assiut University, Assiut, Egypt.

The purpose of this experiment was to study the effect of age, body weight and sex ratio on fertility and hatchability in the Japanese quail raised under subtropical conditions. Three hundred, newly hatched chicks were raised in brooders under standard temperature, humidity and photoperiod regimen until puberty. Birds from both sexes were divided according to their weights into high (HBW; 160-180 gr.) and low (LBW, 120-150 gr.) body weight. Each body weight group was divided into two subgroups; the male/ female ratios were 1:1 and 1:2, respectively. A total of 400 eggs (100/subgroup) were collected over the course of 13 time periods, each consisted of 28 days. These eggs were incubated and then measurements of fertility and hatchability were determined. The results from this experiment showed highly significant differences ($P < 0.01$) in fertility and hatchability in all subgroups with respect to age. No significant differences were found in both traits between groups (HBW and LBW) and between sex ratio (1:1 and 1:2) in all periods. The highest fertility was 95.0; 95.7% and 95.8; 95.9% while the highest hatchability was 82.1; 85.7% and 90.7; 87.8 % in HBW and LBW at sex ratio of 1:1 and 1:2, respectively. Therefore, HBW and 1:2 sex ratio is considered economically cost-efficient for quail breeders under subtropical conditions.

Key Words: Quail, Sex ratio, Fertility and hatchability

1091 Optimum Timing of Amino Acid Injections in Broiler Breeder Eggs. Y. Ohta^{*1}, T. Yoshida², and M. T. Kidd¹, ¹Department of Poultry Science, Mississippi State University, Mississippi State, MS 39762, ²Nippon Veterinary and Animal Science University, Tokyo, Japan 180-8602.

Amino acid (AA) injection *in ovo* in broiler breeder eggs results in heightened BW at hatch. However, recent research has indicated that *in ovo* AA injections into the yolk and extra-embryonic coelom, but not the amniotic cavity, result in optimal responses to AA. Because egg constituents and cavities change over time, we conducted this study to determine the optimal injection time for AA *in ovo*. An AA solution, identical to the AA pattern of the egg, was injected over time in three experiments and subsequent BW and hatchability of chicks were measured. In Experiment 1, the AA solution was injected into eggs on Days 1, 3, 5, 7, 9, 11, and 14 of incubation. In Experiment 2, the AA solution was injected into eggs on Days 7, 8, 9, 10, 11, 12, 13, and 14 of incubation. In Experiment 3, the AA solution was injected into eggs on Days 14, 15, 16, 17, 18, and 19 of incubation. *In ovo* AA injections at Days 1 and 7 reduced ($P < 0.05$) hatchability. Injection of AA *in ovo* at Days 9 and 14 in Experiment 1, Days 9, 11, and 14 in Experiment 2, and all levels in Experiment 3 increased ($P < 0.05$) relative chick BW to egg weight over that of chicks from eggs not injected with an AA solution. The optimal time to inject AA solution *in ovo* in broiler breeder eggs may be Day 14 of incubation.

Key Words: Amino Acid, *In ovo*, Chick Weight

1092 Effect of number of birds per cage on the reproductive performance of Japanese quail breeders. J.F. Obregon¹, G. Contreras¹, A. Montoya¹, M.E. Gamez¹, and R. Barajas¹, ¹FMVZ-Universidad Autonoma de Sinaloa (Mexico).

To determinate the effect of the number of birds per cage on the reproductive performance of Japanese quail breeders, a complete randomized experiment was conducted with one hundred sixty Japanese quail (40 males and 120 females; 16 weeks old). Treatments consisted of: 1) Six females and two males allocated in a 0.25 x 0.3 m wire cage (2-M; and 2) Three females and one male allocated in a 0.25 x 0.15 m wire cage (1-M). Birds were fed a diet containing 21% CP and 2.9 Mcal DE/kg. After an adaptation period of seven days, eggs were collected during six weeks. Dead animals were replaced with birds of the same age and sex. Number of eggs hatched, was 10% higher ($P < 0.02$) with the 1-M treatment (46 vs. 51 egg). Percent hatching was increased ($P < 0.01$) by 22% as result of one male and three females (62.8 vs. 76.8%). Hatchability as a mean value was 54.2% and was not affected ($P > 0.02$) by treatments. The number of hatched quails per day, was improved ($P < 0.03$) by 24%

for 1-M treatment (25 vs. 20 quails). It is concluded, that allocation of one male and three females per cage, is a better management system than placing two males and six females in the cage.

1093 Multiple-objective programming to reduce ration cost and nutrient excretion. P.R. Tozer* and J.R. Stokes, *The Pennsylvania State University, University Park, PA.*

Typical dairy rations are formulated to meet the nutrient requirements of the cow at the least cost. This approach is single objective oriented, and that is to minimize cost. In this paper we examine the use of multiple objective programming to formulate rations that minimize cost, and minimize phosphorus and nitrogen excretion. A ration formulation model was developed using the National Research Council's recommendations for nutrient requirements, and functions for protein intake and digestion, a phosphorus excretion function, and a set of prices of representative feeds for the northeastern United States. A "standard" cow was used in the model, this cow weighed 600kg, produced 30 kg of milk per day with a fat content of 3.5 per cent and was gaining 300 g per day. The cost of the minimum cost ration was \$2.81 per day and consisted

1094 Feeding neonatal calves high levels of milk replacers (MR) with different protein and fat levels. T. M. Hill*, J. M. Aldrich, A. J. Proeschel, and R. L. Schlotterbeck, *Akey, Inc., Lewisburg, OH.*

Recent research with neonatal calves not receiving starters has suggested that feeding MR at high levels (over .6 kg daily) and with a high crude protein (CP) content (26 # 30%) will result in more efficient and faster gains. However, trials with a 20% CP MR fed at .57 vs. .45 kg daily observed no differences in gains because of reductions in starter feed intake with increased MR fed. We conducted a series of trials to examine how feeding rate and level of CP and fat in MR affect calf performance. In all trials, bull calves were randomly assigned to MR treatments and fed fixed amounts of MR (all milk CP plus synthetic lysine and methionine) with free-choice starter for 6 weeks. Calves were fed starter alone after 6 weeks. Calves were weighed initially and weekly. Starter intake was measured and fecal scores and medical treatments recorded daily. In all trials, a 20% CP, 20% fat MR fed at .45 kg daily served as a control treatment. Average initial body weights were 40 to 42 kg. Feeding a 28% CP, 20% fat MR stepped-up to 1.13 or 1.36 kg daily resulted in no increase in gains, increased ($P < .1$) fecal scores and medical treatments, and reduced ($P < .1$) starter feed intake by 7 weeks of age compared to the control. Feeding a 28% CP, 20% fat MR at .68 kg daily increased gains, medical treatments, and fecal scores, but decreased starter intake vs. the control ($P < .1$). When .68 kg daily of a 13% fat MR was fed with CP levels from 20 to 28%, gains increased ($P < .1$) in a quadratic manner (optimum of 26%) and starter intake was no different from the control. When .68 kg daily of a 24% CP MR was fed with fat levels between 11 and 17%, gains increased ($P < .1$) linearly and starter intake was no different from the control. These results indicate that MR fed should be limited (to near .68 kg daily) so not to depress starter intake and that the CP (optimum near 26%) and fat (optimum near 17%) levels critically impact performance.

Key Words: Protein, Fat, Calves

1095 Feeding neonatal calves milk replacers (MR) containing egg proteins. T. M. Hill*, J. M. Aldrich, A. J. Proeschel, and R. L. Schlotterbeck, *Akey, Inc., Lewisburg, OH.*

Alternative crude protein (CP) to milk CP interest the calf raising industry because of the high price of milk CP. Soy CP sources are popular because of their low cost relative to milk CP sources but, depending upon the type and level included in a milk replacer, performance can be compromised. Our objectives were to 1) evaluate how calf performance is affected by the level of milk CP replacement with egg CP, 2) compare two whole egg sources, and 3) combine egg, soy protein concentrate (SPC), and milk proteins in MR. In each trial, 50 bull calves were randomly assigned to MR treatments and .45 kg of MR was fed with free-choice starter for 6 weeks. Calves were fed starter alone after 6 weeks.

principally of alfalfa hay, straw, dry distillers grain, bakery product and dry shelled corn. The ration contained less than 100g of mineral supplements. The "standard" cow excreted 279 g/day of nitrogen and 32.1 g/day of phosphorus. Rations were also formulated to minimize nitrogen and phosphorus. The results of the three single objective models were combined into a multiple-objective programming model to minimize the maximum deviation from the goals generated in the single objective models. The multiple objective models resulted in marginal reductions in nitrogen and phosphorus excretion. The most marked change in ration formulations occurred when the efficiency of phosphorus utilization was increased. The base ration contained an unacceptably large proportion of straw and no corn silage, hence other multiple objective rations were formulated to reduce the straw and increase the corn silage contents. These rations increased the costs of the ration by 0.05 - 0.35 per day and marginally increased the level of nitrogen and phosphorus excreted. Another result of this ration formulation research is that all rations formulated contained less than 100 g/day of mineral supplements, indicating that the use of these supplements is a costly expense and any amount of supplement fed over those formulated leads to excretion of excess nutrients.

Key Words: Ration formulation, nutrient management, mathematical programming

Calves were weighed initially and weekly. Starter intake was measured daily. Fecal scores and medical treatments were recorded daily. In all trials, a 20% CP (from milk protein) and 20% fat MR served as a control treatment. The egg CP source was used to replace a percentage of the total protein in the MR. Average initial body weights were 41 to 43 kg. In two trials, 10, 20, and 30% egg CP from source A and 20% egg CP from source B replaced whey CP. Increasing egg CP from source A resulted in a quadratic response ($P < .1$) of gain and starter intake with 30% being inferior to other lower levels of egg and the control. The 20% egg CP from source B supported lower ($P < .1$) gains and starter intakes than the control. Additionally, three trials were conducted to compare 15% egg CP from source A, 15% SPC CP, and 70% milk CP in a MR to the control MR. There were no differences in gains and starter intake. Fecal scores and medical treatments were not different from the control when egg CP from source A was used alone or combined with SPC. Egg CP can be used successfully as a partial replacement for whey CP in calf MR, but source of egg CP differs.

Key Words: Protein, Egg, Calves

1096 Protein levels for neonatal calf starters. T. M. Hill*, J. M. Aldrich, A. J. Proeschel, and R. L. Schlotterbeck, *Akey, Inc., Lewisburg, OH.*

Previous research has suggested that approximately 18% crude protein (CP; as-fed basis) is adequate for neonatal calf starters, however, some feed companies and universities have suggested that higher levels of CP may be required. To investigate CP requirements for calf starters we fed calves starters that contained graded levels of CP along with either a 20% CP (all milk CP plus synthetic lysine and methionine), 20% fat milk replacer at .45 kg daily (trial 1) or a 26% CP (all milk CP plus synthetic lysine and methionine), 17% fat milk replacer at .68 kg daily (trial 2). In each trial, 50 bull calves were randomly assigned to starter protein levels of 18, 20, 22, 24, and 26% as-fed basis (88% DM) and fed milk replacers and free-choice starter for 6 weeks. Calves were fed starter alone after 6 weeks. The starters were a corn-based pellet with 15% wheat midds and a fixed protein blend replacing corn with elevated levels of CP. The protein blend consisted of 75% soybean meal (48% CP), distiller's grains, blood meal, corn gluten meal, and fish meal. Mineral and vitamins levels were equal among starters. Calves were weighed initially and weekly. Starter intake was measured daily. Fecal scores and medical treatments were recorded daily. Hip widths and body condition scores was measured initially and every two weeks. Data were analyzed as a completely randomized design with linear, quadratic, and cubic contrasts relative to level of protein in the starters. Average initial body weights were 40 and 41 kg. In both trials, there were no differences ($P > .1$) in any measurement taken. These results indicate that neonatal calves fed 20% CP, 20% fat milk replacers at .45 kg daily and

26% CP, 17% fat milk replacers at .68 kg daily do not require starters with protein levels exceeding 18% CP (as-fed basis).

Key Words: Protein, Calves

1097 Behaviour and meat quality of veal calves receiving solid feeds for welfare purpose. G. Cozzi^{*1}, F. Gottardo¹, S. Mattiello², E. Canali², G. M. Burato¹, S. Segato¹, and I. Andrighetto¹, ¹University of Padova, Italy, ²University of Milano, Italy.

Behaviour, growth performance, carcass and meat quality of veal calves fed a traditional milk replacer diet (C) were compared to those obtained from calves fed the same diet plus 250 g/head/d of dried beet pulp (BP) or wheat straw (WS). The study lasted 160 d and used 138 Polish Friesian calves which were assigned to the 3 dietary treatments according to their initial BW. In comparison to C, calves fed WS diet reduced the frequency of abnormal oral behaviors throughout the fattening period. The WS calves showed also a higher chewing activity until the 17th wk of the trial. Subsequently, their chewing activity was similar to C calves likely because the daily dose of roughage became limiting. Behaviour of C and BP was similar. The provision of both solid feeds did not affect milk replacer intake, but it improved calves health status reducing the incidence of medical treatments. In C calves, iron intake throughout the fattening period was 6.34 g. Feeding WS and BP diets significantly increased total iron intake by 41 and 130% respectively ($P < .001$). However, before slaughtering, only BP calves showed hemoglobin and plasma iron concentrations higher than the C ones. Therefore, iron provided by WS was less available for the calf metabolism, likely because it was bound by NDF. Only feeding BP increased calves ADG (1178 g/d) ($P < .01$), whereas C and WS were similar (1078 and 1100 g/d, respectively). Both solid feeds led to empty fore stomachs heavier than C without affecting dressing percentage. The administration of BP resulted in a better carcass conformation than C and WS, but it had a detrimental effect on carcass colour which was the darkest. Consistent with this result, meat colour of BP calves was darker than C and WS. In conclusion, a solid feed with a high roughage value and a low bioavailability of iron, such as wheat straw, has shown to improve veal calves welfare allowing the production of veal meat which fulfills the colour standard required by the market.

Key Words: veal calf, solid feeds, behaviour and meat quality

1098 Effects of milk replacer fermented with yogurt culture on performance and health of dairy calves. S.C. Chan^{*}, Department of Animal Science, Chinese Culture University, Taiwan.

The objective of the study was to determine effects of non-medicated milk replacer fermented with yogurt culture on performance and health of calves and to compare economic benefit and performance of calves weaned at different time. Twenty-four female Holstein calves were randomly assigned at five days of age to one of 4 treatments in a completely randomized block design with 2 x 2 factorial arrangement of treatment. Factors were: (1) weaning time: 6 or 8 weeks; (2) milk replacer (MR): MR fermented with yogurt culture or MR without adding yogurt culture. Calves were fed colostrums twice daily through nipple bottles for 4 days. During the study calves were housed in individual, elevated calf crates. Since day 5, calves were fed non-medicated fermented MR that contained yogurt culture or non-medicated MR. A commercial, calf starter was fed "ad libitum" from day 5 to the end of trial. Body weight, wither height and heart girth were recorded when calves were on trial, and at the end of 3, 6 and 8 weeks of age. Rectal temperature and incidence of all health disorders were recorded daily. Fecal consistency scores for calves were recorded twice daily. Total bacterial, lactic acid producing bacteria, and coliform counts were determined at day 5, and at the end of 3, 6 and 8 weeks of age. Calves fed yogurt cultured MR had higher lactic acid bacterial and lower coliform numbers at week 3 and 6 ($P < 0.05$). Fecal consistency scores and days calves suffered diarrhea tended to be lower for calves fed cultured MR. Body weight gain from day 5 to week 3 tended to be lower for calves fed cultured MR than those fed regular MR ($P < 0.10$). Results also indicated that calves weaned at week 6 tended to have higher water intake and starter intake from week 6 to week 8 than those calves weaned at week 8 ($P < 0.10$).

Key Words: Calves, Milk Replacer, Yogurt Culture

1099 Absorption of immunoglobulin G in calves fed colostrum or colostrum replacement and animal plasma in milk replacer. C. M. Mowrey^{*1}, R. E. James¹, J. D. Quigley, III², and M. L. McGilliard¹, ¹Virginia Tech, Blacksburg VA, ²American Protein Corporation, Ames IA.

Newborn Holstein (n = 48) and Jersey (n = 30) calves were studied to compare the absorption of immunoglobulin G (IgG) from maternal colostrum (n = 39) or a colostrum replacement product derived from bovine serum (n = 39). Calves were also fed milk replacer with (n = 38) or without (n = 40) animal plasma to 29 d of age to determine the effect of plasma protein on IgG status, health and growth. Colostrum replacement was fed (Holsteins 1.89 L/feeding, Jerseys 1.42 L/feeding) at 1.0 and 13.0 h of age and provided a total of 250 (Holsteins) or 180 (Jerseys) g of IgG. Amount of pooled maternal colostrum fed (at 1.1 and 13.1 h) was adjusted to provide IgG equal to the replacement (Holsteins 249 g, Jerseys 186 g). Milk replacer (reconstituted to 12.5% DM) was fed at 10% of birth weight (2 feedings/d). Jugular blood was sampled at 0 h, 24 h, and weekly to determine plasma IgG. At blood collection calves were also weighed and measured to determine growth performance. Health scores, fecal scores, and grain intake were measured daily. Mean plasma IgG at 24 h did not differ between calves fed colostrum (13.78 ± 0.39 g/L) and replacement (13.96 ± 0.38 g/L). Plasma IgG and performance were not affected by addition of animal plasma to milk replacer. The colostrum substitute successfully replaced colostrum as the source of IgG for newborn calves. Animal plasma was an acceptable source of protein, but did not enhance growth or immunity.

Key Words: Colostrum Replacement, Immunoglobulin G, Animal Plasma

1100 Growth characteristics of replacement heifers in selected high producing Wisconsin dairy herds. N.C. Dorshorst^{*1}, H.A. Lonning², P.C. Hoffman¹, K.A. Weigel¹, and C. Dechow¹, ¹University of Wisconsin-Madison, ²University of Wisconsin-River Falls.

A field survey was conducted to assess growth characteristics of dairy replacement heifers in selected high producing Wisconsin dairy herds. From a pool (n=35) of Wisconsin dairy herds with herd milk production > 13,500 kg/lactation, twenty herds were randomly selected. The project involved collection of herd production data, a management survey, physical measurement of all calves and replacement heifers, and identification of sires for all calves and heifers for each herd. Physical measurements included estimation of weight via heart girth, wither height, body length, and body condition score. Statistics were compiled for herd inventories, milk production, and age at first calving. Physical measurements of heifers from all herds were compiled and summarized by month of age. Pre- and post pubertal growth of heifers for each farm were estimated using first order regression techniques. A summary of project results is as follows. Age at first calving in the selected herds was 25.9 ± 1.5 months and replacement heifers calved at an estimated pre-calving weight of 666 ± 60 kg. Regression estimated pre- and postpubertal growth rates of replacement heifers in the selected herds was 887 ± 120 and 741 ± 96 g/d, respectively. Estimated prepubertal growth rates ranged from 758 to 1243 g/d. Growth characteristics of Holstein calves and replacement heifers in the selected herds were similar to guidelines published in the literature. Survey data indicated that use of 3 x milking and rBST on both multiparous and primiparous cows was high at 77.8, 83.3, and 72.2%, respectively. Selected herds fed calves starter later, forage earlier than recommended guidelines and weaned calves using age criteria. Selected herds bred heifers using age (83.3%) more so than weight (16.7%) criteria. Data suggest replacement heifers on selected high producing dairy herds were older and heavier at first calving as compared to recommended guidelines. The influence of genetic selection on these data is yet to be determined.

1101 Comparison of Lactational Response of Dairy Cows in Georgia and Israel to Heat Load and Photoperiod. Y. Aharoni¹, O. Ravagnolo², and I. Misztal², ¹Department of Beef Cattle, Agricultural Research Organization, Neve Yaar Research Center, Israel, ²Animal and dairy Science Department, University of Georgia, Athens 30605.

The seasonal effects of heat load (HL) and photoperiod (PP) during the lactation on milk yield and composition of primiparous cows were studied using test day records that were collected over an 8-year period 1990 through 1997 from 8968 cows in 76 farms in Georgia. The effect of prepartum PP on milk production in the subsequent lactation was also evaluated for these cows. These effects were tested in a regression model that accounted for a 4th order polynomial of days in milk (DIM) and fixed effects of year and farm in addition to the seasonal effects. The seasonal effects estimated for this database were compared with those estimated previously (Aharoni et al., 2000) for multiparous cows in Israel. The PP effect accounted for a difference of 2.7 kg/d of milk, 3.3 g/kg fat and 1.9 g/kg of protein in milk between peak and trough dates of the year, with peak dates at 5/02, 1/27 and 1/13 for milk yield and fat and protein contents in milk, respectively. The HL during the lactation had negative effects on milk yield and contents. The day length during the prepartum period had also negative effects on milk yield and contents. Most of the effects were highly ($P < 0.001$) significant. The match between the combined effect of HL and PP during the lactation in Georgia and Israel yielded r^2 values 0.978 and 0.984 for effects on milk yield and protein content, respectively, and $r^2 = 0.516$ for the effect on fat content. The effect of prepartum PP was similar in dates, but higher in Israel than in Georgia. This study indicated that the effects of both HL and PP during the lactation on milk yield and composition of primiparous cows in Georgia are very similar to these effects on multiparous cows in Israel. The mismatch of estimations on fat content could be explained by seasonal dietary changes due to a grazing season in Georgia, which is absent from the Israeli management. The difference in response to prepartum PP could be explained as the difference between heifers before their first calving in Georgia, and mature cows in Israel.

Key Words: Photoperiod, Heat Load, Milk Production

1102 Seasonal variation in the composition of milk from New Zealand Friesian and US Holstein dairy cows: impact of nutrition. M.J. Auldust*, A.R. Napper, and E.S. Kolver, Dexcel Ltd. (formerly Dairying Research Corporation Ltd.), Hamilton, New Zealand.

The manufacturing efficiency of dairy products is significantly limited by the seasonal variation in milk composition from pasture-based, seasonally calving dairying systems. This study tested the hypothesis that seasonal variation in milk composition is caused by changes in pasture composition and availability. Variation in milk composition was measured in 20 NZ Holstein-Friesian (NZHF) and 20 Northern Hemisphere Holstein-Friesian (NHHF) dairy cows grazing pasture or fed a total mixed ration (TMR). The study was conducted over two lactations, with samples of daily milk collected on 7 evenly-spaced occasions during Year 1 and 5 occasions in Year 2. In both years, NHHF cows produced more milk with lower concentrations of the major milk solids fat and protein, but higher concentrations of lactose than NZHF cows. Diet also affected concentrations of some major milk components. Detailed milk composition was generally unaffected by both genotype and diet. Feeding TMR for the entire lactation reduced seasonal variation in both years for lactose concentration, and in Year 1 for milk yield, fat, casein number, urea and Na. Overall, however, the reduction in seasonal variation due to TMR, if any, was minimal. The pattern of change in milk composition as the season progressed was similar for all treatment groups and could not be explained by diet. It is concluded that improved nutrition of grazing dairy cows would not significantly reduce seasonal variation in milk yield and composition.

Year	NZHF Grass		NZHF TMR		NHHF Grass		NHHF TMR		P A1

1103 Milk and meat samples obtained in Illinois contain variable amounts of conjugated linoleic acid. A.D. Beaulieu* and J.K. Drackley, University of Illinois, Urbana .

The objective of this study was to determine the mean content and variability of conjugated linoleic acid (CLA) in Illinois meat and milk. Samples of whole milk were obtained from 30 grocery stores over a one-year period and from 5 to 6 farms (bulk tank samples) in three geographic locations at three-month intervals for one year. Producers supplied feeding and management records. Eight cuts of meat were purchased from 24 stores at six-month intervals for one year. Sites were selected for sampling based on population density. Store milk contained a mean CLA content of 0.53 ± 0.02 (mg/100 mg fatty acids (FA) mean ± SEM) with a range of 0.43 to 0.81 mg/100 mg FA. The CLA content of milk obtained from producers averaged 0.53 ± 0.21 mg/100 mg FA with a range of 0.29 to 1.63 mg/100 mg FA. The highest value was from the only producer reporting 100% grazing. Complete or partial grazing increased ($P < 0.05$) CLA content of milk fat. Season, state location, breed, and fat supplementation did not affect ($P > 0.05$) CLA content of milk fat. The CLA content of milk fat was positively correlated ($P < 0.05$) with the C18:1_{cis-9} and the C18:1_{trans} content of milk fat and total milk production (kg/d) and negatively correlated ($P < 0.05$) with milk fat and milk protein percent. The following table presents the mean CLA content of the meat samples (lean tissue unless specified otherwise). The content of CLA in meat samples was similar ($P > 0.05$) among stores. The variable CLA content of milk and meat hinders the accurate estimation of CLA intake by a population. However, identifying the source of this variability will assist the development of CLA-enriched milk and meat.

Sample	CLA (mg/100 mg FA)			
	Mean ¹	Season		P-value Season
		March	August	
Ground beef	0.57 ^a	0.53	0.61	0.0023

1104 Relationship of milk urea nitrogen and DHIA production variables in western commercial dairy herds. R.G. Johnson*, J.L. Walters, and A.J. Young, Utah State University, Logan, Utah.

Studies have shown relationships between milk urea nitrogen (MUN) and milk production levels in eastern and central North America. Feeding and management are different under western conditions and standard MUN concentrations are not known. Because MUN concentration has been associated with nitrogen utilization efficiency, it could become a useful management tool for dairy producers. The objective of this

study was to evaluate the relationship of MUN values with DHIA production values in commercial dairy herds in Utah and Idaho. Individual cow monthly test records (approximately 25,000) from 37 Holstein and 4 Jersey herds were analyzed. Records spanned two consecutive years ending December 2000. Mean test day milk yield per cow for all animals was 31.9 kg. Overall mean MUN was 14.88 mg/dl. Two statistical models were developed using the General Linear Model procedure of SAS. One model with MUN as the dependent variable had an r-squared of 0.27. Significantly related independent variables were: parity and somatic cell count (both linear); milk per cow, milk protein %, milk fat %, days in milk and month of year (cubic). When milk per cow was the dependent variable the r-squared was 0.51. Significantly related independent variables were: milk fat %, parity, MUN, milk protein %, somatic cell count, days in milk and month of year (all cubic). There were differences between cows of the Holstein and Jersey breeds with respect to MUN and season. Holstein MUN was highest in winter, while Jersey MUN was highest in summer. There was no significant breed difference in mean MUN. Our data show that MUN is associated with DHIA production variables and can be used to develop optimal MUN concentrations unique to western dairies.

Key Words: MUN, DHIA

1105 Stochastic modeling of different approaches to dairy cattle reproductive management. M.W. Overton*, U.C. Davis- *Veterinary Medicine Teaching and Research Center.*

A stochastic simulation model was used to compare potential economic returns of three popular synchronization programs, Ovsynch, Presynch, and Modified Presynch, as compared to a traditional breeding program based on artificial insemination following heat detection. The model applied these programs early in the breeding period, followed by traditional breeding for the remaining cycles. Interventions were modeled using a combination of decision tree analysis, partial budgeting, stochastic simulation modeling, and economic sensitivity analysis. Herd specific inputs included voluntary wait period, drug costs, breeding expenses, and labor costs. Conception rate, heat detection rate, and rolling herd average were input as distributions rather than discrete probabilities. Data from over 100 conveniently sampled California dairy herds was used to fit the specific distributions. Conception rate and heat detection rate changes over the breeding period were modeled by applying correction factors to the original distributions. Pregnancy rate results predicted for each cycle were then used to project cumulative pregnancy rate over 10 breeding cycles. Results were obtained by running 5000 iterations through the use of simulation software and are displayed as probability distributions, with a mean and standard deviation. The model predicted that implementation of any of the three breeding programs early in the breeding period would improve pregnancy rate during the modeled cycle and throughout the balance of the breeding program. Predicted economic returns, using modifications of the Woods equation, were greater for each of the interventions as compared to traditional breeding utilizing current levels of heat detection and conception rate.

1106 Changes in rumen temperature, vaginal temperature and drinking behaviour throughout the estrous cycle in dairy cows. A. D. Kennedy* and S. R. Mathew, *University of Manitoba.*

Four first calf Holstein dairy heifers (71 to 161 d postpartum) fitted with rumen cannulae were monitored continuously for 66 d. Temperature radiotransmitters were situated in both the rumen and vagina and temperature values were recorded every 4 minutes. Heifers were synchronized twice using the Ovsynch program with the first GnRH injections given on days 9 and 53 such that there were two induced ovulations and one natural ovulation expected during the study. Milk progesterone analysis indicated 13 periods of corpus luteum (CL) regression but temperature values were available for only 8 (vaginal) and 7 (rumen) of these occasions. Vaginal and rumen temperature peaks were found during 8 of 8 and 5 of 7, respectively, periods of CL regression. Rumen temperature was highly variable and a number of peaks were observed when the CL was not regressed (26 false positives). Reduced drinking behaviour was found on the day of estrus suggesting that peaks in rumen temperature reflect reduced water intake.

Key Words: Temperature, Vaginal, Rumen

1107 Follicular growth in lactating cows receiving recombinant bovine somatotropin, gonadotropin releasing hormone, and prostaglandins: contrasts between winter and summer months. Z Keister*, R Collier, and R Ax, *University of Arizona, Tucson, AZ/USA.*

Three experiments were conducted with Holstein (n = 72) and Brown Swiss (n = 73) cows beginning 56 ± 3.5 d postpartum to determine ovulation rates in a thermal stress arid climate over three consecutive seasons (Summer, 1999; Winter, 1999-2000; and Summer, 2000). All cows received recombinant bovine somatotropin (rbST) beginning d 63 ± 3.5 postpartum regardless of treatment. For Exp.1, 58 cows were assigned at calving, beginning June 1, 1999, to either a cooled (Korral Kool#) or non-cooled (shade only, control) pen. At d 56 ± 3.5 postpartum, all cows commenced a hormonal program coined Select Synch, comprised of an injection of gonadotropin releasing hormones (GnRH, 100 micrograms) agonist (Factrel#) followed 7 d later with an injection of prostaglandin (25 mg In-Synch#), at which time ultrasonography was initiated and continued until ovulation or follicular turnover. Exp. 2 was the same as Exp. 1, with assignment of cows starting Nov. 1, 1999. In Exp.3, all cows were assigned the same as Exp. 1 and 2 beginning June 1, 2000. At d 56 ± 3.5 postpartum, cows were scheduled to commence Ovsynch, which was identical to Select Synch, except a second Factrel# injection was administered 33 h after 35 mg Lutalyse#. Ovsynch was more effective at causing subsequent ovulations for the non-cooled and cooled cows (77.3 and 69.6%, respectively), than Select Synch for the non-cooled, cooled, and winter treatments (27.6, 24.1 and 29.4 %, respectively). In conclusion, ovulation outcome was related to hormonal programming rather than season.

Key Words: Follicle growth, GnRH, prostaglandin

1108 The relationship of indicators of thermal balance and milk production of cows on Missouri dairy farms. James Spain*¹, Julie Sampson¹, and Don Spiers¹, ¹*University of Missouri.*

Three dairy farms cooperated in conducting an on farm experiment to evaluate heat stress of dairy cattle. The farms were located in Missouri in Bates, Callaway, and Franklin counties. All three farms used Holsteins housed in free stall housing systems. Farms provided cows with total mixed diets unique to the specific farm. All three farms milked twice daily (0400 to 0800 and 1600 to 2000). Lactating dairy cows were selected on each farm to create uniform groups of cows across the farms. Selected sentinel cows were housed together within larger groups of cows. Milk yield was measured and recorded on each cow at each milking during the experiment. Respiration rate, rectal and skin temperatures were measured for each cow three days a week (Monday, Wednesday and Friday) and three times per day (0800, 1400 and 2000 hours). Skin temperatures were measured at three different locations (tail head, rump and shoulder). Animal thermal balance indicators were regressed with milk production to identify those factors affecting milk yield. On Farm A, two barns were used with primiparous cows and multiparous cows housed separately. Regression analysis found a strong and significant relationship between animal thermal balance and milk yield on all three farms. On Farm A, the shoulder and rump skin temps at 0800, shoulder and rump temps at 1400, and tailhead skin temps at 2000 were related to milk yield (R²=.72). In comparison, the primiparous cows included all skin temps and rectal temp recorded at 0800, shoulder and tail skin temps at 1400, rectal and shoulder temps at 2000 as well as respiration rates at 1400 and 2000 (r²=.61). Milk production of cows on Farm B was related to Respiration rate at 0800 and 2000, Rump temp at 0800 and 1400, shoulder skin temps at 1400 and 2000 and rectal temps at 0800. Cows on Farm C had milk production related to the 0800 rectal, rump skin, and tail skin temps, 0800 rectal temp, rump and shoulder skin temps at 1400 and 2000 and respiration rates at 0800 and 1400. The 1400 and 2000 measurements were less consistent in predicting milk yield. Early morning measurements were consistently and strongly related to milk yield indicating night time environmental conditions strongly affect the cows thermal balance and milk yield.

Key Words: Heat Stress, Thermal Balance, Milk Production

1109 Effect of feeding of yeast to crossbred calves. DilipKumar Garikipati*¹, Sarjan Rao Kapa¹, Rajasekar K², and Kailash MM³, ¹College of Veterinary Science, Tirupati, ²College of Veterinary Science, Hyderabad, ³Bangalore Agricultural University.

Thirty eight HF crossbred calves of F2 generation (age= 1 day) were allotted to one of two dietary treatments. Calves were offered a commercial calf starter with (yeast) or without (control) 10g/Kg of commercial yeast ad libitum for 56 days. Calves were allocated to treatments over 40day period and were housed in individual calf hutches. Calves were fed 4L/day pasteurized milk in 3 equal feedings. Calves starter (yeast and control) were offered ad libitum starting day 2 until day 56. Calves were weaned when they consume 800g of calf starter for 3 consecutive days. Body weight of calves was recorded at entry, weaning 4 at (BW) 56 days. Data were analysed as a completely randomized design using ANOVA procedures. Three calves one from control and two from yeast were removed due to health problems. Calves fed control were weaned earlier (51.8 Vs 55.2, p<00.2) as compared to calves fed yeast. Inclusion of calf starter reduced 56 day starter in take (23.9 Vs 30.6 kg, p<00.4). There were no differences in BW at weaning, BW at 56d, average daily gains or feed efficiency between calves fed control or yeast. Data suggest yeast culture inclusion in calf starter decreased starter in take and increased weaning age.

1110 The response of a non-medicated replacer containing a mannanoligosaccharide on growth and health parameters in neonatal dairy calves. A. J. Heinrichs*, M. R. Long, and T. S. Schriefer, *The Pennsylvania State University, University Park, PA.*

The objective of this experiment was to study the effectiveness of a non-medicated milk replacer containing a mannanoligosaccharide (BioMos, Alltech, Inc) on growth and health in dairy calves. Seventy-two Holstein calves (heifers and bulls) were used to evaluate a 20% CP 20% fat milk replacer with either Neo-Terramycin (400gms/ton Neomycin + 200 gms/ton Oxytetracycline; NT), mannanoligosaccharide (4 g/hd/day; MO) or no additions (C) in a randomized block design. The replacer was mixed at 10 oz./2 quarts of water and fed at a rate of 12 percent of birthweight/day through the end of the first week of age and then increased to 14% of birthweight until weaning at 35 d. Calves had a significantly higher probability (P < .01) of normal fecal scores including consistency, color, and severity of scours, with both the NT and MO treatments. Treatment of clinical scours occurred on 5 calves on C, 3 on NT, and 2 on MO. The rate of feed intake increase as determined by week of age, was significantly greater (P < .05) for the MO treatment over the NT treatment. There were no significant differences in any weight gain or structural growth at the conclusion of the study. Total blood protein levels were not different for any treatments; values were 5.3, 5.3, and 5.4 mg/ml for C, NT, and MO treatments respectively. Blood urea nitrogen values were 10.0, 10.4, and 10.0 mg/dl for C, NT, and MO treatments, respectively. The addition of a mannanoligosaccharide improved fecal scores in a similar or slightly better manner than did the NT treatments over the C calves in this study. Feed intake was improved in the calves fed the MO over the NT treatment, however this increased feed intake was not great enough or for an extended period of time to cause any differences in body weight during the 6 weeks of this study. The NT treatment appeared to improve feed efficiency at the end of the study. The addition of a mannanoligosaccharide in the milk replacer appeared to be beneficial to reducing scours in the calves and promoted greater feed intake.

Key Words: Dairy calves, Growth, Milk replacer

1111 Evaluation of spray dried animal plasma addition to milk replacer fed to calves at 2 feeding rates. D. R. Catherman*, *Strauss Feeds, Watertown, WI.*

Eighty-five Holstein heifer calves (average 37.9 kg BW) were used to evaluate the addition of 5% spray dried animal plasma (AP) to milk replacer (MR) compared to all milk proteins (AM) when fed a two feeding rates. Calves were allotted by weight to one of four treatment groups and fed as follows: treatment 1, AM fed at 454 g/d; treatment 2, AP fed at 454 g/d; treatment 3, AM fed at 681g/d and treatment 4, AP fed at 681 g/d. All treatments were formulated at 22% protein and 20% fat and fed in a volume of 3.8 l/d. Calves were weaned at 35 d and feed intake was recorded for 42 d. Calves were weighed at 0, 21 and 42 d. Water and starter grain (18% protein) were offered free choice from d 3. Total MR intakes were 13.5, 13.5, 18.0 and 18.0 kg for treatments 1 through 4, respectively. Total starter intakes were numerically higher for treatments 1 (37.4 kg) and 2 (38.3 kg) than for treatments 3 (34.6 kg) and 4 (36.1 kg). Weight gains between d 0 and 21 were lower (P<.05) for treatments 1 (10.0 kg) and 2 (10.0 kg) than for treatments 3 (12.2 kg) and 4 (12.3 kg). Between d 21 and 42, weight gains were higher (P<.05) for treatments 1 (12.4 kg) and 2 (13.6 kg) than for treatments 3 (11.8 kg) and 4 (11.3 kg). Overall weight gains (d 0 to 42) were not different. Feed cost per kg of gain was not different, but tended to be lower for treatments 1 (\$1.36) and 2 (\$1.28) than for treatments 3 and 4 (\$1.52). Scour scores were not different. Medication costs tended to be lower in treatments containing AP (\$10.49, \$9.96, \$10.18 and \$9.32 per calf for treatments 1 through 4, respectively). These data indicate AP offers an acceptable alternative to whey proteins in milk replacer formulations at 5% inclusion rate. Feeding rate did not impact the acceptability of AP. Inclusion of AP may have influenced the overall health of the calves based on medication costs, although more data will be required to confirm this tendency.

Key Words: calves, milk replacer, animal plasma

1112 Effects of Supplemental Vitamin E and Lasalocid on Disease Severity and Immune Responses of Calves Challenged With *Eimeria bovis*. G. E. Goodier*¹, C. C. Williams¹, K. L. O'Reilly², T. G. Snider², J. C. Williams¹, H. G. Bateman, II¹, D. T. Gantt¹, and C. M. Cheatham¹, ¹LSU Agricultural Center, Baton Rouge, LA, ²LSU School of Veterinary Medicine, Baton Rouge, LA.

Thirty-two male Holstein calves were utilized in a completely randomized design with a 2x2 factorial arrangement of treatments to investigate the use of Vitamin E (Vit E) alone or in combination with lasalocid (LAS) in the control of coccidiosis. Coccidiosis was experimentally induced using an oral dose of 100,000 *E. bovis* oocysts when calves were 2 wk of age. Calves received colostrum (COL) for the first feeding and then the colostrum supplement Lifeline® (LL) (American Protein Corporation) at the second feeding. All calves were fed milk replacer (MR) containing 20 IU Vit E/lb at 10% of birth weight. At wk 4, MR was reduced 50% and calves abruptly weaned at wk 5. Vit E treated calves (n=16) were given 180 IU Vit E (Roche Vitamins, Inc.) in the MR once daily and then orally drenched after weaning. LAS treated calves (n=16) were given LAS (Roche) at 1mg/kg of body weight in both MR and starter. Fecal scores were recorded twice daily, and body weights were recorded weekly through the 8 wk study. Blood samples were collected and analyzed for whole blood IgG (Midland BioProducts) before the LL feeding and 24 hours later. Blood and saliva were collected from each calf at 24 hrs and 2, 4, 6, and 8 wk of life to determine levels of total Igs, IgG₁, IgM, and IgA. Four calves from each study were killed at wk 8 for examination of grossly visible intestinal lesions. Whole blood IgG revealed 14 calves failed to receive adequate Igs from COL or LL, but these results had no effect on calf performance. Calves fed LAS had higher (P = 0.06) levels of total Igs from wk 3 until the end of the study. Control (C) calves had lower IgM levels throughout the study (P > 0.05), and calves fed Vit E alone had increased levels of IgM at wk 6 and 8 (P < 0.05). No differences in IgG₁ and IgA levels were observed between treatment groups (P > 0.05). Prevalence and severity of infections were greater in C and Vit E calves compared to those fed LAS. Post mortem analysis revealed that by wk 8 no intestinal lesions were present, indicating recovery from the disease. While supplemental Vit E alone did not improve calf performance, LAS was effective in decreasing severity of coccidiosis in this study.

Key Words: Coccidia, Lasalocid, Vitamin E

1113 Effect of monensin, lasalocid, and decoquinatone on growth, feed intake, and feed efficiency of dairy heifers. D.G. Schmidt^{*1}, J.E. Shirley¹, E.C. Titgemeyer¹, M.V. Scheffel¹, and E.E. Thomas², ¹Kansas State University, Manhattan., ²Elanco Animal Health, Greenfield, IN.

One hundred eighty Holstein heifers were used in a randomized block design to evaluate response to starter diets containing decoquinatone (D), monensin (M), or lasalocid (L) and the benefits of ionophores in grower diets during the transition from individual hutches to group pens. Treatments (90% air dry basis) for the first eight weeks of age (Phase 1) were M (33 mg/kg), L (83 mg/kg), or D (33 mg/kg). Heifers within each Phase 1 treatment group were ranked by weight and alternately assigned to either M or L and housed in pens containing 5 heifers each during an 84-d growing period (Phase 2). During Phase 2, heifers were fed only a grain mix containing M (31 mg/kg) or L (31 mg/kg) for the first 14 d, then a grain mix with chopped alfalfa hay during the second 14 d and a TMR the last 56 d. Diets were fed during the first 28 d to allow ad libitum intake (5% orts). Ionophores were delivered (100 mg/heifer daily) with the TMR as a top dress with finely ground corn. No difference in daily gain, feed intake, feed efficiency, or body weight gain was observed among treatments during Phase 1. Heifers fed ML gained slower during the 84-d growing period (Phase 2) than heifers fed the other treatments ($P < 0.05$). Heifers fed D (Phase 1) performed similarly when switched to M or L. Heifers switched from L to M performed similarly to heifers fed LL or MM. Results of this study suggest that heifers fed D or L prior to weaning can be successfully switched to M during the growing phase, but heifers fed M prior to weaning will not perform as well if they are switched to L during the growing phase.

1114 Effect of rearing methods of dairy-heifers prior to weaning on growth and reproduction. Jan J.J. Broucek^{*1}, Clive W. Arave², Ted H. Friend³, Stefan Mihina¹, Michael Uhrincat¹, Anton Hanus¹, Stefan Marencak¹, and Peter Kisac, ¹Research Institute of Animal Production, Nitra, Slovakia, ²Utah State University, Logan, USA, ³Texas A&M University, College Station, USA.

Holstein heifer calves (n = 92) were assigned to one of five rearing treatments after having nursed their dams for 24 h: A) individual hutches until 7 d of age followed by group housing with a machine milk feeder until weaning at 8 weeks; D) penned with dam until 7 d of age followed by group housing with a machine milk feeder until weaning; H) individual hutches until weaning; M) penned with dam for the first 7 d followed by an individual hutch until weaning; N) penned with dam for the first 7 d followed by penning with a nursing cow until weaning. Animals of all groups were kept after weaning in age-balanced groups in bedded pens with the same balanced ration. Parturition was classified according to a point system, i.e. 1) - no help, 2) - assisted by one person, 3) - assisted by 2 to 3 persons, a small injury of the genital tract, 4) - difficult parturition. Live body weight at the birth was not significantly different. At 180 d of age, statistically significant differences $P < .05$ were found in weight gains between N, D and A, and between H and A. The ranking of animals was: N (.79 kg), H (.74 kg), M (.71 kg), D (.68 kg), A (.64 kg). A slightly increased growth in live body weight in the groups N, M and H continued until the age of 630 days. The order of groups according to the average live body weight at 21 months was: N (491 kg), H (486.5 kg), M (481.6 kg), A (477 kg), D (468 kg). From the birth until the twenty-first month, the average daily weight gains were no significant: N (.71 kg), H (.71 kg), M (.70 kg), A (.69 kg), D (.67 kg). Conception ages (H=555 d, M=554.7 d, N=549 d, D=534.5 d, A=530.6 d) nor live body weights at day of conception (H=455.4 kg, N=449 kg, A=426.6 kg, M=426.5 kg, D=418 kg) were not significant. The most difficult calvings (not significantly) were in group M (2.4) and the easiest in group H (1.6). A significant difference ($P < .05$) was found in the birth weight of calves born to mothers in groups N (42.4 kg) and D (36.4 kg). The

results show that the rearing conditions had little long-term effect on the variables measured.

Key Words: Dairy cattle, Rearing, Growth

1115 Prediction and ranking of first lactation milk production using parents' predicted transmitting abilities. B. R. Radke^{*1}, J. W. Lloyd², J. B. Kaneene², J. R. Black², and S. Harsh², ¹Alberta Agriculture, Food and Rural Development, Edmonton, AB, ²Michigan State University, East Lansing, MI.

Decreased culling rates can increase the net income of dairy producers by increasing cow longevity. To decrease the culling rate, the replacement rate must also be reduced, necessitating a method of prepartum heifer selection. First lactation milk production is a proxy for dairy cow profitability and is a suitable heifer selection objective. The objectives of this study included determining: 1) the ability of parents' predicted transmitting abilities (PTAs) for milk, fat and protein to predict daughters' subsequent first lactation milk production; 2) the ability of the predictions of first lactation milk production to correctly rank heifers within herd based on actual milk production; and 3) whether, in estimating this linear relationship, the herd effect needed to be estimated as a fixed effect. The data consisted of first lactation mature equivalent milk production of 5,123 Michigan Holstein heifers from 576 herds, and the heifers' parents' animal model evaluations immediately prior to the heifers' calvings. The heifers were born in the last six months of 1992 and calved in the last six months of 1994. Linear regression of parents' PTAs on daughters' subsequent first lactation milk production resulted in $R^2 = 0.068$ and $R^2 = 0.067$ when herd was estimated as a random and fixed effect, respectively. The distribution of within herd Spearman rank correlations between the predicted mature equivalent milk production (based on parents' PTAs) and the actual mature equivalent milk production was diffuse, skewed to the left, and had a median of 0.25 with 65% of the herds having a positive rank correlation. This suggested the PTAs had some ability to correctly rank the prepartum heifers' subsequent first lactation milk production, and therefore may be useful in prepartum heifer selection. Treating herd as a fixed or random effect resulted in statistically different ($P < 0.0001$) models. However, the predictions from the two models had Spearman rank correlations greater than 0.90 for 96% of the herds suggesting that in practical terms, it is unclear whether herd needs to be estimated as a fixed effect.

Key Words: Prediction First Lactation Production, Random Effect, Fixed Effect

1116 Effect of wheat variety and replacing wheat with maize grain on feed intake and milk production of Holstein dairy cows. R.H. Phipps^{*}, J.D. Sutton, and A.K. Jones, *The University of Reading, Reading, UK.*

Fifteen multiparous cows were used in a 5 x 5 latin square trial with five, four-week periods. Cows were offered ad libitum a forage mixture of maize silage (368 g DM/kg, 308, 329 and 85 g/kg DM, starch, NDF and CP) and grass silage (325 g DM/kg, 496 and 132 g/kg DM, NDF and CP) in a 3:1 DM ratio. Cows received 12kg/d fresh weight (fwt) of one of five different concentrates (T1-T5), all of which contained 400 g/kg fwt of cereal grain. The nutritive value of concentrates was similar. In T1 and T2 wheat varieties Rialto (high viscosity) and Soissons (low viscosity) formed 100% of the cereal grain component. In T3, T4 and T5 maize grain replaced Rialto wheat to give the following proportions of wheat and maize grain, 62.5:37.5, 37.5:62.5 and 0:1. Feed intake and milk yields, for T1-T5 (respective means and s.e.d.) were 22.1, 21.5, 21.8, 22.3, and 22.2 (0.31) kg/d and 35.8, 36.3, 35.7, 36.6 and 37.4 (0.77) kg/d. The corresponding values for milk fat and protein contents were 37.1, 36.7, 35.9, 35.5 and 37.3 (1.64) g/kg and 31.7, 31.6, 31.7, 31.8 and 31.6 (0.29) g/kg. Yields of milk fat and protein for T1-T5 were 1326, 1330, 1279, 1285 and 1386 (60.6) g/d and 1128, 1142, 1126, 1157, and 1179 (25.5) g/d, respectively. Although feed intake for T1 was higher ($P < 0.05$) compared with T2, milk production was unaffected by wheat variety. Replacing Rialto wheat with maize grain did not affect feed intake but increased ($P < 0.05$) milk yield from 35.8 to 37.4 kg/d. Regression analysis showed a linear effect ($P < 0.05$) of increasing the proportion of maize grain in the concentrate (from 0 to 100% of cereal grain) on milk yield (1.7 kg/d 0.75) and protein yield (55 g/d 24.7). There were no effects on milk composition. Results indicate that increased supply of bypass starch through the use of maize grain could

increase milk production in UK dairy herds but a cost benefit analysis is required to determine its economic feasibility.

Key Words: Dairy cows, Milk production, Maize and wheat grain

1117 Evaluation of cow preference between modern and old free-stall design. R. J. Norell^{*1}, A. Ahmadzadeh², and E. P. Wagner², *University of Idaho*, ¹*Idaho Falls*, ²*Moscow*.

Cow preference was assessed between old and modern design freestalls. Two pens of 20 lactating Holstein cows were each provided 9 modern stalls (MOD) and 9 old stalls (OLD). MOD stalls were wider (1.22m vs 1.14m), had taller stall dividers (1.22m vs 0.91m), and had improved forward/sideways lunge space. OLD stall bases were deep sand over concrete blocks in pen 1 and deep sand over clay filled tires in pen 2. MOD stalls had sand over commercial rubber filled mattresses. Cow behavior was scanned every 15 minutes during a 7.5 h observation period on nine evenings (8PM to 3:30AM). Behavioral data were summarized by stall and analysed with a split plot in time ANOVA for each pen. For pen 1, LSM means and SE for %occupancy, %resting, %standing, and stall turnover rate were: 84.7 vs 78.2 ±2.8; 74.1 vs 67.0 ±2.3; 10.5 vs 11.1 ±0.9; 3.3 vs 3.9 ±0.2 for MOD and OLD, respectively. For pen 2, LSM means and SE for %occupancy, %resting, %standing, and stall turnover rate were: 90.5 vs 64.0 ±5.0; 82.2 vs 50.4 ±5.4; 8.3 vs 13.6 ±1.4; 3.2 vs 3.0 ±0.2 for MOD and OLD, respectively. Cows spent more time occupying MOD in pen 2 ($p < 0.006$) but not in pen 1. Cows spent more time resting in MOD stalls in both pen 1 ($p = 0.06$) and pen 2 ($p < 0.003$). Standing behavior was not different in pen 1 but was higher ($p < 0.03$) for OLD in pen 2. Stall turnover rates were similar between stall designs in both pens. We conclude that modern stalls with greater width, improved lunge space, and rubber filled mattress are preferred by lactating cows as evidenced by improved occupancy and resting behavior.

Key Words: Free-stalls, Cow Preference

1118 Whole-farm nitrogen efficiency and balance compared with the milk urea nitrogen test. R.A. Swain^{*1}, J.L. Walters¹, R.A. Kohn², and A.J. Young¹, ¹*Utah State University, Logan, UT*, ²*University of Maryland, College Park, MD*.

Environmental legislation has made it necessary for producers to be able to quantify and adjust the nitrogen (N) balance on their farms. Milk urea nitrogen (MUN) was evaluated as a practical means of evaluating whole-farm N balance. Forty-one commercial dairies in UT and ID were contacted and evaluated for whole-farm N balance using the University of Maryland Nutrient Balancer. Producers were interviewed in order to obtain annual amounts of purchased feed and fertilizer, crops grown and sold, cows purchased and sold, exported manure, pounds of milk sold, number of cows and heifers, and production characteristics such as milk protein and rolling herd average. MUN concentrations were collected from two consecutive DHIA tests. Freshly excreted and stored manure samples were collected. Individual whole-farm N balance and N utilization efficiency were determined. Whole farm N utilization efficiencies, based on MUN, were calculated using the models of Jonker et al. (J. Dairy Sci. 81:2681) and Kauffman and St. Pierre (J. Dairy Sci. 82 (Suppl. 1): 95). Herds ranged from 57-1960 cows, 6568-13863 kg of milk/cow, 9.5-20.5 mg/dl MUN, 12.6-36.2% N utilization efficiency, and 2.52-445.52 tonnes/yr potential N loss. A multiple regression model was run with whole-farm N balance (tonnes/yr) as the dependent variable. Significant independent variables were: number of cows, imported feed and fertilizer N, exported manure N, and herd N utilization ($r^2 = 0.98$). This suggests lower N balance on farms where all feed is imported. Herd N utilization had the single largest effect on N balance; an increase of 1.0 % resulted in a decrease of 1.88 tonnes/yr ($P < 0.0001$). Number of cows showed the smallest effect and did not affect N balance per unit of product produced ($P = 0.585$). The Jonker et al. ($r^2 = 0.15$, $r^2 = 0.19$) and Kauffman and St. Pierre ($r^2 = 0.12$, $r^2 = 0.10$) models were significant when regressed on herd N utilization and N balance, respectively. MUN may be a useful indicator of whole-farm N balance. Funded by SARE grant SW99-024.

Key Words: MUN, Whole farm nitrogen balance, Nitrogen efficiency

1119 Determining the relationships among milk urea nitrogen and milk production, milk protein, milk fat and somatic cell count from lactating cows in Texas. G.M. Goodall^{*1}, M.A. Tomaszewski¹, L.W. Greene², R.B. Schwartz¹, J.W. Stuth¹, and E.M. Sudweeks³, ¹*Texas A & M University, College Station, TX./USA*, ²*Texas A&M University Research and Extension Center, Amarillo, TX./USA*, ³*Texas A&M University Research and Extension, Overton, TX./USA*.

The objectives of this study were; 1) determine the relationship among Milk Urea Nitrogen (MUN) and milk production, milk protein, milk fat and somatic cell count, 2) determine economic consequences of reducing excessive milk urea nitrogen and phosphorus in the dairy cow diet. The potential impact was the development of a relationship among the components and MUN levels to alert producers of protein inefficiencies or excesses. Excessive protein has increased environmental nitrogen loading, increased feedcost, and resulted in adverse reproductive performance. Component pricing of milk has encouraged critical evaluation of milk records. This included the evaluation of the fat: protein ratio. The data was collected monthly over the course of 3 years. Over 20,000-cow testday records were collected including; calving interval, freshening date, days open, lactation number, longevity, days in milk, test day milk, milk components and their ratios, peak milk, MUN, and feeding program. The herd size varied from 110 cows to 852 cows. The feeding programs represented included Total Mixed Ration (TMR) fed herds and pasture-grazed herds. The economic evaluation objective looked at two main goals; 1) evaluation of the effect of milk urea nitrogen on longevity and milk production, and 2) calculation of decreased costs associated with decreased phosphorus levels. Previous TAMU extension demonstration data indicated a potential saving of \$14,000.00 per year for a 16% reduction in manure phosphorus in a 1000-cow herd. MUN levels were significantly affected by season, and feeding program. Peak milk production was significantly lower and MUN levels were significantly higher with the grazing herds. The data indicates the need to evaluate MUN levels based on feeding programs and season. Combining the MUN and component evaluation utilizes herd records for economic and environmental benefit.

1120 Comparing nutrient analysis of liquid dairy waste in storage versus field application. R. J. Norell^{*1}, S. C. Parkinson², and D. E. Falk³, *University of Idaho*, ¹*Idaho Falls*, ²*Preston*, ³*Twin Falls*.

Sampling of liquid dairy waste is necessary for reliable nutrient application rates to farm crops. The objective of this study was to compare sampling from storage versus sampling during land application. Three methods of land application were evaluated: (GRAVITY) liquid transport by gravity flow to gated pipe irrigation, (PUMP) pumping to gated pipe irrigation, and (TANK) pumping into a tractor drawn vacuum tank. Four pairs of samples were collected at each dairy. Each pair included a storage sample and a land application sample. Overall data were analyzed with a paired t-test ($n=48$ pairs). Mean storage concentration, mean difference (storage minus field) and SE of difference were: 0.99, 0.19±0.07; 0.48, 0.21±0.07; 506.0, 69.1±18.9; 91.2, 14.8±4.0; 39.5, -0.6±1.0; and 1272.6, -9.3±14.6 for (DM) % dry matter, (SS) % suspended solids, (TKN) ppm total kjeldahl nitrogen, (P) ppm total phosphorus, (OP) ppm ortho-phosphorus, and (K) ppm potassium, respectively. DM, SS, TKN, and P were significantly higher in storage samples ($p < 0.005$) but OP and K were not different between storage and field sample pairs. Mean differences in SS, P, and K were larger for TANK ($p < 0.05$) than in GRAVITY and PUMP sample pairs. Sampling liquid waste at the storage facility appears to overestimate the amount of nutrients actually applied to field crops.

1121 Utility of body condition score (BCS) system in relation to the physical and production parameters in crossbred cows. Dilipkumar Garikipati^{*1}, Sarjanrao Kapa¹, and Kailash MM², ¹*College of veterinary science, Tirupati, ANGRAU*, ²*University of Agricultural science, Bangalore*.

Body condition score (BCS) system is a subjective scoring method of evaluating the energy reserves of dairy cows which provide the better

reporting, via radio signals, of the GPS positional locations to an on-site computer. In addition to the animal GPS units, fixed GPS units were located at known locations within the pastures for additional data correction factors. In the summer of 2000, 16 crossbred steers were used to test the units and collect initial data. Data points were collected and transmitted to the on-site computer at one-minute intervals for a period of 28 hours, with 3108 data points collected on two steers. Battery life is affected by the data transmission interval, which may be set over a range of 10 second to 40 minute intervals. Costs for the cattle tracking GPS system, excluding labor for fabrication, were \$1000-\$1500 for the animal units (depending on the type of battery used), \$1300 for the DGPS base station, \$500 for the GPS position receiving base station, \$700 for fixed location GPS units, and the cost of a computer to download the data. This system allows for real-time monitoring of cattle grazing pastures at a lower price than commercially available units and should be useful for a wide variety of applications.

Key Words: GPS, Cattle, Grazing

1126 Effects of liquid supplement pH and acid source on liquid supplement intake of beef heifers and gestating beef cows. P.A. Davis¹, W.E. Kunkle¹, and J.D. Arthington², ¹University of Florida, Gainesville, ²UF-IFAS Range Cattle Research and Education Center, Ona, FL.

Effects of lowering pH of sugarcane molasses-based liquid supplements (MOL) on ad libitum supplement intake were evaluated in two experiments. For Exp.1, four treatments were a 16% crude protein MOL, pH 4.2 (T4.2) and T4.2 acidified to pH 3.4 (T3.4), 2.9 (T2.9), and 2.3 (T2.3) using feed grade phosphoric acid added at 3, 6 and 9%, respectively. Intakes of these supplements were compared using a 4 x 4 Latin square design with five crossbred beef heifers (273 to 386 kg initial BW) in each of four 1.8 ha bahiagrass pastures. Each treatment was offered ad libitum in 288 kg capacity tanks with one lick wheel. Each period of the Latin square was three wk long and MOL consumption was measured weekly. This 84 d experiment was conducted twice, at Gainesville (GNV) and Ona (ONA) locations, during Summer 2000. In Exp. 2, seven treatments included T4.2 and T4.2 lowered to pH 3.25 with hydrochloric (C), phosphoric (P) or sulfuric (S) acids creating treatments C3, P3 and S3, respectively; and to pH 2.30 with C, P and S creating treatments C2, P2 and S2. Seventy Angus beef cows (560 kg BW) were assigned randomly to 14 bahiagrass pastures divided into two replicates in a complete block design. Supplement consumed was measured weekly during an initial three wk period then treatments were reassigned to new pastures for a second three wk period in Fall 2000. In Exp.1, daily supplement consumption (DCON) for GNV averaged 2.58 kg (range 1.43 to 3.29 kg) and avg DCON for ONA was 1.93 kg (range 0.84 to 2.87 kg). Across both locations, DCON decreased 13% (P=.08) for T3.4, 30% (P<.01) for T2.9 and 64% (P<.01) for T2.3 compared to T4.2 (3.08 kg). In Exp. 2, DCON averaged 3.99 kg (range 2.55 to 5.38 kg) with decreases of 53, 38, 33, 30 and 18% (P<.02) from T4.2 (5.38 kg) for P2, S2, P3, C2, S3, respectively. DCON for C3 (4.89 kg) was similar (P=.13) to T4.2. Lowering pH of MOL was an effective method of reducing MOL consumption. Effectiveness of acid source varied, with P most and C least effective at similar pH.

Key Words: Beef Cattle, Molasses, Intake

1127 Effects of Plane of Nutrition on Milk and Weight Traits in Lactating Beef Cows. M. A. Johnson*, A. D. Herring, L. J. Hughes, and P. D. Bleick, *Texas Tech University, Lubbock, Texas*.

Twenty-eight lactating Angus cows were utilized to determine the effects of plane of nutrition on cow weight change, calf weight gain, milk yield, and milk composition (protein, fat, and somatic cell count (SCC)) from d 45 to 157 of lactation in 2000. Cows were randomly split into two groups (n = 14) and fed either a diet formulated to meet NRC maintenance requirements (MAINT) or one that exceeded maintenance requirements by 25% (MAINT125). Feed allotment was adjusted each 28 d period to reflect current cow weight and period of lactation. Diets consisted of a custom mixed protein/energy supplement and sorghum silage. Cows were machine milked every 28 d to measure milk yield, percent protein, percent fat, and SCC. Calves were separated from cows 16 h before milk collection, and cows and calves were weighed prior to milking. Data were analyzed as a repeated measures design with independent variables of diet, cow nested within diet, period, diet by period

interaction, calf sex, the regression on cow milk expected progeny difference (CEPD), and the regression on cow age in years; cow within diet was used to test diet effects. A time period effect (P < .01) was evident with all measured variables except SCC. Diet main effect was insignificant for all variables; however, a diet by period interaction was present (P < .05) for calf weight and milk protein. The interaction resulted because weight of MAINT125 calves was higher during the last three collection times when compared to MAINT calves, with a similar effect evident for milk protein. Calf sex (P < .01), CEPD (P = .047), and cow age (P = .048) additionally affected calf weight. CEPD ranged from -0.91 to 8.62 kg (3.63 kg average), and influenced milk yield (P < .01) and milk protein (P < .01). Average milk yields for collection times 1 through 5 were 5.4, 5.2, 4.8, 4.6, and 4.2 kg, respectively. Cow weight varied between collection times (P < .01) and was influenced by cow age (P < .01). Average initial (and final) weights for MAINT and MAINT125 cows were 577 (565) kg and 584 (581) kg, respectively. These data suggest that enhanced performance and milk composition does not result when Angus cows are fed 25% above maintenance requirements.

Key Words: Beef Cows, Milk Production, Weight

1128 Effects of feedbunk management strategies and monensin levels on feedlot performance in cattle fed to harvest. G.J. Vogel¹, J.C. Parrott¹, S.B. Laudert¹, and D.R. White¹, ¹Elanco Animal Health, Indianapolis, IN.

Two trials involving 3,408 crossbred steers with an average initial weight of 280 kg were conducted to evaluate the effects of different clean feedbunk times (i.e., targeted time for cattle to have consumed daily feed issue) and monensin levels on animal performance in cattle fed to harvest. Each trial consisted of 3 treatments with 6 replications. Treatments consisted of either a targeted clean feedbunk time of 0600 h with monensin included at 29 mg/kg of diet DM (T29), or a targeted clean feedbunk time 8 h earlier at 2200 h with monensin included at either 29 (C29) or 36 (C36) mg/kg of diet DM. Tylosin was fed throughout both trials to all cattle at 90 mg/d. Animals were fed twice daily at 0600 and 1300 h. Feedbunks were evaluated at 0600, 2000, 2200, and 0000 h for feed availability. Feed delivery was adjusted daily based on feedbunk readings. Cattle pen weights were obtained for each pen at the start of the trial, re-implant time, and at slaughter. All animals which died during the trial were necropsied. Data were analyzed as a randomized complete block design using pen as the experimental unit. Orthogonal contrasts were conducted to evaluate clean feedbunk time and monensin levels within clean feedbunk time. In trial 1, no differences in DM intake (7.81, 7.72, 7.73 kg), daily gain (1.31, 1.28, 1.32 kg/d) or final weight (505, 502, 509 kg) were noted among treatments T29, C29, and C36, respectively (P>.05). In trial 2, DM intake (8.83, 8.58, 8.51 kg), daily gain (1.52, 1.47, 1.46 kg/d) and final weight (557, 548, 548 kg) were reduced (P<.05) for cattle on the earlier clean feedbunk time at both monensin levels. Across both trials feed conversions were improved within the earlier clean feedbunk time with increased monensin level [5.92 (C29) vs 5.84 (C36); P<.05]. No differences in digestive death loss were observed among the treatments (.08%, .23%, .30%; P>.30). Results from these trials indicate that animal performance may be reduced if DM intake is compromised when an earlier clean feedbunk time is used. Feed conversions are also improved when higher levels of monensin are fed.

Key Words: Cattle, Monensin, Feedbunk Management

1129 Serum concentrations of trenbolone acetate and estradiol benzoate in cattle implanted with coated SYNOVEX Plus long-acting implants. L. A. Kraft¹, D. M. Henricks², S. Gray², A. N. Sinha¹, and K. L. Simkins¹, ¹Fort Dodge Animal Health, Princeton, NJ, ²Clemson University, Clemson, SC.

Commercial SYNOVEX Plus (SP) implants were coated (15% w/v) to extend the release of trenbolone acetate (TBA) and estradiol benzoate (EB) for about 200 days. Thirty Hereford crossbred steers (250-350 kg) were used to compare the serum concentrations of TBA and EB from coated Long-Acting (LA) and SP implants in cattle for 200 days. The cattle were blocked by pretreatment body weight and randomly assigned to one of the two implant groups within each block. All animals received either a LA implant or a SP implant in one ear. All implanted cattle were maintained together on pasture and supplemented daily with 1-2 kg/hd of a 16% crude protein concentrate. Ears were examined on Days 1, 4, 7, 14, 21, 28, 42, 56, 70, 91 and 112 for inflammation and presence of implants. Implants were detected in all animals through Day 70, but

could not be detected with certainty after Day 70 due to the normally expected depletion and decrease in size. Implant site reactions were minimal. Blood samples were obtained from the contralateral jugular vein on Days -2, -1, 0, 1, 4, 7, 14, 21, 28, 42, 56, 70, 91, 112, 133, 154, 175 and 200. Serum samples were assayed for trenbolone-17 β (TBOH) and estradiol-17 β (E₂), the active metabolites of TBA and EB. Serum TBOH for the LA implant was lower (P<0.10) than for the SP implant on Days 1-42 and higher (P<0.10) on Day 133. Similarly, serum E₂ was lower for the LA implant on Days 7-56 and higher on Day 133. The areas under the curve (AUC), the maximum analyte concentration (C_{max}) and time at which it was observed (T_{max}) were calculated. There were no differences (P>.10) in C_{max} for the LA and SP implants (317±37 vs. 347±33 pg/ml for TBOH and 12.5±1.8 vs. 11.3±0.9 pg/ml for E₂). However, the T_{max} for TBOH was 55±13 days for the LA implant compared to 19±4 days for the SP implant. The respective T_{max} values for E₂ were 122±14 and 44±8 days. The AUC for serum TBOH was lower (P≤.10) for the LA implant than for the SP implant suggesting that the coated LA implant was not completely depleted by Day 200 when serum TBOH was 13.7 pg/ml compared to 1.6 pg/ml for the SP implant. In summary, coating the commercial SYNOVEX Plus implant significantly reduced the early release of TBA and EB resulting in an extended release implant that lasted approximately 200 days.

Key Words: Beef Cattle, Trenbolone Acetate, Estradiol Benzoate

1130 Factors affecting net value of feedlot steers. N.K. Grathwohl¹, W.B. Epperson¹, B.J. Johnson², and S.W. Fausti¹, ¹South Dakota State University, ²Kansas State University.

Data from 874 steers enrolled in South Dakota State University's Calf Value Discovery (CVD) Program (1998 and 1999) were used to investigate factors affecting net value of feedlot steers. This analysis was conducted to evaluate how ranch of origin management (ROM) and feedlot health impact economic value. An OLS regression procedure was employed to analyze the data. The dependent variable, net value, was defined as: carcass revenue - feedlot cost. Overall fit of model was good as indicated by coefficient of determination R²=.9569. Regression results for health and ROM factors affecting net value is provided in the table below. Factors in the table are defined as: a) prewean was a categorical variable whose value was dependent on the days from weaning to feedlot entry - 0=if steers were weaned 0-3 d before entry, 1=if steers were weaned 4-14 d before feedlot entry, 2=if steers were weaned 15-29 d before feedlot entry, 3=if steers were weaned 30-44 d, and 4=if steers were weaned > 45 d before feedlot entry; b) modified live vaccine - if calf received a modified live viral IBR/BVD/BRSV/PI3 vaccine prior to feedlot arrival; c) in weight - weight (kg) of the calf at arrival to feedlot; and d) respiratory illness - if calf was treated for respiratory illness in feedlot. Results from this study found respiratory illness at the feedlot reduces net value of feedlot steers, while use of a modified live vaccine and preweaning at the ranch increases net value along with in weight. As anticipated, these factors contributed relatively little to overall net value. However, these data suggest ROM and health can impact the net value of feedlot steers at harvest. A more thorough understanding of these factors may help producers increase the net value of their product.

Factors	Parameter			
	Estimate	SE	Partial R ²	P-Value
Prewean	1.9698	.9560	.0003	.0398
Modified Live Vaccine	13.5639	2.2133	.0032	.0001
In Weight (kg)	1.2625	.0263	.1639	.0001
Respiratory Illness	-22.0417	3.6710	.0027	.0001

Key Words: Beef Cattle, Management, Health

1131 A systems approach for adding value to Montana feeder calves. D. J. Fennewald*, J. A. Paterson, R. N. Funston, and L. P. Anderson, *Montana State University-Bozeman Bozeman, MT.*

ABSTRACT: Two thousand eight hundred ninety-eight calves from 12 ranches were individually identified to evaluate if a standardized weaning protocol following prescribed vaccinations, nutrition and 45-d of backgrounding could reduce morbidity from weaning to harvest. Freshly

weaned calves were allocated to 1) CONTROL (defined as present weaning practices which may or may not provide pre-weaning vaccinations and do not retain calves for 45 d after weaning) or 2) TREATMENT (calves fed either 1.82 kg/d of a pellet or 0.45 kg/d of liquid supplement for 28 d containing additional levels of Cu, Zn, Mn, CP, vitamins A and E and a coccidiostat). Ranches chose viral and clostridial vaccines (MLV or killed) and described pre- and post-weaning management. Calves were fed in six states. Seven of the ranches divided calves into control and treatment groups (826 and 855, respectively) while three ranches had only treatment (n = 835) and two ranches had only control (n = 382). Results suggested calf morbidity was reduced (P<0.05) for calves backgrounded for 45-d or longer compared to calves backgrounded less than 45 d (6 vs. 21%). Death loss was lower (P<0.001) for 45-d backgrounded calves (0.3%) vs. 2.4% for calves backgrounded less than 45-d. Although not significant (P=0.17) calves fed the treatment pellet appeared to numerically have lower morbidities from weaning until harvest (6.3%) compared to control calves (19.5%). Range in morbidities was 0-100% for control vs. 0.5-20.9% for treatment. Boosting vaccinations appeared to help reduce (P=0.18) morbidity in the feedlot (7.4% for calves that received boosters vs. 21% for calves that received a single vaccination). Carcasses from six ranches were priced the week of harvest to compare gross income when priced as a base carcass price, on a quality or on a yield grade grid. Carcass weight correlations to gross income were 0.939, 0.838 and 0.926 when priced as a base carcass price, on a quality or on a yield grade grid, respectively (P<0.0001). Morbidity and death loss may be reduced when a weaning management strategy includes nutrition, proper vaccination and 45-d backgrounding. Carcass weight was highly correlated to gross income by marketing heavier carcasses that did not exceed industry specifications.

Key Words: Beef cattle, Weaning, Morbidity

1132 Predicting nutrient balance in the feedlot. H. Fairweather, K. A. Beauchemin, and K. M. Koenig, *Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

There is a one-time feeding capacity of over 1,000,000 head of beef cattle in a 70,000 ha area in Southern Alberta. Therefore, there is a potential for nutrients to cease being an asset to the production system and become a liability to the environment. A whole system model (FeedNuts) is being developed to predict the nutrient balance in the feedlot by means of a daily time step stochastic simulation. The model was run for a 1000 head feedlot; cattle were fed a ration of 90% barley grain, 6% barley silage and 4% canola meal (DM basis). Initial weight of the cattle was 350 kg, final weight was 575 kg, and the feeding period was 150 d. Predicted N intake in the feedlot for the entire period was 38.1 t and the predicted P intake was 6.9 t. At the end of the simulation there was 1.7 t of soluble N and 9.1 t of insoluble N in the manure stockpile. A total of 14.9 t of N was volatilized from the manure (5.8 t during the time the animals were in the feedlot and 9.1 t in the 4 months the manure was stockpiled), 7.3 t was lost in runoff, all of which was volatilized from the holding pond. No P was lost to volatilization, however 0.2 t of P was lost in runoff and the manure stockpile contained 0.3 t soluble P and 5.5 t of insoluble P. This resulted in manure containing 3.0% total N and 1.6% total P (DM basis). Most crops take up from 5 to 13 times the amount of total N to total P and, therefore, if this manure was applied to a cropping system to meet the N requirement, P would accumulate in the soil. The system becomes more unbalanced if the losses of N in the soil are compared with the relatively small losses of P. Another complicating factor is the percentage of each of the nutrients in the applied manure that is available for crop uptake. The FeedNuts model simulates each of the pathways and changes in the nutrients as a function of different rations and provides a mechanism for investigating the nutrient balance at any point in time by conducting 'virtual' experiments. These experiments predict considerable variation in the soil nutrient balance for different rations.

Key Words: Nutrient balance, System model, Simulation

1133 Farm-level management practices of cattle: Effects on Enterohemorrhagic *Escherichia coli* and *Salmonella* in feedlot cattle. A.D. Herring¹, A.R. Barham*¹, S.K. Misra¹, C. Akers¹, and J.R. Blanton Jr.¹, *Texas Tech University, Lubbock TX.*

The objective of this study was to generate preliminary evidence to investigate the potential that farm-level management of cattle may affect

shedding of Enterohemorrhagic *Escherichia coli* (EHEC) and *Salmonella* (SAL) in the feedlot. Cattle from 5 climatic/geographical origins within Texas were studied. Management practices were: origins 1, 2, 3 and 4 utilized stocker-managed cattle, whereas origin 5 utilized backgrounded animals. Origins 1 and 3 employed an implant during the pre-feedlot period. Animals from origin 1 were 25% Brahman-25% British-50% Continental, origins 2 and 5 were 25% Brahman-75% British; origin 3 were 50% British-50% Continental and origin 4 cattle were 100% British. Steers composed all treatment groups except 9 heifers in origin 2. Fecal grab samples were collected prior to and following shipment to feedlot, on day 56 of the feedlot period, and prior to and at the slaughter facility. On arrival at the feedlot, cattle (n = 84) received clostridial and respiratory disease vaccinations, pour-on insecticide, and were assigned to pens (n = 6 anim) blocked by origin. Diets consisted of a corn-based grower/finisher ration that exceeded NRC requirements. Fecal grab samples were collected pre- and post-feedlot arrival, on day 56 of the feedlot period and pre- and post-exsanguination. EHEC and SAL prevalence were evaluated utilizing FSIS approved protocols. Pen was experimental unit with percent incidence analyzed using GLM procedures with a model that included origin, time, pen (origin) and origin*time interaction. EHEC levels were effect by origin (P < .05). Origin 4 had the highest incidence level of EHEC shedding (20.3%), whereas origin 3 had the lowest incidence (2.5%). While there were not any significant origin or time main effects for SAL, there was an origin*time interaction (P < .05). SAL incidence increased over time for origins 2 and 4, but decreased for origins 1, 3 and 5. Overall, these data indicate that cattle origin (location, management etc.) can result in different level of EHEC and SAL shedding in feedlot cattle.

Key Words: Salmonella, Escherichia coli, Cattle

1134 The Effect on Economics of Integrating Pasturing Systems into Cattle Finishing Programs. H Koknaroglu*¹ and M.P. Hoffman¹, ¹Iowa State University.

A three-year study, using 84 fall-born and 28 spring-born calves of similar genotypes each year, was conducted to integrate pasturing systems with drylot feeding systems. Fall and spring-born calves were started on test in May and October, respectively. Seven treatments were imposed: 1) fall-born calves directly into feedlot; 2 and 3) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of July; 4 and 5) fall-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October; 6 and 7) spring-born calves put on pasture with or without an ionophore and moved to the feedlot at the end of October. A 12.1 ha bromegrass pasture divided into 16 paddocks was available. Each treatment group had access to one paddock at a time and was rotated approximately at 3 day intervals. In the feedlot, steers were provided an 82 % concentrate diet containing whole-shelled corn, ground alfalfa hay, a protein, vitamin and mineral supplement containing ionophore and molasses. When pens of cattle reached approximately 522 kg average live weight, they were processed and carcass traits were evaluated. Overall, cattle started directly in the feedlot gained faster (P<0.001). Treatment influenced yield grade (P<0.001), however all treatments were YG 2. All treatment groups graded 75 % Choice or higher. Cattle started directly in the feedlot were the least profitable (\$-16 vs \$27; P<0.001). Cattle not receiving ionophore on pasture were a little more profitable (\$29 vs \$25; P>0.7), except fall-born cattle moved to the feedlot in October (\$22 vs \$30). Feeder and carcass prices were the two most important variables explaining the variation in profitability. These results indicate that cattle fed on pasture for varying periods of time produced acceptable carcasses and that feeder and carcass prices were the two most important variables affecting profitability. Thus, the timing of marketing is critical for optimizing profit.

Key Words: Steers, Feedlot, Pasture, Economics

1135 Repeated administration of implants to Holstein steers increases average daily gain, longissimus muscle area and the percentage of USDA Select carcasses. J.M. Scheffler*, D.D. Buskirk, S.R. Rust, J.D. Cowley, and M.E. Doumit, Michigan State University, East Lansing, MI.

The objective was to determine the effect of repeated use of implants on feedlot performance and carcass characteristics. Holstein steers (n=128) weighing an average of 211 kg were blocked by weight and randomly assigned to 16 pens. At the initiation of the trial (d 0), pens were assigned

to one of four treatments: non-implanted control (C), implant on d 0, d 100 and d 200 (I3), implant on d 100 and d 200 (I2) and implant on d 200 (I1). ComponentTM TE-S implants (120 mg trenbolone acetate and 24 mg estradiol per implant) were used for all treatments during the 268-day feeding period. During the first 200 d of trial, implanted steers had higher ADG compared to non-implanted steers (P<.01). Only I1 steers had greater ADG than C during the last 68 d (P<.05). Steers were harvested at a commercial abattoir on d 269. Hot carcass weights of I2 and I3 were similar to each other and greater than C and I1 (P<.05). Dressing percentage, adjusted 12th rib fat, percent kidney, pelvic and heart fat, yield grade and CIE L*a*b* values were not different between treatments. Longissimus muscle areas (LMA) from I2 and I3 were larger than LMA of C (P<.01). No USDA Select carcasses were produced from control cattle, while the percent Select from implanted cattle ranged from 9-17%. Repeated administration of ComponentTM TE-S implants improved ADG and resulted in heavier carcasses with larger LMA, but increased the percentage of carcasses grading USDA Select.

Key Words: Implants, Holstein, Average daily gain

1136 Effects of pre and/or postpartum fat supplementation on reproduction in mature beef cows. S.K. Johnson*, J.S. Stevenson, K.R. Harmony, and J.R. Brethour, Kansas State University.

The objective of this study was to determine the effects of level of supplemental fat either prepartum, postpartum or both on reproduction in beef cows fed a sorghum-sudan hay base diet. Multiparous crossbred cows (n=269) received a low fat milo-based supplement (2% EE, 18% CP; 2.7 kg/hd/d; LF) or a high fat sunflower-based supplement (26% EE, 18% CP; 1.6 kg/hd/d; HF) either prepartum (PRE) or postpartum (POST) in a 2 x 2 factorial arrangement of treatments. Sorghum-sudan hay was offered ad libitum and ranged in quality from 5 -12% CP. The lowest quality hay was fed prepartum. Mean length of supplementation was 64 d PRE and 76 d POST and continued through a 5-d AI period. Two blood serum samples were collected 14 d apart just before administering 25 mg of PGF_{2α} to synchronize estrus. At the end of the AI period, cows were transported to summer pastures and exposed to bulls for 53 d beginning 9 d after transport. No effect of type of supplement fed PRE was observed for reproductive measures. In contrast, the proportion of cows cycling at the beginning of the breeding season (74% vs 65%) and the pregnancy rate to AI (44% vs 32%) was greater (P<.05) for cows receiving LF as compared to HF POST, respectively. Level of fat supplementation had no effect on pregnancy rate for the entire breeding season (95.4%). Cows fed LF POST had a higher body condition score (BCS) at breeding (5.2 vs 4.7), lost less BCS from calving to breeding (-0.3 vs -0.6) and weighed more at breeding (497 vs 482 kg) than HF cows, respectively (P<.05). There was no difference in cow weight or BCS at weaning due to treatment; however, cows receiving HF POST gained condition from breeding to weaning while LF cows lost condition during the same time period. Calf birth weight, calving difficulty score, and calf weaning weight did not differ due to treatment. Increased supplemental fat fed prepartum, postpartum, or both did not improve reproductive traits of mature cows in a herd already in good body condition and with high reproductive performance.

Key Words: Cows, Fat supplementation, Pregnancy rate

1137 Comparison of pregnancy rates in beef cows for two synchronization regimens using GnRH, PGF_{2α} and MGA. W.A. Greene and M.L. Berger*, The Ohio State University, Wooster USA.

Seventy-seven beef cows were allotted to two similar groups based upon breed, age, postpartum interval, and postpartum cyclicity (as determined by ultrasonography) to compare pregnancy rates (PR) resulting from two synchronization regimens using GnRH, prostaglandin F_{2α} (PGF_{2α}), and melengesterol acetate (MGA). Both groups received 50 μg GnRH i.m. on d 0 and 25 mg prostaglandin F_{2α} (PGF_{2α}) i.m. on d 7. Group 1 was fed MGA from d -26 to d -12 at a rate of .5 mg/cow/d. These cows were observed for estrus 0700 and 1900 and were artificially inseminated (AI) 8-16 h after estrus was observed or 80 h after PGF_{2α} if estrus was not observed. Group 2 was fed MGA (.5 mg/cow/d) from d 0 to d 6, received a second GnRH i.m. on d 9 (48 h after PGF_{2α}), and were AI 16 h after the d 9 GnRH injection. Following the synchronization period, repeat breedings were done until d 58. Cows were

pregnancy diagnosed by ultrasonography on d 84. PR to synchronization (PR-SYNC) and overall PR were similar for both groups ($P > .05$). PR-SYNC for Groups 1 and 2 were 59.5 and 55.0%. Overall PR for Groups 1 and 2 were 94.6 and 87.5%. PR-SYNC tended to be higher for cycling cows (61.7 vs. 41.2%, $P = .17$) while overall PR was not affected ($P > .05$) by postpartum cyclicity status at time of synchronization.

1138 Predicting resistance to compression of wool fibers. F.A. Pfeiffer*, C.J. Lupton, and B.A. Kuykendall, *Texas Agricultural Experiment Station, San Angelo, Texas/USA.*

Resistance to compression (RTC) is the force per unit area required to compress a fixed mass of wool to a fixed volume. Units of measure are kilopascals (kPa). Together with other important characteristics such as staple length (SL) and average fiber diameter (AFD), RTC is used to predict processing and product performance of wool, this being part of the value determining process for some raw wools. Objective measurement of RTC requires several preparation steps (washing, drying, carding, and conditioning) and a specialized testing apparatus not generally available in U.S. wool testing labs. On the other hand, fiber diameter distribution is now routinely measured by fast, accurate, high-tech instruments. Recently, the capabilities of one such instrument, the Optical Fiber Diameter Analyser, were expanded to include concurrent measurement of fiber diameter and fiber curvature (FC) distributions. One hundred and four samples representing a broad cross section of commercially available wools were quantified individually using standard methods for SL (mean = 9.6 cm, range 6.1 to 18.2 cm), AFD (24.1, 18.0 to 43.1 μm), FC (82.9, 20.0 to 121.1 degrees per cm), clean yield (CY; 67.1, 41.4 to 88.7 %), vegetable matter content (VM; 1.6, 0.1 to 6.7 %), crimps per unit length of staple (CR; 3.9, 0.7 to 7.0 crimps per cm), and RTC (9.1, 6.7 to 13.1 kPa) in order to study the relationships between RTC and the other measured traits. Resistance to compression was shown to be significantly ($P < 0.05$) but not highly correlated with SL, AFD, FC, CY, and CR ($r = -0.36, -0.21, 0.57, -0.52, \text{ and } 0.42$, respectively). As expected, FC was highly correlated with CR and AFD ($r = 0.94$ and -0.83 , respectively). Stepwise multiple regression analysis was used to predict RTC using all the measured variables (and their SD values for all traits except CY and VM). The resulting equation was $\text{RTC} = -2.13 + 0.22 \cdot \text{AFD} + 0.07 \cdot \text{FC}$, $r^2 = 0.54$. No other variables met the 0.01 significance level for entry into the model. We concluded that for textile applications in which a specific RTC is required, it still will be necessary to measure this characteristic directly because it cannot be accurately predicted using other raw fiber traits.

Key Words: Wool, Resistance to compression, Fiber traits

1139 Evaluation of forages for outdoor gestating sows. H. A. Rachunyo*¹, V. G. Allen¹, J. L. Morrow-Tesch², J. W. Dailey², and J. J. McGlone¹, ¹*Texas Tech University, Lubbock*, ²*USDA-ARS, Lubbock*.

Sustainable outdoor pig production requires vegetation that can maintain ground cover, take up manure nutrients, and prevent soil erosion. Two studies were conducted using 4 forages, alfalfa (*Medicago sativa*), tall fescue (*Festuca arundinacea*), white clover (*Trifolium repens*) and buffalograss (*Buchloe dactyloides*). Individual plots of single forage covered about 6 m². In first study, 8 pregnant gilts were given free access to 4 blocks of forages during a 2-d adjustment period and then gilts (2 per block) were assigned randomly to four blocks of 4 forages. Percentage ground cover was visually estimated at time 0, 24, and 48 h of study and analyzed as a split plot. Behavior data including walking, eating, grazing, rooting, drinking, standing, lying, and time-spent in-hut were monitored continuously by camera for 48 h. Percentage ground cover, which started at 100%, was reduced ($P < .01$), especially for clover (48.70.63%) and alfalfa (62.50.63%) but not for fescue (98.70.63%) or buffalograss (98.70.63%). In a second study, six gilts from the initial group were used; each one was assigned randomly to individual forages. Clover was excluded in second study because of damage by gilts during first phase. Rate of loss for percentage ground cover was higher ($P < .01$) for alfalfa than buffalograss or fescue (-31.3, -1.7, -1.8%/d, respectively) in second study. Behavioral analysis in first study showed that sows spent more ($P < .01$) time grazing clover (16.3 1.97 min) and alfalfa (11.2 1.97 min) than fescue (.81.97 min) or buffalograss (.31.97 min), and rooted more ($P < .04$) clover than other forages. In second study, gilts spent more ($P < .01$) time grazing alfalfa (15.82.36 min) than buffalograss (1.52.36 min) or fescue (0.72.37 min). Pigs have clear preferences for grazing alfalfa and clover, and rooting clover. Rates of loss of ground cover were

lower for fescue and buffalograss than other more preferred forages and, thus, these forages may have potential in pastures for swine to provide ground cover. Longer-term studies are needed.

Key Words: Pig, Environment, Forage

1140 Improving the viability of piglets with oxygen. J Zhang, V Osborne, M Fan, and R Hacker*, *Dept. of Animal & Poultry Science, University of Guelph, Guelph, Ontario Canada N1G 2W1.*

The objective of this study was to improve piglet viability and to reduce piglet mortality during the first 7 d of life with oxygen treatment. Two chambers (51x28x30.5cm) were purchased from a retail fish aquarium shop. The treatment chamber was fitted with a lid, an oxygen port and a monitoring port. Oxygen was supplied to the treatment chamber via a controller (#1630 Engineered Systems & Designs) which was connected to a mobile oxygen tank. Piglets (231) received oxygen immediately after birth or were maintained (232) in an identical control chamber with no supplemental oxygen. Temperature in both chambers was kept between 31 and 35°C and no more than three piglets occupied a chamber simultaneously. Oxygen content in the chamber was verified with a Stat Profile Plus-9 Component of NOVA Biomedical Canada Ltd. The movement of the piglets' front legs was counted in the first 20 s after removal from the chamber. Piglet BW was recorded at the birth and at d 7, with the difference used to calculate gain. Total mortality during the first 7 d of life was compared with 974 background piglets that were farrowed during the experimental period in the herd, with little or no attention during farrowing. Data were analyzed by the GLM procedure of SAS. Oxygen inhalation for 10 min improved ($P < 0.05$) piglets' movement and weight gain compared with the 10-min control group. However, there was no difference ($P > 0.05$) between the 15-min groups. Cumulative mortality of all experimental groups during the first 7 d after birth was lower ($P < 0.01$) than that for the background group. This was especially true for the 10-min oxygen group, which was lower ($P < 0.01$) than the background group by 88.0% during the first 3 d of life (0.8 vs. 6.9% on d 1 and 0.8 vs. 8.0% at d 3). It can be concluded that providing 10-min of oxygen immediately after birth increases piglet viability and growth during the early postnatal period.

Key Words: Oxygen, Temperature, Mortality

1141 The impact of farrowing crate design on litter performance traits in swine. S.J. Moeller*, K.M. Irvin, K.R. Black, and S.M. Neal, *The Ohio State University, Columbus, OH.*

Litter records representing 1,249 multi-parous females were used to evaluate the impact of farrowing crate design on litter, piglet and sow performance traits. Five farrowing crate designs with variability in lower bar design, width of crate and orientation within farrowing pen were compared. The crate designs were: B1, 188 x 42 cm, finger side; B2 188 x 47 cm, finger side; K1, 185 x 42 cm, finger side; K2 185 x 42 cm, bow-bar side; and Z, 197 x 42 cm, finger side. Total farrowing pen space was 213 x 152 cm for B1, B2, K1 and K2, and 213 x 137 cm in the Z-crate. The Z-crate was placed diagonally within the pen and pen size was smaller by design. Farrowing crates were randomly placed with sows randomly assigned to crates upon entering the farrowing facility. Subsets of crate-type were evaluated in statistical models to evaluate crate width (narrow vs wide), lower-bar type (finger vs bow-bar), or manufacturer type. Statistical analyses were performed using mixed model procedures of SAS, with a random effect of farrowing group and fixed effects of parity, female breed and crate characteristic. Interactions were tested. Covariates were used to standardize litter traits to a 21 d lactation length where appropriate. Twenty-four dependent variables were evaluated encompassing birth and weaning numbers, survival rates, litter weights, female weight loss and fat loss. Results comparing B1 vs B2 (narrow vs wide) finger crates (N=627) revealed no differences in pig, sow, or litter measures. Litters raised in bow-bar crates (K2, N=269) were found to have significantly ($P < .05$) more pigs (.34 pigs/litter) and heavier litter weight (2.18 kg/litter) at 21 d than finger-crates (K1, N=186). The number of pigs dying within 1 d of birth was significantly higher ($P < .05$) in the Z-crate (0.80 pigs) when compared to the K1 crate (0.54 pigs), but no differences were found in number of pigs weaned at 21 d. Parity and female breed effects were significant for most traits measured. In this study crate width did not impact sow or

litter performance. However, bow-bar crate type resulted in more pigs and heavier litter weights at 21d.

Key Words: Swine, Farrowing, Litter

1142 Supplemental feeding lactating Fallow does increased body condition score and circulating leptin but failed to improve reproductive efficiency. K. C. Candler^{*1}, C. G. Brown¹, D. A. Neuendorff¹, A. W. Lewis¹, J. A. Sterle², D.H. Keisler³, and R. D. Randel¹, ¹Texas Agricultural Experiment Station, Overton, ²College Station, ³University of Missouri, Columbia.

Gestating does (*Dama dama*); (BW=51.3kg) were allotted into groups: 1) Control (C; No Supplement n=12), 2) Supplement (S; 4:1, corn:soybean meal n=12), or 3) Rice Bran (R; 3:1:1, corn:soybean meal:20% fat rice bran n=12) formulated to be isonitrogenous and isoenergetic and grazed Coastal bermudagrass/ryegrass pastures. S and R were fed .5kg ration/head/day for 112d. All does were weighed, body condition scored (BCS), and blood sampled at 7d intervals for 14d prior to and for 35d after weaning. Serum progesterone (P4) and leptin concentrations were determined using RIA. Pregnancy was determined by ultrasonography 30 and 75 d after buck exposure. S does tended (P<.075) to lose less weight (-.062±.004kg/d) than C (-.073±.004kg/d) or R (-.071±.004kg/d). C does tended (P<.08) to have lower BCS than R but were lower (P<.002) than S. S does lost less (P±.001) BCS (-.636±.310) than C (-2.167±.297) with R being intermediate (-1.432±.310). Fawn birth weights did not differ (5.2±.2kg/d, 5.1±.2kg/d, 5.3±.2kg/d; C, S, and R, respectively). C fawns had the lowest (P<.003) ADG (.128±.010kg), S the highest (.185±.010kg) and R intermediate (.162±.010kg). Serum leptin (ng/ml) increased over time (P<.001) and differed by treatment (P<.06) with S being the highest and C and R being similar (P<.10) and lowest. Preweaning P4 was higher (P<.003) in S (2.4±.2ng/ml) than either C (1.5±.2ng/ml) or R does (1.7±.2ng/ml). 100% of S does were estrous cycling before weaning compared with 66% of C and 75% of R. Postweaning P4 increased over time (P<.0001) but was not affected by treatment (P>.10). By d 30 of the breeding season, 100% of S does were pregnant compared with 91% of C and R and all does were pregnant by d 75. Inclusion of rice bran failed to improve performance but supplement corn and soybean meal supplement increased

BCS and circulating leptin. Weaning and buck exposure resulted in equal breeding performance in thinner does.

Key Words: Rice bran, *Dama dama*, Dietary energy

1143 Angus steer performance grazing bermudagrass on degraded soils fertilized with poultry litter, ammonium nitrate, or crimson clover. D. H. Seman^{*1}, J. A. Stuedemann¹, and A. J. Franzluebbers¹, ¹USDA-ARS, Watkinsville, GA USA 30677.

We have been investigating the impact of using cattle in forage systems to restore degraded cropland in the Southeastern US. The object of this study was to evaluate performance of steers grazing bermudagrass pastures that were fertilized by three fertilizer treatments and were stocked at two grazing pressures. Yearling Angus steers were randomly assigned to 18 paddocks (.65 to .75 ha) which were organized in three blocks. Three nitrogen (N) treatments included N provided as ammonium nitrate (M), poultry litter (L) or by crimson clover plus ammonium nitrate (C). Ammonium nitrate and L were applied twice each year to annually provide 200 kg N/ha. Cattle grazed for 140 days from mid-May until mid-October for five years. The high grazing pressure (HP) was to maintain 1,500 kg forage/ha and low grazing pressure (LOW) maintained 3,000 kg/ha with a differential of 1,500 kg/ha between both rates. Stocking rates were adjusted every 28 days by put-and-take. After five years, the M treatment had greater average total grazing days (1,092) than C (926) and L (944), (P<.05). The L treatment had less total animal gain/ha, 607 kg/ha than did M (733 kg/ha) and C (688 kg/ha) treatments (P<.05). Average daily gain (ADG) was greater for C (.78 kg/d) than L (.69 kg/d) (P<.05) with M intermediate (.74 kg/d). Steers grazing HP had 1,118 grazing days vs. 857 LOW (P<.05). Steers grazing HP had greater total animal gain/ha, 732 than LOW with 620 kg/ha (P<.05). Steers grazing LOW had greater ADG .82 kg/d than HP .65 kg/d (P<.05). Steers exhibited excellent gains while grazing bermudagrass during summer. Poultry litter supported acceptable steer production even though animal production was less than M and C. Soil organic carbon was positively correlated with grazing days $r=.49$ (P=.0378). Results imply that grazing cattle can be employed to restore eroded cropland.

ASAS/ADSA Animal Behavior and Well Being

1144 Quiet handling of heifers reduces aversion to restraint. V. Littlefield¹, T. Grandin¹, and J. L. Lanier^{*1}, ¹Colorado State University.

On eight non-consecutive days, 192 Hereford x Charolais heifers were restrained in a scissors type, hydraulic squeeze chute. Squeeze chute temperament and balking behavior was scored with 4-point scales. Squeeze chute temperament scores were 1= calm, stood still, 2 = struggled once, 3 = struggled multiple times, flexed shoulder muscles, and 4 = violent and consistent struggling. Balking behavior at the squeeze chute entrance was 1= entered chute without hesitation, 2 = Hesitation, moved into chute after being touched, 3 = Hesitated, tail twisted, and 4 = electric prod used. Gentle and quiet handling was maintained during all handling of the cattle, for all days. Squeeze chute and balking scores decreased with repetitive handling (P < .01). Mean squeeze chute score was reduced from 1.94 to 1.39 during the eight days. Balking before entering the squeeze chute was reduced from a mean of 1.89 on day one to a mean of 1.58 on day eight. Heifers with higher temperament scores typically entered the squeeze chute last (R2=.84, P<.01). Gentle, repetitive handling of cattle decreases balking in the handling facility and decreases reactivity to restraint in a squeeze chute. Cattle became easier to move into the squeeze chute with each successive handling.

Key Words: Cattle, Behavior, Temperament

1145 Genetic determination of maintenance behavior of calves. Jan J.J. Broucek^{*1}, Ted H. Friend², Clive W. Arave³, Paul Flak¹, Stefan Mihina¹, Michael Uhrincat¹, Anton Hanus¹, and Peter Kisac¹, ¹Research Institute of Animal Production, Nitra, Slovakia, ²Texas A&M University, College Station, USA, ³Utah State University, Logan, USA.

We assessed 21 Holstein calves (12 males and 9 females) descended from 3 bulls (AMS1, n=6; STB9, n=8; PEL2, n=7). The calves were kept in loose housing. We conducted three observations of maintenance behaviour, at 14 (A1), 16 (A2) and 19 (A3) weeks of age. The general activity of each of the animals was recorded at 10 min intervals over 24 hours. A significant effect of sire was found in the number of standing bouts (AMS1=36; STB9=38; PEL2=40, P<.05); a significant effect of gender in the time of lying (832 min males vs 802 min females, P<.05) and standing (608 min males vs 638 min females, P<.05), in the number of bouts when lying on the right side (20.1 males vs 18 females, P<.05) and standing (37.6 males vs 39.3 females, P<.05). The effect of age was highly significant in the time spent lying (A1=750 min; A2=826 min; A3=881 min, P<.01), in the time spent lying while ruminating (A1=325 min; A2=416 min; A3=450 min, P<.01), in the time of lying on the right side with rumination (A1=136.7 min; A2=157.6 min; A3=172.4 min, P<.01), in the time of standing (A1=690 min; A2=613 min; A3=559 min, P<.01), ruminating (A1=336 min; A2=442 min; A3=475 min, P<.01) and feeding (A1=289 min; A2=397 min; A3=327 min, P<.01), in the number of bouts lying while ruminating (A1=12.4; A2=15.8; A3=16.3, P<.01), number of bouts lying on the left side with rumination (A1=6.6; A2=8.8; A3=9, P<.01) and in the number of ruminating periods (A1=13.9; A2=18; A3=18.7, P<.01). A significant effect of age was found in the number of lying bouts on the right side (A1=17; A2=20.6; A3=20, P<.05). Significant interactions for sire x gender were found in the number of standing bouts (P<.05),

sire x age in the time of standing ($P < .05$), time of lying while ruminating ($P < .05$) and in the number of lying bouts on the right side ($P < .01$), and gender x age in the number of standing periods ($P < .01$). The results show that females stood more. Times spent lying, ruminating and feeding were increasing with the age, similar as the number of bouts lying while ruminating, lying on the left side with rumination, ruminating and lying bouts on the right side. We concluded from the analysis, that the effect of the sires' genotype was manifested only in the number of standing bouts.

Key Words: Calves, Behaviour, Sire

1146 Feeding behavior of lactating dairy cows as measured by real-time control system. Zadok Shabi^{*1}, Michael Murphy¹, and Uzi Moallem², ¹University of Illinois, ²A.R.O, The Volcani Center, Israel.

To increase milk production various management schemes are used by dairy producers. These include increase feeding-frequencies, cooling system, more milking per day, artificial lighting, processing of feedstuffs, and manipulating the diet composition. Using one of these management tools or combination of two or more might affect eating behavior. The effect of most of these management tools on daily eating behavior pattern is not yet known. Dairy producers can use knowledge of animal behaviour to improve cow well being and performance. A real-time control system for individual food intake of group-housed lactating dairy cows was used to evaluate feeding behavior. The system consists of 40 feeding stations, one for each cow. Each station equipped with individual identification system, on line scale and logic controller. These systems enabled measurement and recording for each visit the date, entrance time, exit time, and food consumed. Later, daily food consumption, number of visits, meal duration, and rate of food intake were calculated from the recorded database. The average daily intake was 36.0 kg as fed /d, time spent eating was 170.3 min/cow/d, and 12.0 visits daily. A statistic model, which combines two normal curves, was fitted to data from 2 mo during the summer. The bi-normal model explained more than 91.0% of variation in feeding behavior ($P < 0.01$). The first peak was at 0814 (mean sunrise 0508) with a CV of 24.0%. The second peak was at 1634 (mean sunset 1818) with a CV of 6.4%. The later the second peak in feed consumption, the more visits cows made to the feeder ($r = .363$, $P < 0.02$). The broader the second peak in feed consumption, the more total feed was consumed ($r = .378$, $P < 0.03$). On average, 61% of the total intake was associated with the first peak. These results have likely implications for scheduling milking and feeding times to maximize intake and production.

Key Words: Feeding behavior, Dairy cows

1147 Behavioral and physiological responses of calves to dehorning using a long acting local anesthetic. J. W. Forehand^{*1}, H. G. Kattesh¹, T. J. Doherty¹, M. G. Welborn¹, A. M. Saxton¹, J. L. Morrow², and J. W. Dailey², ¹University of Tennessee, Knoxville TN, ²ARS-USDA, Lubbock, TX.

Behavioral and physiological responses after dehorning by heat cauterization were measured in 32, 10 to 12-wk old female Holstein calves. Each calf was randomly allotted to one of four treatments; 5% lidocaine followed by dehorning (F), 2% lidocaine followed by dehorning (T), saline followed by dehorning (S), or 5% lidocaine followed by sham dehorning (C). Physiological responses were assessed by collecting blood via a jugular catheter at -0.5, 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 9, 12, 24, 48, and 72 h. Feeding, drinking, scratching, grooming, rubbing, licking, and inactivity behaviors were observed in the standing and recumbent positions using a 10-min scan sampling method and analyzed on a time period and daily basis for 72 h following the procedure. Acute phase proteins and immunological components were determined at 0, 12, 24, 48, and 72 h. Plasma cortisol was not affected by treatment ($P = .07$) or treatment by time interaction ($P = .06$), but there was an overall significant ($P < .001$) time effect. Calves showed an immediate increase in cortisol within the first 0.5h (9.3 ± 1.1 vs. 18.8 ± 2.2 ng/mL) and again from the 4 h to 6 h samples (5.7 ± 1.4 vs. 10.4 ± 1.3 ng/mL). Fibrinogen concentration and neutrophil:lymphocyte (N:L) ratio were not altered ($P > .1$) by treatment. However, N:L was highest ($P < .01$) at 12 h. For the first 24 h post-dehorning, behaviors of all calves were similar and frequencies of scratching, licking, grooming, and head rubbing in the recumbent and standing positions were near zero. Treatment differences in recumbent inactivity were not significant ($P = .09$),

but there was an overall increase in inactivity for all groups over time ($P < .001$). Eating and drinking frequency were not affected ($P > .05$) by treatment. Thus, behavioral and physiological responses following dehorning by heat cauterization do not appear to be different in calves with or without prior administration of 2 or 5% lidocaine.

Key Words: Dehorning, Behavior, Anesthesia

1148 The effects of management stressors on cortisol production in various breeds of bulls. J.W. Koch^{*1,2}, S.R. Tatman¹, D.A. Nueundorff¹, T.W. Wilson¹, A.W. Lewis¹, C.C. Chase³, T.H. Welsh², and R.D. Randel¹, ¹Texas Agricultural Experiment Station, Overton, TX, ²College Station, TX, ³ARS, USDA, Brooksville, FL.

Beef management practices may induce stress responses in cattle. The influence of breed on response to transportation and restraint was studied using Angus ($n=7$, A), Bonsmara ($n=8$, BO), Brahman ($n=8$, BR), Romosinuano ($n=10$, R), Tuli ($n=10$, T) and Wagyu ($n=10$, W) bulls. Blood samples were obtained by tail venipuncture [5 min prior to and post transportation (30min, 18mile)] and by jugular cannula every 15 min for 6 h. Pre-transportation plasma cortisol did not differ among breeds (13.9 ± 3.5 , A; 4.5 ± 3.5 , BO; 12.6 ± 3.2 , BR; 9.5 ± 3.0 , R; 8.0 ± 3.0 , T; 5.2 ± 3.2 , W ng/ml, respectively). BR, R, A, and T had similar post-trailer cortisol concentrations (26.3 ± 4.0 , 24.3 ± 3.8 , 18.5 ± 4.4 , 17.1 ± 3.8 , respectively). However these values exceeded ($P < .02$) that of the BO (2.4 ± 4.4) bulls which was similar ($P > .22$) to the W (9.7 ± 4.0) bulls. Post-trailer cortisol did not differ among A, T and W bulls. R, BR and T had similar change of post-trailer and pre-trailer cortisol concentrations (14.8 ± 3.4 , 13.6 ± 3.6 , 9.1 ± 3.4 ng/ml), but greater ($P < .04$) than that of the BO (-2.1 ± 3.9). The R (14.8 ± 3.4) differed ($P < .05$) from the A and W (4.6 ± 3.9 , 4.5 ± 3.6) which were similar ($P > .08$) to that of the BO, T and BR (-2.1 ± 3.9 , 9.1 ± 3.4 , 13.6 ± 3.6). There was a breed difference ($P < .05$) for cortisol concentrations for the first two hours, but no difference for the second two or third two hours. The average plasma cortisol concentrations for all samples during the 6-h period, average cortisol for the middle two and last two hours and lowest cortisol concentration for the six h window did not differ ($P > .13$). BR, A, R and T had similar highest mean cortisol concentrations (25.7 ± 3.8 ; 25.5 ± 4.4 ; 22.5 ± 3.4 ; 21.1 ± 3.4 , respectively). BO and W had similar highest mean cortisol concentrations (12.9 ± 3.8 ; 12.6 ± 3.4), but this was lower than that of BR, A and R bulls. Various breeds of bulls respond differently to normal management stressors.

Key Words: Bulls, Transportation, Restraint

1149 Effects of cooling strategies on physiological responses to heat challenge. K. M. Spurlin^{*}, D. E. Spiers, M. Eilersieck, and J. N. Spain, University of Missouri - Columbia.

An environmental chamber study was designed to evaluate physiological responses initiated at various levels of heat stress with particular interest in digestive function. Thermal status measurements are summarized. Four fistulated cows were used to compare 4 cooling strategies. Treatments were 24 h (24h; continuous fan cooling), 12 h nighttime (12N; fans on between 1900 and 0700), 12 h daytime (12D; fans on between 0700 and 1900), and no cooling (NO). Treatments were administered during consecutive 14-d periods arranged as a 4x4 Latin Square. Cows were housed in a climate-controlled room during the experiment. Periods included 6 d thermoneutral (20 C), 3 d step-up, followed by 5 d heat challenge. During heat challenge, maximum ambient temperature reached 32 C between 1400 to 1800 and was lowered to 22 C from 0200 to 0600. On d 6 to 14, respiration rates (RR), skin temperatures at the tailhead (TT), rump (RuT), and shoulder (ST), as well as rectal temperatures (ReT) were recorded at 0500, 1000, 1500, 1900, and 2200 h. There were no treatment effects ($P=0.28$) for ReT; however, there was a trend toward significance for RR and TT ($P=.16$ and $P=.11$, respectively). These responses indicate animals were able to effectively respond to the thermal challenge. Mean RuT temps were 33.4, 33.7, 33.8, and 33.8C for 24h, 12N, 12D, and NO, respectively. RuT for the 24h group was lower than that of all other groups ($P < .05$); RuT for the 12N group tended ($P=.06$) to be lower than that for the NO group. Least square means for SS temperatures were 33.0, 33.2, 33.6, and 33.7 C for 24h, 12N, 12D, and NO, respectively. Both 24h and 12N ST were different ($P < .05$) from each other and the other 2 groups. A treatment by time interaction ($P < .05$) was only observed for ST measurements. All measurements had significant ($P < .05$) day, time, and day by time

effects. Animal responses indicate that the minimum nighttime temperature was low enough to allow sufficient heat loss to cool at night without fans. Regardless of cooling strategy, animals maintained thermal balance through effective thermoregulatory responses during the 5 d heat challenge.

Key Words: Heat stress, Thermal status, Cooling

1150 Evaluation of a model to predict internal body temperature in feedlot cattle during summer heat. L. E. McVicker*, M. J. Leonard, and D. E. Spiers, *University of Missouri, Columbia, MO.*

Exposure of feedlot cattle to summer heat in the absence of shade results in reduced overall performance. A 12-day field study was conducted in year 2000 to refine a predictive model of core temperature by comparison with our 1999 model. Angus x Simmental steers (445+/-9 kg; n=24) were kept in unshaded feedlot pens, and provided with a typical finishing diet and water *ad libitum*. Implanted telemetric temperature transmitters (CowTemp, Model BV-010) were placed in the peritoneal cavity (T_{core}) and rumen (T_{rm}) in years 1999 and 2000, respectively, to continuously monitor core temperature. Data loggers (Onset "Hobo") recorded ambient conditions, including percent relative humidity, air temperature (T_a), and black globe temperature (BG) to identify radiant heat load. Both temperature-humidity (THI) and black globe temperature-humidity (BGTHI) indices were calculated using these values. Initial comparisons showed that T_{rm} was 0.6°C higher than T_{core} at non-heat stress T_a of 25°C or less, with a gradual reduction to 0.3°C at 35°C. Temperature of both sites reached lowest level at 0700 and highest within 1-2 h of daily maximum T_a . Further analyses used only day values. Highest correlation coefficients for prediction of T_{core} (1999) were obtained with $T_a \times BG$ ($r = .90$; $P < .001$) and $THI \times BGTHI$ ($r = .89$; $P < .001$) values that preceded T_{core} by 1 h. In 2000, highest correlation coefficients for prediction of T_{rm} utilized $THI \times BGTHI$ ($r = .84$; $P < .001$) and $T_a \times BG$ ($r = .81$; $P < .001$) values at 3 h before T_{rm} . A second-order polynomial expression best described these relationships with only a 1-2 h delay. However, comparable correlations at a 3 h delay required only a linear expression. Changes in thermal status of cattle in a feedlot environment can be predicted using the combination of air and black globe temperature inputs. Predictive success is improved with inclusion of time delays of 1-3 h. Separate predictive equations for internal temperature must be developed for different core regions.

Key Words: Heat Stress, Models, Cattle

1151 Effects of simulated preslaughter holding and isolation on stress responses and live weight shrinkage in goats. G. Kannan*, T. H. Terrill, B. Kouakou, S. Miller, S. Gelaye, and E. A. Amoah, *Agricultural Research Station, Fort Valley State University, Fort Valley, GA.*

The objective of this experiment was to determine the effects of preslaughter feed withdrawal duration and isolation on physiological responses and shrinkage in goats. A total of 84 Spanish does (6 mo of age, average weight 35 kg) were individually weighed and scored for excitability before the two replicate (day) trials. The does were feed deprived (FD) or fed (F) in holding pens (treatment, TRT) for either 0, 7, 14, or 21 h (TIME). At the end of the holding periods, FD and F does were blood sampled (n = 6 does/treatment/time/replicate) and weighed again to assess physiological responses and shrinkage. Individual does from each pen were then subjected to one of three handling post-treatments (PTRT): a 15-min isolation with no visual contact with other does (I); a 15-min isolation with visual contact (IV); or no isolation (C, control). Blood samples were collected again after imposing PTRT. The data were analyzed as Split-Unit designs using MIXED procedures in SAS. Plasma cortisol concentrations were influenced by TIME ($P < 0.01$), but not by TRT when measured after the holding periods. Plasma T3, T4, and leptin concentrations, and differential leukocyte counts (neutrophil, lymphocyte, eosinophil, monocyte) were not influenced by any of the factors. Excitability scores did not have any significant effect on the variables measured. Shrinkage increased with increasing holding time ($P < 0.01$), but more prominently in the FD group (TRT x TIME, $P < 0.01$). The FD group also had greater shrinkage than the F group ($P < 0.01$). Plasma cortisol concentrations were greater in I and IV groups than in the C group ($P < 0.01$). The results

indicate that the novelty of environment during preslaughter holding may be a more potent stressor than feed deprivation in goats, although shrinkage may increase with increasing feed withdrawal times. Stress can significantly increase when animals go through the isolation chutes just prior to slaughter.

Key Words: Goats, Preslaughter holding, Isolation stress

1152 Effect of animal handling method on the incidence of stress response in market swine in a model system. M. E. Benjamin*¹, H. W. Gonyou², D. J. Ivers³, L. F. Richardson³, D. J. Jones³, J. R. Wagner³, R. Seneriz³, and D. B. Anderson³, ¹Elanco/Provel Animal Health, Calgary, Canada, ²Prairie Swine Centre, Saskatoon, SK, Canada, ³Elanco Animal Health, Greenfield, Indiana.

The relationship between aggressive handling of lean pigs, including the use of an electric prod, and subsequent behavioral and physiological responses was studied to develop methods for simulating conditions which may result in non-ambulatory (SUBJECT) pigs at slaughter plants. One-hundred eight barrows and gilts weighing approximately 120 kg were randomly assigned to groups of six for moving, loading and unloading in one of two handling treatments. In the aggressive handling treatment (AGGRESS), the handler moved the animals through a 300 m course, including a high loading ramp, with frequent use of an electric prod. In the gentle handling treatment (GENTLE), the handler proceeded at a moderate pace through the same course, except that the loading ramp was lower and a plastic cane was used in place of the prod. Groups were treated consecutively to avoid circadian and ambient temperature bias. The handler and pig behavior were documented using direct observation. The same handler conducted both treatments. Serum lactate, glucose, NEFA, CPK, BUN, ammonia, acetacetate and cortisol were measured immediately after handling. Heart rate (HR) and skin and rectal body temperatures (sTEMP, rTEMP) were measured pre, during and post handling. Subjective scores were recorded for indications of blotchy skin (SKIN), open mouth breathing (BREATH) and vocalization (VOCAL). Pigs wedged (STUCK) during handling were recorded as well as the dependent behavior SUBJECT (inability to move, higher rTEMP, blotchy skin). This study suggests that the AGGRESS treatment resulted in a significant increase in SKIN, BREATH and VOCAL during each of the observation points ($P < 0.001$). Analysis of pen means demonstrated a significant association between AGGRESS treatment and dependent variables sTEMP, rTEMP and HR. Serum lactate and glucose were higher ($P < 0.005$) in the AGGRESS treatment group. While eleven pigs were classified as SUBJECT pigs in AGGRESS, none were found in GENTLE. When individual SUBJECT pigs were compared with the remaining pigs of AGGRESS there were significant positive associations with dependent variables ammonia ($P < 0.05$) and STUCK ($P < 0.05$). The behavioral and physiological responses of the pigs provide strong indicators of the stress induced by aggressive handling.

Key Words: Swine, Handling, Subject animals

1153 Variation in Hen Vocalizations During Pre-hatch, Hatch and Post-Hatch. M.B. Woodcock*, M.A. Latour, and E.A. Pajor, *Purdue University, West Lafayette, IN 47907.*

Vocalizations between hens and chicks around the time of hatch are commonly reported for poultry kept in natural conditions. Commercial incubators do not presently include such sounds, which may result in a more asynchronous hatch than under natural conditions. Before this hypothesis can be tested a better understanding of the hens calls, and their function is required. Although the occurrence of vocalizations around the hatch has been previously reported, details regarding the frequency and duration of hen calls have not. The purpose of this study was to describe in detail the pattern of a hen's vocalizations around a natural hatch. Four hens were placed in pens and audio and videotaped each day, during a 16 h light period (0400 to 2000 h), for 30 d (20 d before hatch and 10 d after hatch). Hen vocalizations were quantified in detail during three periods: pre-hatch (48 h before hatch), hatch (0 to 24 h), and post-hatch (48 h after hatch). Of the 4 hens, only two hens became broody and vocalized. Hens vocalized less at pre-hatch than during the hatch ($p < 0.001$) or post-hatch ($p < 0.001$). The average call rates on the day of hatch and post-hatch did not differ. However, the daily

pattern of calls differed greatly. On the day of hatch, calling rate gradually increased over the 16 h period. In contrast, during the post-hatch period, hen calls increased quickly during the first nine h, and then declined dramatically. The amount of time spent calling changed over the duration of the 16 h period. Hens spent more time calling at hatch than pre-hatch ($p < 0.001$), and more time calling in post-hatch than hatch ($p < 0.05$). In summary, the hens called more and spent more time calling as incubation progressed through hatch. A better understanding of parent - offspring communication during hatching may lead to beneficial applications to the commercial poultry industry.

Key Words: Poultry, Vocalization, Incubation

1154 The relationship between physiological parameters and behavioral response to social stress among three genetic lines of laying hens. R. Freire*², P. Singleton¹, Y. Chen¹, M.W. Muir², Ed. Pajor², and H.W. Cheng¹, ¹USDA-ARS, Livestock Behavior Research Unit, ²Dept of Animal Science, Purdue University.

Two genetic lines of White Leghorn hens have been selected for high (HGPS) and low (LGPS) group productivity and survivability resulting from cannibalism and flightiness. Different behavioral patterns induced by heat and cold stress have been reported between the selected HGPS line and a commercial Dekalb XL (DXL) line. The aim of this study was to examine differences in the behavioral response to social stress among the three genetic lines and relate these differences to physiological variables that were reported previously. Twenty hens from each of the three genetic lines were paired to form 3 mixed line combinations and kept in cages from 17-wk to 24-wk of age. Activities were recorded from video using instantaneous sampling at 1-min intervals for 30 min and continuous recording of aggressive pecking in a 10 min period started at 0800 daily. No evidence was found that the three genetic lines differed in dominance status ($P > 0.1$ for 3 combinations) or attack latencies ($P > 0.7$). The HGPS hens spent less time pecking at the feathers or body of another hen (damaging pecking) than LGPS hens ($P < 0.05$). In addition, pecking at the cage (cage pecking) was lower in HGPS and LGPS hens than in DXL hens ($P < 0.01$). The differences in damaging pecking could not be explained by variation in physiological variables ($P > 0.2$), but a large proportion of the variation in cage pecking ($r^2=59\%$) among the lines ($P < 0.001$) was explained by physiological variables, such as its unique alterations of heterophil/lymphocyte (H/L) ratio and corticosterone levels reported previously. In conclusion, the lower damaging pecking and cage pecking in HGPS hens may be related to their

lower social stress in 2-hen cages when compared to the other two lines. The data suggests that the genetic lines could be used as animal models for stress physiological observations.

Key Words: Social stress, behavior, Genetic selection, chickens.

1155 Stress induced alterations of IgG concentrations and hematological parameters in genetically selected chicken lines. Y. Chen*¹, P. Singleton¹, M.W. Muir², and H.W. Cheng¹, ¹USDA-ARS, Livestock Behavior Research Unit, ²Dept of Animal Science, Purdue University.

Two genetic lines of White Leghorn hens were selected for high (HGPS) and low (LGPS) group productivity and survivability resulting from cannibalism and flightiness. The aim of this study was to examine whether the selection alters the hens' immunity and hematology differently in response to social stress. At 17-wk of age, hens were randomly assigned into single- and 2-hen cages. The 2-hen cages contained one hen from HGPS or LGPS and one from a commercial Dekalb XL line that was used as standardized genetic competitor. At 24-wk of age, blood samples were collected from 70 hens (10 hens from 3 line, 2 replicates, plus 10 extra testers). Blood smears were prepared and stained with Wright's stains. A differential leucocyte count was collected from 200 leukocytes per hen. Concentrations of plasma IgG were quantified using ELISA. In single-hen cages, compared to HGPS hens, LGPS hens had a greater heterophil/lymphocyte (H/L) ratio ($P < 0.01$). In addition, LGPS hens had a greater number of eosinophils ($P < 0.01$). However, there was no difference in the concentrations of IgG between HGPS and LGPS hens. In 2-hen cages, when compared with these same lines in the single-hen status, LGPS hens exhibited a heterophilia, and a greater ratio of H/L ($P < 0.01$). In addition, although both HGPS and LGPS hens had an eosinophilia in 2-hen cages, a more intense increase was found in LGPS hens ($P < 0.001$). In contrast, HGPS hens had a greater increase in the concentrations of IgG in 2-hen cages vs. single-hen cages ($P < 0.01$). The data indicates that the immunity and hematology were differently regulated by the selection in the HGPS and LGPS lines. The changes of these physiological parameters in HGPS hens could be associated with their better adaptation to social stress that has been reported previously. Some of the parameters, such as ratio of H/L, eosinophilia, and IgG concentrations, could be used as an indicator of chicken well-being.

ASAS/ADSA Ruminant Nutrition: Feed Additives, Rumen Fermentation, Minerals, and Transition Cows

1156 Use of exogenous enzymes from amylases from *Bacillus licheniformis* and *Aspergillus niger* in high-grain diets. R Rojo, G Mendoza*, S Gonzalez, R Barcena, M Crosby, and L Landois, *Colegio de Postgraduados*.

Two industrial amylases, alpha-amylase from *Bacillus licheniformis* and glucoamylase from *Aspergillus niger* were evaluated as exogenous enzymes in sheep fed high-grain diets. Amylolytic activity was compared with ruminal amylases at conditions of pH and temperature similar to the rumen. In situ DM digestibility of sorghum diets (79%) was measured at 12 h of ruminal incubation. Amylases were added to the sorghum (2.9 g enzyme/kg grain) before mixing the diet. Fifteen sheep were used in a completely randomized design (control, amylase or glucoamylase) and individually fed for 40 d. The highest activity (units/mg protein) was found ($P < 0.01$) in the amylase from *B. licheniformis* (4.1893) followed by the *A. niger* (1.9522) and ruminal fluid (0.0621). Addition of alpha-amylases increased in situ DM digestibility (%) at 12 h (control, 60.78), being greater with *B. licheniformis* (65.6) than *A. niger* (64.3). Intake was not affected by enzyme addition and no statistical differences were found in ADG (Control 238, *A. niger* 258, *B. licheniformis* 270 g/d), even when feed conversion numerically tended to be improved with the amylases (Control 4.59, *A. niger* 4.01, *B. licheniformis* 3.93 g/d). Despite the high amylolytic activity of the amylases and the improvements on in situ DM digestibility, no differences were detected in sheep performance.

Key Words: Enzymes, Grains, Starch

1157 Effect of direct-fed microbials supplementation on dairy cows fed nitrogen deficient diets and on *in vitro* bacterial growth. D. R. Ouellet* and J. Chiquette, *Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, Canada*.

Eight rumen fistulated Holstein dairy cows (679 kg BW; SEM = 5) were used in a duplicated 4 x 4 Latin square design with a 2 x 2 factorial arrangement of treatments. Dairy cows were fed diets formulated to be adequate (CTL) or deficient (DEF) in metabolizable protein (MP; 12% less than requirements). The two diets were fed with or without direct-fed microbials (DFM) supplement (10 g /head/d of a mixture of *Aspergillus oryzae* and *Saccharomyces cerevisiae*). Total mixed ration (60:40 grass silage:barley based concentrate) was fed 12 times daily. Dry matter intake, milk production and composition were determined. The DFM mixture was also supplied, *in vitro*, to pure bacterial cultures in order to study the effect on bacterial growth rate. Given the high milk yield, both diets were estimated (NRC, 2001) to be deficient (10 and 14% less MP than requirements for CTL and DEF, respectively). Milk production averaged 40.3 kg/d and was not affected by the level of MP in the diets or by DFM. Dry matter intake tended to be lower for cows fed DEF (21.2 vs 22.9 kg/d, $P < 0.07$) resulting in a tendency ($P < 0.09$) to improve milk efficiency by 9%. Milk constituents (protein, fat and lactose) were unaffected by treatments. When supplied *in vitro*, the DFM mixture stimulated the growth of *Selenomonas ruminantium* ($P < 0.001$), *Streptococcus bovis* ($P < 0.02$) as well as some cellulolytic species such as *Butyrivibrio fibrisolvens* ($P < 0.02$) and *Fibrobacter succinogenes* ($P < 0.01$). On the other hand, DFM did not

affect the growth of *Ruminococcus albus* or *Ruminococcus flavefaciens*. In conclusion, except for bacterial growth *in vitro*, addition of direct-fed microbials to diets deficient in metabolizable protein had no effect on the *in vivo* parameters reported.

Key Words: Direct-fed microbials, Dairy Cattle, Protein Deficiency

1158 Exogenous amylases from *Bacillus licheniformis* and *Aspergillus niger* improve starch digestion but not performance of sheep. G Mora, R Barcena, G Mendoza, S Gonzalez, and J Herrera, *Colegio de Postgraduados*.

Two industrial amylases, alpha-amylase from *Bacillus licheniformis* and glucoamylase from *Aspergillus niger*, were evaluated as exogenous enzymes in sheep fed 50% sorghum grain (30% corn stover; 9% soybean meal; 9% molasses; 1% urea; 1% minerals). Enzymes were added at 2.1 g/kg sorghum, with three treatments: Control, amylase from *Bacillus licheniformis* and glucoamylase from *Aspergillus niger*. A metabolic trail was conducted using a 3 x 3 Latin Square design with 3 sheep (68 3.0 kg BW) fitted with ruminal and duodenal cannula. The same treatments were randomly allotted to 21 lambs (26 23.9 kg initial BW) individually fed during 60 days; a Completely Randomized Design with initial BW as a covariate was used. Ruminal starch digestion was lower ($P < .05$) in the control group (75.1%), as compared to exogenous enzymes (82.95% amylase; 87.2% glucoamylase); ruminal pH, ammonia-N or VFA did not change. No differences ($P > .05$) were found in total tract starch digestion. In the growing assay, enzymes did not change ($P > .05$) (kg/d; 1.16 control; 1.29 amylase; 1.19 glucoamylase), daily gain (g/d; 211 control; 231 amylase; 209 glucoamylase) or feed conversion. Although ruminal starch digestion was improved with exogenous enzymes, no differences were detected in sheep performance.

Key Words: Starch, Digestion, Enzymes

1159 Influence of monomer or dimer forms of isopropyl ester of HMB, on the supply of metabolisable methionine to the blood of ruminants. J.C. Robert*, C. Richard, and B. Bouza, *Aventis Animal Nutrition, Antony, France*.

In this experiment, three products were tested : HMBi(M) (2 hydroxy 4(mthyl thio) butanoic acid isopropyl ester), containing 99% of monomers ; HMBi(MD) composed of 57% of monomers and 40% of dimers and SmartamineTM M(Sm M) a methionine coated with a pH sensitive polymer based coating. Two non lactating rumen cannulated Holstein cows were used. Four treatments were given (4x one week periods) randomized between the two cows in a single dose : T1 : 65 g (M) ; T2 : 65 g (MD) ; T3 : 111 g (MD) ; T4 : 63 g Sm M. T4 was supplied at 1600h the first day (D1) for each experimental period and T1, T2 and T3 on D2 at 0800h. The animals were offered 10 kg/animal/day of a ration comprising 75% hay and 25% concentrate delivered in equal quantities twice a day. Blood samples were obtained on D2 of each experimental period at 0800, 0900, 1000, 1100, 1300 and 1500h and on D3 at 0800h. For T4, some additional blood collections were realized on D2 at 1800 and 2000h and on D3 at 0800, 1100 and 1500h to describe more completely the appearance of methionine in the blood. Blood plasma methionine concentrations (BPMC mg/100g) were measured on D1 at 1100h to establish base line values. Based on comparison of AUC and taking into account a reference value of 80% for bioavailability of methionine from SmartamineTM M , the bioavailability of methionine into the blood from an oral single dose was 44% for HMBi(M). Dimers did not show any methionine bioavailability.

1160 A blood kinetics methodology to measure bioavailability of rumen protected methionine sources for ruminants. J.C. Robert*, G. Etave, T. D'Alfonso, and B. Bouza, *Aventis Animal Nutrition, Antony, France*.

This experiment was designed to describe the relationship between spot digestible methionine supply and plasma methionine response in terms of Area Under the Curve (AUC). Four non lactating rumen cannulated Holstein cows were randomly assigned to four treatments in a latin square design (4x1week periods) . The four treatments comprised four levels of SmartamineTM M - a methionine coated with a pH sensitive polymer based coating : T1 : 7.1, T2 : 17.8, T3 : 28.6 and T4 : 39.3 ; all values relate to estimated intestinal available methionine(g/day). SmartamineTM M was supplied through the rumen cannula into the rumen liquid phase at 1600h on the first day (D1) of each experimental period. The animals were offered 10 kg/animal/day of a ration comprising 75% hay and 25% concentrate delivered in equal quantities twice a day. Blood samples were obtained on the second day (D2) of each experimental period, every two hours, starting at 0600h for the first eight samples and thereafter every four hours from 0600 until 1800h for D3 and D4. Blood plasma free methionine concentrations (BPMC mg/100g) to determine base line values were measured on D1 at 0900, 1100 and 1500h. The best relation between AUC(Y) and quantity of digestible methionine (X :g) was described by the exponential equation: $Y = - 15.937454 (1 - \exp(0.038261 X))$ (SED=0.57). The objective, in the future, is to use this equation as a calibration to calculate the bioavailability of different sources of rumen protected methionine.

1161 Effect of live yeast versus yeast culture on milk yield and related parameters in early lactation cows. G. Higginbotham*¹, J. Merriam², E. DePeters³, and J. Sullivan⁴, ¹University of California Cooperative Extension, Fresno/Madera Counties, ²University of California Cooperative Extension, Stanislaus/Merced Counties, ³University of California, Davis, ⁴Nutrius/Bioproducts, Kingsburg, CA.

Live yeast and a yeast culture were compared in the diets of lactating cows. Two pens of early lactation Holstein cows on a commercial dairy farm, each totaling approximately 200 cows, were used to investigate effects of supplementing their diets with a feed additive containing

live *Saccharomyces cerevisiae* yeast (BIOY) or an additive containing fermentation products produced from a yeast culture (YC). Pens were similar in cow composition for parity and averaged 100 days in milk at the start of the study. Experimental design was a crossover with two 4-week periods. Both treatment pens were fed a mixed ration 2x daily composed of alfalfa silage, alfalfa hay, flaked corn, whole cottonseed, corn distillers, almond hulls, wheat millrun, soybean meal, mineral mix, molasses, animal fat and EnerGII[®]. Both feed additives were fed once daily in the TMR. The BIOY group received 114g/cow/day of BIOyeast[®] which provided 4g of Procreatin-7[®] (SAF Products, Minneapolis, MN), or 60 billion live CFU. The YC group received 114g/cow/day of Diamond V yeast culture[®] (Cedar Rapids, IA). Cows were milked three times daily and housed in freestalls with access to an open dry-lot. Milk yield and composition were recorded by measuring milk weights from two milkings for three consecutive days during the last week of each period. Daily feed intake as well as feed refusal were measured on a pen basis using the EZfeed[™] feed management program Adjusted mean production per cow for the complete trial, based on milk measurements at the end of each period, was not different and averaged 44.2 and 44.5 kg/d (milk) and 43.6 and 43.5 kg/d (3.5% FCM) for BIOY and YC groups respectively. No difference in percentages of milk fat, protein, lactose and SNF occurred. Rumen fluid pH, total VFA concentration and blood urea N as measured from 8 cows per treatment were unaffected by treatment. Dry matter intake, which was measured on a pen basis, was similar. Results suggest that similar milk production responses can be achieved by feeding either live yeast or the metabolites produced from a yeast fermentation process.

Key Words: Yeast, Yeast culture, Milk production

1162 Milk production effects of a mycotoxin binder in diets with normal levels of contamination. A. Garcia^{*1}, M. L. Cuevas¹, G. A. Loarca², C. Landetta³, and R. A. Patton⁴, ¹Instituto Tecnológico y de Estudios Superiores de Monterrey, Queretaro, Qro/Mexico, ²Universidad Autónoma de Queretaro, Queretaro/Qro/Mexico, ³Grupo Karluis, Queretaro, Qro/Mexico, ⁴Nittany Dairy Nutrition, Mifflinburg, PA/USA.

We investigated the effect of inclusion of a specific mycotoxin binder (Mexsil^{MR}, Grupo Karluis) on the milk producing ability of dairy cows fed low levels of dietary mycotoxins. Cows were divided equally into 2 treatment groups based on milk yield and parity. They were fed TMR and were milked 2X per day for 12 periods of 2 weeks each. Dietary treatments consisted of the normal diet and normal diet plus 125 g of mycotoxin binder. Feed samples were submitted to a laboratory for nutrient and mycotoxin analysis. Corn silage and TMR were screened for aflatoxin, zearalenone, deoxynivalenol (DON), fumonisin and T-2 toxin using commercial kits. Milk production and milk components were determined biweekly. Health and reproduction data were recorded. Statistical analysis was performed using Proc Mixed of SAS with pretreatment production variables used as covariates. Factors in the model were diet, parity, period and BST. TMR samples had greater mean concentration of mycotoxins than did corn silage samples except for zearalenone. Mean mycotoxin levels in the TMR across the study were below accepted tolerances. However, mycotoxin concentration was not constant due to SE of about 100 percent. Mean biweekly T-2 levels were elevated in periods 6 and 8. Total mycotoxin levels were elevated in periods 6, 8 and 10. Milk production of control cows declined in periods of higher mycotoxins. SCC and BCS were improved overall for binder treated group. Mean production response to feeding mycotoxin binder for 12 weeks is presented below. We conclude that when feed levels of T-2 are in excess of recommended even for a short time, inclusion of this mycotoxin binder will lessen production decreases.

1163 Milk production in Holstein cows supplemented with different levels of ruminally protected methionine. A. Lara^{*1}, G.D. Mendoza², R. Barcena², C.M. Garcia², and L. Landois², ¹Universidad Autónoma Chapingo, ²Colegio de Postgraduados.

The effect of different levels of ruminally protected methionine (RPMet) were studied in lactating cows. Forty multiparous Holstein cows were fed a basal diet (18.8% CP, 35% ruminal degradable protein, and 1.7 Mcal kg-1 Enl) with alfalfa, corn silage and concentrate (48% forage: 52% concentrate). After calving, cows were randomly assigned to the treatments, which consisted in four levels of RPMet: 0, 8, 16 and 24 g d-1 of MepronM85 (Degusa Co.). Milk production and composition were measured over 120 d postpartum. Body weight and condition score, DM intake and milk production were measured each 15 d (3 consecutive days) starting on day 5 post-partum. Milk samples were also collected (07:00 and 18:00 h). Data were analyzed with the repeated measures (four treatments in 8 periods through lactation). No treatment effects (P>.05) were detected on DM intake (25.48 ± 2.51 kg d-1), body weight (599.78 ± 19.78 kg), body condition score (2.51 ± 0.19 units) and milk fat. However, milk production and protein were increased with addition of RPMet (P<.01). Cows supplemented with 8, 16 and 24 g of RPMet produced 2.2, 4.4 and 2.3 kg d-1 of more milk above the control, whereas milk protein output was increased by 93, 158 and 72 g d-1, respectively. Milk production responded quadratically (P<.05) to methionine level (Y = 31.11 + 0.5354 X + 0.0175 X²), with the maximum milk production estimated with 16.2 g d-1 RPMet. Results indicated that Holstein cows with a mean of 35 kg d-1 milk, will require addition of ruminally protected methionine (16 g d-1) to improve milk production.

Key Words: Methionine, Milk production, Milk composition

1164 Enzymic release of reducing sugars from oat hulls by cellulase, as influenced by a synergistic interaction between *Aspergillus ferulic acid esterase* and *Trichoderma xylanase*. P. Yu^{*1}, J.J. McKinnon¹, D.D. Maenz¹, V.J. Racz^{1,2}, and D.A. Christensen¹, ¹Department of Animal and Poultry Science, University of Saskatchewan, Canada, ²Prairie Feed Resource Centre Inc., Canada.

High amounts of hydroxycinnamic acids, mainly *p*-coumaric (PCA) and ferulic (FA) acids, are believed to be inhibitory to oat hull biodegradability by rumen microorganisms. Previous studies have shown that a novel enzyme - *Aspergillus ferulic acid esterase* (A-FAE) and *Trichoderma xylanase* (T-XYL) act synergistically to break the ester linkage between FA and the attached sugar of feruloyl-polysaccharides, releasing FA from oat hulls. We examined maximum enzymic release of reducing sugars from oat hulls with particle size of 250 µm by the action of individual enzyme alone (A-FAE at 4678.4 U/assay; cellulase at 22 levels, ranging from 0 to 2772.7 U/assay; T-XYL at twenty-two level, ranging from 0 to 4096 U/assay) and by the action of cellulase at six levels (6.3 mU, 2 U, 16 U, 128 U, 1024 U and 2772.7 U/assay), as influenced by a synergistic interaction between A-FAE (13 mU/assay) and T-XYL (1 U or 256 U/assay). Total acid-extractable reducing sugars in the oat hulls used in this study were 793.8 µg/mg. The results show that after a 24 h incubation with A-FAE alone, no reducing sugars were observed to be released from oat hulls. With cellulase alone, as the concentration increased from 0 to 2772.7 U/assay, the release of reducing sugars increased (P<0.01) from 0 to 39% with the highest release of reducing sugars at 512 U/assay. With T-XYL alone, as the concentration increased from 0 to 4096 U/assay, the release of reducing sugars increased (P<0.01) from 0 to 33% with the highest release at 2048 U/assay. When incubated together with T-XYL (1 U or 256 U/assay) and A-FAE (13 mU/assay), cellulase (6.3 mU-2772.7 U/assay) significantly increased (P<0.01) release of reducing sugars from 8 to 68%. These results indicate that the synergistic interaction between A-FAE and T-XYL on release FA from feruloyl-polysaccharides could make the remainder of the polysaccharides open for further hydrolytic attack and facilitate the accessibility of the main chain of polysaccharide to cellulase. This action extends the cell wall hydrolysis, thus releasing a higher yield of reducing sugars. Such enzymic pre-treatment of oat hulls may provide a unique advantage to rumen microorganisms for the biodegradation of the complex cell wall of oat hulls.

Key Words: Reducing sugars, Synergistic interaction, Oat hulls

1165 Effects of exogenous enzymes on fiber degradation of corn stalks. G. Tirado-Estrada¹, I. Mejia-Haro¹, C.R. Cruz-Vazquez¹, G.D. Mendoza-Martinez², I. Tovar-Luna³, and J. Fajardo-Pea¹, ¹CIGA ITA de Aguascalientes, Mexico, ²Colegio de Posgraduados, Texcoco, Mexico, ³URUZA- UACH.

To evaluate effects of corn stalks treated with exogenous fibrolytic enzymes on digestibility and ruminal fermentation, a study was carried out in three experimental phases: I, IVDMD; II, in situ DM digestibility (ISDMD); and III, ruminal fermentation patterns. In phase I the effect of the enzyme concentration (E) was evaluated: 0 (control), 1.5 and 3 g kg⁻¹ with three application methods of the enzyme: 1) dry (DE); 2) dry + 250 ml of water (DE+W); and 3) in a solution of 500 ml of water (SE). Treatments were: 0 enzyme (T0; control), 1.5 g of DE (T1), 3 g of DE (T2), 1.5 g of DE+W (T3), 3 g of DE+W (T4), 1.5 g of SE (T5), 3 g of SE (T6). In Phase II, four enzyme levels were used: 0, 1, 2 and 3 g kg⁻¹, two treatment times of corn stalks (0 h = T0 h and 24 h = T24 h), and two forage:concentrate rates, 82:18 (DI), and 73:27 (DII). In Phase III, the effect of the four enzyme levels on digestibility was evaluated on six sampling times 0, 3, 6, 9, 12 and 24 h after the application of the enzyme. Data were analyzed by ANOVA using the GLM of SAS (1985). IVDMD was affected ($P < 0.06$) by enzyme application. T1 was higher ($P < 0.05$) than T0, T4, T5, and T6. ISDMD and residual NDF disappearance (NDFR) of corn stalks were affected ($P < 0.01$) by the E level due to type of diet and E x T and T x D interactions. Treatments with exogenous enzymes had greater values ($P < 0.05$) of ISDMD than the control, and using 1g of E to 24 h presented the highest value ($P < 0.05$). No differences ($P > .05$) were produced by enzyme level on the degradation of ADF. DI was higher ($P < .01$) than DII in both IVDMD and NDFR. In the reduced model (data of DI; 4 x 2) treatment of 1 g of E to T24 h was greater than the rest of the treatments ($P < 0.05$) for ISDMD and NDFR. Quadratic and cubic trends in the complete experiment (Factorial 4 x 2 x 2) were shown for ISDMD and NDFR by enzyme effects and also in the E x T to 24 h interaction ($P < 0.01$). The greatest concentration of total VFA was obtained with 1 and 2 g of E at 3 and 9 h of sampling ($P < 0.05$), and propionate was increased at 1 g of E ($P < 0.05$). The highest concentration of N-NH₄ was reached with 1 and 2 g of E at 3 h ($P < 0.05$). Results indicated exogenous fibrolytic enzymes affect digestibility and fermentation of corn stalks.

Key Words: Fibrolytic, enzymes, Fiber

1166 Effects of an acetyl esterase containing preparation produced by a ruminal fungal isolate on *in vitro* ruminal fermentations. J. M. Tricarico*¹ and K. A. Dawson², ¹University of Kentucky, Lexington, KY, ²Alltech Biotechnology Inc., Nicholasville, KY.

An anaerobic fungus was isolated from the rumen of a steer fed a fescue hay-based diet and was grown anaerobically to produce a crude acetyl esterase containing enzyme preparation. This preparation did not contain measurable amounts of cellulase or xylanase activity. A series of studies were then performed to examine the effects of this enzyme preparation on *in vitro* digestion of a fescue hay-based diet by ruminal microorganisms. Batch cultures, established with rumen fluid from a steer fed the same diet, were used to examine the effects of supplemental acetyl esterase on *in vitro* VFA production. The effects of supplemental acetyl esterase on NDF digestion were examined using the Daisy^{II} *in vitro* incubation system and Ankom²⁰⁰ fiber analyzer (Ankom Technology Corp., Fairport, NY). After incubation at 39°C for 12 h, total VFA production and estimated hexose utilization rates were greater ($P < 0.05$) in cultures receiving the fungal preparation at 0.855, 2.85, 5.70, 8.55 and 11.4 units acetyl esterase/L than in control cultures. Acetyl esterase supplementation increased total VFA production mainly by enhancing ($P < 0.05$) acetate production without affecting the productions of propionate and butyrate except at acetyl esterase concentrations of 11.4 units/L. Total VFA production was greater ($P < 0.05$) in cultures receiving 1.14 units acetyl esterase/L than in control cultures as early as 2.5 h into the incubation. However, NDF digestibility after incubation for 3, 6, 9 or 12 h and the rates of total VFA production calculated for the period of time between 3 and 12 h of incubation were not different between cultures receiving 1.14 units acetyl esterase/L and control cultures. These results indicate that acetyl esterase containing preparations enhance ruminal *in vitro* fermentation of feed and may have an impact on ruminant performance.

Key Words: Ruminants, Digestion, Esterases

1167 Contribution of an acetyl esterase containing enzyme preparation to the action of exogenous enzyme supplements for ruminants. J. M. Tricarico*¹ and K. A. Dawson², ¹University of Kentucky, Lexington, KY, ²Alltech Biotechnology Inc., Nicholasville, KY.

Two studies were performed to examine the effects of combining a fungal enzyme preparation containing acetyl esterase activity and a commercial enzyme supplement for ruminants (Fibrozyme, Alltech, Inc., Nicholasville, KY) on *in vitro* fermentation of feed by ruminal microorganisms. The addition of both enzyme supplements to 1-L ruminal-simulating continuous cultures fed a fescue hay-based diet increased DM digestibility (47.4 vs. 60.2 g, $P < 0.10$), total VFA concentrations (112.7 vs. 122.8 mmoles/L, $P < 0.05$), estimated hexose utilization (62.5 vs. 68.3 mmoles/L, $P < 0.05$) and ammonia concentrations (30.8 vs. 31.4 mmoles/L, $P < 0.05$). Concentrations of acetate, propionate and butyrate were 7.8, 10.8 and 11.7 % greater ($P < 0.05$) in cultures receiving the enzyme supplements than in control cultures, respectively. In addition, enzyme supplementation reduced the acetate to propionate ratio (3.47 vs. 3.37, $P < 0.05$) and the pH (6.92 vs. 6.86, $P < 0.05$). The concentrations of total anaerobic, lactic acid-utilizing and cellulolytic bacteria did not differ in enzyme supplemented and unsupplemented cultures. In the second study, gas production was used to examine the kinetics of digestion in batch cultures fed a fescue hay-based diet, or its water-insoluble fraction, in the presence and absence of supplemental enzymes. Cumulative gas production over a 24-h period was 14 % greater (44.4 vs. 50.7 mL, $P < 0.05$) in cultures receiving the enzyme supplements than in control cultures when the fescue hay-based diet was used as the substrate. The maximum rate of gas production was reached 2 h earlier in enzyme supplemented cultures than in unsupplemented cultures when the water-insoluble fraction from the fescue hay-based diet was used as the substrate. These studies indicate that exogenous enzyme supplements containing acetyl esterase activities enhance ruminal fiber digestion by reducing the time required to reach the maximum rate of fermentation of insoluble substrates in feed.

Key Words: Ruminants, Digestion, Esterases

1168 Intake and milk production of dairy cows fed lactic acid bacteria and mannanoligosaccharide. J. Gomez-Basauri*¹, M.B. de Ondarza², and J. Siciliano-Jones², ¹Alltech, Inc., Nicholasville, Kentucky, ²F.A.R.M.E. Institute, Homer, New York.

The objective of this 28-day study was to determine the effect of a supplement (27.27 g/d) containing strains of lactobacilli *Lactobacillus acidophilus*, *Lactobacillus casei*, *Enterococcus (Streptococcus) faecium* (Total lactic acid bacteria 1 billion CFU's/g) and mannanoligosaccharide (Bio-Mos[®], Alltech, Inc, Nicholasville, KY) on daily dry matter intake (DMI), milk yield, and milk component concentration. Study animals consisted of two groups of 100 cows on a commercial dairy farm. Each group had similar initial milk yield (39.2 Kg/day) and days in milk (DIM, 154 days). Prior to the start of the study, it was determined that no pen effect existed. Cows entering any group during the course of the study were paired on production and days in milk. The basal ration consisted of corn silage, alfalfa/grass hay crop silage, whey, and commercial feed blend. Total ration composition was 17.7% CP, 38% UIP, 37.5% NFC, 4.5% fat, 28% forage NDF, and 1.67 Mcal/Kg NE_l. Thirteen days of milk yield data were used for statistical analysis. Milk was sampled from each cow during one milking on one day during week 3 and week 4 and analyzed for milk components. Cows fed lactic acid bacteria and mannanoligosaccharide consumed 0.42 Kg less DM ($P < 0.03$) and produced 0.73 Kg/d more milk ($P < 0.06$). There was a significant treatment by date interaction ($P < 0.03$). Cows fed lactic acid bacteria and mannanoligosaccharide increased milk yields over time while control cows maintained constant milk yields.

	Treatment	Control	SE	P <
DMI (Kg/d)	24.56	24.98	0.13	0.03
Milk (Kg/d)	39.57	38.84	0.27	0.06
Milk Fat (%)	4.44	4.24	0.07	0.07
Milk Protein	3.04	3.02	0.02	NS

1169 Effects of a commercial bacterial culture feed supplement on ruminal microorganisms. S. A. Martin*, *University of Georgia.*

The objective of this study was to examine the effects of a commercial bacterial culture feed supplement on growth and lactate production by mixed ruminal bacteria grown in batch culture. In addition, the effect of the feed supplement on the *in vitro* fermentation of ground corn or soluble starch by mixed ruminal microorganisms was investigated. When mixed ruminal bacteria were grown in medium that contained 2 g/L maltose, bacterial growth and lactate production peaked at 8 h and lactate was utilized over the next 22 h. Similar incubations were conducted using only the bacterial feed supplement and bacterial growth and lactate production peaked at 24 h and some lactate was utilized over the next 24 h. When mixed ruminal bacteria were incubated in the presence of the bacterial feed supplement, bacterial growth peaked after 8 h and lactate production peaked at 8 h and most of the lactate was utilized over the next 40 h. In 24 h ground corn fermentations by mixed ruminal microorganisms, 3.5 and 7 g/L of bacterial feed supplement decreased ($P < 0.05$) final pH and the acetate:propionate ratio, while 7 g/L decreased methane ($P < 0.05$) and butyrate concentrations and increased ($P < 0.05$) propionate and lactate concentrations. Similar treatment effects were observed in 48 h ground corn incubations except that the 7 g/L treatment increased ($P < 0.05$) butyrate concentration and no lactate accumulated. Fermentation of soluble starch in the presence of both concentrations of bacterial feed supplement for 48 h decreased ($P < 0.05$) final pH, hydrogen, methane, propionate, and butyrate and increased ($P < 0.05$) lactate. Collectively, these results suggest that the bacterial feed supplement alters the mixed ruminal microorganism fermentation.

Key Words: rumen, microorganisms, bacterial feed supplement

1170 Effect of forage level and fibrolytic enzymes on nitrogen digestion in beef cattle diets. M. Murillo, M.S. Vazquez, H.L. Castro, J.F. Sanchez, and M.A. Cerrillo*, *Universidad Juarez del Estado de Durango, Durango, Dgo. Mexico.*

Four Simmental bulls (550 ±45 kg BW) fitted with cannulae in rumen and duodenum were used in a 4x4 Latin Square design with a 2x2 factorial arrangement to evaluate the interaction of forage level (66 vs 33%) and fibrolytic enzymes (0 vs 15 g/d, Fibrozyme®) on ruminal digestion and post-ruminal nitrogen flow. There were no interactions between forage level and fibrolytic enzymes on ruminal digestion and post-ruminal flow of nitrogen ($P > .05$). However, low forage level in the diet increased intake and ruminal digestion of nitrogen, 12.5 and 10% respectively, ($P < .01$). The addition of fibrolytic enzymes to the diet affected neither ruminal digestion of nitrogen nor microbial efficiency ($P > .05$). However, low forage level increased microbial efficiency 9.7% ($P < .05$). Flow of feed and microbial nitrogen to the small intestine as well as post-ruminal and total tract digestion of nitrogen were not affected by the addition of enzymes to the diet ($P < .05$). High level of forage increased flow of feed nitrogen to the duodenum (28.3%, $P < .05$, whereas low forage level increased the flow of microbial nitrogen (14%, $P < .01$). These results indicate that the addition of fibrolytic enzymes to the diets evaluated in this study did not affect nitrogen digestion.

Key Words: Fibrolytic enzymes, Cattle, Nitrogen digestion

1171 The effect of monensin and bovine somatotropin on lactation performance and body condition score of dairy cows. L J Erasmus*¹, L C Coetzee¹, C H Hesse², and T E Spike³, ¹*Agricultural Research Council, Irene, South Africa*, ²*Elanco Animal Health, Bryanston, South Africa*, ³ *Elanco Animal Health, Indianapolis, IN.*

Monensin supplementation has been associated with an improved energy status in dairy cows resulting from an increased supply of glucogenic precursors in the form of propionate. Bovine somatotropin (bST) administration is known to prolong the period of negative energy balance experienced by cows during early lactation. This study investigated the effect of bST (somatitrove/500mg/14 d) administration (commencing d 60 or d 100), with or without monensin supplementation on the productivity of dairy cows. Sixty four Holstein cows (32 multiparous and 32 primiparous) were used in a completely randomized block design. All cows received an alfalfa-corn based total mixed ration (18.5% CP, 11.3 MJ ME/kg DM) supplemented with 16 ppm monensin from 3 wk

prepartum until 3 wk postpartum whereafter cows were blocked and assigned to treatments based on parity, milk production from d 15 to d 21, body weight, and body condition score (BCS). The four experimental treatments which were fed until d 240 postpartum were: 1) no monensin, bST d 60 (B60); 2) no monensin, bST d 100 (B100); 3) monensin plus, bST d 60 (MB60); 4) monensin plus, bST d 100 (MB100). Milk production varied from 31.3 kg/d (MB100) to 33.4 kg/d (B60) and did not differ among treatments ($P > 0.05$). Dry matter intake was higher for cows that received bST on d 100 compared to d 60, the effect being most pertinent amongst primiparous cows ($P < 0.05$). Monensin supplementation per se did not affect intake but tended to depress butterfat percentage ($P = 0.08$). Body condition score was significantly increased ($P < 0.05$) by monensin supplementation (2.60 vs 2.82); earlier administration of bST had no effect on BCS. Gross efficiency of milk production was increased ($P < 0.01$) by earlier bST administration; 1.43 vs 1.30 for cows administered with bST on d 60 and d 100 respectively. These data suggest that monensin can play a positive role in recouping BCS before the next lactation and earlier bST administration (d 60) can improve gross efficiency of milk production.

Key Words: Dairy cows, Somatotropin, Monensin

1172 Differential response of D- and L-Met free plasma in cows fed different sources of rumen protected Met. Mercedes Vazquez-Anon, David Parker*, and Julia Dibner, ¹*Novus International, Inc. St. Louis, MO.*

L-Met is the biologically active form of Met. D-Met can also be used as a Met source by the cell after its conversion to L-Met. In this study, the contribution of different Met sources to plasma D- and L-Met is evaluated. Five dairy Holstein cows were used in a 5 x 5 Latin Square design. Oral doses of 49 g of DL-Met (E), 56 g of Alimet® (A), 32 g of Smartamine (S), and 28 g of Mepron (M) were mixed with 454 g of corn meal and offered to cows for 4 days. On day 4, the dose remaining after 30 minutes was placed within the rumen under the mat layer. All doses were calculated to supply equivalent amount of Met to the animal. Blood samples were taken on day 4 at 0, 1.5, 3, 6, 9, 12 and 24 h intervals for analysis of total free Met. In addition, analysis of D- and L-Met was undertaken using a chiral column from samples of two of the cows fed A, S and M. The averaged total free Met concentration over time was 2.27a, 2.40a, 3.03b, 3.68c and 5.12d ug/ml (± 0.38) for control, E, A, M and S, respectively (numbers with different letter differed $P \leq 0.01$). A significant time by treatment interaction was observed ($P \leq 0.01$). Plasma Met concentrations peaked at 6, 12 and 12 h after feedings from cows fed A, S and M, respectively. The rapid appearance of Met in cows fed A is due to its faster ruminal clearance with the rumen liquid phase and partial absorption across the omasum prior to its arrival in the duodenum. Met from S and M is not absorbed until they reach the transporter systems in the small intestine. Distribution of D- and L-Met isomers differed among sources. Of the total plasma Met over the 24-h sampling period, 100 % was in the form of L-Met in cows fed A. In animals fed S, D- and L-Met contributed 52 and 48 % to the total plasma Met. In animals fed M, D- and L-Met contributed 50 % and 50 %, respectively. Differences in the peak response in plasma free Met concentration to rumen protected methionine sources can be partially explained by the contribution of D-Met to the plasma free Met pool in animals given M and S.

Key Words: Plasma, Methionine

1173 Effect of ruminally protected methionine and inert fat on milk production in primiparous Holstein cows. J Ayala*¹, G Mendoza², L Landois², A Ramirez³, and S Vega³, ¹*Universidad Autonoma Chapingo*, ²*Colegio de Postgradua-dos*, ³*Universidad Autonoma Metropolitana.*

The effects of two levels of ruminally protected methionine (RPMet) and inert fat were studied in lactating cows. Thirty two primiparous Holstein cows were fed with a basal diet with alfalfa, corn silage and concentrate (60% forage: 40% concentrate). After calving, cows were randomly assigned to the treatments in a completely randomized design with factorial arrangement (2 x 2), which consisted in combinations of two levels of RPMet: (0 and 20 g d⁻¹ of MepronM85; Degusa Co.) with inert fat (0 and 3.5% of DM). Intake was estimated with markers. Milk production was measured during the first 45 days post-partum. Milk samples were collected during lactation peak (07:00 and 18:00 h). Daily intake was (kg) improved with fat (control 18.9^b; Met 18.3^b; fat

19.3^{ab}; Met+fat 20.3^a). Milk production (kg/d) at lactation peak was lower ($P < .05$) in control group (17.0^a vs. Met 23.5^b; fat 24.7^b; Met+fat 23.9^b), with lower persistency. There were no interactions fat x Met; main effects on milk production (45 d post-partum) were: met 21.6^b; fat 19.32^{ab}; 16.0^a control. Milk fat (%) was increased ($P < .05$) with inert fat (control 2.89^a; Met 2.71^a; fat 3.22^b; Met+fat 2.78^a) whereas milk protein (%) was augmented with RPMet (control 2.61^a; Met 2.95^b; fat 2.58^a; Met+fat 2.84^b). There was a positive response in primiparous Holstein cows receiving ruminally protected methionine and inert fat.

Key Words: Methionine, Inert fat, Milk production

1174 **Ruminal degradability of different feeds in the presence of *Saccharomyces cerevisiae*.** G. Scaglia^{*1}, J.J. Williams¹, L.W. Greene¹, and N.A. Cole², ¹Texas A&M University Agricultural Research and Extension Center, Amarillo, ²USDA-ARS at Bushland.

Research from our laboratory has shown that feeding *Saccharomyces cerevisiae* (SC) to growing steers increased ruminal fluid pH and digestibility of certain nutrients. Therefore, the objective of this study was to determine the *in situ* dry matter disappearance (DMD) of grain and hay sources, and ruminal fluid pH in the presence of different yeast strains. Three ruminally-cannulated cows were individually fed either no yeast, 10 g of SC47 (BIOSAF; 8x10⁹CFU/g), or 5.3 g of P7 (PROCREATIN-7; 1.5x10¹⁰CFU/g) daily in a 3 X 3 Latin Square (LS) design. Each period of the LS consisted of a 12-day adaptation and 3-day data collection. Cows were fed 7.7 kg of a concentrate diet (80% corn grain, 10% cottonseed hulls, and 10% of a protein/vitamin/mineral supplement) using electronic Calan gate feeders. On day 13, 5 g of steam-flaked corn grain, wheat grain, milo, alfalfa hay, and low and high quality sorghum hay was introduced into the rumen contents using *in situ* digestion bags at 0, 24, 36, 40, 44 and 48 hours (3 replicates/feed/time). At 48 h, bags were removed and washed with hot water until rinse water was clear. Bags were dried at 60 C and weighed to determine DMD at the different times of incubation. On day 15, ruminal fluid pH was measured at 0, 2, 4, 6 and 8 h after feeding. Wheat grain was the most rapidly digested followed by corn grain and then milo. Alfalfa hay was the most rapidly digested among the forages, with both sorghum hays having similar ($P > 0.10$) DMD. Yeast had no effect ($P > 0.10$) on the rate or extent of the *in situ* DMD of grains or hays. The regression of indigestibility (1-DMD) did not indicate that yeast strains used in this study affected the DMD of grains or hays. Ruminal fluid pH (6.45, 6.47, and 6.30) was similar ($P = 0.16$) when cows were fed the control, P7, and SC47 diets, respectively. These data suggest that there was no effect of the yeast strains tested on the DMD of the grains or hays and on ruminal fluid pH.

Key Words: grains, hays, yeast

1175 **The effects of ethoxyquin on performance and antioxidant status of feedlot steers.** K. W. McBride^{*1}, L. W. Greene¹, N. K. Chirase¹, E. B. Kegley², and N. A. Cole³, ¹Texas A&M University System, Amarillo, TX, ²University of Arkansas, Fayetteville, AR, ³USDA-ARS, Bushland, TX.

The effect of dietary ethoxyquin (EQ) on antioxidant status, VFA status, feed conversion, ADG, and volatile N losses from manure were determined. Eighty feeder steers (219 kg) were purchased and transported to Fayetteville, AR. Steers were housed in 16 pens during a 42-d backgrounding period, and fed either a control diet or 150 ppm EQ (Agrado; Solutia Inc., St. Louis, MO). Pre-transit blood and ruminal fluid samples were obtained at 0700 on d 42 and steers were transported by truck to Bushland, TX that evening. On arrival (0600), steers were processed and allotted to 6 pens equipped with pin-pointer feeders or 2 bunk pens (10 hd/pen). Steers were fed either a control or 150 ppm EQ diet in a 2 x 2 factorial arrangement with pre-transit diet. Jugular blood was drawn on d 0, 28, and 87 post-transit. Weights were obtained at 28-d intervals, and rumenocentesis was performed on d 5 and 28 to determine ruminal fluid VFA. Samples of excreta were collected from pen surfaces on d 28 to determine NH₃ volatilization using an *in vitro* gas emission chamber. Steers fed EQ in Arkansas had lower ($P < 0.05$) serum vitamin E concentrations pre-transit than control steers (1.93 vs 2.23 µg/mL). Post-transit, steers that received EQ in Arkansas had higher ($P < 0.04$) vitamin E concentrations than control steers. Steers receiving EQ post-transit had greater vitamin A concentrations ($P < 0.03$) than control steers on d 28 and 87. Steers fed EQ consumed more ($P < 0.001$) feed

(8.58 vs 7.25 kg/d) for d 1 to 182, and subsequently had greater ($P < 0.05$) ADG (1.61 vs 1.45 kg/d). Butyrate and iso-valerate were the only VFA affected by treatment, post-transit. The excreta harvested from pens housing steers fed EQ had 37% greater ($P < 0.03$) NH₃ volatilization than control pens. These results suggest that adding ethoxyquin to a typical feedlot diet may increase ADG of feedlot steers, and may effect certain antioxidant concentrations during the receiving period.

Key Words: Steers, Antioxidant, Feedlot Performance

1176 **Effect of exogenous fibrolytic enzymes on the digestion of alfalfa hay and barley straw by cellulolytic ruminal bacteria.** Y. Wang^{*1}, T. A. McAllister¹, L. J. Yanke¹, K. A. Beauchemin¹, D. P. Morgavi¹, L. M. Rode², and W. Yang¹, ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, ²Rosebud Technology Development Ltd., Lethbridge, AB.

The effects of exogenous fibrolytic enzymes on colonization and digestion of ground barley straw and alfalfa hay by *Fibrobacter succinogenes* S85 and *Ruminococcus flavefaciens* FD1 were studied *in vitro*. Particles 1.5-2.0 mm diameter were used in the study. The enzyme was a mixture of two preparations from *Trichoderma* spp., with predominant xylanase and β-glucanase activities. Substrates (100 mg) were incubated in 5 ml of medium containing 0, 28 or 280 µg/ml enzyme for 24 h at 39°C, then were inoculated with medium or 24-h bacterial culture (0.1 ml) and incubated for a further 48 h ($n = 4$). Substrate colonization (via scanning electron microscopy) and NDF disappearance were determined. Glucose was included in an additional set of controls to assess possible effects of reducing sugars (RS) in the enzyme, but RS were found not to affect colonization or NDF digestion. Both levels of enzyme and both bacteria were effective at digesting NDF from hay and straw. With both substrates, more NDF hydrolysis ($P < 0.01$) was achieved with enzyme at high rate than at low. Strain FD1 had a greater capacity ($P < 0.01$) to digest hay than did S85, but digestion of straw was similar ($P > 0.05$) between the species. Presence or amount of enzyme did not affect ($P > 0.05$) extent of hay digestion by S85. A synergistic effect ($P < 0.01$) of S85 and enzyme on straw digestion was observed with 28 µg enzyme/ml but not 280 µg/ml. Strain FD1 digested more ($P < 0.01$) hay and straw with high enzyme than with low or no enzyme, but the effect was additive rather than synergistic. Bacterial colonization of both substrates was enhanced by preincubation with enzyme. Included in the incubation medium, exogenous enzymes showed potential to improve fiber digestion by cellulolytic ruminal bacteria. Their efficacy was dependent on bacterial species and rate of application.

Key Words: Exogenous enzymes, Cellulolytic bacteria, Fiber digestion

1177 **Sources of non-protein nitrogen and the addition of *Sacharomyces cerevisiae* to sugar cane based diets for young bulls: Intake, digestibility, nitrogen balances and ruminal parameters.** E. S. Pereira^{*1}, A. C. Queiroz², S. C. Valadares Filho², L. F. Miranda³, and A. M. V. Arruda¹, ¹Universidade Estadual Oeste Parana, ²Universidade Federal Viosa, ³Universidade Federal Minas Gerais, Brazil.

The objective of the present study was to evaluate the effects of the non-nitrogenous sources and the addition of *Sacharomyces cerevisiae* to sugar-cane based diets on the intakes and the total and partial apparent digestibility of dry matter (DM), organic matter (OM), crude protein (CP), ether extract (EE), total carbohydrates (TC), neutral detergent fiber (NDF) and non- structural carbohydrates (NSC). The nitrogen balance and ruminal parameters were also evaluated. Four Holstein-Zebu young bulls rumen and abomasal fistulated were allotted to a 4x4 Latin Square design in a 2 x 2 factorial arrangement. The animals were fed with sugar cane based diets, supplemented with two nitrogenous sources (urea or poultry litter) and two daily *Sacharomyces cerevisiae* addition (0 and 10 g/animal). The indigestible neutral detergent fiber (NDFi) was used as a marker, to determine the total and partial apparent digestibility of the nutrients. The intakes of DM, OM, EE, TC, NSC was not influenced by the nitrogenous sources and by the *Sacharomyces cerevisiae* addition. The intakes of CP and NDF were higher for the diets supplemented by poultry litter. The coefficients of total digestibility of CP and EE were higher for diets with urea. The apparent total digestibility of DM, OM, TC, and NDF were not influenced by the nitrogenous sources and by the *Sacharomyces cerevisiae* addition. The ruminal pH linearly decreased for the diets supplemented with urea, and presented a quadratic behavior when to these diets were

added Sacharomyces cerevisiae. The ruminal ammonia concentrations presented a quadratic behavior, and the maximum estimated values of 16.90; 26.12; 18.48 and 14.40 mg/dL for the diets with sugar-cane and urea, sugar cane, urea and Sacharomyces cerevisiae; sugar-cane and poultry litter; sugar-cane, poultry litter and Sacharomyces cerevisiae, respectively.

Key Words: Bovine digestibility, Intake, Supplements

1178 Effects of Live Yeast Concentrates on the In Vitro Semi-Continuous Culture Fermentation of a High Concentrate Diet. J. J. Williams*, G. Scaglia, and L. W. Greene, Texas A&M University Research and Extension Center.

A semi-continuous culture fermentation system was utilized to examine the effects of live yeast concentrate on ruminal pH in vitro. The experiment was designed as a 6 X 6 latin square utilizing 5 different strains of live yeast concentrate including: L13 (1×10^{10} cfu), L30 (1×10^{10} cfu), L11 (1×10^{10} cfu), SC47 (8×10^9 cfu) and proceatin 7 (1.5×10^{10} cfu) yeast strains. Six fermentation vessels containing inoculum from a ruminally fistulated cow were fed a high concentrate diet for 6 periods of 14 d. Each vessel was fed 7.5 g of diet containing a specific live yeast concentrate 3 times daily at 8 h intervals. Each canister was flushed with carbon dioxide (CO_2) to maintain anaerobic conditions. All fermentors were maintained in a circulating heated water bath kept at a temperature of 39C. Standard McDougall's artificial saliva was utilized as a buffer at a flow rate of .56 ml per min. Yeast treatments were included in each of the diets based on equal quantities of colony-forming units (cfu). After a 2 d adjustment period all fermentors were fed their respective diets for 12 d. On d 10 and 11 pH of the inoculum was measured every 2 h for 8 h. On d 12 samples were taken every 2 h for 8 h. All samples were immediately placed in a -20C freezer. During periods 1 - 5 of the experiment, the SC47 treatment displayed pH values less than ($p < .05$) control. There were however no differences among any treatments when all periods were combined. The pH data for the L11 treatment also displayed values that were consistently less than ($p < .05$) control, however, again no difference overall was determined among any treatment. Although none of the yeast treatments displayed a significant ($p < .05$) increase in pH above control, the L13 and L30 yeast treatments did show a consistent numerical increase over the pH values of all other treatments.

Key Words: Continuous Culture, pH, yeast

1179 Use of gas production technique to estimate the rate and extent of starch degradation from starchy feedstuffs in rumen fluid. Weizhong Chai¹, A. H. van Gelder¹, and J. W. Cone¹, ¹ID TNO Animal Nutrition, Institute for Animal Science and Health, The Netherlands.

Abstract Gas production (GP) and starch degradation (STAD) from starchy feedstuffs were measured simultaneously by in-vitro incubation in buffered rumen fluid after 0, 4, 6, 8, 12, 16 and 24 h incubation to explore the possibility to estimate STAD via GP technique for starchy feedstuffs. The results showed the ranking in the initial degree of starch degradation and gas production. Potato starch and maize had the slowest initial rate, and tapioca, corn cob mix and barley had the fastest ones in STAD. Starch degradation of Over 75% took place after 6-h incubation and nearly finished completely in 24-h incubation. Potato starch and maize, likewise, had the slowest initial rate of gas production, and however the fastest initial rate was found in the samples with smallest total starch content (TSC) such as pea and barley. Gas production was in line with the starch degradation, but the linking degree between GP and STAD varied with the samples with different TSC, especially in the initial incubation. Overall regression indicated a strong correlation between GP and STAD with R2 0.88 and for individual sample, R2 ranged from 0.93 1.00. The regression relationship was affected by TSC of the sample. A larger TSC displayed a higher coefficient and constant as well. R2 for the constant and coefficient regression with TSC was 0.88 and 0.91 respectively. The multiple linear regression was made via TSC and GP as two main predictors: $\text{STAD} = -318.14 + 0.427 * \text{TSC} + 1.876 * \text{GP}$ ($R^2 = 0.95$, $\text{RSD} = 48.71$, $P = 0.0000$). The estimation equation was further modified by using GP as main predictor and its constant and coefficient was, however, indirectly estimated by incorporating the regressions of constant and coefficient with TSC instead of direct estimation: $\text{STAD} = (0.2088 * \text{TSC} + 168.55) + \text{GP} * (0.00136 * \text{TSC} + 0.9654)$ ($R^2 = 0.97$,

$\text{RSD} = 41.2$, $P = 0.0000$). R2 and RSD in both equations were well improved if compared with the values of 0.88 and 76.15 of the regression using GP as unique predictor. The much higher in R2 and RSD of the second equation indicated the modified equation was more accurate and robust. Gas production technique can be used to estimate the rate and extent of starch degradation in rumen fluid, as long as the starch content is taking into account.

Key Words: Gas production, Starch degradation, Rumen fermentation

1180 The effects of substrate, ammonia and pH on gas production and starch degradation from starchy feedstuffs in buffered rumen fluid. W. Z. Chai¹, J. W. Cone^{*1}, A. H. van Gelder¹, and A. A. Kamman¹, ¹ID TNO Animal Nutrition, The Institute for Animal Science and Health, The Netherlands.

Abstract Three experiments were conducted to evaluate effects of pH, substrate and ammonia levels on starch degradation (STAD) and on gas production to look into the optimal conditions for GP technique in starchy feedstuff evaluation. The pH effect on STAD of six starchy samples was studied by using phosphate buffer mixed with rumen liquor in 24-h in-vitro incubation. The results indicated pH 5 adversely affected STAD and no significant differences were found among pH 7, 6 and 5.5, even though STAD appeared larger at pH 6. The ranking in STAD degree of the starchy feedstuffs was found in vitro degradation with rumen fluid at all pH levels. Barley, wheat and tapioca showed the highest STAD and potato starch and maize the lowest in STAD at each pH level. Minimum STAD took place in first 4-h incubation. Substrate level did not affect total GP (g-1OM), but influenced total GP per incubated bottle. On the other hand, substrate concentration significantly affected the shape of gas curve. Increased substrate reduced the time to reach the half-maximal gas production and curve sharpness. Thus substrate concentration affected the fermentation rate, and higher increased substrate concentration increased GP rate in the OM range of 100 500mg substrate. Ammonia carbonate concentration (ACC) did not affect total GP (g-1OM) in such starchy feedstuffs, but it affected the shape of GP profile. GP rate was improved with the increase of ammonia carbonate in the buffer. GP rate of 0.0 ACC was significantly slow from those of other ACC. Though GP rate of 1.0 ACC was the fastest, but no significant differences were found among ACC levels of 1.0, 1.5 and 2.0 in GP rate. The finding from this study proved pH 6.9, 1.0g ACC and 400mg substrate in buffered rumen fluid, the condition of media was currently used in ID-Lelystad, were appropriate in GP technique for the STAD evaluation of starchy sample. These experiments emphasize the need for standardization of GP technique to facilitate the comparison of results among the samples and laboratories. This need will be extreme when GP is used for feed evaluation. The sensitiveness in GP rate and extent among starchy samples imply the great potential and accuracy of GP technique in evaluating the characteristics of different starchy feedstuffs.

1181 Splanchnic first pass sequestration of acetate absorbed from the washed reticulo-rumen of dairy cows. N. B. Kristensen*, Danish Institute of Agricultural Sciences, Tjele, Denmark.

The present study was undertaken to investigate the sequestration of acetate in the reticulo-ruminal epithelium and liver of dairy cows. Four ruminally fistulated Holstein cows yielding 15 to 25 kg milk/d were infused with 2-13C-acetate (6.2 ± 0.1 mmol/h) in a jugular vein and blood was sampled from the other jugular vein or V. epigastrica. The reticulo-rumen was emptied and washed in warm tap water and isotonic NaCl. The buffers incubated in the ru-men was bicarbonate buffered, adjusted to pH 6.8 and heated to 39C before administration. The experimental protocol was divided into 3 periods of intraruminal incubations: C1) 45 min with 20 l of control buffer without VFA, Exp) 180 min with 20 l VFA buffer and con-tinuous intraruminal infusion of VFA, and C2) 45 min with 20 l of control buffer without VFA. The isotopic composition of acetate was measured by gas/liquid chromatography - isotope ratio mass spectrometry. During the Exp period 4.55 ± 0.02 mole of acetate, 2.06 ± 0.01 mole of propionate and 0.42 ± 0.00 mole of butyrate were added to the rumen. During the Exp period the cows absorbed 2.87 ± 0.05 , 1.36 ± 0.01 , and 0.28 ± 0.00 mole of the acetate, propionate and butyrate, respectively. The irreversible loss rate (ILR) of acetate

(357 ± 32 mmol/h) was not different ($P = 0.3$) in period C1 compared with period C2 and this value was used as an estimate of acetate supply of non-ruminal origin. The ILR of acetate re-sponded promptly to the introduction of VFA buffer into the rumen. After 10 min of VFA buffer incubation the ILR had increased ($P < 0.001$) to the level maintained throughout the 180 min period (1115 ± 47 mmol/h). Of the acetate absorbed by the cows 20 ± 2 % did not enter the peripheral circulation. During VFA buffer incubations the splanchnic first pass se-questration of acetate was 193 ± 25 mmol acetate/h. These results show that the maximum possible acetate metabolism in the reticulo-ruminal epithelium under these experimental conditions is insignificant in relation to the ILR of acetate in a non-nutrient deprived cow.

Key Words: VFA, Metabolism, Dairy cows

1182 The effect of dietary roughage on rates of glucose, acetate and beta-hydroxybutyrate clearance from plasma in dairy calves. D.L.J. Benschop^{*1}, J.P. Cant¹, and R. Spratt², ¹University of Guelph, Guelph, Canada, ²Agribands Purina Canada Inc., Woodstock, Canada.

It has been suggested that the ability to utilize VFA post-absorptively occurs subsequent to the structural development and ability to produce VFA in the rumen. To test the effect of dietary roughage on post-absorptive utilization of glucose, acetate and beta-hydroxybutyrate (BHB), 24 male Holstein calves were stratified by liveweight at one week of age and randomly assigned to one of four dietary treatments (n=12) for a period of eight weeks. Treatments were a processed-grain control diet (CON), and three diets in which the grain was partially replaced by 10% roughage (10R), 20% roughage, or cracked corn (CC). Analyzed NDF levels in the CON, 10R and 20R diets were 18%, 20% and 23% of DM, respectively. Glucose, acetate and BHB clearance tests were carried out on weeks two, six and eight of age. Calves were weaned from milk replacer at week 5. BHB was injected through a jugular vein catheter as a bolus of 0.036 mmol/kg bodyweight (BW) at week 2 and 0.09 mmol/kg BW at weeks 6 and 8. Due to the fast rate at which BHB levels returned to baseline, blood samples were collected at -10, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 25 and 40 minutes post-injection. Glucose (2.78 mmol/kg BW) was infused over a 1-min period and samples were taken -10, 0, 5, 10, 15, 20, 25, 30, 45, 60, 90, 120 and 150 min after infusion. Sodium acetate (0.8 mmol/kg BW) was infused over a 3-min period and samples were obtained at -10, 0, 2, 4, 6, 8, 10, 15, 20, 25 and 30 min post-infusion. Baseline glucose concentration in plasma was not affected by treatment but increased from 4.5 to 6.2 mM between 2 and 8 weeks of age. Glucose clearance also was not affected by dietary treatment but increased from 3.42 to 4.39 ml/(min kg) between weeks 2 and 6. Plasma acetate concentrations increased as the calves developed and at week 8, acetate concentration in plasma was significantly increased to 0.15 mM on 20R compared to 0.09 mM on CON. Acetate clearance, however, was significantly lower at 21.4 ml/(min kg) on 20R compared to 48.4 on the CC diet. Acetate clearance was greatest at week 2. The increase in acetate concentrations in blood as the calves developed was due to an increased production of acetate in the rumen with no improvement in the capacity to utilize acetate post-absorptively.

Key Words: Roughage, Rumen, clearance

1183 Altering ruminal microbial colonization and synthesis by manipulation of dietary factors. W. Z. Yang^{*1}, K. A. Beauchemin¹, and L. M. Rode², ¹Agriculture and Agri-Food Canada, ²Biovance Technologies Inc..

Effects of dietary factors including kernel thickness of processed barley grain, ratio of forage to concentrate (F:C), and forage particle size on bacterial colonization of feed particles and distribution in the rumen, and duodenal flow of bacteria in dairy cows were evaluated. The experiment was designed as a double 4 × 4 Quasi-Latin square with a 2 × 3 factorial arrangement of treatments using eight lactating cows with ruminal and duodenal cannulas. Barley grain was steam-rolled to a coarse (1.60 mm) or flat (1.36 mm) thickness; ratio of F:C was low (35:65) or high (55:45); and forage particle size was long (7.59 mm) or short (6.08 mm). Cows were offered ad libitum access to a total mixed diet. Bacterial colonization was linearly increased ($P < 0.01$) from about 5 to 70% with decreasing size of rumen particles. The degree of colonization on each fraction of the rumen particulate matter as determined by sieving was only affected ($P < 0.10$) by ratio of F:C with consistently higher ($P < 0.10$) bacterial colonization for high than for low F:C ratio diets.

Concentration of solid associated bacteria (SAB) in duodenal digesta was greater ($P < 0.05$) than that of ruminal digesta. Of the total bacterial mass within the rumen, less than 20% was associated with the liquid (LAB) and with over 70% was associated with the small particles that passed through the 0.6-mm sieve. In general, bacterial distribution in the rumen was not influenced by dietary factors. While the bacterial pool in the rumen was lower ($P < 0.04$) when flatly rolled barley, rather than coarsely rolled barley, was fed, bacterial flow to the duodenum was greater ($P < 0.10$) with increasing F:C ratio. These results indicate that manipulation of dietary factors such as F:C ratio has the potential to alter bacterial colonization of rumen particles and the relative proportion of LAB to SAB, which were positively correlated to bacterial flow to the duodenum.

Key Words: Dietary Factors, Bacterial Colonization and Distribution, Microbial Protein Synthesis

1184 Metabolism of 2-13C-propionate in the rumen epithelium of sheep. N. B. Kristensen^{*1}, T. H. Steensen¹, S. G. Pierzynowski², and A. Danfr¹, ¹Danish Institute of Agricultural Sciences, Tjele, Denmark, ²Lund University, Lund, Sweden.

The aim of the present study was to estimate the contribution of ruminal 2-13C-propionate to the net portal flux of lactate in sheep fed barley based concentrate. Three rams (46 ± 2 kg BW) were fitted with silicone catheters in A. mesenterica, V. ruminalis and V. porta. During blood sampling the sheep were fed every hour and continuously intraruminally infused with water + 0.30 mmol/h of 2-13C-propionate (Trt0) or 20 mmol/h of propionate + 0.42 mmol/h of 2-13C-propionate (Trt20). Blood flow was measured using p-aminohippuric acid dilution. Concentration and isotopic composition of propionate, lactate and glucose were measured by gas/liquid chromatography - isotope ratio mass spectrometry. The contribution of ruminal 2-13C-propionate to the net portal flux of lactate was calculated from a balance equation with the assumption that no arterial lactate was metabolized in the portal drained viscera (PDV) and that lactate produced in the PDV was derived only from arterial glucose or ruminal propionate. The irreversible loss rate of propionate in the rumen tended to increase ($P = 0.06$) with Trt20 (81 ± 20 mmol/h) compared with Trt0 (71 ± 19 mmol/h). The relative enrichment of 13C in arterial lactate, portal lactate and arterial glucose compared with ruminal propionate was not affected by treatment ($P > 0.10$) and estimated as 21 ± 4, 22 ± 4 and 37 ± 4 %, respectively. The portal net flux of lactate (6 ± 1 mmol/h) was not affected by treatment ($P > 0.10$). In one sheep the 13C enrichment of lactate produced in the PDV was numerically lower than the 13C enrichment of arterial glucose. The contribution of propionate to the lactate flux in this animal was set to 0. The calculated conversion of ruminal propionate into portal lactate was 0.8 ± 0.4 % of the ILR of ruminal propionate and was not affected by treatment ($P > 0.10$). These results show that the amounts of ruminal propionate recovered as lactate in the portal vein is insignificant compared with the ILR of propionate in the rumen.

Key Words: VFA, Metabolism, Ruminant

1185 Validation of the Sulphur hexafluoride(SF₆) tracer gas technique in measuring methane and carbon dioxide production of cattle. D. A. Boadi^{*}, K. M. Wittenberg, and A. Kennedy, University of Manitoba, Winnipeg, Manitoba Canada.

Methane (CH₄) and carbon dioxide (CO₂) production from six crossbred yearling beef heifers (399.8 ± 12.8 kg) were measured for six days, using a SF₆ tracer gas technique (TRACER) and the open-circuit calorimetry hood method (CAL), to validate the former in estimating CH₄ and CO₂ production in the field. Animals were individually fed, 50% barley concentrate and 50% alfalfa cubes at 1.3x maintenance requirements daily. After feeding, 24 hr gas measurements were taken on three heifers by each method. The three heifers as a group, were switched on subsequent days between CAL and TRACER methods in an incomplete block design. Methane production ranged from 107.5 to 144.6 Ld⁻¹ (mean 129.6 ± 4.0 Ld⁻¹) on CAL, and 90.2 to 165.6 Ld⁻¹ (mean 136.7 ± 4.0 Ld⁻¹) on TRACER. The mean CH₄ production (Ld⁻¹) was not different ($P = 0.24$) between methods. In contrast, TRACER CO₂ production was 20% higher than CAL CO₂ production ($P < 0.01$). The range in CO₂ production was 1573.7 to 2048.7 Ld⁻¹ (mean 1892.4 ± 74.0 Ld⁻¹) by CAL and 1540.7 to 3330.2 Ld⁻¹ (mean 2353.5 ± 74.0 Ld⁻¹) by the TRACER method. Day to day variation in CH₄ production, was not different between methods ($P > 0.05$), however animal to animal variation (11.7%) was significant by TRACER method ($P = 0.04$) but not CAL method

($P = 0.53$). Comparison of the equality of variance between the two methods showed that there were no differences in variations ($P > 0.05$) between CAL and TRACER for CH_4 production. On the other hand, variations in CO_2 production was not equal ($P > 0.05$) between methods. It is concluded that the SF_6 tracer technique can accurately estimate CH_4 production, but not CO_2 production. The study implies that for field CH_4 measurements using the TRACER method, more animals are needed than CAL in order to reduce animal to animal variations.

Key Words: Methane and CO_2 measurements, SF_6 tracer gas technique, Validation

1186 Effect of pH and solid dilution rate on microbial fermentation and nutrient flow in a dual flow continuous culture system. M. Rodriguez, S. Calsamiglia*, and A. Ferret, *Universidad Autonoma de Barcelona, Spain.*

Eight dual-flow continuous culture fermenters (1320 mL) were used in two consecutive periods to study the effects of pH and solid dilution rates on microbial fermentation and nutrient flows using liquid (LAB) or solid (SAB) associated bacteria. Fermenters were fed continuously a 60 to 40 forage to concentrate ratio (17% CP, 29.3% NDF). Each period consisted in 7 days for adaptation and 3 for sampling. The last day of the experiment, LAB and SAB pellets were isolated from each fermenter. Fermenters were maintained at a constant temperature (38C) and liquid dilution rate (10% per h). Treatments were arranged in a factorial design, being pH (H = 6.4; L = 5.5) and solid dilution rate (S = 5, and F = 10 % per h) the main factors. No significant interactions were detected. Treatments L and F resulted in lower apparent DM, OM, NDF and ADF digestibilities. True digestibility of DM and OM were only significant in L and F when SAB were used for calculations. Total volatile fatty acids were lower in F vs S (61.4 vs 73.2 mM, respectively). At low pH, the concentration of propionate increased (25.4 vs 16.9 % for L and H, respectively) and that of acetate decreased (58.2 vs 64.9 %, for L and H, respectively). Solid dilution rate did not affect ammonia N concentration, but S increased dietary N flow, and reduced bacterial N flow, protein degradation and the efficiency of microbial protein synthesis when SAB were used. Similar results were obtained with LAB, but differences in dietary N flow and protein degradation were not significant ($P > 0.05$). Low pH reduced ammonia N concentration (10.8 vs 17.6 mg/100mL), but did not affect the efficiency of bacterial N synthesis or bacterial N flow. Dilution rate and pH affected microbial fermentation profile. However, results were different depending on the bacterial population selected for calculations. Acknowledgments: Financial support provided by Project CICYT AGF097/0444.

Key Words: Microbial fermentation, dilution rate, pH

1187 A dynamic mechanistic model of small intestinal starch digestion and glucose absorption in the dairy cow. J A N Mills*¹, L A Crompton¹, J Dijkstra², J A Maas³, C K Reynolds¹, and J France¹, ¹*The University of Reading, Reading, UK*, ²*Wageningen University, Wageningen, NL*, ³*University of Delaware, Delaware, USA.*

The high contribution of postruminal starch digestion to total tract starch digestion on certain energy dense diets demands that limitations to small intestinal starch digestion are identified. A dynamic mechanistic model of the small intestine was constructed and evaluated with regard to its ability to simulate published experimental data for abomasal carbohydrate infusions in the dairy cow. The seven state variables represent starch, oligosaccharide, glucose and pancreatic amylase in the intestinal lumen, oligosaccharide and glucose at the unstirred water layer (UWL), and the intracellular glucose of the enterocyte. Enzymic degradation of starch is a two stage process involving luminal pancreatic amylase and oligosaccharidase on the brush border of the enterocyte confined within the UWL. Na⁺ dependent glucose transport (SGLT1) into the enterocyte is represented along with a kinetically asymmetrical facilitative GLUT2 transport system on the basolateral membrane. The small intestine is subdivided into three main sections representing the duodenum, jejunum and ileum for parameterisation. Further sub-sections are defined between which there is a continual flow of digesta represented as a fractional rate. The model predicted non-structural carbohydrate disappearance for cattle unadapted to duodenal infusion with an $r^2 = 0.92$ and a root mean square prediction error (rootMSPE) of 25.4%. Simulation of glucose disappearance for mature Holstein heifers adapted to various levels of duodenal glucose infusion yielded an $r^2 = 0.81$ and a rootMSPE of 38.6%. Behavioural analysis identified the limitations

for small intestinal starch digestion efficiency at high levels of duodenal starch appearance. Limitations to individual metabolic processes, particularly to starch digestion in the proximal section of the intestine, can create asynchrony between starch degradation and glucose uptake capacity. The model indicated that there were a series of rate limiting steps in small intestinal starch metabolism including pancreatic amylase secretion, oligosaccharidase activity, and glucose uptake via SGLT1.

Key Words: Small Intestine, Dynamic Model, Dairy Cow

1188 Effect of rumen degradable protein and fiber quality on ruminal bacterial populations in continuous culture. D. L. Hastings*¹, K. E. Griswold¹, G. A. Apgar¹, S. A. Kocherginskaya², R. I. Mackie², and B. A. White², ¹*Southern Illinois University, Carbondale, IL*, ²*University of Illinois, Urbana, IL.*

The effect of rumen degradable protein and fiber quality on bacterial biodiversity was examined using dual-flow continuous culture. The experimental design was a 4 x 4 Latin square with a 2 x 2 factorial arrangement of treatments. Factors were level of rumen degradable protein and quality of fiber, and the treatments were: 1) high degradable protein (12% of dietary DM) with high quality alfalfa (HPHF), 2) high degradable protein (12% of dietary DM) with low quality alfalfa (HPLF), 3) low degradable protein (9% of dietary DM) with low quality alfalfa (LPLF), and 4) low degradable protein (9% of dietary DM) with high quality alfalfa (LPHF). Periods were 10 d with 7 d for equilibration and 3 d for sampling. Bacterial samples were collected from inoculum, and the fermentor vessels during each 3 d sampling period. Samples were separated into particle associated bacteria (PAB) and planktonic bacteria (PLB), and whole DNA was extracted. DNA was subjected to PCR amplification of the V3 hypervariable region of the 16s rRNA gene. The resulting oligonucleotides were separated using denaturing gradient gel electrophoresis (DGGE) to assess bacterial diversity in each sample. Data were analyzed using the GLM procedures of SAS. Results indicated that the bacterial diversity of samples from the 3 sampling days were 16.88 - 20.85% similar for PAB and 19.23 - 23.03% similar for PLB compared to the inoculum used in the system. There were no treatment effects on similarity of sample diversity to inoculum diversity ($P > .05$). Indices of similarity were calculated to determine if RDP or fiber quality would alter bacterial populations. There was a trend for treatments containing low quality fiber to select for more highly similar bacterial populations compared to high quality fiber treatments (50.4 vs. 31.7 for PAB and 32.1 vs. 15.0 for PLB, respectively) ($P = .085$). Level of RDP had no effect on similarity of bacterial populations. Altering dietary elements can cause changes in ruminal bacterial diversity in continuous culture.

Key Words: RDP, Fiber Quality, Bacterial Diversity

1189 Effects of an Inhibitor of Obligate Amino Acid Fermenting Bacteria upon Ruminal and Nutrient Utilization by Calves. E.L. Moody*¹, C.E. Cole¹, F.O. Carrette-Carron¹, W.C. Ellis¹, G. Wu¹, M.M. Kothmann¹, and R.J. Wallace², ¹*Texas A&M University*, ²*Rowett Research Institute.*

Deamination of amino acids in excess of that required by rumen microbes is nutritionally wasteful for the ruminant's tissues. Obligate amino acid fermenting bacteria account for most amino acid deamination and an inhibitor of these bacteria has been identified (Floret, et al., 1999 Appl. Environ. Microbiol. 65:3258-3260). The objective of this experiment was to investigate effects of LY29 upon ruminal and animal utilization. Effects of LY29 were determined during successive periods involving lagged ruminal additions of 0, 0.8, 1.6, 0 and 0 g/d of LY29/d to 12 cattle having rumen and duodenum cannula. The two levels of LY29 were evaluated in a mixed diet of 30% cottonseed hull and 70% concentrate diet (160g CP/kg DM). Each period consisted of a 9 d adaptation period and a 5 d period for collection of digestion data. Flux of nutrients to the duodenum was computed with reference to nutrient and indigestible NDF, IF, ratios at the duodenum and diet. Intake of diet DM was determined during d 7-14. Responses to 1.6 g LY29 are reported because most responses were not maximal for 0.8 g/d dose. For the mixed diet, responses to 1.6 g/d of LY29 vs. the control resulted in significant ($P < 0.05$) responses in feed intake (0.82), feed efficiency (1.15), rumen ammonia (0.45), M% of ruminal acetate (1.18), propionate (0.53), butyrate (1.24), isobutyrate (0.72) and valerate (0.73), duodenal flow of OM and IF (0.81) and duodenal flow of N (0.67). Rate of gain was not significantly affected by LY29. These results suggest that LY29

was effective in improving efficiency of ruminal utilization of feed CP by reducing excessive ruminal deamination of amino acids by obligate amino acid fermenting bacteria.

Key Words: rumen, bacteria, amino acid deamination

1190 Colonization Patterns of Forage Fragments by Rumen Microbes. C.A. Marsh*, W.C. Ellis, J.H. Matis, E. Moody, C. Lowe, and J. Johnson, *Texas A&M University, College Station, TX, Brazos.*

Level and rate of colonization of forage tissues by rumen microbes is postulated as causal of enhanced digestion rate of potentially digestible NDF, and its rates of turnover and voluntary intake. The time course of association of diaminopimelic acid (DAPA) with residues of plant tissues *in situ* was studied to reflect patterns of immigration/growth rate and migration/lysis rate by the microbial ecosystem. It is recognized that DAPA concentrations vary among individual species of microbes, however, for present purposes it is assumed that the dynamics of DAPA is representative of dynamics of the microbial population. Leaf and stem parts of bahia grass (*Paspalum notatum Fuegge*) hay were separated and ground to pass a 2 mm sieve and then placed in the rumen in 40 micro porosity bags until removed after 0, 3, 6, 12, 18, 24, 36, 48, 60, 72, 96, 144 and 168 h residence time. Dried material from within the bag was hydrolyzed in sealed tubes in 6M hydrochloric acid and DAPA and amino acids determined via HPLC. Observed time courses of DAPA/g of initial DM appeared to involve three phases: 1) an initial rapid influx and efflux of DAPA, suggesting a rapid immigration/growth rate and subsequent rapid migration/lysis rate within the first 24 h, 2) a more gradual immigration/growth rate in excess of migration/lysis rate which reached an asymptotic level around d 5 and 3) a migration/lysis rate in excess of immigration/growth rate after d 5. The more gradual accumulation over d 2 through 5 conforms to a logistic model in which availability of substrate was not limiting the level of DAPA accumulation until after d 5. It is proposed that the patterns of DAPA observed reflect the dynamics of colonization of feed fragments by successive species of microbes having specific attachment preferences for different ecological niches associated with residues of the feed fragment. The rate and level of colonization must then be modeled as the sum of two phases: 1) the initial influx-efflux phase and 2) the subsequent logistic accumulation phase.

Key Words: Rumen, Microbes, Diaminopimelic acid

1191 Effect of pH and solid dilution rate on the amino acid profile of liquid and solid associated bacteria, and its impact on the estimation of the contribution of microbial amino acids to the total amino acid flow in a continuous culture system. M. Rodriguez, S. Calsamiglia, and A. Ferret, *Universidad Autonoma de Barcelona, Spain.*

Eight dual-flow continuous culture fermenters (1320 mL) were used in two consecutive periods to study the effects of pH and solid dilution rates on the estimation of the contribution of microbial amino acids (AA) to the total amino acid flow. Fermenters were fed continuously a 60 to 40 forage to concentrate ratio (17% CP, 29.3% NDF, 20.4% ADF). Fermenters were maintained at a constant temperature (38°C) and liquid dilution rate (10% per h). Treatments were arranged in a factorial design, being pH (H = 6.4; L = 5.5) and solid dilution rate (S = 5, and F = 10 % per h) the main factors. Each period consisted in 7 days for adaptation and 3 days for sampling. The last day of the experiment, LAB and SAB pellets were isolated from each fermenter and their AA content (mg AA/g DM) analyzed. To estimate the contribution of microbial AA to the total AA flow using LAB or SAB, the AA content of each bacterial isolate was multiplied by the bacterial DM flow estimated within each isolate. Solid dilution rate and pH affected ($P < 0.05$) the AA profile of LAB and SAB. When the AA content was multiplied by the estimated bacterial DM flow within type of bacterial isolate, pH and dilution rate did not affect the estimated flow of AA. When the average across all treatments of the AA content (g/g DM) or flow (g/d) of SAB vs LAB were compared, no significant differences were detected, except for de content (g/g MS) of Tyr, His and Phe. Results demonstrate that the AA content of SAB and LAB may be different and affected by ruminal fermentation conditions. However, its implications on the estimation

of the contribution of microbial AA to the total supply may be quantitatively less important. Acknowledgment: Financial support provided by CICYT AGF97/0444.

Key Words: Bacteria amino acid profile, pH, Dilution rate

1192 Methane emissions from lactating dairy cows fed diets based on conserved forage and grain or pasture. T. R. Dhiman*, K. C. Olson, M. S. Zaman, I. S. MacQueen, and R. L. Boman, *Department of Animal, Dairy and Veterinary Sciences, Utah State University, Logan, UT 84322-4815.*

Methane (CH₄) emissions from cows are energetic losses and contribute to atmospheric greenhouse gases. Six lactating dairy cows (692 ± 58.9 kg BW, 3 intact and 3 rumen-cannulated) were used in a replicated 3 x 3 Latin Square experiment to study the influence of diet on methane emissions. Each period was 28 d. The first 21 d was for adaptation to diets and data were collected during the last 7 d in each period. Treatments were (1) a TMR containing grain and alfalfa hay in a 60:40 ratio, (2) 40% of daily requirements from grazing predominately perennial ryegrass and 60% from a grain mix, and (3) all nutrient intake from pasture grazing. Milk production and feed intake were recorded. Methane emissions from each cow were measured using sulfur hexafluoride as an external marker. Ruminal pH, NH₃-N, and VFA concentrations were measured in the rumen-cannulated cows. Daily DM intakes were 18.3, 13.3 and 15.9 kg d⁻¹ ($P = 0.07$) and 3.5% fat-corrected milk yields were 21.8, 20.4, and 18.3 kg d⁻¹ ($P = 0.76$) in treatments 1 through 3, respectively. Milk fat, protein, lactose, solids not fat, and urea contents did not respond to treatments. Methane emissions did not differ among treatments when expressed as g cow⁻¹d⁻¹ ($P = 0.96$), g kg⁻¹ of DM intake ($P = 0.46$), or g kg⁻¹ of fat-corrected milk ($P = 0.42$), with overall mean across treatments of 445.0 g cow⁻¹ d⁻¹, 29.2 g kg⁻¹ of DM intake ($P = 0.46$), and 29.1 g kg⁻¹ of fat-corrected milk. Acetic acid decreased and propionic acid increased ($P = 0.02$) under the pasture plus grain treatment relative to the other treatments. Ruminal pH, NH₃-N and other VFA concentrations did not differ among treatments. Dietary differences in this experiment had minimal influence on ruminal fermentation variables, or methane emissions in lactating dairy cows. The results from this study suggest that energetic loss in the form of methane from cows fed conserved forage and grain based diets was similar to those fed high quality pasture only.

Key Words: Cow, Milk, Methane

1193 A Role for Rumen Microbial Protein Synthesis in Regulating Ruminal Turnover. W.C. Ellis*¹ and J. H. Matis¹, ¹Texas A & M University.

Ruminal turnover is commonly considered a physical process determined by passive, mixing and dilution of intake rate of undigested NDF, UF, by rumen load of UF. Ruminal flux of degraded dietary entities was investigated as possible regulating nutrients. Literature sources were used that reported varied expressions of turnover that were converted to a common expression of mean turnover rate through two rumen compartments, UF_{ke}. The UF_{ke} was computed from rare earth-compartmental model data. Where the turnover rate, k, was determined as the exponential dilution rate of intake rate of an indigestible marker/rumen load of indigestible marker, UF_{ke} was computed as 1/k. Mean rate of digestion of potentially digestible NDF, PDF (PDF_{kd}), was computed as the natural logarithm of NDF digested in the rumen/mean ruminal residence time of UF (1/UF_{ke}). Rumen degraded protein, RDP, ruminal degraded NDF, RDF, and rumen microbial protein efflux, MPE, were as reported. Ruminal flux of non-structural carbohydrates, RDNSC, was computed as OM - [(NDF+lipids+CP)0.8]. Ruminal flux of degraded carbohydrates, RDCHO, was computed as RDF+ RDNSC. Energetic efficiency of MPE was computed as MPE/RDCHO. The database consisted of 85 treatment means from 28 experiments. All variables were expressed as daily flux per kg BW and relationships were examined with MPE as the dependent variable and daily flux of ruminally degraded nutrients as the independent variables. A non-linear, convex relationship existed between rumen load of UF and UF_{ke}. This relationship possessed greater curvature than conformed to exponential expectations for a passive, mass action, turnover of UF. In experiments with cattle fed mixed diets, significant ($P < 0.05$) regression existed between rumen load of UF and intake rate or dietary concentrations of UF. Efficiency of rumen microbial protein efflux, MPE/RDCHO, was correlated ($P < 0.05$) with rates of ruminal degradation of RDP, PDF, and RDP/RDCHO. The same relationships lacked significance ($P > 0.05$) in the data for forage fed animals. These results imply that in cattle

fed mixed diets, ruminal turnover of UF was regulated metabolically in response to flux proportions of RDP/RDCHO that enhances efficiency of rumen microbial synthesis, MPE/RDCHO.

Key Words: Rumen, Microbial, Protein

1194 Effect of replacing dietary starch with sucrose on nutrient utilization by ruminal microorganisms during continuous culture fermentation. G. A. Varga¹, T. W. Cassidy¹, V. A. Ishler¹, X. Markantonatos^{*1}, N. D. Luchini², and G. A. Broderick³, ¹Pennsylvania State University, ²Bioproducts, Inc, ³U.S. Dairy Forage Research Center.

A dual flow continuous culture system was used to investigate the effects of replacing dietary starch with sucrose at various concentrations on nutrient digestibility and ruminal fermentation. Four diets were evaluated using a completely randomized design during four replicates. Diets were formulated to contain on a DM basis 40% alfalfa silage, 20% corn silage, 20.5% rolled high moisture shelled corn, 9% soybean meal, 2% fat, 1% vitamin-mineral supplement, 7.5% supplemental non-structural carbohydrate (NC) with a nutrient composition of 16.7% CP, 1.7 Mcal/kg NEL and 29% NDF. The NC fed in the four diets was: A) 7.5% starch, 0% sucrose; B) 5% starch, 2.5% sucrose; C) 2.5% starch, 5% sucrose; and D) 0% starch and 7.5% sucrose. Four continuous culture fermenters were used with solid mean retention time and liquid dilution rate of 24 h and 11%/h, respectively. On day 7-9 effluents were collected daily and composited for nutrient digestibility determination and for analysis of ammonia-N, and VFA. No differences were observed in pH throughout the day ranging from 5.67 to 6.21 with an overall mean of 5.97 ± 0.08. Ammonia-N concentration averaged 9.23 mg/100ml ± 0.66 with a trend (P<0.11) for a positive linear effect with increasing sucrose in the diet. Apparent DM digestibility was not different among treatments and averaged 46.8% ± 1.5. NDF digestibility increased linearly when sucrose was added to the diet and at the highest inclusion was 66.1% vs. 60.9% when compared to the all starch diet. Total VFA was not different among treatments and averaged 103.9 ± 0.66 mM. Branched chain VFA concentration decreased linearly with increasing sucrose in the diet. Bacterial N content was not affected by treatment. Replacing starch with sucrose in the diet resulted in an alteration in microbial fermentation such that NDF digestibility was enhanced.

1195 In vitro effects of lactate-utilizing rumen bacteria on ruminal fermentation. S.-W. Kim*, S. R. Rust, H. Roman-Rosario, and M. T. Yokoyama, Michigan State University, East Lansing, MI.

A facultative lactate-utilizing bacterium (Isolate 1) was isolated from the rumen of beef cattle fed a diet consisting of 95% corn silage and 5% of a protein-mineral supplement. The isolate was a gram positive rod with a Chinese character arrangement. It produced 36 mM of acetate, 58 mM of propionate and 37 mM of butyrate from 159 mM of lactate. When glucose was the carbon source, the bacterium produced only lactate. The bacterium was placed into a mixed rumen culture to evaluate its potential to alter VFA production. One mL of Isolate 1 was added to a round bottom flask that contained rumen fluid (50 mL) from hay-fed heifers, buffer (50 mL) and 3 g of readily fermentable substrates (starch, glucose, cellobiose, xylose, and casein). Triplicate flasks were incubated anaerobically at 39°C. Three mL of culture were removed at 0, 3, 6, 12, and 24 h of incubation while gassing flasks with O₂-free CO₂. The concentrations of lactate in cultures were 0.5, 4.1, 51.5, 117.7, and 128.0 mM for control and 10.8 (P < 0.05), 10.1, 45.4, 124.3, and 150.4 mM (P < 0.01) for Isolate 1 at 0, 3, 6, 12, and 24 h of incubation, respectively. VFA concentrations were not different among treatments through 24 h of incubation. Acidity was higher in Isolate 1 at 24 h (P < 0.01). The fermentation products after 24 h of incubation are shown in the Table below. The Isolate 1 did not affect VFA composition but increased the lactate concentration in mixed culture.

Item	Control	Isolate 1	SEM	P
Lactate (mM)	128.0	150.4	2.26	< 0.01
Total VFA (mM)	126.8	125.0	1.21	0.17
Acetate (mM)	66.6	65.6	0.42	0.49
Propionate (mM)	35.9	36.5	0.54	0.35
Butyrate (mM)	19.0	18.0	0.66	0.30
pH	4.33	4.19	0.02	< 0.01

1197 Ethanol absorption from the rumen. T. Veresegyhazy*¹, H. Febel², G. Nagy¹, and A. Rimanoczy¹, ¹Faculty of Veterinary Science, Szent Istvan University, Budapest, ²Research Institute of Animal Breeding and Nutrition, Herceghalom.

Ethanol absorption through the rumen was investigated in *in situ* experiments. Three British Milk ewes fitted with rumen cannula (Bar Diamond 8C) were used. The ruminal content was removed and the forestomachs were washed out with water. Subsequently the apparatus developed by Engelhardt and Sallmann (1972) for the isolation of rumen was put in place. After closing the cannula, 2.8 L of physiological saline solution, either 20 or 60 mL ethanol, 2 mL Cr-EDTA were infused respectively and the fluid volume was completed to 3 L with physiological saline solution. This was followed by removal of the 0-min sample intended for the determination of the initial ethanol and Cr-EDTA concentrations. Further samples were taken at 5, 15, 30, 45, 60 and 75 min. This process was repeated with each animal. Every data point represents the mean of 6 measurements. The Cr content was determined by atomic absorption. The concentration of ethanol was determined by gas chromatography. The fluid volume and ethanol content in the rumen were calculated according to the dilution rate of Cr-EDTA and the ethanol concentration in the samples. Absorbed ethanol was considered to be the difference of the ethanol content of the sample taken at 0 min and the other sampling time. During 75 min absorbed 81% of 20 mL and 64.2% of 60 mL ethanol. The amounts of absorbed ethanol were 16.2 and 38.5 mL respectively. The equations of absorption are $y = -0.0474x^2 + 5.6544x + 10.869$ and $y = -0.1377x^2 + 19.541x + 24.606$ using 20 and 60 mL ethanol respectively. Ethanol absorption is quicker when the ethanol concentration is higher. The speed of ethanol absorption decreased during experiments because of saliva production and ethanol elimination through the rumen wall. Drawing a graph the curves are characteristic to passive transport. Ethanol can penetrate through the rumen wall probably by passive transport mechanism.

Key Words: ethanol, absorption, rumen

1198 Influence of drinking saline water and feeding level on feed and water intake, digestibility, thermo-respiratory response and blood constituents in sheep. Mostafa Kobeisy*¹, Faisal Elhommosi¹, Galal Abdel-Hafiz¹, and Hassanain Badawy², ¹Animal Prod. Dept., Fac. of Agric., Assiut University, Assiut-Egypt., ²Desert Research Center, Cairo-Egypt.

The trial aimed to study the influence of drinking saline water along with different nutritional conditions on digestive function, thermo-respiratory response and blood constituents in Saidi sheep. Six clinically healthy Saidi rams over one year old with an average body weight of 40 kg were used in this study. Saline water was fresh tap water containing 1.5% of commercial sodium chloride. Feed and water intake were recorded daily and blood samples were taken for Hb and PCV %, and serum total protein, albumin, globulin, triglycerides, cholesterol, AST and ALT determination. Drinking saline water decreased feed intake by about 15% and increased (P<0.01) water intake by about 42%. Digestibility coefficients of ether extract and acid detergent fiber were lower (P<0.05) in animals drinking saline water than those drinking tap water. Drinking saline water decreased (P<0.05) respiration rate, whereas rectal temperature was not significantly affected. Animals drinking saline water had higher (P<0.01) PCV %, and serum albumin and triglycerides concentrations than those drinking tap water. Under drinking saline water conditions, animals fed ad libitum level had significantly higher concentrations of Hb, PCV and serum albumin than those fed restricted level.

Key Words: Sheep, saline water, digestibility, blood, thermo-respiratory response

1199 Influence of supplemental chromium on performance, concentrations of liver triglycerides, and blood metabolites during the transition period of dairy cows. J. A. Jackson*, V. Akay, R. Scaletti, S. T. Franklin, D. M. Amaral-Phillips, C. H. Hamilton, and R. J. Harmon, *University of Kentucky, Lexington, Kentucky.*

This study evaluated the effects of dietary Cr supplementation on DMI, milk yield, liver triglycerides and blood metabolites in lactating dairy cows from wk 4 prepartum until 8 wk postpartum. Twenty-four Holstein cows (10 primiparous) were blocked by expected calving date and parity and randomly assigned to either the basal diet (control) or control diet supplemented with 11.5 or 8.0 mg / head / d of Cr, as chromium picolinate, for multiparous and primiparous cows, respectively. Cows were housed in tie stalls for approximately 40 days before the expected calving date and fed a close-up dry cow TMR until calving. At calving, they were fed a lactation TMR with DM containing 30 % corn silage, 30 % alfalfa silage and a 20 % crude protein concentrate mix. Blood samples were collected on d 30 and 15 before expected calving date and on d 3, 30 and 60 after calving and analyzed for plasma NEFA and BHBA, and serum triglyceride, insulin and cortisol. Liver samples were obtained on d 30 and 15 before calving and on d 3 and 30 after calving and analyzed for triglycerides. No differences were detected in DMI between treatments. Least squares means for wk 5 to 8 were 22.0 versus 21.8 kg/d for the control and Cr supplemented groups. No differences ($P > 0.05$) were detected in milk yield between treatments and averaged 36.8 and 34.6 kg/d for control and Cr supplemented groups, respectively. The percentage of fat was higher ($P < 0.05$) and protein trended higher ($P = 0.13$) in the milk of cows fed the Cr supplemented diet. Liver triglycerides averaged 3.9 and 3.3 % wet weight (NS) on d 3 after calving for the control and Cr supplemented groups, respectively. Chromium supplementation did not significantly alter plasma NEFA and BHBA, or serum triglyceride, insulin or cortisol concentrations at any sampling date or when averaged over the sampling dates. However, BHBA trended lower ($P = 0.10$) for the Cr supplemented versus the control cows on d 3 after calving. Results suggest that Cr supplementation during the transition period had no effect on DMI or milk yield. Blood metabolites and liver lipids were largely unaffected by Cr supplementation.

Key Words: Transition dairy cow, Dietary chromium supplementation, Fatty liver disease

1200 Effect of dietary phosphorus concentration on estrous behavior of lactating dairy cows. H. Lopez*¹, Z. Wu¹, R. Chere², L. D. Satter^{1,2}, and M. C. Wiltbank¹, ¹*Dairy Science Department, University of Wisconsin, Madison*, ²*US Dairy Forage Research Center, USDA-ARS, Madison.*

It is common for dairy producers to increase dietary phosphorus (P) above NRC requirements in an attempt to increase expression of estrus. The objective of this study was to determine the effect of dietary P concentrations of .38 or .48% of the TMR (DM basis) on estrous behavior of lactating cows as measured by a radiotelemetric system (HeatWatch[®] DDX, Denver, CO). At calving 48 Holstein cows were randomly assigned to one of the dietary treatments. Cows were housed in a free-stall barn and received a radiotelemetric transmitter on d 45 postpartum to record estrous standing activity. Observations on estrous behavior presented here are from the first year of a two-year study published elsewhere (J. Dairy Sci. 83:1052). The radiotelemetric system was employed only during the first year of that study. The total number of estrous periods recorded for the 48 cows was 83. The mean duration of estrous cycles was 22±0.8 d with a range of 17 to 26 d and 21±0.6 d with a range of 16 to 29 d for cows fed the .38 and .48% P diets, respectively ($P = 0.82$). The mean duration of estrus was 9.1±1.0 and 8.8±1.1 h for cows fed the .38 and .48% P diets, respectively ($P = 0.82$). The average number of mounts during estrus was 7.5±1.2 and 8.0±1.5 ($P = 0.81$) and the total mounting time was 29.6±1.0 and 31.9±5.8 s ($P = 0.75$) for cows fed the .38 and .48% P diets, respectively. Phosphorus treatment had no detectable effect ($P = 0.87$) on intensity and duration of estrous behavior.

Intensity and duration of estrus ¹	.38% P (n=42)		.48% P (n=41)	
	n	%	n	%
Low intensity, short duration	10	24	13	32
Low intensity, long duration	19	45	17	41
High intensity, short duration	11	26	9	22
High intensity, long duration	2	5	2	5

¹Estrus was characterized by standing events as low (<1.5/h) or high (≥1.5/h) intensity and by estrus duration as short (<7 h) or long (≥7h).

Key Words: Dairy Cows, Estrous Behavior, Phosphorus Requirement

1201 Mineral content of Acacia mangium Willd under defoliation conditions. T. Clavero*, E. Miquelena, and A. Rodriguez-Petit, ¹*La Universidad del Zulia.*

A field experiment under tropical dry forest condition was carried out in Zulia, Venezuela with the objective of determining the effect of cutting frequency and height of clipping on mineral content of leaves on Acacia mangium Willd. The factors studied were three frequencies (6, 9 and 12 weeks) and three defoliation heights (50, 75 and 100 cm) A split-plot in a random block design with three replications was used. The results showed highly significant differences ($P < 0.05$) for frequency and height interaction on the concentration of K, Mn and Zn. Calcium, Mg, Na and P were only affected by maturity. The principal effect on mineral content of leaves in Acacia mangium was age. Mineral concentration decreases due to translocation from leaves to branches and stems with increasing maturity.

Key Words: Acacia mangium, mineral composition, defoliation

1202 Pasture applied biosolids as related to copper status of grazing beef steers. M. E. Tiffany, L. R. McDowell*, G. A. O'Connor, F. G. Martin, N. S. Wilkinson, and H. Q. Nguyen, *University of Florida.*

Angus yearling steers (N=96) were randomly assigned to bahiagrass pastures (N=32) treated with 3 high Mo-containing biosolids varying in mineral content for 151 d and evaluated for mineral status, with special attention to Cu. The biosolids are classified as high quality and originated from Tampa (T) and Largo (L), FL and Baltimore (B), MD. Copper concentrations of biosolids varied from 431-989 ppm and Mo from 12-60 ppm. Biosolids and NH₄NO₃ (control) fertilizer was applied to 0.81-ha pastures at a rate of either 179 kg N/ha (X) or 2, 3 and 6X: 1) control C, 1X; 2) L1X; 3) L2X; 4) B3X; 5) B6X; 6) T3X; and 7) T6X. The soils were acid (pH 5.0-5.8) and well drained (soil series of Millhopper sand). There were 3 animals per pasture with 4-6 replicates of treatments. One of 3 steers of each plot received a 3-ml subcutaneous injection of Cu glycinate (60 mg Cu/ml). Forage concentrations were low in Cu (<6 ppm) and Mo (<2 ppm) and high in S (>0.4%). At experiment termination, 1/3 of steers had slight-to-moderate hair discoloration. Cupric glycinate injections dramatically increased liver Cu, with an overall average of 185.9 ppm (dry basis) for injected steers compared to 96.6 ppm for noninjected cattle. Cu-injected animals had higher ($P < 0.001$) liver Cu than the two corresponding pen mates. At the end of the experiment, the means of all biosolids treatment animals that did not receive supplemental Cu had liver Cu considerably less than the control. Five of 6 biosolids treated steer groups had lower ($P < 0.001$) liver Cu (ppm) than the control C 1X (127) as follows: B3X (97), L1X (82), B6X (72), T6X (56) and T3X (49). In agreement with declining Cu status in livers, all plasma Cu treatment means resulting from biosolids applications were less than the critical concentration of 0.65 μg/ml. In agreement with low forage Mo concentrations, all liver samples were low in Mo. Liver Mo concentrations were well below the 5 mg/kg level considered toxic. Biosolids treated steers all had lower ($P < 0.05$) liver Zn than the controls, and steers on pastures B6X, T3X and T6X had lower liver Fe than controls. Implications: Pastures treated with high Mo-containing biosolids resulted in a decline of Cu status of steers. The decline in Cu status was not due to Mo, but most likely from low forage Cu (<6 ppm) and high forage S (>0.4%).

1203 Effect of shade and organic zinc supplementation on performance of Brahman bull calves fed growing diets in dry tropic weather. R. Barajas* and A. Felix, *Universidad Autonoma de Sinaloa (Mexico).*

To determine the effect of shade and organic zinc supplementation on performance of Brahman bull calves feeding growing diets in dry tropic weather, 64 Brahman bull calves (BW = 294 kg) were used in a 28 day complete randomized block design experiment (September/2000). Shade (WS) or no shade (NS) in pens and diet supplemented or not with additional 30 ppm of zinc from Availa-Zn 100TM (Zinpro Corp.

MN). No shade pens were ground floors pens (6 x 16 m), provided with metallic feed bunker (2.8 m); in each of four NS pens, six bull calves were placed (16 m of of vital space and 0.46 m of feed bunk by head). Shaded pens were 6 x 26 m, ground floor and central shade (4.8 x 6.7 m; belted type; 3.5 m high; north-south oriented) supplied with metallic layer; ten bull calves were placed in each (15.6 m of vital space and 3.14 m of shade, and 0.6 m of feed bunk by head). Shade increased ($P < 0.03$) the final weight 2.3% (334 vs 342 kg) and ADG by 19% (1.42 vs 1.7 kg/d). The use of shade diminished ($P < 0.05$) DM intake 5% (10.08 vs 9.54 kg/d) and feed/gain by 20% (7.15 vs 5.71). The dietary intakes of net energy was 17% and 24% higher ($P < 0.02$) in the calves in WS treatment than in NS treatment. Extra zinc supplementation had no effect ($P > 0.10$) on performance of bull calves. An additive effect of shade plus zinc supplementation was observed ($P < 0.05$), improving final weight, ADG, feed/gain and NEM content of the diet. WS + Zn tended ($P < 0.06$) to increase NEg content of the diet, and had no effect ($P > 0.10$) on DM intake. It is concluded that the use of shade in pens improved the performance of Brahman bull calves in feedlots during the ending summer under dry tropic weather condition, and that organic zinc supplementation support and benefits for feedlot cattle only if environmental conditions are adequate.

1204 Supplementation of ascorbic acid and plasma concentration in the neonatal dairy calf. T.R. Johnson^{*1}, S.D. Eicher², C.A. McKee¹, K.L. Cutshall³, M.L. Henry³, and S.P. Coburn³, ¹Purdue University, West Lafayette, IN, ²USDA-ARS, West Lafayette, IN, ³Indiana University Purdue University Fort Wayne, IN.

Forty-six female neonatal Holstein calves were fed colostrum and treated for 3 d as described in Purdue Dairy SOP C-1.0 Management of newborn calves. Calves were then switched to milk replacer (20% CP, 20%fat, all milk) fed in 2 equal feedings at 10% BW/d and adjusted weekly for the 6 wk study. Treatments were: 1. Control; 2. BG (a β -glucan product fed at 2.5% of dry milk replacer, NaturalChem. Industries, Ltd.); 3. Ascorbic acid (AA; Vitamin C 500 mg STAY-C 35, Roche Vitamin, Inc.); and 4. BG+AA, at the same concentrations as each supplement when fed alone. Milk replacer, water and supplements were mixed with a bakery wisk and fed in individual pails. Calves were fed replacer and supplements at 0600h and 1300h, and plasma was taken by jugular venipuncture into in heparinized vacutainers at 0830 h. Plasma was frozen at -80°C. Analysis of plasma AA concentration was conducted using a microspectrophotometer method (Bio. Chem. Med. 1973. 11:41-48). Data were analyzed by SAS PROC MIXED REML, with combined symmetry (CS) as covariate. Mean plasma AA were: Control, 2.15 \pm .34; BG, 2.24 \pm .34; AA, 2.46 \pm .36; BG+AA, 2.67 \pm .37 μ g/ml. Week effects approached significance ($P < .06$); and treatment and treatment x week effects were not different ($P > .65$). Although AA+BG effects were reflected in physiological, production and immunological variables (McKee et al. 2000. JDS 83: Suppl. 1. 134), the present plasma AA data supports other reports that suggest that plasma is not a good indicator of AA status.

1205 Effect of organic (Availa-Cu) versus inorganic (CuSO₄) Cu on the rate and extent of copper repletion in post-partum Brangus heifers. G. P. Yost¹, L. R. McDowell¹, C. K. Swenson³, and J. D. Arthington^{*2}, ¹University of Florida - IFAS, Dept. of Animal Sciences, Gainesville, ²Range Cattle Research and Education Center, Ona, ³Zinpro Corporation, Eden Prairie, MN.

It has been proposed that organic copper (Cu) is more bioavailable than inorganic sources of the element. In beef cattle research these benefits have been variable. We hypothesized that the bioavailability of organic Cu should be of specific importance to stressed cattle. The post-partum stress associated with first calf heifers is a result of increased calving difficulty, lactation, and continued growth of the heifer. Therefore, the objective of this study was to compare the effect of organic (Availa-Cu, Zinpro Corporation, Eden Prairie, MN) vs. inorganic (copper sulfate)

Cu supplementation in post-partum, lactating, first-calf heifers. Thirty-seven Cu-deficient, Brangus heifers were selected from a south-central Florida ranch. Two 14 d enrollment periods were utilized to account for calving dates over a 4-wk period. Within each period, and after calving, heifers were allocated to one of two treatments ($n = 12$ and 15 for organic and inorganic treatments, respectively). Copper treatments were formulated into a corn/cottonseed meal carrier at a targeted level of 15 ppm. Treatments were delivered for 83 d to individual pens housing 2 or 3 heifers. All heifers were provided ad-lib access to long stem limpgrass hay containing 8.7 ppm Cu. Heifers assigned to both treatments were initially Cu deficient (56 and 51 ppm liver Cu for organic and inorganic treatments, respectively). Liver Cu increased in all heifers regardless of treatment, however, heifers supplemented with organic Cu tended ($P = 0.17$) to have higher mean liver Cu values compared to those receiving inorganic Cu (139 vs. 109 ppm). Over 83 d of supplementation the rate of liver copper repletion was 2.21 vs. 1.73 mg/kg/d for organic and inorganic Cu, respectively. No treatment differences were detected in plasma ceruloplasmin concentrations. By d 83 post-partum, only 4 of 27 heifers had returned to estrus ($n = 2$ /treatment) as determined by P4 levels > 1 ng/mL for two consecutive 7 d samples. These data suggest that organic copper may provide post-partum, first calf heifers with a more bioavailable form of supplemental copper.

Key Words: Organic mineral, Copper, Heifer

1206 Supplementation effects of calcium salts of unsaturated fatty acids on ruminal environment and forage digestion in grazing dairy cows. S. Wagner¹, G.F. Schroeder^{*1-2}, G.A. Gagliostro³, I. Vidaurreta¹, and J. Couderc¹, ¹Fac.Cs. Agrarias UNMDP, ²CONICET, ³INTA EEA Balcarce, Argentina.

The objective was to determine if the supply of calcium salts of unsaturated fatty acids (UFA-Ca, 65% unsaturated FA) would affect ruminal environment and pasture NDF and CP digestion in dairy cows grazing an alfalfa pasture (DM=22.7%; NDF=25.7%; CP=25.0% and IVDMD=71.3%). Three Holstein cows fitted with ruminal cannulas were allotted to a 3 x 3 Latin Square. Treatments were as follows. In T0, cows received pasture plus 5 kg/d of ground corn and 0.4 kg/d of fish meal. In T1, 0.8 kg/d of UFA-Ca were added to the T0 diet and in T2 corn grain was isoenergetically replaced by 0.8 kg/d of UFA-Ca. Nylon bags containing fresh forage (5 g DM/bag) were incubated in the rumen and removed at 0, 3, 6, 9, 12, 16, 20, 24, 36, 48, and 72 h to estimate the in situ disappearance of NDF and CP. Ruminal pH values, concentrations of NH₃-N and total volatile fatty acid and parameters of in situ pasture NDF and CP disappearance were not affected by UFA-Ca supply. Results suggested that UFA-Ca behaved as inert fats when they were added to the diet of dairy cows grazing alfalfa pastures.

1207 Effects of Zinc and(or) monensin on the utilization of a barley-alfalfa diet in beef cattle. H. M. Arelovich*¹, H. E. Laborde¹, C. J. Ackerman², M. I. Amela¹, and M. B. Torreal¹, ¹Universidad Nacional Del Sur, Bahia Blanca, Argentina, ²Oregon State University, Corvallis, OR.

Previous research has indicated that the addition of 250 to 400 ppm Zn to low-quality forage diets altered rumen fermentation by retarding ammonia accumulation and increasing molar proportions of propionate. This experiment was designed to investigate the impacts of dietary inclusion of Zn and(or) monensin on the productive performance and blood metabolite changes in sixteen recently weaned Angus steer calves (198 kg initial liveweight). Steers were individually housed and fed a mixed diet of 50% cracked barley grain, 40% ground alfalfa hay and 10% sunflower meal at 0800 and 1700 daily in equal proportions. The composition of the diet was 14.3% CP, 46.1% NDF, 20.5% ADF and 6.7% ash. Four treatments were randomly allotted to four individually fed steers/treatment. Treatments were: 1) Control (C); 85% wheat middlings + 15% NaCl, 2) Zinc (Z); C + 450 ppm ZnCl₂; 3) monensin (M); C + 300 mg monensin and 4) zinc + monensin (ZM); C + 450 ppm Zn + 300 mg monensin. All treatments were added to the basal ration at a rate of 200 g/steer at 0800 and were fed for 77 d. Blood samples were collected via jugular venipuncture. Data was analyzed using non-orthogonal contrasts; 1) C vs all other treatments, 2) C vs Z, and 3) Z vs ZM. No differences ($P > .10$) were detected in any of the parameters measured. Therefore, we conclude that inclusion of zinc at the level of 450 ppm did not alter performance or blood parameters of steers fed a basal diet consisting of 50% cracked barley grain, 40% ground alfalfa hay and 10% sunflower meal. Dry matter intake, ADG, feed conversions (FC), total tract apparent OM digestibility (DIG), and results of blood analysis for hematocrite (HTC), glucose (GLU), urea (U), total protein (TP), alkaline phosphatase (ALKP) and creatinine (CRT), are reported in the following table.

	Blood Serum

1208 Performance and conservation of phosphorus in growing cattle. L. W. Greene*^{1,2}, F. T. McCollum III¹, N. K. Chirase^{1,2}, and T. M. Montgomery², ¹Texas A&M University Agricultural Research and Extension Center, ²West Texas A&M University.

One hundred forty four crossbred heifers (average initial weight, 178 kg) were used in a 43 d receiving and 103 d growing trial. Cattle were randomly assigned to 12 pens and fed ad libitum a diet consisting of 50% steam flaked corn (SFC), 40% cottonseed hulls (CSH) and 10% protein/mineral/vitamin (PMV) supplement. Each pen was randomly assigned to either 1.4 kg brewers' grain yeast (BGY) top-dressed on the feed daily or no BGY. On d 44, growing diets were formulated using either SFC (39.7%), CSH (5.0%), soybean hulls (38.8%), fat (3.6%) and PVM-1 (13.0%) to contain 0.22% P or SFC (69.7%) CSH (18.0%), fat (1.8%) and PVM-2 (10.5%) to contain 0.33% P. The P diets were assigned to the 12 pens in a 2 X 2 factorial arrangement with BGY. During the growing period, diet intake was adjusted at 2 wk intervals to produce a projected ADG of 0.9 kg/d. On d 146, cattle were weighed and total pen manure weighed and sampled. Heifers fed BGY during the receiving period consumed 6.5% more feed ($P = .0001$; 6.7 vs 6.2 kg/d) and gained 23.4% more ($P = 0.02$; 0.94 vs 0.76 kg/d) than those fed the control diet. Heifers fed BGY were 15% more ($P = 0.01$) efficient than those fed the control diet (0.137 vs 0.119 gain/feed). No interaction occurred between BGY and dietary P during the growing period. Heifers fed BGY consumed more feed ($P = 0.03$; 5.58 vs 5.47 kg), had greater ADG ($P = 0.01$; 1.0 vs 0.93 kg/d) and improved feed conversion ($P = 0.04$; 0.178 vs 0.169 gain/feed) compared to those fed no BGY. BGY did not affect ($P = .50$) N and P retention on the pen surface. Feeding 0.22% P did not affect feed intake ($P = 0.98$), ADG ($P = 0.15$) or feed efficiency ($P = 0.12$) compared to heifers fed 0.33% P. However, feeding 0.22% P reduced the amount of P retained on the pen surface by 29% ($P = 0.03$).

Feeding BGY during the receiving and growing period increased heifer performance. Reducing dietary P in growing diets reduced the quantity of pen surface P without reducing performance.

Key Words: phosphorus, environment, yeast

1209 The effect of copper source and level on the rate and extent of copper repletion in Holstein heifers. G. P. Yost*¹, L. R. McDowell¹, C. K. Swenson³, and J. D. Arthington², ¹University of Florida – IFAS, Gainesville, ²University of Florida – IFAS, Ona, ³Zinpro Corporation, Eden Prairie, MN.

The objective of this study was to evaluate the rate and extent of Cu repletion in Holstein heifers using two Cu sources (organic and inorganic) at two levels (15 and 30 ppm). An additional repletion treatment included a Cu oxide bolus. Heifers (n=50) were individually fed a depletion diet fortified with Fe, S, and Mo at 50 ppm, 0.40%, and 15 ppm DM of the total diet, respectively. Following 70 d of depletion, heifers were stratified by liver Cu and randomly allotted to one of five repletion treatments. Four treatments consisted of feed sources of Cu (Feed-Cu), 1) CuSO₄ at 15 ppm, 2) CuSO₄ at 30 ppm, 3) Availa-Cu at 15 ppm, and 4) Availa-Cu at 30 ppm. A fifth treatment, consisting of an intraruminal bolus (Bolus), contained 12.5 g of Cu oxide needles. Repletion treatments were delivered in the same total mixed ration without supplemental Fe, S, and Mo. Copper status was assessed in blood and liver samples collected on 14 d intervals for 70 d. Irrespective of treatment, all heifers increased in body weight during the repletion period. Liver Cu increased in each Feed-Cu treatment over time. Bolus heifers reached a peak in liver Cu concentration (165.5 ppm) on d 28. Heifers receiving CuSO₄ at 30 ppm achieved higher liver Cu compared to heifers receiving CuSO₄ at 15 ppm, but not those receiving Availa-Cu at 15 or 30 ppm (88.2 and 137.3, and 98.1 and 118.5 ppm for CuSO₄ at 15 and 30 ppm and Availa-Cu at 15 and 30 ppm, respectively). Mean liver Cu for Bolus heifers (131.1 ppm) was greater ($P < 0.05$) than CuSO₄ at 15 ppm, but not other Feed-Cu treatments. Plasma ceruloplasmin was higher ($P < 0.001$) in Bolus heifers versus other treatments. No differences in plasma ceruloplasmin were detected for Feed-Cu source or level. Red blood cell superoxide dismutase activity was higher ($P < 0.05$) in Bolus heifers compared to heifers receiving Availa-Cu at 15 ppm, but not other Feed-Cu sources (1.03 and 0.79 units of activity for Bolus and Availa-Cu at 15 ppm, respectively). These results indicate that all Cu sources evaluated in this study elevated Cu status of depleted heifers, particularly when provided at higher dietary levels.

Key Words: Holstein, Repletion, Copper

1210 Effects of biotin on liver metabolism in lactating dairy cows. C. K. Reynolds*¹, A. J. Packington², and G. M. Weber³, ¹The University of Reading, UK, ²Roche Vitamins (UK), ³F. Hoffmann-La Roche Ltd., Switzerland.

The objective was to measure effects of supplemental biotin on portal-drained viscera (PDV) and liver (LIV) metabolism in 3 multiparous, catheterized, mid-lactation Holstein x Friesian cows (664 kg BW). A TMR of 30 % dried lucerne, 20 % grass silage, 50 % concentrates and 17.8 % CP (DM basis) was fed hourly at 97 % of ad libitum DMI. Added carrier (.5 kg ground wheat/d) without or with biotin (20 mg/d) was fed in a switch-back design with three 2-wk periods. Hourly measurements (8) of PDV and LIV blood flow and net nutrient flux (mmol/h) were obtained on d-14 of each period. Biotin had no effect ($P > .57$) on DMI (22.2 kg/d), milk yield (29.5 kg/d) or blood flow (L/h) for PDV (2020) or LIV (2570), but increased ($P < .02$) arterial hemoglobin (94.5 vs 98.7 g/L) and oxygen (5.35 vs 5.57 mM) concentration and decreased ($P < .07$) arterial CO₂ concentration (27.22 vs 26.94 mM). There was no effect ($P > .45$) of biotin on net flux of glucose, lactate, oxygen or b-OH-butyrate across PDV (19, 174, -3672 and 281, respectively) or LIV (686, -95, -3892 and 394, respectively). Similarly, biotin had no effect ($P > .28$) on net flux of acetate, propionate or n-butyrate across PDV (3390, 932 and 212, respectively) or LIV (1814, -858 and -152, respectively). Biotin did increase net PDV release of ammonia (703 vs 945; $P < .01$) and removal of urea (49 vs -218; $P < .07$). This was associated with a numerical increase in net PDV acetate release (3087 vs 3694) and suggests an effect on rumen fermentation and/or urease activity. Net LIV flux of ammonia (-882) and urea (824) were not affected ($P > .24$), but removal of i-valerate was increased (-39 vs -47; P

< .07), indicating an enhancement of LIV methylcrotonyl-CoA carboxylase activity. The decrease in blood CO₂ also suggests an enhancement of biotin dependent carboxylase activity. Biotin effects on carboxylase activity and hemoglobin may be of benefit to the dairy cow, especially in early lactation.

Key Words: Biotin, Liver, Lactation

1211 Organic chromium and selenium effects on performance, digestibility and carcass characteristics of lambs. I Dominguez-Vara^{*1}, S Gonzalez², C Garcia-Bojalil², R Barcena², M Cobos², G Mendoza², and L Landois², ¹Universidad Autonoma del Estado de Mexico, ²Colegio de Postgraduados.

Organic selenium (0.0, and 0.3 ppm as Sel-Plex-50) and chromium (0.0, 0.250 and 0.350 ppm as Biochromium; Alltech, Inc.) were fed for 95 d to 54 Rambouillet cross lambs (27.04.83 kg BW) in a complete random design experiment with a 2x3 factorial arrangement of treatments. An in vivo digestibility and nitrogen balance trial was done with 24 lambs (four/treatment). Lambs were slaughtered at the beginning (four) and at the end (30; 45.383.13 kg) to evaluate carcass variables by comparative slaughter and specific gravity. Means were analyzed by orthogonal contrasts (C): C1) 0 Se vs 0.3 ppm Se; C2) 0 Cr, 0 Se vs 0.250+0.350 ppm Cr, 0 Se; C3) 0 Cr, 0.3 ppm Se vs 0.250+0.350 ppm Cr, 0.3 ppm Se; C4) 0.250 ppm Cr, 0 Se vs 0.350 ppm Cr, 0 Se; 5) 0.250 ppm Cr, 0.3 ppm Se vs 0.350 ppm Cr, 0.3 ppm Se. Biochromium (0.0, 2.5 and 3.5 g/lamb/d) and Sel-Plex-50 (0.0 and 3.0 g/lamb/d) were fed individually every morning with the basal diet (% DM): sorghum grain 65.2, corn stover 12.8, DPW 12.0, alfalfa hay 2.0, vitamin and mineral premix 2.0, SBM 2.0, wheat bran 1.5, fish meal 1.5, urea 1.0. DMI was higher (P<0.08) for unsupplemented lambs (C2; 1265 vs 1186 g/d). Lambs receiving Cr and Se (C3) had better (P<0.05) feed conversion (6.4 vs 10.1), higher (P<0.01) ADG (229 vs 184 g/d), and heavier BW (48.7 vs 44.3 kg; P<0.001) and carcass (22.4 vs 20.9 kg; P<0.01). Cr (0.350 ppm) without Se (C4) improved feed conversion (5.92 vs 9.73; P<0.07), carcass weight (23.1 vs 20.7 kg; P<0.02); and yield (56.9 vs 53.4%; P<0.06). Lambs fed Cr with (C3) or without (C4) Se had higher digestibility of DM (70.3 vs 61.9%, P<0.0002, C3; 73.3 vs 62.6%, P<0.0001, C4) and CP (60.7 vs 48.9%, P<0.0002, C3; 65.1 vs 51.2%, P<0.0002, C4). Lambs receiving Cr and Se (C3) retained more (P<.0343) N (28.18 vs 11.74 g). Addition of organic Cr improved BW gain, carcass variables, feed conversion and digestibility, and N retention in lambs fed a 65% sorghum grain diet.

Key Words: Organic chromium, Organic selenium, digestibility

1212 Effects of source of supplemental zinc on heifer performance during receiving and finishing phases. G. A. Nunnery^{*1}, M. L. Galyean¹, and J. Horton², ¹Texas Tech University, Lubbock, TX, ²Kemin Industries, Des Moines, IA.

Ninety-seven beef heifers (British x Continental; average initial BW = 223.7 kg) were used to study the effects of Zn source on health and performance. On arrival at the Texas Tech University Burnett Center, heifers were weighed, tagged, vaccinated, treated with Micotil, dewormed, and assigned randomly to dirt-floor pens (three pens per treatment; eight heifers per pen). All heifers were fed a 65% concentrate diet that contained NRC (1996) recommended levels of vitamins and minerals, except Zn. Treatments were: control (no supplemental Zn) and 75 mg/kg of supplemental Zn from either zinc sulfate, zinc methionine, or zinc propionate (KemZin 2700TM; Kemin Ind., Des Moines, IA). During the 35-d receiving phase, heifers were monitored daily for signs of bovine respiratory disease, and suspect calves with rectal temperatures \geq 39.7° C were treated and returned to their pens. At the end of the receiving phase, all heifers were group-fed the control diet for 42 d, during which, the concentrate level of the diet was increased to the final 88% concentrate finishing diet. Heifers were then stratified by BW (within original treatments), assigned to feedlot pens (four heifers per pen; six pens per treatment), and implanted with Revalor H. Heifers were weighed at 28-d intervals throughout the finishing period. During the receiving phase, control heifers had a higher (P < .05) d-35 BW and were more efficient (P < .05) than heifers in the other three treatments. Dry matter intake and ADG did not differ (P > .05) among treatments for the 168-d finishing period; however, feed:gain was poorer (P < .05) for heifers in the control group than for the average of the other treatments. With the exception of KPH, which was less (P < .04) for ZnSO₄ than for the two organic Zn sources, carcass characteristics did not differ (P < .05).

In newly received cattle, neither level nor source of supplemental Zn affected heifer performance. Moreover, Zn source had minimal effects on performance and carcass characteristics of finishing heifers, but lack of supplemental Zn might negatively affect feed efficiency during the finishing phase.

Key Words: Zinc, Cattle, Feedlot

1213 Adaptations in amino acid concentrations, body fat and body protein in dairy cattle fed varying amounts of protein in the transition period. J. P. McNamara^{*}, J.J. Sage, T.L. Citron, and G.J. Phillips, Washington State University.

The objectives were: to determine effects of prepartum protein intake and dietary amino acid balance on production, amino acid concentrations, adaptations in body fat and protein and, indirectly, body protein breakdown in early lactation and to determine the effects of rates of milk production and feed intake on adaptations in body fat, protein and rate of protein breakdown. Holstein cows (42) were fed two concentrations of protein for 21 days prepartum (11 and 14 percent) with or without 20 g per d methionine hydroxy analog and then fed a common diet of 16 percent CP for 120 days postpartum. Subcutaneous fat biopsies were taken from 31 cows at 14 d before, 60, and 120 days after calving and the diameters of fat cells (FCD) were determined and body fat (BF) and protein (BP) were calculated using validated equations. Dry matter intake averaged 25.4 kg (SD 3.1 kg) and milk production 41.6 kg (SD 1.4 kg). Protein intake prepartum was positively related to DMI and milk production postpartum (P < 0.05); cows fed the 14 % CP ration ate 0.9 kg more DMI and gave 1.7 kg more milk than those fed the 11 % ration. Cows fed AT88 prepartum lost less (P < 0.05) body protein by d 60. From d 60 to d 120 BF increased 8.5 kg and 11.5 kg for low and high protein groups and BP increased 0.5 kg and 1.0 kg. Serum concentrations of branched chain amino acids fell (P < 0.05) 17 percent in the first 4 weeks postpartum, lysine fell 12 to 15 percent, histidine fell 16 percent, and methionine and cysteine increased 20 to 30 percent (all P < 0.05). The ratio of serum 3-methylhistidine to creatinine (3-MH:C) was determined to indicate muscle protein degradation. An increase in the 3-MH:C ratio in late gestation and very early lactation (P < 0.05) indicated increased BP breakdown, there was no effect of prepartum ration. This data set provides adequate information to challenge a mechanistic model of nutrient use in dairy cows during the early lactation period.

Key Words: lactation, metabolic model, body composition

1214 Challenging performance of a mechanistic model of metabolism to describe nutrient flux and body pools in early lactation. J. P. McNamara^{*}, J.J. Sage, T.L. Citron, and G.J. Phillips, Washington State University.

Data were collected to challenge the behavior and sensitivity of existing metabolic models (Molly, AAMolly, University of California, Davis) to describe changes in body fat, protein and amino acid concentrations in early lactation dairy cows. Holstein cows (42) were fed 11 or 14% CP diets with or without methionine analog (AT88) for 21 days prepartum and a common 16% CP diet from 1 to 120 DIM to determine effects on production, nutrient metabolism, and body composition. Rates of intake, milk composition and yield, serum metabolites, body fat and protein content were determined at intervals for the first 120 d of lactation. Postpartum dry matter intake averaged 25.4 kg/d (SEM = 0.7 kg/d) and the cows produced a mean of 40.7 kg/d milk (SEM = 1.2 kg/d). From 14 days precalving to 60 d postcalving, BP decreased (P < 0.05) 8.2 kg and 8.5 kg for the 11% and 14% CP treatments. From d 60 to 120, BP increased 0.6 kg. The ratio in serum of 3-MH:C was elevated at 7 d postpartum (P < 0.05) and the 3-MH:C ratio at d 7 was greater (P < 0.05) in cows fed 11% CP prepartum than in cows fed 14% CP. Higher-producing (> 45 kg milk/d) cows in this study mobilized (P < 0.05) up to 18 kg body protein in early lactation. Feed composition, DMI, initial body weight and composition observations were explicit model inputs. The model described milk production from feed intake only with as: simulated milk (kg/d) = 0.26 * observed + 28.9 kg /d with a regression coefficient of 0.61. When milk production potential was entered on an individual cow basis, the relation between observed and simulated milk production was: simulated = 0.903 * observed + 2.9 kg/d with a regression coefficient of 0.96. The model simulated BP change to 120 d similarly (within 1 SD) to observed (observed = 7.5, simulated = 10.5 kg) but a greater increase in body fat (124.8 kg

simulated vs - 41.7 kg observed). The model AAmolly describes use of sulfur amino acids, histidine and lysine and predicted utilization of these amino acids from body stores in early lactation, as was observed. These mechanistic models describe milk outputs from quite well, within 1 SD of observed. The description of changes in body fat and protein over a period of 1 to 3 weeks postpartum is still inadequate and will require better experimental data for improvement.

Key Words: lactation, metabolic model, body composition

1215 Effects of prepartum intake, postpartum induction of primary ketosis, and periparturient disorders on performance and blood metabolites in dairy cows. H. M. Dann*, J. K. Drackley, and D. E. Morin, *University of Illinois, Urbana.*

Multiparous Holstein cows were used to determine the effects of different prepartum intakes and postpartum health statuses on dry matter intake (DMI), milk yield, and blood metabolites. Cows were fed a diet (1.54 Mcal NE_L/kg, 14.1% CP) from dry-off to parturition at either ad libitum (A; n=17) or restricted (R; 80% of calculated NE_L requirements; n=18) intake. After parturition, all cows were fed a lactation diet (1.58 Mcal NE_L/kg, 16.8% CP). At 4 d in milk (DIM), cows were assigned to 3 groups: healthy-control (HC; n=6), healthy-ketosis induction (HK; n=9), and periparturient disorder (PD; n=17), based on a physical examination. HC and PD were fed for ad libitum intake. HK were fed at 50% of d 4 DMI from 5 DIM to signs of clinical ketosis or 14 DIM, and then returned to ad libitum intake. Prepartum DMI was higher and serum nonesterified fatty acids (NEFA) were lower for A than R (*P*<0.05). Serum glucose, Ca, and albumin did not differ between A and R at -14 DIM. Prepartum intake (A vs. R) did not affect DMI, milk yield, or blood metabolites postpartum. From 1-4 DIM, DMI was higher (*P*<0.05) for HC and HK than for PD. Milk yield was higher (*P*<0.05) for HC than PD; HK was intermediate. At 4 DIM, HC and HK had higher (*P*<0.05) Ca than PD. Albumin was higher (*P*<0.05) for HK than PD; HC was intermediate. Glucose and NEFA did not differ. From 5-14 DIM, DMI was higher (*P*<0.05) for HC than PD. HC produced more milk (*P*<0.05) than HK and PD. At 14 DIM or onset of clinical ketosis, glucose was higher (*P*<0.05) while NEFA and β-hydroxybutyrate (urine and plasma) were lower (*P*<0.05) for HC and PD than HK. Albumin was higher (*P*<0.05) for HC and HK than PD. Calcium was lower (*P*<0.05) for HK and PD than HC. From 15-42 DIM, DMI and milk yield did not differ. At 21 DIM, glucose, NEFA, Ca, and albumin did not differ. Prepartum intake did not affect postpartum performance or blood metabolites. Periparturient disorders and induction of ketosis negatively affected performance and blood metabolites.

Key Words: Ketosis, Transition Cow, Metabolism

1216 Rumen volume and liquid dilution rate in transition dairy cows. C. K. Reynolds*, D. J. Humphries, and J. D. Sutton, *The University of Reading, UK.*

The objective was to measure effects of transition and supplemental barley on rumen digesta fill and liquid dilution rate in 10 rumen cannulated Holstein x Friesian cows in late gestation and early lactation. Cows were fed a grass-silage based gestation TMR for BW (671 kg) stasis without (n = 5) or with (n = 5) 1 kg (as fed) barley/d for 6 wk before expected calving date (CD) and a maize-silage based lactation TMR beginning 7 d before expected CD (2 kg DM/d). After calving lactation TMR was fed for ad libitum DMI. Cows were fed equal meals at 8-h intervals. Rumen liquid volume, DM content and liquid dilution rate were estimated by marker dilution at an average of 17 and 8 d before and 10, 20 and 31 d after calving. Markers (CrEDTA or CoEDTA) were introduced into the rumen at separate times, either 1 h before or 1 h after feeding at 0830 h. Subsequent representative rumen samples were analyzed to determine marker dilution and DM concentration and results for each marker were averaged. Feeding barley had no effect (*P* > .10). Milk yield at d 10, 20 and 30 after calving was 36.5, 41.9 and 43.3 (SEM 1.5) kg/d, respectively. The data show that increases in DMI after calving are associated with increased rumen DM fill and liquid turnover, but total liquid content was not affected.

Day from CD...	-17	-8	10	20	31	SEM	P-Day
DMI, kg/d	10.8	9.8	16.5	20.2	18.8	.7	.01
Rumen DM, kg	7.1	7.0	8.3	9.5	10.3	.8	.01
Rumen liquid, kg	51.8	50.0	48.9	54.2	57.7	4.3	.26
Total digesta, kg	58.9	57.0	57.1	63.7	67.9	5.1	.15
Liquid dilution, %/h	14.8	15.1	17.7	17.5	16.2	.8	.02

Key Words: Rumen fill, Dairy cows, Transition

1217 Effects of dietary energy density on performance of transition dairy cows. E. Rabelo*, R. L. Rezende, S. J. Bertics, and R. R. Grummer, *University of Wisconsin, Madison.*

Forty cows and twenty heifers were used in a randomized block design to evaluate different dietary energy densities during the periparturient period. Prepartum (d -28 to calving) diets were dry-low (DL, 1.57 Mcal NEI/kg, 14% CP, 42% NDF, 34% NFC) and dry-high (DH, 1.66 Mcal NEI/kg, 14% CP, 34% NDF, 41% NFC). After calving, half of the cows from each prepartum treatment group were assigned to a low (L, 1.67 Mcal NEI/kg, 18% CP, 33% NDF, 37% NFC) or high (H, 1.74 Mcal NEI/kg, 18% CP, 27% NDF, 44% NFC) diet until d 20 postpartum. After d +20 postpartum, all cows were fed H until d +70. Prepartum DMI was higher for animals fed DH than DL (13.1 vs. 11.3 kg/d, *P* < .0001). Treatment differences for DMI during the prepartum tended to be more pronounced for cows compared to heifers (*P* < .13). There was a treatment by time interaction on DMI after calving; animals that were fed DH had higher DMI at the second wk of lactation compared to animals fed DL (*P* < .05). Animals fed H had a higher DMI for the first 20 d of lactation compared to animals fed L (16.3 vs. 15.0 kg/d, *P* < .06). Diets did not affect DMI after the third wk of lactation. Prepartum diets did not affect milk, fat or protein yield. Milk production increased faster for animals fed H compared to animals fed L (*P* < .001). There was a prepartum treatment x time interaction on milk fat content (*P* < .02). Animals fed DH had higher milk fat content during the second wk of lactation than animals fed DL (4.43 vs. 3.91%, *P* < .01); no differences were observed during subsequent weeks. Increasing dietary energy postpartum tended to decrease milk protein percentage (3.14 vs. 3.06%, *P* < .11) and did not affect milk fat percentage. Feeding diets with higher energy density prepartum positively affects DMI during the prepartum period and possibly during early lactation. Increasing energy density of the diet during the first 3 wk postpartum positively affects DMI and milk production during the first 3 wk of lactation.

Key Words: Transition cow, Dietary energy, Lactation

1218 Effects of dietary energy density on blood parameters and liver triglyceride of transition dairy cows. E. Rabelo*, R. L. Rezende, S. J. Bertics, and R. R. Grummer, *University of Wisconsin, Madison.*

Forty cows and twenty heifers were used in a randomized block design to evaluate dietary energy densities during the periparturient period. Prepartum (d -28 to calving) diets were dry-low (DL, 1.57 Mcal NEI/kg, 14% CP, 42% NDF, 34% NFC) and dry-high (DH, 1.66 Mcal NEI/kg, 14% CP, 34% NDF, 41% NFC). After calving, half of the cows from each prepartum treatment group were assigned to a low (L, 1.67 Mcal NEI/kg, 18% CP, 33% NDF, 37% NFC) or high (H, 1.74 Mcal NEI/kg, 18% CP, 27% NDF, 44% NFC) diet until d 20 postpartum. After d +20 postpartum, all cows were fed H until d +70. Blood samples were taken at d -7, +1, +4, +7, +21 and +35 relative to calving and analyzed for plasma BHBA, glucose, and NEFA, and serum insulin. Liver biopsies were taken on d +1, +21 and +35 relative to calving. Data through d +1 were statistically analyzed separately from data after d +1. Treatment differences for blood and liver parameters on specific days are indicated only when a treatment x day interaction was significant. There was a prepartum treatment effect on NEFA through d +1 (247 vs. 331 uEq/L, *P* < .01, DH vs. DL), with treatment differences being greatest at d +1 (500 vs. 733 uEq/L, *P* < .0001, DH vs. DL). Animals fed DH had lower NEFA at d +4 (483 vs. 511 uEq/L, *P* < .01) and BHBA at d +21 (5.8 vs. 8.2 mg/dl, *P* < 0.05), and higher glucose at d -7 and +7 (54.6 vs. 52.6 mg/dl, *P* < .10; 47.9 vs. 45.6 mg/dl, *P* < .10) and insulin at d -7 (17.8 vs. 13.7 uIU/ml, *P* < .01) than animals fed DL. At d +7 and +21, animals fed H had higher glucose (48.5 vs. 44.9, 49.6 vs. 44.6 mg/dl, *P* < .001) and insulin (12.3 vs. 9.9, 15.5 vs. 11.7 uIU/ml, *P* < .01), and

lower BHBA (4.8 vs.8.2, 4.5 vs. 9.6 mg/dl, $P < .001$) than animals fed L. Liver triglyceride at d +21 was lower for animals fed H compared to animals fed L (11.0 vs. 15.6 ug TG/ug DNA, $P < .06$). A more favorable metabolic profile occurs when increasing the energy density of the diet prepartum or immediately postpartum compared with delaying the increase until d +20 postpartum.

Key Words: Transition cow, Dietary energy, Blood and liver

1219 Changes in hepatic methylmalonylcoenzyme A mutase (MCM, E.C. 5.4.99.2) activity during the transition period in the dairy cows. B. Graulet^{*1}, A. Desrochers², and C.L. Girard¹, ¹Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, ²Facult de Mdecine Vtrinaire, St-Hyacinthe, Canada.

The objective was to look at the activity of the hepatic cobalamin-dependent enzyme MCM in dairy cow during the transition period. This enzyme controls the utilisation of methylmalonyl-CoA for neoglucogenesis and thus might be strongly stimulated in dairy cow by the intake of transition and early lactation diets and the increased needs in glucose for milk production. Liver biopsies were taken up repeatedly from 6 multiparous cows 3 wk before calving (-3 wk) and at 2, 4 and 8 wk of lactation. MCM activity was assayed spectrophotometrically from purified mitochondrial matrix. MCM activity decreased from 14.04 ± 1.29 to $7.58 \pm .75$ nmol/min/mg of intramitochondrial proteins ($P < .037$) between -3 wk and 2 wk of lactation then returned ($P < .004$) and stayed at its initial level at wk 4 and 8. Apparent Km and Vmax values towards methylmalonyl-CoA (mean initial values : 175.2 ± 34.0 μ M and 19.96 ± 3.16 nmol/min/mg of protein, respectively) followed the same quadratic pattern ($P < .052$). The dose-response curves of MCM activity towards its cofactor adenosylcobalamin (AdoCbl) indicated the same variations around calving for the apomutase but not for the holomutase part of the activity which remained stable until wk 2 then increased from $4.95 \pm .45$ to $8.00 \pm .80$ nmol/min/mg of protein at wk 8 ($P < .023$). Holomutase activity represented 41.2, 65.3, 61.5 and 59.6 % of total MCM activity at -3, 2, 4 and 8 wk, respectively. This increase was associated to a reduction in plasma vitamin B12 concentrations (-33 %, $P < .003$). Apparent Vmax values towards AdoCbl (initial level $8.59 \pm .71$ nmol/min/mg of protein) varied also quadratically. Apparent Km values towards AdoCbl were constant until wk 2 ($.58 \pm .20$ to $.69 \pm .14$ μ M), decreased by 36 % at wk 4 ($P < .056$) and then returned to the

initial values at wk 8 ($P < .001$). Our results show that MCM activity is decreased during the first weeks of lactation and consequently might reduce neoglucogenesis.

Key Words: MethylmalonylCoA mutase, Cow, Lactation

1220 Effects of a modified stair-step compensatory growth model for gestating beef heifers. A. M. Encinias^{*}, H. B. Encinias, T. D. Klein, G. P. Lardy, M. L. Bauer, and C. S. Park, ¹North Dakota State University, Fargo, ND USA.

Thirty-six gestating Angus and Angus-cross heifers were used to evaluate the effects of energy restriction imposed at 90 d of gestation. Heifers were grouped by verified AI date into six pens (6 heifers/pen) and fed a grass hay/corn silage diet for 10 d. At 90 d of gestation, pens of heifers were assigned randomly to one of two dietary energy treatments: control (CON) or stair-step (SS). Control heifers were fed 20.4 Mcal ME/d from d 90 to 210 of gestation and 23.0 Mcal ME/d through d 270, to achieve 0.54 kg ADG (minus fetus). Stair-step heifers were fed 13.3 Mcal ME/d (65% of CON) from d 90 to 210 (restriction) of gestation and 29.9 Mcal ME/d (130% CON) through d 270 (refeeding). During restriction, diet was formulated to elicit no gain (minus fetus) in SS heifers. Three-day consecutive weights were used to measure initial and final period BW. Initial and final body condition was estimated for each period. Initial BW ($P = 0.72$; 463 (CON) vs 474 (SS) ± 21) and BCS ($P = 0.81$; 6.1 vs 6.1 ± 0.1) were not different between treatments. Imposed restriction, did not influence BW ($P = 0.20$; 540 vs 490 ± 26 kg) between CON and SS, respectively. However, by design, CON heifers had a greater BW change ($P = 0.004$; 77 vs 16 ± 8 kg) and ADG ($P = 0.004$; 0.64 vs 0.13 ± 0.06 kg) during the restriction period. As a result SS heifers decreased ($P = 0.001$) in BCS. During refeeding phase, compensatory response (2.77 kg ADG) was observed in SS through d 28. Energetic efficiency (kg ADG:Mcal ME) was also greater for SS during refeeding ($P = 0.002$; 0.054 vs 0.031). In addition, SS heifers achieved a higher ADG ($P = 0.001$; 1.61 vs 0.73 ± 0.05 kg) than CON during refeeding. At the conclusion of feeding phase, heifer BW ($P = 0.95$; 584 vs 587 ± 13 kg) and BCS ($P = 0.70$; 6.2 vs 6.1 ± 0.2) were similar among CON and SS, respectively. Compensatory response elicited by SS during refeeding, allowed heifers to reach a similar final BW and BCS compared to conventionally reared gestating beef heifers.

Key Words: Beef heifer, Stair-step compensatory growth, Gestation

1221 Influence of CO₂ cryogenic cooling on low populations of Salmonella Enteritidis in inoculated table eggs. J.B. Gurtler^{*} and D.E. Conner, Department of Poultry Science, Poultry Product Safety and Quality Program, Auburn University, AL .

Because Salmonella Enteritidis (SE) is the primary cause of foodborne illnesses arising from table eggs, there is interest in developing processes to limit SE risk. Cryogenic cooling with CO₂ improves microbial counts of naturally contaminated eggs and can reduce high SE populations in inoculated eggs. Furthermore, elevated CO₂ levels decrease SE growth in yolk-containing media. The present study was undertaken to determine the effects of CO₂ cryogenic cooling on SE propagation in eggs at low inoculum levels. Fresh eggs (with a mean temperature of 27C) were gathered and inoculated, via injection into albumen, to ca. 160 cfu/egg with SE. One half of the eggs were cooled at ca. -60C for 6 min with CO₂ in a prototype cryogenic cooling unit, producing a post-cooling egg temperature of 12.9C, and then stored at 7C. The remaining eggs were traditionally cooled, requiring 5 days to achieve 7C and held at that temperature thereafter. Egg pH and SE populations were determined every three days up to day 15 and then weekly up to day 49 of storage. Populations of SE remained static over the 49 days following cryogenic cooling, whereas SE populations increased significantly in traditionally cooled eggs. After day 6, cryogenically cooled eggs' SE populations were consistently 2.5-4.5 log₁₀ cfu/ml lower than those traditionally cooled. No marked difference was noticed in pH values. Rapid cooling with CO₂ effectively inhibited SE growth in stored table eggs, and therefore may provide an efficient controlled cooling process for maintaining and increasing safety of table eggs.

Key Words: Salmonella Enteritidis, eggs, CO₂

1222 Effect of soybean soapstock on laying hen performance and egg quality parameters. V. Pardo^{*1}, L. Landin¹, K. Waliszewski², M. Avalos¹, A. Flores¹, and L. Guzman¹, ¹Universidad Veracruzana, Veracruz, Veracruz/Mexico, ²Instituto Tecnológico de Veracruz, Veracruz, Veracruz/Mexico.

The aim of the study was to determine the effects of soybean soapstock in laying hen diets on performance and egg quality parameters since variations in feed can adversely affect egg parameters resulting in economic losses to poultry producers. A total of 192 White Leghorn laying hens, 20 wk of age, was housed in two double-deck cage batteries with 4 birds in each cage at 25C. The birds were allotted to six dietary treatments, with each treatment replicated four times randomly among the batteries with 8 birds for replicate. The diets were sorghum-meal ground based with soybean oil at 3.5% and were isocaloric and isonitrogenous. Feed and water were provided for *ad libitum* consumption. Diet T1 had 25%, diet T2 50%, diet T3 75% and diet T4 100% of soybean soapstock, which was added in the amount to reach the requirement of 1.5% linoleic acid and complemented with soybean oil, control diet with pigment (T5) and control diet without pigment (T6) had 100% soybean oil. Four eggs from each replicate were randomly selected daily during eight weeks, kept at 4C and analyzed within two days after collection for determination of egg quality parameters: egg weight, shell thickness, Haugh unit score, albumen and shape index. Production performance -number and weight of eggs produced, feed conversion and percentage of production per treatment were recorded. Data were analyzed by ANOVA ($P < 0.05$) and significant differences among treatment means were analyzed by Tukey and Dunnett tests using Minitab 10.5 statistical program. Results indicated that the egg quality parameters among treatments were not statistically different during the eight weeks. No statistical differences were observed in production performance during the first two

weeks but statistical difference was observed among T1, T2 and T3 diets with T4, T5 and T6 diets from the third to sixth week and no statistical difference was observed among T4, T5 and T6 diets. There were no statistical differences among treatments at the seven and eight weeks of production. Nevertheless, T4 production parameters were numerically higher than other treatments. Soybean soapstock can be recommended as a substitute of vegetable oil since no adverse effects on egg quality and production parameters were detected.

Key Words: Soybean soapstock, egg quality, production performance

1223 Development of generic HACCP model plans for the egg processing industry. Mindy Brashears¹, Shelly McKee-Hensarling¹, Jason Mann*¹, and Dennis Burson¹, ¹University of Nebraska.

To assist the egg processing industry with HACCP implementation and to help ensure the consuming public a safe egg product supply, a team of Extension Specialists with expertise in food safety, Hazard Analysis and Critical Control Points (HACCP) systems and egg processing developed 5 generic HACCP plans similar to those available for use at the USDA by meat and poultry processors. After examining various egg processes, 5 process categories were identified based on similarities among the various processes. The categories were as follows; not ready-to-eat shell eggs; spray dried egg products; pasteurized liquid egg products; ready-to-eat, heat treated egg products-boiled; and ready to eat specialty egg products. A flow diagram and product category description was developed for each category and verified by industry experts. The seven principles of HACCP as described by the National Advisory Committee for the Microbiological Criteria for Foods were followed to develop the HACCP plans. The majority of the hazards identified were microbial, primarily Salmonella. Metal could also be a significant hazard in some processes. For pasteurized liquid egg products, Critical Control Points (CCPs) were identified at the pasteurization step and the cooling steps. Pasteurization was also a CCP for the spray dried egg products. Ready to eat specialty egg products and boiled egg products had CCPs identified at the cooking and/or pasteurization steps, depending on the process. For the shell eggs, there were no kill steps in the process so storage temperatures and the anti-microbial wash steps were identified as being critical to ensure safety of the product. The generic plans also contain a list of references to support decisions made in the hazard analysis section of the plans. An overview of HACCP and how to use the generic plans are also included. The generic plans will be available to processors in hard copy format, electronic/CD ROM format and on-line for use by egg processors.

Key Words: egg processing, HACCP, Food Safety

1224 Tuna Oil as n-3 Fatty Acids Source to Egg Yolk. C. Castillo Badillo¹, M. Gonzalez Alcorta¹, E. Morales Barrera², S. Carrillo Dominguez*³, and R.M. Castillo Domnguez³, ¹Universidad Autonoma de Chapingo, Chapingo, Texcoco, Mexico, ²Instituto Nacional de Investigaciones Forestales, Agrcolas y Forestales, Chapingo, Texcoco, Mexico, ³Instituto Nacional de Ciencias Mdicas y Nutricion Salvador Zubirn, Mexico D.F., Mexico.

The inclusion of tuna oil in the laying hens diet can rebound in benefits for the human health because it enrich the egg with fatty acids omega 3, which diminishes the cardiovascular human disease incidence. The aim of this study was to evaluate the effect of substitution safflower oil by tuna oil in the laying hens ration, on egg lipids and fatty acids omega-6 and omega-3 content. The study was carried out with 160 Leghorn laying hens, 90 weeks old, allocated in four treatments (3:0, 2:1, 1:2, 0:3) with four replicates each one. The experimental data were collected during 56 days. It was carried out two egg sampling, at the 28 and at the 56 experimental days. It was randomly taken four eggs of each replicate. The eggs were freezing. AGn-6 and AGn-3 were analyzed by gas chromatography. It was not detected any significant difference ($P>0.05$) on the egg total lipids (TL) content at the first 28 experimental days. However, the AGn-3 egg content (mainly EPA and DHA) increased to 30 mg/g lipid in the treatment 2:1. To 56 days the TL content was reduced 7% in the same group and the egg fatty acids content was higher significantly ($P<0.05$), obtained until 32mg/g lipid AGn-3, mainly EPA and DHA. Those observations suggest that tuna oil dietary inclusion has a positive relationship with the fatty acids omega-3 egg enrichment.

Key Words: Tuna oil, n-3 Fatty acids, egg yolk

1225 Effect of cooking methods and packaging conditions on the TBARS and COPs of turkey thigh meat patties during storage. S. J. Hur*, M. Du, K. C. Nam, Y. H. Kim, and D. U. Ahn, Iowa state university.

Turkey thigh meats with skin were ground twice through a 3-mm plate and patties were prepared. Patties were cooked using 5 different methods (pan frying, oil deep frying, boiling, oven cooking, and microwaving) to an internal temperature of 85-90°C and packaged in either oxygen permeable PVC zipperbags or oxygen impermeable PVDC bags. The samples were analysed for TBARS and cholesterol oxidation products (COPs) after 0, 3, and 7 days of storage at 4°C. The TBARS of cooked meat increased during the storage regardless of cooking methods, but vacuum packaged thigh meat produced less TBARS and COPs than the aerobically packaged samples. At the beginning of storage, aerobically packaged meat cooked by boiling method produced higher TBARS than that of others. However, the TBARS of microwaved meat with vacuum packaging increased rapidly after 3 days of storage at 4°C. The amount of total COPs in cooked thigh meat increased with storage and the increase was linear with storage time. The level of total COPs in aerobically packaged cooked meat was higher than the vacuum-packaged meat. Microwaving produced higher level of total COPs in meat than other cooking methods during storage. The results indicated that the progress of cholesterol oxidation in cooked meat was similar to that of lipid oxidation, and the formation of lipid and cholesterol oxidation products in cooked meat was closely related to cooking temperature, cooking time, storage time, and packaging conditions.

Key Words: cooking methods, cholesterol oxidation products, TBARS

1226 Identification of Bacteria Found in Broiler Deboning Operations. Tam Mai* and Donald Conner, Auburn University.

Research was conducted to identify bacterial community members found in broiler deboning operations. The objectives of this study were to gain a general idea of identity of bacteria in chicken products and the processing environment, and to determine effects of processing on bacterial types. Samples were collected at random at the postchill-debone lines of the same commercial processing facility over three visits. Collection at each sampling time consisted of 20 whole carcass (C), 20 breast meat (B), 20 skin (S), and 20 equipment (E) samples. Each sample was cultured on tryptic soy agar, incubated at 37°C for 24 hours. Colonies with different morphology were picked and streaked for isolation. Using this procedure, a total of 600 bacterial isolates were obtained (201 C, 222 B, 80 S, 97 E). Each isolate was identified based on whole cell lipid composition. Among the 600 isolates, there were 35 different genera, representing 100 different species. *Staphylococcus* (21%), *Pseudomonas* (17%), *Flavobacterium* (16%), and *Acinetobacter* (13%) were the predominant genera. Bacterial community composition varied at the different sampling times; however, similar genera of bacteria were found consistently in breast meat and on processing equipment. Data indicate that predominant bacterial types in broiler meat change as products are processed.

Key Words: Bacteria, Identification, Processing

1227 Broiler skin and meat color changes during storage. M. Petracci*² and D. L. Fletcher¹, ¹University of Georgia, Athens, USA, ²University of Bologna, Bologna, ITALY.

It has been reported that both broiler skin color and meat color change during slaughter, processing, and storage. In recent years, systems have been developed for the express purpose of using computer based machine vision for evaluating carcass and meat quality. Many of these systems use color discrimination as a criteria. Therefore, a better understanding of the time scale and degree of color change is necessary to calibrate such systems and to predict ultimate product color. Four experiments were conducted to study the color changes during processing and storage of broiler carcass skin, and breast and leg meat. For skin color, broilers were subjected to either a semi-scald (50 C for 120 sec) or a sub-scald (57 C for 90 sec). Color was measured both on and off the pectoral feather tract. For breast and leg meat color, color was measured directly on the meat surface (without packaging) or on the packaged meat surface. CIELAB color values of lightness (L*), redness (a*), and yellowness (b*)

were measured every 20 min for the first 3 hours, every 30 minutes between 3 and 8 hours, hourly between 8 and 12 hours, and daily for 8 days. Results clearly show that both skin and meat color change dramatically during the first 6 hours postmortem, after which the change is less dramatic over the 8 days of storage. Semi-scalded birds changed more than sub-scalded birds, presumably due to the more stable color of the xanthophylls in the epidermis and less influence of changes in the underlying muscle tissue. These results show that computer assisted vision or color systems must account for these changes and should be factored into system calibration. Also, early color analyses for market products, although highly correlated with later product color, may not reflect final product color specifications.

Key Words: Broiler skin color, Broiler meat color, Color change during storage

1228 Use of marine algae to enrich DHA content of heavy broiler breast and thigh muscle. J.E. Garrett*¹, J.R. Abril¹, and M.D. Sims², ¹Omega Tech, Inc., Boulder, CO, ²Virginia Scientific Research, Harrisonburg, VA.

The production of meat enriched with omega-3 fatty acids has the potential to provide an alternative source to fatty fish for of these nutrients. Four hundred 44-day old broilers (200 male and 200 female) were sorted by sex randomly allotted to one of four treatments: Control (C); 17 g algae/bird/wk for 7 days followed by 3 g algae/bird/wk for 7 days (N); 10 g algae/bird/wk for 2 wks (E); and 34 g algae/bird/wk for 7 days followed by 6 g algae/bird/wk for 7 days (D). Marine algae used study was DHA Gold[®], Omega Tech, Inc., a rich source of decosahexaenoic acid (DHA). Diets were formulated to meet NRC requirements. Bird performance was not significantly ($P > .05$) affected by any treatment. At the end of the two-week feeding period, 30 males and 30 females were collected from each treatment and processed for carcass data. Twenty carcasses (10 male and 10 female)/trt were processed ready to cook and then ground for analysis, 20 carcasses (10 male and 10 female)/trt had breasts and thighs removed for analysis and 20 carcasses (10 male and 10 female)/trt were retained for sensory panel evaluation. Breast muscle had the following DHA concentration (mg/100 g of tissue) 9.6, 35.8, 50.7 and 69.7 for C, N, E and D, respectively. Thigh muscle had the following DHA concentration (mg/100 g of tissue) 12.2, 54.3, 76.4 and 109.2 for C, N, E and D. Each treatment resulted in a significant enrichment from other treatments. Sensory panel evaluation showed no difference in breast quality for 3 or 10 day cold storage, with the exception that breasts from D were identifiable but not objectionable. Thigh quality showed similar results with no difference in quality though D thighs were identifiable at 3 and 10 days of cold storage. Efficiency of enrichment of DHA averaged 20.6, 25.7 and 21.4% for N, E and D, respectively. Conclusions from this study indicate that feeding of marine algae is a viable method to provide an alternative source of DHA compared to traditional fish sources.

Key Words: Omega-3 fatty acids, Broiler, DHA, Breast muscle, Thigh muscle

1229 Growth of *Campylobacter jejuni* under Acidic Conditions. Lei Zhang* and Donald Conner, Auburn University.

Campylobacter jejuni is a prominent cause of human bacterial gastroenteritis, and there is a high prevalence of the organisms in raw poultry products. Acid resistance is an important factor affecting ability of enteric bacteria to colonize the GI tract, therefore, acid tolerance can affect efficiency of subsequent acidic treatments in eliminating enteric pathogens from processed carcasses. To test the effect of pH reduction on growth of *C. jejuni*, Brucella broth was acidified with citric, hydrochloric, or tartaric acid to pH 4.5-6.5 in 0.5 unit increments. Triplicate tubes with 10 ml acidified Brucella broth were inoculated with *C. jejuni* (10^4 CFU/ml) and incubated in an atmosphere of 10% CO₂, 5% O₂ and 85% N₂ at 42 °C. CCDA and Campy-Cefex plating media were used to enumerate *C. jejuni* at 0, 48, and 96 hours. The minimum test pH at which *C. jejuni* did not grow (inhibitory pH) was determined for each acid. In the pH range tested, the inhibitory pH was 4.5 for citric and hydrochloric acids, and pH 5.0 for tartaric acid. In the non-inhibitory pH range (pH 5.0-6.5 for citric and hydrochloric acids, pH 5.5-6.5 for tartaric acid), initial populations of viable cells increased to their highest numbers at 48 hours. Populations of viable cells were 2-3 LOG₁₀ CFU/ml higher at pH 6.5 than at the lowest pH value at which growth occurred (pH 5.0 for citric and hydrochloric acid, 5.5 for

tartaric acids). Results showed that *C. jejuni* has the ability to grow at moderately acidic environments; however, type of acidulant affects survival.

Key Words: *Campylobacter jejuni*, acidic conditions, growth

1230 Comparison of carcass damage in turkeys stunned on constant voltage and constant amperage electrical pre-slaughter stunning systems. J.D. Reiman* and J.A. Marcy, University of Arkansas.

Unacceptable carcass damage, primarily hemorrhage in the breast muscles, has been associated with electrical stunning systems. One factor that may induce hemorrhage is the fluctuation of current (amperage) applied to a single bird. This fluctuation is a function of the variation in resistance between birds and with the number of birds in the system in a constant voltage stunner. In four experiments, turkeys were stunned with either a constant voltage (DC, 480 Hz) or constant amperage (square wave AC, 480 Hz) electrical pre-slaughter stunning system, processed and evaluated for carcass damage. For each experiment, 60 commercially grown 4.5-6.5 kg female turkeys were randomly and individually subjected to one of four stun treatments (low constant voltage 13 V; high constant voltage 32 V; low constant amperage 10 mA; high constant amperage 25 mA). The physical reaction at the time of stun and during exsanguination was observed as the turkeys were processed through an automated slaughter system. The carcasses were chilled and held for 24 hours before cut-up and visual inspection. At 24 hours, each carcass was fabricated, the parts subjectively scored to describe the presence and severity of hemorrhagic damage, the pH of the breast muscle recorded (0.25, 1, 2, 24 h) and CIE L*a*b* values (24 h) measured. No difference ($P < 0.05$) in carcass damage was observed between any of the electrical stunning treatments. A lower pH ($P < 0.001$) occurred at 1 and 2 hours for both the low voltage and low amperage treatments. This may have resulted from a more rapid state of rigor development caused by greater physical activity at the time of stun, venisection and exsanguination as supported by higher stun reaction scores and observations. These results suggest little difference between constant voltage and constant current systems for preventing hemorrhaging in turkey carcasses along the parameters used in this study.

Key Words: Stunning, Turkey, Carcass damage

1231 Survival of *Campylobacter jejuni* on Poultry Skin and Meat at Varying Temperatures. M. A. Davis* and D. E. Conner, Auburn University, AL, USA.

Recent research showing a much higher prevalence of *Campylobacter* on skin-on poultry products vs skinless products suggests that contamination is associated primarily with poultry skin and that *Campylobacter* may not survive well on poultry meat. Therefore, survival of *Campylobacter* on poultry skin vs. meat was quantified. Pieces of skin and meat were irradiated to eliminate native microflora, and inoculated with *Campylobacter jejuni* ($>5.0 \times 10^5$ cfu/ml). Meat and skin samples were packaged in polystyrene trays, covered with Cryovac[®] film, then subjected to one of the following storage conditions: 1) 4C for 11 days, 2) 4C for one day, then -3C for 10 days, 3) 4C for one day, -3C for one day, then 4C for 9 days, or 4) 4C for one day, -3C for one day, 20C for one hour on day 2, then 4C for 9 days. On days 0, 2, 3, 5, 7, 9 and 11, populations of *Campylobacter* were determined. The experiment was replicated three times. In each experiment, populations of surviving *Campylobacter* were not affected by storage conditions ($p \geq 0.05$), and there was no interaction between temperature treatments and sample type. Surviving *Campylobacter* populations were affected ($p < 0.05$) by sample type (skin vs meat). *Campylobacter*, in the absence of competing microflora, survived well on both poultry skin and meat at the varying temperatures tested. In all experiments, higher populations were established on the inoculated skin vs inoculated meat. These populations remained consistently 0.4-0.9 log₁₀ cfu/g higher on skin vs meat. Poultry skin topography, which provides for rapid attachment and entrapment of *Campylobacter*, may account, in part, for these higher populations on skin.

Key Words: *Campylobacter*, Poultry, Skin

1232 Comparison of electrolyzed oxidizing water with various antimicrobial interventions to reduce *Salmonella* spp. on poultry. K. A. Barstad*, R. R. Sharma, A. Demirci, and C. N. Cutter, *Penn State University*.

Recently, electrolyzed oxidizing (EO) water has been demonstrated to significantly reduce foodborne pathogens associated with cutting boards, vegetables, and cell suspensions. EO water is generated by passing a dilute salt solution through an electrical field, resulting in a solution with a pH of approximately 2.6, a residual chlorine level of 10-60 mg/liter, and oxidation-reduction potential of about 1,150 mV. In this study, EO water, chlorine (CL), ozonated water (OZ), acetic acid (AA), and trisodium phosphate (TSP) were used to treat freshly slaughtered chicken carcasses experimentally inoculated with *Salmonella* Typhimurium ATCC 13311. Antimicrobials were applied to inoculated carcasses either by submersion (4C, 45 min) or spray washing (85 psi, 25C, 15 sec). Following treatments, remaining bacterial populations were determined and compared at day 0 and after 7 days of refrigerated storage. Immediately following submersion experiments, treatments with TSP and AA demonstrated a 1.41 log₁₀ reduction of *S. Typhimurium*, while EO water reduced the pathogen approximately 0.86 log₁₀. After 7 days of aerobic storage at 4C, EO water, OZ, TSP, and AA significantly reduced the pathogen, with detection of the pathogen only after selective enrichment. Remaining bacterial populations immediately following spray washing experiments were not statistically significant between treatments at day 0; TSP and EO water exhibited a 0.9 and 0.59 log₁₀ reduction of *S. Typhimurium*, respectively. After seven days of refrigerated storage, TSP, AA, and EO water affected a 2.17, 2.31, and 1.06 log₁₀ reduction, respectively. While TSP and AA are effective in reducing *S. Typhimurium* in these experiments, these compounds may be expensive for processors to use and can adversely affect the environment following disposal. The data from this study suggest that EO water, delivered to contaminated surfaces by submersion or spray washing, can effectively control pathogens on poultry surfaces, especially following extended refrigerated storage. In order to improve the immediate and long-term effect of EO water spray washing treatments against *S. Typhimurium* associated with poultry surfaces, further optimization studies are warranted.

Key Words: Electrolyzed oxidizing water, *Salmonella* spp., processing

1233 Application of Sodium Citrate or Sodium Lactate in Breast Meat Chicken Roll Processing. A. Supatanont¹ and T. C. Chen*¹, ¹*Mississippi State University*.

Studies were conducted to investigate and compare the effects of sodium citrate and sodium lactate on yields and quality characteristics of restructured breast meat chicken roll. Chicken breast meats were hand deboned from broiler carcasses, skinned, excess fat removed, and cut into approximately 2.5 cm cubes. The meat cubes were mixed with other ingredients and stuffed into casings to form 6 cm diameter chubs, which were cooked at 82.2C until the internal temperature reached 71.1C. After cooling, processing yields and quality characteristics of the chicken rolls were measured. Processing yield of chicken rolls were increased ($P < 0.05$) by the addition of either sodium citrate or sodium lactate. No differences ($P > 0.05$) in yield were observed among the 0.25%, 0.50%, and 0.75% of either of the additives. When compared to those of the non-treated controls, the Hunter color readings, WB shear values, and Hedonic sensory scores of chicken rolls were not affected ($P > 0.05$) by the addition of either sodium citrate or sodium lactate. The refrigerated shelf life of chicken rolls were effectively extended by the presence of sodium citrate or sodium lactate. The presence of 0.50% sodium citrate also retarded ($P < 0.05$) the rancidity development of chicken rolls, while little or no effects were observed for the sodium lactate. Data suggested that sodium citrate can serve as an alternate for the preservation of processed muscle foods.

Key Words: chicken roll, sodium citrate, sodium lactate

1234 Influence of measurement position on the color values of turkey breast meat. T. J. Buttles¹, J. Kalbfleisch¹, S. L. Noll¹, and B. S. Walters*², ¹*University of Minnesota, St. Paul, MN*, ²*University of Wisconsin - River Falls, River Falls, WI*.

Color has been identified as a quick, non-destructive method to screen poultry meat for abnormal muscle characteristics including pale, soft, and exudative (PSE). A uniform protocol for taking color measurements

has not been developed. One of the factors in developing a standard protocol is determining where to take the measurement. The objective of this study was to determine if different positions on the muscle give different color readings. CIE color readings for lightness (L^*) were taken on breast meat from 104, 20-wk-old turkey toms. The breast meat was deboned 24h postmortem and the color readings taken immediately after deboning. Ten different locations on the internal surface, 5 on each half of the breast, were analyzed. The mean L^* value was 49.75. Linear correlations between the 10 locations were determined by Pearson's correlation coefficients. The L^* values at the different positions were positively correlated, with values ranging from 0.12 to 0.71 with a mean value of 0.34. While many of these correlations were statistically significant, they did not show strong correlations. These results indicate that the position of the measurement may impact how the meat is categorized as normal versus light or dark. Further research is needed to confirm these results and to determine the best position for taking color measurements.

Key Words: Turkey, Meat color, Poultry

1235 Pinking in further-processed turkey due to residual nitrate reduction by *Pseudomonas fluorescens*. Chad Clem* and John Marcy, *University of Arkansas, Fayetteville, AR*.

Cooked poultry products occasionally develop a "pink" tint that is unappealing to consumers. A possible reason for this color development is the microbial reduction of residual nitrate in the processing water. This study investigated the role of *Pseudomonas fluorescens* in the nitrate reduction of processed turkey and the resulting pink discoloration found in the meat. Shaved turkey product, divided into 12 groups, was inoculated with 0, 50, or 200 ppm sodium nitrate (NaNO_3). Half of the treatments also received inoculums of *P. fluorescens*. After stuffing into impermeable casings and storing for either 12 or 60 h, the meat was cooked to 82 C and then evaluated for nitrite (NaNO_2) and color differences by colorimeter and sensory panel. The mean colorimeter value for redness from the samples treated with 200 ppm NaNO_3 and bacteria and stored for 60 h was 4.07, whereas that of the samples that were not treated with any NaNO_3 or bacteria and were held for only 12 h was 2.65. Sensory panels also rated samples treated with 200 ppm NaNO_3 significantly pinker than samples containing no added NaNO_3 . Storage time had a significant effect on the color of the turkey with 60 h treatments receiving significantly higher redness values than 12 h treatments. The samples with the highest NaNO_3 treatments that also received *P. fluorescens* inoculums produced the greatest NaNO_2 levels after cooking. These results indicate residual NaNO_3 , *P. fluorescens*, and extended storage time may all contribute to the unwanted pink color development that is sometimes seen in further-processed turkey meat.

Key Words: Pinking, Bacterial Nitrate Reduction, Processed Turkey Meat

1236 Effect of rosemary oleoresin on quality of ground thigh chicken meat packed in high oxygen modified atmosphere environment. T. Keokamnerd*, I. Y. Han, and P.L. Dawson, *Clemson University, Clemson, SC*.

This research was conducted to compare an antioxidant effect of four different rosemary oleoresin extracts and a control sample (no antioxidant added) on quality of ground chicken thigh packed in a high oxygen modified atmosphere (80% O_2 : 20% CO_2). All samples were stored in the "dark" at $0 \pm 3^\circ\text{C}$ from day 0 to day 3, after that the meat samples were transferred to a "lighted" refrigerator at $3 \pm 1^\circ\text{C}$ with a light intensity of approximately 850 lux. Color, total aerobic plate count, and TBARS of ground chicken meat were measured at days 0, 3, 6, 9 and 12. The sensory impact of rosemary oleoresin on odor and flavor of the samples was evaluated by a panel on day 1. Meat with added antioxidant had a slower rate of increase in TBARS compared to meat without added antioxidant. No difference in color change was observed due to the addition of antioxidant. Antioxidants used in this experiment did not show anti-microbial effect, however, rosemary oleoresin seemed to improve meat odor and flavor.

Key Words: Modified atmosphere, Ground chicken meat, Rosemary oleoresin

1237 Imaging system for fecal and ingesta detection on poultry carcasses. K. C. Lawrence, B. Park, W. R. Windham, and D. P. Smith*, *USDA, ARS.*

A hyperspectral imaging system was developed to detect surface contaminants on poultry carcasses. The system consists of a transportable stand, two quartz halogen line lights, a prism-grating-prism imaging spectrograph connected to a 1280x1024 pixel silicon CCD camera, and a computer with a frame-grabber card. The imaging system is capable of collecting spectral reflectance information from 430 to 900 nm with 1-nm resolution for every pixel of a carcass image. The resulting three-dimensional image cube is typically reduced to 320x340 pixels of spatial information with 512 pixels of spectral information for each spatial pixel. This paper reports the results of this system for the detection of ingesta from the crop or gizzard and feces from the duodenum, ceca, and colon on the surface of a poultry carcass. Sixteen six-week old male birds on a corn/soybean diet were meal-fed, subjected to an 8-hour feed withdrawal, cooped, slaughtered, hard scalded (57.5 C for 2 min.), picked, eviscerated, and feces and ingesta was collected. Uncontaminated carcasses were then immediately imaged. Next, feces and ingesta were applied to varying locations on the breast, wings, and legs of the carcass, typically three spots per contaminant, 12 spots per bird, for a total of 190 contaminant spots, and second images were taken. Results are presented for several data analysis techniques including principal component analysis, which includes all measured wavelengths, and the wavelength ratio of the 565-nm image divided by the 517-nm image. The wavelength-ratio images were further processed with background masking, thresholding, and histogram stretching. The threshold and histogram stretching values were fixed for all birds. Linear and square root histogram stretches were performed. Results indicated that 97.3 and 100 percent of the contaminants were detected with the linear and square-root histogram stretches, respectively. The research shows the feasibility of a real-time system for fecal and ingesta detection from two wavelength images at typical poultry processing line speeds.

1238 Effects of post-mortem deboning time and L-value classification of raw fillets on color and texture characteristics of cooked broiler breast meat. B. G. Lyon*¹, E. T. Moran², C. E. Lyon¹, and E. M. Savage¹, ¹*USDA, ARS, Russell Research Center, Athens, GA*, ²*Auburn University, Auburn, AL.*

Color of raw broiler meat has consumer implications and may also be indicative of functional properties of the meat. In this study, broiler breast samples from two deboning times were sorted by instrumental color (Minolta); then evaluated for cooked color, aroma and texture. Samples were from 8 wk old male broilers (Ross X Hubbard HiY) subjected to common live production and normal pre-slaughter handling. After processing, *pectoralis majors* were removed from chilled carcasses either at 4-6 h (early, ED) or 24-30 h (late, LD) post-mortem. Fresh fillet light reflectance was measured 48 h after slaughter. Each fillet was

IQF, held at 0C, and sorted by L-value (lightness) into two groups, low (<46, LL) or high (>52, HL) from the total having a grand mean of 49. Thawed samples were cooked individually in heat-and-seal bags immersed in 85C water to internal temperature of 78C, and evaluated for aroma, shear force, and light reflectance measurements of outside surface, inside cut surfaces and decanted cook fluid. Thawed raw weight and cooked yield were not significantly different. Cooked L-values for outside and inside cut surface of EDHL were significantly higher than the other three groups. Significant differences in cooked liquid color measurements were found (EDLL < EDHL). Shear force values were significantly higher for EDHL breast meat. Aroma of EDLL was the least brothy, most chickeny and most bloody/serumy; EDHL samples were most metallic. These results agree with other reports that cooking reduces color variation. However, early deboning may present more color differences than late deboning. Further work is needed to elucidate factors that can allow prediction and control of breast meat color and quality.

Key Words: Broiler breast meat color, Instrumental L-values, Deboning time

1239 Lipid and Fatty Acid Composition of Some Specialty Eggs. Gita Cherian*, Troy B. Holsonbake, and Mary P. Goeger, *Oregon State University, Corvallis, Oregon, USA.*

Many specially fed and raised chicken eggs are available in the United States with labels such as 'vegetarian', 'cage-free', 'organic', 'non-medicated', 'naturally-nested' or 'free-range'. The objective of the present study was to compare the egg components, total fat and nutritionally important fatty acids in eggs with special labels or claims. A total of six different brands of eggs with labels such as 'vegetarian high n-3', 'free-range', 'organic', 'uncaged-non-medicated', 'vegetarian-cage-free' or 'cage-free-naturally-nested' were collected and analyzed. A significant (P <.05) difference was observed in the egg components and fatty acid content in different brands. The percent yolk was lower (P <.05) in 'organic' and 'cage-free-vegetarian eggs' with a concomitant increase (P <.05) in the percent white. The percent shell was lower (P <.05) in 'cage-free-vegetarian' and 'naturally-nested cage-free' eggs. No difference (P >.05) was observed in the total edible portion. The total lipids were lower (P <.05) in 'cage-free-vegetarian' eggs. However, this was not noticed in 'free-range', 'vegetarian' or 'naturally-nested-cage-free' eggs. The content of C16:0, C18:0 and total saturated fatty acids were lower (P <.05) in 'vegetarian high n-3' eggs. No difference was observed in the content of C16:1, C18:1 or total monounsaturated fatty acids. The content of n-3 fatty acids were lower (P <.05) in 'organic', 'vegetarian free-range' and 'cage-free' eggs. The ratio of total n-6:n-3 polyunsaturated fatty acids ranged from 39.2 for 'cage-free' to 11.5 for 'vegetarian high n-3' eggs (P <.05). No difference was observed in the total polyunsaturated fatty acid content of eggs (P >.05).

Key Words: Specialty Eggs, Lipids, Fatty Acids

PSA Immunology

1240 Enhanced macrophage function in broilers fed diets supplemented with *E. coli* bacterial cell powder. G. F. Erf*¹, T. K. Bersi¹, and Y. Toride², ¹*University of Arkansas, Fayetteville, AR, USA*, ²*Ajinomoto Co., Inc., Tokyo, Japan.*

Bacteria are important members of the gut flora and are known to play a role in innate immunity. Additionally, bacterial cell wall products such as lipopolysaccharide (LPS) and peptidoglycan are known to have immunopotentiating effects. In chickens, little information is available on immunopotentiating effects of orally administered bacterial cell wall products. This study was designed to examine and compare the effects of dietary administration of purified *E. coli* LPS and of *E. coli* bacterial cell powder (BCP) on macrophage function in broilers. Newly-hatched male broiler chicks were assigned to 8 treatment groups consisting of standard diet (control), standard diet supplemented with 1, 10, 100, or 1000 ppm *E. coli* BCP, or standard diet supplemented with 0.034, 0.34, or 3.4 ppm *E. coli* LPS. When the broilers were 3 to 4 weeks of age, Sephadex-elicited abdominal exudate cells (macrophages) were collected. Macrophages from at least 10 birds per diet were then cultured with or without *in vitro* LPS stimulation to assess oxidative radical production (oxidation of 2',7'-dichlorofluorescein diacetate), nitric oxide

production (nitrite assay), and tumoricidal activity (% killing of RP9 tumor cells). Dietary *E. coli* BCP administration did not affect oxidative radical production by macrophages, but did increase macrophage nitric oxide production and tumoricidal activity compared to controls. Similarly, addition of purified *E. coli* LPS to the diet had no effect on oxidative radical production. Macrophages from broilers fed 0.034 ppm *E. coli* LPS exhibited enhanced nitric oxide production and tumoricidal activity, however, these enhancing effects of dietary *E. coli* LPS were masked when macrophages were further stimulated with LPS in culture. Although both *E. coli* products enhanced macrophage function in young broilers, the immunopotentiating effects of *E. coli* BCP were more consistent than those of pure *E. coli* LPS.

Key Words: Broiler macrophage, Lipopolysaccharide, *E. coli* bacterial cell powder

1241 Enhanced macrophage function in broilers fed diets supplemented with digested bacterial cell powder prepared from *Brevibacterium lactofermentum*. T. K. Bersi*¹, B. B. Madison¹, M. K. Redhorse¹, Y. Toride², and G. F. Erf¹, ¹University of Arkansas, Fayetteville, AR, USA, ²Ajinomoto Co., Inc., Tokyo, Japan.

Bacterial cell wall products such as lipopolysaccharide (LPS) and peptidoglycan are known to have immunopotentiating effects. In chickens, little information is available on immunopotentiating effects of orally administered bacterial cell wall products. This study was designed to examine and compare the effects of dietary administration of purified muramyl dipeptide (MDP) and digested bacterial cell powder (DBCP) prepared from *B. lactofermentum* on macrophage function in broilers. Newly-hatched male broiler chicks were assigned to six treatment groups consisting of standard diet (control), standard diet supplemented with 10, 100, or 1000 ppm DBCP, or standard diet supplemented with 0.35 or 3.5 ppm purified MDP. When the broilers were 3 to 4 weeks of age, Sephadex-elicited abdominal exudate cells (macrophages) were collected from at least 10 birds per diet. Various aspects of macrophage function were examined *in vitro*, including adherence, phagocytosis of sheep red blood cells (SRBC), and phagocytosis of antibody-opsonized SRBC. Additionally, to assess oxidative radical production (oxidation of DCF-DA), nitric oxide production (nitrite assay), and tumoricidal activity (% killing of RP9 tumor cells), the cells were cultured with (stimulated macrophages) or without (unstimulated macrophages) LPS. Macrophages from broilers fed the DBCP diets exhibited enhanced phagocytosis of antibody-opsonized SRBC compared to controls. Additionally, dietary DBCP resulted in enhanced nitric oxide production and tumoricidal activity by unstimulated macrophages, and enhanced production of oxidative radicals and nitric oxide by stimulated macrophages. These enhancing effects of DBCP on macrophage function were observed when the diets contained 100 or 1000 ppm DBCP. Dietary administration of purified MDP did not significantly affect any of the parameters examined.

Key Words: Broiler macrophage, Muramyl dipeptide, Digested bacterial cell powder

1242 The Effects of Epigallocatechin Gallate on the Avian Macrophage *In Vitro*. Jennifer Paquette* and Fred McCorkle, PhD., Central Michigan University, Mt. Pleasant, MI.

Epigallocatechin gallate, EGCG, is the active polyphenol in green tea. EGCG has been shown to inhibit the growth of certain tumors through the inhibition of certain transcription factors. EGCG has also been shown to promote IL-1 production in monocytes and enhance the proliferation of B-cells. In this study, the effects of EGCG on several avian macrophage functions were examined. The macrophage is a major secretory cell within the immune system and aids in the phagocytosis and destruction of invading matter. The MQ-NCSU macrophage cell line was used. The null hypothesis was that EGCG would have no effect upon the avian macrophage function. Macrophage functions tested included the adherence and the phagocytosis. All data was performed in triplicate format and was analyzed using a one-way ANOVA. The cytotoxicity of EGCG to macrophages was performed at concentrations of 1×10^{-6} to 1×10^{-12} M. EGCG had no cytotoxic effects upon the avian macrophage. The remaining assays used concentration levels of 1×10^{-8} to 1×10^{-12} M. EGCG affected the ability of macrophages to adhere to a substrate at all doses tested (113.11 ± 16 at 1×10^{-12} M vs. 260 ± 24.9 for controls). The phagocytosis assay used sheep red blood cells (SRBC) and *Escherichia coli* (*E. coli*) as substrates. EGCG did not affect the ability of MQ-NCSU macrophages to phagocytize either substrate and did not affect the number of substrate particles taken into a macrophage ($24.00\% \pm 2.71$ at 1×10^{-8} M vs. $23.89\% \pm 2.31$ for controls). EGCG does affect the ability of MQ-NCSU macrophages to adhere but is not cytotoxic at the concentrations tested and does not affect phagocytosis of SRBC or *E. coli*.

Key Words: Epigallocatechin Gallate, Macrophage

1243 The *in vitro* effects of Caffeic Acid Phenethyl Ester, the active component of Bee Propolis, on the avian macrophage. Tricia Anscomb*¹ and McCorkle Fred¹, Central Michigan University, Mt. Pleasant, MI.

Interest in nutritional supplements has increased within the past decade. This includes increased interest in products from the common honeybee, *Apis* species. Dose ranges of caffeic acid phenethyl ester (CAPE), the active component of bee propolis, are unclear and few studies have determined the effects of CAPE on the immune system. The macrophage is one of the main cells of the immune system. This study determined the effects of CAPE on the avian macrophage line MQ-NCSU *in vitro*. MQ-NCSU is a well-established and studied macrophage line. The effects of CAPE on cytotoxicity, adherence, and phagocytosis were tested. Using the trypan blue exclusion test, CAPE was not cytotoxic to avian macrophages from 1×10^{-3} to 1×10^{-12} M. The average macrophage viability for controls and CAPE concentrations was 92%. CAPE did not have any effect on macrophage adherence (controls 128 ± 10 adhered cells versus 1×10^{-7} M CAPE 133 ± 8 adhered cells). The effect of CAPE on the ability of macrophages to phagocytize *Escherichia coli* was determined. The number of macrophages undergoing phagocytosis of *E. coli* was not statistically different (38 ± 2 macrophages). At 1×10^{-10} M CAPE statistically lowered the number of *E. coli* taken up per phagocytizing macrophage ($1.6 \pm .07$ *E. coli* versus $2.2 \pm .25$ *E. coli* for controls). All statistics were analyzed using a one-way ANOVA and performed in triplicate for reproducibility. This study suggests that CAPE is not toxic to the avian macrophage and does not inhibit macrophage adherence to substrate or phagocytosis of *E. coli*, at the concentrations tested. The results suggest that human consumption of bee products with CAPE does not harm macrophage functions.

Key Words: Caffeic Acid Phenethyl Ester, Macrophage, Immune system

1244 Pulmonary hypertensive response to endotoxin and immune activity in primed and unprimed broiler chickens. W. Wang*, R. F. Wideman, and G. F. Erf, University of Arkansas, Fayetteville, AR, USA.

Pilot studies in broiler chickens indicated that the magnitude of pulmonary hypertensive responses to intravenous endotoxin varied widely among individual birds, which might contribute to their variable susceptibilities to pulmonary hypertension syndrome (PHS, ascites). The purpose of this study was to determine whether immunologically primed broilers have more consistent and enhanced pulmonary hypertensive responses to intravenous endotoxin injections than controls. For this study, birds were primed using a particulate immunological stimulus known to result in an increase of lymphocyte aggregates in the lungs. The pulmonary and peripheral arterial pressures prior to and following intravenous administration of *Salmonella typhimurium* endotoxin were examined in primed and unprimed broilers when the birds were between four and five weeks of age. Additionally, the number of lymphocyte aggregates in the lungs, as well as, the proportions and concentrations of circulating white blood cells were assessed in primed and unprimed broilers. Results showed that the primed group resembled the control group in their pulmonary hypertensive responses to endotoxin in terms of time of onset, magnitude, duration, as well as the variability in response among individual birds. The respiratory rate was higher in primed than in control broilers. The concentration of white blood cells was similar in both groups, whereas the percentage of eosinophils in the blood was higher in primed broilers compared to controls ($P < 0.05$). Lung tissue weight decreased ($P = 0.056$) in the primed birds within 48 hours after priming. The right ventricle to total ventricle weight ratio was similar for the two groups. In conclusion, priming reduced lung weight and increased the density of pulmonary lymphocyte aggregates but did not affect the magnitude or consistency of the subsequent pulmonary hypertensive response to intravenous endotoxin challenge.

Key Words: Broiler leukocytes, Endotoxin, Pulmonary hypertension

1245 Humoral Immunity Against Newcastle Disease Virus in Broilers fed *S. cerevisiae* cell wall and aflatoxin. Elizabeth Santin*¹, A.C. Paulillo¹, E.L. Krabbe¹, A. Maiorka¹, and M. Macari¹, ¹FCAV - Universidade Estadual Paulista.

This study aimed to evaluate the effect of aflatoxin in the diet, in the presence or absence of cellular wall of *Saccharomyces cerevisiae* (CWSC) on the humoral immune response of broilers vaccinated and challenged

against Newcastle disease virus (NDV). The exposure of 320 broilers to 1 ppm of aflatoxin reduced their humoral immune response in broiler vaccinated against NDV ($P < 0.05$), and the CWSC ameliorated this parameter but did not significant ($P > 0.05$). All groups reacted to antigenic stimulation to NDV at 11 days of age, but the best hemoagglutination inhibiting (HI) antibodies titers was obtained in birds not exposed to aflatoxin (GMT 7.75, 7.50, 6.37 and 5.75 to the birds fed without aflatoxin and CWSC; birds fed CWSC; birds fed aflatoxin and CWSC and birds fed only aflatoxin, respectively). When these birds were challenged with the velogenic strains of VDN, all the birds exposed at aflatoxin died, but in the birds fed with aflatoxin plus CWSC it was observed 50% of protection against VDN, demonstrating the deleterious effects of this mycotoxin in the immune response of the broilers vaccinated against Newcastle disease, and although the CWSC did not show significant improvement in HI antibodies titers, the cell wall of *S. cerevisiae* ameliorated the immune response of the birds challenged with VDN. FAPESP:Proc. n. 99/12952-7

Key Words: Aflatoxin, Immunity, *S. cerevisiae*

1246 *In Vitro* or *In Vivo* Effects of Recombinant Turkey Interferon Gamma (rtIFN γ) on *Eimeria* Invasion or Infection. R Beltran^{*1}, P Augustine², M El Halawani³, H Danforth², A McElroy⁴, and D Caldwell¹, ¹Texas A&M University, College Station, TX, ²USDA/ARS/LPSI/PBEL, Beltsville, MD, ³University of Minnesota, St. Paul, MN, ⁴Virginia Tech, Blacksburg, VA.

IFN γ is integral to many parameters of cellular immunity and promotes the barrier nature of mucosal membranes to enteric pathogens in mammals. Our interest in gut immunity in commercial poultry led to our investigation of the *in vitro* and *in vivo* effects of rtIFN γ on pathophysiology and immunity to avian coccidia. *In vitro* experiments consisted of exposing baby hamster kidney cells (BHK) to increasing concentrations of rtIFN γ and measuring subsequent *E. tenella* (ET) sporozoite invasion in short-term culture. When BHK were pretreated with 0, 2.5, 25, 250, 500, or 1000 ng rtIFN γ per ml of cell culture medium 45 min prior to the addition of the sporozoites to confluent monolayers, ET invasion was significantly reduced ($P < .05$) in BHK exposed to concentrations of 25 ng rtIFN γ and higher. In a subsequent experiment, when BHK were pretreated with the same concentrations of rtIFN γ for 48 hours prior to sporozoite addition, significant differences in cellular invasion were not observed. *In vivo* investigation consisted of administering rtIFN γ to day-of-hatch turkey poults by intraperitoneal injection 30 min prior to *per os* challenge with *E. adenoeides* (EA) and measuring effects on cecal lesion development and body weight gain 6 days post EA challenge. When poults received rtIFN γ at concentrations of 0.25, 2.5, or 12.5 $\mu\text{g/poult}$, cecal lesions associated with EA challenge were significantly reduced ($P < .05$). Body weight gains of poults receiving rtIFN γ and EA were not statistically different from that of poults administered EA alone. Further, administration of rtIFN γ at 12.5 $\mu\text{g/poult}$ and EA resulted in body weight gains not statistically different from that of poults receiving only rtIFN γ . These data, while preliminary, suggest the potential involvement of IFN γ in the development of immunity to avian coccidia in commercial poultry.

Key Words: IFN γ , Coccidial Immunity

1248 Croos reactivity determination for *Salmonella enteritidis* biovar issatschenko and *Salmonella gallinarum* using LT antibodies in immunoblot technique. O. Urquiza^{*1}, G. Tellez¹, L. Paasch¹, G. Ruiz-Palacios², and B. Diaz², ¹Departamento de Produccion Animal Aves, FMVZ, UNAM, ²Departamento de Infectologia e Investigacion del instituto nacional de nutricion (INNSZ).

This study was carried out to determine by Immunoblot, cross reactivity among supernatant proteins (SP) and periplasmic proteins (PP) of *Salmonella enteritidis* biovar. Issatschenko against CT and LT antibodies and *Salmonella enteritidis* biovar. Issatschenko SP and PP antibodies produced in rabbit and *Salmonella gallinarum* total antibodies produced in chicken. Results obtained showed that *Salmonella enteritidis* biovar. Issatschenko after a 24 hours of growing is able to produce 1.7 mg/mL of SP and 0.303 mg/mL of PP. In 15% SDS- PAGE there were protein bands corresponding to 97, 66.2, 45 y less than 31 kDa with SP and with PP 66, 42, 35, 33, 32 y 24 kDa. The Immunoblot using Avidina \times Biotin and Peroxidasa conjugates, reveled homologous and cross reactivity more intensive with anti LT, anti SP and anti PP of

Salmonella enteritidis biovar. Issatschenko antibodies and anti Sg of *S. gallinarum* against *Salmonella enteritidis* biovar. Issatschenko SP and PP and PS and PP of the same *Salmonella* but produced a year ago. Any one of the antibodies used were able to detect reactivity against CT, except the homologous antibodies whose were positive controls. In the other hand, utilizing the anti Sg antibody against SP, PP and SP and PP of one year old of *Salmonella enteritidis* biovar. Issatschenko and PP of Sg FVA #1, a high number of protein bands were reveled and more bands were observed with fresh *Salmonella enteritidis* biovar. Issatschenko PP. The reactivity observed with anti LT against *Salmonella enteritidis* biovar. Issatschenko PP and *Salmonella gallinarum* PP could discriminate different protein bands by Immunoblot whom are visible by the use of total Sg antibodies. That discrimination could be used as a tool for differentiation among some salmonelas.

Key Words: *Salmonella issatschenko*, Exotoxins, Enterotoxic activity

1249 The Interleukin-1 β sequence of Japanese quail (*Coturnix coturnix japonica*) and Mallard ducks (*Anas platyrhynchos*). B.D. Humphrey^{*}, E.A. Koutsos, and K.C. Klasing, University of California, Davis, Davis, CA.

The Interleukin-1 β (IL-1 β) DNA sequence of Japanese quail and Mallard ducks was determined. This cytokine is produced in response to inflammatory agents such as gram-negative bacteria, and induces localized responses including tissue destruction and activation of lymphocytes and vascular endothelial cells. In addition, systemic effects of IL-1 β include induction of fever and the hepatic acute phase response. To stimulate production of IL-1 β , Japanese quail were injected with 7.5 mg lipopolysaccharide (LPS; isolated from *Salmonella typhimurium*)/kg body weight, and ducks were injected with 10⁶ fixed *E. coli* (wild type K12). Two hours after inoculation, spleen samples were taken from both quail and duck and analyzed for IL-1 β mRNA levels using RT-PCR procedure. PCR conditions for IL-1 β were based on previous work in our lab, and the PCR primer encompassed nucleotides 37 through 828 from the published chicken IL-1 β sequence (GenBank #Y15006). PCR products were isolated, purified, and the nucleotide sequence was determined. The quail and duck nucleotide sequences were analyzed for sequence homology using a protein-nucleotide database search program (BLAST). The isolated nucleotide sequence (735 nucleotides) from the spleen of Japanese quail was determined to be 93% homologous to chicken IL-1 β . The nucleotide sequence isolated from the spleen of Mallard ducks (637 nucleotides) was found to be 85% homologous to chicken IL-1 β . Isolation of the complete IL-1 β sequence is required to assess phylogenetic differences between chicken, quail and duck IL-1 β structure. However, it seems that the pro-inflammatory cytokine cascade functions in a similar manner in these avian species, as IL-1 β mRNA was induced and a systemic acute phase response occurred in Japanese quail and Mallard ducks as in chickens.

Key Words: IL-1 β , Japanese quail, Mallard duck

1250 Initiation of Humoral Immunity: The Role of Cytokines and Hormones in the Initiation of Humoral Immunity Using T-Independent and T-Dependent Antigens. A.E. Gehad¹, H.S. Lillehoj², G.L. Hendricks III³, and M.M. Mashaly^{*3}, ¹Virginia Commonwealth University, Richmond, VA/USA, ²USDA-ARS, Beltsville, MD/USA, ³The Pennsylvania State University, University Park, PA/USA.

The purpose of the present study was to investigate the role of different cytokines and hormones in the initiation of humoral immunity. Immature Cornell K-strain male chickens were injected i.v. with 8mg/kg BW of lipopolysaccharide (LPS) from *Escherichia coli*, a T-independent antigen or with 40mg/kg BW BSA, a T-dependent antigen. Control birds were injected with 0.9% saline. Blood and spleen were collected 0, 1, 3, 6, and 24 h following the injections. The blood was centrifuged and the plasma was collected. Plasma samples were assayed for Interleukin-1 (IL-1) like activity using the thymocyte co-mitogenesis assay following the precipitation of inhibitory factors with polyethylene glycol. Tumor necrosis factor- α (TNF- α) like activity was measured as cytotoxic activity against the L929 mouse fibroblast cell line. The plasma was also assayed for corticosterone and T₃ by RIA. Interleukin-2 (IL-2) activity was measured in the conditioned medium from splenic lymphocytes following their stimulation with the T-cell mitogen Concanavalin-A (Con-A) for 24 h. Interleukin-1 activity was increased significantly at 1, 3,

and 6 h post-LPS injection, whereas there was no change in IL-1 activity at any time postinjection in the BSA-injected birds. TNF- α activity significantly increased at 6 and 24 h post-LPS injection, whereas there was no difference in the TNF- α activity at any time postinjection in the BSA-injected birds. Interleukin-2 activity was decreased significantly at 3 h post-LPS injection compared to base line levels at 0 h. However, IL-2 activity increased at 3 h post-BSA injection compared to 3 h post saline injection. Corticosterone levels significantly increased 1, 3, and 6 h post-LPS injection, whereas there was no change in corticosterone levels at any time postinjection in the BSA-injected birds compared to saline injected birds. Tri-iodothyronine levels significantly decreased 3, 6, and 24 h post-LPS injection, whereas there was no change in T₃ levels at any time postinjection in the BSA-injected birds compared to saline injected birds. The results indicate that although LPS and BSA injection can induce a humoral antibody response in chickens, the mechanism of the initiation of this antibody response involving the activation of the cytokine network and the neuroendocrine system are different for each antigen.

Key Words: Chickens, Antigen, Cytokines and Hormones

1251 Control of coccidiosis in chicken by trickle immunisation. Srinivasan K¹, Dilipkumar Garikipati*², and Venkaram A², ¹Madras Vety College, ²College of Vety Sci, Tirupati.

Immunisation control of coccidiosis caused by *Eimeria tenella* was carried out by trickle immunisation (TI) method. Immunizing chickens daily with 100 number of oocysts at 1-7 days of age (experiment I), 1-14 days (experiment II), and 8-14 days (experiment III) of age. The corresponding doses were also administered at 1 and 8 days as double dose and at 8 days as single dose in experiment II and III, respectively. Chickens were challenged with 50,000 oocysts at 28 days of age and were sacrificed 7 days after injection. Highly significant increase in ceacal length was observed in experiment I and II, whereas no significant difference was noted in experiment II when compared to control. Trickle-immunized chickens showed lesser lesion score, decreased fecal oocyst output, and ceacal oocyst contents when compared to control. Further trickle immunized groups showed higher immunizing response than their corresponding single or double dosed groups against challenge infection. The results suggested that trickle immunization of chickens continuously

for 1-14 days of age conferred better protection than trickle immunization for 1-7 days or 8-14 days of age.

Key Words: coccidia, chicken, trickle immunisation

1252 gamma-Interferon and IL-2 activities in supernatant of lymphocytes on chicken splenocytes stimulated with concanavalin A. G. Gomez*¹, G. Tellez¹, A. Isibasi³, and V. Ortiz², ¹Departamento de Produccion Animal Aves, FMVZ, UNAM, ²Departamento de Biomedicina Molecular del CINVESTAV del IPN, ³Unidad de Investigacion Medica en Inmunoquimica del hosp. de especialidades del centro medico nacion.

Previous studies have shown a protection for the experimental challenge against infections resulting from *Salmonella gallinarum* and *Salmonella enteritidis* in chickens, through the manipulation of birds' immunocompetent system by the use of lymphokines (ILK) raw extract obtained from T lymphocytes of hyper-immunized birds with *Salmonella gallinarum* (ILK-Sg) or *Salmonella enteritidis* (ILK-Se), and re-stimulated with concanavalin A. In order to identify interleukines present in the ILK, the presence of interleukine-2 (IL-2) and Interferon was assessed. The results obtained show the presence of both interleukines in ILKSe. The chicken IL-2, as in other mammals, participates in the proliferation of T lymphocytes; however, a significant difference compared to other species is that there was a species barrier in its biological activity. The INF induced an increase in the expression of class I and class II molecules of the Major Histocompatibility Complex (MHC). The presence of INF in the supernatant, suggests that this interleukine could be participating in the protection effect which is conferred by the administration of ILK, encouraging macrophages and heterophils activation, which could be responsible for the bacteria elimination. Besides, these studies offer more evidences indicating that the observed immunity in the in vivo studies against *Salmonella gallinarum* and *Salmonella enteritidis* is probably induced by these important lymphokines. Studies are in progress to purify and identify the effector lymphokines genes in chickens, as well as a systemic research regarding the mechanism by means of which these lymphokines potentialized their protective effects.

Key Words: interleukines, interferon-gamma, interleukine-2

ADSA Dairy Foods: Microbiology and Cheese Technology

1253 Flavor development of cholesterol-reduced Cheddar cheese slurries. H. S. Kwak*¹, C. S. Chung¹, S. J. Lee¹, and J. Ahn¹, ¹Sejong University.

This study was carried out to find the development of flavor in cholesterol-reduced Cheddar cheese slurries by β -cyclodextrin (β -CD). The cheeses were made by 3 different treatments as followings: 1) control (no homogenization, no β -CD treatment), 2) Treatment A (1000psi homogenization, 10% -CD), and 3) Treatment B (cream separation, 10% β -CD). The cheese slurry was aged for 3 wk. The cholesterol removal was 79.30% (Treatment A) and 91.22% (Treatment B). Among 8 volatile flavor compounds, dimethylsulfide, 2-pentanone and 2-heptanone appeared to be insignificantly increased during 3 wk storage, and no difference was found among treatments as expected. The amounts of acetone and ethylacetate were slightly increased in control at 3 wk, however, no difference was found in others. Ethanol production was dramatically increase at 1 wk and decreased thereafter in all treatments. Most volatile flavor compounds were not significantly different among control and treatment A and B as expected. Based on our results, cheese slurry made by cheese milk after cream separation (36% milk fat) and 10% β -CD treatment showed a highest cholesterol removal. Therefore, this study provided a possibility of cholesterol-reduced Cheddar cheese manufacture without any flavor change.

Key Words: Low cholesterol Cheddar cheese, Flavor, Beta cyclodextrin

1254 Dynamic headspace analysis and sensory characteristics of ewes milk La Serena cheese. Mara Carbonell, Estrella Fernandez-Garcia*, and Manuel Nunez, Instituto Nacional de Investigacion y Tecnologia Agraria y Alimentaria (INIA).

La Serena cheese is a semi-soft variety, made in Extremadura (Spain) from raw milk of Merino ewes, coagulated with vegetable rennet. The objective of our study was to investigate the composition of the volatile

fraction of La Serena cheese, and its correlation with sensory characteristics. Duplicate batches of La Serena cheese were made at 4 dairies during the 4 seasonal periods. Cheese (60-day-old) samples were homogenized with sodium sulfate and an internal standard. An aliquot was extracted in a purge and trap apparatus. Volatiles were concentrated in a Tenax trap at 30C, and desorbed with He during 1 min at 230C directly into the injection port. Gas chromatography was carried out in a HP-6890 apparatus equipped with a HP Innowax capillary column and a HP 5973 mass spectrometer. Peaks were identified by comparison of retention times and ion spectra with those of real standards and of Wiley 275 library spectra. Quantitation was carried out by sum of characteristic ions abundance. Cheeses were scored by 14 trained panelists for quality and intensity of odor and aroma, on a 7-point scale. Volatile compounds found in the headspace of 60-day-old La Serena cheeses were 13 aldehydes, 8 ketones, 24 alcohols, 24 esters, 10 hydrocarbons, 14 terpenes, 3 sulfur compounds, 3 nitrogen compounds, 7 aromatic compounds and 5 free fatty acids. Most compounds were detected in cheeses made in all seasonal periods, and higher concentrations of most volatiles found in spring cheeses. Some terpenes were only detected in winter and spring cheeses. Analysis of variance showed significant seasonal differences of quality and intensity of cheese odor and aroma. Spring cheeses obtained the best quality scores, whereas winter cheeses had a more intense aroma. Odor intensity correlated positively with 2-butanone and 3-methyl-1-butanol, and negatively with terpenes, ethyl esters and quality of odor and aroma. A high concentration of 2-butanone was responsible for low quality scores, but high levels of esters resulted in improved quality scores even in the presence of high 2-butanone concentrations, as shown by Principal Component Analysis. Stepwise discriminant analysis of selected volatile compounds achieved

a correct classification of 100% cheeses in their respective seasonal periods.

Key Words: Volatile compounds, Sensory characteristics, La Serena cheese

1255 The volatile compounds of raw milk Manchego cheese and their relationship to some sensory attributes. Estrella Fernández-García* and Manuel Nunez, *Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA).*

Manchego cheese is the best known of Spanish ewes milk cheeses. The objective of this study was to isolate, identify and compare the relative amounts of volatile compounds in 6-month-old raw milk Manchego cheese made throughout the year. The correlation of certain volatile compounds with sensory characteristics is discussed. Cheese (15 g) was homogenized in an analytical blender with sodium sulfate (20 g) and an internal standard. The mixture (2 g) was subjected to helium purge at 50°C, 15 min, 10 min previous equilibration. Compounds were concentrated in a Tenax trap at 25°C. Desorption was at 230°C/0.5 min directly into the injection port at 220°C. Chromatography was carried out in a GC-MS system equipped with an HP Innovax capillary column. Main chemical families found in Manchego cheese were aldehydes, methylketones, alcohols and esters. Terpenes, sulfur and aromatic compounds, and hydrocarbons were also detected. Most aldehydes were at higher concentrations in spring cheeses. Major ketones were 2-propanone and 2-butanone. 2,3-Butanedione was more abundant in summer cheeses, possibly due to the higher level of starter inoculation in summer. Alcohols were quantitatively the main chemical family. Large quantities of ethanol, 2-propanol, 2-butanol and 3-methylbutanol were observed, but also of 2-pentanol and 2-heptanol. Branched chain alcohols were at higher concentrations in fall and winter, and at lower concentrations in summer cheeses. Twenty three species of esters were identified, with ethyl, propyl, branched chain alkyl and butyl esters as the most quantitatively important. Branched chain alkyl esters were less abundant in summer cheeses. Abundance of volatile compounds and sensory data were subjected to principal components analysis. Primary and secondary alcohols, 2-methylketones, and branched chain aldehydes and esters showed a high positive correlation with function 1, together with the descriptors rancid and piquant and aroma intensity. Aroma quality together with dimethyl disulfide showed a negative correlation coefficient with function 1. Branched chain alcohols, 2-butoxy-ethanol, butyl glycol acetate, dimethyl sulfide and isoamyl butyrate showed a high positive correlation with function 2, together with the aroma descriptor fruits-flowers.

1256 Effect of long term frozen storage on Manchego-type cheese proteolysis. Esther Sendra*¹, Jose Pons¹, Jordi Saldo², Reyes Pla², Montserrat Mor-Mur², and Ventura Guamis², ¹Universidad Miguel Hernández, ²Universitat Autònoma de Barcelona.

Two batches of Manchego-type cheese were manufactured. After press, curds were distributed in 2 groups of 8 units each; control and treated (which were packaged in polyethylene bags, frozen at an ice front velocity of 1.5 cm/h). Control analysis were run in 1993: before salting (C₀) and after salting and 60 days of ripening (C₆₀). Treated groups were kept at -20° C during 7 years, defrosted at 0° C and sampled: just defrosted (day 0), after salting (days 1, 30 and 60 of ripening). Overall composition, nitrogen (nt) and nitrogen soluble fractions (ncn: at pH 4.6, nTCA: in 12% trichloroacetic acid) were determined (in duplicate) in all curds and cheese units and their relative indexes were calculated (nnc/nt, nTCA/nt). Moisture significantly decreased during frozen storage. Salt content dramatically increased. An increase in ncn/nt and nTCA/nt was observed in defrosted curds (P<.05). Therefore, rennet and bacterial induced proteolysis still go on at freezing conditions. Proteolysis was more intense in cheese obtained from frozen curds than in control.

1257 Texture of artisan Spanish fresh goat's milk cheese. Esther Sendra*¹, Laura Alenda¹, Casilda Navarro¹, Estrella Sayas¹, Juana Fernández-Lpez¹, and Jos Angel Prez-Alvarez¹, ¹Universidad Miguel Hernández.

Servilleta is an artisan fresh goat's milk cheese that has not been typified or characterized. Distinctive characteristics are pasteurization conditions (82°C 10s), wrapping and pressing in cotton gausses with no use of molds and mild salting. Cheeses were sampled from 3 manufacturers, 3 times at monthly intervals (total: 9 samples per manufacturer). Overall composition (triplicate), stress relaxation test (4 replicates) and 80% uniaxial compression test (6 replicates) were run. Oneway ANOVA analysis was run (P<.05). There is no uniformity in the textural and compositional characteristics of commercial artisan Servilleta cheese. Its moisture content is higher than that of other fresh goat's milk cheeses. It is soft, and its viscoelastic parameters showed high elasticity and a great fluid behavior. The high pasteurization temperature may affect moisture retention and textural properties.

1258 Survivability of Probiotic Cultures in Symbiotic Goat's Milk Yogurt. Patricia Buldo*, Velitchka Gotcheva, and Mingrui Guo, *University of Vermont, Burlington VT.*

The ingestion of prebiotics and probiotics is proved to have a positive effect on maintaining healthy balance of the microflora in human digestive system. In this study, symbiotic goat's milk yogurt prototypes were prepared by combining probiotic cultures (*Lb. paracasei ssp. paracasei*, *Lb. acidophilus*, and *Bifidobacteria*) with prebiotic substances (fructooligosaccharose, FOS, and inulin). Changes in pH, titratable acidity (TA), and survivability of the probiotic cultures in six prototype yogurt products, i.e., control, fortified with goat's milk powder (4%), FOS (1 and 3%), and inulin (1 and 3%) were evaluated during nine-week refrigerated storage (4°C). Titratable acidity and pH were within the ranges of 1.11 to 0.89% and 4.26 to 4.06, respectively, throughout the period. Selective media (LP-MRS and B-MRS) were used to enumerate the viable cells of the probiotic strains during the storage. The effect of the prebiotics on the cultures was also studied. In all of the yogurt combinations, the three probiotic strains showed good survivability, starting at levels of 10⁹ CFU/g and decreasing to about 10⁷ CFU/g after 9 weeks of storage. The addition of milk powder seems to improve the viability of the probiotics compared to the other combinations. The survivability of the three strains varied, but, in general *Lb. acidophilus* and *Bifidobacteria* maintained higher concentrations than *Lb. paracasei ssp.*, except for the sample fortified with milk powder, in which *Lb. acidophilus* and *Lb. paracasei ssp.* showed better viability than *Bifidobacteria*. Chemical composition and the mineral profiles (Ca, K, Mg, Na, and Zn) of the six yogurt prototypes were also analyzed. There are no considerable differences in concentrations of all the minerals analyzed between

the control and the samples fortified with FOS, and inulin but the sample fortified with milk powder. In conclusion, the probiotic cultures in all prototypes remained at acceptable level ($>10^7$) for more than two months under refrigerated conditions. The addition of the prebiotic substances in the goat's milk yogurt seemed to have no positive impact on the survivability of the probiotic strains. The addition of milk powder contributed a better texture of the yogurt, as well as higher values of CFU/g.

Key Words: Pre-,probiotics, yogurt, goat's milk

1259 Protein profiles and rheological properties of fresh goat milk cheese. D. L. Van Hekken*¹, M. H. Tunick¹, and Y. W. Park², ¹USDA-ARS-ERRC, ²Fort Valley State University.

Soft fresh goat milk cheese is a highly valued dairy food, yet its production is limited by seasonal milk supply and its availability by short shelf-life. Protein profiles and rheological properties of the fresh cheese were determined to examine their variation during refrigerated storage. The cheeses were purchased from a commercial manufacturer within 24 hr of packaging and stored at 4°C for 7, 14, and 21 d. Protein extracts were prepared using either SDS or urea buffers, and protein profiles were examined using SDS-PAGE. Rheological properties were measured using a universal testing machine and a small strain oscillatory analyzer. Over the three week storage time, β -casein decreased approximately 10% with a concomitant increase in the β -casein fragments. During the three weeks of storage, rheological properties averaged 2.9 ± 0.5 N for hardness, 9.9 ± 0.4 mm for springiness, 21 ± 3 kPa for elastic modulus, 6.5 ± 0.9 kPa for viscous modulus, and 0.22 ± 0.03 kPa-s for complex viscosity. Only cohesiveness significantly changed over that time with a decrease from 0.25 to 0.12. Storage of fresh soft goat cheese at 4°C for up to 21d showed minimal changes. Protein profiles and cohesiveness were the best indicators of change in fresh soft goat milk cheese as it aged and may be useful in monitoring shelf-life.

Key Words: Goat Cheese, Rheology, SDS-PAGE

1260 Characterization of potential probiotic and milk fermenting properties of lactic acid bacteria strains. Velitchka Gotcheva*², Ely Hristozova³, Tsonka Hristozova⁴, Angel Angelov², Zlatka Roshkova², and Mingruo Guo¹, ¹University of Vermont, Burlington 05405, ²Higher Institute of Food and Flavor Industries, Plovdiv, Bulgaria, ³Medical Academy, Plovdiv, ⁴Institute of Microbiology, Plovdiv.

Several species lactic acid bacteria were isolated from a traditional Bulgarian cereal-based fermented beverage. These strains have been consumed for ages and proved to be safe. Two strains *Lb. plantarum* (B25 and B28), and one *Lb. casei ssp. pseudoplantarum* (B29) were studied in the present work for selected probiotic properties. Acid and bile resistance of the strains were evaluated. Results showed that the LAB tested are tolerant to low pH values (2.0-3.0) and bile concentration within 0.2-0.4%. Further, tests for antagonistic activity against some of the most common pathogens (*Salmonella*, *Pseudomonas*, *E. coli*, and *Enterococcus*) were carried out. *Lb. plantarum* B28 has a good antagonistic activity towards almost all the test-pathogens. Resistance of the LAB strains to the most commonly used antibiotics was also evaluated. Thirty-nine antibiotic compounds were used for the experiment. Strain *Lb. plantarum* B25 was resistant to 13 of them, and *Lb. plantarum* B28 was unaffected by 18 of the antibiotics. The third strain, *Lb. casei ssp.* was resistant to 16 of the substances tested. The potential use of the three LAB strains in milk fermentation was studied as well. They were tested for their ability to coagulate milk singly or in combinations. Fermentation trials showed that LAB at concentration 10^5 CFU/ml coagulated milk in about 10 h at 43°C. Incubation time varied for the three single strains and the combinations to clot the milk samples. *Lb. plantarum* strains had a faster rate of acid production than *Lb. casei ssp.* The combination of the three strains resulted in fermented milk with good texture and flavor. In conclusion, the LAB strains isolated from the cereal-based product have the potential to be probiotics. Further investigations are needed to evaluate other probiotic properties of the LAB strains and their milk coagulation characteristics.

Key Words: Lactic acid bacteria, probiotic properties, milk fermentation

1261 Melt and proteolysis of Mozzarella cheese as affected by starter culture and coagulating enzymes. P. Sharma*¹, R. I. Dave¹, K. Muthukumarappan¹, D. J. McMahon², and J. R. Broadbent², ¹MN-SD Dairy Center, South Dakota State University, Brookings, SD 57007, ²Western Dairy Center, Utah State University, Logan, UT 84322.

Low moisture part-skim Mozzarella cheeses were made to elucidate if the melt characteristics of mozzarella cheese were affected by starter cultures, or coagulating enzymes and how they were correlated with the proteolysis. Cheeses were prepared using single culture (SC) of *Streptococcus thermophilus*, or mixed culture (MC) of *Streptococcus thermophilus* and *Lactobacillus delbrueckii ssp. helveticus* using 1× or 6× of cheese coagulants, Rennet or Sure curd. Cheeses were analyzed for total solids, fat, protein, ash, salt, and calcium on day 1. Changes in melt characteristics and proteolysis during storage (4°C) were monitored on 1,7,15, and 30 days (d). The melt characteristics were measured using modified Schreiber test and SDSU-meltemeter (Creep test). Proteolysis was measured using capillary electrophoresis and soluble nitrogen. After 30 d storage, melt area as measured by modified Schreiber test increased only by ~2 times in cheeses made with ST as against ~3-4 times in the cheeses made with MC. On d 30, creep test showed that the fall in height increased by ~4-5 times in the SC cheeses but ~7-9 times in the cheeses made with MC, when compared with the values obtained on d1 for SC cheeses. Melt characteristics on d 7 for cheeses prepared with MC almost corresponded to that of d 30 cheeses made with SC; suggesting faster ripening and better improvement in the melt of cheeses made with MC. Soluble nitrogen was also higher in MC cheeses as compared to those made with SC only. The highest % breakdown of α_s casein was ~75% on d 30 in cheese samples prepared with MC using 6× rennet enzyme and that of β casein was ~50% in cheese samples prepared with MC using 6× sure curd. Results clearly indicated that selection of starter culture followed by type and concentration of coagulants were crucial in deciding the melt and rheology of part-skim Mozzarella cheese.

Key Words: Mozzarella cheese, Melt characteristics, Proteolysis

1262 Effects of Refrigerated Storage on Proteolytic and Lipolytic Properties of Soft Goat Milk Cheeses Manufactured in a Southern U.S. State. Aref Kalantari*¹, Young W. Park¹, and Diane Van Hekken², ¹Agricultural Research Station, Fort Valley State University, Fort Valley, GA, ²Eastern Regional Research Center, USDA/ARS, Wyndmoor, PA.

Information on shelf-life of commercial goat milk cheeses is extremely limited. Fresh soft goat cheeses were purchased from a commercial goat dairy manufacturer in a southeastern state, and stored at 4°C for 0, 7, 14, and 21 days for evaluation of shelf-life of the cheeses in relation to proteolytic and lipolytic parameters. One batch of the soft cheeses was frozen, stored for 3 months, thawed, and compared for the differences in shelf-life and storage quality between the fresh and frozen-stored products. Total N, percent water soluble N (WSN), pH and acid degree values (ADV) were determined, and protein profiles of fresh cheeses were examined using SDS-PAGE and densitometric analysis. The percent WSN ranged from 4.4 to 11.1 in the fresh cheeses for 3 weeks storage, and WSN increased with storage period, which occurred with the concomitant decrease in beta-casein as revealed in the SDS-PAGE and densitometric results. There was a greater increase in WSN in frozen-stored cheeses than that in the fresh counterparts, suggesting that frozen-storage and thawing accelerated protein degradation in the frozen thawed cheeses, presumably due to the denaturation of cheese proteins as well as activation of some proteinase enzymes. The mean ranges of pH for the testing period in both fresh and frozen-stored cheeses were 4.14 to 4.81, and tended to decrease with storage times. ADVs were significantly increased with time, especially at 21 days. ADVs were higher in the frozen-stored cheeses than fresh ones. It was concluded that the food quality of the soft goat cheeses had begun to deteriorate significantly at 21 days refrigerated storage especially when the sealed packages were open and stored, as evidenced by the elevated proteolytic and lipolytic indices.

Key Words: Soft goat cheese, storage, shelf-life, proteolysis, lipolysis

1263 Fluid milk quality: Microbiological analysis of fluid milk at the carton encoded sell by date. T.J. Pritchard*¹ and P.S. Kindstedt¹, ¹ *Northeast Dairy Foods Research Center, University of Vermont.*

The objectives of our study were to evaluate the temperature of dairy display cases and to determine the microbiological load of fluid milk at the carton-encoded sell by date. A total of 211 reduced fat fluid milk samples were obtained from 174 dairy display cases throughout Northern New England. Stores evaluated ranged from small mom and pop stores to large multi-state chain stores. Dairy display case temperatures were obtained by recording the temperature of product present in the case. Samples were packaged in ice during transport back to the lab. Milk samples were maintained at 38F or below until the sell by date. Milk samples were diluted in a peptone-NaCl solution and evaluated utilizing both 3M APC Petrifilms and 3M coliform Petrifilms. The temperature of the display cases ranged from 33F to 53F. One hundred forty-two of the coolers registered temperatures at or below the US Food Code designated upper limit of 45F while 32 of the coolers registered temperatures above 45F. The aerobic plate count of the samples ranged from a low of <1 to a high of >10⁸ CFU/ml. Sixty-eight of the samples were still within Pasteurized Milk Ordinance standards at their sell by date. Two-thirds of the samples, 143 of 211, failed to meet the requirements for fluid milk outlined in the PMO. The majority of the sample which failed PMO standards, 111 of 136, contained 10⁶ CFU/ml or more. Eight of these samples contained greater than 10⁸ CFU/ml. Analysis of 210 of the milk samples for the presence of coliform bacteria indicated that 90% of the samples, 189 of 210, were at or below the PMO limit for pasteurized fluid milk. Twenty-one samples contained >10CFU/ml of coliform bacteria. Within the samples that failed, counts ranged from 11CFU/ml to >10³ CFU/ml. The results of our survey indicate that dairy display cases are a potential site for temperature abuse of fluid milk which require further scrutiny. Furthermore, the sell by date encoded on packages of fluid milk does not necessarily indicate the microbiological quality of the product contained within.

Key Words: Milk Quality, Microbiology, Shelf-life

1264 Linoleic acid isomerase activity in *Lactobacillus acidophilus* and *Propionibacterium freudenreichii* subsp. *shermanii*. T Lin*¹, C Lin², and Y Wang², ¹ *Chinese Culture University*, ² *National Taiwan University.*

Crude protein extracts of *Lactobacillus acidophilus* (CCRC14079) and *Propionibacterium freudenreichii* subsp. *shermanii* (CCRC11076) were reacted with linoleic acid at 50°C for 10min at pH 5, 6, 7, and 8, and the levels of conjugated linoleic acid (CLA) isomers formation were determined by high performance liquid chromatography. The activity of linoleic acid isomerase was observed in >100 Kd crude protein filtrates of both culture extracts, as evidenced by the formation of conjugated linoleic acid isomers after the reaction. The filtrate of *L. acidophilus* produced more CLA (1125.63 µg /mg protein) than *P. freudenreichii* subsp. *Shermanii* (620.89 µg /mg protein). Higher levels of CLA isomers were formed at pH 5 of *L. acidophilus* treatment. However, no significant difference in CLA formation was observed among four pH treatments of *P. freudenreichii* subsp. *Shermanii*. While the amounts of eight CLA isomers produced varied with culture and pH, more c10,t12-CLA was formed, followed by c9,t11-CLA, in most of the treatments.

Key Words: Conjugated linoleic acid, Isomerase, *Lactobacillus acidophilus*

1265 Comparison of effect of vacuum condensed and ultrafiltered milk on Cheddar cheese quality. M. R. Acharya* and V. V. Mistry, *MN-SD Dairy Foods Research Center, South Dakota State University, Brookings.*

Raw whole milk was separated to approximately 0.4% fat, pasteurized and split in 3 parts. One part (175 kg) was vacuum condensed to 11-12% protein (CM) and another (175 kg) was ultrafiltered to 15-16% protein (UF). The third part, pasteurized cream and CM or UF were blended to casein to fat ratio of 0.7 and protein of 4.5% (UF1 and CM1) and 6.0% (UF2 and CM2). No concentrate was added to the control (C), 3.2% protein. Total quantity of blended milk was 100 to 105 kg for C, 72.5 kg for UF1 and CM1 and 54.5 kg for UF2 and CM2. Cheddar cheeses (5 replicates) were made using frozen concentrated starter (7g/kg protein

in cheese milk) and rennet (9ml/45.4 kg milk for C and 6ml/45.4 kg milk for the concentrates). At 1 wk, the moisture content of Cheddar cheeses was 39.2 (C), 37.8 (UF1), 36.5 (UF2), 38.5 (CM1) and 36.7% (CM2). At 12 wk it had dropped to 38.8 (C), 37.3 (UF1), 35.6 (UF2), 37.7 (CM1) and 35.5% (CM2). The fat content ranged from 31.5 to 32.4% and salt from 2.05 to 2.14% with no significant differences between treatments. Calcium content was higher in UF cheeses (0.75%-UF1 and 0.79%-UF2) than CM cheeses (0.71%-CM1 and 0.76%-CM2) followed by C (0.68%) and it increased with protein content in cheese milk. UF milk produced cheese with higher protein content (25.6%-UF1 and 26.4%-UF2) than CM milk (24.7%-CM1 and 25.4%-CM2). The soluble protein content of all cheeses increased during 12 wk of ripening. Control cheeses exhibited the highest extent of proteolysis followed by treatments with 4.5 and 6.0% protein in cheese milk, respectively. CM cheeses exhibited higher level of proteolysis than UF cheeses. Counts of lactic starters were in the range of 9-10 logs at 1 wk, which reduced to approximately 6-7 logs after 12 wk, and the counts of non-starter lactic acid bacteria were about 2-3 logs at 1 wk and increased to 4-5 logs after 12 wk, but there were no differences in the counts among treatments. These cheeses will be used for process cheese manufacture.

Key Words: Vacuum condensing, Ultrafiltration, Cheddar cheese

1266 Comparison of rennet curd formation characteristics of milk concentrated by vacuum condensing and ultrafiltration. V. V. Mistry*, P. Upreti, and M. R. Acharya, *MN-SD Dairy Foods Research Center, South Dakota State University, Brookings.*

Raw whole milk was separated to 0.4% fat, pasteurized and split into three parts. One part was vacuum condensed to 11-12% protein (CM), and another ultrafiltered to 15-16% protein (UF). The third part, pasteurized cream, and CM or UF were blended to casein to fat ratio (CF) of 0.7 and protein of 4.5% (CM1 and UF1) and 6% (CM2 and UF2). The control (C) was a blend of milk and cream with no concentrate and CF of 0.7 and 3.2% protein. A Formagraph was used to determine rennet clotting time (RCT), amplitude (or curd firmness) at 40 min, (A40), and time to achieve amplitude of 20 mm (k20). Rennet was added at 9-mL/45.4 kg milk and with no starter added. The RCT for C was 33.3 min. It was lower for CM than for UF and for 6% protein than for 4.5%. The k20 for 3.2, 4.5 and 6% protein was 43.5, 8.4 and 4.3 min, respectively, and was not affected by method of concentration. The A40 was dependent on protein (3, 35 and 54 mm for 3.2, 4.5 and 6% protein, respectively) and milk (46 mm, CM and 44 mm, UF). A Brookfield viscometer equipped with a UL adapter was used under a constant rate of strain of 1/306 s to determine viscosity every minute for 40 min at 32°C after addition of starter (same rate as in cheese making) and rennet at 6 and 9-mL/45.4 kg milk. There were three distinct phases. In the first phase there was no change in viscosity. This initial viscosity increased with protein and was higher for the CM than for the UF milk for the same protein content. In the second phase there was a sharp increase until a maximum was reached. In the third phase there was a decline in viscosity. Viscosity began to increase approximately 7 min earlier for samples with 9 mL rennet than with 6 mL. The time at which the maximum viscosity occurred was affected by amount of rennet and occurred earlier in UF than in CM. The maximum viscosity depended on protein content and method of concentration (23.2-CM2, 16.5-UF2, 10-CM1, 8.5-UF1, 5.1 mPa.s- C). For the same protein content maximum viscosity was lower for UF milks than CM.

Key Words: vacuum condensing, ultrafiltration, rennet coagulation

1267 Standardization of cheesemilks using cold ultrafiltration retentates for the manufacture of Parmesan cheese. J.J. Jaeggi*¹, S. Govindasamy-Lucey¹, M.E. Johnson¹, and J.A. Lucey², ¹ *Wisconsin Center for Dairy Research, University of Wisconsin, Madison, Wisconsin/USA*, ² *Department of Food Science, University of Wisconsin, Madison, Wisconsin/USA.*

Milk for Parmesan cheese is generally standardized by cream removal. This method of standardization and the low fat and moisture contents of Parmesan cheese results in low yield efficiency. The addition of NFD is not usually practiced because of increased concentration of residual sugar in the cheese. One solution to the problem of lower cheese yield efficiency, and one that would overcome the problem of excessive residual sugar, is the use of UF milk. Milks concentrated by cold UF (<7C) were used to manufacture Parmesan cheese. Milks for cheesemaking were made by blending cold (whole milk) UF retentates (26% solids)

with partially skimmed milk (1.0% fat) to obtain blends with 14.5% solids and a casein:fat ratio of 1.1. A second approach was used where skim milk was concentrated by cold UF to 26% solids and blended with partially skimmed milk (3.4% fat) to obtain blends with 14.5% solids at a casein:fat ratio of 1.1. Control milks were partially skimmed to a casein:fat ratio of 1.1 and total solids of 11.3%. Traditional Parmesan manufacturing protocol was followed. Setting times were 16 and 22 min for experimental and control milks, respectively. Following brining for 70 h, the cheeses were dried at 60% relative humidity and 12C in a commercial Parmesan drying facility until a target moisture of around 32% was reached. As expected, cheese yields were higher in the higher solids milks (12-13%) compared to control cheese (7.5%) due to higher protein and fat levels in the cheesemilk. However, there were higher fat losses in the whey, derived from milk blended with whole milk UF retentates, possibly due to fat damage during the UF process. Higher protein recoveries were obtained in cheeses manufactured using cold UF retentates. There was no difference in the pH (5.14-5.15) and moisture contents (40.1-40.6%) of the cheeses prior to brining. No residual lactose or galactose was left in the cheeses. Experimental cheeses had higher moisture contents (33.0-35.2%) than control cheeses (32%) after drying for 9 weeks. It appeared to be more difficult to dry cheeses made from the higher solids cheesemilks, probably due to an altered structure in these cheeses. The use of milk concentrated by cold UF appears to be a promising way of improving the yields of Parmesan cheeses.

Key Words: Ultrafiltration, Parmesan cheese, Standardization

1268 Modulation of colonic microbiota with sweet bifidus milk. Elisa Teshima¹, Celia L. L. F. Ferreira^{*1}, Neuza M. B. Costa¹, Ferlando L. Santos¹, and Izabele D. P. Marliere¹, ¹Federal University of Viosa.

The human gastrointestinal tract constitutes a complex microbial ecosystem and colon is the most heavily colonized region. Through the process of fermentation, colonic bacteria are able to produce a wide range of compounds that have both positive and negative effects on the gut physiology. Therefore, there is some interest in manipulation of the composition of the gut microbiota towards a more salutary regimen, increasing the numbers and activities of bacterial groups such as bifidobacteria and lactobacilli. One of approaches to increase the number of these organisms in the gut is through the oral administration of live, beneficial microbes, termed probiotics. Dairy products are the most common carriers of probiotic organisms, mainly in fluid milk, yogurt or fermented milk. Although many products have been commercialized, few probiotics strains were analyzed for its ability of modification on the microbiota composition. New isolates of *Bifidobacterium breve* from neonates were selected in our laboratory, with high resistance to gastric juice and bile salts, therefore suitable candidates for use as probiotics. The purpose of this study was to elucidate effects of sweet bifidus milk containing a pool of these bacteria in cecal and colonic microbiota levels in rats. Twenty female adults Wistar rats were randomly assigned to one of two treatments: 1) control diet (AIN-93 diet for rodents) or 2) control diet + sweet bifidus milk (Log 8 cfu/ml). The duration of the study was 28 days. The cecal and colonic content was analyzed for total anaerobes, bifidobacteria, total aerobes, lactobacilli and *E. coli* using selective media. The consumption of sweet bifidus milk resulted in higher bifidobacteria levels in cecum (Log 8.28 cfu/ml) and colon (Log 8.49 cfu/ml) when compared to levels in cecum (Log 6.55 cfu/ml) and colon (Log 7.06 cfu/ml) of control group (P<0.01). The total anaerobes and aerobes levels were not affected (P>0.05) by the treatment in both segments of the gut. The numbers of *E. coli* were lower (P<0.05) in cecum, but not in the colon of probiotic feed animals. Inversely, the numbers of lactobacilli were lower (P<0.05) in the colon but not in the cecum. Therefore the consumption of sweet bifidus milk may be beneficial in improving gastrointestinal health.

Key Words: Bifidobacteria, Microbiota, Rats

1269 Structural and functional properties of a small cryptic plasmid of *Streptococcus thermophilus*. G.A. Somkuti and D.H. Steinberg, Eastern Regional Research Center, ARS-USDA.

A small cryptic plasmid designated as pER13 was isolated from the lactic starter bacterium *Streptococcus thermophilus* strain ST113. The complete sequence of pER13 was 4137 bp with five distinct open reading frames (ORFs), some sharing a high level of homology with ORFs of the pMV158 family plasmids found in *S. suis* (SS) and *S. agalactiae* (SA), clinical streptococci which cause diseases in domestic animals and humans. In *S. thermophilus*, ORF1 encodes a 45-residue protein that

is identical to the CopG protein in plasmids of SS (pSSU-1, 4.9 kb) and SA (pMV158, 5.5 kb). The ORF2 (*rep*) encodes a 179-residue protein, shorter than but with high level of homology to the RepB proteins found in the other two species. In addition, the 500-amino acid protein encoded by ORF3 is highly homologous to the mobilization proteins (Mob) encoded on the SS and SA plasmids. The presence of a *mob* gene in pER13 allows its mobilization and transfer into new hosts by functions of conjugative plasmids in the pIP501-pAM β 1 family. When one of these plasmids is electrotransformed into ST113, the subsequent co-transfer of pER13 and pIP501 into lactococci occurs by a conjugative process, possibly involving the formation of a cointegrate as shown by agarose gel electrophoresis. This permits the development of pER13 as a cloning vector and offers another approach to introducing new genetic functions into lactic fermentation bacteria. The presence of several highly homologous ORFs in *S. thermophilus*, SS and SA also implies the possibility of horizontal gene transfer between clinical and nonclinical species of streptococci.

Key Words: Plasmid, *Streptococcus thermophilus*

1270 Production and functional properties of dairy products fermented with probiotic bacteria. Sharareh Hekmat^{*}, Brescia College at University of Western Ontario.

The concept of probiotics which is the use of bacteria to enhance health has gained increased interest in the dairy food industry. *Lactobacillus acidophilus* and *Bifidobacterium bifidum* are two examples of probiotic bacteria that could be delivered to consumers through fermented dairy products. Some of the potential benefits of these bacteria are maintaining optimal balance of microbial organisms, and producing antibiotics, organic acids and *B*-galactosidase in the intestine. Many dairy products such as milk, yogurt, frozen yogurt, carbonated liquid yogurt, and ice cream could be fermented with these bacteria. This paper reviews the production of different probiotic dairy foods, the survival rate of these bacteria during manufacture and storage, the enumeration techniques, and the optimum growth condition in terms of pH, nutrients, and temperature. It will also examine *B*-galactosidase activity during storage and sensory properties of these fermented dairy products.

Key Words: Probiotic bacteria, Fermented dairy products

1271 Changes in functionality of Mozzarella cheese produced from bovine and caprine milk during refrigerated storage. E. J. Oh¹, J. Y. Imm^{*2}, K. S. Han¹, J. S. Kim², S. Oh³, and S. H. Kim¹, ¹Korea University, ²Korea Food Research Institute, ³Korea Yakult Co. Ltd..

Up to present, only limited information is available for functionality of caprine Mozzarella cheese (MC). The objective of this study was to compare functionality of caprine MC with bovine MC during refrigerated storage. Low moisture part skim MC was prepared from fresh bovine and caprine milk using commercial starter and rennet. Changes in meltability, free oil, browning, texture characteristics and microstructure was monitored for 8 weeks. Proteolysis was determined by measuring 12% TCA and pH 4.6 soluble nitrogen and relative degradation of major caseins was quantified by SDS-PAGE and densitometric scanning. The data were analyzed by ANOVA using PROC GLM of SAS and Duncan's multiple comparison test. Largest increase in meltability was found at early refrigerated storage from 1 to 7 days both for bovine and caprine MC. Except the first day, meltability did not show significant difference between bovine and caprine MC during storage. Bovine MC formed significantly higher amount of free oil than that of caprine MC throughout storage. The major decrease of TPA hardness in bovine MC occurred between 2 and 4 weeks storage, but hardness of caprine MC gradually decreased throughout the storage. Although bovine MC appeared to have denser protein matrix at early storage (2 weeks), degradation of protein matrix in bovine MC was much greater than caprine MC for more than 4 weeks storage. Significantly higher soluble nitrogen content of bovine MC in 12% TCA or pH 4.6 acetate buffer indicated that greater extent of proteolysis was occurred in bovine MC during the storage. Breakdown of α_{s1} -casein was dominant in the storage of bovine MC and only 65% of α_{s1} -casein was remained after 8 weeks storage. For caprine MC, β O-casein showed major change and 77% of initial β O-casein was remained intact. When MC was baked bovine MC showed significantly higher brown color intensity than that of caprine MC throughout the storage. The intensity of brown color was not significantly affected by storage period for caprine MC.

Key Words: Mozzarella cheese, caprine milk, functionality

1272 Effect of *Lactococcus lactis* ssp. *lactis* ml3 and c2 bacteriophage peptides and *Lactobacillus plantarum* yit0068 bacteriophage peptides on the growth of *L. lactis* ssp. *lactis* C2 and the inhibition of ml3 and c2 bacteriophage proliferation. C. Hicks*¹, I. Surjawan¹, N. Jose¹, C. Jose², and B. Barlow¹, ¹University of Kentucky, Lexington, Kentucky, ²University of Riau, Pekanbaru, Indonesia.

Phage-peptides were prepared from *L. lactis* ssp. *lactis* ml3 and *L. plantarum* yit0068 bacteriophage using a ficin hydrolysis. The ml3 and yit0068 peptides were compared to *L. lactis* ssp. *lactis* c2 bacteriophage peptides to determine growth inhibition of C2 host and inhibition of both ml3 and c2 bacteriophage. M17 with .011 mM CaCl₂ media with and without phage peptides (2 or 2.5%) were heat treated, cooled to 22°C, inoculated with C2 host, and infected with ml3 or c2 bacteriophage at 0, 10², 10⁴, 10⁶, or 10⁸ pfu/mL. Culture growth and lysis were monitored spectrophotometrically (λ_{600nm}) for 6.5 h. Growth of C2 culture in ml3 or yit0068 peptide media was dramatically slower and cell density was lower at the stationary phase than when the culture was grown in a medium without peptides. Growth time to the stationary phase was essentially the same for media with and without peptides added. C2 culture grown c2 peptide medium was not significantly inhibited. When C2 culture was grown in medium containing ml3 or yit0068 peptide there was little inhibition of ml3 bacteriophage proliferation. When the medium contained c2 peptide the ml3 bacteriophage proliferation could be partially inhibited. When C2 host was grown in media containing ml3 peptide and infected with c2 bacteriophage only a slight inhibition of bacteriophage proliferation occurred. However, c2 bacteriophage proliferation was inhibited when C2 host was grown in media containing yit0068 or c2 peptide. Culture growth (C2) was extended by 20 and 50 min before the culture started to lyse when infection levels were 1 x 10³ pfu/mL and 1 x 10⁴ pfu/mL, respectively. Lysis did not occur when C2 culture was grown in media containing c2 or yit0068 peptide and infected with 1 x 10² pfu/mL of c2 bacteriophage. These data suggest that the best growth medium and phage inhibitory medium was the medium that contained the c2 bacteriophage peptide.

Key Words: *Lactococcus lactis* ssp, bacteriophage inhibition, ml3, yit0068, c2.

1273 Effect of black pepper essential oils and orange peel terpenes on the inhibition of *Lactobacillus plantarum* and the inhibition of *L. plantarum* yit0068 bacteriophage proliferation. C. Jose¹, N. Jose², C. Hicks*², and I. Surjawan², ¹University of Riau, Pekanbaru, Indonesia, ²University of Kentucky, Lexington, Kentucky.

Effect of essential oils of black pepper and orange peel terpenes on the growth of *L. plantarum* and proliferation of yit0068 bacteriophage was determined collaboratively at University of Kentucky and University of Riau. Orange peel terpene and Indonesian extracted black pepper essential oils were used to determine the concentration that would allow the growth of *L. plantarum* but inhibit the proliferation of yit0068 bacteriophage. Bacteriophage inhibition tests were done by growing *L. plantarum* (4%) in MRS medium (25 ml) containing .011 mM CaCl₂ with and without terpenes (0, 5, and 25 ppm) at 35°C. One half of the media were infected with *L. plantarum* yit0068 bacteriophage (0.01%; 1 X 10⁸ pfu/ml) after 1 h of incubation or after 0.1 increase in absorbance (λ_{600nm}). Dilutions were made by dissolving the essential oil stock in 1,2 -propanediol. Cell growth and lysis was spectrophotometrically observed (λ_{600nm}) after inoculation for up to 6 h at 10 min intervals. Other studies (in Indonesia) of essential oils of black pepper fractionated using n-hexane or methanol were conducted in a similar manner, except that the concentration of the oil fraction in the media were 1.0, 1.5, 2.0, and 2.5 %. Results from both laboratories suggested that essential oil of black pepper, its fractions (n-hexane and methanol extracts) and orange peel terpene were effective inhibitors of culture growth at the concentrations tested. Both laboratories confirmed that there was no concentration of black pepper essential oil nor orange peel terpene where *L. plantarum* grew that yit0068 bacteriophage was inhibited. These negative results do not agree with a previous study suggesting that black pepper essential oils are inhibitory to *L. plantarum* bacteriophage proliferation during vegetable fermentations.

Key Words: *Lactobacillus plantarum*, yit0068 bacteriophage, essential oils, black pepper, terpenes, inhibition

1274 Estimation of vitamin D₃ content in process cheese. P. Upreti*¹, V. V. Mistry¹, and J. J. Warthesen², ¹MN-SD Dairy Foods Research Center, South Dakota State University, Brookings, ²University of Minnesota, St. Paul.

The goal of this project is to develop a procedure for the fortification of process cheese with vitamin D₃. To monitor the vitamin D₃ content of this process cheese a high-performance liquid chromatographic (HPLC) method was developed and is presented here. 4 to 5 g of shredded cheese sample was saponified in a low-actinic Erlenmeyer flask using 20-mL KOH (60%) and 20-mL ethanol (95%) at 70°C for 30 min in the presence of 50 mL of 6% ethanolic pyrogallol as an antioxidant. The unsaponifiable matter from cheese was extracted using a mixture of petroleum ether (90 parts) and diethyl ether (10 parts). The ether layer was washed with ice-cold water until neutralization. It was then separated and partially dried in a rotary evaporator, and then completely dried under nitrogen. The dried extract was reconstituted in 3-mL hexane and applied to a 1-mL silica cartridge for solid phase extraction. Vitamin D₃ was eluted with 5-mL of a mixture of hexane (21.5 parts) and chloroform (78.5 parts). The eluent was evaporated to dryness under nitrogen and reconstituted in 2-mL acetonitrile. Of this 100 μ L was injected into the HPLC. The HPLC system included a C₁₈ liquid chromatographic column (4.6-mm ID x 15 cm, 5- μ m particle size) with UV detection at 254 nm and a flow rate of 1 mL/min. A mixture of acetonitrile and methanol in the ratio of 30 to 70 was the mobile phase. This ratio was selected on the basis of satisfactory resolution of vitamin D₃ and separation of the vitamin from interfering shouldering peaks. Vitamin D₃ eluted at approximately 9 min. A standard curve of vitamin D₃ was prepared by adding known quantities of crystalline vitamin D₃ to the cheese at six levels (0, 4.46, 8.93, 17.86, 26.79, 35.71 IU per 5 g of cheese) and quantitated using the above procedure. This was replicated five times. The standard curve had a r² of 0.9722. The method can be used to assess the process cheeses fortified with vitamin D₃. Process cheeses fortified with Vitamin D₃ will be manufactured and the above procedure will be used for quantification.

Key Words: vitamin D, process cheese, HPLC

1275 Cheese treated by high pressure in an early stage of ripening. Changes in textural attributes. J. Saldo¹, E. Sendra*², and B. Guamis¹, ¹Planta de Tecnologia d'Aliments, UAB. CeRTA. XiT. Bellaterra, Spain, ²Divisin de Tecnologia de Alimentos. Universidad Miguel Hernandez. Orihuela, Spain.

High pressure (400 MPa, 5 min) was applied to cheese the day after salting in brine to promote accelerated ripening. The high pressure treatment (HPT) caused changes in cheese texture. The extent of these changes and its evolution along ripening will be studied. Two batches of Garrotxa cheese were manufactured. This is a mixed curd, uncooked, pressed, goat milk cheese. Uniaxial compression and stress relaxation tests were performed on cylindrical cheese samples (2.54 cm diameter and 2 cm height) and replicated 6 times for each cheese piece. All parameters measured from uniaxial compression test were different between treatments (p<0.05). Stress at breaking point (σ_f) and at maximum strain ($\sigma_{0.7}$) decreased in treated samples, while strain at breaking point (ϵ_f) was higher. The adherence of samples to the probe (σ_{ad}) was higher for treated cheeses. HPT cheese became softer and yielding, with an increased adherence. Stress relaxation was modelised using a linear model which parameters are k₁ and k₂, according Peleg & Normand (1983). Moisture in HPT samples were higher than in control ones and proteolysis was increased too. This would help those changes in texture. Multivariate analysis discriminate between young and old cheese along first principal component. Dramatic changes were observed after day 30 of ripening. Second principal component discriminate between treatments. σ_f , ϵ_f and $\sigma_{0.7}$ were significant for PC1, while σ_{ad} , k₁ and k₂ were significant for PC2.

1276 Cheeses of Spain: classification and description. M. Almena Aliste^{*1,2}, A. Cepeda Sez¹, and Y. Nol², ¹*Hygiene and Food Inspection, Faculty of Veterinary Lugo-University of Santiago de Compostela, Spain*, ²*INRA Dairy Technology and Analysis Research unit Poligny, France*.

In Spain there are more than 100 varieties of traditional cheeses. Eleven such cheeses already carry the quality label of origin "Protected Designation of Origin" (PDO), and other six denominations have recently been submitted. However, Manchego cheese is the only internationally known cheese from Spain. The diversity of the cheese varieties makes the classification of Spanish cheeses difficult. Furthermore, a one-dimensional classification based on a single criterion would be insufficient and confusing. This work showed the great variety of cheeses from Spain by using two kinds of classifications that combine different criteria: origin of milk, technology of elaboration and cheese characteristics (composition, texture and other key properties). The study was completed with a table that closely described the main properties of the current PDO-Spanish cheeses: *Tetilla*; *Cabrales*; *Picn Bejes-Tresviso*; *Quesucos de Libana*; *Cantabria cheese*; *Idizabal*; *Roncal*; *Zamorano*; *Mahn*; *Manchego*; *Majonero* and *La Serena* cheese. The approach used allows a general but precious overview of the cheeses manufactured in Spain and illustrates possible strategies for classifications that could be applied to other cheeses.

Key Words: Cheeses from Spain, Multidimensional Classification, Description

1277 Stress relaxation test: an approach to study cheese openness. C. Achilleos, M. Almena Aliste*, and Y. Nol, *INRA Dairy Technology and Analysis Research unit Poligny, France*.

The quality of Comt cheese is determined not only by flavor and texture but also by openness: few eyes, slits, or none (blind cheese). In order to investigate mechanisms of eye development, we need instrumental methods to characterize the mechanical properties of cheese, which affect eye development. Stress relaxation tests at different initial deformation levels (from 5% to 60%) were evaluated with 3 Comt cheeses in comparison with uniaxial compression at constant displacement rate. Each cheese selected had a typical openness, either eyes, or slits or none. For stress relaxation, the initial compression that appeared interesting for the characterisation of the mechanical properties was 20%, which was large enough to avoid errors due to sampling while cracks did not develop in the samples. At this initial deformation level, stress relaxation allowed a quite good characterisation of the cheeses with the 3 typical openness (84.6% of the observations were well classified). Nevertheless, compression test allowed the best discrimination between the 3 types of Comt cheeses with 100% of the observations well classified. A set of 30 experimental Comt cheeses was analysed to evaluate the stress relaxation as a method to characterize the mechanical properties in relation with openness. The well classified cheeses represented 73.3% of the whole set. Stress relaxation provided promising results since the set of cheeses had complex openness associating slits and eyes.

Key Words: Relaxation and compression tests, Openness, Comt cheese

1278 Evaluation of reduced fat Cheddar cheese made with attenuated and not attenuated adjunct culture of *Lactobacillus helveticus* I: Effect of make procedure and cell attenuation. S.A. Madkor¹, P.S. Tong^{*1}, and M. El-Soda², ¹*California Polytechnic State University*, ²*Alexandria University*.

Adjunct culture of *Lb. helveticus* I was selected for evaluation in stirred and milled curd reduced fat Cheddar cheese making trials. *Lb. helveticus* I was cultivated in MRS broth and harvested by centrifugation at 4°C (4000 g for 30 min). A portion of the culture suspension was attenuated by freeze shocking at -20°C. Untreated (not attenuated), freeze-shocked or untreated/freeze-shocked mixture of *Lb. helveticus* I cells were inoculated (10^8 cfu/gm) in the starter-treated cheese milk prior to rennet coagulation. Inoculation of adjunct did not affect the manufacturing parameters in stirred or milled curd cheese. Cell counts of both

Lactococcus on M17 agar and *Lactobacilli* on Rogosa agar were determined after one day of ripening and monthly for 6 months thereafter. The viable count of *Lactobacilli* in one day cheese was lower than the number expected to be retained in cheese possibly due the loss of culture cells in the whey during cheese processing. The number of *Lactobacilli* increased up to the third month of ripening and slightly decline thereafter. The rate of *Lactobacilli* reduction was greater in cheese made with freeze-shocked *Lactobacilli*. Cheeses made with adjunct *Lb. helveticus* I showed higher levels of proteolysis as indicated by FAA levels with the progress of ripening when compared to control cheese without adjunct. A slightly higher level of free amino acids were observed in stirred curd cheese compared to milled curd cheeses. Taste panel results indicated addition of *Lb. helveticus* adjunct culture to milled or stirred curd reduced fat Cheddar cheese positively influenced the flavor/aroma score and prevented bitterness throughout the entire ripening period. This effect was most pronounced in cheese treated with a mixture of untreated and attenuated adjunct cultures. The general conclusion reached from this work indicate that we believe that *Lb. helveticus* I adjunct will lead to enhanced and improved flavor quality in stirred or milled curd reduced fat Cheddar cheese.

Key Words: Cheddar, cheese, adjunct

1279 Genetic typing of Swiss cheese starter culture strains by pulsed field gel electrophoresis and arbitrarily primed-PCR. J. K. Jenkins*, W. J. Harper, and P. D. Courtney, *The Ohio State University Columbus, Ohio*.

The manufacture of Swiss cheese requires growth of three bacterial species, *Propionibacterium freundenreichii*, *Lactobacillus helveticus* and *Streptococcus thermophilus*. Two genetic typing methods were compared for their ability to discriminate between strains of each species. Isolated colonies from single and multiple strain cultures were obtained on appropriate selective media. For multiple-strain cultures, ten to twenty single colonies were typed by one or both methods to separate the strains. The arbitrarily primed-PCR (AP-PCR) was performed at three annealing temperatures, 38, 40 and 42°C as described by Cusick and O'Sullivan (Appl. Environ. Microbiol. 66:2227-2231), followed by electrophoresis of products. Pulsed field gel electrophoresis (PFGE) was used to analyze *Apa*I and *Sma*I digestions of *Lactobacillus* and *Streptococcus* genomes and *Spe*I digestions of *Propionibacterium* genomes. Other enzymes or enzyme combinations tested for *Propionibacterium* genome digestion (*Apa*I, *Bam*HI, *Bgl*II, *Cla*I, *Eco*RV, *Hind*III, *Pst*I, *Sma*I and *Sph*I) were unable to yield the appropriate number of fragments for analysis. Of the nine *S. thermophilus* strains analyzed, AP-PCR distinguished six electrophoretic patterns. PFGE of both *Apa*I and *Sma*I digestions revealed eight distinct patterns with two strains having identical patterns. The results with all three species indicate that pulsed field gel electrophoresis, though more labor intensive, is more effective at discriminating between strains than AP-PCR.

Key Words: Lactic acid bacteria, Pulsed field gel electrophoresis, Arbitrarily primed-PCR

1280 Salt tolerance of dairy propionibacteria. O. Anggraeni, J. K. Jenkins*, and P. D. Courtney, *The Ohio State University Columbus, Ohio*.

Propionibacterium species are required to produce the characteristic appearance and flavor of Swiss cheeses. Differences in salt tolerance among propionibacteria strains may influence strain performance depending on conditions in a specific cheese. Many bacteria can import compatible solutes, such as betaine and proline, to counteract the effects of high osmotic pressure in the environment. Six strains of *Propionibacterium freundenreichii* were grown in a minimal defined medium with various levels of NaCl for seven days at 28°C, anaerobically. Growth was monitored by measuring culture turbidity (absorbance at 600 nm). All strains grew in the minimal medium without salt, though the lag phase varied among the strains from one to four days. 1% NaCl extended the lag phase of all strains by approximately one day and reduced the maximum cell density reached by four of the strains. Growth of three strains was completely inhibited by 2 and 3% NaCl. Two strains had markedly suppressed growth at these concentrations. One strain, P273, was able to reach the same cell density in 2% salt as in the absence of salt, though with an extended lag phase. In medium containing 3% salt, strain P273 grew at a significantly faster rate than the other five strains. No significant growth of any strain was observed at salt concentrations

of 4, 5, 6 and 7%. Betaine (1 mM) or proline (5.9 mM) was added to each growth medium to assess their effectiveness as osmoprotectants. Neither betaine nor proline improved growth of four of the strains at any salt concentration. Strains P273 and P812 were able to grow faster and to a higher cell density with betaine or proline in medium containing 3 or 4% salt. Salt tolerance varies among dairy propionibacteria and the

presence of proline or betaine in the medium can dramatically improve the salt tolerance of some strains. During cheese ripening, proteolytic breakdown of caseins, which have high proline contents, may contribute to osmoprotection of some *Propionibacterium* strains.

Key Words: *Propionibacterium*, salt tolerance, osmoprotectant

ASAS/ADSA Milk Synthesis

1281 Feeding dairy cattle to increase the content of conjugated linoleic acid in milk. Ying Huang, Barry Bradford*, Nicholas Heig, Jerry Young, and Donald Beitz, Iowa State University.

To evaluate effectiveness of conjugated linoleic acid (CLA) as the free acid and as the calcium salt to increase CLA in milk fat, 36 Holstein cows were fed six diets in a completely randomized block design with a 4-wk period for each replication. The control diet consisted of corn silage, alfalfa hay, and concentrates, and supplements were 1) 5% soy oil, 2) 1% CLA as free acid, 3) 1% CLA as the calcium salt, 4) 4% soy oil plus 1% CLA as the free acid, or 5) 4% soy oil plus 1% CLA as the calcium salt (Ca(CLA)2). No significant effects of dietary supplementation were found on daily milk yield, milk protein concentration and production, or milk lactose concentration and production. Supplementation of soy oil, CLA, or Ca(CLA)2 decreased milk fat concentration and production but had no effects on rumen VFA concentrations. Milk CLA was increased from 0.4% to 0.7% with 1% dietary CLA and to 1.3% with 1% dietary CLA plus soy oil. Dietary Ca(CLA)2 increased CLA milk fat to 0.9%; feeding Ca(CLA)2 with soy oil increased CLA in milk fat to 1.4%. Soy oil supplementation alone increased CLA content to 1.2%. In summary, dietary soy oil (5%) was as effective in increasing milk CLA as feeding dietary CLA (1%) or (Ca(CLA)2) (1%) with or without 4% soy oil. Dietary (Ca(CLA)2) resulted in greater concentrations of CLA in milk than did dietary CLA as free acids.

Key Words: Dairy Cows, Conjugated Linoleic Acid, Milk Fat

1282 Dietary fish oil plus vegetable oil maximizes trans-18:1 and ruminic acids in milk fat. D.L. Palmquist*¹ and J.M. Grinari², ¹OARDC/The Ohio State University, Wooster, Ohio, ²University of Helsinki, Finland.

Four Holstein cows were fed 4 diets in a 4 x 4 latin square design with 3-week periods. Diets were 60% haylage/40% corn-soy base concentrate (DM) with 3% added oil, consisting of 0, 33, 67 or 100% fish oil, with the balance made up with sunflower oil. Cows were fed for ad libitum intake; rumen contents were taken at 2 and 6 hours postfeeding, and milk was sampled on the last day of each period. Dry matter intake, milk yield and milk fat percentage were not different ($P > 0.05$) among treatments, nor were ruminal pH and concentrations and proportions of VFA at 2 and 6 hours postfeeding. However, there was a tendency ($P = 0.09$) for fish oil to increase molar proportion of butyrate at 2 hours postfeeding. All saturated milk fatty acids (4-16), 16:1, 20:4 n-6, and 20:5 n-3 were lowest with no fish oil, whereas fish oil decreased stearic, oleic and linoleic acids; linear regressions of percentage fatty acid on proportion of fish oil were significant. Quadratic effects of fish oil were significant for trans 18:1 ($P < 0.10$) and ruminic ($P < 0.01$) acids; treatment means (+/- SD) for 0 to 3% fish oil, respectively, were for trans 18:1: 14.2 (7.5), 18.1 (3.6), 18.6 (6.1), 13.7 (4.4)%, and for ruminic acid: 4.0 (1.2), 6.1 (1.7), 5.8 (2.1), and 3.4 (1.2)% of total milk fatty acids. Fish oil fatty acids may influence ruminal metabolism to maximize conversion of linoleic acid provided by sunflower oil to vaccenic acid. This approach increases milk fat ruminic acid up to ten-fold.

Key Words: Milk Fat, Vaccenic Acid, CLA

1283 Effect of dietary conjugated linoleic acids on the yield and composition of cow's milk. K.N. Simard*¹, P. Lacasse², L. Delbecchi², and P.Y. Chouinard¹, ¹Universite Laval, QC, Canada, ²Agriculture and Agri-Food Canada.

Conjugated linoleic acid (CLA) is an octadecadienoic fatty acid (FA) which has several effects on lipid metabolism. Previous work (Chouinard et al., 1999. J. Nutr. 129:1579) showed that abomasal infusion of CLA (CLA-60; Natural Lipids LTD, Hovdebygda, Norway) resulted in a significant reduction of milk fat synthesis. The objective of the present

study was to evaluate the effects of different forms of inclusion of dietary CLA (protected vs. unprotected) and the site of infusion in the gastrointestinal tract (rumen vs. abomasum) on milk fat synthesis in lactating dairy cows. Four multiparous Holstein cows in mid-lactation were utilized in a 4 x 4 Latin square design. Treatments were C) control (no CLA-60); R) addition of unprotected CLA-60 in the rumen; P) addition of protected CLA-60 in the rumen; and A) addition of unprotected CLA-60 in the abomasum. The CLA-60 mixture (unprotected and protected) contained 61% of CLA and was added (150 g/d) in the rumen or the abomasum three times daily (50 g at 0800, 1300, and 1800 h). At each period, treatments were administered for 7 days followed by 7 days of washout. Rumen protection of lipids was obtained by microencapsulation. Data from days 6 and 7 of the treatment periods were used for statistical analysis. Treatments had no effect on DMI and milk protein content. Milk yield was increased by protected CLA and averaged 23.7^{bc}, 24.7^{ab}, 26.8^a, and 21.7^c kg/d for C, R, P, and A, respectively ($P < 0.01$). Administration of CLA reduced milk fat content which averaged 3.94^a, 3.38^b, 2.94^c, and 1.86^d for C, R, P, and A, respectively ($P < 0.01$). Addition of CLA-60 in the abomasum increased CLA content of milk fat from 8.6^b (control) to 40.4^a mg/g FA. Milk CLA contents were not affected by R (11.8^b mg/g FA) or P (9.4^b mg/g FA). Feeding CLA-60 in unprotected form decreased milk fat content, but this decrease was of lower magnitude than that obtained with protected or abomasally infused CLA-60. Supported by Agribrands Purina Canada Inc.

Key Words: Dairy cows, Milk fat, CLA

1284 The effect of trans-10, cis-12 conjugated linoleic acid (CLA) infusion on milk fat synthesis and expression of lipogenic enzymes in the mammary gland of lactating cows. E. Matitashvili*¹, L.H. Baumgard¹, and D.E. Bauman¹, ¹Department of Animal Science, Cornell University.

Four cows in late lactation were used in a 2x2 crossover design, receiving either 0 or 14 g/d of trans-10, cis-12 CLA. Treatments were emulsified in skim milk and delivered by continuous abomasal unfusion (5 d) with a 14-d interval between treatments. Mammary gland biopsies were taken on d 5 of treatment. One portion was used for metabolic flux measurements and the other for Northern blot analysis. cDNA probes included: ovine acetyl-CoA carboxylase (ACC) and delta-9 desaturase (SCD), (both from M.T. Travers and M.C. Barber, Hannah Res. Inst., UK), ovine fatty acid synthase (FAS) (C. Leroux, LGBC-INRA, France), fatty acid binding protein (FABP) (purchased from ATCC), and bovine ESTs with sequence homology to glycerol phosphate acyltransferase (GPAT) and lipoprotein lipase (LPL) (both from J.C. Byatt, Monsanto Co.). The CLA treatment decreased milk fat percent and yield by 45% and 47%, respectively. Mammary explant incubations were designed to measure metabolic capacity and results indicated that CLA treatment reduced rates of acetate incorporation into fatty acids and oxidation to CO₂ by 82% and 61%, respectively. RNA analysis demonstrated that CLA treatment reduced abundance of all specific mRNA measured by 39 to 54%. Thus, treatment with trans-10, cis-12 CLA altered processes associated with *de novo* synthesis (ACC and FAS), uptake of preformed fatty acids (LPL), fatty acid transport and esterification (FABP, GPAT), and plasticity of milk fat (SCD). Furthermore, the magnitude of the reduction in message for these enzymes observed with CLA treatment was similar to that observed with *in vitro* rates of acetate utilization for fatty acid synthesis and oxidation to CO₂ and *in vivo* measurements of milk fat yield.

Key Words: Conjugated linoleic acid, Mammary, Lipogenesis

1285 In vitro lipid synthesis using bovine mammary homogenate. T. C. Wright*, J. P. Cant, and B. W. McBride, *University of Guelph*.

An in vitro system for lipid synthesis using bovine mammary homogenate was validated. Mammary tissue from Holstein cows producing 26.4 ± 3.5 kg/d (mean and standard error) of milk was isolated immediately after slaughter. Tissue samples were ground under liquid N to a fine powder and stored at -70°C until analysis. Tissue was homogenized in two volumes of isotonic sucrose in a Potter-Elvehjem tissue grinder and centrifuged at $15\,000 \times g$. Incubations were done at 37°C for 1h at pH 7.0 in a shaking water bath. The incubation solution (3.0ml) contained: 80 mM Tris-HCl, 0.80 mM MnCl_2 , 20 mM NaHCO_3 , 0.05 mM Coenzyme A, 1.7 mM ATP, 10 mM sodium citrate, 0.5 mM glucose 6-phosphate, 1.7 mM sodium acetate, 4.2 mM glutathione, 0.05 NADP, 20 mg/ml fatty acid free bovine serum albumin and 1 to 5 mg mammary protein. Incubations also contained approximately $1 \mu\text{Ci } 1\text{-}^{14}\text{C}$ sodium acetate. Exogenous fatty acids or synthetic detergent was bound to albumin before introduction to the incubation medium. Final exogenous concentrations ranged from 70 to $350 \mu\text{M}$. Lipid synthesis was linear with respect to protein content and time. Lipid products were extracted and an aliquot was counted in a scintillation counter. Supernatant protein concentration was estimated using the bicinchoninic acid method with bovine serum albumin as the standard. Results ($n=3$) indicated that when caprylic acid was incubated at a $350\text{-}\mu\text{M}$ concentration there was a 2.4% ($\pm 5.0\%$) increase in lipid synthesis compared to control incubations. At all concentrations from 70 to $350 \mu\text{M}$ exogenous palmitic acid decreased lipid synthesis (12 to 25% respectively). Albumin bound detergent did not decrease lipid synthesis. Results indicated that palmitic acid inhibits lipid synthesis in vitro and results are not a non-specific detergent effect.

1286 Kinetics of glucose transport by isolated bovine mammary epithelial cells. Changting Xiao*, John P. Cant, Michael I. Lindinger, and Brian W. McBride, *University of Guelph, Guelph, Ontario, Canada*.

Glucose is the sole precursor for lactose synthesis in lactating-cow mammary gland. The purpose of this research was to identify an appropriate description of glucose transport kinetics from extracellular fluid into lactating-cow mammary epithelial cells. Viable epithelial cells were isolated from lactating-cow mammary tissue by a collagenase dissociation technique. Cells were incubated with 3-O-methyl-D-[1- ^3H]glucose (3OMG) at 37°C , and initial rates of 3OMG entry were measured under four different experimental conditions: zero-*trans*, where extracellular [3OMG] were varied while intracellular [3OMG] was kept at zero; equilibrium-exchange, where intracellular and extracellular [3OMG] were the same and varied simultaneously; infinite-*cis*, where extracellular [3OMG] was saturating and intracellular [3OMG] varied; and infinite-*trans*, where extracellular [3OMG] varied and intracellular [3OMG] was saturating. Uptake of 3OMG by isolated mammary epithelial cells exhibited saturable kinetics and was inhibited by phloretin and HgCl_2 . The K_m and V_{max} for zero-*trans* entry and equilibrium-exchange measured in 3 cows were 6.95 ± 1.01 mM and 24.92 ± 3.41 nmol per min per mg cell protein, and 17.78 ± 1.74 mM and 39.77 ± 0.91 nmol per min per mg cell protein, respectively. The results demonstrated that both extracellular and intracellular concentrations of glucose need to be considered when simulating glucose transport by bovine mammary epithelial cells.

1287 Factors affecting lactose production of lactating rat mammary acini. K. H. Myung*¹ and S. R. Davis², ¹Chonnam National University, Kwangju, Korea, ²AgResearch, Rukura Research Centre, Hamilton, New Zealand.

In vitro performance of mammary acini from lactating rats was assessed by the measurement of lactose secreted into media during 24 h of culture using a highly sensitive bioluminescence assay. Lactose production was significantly higher in cells from fed relative to starved (18h) animals ($p<0.01$) and increased linearly with increasing glucose concentrations in the media ($p<0.0001$) over 0-6h culture period. Lactose production of cells prepared from fed rats maintained in media containing 30 mM

glucose was 8.9 fmol/cell/h over 0-6h of culture, but declined thereafter. Over 6-24h of culture period the highest lactose production was 3.6 fmol/cell/h of fed cells in 40 mM glucose concentration media and there was no significant difference in the productivity of cells prepared from rats starved for 18h. Prolactin, hydrocortisone or a combination of prolactin, hydrocortisone and insulin significantly ($p<0.0002$) decreased lactose production over both 0-6h and 6-24h culture periods. Insulin alone had no effect. No effects of shaking, Matrigel coating or cell density at seeding on lactose secretion were found. Aeration during tissue digestion significantly ($p<0.05$) increased lactose production over 0-6h culture period. In conclusion, lactose production by mammary acini in vitro approached in vivo rates for 6h of culture and was sensitive to nutritional state of donor animals and aeration during tissue digestion. Hormonal additions had a negative effect on cell performance.

Key Words: Lactose, Lactation, Cell culture

1288 The expression polymorphism of kappa-casein gene affects cheese yield. G Robitaille*¹, D Petitclerc¹, J Morisset², and M Britten³, ¹DSRDC, Agriculture and Agri-Food Canada, Lennoxville, Canada, ²Sherbrooke University, Sherbrooke, Canada, ³FRDC, Agriculture and Agri-Food Canada, St-Hyacinthe, Canada.

A differential allele-specific expression of kappa(κ)-casein gene was recently detected in Holstein cows genotyped κ -casein AB. Two different populations were defined: a group of cows presenting a similar level of expression for alleles A and B- specific κ -casein gene (cows HH) and a group of cows over-expressing the allele B-specific κ -casein gene compared to allele-A (group HL). The objective of this study was to evaluate the effect of this expression polymorphism on cheese yield to verify that an optimal expression of κ -casein gene effectively affects milk composition so that the cheese yield can be improved. Laboratory-scale cheddar-type cheeses were made from 144 ml of blended-milk samples at 7 test-days. At each test-day, milk samples from individual cows were pooled based allele-specific expression of κ -casein ($n=5$ for each group of cows), skimmed, dialyzed overnight at 4°C against bulk milk adjusted at pH 6.2 with lactic acid, and standardized for protein content. Cream was added so that protein to fat ratios were identical and close to 0.9 before cheese production. Data were analyzed by analysis of variance. The 37% (w/w) moisture-adjusted cheese yield from milk of cows HH was significantly higher ($P<0.005$) than the one obtained from milk of cows HL, 9.95 ± 0.03 % and 9.82 ± 0.03 % for cows HH and cows HL, respectively. The decrease in cheese yield observed for milk of cows HL was mainly due to protein lost in the whey. In conclusion, the 37% (w/w) moisture-adjusted cheese yield was higher when the κ -casein gene expression was improved. Funded by FCAR-NOVALAIT.

Key Words: kappa casein, gene expression, cheese yield

1289 Distribution of delta-9 desaturase mRNA in bovine tissues: effect of physiological state and diet. E. Matitashvili*¹, D.G. Peterson¹, D.H. Beermann¹, and D.E. Bauman¹, ¹Dept. of Animal Science, Cornell University.

Delta-9 desaturase introduces a cis-9 double bond in fatty acids and plays an important role in determining the plasticity of synthesized lipids and the endogenous synthesis of CLA. Tissue distribution of delta-9 desaturase (stearoyl-CoA desaturase, or SCD) mRNA was analyzed by Northern blot in Holstein cows ($n=9$) in different physiological states and in crossbred beef steers ($n=10$) fed different diets. Tissues included liver, mammary gland, subcutaneous and intermuscular adipose tissue, semitendinosus and longissimus dorsi muscle, heart, kidney, lung and brain. We have identified SCD mRNA as a 5 kb transcript using ovine SCD cDNA (M.T. Travers and M.C. Barber, Hannah Res. Inst., UK). Comparisons of cows in early and late lactation, and non-lactating, non-pregnant cows indicated highest expression of SCD mRNA in lactating mammary gland, and in adipose tissue independent of physiological state. Hepatic SCD expression in cows was low in all physiological states. Expression of SCD mRNA was about 30 times greater in lactating mammary gland than in the non-lactating state. Expression of SCD mRNA in liver and adipose tissue was greatest in non-lactating cows. Highest expression of SCD mRNA in steers was found in subcutaneous and intermuscular adipose tissue. Lower levels of SCD mRNA were found in kidney, lung and brain, but expression in liver was negligible. Steers ($n=5$) fed full-fat extruded soybeans at 25.6% of total dry matter intake for 111 days prior to slaughter exhibited markedly

elevated (2-3 times) levels of SCD mRNA in subcutaneous and intermuscular adipose tissue when compared to control steers (n=5) fed a corn-based diet. Overall, the greatest expression of SCD mRNA was observed in adipose tissue in steers and cows and in mammary gland in lactating cows and expression was regulated by physiological state and diet.

1290 Milk fat globule size is not affected by diet restriction or soy oil supplementation. A.D. Beaulieu^{*1}, J.K. Drackley¹, J.M. Lynch², and D.M. Barbano², ¹University of Illinois, Urbana, ²Cornell University, Ithaca, NY.

Milk fat globule size and distribution influence the processing characteristics of milk fat. Abomasal infusion of high-oleic sunflower free fatty acids increased ($P < 0.001$) milk fat globule volume mean diameter (VMD) and decreased ($P < 0.001$) DMI (Overton et al., 1998, J. Dairy Sci. 81 (Suppl. 1): 352). An experiment was conducted to determine whether the increase in globule size was a result of the infusion or the DMI depression. Lactating Holstein cows (n=6) consumed a TMR ad libitum for 3 wk. During wk 4, 5, and 6, one-half of the group was restricted to 64%, 50%, and 37%, respectively, of ad libitum DMI. Milk production was decreased ($P < 0.05$) and milk fat percent was increased ($P < 0.05$) by 50% and 63% restriction. The proportions of C18:1_{cis-9}, C18:1_{trans}, and C18:2 in milk fat increased ($P < 0.05$) and proportions of C12:0, C14:0, and C16:0 decreased ($P < 0.05$) when cows consumed 50% or 37% of ad libitum intake. Neither the VMD nor the diameter below which 90% (d 0.9) or 50% (d 0.5) of the volume of milk fat is contained were affected ($P > 0.05$) by diet restriction. Milk fat globule size was positively correlated ($P < 0.05$) with C6:0 to C12:0 and C16:0 in milk fat and negatively correlated ($P < 0.05$) with C18 fatty acids. A second experiment examined the effect of soy oil supplementation on milk fat globule size. Six lactating Holstein cows were adapted to a basal TMR. Three cows then were fed the basal diet supplemented with soy oil (4% of DM) for 4 wk. Soy oil did not affect milk production or fat content ($P > 0.05$) but increased ($P < 0.05$) milk protein content. Soy oil did not affect ($P > 0.05$) milk fat particle VMD, d(0.9), or d(0.5) but decreased ($P < 0.05$) the contents of C4:0 to C16:0 and increased ($P < 0.05$) C18:1_{cis-9}, C18:1_{trans}, C18:2_{cis-9}, C18:2_{cis-12}, and C18:2_{cis-9, trans-11}, in milk fat. Although DMI restriction and soy oil supplementation affected milk fatty acid composition, milk fat globule size was unchanged.

Key Words: Milk fat globule size, milk fatty acids

1291 Supplementary infusion of amino acids and bovine somatotropin in atropine treated cows. P.H. Luimes^{*1}, J.P. Cant², X. Zhao¹, and D. Petitclerc³, ¹McGill University, St.Anne-de-Bellevue, Quebec, ²University of Guelph, Guelph, Ontario, ³Agriculture and Agri-Food Canada, Lennoxville, Quebec.

In cattle and sheep, muscarinic cholinergic antagonists, such as atropine, will decrease milk and milk protein yield. In cattle, blood concentrations of amino acids (AA) have been shown to decrease due to atropine, whereas, in sheep, muscarinic cholinergic antagonists have been shown to decrease serum somatotropin (ST) concentrations. Thus, atropine may provide an interesting model to determine the relative importance of endocrine and nutrient factors involved in milk synthesis. An experiment was conducted in which AA, bovine (b) ST or both were infused over 8h into cattle treated with atropine to determine whether one or both of these factors were responsible for the decline in milk protein production. Five mature Holstein cows were used in a 5 x 5 Latin square design, the treatments being: saline (0.9%), atropine (120 $\mu\text{g}\cdot\text{kg}(\text{MBW})^{-1}\cdot\text{h}^{-1}$), atropine + bST (850 $\mu\text{g}\cdot\text{h}^{-1}$), atropine + AA (25 $\text{g}\cdot\text{h}^{-1}$) and atropine + AA + bST. The AA profile of the infusate was designed to emulate the profile of milk protein. Atropine was unable to decrease plasma bST concentrations in lactating cows, though it did decrease plasma α -amino nitrogen (α -AN). Neither bST nor AA infusion were able to restore milk protein percent or milk protein yield. Perhaps other nutrient or endocrine factors, such as glucose, somatostatin, insulin and/or IGF-1 are involved in these effects of atropine infusion.

1292 Correlations between specific binding of bST to desaturated hepatic membranes and various serum endocrine and nutrient components. M. Lonard¹, P.H. Luimes¹, E. Block¹, and D. Petitclerc^{*2}, ¹McGill University, St.Anne-de-Bellevue, Quebec, ²Agriculture and Agri-Food Canada, Lennoxville, Quebec.

Six mature Holstein cows were injected with 30.9 $\text{mg}\cdot\text{d}^{-1}$ of recombinant bovine somatotropin (rbST) from d 15 to 41 of lactation. Cows were assigned to one of two 3 x 3 Latin squares in which periods were of 6 d duration. Rests of 3 d were allocated to cows between periods. The experimental treatments, which began on day 18 of lactation, were saline (0.9%), glucose (50 $\text{g}\cdot\text{h}^{-1}$) and insulin + glucose (12.5 $\text{IU}\cdot\text{h}^{-1}$ + 50 $\text{g}\cdot\text{h}^{-1}$, respectively). Data concerning serum concentrations of endocrine and nutrient components were previously published (Léonard and Block, 1997; J.Dairy Sci. 80:127-143). Data regarding percent specific binding (¹²⁵I-bST.200 mg^{-1}) of hepatic membrane protein to bST were published by Léonard et al. (1992; J.Dairy Sci. 75(Suppl.1):182). Pearson correlation coefficients (r) were determined between specific binding of bST to desaturated hepatic membranes and serum insulin concentrations ($r = 0.82$, $P < 0.01$), serum IGF-1 concentrations ($r = 0.48$, $P < 0.05$), energy balance ($r = 0.47$, $P < 0.05$) and serum concentrations of NEFA ($r = -0.59$, $P < 0.01$). Serum glucose was not correlated with specific binding of bST to desaturated hepatic membranes. The mechanism by which insulin, which is usually at its nadir during early lactation, increases serum IGF-1 concentrations appears to be via an increase in specific binding of bST to its hepatic receptors.

Key Words: Specific Binding, Growth Hormone, Insulin

1293 Effect of 17-estradiol on milk production and mammary gland involution in Holstein cows in mid-late lactation. L. Delbecchi^{*}, D. Petitclerc, and P. Lacasse, AAFC-Dairy and Swine R&D Centre, Lennoxville, Quebec, Canada.

This study was conducted to assess the effects of estrogens on milk production and persistency of lactation in mid-late lactating cows. The hypothesis was that the increasing amounts of estrogens in the blood of pregnant lactating cows is one of the factors inducing or accelerating the progressive involution of the mammary gland observed during the declining phase of lactation. Eight non-pregnant Holstein cows, ranging from 177 to 338 d of lactation, received subcutaneous injections of either 17-estradiol (15 $\text{mg}/\text{cow}/\text{day}$; treated group, n=4) or excipient (95% ethanol; control group, n=4) from d 0 to d 8. Treated and control cows were paired according to the number of parities and milk yield. Milk production was measured from d -10 to d 20. Milk composition was evaluated on samples harvested before, during and after estradiol injection. One treated cow presented signs of acute mastitis on d 4 and was removed from the experiment. Milk production was reduced ($P < 0.01$) in treated versus control cows by 14.8% on d 3, 37.2% on d 6, 76.5% on d 8, and 81.6% on d 11. Two treated cows dried-off spontaneously by d 8 and d 9, respectively. Changes in milk composition characteristic of a mammary gland in involution were observed in treated cows. Between d 0 and d 7, milk fat content and lactose concentration decreased ($P < 0.05$) by 37.6% and 15.9%, respectively. During the same interval, milk protein concentration increased by 61.9% ($P < 0.05$). Control cows showed no significant variation in these parameters during the same period. Effects of estradiol at the molecular level are currently investigated. These results support the hypothesis that estrogens produced by the foeto-placental unit induce a gradual decline in milk production in pregnant lactating cows. This work was supported by Dairy Farmers of Ontario and Agriculture and Agri-food Canada.

Key Words: Involution, Mammary gland, Estrogens

1294 Transgenic Sows Overexpressing Alpha-lactalbumin: Piglet Growth and Milk Component Intake Early in Lactation. M.S. Noble*, M.B. Wheeler, and W.L. Hurley, *University of Illinois, Urbana, IL.*

Piglets reared by transgenic sows overexpressing α -lactalbumin (α -LA) grow at a significantly faster rate compared to piglets reared by control sows. Differences in piglet weight gain occur ($P < 0.05$) by d 6 of lactation and continue throughout the lactation period. By weaning (d 21 of lactation), transgenic reared piglets are 13% heavier than piglets reared by control sows. The objective of this study is to determine if increased preweaning growth by transgenic reared piglets is associated with altered milk component composition and component intake. Milk samples were collected from first parity α -LA transgenic sows ($n = 11$) and their non-transgenic littermates ($n = 13$) on d 3, 6, 9, and 12 of lactation. Milk samples were analyzed for concentrations of bovine α -LA, lactose, total protein, and total solids. Lactose, total protein, and total solids intake by transgenic reared and control reared piglets were determined from milk production data previously reported. Bovine α -LA was expressed throughout the lactation period (approximate mean concentration = 400 g/ml). Lactose concentrations were greater ($P < 0.05$) on d 3 and 6 of lactation, but not different on d 9 or 12 of lactation in milk of transgenic sows when compared with milk from control sows. Total protein and total solids concentrations in the milk of transgenic sows and control sows were not significantly different on d 3, 6, or 12 of lactation. Lactose and total solids intake were greater ($P < 0.05$) on d 3 and 6 of lactation for transgenic reared piglets compared to control reared piglets. Total protein intake was greater on d 3, 6, and 9 of lactation for transgenic reared piglets compared to control reared piglets. These data suggest that the elevated levels of lactose, total protein, and total solids intake by transgenic reared piglets early in lactation may account for the significant increase in their rate of preweaning growth.

Key Words: alpha-lactalbumin, transgenic sow, piglet growth

1295 A redefinition of the effects of mammary cell numbers and enzyme activities on predictions of milk yield and composition by a lactating dairy cow model. M. D. Hanigan*, F. E. Standaert, and D. C. Weakley, *Purina Mills, Inc., St. Louis, MO.*

The model of Baldwin (1995) provides a method to predict milk yield and composition over time. This allows accommodation of time-dependent effects such as previous plane of nutrition. However, in evaluating the model, it was found to be inadequate with respect to predictions of milk fat and protein. It was determined that an updated representation of mammary cell numbers and cell enzyme activities was required to resolve the problem. The model of Dijkstra et al. (1997) was adopted for representation of each.

$$Mass_{Mammary} = \alpha BW_{DIM0} e^{(-\beta + \chi Trt) \times DIM}$$

$$Synthesis_i = Enz_{i,DIM} e^{(\alpha_i (1 - e^{\beta_i \times DIM}))}$$

$$Degradation_i = Enz_i e^{(-\delta \times DIM)}$$

where cell numbers were calculated from mass of protein and total enzyme activity for each component ($i =$ lactose, protein, or fat) was calculated as the product of cell numbers and enzyme per cell. The mammary mass equation was parameterized from the data of Gibb et al. (1992) (see table). After adoption of the protein equation as a predictor of cell numbers, mammary enzyme equations were parameterized using a small production data set assembled from past studies conducted at the Purina Mills, Inc. research unit. After fitting to the data, predictions of lactation curves for milk fat and protein were significantly improved with root mean square prediction errors for milk and milk component yields declining by approximately 2 fold suggesting that this alternative representation was justified.

	α	β	χ	$P \leq .05 Trt$
Udder Mass	.044(.0016) ^a	.0019(.0004)	.0006(.0002)	*
Udder Protein	.005(.0002)	.0015(.0004)	.0006(.0002)	
Udder Fat	.006(.0004)	.001(.0007)	.0009(.0004)	*

Parameter estimates (SE) for Eq. (1) when fitted to the udder composition data of Gibb et al. (1992). Treatments (Trt) were 3 dietary energy intakes. ^aAll α and β coefficients were significantly different from 0 excepting β for udder fat.

1296 Amino peptidase gene expression in caprine mammary gland; A possible role in peptide-bound amino acid uptake. S.J. Majeesh*¹, M. Cohen¹, O. Gal-Garber¹, A. Shamay², and Z. Uni¹, ¹The Hebrew University of Jerusalem, ²Agricultural Research Organization, The Volcani Center.

This experiment was conducted to isolate gene that express the enzyme aminopeptidase N (APN) in mammary gland of lactating goats. APN are enzymes anchored to the cell membrane via an N-terminal hydrophobic sequence of 20 amino acids that span the membrane only once. APN are highly expressed at the brush border membrane of the small intestine and are responsible for peptides hydrolysis and protein digestion. The mammary gland of ruminants do not express gene for peptide transporter (Pept1), however indirect evidence for peptide uptake by the gland is apparent. We hypothesized that APN enzyme would be expressed in the mammary gland of lactating ruminants and it may play an important role in peptide-bound amino acids uptake in the mammary gland. The first step in investigation this hypothesis was to isolate the gene from the mammary tissue. Caprine mammary gland tissue was collected for RNA isolation and basal-membrane vesicles (BMV) preparation. Total RNA was isolated from the mammary tissue and the APN gene was detected by RT-PCR using specific primers chosen from conserved regions of APN genes which identified as 531 bp cDNA. This cDNA fragment showed 83% homology to human, rabbit and rat intestinal APN. This cDNA fragment was used as probe in northern blot analysis which revealed a transcript of approximately 4.0 kb. Western blot analysis detected a protein of 155 KDa in BMV prepared from the mammary tissue. APN kinetics measurements in BMV revealed a high affinity enzyme with $k_m = 57 \mu M$ and $V_{max} = 270 \text{ pmol. mg prot}^{-1} \cdot \text{min}^{-1}$.

1297 Analysis of the sources of variation in CLA production in dairy cows. J.A. Kelsey*, D.G. Peterson, and D.E. Bauman, *Cornell University, Ithaca, NY.*

Conjugated linoleic acid (CLA) has a wide variety of health benefits based on animal models. Ruminant derived foods are the major dietary source and this relates to incomplete biohydrogenation of fatty acids. Some CLA escapes complete biohydrogenation in the rumen, but the major source is endogenous synthesis via Δ^9 -desaturase from *trans*-11 C_{18:1}, another biohydrogenation intermediate. Thus, milk fat CLA can vary because of rumen outflow of CLA and *trans*-11 C_{18:1} or activity of Δ^9 -desaturase. Our objective was to examine individual consistency and sources of variation in milk fat CLA. Holstein cows were divided into 3 groups ($n=10/\text{treatment}$) for the 12 wk study. One group (low) was fed a traditional corn-based TMR, a second group (high) was fed extruded, full-fat soybeans to achieve higher milk fat CLA, and the third group (switch) alternated treatments at 3 wk intervals between low (periods 1 and 3) and high (periods 2 and 4) diets. Average CLA concentration in milk fat was relatively constant among individuals and groups over the 12 wk for low and high treatments. Milk fat CLA was 3-fold greater in the high treatment and there was a 2- to 3-fold range among individuals for both diets. The switch treatment was also relatively constant within dietary treatment, with CLA concentration varying as expected, according to diet. In milk fat synthesis, Δ^9 -desaturase has four primary substrates; C_{14:0}, C_{16:0}, C_{18:0}, and *trans*-11 C_{18:1}. The ratio of these substrates and their corresponding products serves as a proxy for Δ^9 -desaturase and all 4 ratio comparisons allowed for similar conclusions. We focused on the C_{14:1}/C_{14:0} ratio because the predominant source of these fatty acids is mammary synthesis. Regardless of diet, ratios of C_{14:1}/C_{14:0} were similar for treatment groups with a 2- to 3-fold range among individuals. Furthermore, individual cows displayed remarkable consistency in the hierarchy across periods for all treatments, including the switch treatment where the diet and supply of substrate for desaturation varied in successive periods.

Key Words: CLA, milk fat, desaturase

1298 Effect of postpartum changes in BCS on milk components. DilipKumar Garikipati*¹, Sarjan Rao Kapa¹, and Kailash M.M.², ¹College of Vety Science, Tirupati, ²College of Vety Science, Bangalore.

Body condition scoring system with 1 to 5 scale (Edmonson et al,1989) was used in 137 crossbred HF cows in early to mid lactation to evaluate the post partum losses in body fat reserves and its influence on milk components. The effect on dry matter intake (DMI) was linear and a reduction of DMI (kg/day) with the increase in BCS ranged from 10.78 to 13 Kg/day for BCS 4.5 to 2.5 DMI decreased by 1.3 Kg/day for an additional increase in one unit of condition score. This showed that the DMI of fatty cows was less than the thin cows. As the live weight (kg) of the animals increased the BCS also increased indicated increase, in body fat reserves. Mean daily and peak milk yield over the first 6 months of lactation in relation to BCS were linear and there was a increase of 4.1 Kg and 7.8 Kg of daily milk yield and mean peak milk yield, respectively for every increase of one unit of condition score. Milk fat yield ranged from 3.1 to 3.9 percent and there was a positive response of 5 g/kg with an increase of one unit of condition score over the range 3 to 4 BCS. A positive milk protein output response was also observed with milk protein yield ranged from 32 to 34 g/kg with a meagre increase of 1g/kg over the range of 3 to 3.5 BCS and a decrease of 2g/kg for every one unit increase of BCS over the range of 3.5 to 4.5. The pattern of prediction equations for change in BCS to 120 DIM and 305 days FCM yield showed the BCS loss of 0.75 to 1.0 unit which was associated with more milk production. Higher rates of loss in BCS in second and third lactation numbers that have been associated with diminished milk production compared with its potential production. This suggested that increased feeding levels are warranted as the number of lactations advanced. Post partum decrease in BCS was observed upto three months and this was due to loss of body reserves through milk production which gradually recouped from fourth month onwards. This suggested that the increase in the post partum feeding levels will prevent the loss in BCS.

Key Words: BCS=Body Condition Score, fat, milk

1299 Evaluation of the antibacterial activities of lactoferrin derived peptides. P.-W. Chen, C.-L. Shyu, and F. C. Mao*, National Chung Hsing University, Taichung, Taiwan.

The hydrophobic and basic regions of N-terminal of lactoferrin, which contained 10 amino acids, originated from bovine (bLF20-29), caprine (cLF20-29), porcine(pLF20-29), human (hLF21-30) and murine (mLF20-29) were chemically synthesized. The minimal inhibition concentration (MIC) and minimal bactericidal concentration (MBC) against Gram-positive bacteria (*S. aureus* ATCC 25923 and *E. faecalis* ATCC 29212) and Gram-negative bacteria (*E. coli* ATCC 25922 and five wild strains of *E. coli* that resisted to broad spectra of antibiotics) were determined. The MIC and MBC of bovine lactoferrin and pepsin-digested bovine lactoferrin hydrolysates against selected bacteria were also determined and compared with that of synthesized peptides. The bLF20-29 had potent antibacterial activity that it inhibited and killed all the selected bacteria. The MIC for bLF20-29 was 30 µg/ml and the MBC was 60 µg/ml in selected *E. coli*. However, the peptides of cLF20-29, pLF20-29, hLF21-30 and mLF20-29 had less antibacterial activity. The MIC for these peptides were more than 500 µg/ml among the selected bacteria. According to the hydrophobic and basic pattern, two peptides modified from the bLF20-29 and cLF20-29 origin were synthesized, named LFM1 (Arg Arg Trp Trp Trp Arg Trp Arg Arg Trp) and LFM2 (Arg Arg Trp Trp Arg Arg Trp Arg Arg Trp). Both the LFM1 and LFM2 had excellent antibacterial activities. The MIC and MBC for these two peptides were similar in selected bacteria. The MIC and MBC were 2.8 µg/ml and 3.75 µg/ml in selected *E. coli*. The antibacterial activities of LFM1 and LFM2 were much better than the bLF20-29. The potent

antibacterial property of these peptides could be useful in further study and field application.

Key Words: lactoferrin, lactoferricin, antibacterial peptide

1300 Local expression of IGF-1 and IGFBP-3 mRNA in mammary tissue of prepubertal heifers after treatment with growth hormone. P.M. Jobst*¹, S.D. Berry¹, M.L. McGilliard¹, D. Ayares², D.A. Henderson¹, W.E. Beal¹, and R.M. Akers¹, ¹Virginia Polytechnic Institute and State University, ²PPL Therapeutics Inc.

Two experiments were conducted to determine the effects of bovine growth hormone (GH) and estradiol (E₂) on mRNA expression of insulin-like growth factor-1 (IGF-1) and IGF-binding protein-3 (IGFBP-3) in mammary tissue of prepubertal heifers. In experiment one seven heifers treated were with GH for 7d. Mammary parenchyma and stroma were collected by surgical biopsy before and after GH. Explants of parenchyma and stroma were cultured for 36h in media without or with GH (1µg/ml), E₂ (20pg/ml), GH + E₂, or IGF-1 (100ng/ml). RIA indicated serum IGF-1 and GH levels were elevated following GH treatment. Expression of IGF-1 and IGFBP-3 mRNA was not affected by GH treatment or hormones in culture. However, expression of IGF-1 mRNA was greater in stromal than parenchymal tissue. In experiment two, nine prepubertal heifers were administered placebo or GH. GH (Posilac[®]) was given every 14 days for three months. Blood samples were collected weekly. Heifers were sacrificed and mammary tissue collected. Stroma and parenchyma explants were cultured and analyzed for expression of mRNA as described above. Serum IGF-1 and GH levels were elevated following Posilac[®] treatment. Prior treatment of heifers with Posilac[®] did not affect the response of tissue explants in culture. However, in both parenchymal and stromal explants, IGF-1 increased (24%) expression of IGFBP-3 compared with explants in the absence of hormones. Stroma produced 27% more IGFBP-3 mRNA than parenchyma. Stroma explants cultured in E₂ or E₂ + GH produced 60% and 54% more IGF-1 mRNA respectively, compared to explants without hormones. Overall stromal explants produced 2.4-fold more IGF-1 mRNA than parenchyma explants. These data indicate that E₂ and IGF-1 elicit acute changes in the local IGF-1 axis of the bovine mammary gland.

Key Words: IGF-1, Growth hormone, Mammary gland

1301 Milk yield and constituents of Fleckvieh cattle in Bavaria:1-First lactation. Kamal Marzouk*[#], [#]Minia Univ..

Data from 3814 first lactation of Fleckvieh cattle was collected from 29 herds. This data came from milk recording organization in Bavaria, Germany. The aim of this study was to evaluate the milk yield and constituents of first lactation to erect a selection programme. The means of kg milk, 100-days for different traits of milk production and constituents were 1823.68 kg,72.40 kg,3.96%, 57.9 kg, 3.20%, 1.24%,0.75% and 2.14 MJ for milk yield, kg fat,%F,kg protein,%protein, Fat/Protein (F/P)ratio, index fP=(% fat-%protein)and energy in milk[milk energy yield (MJ)=milk yield* (0.37 * %fat+0.21* %P + 0.95)+milk yield * 0.07]], resp. The same traits at kg-milk, 200-days were 3395.42 kg, 134.14 kg, 3.95%, 111.01 kg,3.27%, 1.30%,0.67% and 2.16 MJ, resp. Also, at kg milk, 305-days the previous traits were 4553.44 kg, 183.50 kg, 4.07%, 152.4 kg, 3.32%, 1.68%, 0.76% and 2.21 MJ,resp. Effect of herd-years was significant on all milk yield and constituents traits at different periods except on fat/protein ratio at kg milk, 200-days. Seasons at calving had a significant effect on all traits at kg milk, 100-days except index fp,% fat, index fp at kg milk; 200 days and %fat, f/p ratio, index fp and energy in milk at kg milk, 305-days. On the other hand,the means of persistency=[(milk yield days 101-200/milk yield days 1-100)*100] was 82% and not affected by seasons of calving.

ASAS/ADSA Extension Education and ASAS/ADSA Teaching Undergraduate and Graduate Education

1302 Dairy farm HACCP: PMO bulk tank temperature and wash cycle compliance on 10 Minnesota dairies. S. Nagel and J. K. Reneau*, University of Minnesota, St. Paul, MN, USA.

Bulk tank temperatures should be a critical control point in a dairy farm HACCP plan. This study used temperature recording data loggers to

observe bulk tank temperature patterns on 12 Minnesota dairies. From a list of potential cooperators supplied by the Minnesota Department of Agriculture, 12 dairies were selected by geographical distribution and herd size. Onset Computers' HOB0[®] temperature recording data loggers were placed inside bulk tanks near the outlet. The thermometers

were programmed to record temperature every 10 min for 24 hr/d ranging from 2-14 mo. On one farm, the data logger failed and the data was irretrievable; on another, the electronic data was inadvertently lost. Electronic data was downloaded monthly and imported into a spreadsheet where descriptive statistical calculations and graphic presentations of data were accomplished. A total of 333,537 individual bulk tank temperatures were recorded at 10-min intervals in 11 bulk tanks on 10 of the farms. Preliminary analysis of a data subset indicated that maintaining commingled raw milk temperatures <50°F at subsequent milkings was a common problem. Farm 9 had a cooling failure. The tank's digital thermometer read 40°F but the tank was cooling milk at 50°F. During summer 1998, the tank on Farm 3 routinely recorded commingled milk at temperatures >50°F. With the exception of Farms 3, 5 and 9, all other bulk tanks appeared to meet PMO requirements to cool raw milk to <45°F within 2 hr after end of milking. In general, cooling milk to 45°F by 2 hr after end of milking did not seem to be a problem except on Farm 9 where the bulk tank was not functioning properly. Data loggers also recorded wash cycles. An average of 97% of the time, bulk tanks were sanitized after each milk pickup. Since herds were not randomly selected, it cannot be assumed that observations in these case studies accurately reflect bulk tank function or wash cycle compliance of the Minnesota dairy industry in general. As a pilot program, these findings support the need for further study. Monitoring bulk tank temperatures should be part of a dairy farm HACCP plan.

Key Words: HACCP, bulk tank, temperature

1303 Environmental mastitis pathogens in fresh bedding material. V. Eckes, M.A. LaValle, R.F. Bey, R.J. Farnsworth, and J.K. Reneau*, *University of Minnesota, St. Paul, MN, USA.*

Bedding type and particle size influence bacterial growth. Bedding samples were separated into three different particle sizes using a No. 8 and No. 18 mesh screen. Fifty ml of each particle size and 50 ml of the original unseparated bedding were each transferred into separate plastic Whirl-pak® bags and labeled. 100 ml of sterile distilled water was added to each Whirl-pak® bag and carefully mixed with the bedding. The mixture was then allowed to settle for 20-30 min. The supernate was pipetted (0.2 ml) from the Whirl-pak® bag and spread onto both CNA and MacConkey plates. Where necessary, serial ten-fold dilutions were prepared before plating the supernate on culture media. Bedding materials were incubated at 37°C and sampled at 0, 24, 48, and 72 hr. All plates were incubated 24 hr at 37°C. Bacterial counts were made to determine number of colony-forming units per cubic centimeter in the bedding materials. Bacteria were identified using biochemical reactions. Results indicate that all bedding materials supported growth of environmental pathogens. The degree to which growth occurred varied with the bedding material type and particle size. Large particulate bedding materials supported the least amount of growth while fine materials supported the greatest amount of bacterial growth. Ground sunflower hulls and chopped straw best supported growth, while pine wood shavings supported the least amount of growth. From these studies, it appears that ground sunflower hulls, hardwood shavings, straw, and fine material of any type are least desirable. The best bedding materials were sand and large pine shavings. Examples of intermediate bedding materials were paper dots, aspen, and a mixture of hard (oak) and soft (pine) wood. Particle size is a critical determinant in the ability of bedding material to support bacterial growth. When selecting bedding material, the type of bedding material and particle size must be carefully considered.

Key Words: bedding, mastitis pathogens, particle size

1304 Phosphorus adsorption implications on phosphorus management on dairies. T Downing* and J Hart, *Oregon State University.*

Management of phosphorus application and accumulation on dairies is a challenge in most established dairy regions in the US. In many areas, continual manure application has increased soil P above amounts sufficient for optimum crop yields leading to increased P loading to surface water, both in solution and attached to soil particles. The dairy industry has traditionally used soil testing to monitor P accumulations and crop needs. A significant dairy industry existed along the Oregon coast for over 100 years. For approximately the last 25 years, most dairies have over applied phosphorus from an agronomic standpoint. Soil test

P concentrations as determined by Bray P1 test indicate many dairy soils are deficient in available phosphorus. This observation has led many dairymen to purchase large quantities of commercial phosphorus fertilizer, even though most are over applying P with their manure applications. In addition, plant tissue phosphorus values and yield data indicate no shortage of phosphorus. The apparent contradiction among P application rates, soil test value and tissue P concentration caused us to evaluate the phosphorus adsorption capabilities of six major soil types on dairies along the coast. Soils were analyzed using the Bray P1 and phosphorus sorption isotherms were constructed by adding one gram of soil to increasing quantities of P ranging from 1 to 1000 mg/l. All assays were performed in triplicate. Bray P1 soil test values ranged from 8 to 83 ppm and averaged 29 ± 11.3 . Solution P values ranged from .07 to .51 mg/l and averaged $.31 \text{ mg/l} \pm .27 \text{ mg/l}$. Phosphorus adsorption characteristics were significantly different between soil types as determined by regression. These results indicate coastal soils in Oregon will respond differently to similar levels of phosphorus loading. These data also indicate that these soils have high absorption capabilities, compared to other results reported nationally. This study has increased our understanding of phosphorus management, but has also increased our interest in desorption possibilities.

Key Words: phosphorus adsorption, sorption isotherms

1305 Evaluation of dairy farmers' use of financial long-range planning. G. W. Robb*, S. B. Nott, and B. A. Dartt, *Michigan State University.*

The objectives of this study were to assess the farmer's use of financial long-range budgeting software output, and identify input factors that could improve accuracy of future projections. Twenty-nine Michigan and nine Minnesota dairy farmers, who had previously completed a Finlrb, Financial Long Range Planning, program within Finpack, University of Minnesota, were personally interviewed. Electronic files containing their projected budgets, as well as actual values invested in completed expansions were collected and compared. Overall usefulness of the program was rated very or extremely useful by 84% of the farms and 100% would recommend its use to their neighbors. The quality of technical assistance from the ten Extension personnel conducting the Finlrb was reported as very or extremely good by 95% of the farms. If charged for the Finlrb projection farmers would have paid an average of \$750. Thirty-one of the 38 farms completed investments at the time of the survey. They reported actual investments totaling \$12,802,161 for a median of \$284,550 per farm. The Finlrb projections of added capital totaled \$10,567,634. As a group the farms spent 21% more \$2,234,527 in their projects than investment numbers used in the Finlrb projection. Excavating, concrete, farm building labor, cattle prices and replacement animal costs were often under estimated. Many other differences between projected and actual investments were due to changes between time of the projection and project completion. Fourteen farms had Finpack's Year End Financial Analysis (Finan) completed for the year following construction completion. Net farm income achieved in the Finan was lower than the Finlrb projection on 71% of the farms while actual milk price received was higher than projected on 85% of farms. Four farms had a negative net farm income. Cow numbers and milk production per cow goals were met on 65% and 70% of the farms respectively. Actual feed and hired labor costs increased on 58% and 75% of the farms respectively. Finlrb was considered a useful decision-making tool. The analyzed Finans showed farmers were more successful in achieving herd size and production per cow goals than limiting feed and hired labor costs.

Key Words: Dairy, Extension, Financial planning

1306 A training workshop for the National Dairy InfoBase. M. A. Varner*¹, ¹*University of Maryland.*

The National Dairy InfoBase (NDIB Ver. 4) has been published on CD-ROM and the Internet by the not-for-profit Agricultural Databases for Decision Support organization (www.adds.org). Use of the NDIB can be accentuated by providing training on the program's use. A hands-on training program was planned for dairy producers and advisors as a pre-conference workshop for the Maryland Dairy Industry Association. The workshop was held in a networked computer lab at a local community college. Registration was limited by ten computers. Two people per computer were allowed, and twelve individuals participated. After completion of the workshop, the goal was for the participants to

be able to: 1) install the ADDS National Dairy InfoBase (NDIB, Ver. 4) from the CD to the hard disk of their computer; 2) start the NDIB on their computer; navigate the various windows within Folio Views; 3) browse through publications in the various subjects; 4) Search the NDIB with single word, multiple word and phrase searches; 5) print various amounts of a publication and 6) use the NDIB over the Internet. The workshop was held in a two hour time period. Introductory remarks were made before each of the six sections and then individuals were encouraged to complete the step-by-step tutorials that would allow them to accomplish the desired tasks when returning home with their CD-ROM disk. After approximately 15 minutes, a short summary was presented and an introduction was made for the next topic. The workshop was presented by one instructor and the time between presentations was spent answering individual questions. All participants were able to complete the workshop in the two hour time frame. Conducting the hands-on workshop for the NDIB as a pre-conference program was desirable as participants could maximize their educational efforts on that day. A copy of the training materials used in the workshop are available at <http://www.wam.umd.edu/markv/NDIB.pdf>.

1307 Teaching pork producers breeding and gestation herd management skills via the Internet. M.T. See* and B.A. Belstra, *North Carolina State University, Raleigh NC.*

To enable distance education for pork producers and their employees a nationally developed curriculum was transformed into an Internet course comprised of interactive HTML lessons, images, and self-grading quizzes. The Breeding and Gestation Herd Management Curriculum is divided into six sections. These sections are not separated to be equal in length but rather to break at distinct phases of breeding and gestation management. The Internet course was pilot tested in cooperation with the National Pork Producers Council during the spring of 2000. In the pilot class 39 participants enrolled and 26 completed the course. Participants were from 17 states (AK, AR, CA, FL, GA, IA, ID, IN, IL, MI, MN, MO, NC, NE, NH, OH, OK), Ecuador, Colombia and the Philippines. Of the 26 participants completing the course 14 were owner/operators, 6 were farm managers, 2 were breeding and gestation managers, 3 were employees and 1 was an educator. Of the 26 completing the course 20 were male and 6 were female. After completion of the six lessons and quizzes students were asked to complete a survey response. Average time spent on this course was 12 hours per student and most students worked on the material in the evenings. The completion of the pilot Internet course resulted in an average quiz score of 88.2%. Ninety-six percent of the participants completing the course agreed that Breeding and Gestation Herd Management provided him or her with an opportunity to improve their job skills. When asked about their improvement of knowledge on 14 key concepts the average responses ranged from 2.0

to 2.5 for every concept where 1 is Strongly Agree and 5 is Strongly Disagree. Furthermore 46% of the completing students indicated that they planned to make changes in their breeding and gestation barn practices based on information they learned in Breeding and Gestation Herd Management. Ninety-six percent of respondents also indicated that they would be interested in taking additional courses over the Internet. These results demonstrate that distance education programs not only makes information readily available at a time convenient to the clientele but that it is also effective in delivery and can result in improved knowledge and job skills.

1308 Undergraduate education: exposing first- and second-year students to laboratory research. G. F. Erf*, W. G. Bottje, H. D. Chapman, M. Iqbal, R. Okimoto, and M. S. Parcels, *University of Arkansas, Fayetteville, AR, USA.*

In agricultural colleges with a strong research base, there are many research opportunities for undergraduate students in formal and informal settings (e.g., special problems courses, internships, work study and honors programs, etc.). However, entry-level undergraduate students interested in research opportunities may not pursue these interests due, in part, to limited exposure to the research environment, a lack of confidence, and difficulties in identifying a research mentor. The laboratory course entitled Rotations in Agricultural Laboratory Research described below was developed to provide first- and second-year undergraduates interested in science-based agricultural programs with the opportunity to conduct hands-on, interdisciplinary, team-based research. During the first 8 wk, students were taught research techniques and approaches during a 4-h structured laboratory and a 1-h discussion-session per wk. The teachers involved were researchers from three disciplines. For example, during Year 1, nine students conducted laboratory exercises in parasitology, immunology, and molecular virology. During wk 9, the students split into two groups and, with the aid of their teachers, each group developed a 4-wk research project integrating techniques used from at least two of the three disciplines. The teachers served as mentors for projects involving their discipline throughout the project period. The students reported their project and final results in an oral presentation and a written abstract. Students were evaluated based on the quality of their laboratory notebook, weekly quizzes on concepts learned in the laboratory, and their final abstract and presentation. Although still at the experimental stage, this course was very successful in providing students with confidence, enthusiasm, and the contacts to successfully pursue laboratory research opportunities. Currently (Year 2), disciplines taught are cellular physiology, immunology, and molecular genetics.

Key Words: Education, Laboratory course, Experiential learning

1309 Interaction between chopping length of corn silage and long hay on chewing activity of dry cows. Paolo Berzaghi*^{1,2}, Giulio Cozzi¹, Flaviana Gottardo¹, and Iginio Andrighetto¹, ¹University of Padova, Italy, ²US Dairy Forage Research Center, Madison, WI.

Five Holstein dry cows were used in a 5 x 5 Latin square design with periods of 14d. Diets consisted of corn silage chopped at 6.7mm (S) and 14mm (L), long grass hay (H), and a combination of hay (20 %DM of the forages) with the short (SH) and the long (LH) corn silage. In all of the diets, soybean meal and a mineral premix were mixed to the forages to obtain a TMR with a CP concentration of 10 % DM. Diets were fed ad libitum (10% refusals) once a day. Chewing activity was monitored during the last 5d of each period using a portable APEC device (INRA, Clermont Ferrand, France) connected to a foam filled balloon placed under the lower jaw of the cows. The greater NDF content of grass hay (71.1 %DM) than the corn silages (44.6 %DM) reduced ($P < .01$) DM intake of H diet, but it maximized its NDF intake (7.0 vs. 5.6 kg; $P < .001$) in comparison to the four corn silage based diets. In diet S 2.6 % of the particles were retained by a 19mm screen. The coarser chopping of L diet increased this value up to 7.2 %. The different particles size did not affect DM intake and eating time, but it resulted in longer rumination time (491 vs. 389 min/d; $P < .02$) for L compared to S diet. The addition of hay to the corn silage diets resulted in a higher content (+3.7

%DM) and intake of dietary NDF (5.9 vs. 5.3 kg/d; $P < .02$). However, the rumination time of SH and LH diets was similar, leading to a significant ($P < .03$) hay addition x silage chopping length interaction. The same interaction tended to be significant ($P < .06$) for effective NDF, measured as time spent chewing per kg of NDF intake. The results indicate that chewing activity is affected by the particle size of the forage and by associative effects among forages with different composition and particle size. These results would also support the suggestion that in dry cows normal chewing activity is maintained by providing diets with 10-15 % of forage particles retained by a 19mm screen.

Key Words: corn silage, chopping length, chewing activity

1310 The peruvian dairy sector: farmers' perspectives, development strategies and policy options. Thomas Bernet¹ and Carlos Gomez*², ¹International Potato Center, Lima/Swiss Agency for Development and Cooperation, ²Universidad Nacional Agraria La Molina, Lima.

This work assesses how expected market changes, farm strategies, and policy interventions might affect typical milk producers within the main Peruvian milksheds: Arequipa (coast), Lima (coast) and Cajamarca

(highlands). The analysis is based primarily on the application of a flexible farm-household optimization model able to project farmer behavior in different farming systems under varied production conditions. Cross-regional analysis shows a certain distortion in the current market situation, driven by varying degree of competition among the main milksheds for regionally produced milk. In Lima, the elevated number of regional milk buyers, many with under-used processing capacities, have caused strong competition on the demand side, provoking high milk prices. In Arequipa and Cajamarca, prices are much lower, since there are fewer wholesale milk buyers and thus less competition for farmers milk supply. Because condensed products for the Lima market (evaporated milk and cheese) are produced most cheaply in Arequipa and Cajamarca with local milk supply, corresponding growth in milk demand is likely to increase milk prices in those milksheds. The effect is enhanced by the fact that imported milk powder is more expensive than regionally collected milk, thanks to Peru current import taxation scheme. In Lima, a drop in milk price will consolidate the prevalence of better managed, more efficient larger dairy farms, because small and medium farms lack economies of size and tend to become unprofitable. In Arequipa, despite the expected increase in milk prices, dairy production is expected to decline, as farmers will tend to shift stronger towards agricultural crops when the price risk decreases in crop production. In contrast, in Cajamarca, the expected increase in milk prices will provide an important incentive for farmers to identify dairy production with improved feed and herd management. Potential government interventions could also reinforce and accelerate the expected upturn of dairy production in highland areas.

Key Words: Milk Production, Peru, Dairy Development

1311 Macedonian Dairy Industry situation and outlook. Aleksandra Depinovska*¹ and Mingruo Guo², ¹*Land O'Lakes-Macedonia, Kej 13 Noemvri bb,1000 Skopje, Macedonia,* ²*University of Vermont, Burlington VT 05405.*

Macedonia is a small country situated in the heart of the Balkan Peninsula, approximately the same size as Vermont. The dairy industry of Macedonia has undergone a difficult process of transition since 1991. Dairy herds in Macedonia consist mainly of cows and sheep. The dairy cow population increased from 90,000 in 1991 to a peak of 93,000 in 1996 and decreased back to about 90,000 in 2000. The raw milk supply is primarily collected from thousands small farms with an average of 5-10 cows each. The average milk production per cow is still very low compared with the US standard. However, milk productivity has been improved through genetic breeding since 1991. The average annual yield was increased from 1,357 liters per cow in 1991 to 1,700 liters in 2000. Total cow's milk production was increased from 119,194 tons in 1991 to 148,445 tons in 2000. Sheep milk is the second important source of dairy production for the country. The share of sheep milk was about 25% of the total milk production in 2000. In contrast, the population of sheep has been decreasing since 1991 from nearly 1.5 million to about 1 million in 2000 due to the embargo on the export of Macedonian lamb imposed by the EU. Presently there are 49 registered dairy processing plants in Macedonia. The majority of them are small operations ranging from 5 to 10 tons of processing capacity, with except of the Bitola Dairy Plant which can process up to 200 tons of milk per day. Per capita milk consumption is more than 120 kg per year. The major domestic dairy products in Macedonia are cheese and fluid milk products including yogurt. Domestic products are only enough for 75% of the Macedonian market needs and the rest are imported from Europe, especially dry milks, butter, and nearly all the functional additives, including stabilizers, flavoring agents, starter cultures, and other nutritional additives. The dairy industry has a potential to grow. Challenges faced by Macedonian dairy industry include procuring high quality of raw milk from the small family farms, developing new and high quality dairy products, improving production efficiency, and developing a well-trained work force.

Key Words: Macedonia, Dairy Industry, Milk Products

1312 The suitability of the Beefmaster as a dam breed in hot and arid regions of Israel. J.E. Huston¹, Z. Holzer², P.V. Thompson*¹, Y. Aharoni², and B.S. Engdahl¹, ¹*Texas A&M University System, San Angelo, TX,* ²*Israeli Ministry of Agriculture, Haifa, Israel.*

A study supported jointly by the Texas Department of Agriculture and the Israeli Ministry of Agriculture was conducted to evaluate the adaptability of Texas Beefmaster cows to the environmental conditions of southern Israel. Beefmaster embryos were transferred from Texas donor cows into Israeli recipients, and the resulting offspring were raised under local conditions to 2 and 3 yr of age. These cows were compared to similar aged Simford cows (products of crossing European breeds, Simmental and Hereford) on a cooperating site in southern Israel over a 3-wk period during August 2000. Each animal was monitored for time spent lying, standing, walking and grazing over 24-h periods. Heart rates and body temperatures were monitored for 24-h cycles using data loggers, and energy expenditures were estimated by measuring oxygen consumption. Voluntary intake of forage was calculated for each cow from fecal output estimated using intraruminal chromic oxide boluses. Behavioral activities showed greater similarities than differences. Each group was active during the early morning hours, rested during the afternoon, and then resumed grazing during the early evening. Heart rates and skin temperatures for the Beefmaster cows were lower during the early morning hours, indicating a greater capacity to dissipate body heat during nighttime hours. The energy expenditure (kilo joules / (W^{0.75}*d)) varied greatly among individual cows. Fecal output and forage intake did not differ between breed groups. The Beefmaster cows produced from embryos transferred from Texas cattle appeared at least equally well adapted to Israeli conditions as cattle currently produced in the area. Subsequent studies measuring productivity (reproductive rate, growth rate and efficiency, and carcass value) are needed to determine whether the Beefmaster breed can improve productive and economic efficiencies of cattle herds in this region.

Key Words: Beef cattle, Adaptability, Israel

1313 Effect of seasons on milk production and calving pattern in nili ravi buffaloes . Syed Hassa Raza*¹, Arshad Iqbal¹, M.S. Khan¹, Shahid Mahboob², and M. Abdullah¹, ¹*Faculty of Aniaml Husbandry, University of Agriculture, Faisalabad, Pakistan,* ²*Dept. Zoology, Govt. College, Faisalabad, Pakistan.*

Although buffaloes are not seasonal breeder but they do show seasonality in breeding and calving which ultimately results in shortage of milk in summer, when its demand is at peak. To investigate the effect of different seasons on traits of economic importance in dairy buffaloes, this study is conducted. The data on five years (1983-1987) regarding calving, milk production and breeding in Nili Ravi buffaloes, maintained at the Livestock Experiment Station, University of Agriculture, Faisalabad were collected and statistically analyzed. It was inferred that seasons have significant (P<0.01) effect on calving pattern, milk production and occurrence of heat in dairy buffaloes. Maximum calving took place in autumn (45.29 %) and minimum in winter and spring (5.66 %) in each case. The highest values for milk production were observed in autumn (25,528 lit.) and lowest in summer (14,507 lit.). Out of the total, about 48% buffaloes exhibited heat in winter and only 2.39% in summer. These revealed that severe summer season adversely impair the reproductive efficiency of the lactating females. Through adoption of certain management practices, this effect of heat stress can be minimized to alleviate the situation for the improvement in milk supply.

Key Words: Buffalo, Milk, Environment

1314 Effect of high-levels of brewery supplementation on blood metabolites of Holstein cows from a semi-intensive dairy in north-central Mexico. E Guzman, RM Rincon, DF Cortes, R Baulos-Valenzuela*, and CF Archiga, ¹*Universidad Autonoma de Zacatecas. Zacatecas, Mexico..*

The purpose of this study was to determine blood- metabolite differences in response to a high-level of brewery supplementation, which has become a routine practice in typical semi-intensive dairies from north-central Mexico (Fresnillo, Zacatecas) with low level of technology and grain scarcity. Twenty-one lactating dairy cows were exposed to 3 different levels of brewery supplementation: 25, 50 and 75% of the

diet. Besides brewery, cows received corn silage, concentrate, and access to a rye-grass pasture during 4 h/d. Brewery supplementation at the 75% level increased blood pH ($P < 0.01$), reduced glucose ($P < 0.001$), and tended to increase protein ($P = 0.10$). Besides, there was a general correlation within glucose and protein, glucose and glutamic-oxaloacetic transaminase (GOT), pH and GOT, protein and GOT. In conclusion, high levels of brewery supplementation increase blood pH, tended to increase protein and reduce glucose in dairy cows.

Key Words: Dairy Cow, Blood Metabolites, Mexico

1315 Timed-embryo transfer (Gyr/Holstein) in recipient cows exposed to a synchronized ovulation. BA Barrios, LA Guillen, JC Acua, and CF Arechiga*, ¹Universidad Autonoma de Zacatecas, Zacatecas, Mexico.

The purpose of the present work was to evaluate heat induction and pregnancy rates in response to a frozen/thaw embryo transfer (Gyr/Holstein embryos) in the uterine horn ipsilateral to the corpus luteum of recipient cows exposed to a synchronized ovulation. Experiment was done from April to August. Twenty-six cows from different locations and genetic background were exposed to a synchronized-ovulation protocol (d 0, GnRH; d 7, PGF2a; d 9, GnRH; d 10, checking estrus instead of timed AI; d 17, embryo thawing and deposition). Cows were rectally palpated at each farm on d 10 of treatment and signs of estrus were observed. However, cows were not inseminated but rather and embryo was deposited in the uterine horn ipsilateral to the corpus luteum palpated at d 17. During embryo transfer cows were rectally examined, feces were removed, and perianal region was washed. Then the embryo was deposited using a Cassou AI gun passing through the cervix of the uterus and leading it into the uterine horn ipsilateral to the ovary that contains a corpus luteum. Sixty days after embryo transfer, cows were diagnosed for pregnancy and 19.2% of the recipient cows were pregnant (i.e., 5/26). One of the cows received two embryos and the cow delivered both calves alive. In conclusion, the synchronized-ovulation protocol could be utilized for synchronization of cows included in embryo transfer programs. However, in this preliminary study, pregnancy rates were low probably due to the heterogeneity of the cows included in the trial.

Key Words: Synchronized Ovulation, Embryo Transfer, Mexico

1316 Meat quality characteristics of loin eye and tenderloin muscles of native Korean (Hanwoo) steers. Y.K. Lee¹, K.H. Kim*¹, Y.S. Kim², S.S. Sun¹, and M.G. Baik¹, ¹Chonnam National University, Kwangju, Korea, ²University of Hawaii at Manoa, Honolulu.

The objective of this study was to investigate postmortem glycolysis, histochemical, and meat quality characteristics of longissimus dorsi (LD) and psoas major (PM) muscles of Hanwoo (native Korean) steers. Four steers weighing about 550 kg were slaughtered, then 20 g of LD at the 13th rib and PM at the 4th lumbar vertebra were collected at 1, 2, 6, 12, and 24 hr postmortem to measure changes in metabolite concentrations and pH. At 24 hr later, 1 cm³ of LD and PM samples were cut for histochemical analysis. At 1, 3, 7, 14, and 21 day postmortem, LD samples between 6th and 12th rib and PM were collected for TBA value and shear force measurements. Three 1.8 cm diameter cores were prepared for shear force measurement from 2.54 cm thick steaks that were

vacuum packaged and cooked in a water bath at 70°C. ATP and pH in PM declined faster ($p < 0.05$) than those in LD during the 24 hr post-mortem period, and remained lower at 24 hr after slaughter (0.47 vs 0.62 μ moles/g muscle, 5.92 vs 5.64). Glucose-6 phosphate in PM increased faster ($p < 0.05$) than in LD muscles, and remained higher (11.5 vs 5.5 μ moles/g muscle). LD had a lower ($p < 0.05$) proportion of type I fiber than PM (51.1% vs 58.3), but higher ($p < 0.05$) proportion of type IIB fiber than PM (18.9% vs 9.0%). The shear force to cut cooked PM was lower than that for LD in 1 and 7 day aged samples, but no difference was observed between the two muscles in 21 day aged samples. The TBA value increased gradually during the 21 day aging period in both muscles. The increase in TBA value was similar in both muscles up to 14 days, but at 21 day the TBA value of PM was significantly higher than that of LD. In summary, this study demonstrated that the rate of postmortem glycolysis is faster in the PM than in the LD. The study also indicated that PM muscle needs less aging time than LD muscle for optimum meat quality.

Key Words: Native Korean steer, Meat Quality, Postmortem metabolism

1317 Characterization of forage trees as strategic feed sources for goats under semiarid rangeland conditions of Tamaulipas, Mexico. R. Hernandez¹, A. Tewelde¹, S. S. Gonzalez*², E. Gutierrez³, H. Diaz⁴, and F. Briones¹, ¹U. Autonoma de Tamaulipas, ²Colegio de Posgraduados, ³U. Autonoma de Nuevo Leon, ⁴U. Autonoma Agraria Anotonio Narro.

Ten locally available forage trees under semiarid rangeland in the State of Tamaulipas were identified and characterized as main feed sources for goat based production systems that predominate in the area (22 C average temperatures; 500 mm average rainfall in August- December). The forage trees included Guajillo (Acacia berlandieri), Gabia (A. rigidula), Huizache (A. romeriana), Granjeno (Celtis spinosa), Pata de gallo (Chloris virgata), Cruceto (Condalia lycioides), Nacahua (Cordia boissieri), Vara dulce (Eysenhardtia polystachya), Escoba (Fraxinus greggii), and Charrasquillo (Pithecellobium elasticophyllum). Density was estimated by the Point Quarter Center method (Bruce, 1986) using the formula of Arvanitis and Portier (1997): $D = 1/x^2$, where D is plant density by m², and x is the average distance between each sampling. Results showed densities (%) of: A. berlandieri 29.99, C. virgata 29.91, C. boissieri 13.29, A. romeriana 7.47, A. rigidula 5.48, C. spinosa 4.06, F. greggii 3.32, E. polystachya 2.65, C. lycioides 2.25, P. elasticophyllum 1.53. Production (kg/ha) of biomass, wood and forage was higher for A. berlandieri (3871, 2879, 993, respectively) and lower for P. elasticophyllum (44, 39, 5, respectively). Proximal analysis and in vitro DM digestibility (IVDMD) values (%) ranged from 82 to 94, 11 to 21, 26 to 58, 16 to 38, 5 to 17, 11 to 46 for DM, CP, NDF, ADF, ashes and IVDMD, respectively. The CP (21%) and IVDMD (46%) values were higher for C. spinosa. Intake of plant parts by goats, measured by direct field observation showed: foliage in A. romeriana, C. virgata, A. berlandieri, A. rigidula, C. lycioides, E. polystachya, P. elasticophyllum; leaves in C. spinosa, F. greggii; fruits in C. boissieri, C. virgata; pods in A. berlandieri; stems in F. greggii. Six of the forage trees (A. romeriana, C. boissieri, C. spinosa, A. rigidula, A. berlandieri, C. lycioides) are used as fuel wood by local farmers.

Key Words: Forage Trees, Goats, Semiarid Rangelands

ASAS Nonruminant Nutrition: Specialty Grains and Amino Acids

1318 Soybean meal from Roundup Ready® or conventional soybeans in diets for growing-finishing pigs. G. L. Cromwell*¹, M. D. Lindemann¹, J. H. Randolph¹, E. P. Stanisiewski², and G. F. Hartnell², ¹University of Kentucky, Lexington, ²Monsanto Co., St. Louis, MO.

Dehulled soybean meal (SBM) prepared from genetically-modified, herbicide-tolerant soybeans containing the CP4 EPSPS protein (Roundup Ready® [RR]) and near-isogenic conventional (C) soybeans were assessed in an experiment with growing-finishing pigs. The soybeans were grown in yr 2000 under similar agronomic conditions, the RR soybeans were sprayed with Roundup®, and both were processed at the same plant. The C-SBM and RR-SBM were indistinguishable in composition (DM: 90.3, 91.0%; CP: 51.5, 51.2%; NDF: 4.95, 4.85%; ADF:

3.50, 3.94%; lysine: 3.16, 3.09%; meth+cys: 1.47, 1.51%). Crossbred pigs (n=100) were fed fortified corn-soy diets containing C- or RR-SBM from 24 to 111 kg BW. Diets contained 0.95% lysine initially, then lysine was reduced to 0.80 and 0.65% when pigs reached 54 and 87 kg BW. There were 10 pens (5 pens each of barrows and gilts)/treatment with 5 pigs/pen. All pigs were scanned at 104 kg mean BW, and all barrows were killed at the end of the test for carcass measurements and tissue collection. ADG (833 vs 854 g), ADFI (2.53 vs 2.64 kg), feed:gain (3.04 vs 3.09), scanned backfat (BF, 18.8 vs 19.1 mm) and longissimus area (LEA, 34.9 vs 33.8 cm²), and calculated carcass lean (52.9 vs 52.5%) were not different ($P > 0.05$) for pigs fed C- and RR-SBM. Gilts gained slower, but they were more efficient and leaner ($P < 0.05$) than barrows. Responses to type of SBM were similar for the two genders. Carcasses

were not different ($P > 0.05$) for barrows fed C- and RR-SBM (71.8 vs 71.2% dress, 26.8 vs 27.4 mm 10th rib BF, 37.8 vs 35.5 cm² LEA, 48.1 vs 47.3% fat-free lean). Longissimus samples from barrows fed C-SBM tended to have less fat than those fed RR-SBM (3.0 vs 3.4%; $P < 0.06$), but water, protein, and ash were similar (72.8 vs 72.5%; 23.4 vs 23.3%; 1.05 vs 1.05%). The CP4 EPSPS protein was not detected in loin tissues of any of the pigs fed RR-SBM. The results indicate that RR-SBM is essentially equivalent in composition and nutritional value to C-SBM for growing-finishing pigs.

Key Words: Pigs, Soybeans, Biotechnology

1319 Comparison of apparent ileal amino acid digestibility values of high oil (HOC), high oil/high oleic acid (HOHOC), and low phytate (LP) corn diets fed to finishing pigs. J. W. Frank*¹, G. L. Allee¹, and T. E. Sauber², ¹University of Missouri, Columbia, MO, ²Dupont Specialty Grains, Johnston, IA.

Two experiments were conducted to evaluate the apparent ileal amino acid digestibility values of multiple corn varieties. In both experiments pigs were surgically fitted with T-cannulas and allowed a minimum of 2 weeks to recover. All animals were fed twice daily (0600 and 1800 hr) at a rate of .09 × BW^{0.75} for a five day adjustment period, followed by two days of twelve-hourly collections. Pigs were allowed ad-libitum access to a nipple waterer. Samples were immediately frozen (-20 °C) as collected. At the end of both studies pooled samples from the two day collection were sub-sampled, freeze dried, ground, and analyzed for amino acid content along with the corn based diet. In experiment 1, six crossbred barrows (initial BW = 101.8 kg) were arranged as two 3 × 3 Latin squares and housed in 2.43 × 1.83 m pens at a temperature of approximately 23 °C. The three dietary treatments consisted of HOC, HOHOC, and a typical corn equivalent (TC). Tryptophan digestibility was greater in HOHOC (64.2%) compared to TC (54.2%), but not different than HOC (61.6%; $P < .10$). In contrast proline digestibility was greater in TC (74.3%) and HOC (71.9%) compared to HOHOC (64.7%; $P < .05$). There were no other differences in apparent amino acid digestibility. In experiment 2, five crossbred barrows (initial BW = 89.3 kg) were used in a crossover design and housed in stainless steel metabolism crates. The two dietary treatments were LP corn and a typical corn equivalent (TYP). Phosphorus digestibility was greatest in the LP corn compared to the TYP corn ($P < .01$). Tryptophan digestibility was also greater in LP corn compared to TYP corn (62.0 vs. 50.9%; $P < .05$). As in experiment 1, there were no other differences in amino acid digestibility. In conclusion most amino acid digestibility values were not different in the high oil, high oil/high oleic acid, and low phytate corn varieties compared to their typical corn equivalents.

Key Words: Pigs, Corn, Amino acid digestibility

1320 Effects of low-phytic acid corn on growth performance, bone strength, and serum osteocalcin concentration in growing-finishing pigs. M. W. Klunzinger*, K. D. Roberson, G. M. Hill, D. W. Rozeboom, and J. E. Link, Michigan State University.

A 91-d experiment was conducted to evaluate whether low-phytic acid corn (NDLP, Exseed Genetics) (90% phosphorus (P) availability) could replace dent corn (DC) without adversely affecting growth performance or bone parameters in growing-finishing pigs. Total P and phytate P were 0.24 and 0.16% in DC; 0.32 and 0.03% in NDLP, by analysis. Pigs were blocked by initial BW (18.5 to 22.5 kg) into four pens per treatment (trt) of eight crossbred pigs per pen. Two trts were fed; trt 1 contained DC and trt 2 contained NDLP. Three phases were fed; each was four wks in length. Dietary calcium and non-phytate P were computed to provide 0.75 and 0.36, 0.63 and 0.30, or 0.55 and 0.28% in phases I, II, and III, respectively. Total P was computed to provide 0.57, 0.50, or 0.47% for trt 1; and 0.47, 0.40, or 0.36% for trt 2, in phases I, II, and III, respectively. Dicalcium phosphate concentration was decreased by 0.73, 0.78, and 0.85% units in trt 2, for phases I, II, and III, respectively. One gilt per pen was chosen, based on average pen BW (92 to 106 kg), for slaughter at 91d. All third and fourth metacarpals (MC) and metatarsals (MT) were used to analyze bone-breaking strength. Blood was collected from two pigs per pen at 90d for serum osteocalcin (OC) analysis (an indicator of bone turnover). Gain/feed (trt 1 = 316, trt 2 = 350, $P > 0.09$), BW (trt 1 = 97.3 kg, trt 2 = 98.7 kg, $P > 0.71$), and ADG (trt 1 = 840 g/d, trt 2 = 860 g, $P > 0.57$) were not affected. There were no differences in bone strength of third and fourth MC and

fourth MT bones ($P > 0.28$). Overall, MC and MT bone strength was higher (15.04 vs. 12.83 MPa, $P < 0.01$) for gilts fed trt 1 vs. trt 2. This was due to a difference ($P < 0.01$) in third MT bone strength. Serum OC was not affected (trt 1 = 297 ng/mL, trt 2 = 276 ng/mL, $P > 0.92$), suggesting no difference in bone turnover. This study proposes that NDLP corn can be formulated with 90% P availability and replace dent corn without adversely affecting pig performance.

Key Words: Low-phytate corn, Bone strength, Pig

1321 Comparison of broiler performance when fed diets containing YieldGard® corn, YieldGard® and Roundup Ready® corn, parental lines, or commercial corn. M.L. Taylor*¹, G.F. Hartnell¹, M.A. Nemeth¹, B. George², and J.D. Astwood¹, ¹Monsanto Company, ²Colorado Quality Research.

Broiler chickens (Cobb x Cobb) were used to compare the broiler performance and processing parameters of YieldGard® corn (YG) and YieldGard® and Roundup Ready® corn (YG X RR) (both containing the Cry1A(b) protein and the latter also containing the maize EPSPS protein) with their parental lines and four commercial lines of corn. From days 1-20, broilers were fed a starter diet with approximately 50% w/w corn, and from days 20-42, broilers were fed a grower/finisher diet with approximately 60% w/w corn. Feed and water was provided ad libitum. Birds were housed in concrete floor pens and the environment controlled for light and temperature. Eight treatments (5 male and 5 female pens/treatment with 10 birds/pen) were assigned using a randomized complete block design. The standard randomized block analysis of variance (ANOVA) statistical model was used to analyze the data. Means were compared to each other at the 5% level of significance. An additional analysis compared the fit of YG corn and YG x RR corn with the population of responses from the commercial varieties using a linear mixed model procedure in SAS ($P < 0.05$). Performance parameters (live weight, feed intake on a per bird basis, feed efficiency, and adjusted feed efficiency) were similar ($P > 0.05$) among broilers fed the eight treatment diets. On a weight basis or percentage basis, carcass measurements of live/chill weight, thighs, drums (weight basis only), wings, and fat pad weights were similar across treatments ($P > 0.05$). Drum measurements as a percent of chill weight and breast meat weight were similar for YG corn and YG x RR corn and their parental lines and multiple commercial lines. No differences were observed in the percentage of moisture, protein, and fat in breast meat or thigh meat across treatments. Results support there were no biologically relevant differences in performance parameters, carcass yield, and meat composition between broilers fed the YG corn or YG x RR corn and their parental lines or commercial lines. In conclusion, YieldGard® corn and YieldGard® and Roundup Ready® corn were nutritionally equivalent to their corresponding parental lines and four commercial lines when fed to broilers.

Key Words: Corn, Broilers, Performance

1322 Comparison of swine performance when fed diets containing Roundup Ready® corn (GA21), parental line or conventional corn. E. P. Stanisiewski*¹, G. F. Hartnell¹, and D. R. Cook², ¹Monsanto Company, St. Louis, MO, ²Akey, Inc., Lewisburg, OH.

One hundred sixty pigs (80 barrows and 80 gilts) were used in a growth trial (72 to 117 kg body weight) to determine the effect of corn variety; Asgrow RX826, feed mill purchased corn (CPFM), Parental line DK626 and Roundup Ready® line DK626RR, on growth performance and carcass characteristics. Line DK626RR is a glyphosate-tolerant variety containing event GA21 (mEPSPS protein). Pigs were given ad libitum access to corn-soybean meal based diets and water throughout the trial. Each diet utilized one of the four corn varieties and all diets contained the same percentage of corn. Dietary amino acid levels were standardized across diets with crystalline amino acids. Barrows and gilts were penned (4 pigs per pen) separately in 1.5 × 2.4 m pens on concrete slats in a mechanically ventilated building. Pig and feeder weights were recorded weekly. Pigs were slaughtered at approximately 117 kg body weight and carcass data were collected. Over the duration of the trial, no significant ($P > .05$) gender by dietary treatment interactions were observed for any criteria measured. No significant differences ($P > .05$) were observed in response to corn variety for average daily body weight gain (ADG), average daily feed intake (ADFI) or feed efficiency (FE). As expected, barrows had greater ($P < .05$) ADG (880 vs 821 g/d) and

ADFI (2.81 vs 2.49 kg/d), and poorer ($P < .05$) FG (3.19 vs 3.03) compared with gilts. There were no overall treatment effects on chemical composition of muscle. Based on these data, DK626RR corn has a feeding value for pigs similar to its parental variety as well as commercially available varieties.

Key Words: Pigs, Corn

1323 Comparison of broiler performance when fed diets containing Roundup Ready® corn event NK603, parental line, or commercial corn. M.L. Taylor*¹, G.F. Hartnell¹, M.A. Nemeth¹, B. George², and J.D. Astwood¹, ¹Monsanto Company, ²Colorado Quality Research.

Broilers (Ross x Ross) were used to compare performance and processing parameters using the Roundup Ready® corn event NK603 containing the CP4 EPSPS protein with its parental line and five commercial lines of corn. From days 1-20, broilers were fed a starter diet with approximately 55% w/w corn; from days 20-42, broilers were fed a grower/finisher diet with approximately 60% w/w corn. Feed and water were provided ad libitum. Birds were in concrete floor pens and the environment controlled for light and temperature. Eight treatments (5 male and 5 female pens/treatment and 10 birds/pen) were assigned using a randomized complete block design. The standard randomized block analysis of variance (ANOVA) statistical model was used to analyze the data. Means were compared at the 5% level of significance. An additional analysis compared the fit of NK603 with the population of responses from the commercial varieties using a linear mixed model procedure in SAS. Performance parameters (live weight, feed intake, and feed efficiency) were similar ($P > 0.05$) among the broilers fed diets of the eight treatments. Carcass measurements of live/chill weight, breast meat (expressed as percent of chill weight), thighs, drums, and wings were similar across treatments ($P > 0.05$). Fat pad weights of broilers fed diets containing NK603 were not different from those fed diets containing one commercial line (1.5% vs 1.6% of live weight, respectively, $P > 0.05$) and were less than the parental line and four commercial lines (all 1.7% of live weight, $P < 0.05$). No differences were observed in percentages of moisture, protein, and fat in breast meat or protein and fat in thigh meat across treatments. Moisture content of thigh meat was similar between the NK603, parental, and three commercial lines and approximately 1% higher than NK603 in two commercial lines. The results of this study show that there were no biologically relevant differences in performance parameters, carcass yield, and meat composition between broilers fed the NK603 event, the parental, or commercial lines, and all data generated are similar to historical values for Ross x Ross strains. In conclusion, the Roundup Ready® corn line containing the NK603 event was nutritionally equivalent to its corresponding parental line and commercial lines when fed to broilers.

Key Words: corn, broilers, performance

1324 Growth performance of broilers fed insect-protected (MON 810) or near isogenic control corn. G. Piva*¹, M. Morlacchini², A. Pietri¹, F. Rossi¹, and A. Prandini¹, ¹Istituto di Scienze degli Alimenti e della Nutrizione, U.C.S.C., Facoltà di Agraria, Piacenza, Italy., ²CERZOO, Piacenza, Italy.

The aim of the present work was to compare the nutritive value for broilers of insect-protected (Bt) corn containing the Cry1A(b) protein (MON 810) with near isogenic control corn (IC), each grown on three Italian farms located in Lodi, Cremona and Venezia provinces. The study utilized 432 Ross male broilers (72 birds in four pens for each of the six treatments). Nutritional analytes were not different ($P < 0.05$) between IC and Bt corn. Diets were formulated to meet Ross broiler requirements and contained about 50% corn. Birds were fed diets for 42 days (first 21 days, grower phase; second 21 days, finishing phase). Feed intake, average daily gain (ADG) and feed:gain of birds fed Bt or IC corn did not differ ($P < 0.05$) regardless of the source of the Bt and IC corn. Final live weight of birds was significantly ($P < 0.05$) greater for the birds fed diets containing Bt corn as compared to IC corn from Lodi (2796 g vs 2707 g; $P < 0.05$; +3.3%) and Venezia (2619 g vs 2506 g; $P < 0.01$; +4.5%). When all performance variables from the birds fed the Bt treatments were averaged and compared with the mean of IC fed birds, ADG (63.4 vs 61.8 g/d), feed intake (125.7 vs 125.0 g/d) and feed:gain (1.98 vs 2.02) were similar ($P < 0.05$) and final live weight was 2.7% greater (2693 vs 2621 g; $P < 0.01$) for the Bt group. The difference could be due to Bt corn having a 72% lower level of fumonisin B₁

than IC corn. Aflatoxin and deoxynivalenol (DON) levels were low in all treatments. We conclude that performance of broilers fed Bt corn is at least as good as those fed IC corn.

Key Words: Broiler, Transgenic corn, Fumonisin B₁

1325 Evaluation of *Streptomyces lividans* and *Pichia pastoris* as extra-cellular expression systems for *Escherichia coli* phytase. C.H. Stahl* and X.G. Lei, Cornell University, Ithaca, NY.

Our previous research has shown that enzymatic properties and yield of individual phytases are greatly affected by the expression host utilized. The objective of this study was to determine the efficiencies of a bacterial (*S. lividans*) and a yeast (*P. pastoris*) system in expressing an *E. coli* phytase gene (*appA*), and to compare the thermo-tolerances, pH profiles, and optimal temperatures of the recombinant phytases. The *appA* was inserted into *S. lividans* TK24, after being cloned into a vector under control of the pLT1 promoter with the Spe2 signal peptide of endoglucanase E2 from *Thermomonospora fusca*. For expression in *P. pastoris*, *appA* was inserted into the vector pPICZaA (Invitrogen, San Diego, CA) under control of the AOX1 promoter, and transformed into *P. pastoris* X33. An active phytase was expressed and secreted into the media by both hosts. The protein expressed in *S. lividans* (SLEP) was not glycosylated and was the same size (approximately 45 KDa) as the de-glycosylated phytase expressed in *P. pastoris* (PPEP) that had multiple levels of glycosylation. Both enzymes had an optimal temperature of 65°C, but the relative activity of PPEP was 32 and 25% higher ($P \leq .05$), respectively, at 45 and 55°C, and 52% lower ($P \leq .05$) at 75°C than that of the SLEP. The pH optimum of SLEP was 4, and was between 3.5 - 4 for PPEP. At pH 2 - 3.5, PPEP had approximately 50% more ($P \leq .01$) relative activity than SLEP. The thermo-tolerance of SLEP was higher ($P \leq .05$) at 45 and 55°C, but lower ($P \leq .05$) at 65 and 75°C than that of PPEP. In conclusion, *S. lividans* can be used to produce an active extra-cellular phytase that may have different biochemical traits than the phytase produced by *P. pastoris*.

Key Words: Heterologous protein expression, Gene, *Streptomyces lividans*

1326 Apparent and true ileal digestibility of amino acids in soybean meals as affected by heat treatments and trypsin inhibitors. S. W. Kim*¹, Z. H. Zhang², L. A. Johnson³, and R. A. Easter², ¹Texas Tech University, ²University of Illinois, ³Iowa State University.

Heat treatment in producing soybean meal is an important factor affecting nutritional value of the material. Underheating can cause failure to eliminate trypsin inhibitors whereas overheating can reduce digestibility and availability of amino acids. This project was undertaken to investigate how different levels of heat treatment affect amino acid digestibility in growing pigs as it relate to the disappearance of trypsin inhibitors. Four soybean meals were processed under different cooking conditions. These treated soybean meals were compared with a control soybean meal and soy protein concentrate obtained from the Ohio State University. A casein based diet was used to measure endogenous protein losses based on the assumption that casein is fully digestible. The experiment were conducted as two replicates of 7 x 7 Latin Square. Fourteen surgically-cannulated pigs were used to determine ileal digestibility of amino acids in soybean meals. Both undercooking and overcooking of soybean meals decreased ($P < 0.05$) true and apparent ileal digestibility of amino acids. However adverse effect on ileal digestibility of amino acids was greater ($P < 0.05$) when soybean meals were undercooked than overcooked. Undercooked soybean meals contained significantly greater amount of trypsin inhibitors (38,300 and 32,800 TIU/g) than the control soybean meal (4,600 TIU/g) even though KOH solubilities of those soybean meals (78 and 69%) were close to that of control soybean meal (74%). The moderately overcooked soybean meal containing 15,700 TIU/g but a low KOH solubility (59%) had a lower ($P < 0.05$) true and apparent ileal digestibility of amino acids than control soybean meal but higher ($P < 0.05$) than undercooked soybean meals. Severely overcooked soybean meal had a low KOH solubility (40%) but the content of trypsin inhibitor (6,700 TIU/g) was close to that of control soybean meal. True and apparent ileal digestibility of amino acids were

lower ($P < 0.05$) than in control soybean meal but higher ($P < 0.05$) than in undercooked soybean meal.

1327 Effect of increased levels of crystalline nonessential amino acids on growth performance and nitrogen retention of broiler chicks fed low-CP diets. K. Bregendahl* and D.R. Zimmerman, *Iowa State University, Ames.*

In spite of meeting the requirements for essential AA, low-CP diets may not supply sufficient nonessential AA (NEAA) to sustain maximal growth performance of pigs and broiler chicks. Therefore, an experiment was conducted to investigate whether increased dietary levels of crystalline NEAA improve growth performance and N retention of broiler chicks fed low-CP diets. A total of 306 day-old broiler chicks was fed a common corn-soybean meal (SBM) diet (23% CP) for 1 wk, after which the chicks were allotted to one of five diets (D) in a completely randomized design (10 chicks per pen, 6 replications; 123 g initial BW). Chicks had free access to the isoenergetic diets (3.20 Mcal ME_n/kg), which were formulated to meet or exceed all NRC (1994) requirements. The diets consisted of a control diet (D1; 23.4% CP), D2 (18.3% CP), D3 (18.7% CP), D4 (19.4% CP), and D5 (20.3% CP). The CP content of D2 was reduced by altering the corn:SBM ratio in D1 and adding crystalline AA (Arg, Ile, Lys, Met, Thr, and Val) to 105% of NRC (1994) AA levels. Diets D3, D4, and D5 were formulated by replacing cornstarch in D2 with a 1:1 mix of Glu and Asp at 1, 2, and 3%, respectively. After 2 wk on test, chicks were weighed, fasted for 24 h, and two chicks per pen were euthanized. The whole-body N contents of the chicks fed D1 through D5 as well as six baseline chicks were determined. Treatment means were compared using orthogonal contrasts. Feed utilization (G:F; 0.753, 0.711, 0.716, 0.712, 0.723 for D1, D2, D3, D4, and D5, respectively) and N retention (1.19, 1.08, 1.10, 1.10, 1.11 g/d) of chicks fed D1 were superior ($P < 0.001$) to that of chicks fed D2 through D5, while ADG (43.9, 42.6, 42.5, 42.5, 42.6 g/d) and ADFI (58.3, 59.9, 59.4, 59.7, 59.0 g/d) did not differ ($P > 0.05$). No linear or quadratic effects ($P > 0.05$) of increasing the NEAA levels on ADG, ADFI, G:F, or N retention were observed. Based on these results, the inferior growth performance of chicks fed low-CP diets is not caused by a deficiency of NEAA.

Key Words: Low Crude Protein, Growth Performance, Nonessential Amino Acids

1328 Lysine to Protein ratios in growing-finishing pigs. E. O. Castaneda-Silva*¹ and J. A. Cuaron², ¹*Nutrimentos Concentra, S.A. de C.V.*, ²*C. N. I. Fisiología y Mejoramiento Animal, INIFAP, Queretaro, Mexico.*

Using sorghum-soy based diets, 3.23 Mcal ME/kg, two experiments were conducted to find the best total Lys concentration in dietary crude protein (CP), provided that other limiting amino acids (Thr, Trp, Met) were maintained in a constant (ideal) ratio to Lys, on a true ileal digestible basis. A nitrogen (N) balance experiment was conducted using 4 CP levels: 12, 15, 18 and 21% of the diet. In all cases, Lys was constant at 6% of CP. Twenty-four barrows, of an initial wt. of 47±2.8 kg were used. After a preliminary feeding period of 21-d, a 6-d total excretion collection phase was followed. Nitrogen retention was linearly increased ($P < .01$) by dietary CP: 18.58, 21.29, 21.21 and 24.73 g/d. In response to the increase in CP, efficiency of N retention was linearly decreased ($P < .01$): 43.20, 39.43, 34.12 and 34.10% of N intake. Giving equal importance to retention and efficiency of N retention, the best CP level was estimated at 14.7% of the diet. In Exp. 2, three Lys:CP ratios (5.0, 5.8 and 6.6%) were tested at 2 CP levels: 14.7 and 16.7% for growing (25-65 kg BW), and 13.5 and 15.5% for finishing pigs (66-107 kg BW). The CP level and the Lys:CP ratios interacted ($P < .05$) in voluntary feed intake, daily wt. gain and lean eye area. At lower CP, a positive linear response ($P < .01$) was observed after the increasing levels of Lys but, at higher CP, a quadratic effect ($P < .01$) was evident above the 5.8% ratio. Feed intake was: at lower-CP, 2.4, 2.3 and 2.5; at higher-CP, 2.4, 2.4 and 2.2 kg/d, in both cases for the 5.0, 5.8 and 6.6% Lys:CP ratios. In the same order, results for BW gain were: lower-CP, 0.72, 0.73 and 0.78; higher-CP, 0.74, 0.76 and 0.69 kg/d. Similarly, lean eye area was: lower-CP, 28, 32 and 30; higher-CP, 34, 30 and 33 cm². Following a broken line analysis, the best Lys:CP ratio was calculated as 5.8 Lys as % of CP.

Key Words: Lysine, Crude protein, Growing pigs

1329 Effect of synchronizing dietary protein and glucose supply on nitrogen retention of growing pigs. W.J.J. Gerrits*, K.P.C.M. Frijters, J.M. Linden, M.J.W. Heetkamp, T. Zandstra, and J.W. Schrama, *Wageningen Institute of Animal Sciences, Wageningen, The Netherlands.*

An experiment was conducted to test and quantify the effect of synchronizing the dietary supply of protein and glucose to pigs. Six barrows (40 kg) were subjected to one of two dietary treatments (synchronous or asynchronous supply of protein and glucose) in a change-over design. The synchronous treatment consisted of two complete meals: one at 0800 and one at 1600. At the asynchronous treatment, protein and starch were supplied in separate meals: the pigs consumed 95% of the daily protein supply with the 0800 meal and 99% of the starch supply with the 1600 meal. Daily intake of all nutrients and dietary ingredients was identical between the treatments. The gross energy intakes at 0800 and those at 1600 were equal for both treatments. Pigs were housed individually in climate controlled open circuit respiration chambers and fed at 2.1 x the energy requirements for maintenance. Faeces and urine were collected quantitatively for 13d. Heat production was measured by indirect calorimetry. Preliminary results indicate that synchronizing the dietary protein and starch supply did not affect apparent fecal digestibility of DM, N, energy, crude fat and ash (mean values of 88.5, 91.9, 88.9, 72.8 and 55.0, respectively; $P > 0.2$). It did, however, markedly increase N retention from 0.91 (asynchronous) to 1.08 g N/kg BW^{-0.75}·d⁻¹ (synchronous) ($P < 0.01$). The efficiency with which digestible N was retained increased from 49.5 (asynchronous) to 59.9% (synchronous; $P < 0.01$). Due to technical problems, the results of the heat production measurements could not be used. In conclusion, the results of this non invasive study illustrate the potential effect that synchronization of dietary protein and glucose supply may have on nitrogen retention.

Key Words: Pigs, Protein Metabolism, Nutrient Synchrony

1330 Portal recovery of enteral supplied alpha-ketoglutaric acid in growing pigs. N. B. Kristensen*¹, S. G. Pierzynowski², H. Jungvid², and J. A. Fernandez¹, ¹*Danish Institute of Agricultural Sciences, Tjele, Denmark*, ²*Gramineer Int. AB, Lund, Sweden.*

The present study was undertaken to study the portal recovery of alpha-ketoglutaric acid (AKG) fed to growing pigs. Five crossbreed Danish female pigs (50 ± 2 kg BW before surgery) were fitted with silicone catheters in A. iliaca externa, V. mesenterica and V. porta. The pigs were fed a barley-wheat-soybean meal based diet (3 % of BW/d). The average daily gain during the experimental period was 801 ± 55 g/d. During blood samplings the diet was divided equally into 24 daily meals, fed every hour and added 5 % (wt/wt) of glucose (Control) or 5 % (wt/wt) of AKG, i.e. 342 mmol of AKG / kg feed (AKGfeed). Three pigs received in a later experiment an equivalent amount of AKG by i.v. infusion into V. mesenterica (AKGiv). Portal blood flow was measured by down stream dilution of p-aminohippuric acid continuously infused into V. mesenterica. Blood plasma concentrations of AKG were measured by gas-liquid chromatography of O-ethylxime ethyl esters of AKG. The arterial concentration of AKG increased ($P < 0.01$) from 18 to 25 ± 3 μmol/l with Treatment AKG compared with control. With Treatment AKGiv, the arterial concentration of AKG was 425 ± 27 μmol/l. The portal blood flow was not obtained for all pigs, however, the data obtained did not indicate any treatment effect on portal blood flow (131 ± 6 l/h; n=9). The portal net appearance of AKG (calculated as whole blood flux) increased ($P < 0.01$) with Treatment AKGfeed (35 ± 9 mmol/ kg feed) compared with control (9 ± 5 mmol/kg feed). The increased net portal appearance of AKG could account for 8 ± 2 % of the AKG added to the feed. When AKG was infused into the mesenteric vein it could be completely accounted for (100 ± 2 %) in the portal vein. These results suggest that enteral supplied AKG has a low availability (8 %) for liver and peripheral tissues in pigs. Thus a large fraction of AKG is probably metabolized within the digestive tract or in the intestinal mucosa.

Key Words: Alpha-ketoglutaric acid, Digestive absorption, Pigs

1331 The change of growth performance and carcass characteristics in finishing pigs treated with N-methyl-D,L-aspartate(NMA). Gang Xi¹, Zirong Xu², and Ping Xiao², ¹University of Minnesota, St. Paul, MN, ²Zhejiang University, Hangzhou, China.

A total of 84 cross bred finishing pigs (average initial BW of 56±0.37 kg) were used to determine the effect of dietary N-methyl-D,L-aspartate(NMA) on growth performance and carcass characteristics. There were 14 pigs (7 gilts and 7 barrows) per pens and 3 pens for each treatment. Treatments were: 1) corn-soybean meal without NMA; 2) added 50 mg/kg NMA to the diet. All pigs were given free access to feeds and water. After feeding trial, 8 pigs from each treatment (4 gilts and 4 barrows) were sacrificed to determine the carcass traits. The addition of NMA in diet improved the ADG 9.31% ($p < .01$) and the G/F 7.66% ($p < .02$) in finishing pigs. No difference was observed in ADFI between two treatments. Pigs fed NMA had 6.54% higher ($p < .01$) carcass lean proportion and 21.01% larger ($p < .04$) longissimus muscle area(LMA) compared to pigs fed the control meal. In addition, the carcass fat proportion of NMA treated pigs was 11.76% lower ($p < .01$) and back fat depth (10th rib) was 19.72% less ($p < .01$) than that of pigs without NMA in diet. There were no differences in dressing percentage, carcass skin proportion, and carcass bone proportion between two treatments. The weight of longissimus muscle, biceps femoris, and Semimembranosus were improved with 12.30% ($p < .01$), 10.09% ($p < .01$) and 14.44% ($p < .01$), respectively, with addition of NMA in diet, but no differences were found in quadriceps femoris and semitendinosus. Also, there were no differences in weight percentage of brain, heart, liver and kidney between two treatments. These results suggest that addition of 50 mg/kg NMA in diet will improve the ADG, G/F and increase muscle production and reduce the accretion of body fat in finishing pigs.

Key Words: NMA, Growth Performance, Carcass Characteristics

1332 Response of weanling pigs to dietary lysine sulfate fermentation product or L-lysine-HCl supplementation. B. R. Frederick* and E. van Heugten, North Carolina State University, Raleigh.

Two trials involving a total of 192 weanling pigs, 7.3 and 6.6 kg initial BW for trial 1 and 2 respectively, were conducted to determine the effect of a lysine-SO₄ fermentation product (Biolys[®] 60, containing 46.8% free + 0.5% protein bound L-lysine) on pig performance. In each trial, 96 pigs (4 pigs/pen) were weaned and fed a commercial, prestarter diet for 8 d in trial 1 and 5 d in trial 2 to ensure adequate dietary adjustment to solid food. At that time pigs were allotted by weight to one of three lysine supplementation treatments: 1) control containing 0.90 and 0.70% lysine for the prestarter and starter period, respectively, 2) control with 0.20% lysine from L-lysine-HCl, or 3) control with 0.20% lysine from lysine-SO₄ product. Diets contained 110% of the ideal amino acids:lysine ratio and were iso-nitrogenous and iso-energetic within each period. Pigs consumed the prestarter, experimental diets for 7 d and 14 d and the starter, experimental diets for 24 d and 21 d in trial 1 and 2, respectively. Pigs were allowed free access to feed and water for the duration of the study. Data were analyzed as a randomized complete block design blocked by weight and pen was used as the experimental unit. Pigs fed the lysine-supplemented diets consumed more feed ($P < 0.001$) than control pigs, 814 vs 675 20 g/d in trial 1 and 520 vs 435 ± 17 g/d in trial 2, respectively. Lysine supplementation increased average body weight gain ($P < 0.001$) compared to the control, 457 vs 320 ± 11 g BW gain/d in trial 1 and 315 vs 226 ± 11 g BW gain/d in trial 2, respectively. Furthermore, lysine supplementation improved efficiency of feed utilization ($P < 0.001$) compared to the control, 563 vs 478 ± 8 g BW gain/kg feed intake in trial 1 and 607 vs 519 ± 8 g BW gain/kg feed intake in trial 2, respectively. However, feed intake, body weight gain, and efficiency of feed utilization did not significantly differ ($P > 0.05$) between L-lysine-HCl and lysine-SO₄ product treatments for the duration of both trials. Therefore, lysine-SO₄ product is a possible alternative to L-lysine-HCl in commercial, weanling pig diets.

Key Words: Pig, Lysine, Sulfate

1333 Effects of dietary supplementation of crystalline L-glutamine on the gastrointestinal tract and whole body growth in early-weaned piglets fed corn and soybean meal-based diets. D. Lackeyram*¹, X. Yue¹, and M.Z. Fan¹, University of Guelph, Guelph, Ontario, Canada.

This experiment was conducted to examine the effect of dietary supplementation of crystalline L-glutamine on the gastrointestinal tract and whole body growth in early-weaned piglets. A total of 36, 10-d old piglets with an average initial BW of 3.5 kg were used. Piglets were blocked by replication time, equalized for gender and allocated randomly to one of four dietary treatments in a randomized complete block design. Piglets were housed individually in an environmentally controlled room at 25 degrees Celsius with heating lamps in rubberized-floor pens. The control diet (GC) (n=18) contained 56% soybean meal and 16% corn and was formulated to meet NRC (1998) requirements for all nutrients. Three treatment diets (n=6) were formulated by supplementing the control diet with crystalline L-glutamine at the level of 0.8 (Gln1), 1.6 (Gln2), and 2.4% (Gln3), respectively. Diets were fed for a period of 12-d and piglets were allowed free access to feed and water. Piglets weaned on the Gln1 diet had a 59% greater ($P \leq 0.01$) BW gain than the control group (92.4 ± 16.1 vs. 57.9 ± 10.9 g/d), whereas piglets fed the Gln2 and Gln3 diets did not differ ($P \geq 0.01$) from the GC-fed animals. Piglets fed the Gln1 diet had heavier ($P \leq 0.01$) stomachs than the control animals (0.61 ± 0.05 vs. 0.45 ± 0.04 g/kg BW/d). A 53 and 74% increase ($P \leq 0.01$) in the weights of the small intestine in piglets fed the diets Gln1 and Gln2 were observed (1.10 ± 0.13 and 1.25 ± 0.14 vs. 0.72 ± 0.17 g/kg BW/d) respectively. Similar increases ($P \leq 0.01$) in liver weight gains were observed between the GC and the Gln1, Gln2 and Gln3 groups (-0.04 ± 0.09 vs. 0.48 ± 0.21; 0.44 ± 0.16 and 0.22 ± 0.17 g/kg BW/d). These results suggest that the inclusion of crystalline L-glutamine at a level of 0.8% in corn soybean meal-based diets is effective in enhancing the BW gain, the small intestine growth and other visceral organ growth in early-weaned piglets, however the level of supplementation higher than 1.6% did not induce such effects.

Key Words: L-Glutamine, The gastrointestinal tract growth, Early-weaned piglets

1334 The performance and protein, amino acid and phosphorus utilization of piglets were improved by phytase supplementation. Keying Zhang*, Daiwen Chen, Bing Yu, Xianmei Luo, and Yongyi Li, Institute of Animal Nutrition, Sichuan Agricultural University, Yaan, Sichuan 625014, P.R. China.

Efficacy of phytase in improving utilizations of dietary protein and amino acids needs to be further investigated. In this study, forty eight Yorkshire x Landrace were used in two balance trials to study the performance and nutrient utilizations of 40-days-old pigs fed diets with or without supplementation of microbial phytase at the dose of 500 units per kg diet. In trial one, phytase was added into diets of normal available phosphorus (AP) (0.36%) or low level AP(0.26%). The decrease of AP from 0.36% to 0.26% resulted in the decrease of average daily gain (ADG), feed intake (FI) and feed conversion rate (FCR) by 17.2, 7.4% and 11.2 respectively ($P < 0.01$). ADG, FI and FCR were improved by 10.8%, 6.5% and 3.5% respectively after the addition of phytase ($P < 0.05$). The improvement was greater for phytase addition into 0.26% AP than into 0.36% AP. The supplementation of phytase in 0.36%-AP diet did not affect the digestibilities of phosphorus(P)protein (CP) and amino acids(AA), and the retention of P. But CP biological value (BV) was improved by 3.3($P < 0.05$). However, phytase in 0.26%-AP diet improved P digestibility, P retention and BV of CP by 12.8, 13.1 and 16.0 respectively ($P < 0.05$). In trial two, two diets were designed with same AP (0.26%) but different lysine level (0.97% vs 0.92%). The decrease of lysine from 0.97% to 0.92% reduced ADG, FCR ($p < 0.01$), and BV of CP (54.7% vs 51.5%) ($P < 0.1$), but enhanced essential AA ileal digestibility $p < 0.05$. The addition of phytase improved ADG and FCR ($p < 0.01$), P digestibility and retention ($P < 0.01$), BV of CP ($p < 0.25$) and lysine ileal digestibility ($p < 0.25$), with greater improvement at higher than lower dietary lysine level. It is concluded that dietary supplementation of 500U phytase /kg can significantly improve the performance of piglets and the utilizations of phosphorus and protein. The extent of improvement is affected by the dietary phosphorus and lysine level.

Key Words: Phytase, Nutrient Utilization, Piglets

1335 Metabolic adaptation to synthetic feed and different amino acid patterns. J. A. Nolles, V. V. A. M Schreurs, R. E. Koopmanschap, and M. W. A. Verstegen*, *Wageningen Institute of Animal Sciences (WIAS)*.

Metabolic adaptation to free amino acids as well as to 3 different methionine (MET) levels in the feed was studied in 36 male Wistar rats, assigned to 6 groups with 3 different dietary groups. The dietary groups were subdivided in an adaptation and a nonadaptation group. All diets contained 21% free amino acids. The pattern was equal to casein protein, except for MET. Diet 1; MET level 50%, diet 2; 100% and diet 3; 200%. Postprandial oxidation of $1\text{-}^{13}\text{C}$ -methionine (13MET) was measured during 5 hours after a meal (t_0 = start meal, t in min) by recovery of $^{13}\text{CO}_2$ in the breath, expressed as rate % dose/30 min or cumulative % dose. For each diet, the nonadaptation group was tested after 5 days, the other group was tested after an adaptation period of 3 weeks. Incorporation of 13MET in several tissues was measured at $t = 300$, expressed as At % excess. Statistical analysis; t-test with Bonferroni correction. Nonadaptation groups: There was no difference in the oxidation rate between the 100% and the 50% group at $t = 150$ (2.4 0.27 vs 2.3 0.47 % doses/30 min). The 200% group was significantly higher (peak value 3.6 % doses/30 min 0.38, on $t = 150$). Our results indicate that percental oxidation rate in time of MET remains equal under normal and low MET supply. Only extreme high levels (200% group) cause an acute raise in oxidation. Adaptation to the diets caused a time lag of 60 minutes for maximal oxidation rate in all dietary groups. However the peak and the cumulative values did not change for the 100% (2.6 0.15 at $t = 210$, cumulative 20.3 0.51) and the 200% (3.5 0.10 at $t = 210$, cumulative 27.1 0.80) groups. Only the 50% group had a lower peak (1.6 0.12 at $t = 210$) and cumulative oxidation (11.8 0.44) after the adaptation period. Tissue samples of all organs showed that the incorporation of MET was the highest in the 50% group. The most pronounced result of this experiment was the adaptation effect on organ level. In general after the adaptation period 10 to 20% more 13MET was incorporated in all dietary groups. However the longissimus showed for all groups an increase of 40 to 50%. We therefore concluded that muscles play an important role in adaptation to different amino acid patterns in the feed.

Key Words: Breath-test, Adaptation, Amino Acids, Methionine, Protein Metabolism

1336 Cysteine and sulfite enhance reduction of trypsin inhibitor during heating of soybeans. Y.X. Huang and E.L. Miller*, *Department of Clinical Veterinary Medicine, University of Cambridge*.

Heat treatment of soybeans is a compromise to reduce trypsin inhibitor without causing protein damage. The objective was to determine whether sulfitolysis of disulfide bonds with cysteine or sulfite reduces trypsin inhibitor (TI) content of soya and can reduce the extent of heat treatment needed for reduction of TI. Dehulled soybeans were ground and extracted with petroleum spirit and adjusted to moisture of 100, 140, 180, 220 g/kg. The initial TI was 65 mg/g DM and 4.84 (SD 0.043) mmole/kg DM reactive SH determined with 4,4'-dithiodipyridine. Samples (4 g) of extracted soya were heated in screw cap test tubes at 99C for 5 minutes to rapidly bring the sample to temperature and then heated 10, 20, 40 and 60 minutes at 95C. TI decreased very little at 100 g/kg moisture but more rapidly with increased moisture. Reactive SH groups followed a similar pattern. TI was related exponentially to SH ($\text{TI mg/g} = 0.2124e^{1.1512x}$; $r = 0.923$) where x is SH mmole/kg. Urease activity (pH change) was linearly related to SH ($y = 0.6699\text{SH} - 1.2458$; $r = 0.939$). The rate of loss of TI under each moisture condition was determined as a second order reaction (reciprocal of TI v time plot). The moisture-adjusted soya was mixed with sodium metabisulfite (S) at the rate of 11.8 g/kg DM or with cysteine (C) at 15 g/kg DM, each supplying 0.25 mole SH per kg protein, and heated as for soya alone. Unreacted S or C were removed by washing and centrifugation over a 10,000 dalton membrane. Addition of C and S increased reactive SH. Values (mmole/kg DM) at 220 moisture for soya: 4.80, 4.48, 3.84, 3.57, 2.82; S 6.04, 7.39, 8.17, 6.19, 4.07; C 7.34, 10.49, 8.25, 11.99, 4.31 at 0, 10, 20, 40, 60 min. Addition of C did not increase loss of TI at 100 or 140 g/kg moisture but increased the rate of loss 1.9 and 3.3 times at 180 and 220 g/kg moisture. S was more active increasing rate of TI loss 3.0, 5.8, 6.2 times at 140, 180 and 220 g/kg moisture. Heating moist soya alone reduced reactive SH groups. Heating in the presence of S or

C decreased the time to reduce TI to low levels and increased reactive SH.

Key Words: Trypsin inhibitor, Sulfhydryl, Sulfitolysis

1337 Effect of Zinc-Methionine on growth performance of Japanese quail (*Coturnix coturnix japonica*) fed with starting-growing diets. A. Montoya*¹, R. Barajas¹, and G. Contreras¹, ¹*FMVZ-Universidad Autonoma de Sinaloa*.

With the objective of determinate the effect of Zinc-Methionine on growth performance of Japanese quail fed with starting-growing diets, a complete randomized design experiment was conducted. Six hundred Japanese quail, one day old (male and female; BW = 10.4 g) were used. The animals were randomized divided in 12 groups of 50 quails. Each group was allocated in metallic crates with cement floor provided with wood saves. The quails were assigned to consume one of two diets in that consisted the treatment: 1) Diet with 21% CP and 3.2 Mcal DE/kg (CodoriniciarinaTM; PURINA MILLS, CO.) containing 40 ppm of Zn from unknown source (control); and 2) Diet similar to control, supplemented with additional 25 ppm of Zn from zinc-methionine (ZINPRO-100TM; ZINPRO,CO.) designed as Zn-Met treatment. Quails were weight at starter and end of experiment (28 days), feed intake was recorded weekly, mortality were recorded daily, and animal deaths were not replaced. The data were analyzed as a complete randomized design experiment with six repetitions, taken a crate (50 quails) as one observation. Final weight was not affected ($P > 0.10$) by treatments (mean = 193.5 g). Daily feed intake of the experiment was 18.94 g/day and a similar ($P > 0.10$) for both treatment. The average daily gain of the experiment was 6.54 g/day, and was not influenced ($P > 0.10$) by treatments. Zn-Met not improved ($P > 0.10$) feed efficiency (experiment mean 0.35 kg gain/kg food). Mortality was unaffected ($P > 0.10$) for Zn-Met supplementation (7.0 vs 6.67%). It is concluded, that supplementation with 25 ppm of Zn from Zn-Met to starting diets do not improve growth performance of Japanese quail.

Key Words: Zinc, Supplementation, Japanese quail

1338 Effect of chromium-methionine level in diet on hatchability of Japanese quail in dry tropic weather:II. Response under temperature-controlled in winter season. G. Contreras*¹ and R. Barajas¹, ¹*Universidad Autonoma de Sinaloa*.

To determinate the effect of chromium-methionine level in diet on hatchability of Japanese quail in dry tropic weather under temperature-controlled in summer season, a completely randomized design experiment was conducted (four treatments; ten replicates by treatment). Thousand two hundred eighty Japanese quail (960 females and 320 males), they were divided in 160 groups of eight (six females and two males), and were allocated in wire cages (25 x 30 cm); groups of four cages (32 quails) formed an observation. The avian were randomized assigned to consume diets (21% CP; 2.9 Mcal DE/kg), in that consist the treatments, containing one of four levels (0, 100, 200 and 400 ppb) of supplemental chromium from chromium-methionine (MicroplexTM Zimpro,CO.MN). Mean daily feed intake by quail in the experiment was 31.7 g and was not affected ($P > 0.10$) by treatments. The hatching was increased 12% ($P < 0.05$) with Cr 100 ppb treatment. Percentage of egg hatching was not affected ($P > 0.10$) by treatments (74%). Level of 100 ppb of Cr increased ($P < 0.05$) in 22% the number of newly born quails by day (103 vs 84) with respect to zero Cr level, cubic effect ($P < 0.05$) of Cr-Met supplementation was found (84, 103, 88 and 92 newly born quails for 0 to 400 ppb of Cr in diet). Hatchability in Cr-400 was higher ($P < 0.05$) than control (64.8 vs 74%), a linear effect of chromium was detected ($P < 0.05$). The weight of newly born quail was diminished ($P < 0.05$) by chromium levels of 100 and 200 ppb with respect of Cr 0 ppb treatment, a quadratic ($P < 0.01$) effect of chromium was observed, with values of 10.17, 9.82, 9.7 and 10.12 g for chromium levels of 0, 100, 200 and 400 respectively. It is concluded, that 100 ppb of supplemental Cr from Cr-Met, improve hatching and newly born quails by day of Japanese quail in dry tropic weather under temperature-controlled in winter season.

Key Words: Japanese quail, Chromium, Hatchability

1339 Effect of chromium-methionine level in diet on hatchability of Japanese quail in dry tropic weather: I. Response under temperature-controlled in summer season. G. Contreras*¹ and R. Barajas¹, ¹Universidad Autonoma de Sinaloa.

To determinate the effect of chromium-methionine level in diet on hatchability of Japanese quail in dry tropic weather under temperature-controlled in summer season, a completely randomized design experiment was conducted. Thousand two hundred eighty Japanese quail (960 females and 320 males), they were divided in 160 groups of eight (six females and two males), and were allocated in wire cages (25 x 30 cm); groups of four cages (32 quails) formed an observation. The avian were randomized assigned to consume diets (21% CP; 2.9 Mcal DE/kg), in that consist the treatments, containing one of four levels (0, 100, 200 and 400 ppb) of supplemental chromium from chromium-methionine (MicroplexTMZinpro,CO.MN). Chromium 100 ppb increased ($P < 0.05$)

the average daily feed intake with relation of the remainder treatments (36.9 vs 36.3 g/day). The hatching was not affect ($P > 0.20$) by treatments (mean value = 78%); egg hatching was similar ($P > 0.20$) across treatments (66%). Supplementation with level of 100 ppb of Cr increased ($P > 0.05$) in 19% the number of newly born quails by day (81 vs 68), and hatchability in 22% (55 vs 67.5%) with respect to control (Cr 0 ppb). Levels of 200 and 400 ppb tended ($P = 0.11$) to decrease in 18% the number of newly born quails by day (68 vs 56) respect to control. Chromium 200 and 400 ppb had similar ($P > 0.20$) hatchability than control (55 vs 46%). It is concluded, that 100 ppb of supplemental Cr from Cr-Met, improve hatchability and newly born quails by day of Japanese quail in dry tropic weather under temperature-controlled in summer season.

Key Words: Japanese quail, Chromium, Hatchability

PSA Nutrition: Amino Acids, Feed Ingredients, and Feed Processing

1340 Digestible lysine levels in the diets of broilers from 1 to 21 days of age. L. F. Araujo*¹, O. M. Junqueira¹, C. S. S. Araujo¹, and S. M. Baraldi Artoni¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal - SP - Brazil.

The purpose of this experiment was to evaluate different levels of digestible lysine on performance of chickens from 1 to 21 days of age. A total of 1000 one day-old chicks was fed diets with 5 levels of digestible lysine (1.18%; 1.30%; 1.42%, 1.54% and 1.66%) in four replications of 50 birds each. The same ideal relationship of Lis:Met+Cis:Met:Thr (100:71:39:63) was maintained in all diets. The basal diet was formulated according to the recommendations of Rostagno et al. (2000) with 3,100 kcal ME/kg and 22% crude protein. At 21 days of age, the best results were observed in broilers fed the diet containing 1.18% digestible lysine. As the level of digestible lysine increased in the diet, there was a reduction in feed intake, affecting weight gain. So that, the 1.66% level of digestible lysine produced lower weight gain and poorest feed conversion. From the results obtained in this experiment, it is possible to conclude that 1.18% digestible lysine is enough to maintain the requirements of broilers from 1 to 21 days of age. Financial Support: FAPESP. Proc. 98/06355-3

Key Words: Broilers, Lysine, Performance

1341 Dietary crude protein levels needed for broilers from three to six weeks of age as influenced by gender. Q. Jiang*, C. A. Fritts, and P. W. Waldroup, *University of Arkansas.*

Development of crystalline amino acids have allowed for a reduction in overall crude protein content in broiler diets. However at some point performance declines even though all nutrient recommendations are provided. The objective of this study was to determine the minimum level of CP that might be needed by broilers from three to six weeks of age. Because some studies have suggested that males and females may differ in their response to CP or amino acids, separate sex feeding of diets with different levels of crude protein was examined. Diets were formulated using corn and soybean meal of known composition to provide diets with 15 to 20% CP in increments of 1%. Crystalline amino acids were used to provide at least 100% of NRC (1994) recommendations. Dietary electrolyte balance was maintained at a minimum of 200 meq/kg. From one to 21 d of age chicks were fed 24% CP and then placed on test diets from 21 to 42 d. Body weight gain and feed conversion were determined and samples of birds processed at 42 d. Four pens of 25 males and four pens of 25 females were fed each CP level. Although males differed significantly from females in BW gain or feed conversion there were no significant interactions of gender and CP level. Diets with 17% supported BW and FCR that did not differ from that of birds fed diets with higher levels; lower CP levels resulted in a significant reduction in performance. Females had a higher percentage of breast meat and greater amounts of abdominal fat than males but there were no interactions between dietary CP and gender for any parts yield. A CP level of 17% supported breast yield equal to that of higher levels.

Key Words: Crude protein, Gender, Carcass yield

1342 mRNA that encode for proteins capable of transporting L-methionine and/or dl-2-hydroxy-4-(methylthio) butanoic acid are present in the intestinal epithelium of broilers. Y-X. Pan*¹, E. A. Wong¹, J. J. Dibern², and K. E. Webb, Jr. ¹, ¹Virginia Tech, Blacksburg, VA, ²Novus International, Inc., St. Charles, MO.

The presence of mRNA that encode for proteins capable of transporting L-methionine (L-Met) and/or dl-2-hydroxy-4-(methylthio) butanoic acid (HMB) in broiler intestinal epithelium was examined. Total RNA was extracted from duodenal, jejunal, and ileal epithelium collected from male broilers (42 d old, BW 2.03 kg). Poly(A)⁺ RNA was isolated and size-fractionated by sucrose-gradient centrifugation when needed. Healthy oocytes at stage V-VI were collected from *Xenopus laevis* and then microinjected with either water, poly(A)⁺ RNA, or size-fractionated poly(A)⁺ RNA. The ability of the injected oocytes to uptake either L-Met or HMB was examined by incubating oocytes with [³H]-L-Met or [¹⁴C]-HMB 3-6 d post-injection. A greater uptake of L-Met ($P < 0.001$) and HMB ($P < 0.05$) by oocytes injected with poly(A)⁺ RNA from all three segments of the small intestine was observed compared with water-injected oocytes. The greatest ($P < 0.05$) uptake occurred when poly(A)⁺ RNA from the jejunum or ileum were injected. Injections from four different pools of sucrose gradient-fractionated poly(A)⁺ RNA from all three intestinal segments induced more ($P < 0.01$) L-Met uptake than did water injection. There were three, four, and four different pools of sucrose gradient-fractionated poly(A)⁺ RNA from the duodenum, jejunum, and ileum, respectively, that induced more ($P < 0.05$) HMB uptake than did water. Uptake of HMB was greater at pH 5.5 than at pH 7.5 and was independent of Na⁺. Uptake of L-Met induced by all four poly(A)⁺ RNA pools decreased dramatically when Na⁺ was removed from the uptake buffer, which indicated that the majority of L-Met uptake was Na⁺-dependent. These results indicate that there are multiple mRNA that encode for proteins capable of mediated transport of L-Met and/or HMB present in broiler intestinal epithelium.

1343 Effects of amino acids and calcium levels on radiographic density and calcium excretion in broilers from 1 to 21 days of age. C. S. S. Araujo*¹, S. M. Baraldi-Artoni¹, L. F. Araujo¹, M. J. Q. Lousada², and O. M. Junqueira¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal - SP - Brasil, ²Universidade Estadual Paulista - UNESP/Araatuba - SP - Brasil.

An experiment was conducted in broilers to determine the effects of amino acids (AA) and calcium (Ca) levels on bone development and calcium excretion from 1 to 21 days of age. A total of 540 one-day old Avian Farms male chicks were randomly assigned to 6 treatments in a 3x2 factorial arrangement, considering the factors AA levels (100, 125 and 150% NRC, 1994) and Ca levels (75 an 100% NRC, 1994), in three replications and 30 birds each. The AA analyzed were methionine, lysine and threonine. Diets and water were available free choice. Experimental diets were comprised primarily of corn and soybean meal and were formulated to be isocaloric and isoproteic. Requirement levels for AA were accomplished when necessary by adding crystalline AA. Bone development was determined through radiographic density and tibia variables (tibia weight, tibia length, compact bone thickness and spongy bone

thickness). Total fecal output was collected for 72 h from days 19 to 21 to determine the treatment effect on Ca excretion. Percentage Ca excretion was calculated as grams of Ca in feces divided by grams of Ca consumed in the 72-h period. At 21 days, two broilers from each pen were slaughtered and the left tibia of the birds were collected and analyzed according to radiographic density (mm Aluminium equivalent). There were interactions in the trial between AA level and Ca level for radiographic density ($P < 0.05$). However, the results showed that AA or Ca levels did not affect tibia variables and Ca excretion. Acknowledgements: FAPESP for financial and technical support .

Key Words: Amino Acids, Calcium , Broilers

1344 Effects of amino acids and calcium levels on radiographic density and calcium excretion in broilers from 22 to 42 days of age. C. S. S. Araujo*¹, S. M. Baraldi-Artioni¹, L. F. Araujo¹, M. J. Q. Louzada², and O. M. Junqueira¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal, SP - Brazil, ²Universidade Estadual Paulista - UNESP/Araatuba, SP - Brazil.

The purpose of this experiment was to evaluate different levels of amino acids (AA) and calcium (Ca) on radiographic density (mm Aluminium equivalent), tibia variables (tibia weight, tibia length, compact bone thickness and spongy bone thickness) and Ca excretion from 22 to 42 days of age. A total of 540 one-day old Avian Farms male chicks were randomly assigned to 6 treatments in a 3x2 factorial arrangement, considering the factors AA levels (100, 125 and 150% NRC, 1994) and Ca levels (75 and 100% NRC, 1994), in three replications and 30 birds each. The AA analyzed were methionine, lysine and threonine. Diets and water were available free choice. Experimental diets were comprised primarily of corn and soybean meal and were formulated to be isocaloric and isoproteic. Requirement levels for AA were accomplished when necessary by adding crystalline AA. Total fecal output was collected for 72 h from days 40 to 42 to determine the treatment effect on Ca excretion. Percentage Ca excretion was calculated as grams of Ca in feces divided by grams of Ca consumed in the 72-h period. At 42 days, two broilers from each pen were slaughtered and the tibia left of the birds were collected and analyzed according to radiographic density (mm Aluminium equivalent). The AA or Ca levels unaffected radiographic density, tibia variables and Ca excretion. There were found interactions between the two factors. 1345 Effects of amino acids and calcium levels on radiographic density and calcium excretion in broilers from 43 to 49 days of age. S. M. Baraldi-Artioni¹, C. S. S. Araujo*¹, L. F. Araujo¹, O. M. Junqueira¹, M. J. Q. Louzada², and N. K. Sakomura¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal, SP - Brazil, ²Universidade Estadual Paulista - UNESP/Araatuba, SP - Brazil.

Male broiler Avian Farms (n=540) were used from 43 to 49 days of age were subjected to a 3x2 factorial design consisting of three levels of dietary amino acids (100,125 and 150% NRC, 1994) and two levels of dietary calcium (75 and 100% NRC, 1994) with a total of 6 treatments replicated three times per treatment. Radiographic density (mm Aluminium equivalent), tibia variables (tibia weight, tibia length, compact bone thickness and spongy bone thickness) and Ca excretion were evaluate. The AA analyzed were methionine, lysine and threonine. Diets and water were available free choice. Experimental diets were comprised primarily of corn and soybean meal and were formulated to be isocaloric and isoproteic. Requirement levels for AA were accomplished when necessary by adding crystalline AA. Total fecal output was collected for 72 h from days 47 to 49 to determine the treatment effect on Ca excretion. Percentage Ca excretion was calculated as grams of Ca in feces divided by grams of Ca consumed in the 72-h period. At 49 days, two broilers from each pen were slaughtered and the tibia left of the birds were collected and analyzed according to radiographic density (mm Aluminium equivalent). The AA or Ca levels unaffected radiographic density, tibia variables and Ca excretion. There were found interactions between the two factors. 1346 Effect of diets containing cashew nut meal and an enzyme complex on broiler performance. M.F.F. Fuentes*¹, S.F. Militao¹, E.R. Freitas¹, and G.B. Espndola¹, ¹Universidade Federal do Cear, Fortaleza, CE, Brasil.

An experiment was conducted to evaluate the effect of diets containing different levels of cashew nut meal (CNM) supplemented or not with an enzyme complex (Avizyme[®]) on broiler performance. One hundred and forty four day-old broiler chicks were allotted in individual cages during a period of 42 days. Birds were distributed in a randomized complete block design with six treatments and six replicates of four birds in each experimental unit. A factorial arrangement 3 x 2 (CNM x Enzyme) was applied. Diets used during the initial (1 to 21 days) and final (22 to 42 days) periods were isoproteic and isocaloric and contained 22% crude protein with 3,000 kcal ME/ kg and 20% crude protein with 3,100 kcal ME/ kg, respectively. Treatments were: T1 = 0% CNM; T2 = 0% CNM + 0.1% enzyme; T3 = 7.5% CNM; T4 = 7.5% CNM + 0.1% enzyme; T5 = 15% CNM; T6 = 15% CNM + 0.1% enzyme. Data were analyzed for the whole period (42 days). Results showed that the inclusion levels of CNM and the enzyme supplementation did not significantly ($P > 0.05$) affect body weight gain or feed intake. CNM levels, however, significantly ($P < 0.05$) affected feed conversion. Birds fed the diet containing 15% of CNM had better feed conversion than those fed the 0% and 7.5% CNM diets. Abdominal fat level in birds fed the diet with 7.5% of CNM was significantly ($P < 0.05$) lower than that from birds fed 15% CNM diet. Enzyme addition, however, did not affect this variable. It is concluded that bird performance was influenced by the level of CNM but not by the addition of enzyme to the diet.

Key Words: Cashew Nut Meal, Enzymes, Feed Conversion

1347 Dehydrated poultry meal as a replacement for soybean meal in broiler diets. J.B. Hess*¹, J.P. Blake¹, R.A. Norton¹, K.M. Downs², A. Kalinowski¹, and A. Corzo¹, ¹Poultry Science Department, Auburn University, Auburn, AL, ²Middle Tennessee State Univ., Murfreesboro, TN.

An experiment was conducted to evaluate broiler live performance in birds fed varying levels of a locally-produced dehydrated poultry meal (DPM) in place of soybean meal (SBOM). This product was produced commercially from farm-frozen broiler mortalities. Six replicates of five dietary treatments were assigned to Petersime battery units at 10 birds/cage. Broilers were raised to 42d on a two-feed program. Starter diets (0-21d) had DPM levels added to reduce SBOM levels from 36% to 27, 18, 9 and 0% of the diet. Grower feeds (21-42d) had DPM added to reduce SBOM to 24, 18, 12, 6 or 0% of the diet. Live production performance was evaluated at 21 and 42 days of age. No differences were detected in body weight across treatment groups, although birds fed DPM in total replacement of SBOM showed numerically reduced body weights of 49g at 21d and 89g at 42d. Similar non-significant trends were seen in feed intake, with no relationship to diet noted in 21d (1.35) or 42d (1.73) feed conversion efficiency. No differences were recorded between treatments for mortality. Use of this product in broiler feeds did not increase mortality or unduly influence weight gain or feed conversion at levels that might be used in the field.

Key Words: Dehydrated Poultry Meal, Broilers, Farm Mortality Disposal

1348 Biological evaluation of a phosphorus source prepared with a new process on broiler chicks. H. Motallebi¹, M. Masoumi Esfahani*², and A. Faghijnasirj³, ¹University of Mazandaran, ²Telavang Co., ³Deputy of Livestock Affairs.

This experiment was conducted to evaluate the quality of a phosphorous source produced from a phosphate rock. The phosphate rock obtained from Yard Asfordy mine in Iran and converted to dicalcium phosphate by using the direct process method. The process consisted of three main steps including: a) digestion, b) deflourination, and c) neutralization of the phosphorous rock. In a randomized design experiment the produced P was fed to a total of 450 day-old mixed sex broiler chicks up to 21 day of age. Meanwhile, a commercial dicalcium phosphate (DCP) was used as control and the performances of the 6 dietary treatments were compared among each of three replicates. Experimental diets contained adequate levels of all nutrients except for P. The basal control diet contained about .23 % available P and the same amount of Ca. The experimental diets were supplemented either with the standard source of DCP to provide P levels of 85, 90, 95, 100 % or with the new DCP at

two levels of 85 and 100 % of the recommended levels by NRC (1994). Calcium content of the diets was kept constant at about .9% during the experimental period. Biological value and relative biological value of P source and performance of broiler chicks was determined at 21-day age. Data reported here shows that the broilers performance was not significantly different ($P>0.05$) among the two P sources tested. Likewise, the results of this experiment showed that the new P source was both desirable and more economical during the testing period. Although, reduction of P up to 15 % below the recommended NRC (1994) level had no significant effect on broiler performance ($P<0.05$).

Key Words: Broiler, Phosphorous, Dicalcium Phosphate

1349 Organ and body growth in full-fed and paired-fed chickens consuming raw and heated velvet beans (*Mucuna pruriens*). L. B. Carew^{*1}, J. Weis¹, A. G. Gernat², F. A. Alster¹, and E. I. Zakrzewska¹, ¹University of Vermont, Burlington, VT/USA, ²Escuela Agricola Panamericana, Tegucigalpa, Honduras.

The velvet bean plant (*Mucuna pruriens*) is used widely in tropical regions as a green manure cover crop. The beans harvested from this crop are used in both animal and human diets. We showed previously that feeding the raw, untreated beans to chickens causes changes in the growth of certain organs. The objective of this study was to determine if dry heating of the beans alters these effects. Triplicate groups of seven male broiler chicks were fed the control diet or diets containing 20% raw (RVB) or heated (HVB) velvet beans from 1-24 days of age in a completely randomized design. Beans were analyzed for nutrient content and substituted into a commercial-type broiler diet at the expense of corn and soybean oil meal. Essential amino acid content was almost identical among all diets. Groups of control chicks were pair-fed with chicks fed the velvet beans by using the same amount of control diet on a daily basis. Data were considered significant at $p\leq 0.05$. At 24 days, chicks were euthanized and heart, liver, pancreas, gizzard and proventriculus weighed. Lengths of small and large intestines and ceca were also measured. Feeding RVB but not HVB caused a reduction in body weight (-8%); feed intake was 9% less although not significant. Chicks fed RVB were smaller than pair-fed and free-fed controls. Weights of pancreas, gizzard and proventriculus relative to body weight were heavier as was cecal length in chicks fed RVB. However, their size was smaller in chicks fed HVB but larger than in full-fed controls. Pair feeding did not account for these differences. Small and large intestines were relatively longer in chicks fed RVB but not different from those fed HVB. Relative weights of liver, heart and thyroid were not significantly affected by feeding either RVB or HVB. We conclude that intake of RVB has marked effects on the growth of certain organs, and in some cases this is modified by heating the beans. This suggests that RVB contain a growth factor that is altered by heat. Heating may have reduced the weight of the pancreas due to destruction of the trypsin inhibitor present in RVB. Where heating of the beans was ineffective in altering organ growth, as with lengths of the small and large intestines, the effect may be due to the increased presence of fiber.

Key Words: Velvet bean, Intestinal length, Organ weight

1350 Effect of moisture, polyamines, and iron concentration on the nutritional value of biosolids harvested from poultry processing effluent. D.V. Maurice, S.F. Lightsey*, Zulfan, D. Wicker, and J.E. Toler¹, Department of Animal & Veterinary Sciences, ¹Department of Experimental Statistics, Clemson University, Clemson, SC 29634-0361.

Three experiments were conducted to determine the effect of moisture content, polyamines, and iron content of the protein fraction of biosolids (PFBS) on broiler performance and health. High moisture (30%) and low moisture (8%) PFBS were included in corn-soy diets at 0-10% and 0-5% respectively. Inclusion of high-moisture PFBS severely depressed growth, increased mortality, decreased plasma and hepatic vitamin E, and increased erythrocyte fragility and hepatic iron but treatment effects were not detected in bone ash, organ weights, and hepatic zinc and copper. The use of low-moisture PFBS in chick diets had no adverse effects and differences were not detected in tissue elemental profile and serum glycoprotein. The effect of polyamines was evaluated in a 2 x 2 factorial experiment with PFBS included at 0 and 5% and with and without a cocktail of polyamines (4.8, 49, 197, and 131 mg/kg of phenylethylamine, putrescine, cadaverine, and histamine respectively). Neither a diet x polyamine interaction nor treatment effect was detected

in growth, feed efficiency, organ weights, condition of the gastrointestinal tract, and inflammation. The response to iron was ascertained by inclusion of low-Fe (0.6%) and high-Fe (2.42%) PFBS at 0, 2 and 4% on a nutrient basis in practical corn-soy diets to market age. Birds fed diets with the low-Fe PFBS were slightly heavier and ate more feed ($p<0.05$) than birds fed diets with high-Fe PFBS. Significant treatment effects were not detected in hepatic vitamin E, plasma ascorbic acid, abdominal fat, and organ weights. The results clearly indicated that moisture content is the major determinant of the nutritional value of heat-treated PFBS. Neither polyamines nor iron content of the PFBS induced adverse biochemical effects that impacted performance. The small advantage in favor of the low-Fe meal may be ascribed to its higher fat content.

Key Words: DAF Sludge, Biosolids, Chickens, Polyamines, Iron, Vitamin E

1351 Utilization of spent hen meal in diets for laying hens. C. A. Fritts*, J. A. Kersey, and P. W. Waldroup, University of Arkansas.

Hens at the end of their laying cycle were processed at three conventional rendering facilities to produce a high-protein spent hen meal (SHM). Meals were analyzed for nutrient content and amino acid digestibility determined using cecectomized cockerels. Diets were formulated to digestible amino acid (DAA) requirements using 0, 5, 10, and 15% of each meal. The DAA requirements were set at a minimum of 95% of the total amino acid requirements for hens consuming 100 g/day (NRC, 1994). This resulted in a total of ten dietary treatments (0 control, 3 levels of SHM x 3 locations). Each diet was fed to six groups of 12 individually caged hens (Hyline W-36) for 84 d beginning at 26 wk of age. At the end of each 28 d period eggs were weighed and shell thickness determined. Hen-day egg production, feed consumption, and mortality were determined for each 28 d period. Compared to the group with 0% SHM, the inclusion of up to 15% SHM had no significant effect on daily feed intake, feed consumed per dozen eggs, Haugh units, or eggshell thickness. Rate of egg production and egg weight declined when SHM from one of the three sources increased above 5% of the diet. However, it was difficult to ascertain the reason for the reduced performance of hens fed this source of SHM. Results of the study indicate that SHM is an acceptable ingredient for use in layer feeds but more information is needed regarding potential factors that may inhibit production.

Key Words: Spent hens, High protein meal, Laying hens

1352 Nutritive and economic values of High Oil Corn in laying hen diets. D. J. Kim and B. D. Lee*, Chungnam National University, Daejeon, South Korea.

A layer feeding trial was conducted in Korea for 15 wks to demonstrate the nutritive and economic values of high oil corn (HOC). A corn-soybean meal based commercial diet was chosen as the control diet. The yellow dent corn in the control diet was replaced with HOC to give an iso-caloric diet, or replaced with HOC on 1:1 basis to give a high energy diet. A total of 510 23-wk-old ISA Brown layers were allotted to the 3 dietary treatments with 5 replicates per treatment. In order to measure the ME values of typical corn and HOC, two metabolism trials were carried out with layers and adult roosters. The HOC used in this trial contained approximately 94% higher crude fat (6.60% as-fed basis) compared to typical corns. The GE, AMEN, and TME values of HOC are 5.7-7.7% higher than those of typical corns, indicating that the energy utilization of each corn were similar. HOC feeding, on an iso-calorie basis or on 1:1 replacement with typical corn, did not exert any effect on various laying performances, including the physical quality of egg. This reflects the quality of the commercial diet chosen as the control diet, which was already fairly good, such that the performance was already maximal. The polyunsaturated fatty acid content in yolk from hens fed HOC were higher than that from hens fed typical corn. If used alone replacing typical corn completely in a layer diet, the acceptance price of HOC was estimated to be 154 won/kg when the price of typical corn was 131 won/kg (118:100). When both corns were allowed to be used, the acceptance price of HOC increased up to 184 won/kg (140:100), indicating that a lot cheaper diet can be formulated when both HOC and typical corn are used in laying hen diet formulation.

Key Words: High Oil Corn, Laying Hen, Economic Value

1353 Effect of treated ervil (*Vicia ervilia*) diets on the performance of laying hens. M. T. Farran*, W. S. Halaby, F. T. Sleiman, M. G. Uwayjan, and V. M. Ashkarian, *American University of Beirut, Beirut, Lebanon*.

Two experiments were conducted to study the effect of water and acetic acid (AA) soaked ervil seeds in layer diets on the performance and egg quality parameters. In one experiment, ground ervil seeds, soaked in water (10:1, vol/wt) at 40 C for 72 h with water change every 12 h, and in 1% AA at room temperature (RT) and at 40 C for 24 h, and dried at RT. Isocaloric and isonitrogenous diets containing 60% raw or treated ervil were fed to 100 individually caged SCWL Layers of similar age, body weight, and production rate for a period of 42 d. Birds fed the untreated ervil had the highest BW loss and least feed intake and egg production rate. All ervil diets resulted in a significantly lower feed intake, egg production, and BW and in higher feed conversion rate, compared to the control. Hens fed the treated ervil seed diets, produced eggs with significantly higher Haugh Unit score and poorer shell thickness compared to control. Yolk color scores of treated ervil diets except for RTAA were lower than those of the control. In another experiment, diets containing 0, 10, 20, and 30% ervil seeds soaked at 40 C in 1% AA, and 30% raw ervil seeds were fed to hens for 56 d. Performance and egg quality parameters of birds fed all levels of treated ervil seeds were comparable to those of the control. A level as high as 30% of acetic acid treated ervil seeds can be used in layer diets.

Key Words: *Vicia ervilia*, Acetic acid soaking, Laying hens

1354 The effect of Eggshell 49TM and mussel shell on performance and eggshell quality of laying hens. Ruedi Hadorn¹, Hans Wiedmer¹, and Peter Spring*², ¹*Swiss Poultry Husbandry School, Zollikofen, Switzerland*, ²*Swiss College for Agriculture, Zollikofen, Switzerland*.

The aim of the present study was to evaluate the effect of Eggshell 49 and mussel shell on eggshell quality and performance of laying hens during the late phase of production. The trial was setup as a 2x2 factorial design with Eggshell 49 (0 and 1 kg/t) and mussel shell (no access and offered *ad libitum* during the afternoon) as experimental factors. The 20-week trial was conducted with 10 groups of White Lohmann Leghorn hens (176 hens per group). Hens were 49 weeks of age at the beginning of the trial. Hens were housed during their entire production cycle in floor pens. Each pen (23 m²) was equipped with a family nest box for egg laying. Feed (crumbles) and water were provided *ad libitum* in round feeders and on nipple drinkers, respectively. Birds received two different feeds (phase 1: 49-60 wks of age; 11.9 MJ UE, 18.0% CP, 3.75% Ca), phase 2: 61-68 wks of age; 11.6 MJ UE, 16.5% CP, 3.90% Ca) with nutrient contents meeting Swiss commercial diets. Egg production and mortality were determined daily. Egg classification was conducted once per laying period (28 d) while egg weight distribution was determined twice per laying period. In week 49, 58, and 66 thirty eggs per treatment were analyzed for specific weight, shell thickness and eggshell quality. Data were analyzed as a 2 x 2 factorial design with Eggshell 49 and mussel shell as experimental factors. Average egg production over the entire trial period was 86.1% and average daily feed intake was 136.0 g. Both egg production and feed intake were not affected by treatment. However, mortality over the entire trial period was significantly (P<0.05) reduced by the addition of Eggshell 49 (3.2 vs. 1.8%). Dietary supplementation with Eggshell 49 led to a change in egg size distribution. The percentage of regular size eggs (53-65g) was increased by 5%-points (38.6 vs. 43.6 %) and the proportion of large eggs (>65g) was decreased by 5 %-points (61.3 vs. 56.3 %) with Eggshell 49 supplementation (P<0.05). Eggshell quality and percentage of cracked eggs were not affected by treatment. In the present study *ad libitum* access to mussel shell had no effect on performance and eggshell quality in laying hens. However, Eggshell 49 changed egg size distribution and significantly reduced hen mortality.

Key Words: Eggshell 49, Mussel shell, Mortality

1355 High oleic acid corn in turkey diets: carcass composition and parts yield of market tom turkeys. T. Ergul*¹, P.B. Addis¹, J. Brannon¹, M.L. Endres², and S.L. Noll¹, ¹*University of Minnesota, St. Paul, MN/USA*, ²*Mycogen Seeds, Inc., Eagan, MN/USA*.

Male market turkeys (Large White, Nicholas strain) were evaluated to determine the effect of feeding high oleic acid corn (HOAC) on carcass

composition and parts yield. Poults (450) were randomly assigned to 45 pens at day of age and fed one of five different dietary treatments (TRT) varying in source of corn to 20 wks of age. TRT 1 (Control) diets contained a conventional corn hybrid. TRTs 2, 3, 4 and 5 had 25, 50, 75 and 100% of the control corn replaced with HOAC, respectively. Diets were isocaloric and formulated based on NRC (1994) requirements. The experimental design was a randomized complete block design. Birds were weighed individually at 20 wks, and one turkey per pen (nearest the mean pen weight) was selected for carcass measurements. Live body weight, carcass weight (RTC without neck), parts yield weight and percentage of carcass parts (boneless and skinless breast, drums, thighs, wings, rack) were obtained. The carcass was ground once through a 3/4-inch diameter sieve and twice with a 3/16-inch diameter sieve. Homogenous samples were taken and freeze dried. Proximate analyses were conducted (DM, CP, gross energy, crude fat, ash). No significant differences were detected among the five TRTs for live weight, carcass weight and parts weight. Breast meat yield (% of carcass weight) was significantly affected by TRT (P < 0.05), with TRT 5 having a greater yield in comparison to other TRTs. Carcass composition test results indicated that percentage CP, fat, DM and amount of gross energy were not influenced by TRT. Inclusion of HOAC corn significantly (P < 0.05) lowered ash content of carcasses from turkeys fed TRTs 2 and 4 compared with Control. Inclusion of HOAC in place of normal corn in isocaloric and isonitrogenous diets produced equivalent carcass composition except for ash and carcass yield and also equivalent carcass yield except for breast meat in market tom turkeys.

Key Words: Turkey, Corn, Composition

1356 Evaluation of chachafruto (*erythrina edulis*) foliage meal as a source of protein in laying diets for Japanese quails. H Collazos* and L.E. Davila, *Universidad Nacional Abierta y a Distancia, UNAD, Departamento de Zootecnia*.

Chachafruto is a legume native to the Interandean valleys from Venezuela to Bolivia. It is a multipurpose tree valuable in subsistence and sustainable agriculture. An 8 week trial was designed to determine the influence of chachafruto foliage meal and its influence to laying quail performance, egg yields, and egg shell quality. 128 8 week-old Japanese laying quails were allotted in a completely randomized design with four treatments (0, 10, 20, and 30% of chachafruto foliage meal), four replicates and 8 birds per replicate. Birds were reared in a quad/deck cage in an environmentally controlled house. Diets were formulated to meet or exceed NRC recommendations. Water and feed were provided *ad libitum*. Feed intake, egg weight, specific gravity, egg shell thickness, egg shell breaking strength and egg shell percentage were not affected by treatment (P>0.05). Egg production percentage and feed conversion (kg/dz) were affected by treatment (P<0.05). Haugh units were significantly improved (P<0.05) by the higher rate of supplementation.

Key Words: Chachafruto, Quail, Haugh Units

1357 Cholecalciferol, 25-hydroxycholecalciferol and vitamin C for laying hens during the initial phase of the cycle of lay. Douglas Faria*¹, Daniely Salvador¹, Monica Mazalli¹, Samir Correa¹, and Diogo Ito, *Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brasil*.

An experiment was conducted to evaluate the influence of two sources of vitamin D (cholecalciferol and 25-hydroxycholecalciferol) at three levels of vitamin C (0, 100 and 200 ppm) on performance and internal and external egg quality characteristics. Total blood calcium and ionic calcium concentrations were determined. The basal level of cholecalciferol was 2,756 IU/kg corresponding to 5.51 g of Hy.D[®] per ton of feed, as the source of 25-hydroxycholecalciferol. Two hundred and eighty eight Isa Babcock B-300 commercial laying hens 23 weeks of age were used during the 12-week study. A 2 x 3 factorial arrangement with eight replicates of six hens each was utilized. Feed intake, egg production, egg weight and egg mass were not influenced by treatments. An interaction (P≤.01) was observed for improved feed conversion when vitamin C was not added and 25-hydroxycholecalciferol was fed. Haugh units and yolk index were not altered but interactions were verified for improved albumen percent (P≤.01) and yolk percent (P≤.05) with 200 ppm of vitamin C. Eggshell percent, total and ionic calcium were not modified by the factors studied. It was concluded that, for laying hens during the initial phase of the cycle of lay, feed conversion could be improved by

using 25-hydroxycholecalciferol and that the inclusion of vitamin C was not beneficial.

Key Words: Ascorbic acid, Cholecalciferol, 25-hydroxycholecalciferol

1358 Effect of formulation density and feed moisture type additives on feed manufacturing and pellet quality. J.S. Moritz*, K.J. Wilson, K.R. Cramer, R.S. Beyer, L.J. McKinney, and W.B. Cavalcanti, *Kansas State University, Manhattan, KS.*

Moisture addition to corn soybean-based diets at the mixer has been shown to increase pellet durability, decrease pellet mill energy consumption and improve adjusted broiler performance. These results were directly related to moisture addition being the sole treatment difference. Moisture added at the mixer can result in a diluted nutrient profile for diets originally formulated to NRC specifications. Diets of diluted nutrient profiles are not economically practical for feeding poultry. The primary objective of the current study was to clarify the relationship between moisture addition and formulation density and how the two factors influence the feed manufacturing process. A secondary objective was to compare different types of moisture additives for potential use in broiler feeds. Treatments consisted of different moisture type additives (water/surfactant solution vs. water) and formulations of different nutrient densities (NRC density vs. adjusted -high density). Negative control treatments, which consisted of the two diets of different nutrient densities without moisture additives were also produced. Each of the six treatments were applied to four 1,000 lb (454 kg) replicate batches. Improved pellet quality, defined as increased pellet durability ($P = 0.0001$) and decreased fines ($P = 0.001$), was established for both NRC and adjusted -high density formulations when moisture additives of either type were applied. Adjusted -high density treatments that included moisture had slightly higher yet statistically similar pellet quality parameters compared to the NRC negative control treatment. Pellet mill production rates were increased for adjusted -high density treatments compared to NRC treatments, although differences were not statistically significant. These results conclude that adjusted -high density broiler diets may increase pellet mill production rates, and with the addition of moisture maintain similar pellet quality compared to NRC diets.

Key Words: Feed Manufacturing, Diet Density, Moisture

1359 Influence of expander conditioning and feed form on broiler performance. K. J. Wilson, K. R. Cramer*, J. S. Moritz, W. B. Cavalcanti, and R. S. Beyer, *Kansas State University.*

The objective of the following two experiments was to evaluate the effects of expander conditioning and feed form on broiler performance in the starter phase. The treatments consisted of an unprocessed mash which served as a negative control, and 5 treatments conditioned at 180° F (82° C) but at different expander cone pressure levels. The expander cone pressure levels included 0, 100, 200, 300, and 400 lbs/in² (0, 7, 14, 21, 28 kg/cm²). The 6 treatments were used in both experiments. The expansion conditioning was performed using a Amandus Kahl model OE 15.2 annular gap expander and pellets were produced using a CPM pellet mill equipped with a 5/32-inch x 1 1/4-inch (4mm x 32mm) pellet die. The pellets were crumbled using a roll gap width of 2.2 mm. The chicks were housed in grower cages during both of the experiments. The diet was a standard NRC corn-soy starter ration. In experiment 1 all of the diets were reground and fed as a fine ground mash. This was performed to test for a potential nutritional effect due to the expansion process and to eliminate the confounding effect of feed form. The feed was reground using a Prater Pulverizer hammermill equipped with a 1/8-inch (3.18 mm) screen. The 6 treatments were fed to 10 replicate pens containing 10 chicks (day-old) in each pen. Broilers fed the unprocessed mash treatment had higher weight gain ($P=0.0001$), feed intake ($P=0.0227$), and improved feed efficiency ($P=0.0499$) compared to all of the thermally processed diets. In experiment 2 the crumbles were screened using a Tyler number 12 sieve (1.41 mm openings) in order to remove the fines. The screened crumbles and mash control was fed to 7 replicate pens with 10 chicks (day-old) in each pen. Broiler weight gain increased linearly ($P=0.0075$) and feed efficiency was improved ($P=0.0001$) as the level of

expander cone pressure increased. Based on the results of these experiments changes in broiler performance appear to be due to the effect of feed form.

Key Words: Feed Form, Expander Conditioning, Crumbles

1360 Effect of increasing level of fines in a crumbled starter diet on broiler performance. K. J. Wilson*, J. S. Moritz, K. R. Cramer, R. S. Beyer, and W. B. Cavalcanti, *Kansas State University.*

Fines are feed particulates, which do not remain in a bonded pellet or crumble form. There are a number of factors that can influence the amount of fines generated during and following the feed manufacturing process. In past research increasing levels of fines in pelleted diets has negatively influenced broiler performance. The majority of this research has been conducted during the grower and finisher phases when diets are fed in the pellet form. The objective of this experiment was to determine the level of fines at which broiler performance would be negatively influenced when fed a crumbled starter diet. Crumbles were manufactured from pellets of high durability. A conditioning temperature of 180° F (82° C) and expander cone pressure level of 200 lbs/in² (14 kg/cm²) was used for the pelleting process. The expansion conditioning was performed using a Amandus Kahl model OE 15.2 annular gap expander and pellets were produced using a CPM pellet mill equipped with a 5/32-inch x 1 1/4-inch (4mm x 32mm) pellet die. The pellets were crumbled using a roll gap width of 2.2 mm. The crumbles were then screened using a Tyler number 12 sieve that had openings of 1.41 mm. The fines were produced by grinding pellets through a Prater Pulverizer hammermill that was equipped with a 3/32-inch (2.38 mm) screen. The pellets used for the production of the crumbles and fines were from the same source. The fines were then mixed with the sifted crumbles in order to have 0, 25, 50, 75, and 100 percent fines inclusion. The fines and crumbles were combined together using a Hobart mixer with a mix time of 30 seconds and at the lowest speed setting. The 5 treatments were fed to 7 replicate pens containing 10 chicks (day-old) per pen. The chicks were housed in grower cages during this experiment. The diet was a standard NRC corn-soy starter ration. Broiler weight gain, feed intake, and feed efficiency were negatively influenced by increasing levels of fines (Linear, $P=0.0001$). Based on the results of this experiment a level of fines exceeding 25 percent can negatively affect broiler performance in the starter phase.

Key Words: Crumbles, Fines, Broiler Starter Phase

1361 Impact of increasing levels of expander cone pressure on feed manufacturing characteristics of a broiler starter ration. K. J. Wilson*, L. J. McKinney, K. R. Cramer, J. S. Moritz, W. B. Cavalcanti, R. S. Beyer, and K. C. Behnke, *Kansas State University.*

The objective of this experiment was to evaluate how increasing levels of expander cone pressure impacts the feed manufacturing characteristics of a broiler starter ration. The feed milling characteristics that served as the response criteria included pellet and crumble durability, pellet and crumble bulk density and specific electrical energy consumption for both the annular gap expander and pellet mill. This experiment was arranged as a randomized complete block design with treatment processing order as the blocking criterion. Five levels of expander cone pressure consisting of 0, 100, 200, 300, and 400 lbs/in² (0, 7, 14, 21, and 28 kg/cm²) were evaluated in this experiment. Each of the five treatments was replicated three times. A conditioning temperature of 180° F (82° C) was used for all treatments. The expansion conditioning was performed using an Amandus Kahl model OE 15.2 annular gap expander and pellets were produced using a CPM pellet mill equipped with a 5/32-inch x 1 1/4-inch (4mm x 32mm) pellet die. The pellets were crumbled using a roll gap width of 2.2 mm. The diet was a standard NRC corn-soy starter ration. Raising the expander cone pressure level improved both pellet ($P=0.0001$) and crumble durability ($P=0.0031$). Pellet ($P=0.0150$) and crumble ($P=0.0217$) bulk density improved as the level of expander cone pressure increased. There was a linear ($P=0.0001$) increase in specific electrical energy consumption for the expander as cone pressure level increased. There was a linear ($P=0.0001$) decrease in energy required to pellet the broiler ration as expander cone pressure level increased. Based on the results of this experiment the pellet and crumble durability can be improved by increasing the level of pressure applied to the feed via the annular gap expander. The crumble and pellet bulk densities can

also be improved by increasing the level of cone pressure. A reduction in the energy required to pellet feed was obtained by raising the expander cone pressure, however total electrical energy usage increased with each corresponding rise in cone pressure level. To economically justify using an expander the benefits must offset the higher capital and operational expenses.

Key Words: Crumble Durability, Expander Cone Pressure, Pellet Durability

1362 Effect of crumble quality on broiler performance. K. J. Wilson*, R. S. Beyer, J. S. Moritz, K. R. Cramer, W. B. Cavalcanti, L. J. McKinney, and K. C. Behnke, *Kansas State University*.

In a previous feed manufacturing experiment crumble durability was improved by increasing the level of expander cone pressure. Crumble durability is one method used to define the physical quality of the crumbled feed. The objective of the following two experiments was to determine the effect of crumble quality on broiler performance. The diet used in these experiments was a standard NRC corn-soy starter ration. The treatments consisted of an unprocessed mash which served as a negative control, and 5 treatments conditioned at 180° F (82° C) but at different expander cone pressure levels. The 6 treatments were used in both experiments. The expander cone pressure levels included 0, 100, 200, 300, and 400 lbs/in² (0, 7, 14, 21, 28 kg/cm²). The expansion conditioning was performed using an Amandus Kahl model OE 15.2 annular gap expander and pellets were produced using a CPM pellet mill equipped with a 5/32-inch x 1 1/4-inch (4mm x 32mm) pellet die. The durability of the pellets improved from 27.43 percent up to 87.76 percent as the expander cone pressure level increased. The fines were not separated from the pellets prior to crumbling. The pellets were crumbled using a roll gap width of 2.2 mm. A durability test was conducted to provide descriptive information related to the quality of the crumbles. The crumble durability values were improved by increasing the expander cone pressure level indicating an improvement in crumble quality. In both experiments the six treatments were fed to 5 replicate floor pens containing 40 chicks (day-old) per pen. Feeding mash compared to the thermally processed treatments resulted in inferior (P<0.05) weight gain and feed efficiency in both experiments. Within the thermally processed treatments there were slight differences (P<0.05) in broiler weight gain for experiment 1 but not for experiment 2. Feed efficiency improved in both experiments as the level of cone pressure increased (P<0.05) and was most likely due to improvements in crumble quality. Based on the results of these two experiments broiler performance may be influenced by crumble quality. The initial durability of the pellets plays a direct role in determining the quality of the crumbles.

Key Words: Crumble Quality, Pellet Durability, Expander

1363 Effect of *Aspergillus* sp and bacterial phytase containing broiler diets on body weight, gastrointestinal transit time and the crop and cecum pH of the broiler chick. G Nava*¹, N Ledesma¹, A Priego², C Priego², L Sutton³, and G Tellez¹, ¹Departamento de Produccion Animal: Aves, Facultad de Medicina Veterinaria y Zootecnia, UNAM-Mxico, ²Productos Quimicos-Agropecuarios S.A. de C.V. Mexico, ³PetAg Inc, Hampshire, IL 60140 USA..

Both enzyme (bacterial phytase) and prebiotic (*Aspergillus* sp) have been used to improve broiler performance but the specific mechanism of action is not well known. A trial was conducted to determine the effects of adding 0.2% prebiotic, 0.04% enzyme and the combination on body weight (BW), gastrointestinal transit time (GTT) and pH changes in crop and cecum of the broiler chick. This experiment employed a completely randomized design. All of the sorghum plus soybean (S/S) diets were isocaloric and isonitrogenous and consisted of four diets with two replicates of 30 birds each (n = 240). The four experimental diets were: 1).Control S/S diet; 2).Control plus prebiotic; 3).Control plus enzyme; and 4).Control plus prebiotic and enzyme. On days 1, 9, 16 and 27, ten chicks from each diet were weighed. GTT was evaluated on days 15 and 26 using ten chicks from each diet. Crop and cecal content pH were performed on days 10 and 20 using ten chicks from each diet. There were no significant differences (P>0.05) between diets for body weight. The dietary effect was not significant for the GTT measurements at day 15 (results: 135.20^a, 168.60^a, 152.40^a and 152.20^a minutes for diet one through four, respectively). The dietary effect upon GTT at day 26

was significantly longer (P<0.05) for the prebiotic diet (results: 161.9^b, 193.20^a, 187.20^{ab} and 178.80^{ab} minutes for diet one through four, respectively). The cecum pHs were modified (P<0.05) at days 10 by the enzyme diet and the prebiotic diets (results: 6.06^a, 5.79^{ab}, 5.40^b and 5.82^{ab} pH units for diet one through four, respectively). The prebiotic and enzyme may function as a bacterial substrate that modify the intestinal microflora resulting in changes in the intestinal physiology and bacterial metabolite production.

Key Words: Prebiotic, Enzyme, Transit

1364 Effect of *Aspergillus* sp and bacterial phytase containing broiler diets on intestinal villi size and blood chemistries of the broiler chick. G Nava*¹, N Ledesma¹, A Priego², C Priego², L Sutton³, and G Tellez¹, ¹Departamento de Produccion Animal: Aves, Facultad de Medicina Veterinaria y Zootecnia, UNAM-Mxico, ²Productos Quimicos-Agropecuarios S.A. de C.V. Mexico, ³PetAg Inc, Hampshire, IL 60140 USA..

The addition of enzyme (bacterial phytase) and prebiotic (*Aspergillus* sp) to the broiler chick diet improve gastrointestinal microbial activity causing an increase of fatty volatile acid (VFA). The increase of VFA has been related to the nutrient absorption process. A trial was conducted to determine the effects of adding 0.2% prebiotic, 0.04% enzyme and the combination on the intestinal villi size and blood chemistries of the broiler chick. This experiment employed a completely randomized design. All of the sorghum plus soybean (S/S) diets were isocaloric and isonitrogenous and consisted of four diets with two replicates of 30 birds each (n=240). The four experimental diets were: 1)Control S/S diet; 2)Control plus prebiotic; 3)Control plus enzyme; and 4)Control plus prebiotic and enzyme. On day 10 and 20, ten serum samples per experimental diet were analyzed for glucose, calcium, phosphorus and alkaline phosphatase. From the same chicks samples of the ileum and cecum were fixed in 10% formaline and subsequently microscopically evaluated for morphological changes. There were no significant dietary effects (P>0.05) on the blood parameters analyzed. The intestinal villi size of the ileum and cecum of the 10 day-old broiler chick demonstrated no dietary effect (P>0.05). The intestinal villi size of the ileum of the 20 day-old broiler chick demonstrated significant dietary effect (P<0.05) due to the prebiotic addition (results: 392.4^b, 768.0^a, 505.^b 2 and 411.6^b microns for diet one through four, respectively). There were no significant dietary differences (P>0.05) in the length of the cecum villi in the 20 day-old chick (results: 233.40^a, 249.60^a, 199.20^a and 233.40^a microns for diet one through four, respectively). The prebiotic supplementation in neonatal broiler chick diets may improve the intestinal microflora activity and bacterial metabolite production (VFA) as related to the increase of 20 day-old ileum villi length.

Key Words: Apergillus meal, Phytase, Ileum villi

1365 Effect of phytase, organic trace minerals and age at photostimulation on performance of brown eggshell laying hens. T. Ao*, N. D. Paton, A. H. Cantor, A. J. Pescatore, M. J. Ford, and C. A. Smith, *University of Kentucky*.

The effects of supplementing a low-phosphorus basal diet with phytase (Alltech, Nicholasville, KY) and organic forms of Mn, Zn and Cu (ES49) (Eggshell 49, Alltech) and of age of pullets at photostimulation on egg production variables were studied. Using a commercial strain of laying hens (Hy-Line) producing brown shelled eggs, 18 replicate groups of 12 hens, housed two per cage, were assigned to each of four dietary treatments. Hens were housed and subjected to photostimulation at 15, 16 or 17 wk of age. The basal diet was fed alone or supplemented with phytase (11,500 ptu/kg diet) or ES49 (providing 4.5 mg Mn, 7.5 mg Zn and 1 mg Cu per kg diet as proteinates) in a factorial arrangement. Calculated nutrient values of the basal diet were: 2900 kcal AME/kg, 16.6% CP, 0.47% Met, 3.75% Ca and 0.17% available P. A trace mineral supplement used in all diets provided 51 mg Mn, 60 mg Zn and 8 mg Cu per kg diet as inorganic salts. Production variables were measured during a 52-wk period, starting at 17 wk of age. Feed intake during the 52-wk period was unaffected by diet, but responded linearly (P < 0.05) to age at housing. Hens housed at 15, 16 and 17 wk of age consumed 104, 105 and 107 g/hen/d, respectively. Hen-day egg production for the 52-wk period (mean = 81.5%) was unaffected by both age at housing and diet. Housing at 17 wk (*vs.* 15 and 16 wk) increased average egg weight (61.6 g *vs.* 60.5 and 60.4 g) but decreased average per cent shell

(8.93% vs. 9.18 and 9.12%). Phytase significantly increased the breaking strength of the humerus, but not the tibia, measured after 45 wk of production. These results indicate that early photostimulation decreases egg weight and feed intake and increases per cent shell, and that the levels of available P, Mn, Zn and Cu in the basal diet are adequate to support layer performance. However, the increased humerus breaking strength due to phytase suggests that the level of P was marginal for maintaining bone strength.

Key Words: Phosphorus, Phytase, Photostimulation

1366 Sources and levels of total phosphorus in the diet of broilers from 2 to 28 days of age. L. F. Araujo*¹, O. M. Junqueira¹, D. Mucke², R. Knoop², and C. S. S. Araujo¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal - Brazil, ²Burge Fertilizantes S/A - Sao Paulo - Brazil.

One experiment was conducted to evaluate the performance of broilers receiving various sources and levels of phosphorus from 2 to 28 days of age. Four hundred chickens, 2 days of age, were distributed in a 4 x 2 factorial design (4 sources of phosphates - fine dicalcium phosphate (FDP); granulate dicalcium phosphate (GDP); a mixture of dicalcium phosphate + sodium (DPS); defluorinated phosphate (DFP) and two total phosphorus levels - 0.60% and 0.70%) with 8 treatments and 5 replications of 10 birds each. At the end of the experiment, two birds of each pen were slaughtered to obtain the tibia bone for phosphorus, calcium, magnesium and fluorine. There were no interactions between the treatments. The best weight gain and feed conversion were found in the birds receiving the diet containing GDP in the presence of 0.70% total phosphorus. The worst weight gains and poorest feed conversions were from birds fed the diet with DPS and 0.70% total phosphorus. The highest feed intakes were from diets containing GDP and 0.70% total phosphorus. There was no difference in the tibia calcium, phosphorus and magnesium between studied treatments. However, broilers fed the diets containing DPS and DFP showed, respectively, higher and lower tibia fluorine. According the results obtained, it is concluded that the best performance was from broilers fed diet with GDP and the level of 0.70% total phosphorus. The tibia fluoride level was lower in DFP diets. Acknowledgements: Burge Fertilizantes S/A Brazil for technical support.

ASAS/ADSA Animal Health

1368 *In vitro* aflatoxin binding characteristics of an esterified glucomannan product. J.W. Evans* and M. Kudupojje, *Alltech Biotechnology Inc., Nicholasville, KY.*

Mycotoxin binders have been shown to reduce the deleterious effects of aflatoxin in animals. A series of experiments were conducted to examine the binding characteristics of an esterified glucomannan (EGM) derived from the yeast cell wall of *Saccharomyces cerevisiae*. The EGM has been shown to reduce the toxic effects of aflatoxin in livestock. In the first study, an *in vitro* binding assay was used to determine the saturation point of aflatoxin binding by EGM in water or phosphate buffer. The binder (0.1%) was mixed with increasing concentrations of toxin (2,4,6,8 and 10 ppm in water/18, 20, 22, 24 and 26 ppm in buffer), centrifuged and unbound toxin concentrations were determined in the supernatant. The saturation point was defined as the minimum binder concentration at which maximum binding is reached. The saturation point for aflatoxin binding was greater in phosphate buffer than in water (8 vs. 24 ppm). In addition, aflatoxin binding responded to phosphate concentrations in a quadratic fashion ($P < 0.001$). Another trial was conducted to determine binding strength in water and phosphate buffer. Aflatoxin (1 ppm) and EGM (0.1%) were mixed, incubated at 37°C for 1 h, and centrifuged. Toxin concentrations were determined in the supernatant and pellet after three methanol extractions. Binding was stronger in the phosphate buffer than in water as indicated by lower aflatoxin recovery in the buffer (568 vs. 279 ppb, $P < 0.001$). A third study compared the saturation points of the EGM and a clay binder (CB). Both binders were mixed in water with increasing toxin concentrations until saturation was reached. The binding capacity of EGM in water was more than four times higher than CB (5.2 vs. 1.2

1367 Total phosphorus (TP) requirements of meat chickens from 3 to 7 weeks of age. A. Abudabos*, D. V. Maurice, S. F. Lightsey, and W. C. Bridges, Jr.¹, *Animal & Veterinary Sciences, ¹Department of Experimental Statistics, Clemson University, Clemson, SC.*

We previously reported that dietary phytate P is utilized and TP could be decreased without impairment in productivity and substantial reduction in P excretion. However, the variation in body weight between birds on the same treatment prompted us to examine the response of birds, sorted by weight, to dietary TP. The aim of this experiment was to determine the effect of dietary TP in birds sorted into 2 groups: heavy (H) and light (L) at 3 wk. of age; then each group received 4 different diets. Corn-soybean diets were formulated, based on assayed TP values checked with standard reference materials, to contain 0.5, 0.55, 0.6 and 0.65% TP from 3-6 weeks and 0.38, 0.55, 0.6, and 0.65% TP from 6-7 weeks of age. Each diet was fed to 3 pens of each weight group. We measured the effects of TP, gender, and weight groups on growth, breast muscle yield, serum P, bone ash and measures of bone integrity, and intestinal phytase activity. Interactions were not detected and neither dietary TP or weight group had a significant effect on feed intake, body weight gain, feed conversion, breast muscle yield, and intestinal phytase at 6 weeks. Serum P was decreased in birds fed 0.5 % TP when compared to those fed the other three diets ($P < 0.001$). The responses at 7 weeks were similar to those observed at 6 weeks except that gender and weight group effects were detected. Serum P was a function of the amount of inorganic P in the diet ($P < 0.0001$). Phytase activity was dramatically affected by diet ($P < 0.02$); birds that received the 0.38% TP diet (no inorganic supplement) had the highest activity. Bone ash decreased ($P < 0.0001$) as dietary TP was lowered but femoral and tibial length, weight, cross-sectional area, polar moment of inertia, and area moment of inertia were not affected by diet. The results show that dietary P can be lowered from 3 to 7 weeks without loss in performance and reduction in mechanical properties of long bones.

Key Words: Dietary Phosphorus, Intestinal Phytase, Growth, Bone Integrity

$\mu\text{g}/\text{mg}$ binder, $P < 0.001$). This series of studies showed that EGM is able to bind aflatoxin and not mask or destroy it. In addition, aflatoxin binding by EGM is phosphate dependent and more efficient at binding aflatoxin than binding by the CB tested.

1369 Growth and immune function of calves fed milk replacer with added nitrate. S. T. Franklin, R. O'Carra, R. J. Harmon, D. M. Amaral-Phillips, and J. A. Jackson, *University of Kentucky, Lexington, KY.*

A concentration of 10 - 20 ppm nitrate-N in water is considered a health risk for humans and may cause methemoglobinemia. Little is known, however, of the effects of nitrate-N on health and immune function of neonatal dairy calves. Thus, 24 calves (4 Jersey and 20 Holstein; male = 12 and female = 12) were assigned to treatments of 0, 10, 20, or 40 ppm nitrate-N (as potassium nitrate) added to reconstituted milk replacer. Calves were moved to individual calf hutches and assigned to treatments at an average of approximately 5 d of age. Milk replacer (20% protein and 20% fat) was reconstituted in water to provide 0.45 kg of solids daily and fed in two equal feedings. Nitrate-N was added to reconstituted milk replacer at each feeding. Milk replacer intake was recorded at each feeding and starter consumption was determined daily. At 5 wk of age, milk replacer was fed once daily and calves were weaned at 6 wk of age. Calves were weighed when moved to hutches and weekly thereafter. Blood samples were obtained at 2 wk intervals for total white blood cell counts, neutrophil function assays, and proliferation assays. There was no effect ($P > 0.05$) of nitrate-N addition to milk replacer on

body weights of calves, total white blood cell counts, ingestion or killing of *Staphylococcus aureus*, or proliferation of mononuclear leukocytes in response to mitogen stimulation. Both ingestion and killing of *Staphylococcus aureus* decreased ($P < 0.01$) over the 6 wk study. For wk 0, ingestion of *S. aureus* averaged 11.5 bacteria per neutrophil and for wk 6 averaged 8.4 bacteria per neutrophil. Killing for wk 0 averaged 34% of added bacteria compared to 23% for wk 6. Ingestion and killing also were lower ($P < 0.01$) for winter versus spring calves. Ingestion of *S. aureus* averaged 10.8 bacteria per neutrophil for winter calves and 9.1 bacteria per neutrophil for spring calves. Similarly, killing averaged 33% of added bacteria by neutrophils from winter calves compared to 26% killing of added bacteria by neutrophils from spring calves. In conclusion, nitrate-N at concentrations up to 40 ppm in milk replacer did not greatly affect growth or immune function of neonatal calves, however, neutrophil function decreased as calves aged and was lower in spring compared to winter.

Key Words: Nitrate, Calves, Immune function

1370 Brain cholinesterase activity in cattle exposed to coumaphos in Mexico. V. Pardo^{*1}, N. Ibarra¹, A. Velasquez², B. Nochebuena¹, E. De la Cruz¹, and J. Alfaro¹, ¹Universidad Veracruzana, Veracruz, Veracruz/Mexico, ²Instituto Mexicano del Seguro Social, Veracruz, Veracruz/Mexico.

The purpose of the study was to determine Cholinesterase (ChEs) activity values from brain stem of cattle to evaluate the exposure to organophosphate pesticides, since the intensive use of these pesticides in Mexico represents a potential danger to livestock and to human health. Four groups of ten animals from different areas were sampled. Brain stems from mature male adults *Bos taurus* x *Bos indicus* 18 months of age were collected at the Federal Inspection slaughter in Veracruz, Mexico. Brain stem was removed according to official Mexican procedure and placed into cold buffered isotonic solution. Brain stem was sectioned into protuberance, medulla oblongata and the cervical region of spinal cord. ChE activity determination was according to Ellman method and AchE was assayed with iso-OMPA. Cholinesterase activities were expressed as UI/mL. Results were analyzed by ANOVA with Minitab 10.5. The mean AchE activity in medulla oblongata section of the animals dipped in coumaphos at the recommended dose every 21 days during 3 months was significantly lower than a group of animals not treated with any pesticide from the farm of the Faculty of Veterinary Medicine, but not statistically different from the other groups analyzed. The mean ChE and AchE activities in medulla oblongata and spinal cord of a group of animals dipped in coumaphos at the recommended dose every 21 days during 6 months were significantly lower than a group of animals not treated with any pesticide and than the group of animals dipped during 3 months. The mean AchE activities in medulla oblongata and spinal cord of the group of animals sprayed with coumaphos at the recommended dose twice a month during 6 months were significantly lower than the group of animals not treated with any pesticide and than the group dipped during 3 months. Among the three sections of tissue analyzed, medulla oblongata mean AchE activity was statistically higher than the AchE activities of the protuberance and spinal cord. Results indicate that medulla oblongata of cattle represents a useful area for measurement ChE activity for laboratory screening as an aid in diagnosing anticholinesterase insecticides exposure in cattle.

Key Words: Organophosphate pesticides, cholinesterase activity, brain stem

1371 Extension needs and approaches towards livestock health improvement in Bangladesh : Proshika experience. Nuru Miah, *Proshika Manobik Unnayan Kendra, Bangladesh.*

Livestock contributes 6.5% percent of the GDP and 13% of the agricultural GDP in Bangladesh. The livestock sector has been trapped in low productivity levels due to inadequate extension coverage of the Govt. sector. Proshika, one of the largest Non Govt. Development Organisations in Bangladesh has been operating livestock extension and support services in its working areas. It provides livestock extension services to cattle and poultry farmers through well trained resource persons. About 60 to 100 vaccinators, 10 to 15 paravets, 4 to 6 A.I. technicians, and 4-6 feed sellers in each upzilla are engaged in providing vaccination, deworming, treatment, artificial insemination services, and suppling quality feeds to rearers of cattle and poultry. Veterinary drug pharmacies are operated by advanced paravets. These extension agents

are selected from proshika group members, trained for particular skills, provided equipment boxes with equipment's, and are allocated to working areas to maintain strong links to producers. Vaccines not produced locally are imported by Proshika and supplied to the beneficiaries. Fees are collected from cattle and poultry owners for their livelihood. These extension activities have reduced poultry mortality from 20 percent to 5 to 7 percent; cattle mortality has been reduced from 10 to 15 percent to 3-4 percent. These efforts have significantly increased the livestock and poultry population. Farmers undertaking different livestock rearing projects have increased their income up to 150 percent. The monthly net income of vaccinators, paravets and A.I. technicians varies from US Dollar 15 to 45 based on the activity. These extension approaches contribute towards the increased productivity of livestock resources, enhancement of gender equity and equality, and ensure participation of vulnerable women in productive enterprises.

1372 Bedding material preferences of crossbred cattle. DilipKumar Garikipati^{*1}, Kailash M. M.², and Sarjan Rao Kapa¹, ¹College of Veterinary Sciences, Tirupati, ²Bangalore Agricultural University.

Twenty crossbred HF cattle were examined for preferences in bedding materials. Two experiments were done. In experiment 1, crossbred cattle (n=10) were housed individually with access to 3 free stalls, each with different bedding material: Paddy straw, sawdust, or deep-bedded sand. After access to all 3 materials for 10 days, preference was determined by stall use and lying times, recorded for 24 h by videotape recorder. Each animal was then restricted to either sand or paddy straw for period of one week. Average lying time, and numbers of transitions between standing and lying, were significantly ($p < 0.05$) less than when animals were restricted to sand or paddy straw. After the restriction phase, animals were again allowed access to all 3 bedding types and final preference was determined. Nine of 10 animals continued to choose sawdust. In experiment 2, 10 more animals were tested with sawdust, sand (both as described above), and paddy straw and waste paper materials. Initial & final preference tests as described above showed that 8 of 10 cows preferred sawdust. In the middle stage of the experiment all animals were restricted to each bedding material, in turn, for 5 days. Average lying time, time spent in the stall, and transition to lying were significantly ($P < 0.02$) lower for the sand - bedded stalls but there was no differences between other 2 surfaces. These results indicate that (1) cows prefer deep bedded sawdust, (2) that lying time, time spent in the stall, and number of lying transitions are affected when cows are provided with sand and paddy straw, but not with paddy straw covered with waste paper material.

Key Words: cow comfort, behavior, well-being

1373 Economic Efficacy of Treatment Protocols for Clinical Mastitis. E.H. Shim^{*}, R.D. Shanks, and D.E. Morin, *University of Illinois, Urbana.*

The objective was to quantify the costs associated with two treatment protocols and the differences between the use of supportive therapy alone versus antibiotics in addition to supportive therapy. Between January 1994 and December 1995, 116,876 daily milk (DM) records on 676 lactations were taken at the University of Illinois Dairy Unit. Mastitis was diagnosed during 124 lactations with 25,047 DM records. Based on examination, each cow with clinical mastitis was assigned a severity score of 1 (least severe) to 3 (most severe) and randomly assigned to one of two treatment groups: N (supportive treatment only) and A (antibiotics in addition to supportive treatment). Extent of antibiotic and supportive treatment varied according to protocols. A treatment cost analysis was calculated for all lactations with at least one case of mastitis. Predicted and actual DM yields were estimated utilizing a random regression-test day model. The differences between the predicted and actual DM were summed for all 305 days of lactation to estimate milk loss for each mastitic lactation. Lactations that utilized antibiotics in addition to supportive therapy incurred \$21 per lactation more in average treatment costs than lactations utilizing supportive therapy alone. Cows treated with supportive therapy alone lost 1,530 kg more marketable milk per lactation than cows treated with both antibiotics and supportive therapy. The addition of antibiotics to supportive therapy reduced the total economic loss by \$382 per treated lactation. Based on smaller milk yield and economic losses, the efficacy of antibiotics

in addition to supportive therapy was greater than supportive therapy alone.

	A	N
Average number of days with clinical mastitis	13	22
Average treatment cost	\$49	\$28
Average 305-day milk yield loss (kg)	182	1809
Milk loss due to unmarketable or unproduced milk (kg)	513	2043
Cost of lost milk*	\$135	\$538
Total cost (cost of lost milk and treatment)*	\$184	\$566

*based on the February class 1 mover milk price of \$0.2632 per kg

1374 Effect of Left Displacement of Abomasum (LDA) Corrected by Toggle Pin Suture on Performance of Holstein Dairy Cows. J.E.P. Santos¹, E. Raizman^{*1}, L.G. Corbellini², and R.A. Cerri¹, ¹University of California, Davis, ²Universidade Federal do Rio Grande do Sul.

Objectives were to evaluate the effects of left displacement of abomasum (LDA) corrected by toggle pin suture on performance of lactating Holstein cows. Cows calving between June 1997 and February 2000 (374; 188 LDA and 186 controls) from a commercial dairy farm in central California were followed during the first 320 days in milk (DIM). Cows were diagnosed with LDA by the herd veterinarian and treated by the herd personnel by rolling the cow over her back and tacking the abomasum with toggles introduced after trocar punctures. Every LDA cow was matched with a herdmate that calved within 14 d of the affected cow's calving date, was in the same lactation and had a similar 305-d mature equivalent (ME) milk yield in the previous lactation (300 kg). Only cows that stayed in the herd for more than 60 DIM were included in the analyses. Continuous variables were analyzed by ANOVA and binomial data by Chi-square. Cows affected with LDA produced less milk (33.3 vs 31.6 kg/d; $P < .01$) and 3.5% FCM (33.2 vs 32.0 kg/d; $P < .06$), and had a lower 305-d ME milk yield (12,563 vs 12,073 kg; $P < .05$). However, milk fat yield (1.16 vs 1.13 kg/d; $P < .22$) and linear SCC (2.68 vs 2.86; $P < .24$) were similar, and milk fat content tended to be higher for cows with LDA compared with controls (3.51 vs 3.60; $P < .08$). Cows with LDA had a prolonged period from calving to first AI (77.9 vs 92.8; $P < .001$), but first AI conception rate, percentage of cows pregnant by 150 and 320 DIM were unaffected by LDA. Mean days open for pregnant and for all cows were unaffected by LDA, as well as the incidence of abortion and mastitis. Days in milk at the first clinical mastitis case tended to be lower for cows with LDA (140.7 vs 94.0; $P < .12$). Nevertheless, more LDA cows died (1.1 vs 8.0%; $P < .001$) or were sold (9.1 vs 27.7%; $P < .001$) by the end of the study. In addition, LDA cows left the herd (dead or sold) earlier in lactation (230.2 vs 102.1 DIM; $P < .001$). In conclusion, cows affected with LDA produced less milk, but most of the lactation losses were caused by increased death and culling early in lactation.

Key Words: Left displacement of abomasum, Dairy cows, Lactation

1375 Effect of disease on fertility traits in Swedish dairy cattle using survival analysis methodology. D.O. Maizon^{*1,2} and P.A. Oltenacu¹, ¹Department of Animal Science, Cornell University, ²Facultad de Ciencias Veterinarias, Universidad de Buenos Aires.

Fertility traits are economically important in dairy cattle herds. In this study, the effect of disease on days from calving to conception was estimated. A sample of 20% of all cows that calved in Swedish farms in 1991 was used. The final data set was restricted to cows in their second or greater lactation with at least one service after calving, and consisted of 18,114 Ayrshire (SRB), and 12,530 Friesian (SLB) cows. Since days from calving to conception is a time-to-event variable, and about 26% are censored records in each breed, the analyses were performed using the Survival Kit software. A Weibull model was assumed, each breed was analyzed separately, and assessments were based on the likelihood ratio test. The models included the following confounders: season of calving, length of previous dry period, herd size, and average fat corrected milk of herd and cow, all treated as classificatory variables. The diseases studied were dystocia (DYST), milk fever (MKFV), and retained placenta (REPL) as time-independent covariates, and cystic ovaries (CYST), metritis (METR), other reproductive diseases (OTRE), mastitis (MAST), ketosis (KETS), feet and leg disorders (FFET), and

other diseases (OTHE) as time-dependent covariates. The diseases with negative and statistically significant ($p < 0.05$) effects on days from calving to conception were RTPL, CYST, and MAST in SRB cows, and DYST, OTRE, METR, MAST, and OTHE in SLB cows. The corresponding risk ratios, statistically different from one ($p < 0.05$), for these diseases were 0.785, 0.893, and 0.876 in SRB cows, and 0.638, 0.669, 0.742, 0.871, and 0.82 in SLB cows, respectively. These risk ratios indicate that these diseases decrease the probability of conception, and increase the time-to-conception.

1376 The diagnostic value of serum cholesterol in cows and newborn calves. R. Skrzypek^{*}, Agricultural University of Poznan, Poland.

The study was conducted on 210 cow-calf pairs of crosses between native Black-and-White cattle and Holsteins. Cows were sampled 7-8 weeks before expected parturition, and 12-14 hours after parturition. Calves were sampled at the age of 24 hours, and 5 days after birth. There was found no significant relationship between the course of the parturition period (normal delivery, dystocia, placenta retention, and milk fever), and concentration of serum total cholesterol (TCh) in cows, as well as in their calves. In cows, serum TCh concentration tested before parturition was correlated negatively with the number of insemination services per confirmed pregnancy, and length of calving interval ($r \sim -0.2$; $P \leq 0.05$). Before parturition, cows with the shortest calving interval (≤ 365 days) compared to cows with the longest calving interval ($401 \leq$ days) had significantly higher serum TCh concentration by 0.20 mmol/L ($P \leq 0.05$). After parturition, the highest serum TCh concentration was found in the group of cows with medium length of calving interval (366-400 days). In calves that were afflicted with diarrhoea or died during the first month after birth, at both samplings it was found significantly lower serum TCh concentration (range from 0.10 mmol/L; $P \leq 0.05$ to 0.19 mmol/L; $P \leq 0.01$), as compared to control calves. It is concluded, that serum total cholesterol concentration is associated positively with reproductive performance of cows, as well as health and survival of the newborn calves.

Key Words: Cattle, Serum cholesterol, Diagnostic value

1377 Development of a DNA-based vaccine for the prevention of staphylococcal mastitis. E.W. Carter^{*} and D.E. Kerr, University of Vermont, Burlington VT.

Staphylococcus aureus often results in a chronic infection of dairy cows. Current vaccine formulations are often ineffective in preventing infection. The objective of this study was to stimulate an immune response in dairy cows through injection of plasmid DNA containing a staphylococcal Protein A gene. To determine the most effective method of DNA-based vaccination of cows, intramuscular and intradermal vaccination sites were evaluated using a plasmid containing the jelly-fish Green Fluorescent Protein (GFP) gene. DNA was delivered by needle and syringe, or by high or low-pressure jet injection. For each injection site, 15 animals, six weeks prepartum, were assigned to receive DNA by one of the three delivery techniques. On each of three days, at two week intervals, each animal was given three injections (0.17 ml) containing a total of 0.5 mg of plasmid in 0.15 M saline. Serum samples were collected at two week intervals for anti-GFP antibody analysis by ELISA. Antibody titers (1/100 dilution) peaked approximately two weeks after the final injection. It was found that intradermal high-pressure jet-injection elicited the best response (3 of 4 animals responding). In contrast, needle and syringe delivery was ineffective while response to low pressure injection was intermediate. Similar results developed from intramuscular injection. A Protein A expression plasmid was constructed with an 827bp fragment of the Protein A gene inserted downstream of the CMV promoter region in the pcDNA3 vector. Protein A expression by eukaryotic cells was evaluated by transfection of COS-7 cells followed by Western blot analysis. The results confirmed the expression of the expected 32 kD Protein A. This plasmid is currently being evaluated as a vaccine in cows using high-pressure jet-injection. Specific humoral (ELISA) and cell mediated (lymphocyte proliferation assay) immune responses will be monitored. We have shown that an antibody response to a foreign antigen can be raised in dairy cows using a DNA-based vaccine. The needle and syringe delivery method was not as effective as jet injection

1378 Immunogenicity of a putative intranasal vaccine against bovine respiratory syncytial virus (BRSV) in calves. B. Earley^{*1}, O. Kavanagh², B. Adair², and R. Fallon¹, ¹Teagasc, Grange Research Centre, Dunsany, Co. Meath, Ireland., ²Veterinary Science Division, Stormont, The Queen's University of Belfast, BT4 3SD, Northern Ireland.

The objective of the study was to evaluate the effects of microencapsulated synthetic peptides of bovine respiratory syncytial virus (BRSV), following intranasal administration, on the cellular and humoral immune responses of calves. F peptide (F111-148)(0.5mg) and G peptide (G174-187)(0.5mg) representing known protective epitopes against BRSV were microencapsulated. Fifty-two Holstein/Friesian calves, approximately 56 days of age, were allocated randomly to one of the following 4 treatments (13 per treatment); 1). Soluble F-peptide (SF) and soluble G-peptide (SG) in phosphate buffer saline (PBS); 2). Microencapsulated poly(lactide-co-glycolide (PLG)-peptide-F and PLG-peptide-G); 3). Microencapsulated coupled to ovalbumin (OVA) (PLG OVA-peptide-G and PLG OVA-peptide-F); 4). Phosphate buffered saline control. Interferon (IFN) gamma production in response to concanavalin-A (Con-A) was determined in cultured lymphocytes on days 28 and 142 post-primary inoculation. Serum immunoglobulins (Ig) were measured quantitatively by single radial immunodiffusion on day 28 post-inoculation. The data were analysed using analysis of variance procedure and if a significant difference was observed, Duncan's multiple range F-test was applied to determine statistical differences between treatments. There was no difference ($P > 0.05$) between treatments in response to Con-A induced IFN gamma-production from lymphocytes cultured on days 28 or 142 indicating that the vaccination had no effect on the cellular immune response. There was no significant difference in serum Ig concentrations between treatments ($P > 0.05$). A sustained antigen-specific IgA response was induced in the calves nasal mucosa and lungs by all treatments ($P < 0.05$) when compared with PBS control calves on day 28 for the SF and SG peptides. On Day 77 post-primary inoculation the antigen-specific IgA response to the F peptide subunit was maintained in all treatments compared with control while the response of the G peptide subunit ($P > 0.05$) was not sustained. Non-live subunit vaccines encapsulated in biodegradable microparticles are a novel approach to achieving a protective immune response against specific pathogens in the hosts' respiratory tract.

1379 Differential tyrosine phosphorylation on bovine PMN. Kynita Campbell¹, Max Paape², Mulumebet Worku^{*1}, and Yan Wang², ¹North Carolina Agricultural and Technical State University, ²USDA Beltsville, Maryland.

Protein tyrosine phosphorylation is a key step in pathogen destruction by neutrophils (PMN) following ligand receptor interaction. Bovine blood PMN were isolated by differential centrifugation and hypotonic lysis of red blood cells. Viability was assessed by Trypan blue dye exclusion, purity by differential cell counts and concentration using a Coulter counter. Isolated PMN (10^7) were treated with *Escherichia coli* lipopolysaccharide (LPS)(1,000ng/ml, 100ng/ml), Dexamethasone (0.25mg/ml, 0.15mg/ml) and Sodium Butyrate (160 μ M, 80 μ M) or maintained in buffer (1 hour, 37°C). Cells were then lysed with Laemmli buffer, boiled, sonicated and analyzed by SDS-PAGE. Tyrosine phosphorylation was detected by western blotting with a mouse anti-phosphotyrosine monoclonal antibody and alkaline phosphatase conjugated goat anti-mouse antibody using BCIP-NBT substrate (Kirkegaard and Perry Laboratories). The number and intensity of phosphorylated protein bands after treatment were compared to untreated PMN. Lysates from untreated PMN contained six distinct bands. LPS and Dexamethasone treatments resulted in dephosphorylation of all bands. One unique band remained phosphorylated after treatment with Sodium butyrate. Dexamethasone (0.25mg/ml) resulted in the appearance of a unique band (64KDa). These proteins may play a significant role in modulation of bovine PMN function.

Key Words: Polymorphonuclear (PMN), Protein phosphorylation

1380 Bovine PMN release the COX-2 protein when stimulated with bacterial lipopolysaccharide. Jenora Waterman and Mulumebet Worku^{*}, North Carolina Agricultural and Technical State University.

Neutrophils (PMN) are central to the inflammatory response of mammals. Cyclooxygenase-2 (COX-2) is one of two isoforms of the enzyme that catalyzes the production of prostaglandins from arachidonic acid. We show here that bovine PMN release the COX-2 enzyme when stimulated with *Escherichia coli* lipopolysaccharide (LPS). Bovine blood PMN from the caudal vein were isolated by differential centrifugation and hypotonic lysis of red blood cells. Viability was determined by Trypan blue dye exclusion, purity by differential cell counts and concentration using a hemocytometer. Isolated viable PMN (10^7) were incubated for 0.5, 1, 1.5, 2, 2.5, and 3 hours in the presence or absence of 10 ng/ml LPS. Cells were harvested, lysed and fractionated using 12% SDS-PAGE. COX-2 was identified by western blot analysis and enhanced chemiluminescence. COX-2 is expressed by bovine PMN. Expression of COX-2 can be modulated by treatment with LPS. Thus, bovine PMN may actively influence the eicosanoid composition during inflammation.

Key Words: Cyclooxygenase-2, PMN

1381 Modulation of apoptosis in bovine blood PMN by actinomycin-D, lipopolysaccharide, and sodium butyrate. P Matterson^{*}, S Knight, and M Worku, NC Agricultural and Technical State University.

The longevity of neutrophils (PMN) is critical to cell function and resolution of inflammation. The development of methods to assess apoptosis in bovine PMN is essential to development of new therapies to control inflammations such as mastitis. Here we describe a modified assay to detect apoptosis in bovine PMN by comparing the effect of actinomycin-D (160 μ M), sodium butyrate (160 μ M), *E. Coli* lipopolysaccharide (LPS)(10ng/ml) treatments versus untreated isolate of PMN. Whole blood was collected from healthy, lactating Holstein cows (N=3) in 15ml vacutainer blood collection tubes pretreated with 250 IU of heparin sodium. The blood was pooled, diluted with 1X PBS, separated by gentle centrifugation and RBC were lysed with 0.83% ammonium chloride several times until a white pellet and clear supernatant was obtained. Viable, isolated PMN were verified by microscopic observation and counting, using Trypan Blue exclusion for viability (98.0%) and Wright stain differentials. Treated and control PMN were spotted onto poly-L-Lysine, subbed slides. After drying, slides were then assayed for apoptosis detection using Promega's Apoptosis Detection Kit which is based on the TUNEL method of labeling fragmented DNA of apoptotic cells with Fluorescein. The percentage of cells incorporating green fluorescence was evaluated microscopically. Actinomycin-D induced apoptosis (37%) while LPS only tended to induce apoptosis (19%). Sodium butyrate maintained (12%) PMN longevity compared to control cells (13%). Although cow to cow variation was observed, this method was effective in determining the effect of modulators of inflammation on bovine PMN.

Key Words: apoptosis, neutrophil, mastitis

1382 Techniques for RNA isolation and cDNA integrity in bovine blood PMN. S Knight^{*}, M Worku, P Matterson, and S Dance, NC Agricultural and Technical State University Greensboro, NC USA.

Obtaining full-length quality cDNA is critical to experiments involving RNA analysis and library construction. This is even more so in neutrophils. Studies were conducted to evaluate two methods of RNA isolation and a cDNA integrity kit developed by Kirkegaard and Perry Laboratories, for determination of quality cDNA in the human, mouse, and rat systems. Bovine neutrophils (PMN) were isolated by differential centrifugation and hypotonic lysis of red blood cells. Viability was assessed by Trypan blue dye exclusion, concentration was determined by hemacytometer counts and purity by Wright's stained smears. Two methods of RNA isolation (Tri-Reagent and RNAzol) were compared and RNA quality determined by electrophoresis. To determine cDNA integrity, RNA was isolated from viable PMN using Tri-Reagent and a denaturing MOPS/formaldehyde agarose gradient gel. The RNA was reverse transcribed and the cDNA amplified by PCR using six primers specific for regions of the 3' and 5' ends of the housekeeping gene GAPDH, two

common ribosomal protein genes, L3 and S6, and the 3' and 5' regions of the clathrin gene. Tri-Reagent produced the purest RNA preparation with minimal DNA contamination. The cDNA kit may also be applicable for determination of bovine neutrophil cDNA integrity, and identity of conserved sequences. Acknowledgement to KPL for enabling us to serve as Beta tester.

Key Words: Neutrophil, cDNA, RNA

1383 Isolation of membrane protein associated with IgM binding from bovine neutrophils. A Johnston-Ward*, S Knight, and M Worku, *NC Agricultural and Technical State University Greensboro, NC USA.*

Isolation of membrane protein Fc receptors for IgM is essential to the determination of their role in bovine neutrophil (PMN) function for the formulation of possible therapeutics against bovine mastitis. Bovine PMN from two Holtstein-Friesians were isolated by hypotonic lysis of red blood cells and centrifugation. PMN were biotinylated and lysed. The lysates were incubated with purified bovine IgM, followed by goat anti-bovine IgM antibody, and immunoprecipitated with Protein A/G sepharose beads. Proteins were detected using western blotting and enhanced chemiluminescence (ECL) following binding of horseradish peroxidase conjugation Streptavidin. Two to three proteins ranging from 30-90kDa were shown using Coomassie Blue stain. After biotinylation, six proteins of 38-90 kDa were seen using ECL detection. Following immunoprecipitation a unique protein at 28 kDa was also detected with ECL. Further analysis is needed to identify and characterize this protein and any other associated membrane proteins.

Key Words: biotinylation, IgM, Neutrophils

1384 Establishing and comparing profiles of antimicrobial resistance in *Staphylococcus aureus* isolates from selected organic and conventional dairy farms in Vermont. C. Nugent*, P. Murdough, W. Panky, and J. Barlow, *University of Vermont, Burlington, VT.*

Resistance to antimicrobial agents has become a great concern in human medicine, and has been linked to the use of antimicrobials in agriculture (Khachatourians, 1998). Antibiotics are used in agriculture both to increase growth rates in livestock as well as to treat and prevent disease. In the dairy industry, antibiotics are commonly used to combat bovine mastitis. The purpose of this study is to describe and compare the antimicrobial resistance patterns among bacterial isolates obtained from individual quarter milk samples of cows on selected dairy farms in Vermont. Bacterial isolates were collected over an 18 month period from 10 dairy farms, including 6 certified organic dairies where antibiotic use is avoided, and 4 conventional dairy farms that routinely use antibiotics for treatment and prevention of disease. In this preliminary study, the antimicrobial resistance profile of 180 *Staphylococcus aureus* isolates (54 from conventional farms and 126 from organic farms) was established by standard disk diffusion and minimum inhibitory concentration (MIC; Sensititre, Trek Diagnostics, WestLake, OH) methods. Sixteen antibiotics were evaluated. Increased proportions of isolates showing resistance to ampicillin, penicillin, pirlimycin, sulfamethizole, and tetracycline were observed from conventional dairy farms compared with organic farms. No differences in proportion of resistant isolates were observed for amoxicillin plus clavulonic acid, cephalothin, ceftiofur, enrofloxacin, erythromycin, florfenicol, gentamycin, lincomycin, neomycin, oxacillin, and penicillin plus novobiocin. Data on the prevalence of mastitis isolates (such as *Staphylococcus aureus* and *Escherichia coli*) displaying antimicrobial resistance may be used to evaluate the potential impact of current treatment practices on the development of antibiotic resistant pathogens on dairy farms.

1385 Improved quantification of total lipids from liver samples. B. N. Ametaj*, Y. Lu, G. Bobe, J. W. Young, and D. C. Beitz, *Iowa State University, Ames, IA.*

Fatty liver is a major metabolic disease of dairy cows, and early diagnosis, as based upon total lipid percentage of the liver, is important for effective treatment or prevention. Previous methods for assaying total lipids in liver biopsy samples involved freezing in liquid nitrogen, pulverization of samples by percussion, extraction by shaking overnight in 2:1

chloroform and methanol (vol:vol), evaporation of solvent, and weighing of total lipids. Pulverization causes variable losses of liver sample, and utilization of liquid nitrogen is hazardous. We evaluated combinations of sonication, homogenization, and pulverization, followed by shaking for extraction of total lipids from liver samples. Results from samples obtained by biopsies of livers of dairy cows indicate that sonication is safer and faster than pulverization of liver samples. The sufficient amount of time for sonication (0, 10, 20, 30, 40, 50, and 60 sec) was 30 sec. Homogenization for 2 min and shaking overnight in chloroform:methanol (2:1 vol:vol) did not affect the amount of total lipids extracted ($P > 0.1$) compared with sonication and shaking for 2 h. From different amounts of liver sample (50, 100, 150, 200, and 250 mg), the amount of lipid extracted from at least 150 mg resulted in repeatable results ($CV < 10\%$). Our data indicate that sonication for 30 sec, shaking for 2 h, sitting overnight at 4° C, and drying samples under air for 6 h is an efficient and reproducible method for quantification of total lipids from bovine liver. (Partly supported by funds from CSREES-USDA agreement 99-35004-8576)

1386 Effect of slow-release insulin on bovine hepatic lipidosis. A. Hayirli*, J. E. Kayhart, S. J. Bertics, and R. R. Grummer, *University of Wisconsin, Madison.*

The aim of this study was to determine if there is a dose of insulin that decreases concentrations of plasma NEFA and liver TG, without compromising plasma glucose concentration. Forty Holsteins were blocked according to calving date and assigned randomly to a single IM injection of one of four doses of slow-release insulin on d 3 postpartum. Cows were allowed ad libitum consumption of the same diet from 15 d prepartum to 6 d postpartum; on d 3 postpartum, they were fed hourly to minimize fluctuations in blood metabolites due to intake pattern. Blood samples were collected every hour from 0 to 24 h and every 6 h from 24 to 48 h following injection. Pre- and post-injection liver samples were taken on d 2 and 5 postpartum, respectively. Main and polynomial effects of insulin were tested by ANCOVA using a mixed model with repeated measures. One cow receiving .29 and two cows receiving .43 IU insulin/kg BW could not complete the trial due to severe hypoglycemia and their data were excluded from analyses. Both DMI ($P < .13$) and milk yield ($P < .15$) increased quadratically by insulin injection. Plasma glucose linearly decreased ($P < .0001$), serum insulin linearly increased ($P < .0001$), and plasma NEFA quadratically decreased ($P < .05$) for 24 h following injection. On d 4 postpartum, serum insulin concentration remained higher in insulin-injected cows than in saline-injected cows ($P < .08$) and the quadratic effect of insulin on plasma NEFA continued ($P < .02$). Percent change in liver TG decreased quadratically by insulin injection ($P < .08$). The low dose of slow-release insulin could be considered for prophylactic use against hepatic lipidosis.

Response Variable	Dose ¹				SEM
	0	.14	.29	.43

1387 Utility of RAP-PCR to identify genes in bovine liver differentially expressed following in vivo endotoxin (LPS) challenge. E. E. Connor*, C. M. Ashwell, S. Kahl, and T. H. Elsasser, *USDA-ARS, Beltsville, MD.*

The liver is a target organ of cytokine action during an immune response and is the principal site of acute phase protein synthesis. In the present study, RNA arbitrarily primed polymerase chain reaction (RAP-PCR) was used to evaluate hepatic gene expression profiles of saline and low-level LPS-treated cattle to gain novel information on gene expression in inflammatory disease. A single bolus of either saline (n = 4) or LPS (*E. coli* 055:B5, 0.2 μ g/kg, n = 6) was administered through a jugular

catheter on two occasions 5 d apart. Liver biopsy was performed on each animal 8 h after the second LPS challenge to obtain tissue for total RNA isolation and subsequent RAP-PCR analysis. RAP-PCR analysis identified six genes as differentially expressed by LPS challenge. Increases in expression of vascular cell adhesion molecule-1 ($P = 0.02$) and a bovine homolog of a novel human protein, hT41 ($P = 0.04$) were confirmed in LPS-treated livers. No differences in expression ($P > 0.05$) of the four other genes were detected by Northern analysis. Our results indicate that RAP-PCR is a useful tool for identifying novel genes expressed in cattle; however significant validation is required for accurate interpretation of results. Additional study is needed to determine the role of hT41 in the acute phase response in cattle.

Key Words: Endotoxin, RAP-PCR, Cattle

1388 **Prepartum body condition score and liver glycogen concentration decrease circulating memory activity to viral antigens in periparturient dairy cows.** D. C. Donovan^{*1}, A. R. Hippen¹, and D. J. Hurley¹, ¹*South Dakota State University, Brookings.*

The objective of the study was to correlate physiological effects associated with periparturient condition, and the related fatty liver and ketosis complex, with suppression of nonspecific responses and specific responses to viral antigens. Eight Holstein multiparous cows with a mean prepartum body condition score (PBCS) of 3.38 (range: 3.0-4.0) were utilized from a concurrent trial. Blood samples were taken weekly from 7 to 21d postpartum. T cell memory activity to bovine viral disease virus (BVDV), bovine respiratory syncytial virus (BRSV), and parainfluenza 3 (PI3) were measured in vitro. Staphylococcus aureus exotoxin B (SEB) was used as an internal standard of nonspecific lymphocyte proliferation. A negative correlation ($r = 0.42$, $P = 0.02$) was demonstrated between T cell proliferation induced by SEB in culture and PBCS. T cell memory response to BVD in culture was also strongly and negatively correlated ($r = 0.41$, $P < 0.04$) with PBCS. In contrast, T cell memory response to BRSV in culture was not correlated with PBCS, but strongly, negatively correlated ($r = 0.46$, $P = 0.07$) with liver glycogen concentration. The proliferative response to PI3 was not correlated with any of the physiological parameters measured. Nor were any of the responses correlated to liver lipid concentrations. This data suggests that gross physiological measures (prepartum body condition score) and specific indicators of physiological status (liver composition) are predictive of the capacity to mount specific and nonspecific immune responses. As such, they are indicative of increased susceptibility to infectious disease.

Key Words: Prepartum body condition, T cell memory, Virus

1389 **Impact of season and heat stress on SCC from infected and uninfected quarters.** B. A. Broadus^{*}, R. J. Harmon, R. W. Scaletti, K. Akers, B. A. Smith, S. H. Hayes, and C. H. Hamilton, *University of Kentucky, Lexington, KY.*

Infection data were obtained monthly from June, 1999 to September, 2000 at the University of Kentucky dairy. The herd was comprised of Holsteins and Jerseys, averaging 120 lactating cows per month. Quarter foremilk samples were collected for bacteriological determination and somatic cell counts (SCC). The Livestock Stress Index (LSI) estimated heat stress by using the peak mean value for the seven days prior to sample date. LSI is calculated by combination of temperature and humidity. During the sample period two different summer conditions were observed; the first summer had 20 days of temperature in excess of 35° C, but the second summer had nine days at those temperatures. The first summer was during a drought with no more than three cm of rain, compared to the second where an excess of nine cm was reported. For uninfected quarters the geometric mean SCC was 29,000 cells/ml. For infected quarters the geometric mean SCC was 207,000 cells/ml. Coagulase-negative staphylococci (CNS) infections comprised 61 percent of the total infected quarters with a geometric mean SCC of 146,000 cells/ml. *Staphylococcus aureus* infected quarters had a geometric mean SCC of 621,000 cells/ml. The relationship of SCC of infected quarters to LSI differed when comparing the two different summers. There were no significant correlations between log SCC and LSI when looking at the total sample period. However, when evaluating October, 1999 through September, 2000, significant positive correlations were found for LSI and log SCC of uninfected quarters ($P < 0.0013$), infected quarters ($P < 0.0001$), major pathogens ($P < 0.0175$), minor

pathogens ($P < 0.0004$), and CNS ($P < 0.0003$). All correlation coefficients were less than 0.12. The correlation of SCC and LSI for uninfected quarters was 0.049. The results suggest no marked changes in SCC were observed in uninfected quarters during hot summer weather. Hot summer weather may have a minor impact on SCC in infected quarters, but the effect is variable. Thus, infection status of the mammary gland, not heat stress, is the major factor determining SCC.

Key Words: Somatic Cell Count, Mastitis, Heat Stress

1390 **Relationship of somatic cell score with fertility measures.** R.H. Miller¹, J.S. Clay², and H.D. Norman^{*1}, ¹*Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD,* ²*Dairy Records Management Systems, Raleigh, NC.*

Dairy Herd Improvement data from 284,450 Holstein and Jersey cows in 37 states were examined to determine relationships of test-day somatic cell score (SCS), herd, calving year, parity, lactation stage, and calving ease score with fertility measures [rate of nonreturn to estrus by 70 d after first service, days to first service (D1), and days open (DO)]. Relationship of elevated SCS prior to first insemination with nonreturn rate was of primary interest, but factors other than SCS were examined to ensure that estimation of SCS effect was independent of other variables. Nonreturn rates differed greatly by month. Rates were highest during April and May and lowest during June (a difference of 8 to 9% for Holsteins and 12% for Jerseys). Nonreturn rate also was affected by parity (6 to 7% higher nonreturn rate for first parity than for sixth parity and later), lactation stage at first service (increase in nonreturn rate of 8 to 13% from early to late lactation), and calving ease [a 7% decline in nonreturn rate from score 1 (no birth difficulty) to score 5 (extreme birth difficulty)]. For Holsteins, linear regression of nonreturn rate on preceding test-day SCS was significant ($P 0.01$), particularly for SCS recorded within 2 to 3 wk prior to insemination; however, regression coefficients were small (0.004 to 0.005). A similar relationship was not found for Jerseys. Quadratic regression of D1 on SCS was significant for Holsteins ($P < 0.05$) and Jerseys ($P < 0.01$); linear regression of DO on SCS was significant ($P < 0.01$) for Holsteins. The magnitude of SCS effect on fertility traits does not warrant postponement of first service for cows in estrus because of elevated SCS on previous test day. However, additional emphasis on mastitis control and, consequently, a slight increase in the economic weight for SCS in genetic selection may be justified.

Key Words: Fertility, Nonreturn rate, Somatic cell score

1391 **Efficacy of a concentrated equine serum product to prevent failure of passive transfer of immunity in neonatal foals.** C.J. Hammer^{*1}, J.A. Booth¹, L. Etzel², and H.D. Tyler¹, ¹*Iowa State University, Ames, IA USA,* ²*Proliant, Ames, IA USA.*

Colostrum antibodies are the most important factor providing immunological protection to the neonatal foal. Foals that fail to obtain adequate amounts of these antibodies, those classified with failure of passive transfer, are at an increased risk for developing infection and/or death. The primary objective of this study was to determine if an orally administered concentrated equine serum product provided in the first hours of life could prevent failure of passive transfer in foals. To achieve this objective, ten foals of Quarter Horse breeding were utilized. Foals were alternately assigned to serve as a control or to receive the oral product. Treated foals were administered 250 ml of the oral serum product at 1 and 3 h of age via nasogastric intubation. These foals were muzzled to prevent nursing from their dam. Supplemental milk replacer (200 ml/feeding) was provided to the treated foals at 6 and 9 h of age. The dams of treated foals had their udder stripped at 1, 3, 6, and 9 h post parturition. The initial colostrum collected (200 ml) was fed back to the treated foals when the muzzle was removed at 12 h of age. Control foals were allowed to nurse from their dams ad libitum. Ten ml jugular blood samples were obtained from all foals (5 treated/5 control) at 1, 3, 5, 7, 9, 10, 11, 12, 24, and 48 h of age for determination of concentrations of plasma IgG. Plasma IgG concentrations were higher ($p < .05$) for treated foals compared to control foals at 5 h and 48 h of age. Plasma IgG concentrations were not different ($p > .10$) between treated and control foals at all other time periods measured. All treated foals had plasma IgG concentrations over 700 mg/dl by 10 h of age. These data suggest that administration of this concentrated oral plasma product is effective

in raising foal serum IgG concentrations and minimizing the incidence of failure of passive transfer.

Key Words: Immunoglobulin, Colostrum, Foal

1392 Heritability of *Ascaridia galli* egg output in laying hens. Matthias Gauly^{*1}, Christian Bauer², and Georg Erhardt¹, ¹*Institute of Animal Breeding and Genetics, University of Giessen*, ²*Institute of Parasitology, University of Giessen, Germany*.

Twenty week-old Lohmann LSL (n = 46) and Lohmann Brown (n = 40) laying hens were orally infected with 250 embryonated *Ascaridia galli* eggs. The hens descended from 11 different sires. During a 12 month laying period the animals were kept in battery-cages in an environmentally controlled chicken house and faecal samples were collected separately from each bird once a month (samples 1 to 12) to determine faecal egg counts (FEC). A modified McMaster technique was used. Weights of the birds were also taken at monthly intervals. A group of 15 (LSL) and 20 (Brown) control animals, kept under the same conditions, were sampled in parallel. No anthelmintic treatments were given at any time. FEC were transformed as the decimal logarithm of n (number of eggs) + 25 to correct for heterogeneity of variance and to produce normally distributed data. Statistical analysis was performed with the Statistical Package for Social Science for PC (SPSS-PC Version 9.0). The model for estimating heritabilities of log-transformed data included the father as a random effect and age as a fixed effect. All infected animals excreted *A. galli* eggs. The percentage of positive samples (FEC > 50) was 69.1 and 33.7. LSL hens had a significantly (p < 0.01) (2.38, SE: 0.04) higher mean log10 FEC compared to Lohmann Brown (1.89, SE: 0.03). There was no significant (p > 0.05) difference in laying performance between control and infected groups. The relative body weight development of the LSL chicks was significantly (p < 0.05) higher in the control group. The estimated heritabilities for mean log10 FEC were between 0.0 (all samples) and 0.10 (SE: 0.041) (samples 1-6) for Lohmann Brown and 0.13 (SE:0.039) (all samples) and 0.19 (SE:0.029) (samples 1-6) for Lohmann LSL. This opens a way of genetic selection for *A. galli* resistance in chickens, which will be of importance for birds kept in alternative and organic farming systems.

Key Words: Genetic resistance, *Ascaridia galli*, Chicken-Nematoda

1393 Antibiotic effects of Tylosin in the large intestine of swine fed sub-therapeutic concentrations of Tylan. M.D. Howard^{*1}, J.A. Zahn¹, and D.L. Harris², ¹*National Swine Research Information Center, USDA-ARS*, ²*Iowa State University*.

The objectives of this study were to: 1) measure the concentration of tylosin and bioactive tylosin metabolites in the large intestine of pigs fed a typical corn-soy finishing diet, containing a sub-therapeutic level of tylosin (20 g/907 kg of feed); 2) determine the in vitro minimum inhibitory concentration (MIC) for *Micrococcus luteus* and *Brachyspira hyodysenteriae*. Large intestinal digesta of three pigs (107.0 kg 2.0) were solvent-extracted and antibacterial compounds were isolated by coupled preparative reverse-phase liquid chromatography (P-RPLC) followed by a plate diffusion assay with *M. luteus* as the indicator microorganism. Four major bioactive fractions were purified to homogeneity by a second P-RPLC step and structures of the compounds were assigned using electrospray-ionization tandem mass spectrometry (MS-MS). The identity, concentration, and yield of bioactive compounds purified from the digesta were: Tylosin A (112.2 8.2 mg/kg, yield = 74%); tylosin D (241.6 19.3 mg/kg, yield = 81%); demycarose-tylosin A (36.0 2.3 mg/kg, yield = 78%); and demycarose-tylosin D (21.0 1.3 mg/kg, yield = 79%). The MIC of purified tylosin A for *M. luteus* was found to be 4.3 1.3 mg/kg, and the MIC for *B. hyodysenteriae* was found to be 1.1 0.4 mg/kg. The MIC of the four bioactive compounds were found to be statistically (a = 0.05) identical in MIC assays performed using *M. luteus*. Therefore, the normalized concentration of all bioactive forms of tylosin was used to estimate potential sub-therapeutic effects of tylosin on susceptible bacteria in the gut of swine. The total concentration (0.52 mg/kg) of all bioactive forms of tylosin was found to be in the MIC range of *B. hyodysenteriae* (1.0 0.6 mg/kg). This result suggests that sub-therapeutic levels of tylosin may influence microbial community structure in the gut of swine through direct antibiotic effects. Additionally, results of this study show, for the first time, the identity

and concentration of tylosin metabolites in the gut of swine that exhibit antibacterial activity.

Key Words: Tylosin, growth promotion, antibiotic resistance

1394 Adhesion of *Actinobacillus pleuropneumoniae* to swine soluble fibronectin. R.C. Hamer^{*1,2}, I. Enriquez², D. Godinez², R.Z. Martinez², P. Talamas², S. Vaca³, and M. de la Garza², ¹*FMVZ- Universidad Autonoma de Sinaloa. Culiacan, Sinaloa Mexico.*, ²*CINVESTAV-IPN. Zacatenco. Mex. D.F. Mexico.*, ³*ENEP- Iztacala. Universidad Nacional Autonoma de Mexico. Mexico.*

Actinobacillus pleuropneumoniae (Ap) is an important cause of swine respiratory disease. Adhesion to the swine respiratory tract is an initial step in infection. Fibronectin is one of the most abundant extracellular matrix proteins in lung connective tissue. The objective of this work was to show the interaction of Ap with swine soluble fibronectin. Ap cells were seen adhered to fibronectin, using negative staining by transmission electron microscopy. This interaction was observed as protein nets with bacteria adhered. Adhesion kinetic studies of Ap to swine fibronectin films was performed in microtitration plates, adhesion was observed for the first 5 min of incubation and it was maintained for 3 hours. Heat killing of bacteria inhibited adhesion almost completely; heparin or swine serum from convalescent pigs diminished adhesion in less proportion. Also, some carbohydrates and metaperiodate had an important effect on adhesion. Immunofluorescence using anti-swine fibronectin antibodies revealed bacteria adhered to fibronectin when both were in contact. These experiments revealed bacterial-protein interactions, and a possible important role of fibronectin in bacterial recognition of swine lung, colonization, and subsequent infection. Project supported by CONACyT-Mexico grant no. 28755B.

Key Words: Pneumonia, Fibronectin, Swine

1395 Testing for the Presence of Enterotoxigenic *Escherichia coli* Infections Causing Diarrhea in Swine Using PCR and ELISA Techniques. S. Cole^{*1} and R. R. Marquardt¹, ¹*University of Manitoba*.

Five strains of Enterotoxigenic *Escherichia coli* (ETEC) K88 (F4), K99 (F5), 987P (F6), F41, and F18 (F107) have been shown to cause diarrheal disease in young pigs. It is important to identify specific strains of *E. coli* by their colonization factor genes if they are to be treated with therapeutic antibodies as each antibody is specific for a given strain. Among different procedures only genetic and immunological techniques are specific. The objectives of this study were to adapt two types of assays to detect the presence of these five strains of ETEC in swine, the polymerase chain reaction (PCR) and the enzyme linked immunosorbent assay (ELISA). The polymerase chain reaction is a genetic assay applied to the testing of fecal samples from animals with diarrhea where *E. coli* is the suspected cause. PCR has been called the DNA photocopier that replicates many copies of a target DNA strand which can be used for identification of the organism. The ELISA technique can be used to test for the presence of anti-*E. coli* colonization factor antibodies in the blood of swine. The antibodies that result from an infection will persist for a matter of weeks in the animal. In this way even if no animals are sick at the time of investigation, the disease exposure of healthy animals could indicate the presence of a pathogen that has been a problem and may be again. Preliminary refinement and testing of these methods at the University of Manitoba have proven successful by indicating the presence of specific pathogenic *E. coli* strains in the feces of pigs specifically inoculated. In addition the ELISA method too has proven the ability to detect anti-*E. coli* colonization factor antibodies in the blood of pigs. The assays have proven to be fast, specific, sensitive and accurate for the application of therapeutic antibodies in an ETEC control program.

Key Words: Enterotoxigenic *E. coli*, PCR, ELISA

1396 Differential effect of dexamethasone on lymphocyte proliferation and immunoglobulin production *in vitro*. M.R. Rogers*¹, S.C. Lozano¹, K.M. Kammlah¹, T.H. Welsh, Jr.², and J.C. Laurenz¹, ¹Texas A&M University-Kingsville, ²Texas A&M University-College Station.

The present study investigated the effect of the synthetic glucocorticoid, dexamethasone (DEX), on concanavalin (ConA)-induced lymphoproliferation and immunoglobulin M (IgM) production by pig lymphocytes *in vitro*. Blood was obtained from male, crossbred pigs (n=3-6 pigs/experiment; 40-45 days of age) and lymphocytes obtained by density gradient centrifugation over Lymphoprep (Nycomed, Oslo, Norway). Lymphocytes were plated in 96-well plates at 1×10^5 cells/well in DME/F12 containing 10% fetal bovine serum, 2 mM L-glutamine, 10 uM 2-mercaptoethanol, ConA (0 to 10 ug/ml) and/or DEX (0 to 10^{-6} M). Cultures were incubated for 96 h and lymphoproliferation determined using the CellTiter proliferation assay (Promega, Madison, WI). In replicate cultures, supernatants were removed and IgM production determined using an ELISA specific for pig IgM. As expected, ConA induced a dose-dependent increase ($P < .01$) in lymphoproliferation and IgM production with maximal effects occurring at .6 and 1.25 ug/ml, respectively. Although not effecting basal lymphoproliferation, DEX dose-dependently inhibited ($P < .01$) ConA-induced (0.3 and 1.25 ug/ml) lymphoproliferation with maximal effects occurring at 1×10^{-8} M. However, the suppressive effects of DEX (1×10^{-8} M) on lymphoproliferation could be overcome ($P < .05$) with the addition of higher concentrations of ConA (5 to 10 ug/ml). Similarly, when cells were stimulated with low concentrations of ConA (.3 ug/ml), DEX dose-dependently inhibited ($P < 0.01$) IgM production with maximal effects occurring at 10^{-8} M. In contrast, in cultures treated with 1.25 ug/ml ConA, low concentrations of DEX (10^{-10} to 10^{-9} M) actually augmented ($P < .05$) IgM production. Furthermore, DEX (10^{-8} M) induced additional 1.7 to 1.9 fold increases ($P < .05$) in IgM production by lymphocyte cultures treated with higher concentrations of ConA (2.5 to 10 ug/ml, respectively). Collectively, these results demonstrate that glucocorticoids have primarily a suppressive effect on lymphocyte proliferation, but can augment immunoglobulin production depending on both the degree of lymphocyte stimulation and the concentration of glucocorticoid.

Key Words: Pigs, Glucocorticoid, Lymphocyte

1397 Effect of oral administration of dehydroepiandrosterone-sulfate (DHEAS) on pig lymphocyte function *in vitro*. S.C. Lozano*¹, T.H. Welsh, Jr.², and J.C. Laurenz¹, ¹Texas A&M University-Kingsville, ²Texas A&M University-College Station.

The present study investigated the effect of chronic, oral administration of DHEAS on lymphoproliferation and immunoglobulin (IgM) production by isolated lymphocytes *in vitro*. Crossbred, female pigs (n = 12; initial weight 9.3 .5 kg) were assigned by weight to one of two treatments (n = 6 pigs/treatment) and were fed either 0 or 1 mg DHEAS/kg body weight twice daily for 100 days. At the end of the treatment period, blood was obtained via jugular venipuncture and lymphocytes isolated by density gradient centrifugation over Lymphoprep (Nycomed, Oslo, Norway). Lymphocytes were plated in 96-well plates at 1×10^5 cells/well in DME/F12 containing 10% FBS, 2mM glutamine, 10 uM 2-mercaptoethanol, ConA (0 to 2.5 ug/ml), or ConA (.3 or 1.25 ug/ml) in the presence of DEX (0 to 10^6 M). Cultures were incubated for 96 h and lymphoproliferation determined using the Celltiter proliferation assay (Promega, Madison, WI). In replicate cultures, supernatants were removed and immunoglobulin M (IgM) production determined using an ELISA specific for pig IgM. As expected, ConA induced dose-dependent increases ($P < .01$) in lymphoproliferation and IgM production with initial increases apparent at .3 ug/ml and maximal effects occurring at 1.25ug/ml ConA. Although not effecting ($P > .05$) the response of lymphocytes to low concentrations of ConA ($< .3$ ug/ml), feeding of DHEAS to pigs increased ($P < .05$) the extent of lymphoproliferation and tended to increase ($P = .06$) IgM production by lymphocytes at higher concentrations of ConA (.6 to 2.5 ug/ml). In both treatment groups, DEX dose-dependently inhibited ($P < .01$) ConA-induced (0.3 and 1.25 ug/ml) lymphoproliferation with maximal effects occurring at 10^{-8} M. Similarly, when cells were stimulated with low concentrations of ConA (.3 ug/ml), DEX dose-dependently ($P < .01$) inhibited IgM production with maximal effects occurring at 10^{-8} M. In contrast, in cultures treated with 1.25 ug/ml ConA, DEX (10^{-10} to 10^{-8} M) augmented ($P < .05$) IgM production and the effect of glucocorticoid treatment was increased ($P < .01$) in pigs fed DHEAS. Collectively, these results indicate that oral administration of DHEAS can enhance the responsiveness of lymphocytes to antigenic challenge and suggest that DHEAS may be beneficial to enhance immune function in domestic livestock species.

Key Words: pigs, dehydroepiandrosterone, glucocorticoid

ASAS/ADSA Breeding and Genetics: Gene Mapping, QTL, and Statistical Methods

1398 A novel and highly effective method to generate transgenic mice and chickens: linker-based sperm-mediated gene transfer. Jin Qian*¹, Yi-Hsin Liu², Mason Jiang³, Tsehay Mekonnen¹, and Ken Wang¹, ¹BioAgri Corp., ²Center for Craniofacial Molecular Biology, USC, ³Dept. of Anesthesiology, UCLA.

Genetic modification of domestic animal traits can be used to improve productivity and quality or to produce bioreactors for modern medicine. DNA microinjection, the current method to produce transgenic livestock, is time consuming and requires extensive training and special equipment. More importantly, except in mice, microinjection has reported only limited success in larger or higher species. Sperm-mediated gene transfer has been recognized as a potentially powerful alternative method, but has been questioned by many laboratories around the world since the original results were difficult to duplicate. We have developed a linker (mAb C) to bind with sperm and DNA. Using flow cytometry, it has shown cross-reactivity with sperm cells from all tested species including mouse, pig, cow, sheep, goat, chicken, and human. mAb C has been characterized as a basic protein and has been shown to bind DNA through ionic interaction. We report here the use of this novel linker with the sperm-mediated gene transfer method to successfully generate transgenic mice and chickens. Sperm from FVB/N mice were treated first with mAb C and then combined with a linearized DNA fragment, pGL3-control (Promega). After *in vitro* fertilization, fertilized eggs at the two-cell stage were implanted into pseudopregnant mice. 12 offspring were born and used to mate with wild type mice. 2 (16.7%) transmitted transgenic mouse lines (F1) were identified by Southern blot. Furthermore, this novel technology was also tested in the chicken through artificial insemination. The transgene was detected in 10 out of 88 (11.4%) chicken embryos by PCR. Combined with our high success

rate in making transgenic pigs (58.3%) through surgical oviduct fertilization, our data strongly suggests that this novel linker-based sperm-mediated gene transfer method is both universal and effective and could be of great value to modern agriculture and medicine.

Key Words: Linker-based sperm-mediated gene transfer, Transgenic chicken, Transgenic mice

1399 Generation of transgenic pigs by sperm-mediated gene transfer using a linker protein (mAb C). Keejong Chang^{2,3}, Jin Qian¹, Mason Jiang⁴, Ming-Che Wu⁵, Chidar Chen², Hin-Lung Lo³, Meng-Chun Hu², Wen-Wen Lin², Iris Ho², and Ken Wang*¹, ¹BioAgri Corp., ²BioAgri Corp., Taiwan Division, ³Dept. of Chemistry, Soochow University, ⁴Dept. of Physiology, Taiwan Livestock Research Center, ⁵Dept. of Anesthesiology, UCLA.

Sperm-mediated gene transfer (SMGT) has been recognized as a potentially powerful method to make transgenic animals for many years. The current method of gene transfer, microinjection, used widely in transgenic mouse production, has had only limited success in producing transgenic animals from larger or higher species. We report here a sperm-mediated gene transfer method that uses a linker protein to vastly improve the efficiency of large transgenic animal production. A monoclonal antibody (mAb C) that could be used as a linker was identified after screening hybridomas immunized with mouse sperm cells. mAb C is reactive to a surface antigen on mouse sperm cells and is also cross-reactive with sperm cells from many different species such as pig, cow, sheep, goat, chicken, and human. mAb C has been characterized

as a basic protein that binds to DNA through ionic interaction. Therefore exogenous DNA can specifically bind to the sperm surface via mAb C and has been shown to successfully integrate into the chromosome of mouse, pig and chicken offspring. Furthermore, expressed foreign proteins can be detected in the serum of transgenic pigs. Diluted pig sperm cells were mixed with mAb C to form a sperm-mAb complex and then pSEAP-2 reporter gene DNA (Clontech) was added to react with the sperm-mAb complex. In group I and II animals, one half-million treated sperm cells were injected into each side of the oviduct in ovulating pigs by surgical oviduct fertilization. In group I, forty-three pig offspring (F0 founders) were analyzed and 30.2% (13/43) of piglets' tails were shown to contain exogenous DNA integration into the host genome by Southern blot analysis. 58.3% (21/36) of these offspring were found to express SEAP secreted into the serum. In group II, thirty-two pig offspring (F0 founders) were analyzed. Results of Southern blot and SEAP analysis show similar findings as those in group I. In a subsequent study, seventeen F0 founders were randomly selected to mate with wild type pigs. Seven (41.2%) transmitted transgenic lines (F1 generation) were identified by Southern blot analysis. These results demonstrate that transgenic pigs can be generated with a remarkably improved efficiency by sperm-mediated gene transfer using the linker protein, mAb C.

1400 Macroarray analyses of differential gene expression in porcine fetal and postnatal skeletal muscle RNA. S. Zhao*^{1,3}, C. Fitzsimmons¹, C. Ernst², and C. Tuggle¹, ¹Iowa State University, Ames, IA, ²Michigan State University, East Lansing, MI, ³Huanzhong Agricultural University, Wuhan, PRC.

High-throughput analysis of transcript abundance holds great promise to identify genes controlling biological traits important in animal agriculture. To test the utility of such transcriptional profiling for porcine muscle gene expression studies, a cDNA macroarray comprising 327 cDNAs spotted in duplicate onto nylon membrane filters was developed. Total RNA from two muscle samples, 75-day fetal hind limb muscles (including gluteus, semitendinosus and semimembranosus) and 7-week postnatal semitendinosus muscle, were used to make radiolabeled targets for filter hybridization. To test reproducibility, two identical membranes were hybridized to each target in two separate incubations. The intensity of expression at each spot was determined by phosphor imager scanning and evaluated by ImageQuant software. Values for each probe spot were normalized to signal at the beta-actin probe spot and to signal from a complex probe consisting of a mixture of cDNA from spleen, muscle, liver and lung tissues. Correlation coefficients of signal intensity between duplicate spots was greater than 0.98 and normalized signal intensity between two identical membranes was greater than 0.96 (Pearson test), indicating the reproducibility between duplicate spots and identical membranes was very good. Differences in gene expression between the two developmental stages for each gene were then determined by making all possible pair-wise comparisons of the four membranes. This analysis showed that 78 genes displayed increased expression (greater than 3 fold) in fetal over post-natal muscle, and that zero and one gene showed greater than 3 fold expression differences in fetal-fetal and postnatal-postnatal comparisons, respectively. Three genes were up-regulated in postnatal semitendinosus muscle, including alpha-actin, muscle alpha 7-integrin, and one muscle EST with no database match. These experiments show that cDNA macroarrays can identify differentially expressed genes in a cost-effective and rapid manner. Additional time points and Northern analyses will be required to confirm these predicted expression differences.

1401 Production of 17 cDNA libraries and successful EST sequencing of 10,124 clones from porcine female reproductive tissues. C.K. Tuggle*¹, J.A. Green², C. Fitzsimmons¹, R. Woods², R. Prather², S. Malchenko³, M.B. Soares³, C.A. Roberts⁴, K. Pedretti⁴, and T. Casavant⁴, ¹Iowa State University, Ames, IA, ²University of Missouri-Columbia, Columbia, MO, ³Pediatrics-University of Iowa, Iowa City, IA, ⁴ECE-University of Iowa, Iowa City, IA.

Sequencing of cDNAs expressed in reproductive tissues will provide useful information in identifying specific genes involved in quantitative traits for pig reproduction. We have produced a total of 17 libraries from

the following tissues: whole embryo (day 14, 20 and 45 of gestation); term placenta, anterior pituitary (day 0, 5 and 12 of estrus), hypothalamus (day 0, 5 and 12 of estrus) ovary (day 0, 5 and 12 of estrus) and uterus (day 12 and 14 of gestation). To determine the quality of these libraries, we have sequenced randomly selected clones from each library. A total of 10,124 sequences has been produced and will be submitted to Genbank (7,932 submitted to date). The average sequence read length across this dataset is 424 base pairs, with less than 22% shorter than 300 base pairs. As assessed by cluster analysis of 9,911 sequences, these data represent 6,655 different genes for a novelty rate of 67.2%. A sequence similarity analysis using the BLAST program and publicly available data within Genbank (ca. 53,660 porcine genes and ESTs as of December 20, 2000) indicates that 3,939 (59 %) of these clusters are unique relative to existing porcine Genbank entries (BLAST score <50). Further, over 900 (14%) have a significant match with human sequences (BLAST score >400). Thus, these sequences are highly useful for comparative mapping with the human genome. To facilitate selection of genes for such mapping, we have developed software to predict the pig cytogenetic location based on human cytogenetic and RH mapping data. Preliminary testing of the IMpRH panel indicates no technical problems; over 15 loci have been mapped using both the SCHP and the RH panel at this point. A WWW site has been established for public access to these sequences and the analysis data (<http://pigest.genome.iastate.edu>). In summary, this EST project has currently identified over 10,124 pig reproduction ESTs, representing over 3,939 new genes, toward a project goal of 20,000 submissions to Genbank.

1402 Development of a physical map of bovine chromosome 4 that contains the gene responsible for Bovine Progressive Degenerative Myeloencephalopathy (PDME). Mheni Ben Abdallah*, Scott Speidel, Emily Oberg, and Sue DeNise, University of Arizona, Tucson, AZ, USA.

Bovine Progressive Degenerative Myeloencephalopathy (PDME) or Weaver Syndrome is recessively-inherited neurological disease found in the Brown Swiss breed. It has been reported that sires that are heterozygous for PDME had significantly higher genetic merit for milk and fat yield than normal homozygotes due to linkage with a major gene or a pleiotropic effect. To identify candidate genes for PDME, we intend to develop a bovine BAC-contig in the region containing the gene, and use comparative genomics to identify candidate genes and orient the contig. A recombination event in the region near BM1224 indicates that PDME is located telomeric of this microsatellite marker. Initial screening of a bovine BAC library (RPC1-42, BACPAC Resources) using BM1224 and the next mapped marker, BM6437, provided 5 positive BAC clones. We have begun constructing a BAC contig that physically spans the region by end-sequencing these clones and then shotgun sequencing the BACs that comprise the shortest tiling distance. Our rationale is to establish BAC-based contigs by using the human map for orientation and walking toward the center of the contig. The homologous human region is 7p14-13 region. Bovine sequence from the BAC clones are aligned onto human BAC sequences in the region. New EST and STS sequences identified from the human map are amplified in bovine and mapped in the 12000 rad radiation-hybrid panel to determine relative location in the bovine. Using the combined strategy of the bovine physical map and comparative genomics, we hope to identify likely candidates for PDME that can be sequenced and studied in affected and normal animals.

1403 Comparative mapping and linkage analysis to identify the genetic region responsible for Bovine Spinal Muscular Atrophy (SMA). E.A. Oberg*¹, N. Vukasinovic², and S.K. DeNise¹, ¹University of Arizona, ²Utah State University.

Spinal Muscular Atrophy (SMA) is a recessively-inherited neurological disease found in the Brown Swiss breed. Clinical signs of SMA can be observed as early as 3 to 4 weeks of age and result in death of the calf by 12 weeks. Bovine SMA has symptoms similar to several human diseases that have already been chromosomally localized; thus, a search for homologous diseases/symptoms between humans and cattle was performed in order to obtain potential candidate regions to begin a logically organized genome scan in affected families. A resource population of sixty carrier and non-carrier animals was identified through progeny testing and DNA samples collected. Depending on the size of

the candidate regions and the heterozygosity of the chosen markers, approximately 10 microsatellite markers per chromosome are used in the analysis. Microsatellite marker linkage analysis will be performed on the genotypes obtained from animals in the resource population to identify the putative regions where the disease gene resides. The ultimate goal is to create a genetically based test that can easily identify SMA carrier animals so as to eliminate high-risk matings.

1404 Genetic analysis of candidate genes for Weaver Syndrome in Brown Swiss cattle. Scott Speidel*, Emily Oberg, Mheni Ben Abdallah, and Sue DeNise, *University of Arizona, Tucson, AZ/USA.*

Weaver Syndrome or Bovine Progressive Degenerative Myeloencephalopathy (PDME) is a recessively inherited neurological disease described in Brown Swiss Cattle that has been mapped to bovine chromosome 4 (BTA4). To locate the PDME causative gene, human and murine candidate loci have been identified that map to homologous regions on BTA4. The reelin gene (RELN) has been shown to control neuronal migration in the developing brain in mice; and mutations in the gene have shown similar symptoms to PDME. It maps to the long arm of human chromosome 7, which is homologous to BTA4. Primers developed from human studies were used to amplify a 159-bp fragment, which encompasses positions 1136-1295 of the human RELN sequence. After initial sequencing of direct PCR product, the fragment had a 90.06% homology score with human RELN. Mapping RELN using the 5,000 (5K) rad radiation hybrid panel placed the RELN gene outside the area of interest on BTA 4, telomeric to the microsatellite TGLA 116. A recently discovered recombination event narrowed our focus down to an 8 cM region on BTA 4. Human BAC clones in the homologous region of HSA 7 have been identified to contain genes, which would aid in fine mapping the region. Two EST's discovered on HSA 7 in the homologous human BAC will be mapped in cattle to provide a framework for the bovine BAC contig development. The first is annotated as a neuronal precursor to neuroepithelial cells (Accession #AA218986). The second EST has an unknown function and is labeled KIAA0087 gene product (Accession # D42038). These two gene products have been amplified in bovine genomic DNA. The next step is to sequence the product to verify homology, and then they will be mapped using the 12,000 rad radiation hybrid panel.

1405 Evaluation of genetic relatedness and diversity in five goat breeds using randomly amplified polymorphic DNA (RAPD) analysis. J. Luo*¹, Z. G. Liu², G. S. Yang², and X. M. Zhen³, ¹*E(Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK,* ²*Northwest Agricultural University, Yangling, Shaanxi, China,* ³*Biotechnology Laboratory of Hubei Agricultural Science Academy, Wuhan, Hubei, China.*

The primary objective of this study was to apply randomly amplified polymorphic DNA technique to evaluate genetic relatedness and diversity among five goat breeds, namely Boer, Saanen, Angora, Shaannan white, and Guanzhong dairy goat. They were meat, dairy, fiber, and indigenous dual-purpose breed, respectively. The analysis was based on band-sharing frequency, genetic distance, and Shannon diversity index. Blood samples were collected from 17 Boer, 14 Saanen, 13 Angora, 11 Shaannan white, and 5 Guanzhong dairy goats via jugular venipuncture for each individual DNA isolation. DNA pools were formed for 7 individuals from each breed except 5 of Guanzhong dairy goats. A total of 20 arbitrary 10mer primers with GC content of either 40, 50, 60, or 70%, designed according to references and manufacturer's recommendations and synthesized by Dalian Biotechnology company of China thereafter, were employed in RAPD analysis. Seventeen of 20 primers detected an amplified pattern with 2 to 11 bands, 4 of which had amplified polymorphic fragments in each breed; the between-breed average band sharing frequency was from 0.91 to 0.98. Neils standard genetic distance was in the range of 0.02 to 0.09, and a dendrogram based on Neils distance from amplification patterns of four random primers in five goat breeds was constructed. As expected, the estimate of distance between Saanen and Guanzhong dairy goat was lowest among goat breeds. The Shannon diversity index of each goat breed was 0.54, 0.19, 0.12, 0.35 and 0.34, respectively, which indicated a large genetic diversity in Boer, Shaannan white, and Guanzhong dairy goat populations in the sampling region.

It was confirmed that RAPD marker analysis can be used to determine genetic diversity and relatedness among and within goat breeds.

1406 PIT-1 gene sequencing and mutation analysis in sheep. E Bastos*¹, I Parmentier², I Santos³, A Cravador⁴, H Guedes-Pinto¹, and R Renaville², ¹*University of Tras-os-Montes e Alto Douro, Vila Real, Portugal,* ²*Gembloux Agricultural University, Gembloux, Belgium,* ³*National Zootechnical Station, Santarem, Portugal,* ⁴*University of Algarve, Faro, Portugal.*

The pituitary-specific transcription factor Pit-1/GHF1 is a member of the POU domain family of regulatory proteins. It is required for activation of the growth hormone, prolactin, and thyroid stimulating- β genes in somatotrope, lactotrope, and thyrotrope cell types, respectively. In humans, mutations in Pit-1 have been associated with pituitary dwarfism and it has been proposed that this transcription factor can have a contribution in the pathogenesis of pituitary adenomas. In farm animals, there is a strong correlation between a mutation on exon 6 of this gene and milk production in bovine. The aims of the present study were to sequence the Pit-1 gene in sheep and optimize a methodology for the detection of mutations in the coding region. Specific primers were designed for the amplification of the sequence between two subsequent exons, based on the comparison of the gene sequence in human and the mRNA sequence in ovine. Five different clones were obtained, using the Invitrogen PCR cloning kit. The sequencing result was used to design primers near the exons in order to screen possible mutations, by the methodology BESS T/G scan. As the Pit-1 gene can play an important role in lactation and growth, the identification of mutations in this gene can contribute to the explanation of the differences in production and open new prospects for marker assisted selection.

Key Words: Pit-1, Sequence, Polymorphisms

1407 The pairwise relatedness between relatives conditional on genetic markers. Yuefu Liu*¹, Gerald Jansen¹, and Ching Lin², ¹*University of Guelph, Guelph, Canada,* ²*Agriculture and Agri-Food Canada, Lennoxville, Canada.*

The development of molecular genotyping techniques makes it possible to analyze a quantitative trait on the basis of individual loci. With marker information, the classical theory of estimating the covariance between relatives has to be reformulated to improve the accuracy of estimation. This study derived an algorithm for computing the covariance between relatives conditional on a single marker or two flanking markers, and provided procedures for calculating the conditional relationship coefficients due to allelic effects, additive effects, dominance effects, and epistatic interactions including additive by additive, additive by dominance, dominance by additive and dominance by dominance. The relationship coefficients were computed based on conditional transmission probabilities of QTL alleles, which are, in turn, inferred from the transmission probabilities of marker alleles. An example data set with pedigree and marker genotypes of two linkage groups was used to demonstrate the procedure developed. Although this study dealt with two QTLs coupled with linked markers, the same principle can be easily extended to a multiple QTL situation.

1408 Marker assisted selection for first calving age at embryo level: a simulation study. A. J. M. Rosa*¹, R. B. Lobo¹, P. Bijma², M. Rutten², H. N. Oliveira³, and J. van Arendonk², ¹*USP - Ribeirao Preto, SP/Brazil,* ²*Wageningen Institute of Animal Science, Wageningen, Holland,* ³*UNESP - Botucatu, SP/Brazil.*

Potential genetic benefits of marker assisted selection (MAS) at the embryo level to improve first calving age were evaluated by simulation of a MOET closed nucleus, with discrete generations, multi-stage selection (with or without embryo pre-selection) and QTL information. The QTLFCA were included in the selection index as a correlated trait with total substitution effect ranging from .00 to .95 of the additive genetic variance (σ_a^2). In the first simulated situation, MAS at 2 years of age resulted in higher response to QTLFCA corresponding to higher proportion of the σ_a^2 due to the increase in accuracy. Genetic response was increased to .68, 1.76 and 3.70% for QTLFCA with .02, .05 and .1 σ_a^2

reaching 55.76% for QTLFCA of $.95 \sigma_a^2$, while the accuracy increased from .513 and .543 to .981 and .955, respectively for sires and dams. Response to MAS, with QTLFCA effect corresponding to .1, .3 and .5 σ_a^2 , at embryo level and different pre-selection rates was evaluated resulting in lower genetic gains when compared to MAS with one-stage selection due to the lower intensity at 2 years old (when more information is available: own performance for cows, full and half sibs) resulting in smaller total accuracy. Therefore, it is possible to obtain responses larger than 98% of the total response using embryo selection rates of .6, .3 and .2 for QTLFCA substitution effects of .1, .3 and .5 respectively. The production of 3 times more embryos allow to increase the genetic gain approximately 23%, due to the increase in selection intensity. When 13 of the 40 embryos were transferred, even markers with small effect ($.02, .05 \sigma_a^2$) could be used in MAS resulting in satisfactory response: 9.0% and 12.6%, respectively. Considering that most of the total cost in a MOET nucleus breeding program is due to maintenance of recipients and feeding growing animals until selection age the MAS utilization on embryo pre-selection can lead to a substantial improvement in the genetic response, even with markers with small substitution effect, without relevant increase in costs.

Key Words: Marker assisted selection, Embryo pre-selection, Beef cattle

1409 A heterogeneity model for estimating the number of QTL alleles in a segregating population. Jean Xu* and Yang Da, *Department of Animal Science, University of Minnesota*.

A frequently observed phenomenon in data analysis for the detection of a quantitative trait locus in a segregating population is the genetic heterogeneity of a quantitative trait among different families. This heterogeneity could be due to the following situations: 1) some families do not have segregating alleles so that marker effects tend to be zero for those families, 2) families with segregating QTL alleles in fact have multiple QTL alleles, 3) different families have the same QTL effect but different marker-QTL recombination frequencies, and 4) different families have multiple QTL alleles and different marker-QTL recombination frequencies. Assuming situation 2), families with similar QTL effects can be placed in the same group using a cluster analysis and a heterogeneity model can be used to estimate the QTL effects of different family groups. Then, the number of QTL alleles can be estimated under the assumption of equal difference between two adjacent QTL alleles when QTL alleles are ordered according to the sizes of their effects. Let k = the number of QTL alleles, α_m = the average of QTL effects of different family groups, and α_d = the largest QTL distance obtained as the difference between the largest and smallest QTL effects. Then, the number of QTL alleles can be estimated as $k = [2 + (3\alpha_m/\alpha_d - 1)] / (3\alpha_m/\alpha_d - 1)$.

Key Words: Heterogeneity model, QTL alleles, segregating population

1410 Evidence of paternally imprinted QTL around *IGF2* in a Berkshire-Yorkshire cross. H. K. Lee², J. C. M. Dekkers*¹, R. L. Fernando¹, and M. F. Rothschild¹, ¹*National Livestock Research Institute, Korea*, ²*Iowa State University, Ames, IA*.

A paternally imprinted QTL with major effect on muscle mass and fat deposition near *IGF2* on SSC2 has been reported for crosses of the Large White with Pietrain and Wild Boar breeds. Our objective was to confirm the presence of an imprinted QTL on SSC2 in an F2 cross between the Berkshire and Yorkshire breeds. Data on average backfat (ABF) and loin eye area (LEA) from 512 F2 animals and genotypic data for eight markers on SSC2 were used. Breed cross regression interval mapping was implemented using the following QTL models: Mendelian (additive and dominance effects), full imprinting (allowing for different maternal and paternal allele effects plus dominance), paternal imprinting (only paternal expression), and maternal imprinting (only maternal expression). Tests of each model against the no-QTL model and tests of full imprinting against the Mendelian, paternal and maternal imprinting models were used in a decision tree to determine presence and mode of inheritance of QTL. Chromosome-wise significance thresholds were determined by permutation. Tests of the Mendelian against the no-QTL model showed no evidence of QTL for ABF and LEA ($P > 0.05$) but tests of the full imprinting against the no-QTL model detected a QTL for both traits at the same position on the distal end of SSC2p ($P < .01$ for LEA and $P < .02$ for ABF), near *IGF2*. Further testing for mode of inheritance showed that the full imprinting model was not significant over

paternal imprinting ($P > .10$) but highly significant over maternal imprinting ($P < .01$), indicating evidence for exclusive paternal expression. The final analysis of paternal imprinting against the no QTL model was highly significant ($P < .01$). Favorable alleles originated from the Yorkshire and, when transmitted through the sire, reduced average backfat by .1 cm and increased LEA by 1.0 cm², compared to Berkshire alleles. Evidence of these QTL, which were not detected based on a Mendelian model, confirms that the *IGF2* region is imprinted in pigs and harbors important QTL for muscularity and fat deposition. Supported by USDA CSREES # 00-52100-9610

1411 Combined interval mapping of QTL using mixed models in reference families with complex pedigrees and its application to chromosome 13 of swine. X. L. Wu and C. Lee*, *Hallym University, Chuncheon, Korea*.

A method for mapping quantitative trait loci (QTL) was introduced incorporating information from various types of progeny and from multiple generations. Effects and positions of QTL were obtained by a joint estimation using the joint QTL-marker distribution of mixed populations or by a weighted least square method. Interval mapping was used to illustrate the theory based on a mixed model. Analysis of variance using multi-point analysis suggested that a Danish pig family carried a QTL on chromosome 13 which significantly affected slaughter weight (SWT) and average daily gain to slaughter (ADSG) ($P < 0.05$), but QTL effect on backfat depth (BFDP) was inconsistently observed. This QTL was located between loci SW1898 and SW398 ($\rho = 0.52036$). This was a region which flanked the PIT1 gene, an essential transcriptional regulatory factor of growth hormone, prolactin and thyrotropin β subunit. This result agreed with previous results that suggested a QTL for other growth traits at the estimated PIT1 position. Variance contributed by this QTL was 9.37% for SWT and 9.45 % for ADSG.

1412 PIT-1, a candidate gene for mass assisted selection in dairy bulls. I. Parmentier*¹, N. Gengler², S. Fontaine¹, B. Auvray², T. Burnside³, D. Portetelle¹, and R. Renaville¹, ¹*Gembloux Agricultural University, Animal and microbial biology unit, Gembloux, Belgium*, ²*Gembloux Agricultural University, Husbandry unit, Gembloux, Belgium*, ³*Semex-Alliance, Guelph, Canada*.

Pit-1 is a protein important for pituitary cell differentiation and proliferation. It acts as a transactivator that regulates growth hormone and prolactin, TSH-b genes. In a previous study (Renaville et al. 1997, J. Dairy Sci. 80, 3431-3438), we have reported that the polymorphism associated to a transition A to G in the exon 6 of the gene could be associated to milk performances. The aim of this study was to search for eventual associations between Pit-1 polymorphism and dairy production traits by using a representative population of dairy sires. DNA was extracted from 1100 A.I. Holstein bulls using in A.I. scheme by Semex-Alliance (Guelph, Canada). A primer-specific PCR test has been developed to reveal the two alleles of Pit-1 gene which are called A and B. A mixed linear animal model including milk data of 2,400,000 lactations from 1,100,000 daughters of tested bulls was developed. The allelic frequencies were 53% and 47% for A and B respectively. Allelic frequencies were introduced as regression into the mixed linear animal model. The results showed an a value of +46,3 kg, + 1,9 kg and + 1,5 kg for milk, protein and fat yield, respectively. This a value represents the effect, on the trait, of the substitution of a B allele by a A allele. In conclusion, this study showed a significant relationship between the A allele of Pit-1 and dairy production traits of Holstein bulls. This gene could be considered as an interesting tools for marker assisted selection of dairy bulls. (Supported by the Belgian Ministry of Small Enterprises, Traders and Agriculture (grant 5983S), Semex-Alliance (Guelph, Canada) and Tomen Corp. (Tokyo, Japan))

1413 Composite interval mapping analysis of milk production and health traits in US Holsteins. A. B. Kurtz*, S. L. Rodriguez-Zas, H. A. Lewin, and D. W. Heyen, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Identification of quantitative trait loci (QTLs) affecting milk, fat and protein yield, and somatic cell score was performed using composite interval mapping (CIM). Daughter yield deviations and predicted transmitting abilities from eight US Holstein families in a granddaughter design were analyzed. Sons were screened for 174 microsatellite markers distributed across 29 autosomes. Family sizes ranged from 72 to 203 sons and the average number of informative markers per chromosome was three. Interval mapping (IM) model was combined with significant ($P < 0.05$) regressors representing markers at least 10 cM from either side of the interval studied to account for other loci. Univariate and multivariate CIM analyses were implemented within each family using QTL Cartographer. Univariate genome-wide critical P-values were calculated using permutation tests and chromosome-wise critical P-values were calculated using a Bonferroni correction. On chromosome six, results from univariate and multivariate IM ($P < 0.05$) and CIM ($P < 0.025$) models identified a QTL located at 80 cM affecting protein yield in family two. Single-marker model findings suggested similar associations ($P < 0.025$) between protein yield and consecutive informative markers, BMS518 (69 cM) and ILSTS97 (80.3 cM). On chromosome 14, univariate CIM identified a QTL at 1.5 cM affecting milk yield in family four. This finding was supported by multivariate IM, which located a QTL ($P < 0.001$) at 0 cM in family four, and by multivariate CIM that located a QTL at 3.5 cM in family four ($P < 0.01$) and at 5.5 cM in family five ($P < 0.001$). The multivariate CIM approach identified a QTL at 26.3 cM on chromosome 14 for family four ($P < 0.001$), which is consistent with single marker results that identified a marker (BM1508) at 30.5 cM with a significant ($P < 0.05$) effect on somatic cell score. Our study confirmed that the comprehensive multivariate CIM model provided precise QTL estimates while accounting for QTL outside the interval under study.

1414 Interval mapping of quantitative trait loci affecting yield and health traits in dairy cattle. A. B. Kurtz*, S. L. Rodriguez-Zas, H. A. Lewin, and D. W. Heyen, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Phenotypic records for milk, fat and protein yield, and somatic cell score were combined with genetic data from eight US Holstein families in a granddaughter design. The phenotypes were regressed on the conditional probabilities of inheriting a quantitative trait locus (QTL) allele at 1-cM intervals along the chromosome, using an interval mapping (IM) model. A total of 1065 sons were screened for 174 microsatellite markers across all autosomes. The number of informative markers per chromosome ranged from one to eight. A weighted least squares analysis was performed within and across families with weights equal to the variance of the trait. The impact of the use of two different phenotypic measures, daughter yield deviations (DYD) and predicting transmitting abilities (PTA), was compared. Genome-wise critical P-values were calculated using a Bonferroni correction to account for multiple testing. Small differences were observed between the estimates obtained for PTA and DYD. A significant effect ($P < 0.001$) for somatic cell score was detected in family four on chromosome 23 (3 cM). This autosome includes the bovine major histocompatibility complex. On chromosome three, significant effects for milk and protein yield were found. For family one, a potential QTL with significant effect ($P < 0.001$) on milk yield was located at 46 cM and supported by single marker findings. Both DYD and PTA models for protein yield estimated the same position (26 cM) using within and across family analyses. The estimates of the effects were similar, meeting suggestive significance levels ($P < 0.0001$). These results support those obtained with single marker models that detected effects of nominal significance ($P < 0.05$) on protein yield in the same family (five) for the two markers flanking the 16-cM interval containing the effect at 26 cM. The IM model provided an estimate of QTL position in proximity of the center of an interval that was not clearly resolved using single marker models.

Key Words: Least Squares, Protein, Somatic Cell Score

1415 Identification of genome positions associated to monthly production and health records using a single-marker model. S. L. Rodriguez-Zas*, B. R. Southey, H. A. Lewin, and D. W. Heyen, *University of Illinois, Urbana, IL.*

Many traits of agricultural importance such as monthly dairy records are measured repeatedly over time. Current methods of detection of quantitative trait loci (QTL) use single (average or cumulative) phenotypic measurements thereby ignoring the pattern that these traits exhibit. The objective was to identify genome positions expressed at specific stages of lactation or influencing the shape and scale of the lactation curve. A nonlinear single-marker model was used to describe monthly milk yield, fat and protein percentage, and somatic cell score (SCS) records from daughters of 475 sons across three Holstein families. A total of 46 markers along six chromosomes were fitted. Six percent of the hypothesis tests across families, traits, markers, and parameters were significant ($P < 0.0001$) after adjustment for multiple tests. Some positions had significant effects on all parameters describing the lactation curve (chromosome 3, marker at 41 cM affecting the shape and scale of the SCS curve) meanwhile other markers were associated with a significant variation on a specific descriptor of the lactation curve (chromosome 6, marker at 64 cM, only affecting the shape of the protein curve). These results suggest the presence of putative QTL in the proximity of the significant positions that influence not only the magnitude but also the profile of the lactation curve. Identified positions can be incorporated into selection decisions to alter the persistency of production or the somatic cell score fluctuations during lactation.

Key Words: Lactation curve, Longitudinal data, Non-linear model

1416 Random regression models to estimate genetic growth parameters of young zebu beef cattle. E. S. Sakaguti*¹, R. L. Quaas², M. A. Silva³, E. N. Martins¹, P. S. Lopes⁴, and L. O. C. Silva⁵, ¹Universidade Estadual de Maringá, Maringá, Brazil, ²Cornell University, Ithaca, New York, ³Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, ⁴Universidade Federal de Viçosa, Viçosa, Brazil, ⁵EMBRAPA - Gado de Corte, Campo Grande, Brazil.

A total of 66,430 body weights measured at ages ranging from 365 to 650 days on 28,234 Tabapua beef cattle born from 1975 to 1997 and raised under Brazilian pasture conditions were used to evaluate the application of random regression models (RRM). Linear Legendre polynomials were used to describe random effects. Likelihood ratio test was used to compare the animal models. A simple repeatability model was inappropriate to evaluate the current data file because additive genetic and permanent environmental effects were dependent of the age of animal. Therefore the model that used continuous functions to describe these two effects had the most adequate fit. Growth rate estimated by the linear random regression coefficient had heritability equal 0.54 and genetic correlation with live weight at 507.5 days of age equal 0.47. The heritabilities for the live weight ranged from 0.3 to 0.4 within the age interval considered.

Key Words: Random regression, Genetic parameters, Beef cattle

1417 Inversion-free method for variance component estimation under the animal model. Jean Xu* and Yang Da, *Department of Animal Science, University of Minnesota.*

Estimation of variance components using maximum likelihood (ML) or restricted maximum likelihood estimation (REML) under the animal model requires the inversion of the coefficient matrix of the mixed model equations. Matrix inversion is computationally intensive and is a limiting factor for the number of animals that can be analyzed jointly. Under the assumption of constant relationships among family members and independent families, an inversion-free method for variance components is available to estimate three variance components. These three variance components can be additive, dominance, and residual variance components, or additive, permanent environment, and residual variance components. Formulae of this inversion-free method were developed for both ML and REML.

Key Words: Inversion free method, Variance component, Animal model

1418 Incorporating external information in multi-breed genetic evaluation. R. L. Quaas* and Z. Zhang, *Cornell University, Ithaca, NY.*

Some sires in multi-breed genetic evaluation have highly accurate genetic evaluations based on data not included in the multi-breed evaluation. In some cases, the external information is much greater than the internal. It is dissatisfying to breeders that sires rank differently, especially when the multiple breed evaluations are based on relatively limited data. Application of Bayesian principles with some simplifying assumptions provides a framework for incorporating external information. The external information is assumed to be contained in the animals' external Expected Progeny Differences (EPD) and their accuracies. Parameters are included to account for base differences. Effects of incorporating external EPD were investigated with data drawn from the American Simmental Association database. The data set included herds with both Simmental- and Angus-sired calves plus a sample of large Simmental herds. It contained 40680 records of calves sired by 1047 bulls. Data were analyzed with and without incorporating external information. The external information consisted of 64 American Angus Association (AAA) EPD and 51 Red Angus Association of America (RAAA) EPD. Average accuracies of external EPD were 0.91, 0.89, 0.87 and 0.82 for BWT, WWT, YWT and milk from AAA, and 0.78, 0.72, 0.70 and 0.64 for RAAA. Without external information rank correlations between internal EPD and AAA EPD were 0.49, 0.50, 0.47, 0.27 for BWT, WWT, YWT and milk. The corresponding values were 0.64, 0.68, 0.59, 0.20 for RAAA bulls. Following incorporation of external information the rank correlation between internal EPD incorporating external information and external EPD from AAA were 0.87, 0.91, 0.90, 0.91 for BWT, WWT, YWT and milk. For RAAA sires the corresponding values were 0.91, 0.93, 0.95, and 0.90. In contrast the changes for purebred Simmental sires were small; all rank correlations were > .999. The procedure succeeded in ranking Angus bulls similarly to their external EPD but did not effect the ranking of Simmental sires.

Key Words: Expected Progeny Difference, Bayesian Analysis, Beef Cattle

1419 Bayesian linear mixed models employing the contaminated normal distribution: a simulation study in animal breeding. I. G. Pereira*, G. J. M. Rosa, and H. N. Oliveira, *UNESP - Botucatu, SP/Brazil.*

The Gaussian distribution is often assumed in applications of linear mixed model for quantitative traits in animal breeding. This assumption, however, makes inferences vulnerable to the presence of discrepant observations, such as those originated from preferential treatment or error in measurements. Thick-tailed distributions such as the Student-*t* process have been suggested for robust estimation. Here, the contaminated normal distribution is assumed for the residuals of linear mixed models in beef cattle evaluation. A simulation study is used to compare the performance of the Gaussian model and this robust alternative. Fifty data sets were simulated, considering two levels of fixed effects and five generations with 200 animals each, without selection. Different levels of contamination were studied. A Bayesian framework was adopted, and the Gibbs sampler and the Metropolis-Hastings algorithm were used to carry out the posterior analyses. Single chains were run for each model and data set, with 250,000 iterations, after burn-in. Except for data sets without contaminants, the robust model presented better estimates of residual variance. Estimates of heritability were similar for all models, but predict genetic values obtained by the robust model were closer to the real breeding values, as assessed by correlation analysis. The results suggest that the contaminated normal linear mixed model offers a flexible alternative for robust estimation in animal breeding.

Key Words: Contaminated normal distribution, Linear mixed models, MCMC

1420 Effect of reducing the frequency of milk recording on accuracy of genetic evaluation using a random regression model. J.J. Tosh¹, J.A.B. Robinson*¹, G.B. Jansen¹, and C.Y. Lin², ¹Centre for Genetic Improvement of Livestock, University of Guelph, Ontario, Canada, ²Dairy and Swine Research and Development Centre, Agriculture & Agri-Food Canada, Lennoxville, Quebec.

Accuracy of national dairy cattle genetic evaluation programs that use a random regression model was studied to determine the effect of reducing monthly milk recording to less frequent schemes. A large dynamic

population of dairy cattle was stochastically simulated. The population consisted of 1000 herds of 45 cows on average each and heifers, as well as young (n = 160) and proven (n = 40) bulls at an AI stud. Selection and mating mimicked a progeny test with weak to moderate selection on first lactation production (phenotype). All cows left the herd upon completion of their third lactation. Test day records for monthly farm visits were generated for milk, fat, and protein yield, and somatic cell score using a multiple-trait random regression model analogous to that used for genetic evaluation of dairy cattle in Canada. The simulation ran for a period of 20 years, and created more than 6.2 million records. Genetic evaluation was done using the records and industry software. Correlations between estimated breeding values and known true values (i.e., accuracies) were calculated. Accuracies for cows (n = 318680) and bulls (n = 590) were 0.773 and 0.940, 0.772 and 0.935, 0.758 and 0.934, 0.669 and 0.912, and 0.720 and 0.943 for milk, fat, and protein yield, somatic cell score, and lactation persistency, respectively. As expected, accuracy increased for cows with more lactations, and bulls with more daughters (mean = 451; range 1 to 2991). Genetic evaluation was also done after editing the data set to randomly eliminate test days, mirroring reduced milk recording. Halving the frequency of milk recording to every second month did not notably affect accuracy, which decreased by no more than 0.02 for any trait in cows; in bulls the effect was even smaller. Results indicated an average of ten records per cow would suffice as well as twenty. Corresponding reductions in the cost of milk recording could be great. Conducting on-farm milk recording every second month rather than monthly appears justified when a random regression model is used for genetic evaluation of large dairy cattle populations.

Key Words: Dairy Cattle, Milk Recording, Test Day Model

1421 Bayesian analysis of multiple-linear and categorical traits with varying number of categories. D.H. Lee*¹, I. Misztal¹, J.K. Bertrand¹, and R. Rekaya², ¹University of Georgia, Athens, Georgia, ²University of Wisconsin, Madison, Wisconsin.

The purpose of this study was to determine properties of a Bayesian method for joint analysis of multiple linear and categorical traits. Data sets with 10,630 records were simulated for to 3-trait linear models, with effects of sex, 50 contemporary groups, and 14,400 animals in 5 generations using BLUP selection. Selected traits were categorized with a binary and 4-categories. Bayesian analyses used Gibbs sampling. Residual variances for the categorical traits were assumed to be 1. The first threshold was set to 0, and the remaining thresholds were estimated. Sampling of the residual variances was from 1) the inverted Wishart (IW) distribution with rescaling (RS-IW), 2) IW distribution conditioned to residual variances of 1 for categorical traits by extending the methodology of Korsgaard et al. (1999, GSE 29:177) (RT-IW). Estimates were posterior means. Consistent estimates in models involving binary traits were obtained only after location parameters were reparameterized by weights resulting from conversion from samples of IW to RS-IW or RT-IW. This modification also increased the mixing rate several times in other models without affecting the estimates. No bias was observed with one categorical and several linear traits. In several models, biases were the same with RS-IW and RT-IW. In a model with three traits each with four categories, maximum biases were 0.01 for heritabilities and 0.14 for correlation. In a model with one binary and two linear traits, biases were 0.02 and 0.03 for heritabilities and correlations, respectively. In a model with two binary and one 4-category traits, these biases were 0.05 and 0.57 with RS-IW, and 0.04 and 0.30 with RT-IW. Analysis of multiple linear and categorical traits using a Bayesian method via Gibbs sampling is possible but biases can be expected especially for covariances and with binary traits. Differences when using samples of residual variance from RT-IW and RS-IW are small except with binary traits.

Key Words: Bayesian analysis, Threshold model, Reparameterization

1422 Analyses of sequential weights of Brazilian Zebu cattle using a multiple trait model by REML and Bayesian method. P. R. C. Nobre*¹, I. Misztal¹, S. Tsuruta¹, D. Lee¹, J. K. Bertrand¹, L. O. C. Silva², and P. S. Lopes³, ¹University of Georgia, ²CNPGC/Embrapa, Brazil, ³UFV, Brazil.

The purpose of this study was to estimate parameters of birth weight and sequential weights of Nellore cattle. Data collected by the Brazilian Zebu Breeders Association consisted of 620,528 records collected from 1975 to 1999. Weights were recorded at 10-110 days, 102-202

days, 193-293 days, 283-383 days, 376-476 days, 467-567 days, 551-651 days and 633-733 days, respectively. Two sample data sets with all known ancestors with genetic ties were created. The number of animals from all herds was 18,889 and 16,161 from herds with no missing traits. Records preadjusted to fixed age were analyzed by a multiple trait model, which included the effects of contemporary group, class of age of dam, and direct, maternal and permanent environmental effects. Analyses by REML were conducted five traits at a time, and analyses by the Bayesian method using block Gibbs sampling involved all nine traits. For REML and the first data set, the range of estimated direct genetic correlations for each pair of traits was 0.43 to 0.99, with higher values between weights at higher ages. Direct heritability varied from 0.17 to 0.33, and was highest for weight at 551-651 days; however, ma-

ternal and permanent environmental variance decreased after an age of 193-293 days. Additive and residual estimated variance increased from birth weight through weight at 551-651 days, however maternal and permanent environmental variance decreased after age of 193-293 days. Heritabilities with the complete data set were slightly lower. With the Bayesian method, chain length of 50,000 was insufficient to obtain consistent maternal and permanent environment estimates, especially for weights over 476 days. This is most likely due to extreme correlations between these traits. The parameter estimates will be used to validate parameter estimates obtained from random regression models.

PSA Genetics

1423 Influence of genetics on phytate phosphorus utilization by chickens. T. N. Smith, S. E. Aggrey*, R. I. Bakalli, and G. M. Pesti, *University of Georgia*.

An experiment was conducted to determine whether there is a genetic basis for selection for phytate phosphorus (P) utilization in chickens. Fifty-eight Athens-Canadian random bred chickens were fed a phosphorus deficient diet and the phytate P levels in their excreta was determined by Near Infra-red Spectrophotometry. Five roosters categorized as High sire excreta phytate P (SEPP) (1.17 ± 0.002) and Low SEPP (1.09 ± 0.002) were selected to sire progeny. The SEPP values were significantly different ($P < 0.0001$) between the two sire groups. One hundred and seventy chicks from Low SEPP and 180 chicks from the High SEPP were hatched and fed a P deficient diet (.53% P). The chicks were sacrificed at 16 d by carbon dioxide asphyxiation and body weight (BWT) was recorded. The left tibia were collected for ash determination on a fat-free basis. There was a negative correlation ($r = -0.15$; $P = 0.0053$) between sire excreta phytate P and 16 d BWT. The correlation between SEPP and tibia ash was also negative but not significant ($r = -0.01$; $P > 0.05$). Progeny from Low SEPP had higher BWT (152.7 ± 1.5 g) than progeny from High SEPP (146.8 ± 1.4 g) ($P = 0.0042$). Similarly, progeny from Low SEPP had higher tibia ash ($36.57 \pm 0.31\%$) than progeny from High SEPP ($35.55 \pm 0.03\%$) ($P = 0.0187$). This implies that sires that excrete low phytate P, that is, those that are better able to utilize phytate P, produced progeny that were significantly heavier at d 16 and had better bone mineralization than progeny sired by poor phytate P utilizers.

1424 Inheritance of Alkaline Phosphates in Local Iraqi Chicken and its association with Production. Ali Al-Hillali¹ and Khalid Al-Soudi*², ¹*Iraqi Atomic Energy Commission, Baghdad, Iraq*, ²*Animal Production Department, Agriculture College, Baghdad University, Baghdad, Iraq*.

Ninety eight dams and twenty one sires representing the parent stock of local Iraqi chickens, and their progeny (305 pullets) were typed for alkaline phosphates isozymes and activity in order to assess the effect of sex, age and genotype. Genetic analysis revealed three types of electrophoretic isozymes, namely fast, slow and a mixture of a fast and slow band. Gene frequencies of the fast band were 0.41 and 0.39 and that for the slow band were 0.59 and 0.61 for dams and progeny flocks, respectively. Furthermore, age, sex and type of enzyme were found to have significant effects on enzyme activity, and birds of fast isozyme type had higher egg weight, lower age at sexual maturity and higher body weight at sexual maturity. Heritabilities of plasma alkaline phosphatase at different ages and economic traits ranged from moderate to high. Phenotypic, genotypic and environmental correlations between level of plasma alkaline phosphatase and growth rate and production characters indicated that the high activity of alkaline phosphatase was associated with higher growth rate at early stages, earlier sexual maturity and production of heavier but fewer eggs. Genetic and phenotypic correlations among enzyme activities at three ages were positive and high and expected genetic response after one generation of individual selection for alkaline phosphatase activity leads to improved production characters.

1425 Multisource Multitrait Selection Indices For Genetic Improvement In Poultry Breeding Programs For Laying Hens. 2. Construction And Evaluation Of Various Indices. A. A. Enab¹, N. Kolstad², and F.H. Abdou¹, ¹*Fac. Of Agric., Minufya Univ., Shebin El-Kom, EGYPT*, ²*Agricultural Univ. Of Norway*.

Records on 11689 pullets progeny of 326 sires and 1546 dams produced in two hatches of four strains of White Leghorn hens raised under Norwegian conditions were utilized to construct and evaluate general, reduced and restricted selection indices. Eight indices were constructed using five traits and three sources of information for each trait in different combinations. The studied traits were age at sexual maturity (SM); egg number up to 260 days of age (EN); egg weight (EW); body weight (BW) and egg specific gravity (SG). The sources of information used in different combinations for each trait were individual's own phenotypic value (OP) and its full (FS) and half sister's (HS) average. It was noticed that the female general index which included all of the five traits and all of the three sources of information was found to be the most efficient index ($r_{TI} = 0.76, 0.65, 0.69$ and 0.61) in the four lines, respectively. The general index for males which included only two sources of information (FS&HS) for each of the five traits was found to be less efficient ($r_{TI} = 0.60, 0.54, 0.55$ and 0.51) in the four lines, respectively. The restricted index for both EW&BW in line 1 was the lowest efficient index ($r_{TI} = 0.50$). Expected and actual genetic progress (G) achieved in each trait was also maximum for female general index, for most traits in the four lines. It was noticed that the multisource index considering all of the five traits was superior to the multisource index involving only three or four traits. It was concluded that an index based on five traits and three sources of information could be applied to improve egg production and specific gravity traits.

Key Words: Genetic improvement, Multisource selection indices, Layers.

1426 A comparative genomic approach to identify-QTL's for growth in chickens. J. Funk-Keenan and G. F. Barbato, *The Pennsylvania State University, University Park, PA*.

It has long been surmised that different genes must influence different aspects of the growth curve. Unsurprisingly, different sets of QTLs influencing either early or late growth have been identified in mice and pigs. Using data from Vaughn et al (2000), we performed a modified candidate gene approach to identify QTLs influencing early growth in an F2 cross of chickens divergently selected for 14-day exponential growth rate (EGR). By aligning the mouse QTL's with the murine physical map; we targeted QTL's having syntenous genes in both the mouse and chicken genome. We selected the three to five microsatellite markers from the chicken linkage map based on their proximity to the locations of the murine syntenous genes in the chicken genome. Twenty-four microsatellite markers corresponding to six murine QTL's on six chicken chromosomes (1,3,4,5,6 and Z) were targeted for investigation. We chose the top and bottom 3% of chicks from the 14-day EGR distribution from the F2 cross. We then tested whether the microsatellite marker allele frequencies differed between the two tails of the distribution. Of the twenty-four microsatellite markers genotyped, eight markers (representing 5 putative QTL's) exhibited significantly different marker allele frequencies between birds having high or low 14-day EGR. The significant markers were located on chicken chromosomes 3,4,5,6 and Z. Notably, the putative QTL located on chromosome 4 is located at 148cM,

corresponding to a previously identified QTL for feed intake in chickens! These data support our hypothesis that the genetic architecture of growth is highly conserved across species and provides us with an opportunity to pursue QTL's that may have common mechanisms among most domestic animal species.

1427 Preliminary mapping of a gene affecting male fertility in the chicken. K Song^{*1}, F.G. Sizemore III², J.D. Kirby¹, and D.D. Rhoads¹, ¹University of Arkansas, Fayetteville, AR, ²USDA-Avian Disease and Oncology Lab, East Lansing, MI.

SDD is a dominant gene effecting degeneration of the ductules leading from the testis which results in defects in excurrent sperm maturation and thus production of degenerate, immotile sperm in a line of Delaware chickens (Froman, and Bernier. Biol. Reprod. 37:969-977, 1987; Kirby, Bernier, and Froman. Jr. Androl. 11:49, 1990). We used RAPD and bulked segregant analysis to identify a 1500 bp PCR product which appears linked to SDD. This PCR product was used to isolate a single BAC comprising approximately 100 kbp from a Jungle Fowl library (Dodgson). A single, polymorphic, simple sequence repeat was characterized from this BAC clone and was used to screen the East Lansing backcross mapping population. The repeat maps this BAC, and thus the 1500 bp product, to linkage group E41 on the East Lansing map. Based on gene order this linkage group appears syntenic with a region on the long arm of human chromosome 9. We are currently using additional microsatellites from this linkage group to more accurately position SDD on the chicken genomic map. Since most, if not all, of the genes in this region can be identified from the human sequence this should greatly speed isolation of the gene and molecular characterization of the defects responsible for the SDD phenotype. Although SDD was identified in the Delaware line it is likely that other alleles of the SDD gene affect male fertility in commercial poultry lines. Characterization of the SDD gene is of great importance in improving male fertility in the poultry breeding industry and the SDD gene should have homologs which affect testis development and fertility in humans and other species.

Key Words: fertility, male, sperm, gene mapping

1428 Zona pellucida 3 protein (ZP3) and gene (ZPC) expression in the turkey, *Meleagris gallopavo*. M. L. Block^{*1}, K. E. Nestor², and G. F. Barbato, ¹The Pennsylvania State University, University Park, PA, ²The Ohio State University, Wooster, OH.

The purpose of the following study was to characterize the protein expression of the turkey zona pellucida 3 protein (tZP3) and establish the cDNA sequence for tZP3 (tZPC). Six female turkeys from 2 genetic lines: F line and RBC line were used in this experiment. Using antibodies developed to specific amino acid sequences from chicken ZP3 (chZP3), western blot analysis of the perivitelline membranes (PVM) of laid turkey eggs revealed an immunoreactive band with the molecular mass of approximately 45 kD - which is larger than the 42kD chZP3 protein. Western blots of turkey tissue (liver, ovary, infundibulum, granulosa cells, and uterus) confirmed the presence of the tZP3 protein in granulosa cells, ovary and, unexpectedly, in the infundibulum. Further, not all subjects tested showed ZPC protein expression in the ovary and infundibulum. Turkey ZPC cDNA sequences were obtained by rtPCR using primers sets designed from chZPC. Sequence analysis of tZPC revealed high homology of the carboxy-terminus and the mid-portion of tZPC with both chZPC and qZPC (Japanese quail). Results from rt-PCR analysis in turkey tissues (liver, ovary, infundibulum, granulosa cells, and uterus) revealed tZPC mRNA expression in both granulosa cells and the ovary, but not the infundibulum. Together, these data suggest that expression of tZP3 may be temporally regulated in different tissues, perhaps related to hormonal cycling.

Key Words: Genetics, Turkey, Zona pellucida

1429 Molecular characterization of a partial inverted repetitive (PIR) DNA family in the chicken genome. Juan Li, Xiaofei Wang, and Frederick Leung^{*}, University of Hong Kong.

Tandem array repetitive sequences constitute a major component of the eukaryotic genome. Although the general characteristics of the tandem

repeats have been well characterized, the process involved in their origin and maintenance remain unknown. Chicken Partially Inverted Repetitive (PIR) DNA is a novel repetitive DNA family first characterized by our laboratory. With the basic repeat unit of 1.43Kb, it is characterized as tandem array pattern and located on chromosome 8. The central core of the repeat unit consists of 814bp showing 65% homology with w chromosome XhoI/EcoRI repeats. Sequence analyses show that they share the similar characteristics: (A)₃₋₄ and (T)₃₋₅ clusters are separated by 6-7 nucleotides. Such arrangement enables the A and T clusters to appear alternatively at every pitch of the DNA double helix. Hence, they behave as bent molecules in solution affecting the mobility of the repeat unit in the PAGE running slower as compared to its mobility in the agarose gel. Tandem array pattern of repetitive family in the genome is largely due to the unequal exchange happening within homologue chromosomes and sister chromatids. From sequence analyses, we have characterized an 86bp fragment unit flanking the central core in the inverted direction. Detailed sequence analyses further show high frequency of this inverted structure within this repetitive family. Our results indicate that other forces may be involved in the formation of higher organization region of the PIR family. Junction region analyses show that this inverted fragment often associated tandem array repetitive sequence with the non-tandem array repetitive sequence. Such arrangement indicates that the inverted structure may function as the recognition site during the evolution of this repetitive DNA family in the chicken genome. In addition, we observed polymorphism within different populations of domestic gallus gallus species indicating that PIR family is evolving fast. In conclusion, chicken genome may serve as an experimental model for the study of the origin and dynamics of repetitive DNA.

Key Words: Chicken, Repetitive sequence, Inverted structure

1430 The temporal expression of the Myogenic Regulatory Factor genes during proliferation and differentiation of satellite cells derived from chicken *Biceps femoris* and *Pectoralis major* muscles. A Sarver, J Richter^{*}, H Kocamis, S Gahr, and J Killefer, ¹West Virginia University, Morgantown, WV, 26506.

Satellite cells are responsible for postnatal skeletal muscle growth and repair. In the adult muscle, these mononucleate cells are mitotically quiescent until activated by an external stimuli, such as weight bearing or injury. Once activated, they undergo proliferation, differentiation and fusion into new or existing muscle fibers. Skeletal muscle myogenesis in vertebrates is largely managed by the myogenic regulatory factor gene family (MRF): Myo D, Myf-5, Myogenin, and MRF-4. We investigated the expression pattern of MRFs in chicken satellite cells isolated from *Biceps femoris*(BF) and *Pectoralis major*(PM) from the time of quiescence to the fusion of muscle fibers using reverse-transcription polymerase chain reaction (RT-PCR). There was little expression of any MRFs in the quiescent cell of both BF and PM satellite cells. Myo D was first expressed in both muscle types at 24 hr, corresponding with proliferation. Expression level then increased at 48 hr, remained constant to 96 hr, and began to decrease at 120 hr in both BF and PM cell cultures. Myf-5 displayed a similar expression pattern to Myo D in both BF and PM cell cultures. Myogenin was first expressed at 24 hr in both BF and PM. In BF satellite cells, expression remained relatively constant to 72 hr, and increased at 96 hr, corresponding to differentiation. Expression then decreased during late myotube formation (144 hr). In PM satellite cells, myogenin expression gradually increased from 24-96 hr, and then decreased at 120-144 hr. MRF-4 mRNA was at its highest at 72 hr in PM cell cultures and 144 hr in BF cultures. In PM, MRF-4 expression remained low during proliferation and gradually increased through differentiation (72-144 hr). This correlates with its role as a late differentiating gene. Predicted activities and patterns in the expression of members of the myogenic gene family correlate with satellite cell activation in the chicken.

Key Words: satellite cells, myogenic regulatory factor genes, muscle

1431 Social stress induced different alterations of dopamine concentrations and adrenal function in genetically selected chicken lines. P. Singleton*¹, Y. Chen¹, M.W. Muir², and H.W. Cheng¹, ¹USDA-ARS, Livestock Behavior Research Unit, ²Dept of Animal Science, Purdue University.

Dopamine (DA) and corticosterone (CORT) are involved in regulating animals' response to stress. The objective of this study was to examine whether alterations of DA concentrations and adrenal function are associated with behavioral response to social stress in two strains of White leghorns hens that were selected for high (HGPS) and low (LGPS) group productivity and survivability resulting from cannibalism and flightiness in multiple-hen cages. At 17-wk of age, hens were randomly assigned into single and 2-hen cages. The 2-hen cages contained one hen from HGPS or LGPS line and one from a commercial Dekalb XL line that was used as standardized genetic competitors. At 24-wk of age, seventy hens were bled (10 hens from 3 genetic line, 2 replicates, plus 10 extra testers). Plasma concentrations of DA were measured using HPLC. Changes of the adrenal function were indicated by plasma concentrations of CORT, and hypertrophy of the adrenal gland indicated as a percentage of adrenal gland weight/body weight (AW/BW). In single-hen cages, HGPS hens had heavier adrenal glands indicated as a greater AW/BW ratio ($P < 0.05$). However, LGPS hens tended to have greater plasma concentrations of DA ($P = 0.07$). In 2-hen cages, there were no difference in AW/BW ratio between HGPS and LGPS hens ($P > 0.1$). However, both plasma concentrations of CORT and DA were greater in LGPS hens ($P < 0.05$ and $P < 0.01$, respectively). The results suggest that social stress induced an up regulation of DA and adrenal function in LGPS hens but not in HGPS hens. The data was consistent with the previously findings that HGPS hens adapted better to social competition. Some of the parameters, such as concentrations of DA and CORT, could be used as an indicator of chicken well-being.

Key Words: Social stress, Dopamine and corticosterone, Genetic selection, chickens

ASAS/ADSA Forages and Pastures: Silages, Forage Quality, and Digestion

1433 Effect of wilting and molasses on silage quality of *Leucaena leucocephala*. T. Clavero*¹ and Rosa Razz¹, ¹La Universidad del Zulia.

An experiment was conducted in the dryland farming area of northwest, Venezuela in order to evaluate the ensiling properties of *Leucaena leucocephala* through microsilage techniques. Factors studied were two levels of molasses (0 and 5%) added during ensiling and wilting for 0 and 3h. Statistical analysis was made using a 2x2 factorial arrangement and mean values were compared by Fisher's least significant difference test. Response variables considered were: crude protein (CP), content, ammonia nitrogen as percent of total nitrogen, pH, acetic and lactic acid contents. Addition of molasses increasing ($P < 0.05$) lactic acid content (2.01 vs 7.15%), the crude protein content was about the same (21.8 vs 21.6) whatever the molasses treatment, while reducing ammonia products (2.8 vs 1.9%), pH, (4.7 vs 4.1) and acetic acid (4.8 vs 3.6%). Silages prepared from non-dehydrated forage had higher ($P < 0.05$) CP contents (21.5 vs 20.8%), ammonia products (4.1 vs 2.2%) and acetic acid (5.3 vs 2.6%) and lower pH (4.4 vs 4.7) with less lactic acid (3.5 vs 6.5%). This suggests that combination of molasses and wilting can improve the fermentation quality of *Leucaena leucocephala* silage more than each of them being as a single treatment.

Key Words: *Leucaena leucocephala*, molasses, silage

1434 Prediction of reed canarygrass quality as influenced by N fertilization and maturity. D.J.R. Cherney*, D.R. Dewing, and J.H. Cherney, Cornell University, Ithaca, NY.

The need for more control over forage quality will increase with expanding herd size and increasing individual cow production. Our objective was to develop equations for predicting NDF and CP of first cutting reed canarygrass (*Phalaris arundinacea* L.) using growing degree days base 32°F (GDD32) and Julian date. Previous research has indicated a base temperature of 32°F resulted in better predictions than the 41°F base typically used for forage crops. Pure stands of established reed canarygrass in replicated field plots were fertilized with 0, 56, or 112 Kg of N/ha at the onset of spring growth at four locations in central

1432 MHC and Family Effects of Cellulitis on Lymphocyte proliferation in MHC defined broiler chickens. K. S. Macklin*, R. A. Norton, and S. J. Ewald, Auburn University, Auburn, AL.

Previous work, using avian cellulitis origin *E. coli* isolate (EC-AR1) in broilers demonstrated that the MHC (B type) effects lesion development, specifically that B¹³ was resistant, while B²¹ was susceptible. Other researchers have reported that B¹³ in leghorn chickens has a stronger response than B²¹, when tested with a lymphocyte proliferation assay. The purpose of this study was to use a lymphocyte proliferation assay to: 1. Investigate previously reported leghorn MHC responses in broiler chickens. 2. Use pedigreed matings to determine family effects. 3. Determine proliferation responses in MHC family defined (pre-challenged and challenged) birds to 2.5ug ConA, 1:100 Pokeweed and 1x10⁶ killed *E. coli* (EC-AR1). *E. coli* isolate EC-AR1 has been extensively characterized by this lab in developing two cellulitis models. Matings for the following experiments were designed using B¹³/B²¹ birds (1 male: 10 females). Four experiments were conducted with serological MHC typing at three weeks of age. At week four nine birds of the appropriate MHC (B¹³/B¹³ and B²¹/B²¹) and family types (A-D) were bled and a lymphocyte proliferation assay performed. The following day birds were challenged with a subcutaneous injection of *E. coli* (EC-AR1). Eighteen days post challenge these birds were bled for the proliferation assay, sacrificed and assessed for the presence of cellulitis lesions. Results of lymphocyte proliferation assays closely mimic previously reported results for leghorn type chickens in that B¹³/B¹³ birds produce a stronger response than do B²¹/B²¹ birds. A significant sire family difference was also noted in both proliferative response and development of cellulitis lesions. Results support the hypothesis that MHC plays an important role in influencing lymphocyte response and cellulitis development, while also implying that other yet to be identified genes play a role in these responses.

Key Words: MHC, broiler chicken, lymphocyte proliferation

and western New York over two growing seasons. Plots were sampled beginning Mid-May and continued until the end of May or early June. Regression analysis indicated that GDD32 was the best single predictor of NDF ($R^2=0.608$ and $MSE=31.8$) across all locations, years, and N rates. At each individual location and N rate, however, prediction equations generally had R^2 above 0.90 and MSE generally was below 6. The harvest window, when forage NDF was between 50 and 60% NDF, was predicted using regression analysis. Harvest window ranged from 6 to 11 days. Julian date was the best single predictor of CP, but maturity explained only 50% of CP variation. Data suggest that development and use of prediction equations at individual locations would assist producers in developing harvest strategies to optimize forage quality.

Key Words: Forage quality, Grass, Reed canarygrass

1435 A survey of phytoestrogen activity in Kansas Flint Hills native grass pastures. D.A. Blasi*¹, S.I. Paisley¹, W.V. Welshons², and G.E. Rottinghaus², ¹Kansas State University, ²University of Missouri, Columbia.

Plant-derived estrogens have been implicated as a contributing factor to observed increases in bulling activity and/or reduced efficiency to growth-promoting implants. In an effort to characterize Kansas Flint Hills native grass pastures, the botanical composition and basal cover in three pastures were surveyed using a modified step-point procedure to estimate the incidence of individual plant species. In order to better characterize estrogenic activity, one hundred individual plant species were collected from the three pastures over three sampling periods and frozen. Using estrogen-stimulated growth of MCF-7 cells in tissue culture, all plant samples were subjected to a bioassay screening procedure designed specifically for feed/forage samples. Results are expressed on a zearalenone equivalent (ZE) ppm basis, which reflects the level of zearalenone required to elicit a comparable response. Approximately 85% of the plant species counted were warm season perennial grasses.

Leguminous (native and introduced) plants and forbs represented approximately 7 to 12% of the plant species. Estrogenic activity varied dramatically among the forage species assayed. The highest estrogenic activity was found in Many-Flowered Scurfpea *Psoralea Tenulfior*, *Pursh.* and Ladino Clover *Trifolium repens L.* (average = 43.69 and 10.96 ZE, respectively). Intermediate levels of activity were found in Black medic *Medicago lupulina L.* and Korean lespedeza *Lespedeza stipulacea Maxim.* (average = 5.03 and 8.40 ZE, respectively). This initial survey effort reveals that estrogenic activity exists primarily in native and introduced legumes which compromised only 3 to 4% of the species counted. Consequently, it is not known if the incidence of plant species containing appreciable levels of plant-derived estrogen are sufficient to elicit a detectable response.

Key Words: Phytoestrogen, Buller steer syndrome, Native grass

1436 Changes in nutritive value for bermudagrass hay as affected by initial concentration of moisture and sampling date. J.E. Turner*, W.K. Coblenz, D.A. Scarbrough, K.P. Coffey, D.W. Kellogg, L.J. McBeth, and R.T. Rhein, *Animal Science Department, University of Arkansas.*

Concentrations of moisture $\geq 20.0\%$ are widely known to cause spontaneous heating and associated deleterious effects on forage nutritive value in alfalfa hay, but relatively little is known about these relationships in warm season grasses. 'Greenfield' bermudagrass was packaged in conventional rectangular bales at 21.9, 26.5, and 30.2% moisture (LM, MM, and HM, respectively). Bales made at each concentration of moisture were core sampled at storage (d 0) and after 4, 8, 12, 24 and 65 d of storage. The MM and HM bales accumulated more ($P \leq 0.05$) heating degree days $\geq 35^\circ\text{C}$ than the LM bales. Concentrations of most fibrous and fiber-associated N components increased ($P \leq 0.05$) with time in storage. Concentrations of N increased ($P \leq 0.05$) with time in storage for HM and MM bales, but the concentration of N in the LM bales did not change ($P \leq 0.05$). Concentrations of NDF and ADF and N associated with these fiber fractions were regressed on storage time using a nonlinear model ($Y = \alpha - \beta e^{-kt^2}$); this model was generally effective ($r^2 \geq 0.71$) in describing these relationships. Linear regressions were evaluated that related indices of nutritive value with heating degree days $\geq 35^\circ\text{C}$ and included observations obtained on all six sampling dates from bales made at each concentration of moisture. Heating degree days $\geq 35^\circ\text{C}$ were related ($P \leq 0.0001$) to indices of nutritive value in all cases. However, tests of homogeneity indicated that regression lines were not homogeneous ($P \leq 0.05$) across moisture concentrations at baling for each index of nutritive value. The results of this study demonstrate the negative effects on nutritive value that occur in association with packaging bermudagrass hay at concentrations of moisture $\geq 21.9\%$. Nutritive value of the hay decreased with increasing concentration of moisture at baling throughout the 65-d storage period.

Key Words: Hay Quality, Heating Degree Days, Bermudagrass

1437 Partitioning of nitrogen in bermudagrass forages in response to nitrogen fertilization. J.L. Gunsaulis, W.K. Coblenz*, M.B. Daniels, J.E. Turner, D.A. Scarbrough, J.B. Humphry, K.A. Teague, K.P. Coffey, and N.W. Galdamez, *University of Arkansas.*

During 2000, three harvests of common bermudagrass were made at two sites (Latta and Stephens) in northwest Arkansas to assess the effects of N fertilization on the partitioning of N within cell-soluble and cell-wall fractions of bermudagrass. Ammonium nitrate was applied in split applications totaling 0, 56, 112, 168, 224, 280, or 336 kg N/ha for the year. These totals were reached by applying various combinations of 0, 56, 112, or 168 kg N/ha on the two application dates (28 April and 19 July). Forages were harvested on 30 May, 7 July, and 18 August. On the first harvest date, concentrations of total N increased linearly ($P < .0001$) with fertilization rate at both sites. The overall range for concentrations of N in these forages was 1.78 to 3.53% across both sites. Cell-soluble N increased linearly ($P < .034$) with N fertilization rate at both sites, while cell-wall associated N declined in a linear pattern concurrently. During the second harvest, none of these effects were observed at either site ($P > 0.05$). Following the second application of N fertilizer, concentrations of N on the third harvest date increased with linear ($P < .0001$) and quadratic ($P = .002$) trends at the Latta site and in a linear ($P < .0001$) pattern at the Stephens site. Greater ($P < .047$) proportions of the total N pool became associated with the cell

solubles as fertilization rates increased. On the third harvest date, concentrations of ADIN declined linearly ($P < .011$) with N fertilization at both sites from a maximum of 8.58% to a minimum of 5.90% of the total pool of N in the forage. Averaged over all harvests, N fertilization was positively associated with the proportion of N in the cell solubles and the concentration of N in the total plant. Conversely, the proportions of total N remaining after extraction in neutral and acid detergents declined in response to fertilization with N. All of these overall effects were linear ($P < .023$).

Key Words: bermudagrass, N fertilization, cell wall

1438 Brown midrib-3 corn silage as the major forage for transition cows. H.H.B. Santos*, V.R. Moreira¹, Z. Wu², and L.D. Satter^{1,2}, ¹U.S. Dairy Forage Research Center, USDA-ARS, ²University of Wisconsin, Madison.

The objective was to evaluate brown midrib (bm3) corn silage as a forage for transition cows. Cows (29 primiparous and 83 multiparous) were divided into three groups and balanced according to lactation number and 305d ME milk (multiparous). Two of the three groups were combined for one of two prepartum trts. Cows were placed in trt groups 3-4 wk (mean = 23 days) before their projected calving date. The two prepartum diets contained 65% forage and 35% concentrate, with corn silage (CS) providing 60% and alfalfa silage (alf) 40% of the forage (DM basis). The control CS (Dekalb 512 RR) was stored in two tower silos, and the bm3 (Cargill F657) stored in a bag silo. After calving the three groups, two of which were fed control CS prepartum, were assigned to three postpartum diets for 4-5 wk (mean = 33d). The control diet (control 55 F) contained 55% forage and 45% concentrate, with 58% of the F as control CS and the balance as alf. The second and third postpartum diets contained 65% F, 58% of which was CS and 42% alf. One of these was the control CS (control 65 F) and the other was bm3 CS (bm3 65F). Cows fed control CS prepartum were fed control CS postpartum. Cows were fed a TMR once daily in a tie stall barn. Changes in body weight and body condition score were similar across treatments before and after calving. DMI and post-calving health did not differ between trts. Milk production was similar across trts for primiparous cows, but multiparous cows produced 2 kg/d more with the bm3 trt ($P = .09$).

		Control	Control	bm3	—P <—

1439 Effects of the heterotrophic bacterium *Lactobacillus buchneri* on preservation of alfalfa and timothy hay. J. Baah*, L. Bos², F. H. VanHerck¹, R. C. Charley³, and T. A. McAllister¹, ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, ²Wageningen University, Wageningen, The Netherlands, ³Biotol Canada Ltd., Niagara-on-the-Lake, ON.

Alfalfa (*Medicago sativa L.*) and timothy (*Phleum pratense L.*) forage were harvested at low (14-18%), medium (18-22%) and high (23-33%) moisture levels (LM, MM, HM) and treated with a heterotrophic bacterium to determine its efficacy for maintaining forage quality during storage. During baling, each forage was treated with *Lactobacillus buchneri* (1.2×10^6 CFU/g fresh forage) as a liquid (LBL) or as a granular preparation (LBG), or with a buffered propionic acid product (10 mL/kg fresh forage, BPA), or was left untreated (control, CON). Triplicate 500-kg bales of each forage \times moisture level were prepared. Internal bale temperatures were monitored continuously for 24 d (alfalfa) or 36 d (timothy), and core samples were collected for analysis 0, 15, 30 and 60 d after baling. After 60 d, voluntary DM intake and in vivo digestibility of chopped CON, LBL and PA hays were determined using 12 Canadian Arcott wethers in a double randomized complete block design experiment. All additives prevented heating, compared with CON, in both

forages at all moisture levels. With LBL and LBG, crude protein contents of HM timothy (12.9% and 12.2%, respectively) were higher ($P < 0.05$) than in CON (10.8%). In MM bales, ADIN content was highest ($P < 0.05$) in CON (32.3% in timothy, 25.0% in alfalfa) bales than in treated bales. The lowest ($P < 0.05$) ADIN in alfalfa (18.6%) occurred with LBG. Yeast counts were lowest ($P < 0.05$) in 60-d MM PA-treated alfalfa. Mold counts were lowest (< 100 CFU/g; $P < 0.05$) with LBL; no molds were detected in 60-d HM timothy with LBL. Dry matter digestibility did not differ ($P > 0.05$) among treatments. Treating timothy hay with LBL increased ($P < 0.05$) DM intake by sheep by 28.6% (to 1.33 kg/d) over CON, and by 19.7% over PA-treated timothy. The heterolactic bacterium *L. buchneri* can substantially improve the nutritive value of high moisture alfalfa and timothy hays.

Key Words: *Lactobacillus buchneri*, Forage hay, Nutritive value

1440 Effects of maturity and N fertilization on in vitro biohydrogenation of timothy linolenic and linoleic acids. H. Boufaied*¹, P.Y. Chouinard¹, G.F. Tremblay², H.V. Petit³, R. Michaud², and G. Blanger², ¹Université Laval, QC, Canada, ²Agriculture and Agri-Food Canada, Ste-Foy, QC, Canada, ³Agriculture and Agri-Food Canada, Lennoxville, QC, Canada.

Up to 75% of total fatty acids (FA) present in forage complex lipids are α -linolenic (C18:3) and linoleic (C18:2) acids. In the rumen, these polyunsaturated FA are liberated by lipolysis, and hydrogenated by microorganisms. Our objective was to determine the effect of maturity (stem elongation, early heading, late heading, and early flowering) and N fertilization (0 and 120 kg N/ha) on in vitro biohydrogenation of timothy (*Phleum pratense* L.) C18:3 and C18:2 FA. Timothy samples were taken during the primary growth of the first production year from a 2 × 4 factorial experiment in a split-plot design with four replications. Forage samples were dried and ground. Fatty acids were methylated using methanolic HCl, and analyzed by gas chromatography. Concentrations of C18:3 and C18:2 decreased linearly with maturity and increased with N fertilization ($P < 0.05$). Dried samples were incubated with rumen fluid at 39°C for 0, 3, 6, 9, 24, and 36 hours. After each incubation period, the samples were lyophilized, methylated, and analyzed for FA. The C18:3 and C18:2 concentrations decreased with incubation time (t) according to this model: C18:3 and C18:2 = $i + b(e^{-ct})$. The hydrogenation rates (c) of the potentially hydrogenable fraction (b) were not affected by maturity and N fertilization. The non hydrogenable fractions (i) of C18:3 and C18:2 increased with N fertilization ($P < 0.05$) but they were not affected by maturity. The b fraction, the effective hydrogenation [EH = $b/(c+(c+0.06))$], and the bypass (BP = $i + b \# EH$) of C18:3 and C18:2 were higher in timothy harvested at stem elongation and decreased linearly with maturity ($P < 0.05$). Nitrogen fertilization increased the b fraction, the EH, and the BP of C18:3, and it also increased the BP of C18:2 ($P < 0.05$). The ruminal BP of C18:3 and C18:2 would be respectively 75 and 33% higher for timothy harvested at stem elongation and fertilized with 120 kg N/ha as compared with timothy harvested at early flowering with no N fertilization; this is mainly explained by the higher C18:3 and C18:2 concentrations in well fertilized timothy at early stage of maturity.

Key Words: Timothy, Growth Stage, Fatty acids

1441 Effects of ensiling carbohydrates with wheat straw and 4% urea. T.V. Nguyen*, M.J. Montgomery, and C.J. Richards, University of Tennessee, Knoxville, TN.

Two experiments were conducted to evaluate protein fractions of wheat straw ensiled with urea and additional carbohydrate sources. In the first complete randomized design experiment, 40 g of dried molasses, corn meal, rice mill or tapioca were added to 1000 g of wheat straw, 40 g urea and 1000 g water. The combination was ensiled anaerobically for 21 days before grinding for chemical analyses. Wheat straw treated with carbohydrate had a higher ($P < 0.01$) CP content than the control. The CP contents were 8.33, 7.99, 7.74, 7.58 and 7.02% for dried molasses, corn meal, rice mill, tapioca and control treatments, respectively. Soluble nitrogen contents measured by direct distillation were lowest ($P < 0.05$) for dried molasses (1.76) and corn meal (1.88%), intermediate for tapioca (1.96%) and highest ($P < 0.05$) for rice mill (2.27%) and the control (2.06%). Insoluble CP was highest ($P < 0.05$) in dried molasses (7.93%) and corn meal (7.12%) treatments, intermediate in rice mill (4.38%) and tapioca (4.55%) treatments and lowest ($P < 0.01$)

in the control (3.02%). The second experiment was a randomized complete block design. No additional carbohydrate or 3 levels (40, 60, or 80 g) of dried molasses or corn meal were added to 1000 g of wheat straw, 40 g urea and 1000 g water before ensiling and analyses as in the first experiment. Straw ensiled with dried molasses or corn meal had a higher ($P < 0.05$) CP content (avg 8.69 and 8.88%, respectively) than control (7.46%). Level of corn meal addition did not affect ($P > 0.10$) the CP content of ensiled straw, while addition of 80 g of dried molasses resulted in higher ($P < 0.01$) CP concentrations than the addition of 40 g of dried molasses. An addition of carbohydrate into 4% urea treatment of wheat straw could increase both CP content and insoluble fraction of protein of silo.

Key Words: Urea, Crude Protein, Wheat straw

1442 Production and quality of Buffel grass (*Cenchrus ciliaris*) grown and utilized under different conditions in Northern Mexico. C Lizarazo-Ortega, H Bernal-Barragan, and E Gutierrez-Ornelas*, Facultad de Agronomía, UANL, Marín N.L. Mexico.

The objective of this study was to determine the effect of type and intensity of utilization on DM production and quality of Buffel grass (*Cenchrus ciliaris* cv Nueces) grown under natural rainfall or irrigation conditions in Northern Mexico. Sixteen plots (64 m² each) were grazed by Charolais cattle in order to achieve a 50% (G50) or 75% (G75) utilization of DM production. Eight plots (40 m² each) were hand clipped to use 50% (H50) of DM. Half of the experimental plots received only natural rainfall (yearly average = 583 mm), the rest of the plots were additionally irrigated with 70 mm after each utilization, which occurred in September and November 1999, and in June and November 2000. Production and quality variables were analyzed under a randomized block design. Year, type and intensity of utilization and irrigation were included in the model as main factors. Yearly forage crop was 22% higher ($P < 0.05$) for G50 than H50 (1893 vs 1541 kg DM/ha), without affecting ($P > 0.05$) residual forage (1421 vs 1213 kg DM/ha). No differences ($P < 0.05$) in forage crop were found between G50 and G75, after 2 years of study the available forage in G75 plots was similar to G50 (3363 vs 3253 kg DM/ha). Irrigation increased forage crop by 15% ($P = 0.13$) compared to those plots under natural rainfall conditions (1195 vs 1720 kg DM/ha). No differences ($P > 0.05$) due to type and intensity of utilization were found in CP, NDF, and ADF content of Buffel grass, but ADF was increased ($P < 0.05$) in irrigated plots. In vitro DM digestibility was higher ($P < 0.05$) in H50 than in G50 and G75 grazed plots (56.7, 54.7 and 53.3%). Buffel grass production was increased by grazing, but IVDMD was better in hand clipped forage.

Key Words: Buffel grass, Grazing intensity, Forage quality

1443 Effect of Mott Dwarf Elephant grass (*Pennisetum purpureum*) silage on dry matter intake, milk production, digestibility and rumen characteristics in Nili-Ravi buffaloes. M. Q. Bilal, M. Abdullah*, and M. Lateef, University of Agriculture, Faisalabad, PAKISTAN 38040.

The effect of Mott grass (*Pennisetum purpureum*) silage was determined on the performance of 12 lactating Nili-Ravi buffaloes in a Randomized Complete Block Design (RCBD) with three replicates. The four treatments included; 100% green chop (control, T₁), 2/3 green chop and 1/3 Mott silage (T₂), 1/3 green chop and 2/3 Mott silage (T₃) and 100% Mott silage (T₄). The combination of green chop and silage in the treatments T₂ and T₃ was on dry matter basis. Average daily dry matter intake was higher (16.83 kg/d) in buffaloes on T₃ as compared to those fed the control (13.52 kg/d), T₂ (13.96 kg/d) or T₄ (12.00 kg/d) diets. The intake of crude fiber had the same trend as in case of dry matter for different treatments. Buffaloes fed the combinations of green chop and silage produced more 4% FCM than those fed either green chop or silage alone (10.03 and 11.30 vs. 8.23 and 8.47 kg/d) for T₂ and T₃ vs. T₁ and T₄, respectively. Different treatments had no effect on the composition of milk. The digestibility of dry matter and crude fiber was significantly greater ($p < 0.05$) in buffaloes fed the combination diets T₂ and T₃ (65.1 and 65.0%, and 52.4 and 52.8%) as compared to T₁ and T₄ (62.6 and 60.8%, and 50.7 and 51.0%) for dry matter and crude fiber respectively. Increased digestibility may be attributed to some positive associative effect between the two forage sources. The difference in rumen pH (6.69 to 6.72) for all the four experimental diets appeared to be non-significant. However, rumen ammonia nitrogen

was higher ($p < 0.05$) in buffaloes fed the green chop or the silage alone (25.0 and 24.3 mg/100ml, respectively) than in those fed the combination of the two forage sources (16.7 and 16.5 mg/100ml) for T_2 and T_3 , respectively.

Key Words: Mott grass, Buffaloes, Milk production, Digestibility

1444 Assessment of forage quality and DM digestion kinetics for wheat forage as affected by harvest technique and sampling date. W.K. Coblenz, K.P. Coffey, J.E. Turner, D.A. Scarbrough, J.B. Humphry, J.V. Skinner, and D.W. Kellogg, *University of Arkansas*.

A trial was initiated in September of 1999 to assess the effects of harvest techniques and sampling dates on DM digestion kinetics and forage quality of wheat forage. "Delta King 9027" soft-red winter wheat was established at the Forage Research Area in Fayetteville. Wheat forage was grazed lightly throughout the fall to control growth. Forages were harvested on three dates in the spring, which corresponded to vegetative, mid-elongation, and boot stages of growth (6 March, 27 March, and 11 April, respectively). Sampling techniques evaluated on each date included three clipping techniques (whole plant, random pluck, and top half) and two evaluations of masticates (oven dried at 50°C or freeze dried). Concentrations of total N, NDF, ADF, hemicellulose, cellulose, and lignin were affected ($P < .0001$) by the harvest technique and sampling date main effects. In all cases, there was an interaction ($P \leq .0002$) of main effects. Digestion kinetics of DM for these forages were evaluated by the in situ technique using five ruminally fistulated (393±54-kg) crossbred steers. The potential extent of DM degradation was affected ($P < .0001$) by both main effects and their associated interaction. Harvest technique and sampling date both affected ($P < .0001$) degradation rate of DM; but their associated interaction did not ($P > .05$). Averaged over three sampling dates, rates of degradation for freeze-dried masticate (.088/h) were greater ($P < .05$) than all other treatments. Clippings of the top half of the canopy (.076/h) and oven-dried masticate (.070/h) had faster ($P < .05$) degradation rates than did the random-pluck (.055/h) and whole-plant (.055/h) clipping treatments. Lag time was affected ($P = .027$) by harvest technique only; lag times for freeze-dried masticate (.88 h) were shorter ($P < .05$) than all other treatments (mean = 1.65 h). Estimates of effective degradability of DM were high for all treatments (overall mean = 73.3%); however, main effects and their associated interaction were all highly significant ($P < .0001$).

Key Words: wheat forage, degradation kinetics, forage quality

1445 Physical and chemical characteristics affecting in vitro digestibility of corn silages of different particle sizes. G. Ferreira*¹ and D.R. Mertens², ¹*Universidad Catolica Argentina, Buenos Aires*, ²*US Dairy Forage Research Center, Madison, WI*.

Nutritive evaluation of corn silage is complicated by interactions between grain and stover and between chemical composition and physical form. Thirty-two diverse corn silages were selected to study the relationships among in vitro digestibility and silage characteristics. Dried silages were incubated whole and after grinding (4 and 1 mm) for 24 h using in situ bags in a rotating jar in vitro system. Ranges in variables were: DM, 19-48%; CP, 6-12%; starch, 12-36%; aNDF, 30-56%; ADF, 18-35%; ADL, 1.2-3.5%; mean particle size (PS), 2.1-7.3 cm; in vitro DM disappearance (IVDMD) of whole silage, 45-77%; IVDMD 4-mm, 61-79%; IVDMD 1-mm, 59-82%; IV true DM disappearance 1-mm, 68-85%; and IV NDF disappearance 1-mm, 38-57%. Corn kernels and fragments >1/4 kernel were retained on sieves with apertures >4.75 mm. The proportion of total DM recovered as starch in kernels and fragments >4.75 mm ($ST > 4.75$) ranged from 2 to 33%. Total starch was related to nonfibrous carbohydrate (NFC) calculated by difference: starch = $-6.0 + .76(\text{NFC})$, $R^2 = 0.87$; ADF = $0 + .61(\text{aNDF})$, $R^2 = 0.84$; and grain DM = $36.7 + .56(\text{silage DM})$, $R^2 = 0.77$. Individual relationships of aNDF, ADF, or ADL with IVDMD 4-mm or 1-mm yielded R^2 ranging from 0.59 to 0.76, with ADF having the highest R^2 . These R^2 were from 0.21 to 0.40 for IVDMD of whole silages. The relationship of aNDF with IVDMD 4-mm or 1-mm was improved by the addition of ADL suggesting that both the amount and characteristics of fiber are important: IVDMD 1-mm = $96.4 - .26(\text{aNDF}) - 3.26(\text{ADL})$, $R^2 = 0.73$. The R^2 between aNDF and IVDMD of whole silage was improved to 0.64 by the addition of $ST > 4.75$ and ADL. The relationship between IVDMD of 1-mm and whole silage was poor $R^2 = 0.29$, and was improved ($R^2 > 0.74$)

by the addition of $ST > 4.75$, PS, ADL, and CS DM. It is concluded that fiber characteristics impact the ultimate digestion of finely ground corn silages. In addition, particle size and the proportion of DM recovered as starch from kernels and large fragments affect digestion of whole silages.

Key Words: Corn silage, Digestibility, Fiber

1446 Factors affecting the measurement of forage digestibility. W. A. Scheer*, D. M. Chatman, and J. N. Spain, *University of Missouri, Columbia, MO*.

The objective of this study was to evaluate the factors affecting the measurement of the digestibility of various types of forages as related to accurate prediction of relative feed value. Forage samples used in this experiment were obtained from the 2000 Missouri State Fair hay contest and included alfalfa (ALF; n=29), clover (CLV; n=6), cool (CSG; n=12) and warm (WSG; n=3) season grass, and mixed alfalfa-grass hays (MIX; n=6). Representative core samples from two bales of each forage submitted were collected and composited. Samples were ground (5 mm) and analyzed for DM, CP, NDF, and ADF using standard analytical procedures. Samples were then digested in situ in two ruminally fistulated cows fed identical lactation diets. Cow 1 was 105 DIM, second parity, and cow 2 was 334 DIM, fifth parity. For each cow, triplicate 5 g samples of each forage were placed into individual 10 cm x 20 cm Dacron polyester bags with a mean pore size of $50 \pm 15 \mu\text{m}$. Incubation times were 0 and 24 hours. Chemical analysis of forages yielded expected differences and were as follows: ALF: DM 88.0%; CP 21.9%; NDF 42.4%; ADF 29.1%; CLV: DM 88.7%; CP 16.3%; NDF 46.6%; ADF 31.0%; CSG: DM 89.9%; CP 12.4%; NDF 66.0%; ADF 34.0%; WSG: DM 90.2%; CP 13.6%; NDF 75.6%; ADF 34.2%; MIX: DM 88.4%; CP 19.3%; NDF 47.9%; ADF 31.0%. Average 24-hour in situ dry matter digestibility was different (ALF 61.0%^a; CLV 60.2%^a; CSG 53.6%^b; WSG 39.0%^c; MIX 57.8%^a). Furthermore, regression analysis described different relationships between ADF and in situ degradation between forages, as well as differences in the in situ digestion of the same forages between cows. In summary, these results point out the need to standardize the in situ conditions used to describe the DM digestibility of forages.

Key Words: Forages, Digestibility, Relative feed value

1447 Comparison of three methods to estimate digestible NDF of forages. D. K. Combs*¹ and P. Berzaghi², ¹*University of Wisconsin, Madison*, ²*University of Padova, Italy and U.S. Dairy Forage Research Center, Madison, WI*.

The objective of this study was to compare NDF digestibility estimated from in vitro NDF digestion kinetics, in vitro NDF degradation at single time points (24h and 48h) and the empirical equation used in the NRC Nutrient Requirements of Dairy Cattle (2001). Grass, legume and grass-legume hays and silages (n=99) were analyzed for DM, NDF, lignin, and NDFICP. Truly digestible NDF was estimated as $0.75 \times [(\text{NDF} - \text{NDFICP}) \times \text{lignin}] \times [1 - (\text{lignin}/(\text{NDF} - \text{NDFICP}))^{0.667}]$. Dried, ground forages (0.5 g) were incubated in 50 ml of 1:4 medium of rumen fluid and buffer (Goering and Van Soest, 1970) for 0, 3, 6, 9, 12, 24, 36, and 48 h, and the residues analyzed for NDF. Percentage of residual NDF versus incubation time was fitted by a non-linear least squares estimating procedure to a first order model with an indigestible fraction and a discrete lag time before digestion. Kinetics parameters lag time (lag), potentially degradable NDF (Fraction B), rate of Fraction B disappearance (kd), and the asymptotic estimate of indigestible NDF (fraction C), were estimated. Estimated NDF digestibility (% of NDF) at maintenance intake was estimated by assuming a fractional NDF passage rate (kp) of 0.02/hr. NDF digestibility at 24h was similar to the kinetic estimate of NDF digestibility at maintenance and the two estimates were correlated ($r^2 = .68$). However, NDF digestibility at maintenance was more highly correlated to the single time point at 48h ($r^2 = .78$). The empirical and kinetic estimates of NDF digestibility were also similar, but the correlation between the empirical estimate and the single timepoint at 48 h was lower ($r^2 = .42$).

Item	Mean	S.D.	Min.	Max.
NDF, % DM	43.1	5.8	32.1	57.5
Lag, h	1.8	1.5	0.0	7.0
Fraction B, % NDF	52.8	12.4	34.2	100.0
kd, h ⁻¹	0.01	0.05	0.01	0.27
DNDF (kinetic), % NDF	40.0	7.3	26.5	58.2
DNDF (24h), % NDF	44.1	10.8	20.1	72.2
DNDF (48h), % NDF	50.5	10.7	28.1	74.7
DNDF (empirical), % NDF	38.2	5.0	25.1	48.9

Key Words: Forage, Digestibility, NDF

1448 Evaluation of the influence of host animal diet and forage type on the ruminal degradation of grass silage and intercropped pea-wheat silages. A.T. Adesogan*¹, M.B. Salawu¹, and R.D. Dewhurst², ¹IRS, University of Wales, Aberystwyth, SY23 3AL UK, ²Institute of Grassland and Environmental Research, SY23 3EB, UK.

This study compared the rumen degradability of grass silage and intercropped pea-wheat silages in order to understand why dairy cows fed a short straw, pea-wheat intercrop needed only half as much concentrates to produce the same amount of milk as the grass silage (Adesogan et al., 2000). The effect of host animal diet on rumen degradation was also examined. Two spring sown intercrops of wheat and tall (cv. Magnus; MW) or short straw (cv. Setchey; SW) peas were compared with grass silage (GS). The silages were ruminally incubated in three dry Friesian cows in a 3x3 change over design. Degradability was measured in the last week of each period after two weeks of adaptation. Each forage was incubated in quadruplicate in cows fed that forage alone, at maintenance, for 4, 8, 16, 24, 48, 72, and 96 h. The kinetic degradation parameters were described with the exponential model ($D = A+B(1-\exp(c(t-tL)))$) where A = washing loss, B = potentially degradable insoluble fraction, c = fractional degradation rate and tL = lag time. Effective degradability (ED) was calculated using a fractional outflow rate (k) of 0.05/h. To study the effect of host animal diet, four replicate samples of each forage were also incubated for 24 or 48 h in the rumen of cows fed on the other forages in each period. Although A was highest in MW (P<0.05), SW and GS had similar values. The other DM degradation parameters and the N loss after 24 or 48 h were unaffected by forage type. Over 90% of N and 73% of starch disappeared from SW within 24 h. NDF loss was consistently higher in GS. Host diet did not affect the ruminal degradation in the intercrops but affected (P<0.05) the DM, N, starch and NDF degradation of GS. In conclusion host diet only affected the degradation of grass silage, hence grass silage fed sheep can be used to generate accurate degradability data on bi-crops. The rapid degradation of the appreciable starch and N in the intercrops (Adesogan et al., 2000) suggests that they could synchronously supply energy and protein to the rumen and thereby enhance microbial protein production. Reference Adesogan, TA, Salawu, MB and Dewhurst, RD 2000. Concentrate requirement for dairy cows halved with pea-wheat bi-crops. Proc. Res. Conf. Brit. Grassl. Soc. Aberdeen.

Key Words: Rumen degradation, Intercropping, Silage

1449 Eastern gamagrass digestion kinetics and forage quality as influenced by harvest management. D.J.R. Cherney*¹, P.R. Salon², and J.H. Cherney¹, ¹Cornell University, Ithaca, NY, ²USDA-NRCS, Big Flats Materials Center, Big Flats, NY.

Objectives were to evaluate the digestion kinetics and forage quality of eastern gamagrass (*Tripsacum dactyloides* L.) as influenced by date of initial harvest and second-cutting interval (4-, 5-, and 6-wk). Gamagrass, variety 'Pete', was harvested in 1997 and 1998 from triplicate plots of an established stand at Big Flats, New York. Plots were fertilized with 112 kg of N/ha. Crude protein, digestible NDF and in vitro true digestibility decreased (P < 0.05) with increased cutting interval in both years. Mean crude protein was clearly reduced for the 6-wk second cutting interval, regardless of initial harvest date. There were interactions (P < 0.05) between initial cutting date and second cutting intervals for NDF, ADF and lignin both years. Interactions between initial cutting dates and second cutting dates were not significant (P > 0.05) for potentially digestible fiber (Do), indigestible fiber (I), and rate of fiber digestion (k). Gamagrass cut at the 6-wk cutting interval had lower Do (48.2 1.7% vs 50.5 0.6% and 50.3 0.6% vs 55.3 1.5% for 1997 6- vs 4-wk and 1998 6- vs 4-wk, respectively) and higher I (23.0 2.5% vs

20.2 1.7% and 21.7 2.2% vs 17.7 2.2% for 1997 6- vs 4-wk and 1998 6- vs 4-wk, respectively) than the 4-wk cutting interval, regardless of initial harvest date. This was generally true for k as well. Forage quality and digestion kinetics of gamagrass harvested at 5-wk cutting intervals tended to be intermediate between 4- and 6-wk cutting intervals. This data, coupled with yield data suggest that a 5-wk cutting interval is optimal.

Key Words: Eastern gamagrass, Forage quality, Digestion kinetics

1450 Nutrient digestibility and bacterial protein synthesis of a pasture diet in response to increased level of dietary brassica in continuous culture. K. J. Soder*², L. A. Holden¹, S. R. Hershey¹, and M. R. Long¹, ¹The Pennsylvania State University, PA, ²USDA-ARS, University Park, PA.

A dual effluent continuous culture system was used to investigate the effect of inclusion of four levels of brassica in a pasture diet on nutrient digestibility and bacterial protein synthesis and efficiency. Four fermenters were fed three times daily an orchardgrass (*Dactylis glomerata* L.) pasture diet containing either 0%, 15%, 30%, or 45% brassica (*Brassica rapa* L.). Four 10-d periods were conducted, with 7 d for adaptation and 3 d for sample collection in each period. Ruminal pH was recorded at each feeding, and solid and liquid effluent was collected during the last 3 d of each period. Bacterial pellets were harvested at the end of each period. Pasture and effluent samples were analyzed for CP, DM, OM, in vitro DM digestibility, NDF, ADF, and TNC. Bacterial samples were analyzed for DM, OM, CP, and purine content. Bacterial yield and N flow were calculated based on the purine and N content of the effluent and bacterial samples. NDF digestibility increased when brassica was included at 45% of the diet DM compared with the other treatments (70.6, 68.37, 71.6, and 76.0% DM for 0, 15, 30, and 45% brassica, respectively). Valerate increased in a linear fashion with increased brassica inclusion (2.17, 2.53, 2.82, and 3.06, M/ml, respectively), but other VFA's were not significantly affected by diet. Bacterial protein synthesis increased in a linear fashion with increased brassica (44.3, 46.6, 48.1, and 50.2% CP, respectively). Ruminal pH, non-NH₃ N flow and bacterial efficiency were not affected by treatment. This study suggests that brassicas may be utilized in a pasture diet as an alternative forage source to increase NDF digestibility and bacterial protein synthesis, but these increases did not translate into increased bacterial efficiency.

Key Words: Pasture, Brassica, Microbial Protein

1451 Crop processing and chop length effects in brown midrib corn silage on chewing activity and mean particle size of silage and masticates. E. C. Schwab* and R. D. Shaver, University of Wisconsin, Madison, WI.

Brown midrib-3 corn silage was harvested using a crop-processing harvester with rolls set at 2 mm clearance (PR) or unprocessed (UP). Theoretical lengths of cut (TLC) were 13 and 19 mm for UP corn silage treatments (13UP and 19UP), and 19 and 32 mm for the PR corn silage treatments (19PR and 32PR). Mean particle size of 13UP, 19UP, 19PR, and 32PR corn silage treatments were 9.7, 12.0, 9.7, and 10.8 mm, respectively. Twenty-four Holstein cows were used in a replicated 4 X 4 Latin square design with 28-d periods. Orthogonal contrasts were used to evaluate TLC (13UP vs. 19UP and 19PR vs. 32PR) and crop processing (19UP vs. 19PR) effects. Increasing TLC increased (P < 0.05) eating time (min/kg DMI; 9.2 for 13UP vs. 9.9 for 19UP) for UP but not PR. Crop processing of 19 mm TLC silage reduced (P < 0.05) eating time (min/d and min/kg DMI; 244 and 9.9 for 19UP vs. 224 and 8.9 for 19PR, respectively). Rumination time (min/kg DMI) was higher (P < 0.05) for 19UP than 13 UP (15.7 vs. 14.6). Crop processing increased (P < 0.02) and longer TLC of PR silage reduced (P < 0.005) rumination min/kg of NDF intake. Total chewing times (min/d) were unaffected by treatments, but 19UP was greater (P < 0.01) than 13UP when expressed as min/kg DMI (25.6 vs. 23.8). Masticate boluses from respective corn silage treatments were collected at the cardia of 8 ruminally cannulated cows, and mean particle size (MPS) was determined via wet sieving (MPS of 6.4, 7.6, 5.8, and 7.1 mm for 13UP, 19UP, 19PR, and 32 PR, respectively). Increasing TLC had no effect on masticate MPS, silage MPS minus masticate MPS (DIFF), or percent MPS reduction. Crop processing reduced (P < 0.05) masticate MPS (3.8 mm for 19UP vs. 3.2 mm for 19PR) and DIFF (3.7 mm for 19UP vs. 2.6 mm for 19PR). Small differences among treatments in MPS of corn silage masticates may partially explain the lack of response in lactation performance

trials to increased chop length. Crop processing of 19 mm TLC silage reduced eating time and mean particle size of silage and masticates.

Key Words: corn silage, mean particle size

1452 N-alkanes as markers for estimation of dry matter intake and diet composition in steers consuming all-forage or forage-concentrate diets. S.A. Moshtagh Nia^{*1}, K.M. Wittenberg¹, and W. Chen², ¹University of Manitoba, Winnipeg, MB, ²Agriculture and Agri-Food Canada, Brandon, MB.

Eight Holstein steers weighing approximately 208 kg were assigned to four dietary treatments in a three period cross over design to compare the alkane-based and chromium/in vitro-based procedures with the total fecal collection technique relative to estimating of dry matter intake (DMI) and diet composition for forage or forage:concentrate based diets. The four dietary treatments were 1) pure meadow brome grass hay (B); 2) 1/2 B + 1/2 alfalfa hay (BA); 3) 1/2 B + 1/2 barley grain (BB); and 4) 1/4 B + 1/4 alfalfa hay + 1/2 barley grain (BAB). The two types of hay were chosen to achieve a wide range of hydrocarbon intake. Appropriate portions of forages and grain were mixed as a total mixed ration and fed in two equal portions twice daily at 2.5% of body weight. Two controlled release capsules, one containing n-alkanes (C₃₂ and C₃₆) and other chromic oxide were placed into the steer reticulo-rumen by oral administration on day 1 of each period (30 days). Total fecal output was collected twice daily from day 8 to 14 of each period to establish the fecal recovery of chromium and the alkanes. Recovery of alkanes was also calculated by in-vitro digestion of individual feed samples. Fecal recovery of the natural alkanes, C₃₁ and C₃₃, was low, ranging from 59.5 to 73.3%, whereas the range in fecal recovery of the dosed alkanes, C₃₂ and C₃₆, was 83.3 to 95.5%, and of chromium was 82.7 to 95.8 across the diets. The estimated DMI was similar across all diets using the C₃₁/C₃₂ and C₃₃/C₃₂ alkanes; however, the estimated DMI using C₃₁/C₃₂ was significantly (P < 0.05) lower compared to total collection or chromium/in-vitro methods. The use of least-squares to estimate ingredient proportions in the diet using n-alkanes is excellent when marker recovery values from total collection are used. Estimates of ingredient proportions in the diet were less reliable when in-vitro digestion was used for n-alkane recovery estimates.

Key Words: Alkanes, Chromium, Dry matter intake

1453 Estimation of forage intake of lactating dairy cows on pasture using n-alkanes. H. M. Froebe^{*}, K. M. Wittenberg, and S. A. Moshtagh Nia, University of Manitoba, Winnipeg, Canada.

The objective of this study was to determine the forage intake of lactating dairy cows on pasture using the n-alkane marker technique when fed at different levels of concentrate supplementation. In two separate trials, fifteen primiparous Holstein cows weighing approximately 552 ± 49 kg were randomly assigned to three dietary treatment groups according to milk production (33.1 ± 5.0 kg/day) and days in milk (168 ± 89). The three dietary treatments consisting of concentrate supplement were fed at 20% (L), 35% (M), and 50% (H) of pre-trial total dry matter intake (DMI). The supplement was fed in equal portions at each milking

(AM and PM). Cows grazed a primarily orchardgrass (*Dactylis glomerata*) pasture and were moved to a new section of the pasture daily. A controlled-release capsule containing n-alkane (C₃₂ and C₃₆) was placed into the cow reticulo-rumen by oral administration. Fecal grab samples were collected twice daily at milking for a seven day period, starting on the seventh day post administration. Milk production was 21.8, 26.4 and 30.5 ± 1.6 kg/day for the L, M, and H groups respectively. The L group had significantly lower (P < 0.05) milk production compared to the M and H groups. The estimated forage DMI was calculated using the C₃₁/C₃₂ and C₃₃/C₃₂ alkane ratios. The estimated forage DMI using C₃₃/C₃₂ had higher intake of 15.1, 13.3, and 11.0 ± 1.0 kg/day compared to using C₃₁/C₃₂ with intake of 14.0, 12.2, and 10.0 ± 1.0 kg/day for L, M, and H respectively. However, with both ratios, the L treatment had significantly (P < 0.05) higher forage DMI estimates than the H treatment. The estimated total DMI using C₃₃/C₃₂ was similar across all dietary treatments with an average value of 19.4 ± 1.1 kg/day, reflecting 3.5 ± 0.2% of body weight, whereas, the estimated DMI using C₃₁/C₃₂ had an average value of 18.4 ± 1.0 kg/day, reflecting 3.3 ± 0.2% of body weight. Daily fecal output estimates using C₃₆ were similar for all dietary treatments averaging 5.9 ± 0.3 kg/day (DM basis). It was concluded that at lower level of concentrate feeding, the cows compensated by higher level of forage intake on pasture.

Key Words: N-alkanes, Pasture intake, Dairy cow

1454 Evaluation of cultivates of alfalfa (Medicago sativa L.) by in situ degradability technique. E. C. J. Sales, A. R. Evangelista^{*}, R. A. Santos, and J. C. Teixeira, Universidade Federal de Lavras, Minas Gerais, Brazil.

Fifteen cultivates of alfalfa (*Medicago sativa* L.): Alpha 200, SW 8210, High, Rio, Monarca SP INTA, Victria SP INTA, Semit 711, P 30, P 205, F 208, Florida77, MH 4, Br 1, Br 2 and Creole, were studied with to evaluate the ruminal degradability of the dry matter (DM), crude protein (CP) and neutral detergent fiber (NDF). Samples of each cultivate they were placed in nylon bags and incubated in the rumen of cows for 0, 6, 12, 24, 48, 72 and 96 h. The disappearance of the nutrients data (DM, CP and NDF) in the bags, were submitted to the analysis of non linear regression of Gauss-Newton, being used the model $DP = a + b(1 - \exp(-c \cdot t))$, to potential degradability and $DE = a + ((b \times c)/(c+k))$, to effective degradability. Assuming rate of passage of 5 %/h, there was not difference (P > 0.05) between cultivates to dry matter effective degradability. Significant values (P < 0.05) were found to CP and NDF effective degradability, standing out cultivate Loud, Monarch SP INTA, Victria SP INTA, Semit 711, P 30, P 205, F 208, Florida 77, MH 4, Br 1, Br 2 and Creole. To the degradation rate of CP was not verified significant effect (P > 0.05). The largest degradation values of CP, they can be attributed to the largest efficiency of degradation of N for the microorganisms, once the animals received balanced diet with the degradation rate between cultivates. To NDF, there were variations (P < 0.05) in the degradation rate between cultivates. The soluble fraction from CP and NDF differed between cultivates; the difference found in those cultivates can not be attributed to the handle of the samples and consequent bedding of particles, and also due the presence of soluble components (starch, pectin).

Key Words: Alfalfa, Degradability, Cultivate

ASAS/ADSA Ruminant Nutrition: Fat, Protein, Intake, and Feedlot

1455 Effect of Housing and Fat Supplementation on Reproduction and Productivity of Holstein Cows in early Lactation . S.L. Boken^{*}, C.R. Staples, L.E. Sollenberger, W.W. Thatcher, and P.J. Hansen, University of Florida, Gainesville, FL.

The objective of this trial was to investigate the effects of feeding a soybean oil refining byproduct (SORB) on estrus behavior and productivity of early postpartum Holstein cows managed in a free stall barn or in an intensive rotational grazing system of cool season rye-ryegrass pasture. Multiparous Holstein cows (n=35) were assigned randomly at calving to one of four treatments arranged in a 2 by 2 factorial design. The SORB was suspended in a molasses slurry (30% of slurry DM). The SORB was mixed into a TMR (2% of diet DM) for cows in the barn and into the grain supplement (3.9% of DM) for cows on pasture. Control cows were fed liquid molasses without SORB. Cows on pasture grazed in groups of three and were fed supplement twice daily at a rate of 1

kg/ 2.5 kg of milk produced. During the first 14 wk of lactation, milk production of cows kept in free stalls peaked higher (41.8 vs. 38.1 kg/d) and was more persistent than cows kept on pasture (housing x time, P = 0.03). Average milk fat content was greater for barn-fed cows (3.39 vs. 3.16%, P = 0.02) but average milk protein content was unchanged (2.98 vs. 2.89%). Fat supplementation did not affect milk production or composition. Cows on pasture relied more on body reserves to help support milk production as plasma NEFA concentrations peaked higher (772 vs. 579 mEq/L) and later postpartum (wk 4 vs. 1) (housing x time, P = 0.002). Production of microbial nitrogen as estimated by allantoin and creatinine analyses of spot samples of urine was unaffected by treatment (326 g/d, SE = 30). Estrus activity was recorded using the HeatWatch[®] estrus detection system. Cows not detected in estrus (n = 14) were assigned 98 DIM as the number of days to first estrus and this did not differ among treatments (69 DIM, SE = 6). When only

cows that exhibited estrus were analyzed ($n = 21$), number of days to first estrus was similar (50 DIM, SE = 6) and length of first estrus was similar (291 min, SE = 77); however number of mounts during the first estrus (7.7 vs. 4.7) was greater ($P = 0.05$) for cows kept on pasture. Cows managed on pasture produced less milk of lower fat content, had higher concentrations of plasma NEFA, and demonstrated more intense estrus activity during the first 14 wk postpartum.

Key Words: pasture, fat, reproduction

1456 Increasing the concentration of beneficial fatty acids in lamb muscle. K Nuernberg¹, S Grumbach², K Ender¹, and G Nuernberg¹, ¹Research Institute for the Biology of Farm Animals, ²State Institute of Agriculture and Fishery M/V.

The objective of the study was to optimize the production of high quality sheep meat under different production systems and to increase the concentration of n-3 polyunsaturated fatty acids (PUFA) in muscle of lambs. Thirty four male crossbred lambs (Texel x Bleu du Maine) with an initial live weight of 20 kg were used in the experiment. The lambs were randomly divided into three groups (group 1: weaning lambs fed intensively with concentrate, group 2: suckling lambs kept on pasture, group 3: weaning lambs kept on pasture). Animals were slaughtered at an average live weight of 40 kg. The carcass weight, the daily gain and the *longissimus* muscle area were significantly ($P < .05$) lower in weaning lambs kept on pasture (group3) compared to concentrate fed lambs (group 1). The color of lamb meat was not influenced by the feeding systems. There are important effects of production systems on total fatty acid composition of lamb muscle. The concentration of total n-3 fatty acids was significantly ($P < .05$) increased up to 83 mg/100 g muscle in lambs kept on pasture compared to 33 mg/100 g in animals fed concentrate. The elevated biosynthesis of n-3 long chain polyunsaturated fatty acids proved the 2-fold increase of C20:5n-3, C22:5n-3 and C22:6n-3 in muscle. The results of the experiment demonstrated the ability to convert absorbed C18:3n-3 to longer chain n-3 fatty acids. The ratio of n-6 and n-3 fatty acids was beneficially low as well as in concentrate fed lambs (7:1) and in grazing lambs (2:1). The significantly higher ($P < .05$) percentage of stearic acid and the sum of saturated fatty acids in muscle of grazing lambs (group 2 and 3) reflected a higher rumen activity for biohydrogenation of PUFA. Besides the contribution from landscape maintenance as well as nature preservation, a pasture feeding system can be corresponded to the consumer demand for healthier meat because of the increased n-3 fatty acid concentration.

Key Words: fatty acids, muscle, lamb

1457 Modification of essential fatty acids in phospholipids and triglycerides from beef cattle. S Lorenz^{*1}, K Nuernberg¹, and K Ender¹, ¹Research Institute for the Biology of Farm Animals.

Simmental bulls ($n = 10$) and German Holstein steers ($n = 9$) were divided in two feeding groups (intensive feeding = semi ad libitum access to a concentrate diet, extensive feeding = maintaining on a pasture). For each group the intramuscular fat content of the *longissimus* muscle and the fatty acid composition of phospholipids (PL) and triglycerides (TG) was determined. The different feeding regimes led to significant changes in the fatty acid profile of the PL and TG. Simmental bulls showed significant [$P < 0.05$] differences for each fatty acid except for C18:0 and CLA isomers *9c11t*, *7t9c*, *8t10c*. The relative amounts of these two fatty acids were constant in both feeding groups. In contrast to this a significant difference in the C18:0 level for the German Holstein steers was detected. Despite biohydrogenation in the rumen, C18:3 contained in grass was absorbed and deposited into the lipids of the muscle. This led to a significantly [$P < 0.05$] higher percentage of n-3 fatty acids in the PL in the muscle of cattle kept on pasture. The relative amount of total n-3 fatty acids in Simmentals increased from 3.2 % in the intensively fed cattle to 14.4 % in pasture fed cattle. German Holsteins showed a respective increase from 2.5 % to 12.8 %. The n-6/n-3 ratio of extensively kept Simmentals was 1.6 in contrast to 14.8 in stable-kept animals [$P < 0.05$]. However, German Holsteins showed a n-6/n-3 ratio of 1.5 (extensive) in contrast to 15.9 (intensive) [$P < 0.05$]. Differences in the fatty acid composition of TG from both feeding groups were also observed for both breeds. Grass fed Simmentals had a n-3 fatty acid level of 1.2 %; fourfold higher than the value observed in the TG of animals kept in stable. Whereas, German Holstein steers showed only a twofold increase from 0.3 % to 0.6 % [$P < 0.05$]. For both breeds

the amount of CLA isomers *9c11t*, *7t9c*, *8t10c* was constant in both feeding regimes as shown for PL. Maintaining cattle on pasture resulted in an enrichment of n-3 fatty acids in beef. The total n-3 fatty acid content in beef muscle increased from 23.2 mg to 97.8 mg/100 g muscle (Simmentals) and from 20.4 mg to 72.1 mg/100 g muscle (German Holsteins).

Key Words: fatty acids, muscle, beef

1458 Effect of L-carnitine on lamb growth and metabolites. T. W. White^{*1}, J. M. Fernandez¹, G. D. Harding¹, R. L. Walker¹, C. C. Williams¹, H.G. Bateman¹, and M. A. Froetschel², ¹Louisiana State University Agricultural Center, Baton Rouge, ²University of Georgia, Athens.

Two experiments were conducted to study the effect of L-carnitine (LC) on performance and ruminal and plasma metabolites of individually fed lambs. Weights were taken after a 16-h shrink and ruminal (84 d) and blood samples (28 and 84 d) collected 3 h post feeding after a 16-h shrink. In Exp. 1, 32 Katahdin wethers (BW=26 kg) were blocked by weight into four groups. Lambs in each group were assigned to eight treatments in a 2 x 4 arrangement of four levels (0, 50, 100, or 200 ppm) of ruminally unprotected (UP) or protected (P) LC. Lambs were slaughtered after 98 and 126 d when blocks averaged 47 kg. Ruminally PLC improved ($P < 0.06$) ADG when compared with UPLC (199 vs 184 \pm 5.1 g/d). A quadratic ($P < 0.05$) response on ADG suggests 100 ppm as optimum. Carcass composition was not affected by LC. Ruminal ammonia N levels responded ($P < 0.02$) in a linear, quadratic, and cubic manner to LC. Plasma ammonia N at 84 d was lower ($P < 0.01$) when PLC was fed than when UPLC was fed (46.1 vs 52.2 \pm 1.45 μ M). Ruminal butyrate increased ($P < 0.05$) linearly with increases in LC. In Exp. 2, 16 Suffolk wether (BW=33kg) and 16 Suffolk ewe lambs (BW=32 kg) were assigned as in Exp. 1 to corn-based or soyhull-based diets with 0 or 100 ppm PLC. Lambs were slaughtered after 84, 112, or 140 d averaging 50 kg. Lamb fed corn diets gained faster, were more efficient ($P < 0.01$) and graded higher ($P < 0.06$) than lambs fed soyhull diets. Feeding corn diets increased ruminal propionate, reduced ruminal acetate, pH, ammonia N, and plasma urea N and glucose ($P < 0.01$). Feeding PLC improved ($P < 0.09$) DMI and ADG ($P < 0.06$). Ruminal pH, ammonia N, and plasma ammonia N were reduced ($P < 0.05$) on d 84 by PLC. Individual VFA were not affected by PLC. Protected LC appears beneficial in improving ADG and reducing ruminal and plasma ammonia N levels.

Key Words: Lambs, Carnitine, Growth

1459 Effect of fat source on plasma fatty acids in sheep. H. Febel¹, F. Husveth², and T. Veresehyazy^{*3}, ¹Research Institute of Animal Breeding and Nutrition, Herceghalom, ²University of Veszprem, Keszthely, ³Szent Istvan University, Faculty of Veterinary Science, Budapest, Hungary.

This study was designed to determine whether dietary butylsoyamide and hydroxyethylsoyamide made from soybean oil escape ruminal biohydrogenation and increase unsaturated fatty acids in plasma of sheep. The effect of oleamides was compared with other fat supplements containing Ca soap or soybean oil. Five mature wethers (BW 72 kg) were fed five diets in a 5x5 latin square experiment. The control diet consisted of 50% meadow hay and 50% concentrate with no added fat. The control diet was supplemented with Ca soap (CS), hydroxyethylsoyamide (HA), butylsoyamide (BA), or soybean oil (SO). Fat was added at 3.5% of dietary DM. Each period lasted 18 days. Blood samples were taken by jugular venipuncture during the final 2 days of each period at 3h postfeeding, for determination of total cholesterol, triglyceride, total lipid and fatty acids. All fat supplements increased ($P < 0.05$) plasma triglyceride, cholesterol and total lipid. Plasma concentration of cholesterol and total lipid was highest ($P < 0.001$) with SO. Highest ($P < 0.001$) blood triglyceride was observed for the sheep fed CS supplemented diet. Plasma 16:0 decreased ($P < 0.05$) when either HA or SO was added to the diet. The inclusion of CS in the control diet increased ($P < 0.001$) 16:0. All fat supplements increased ($P < 0.05$) plasma 18:0 and decreased ($P < 0.05$) 16:1 and 18:1. Plasma 18:2n-6 was not changed ($P > 0.05$) by feeding CS and SO. However, compared to the control diet, 18:2n-6 increased 12 ($P < 0.05$) and 41% ($P < 0.001$) in plasma fatty acids when sheep were fed HA and BA, respectively. The ratio of 18:2n-6 to saturated fatty acids in plasma for the control, CS, HA, BA, and SO diets were 1.15, 0.76, 1.25, 1.5 and 1.03, respectively. The results of the current study showed that plasma concentration of unsaturated fatty acids

was enhanced more when the amide was synthesised from butylamine than when from ethanolamine. Further work is needed to determine the effect of fat supplements on ruminal fermentation and digestion.

Key Words: Oleamide, Calcium Soap, Fatty Acid

1460 The feeding of fish oil as fish meal with linoleic acid sources enhances milk CLA content. A. A. Abu-Ghazaleh*, D. J. Schingoethe, A. R. Hippen, and L. A. Whitlock, ¹South Dakota State University.

Twelve multiparous Holstein cows at 65 (33-122) DIM were used in a 4 x 4 Latin square with 4 wk periods to study the effect of feeding fish meal (FM) and /or extruded soybeans (ESB) on feed intake, milk yield and composition, and milk fatty acids with emphasis on conjugated linoleic acid (cis-9,t-11 C18:2, CLA) and trans-vaccenic acid (t-11 C18:1, TVA). Treatment diets were 1) Control; 2) 0.5 % fish oil from FM; 3) 2.5% soybean oil from ESB; and 4) 0.5% fish oil from FM and 2% soybean oil from ESB. Diets formulated to contain 18% crude protein and were composed of 50% (dry basis) concentrate mix, 25% corn silage, and 25% alfalfa hay. Intake of DM (29.4, 29.8, 29.0, and 28.8 kg/d for diet 1 to 4, respectively) was not affected ($P = 0.26$) by diet. Milk production (33.3, 34.6, 36.9, and 38.0 kg/d) was increased ($P < 0.05$) by all treatments compared with control. Milk fat percentages (3.74, 3.46, 3.19, and 3.07), and milk protein percentages (3.27, 3.26, 3.07, and 3.10) were decreased ($P < 0.05$) with ESB and FM+ESB diets. Milk fat yield (1.24, 1.18, 1.17, and 1.17 kg/d) was not affected by treatments ($P > 0.05$), but yield of milk protein (1.08, 1.12, 1.13, and 1.18 kg/d) was increased ($P < 0.05$) with supplemental FM and ESB or their blend. When FM, ESB, or their blend were fed, concentrations of CLA in milk fat increased ($P < 0.01$) by 0.4, 1.4, and 3.2, fold and TVA concentrations in milk fat increased ($P < 0.01$) by 0.4, 1.8 and 3.5 fold compared with control. The increases in CLA and TVA were much higher when a blend of FM and ESB was fed than the additive effect of FM and ESB. This indicated that fish oil caused increased production of CLA and TVA from other dietary sources of linoleic acid such as ESB.

Key Words: Conjugated linoleic acid, Fish oil, Extruded soybeans

1461 Validation of a model for the digestion of fat in dairy cows. P. J. Moate*, R. C. Boston, and W. Chalupa, University of Pennsylvania, Kennett Square, PA.

Our objective is development of a model of fat digestion within the structure of CPM-Dairy. Data from 36 diets in eight published experiments that reported intakes and flows (g/d) of long chain fatty acids (LCFA) to the duodenum and to feces were used to develop equations that described lipolysis of fat and biohydrogenation of LCFA in the rumen, ruminal production of LCFA and intestinal digestion of LCFA (J. Dairy Sci. 83(Suppl1):279-280). The model has now been validated for prediction of absorption of LCFA from the intestine using similar in vivo data from another 38 diets in eight published papers. In the table, the mean and range of the measured (X) absorbed LCFA (g/cow/d) is tabulated and the relationship between the predicted absorbed LCFA (Y) and X is given by A (Y intercept) and B (slope). Despite the fact that validation diets covered a wide range in LCFA intakes as well as diverse fat sources, there was good concordance between measured and predicted absorption of total LCFA and acceptable concordance for most individual LCFA.

LCFA	Xmean	X range	A	B	n	R ²	Bias %
Total LCFA	331	86 - 667	0*	1.02	36	0.88	2

1462 Trans fatty acids in milk of Holstein cows fed soybean oil or two forms of conjugated linoleic acid. T. C. Jenkins*, S. A. Mosley, and J. A. Bertrand, Clemson University, Clemson, SC.

The extent that milk *trans* fatty acids can be altered by fat supplements was examined by feeding lactating Holstein cows either a control diet with no added fat or three diets containing 3% added fat as either soybean oil (SBO), unprotected conjugated linoleic acid (CLA-U), or conjugated linoleic acid protected as simple amides (CLA-P). The diets were fed in a 4 x 4 Latin square design with 2-wk periods. The CLA supplement was a mixture of several conjugated dienes including the *cis*-9, *trans*-11 (22.1% of total fatty acids), *trans*-10, *cis*-12 (18.4%), and *trans*-9, *trans*-11 (6.0%) isomers. Converting the CLA supplement to amides reduced the loss of the *cis*-9, *trans*-11 isomer over 48 h from 100 to 57% in ruminal in vitro cultures. The SBO supplement had no effect on dry matter intake, milk yield, or milk protein concentration. Feeding SBO reduced milk fat from 3.2 to 2.9% with an increase ($P < 0.05$) in total *trans* monoenes from 1.89 to 5.42% of total milk fatty acids, an increase ($P < 0.05$) in the *cis*-9, *trans*-11 diene from 0.38 to 0.63% of milk fatty acids, but a decrease ($P < 0.05$) in the ratio of *trans*-11/*trans*-10 monoenes from 2.54 to 1.00. Both CLA supplements reduced ($P < 0.05$) milk fat percentage from 2.9% for SBO to 1.8%, but had no effect on milk yield or intake. Compared to SBO, the CLA-U and CLA-P supplements increased ($P < 0.05$) total *trans* monoenes from 5.42 to 10.68 and 10.71% of milk fatty acids, increased ($P < 0.05$) the concentration of all conjugated dienes, but reduced ($P < 0.05$) the ratio of *trans*-11/*trans*-10 monoenes in milk from 1.00 to 0.56 and 0.50, respectively. The CLA-P diet had higher ($P < 0.05$) *trans*-6/8 monoenes in milk, but lower ($P < 0.05$) *trans*-10, *cis*-12 and *trans*-9, *trans*-11 dienes in milk compared to CLA-U. The results show that feeding conjugated dienes, as either the free acids or amide, to lactating dairy cows increases the concentration of *trans* fatty acids (both *trans* monoenes and dienes) in milk more than feeding an equal quantity of soybean oil.

Key Words: Milk Fatty Acids, Conjugated Linoleic Acid, Milk Fat

1463 Effects of prepartum intake, postpartum induction of primary ketosis, and periparturient disorders on carnitine palmitoyltransferase I activity in dairy cows. H. M. Dann*, J. K. Drackley, and D. E. Morin, University of Illinois, Urbana.

Thirty-five multiparous Holstein cows were used to determine the role of mitochondrial carnitine palmitoyltransferase I (CPT I) in liver on periparturient adaptations of fatty acid metabolism. Cows were fed a diet (1.54 Mcal NE_L/kg, 14.1% CP) from dry-off to parturition at either ad libitum (A; n=17) or restricted (R; 80% of calculated NE_L requirements; n=18) intake. After parturition, all cows were fed a lactation diet (1.58 Mcal NE_L/kg, 16.8% CP). At 4 d in milk (DIM), cows were assigned to three groups: healthy-control (HC; n=6), healthy-ketosis induction (HK; n=9), and periparturient disorder (PD; n=17), based on a physical examination. Cows in HC and PD were fed for ad libitum intake. Cows in HK were fed at 50% of intake at d 4 postpartum from 5 DIM to signs of clinical ketosis or until 14 DIM, and then were returned to ad libitum intake. Liver was biopsied at -30, 1, 14, and 28 d relative to parturition. Mitochondria were isolated by differential centrifugation. Activity of CPT I (nmol palmitoyl-[³H]-carnitine formed·min⁻¹·mg protein⁻¹) was 5.6 and 6.9 for A and R, respectively ($P < 0.05$) at -30 DIM. Sensitivity of CPT I to its inhibitor, malonyl CoA, did not differ ($P > 0.05$) between A and R; mean IC₅₀ was 1.03 μM. Postpartum CPT I activity and malonyl CoA sensitivity were not affected ($P > 0.05$) by prepartum intake (A vs. R), postpartum group (HC vs. HK vs. PD), or time. Mean postpartum CPT I activity was 8.25 and IC₅₀ was 1.48 μM. Prepartum serum nonesterified fatty acids were correlated ($P < 0.05$) with CPT I activity at -30 (Spearman rho = 0.47) and 1 (Spearman rho = 0.48) DIM but not at 14 and 28 DIM. Prepartum intake affected prepartum CPT I activity but not malonyl CoA sensitivity. Neither induction of primary ketosis nor periparturient disorders affected CPT I activity or sensitivity, which indicates that alterations of CPT I may not be involved in the etiology of primary ketosis or other periparturient disorders.

Key Words: Carnitine Palmitoyltransferase I, Ketosis, Transition Cow

1464 Influence of feeding canola seed on lactation performance and conjugated linoleic acid concentration in milk fat of lactating Holstein cows. J.D. Handegard^{*1}, D.B. Carlson¹, M.S. Laubach¹, D.E. Schimek¹, W.L. Keller¹, J.W. Schroeder¹, C.S. Park¹, G.D. Marx², and J.H. Herbein³, ¹North Dakota State University, Fargo, ²University of Minnesota-Crookston, ³Virginia Polytechnic and State University, Blacksburg.

The objective of this study was to determine the optimum level of dietary canola seed supplementation to cause maximum increases in conjugated linoleic acid (CLA) content in milk fat. Twelve lactating Holstein cows were randomly assigned to one of three dietary treatments (0, 6, and 12% of the total diet as crushed canola seeds). Crushed canola seeds were blended into total mixed rations. Cows were housed in tie-stalls and fed individually for a period of 12 wk. Feed intake and milk weights were monitored daily. Blood and milk samples were collected every three wk. Body weight and a body condition score (BCS) were also determined at this time. Fatty acid profiles on milk were determined by gas chromatography. Analysis has shown an increase in CLA concentration in milk fat of cows on the 12% canola seed diet compared with cows on the 0 and 6% diets ($P < 0.05$). Milk production, dry matter intake, body weight, milk fat, and BCS were not significantly different between treatments. Plasma glucose and insulin were not affected by treatment. However, plasma non-esterified fatty acids of cows on the 12% canola seed diet were decreased (ca. 30%) compared to the control group ($P < 0.05$). Dietary supplementation of crushed canola seed up to 2.5 kg/d can increase CLA concentration in milk fat of lactating cows without negatively affecting lactation performance.

Key Words: Conjugated linoleic acid, Canola, Fat supplementation

1465 Conjugated linoleic acids in duodenal and milk lipids of lactating dairy cows fed different diets. L. S. Piperova^{*1}, J. Sampugna¹, B. B. Teter¹, K. F. Kalscheur¹, R. A. Erdman¹, M. P. Yurawecz², K. Ku², and K. Morehouse², ¹University of Maryland, College Park., ²U.S. Food and Drug Administration, Washington, D.C..

Duodenal and milk samples of lactating dairy cows obtained from a previous study (Kalscheur et al, 1997, J. Dairy Sci. 80:2104) were examined to determine the effect of diet on the conjugated linoleic acids (CLA) content. Four lactating Holstein cows, fitted with duodenal cannulas, were fed 4 diets in a 2x2 factorial, 4x4 Latin square design with 3 week treatment periods. The diets had two levels of forage 25% or 60% (LF or HF) with (B) or without (NB) added buffer (1.5% NaHCO₃ and 0.5% MgO). Fatty acid methyl esters were prepared using 0.7N H₂SO₄ in methanol, at room temperature, and analyzed by GLC (100m SP2560 column) and HPLC (triple Ag+- column). The total duodenal CLA were highest (1.7 g/d) in cows fed the LFNB diet, compared to both HF diets and the LFB diet. In contrast, the milk CLA yield was similar among treatments (7.1 g/d - 9.5 g/d). Regardless of the diet c-9, t-11 was the major isomer, greater than t-7,c-9 >t/c-c/t-11,13 >c-8,t-10. The difference between the milk CLA yields and duodenal flow of CLA can be accounted for by the action of the delta-9-desaturase on the t-11- and t-7-18:1 fatty acids absorbed from the duodenum. The LFNB diet produced the greatest amount of t-10, c-12 CLA in milk fat. Although it has been reported that the t-10, c-12 isomer inhibits delta-9-desaturase, the levels of c-9, t-11 and t-7, c-9 were similar in spite of the level of the t-10, c-12 CLA in milk. The results suggest that the majority of milk CLA were formed by post-absorptive synthesis from trans-18:1 fatty acids.

Item	Diets				Effects ($P <$)			
	HFNB	HFB	LFNB	LFB	SED	F	B	F x B

1466 Metabolic fate of long chain fatty acids by ruminant hepatocytes. D.G. Mashek^{*}, S.J. Bertics, and R.R. Grummer, University of Wisconsin, Madison.

The objective was to determine the metabolism of long chain unsaturated fatty acids to oxidation or cellular lipid products. Hepatocytes were isolated from four ruminating calves and exposed for 3 hours in suspension to one of the following treatments: 1 mM palmitic acid (1C16), 2 mM palmitic acid (2C16), or 1 mM of palmitic acid plus 1 mM of oleic (C18:1), linoleic (C18:2), linolenic (C18:3), eicosapentaenoic (C20:5), or docosahexaenoic (C22:6) acid. For treatments 1C16 and 2C16, metabolism of [1-¹⁴C]palmitic acid was measured. For all other treatments, the fatty acid other than palmitic acid contained the radiolabel. Oxidation of [1-¹⁴C]fatty acids to CO₂ or incorporation into cellular triglyceride (TG), phospholipid (PL), cholesterol (C), and cholesterol ester (CE) were measured. Rates of oxidation to CO₂ were 3 to 4-fold higher for C22:6 compared to other treatment fatty acids, with the exception of C20:5, which had intermediate rates of oxidation to CO₂. Treatments 2C16 and C18:1 yielded the highest rates of incorporation into most cellular lipids, whereas the polyunsaturated fatty acids were poor substrates for incorporation into cellular lipids. The most pronounced change was a reduction of polyunsaturated fatty acid incorporation into cellular TG compared to 1C16, 2C16, and C18:1. All polyunsaturated fatty acids were incorporated into cellular TG at rates less than 25% of those observed for 2C16 and C18:1. Therefore, long chain fatty acids vary in their routes of metabolism by bovine hepatocytes. Values in the table below represent incorporation of [1-¹⁴C]fatty acids into metabolic products (pmol/ug DNA/3 h).

Pro-duct	1C16	2C16	C18:1	C18:2	C18:3	C20:5	C22:6

1467 Effects of feeding whole linseed on milk production and composition of dairy ewes. M. V. Pol, R. Casals^{*}, E. Albanell, and X. Such, Universitat Autònoma de Barcelona.

Forty eight multiparous Manchega dairy ewes (45 days in milk) were used in a cross-over design to study the effects of supplementing diets with whole linseed on lactational performance. Animals were blocked into two groups according to previous milk yield and assigned to one of two diets: control (C) and whole linseed (L). After a first 3-wk experimental period, ewes were switched to the alternate diet for a second 3-wk period. Measurements and samplings were done during the last week of each period. Diets were offered as total mixed rations, containing (dry matter basis) 26% dehydrated whole-plant corn, 26% dehydrated alfalfa, 8% alfalfa pellets and 40% concentrate, where barley and soybean meal were the main ingredients. Since whole linseed was included (8%) in the L diet, proportions of barley and soybean meal were reduced to obtain isonitrogenous diets (16% CP). Ether extract of the diets varied from 1.5% (C) to 3.5% (L). Milk fat content (C, 6.88; L, 7.88%) and yield (C, 80.7; L, 91.0 g/d) increased ($P < 0.01$) due to fat supplementation. In contrast, dry matter intake (DMI: C, 2.87; L, 2.85 kg MS/d), milk yield (C, 1.20; L, 1.16 kg/d), and milk protein (C, 6.06; L, 6.11%) and casein contents (C, 4.76; L, 4.77%) were not affected. However, if expressed as percentage of milk protein, casein (C, 78.56; L, 78.08% of CP) tended to decrease ($P < 0.14$). Provisional results suggest changes in the fatty acid profile of milk, with an increase of unsaturated fatty acids in the L group. Blood serum concentrations of nonesterified fatty acids (C, 0.16; L, 0.26 mmol/L), triglycerides (C, 23.6; L, 36.6 mg/dL) and cholesterol (C, 116.5; L, 153.8 mg/dl) were increased ($P < 0.001$) by the use of linseed, but glucose and β -hydroxybutyrate were not modified. In conclusion, whole linseed may be used at moderate doses in rations of dairy ewes as a natural mean to modify milk fat content without negative effects on DMI and milk protein content. Acknowledgments: CICYT-Spain (Project AGF99-0773) and Agribrands Europe-Espaa.

Key Words: Dairy Ewes, Whole Linseed, Milk

1468 Effect of supplementing Solin, a high linoleic acid oilseed, to a TMR containing fresh grass, on bovine plasma and milk conjugated linoleic acid (CLA) and fatty acid levels. A.T. Ward* and K.M. Wittenberg, *University of Manitoba, Winnipeg, Canada.*

The objective of the trial was to compare the CLA and other fatty acids levels in plasma and milk of cows fed three dietary treatments. The diets were fed as TMR's with forage to concentrate ratios of 60:40. The diets contained either conserved or fresh grass cut from the same field, supplemented with tallow, and fresh grass supplemented with solin crushed oilseed. Twelve multiparous Holstein cows were assigned to one of the three diets in a 3 x 3 Latin square design. Average feed intakes and milk yields of the cows fed the grass diets were significantly lower than feed intakes and milk yields of cows fed the hay-tallow diet. Per cent milk fat, however, was similar for the cows fed the three diets. The grass-solin diet lipid contained 54% linoleic acid as compared to 10% linoleic acid in the grass-tallow and hay-tallow diets. The proportion of the short and medium chain fatty acids were lower in the plasma and milk lipid of the cows fed the grass-solin diet compared to the grass-tallow and hay-tallow diets whereas the C18 fatty acids, except for linolenic acid, were higher in the plasma and milk lipid of the cows supplemented with the grass-solin diet. Vaccenic acid and the CLA isomer C18:2 cis-9, trans-11 were significantly higher in the plasma and milk lipid of the grass-solin fed cows compared to the cows fed the grass-tallow and hay-tallow diets. The cows fed the grass-tallow diet had a significantly higher level of C18:2 cis-9, trans-11 in plasma and milk compared to the hay-tallow diet. The milk lipid C18:2 cis-9, trans-11 CLA isomer levels in the grass-solin, grass-tallow and hay-tallow fed cows were 1.3, 1.07 and 0.93% (SEM=0.04), respectively. The cows fed the grass-tallow and hay-tallow diets had significantly higher plasma levels of the C18:2 trans-9, cis-11 CLA isomer than the cows fed the grass-solin diet, which resulted in total plasma CLA levels to be higher in the cows fed the grass-tallow and hay-tallow diets compared to the grass-solin diet. The C18:2 trans-9, cis-11 isomer, however, was not detected in the milk of the cow's fed the three diets.

Key Words: Conjugated linoleic acid, Oilseed, Fatty acids

1469 Effect of feeding frequency and dietary sunflower oil on conjugated linoleic acid (CLA) concentrations in milk from dairy cows. N.W. Lafond¹, V. Girard², and P.Y. Chouinard¹, ¹Universite Laval, QC, Canada, ²Institut de recherche et de developpement en agroenvironnement, QC, Canada.

Previous work (Kelly et al., 1998; J. Nutr. 128:881) showed that CLA content of milk can be enhanced by dietary addition of sunflower oil (SO), which is rich in C18:2. However, large variation has been observed between cows receiving the same treatment indicating that additional factors must be affecting the CLA content of milk. The objective of the present study was to evaluate if feeding behaviour can explain part of this variation. Eight multiparous Holstein cows in mid-lactation were used in a replicated 4 x 4 Latin square design with three weeks periods. Treatments were: 1) basal diet fed in 1 meal; 2) basal diet fed in 12 meals; 3) basal diet + 5% SO fed in one meal; 4) basal diet + 5% SO fed in 12 meals. Diets were fed as TMR. Treatments had no effect on milk yield but administration of SO reduced DMI (P<0.05). Rumination time, number of chews and ruminal pH were increased by the addition of SO in the diet (P<0.05). Increasing the feeding frequency tended to decrease the number of chews (P<0.07), and reduced diurnal variations of ruminal VFA, NH₃-N and pH (P<0.01). Milk fat content was increased, and milk protein content and yield were decreased when feeding frequency was increased (P<0.05). Dietary SO also reduced milk protein content and yield (P<0.05). Addition of SO enhanced the proportions (mg/100 g DM) of C16:0, C18:0, trans-C18:1, cis-C18:1, C18:2 and CLA in ruminal content (P<0.01). Increasing the feeding frequency decreased the proportion of C18:2, but had no effect on the concentration of CLA in ruminal content. Feeding SO decreased the content and yield of milk fatty acids from C6 to C17, and reduced the yield of C18:2 and C18:3 (P<0.05). Moreover, dietary SO increased milk fat content and yield of C18:0, trans-C18:1, cis-C18:1 and CLA (5.6 vs. 24.6 mg/g) (P<0.01). Feeding frequency had no effect on CLA content of milk fat. Concentrations of CLA in milk fat can be increased with the addition of SO in the diet, but feeding frequency has no effect on ruminal production and subsequent milk concentration of CLA. Supported by Dairy Farmers of Canada, NSERC, and FCAR fund.

Key Words: CLA, sunflower oil, feeding behaviour

1470 Comparison of prilled tallow and free fatty acids from tallow as fat supplements for dairy cows. S. T. Franklin*¹, D. M. Amaral-Phillips¹, J. A. Jackson¹, K. J. Touchette², and J. A. Coalson², ¹University of Kentucky, ²Merrick's, Inc.

Twenty-six Holstein cows were used in a 2 X 2 Latin square design to compare production achieved by supplementing diets with fat as prilled tallow (PT) or free fatty acids from tallow (FF). The study was conducted during July and August of 2000 which subjected the cows to heat stress. Cows were in mid to late lactation and were assigned to treatments based on lactation number (first parity = 12 and multiparous = 14), days in milk, and production. Cows were housed in a tie-stall barn to allow for individual feed intake. Diets were fed as TMR and contained 2.8% alfalfa hay, 42.1% alfalfa silage, 18.0% corn silage, 3.5% whole cottonseed, and 32.6% concentrate, DM basis. After 1 wk of acclimation to the tie-stalls, fat supplements were gradually incorporated into the diets to provide approximately 0.45 kg of supplemental fat as PT or FF per cow daily. Each period lasted 5 wk with 2 wk to acclimate to the fat supplements and 3 wk for data collection. Milk weights were recorded at each milking, a.m. and p.m. milk samples were obtained twice weekly, and feed fed and refused were recorded daily. Feed samples were obtained weekly and pooled by period for analysis. Diets were formulated to be isonitrogenous, averaging 18.5% CP, 1.64 Mcal NEL/kg, and 7.6% ether extract. Treatment did not affect (P > 0.05) DMI and averaged 23.5 kg/cow daily. During period 1, energy corrected milk from cows fed PT and FF averaged 28.5 and 30.1 kg/d, respectively, and during period 2 averaged 27.8 and 26.6 kg/d, respectively. Overall means for energy corrected milk did not differ (P > 0.05) and were 28.1 kg/d for PT and 28.4 kg/d for FF. Percent fat, fat yield, percent protein, and protein yield did not differ (P > 0.05) by treatment. Percent fat was 3.63% and yield was 1.0 kg/d for PT whereas percent fat was 3.70% and yield was 1.0 kg/d for FF. Similarly, percent protein was 3.25% and yield was 0.9 kg/d for PT whereas percent protein was 3.24% and yield was 0.9 kg/d for FF. As expected, milk production, fat yield, and protein yield were lower (P < 0.05) for first parity cows compared to multiparous cows, but there were no interactions (P > 0.05) between lactation number and production. In conclusion, milk yield and composition did not differ for cows fed fat supplements of prilled tallow or free fatty acids from tallow.

Key Words: Supplemental fat, Prilled fat, Free fatty acids from tallow

1471 Short-term feeding strategies for altering conjugated linoleic acid (CLA) content of meat. R. A. Robinson*, K. E. Griswold, G. A. Apgar, B. N. Jacobson, D. Johnson, and H. D. Woody, *Southern Illinois University, Carbondale, IL.*

Short-term (6-week) feeding strategies to alter conjugated linoleic acid (CLA) levels in meat were evaluated in a feedlot trial. The trial was designed as an incomplete 3x2 factorial with level of soy oil and level of forage as the factors. Forty Angus x Hereford steers were randomly assigned to one of four treatments (ten animals per treatment) for the last six weeks of a normal finishing period. The treatments were: 1) control standard 80:20 concentrate:forage finishing diet (C), 2) control + 4% soy oil (C4), 3) 60:40 concentrate:forage finishing diet + 4% soy oil (F4), 4) 60:40 concentrate:forage finishing diet + 8% soy oil (F8). Animals were housed in a slatted floor facility with five animals per pen (two pens per treatment), fed ad libitum, and orts were weighed daily to determine intake. Animals were weighed on a weekly basis, and average daily gain (ADG) was calculated. At termination, carcasses were yield graded, and tissue samples were collected from the longissimus dorsi for determination of fatty acid composition by GC analysis. Data were analyzed using the GLM procedures of SAS with pen as the experimental unit for ADG and animal as the experimental unit for carcass and CLA data. ADG was 3.2, 3.1, 3.4, and 3.0 for C, C4, F4, and F8, respectively, and was unaffected by treatment (P>.05). Dressing percentage, kidney, heart and pelvic fat, and quality grade were all significantly lower when oil was added to the diet (P<.05). There was a trend for backfat to be reduced with the addition of soy oil to the diet (P=.07). Increasing forage in the diet significantly increased ribeye area (P<.05), but had no effect on other carcass quality parameters. For CLA analyses, only the cis-9, trans-11 isomer was detectable in the tissue samples. The levels of CLA (mg per g of total fatty acids) found in the tissues were 2.3, 2.2, 2.7, and 3.1 for C, C4, F4, and F8, respectively. There was a significant oil effect (P<.03), and a significant oil by forage interaction (P<.03). There was a trend for a forage effect (P=.10). Short-term finishing period feeding strategies can be utilized to alter meat CLA levels.

Key Words: CLA, Beef, Short-term Feeding

1472 Conjugated linoleic acid (CLA) must be protected from rumen hydrogenation for the greatest impact on milk composition. M.M. Hawley*¹, M.A. McGuire¹, T.W. Hanson¹, and A.F. Kertz², ¹University of Idaho, Moscow, ²Agribands International, St. Louis, MO.

Conjugated linoleic acids (CLA) are fatty acids found in milk that possess beneficial properties for human health. Efforts to increase the content of CLA in milk have focused on alterations of the rumen environment to promote greater production of CLA during biohydrogenation. Certain CLA isomers also cause milk fat depression (MFD), an effect that may improve the economics of marketing milk. Calcium salts of fatty acids are commercial means to protect lipids from alterations in the rumen. The hypotheses tested included: 1) feeding of Ca salts of CLA was required to enrich milk with CLA; and 2) MFD would only occur when rumen protected CLA was fed. Eight lactating Holstein cows were randomly assigned to one of three treatment sequences in a 3 x 3 Latin square design. Periods lasted 7 d with treatments fed d 3 to 7 of each period. A 7 d rest occurred between every period to minimize any treatment carryover effect. Treatments were safflower oil, CLA as a free oil, and Ca salts of CLA. The CLA used was CLA-60, a mixture of CLA isomers. Supplements were fed to provide 100 g of total CLA per day; safflower oil was fed at 333 g/d equal to the total lipid in the Ca salts of CLA. Supplements were offered once a day before the morning feeding. No effect of treatment on DM intake (29.0 kg/d, SEM = 1.9) or milk yield (33.6 kg/d, SEM = 1.9) was detected. On d 5 of supplementation, feeding of safflower oil, CLA oil, and Ca salts of CLA increased ($P < 0.001$) concentrations of cis-9, trans-11 CLA in milk similarly compared to the first 2 d of each period (3.9 vs. 6.8 mg/g fat). The trans-10, cis-12 CLA isomer was increased ($P < 0.001$) during supplementation with CLA oil (0.8 mg/g) or Ca salts of CLA (1.9 mg/g) compared to pretreatment (0.2 mg/g). Milk fat depression was most evident for the Ca salt supplementation (30.5%) but was also detected for the CLA oil treatment (15.1%) on d 5 of supplementation. Conjugated linoleic acid can be enriched in milk without the utilization of a rumen inert form, however the extent of enrichment and MFD is less than when Ca salts are utilized.

Key Words: Milk Fat, Rumen Inert Fat, Dietary Fat

1473 Feeding Calcium Salts of Oleic Acid on Dry Matter Intake, Milk Yield, and Milk Fatty Acid Content. J.E. Delahoy*, L.D. Muller, R.F. Roberts, L.A. Kalwasinski, and F. Bargo, *The Pennsylvania State University, University Park, PA.*

The objective of this study was to evaluate the effects of feeding increasing amounts of calcium salts of oleic acid (CaOleate) on dry matter intake, milk yield, and milk fatty acid content. Ten cows (108 DIM) were paired according to milk yield, DIM, and parity, and used in a repeated measures design with four sampling periods (seven days in length). All cows were fed a basal TMR containing 17% CP, 34.4% NDF, 37% NFC, and 4% lipid. Five cows were fed increasing amounts of CaOleate mixed into the TMR at a rate of 0, 340, 680, and 1020 g/cow/d. A control group of five cows was fed the basal TMR. Milk samples were taken at the end of each period and analyzed for milk fat, milk protein, and milk fatty acids. Milk yield and DMI were determined daily. Fatty acids were measured to determine saturated fatty acid content (C4:0 to C18:0), unsaturated fatty acid content (C14:1 to 18:3), and CLA. Mean milk yield (33.9 kg), DMI (22.5 kg), milk protein (2.92%), and milk fat (3.36%) were not affected by CaOleate supplementation. Milk fat content of saturated fatty acids decreased linearly (71.2 to 59.9%; $P > 0.05$) with increased amounts of CaOleate. Milk fat content of unsaturated fatty acids (28.8 to 40.1%; $P < 0.05$) and CLA (7.1 to 15.5 mg/g of fat; $P < 0.05$) increased linearly with increased supplementation of CaOleate. Milk from cows fed 1020 g of CaOleate was processed into 2% milk and compared in a triangle test to milk from the Penn State dairy herd. Consumers detected no significant differences between the 2% milks. In summary, milk yield, DMI, milk protein, and milk fat did not differ when cows were fed increasing amounts of CaOleate. Milk fat content of saturated fatty acids were decreased and unsaturated fatty acids and CLA were increased with increasing levels of CaOleate supplementation.

Key Words: Saturated fatty acids, Oleic acid, Milk fat

1474 Effect of processing methods on the utilization of corn grain by ruminants. S.Y. Lee* and J.K. Ha, ¹Seoul National University, Suwon, Korea.

To evaluate the effect of processing methods on the utilization of corn grain by ruminants two experiments were carried out. In the in vitro

experiment, DM digestibility and fermentation characteristics were investigated with using differently processed corns (whole, 4mm-ground, finely-ground, flake, and flake-ground corn). In the in situ experiment, DM disappearance was measured and observation of corn incubated in the rumen by scanning electron microscopy was made. In vitro DM digestibility was influenced by corn processing ($P < 0.01$). Whole corn was poorly digested even after 48 h incubation. Finely-ground and flake-ground corn were more digested than the other corns. 4mm-ground corn was more digested than flake corn. Therefore, it is likely that ground corns have more effect on improving the DM digestion than flaked corns. The extent of pH reduction differed between processing methods ($P < 0.01$). pH for whole corn was reduced a little, that for flake and 4mm-ground corn were reduced slowly to 6.2-6.3. And pH for finely-ground and flake-ground corn were reduced rapidly to 6.18-6.19. The highest gas production was obtained in finely-ground and flake-ground corn, followed by 4mm-ground, flake and whole corn. NH₃-N concentration was influenced by processing method after 6 h incubation ($P < 0.01$). After 48 h incubation total VFA was the highest in finely-ground corns, followed by flake-ground, flake, 4mm-ground, and whole corn. Processed corn grains had higher acetate, propionate and butyrate concentration than whole corn. The result of in situ disappearance was similar with that of in vitro digestibility. That is, finely-ground corn grains were digested to the most extent, followed by 4mm-ground, flake and whole corn. Examination by SEM showed that the endosperm of processed corn grains, except for whole corn, was colonized by a variety of rumen bacteria, and showed extensive pitting as a result of bacterial amyolysis. It can be concluded that cattle need some kind of processing to have an improved utilization of corns from the result of in vitro, in situ experiment.

Key Words: Corn, Processing, Ruminants

1475 Effect of two protein sources on ADG, reproductive performance, ruminal fermentation and digestion kinetics in beef cattle. O. Ruiz-Barrera¹, J. Mejia-Haro², J.A. Jimenez-Castro¹, J.A. Ramirez-Godinez¹, I. Mejia-Haro*³, and A. Flores-Marielarena¹, ¹Universidad Autonoma de Chihuahua, Mexico, ²Universidad de Guanajuato, Mexico, ³CIGA-ITA de Aguascalientes, Mexico.

To evaluate the chemical composition of a rye grass-oat pasture and the effect of supplementation of ruminal undegradable protein on performance, 100 bulls and 62 heifers were fed for 112d. Cattle were randomly assigned to one of two treatments: 1) rye grass-oat pasture, oat hay and a ruminal degradable protein supplement (PDR) based on poultry manure and urea; and 2) rye grass-oat pasture, oat hay and a ruminal undegradable protein supplement (PNDR) based on blood meal and cottonseed meal. One month before the end of the experiment SyncroMate-B was applied to all cycling heifers. Blood samples were taken from the jugular vein at implant insertion, implant removal (before feeding) and 8 h after feeding (after implant removal). A cervical mucus sample was taken at estrus to determine pH, and 15 h after the beginning of the estrus, heifers were inseminated. One month before the end of the experiment, the semen quality was evaluated and blood samples were taken from the jugular vein to determine blood pH and urea. Dry matter, OM, CP, ADF, NDF, ME and in vitro digestibility was determined in feed and fecal samples. Data were analyzed by ANOVA using the GLM of SAS (1993). Average daily gain of bulls and heifers was not affected ($P > .05$) by treatments. Values of blood urea were not different ($P > .05$) between treatments. The pH in cervical mucus and blood serum samples taken at implant insertion, implant removal (before feeding) and 8 h after feeding (after implant removal) did not show differences ($P > .05$) between PDR and PNDR. The pregnancy rate was 46 and 77 % for PDR and PNDR, respectively ($P < .05$). Blood urea values were similar ($P > .05$) between bulls of PDR and PNDR. No differences were observed in sperm concentration, percentage of live and dead cells, masal motility, progressive motility, and abnormalities. With maturity of the pasture, a tendency to increase the content of DM, ADF and NDF and decrease CP, DM and OM digestibility, and ME was observed. No differences ($P > .05$) were observed in ADG and values of blood urea, blood pH and pH of cervical mucus samples. The decrease in fertility in heifers fed PDR could be due to the high values of blood urea found 8 h after feeding. Kind of protein did not affect ADG, blood urea and semen quality.

Key Words: Protein, Undegradable, Fertility

1476 Finishing system (feedlot or pasture) and copper supplementation affect conjugated linoleic acid in beef muscle. T.E. Engle*¹ and J.W. Spears², ¹Colorado State University, Fort Collins, ²North Carolina State University, Raleigh.

Sixty Angus steers (413 kg initial wt) were used to determine the effect of copper (Cu), corn type, and finishing system (confinement vs pasture) on performance and fatty acid composition of beef longissimus muscle. Steers in confinement were fed high concentrate diets, containing either control or high oil corn, individually, using Calan gate feeders. Steers grazing pasture (tall fescue) were maintained in 4 replicates with each replicate consisting of 5 steers. Salt was used to limit concentrate intake in pasture steers to approximately 67% of that observed in confinement steers. One half of the steers in each treatment received a CuO needle bolus at the initiation of the study while the remaining steers received no supplemental Cu. Equal number of steers per treatment were slaughtered after 91, 112 or 133 days on feed. Gain was lower ($P < 0.01$; 1.22 vs 1.57 kg/d) for pasture steers compared with those fed in confinement. Copper increased ($P < 0.05$) ADG in steers fed control corn (1.75 vs 1.50 kg/d) and pasture (1.29 vs 1.14 kg/d) but not in steers fed high oil corn diets (1.51 vs 1.54 kg/d). Gain, DM intake and gain:feed did not differ between steers fed control or high oil corn. Longissimus muscle C18:1 ($P < 0.06$), C18:3 ($P < 0.07$) and C18-conjugated dienes ($P < 0.001$) were higher in pasture-finished steers relative to the control and high oil corn finished steers. The C18:1 trans isomer ($P < 0.06$), C18:0 ($P < 0.06$), and total saturated fatty acids ($P < 0.06$) were lower in longissimus muscle of steers that received a Cu bolus. C18-conjugated dienes were higher in longissimus muscle of steers receiving a Cu bolus finished on pasture ($P < 0.06$) and in steers receiving a Cu bolus finished on the control diet ($P < 0.07$) relative to the non-Cu bolus supplemented steers. These results indicate that finishing cattle on pasture with limited grain increases C18-conjugated dienes in longissimus muscle and that Cu supplementation may alter lipid metabolism.

Key Words: Copper, Fatty Acid, Steer

1477 Interaction of steam reduction and tempering on the feeding value of steam-flaked corn for feedlot cattle. R. A. Ware*, S. A. Rodriguez, and R. A. Zinn, *University of California, Davis.*

Two trials were conducted to evaluate the interaction of steam reduction (419 vs 335 kPa pressure along a 6.35 cm diam steam line, measured 90 cm proximal to steam chest splitter valves) and tempering (60 min exposure to 40 g/kg water plus .275 mg/kg of SarTemp[®]; SarTec, Anoka, MN) on the feeding value of steam-flaked corn (SFC) for feedlot cattle. The SFC was prepared by steaming for 30 min before flaking to a density of .31 kg/L. The SFC was then allowed to air-dry before inclusion into experimental diets. Experimental diets contained 76% SFC (DM basis). Ninety-six crossbred steer calves (347 kg) were used in a 56-d trial to evaluate treatment effects on performance and dietary NE value. There were no treatment effects ($P > .20$) on ADG (1.24 kg/d), DM conversion (5.60 kg DM/kg ADG), and dietary NE_m and NE_g (2.24 and 1.55 Mcal/kg, respectively). Expected (NRC, 1984) dietary NE values for maintenance and gain were 2.23 and 1.55 Mcal/kg. Close agreement between observed and expected dietary NE indicates that across treatments the NE values for SFC were consistent with tabular values (2.38 and 1.68 Mcal/kg, respectively). Four Holstein steers (223 kg) with ruminal and duodenal cannulas were used in a 4x4 Latin square design to evaluate treatment effects on digestive function. Intake of DM was limited to 2% of BW. The percentage of corn starch that was reactive to amylglucosidase (a measure of starch solubility) was similar across SFC treatments, averaging 22%. Ruminal digestion of OM averaged 65% and was not affected ($P > .20$) by treatments. Tempering increased (5%, $P < .05$) ruminal starch digestion. However, ruminal starch digestion was not influenced by steam reduction (81 vs 80%, $P > .20$). Total tract digestion of OM and starch also were not affected ($P > .20$) by treatments, averaging 68 and 98%, respectively. We conclude that if the lower quarter of the steam chest is maintained at temperatures greater than 100° C, reducing steam application by as much as 20% will not detrimentally affect the feeding value of SFC. Due to the absence of a main effect of steam reduction on the feeding value, the interaction of tempering at lower level of steam application was not fully addressed in this study.

Key Words: Steam, Corn, Cattle

1478 Alternate equation forms for heat production estimation in ruminant growth and composition models. J.W. Oltjen* and R.D. Sainz, *University of California, Davis.*

As an alternative to the static representation of heat production (HP) as the sum of that used for maintenance and that used for gain in feeding systems or dynamic growth models, we have investigated a multiple regression on visceral (V, kg) and non-visceral (M, kg) protein and accretion of V and M. Either HP representation can be used in our recently developed dynamic model of the two protein and fat pools. That is, the fit of the model to data, using either traditional concepts of net energy and maintenance, or more general functions for heat production, can be compared to choose the best functional description. In the model, net energy for gain, the difference between metabolizable energy intake and heat production, drives the growth of V and M. Our objective was to estimate parameters and fit of heat production equations for both 72 growing lambs (Ferrell et al., 1986, *Brit. J. Nutr.* 56:595) and 144 steers (Sainz et al., 1995, *J. Anim. Sci.* 73:2971) undergoing various trajectories of compensatory and normal growth. The best equation for rams ($r^2=.987$) was HP, mCal/d = .243 ($\pm .080$) M + 2.52 ($\pm .81$) V + 14.6 (± 3.3) dM/dt + 67.6 (± 21.9) dV/dt where figures in parenthesis are SE of regression coefficients. For steers the experimental design provided fewer growth trajectories and no weight loss periods; the equation HP, mCal/d = .0657 ($\pm .0696$) M + 1.63 ($\pm .60$) V + 16.7 (± 3.4) (dM/dt+dV/dt) fit steers ($r^2=.965$). In the regression, heat production per V is generally much greater than that for M. In the growth model, V responds faster than M to changing energy intake by the animal; this makes maintenance requirement a dynamic variable depending on nutritional history as well as current energy intake. Thus, the static form of maintenance function used in traditional feeding systems is likely to be inappropriate, especially in dynamic situations.

Key Words: Energy Metabolism, Body Composition, Growth Models

1479 Effects of moisture, roller setting and saponin-based surfactant on growth performance of feedlot steers. Y. Wang*¹, T. A. McAllister¹, and D. Greer², ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, ²AgriChem, Inc., Anoka, MN.

The effects of roller setting, moisture content, and a saponin-based surfactant (GrainPrep[®], AgriChem, Inc.) on performance of feedlot cattle were studied using 138 individually fed British cross steer calves ($n = 23$) and six barley silage/rolled barley grain diets for backgrounding (Bk) and finishing (Fn). Barley grain was rolled dry (D), tempered to 20% moisture (M), or tempered (20% moisture) and treated with 60 ppm of surfactant (MS); and with rollers set to produce optimal particle size from dry barley (+D) or set to produce optimal particle size from MS barley (+MS). The resulting diets were fed daily as total mixed rations, with a 4-wk transition from Bk to Fn. Dry matter intake (DMI) was higher ($P < 0.01$) during Bk, Fn and overall when barley was rolled at +D, than at +MS. With barley rolled at +D, average daily gain (ADG) was higher ($P < 0.01$) during Bk, but was unaffected ($P > 0.05$) during Fn, and tended to be higher ($P = 0.084$) overall. Feed efficiency (FE) tended ($P = 0.106$) to be improved during Bk, but was poorer during Fn ($P < 0.001$) and overall ($P < 0.011$), when rollers were set at +D than at +MS. Tempering the barley did not affect DMI, ADG or FE during Bk ($P > 0.05$), but greatly increased DMI and ADG ($P < 0.001$) and improved FE ($P < 0.001$) during Fn and overall. Enhancement of growth rate by tempering was greater ($P < 0.05$) if barley had been rolled at +D than at +MS. Tempering with GrainPrep[®] (MS diets) increased ($P < 0.05$) ADG, relative to M diets, when rollers were set at +MS. Roller setting did not affect ($P > 0.05$) carcass characteristics, but M and MS diets increased ($P < 0.05$) warm carcass weight and saleable meat yield and tended to increase ribeye area ($P = 0.072$), relative to D diets. Tempering barley grain prior to rolling improved growth performance relative to rolling dry grain. The positive effects of GrainPrep[®] on performance were enhanced when barley was rolled to 72% of original bulk density (+MS) as compared to 78% (+D).

Key Words: Saponin, Barley grain, Feedlot cattle

1480 Effects of high oil corn and shade on respiration rates and acid-base balance of Angus and Bonsmara x Beefmaster feedlot steers. T. C. Bramble¹, C. R. Richardson*¹, J. D. Thiebaud², F. N. Owens³, and G. R. Chapman⁴, ¹Texas Tech University, Lubbock, ²Texas Tech Howard Hughes Medical Institute, Lubbock, ³Du Pont Specialty Grains, Des Moines, IA, ⁴Amarillo, TX.

This experiment was designed to determine if high oil corn (HO) or supplemental shade affects respiratory rates (RR) and acid-base balance (ABB) of feedlot steers in partially slotted floor outdoor feedlot pens. Steers, Angus (A) (n=59; BW = 322 ± 2.2 kg) and Bonsmara x Beefmaster (B) (n = 56; BW = 294 ± 2.1 kg) breeding were fed for 150 d (July 17 to December 13, 2000). Breed was nested within each of the 24 pens and steers were blocked into pens by weight. Treatments were: NST (no shade, typical corn), NSHO (no shade, high oil corn), ST (shade, typical corn), and SHO (shade, high oil corn). The HO replaced T on a weight basis, and diets were formulated to meet or exceed NRC (1996) requirements. Shade structures, black, 80% light-occluding polypropylene cloth fixed 3 m above pens, covered 67% of the pen area (9.8 m² of shade/steer). On 25 d throughout the study, RR were measured for one A and one B steer in each pen (n = 48) at 0730 and 1600. Blood gas measurements [(pH, pCO₂, pO₂, HCO₂, TCO₂, and base excess (BE)] to assess the ABB of steers were based on jugular vein blood samples (n = 24, 1 steer/pen, 12 A, 12 B) taken on d 0, 28, 56, 85, 115, and 150. The RR was 22% faster (P < .01) for NS than S steers and 80% faster (P < .01) for A than for B cattle in the afternoon (1600). Shades decreased RR of A cattle by 26% (P < .02) and of B cattle by 15% (P < .01). Cattle fed HO had greater (P = .02) RR than cattle fed T. On d 28 and 85, BE values were greater (P = .07) for shaded steers. Bicarbonate values were higher for S cattle on d 28 (P = .07), and blood was more (P < .10) basic in pH on day 85 for cattle fed HO. Shades may increase the alkalinity of venous blood even though they reduce RR. This suggests that respiration rate alone is inadequate as a predictor of blood acid-base balance of growing steers given ad libitum access to feed.

Key Words: High oil corn, Acid-base balance, Respiration rate

1481 An evaluation of breed and diet on plasma leptin concentration in beef steers. K.A. Johnson*¹, P.S. Mir², P.S. Kuber¹, Z. Mir², D.H. Keiser³, C.T. Gaskins¹, J.J. Michal¹, J.R. Busboom¹, and J.J. Reeves¹, ¹Washington State University, Pullman, WA, ²Agri-Food Canada, Lethbridge, Alberta, ³University of Missouri, Columbia, MO.

To examine the impact of breed and diet on plasma leptin concentration 36 steers of Limousin (L n=12), Wagyu (W n=12) and Limousin x Wagyu F1 cross genetics (LW n=12) were randomly assigned to one of two dietary treatments (0% and 6% sunflower oil). Blood samples were collected at the initiation and end of the feeding trial and plasma leptin determined by radioimmunoassay. At the same time, measurements of body weight, ultrasound measurement of ribeye area (REA) and fat thickness (FT) were made. Predictions of intramuscular lipid were made from the ultrasound images. After the background phase (112d), steers were fasted and plasma collected for leptin analysis. At harvest (d 212) carcass weight, FT, REA, yield grade (YG) and marbling measurements were collected. There was no effect of diet on leptin at any time. Initial leptin was not different among breed groups (L 2.04 ± 0.29 ng/ml; LW 3.12 ± 0.61 ng/ml; W 2.97 ± 0.62 ng/ml). Leptin at fasting did not differ (P<.13) by breed (L 1.35 ± 0.31 ng/ml; LW 1.90 ± 0.32 ng/ml; W 2.25 ± 0.40 ng/ml). Wagyu had greater (P<.02) final leptin (13.2 ± 1.43 ng/ml) than L (9.53 ± 0.97 ng/ml) or LW (9.76 ± 0.93 ng/ml). Carcass weight, REA, and YG differed by breed at harvest (P<.01). Marbling scores and quality grade were different (P<.0001) among breed types with W (866.7; prime -) being highest, followed by LW (583.3; choice -) and L (470.8; select +). Correlation analysis indicated no significant relationship between plasma leptin collected at any time and carcass traits. While plasma leptin was not useful as a predictive tool in determining carcass fatness, the final leptin concentration did reflect final quality grade.

Key Words: Leptin, Beef Cattle, Wagyu

1482 Corn processing method in finishing diets containing wet corn gluten feed. T.L. Scott*, C.T. Milton, T.J. Klopfenstein, and R.A. Stock, University of Nebraska-Lincoln.

Four finishing trials were conducted to determine the effects of corn processing method on performance of steers fed diets containing wet corn gluten feed (WCGF). In Trial 1, 300 calves were fed five factorially arranged treatments: 1-4) dry-rolled (DRC) or steam-flaked corn (SFC) with or without 32% WCGF; and 5) SFC+DRC without 32% WCGF. Intake was similar when feeding corn grain and increased (P<0.10) by different magnitudes (1.2 and 0.7 kg/d) when feeding DRC and SFC with WCGF. Feeding WCGF improved (P<0.10) ADG and reduced (P<0.10) efficiency compared to feeding corn grain alone. Intake and performance were similar when WCGF or DRC replaced SFC. Daily gain was similar and efficiency improved (P<0.10) by feeding SFC versus DRC. In Trial 2, the DRC/WCGF and SFC/WCGF from Trial 1 were used as control treatments and another 180 calves were fed three treatments: 1) high-moisture (HMC), 2) finely-ground, and 3) whole corn all with 32% WCGF. When feeding WCGF, whole corn increased (P<0.10) intake compared to SFC, HMC, or finely-ground corn with DRC being intermediate. Processing method did not affect ADG. Efficiency was reduced (P<0.10) by feeding whole corn compared with other treatments. Feeding SFC, HMC, or finely-ground corn improved (P<0.10) efficiency compared to DRC. Efficiency was improved (P<.10) by feeding SFC compared to finely-ground corn. In Trial 3, 192 yearlings were fed four factorially arranged treatments: 1-4) DRC or SFC with or without 22% WCGF. Intake was similar in steers fed corn grain and increased (P<0.10) by different magnitudes (1.1 and 0.5 kg/d) when feeding DRC and SFC with WCGF. Feeding WCGF improved (P<0.10) ADG while feed efficiency was similar. Both ADG and efficiency were improved (P<0.10) by feeding SFC compared to DRC. In Trial 4, the DRC/WCGF and SFC/WCGF from Trial 3 were used as control treatments and an additional 96 yearlings were fed two treatments: 1) HMC and 2) finely-rolled corn both with 22% WCGF. When feeding WCGF, intake was similar; however, SFC improved (P<0.10) both ADG and efficiency compared with other treatments. Performance was similar among steers fed DRC or HMC. Feeding HMC improved (P<0.10) efficiency compared to finely-rolled corn. In diets containing WCGF, feed efficiency tended to be improved by more intensive processing methods.

Key Words: Beef Cattle, Grain Processing, Byproduct Feeds

1483 Sub-clinical ruminal acidosis in feedlot cattle fed a barley-based diet. G. R. Ghorbani*^{1,2}, K. A. Beauchemin¹, and D. P. Morgavi¹, ¹Agriculture and Agri-Food Canada, Lethbridge, AB, T1J 4B1, Canada, ²Isfahan University of Technology, Isfahan, Iran.

Sub-clinical acidosis can reduce feed efficiency and growth rate in cattle, thereby causing significant economic losses to the feedlot cattle industry. A study was conducted to determine the prevalence of subclinical ruminal acidosis in feedlot cattle fed for maximum growth rate. Measurements of rumen pH, blood pH and DMI were made using six ruminally cannulated steers over a 9-week period. On three occasions during the experiment, ruminal pH was measured every 15 min for 6 d using indwelling electrodes. DMI was measured for each animal daily and blood pH was measured before feeding three times during the experiment. Steers were provided ad libitum access to a diet containing steam-rolled barley, barley silage, and a protein-mineral supplement; 87, 9, and 4% (DM basis), respectively. Mean values (SD) were: DMI, 9.29 (1.87) kg/d; blood pH, 7.37 (0.028); ruminal pH, 5.70 (0.41); maximum pH, 6.43 (0.25); minimum pH, 5.17 (0.43); hours pH < 5.8, 12.43 (8.09); area below 5.8 and the curve, 6.59 (5.8) pH x h/d; hours pH < 6.2, 17.8 (5.91), and area below 6.2 and the curve, 12.43 (6.2) pH x h/d. There was a significant effect (P < 0.05) of day on all rumen pH variables, except for maximum pH. Furthermore, there was no correlation (P > 0.05) between pH variables (mean pH, hours pH < 5.8, or < 6.2) and blood pH or DMI. Using the DMI and forage eNDF (measured as the proportion of the DM retained on the Penn State Particle Separator) obtained in this experiment, the NRC (1996) model predicted a mean rumen pH of 5.81, 0.11 units higher than observed. The eNDF needed to be reduced in the model from 34% to 18% to accurately predict the observed pH. In conclusion, the incidence of ruminal subclinical acidosis in feedlot cattle fed barley-based diets is prevalent, and higher than would be predicted based on the NRC (1996) model.

Key Words: Sub-clinical acidosis, Feedlot diet, Rumen pH

1484 Adaptation of the Cornell Net Carbohydrate and Protein System to sheep: validation of feed digestibility. A. Cannas*¹, D.G. Fox², A.N. Pell², and P.J. Van Soest², ¹University of Sassari, Sassari, Italy, ²Cornell University, Ithaca, NY.

A new feeding system for sheep, based on the structure of the Cornell Net Carbohydrate and Protein System (CNCPS) for cattle, was developed. The goal was to overcome some of the limitations of currently available feeding systems for sheep, with special regard to the estimation of feed values at different levels of intake. This system, called sheep-CNCPS, integrated current knowledge on sheep requirements into the structure of the CNCPS for cattle. The equations used to estimate energy and protein requirements were obtained by incorporating those published in the literature. Except for the predictions of feed and liquid passage rates, which were based on new equations developed for this system, the submodels used to estimate the supply of nutrients were those of the CNCPS for cattle. The sheep-CNCPS predictions of feed digestibility were validated by using 14 published *in vivo* total tract digestibility experiments, in which 56 different diets were tested. The sheep-CNCPS slightly underestimated DM digestibility (%) (mean bias -2.07, model bias -3.3, RMSPE 4.17; n=41) and OM digestibility (%) (mean bias -1.17, model bias -1.6, RMSPE 3.97; n=36). NDF digestibility (%) was predicted with lower accuracy than OM and DM (mean bias -2.17, model bias -5.1, RMSPE 9.90; n=56). When two distinct outliers were discarded, the prediction of NDF digestibility was substantially improved (mean bias -1.01, model bias -2.9, RMSPE 7.58). Dietary CP digestibility (%) was grossly underestimated (mean bias -5.58, RMSPE 15.31; n=42), with three feeds having negative digestibility, probably because of the large overestimation of fecal metabolic nitrogen. When they were discarded, the prediction was markedly improved (mean bias -2.53, model bias -2.0, RMSPE 9.45). Overall, the sheep-CNCPS predicted feed DM, OM, and NDF digestibility quite accurately, but it was less reliable in the case of CP digestibility.

Key Words: Sheep, Feeding system, Digestibility prediction

1485 Effect of moisture heat damage on ruminal degradation of cottonseed dry matter and crude protein using nylon bag technique in sheep. A. Estrada* and R. Barajas, Universidad Autonoma de Sinaloa (Mexico).

To determine the effect of moisture heat damage on ruminal degradation of cottonseed dry matter and crude protein a study using the nylon bag technique was conducted. Four sheep (Pelibuey; BW = 34 kg) were fitted with T canula in rumen. The animals were fed a diet containing 12% corn straw, 10% cottonseed, 10% moisture heat damaged cottonseed, 57% sorghum grain, 8% sugar cane molasses, 0.9% urea, and 2.1 mineral premix (15% CP and 3.55 Mcal DE/kg). Moisture heat damaged cottonseed was processed by adding 30% water and bulk-stacking for 7 d. Pairs of nylon bags (12 x 18 cm) containing five grams of ground undamaged cottonseed (UCS) or moisture heat damaged cottonseed (DCS) were placed in the rumen, and incubated for 3, 6, 9, 12, 24, 48, and 72 h. After removal from rumen, residual DM and CP content were determined. Water addition and stack processing increased the cottonseed temperature from 34 to 65 °C in 5 d (7.7 °C/day; R² = 0.99; P<0.001). After that time temperature was constant. DM solubility of DCS was 33% lower (P<0.01) than UCS-DM. At 12 h of incubation DCS-DM was 18% lower (P<0.01) than UCS-DM. The degradation rate (c) of DCS-DM was lowered by 33% (0.09 vs. 0.06%/h). The crude protein solubility was diminished (P<0.03) by moisture heat damage (40 vs. 31%). Rumen degradation rate of CP from DCS was 32% lower than UCS-CP (0.028 vs. 0.019%/h). The true ruminally degraded CP of UCS was calculated to be 79.4% and the corresponding value of DCS was 70.6%. Consequently the rumen undegradable crude protein of cottonseed was increased in 42% (20.6 vs. 29.5%) due to moisture heat damage. It is concluded that the water addition to cottonseed and its further bulk-stacking for 5d is able to increase its temperature enough to reduce the solubility and degradability of cottonseed crude protein in rumen, and to increase significantly its rumen undegradable crude protein content.

Key Words: Cottonseed, Heat damage, Crude protein

1486 Effect of close-up protein supplementation on milk, fat and protein yields of late gestation primiparous Holstein dairy cows. P. H. Robinson*¹, J. M. Moorby², and M. Arana³, ¹University of California, Davis, CA, ²IGER, Aberystwyth, UK, ³UCCE, Stockton, CA.

To define the impact of supplementation of CP in the late (close-up) gestation period of primiparous dairy cows, on yield of milk and its components, a diet of corn silage (17% of DM), alfalfa hay cubes (24%), oat hay (25%), barley (16%) and corn grains (16%) was limit fed at 12.1 kg DM/d. A supplement of canola meal (60%), dried distillers grains (20%), blood meal (10%), feather meal (5%), and corn gluten meal (5%) was not fed (11.7% CP; DM), or fed at 1.1 kg/d (14.4% CP) or at 2.3 kg/d (16.6% CP). Milk, protein and fat yields of 154 primiparous Holstein heifers, that were close-up for 1 to 18 d and offered one of the diets (n = 51, 53 and 50 for diets 11.7, 14.4 and 16.6% CP), were measured monthly for the first 150 d of lactation. Following calving, all cows received the same diet containing 17.7% CP and 32% NDF (DM). For statistical analysis of treatment means, cows were allocated to one of four groups based upon time close-up (1-4, 5-8, 9-12 and 13-18 d). Data were analysed by multiple regression with diet CP, its square, days close-up, its square and cube, and their interactions, with progressive removal of non-significant terms. Milk yield was highest for cows offered the 14.4% and 16.6% CP diets for more than 8 d. Protein yields were similar for all diets, but tended to be highest for the 14.4% CP diet fed for 9-12 d. Fat yields were not significantly described by the parameters of the regression model. The amount of supplement fed close-up, and the length of time that animals were close-up and received it, both influenced milk and milk protein yield. Overall, the optimal combination was 14.4% CP for 9-12 d.

Diet CP %	Days close-up			
	1-4	5-8	9-12	13-18
Milk, kg/d				
11.7	32.6	32.1	33.0	32.3
14.4	29.0	33.8	34.4	33.4

1487 Effect of close-up dry period protein supplementation on milk, fat and protein yields of multiparous Holstein dairy cows. J. M. Moorby¹, P. H. Robinson*², and M. Arana³, ¹IGER, Aberystwyth, UK, ²University of California, Davis, CA, ³UCCE, Stockton, CA.

To define the impact of supplementation of CP in the late (close-up) dry period of multiparous dairy cows, on yield of milk and its components, a diet of corn silage (17% of DM), alfalfa hay cubes (24%), oat hay (25%), barley (16%) and corn grains (16%) was limit fed at 12.1 kg DM/d. A supplement of canola meal (60%), dried distillers grains (20%), blood meal (10%), feather meal (5%), and corn gluten meal (5%) was not fed (11.7% CP; DM), or fed at 1.1 kg/d (14.4% CP) or at 2.3 kg/d (16.6% CP). Milk, protein and fat yields of 177 multiparous Holstein cows, that were close-up for 1 to 18 d and offered one of the diets (n = 46, 68 and 63 for diets 11.7, 14.4 and 16.6% CP), were measured monthly for the first 150 d of lactation. Following calving, all cows received the same diet containing 17.7% CP and 32% NDF (DM). For statistical analysis of treatment means, cows were allocated to one of four groups based upon time close-up (1-4, 5-8, 9-12 and 13-18 d). Data were analysed by multiple regression with diet CP, its square, days close-up, its square and cube, and their interactions, with progressive removal of non-significant terms. Milk yield was highest for cows offered the 14.4% CP diet for 9-12 d, but declined on all diets fed longer. Protein yields were highest for the 16.6% CP diet fed for up to 12 d, lowest on the 11.7% CP diet fed for 1-4 d, and declined with all diets fed for 13-18 d. Fat yields were highest for the 16.6% CP diet for 1-4 d, but declined on all diets fed

for 13-18 d. The amount of supplement fed close-up, and the length of time that animals were close-up and received it, both influenced milk and milk component production. Overall, the optimal combination was 14.4% CP for 9-12 d.

Diet CP %	Days close-up			
	1-4	5-8	9-12	13-18
Milk, kg/d				
11.7	42.1	40.5	42.1	40.2

1488 Simulation of the effect of N excretion on environmental pollution arising from dairy cows using a dynamic model. E. Kebreab*¹, J. France¹, J.A.N. Mills¹, R. Allison², and J. Dijkstra³, ¹The University of Reading, ²ADAS Bridgets, ³Wageningen Institute of Animal Sciences.

Agriculture is one of the major sources of nitrogen (N) pollution. To increase animal products, cattle and especially dairy cows, are offered increasingly higher amounts of N but the efficiency with which N is converted to animal product is low leading to excess N to be excreted in feces and urine. From an environmental perspective, losses of N as urine is less desirable due to its greater tendency to leaching and volatilization as ammonia, the major source of which is urea from urine. A dynamic model was developed to predict the amount and source of N in excreta and to assess the impact of manipulating diet to reduce N pollution by improving N utilization. Five N balance experiments conducted at the Centre for Dairy Research (The University of Reading) were used to parameterize the model and an independent data from experiments conducted at ADAS Bridgets were used to evaluate the model. The model showed that energy and protein content of the diet affect N utilization. The model predicted that cows fed a low degradable starch supplement (corn) gave up to 65% lower N excretion and a higher protein concentration in milk. In addition, feeding cows corn-based diets reduced urinary N excretion by almost 30% compared with barley-based concentrates. As a result, feeding corn-based diets has a potential to reduce ammonia emissions by up to 26%. It was also shown that it is possible to improve N utilization in dairy cows by decreasing protein intake on balanced diets. Reducing the protein content from 190 to 160 g/kg DM substantially reduced N in urine without compromising lactational performance which could potentially reduce ammonia emissions from dairy cows by 21% and nitrous oxide by 15%. Diets with low degradable protein sources also reduced N output in urine with little change in milk production. Inclusion of a lower degradable protein in the diet will potentially contribute to a reduction of ammonia emissions by 20% and nitrous oxide by 8%.

Key Words: N utilization, Environmental pollution, Dairy cows

1489 Should residual plots use Y or Yhat? N.R. St-Pierre*, The Ohio State University.

Evaluation and validation of models (empirical or mechanical) require analyses of error structure in the form of residual plots. The appearance of numerous residual plots in recent literature where the residuals are plotted against observed (Y) values to assess a model's bias raises the question whether residuals should be plotted against Y or against predicted values (Yhat). This requires knowing the expected relationship under the assumption of an unbiased model. The objectives of this research were to derive the expected relationship between residuals and Y and to determine whether Y or Yhat should be used for the assessment of bias. Assume a true model of the form $Y = X\beta + \epsilon$. This model is estimated by $Y = Xb + e$, and $Yhat = Xb$. Least-squares estimates of

b are unbiased and have minimum variance among all linear estimators of β . The correlation between the residual vector e and the vector of observations Y is calculated as follows. The numerator of the correlation coefficient is shown to be equal to $e'e$, the residual sum of squares. The denominator of this correlation is equal to the square root of $e'e$ multiplied by the total sums of squares. Algebraic simplifications show that the correlation between e and Y is equal to the square root of $(1-R^2)$. That is, under the assumption of an unbiased model, the residuals are correlated with the observed values and the slope of e regressed on Y is equal to $(1-R^2)$. Thus, a graph of e versus Y will show a positive slope between e and Y unless the model is a perfect predictor (i.e., the R^2 is equal to 1.0). Significant slopes linking e to Y have been erroneously interpreted as evidence of biased models. The correlation between e and Yhat is easily shown to be equal to zero. Thus, the slope of e regressed on Yhat is expected to be zero under the assumption of an unbiased model. These results clearly prove that plots of residuals on observed values are incorrect for assessing a model's bias. Residual plots should be done on Yhat.

Key Words: Residual plot, Model assessment, Bias

1490 Short-term mammary blood flow responses to changes in circulating metabolite concentrations. S.R.L. Cieslar*¹, D.R. Trout¹, T.G. Madsen², N.G. Purdie³, and J.P. Cant¹, ¹University of Guelph, Ontario, ²The Royal Veterinary and Agricultural University, Frederiksberg C, Denmark, ³University of Queensland, St. Lucia, Australia.

Mammary blood flow (MBF) is locally regulated to match nutrient delivery with demands for milk synthesis. The objective of this experiment was to determine which of the major milk precursors would elicit a MBF response when its concentration was elevated in the arterial supply, and to define the time-course of such a response. Four multiparous cows fed a TMR (CP 14.6%, ADF 27%, NDF 36%, NE_L 1.54 Mcal/kg) twice daily, ad lib or restricted to 70% of ad lib, were infused via an external iliac arterial catheter for 20 min with saline (0.09 g/min), glucose (2.2 g/min), amino acids (complete milk protein profile @2.0 g/min), triglycerides (IntralipidTM @2.0 g/min) or insulin (20 μ g/min). Base line blood flow was determined by venous dilution of arterial PAH 10, 5 and 0.5 min prior to infusion. Following the start of infusion, blood samples were collected continuously via peristaltic pump every 30 sec for the first 2 min and every 2 min for the next 28 min. Iliac plasma flow dropped 15 to 31% within the first minute of infusion of each milk precursor. During glucose and amino acid infusions, plasma flow returned to its baseline value by 20 min, but at the cessation of infusion a reactive hyperemia of 5 to 17% was observed for approximately 4 min. The triglyceride infusion continued to depress plasma flow (40 to 53%) until at least 10 min after the infusion had stopped. Insulin, on the other hand, increased iliac plasma flow by 20 to 101% during and after infusion. There were no differences in response to infusions between ad-lib and restricted feeding of the diet. The results indicate that the mammary glands modify their blood flow rate within seconds of being exposed to a new concentration of milk precursors.

Key Words: Arterial Infusion, Blood Flow, Mammary

1491 True intestinal digestibility of nitrogen, lysine and methionine estimated with sheep on intragastric infusion and by mobile bag technique. T. Hvelplund*¹, L. Misciattelli¹, F.D.DeB Hovell², and M.R. Weisbjerg¹, ¹Danish Institute of Agricultural Sciences, Denmark, ²University of Aberdeen, UK.

Lysine (Lys) and Methionine (Met) are often considered to be the most limiting amino acids in diets for high producing dairy cows. Methods for estimation of their availability in rumen undegraded protein is therefore of great importance. The true intestinal digestibility (dig) of nitrogen (N), Lys and Met was investigated for blood meal (100°C, 90h) and soybean meal (SBM) (0.8% HCHO) and for 16 hour rumen incubated residues of: SBM (120°C, 40min), SBM (160°C, 120 min), rapeseed meal, fishmeal, meat and bone meal, and peas (120°C, 40min). Intestinal digestibility was measured in lambs (n=4), fitted with a rumen cannula, an abomasal catheter and a cannula in the terminal ileum, in 4*4 latin square experiments. Cr-mordanted cellulose powder was used as flow marker. Corrections for endogenous protein secretions was based on values obtained from infusing only cellulose. The lambs received ruminal VFA infusion and abomasal protein infusions at energy intakes of 1.5*maintenance. Intestinal disappearance (dis) of N, Lys and Met

from mobile bags was determined by inserting polyamide bags (11 μ m pores size), into the duodenum and recovering the bags from the faeces, using three cannulated dry cows. Significant correlations between disappearance from mobile bags and in vivo true intestinal digestibility in sheep (n=8) was observed. Blood meal gave very low bag dis, probably due to clogging of the bag pores and results are not included. Lys values for rapeseed meal are missing for analytical reasons. The regression equations were: N-dig = 0.02 + 0.97*N-dis ($P < 0.0001$, $R^2 = 0.96$, n=7) Lys-dig = -0.19 + 1.18*Lys-dis ($P = 0.003$, $R^2 = 0.91$, n=6) Met-dig = 0.26 + 0.76*Met-dis ($P < 0.0001$, $R^2 = 0.96$, n=7) Although based on few observations the results show that the mobile bag technique can predict intestinal digestibility of crude protein and of Lys and Met.

Key Words: Amino acids, Digestibility

1492 Effects of diet on milk allantoin and its relationship with milk production in dairy goats. B.R. Min^{*1}, R. Puchala¹, and S.P. Hart¹, ¹*E (Kika) de la Garza Institute for Goat Research, Langston, OK, 73050.*

Forty-four Alpine goats (56 \pm 11 kg BW) were used to study the relationship between milk production and milk allantoin concentration with pastured dairy goats receiving different levels of concentrate supplementation. Multiparous dairy goats were divided into four groups and were supplemented with 0.66 (groups A and B), 0.33 (group C), and 0 kg concentrate (group D) per kg of milk over 1.5 kg/d. Mixed vegetative forages were rotationally grazed by the goats except for group A (confined and fed alfalfa hay). Milk production was recorded daily and milk samples were collected twice monthly from March to September, 2000 and analyzed for allantoin by HPLC. Milk allantoin (mg/d) was positively correlated ($R^2 = 0.63$; $y = 22.2x - 20.7$; $P < 0.001$) with daily milk yield (kg/d) over the four groups. Allantoin output in milk has significantly correlated with milk production range from $R^2 = 0.58$ ($y = 31.2x - 45$; $P < 0.001$), 0.62 ($y = 23.5x - 29$; $P < 0.001$), 0.53 ($y = 19.1x - 12.6$; $P < 0.01$) and 0.44 ($15x - 4.9$; $P < 0.03$) in groups A, B, C and D, respectively. Increased excretion of allantoin in milk was correlated ($R^2 = 0.44$; $y = 23.5x + 22.7$; $P < 0.001$) to concentrate DM intake suggesting that concentrate provided additional energy for increased microbial protein production with conventional mixed forage diets. Milk allantoin was positively correlated ($R^2 = 0.48$; $y = 0.37x + 23.8$; $P < 0.001$) with milk urea (mg/d), but was not correlated with blood plasma urea concentrations. Milk allantoin has the potential to be used as an indicator for microbial protein synthesis in dairy goats.

Key Words: Allantoin, Microbial protein synthesis, Milk and plasma urea

1493 Correction for microbial contamination does not alter estimates of intestinal digestibility of rumen undegraded protein. Y. G. Goh^{*1} and G. A. Broderick², ¹*Kangwon National University, Chunchon, South Korea*, ²*U.S. Dairy Forage Research Center, Madison, WI.*

Intestinal digestibility was estimated for the putative RUP from 4 protein sources: solvent soybean meal (SSBM), expeller soybean meal (ESBM), blood meal (BM) and corn gluten meal (CGM). RUP were prepared with in situ and in vitro pre-incubations. Proteins were added to dacron bags; bags were soaked in buffer then inserted into the rumens of two cannulated cows. After 16 h of in situ incubation, bags were removed, washed and dried (24 h, 60 C). Residues were harvested and ground. Rumen contents were collected from the same cannulated cows and filtered through 8 layers cheesecloth; this fluid was mixed with an equal volume of McDougall's buffer and incubated with proteins in vitro at 39 C for 16 h under CO₂. Residues were collected by filtering onto 2 layers of cheesecloth, then washed, dried (24 h, 60 C) and ground. Mixed rumen microbes also were isolated by differential centrifugation during in situ and in vitro incubations. Residues and mixed microbes were analyzed for total N and purines. Intestinal N digestibility was estimated by pepsin-pancreatin digestion. Samples (8 mg N) of residues or mixed microbes were incubated with 7.5 ml 0.01% (w/v) pepsin in 0.01 N HCl for 3 h at 39 C. Then 3.75 ml 0.2 N NaOH and 3.75 ml of 0.053% (w/v) pancreatin (0.1 M phosphate buffer, pH 8) were added and incubated for 6 h at 39 C. Incubations were stopped with trichloroacetic acid (TCA); TCA supernatants (30,000 x g) were analyzed for total soluble N. Apparent and true intestinal digestibility of RUP was computed from the total N recovered as TCA-soluble N, before and after correcting for the digestibility and amount of microbial N based on total purines. Apparent and true pepsin-pancreatin digestibility were not different (P

= 0.49). Overall RUP digestibility was different ($P < 0.01$) for protein, averaging 74.3, 71.9, 81.1 and 49.7% for, respectively, SSBM, ESBM, BM and CGM. RUP digestibility for in vitro residues (mean = 71.6%) was greater ($P < 0.01$) than for in situ residues (mean = 67.0%); however, there was a significant pre-incubation by protein interaction ($P < 0.01$).

Key Words: RUP, Pepsin-pancreatin, Intestinal digestibility

1494 In vitro effects of feed oils, ionophores, tannic acid, saponin-containing plant extracts and other bioactive agents on ruminal fermentation and protozoal activity. A. N. Hristov^{*1}, M. Ivan², and T. A. McAllister², ¹*Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330*, ²*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB T1J 4B1.*

The effects of various feed oils and bioactive agents on ruminal fermentation and protozoal activity were evaluated in duplicate 4-h in vitro incubations. Rumen inoculum was obtained from two heifers fed 90% rolled barley grain. ¹⁵N-casein was included in the incubation media as a N tracer. Linseed, canola, coconut, soybean and palm oils, herring meal and lecithin at 0.5, 1.0 and 2.0%, monensin (MON) at 2.5, 5 and 10 ppm and salinomycin (SAL) at 1.25, 2.5 and 5 ppm, Yucca powder (YP), Quillaja extract (QE), tannic acid (TA) and bentonite (BEN) at 0.1, 0.2 and 0.4%, and Tween 80 (T80) at 0.05, 0.1 and 0.2% were studied (n = 4). Blanks (0% or 0 ppm) were prepared for each additive. Compared to the Blank, ammonia concentration was decreased ($P < 0.05$) by MON, SAL, YP, TA and BEN. TA, MON, and SAL increased ($P < 0.05$) and BEN and YP decreased ($P < 0.05$) the total free amino acids concentration. TA reduced ($P < 0.05$) total VFA concentration and acetate:propionate ratio. BEN, TA, palm oil, QE, and SAL reduced ($P < 0.05$) carboxymethylcellulase, xylanase, and amylase activities, TA, lecithin, and QE decreased ($P < 0.05$) protozoal numbers (84% *Entodinium* spp.), and fish meal, TA, MON, and SAL reduced ($P < 0.05$) the rate of protozoal engulfment of bacteria. All levels of fish meal and SAL and the higher levels of QE and T80 depressed ($P < 0.05$) the incorporation of ¹⁵N from casein into bacterial cells. Lecithin was the only additive that effectively reduced protozoal numbers (by 27%) without impeding the growth of rumen bacteria.

Key Words: Rumen Protozoa, Oils, Bioactive Agents

1495 In vitro rates of bacterial incorporation of nitrogen fractions from ¹⁵N-labeled whole-crop barley ensiled at two dry matter contents. A. N. Hristov^{*1} and T. A. McAllister², ¹*Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330*, ²*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB T1J 4B1.*

Greenhouse-grown barley (*Hordeum vulgare* L) was ensiled with and without wilting and used to determine the effect of DM content at ensiling on the in vitro rate of bacterial incorporation of N fractions of whole-crop barley silage. The barley was grown in N-free soil and fertilized with ¹⁵N-ammonium sulfate. It was harvested at early-dough and ensiled in 3-L laboratory silos, either directly (at 18.2% DM) or after wilting to 30.8% DM. Average ¹⁵N-enrichment of barley silage total N was 3.743 at % exc. Freeze-dried silage samples were fractionated into soluble protein N (SP), rapidly degradable protein N (RDP), and slowly degradable protein N (SDP) corresponding to protein fractions B1, B2, and B3 in the Cornell Net Carbohydrate and Protein System. ¹⁵N-enrichment of bacterial N was measured at 18 time-points during duplicate 48-h incubations of the three N fractions in buffered ruminal fluid (n = 4). ¹⁵N-casein was used as a control N source. As determined by the 95% confidence intervals, fractions RDP and SDP did not differ ($P > 0.05$) in the rate of incorporation of their N into bacterial protein: 0.0434 and 0.0350 (RDP) and 0.0347 and 0.0436 h⁻¹ (SDP), unwilted and wilted silage, respectively. Nitrogen from SP was incorporated into bacterial N at a higher ($P < 0.05$) rate (0.2601 and 0.1573 h⁻¹, wilted and unwilted silage, respectively) than N from RDP or SDP with no effect ($P > 0.05$) of silage DM content; the highest ($P < 0.05$) rate of incorporation was observed with casein-N (0.8360 h⁻¹). In the absence of heating or spoilage, DM content of the barley silage did not alter the utilization of SP, RDP or SDP by rumen bacteria. Levels of

soluble protein in the silage may have a major impact on the rate of N incorporation and subsequent bacterial protein synthesis.

Key Words: Barley Silage, Wilting, Nitrogen Fractions

1496 Effect of barley variety and amylopectin content on bacterial utilization of ammonia-N in vitro. A. N. Hristov*, J. K. Ropp, and C. W. Hunt, *Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330.*

The objective of this study was to determine the effect of barley variety and amylopectin content on ammonia utilization by mixed ruminal bacteria in vitro. Three consecutive, 8-hour incubations (n = 3) were conducted with barley and corn grain as substrates (10 g/L incubation media). Ruminal inoculum was obtained from a lactating dairy cow fed a 45% forage:55% concentrate diet. The ammonia-N pool was labeled with ¹⁵N-ammonium sulfate. Samples were taken at 0, 2, 4, 6, and 8 h. Three barley varieties (WestBred Gustoe, WBG; Nebula; Baronesse) and their waxy counterparts were tested in this study. The control grain was corn. All barley varieties were tested at three substitution levels: 25, 50, and 75% with the remaining being corn. Ammonia concentration was progressively reduced (P < 0.001) with incubation time but was not affected (P > 0.05) by grain source or barley amylopectin content. Across sampling points, the waxy variety of WBG effected higher (P < 0.05) bacterial incorporation of ammonia N as compared to corn (by 7.6 and 11.9%, 25 and 75% substitution levels, respectively). Across varieties, barley treatments had numerically higher (P > 0.05) ¹⁵N-enrichment of the bacterial protein compared to corn (by 4.9, 5.0, and 5.4%, 25, 50, and 75% substitution levels, respectively). At the 75% substitution level the waxy barley lines resulted in 8.1% higher (P < 0.01) ¹⁵N-enrichment of the bacterial protein than the non-waxy parent lines. At the end-point of the incubation, barley treatments tended (P < 0.1) to have higher ¹⁵N-enrichment of the bacterial protein as compared to corn, and the waxy barley lines had higher (P < 0.05) ¹⁵N-enrichment than their non-waxy parents (by 3.3, 3.6, and 5.3%, 25, 50, and 75% substitution levels, respectively). These results demonstrated that barley, as compared to corn, tended to stimulate ammonia utilization in the rumen and higher amylopectin content of barley was associated with more intensive ammonia incorporation by ruminal bacteria.

Key Words: Barley, Rumen Ammonia, Bacterial Utilization

1497 Fractionation of ammonia nitrogen isotopes by ruminal bacteria in vitro. A. N. Hristov*, *Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330.*

The heavier of the two stable isotopes of nitrogen, ¹⁵N, is often used as an ammonia tracer in nutritional studies with ruminants assuming identical metabolism of the ¹⁴N/¹⁵N isotopes in the rumen. There is evidence that, at natural abundance level, ruminal microorganisms discriminate against ¹⁵N from ammonia, and as a result, ruminal microbial protein is depleted in ¹⁵N. However, ¹⁵N tracer studies are usually conducted at enrichment levels considerably higher than the natural abundance of ¹⁵N. It is not clear if at these levels of enrichment the magnitude of isotope fractionation is large enough to effect differences in ¹⁵N-ammonia metabolism by ruminal bacteria. To determine this, two incubations with ruminal inoculum obtained from a lactating dairy cow fed a 45% forage:55% concentrate diet were conducted (n = 4). The incubation media contained 5.3 mg/ml carbohydrates (glucose:sucrose:starch, 5:1:2). The ammonia N pool was labeled by addition of ¹⁵N-ammonium sulfate enriched at 10.7 (N10) or 20.5 (N20) at % exc. Incubations were carried out for 6 h and samples were taken at 0, 1, 2, 4, and 6 h. Bacterial pellets were isolated and analyzed for ¹⁵N-enrichment. We hypothesized that if there were a significant discrimination against ¹⁵N by ruminal bacteria, the ¹⁵N-enrichment of the bacterial N from N20 would be less than 91.6% higher than that from N10. Total VFA concentration was increasing (P < 0.001) with incubation time and was not different (P > 0.05) between the two treatments. Individual VFA and acetate to propionate ratio were not influenced (P > 0.05) by treatment. The ¹⁵N-enrichment of bacterial N was increasing (P < 0.001) with incubation time and did not differ (P = 0.266) between the two treatments (1.659 and 1.704 at % exc., N10 and N20, respectively). Source of N by incubation or incubation time interactions were not significant (P > 0.05). The results from this study indicate that,

at ¹⁵N-enrichment levels considerably higher than natural abundance, isotope fractionation by mixed ruminal bacteria is insignificant.

Key Words: Nitrogen Isotopes, Fractionation, Ruminal Bacteria

1498 Effect of Jackbean urease immunization on nitrogen recycling in mature sheep. J.C. Marini*, K.W. Simpson, A. Gerold, and M.E. Van Amburgh, *Cornell University.*

Previous experiments have shown that immunization with Jackbean urease (JBU) reduces urea hydrolysis in the gastrointestinal tract of numerous species. A consequence for farm animals is a lower energy requirement to detoxify ammonia and more energy was geared towards production. We sought to study the effects of JBU immunization on nitrogen (N)-metabolism in mature non-gravid, dry ewes. Sheep were immunized subcutaneously either with Freund's adjuvant (C, n=8), saline and 5,000 IU JBU (S, n=8) or Freund's adjuvant and 5,000 IU JBU (F, n=8) on days 1 and 22. Nitrogen balance and urea kinetic studies were performed on d32-35 and 60-63. A pelleted diet containing 16.4 %CP and 2.6 Mcal/kg ME was fed at maintenance level of intake. Immunization with JBU resulted in an increase (P < 0.05) in circulating anti-JBU IgM and IgG. Group F produced a greater IgG response than group S, but a similar IgM response. Serum from groups S and F inhibited JBU activity in vitro (P < 0.01). The results for N balance and urea kinetics were similar within a group (P>0.05) at days 32 and 60 and were pooled for further analysis. There was no effect of treatment on N balance or N excretion (P > 0.05). Urea kinetics, measured by continuous infusion of [¹⁵N¹⁵N]urea did not differ among treatments (P > 0.05). Urea production (UER), urinary urea nitrogen (UUN), urea recycled to the gastrointestinal tract (GER) and back to the ornithine cycle (ROC) averaged 25.3, 12.8, 12.5 and 5.8 g N/d, respectively. The results indicate that immunization against JBU produce a strong, and effective humoral immune response in sheep. However, immunization against JBU did not alter N-metabolism in mature, non-gravid sheep.

1499 Incorporation of nitrogen from ammonia, amino acids, peptides, or protein by mixed ruminal bacteria in vivo. A. N. Hristov*, J. K. Ropp¹, R. J. Wallace², and T. A. McAllister³, ¹Department of Animal and Veterinary Sci., University of Idaho, Moscow, ID 83844-2330, ²Rowett Research Institute, Bucksburn, Aberdeen AB21 9SB, ³Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB T1J 4B1.

To compare bacterial uptake of different forms of N in the rumen, four sources of ¹⁵N were given as intraruminal pulse doses to dairy cows in a 4 x 4 Latin square experiment. Three ¹⁵N sources were derived from ¹⁵N-casein: protein (PRO, unprocessed casein), amino acids (AA, acid hydrolysis) and peptides (PEP, enzymatic hydrolysis); ¹⁵N-labeled ammonium sulfate (NH3) was used as a control. The cows (DIM 205 17.9) fed a 43% forage:57% concentrate diet were given equal amounts of ¹⁵N from the four N sources. Representative samples (12) of the fluid- and loosely associated to the feed particles ruminal bacteria were collected for a period of 24 h and analyzed for ¹⁵N-enrichment. The areas under the ¹⁵N-enrichment curves (AUC) of bacterial N were not different (P > 0.05) between treatments. The shortest time (P < 0.05) to peak ¹⁵N-enrichment of the bacterial protein was associated with the PEP treatment, 1.65 h, followed by the PR and NH3 treatments (2.0 and 2.5 h, respectively). The AA treatment had the longest (P < 0.05) time to peak enrichment (3.1 h). The rate of incorporation of the tracer was the highest (P < .05 vs AA and NH3 and P < 0.1 vs PR) with the PEP treatment (3.58 h⁻¹) and was similar among the other treatments,

varying from 2.25 (NH₃) to 2.71 (PR) h⁻¹. The peak ¹⁵N concentration in the bacterial protein was higher (P < 0.05) with the NH₃ treatment (0.0151 at % exc.) as compared to the AA and PEP treatments (0.0099 and 0.0125 at % exc., respectively). No differences (P > 0.05) in the rate of tracer disappearance (average of 0.099 h⁻¹) or tracer half-life in the bacterial N pool were detected among treatments. Under the conditions of this trial, ruminal bacteria showed no sizable differences in the extent of incorporation of N from NH₃, AA, PEP, or PR but incorporated N from PEP at a higher rate.

Key Words: Dairy Cows, Nitrogen Source, Ruminal Bacteria

1500 Influence of methionine and/or lysine deficiencies, formulated at three different protein levels, on protein nitrogen metabolism when fed to lactating dairy cows. D. C. Weakley^{*1}, M. D. Hanigan¹, L. F. Reutzel¹, J. A. Besancenez¹, K. B. Cunningham¹, H. C. Puch¹, and B. K. Sloan², ¹Purina Mills, Inc., St. Louis, MO, ²Aventis Animal Nutrition, Alpharetta, GA.

Twelve lactating dairy cows (575 kg, 77 DIM) were assigned by parity to 6 treatments in two periods of feeding in a randomized block design, preceded by a common covariate period. Three of the treatments comprised diets formulated to be deficient in methionine (met) and/or lysine (lys), according to CPM Dairy ver. 1.0, at either 15.5, 17.5 or 19.5% dietary CP. To confirm that these diets were indeed deficient, the remaining three treatments comprised the previous diets supplemented with Smartamine M (M) and/or ML (ML) at levels necessary to establish calculated levels of 2.20 and 6.82% of metabolizable protein, as met and lys, respectively. Diets contained (DM basis) 47% corn silage and 13% alfalfa hay. Cows were allowed to adjust to their diets for a period of two weeks, followed by a 5 day total collection of milk, urine and feces. Neither DM intake (18.0±2.38 kg), milk production (32.5±4.32 kg), milk fat percent (3.36±0.281) or yield (1,070.130 kg) or milk lactose yield (1.54±0.204 kg) were significantly influenced by treatment. However, there was a significant main effect by amino acid supplementation on milk total protein (2.98 vs. 3.10%; P≤0.03), milk true protein (2.56 vs. 2.69%; P≤0.06), and milk lactose (4.82 vs. 4.76%; P≤0.09) for the deficient and supplemented diets, respectively. A greater loss of urinary N with the supplemented 15.5% CP diet, coupled with a loss of retained N but no loss in milk N, suggested a mobilization of amino acid N from body stores. Within the higher protein diets, M and/or ML resulted in a depression in urinary N loss and an improvement in N retention. Met and/or lys supplementation of deficient diets improved milk N across all protein levels.

Protein, %							Effect
M and/or ML	15.5 none	15.5 M	17.5 none	17.5 M + ML	19.5 none	19.5 ML	(P)

Key Words: Lactating cows, methionine, lysine

1501 Effect of level of cracked Pima cottonseed in the diet of lactating dairy cows on milk yield and plasma gossypol. J. Prieto^{*1}, E. DePeters¹, P. Robinson¹, J. Santos¹, J. Pareas¹, S. Taylor¹, M. Calhoun², B. Baldwin², and S. Kuhlmann², ¹University of California, Davis, CA, ²Texas Agricultural Experiment Station, San Angelo, TX.

Lactating Holstein cows were fed one of four diets containing cracked Pima cottonseed to determine its effects on milk yield and plasma gossypol concentration. All diets contained 43% concentrate, 12% cottonseed, and 45% chopped alfalfa hay. The proportion of whole Upland cottonseed to cracked Pima cottonseed varied from 100:0, 66:34, 34:66, and

0:100 (U:P). Primiparous cows (4) were fed the diets in a 4x4 Latin square design. Multiparous cows (3) were fed the diets in a Youden square with five periods. Periods were 35d. Milk yield (kg/d), milk fat (%), and DM intake (kg/d) were not affected by the inclusion of cracked Pima cottonseed into the diet of either primiparous or multiparous cows. For primiparous cows, milk yield, milk fat, and DM intake were 36.9, 4.2, 28.3; 39.0, 3.9, 28.2; 40.3, 3.7, 29.1; and 38.2, 4.1, 27.8 for the 100:0, 66:34, 66:34, and 0:100 U:P diets, respectively. Similar data for multiparous cows were 41.9, 3.7, 33.4; 41.5, 3.7, 30.7; 41.5, 3.7, 31.9; and 38.4, 3.9, 29.3, respectively. Upland and cracked Pima cottonseed contained (% of meats DM) 1.3% and 1.7% free gossypol and 0.52% and 0.85% minus (-) isomer, respectively. Gossypol is a natural defense compound in the plant that protects it against pests and diseases, but it can have anti-nutritional quality affects when consumed by animals. Total plasma gossypol concentration significantly increased linearly with increasing proportion of cracked Pima in the diet for primiparous (4.1, 5.8, 6.9, and 8.7 ug/ml; P<0.01) and multiparous (4.1, 7.1, 9.5, and 11.7 ug/ml; P<0.01) cows. Cracked Pima cottonseed, fed at levels up to 4 kg/d, had no effect on production performance even though plasma gossypol concentrations increased sharply.

Key Words: Cottonseed, Gossypol, Cows

1502 Effects of intake and lactation on absorption and metabolism of leucine and phenylalanine by splanchnic tissues of dairy cows. C. K. Reynolds^{*1}, B. J. Bequette², J. S. Caton³, D. J. Humphries¹, P. C. Aikman¹, B. Lupoli¹, and J. D. Sutton¹, ¹University of Reading, Reading, UK, ²Rowett Research Institute, Aberdeen, UK, ³North Dakota State University, Fargo, USA.

The objective was to measure effects of intake and lactation on endogenous (END) duodenal (DUO) and ileal Leu flow and absorption and kinetic transfer of Leu and Phe across portal-drained viscera (PDV) and liver of 3 multiparous, catheterized, cannulated Holstein x Friesian cows (648 kg BW). A TMR was fed at 2 intakes (Lo and Hi) during 2 stages, late lactation (LAC) and after dry-off, giving 4 levels of DMI (Table). Measurements (mmol/h) of DUO and ileal flow and PDV blood flow and Leu and Phe sequestration (use) and transfer were made during week 4 of 5 wk intake periods using ¹³C-Phe and ¹³C-Leu (jugular vein) and ²H-Phe and ²H-Leu (DUO) infusions. ¹³C-Leu infusion continued for measurement of END Leu flow on d 6 and 7 of infusion. Milk yield was 15.4 ± 2.9 kg/d. Body flux of Leu (51.5, 63.7, 73.6 and 95.1) and Phe (20.5, 25.5, 28.7 and 33.8) increased (P < .02) with DMI. Fractional END Leu flow in the DUO (8 ± 1 %) or ileum (15 ± 2 %) was not affected. DMI and LAC increased DUO flow and thus absorption of Leu and Phe. Within stage, absorptive use of Leu and Phe was greater for Hi than Lo. PDV use of arterial Leu, but not Phe, was increased by DMI. Absorption and arterial use of Leu by PDV were greater than for Phe, while rates of absorptive use of Leu and Phe were more similar. We conclude that intake relative to requirement alters PDV sequestration and absorptive recovery of Phe and Leu.

1503 Peptide amino acid net flux in ruminal vein of dairy cow. D. Remond*¹, C. L. Girard², and B. Chauveau¹, ¹INRA, Clermont Fd-Theix/France, ²AAC, Lennoxville/Canada.

The objective of the study was to determine whether luminal peptides can cross the ruminal epithelium *in vivo*. Four lactating dairy cows were fitted with a ruminal cannula, catheters in the right ruminal vein and in a mesenteric artery, and a blood flow probe around the right ruminal artery. Each cow received a ruminal injection of a solution containing 320 g of peptone from casein and 24 g of glycylglycine. Blood samples were collected at -20, 0, 20, 40, and 60 min (0 was just before the injection). Plasma was deproteinized with sulfosalicylic acid. Supernate was filtered through a 3,000 Mr cut-off filter. Part of the filtrate was hydrolyzed in 6 N HCl at 110°C for 24h. The difference in AA concentration before and after hydrolysis was attributed to peptide (PAA). Control values were obtained averaging sampling times before the injection. The effect of the injection was tested using ANOVA for repeated measurements. Ruminal blood flow (68 ± 7 L/h) and arterial free amino acid (FAA) concentration ($1.89 \pm .07$ mM) were not significantly affected by the injection. Total FAA net flux in the ruminal vein ($-10.4 \pm .9$ mmole/h) was not affected by the injection. Total arterial PAA concentration linearly increased ($P < .05$) from $.15 \pm .01$ before the injection to $.21 \pm .02$ mM 60 min later. Arterial peptide Glu, Gly, and Ala increased linearly ($P < .10$), whereas peptide Pro responded in a cubic manner ($P < .05$). During the control period, total PAA net flux in the ruminal vein was not different from zero. It was not significantly affected by the injection. However, peptide Pro net flux sharply increased ($P < .01$) after the injection (from 0 to 11 μ mole/min 20 min after the injection), and responded in a quadratic manner with time. The increase in arterial PAA concentration suggested absorption of peptides from the digestive tract. The rumen contribution to this absorption appeared limited, but when high peptide concentrations are generated in the rumen, small peptides containing Pro may cross the ruminal wall.

Key Words: Rumen, Peptide, Absorption

1504 Effects of abomasal casein or essential amino acid infusions on splanchnic leucine and phenylalanine metabolism in lactating dairy cows. J. S. Caton*¹, C. K. Reynolds², B. J. Bequette³, B. Lupoli¹, P. C. Aikman¹, and D. J. Humphries¹, ¹North Dakota State University, Fargo, USA, ²University of Reading, Reading, UK, ³Rowett Research Institute, Aberdeen, UK.

The objective was to measure the effects of abomasal casein (CAA) or essential amino acid (EAA) infusion on Leu and Phe absorption and kinetics (mmol/h) in 3 multiparous, late lactation (8.9 kg milk/d), catheterized, cannulated Holstein x Friesian cows (673 kg BW). A TMR of 30 % dried lucerne, 20 % grass silage, and 50 % concentrates (DM basis) was fed hourly at 12.6 kg DM/d. Small intestinal absorption was measured on d 5 and 7 of 7-d abomasal infusions (18 L/d) of water followed by 7-d infusions of CAA or EAA equal to 800 g casein protein/d in a single-reversal design with a 3 wk interval. Portal-drained viscera (PDV) and liver (LIV) kinetic flux was measured using infused ¹³C-Phe and ¹³C-Leu (jugular) and ²H-Phe and ²H-Leu (duodenum) on d-6 of abomasal infusions. Both infusions increased ($P < .01$) body flux and true absorption of Leu (62.5 vs. 87.8 and 37.6 vs 57.9, respectively) and Phe (24.9 vs 30.1 and 18.4 vs 26.3, respectively). Infusion of EAA increased ($P < .09$) sequestration (use) of Leu (-4.9 vs 10.9) and Phe (3.5 vs 11.5) during absorption, but CAA had no effect (0.4 vs 0.2 and 6.9 vs 8.3, respectively). Use of arterial Leu by PDV was increased ($P < .06$) by infusion of EAA (21.0 vs 36.2), but not CAA (26.0 vs 28.2). Of total (absorptive + arterial) PDV use, 6 % of Leu and 66 % of Phe was from absorptive supply. Both infusions increased ($P < .03$) total PDV release of Leu (36.8 vs 56.9) and Phe (12.9 vs 22.6). Total LIV use (17.9) and release (23.0) of Leu was not affected, but infusions increased ($P < .01$) net LIV removal of Phe (8.4 vs 15.8) due to changes in total use (20.8 vs 26.2) and release (12.4 vs 10.4). Data suggest either the form (free vs protein) or composition (EAA vs CAA) of abomasal supply affect PDV utilization of absorbed Leu and Phe.

Key Words: Absorption, Gut metabolism, Amino acids

1505 Effect of type of cottonseed and gossypol intake on plasma gossypol and performance of lactating Holstein dairy cows. J.E.P. Santos*¹, M. Villasenor¹, D. Ringen¹, E.J. DePeters¹, P.H. Robinson¹, M.C. Calhoun², B. Baldwin², and J.P. Reynolds¹, ¹University of California - Davis, ²Texas A&M University.

Objectives were to evaluate the effects of type of cottonseed on lactational performance and plasma total gossypol (TG) concentration of cows. Holstein dairy cows, 856, on 3 dairy farms in central California were assigned at calving to one of two treatment diets (428/treatment) based on lactation number, calving date and previous lactation 305-d mature equivalent milk yield in a randomized complete block design. Cows were assigned 3 to 20 d after calving and remained on diets for 170 d. Cottonseed represented 10% of the diet DM, and treatments consisted of replacing whole Upland cottonseed (WUP) with a blend of WUP and cracked Pima (BUPCP) cottonseed (33:67). Whole Upland and cracked Pima cottonseed contained (% of meats DM) 1.33% and 1.66% free gossypol and 0.60% and 0.89% minus (-) isomer, respectively. Only the 809 cows that remained on the study for more than 60 days in milk (DIM) were included in the analysis. Blood samples were collected from all cows at 60 and 90 DIM for determination of plasma gossypol, but results for statistical analysis were available for 430 cows. Group DM intake did not differ between BUPCP and WUP (24.3 vs 24.4). Estimated free gossypol intake was 26.2 and 17.9 g/d for BUPCP and WUP, respectively. Plasma TG (μ g/ml) at 60 and 90 DIM was higher for cows fed BUPCP than WUP (6.80 vs 2.89, and 8.82 vs 3.37; $P < 0.001$). Proportion of plasma TG as (-) isomer was greater at 60 and 90 DIM for cows fed BUPCP vs those fed WUP ($P < 0.001$). Cows fed BUPCP had a greater increase in plasma TG from 60 to 90 DIM than those fed WUP (+2.47 vs +0.49 μ g/ml; $P < 0.001$). In BUPCP and WUP fed cows, yields of milk (39.8 vs 39.6 kg/d), 3.5% fat corrected milk (40.0 vs 39.6 kg/d), and milk fat (1.40 vs 1.39 kg/d), as well as concentrations of milk fat (3.54% vs 3.51%) did not differ. However, true protein content (2.94% vs 2.90%; $P < 0.003$) increased and milk true protein yield (1.17 vs 1.15 kg/d; $P = 0.11$) tended to increase for cows fed BUPCP vs those fed WUP. Replacement of whole Upland cottonseed with a blend of whole Upland and cracked Pima cottonseed increased plasma TG, as well as the proportion of plasma TG as (-) isomer. Yields of milk and milk components were not affected, but milk protein content was improved.

Key Words: Cottonseed, Plasma gossypol, Dairy cows

1506 Use of an inhibitor *in vitro* method to determine protein degradability coefficients in the NRC (2001) protein evaluation system. J.R. Newbold*¹, B. De Wannemaeker¹, and P. Gerardy¹, ¹Provimi Research and Technology Centre.

NRC(2001, Nutrient Requirements of Dairy Cattle, Seventh Revised Edition) recommends the *in situ* (IS) technique to measure rumen degradable protein (RDP, % of CP), calculated from immediately-degraded N (A), slowly-degraded N (B), undegradable N (C) and rate of degradation of B (Kd). Our objective was to predict these values using an inhibitor *in vitro* (IIV) method. Foods were: solvent-extracted soybean (n=2), sunflower (n=2) and canola meals, corn gluten feed, corn gluten meal, palm kernel expeller meal (PK), potato protein (PP) and a commercial bypass protein ('Aminolac', Provimi BV, Rotterdam). Soy, canola and sunflower meals were solvent extracted. Foods in polyester bags were incubated in rumens of two non-lactating cows for 0, 3, 6, 24, 48 and 210h. In IIV tests, intact foods and a fraction soluble in phosphate buffer were incubated with rumen fluid and inhibitors of deamination and microbial growth for 4h. TCA-soluble N at 0h gave a measure of fraction A. Calculations assumed passage rate=6%/h. Fraction A was higher ($P=0.025$) for IS than IIV (19.6% and 12.3%, $se=2.76$). This was marked for PP (A IS=31.2%, A IIV=2.2%), indicating loss from bags of N in small particles. Excluding PP data, RDP IS was not different from RDP IIV (means=48.8% and 51.5%, $se=3.48$, $P>0.05$). $RDP IS = 9.2 + 0.77(RDP IIV)$, $r^2=0.75$. Fit of the model describing IS data was poorer for PK than other foods. After exclusion of PK, $RDP IS = 13.3 + 0.74(RDP IIV)$, $r^2=0.87$. RDP IIV of soluble N <100% for soybean, sunflower and canola meals, suggesting that the IS method overestimates RDP for these foods. The IIV method can be used to measure RDP as defined by NRC(2001). The IIV method has advantages where particle size is small or where part of fraction B is soluble in rumen fluid.

Key Words: Protein, Degradability, Bypass

1507 Intake and production by Holstein cows fed different amounts and sources of supplemental protein prepartum and postpartum. J.P. Underwood*, J.K. Drackley, and J.H. Clark, *University of Illinois, Urbana, IL*.

Improving metabolizable protein supply in late-gestation cows might benefit health and subsequent milk production. Sixty pregnant non-lactating cows were blocked by expected parturition date and assigned to one of three prepartum diets: 12% CP, soybean meal (SBM) supplement (LSB); 15% CP, SBM supplement (HSB); and 15%CP, animal-marine protein (AMP) supplement. Diets were formulated to supply an estimated 927, 981, and 1100 g/d of metabolizable protein, respectively. Cows were fed diets from 21 d prepartum to parturition. After parturition, cows were assigned to one of two diets containing 18% CP (SBM supplement or AMP supplement); thus, treatments were in a 3 x 2 factorial arrangement. Dry matter intake (DMI) and milk production were recorded for 63 d postpartum. Prepartum DMI did not differ among LSB, HSB, and AMP (10.9, 11.8, and 11.7 kg/d, respectively). Postpartum DMI was similar between groups fed SBM or AMP (19.9 and 18.9 kg/d). Cows fed AMP postpartum produced 36.4 kg/d of milk vs. 34.4 kg/d for cows fed SBM ($P=0.21$). Milk fat and protein percentages were not affected by prepartum or postpartum diets. Cows fed AMP tended ($P=0.10$) to produce more 4%fat-corrected milk (FCM) than SBM supplemented cows (33.8 kg/d vs. 31.8 kg/d). An interaction of protein source (at 15% CP) and postpartum diet was detected for FCM ($P<0.05$); means were 30.8, 34.7, 33.8, and 32.0 kg/d for cows fed HSB prepartum, SBM postpartum; HSB prepartum, AMP postpartum; AMP prepartum, SBM postpartum; and AMP prepartum, AMP postpartum, respectively. Efficiency (FCM/DMI) was greater ($P<0.05$) for cows fed AMP postpartum (1.88 vs. 1.70). An interaction of postpartum diet by week ($P<0.05$) indicated that cows fed AMP postpartum lost more body weight than cows fed SBM. Body condition score (BCS) was not affected by diets. Increasing the amount or source of protein fed to nonlactating cows during the last 21 d prepartum did not affect DMI, milk production, or BCS.

Key Words: Protein, Dry Period, Transition Cow

1508 Effect of barley and rapeseed meal supplementation on amino acid profile of microbial fractions and postruminal amino acid supply in lactating dairy cows fed grass-red clover silage. M. Korhonen*, S. Ahvenjrvi, A. Vanhatalo, and P. Huhtanen, *MTT, Agrifood Research Finland*.

Four ruminally cannulated dairy cows were used to study AA composition of omasal canal digesta, bacterial, and protozoal fractions as well as omasal canal AA flow as affected by diet. Cows were given grass-red clover silage alone (S), supplemented with 6 kg of barley (B), with 2.1 kg of rapeseed meal (R), or with 6 kg of barley and 2.1 kg of rapeseed meal (BR) according to 4x4 Latin Square design with 2x2 factorial arrangement and 21 d periods. During last week of each period silage intake was restricted to 95% of ad libitum intake. Omasal canal DM flow was measured using triple marker (Co, Yb, INDF) method. Amino acid flow entering the omasal canal was calculated based on DM flow and AA composition of reconstituted digesta. Liquid- (LAB) and particle- (PAB) associated bacteria were isolated from reticular digesta and protozoa from omasal canal digesta. Microbial protein flow was determined by using ^{15}N as a microbial marker. Omasal canal AA flows were 1452, 1756, 1754, and 2008 g/d (SEM 92.7) on diets S, B, R, and BR, respectively. On diet R, increase in AA flow was of nonmicrobial, whereas on diet B it was mainly of microbial origin. This changed slightly AA profile of digesta, and resulted in a better marginal utilization of AA for milk protein synthesis (55 vs 44%) on diet R than on diet B. Flows of LAB- and protozoa-NAN were 100, 159, 123, and 173 g/d (SEM 12.4) and 9, 25, 9, and 20 g/d (SEM 4.4) on diets S, B, R, and BR, respectively. Diet had only minor effect on AA composition of microbial fractions, but differences were observed between LAB and PAB for 10 out of 19 AA studied, and also between bacteria and protozoa for 15 out of 17 AA studied. Differences in AA composition and flows of various microbial fractions had, however, only small effect on AA profile of microbial protein. Consequently, AA composition of postruminal digesta seemed to be affected mainly by proportions of microbial and nonmicrobial proteins.

Key Words: Amino Acids, Bacteria, Protozoa

1509 Effect of type of dietary protein on mRNA expression for urea cycle enzymes in lactating dairy cows. J.R. Townsend*, S.M. Crowder, J.C. Velez, and S.S. Donkin, *Purdue University, West Lafayette, IN*.

Liver metabolism adapts to changes in dietary protein level and amino acid profiles. The objective of this study was to determine the response in liver of lactating dairy cows to changes in the type of protein in the diet. Thirty-six Holstein dairy cows were fed a diet containing 18.5% crude protein (CP) and 1.76 Mcal/kg NEL and either 12.6, 11.7, or 10.9% rumen degradable protein (RDP). The quantity of RDP and rumen undegradable protein (RUP) in the diet was manipulated by altering the amounts of soybean meal and heat-treated soybean meal used in the ration. Diets were fed for 11 weeks, milk production and feed intake were measured daily, and milk composition was determined weekly. Liver biopsies and blood samples were obtained from a subset of 16 cows during weeks 2, 5, 8, and 11. Argininosuccinate synthetase (AS) and carbamoyl phosphate synthetase I (CPS-I) mRNA were measured in liver biopsy samples and blood was used for plasma urea nitrogen (PUN) analysis. Milk production was 34.8, 38.2, 37.1 1.8 kg/day, dry matter intake was 23.8, 25.8, 25.4 .82kg/day for 12.6, 11.7, and 10.9% RDP respectively. Protein intake exceeded requirements for CP, RDP, and RUP. Feeding 10.9% RDP decreased ($P<.05$) MUN and PUN compared to the other two diets. A time on experiment effect ($P<.05$) was observed for AS and CPS-I mRNA and PUN. There was a tendency ($P<.10$) for correlation between PUN and dry matter intake ($r=.22$), crude protein (CPI) ($r=.22$), and RDP ($r=.32$) intake. Abundance of CPS-I and AS mRNA were correlated ($P<.05$, $r=.76$) as were MUN and PUN ($r=.56$), and MUN and DMI ($r=.50$). The intake of RDP was correlated ($P<.05$) with MUN ($r=.62$), and CPI was correlated ($P<.05$) with MUN ($r=.50$). The data indicate that when dietary protein is overfed, mRNA for urea cycle enzymes are closely related to other measures of protein utilization such as MUN and PUN. Overfeeding protein in this experiment may have masked any effects of RUP or RDP on mRNA for urea cycle enzymes.

Key Words: Liver, Gene expression, Protein

1510 Responses of dairy cows fed grass silage-cereal diet to increased supply of histidine provided either by abomasal infusion of histidine or dietary inclusion of rape seed meal. A. Vanhatalo*, P. Huhtanen, M. Korhonen, and T. Varvikko, *MTT Agrifood Research Finland, Jokioinen, Finland*.

A 4x4 Latin square was conducted with four cows to investigate responses to supplementation of grass silage-cereal diet with His supplied either with abomasal infusion of 6.5 g/d His (H), 1.5 kg/d of rape seed meal (RSM) and 3.25 g/d of His (HR) or 3 kg/d of RSM (R). Each treatment was designed to provide an additional His supply of 6.5 g/d. The design was aimed to evaluate how much of the response to RSM could be explained by the response to His alone. The control diet (C) consisted of grass silage (18.9% CP) ad libitum and 9 kg/d of a cereal based concentrate (12.6% CP). Glucose was infused abomasally at a rate of 250 g/d on each treatment. Treatments had no significant effects on silage or total DMI, rumen fermentation, microbial protein production, or OM digestibility of diets ($P>.05$). Milk yields for the treatments C, H, HR and R were 32.5, 31.8, 33.4, and 33.2 kg/d (SEM 0.23), protein yields 1080, 1068, 1126 and 1132 g/d (SEM 16.3), and lactose yields 1643, 1611, 1692, and 1680 g/d (SEM 11.2), respectively. Increases of these parameters were linear or quadratic ($P\leq.03$) with increasing amount of RSM. Treatments did not affect milk composition except for milk urea, which increased with increasing amount of RSM ($P<.05$). Arterial plasma concentration of urea, and essential and branched chain amino acids (AA) increased linearly ($P<.03$) with increasing amount of RSM. Arterial glucose was not affected by the treatments, but concentrations of BHBA and insulin increased ($P<.05$), and NEFA decreased due to His supplementation. The production potential of cows was realized exceptionally well with the basal diet because production responses to RSM were less than half of those usually derived with RSM on grass silage diets. Also, opposite to earlier findings, arterial concentration of His on the basal diet ($>42 \mu\text{M}$) was higher than expected suggesting that some other nutrient or AA but His limited milk production in the present study.

Key Words: Grass silage, Histidine, Dairy cow

1511 A comparison of different methods to measure milk urea nitrogen. R.A. Kohn*, K.R. French, and E. Russek-Cohen, *University of Maryland, College Park.*

Milk urea nitrogen (MUN) is measured routinely on dairy farms to evaluate protein nutrition. The objective of this study was to compare methods that are currently used by Dairy Herd Improvement Association (DHIA) labs for analysis of MUN. Two replicate samples from each bulk tank on 10 different dairy farms were sent to 14 DHIA labs throughout the U.S. for MUN analysis. The mean MUN of all samples was 14.0 mg/dl. The lowest farm averaged 6.8 mg/dl and the highest averaged 19.1 mg/dl across labs. For the Foss 6000, Bently Chemspec, Skalar and CL 10 methods, greater than 98% of the variation in measured MUN was attributed to farm to farm differences. This result was desired because it indicates that labs can consistently quantify the variation that occurs among farms. For the Foss 4000 system, less than 60% of the variation in MUN was attributed to farm to farm differences. The remaining variation was attributed to lab differences (33.8%), lab by farm interaction (5.7%), and random error (1%). The results for each method of MUN analysis were compared to reference values determined by CL 10. The difference from the CL 10 method was represented as the root mean square prediction error (RMSPE) where a smaller number indicates greater accuracy. The RMSPE for the Foss 4000, Foss 6000, Bently, and Skalar methods were: 2.48, .63, .65 and .86 mg/dl respectively. The error of the Foss 4000 relative to the CL 10 reference was further partitioned to mean bias (0.7%, $P > .1$), slope bias (51.7%, $P < .01$), lab bias (13.7%, $P < .01$), lab by slope interaction (19.6%, $P < .01$) and residual error (14.3%). The Foss 4000 system underestimated the higher values while overestimating the lower values, and it was not consistent across labs. Thus, this method should not be used to estimate urinary N or protein adequacy. For the other methods, differences from the CL 10 were slight and would not have affected predictions of urinary N or expected MUN.

Key Words: Milk urea nitrogen, Analysis methods

1512 A role for rumen degraded protein in regulating intake rate of digested fiber. W. C. Ellis*¹, J.H. Matis¹, Dennis Herd¹, H. Lippke¹, F.M. Rouquette¹, D. P. Poppi², and R. J. Wallace³, ¹Texas A & M University, ²University of Queensland, ³Rowett Research Institute.

It was hypothesized that insufficient flux of rumen degraded CP, RDP, successively limits growth rate of NDF digesting bacteria, rate of digestion of potentially digestible NDF (PDF) and ruminal turnover and intake rate of digested PDF (DF). Intake rate of DF should then be positively related to ruminal flux proportions of RDP/DF required to optimize turnover of rumen load of DF by digestion and by escape. An experiment was conducted to measure these hypothesized responses in dynamics of intake and digestion of PDF. Ten lambs were fed diets providing ratios of either 0.11 or 0.24 of RDP/DF achieved by use of mineral supplemented cottonseed hulls alone or supplemented with cottonseed meal. The DF and voluntary intake was measured for each of the five lambs per diet. Rumen load of indigestible NDF (IF) was then measured at slaughter two h after an AM feeding. Ruminal turnover of PDF was assumed equal to turnover of IF computed as mean intake rate of IF preceding slaughter divided by rumen load at slaughter. Lambs receiving the 0.11 vs. the 0.24 RDP/DF diet exhibited greater live weight gains and plasma concentrations of amino acids and reduced levels of plasma 3-methylhistidine; responses reflecting greater flux of metabolizable amino acids and deposition rate. Lambs receiving diets of 0.24 vs. 0.11 RDP/DF had greater ($P < 0.05$) rumen load and turnover rates of IF and greater ($P < 0.05$) rates of digestion of PDF and voluntary intake of DF. Buoyancy of feed fragments derived from rate of digestion of PDF was postulated to be the metabolically related force constraining turnover rate of PDF (assuming turnover of PDF equals turnover rate of IF). Assuming 70% ruminal degradation of dietary CP, the results were compared to recomputed literature data from four other related experiments. Results of these five experiments conform to expectations that products of RDP nutritionally limit growth rate of PDF digesting bacteria and, consequently, intake rate of DF over the range of RDP/DF observed.

Key Words: Rumen, Protein, Intake

1513 The prediction of microbial protein supply to growing lambs fed raw and dry roasted legume seeds as protein supplements from the urinary excretion of purine derivatives. P. Yu*¹, L. Boon-ek², A.R. Egan², and B.J. Leury², ¹Department of Animal and Poultry Science, University of Saskatchewan, Canada, ²Institute of Land and Food Resources, University of Melbourne, Australia.

Urinary excretion of purine derivatives was used to estimate the microbial N supply to growing lambs in the experiment designed to examine the effect of supplementation and dry roasting whole lupin (*lupinus angustifolius*) seeds (WLS) and whole faba (*vicia faba*) beans (WFB) as protein supplements on rumen microbial N supply to the host animal. Lambs were fed a fixed quantity of oat straw and alfalfa hay plus a daily supplement of either of the following: no legume seeds (CTRL), raw WLS, roasted WLS, raw WFB, or roasted WFB. Legume seeds were dry roasted at 150C for 45 min (as the desirable conditions in the previous study). All diets were isonitrogenous (15.9% CP). In the supplemented diets, about 55% of protein was supplied by WLS or WFB protein. The amount of legume seeds per metabolic liveweight (WLS: 20 g/LW^{0.75}; WFB: 25 g/LW^{0.75}) was kept the same throughout. At the end of feeding experiment, the excretions of the purine derivatives, allantoin, uric acid plus hypoxanthine and xanthine, were measured after total urine collection during N balance trial to estimate microbial N supply to the duodenum. The results show that lambs fed the five dietary treatments with similar total DM and N intakes, averaging 1158 and 30 g/d across treatments, but different BCP (= rumen bypass feed protein), DVE (= truly digested protein in the small intestine) and OEB (= degraded protein balance) values did not differ in urinary excretion of purine derivatives (averaging 13.0 mmol/d) (allantoin, averaging 10.5 mmol/d; uric acid plus hypoxanthine plus xanthine, averaging 2.5 mmol/d), total purine derivatives absorption (averaging 15.4 mmol/d), microbial N supply (averaging 11.2 g N/d) to the duodenum and efficiency of microbial synthesis (averaging 23.7 g of N/ kg DOMR (digestible OM fermented in the rumen) to growing lambs. No relationships were detected between the estimated protein values of BCP, DVE and OEB and microbial N supply. These results indicated that dry roasting and supplementation had no significant effects on the flow of microbial N into the duodenum.

Key Words: Purine derivatives, Microbial N supply, Lamb

1514 A Role for Ruminally Degraded Protein in Determining Yield and Efficiency of Rumen Efflux Microbial Protein. W.C. Ellis*¹, Dennis Herd¹, J.H. Matis¹, H. Lippke¹, F.M. Rouquette¹, D.P. Poppi², and R. J. Wallace³, ¹Texas A & M University, ²University of Queensland, ³Rowett Research Institute.

Evidence at the microbial level suggests that optimal growth rate and efficiency of the rumen microbial ecosystem requires specific carbon structures derived from ruminal degradation of dietary protein. However, such a requirement at the dietary level remains obscure. The present objective was to evaluate relationships between flux of ruminally degraded entities upon rumen microbial protein efflux, MPE. Data were computed from literature sources reporting MPE and rumen flux of CP (RDP), NDF (RDF) and of non-structural carbohydrates (RNSC), the latter being computed as OM - [(NDF+lipids+CP)0.8]. Ruminal flux of degraded carbohydrates, RDCHO, was computed as the sum RDF+RNSC and energetic efficiency of MPE computed as MPE/RDCHO. The database consisted of 154 treatment means from 36 experiments with data from both non-lactating and lactating cattle and mixed and all forage diets. In order for data with sheep to be expressed, all variables were expressed as daily flux per kg BW and relations between MPE as the dependent variable and daily flux of ruminally degraded nutrients as the independent variables were examined. Variations in MPE were equally ($R^2 = 0.79$ to 0.89) associated with ruminal flux of truly digested OM, RDNSC and RDP. Variations in efficiency of MPE/RDCHO were primarily associated with flux proportions of RDP/RDF ($R^2 = 0.74$). Variations in MPE and MPE/RDCHO were most correlated with flux of RDP and RDF. Thus MPE/RDF was logically and statistically highly correlated with RDP/RDF in animals receiving either forage or mixed diets ($R^2 = 0.89$ and 0.9 , respectively). These associations suggest that variations in MPE were related to the product of flux of RDCHO and energetic efficiency MPE was determined by flux proportions of RDP/RDF. A dietary essential role for deaminated products of amino acids is implicated specifically to enhance growth rate of RDF

digesting bacteria. Variations in RDP/RDCHO were only of a sufficiently range in the forage data to develop reliable prediction equations for MPE: Daily MPE, g/kg BW = daily RDCHO g/kg BW (0.04+0.62 (RDP/RDCHO)); R square=0.83

Key Words: Rumen, Microbial, Protein

1515 Effect of type of cottonseed and gossypol intake on reproduction and health of lactating Holstein dairy cows. J.E.P. Santos*¹, M. Villasenor¹, C.H. Holmberg¹, D. Ringen¹, E.J. DePeters¹, P.H. Robinson¹, B. Bretz¹, and P.W. Jardon², ¹University of California - Davis, ²Visalia, CA.

Objectives were to evaluate the effects of type of cottonseed on reproductive performance and health of dairy cows. Holstein dairy cows, 856, on 3 dairy farms in central California were assigned at calving to one of two treatment diets (428/treatment) based on parity, calving date and previous lactation 305-d mature equivalent milk yield in a randomized complete block design. Cows were assigned 3 to 20 days in milk (DIM) and remained on diets for 170 d. Cottonseed represented 10% of the diet DM, and treatments consisted of replacing whole Upland cottonseed (WUP) with a blend of WUP and cracked Pima (BUPCP) cottonseed (33:67). Estimated free gossypol intake was 26.2 and 17.9 g/d for BUPCP and WUP, respectively. Estrous was synchronized with two injections of PGF2a (Lutalyse) 14 d apart. Cows were inseminated after the second PGF2a injection (> 44 DIM). Within each dairy, the same technician artificially inseminated all the cows with semen from sires randomly distributed across the two treatments. Pregnancy diagnosis was performed 35 to 45 d after AI, and pregnant cows were reconfirmed at 170 DIM. A postmortem diagnosis was performed in cows that died. Treatment did not affect DIM at first AI and it averaged 58.7 d. Estrus detection after the second PGF2a injection tended to be greater for BUPCP vs WUP (56.9 vs 50.9%; $P < 0.09$). In BUPCP and WUP fed cows, first AI conception rate (29.4 vs 28.2%), percentage of pregnant cows at 170 DIM (74.8 vs 79.4%), and incidence of cystic ovarian disease (8.1 vs 6.1%) did not differ. Average days open for pregnant cows was similar between BUPCP and WUP (91.0 vs 89.8). However, incidence of abortions was greater for cows fed BUPCP vs WUP (8.5 vs 4.1%; $P < 0.05$). Percentage of cows dead or sold was similar, and DIM when cows left the study (dead or sold) did not differ between treatment groups. Nevertheless, cows fed BUPCP tended to have a greater incidence of lameness (17.6 vs 13.1%; $P < 0.08$), but a lower incidence of mastitis (10.6 vs 18.6%; $P < 0.003$) than those fed WUP. No dead cow showed any lesions compatible with gossypol toxicity. Replacement of whole

Upland cottonseed with a blend of whole Upland and cracked Pima cottonseed did not affect reproduction and health of lactating Holstein dairy cows.

Key Words: Cottonseed, Gossypol, Dairy cows

1516 Bloodmeal and fishmeal addition to receiving diets. J. W. Lehmkuhler*¹, E.E.D. Felton¹, C.J. Fu¹, and M. S. Kerley¹, ¹University of Missouri.

Two experiments were conducted to evaluate the response of a 1:1 bloodmeal and fishmeal combination (BMFM) in receiving cattle. In experiment one, Simmental calves (six heifers and 30 steers) were randomly assigned to nine pens. Cattle were fed a corn and corn silage based diet. Treatments included a soybean meal (SBM) control, low, and high BMFM. Dietary CP was calculated to be 13%, 13%, and 16%, respectively. Intake was restricted during the first 21 d to model low intake responses of newly received cattle to ruminally undegradable protein (RUP) and was increased the following 25 d. Initial, mid-term, and final weights were similar ($P > .1$) among treatments averaging 347, 351, and 380 kg, respectively. Similarly, no treatment differences were observed for ADG or GF during the 21d restriction period, step-up period, or for the entire receiving period. In experiment two, sixty Angus-sired calves were randomly assigned to twelve pens in a 2X2 factorial design of treatments. Treatments investigated were level of crude protein (low-13%CP vs. high-16%CP) and form of protein (SBM vs. BMFM). Diets consisted of corn, late-bloom alfalfa hay, and the pelleted supplemental treatments. Diets were fed at similar levels for all treatments for 21 d. No treatment differences ($P > .1$) were observed for initial and ending weights (305 and 330 kg, respectively). Form or level of protein had no effect ($P > .1$) on ADG. Average daily gain for treatments were 1.1, 1.2, 1.3, and 1.2 kg/d for the low SBM, low BMFM, high BMFM, and high SBM, respectively. Due to the similar intakes and lack of response in ADG, treatment differences were not significant for GF and averaged 0.16. Though not statistically significant, a numerical difference in the interaction for FG was observed. Feed conversions were 9.1, 6.9, 6.9, and 7.7 for the low SBM, low BMFM, high BMFM, and high SBM, respectively. We inferred that addition of RUP and level of protein may alter performance and efficiency of receiving cattle. Further studies are warranted to investigate the relationship between level and form of protein in relationship to energy intake of newly arrived cattle.

Key Words: feedlot, receiving, ruminant

AMSA Graduate Student Research Posters (M.S. and Ph.D. Divisions) and AMSA General Abstracts

1517 Oxymyoglobin and lipid oxidation in α -tocopherol supplemented pork liver microsomes. S Lee*, A L Phillips, and C Faustman, *University of Connecticut, Storrs, CT.*

The biological antioxidant, α -tocopherol, has been used endogenously or exogenously to delay oxymyoglobin (OxyMb) and lipid oxidation in meat. α -Tocopherol quenches free radicals originating from lipid oxidation and this, in turn, appears to protect OxyMb against oxidation. In muscle membranes, α -tocopherol is located close to membrane-bound enzymes that generate free radicals, and acts to protect membrane lipids by scavenging free radicals. An OxyMb porcine microsome model was used to study the effects of α -tocopherol on OxyMb or lipid oxidation *in vitro*. Pork liver microsomes were isolated from pigs fed either a control or vitamin E-supplemented diet (Phillips et al., 2001, Meat Sci., In press), and combined with horse heart OxyMb prepared by hydrolysate-mediated reduction. OxyMb (0.15 mM) was incubated with microsomes (1mg/ml) at 25 and 37 °C, pH 5.6. During incubation, OxyMb oxidation was measured spectrophotometrically by use of a diffuse-integrating sphere, and percent metmyoglobin (MetMb) was calculated. Lipid oxidation was measured by a thiobarbituric acid reactive substances (TBARS) method. MetMb formation increased with increasing temperature, and was greater at 37 °C than at 25 °C ($P < 0.05$). At 37 °C, MetMb reached 50% within 2 hours incubation, whereas 8 hours was required at 25 °C. There was no significant effect of α -tocopherol on delaying OxyMb oxidation either at 25 or 37 °C. Lower TBARS were observed in microsomes from vitamin E-supplemented than control pork livers ($P < 0.05$). These results differ from those observed with beef mus-

cle microsomes where both OxyMb and lipid oxidation were delayed with elevated α -tocopherol levels.

Key Words: Oxymyoglobin, Lipid oxidation, α -Tocopherol

1518 Effect of high oil corn and vitamin E supplementation on beef steak case-life properties. M.S. Eibs*¹, B.J. Johnson¹, D.M. Wulf¹, B.C. Shanks¹, and T.A. Wittig¹, ¹South Dakota State University.

The objective of this experiment was to investigate the effects of high oil corn and vitamin E supplementation on steak case-life properties. Steers ($n = 84$) were fed a high concentrate diet consisting of either typical corn (C: 79.5% of ration) or high oil corn (HOC: 79.5% of ration) for 112 days with (+E) or without (-E) vitamin E supplementation during the last 50 d (1,000 IU/hd/d). Steaks (2.54 cm thick) were removed 24 h postmortem from the 12th rib and utilized in retail display panel (RDP), thiobarbituric reactive substances determination (TBARS), and tocopherol analysis. Two storage treatments were used prior to RDP: 1) domestic chilled (DC), chilled storage for 13 d postmortem; and 2) export chilled (EC) chilled storage for 34 d postmortem. Steaks were appraised for 9 d (d 0 to 8) under simulated retail meat display conditions by a 5-member panel and color was measured with a Minolta colorimeter. On d 8, TBARS of RDP samples were determined. HOC grain contained more ($P < 0.05$) α - and γ -tocopherol than C grain (14.62 and 84.90 vs 8.01 and 41.68 ppm). Ribeye steaks +E contained higher ($P < 0.05$) levels of α -tocopherol than ribeye steaks -E. Steaks from HOC had higher concentrations of γ -tocopherol than C steaks (P

<.01). Steaks -E had higher concentrations of γ -tocopherol than steaks +E ($P < .03$). Rate of discoloration, as appraised by RDP, was slower ($P < .05$) in HOC+E steaks than in HOC-E steaks for DC and EC storage treatments. In both the DC and EC storage treatment steaks +E had lower ($P < .01$) TBARS than steaks -E. These data suggest supplementing vitamin E while feeding high oil corn in diets for finishing beef steers does not improve beef steak case-life properties beyond typical corn diets with vitamin E supplementation.

Key Words: High Oil Corn, Beef, Tocopherol

1519 Evaluation of growth rate, carcass composition and meat quality of Berkshire- and Yorkshire-sired progeny. M.J. Ritter*, C.P. Allison, S.R. Debar, J.M. Scheffler, R.J. Tempelman, and M.E. Doumit, *Michigan State University, East Lansing, MI.*

Our objective was to examine differences in growth, carcass composition and meat quality traits of crossbred pigs. Berkshire-sired (B; n=16) and Yorkshire-sired (Y; n=16) progeny were blocked by gender, sire and weight at approximately 86 kg. Over the last 27 d of the finishing period, average daily gain (ADG) of Y pigs was 22% greater than B ($P < .02$). Pigs were harvested at a commercial abattoir on two days. Carcass weights did not differ by breed, but Y carcasses were leaner at the tenth rib and last lumbar vertebra, produced heavier hams, more pounds of fat-free lean and lighter bellies than B ($P < .01$). *Longissimus* muscle (LM) temperature and pH were measured at 20, 45, 180 min, and 24 h postmortem. Berkshire-sired pigs had higher 180 min and 24 h pH values. Loin chops from B had higher subjective loin color and marbling scores, and lower Minolta CIE L* values on d 1 postmortem ($P < .05$). A harvest date by breed interaction existed for suspension drip loss and 20 min LM temperature ($P < .05$). This interaction is attributed to disproportionate increases in temperature and drip loss of Y LM on the second harvest day. Berkshire-sired pigs had lower fluid loss from vacuum packaged loin sections stored at 4°C for 7 d than Y ($P < .003$). Yorkshire-sired pigs grew faster and produced more fat-free lean than B, but B pigs had more desirable color and better water holding capacity, presumably due to a more gradual rate of pH decline and higher ultimate pH.

Key Words: Meat Quality, Carcass Composition, Growth Rate

1520 Mechanisms of vitamin D3 on tenderness of lamb. C. T. Boleman¹, J. W. Savell^{*1}, W. S. Ramsey¹, and R. K. Peel¹, ¹Texas A&M University.

Two trials were conducted to determine the effects of Vitamin D₃ (VITD) on the tenderness of lamb: Trial 1 evaluated ionized Ca levels in blood serum, percent intake (PI), and total gain (TG) on 26 rams assigned randomly to one of eight treatments of VITD. These treatments were supplemented at one of four levels: 0 (SO); 250,000 IU of VITD (S250); 500,000 IU of VITD (S500); or 750,000 IU of VITD (S750) or administered as a bolus of 0 (B0); 250,000 IU of VITD (B250); 500,000 IU of VITD (B500); or 750,000 IU of VITD (B750) for four days. There were no ($P > 0.05$) differences at each day for treatment type for ionized Ca levels in blood serum. Rams assigned to the S500 treatment had lower ($P < 0.05$) PI and TG than other supplemented groups. Trial 2 evaluated carcass composition by analyzing Warner-Bratzler shear (WBS) values of chops from the longissimus lumborum (LL), semitendinosus (ST), semimembranosus (SM), and biceps femoris (BF) from each of the 40 carcasses. Forty feedlot lambs were assigned randomly to one of two treatments of a control (CONT) (n=20) or 750,000 IU of VITD (n=20) and fed in a mock feedlot environment for four days before slaughter. There were no differences ($P > 0.05$) for ionized blood Ca levels in blood serum. Vitamin D₃ content in livers and kidneys differed ($P < 0.01$) between VITD vs. CONT (livers - 504.54 vs. 27.13 and kidneys - 1530.20 vs. 21.18 ng/g vitamin D₃). Carcasses from VITD treated lambs had less ($P < 0.05$) average fat thickness (AFT). (0.68 vs. 0.84 cm) and an increase ($P < 0.05$) in overall conformation (OCS). The four muscles were removed, fabricated into chops, assigned randomly to a postmortem aging day of 5 (AG5), 10 (AG10), or 15 (AG15) for WBS determination. Chops from the LL did not differ ($P > 0.05$) for WBS values for CONT vs. VITD for all aging days; however, chops from the SM and ST had ($P < 0.05$) lower WBS values for VITD vs. CONT at 5d aging. Activation and acceleration of calpain dependent proteases could be responsible for

lower WBS values for AG5 chops however, VITD regulators are most likely preventing VITD from increasing Ca levels in blood.

Key Words: Lamb, Vitamin D, Tenderness

1521 Lean lamb production: Bioelectrical impedance as a lean tissue evaluation method. P. T. Berg^{*1}, T. C. Faller², and M. N. Maddux¹, ¹North Dakota State University, Main Station, Fargo, ²North Dakota State University, Hettinger Research Extension Center.

The objective was to evaluate Bioelectrical Impedance (BIA) to predict weight of retail product (LN) in lambs. Carcasses (n=217) were subjected to BIA evaluation 24 h post slaughter. Resistance (Rs), reactance (Xc), length (L) between electrodes and temperature (T), and standard carcass data was recorded. Carcasses were reduced to wholesale cuts according to NAMP specifications. Cut weights were recorded before and after fat was trimmed from shoulder, rack, loin and leg. Lean was exposed over at least 85% of the surface. Sum of the four trimmed wholesale cuts (ACT) was used as dependant variable. An anatomical measurement (LNa) and a BIA based prediction formula (LNb) were developed (Proc. GLM of SAS). Formulas are: LNa = 4.8 + (0.58*c carc wt) + (1.39*REA) - (7.36*12th rib fat) - (5.87*body wall). LNb = 6.72 + (0.4818*c carc wt) - (0.0314*Rs) - (0.0481*Xc) + (0.254*L) + (0.0223*T). R² for LNa = 0.94 and for LNb = 0.91. A second group of lambs (N=182) was used to validate the BIA formula. High R² for LNa suggested potential product loss, time and labor expenses could be minimized using LNa as dependant variable in validating LNb. LNb predictions had an R² = 0.93 when using LNa as dependant variable. Second group (n=182) was also subjected to live BIA evaluation. BIA is non-invasive, causes minimal discomfort, rapid and equipment is affordable. A BIA prediction formula was developed using Rs, Xc, L and live weight: LNI = 0.973 + 0.3118*live wt) + (0.017*Rs) + (0.1739*Xc) + (0.0102*L) The R² between LNI and LNa (dependant variable) = 0.79. Formulas, LNa, LNb, and LNI were validated on 48 Columbia lambs. Live and carcass predictions, using both anatomical and BIA measures were calculated. Dependant variable was ACT. R² values were 0.82, 0.84 and 0.80 for LNa, LNb and LNI respectively. Data indicate BIA can accurately evaluate weight of LN and has application for both value-based marketing of carcasses and in live animal selection.

Key Words: lamb meat, Bioelectrical impedance, evaluation

1522 Impact of HACCP implementation on the Kansas meat and poultry processing industry. E. Boyle^{*1}, D. Hoffman¹, and M. Schoenbeck², ¹Kansas State University, Manhattan, KS, ²Food Brands, Hutchinson, KS.

Profiles were developed from surveys distributed in 1997 and 2000 to assess the impact of HACCP on federal, state and custom meat and poultry establishments in Kansas. Randomly coded surveys included a cover letter and a stamped, self-addressed return envelope. Reminder postcards were sent one week after surveys were initially mailed. Of 221 surveys sent in 1997, 51.6% responses were received, while a response of 39.1% was received in 2000 from 225 distributed surveys. Nearly 70% of respondents to the 2000 survey responded to the 1997 survey. Overall, inspection status changed for nine plants from 1997 to 2000, 82% of respondents had employees who received some form of HACCP training, 87% of plants had a HACCP program with an average of four HACCP plans per plant, and 60% of respondents spent 45 minutes or less each day filling out, filing or reviewing HACCP paperwork. There was minimal change in the amount or type of product produced as a result of HACCP. Six plant characteristics changed from 1997 to 2000 ($P < 0.05$). Plant managers/owners receiving meat training through an apprenticeship declined from 22% in 1997 to 9.4% in 2000. The use of computers in meat and poultry processing businesses increased from 47.3% to 61.4%. The average year of latest plant renovation moved from 1987 (1997 survey) to 1990 (2000 survey). Nearly three-quarters of respondents had undergone renovations since their facilities were constructed. The last renovation occurred as long ago as 1960 or as recently as 2000. The percent of plants that processed franks decreased from 20% in 1997 to 9.3% in 2000. The use of a phonebook as an advertising medium increased from 42.2% in 1997 to 57.7% in 2000. From 1997 to 2000, the industry changed their emphasis on who they relied on for obtaining meat and poultry information. The use of a government inspector for information declined from 75.9% to 63.3% while consulting university resources increased from 38.9% to 64.6%. Additionally, the use of other

information sources such as the Internet increased from 2.8% to 8.9%. While there have been some changes to the Kansas meat and poultry processing industry as a result of HACCP, the overall impact on the parameters in this survey has been minimal.

Key Words: HACCP, Industry profile, Kansas

1523 Development and Evaluation of an Advanced HACCP Workshop for Meat Processors. Mindy Brashears¹, Dennis Burson¹, Liz Boyle², Fadi Aramouni², Jason Mann¹, and Mark Murphy², ¹University of Nebraska, ²Kansas State University.

A one-day advanced HACCP workshop was developed by Extension Specialists at the University of Nebraska and Kansas State University. The overall goal of this workshop was to increase the knowledge of small meat processing establishments to enable them to more effectively manage HACCP systems in their facilities. Topics discussed in the workshop included; HACCP verification, HACCP validation and experimental design, sampling plans, USDA in-depth verification reviews (IDV), reassessment, auditing, HACCP-based inspection model programs (HIMP), and the relationship of HACCP to total quality management (TQM) programs and statistical process control (SPC). The workshop was delivered as a pilot test program to processors to ensure that the content addressed current needs of the industry. The format for topic delivery was 30 min presentations by Extension Specialists. Additionally, participants completed working group activities that allowed them to design studies to validate or change CCPs in a plan, to apply pathogen modeling programs to specific processes and to subject data collected during HACCP monitoring to SPC in order to identify trends. The participants completed an evaluation after each activity and a focus group analysis was conducted at the end of the workshop. While most participants were familiar with the topics covered, 100% of them indicated that presentations contained information that would be useful in their business. The working group exercises were also helpful to most participants with 60% and 87% of the participants indicating that the HACCP validation case studies and SPC activities would be useful, respectively. Focus group results also indicated that all topics were important to meat processors in the day to day management of their plans. They indicated that on-going HACCP training was important to them and that the advanced topics covered in this workshop should continue to be included in future advanced workshops. They indicated that one-day workshops were a good form of training because they resulted in a relatively small amount of time away from their business and kept them up to date on current issues. Based on these results, the advanced HACCP course will continue to be offered in a similar format delivered to the pilot group.

Key Words: HACCP, Verification, Validation

1524 Development of a Beef Myology and Muscle Profiling Cd-rom. S.J. Jones*¹, C.R. Calikins¹, K.S. Podany¹, D.E. Burson¹, and B.L. Gwartney², ¹University of Nebraska, ²National Cattlemen's Beef Association.

The beef carcass is made up of over one hundred different muscles with different properties that affect processing characteristics and consumer acceptability. Today, the majority of the cuts found in the retail meat counter are boneless, therefore by providing the need for knowledge of the musculature of the beef animal. It is possible to develop a CD-ROM that will serve as a resource for the muscular anatomy of the beef animal. The objective of this project was to develop an electronic manual of the muscular anatomy, and a chemical and physical profile of the 39 muscles located in the chuck and round wholesale cuts. Muscle profiling data were collected in a separate project conducted by Dr Chris Calkins of the University of Nebraska, and Dr. Dwain Johnson of the University of Florida. Additional information on each muscle was collected, including: name, origin, insertion, action, innervation, blood supply, wholesale and retail cut location. Six different sections were developed to view the muscular and skeletal anatomy of the carcass: cross-sections, lateral views, sub-primal views, skeletal views and muscle and bone descriptions by scientific and common name. Using any one of the sections, one can access the data. Visual images were collected by cutting 2.54 cm cross-sections from the side of a 340 kg carcass, producing 86 cross sections. A second side was split into hind and fore quarters, then individual muscles were removed and the carcass portion was photographed. Drawings were developed for each picture, and the

muscles were identified and linked to their respective information. Using Institutional Meat Purchasers Specifications, sub-primal cuts were prepared and photographed every 22.5 degrees to obtain a 360 degree view. A strobe lighting system was used in lighting the cross-sections and lateral layers during photography. Photographs were digitized to JPEG format for use in CD-ROM development. Programming of the CD-ROM was done using HTML language and JAVA script so that the program could be used with a web browser on a computer. Drawings that were made of each cross-section and lateral view were formatted as GIF files and linked to each muscle information file. The Beef Myology and Muscle Profiling CD will be a valuable resource for both industry and academia.

Key Words: Beef, Myology, CD-Rom

1525 Microbial condition of aged lamb meat treated with 1% acetic acid. E.C. Vasconcelos¹, J.F.F Zapata*¹, E.A.T. Figueiredo¹, and M.A.A. Castelo-Branco¹, ¹Universidade Federal do Cear, Fortaleza, CE, Brasil.

Organic acids intended to control microbial contamination on meat surface have been used as 1 to 2% acetic or lactic acid solutions or as a combination of both. The objective of this study was to verify the effect of a single dip in 1% acetic acid solution on microbial condition of lamb meat during aging. Lamb shoulders were collected under commercial practices and cut into meat and bone steaks about 3 cm thick. Steaks were dipped for 1 min in either 1% acetic acid solution or distilled water. Steaks were individually packaged in nylon-polyethylene bags and vacuum-sealed before storing at 1 C. On days 3, 13, 23, 33 and 48 of aging meats were analyzed for mesophilic and psychrophilic bacteria, mold and yeast, total and fecal coliform bacteria, Salmonella and sulfite-reducing Clostridia. Mesophilic and psychrophilic bacterial counts were lower ($p < 0.05$) in meats treated with acetic acid on days 13 and 23 and on days 3 and 13, respectively. Although mold and yeast counts were generally lower in meats treated with acetic acid as compared with the untreated meats this effect was significant ($p < 0.05$) only on days 3 and 13 of aging. On day 3 of aging treated meats were significantly ($p < 0.05$) lower in both total and fecal coliform counts than untreated meats. This difference was not observed with 13, 23, 33 and 48 days of aging although the counts for these types of microorganisms were lower than $1.2 \log \text{cfu g}^{-1}$ in this period. Meat samples were found positive for Salmonella with 3, 13 and 23 days of aging and negative with 33 and 48 days of aging. Sulfite-reducing bacteria were absent in meat samples all through the experimental period. It can be concluded that dipping lamb meat pieces in acetic acid 1% for one minute followed by vacuum packaging and cold storage (1 C) can keep low counts of mesophilic, psychrophilic, and coliform bacteria, as well as mould and yeast for 13 days. During this period, however, Salmonella is not inhibited by the acid treatment.

Key Words: Meat aging, Coliform bacteria, Salmonella

1526 Comparison of recovery methods for freeze-injured Listeria monocytogenes, Salmonella Typhimurium and Campylobacter coli associated with cell suspensions and pork surfaces. V. P. Chang*, E. W. Mills, and C. N. Cutter, Penn State University, University Park, PA 16802.

Freezing, heating, or acidification are known to adversely affect pathogenic microorganisms on meat surfaces, resulting in either death or injury. Injured cells resulting from such treatments may not grow during conventional microbiological procedures due to the presence of compounds or dyes in the media that impair the cell's ability to repair. Therefore, quantification of injured cells is important to ensure overall treatment effectiveness. Recovery of injured cells can be accomplished by combining selective and non-selective media into a single system. With such combinations, the diffusion of the selective compounds or dyes is controlled, allowing for resuscitation of injured cells of interest, while also inhibiting the growth of undesirable background microflora. To date, very little information exists on recovery methods for freeze-injured cells associated with pork surfaces. In this study, Listeria monocytogenes, Salmonella Typhimurium and Campylobacter coli suspended in buffer or associated with pork surfaces were subjected to a freeze-thaw cycle (-15C for 24 h; 4C for 4 h). Following treatments, freeze-injured cells were plated onto media incorporating the following recovery methods: overlay (OV); thin agar layer (TAL); or Lutri plate (LP) method. Media used in this study include: Modified Oxford agar

and trypticase soy agar (TSA) for isolation of *L. monocytogenes*; Xylose Lysine Decarboxylase agar and TSA for isolation of *S. Typhimurium*; Campylobacter blood-free and Brucella agar for isolation of *C. coli*. The recovery rates for the pathogens using the TAL and OV methods following freeze treatments in cell suspensions or on pork surfaces were not statistically different ($P>0.05$) from recovery rates associated with non-selective media. The results presented in this study demonstrate that OV and TAL are reliable and consistent recovery methods for isolation of freeze-injured cells. The TAL method was not only easier to perform, but also allowed for improved isolation of single colonies for further characterization. Further research will utilize the TAL method to determine the effectiveness of blast- and commercial-chilling processes to reduce pathogenic bacteria associated with pork surfaces.

Key Words: Pork, Freeze-injured, Pathogens

1527 Incorporation of nisin into a collagen film retains antimicrobial activity against *Listeria monocytogenes* and *Brochothrix thermosphacta* associated with a ready-to-eat meat product. B. J. Miller* and C. N. Cutter, *Penn State University*.

The foodborne pathogen, *Listeria monocytogenes* (LM) is associated with a variety of ready-to-eat (RTE) meat products. Vacuum packaged, refrigerated meats also may be contaminated with spoilage organisms such as *Brochothrix thermosphacta* (BT). The antimicrobial peptide, nisin, is known to inhibit LM and BT on meats. Nisin is currently approved for use in some foods. In this study, collagen films were soaked in a nisin solution and dried to produce biologically active nisin-incorporated collagen films (NICF). Frankfurters were wrapped with NICF or collagen films without nisin (Control), vacuum packaged, heated (30 min, 100C), cooled, and inoculated with approximately $3 \log_{10}$ CFU/g of LM or BT. Inoculated, NICF and control frankfurters were subjected to refrigerated storage (4C) for up to 14 days or temperature abused (24 h, 25C) and refrigerated (4C) for up to 14 days. Immediately after treatments and following refrigerated storage at days 4, 7, and 14, BT was reduced greater than $1.4 \log_{10}$ CFU/g; whereas LM was not reduced greater than $0.6 \log_{10}$ CFU/g. Following temperature abuse and 14 days of refrigerated storage, BT and LM were reduced by approximately $1 \log_{10}$ CFU/g. This research is the first to demonstrate the incorporation of nisin into a collagen film retains activity against bacteria associated with RTE meat products.

Key Words: Collagen film, Nisin, Ready-to-eat meat

1528 Survival of *Listeria* spp. following bacon processing. L. J. Heffner*, S. L. Flowers, S. L. Hestand, G. L. Kehres, S. Doores, E. W. Mills, and C. N. Cutter, *Penn State University*.

Some meat processors are packaging bacon and RTE meats in the same room. There is concern that because bacon is not a thoroughly cooked product, there is the potential for *Listeria monocytogenes* to survive the curing and smoking process and cross contaminate RTE meats in the packaging room. To address this issue, the individual and combined effects of bacon processing against *Listeria* spp. were reviewed. For the first experiment, pork bellies were inoculated with *Listeria innocua* to obtain approximately $4 \log_{10}$ CFU/g. Inoculated bellies were left untreated (U), injected with sterile distilled water and smoked (liquid smoke and heat treatment to an internal temperature of 53C; IWS), injected with a cure solution (water, sodium phosphate, brown sugar, salt, nitrate, and sodium erythorbate) and smoked (ICS), or injected with cure solution only (IC). Microbiological samples were obtained immediately after treatments (day 0), after 24 hours of refrigerated storage (4C; day 1), and after 9 days of vacuum packaged, refrigerated storage (day 9). Results from the first experiment indicate that immediately following treatments and after vacuum packaged, refrigerated storage, curing alone (IC) does not afford any reductions of *L. innocua*. However, smoking with water or cure (IWS or ICS) reduces the organism greater than $2 \log_{10}$ CFU/g ($>99\%$). Subsequent microwave cooking of the bacon to simulate consumer handling resulted in no detectable growth of *L. innocua*. For the second experiment, pork bellies were inoculated with *Listeria monocytogenes* to obtain approximately $3 \log_{10}$ CFU/g. Inoculated bellies were left untreated (U), injected with sterile distilled water and smoked (IWS), or injected with a cure solution and smoked (ICS). Microbiological samples were obtained immediately after treatments (day 0), after 24 hours of refrigerated storage (4C; day 1), and after 7 days of vacuum packaged, refrigerated storage (day

7). Results from the second experiment indicate that immediately following treatments and after vacuum packaged, refrigerated storage, *L. monocytogenes* was reduced approximately $3 \log_{10}$ CFU/g ($>99.9\%$) to undetectable levels by either the IWS or ICS treatments. This information demonstrates that the bacon process appears to significantly reduce populations of *Listeria* spp.

Key Words: *Listeria* spp., Bacon, Survival

1529 Effects of Electrolyzed Oxidizing Water on Microbial Growth, Lipid Oxidation and Color of Displayed Beef during Refrigerated Storage. Seon-Tea Joo¹, Kumar Venkitanarayanan², and Cameron Faustman², ¹*Gyeongsang National University, Chinju, Korea*, ²*University of Connecticut, Storrs, CT, USA*.

Electrolyzed oxidizing water (EO water) produced by the electrolysis of water containing sodium chloride has been reported to possess strong antimicrobial properties. The major antimicrobial elements in EO water include a low pH of 2.7, an oxidation-reduction potential of $>1,100$ mV, and a free-chlorine level of 10 to 80 ppm. The effects of EO water on microbial growth, lipid oxidation and color of displayed beef during 4°C storage were evaluated. Beef cores (3cm diameter \times 1.5cm thick) from longissimus muscle were prepared, and then dip-treated in distilled water (pH 7.2; control) or EO water (pH 2.5; treatment) for 1, 5 and 10 min at 23°C. Total plate counts, lipid oxidation (TBARS) and color (CIE L*a*b*) were measured at 0, 1, 3, 6 and 9 days of storage at 4 °C. Microbial growth on beef cores was not affected by EO water treatment. The population of all samples was approximately $7 \log$ CFU/cm² after 6 days of display. However, TBARS values of samples subjected to 5 and 10 min of EO water treatment tended to be higher than those of control and 1 min EO water treatment after 6 days. Differences in TBARS between control and 1 min EO water treatment appeared negligible. Samples subjected to EO water treatment showed slightly higher CIE a* values compared to controls, while CIE L* and b* values did not appear to differ among treatments during 9 days of storage. Results were not as conclusive as earlier demonstration of antimicrobial effects of EO water on fruit/vegetables and kitchen cutting boards.

Key Words: Electrolyzed Oxidizing Water, Microbial Growth, Meat safety

1530 Thermal conductivity model for predicting heat penetration in non-stirred raw rendered products. A. K. Greene, C. S. Knight, W. B. Bridges, and P. L. Dawson*, *Clemson University*.

Samples of raw beef, pork and poultry rendered products were collected and analyzed for percent moisture, fat, and bone. The nine mixtures of raw rendering materials were examined in heat penetration studies in a Loveless still retort using a TechniCAL CALPlex 32 Datalogger, Ecklund needle thermocouples, 300x406 two piece steel cans and TechniCAL CALSoft data collection software. Throughout the heating process, a datalogger collected heat data at 10 second intervals and recorded the data on CALSoft software (TechniCal, Inc., New Orleans, LA). All samples were processed to at least a 12D process. The computer software was programmed to use a z value of 18°F (10°C). The computer software recorded accumulated D values and reported length of time to reach a 12D process. Using the collected thermal data, models were created to describe the heat conductivity into each product mixture. The "best fit" non-linear regression model was a logistical function. A logistic function was fit for each replicate of the treatments and compared to the quadratic linear models for each replicate. In all cases, the logistic model produced a much smaller residual or Sum of Squares for Error (SSE) indicating an overall better fit than the quadratic linear model. The logistic model would be recommended for future analysis.

Key Words: Rendering, Thermal process, Food safety

1531 Analyzing Plant Sanitation Processes using Statistical Process Control Techniques. K.J.K Getty* and J.G. Surak, *Clemson University, Clemson, SC*.

Microbiological testing is an effective tool for verifying sanitation programs in meat and poultry operations. The objectives of this study were: 1) to determine if line employees, as represented by university students and employees, not only can clean and sanitize processing equipment but

also can perform microbiological environmental sampling, which evaluates the sanitation process; 2) to develop appropriate microbiological environmental processing specifications (CFU/cm²) for equipment and facility areas; and 3) to determine if data from sampling can be analyzed using statistical process control. A 3M Quick Swab and a 15 X 10 cm template were used to swab facilities and equipment. The swab diluent was poured directly onto one of three 3M petri films (aerobic plate counts (APC); yeast and molds (YM); or *E. coli* and coliforms (EC)). Samples were collected nine times over a seven month period resulting in approximately 35 samples per each film type. The APC counts for the contact meat surfaces prior to cleaning and after cleaning ranged from 0.147 to 2.48 and <0.007 (detectable limit) to 0.25 CFU/cm², respectively, whereas, non-contact surfaces; facility areas; and drains ranged from 0.013 to 0.68; <0.007 to 0.013; 0.153 to 1.78 CFU/cm², respectively. The EC counts for contact surfaces ranged from <0.007 to 0.027. The YM counts for contact surfaces ranged from <0.007 to 0.127 and <0.007 to 0.207 CFU/cm² for yeast and mold, respectively. Data were analyzed using simple statistical process control tools (individual moving range control charts, and capability analysis), thus, allowing the identification of sanitation problems in the plant and development of improvement strategies by students and management. This resulted in decreased counts over time. Companies can utilize microbiological testing procedures and link the results to statistical process control techniques to improve the verification of their sanitation programs.

Key Words: plant sanitation, statistical process control, microbiological testing

1532 Recombinant production of chicken egg-yolk antibodies against Enterotoxigenic *Escherichia coli* by use of a DNA vaccine. S.H. Cho*, P.C. Loewen, and R.R. Marquardt, *University of Manitoba, Winnipeg, MB, Canada, R3T2N2.*

DNA vaccines have been shown to elicit both cellular immunity and humoral immunity in animals. Recent reports have suggested that the administration of vaccines consisting of plasmid DNA may significantly enhance long-lasting antigen specific immune responses. The objective of this study was to investigate the efficacy of DNA vaccines against *Escherichia coli* K88 and K99 in mouse and chicken models. Mice and laying hens were injected with; DNA alone, protein alone, and DNA plus protein then the antibody titres in serum and egg yolk were determined by ELISA. The DNA plus protein injection induced higher and long-lasting antibody titre in both mice and chickens compared to that obtained with DNA or protein alone. Also the antibody titre of DNA plus protein injection after 24 weeks was nearly equal to the maximum values obtained after 8 weeks with either alone. The antibody titre after 40 week was almost 10-fold higher for the DNA plus protein injection compared to that of protein injection alone. The data demonstrates that a DNA vaccine can elicit an antibody response in both mammalian (mice) and avian (chicken) species. It also demonstrates that DNA vaccines injected with their corresponding antigen have the ability to considerably enhance subsequently antibody titre in the blood of mice and the egg-yolk of laying hens. The antibodies produced in the yolk of the chicken against *E. coli* can be used to passively control diarrhoea in young pigs and dairy calves.

Key Words: Egg yolk antibodies, DNA vaccines, Enterotoxigenic *Escherichia coli*

1533 Decreasing cost in processed meat products with the addition of pork collagen. D.R. Doerscher*^{1,2}, G. Prabhu¹, and E. Schoenberg¹, *¹Proliant Inc., ²Iowa State University.*

Pork collagen is a cost-effective, functional ingredient that can improve the quality of various meat products due to its water binding and gel forming capabilities. In many types of meat products, it is not only capable of improving yield, texture and purge, but it can provide cost savings as well. This is especially important from a processor standpoint because it can help improve profitability without sacrificing product quality. Cost savings are achieved by utilizing rehydrated pork collagen to replace more expensive ingredients, such as lean meat or other binders. For example, in a typical reduced fat hotdog formula, the replacement of pork 72's with 1% pork collagen hydrated 1:4 can produce yielded cost savings of approximately 2.5%. Pork collagen also performs well in other comminuted products. In a 97% fat free pork breakfast sausage with the same replacement rate, a savings of 3.8% may be obtained when ham trimmings are substituted. Increasing the usage level to 2% in these systems will also provide cost savings while maintaining product quality. The FDA recognizes pork collagen as a binder and

purge reducing food additive in meat products at usage levels up to 3.5%. However, many meat products have USDA standards limiting the use of binders and added water. Nonetheless, its use is currently permitted in non-standard meat products that permit binders as well as many types of products identified with nutrient content claims. As the use of pork collagen expands, it will be beneficial when maximizing non-meat protein in cooked sausages allowing increased flexibility in maximizing added water. This and other economic advantages of pork collagen will potentially yield high returns to the meat processor.

Key Words: Pork collagen, Cost savings, Processed meats

1534 Evaluation of wet salting in the "Charqui" processing. M. Pinto Neto*¹, H.A. Arima¹, R.O. Villarreal, S.B. Toma, and M.L.Q. Andrade, *¹Instituto de Tecnologia de Alimentos, Campinas, Sao Paulo, Brazil.*

"Charqui", a salted and dried beef product, very popular in Brazil, is usually obtained by wet and dry salting followed by sun drying. This product is stable at ambient temperature and is classified as intermediate moisture food. The wet salting (WS) may be done by injecting or tumbling the meat with a brine. The objective of this study was to evaluate the WS process through tumbling, using a central composite non factorial surface design. Boneless beef flank were tumbled with saturated NaCl brine (26°Baumé). The independent variables tested at two levels plus a central point included proportion brine:meat (PBM) at levels 1:0.5, 1:1 and 1:2, brine temperature (TB) at levels 10, 15 and 20°C, and tumbling time (TT) at levels 20, 30 e 40min. The dependent variables NaCl percentage (Cl%), moisture percentage (W%), water activity (aw), and pH were determined after tumbling. The data were analyzed using the package STATISTICA V.5. The mathematical models obtained were $Cl\% = 5.6581 - 1.4062 * PBM + 0.4237 * TT + 0.2462 * PBM * TT$ and $W\% = 70.2327 - 1.2337 * TB + 1.6687 * PBM$. The analysis of variance (ANOVA) for Cl% indicated that the model was significant at $p < 0.05$, and had a R² value of 0.81. Examination of the fitted coefficients using the F test showed that PBM was significant, while TT and TB were not. The effect of PBM on the Cl%, was inversely proportional. The Cl% in the meat increased varying from 3.5% to 7.0%, as the PBM decreased. There was a positive influence of TT in Cl%, but it was negligible in the range of the experiment. W% had 63.5% (R²0.635) of its variation explained by the regression model which showed no significant lack of fit ($p < 0.05$). TT and PBM had a linear effect on W%, while TB was not significant. The W% in meat decreased from 73% to 67%, as the PBM decreased and TT increased (at fixed TB 15°C). The processing variables PBM, TT and TB did not affect aw and pH.

Key Words: Dried meat, Salting, Charqui

1535 Effect of freezing rate and storage on the functional properties of manufacturing beef. M.M. Farouk*, K.J. Wieliczko, and I. Merts, *AgResearch Ltd.*

A prior study found that freezing rate on its own does not affect the functional properties of thawed muscle proteins. This finding led us to hypothesise that it is the interaction between freezing rate and storage temperature and time that affects protein functionality. The present study was designed to validate this hypothesis. Hot-boned semimembranosus muscles (n = 24) from 12 heifers were held at 10°C until rigor. The muscles were assigned to 24 treatment combinations using an incomplete factorial design with two freezing rates (fast, 12.04 mm/h; slow, 0.56 mm/h) x 3 storage temperatures (-18, -35, -75°C) x 5 storage times (0, 3, 6, 9, 12 months). Functional properties (protein solubility, drip loss, water holding capacity, tenderness, cook loss, emulsion activity index, emulsion stability and colour) were determined. The sulphhydryl content and surface hydrophobicity of the extracted proteins were measured and the changes in soluble sarcoplasmic proteins were determined for each treatment using SDS-PAGE. Storage temperature alone had no effect on the functional properties measured. Rate of freezing alone affected only drip loss, which was higher for the slowly frozen samples. Functional properties were mainly affected by storage time and the interaction between storage time and temperature, confirming our hypothesis. It is concluded that, compared to current commercial practice, very fast freezing and ultra low temperature storage—both very expensive operations—do not improve the functional properties of frozen beef. Thus, from a product quality perspective, capital need not be spent on equipment for faster freezing and ultra low temperature storage of manufacturing meat.

Key Words: Beef, Freezing rate, Functional properties

1536 High temperature conditioning prior to rigor onset does not affect the functional properties of beef subsequently chilled rapidly. M.M. Farouk*, A.E. Graffhuis, and K.J. Wieliczko, *AgResearch Ltd.*

This study attempts to exploit the advantages of high and low rigor temperatures to develop a processing regime that will deliver manufacturing beef of desired functionality. Non-stimulated hot-boned semitendinosus muscles were held at 30°C until rigor onset then were transferred to an immersion chiller at -5°C until the completion of rigor. Meat quality from this regime was compared to that from a standard manufacturing-beef chilling regime (blast freezing of hot-boned boxed beef, 30°C, air velocity 3 m/s) and a very fast chilling regime (packaged hot-boned individual cuts immersed in brine at -5°C). Samples from the three regimes were held at -18°C for one month, then were thawed at -1°C and analysed. Chilling regime did not affect the pH, colour, emulsion activity index, emulsion stability or protein solubility of the thawed meat. All three chilling regimes equally caused muscle shortening (sarcomere length was 1.63 to 1.73 µm) and toughening on cooking (MIRINZ Tenderometer values were 16.2 to 17.4 kgF). Chilling regime did not affect the consumer acceptability of soft jerky or roasts made from the meat. Consumers found the soft jerky to be more acceptable overall than the roasts. It is concluded that the effect of rigor temperature on muscle functionality tends to mask the effects of other factors, that electrical stimulation may have to be used for the purpose of manipulating rigor temperatures to achieve desired functionality in rapidly chilled hot-boned beef, and that cold-shortened meat which is too tough for making roast beef can be used to produce a highly acceptable soft jerky.

Key Words: Beef, Rapid chilling, Functional properties

1537 Influence of beef cuts and cooking time on color properties of a beef sausage model system. J.A. Prez-Alvarez¹, J.M. Fernandez-Gins¹, J. Fernandez-Lpez¹, E. Sayas¹, C. Navarro¹, A. Aznar², and E. Sendra¹, ¹ *Universidad Miguel Hernandez*, ² *Universidad Politcnica de Cartagena*.

The influence of beef cuts (lean, dewlap, chop), and cooking time on color evolution during the cooking process was evaluated in a sausage (mortadella type) model system. Four batches of mortadella type sausage (60 units of 200g. each), were manufactured. Nine color determinations were made in each piece following the recommendations of the American Meat Science Association for color measurements in meat and meat products (CIELAB, 1976 color space). Hue (h*) and chroma (C*) were calculated according to the following formulas $h = \text{atan}(b^*/a^*)$ results expressed in degrees, and $C^* = (a^{*2} + b^{*2})^{1/2}$. Analysis of variance (ANOVA) with two factors (meat composition: two levels 40:40:20; 20:40:40 lean: chops: dewlap respectively and cooking time 15 levels, 0, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70 minutes), and Tukey's studentized range test were applied to data (P<0.05). The results of this work are presented in the table. Redness and chroma increased during the cooking time, hue (h*) and yellowness (b*) decreased, this last coordinate was not influenced by meat composition. Lightness evolution during cooking time is related to meat composition, and the meaty system (40:40:20) showed the highest lightness and redness.

1538 Antioxidant effect of dried milk mineral in fresh and cooked ground pork. P. Jayasingh* and D.P. Cornforth, *Utah State University, Logan, UT*.

The antioxidant effects of dried milk mineral (MM), butylated hydroxytoluene (BHT) and sodium tripolyphosphate (STP) were compared in fresh and cooked ground pork stored at 2C. In fresh ground pork, BHT (0.01% of fat) and all levels of MM (0.5, 1, 1.5, 2%) were effective antioxidants, with TBA values < 0.1 after 8 days storage at 2C compared to TBA values > 0.4 for control and samples with 0.5% STP. In cooked ground pork, 0.5% STP and 2% MM were excellent antioxidants, with TBA values < 1.0 after 15 days storage, compared to TBA values > 8 for controls and samples with BHT. Thus, MM was an effective antioxidant in both fresh and cooked pork. STP had antioxidant activity in cooked, but not in fresh ground pork. BHT had antioxidant activity only in fresh ground pork.

Key Words: Antioxidant, Milk, Mineral

1539 Effect of rosemary extract, sodium lactate and film permeability on the shelf-life of vacuum packaged ground ostrich meat. A. C. Seydim, Z. B. Gzel-Seydim, I. Y. Han, and P. L. Dawson*, *Clemson University*.

This research studied the effects of oxygen permeability of films, sodium lactate, and rosemary extract on the shelf-life of vacuum packaged ostrich patties. Ground ostrich patties for each treatment were mixed with 0.02% rosemary extract (AO), 3.3% sodium lactate (SL) and mixture of 0.02% AO and 3.3%SL (MIX). Control (NA) samples containing no additive and samples containing additives were vacuum packaged with high oxygen transmission rate (HiOTR) (4000 cc) and low oxygen transmission rate (LoOTR) (3-6 cc) packaging materials. Samples then were stored at 3±1°C in the dark. Two packages for each treatment were selected at 0, 3, 6, and 9 days to use for pH measurement, 2-thiobarbituric acid (TBA) values, color measurements, and microbiological analysis. There was no significant effect of treatments on pH of meat under different oxygen transmission rate packages OTR (P≥0.05). The pH of ostrich patties ranged from 5.97-6.13. In LoOTR packages, no difference was found between TBA values for all treatments (P≥0.05), whereas in HiOTR packages, AO and SL were significantly different (P≤0.05) than NA and MIX. After 9 day of storage TBA value for NA packaged in HiOTR was 1.64 mg malonaldehyde/kg meat. The control sample had a microbial count of 4.3 CFU/g meat initially. In LoOTR packages, microbial populations (total cell count, coliform, *Lactobacilli* and *B. thermosphacta*) were lower than the HiOTR packages for all treatments. Increase in microbial growth for each treatment was observed during storage, whereas their growth were slowed by addition of SL and MIX to ostrich patties. Samples containing SL and MIX had lower microbial populations than AO and NA. SL and MIX treatments provided 2 log reduction in microbial population during storage in both types of package.

L*, a*, b* values were compared before and after opening the packages for both package type. Total color differences (ΔE) were calculated and reflectance differences ($\Delta R_{630-580}$) were determined. LoOTR packages had better color stability as compared to HiOTR packages. AO had significant effect on the a* values before and after opening the packages ($P \leq 0.05$). Reflectance difference data showed that LoOTR packaged ostrich patties did not lose their appealing cherry-red color during the experiment.

Key Words: Ostrich, Rosemary extract, Shelf-life

1540 **Functionality of prerigor meat on the chemical, physical, and textural properties of beef patties.** J.R. Claus*¹, O. Sorheim², and H.-J. Skarpeid², ¹University of Wisconsin-Madison, ²MATFORSK.

The objectives were to determine the effects of prerigor grinding, prerigor salt injection, and time of cooking on the properties of beef patties. Four patty treatments (six replications) tested were: 1) prerigor ground, patties manufactured, and immediately cooked; 2) prerigor ground, salted, stored overnight; 3) prerigor muscle injected with brine, stored overnight; and 4) postrigor ground. Treatments started with semimembranosus (SM) muscles removed (45 min postmortem) from non-electrically stimulated bull carcasses. Lean was ground through a 3-mm plate. Uncooked patties contained 1.7% sodium chloride and 13% fat. On a lean-only meat basis, patties contained 25% water and 6% starch (native). Patties were cooked to 79 C. The pH values of all treatments were different ($P < 0.05$) and decreased from treatment 1 to 4 (6.23 to 5.53 raw patties; 6.28 to 5.81, cooked patties). Cooking losses were lower ($P < 0.05$) for the two prerigor ground treatments (7.6% and 8.6%) than either treatment 3 (12.6%) or treatment 4 (17.9%). Protein solubility in patties from treatment 1 (67.2 mg/g) was higher ($P < 0.05$) than treatment 4 (44.6 mg/g), while treatment 2 and 3 were intermediate. Instrumental cooked patty hardness values were highest ($P < 0.05$) for treatment 2 (8.9 kg peak force), followed by treatment 1 (6.9 kg), treatment 3 (5.0 kg), and treatment 4 (2.7 kg). Patties manufactured from prerigor ground or injected beef were springier ($P < 0.05$) than patties from postrigor ground beef. Prerigor ground patties were more cohesive ($P < 0.05$) than patties from the injected or postrigor beef. Patty chewiness followed the same pattern as determined for hardness. Tomography X-ray scans of injected SM muscles indicated that sodium chloride was not uniformly distributed at the onset of rigor. This may explain the lower pH in comparison to the prerigor ground treatments. The surface of the patties from the prerigor ground beef was lighter and more yellow ($P < 0.05$) than the other treatments. Prerigor beef can be used to manufacture high yielding, firm cooked patties.

Key Words: Beef, Patties, Prerigor

1541 **Postharvest interventions to overcome the tenderness problems in meat from older animals.** M.B. Solomon*¹, B.W. Berry¹, J. Stika², and W.G. Moody², ¹USDA, ARS, FTSL, Beltsville, MD, ²Univ of Kentucky, Lexington, KY.

Previous studies using hydrodynamic pressure processing (HDP) with meat from older animals (cows) have shown no improvements in tenderness. As a result, the assumption was made that HDP affects myofibrillar tissue and not stromal tissue. It was theorized that including a tenderization treatment (e.g., blade tenderization) which might disrupt the intramuscular connective tissue and when combined with HDP might provide successful tenderization of meat from old cows and cuts of meat with excessive connective tissue. Frozen boneless rib (longissimus) muscles (N=4) from ten year old beef cows and two hot boned (<1 hr postslaughter) strip loins, immediately frozen after boning, from one three year old dairy cow were thawed for 48 h at 2 C, then cut into sections. These sections were designated as controls, blade tenderized (BT) only or BT combined with HDP (100 g of explosive @30.5 cm from the meat surface using plastic explosive containers). For the ten year old cows, BT reduced shear force 13% (5.95 vs 5.16 kg), whereas, BT+HDP reduced shear force 21% (5.95 vs 4.71 kg). For the three year old cow, BT reduced shear force 4% (5.38 vs 5.18 kg) while BT+HDP reduced shear force 17% (5.38 vs 4.49 kg). Results suggest that combining BT with HDP may overcome the tenderness problems often encountered with meat from older animals.

Key Words: Cow beef, Tenderness, Postharvest interventions

1542 **Improving tenderness of beef round and sirloin muscles through pre-rigor skeletal separations.** B. C. Shanks*, D. M. Wulf, B. J. Reuter, J. M. Bok, and R. J. Maddock, South Dakota State University.

Thirty crossbred steers were used to explore and compare tenderness improvements in beef round and sirloin muscles resulting from various methods of pre-rigor skeletal separations. Animals were slaughtered according to industry procedures and at 60 min postmortem one of six treatments was applied to each side: **A**) control, **B**) saw pelvis at the sirloin-round junction, **C**) separate the pelvic-femur joint, **D**) saw femur at mid-point, **E**) combination of B and C, and **F**) combination of B and D. After 48-h, the following muscles were excised from each side: semimembranosus (SM), biceps femoris (BF-R), semitendinosus (ST), and adductor (AD) from the round; vastus lateralis (VL) and rectus femoris (RF) from the knuckle; and gluteus medius (GM), biceps femoris (BF-S) and psoas major (PM) from the sirloin. Following a 10-d aging period, samples were removed from each muscle to determine the effect of treatment on sarcomere length and Warner-Bratzler shear force. Most skeletal separation treatments resulted in longer sarcomeres than controls for SM, AD, ST, and GM muscles. All skeletal separation treatments yielded shorter sarcomeres for the PM as compared to controls. Warner-Bratzler shear force differed among treatments for RF, ST and PM. For RF, treatments C, D, E, and F resulted in lower ($P < 0.05$) shear values than for controls. Treatments B, D, and F increased shear force of the ST relative to controls ($P < 0.05$). Treatment F resulted in higher shear force values for the PM than controls ($P < 0.05$). Correlations between sarcomere length and shear force were found to be low and quite variable among muscles. In general, treatments increased sarcomere length of several muscles from the sirloin/round region, but had mixed effects on shear force values.

Key Words: Beef, Skeletal separations, Tenderness

1543 **Relationship of Pork Quality Traits to Consumer Acceptability.** T.K. Ford*¹, R.K. Miller¹, S.J. Moeller², and R.N. Goodwin³, ¹The Texas A&M University, ²The Ohio State University, ³National Pork Producers Council.

To understand the effect of pork lean quality attributes and consumer acceptability, a centrally-located, consumer sensory study was conducted in Boston, Chicago, and Denver. Consumers were served 12 samples of either pork loin chop, inside ham chop, and chicken breast combinations. Pork was obtained from the National Pork Producers Council's Quality Lean Growth Modeling Project so that pork loin and inside ham chops varied in pH, intramuscular fat, and Warner-Bratzler shear force (kg). Chicken breasts were commercially purchased in each city. Consumers rated overall like, juiciness like, tenderness like and flavor like using 5-point, end-anchored hedonic scales. Pork consumer responses were affected by city, cut and, the interaction of city by cut ($P < .01$). In Boston, cuts were rated lower in juiciness, tenderness, flavor, and overall like (3.3, 3.4, 3.3, 3.3, respectively) than consumer ratings in Denver and Chicago (3.5 and 3.5, 3.6 and 3.5, 3.4 and 3.4, 3.4 and 3.3, respectively). Consumers liked ($P < .01$) the juiciness, tenderness, flavor, and overall acceptance of the chicken breasts when compared to the loin chops (3.6, 4.1, 3.6, 3.7 vs. 3.3, 3.3, 3.3, 3.2, respectively). Consumers liked ($P < .01$) the tenderness and overall acceptability of the loin chops compared to the inside ham chops (3.3, 3.2 vs. 3.2, 3.2, respectively), but both chops were rated similarly for juiciness and flavor (3.3, 3.3 vs. 3.3, 3.2, respectively). pH category affected consumer acceptability. As pH increased from the low and medium pH categories to the high pH category, juiciness, tenderness, and overall like increased ($P = .04$, .0165, and .03, respectively). As Warner-Bratzler shear force values decreased, consumer like ratings increased for juiciness, flavor, tenderness, and overall acceptability ($P = .0001$) for loin chops. Lipid category did not affect consumer sensory responses for juiciness, tenderness, flavor, and overall acceptability ($P = .20$, .19, .09, and .18, respectively). As pH increased, consumers liked the juiciness, tenderness, flavor, and overall acceptability of inside ham cuts ($P < .05$). Consumers liked the tenderness of inside ham chops with lower Warner-Bratzler shear force values ($P < .05$).

Key Words: pork, consumer, quality

1544 **Repeatability of Warner-Bratzler shear values in beef steaks using three different cooking methods.** C.R. Kerth*, L.K. Blair-Kerth, and W.R. Jones, Auburn University, Auburn AL.

Instruments used to cook steaks and chops are often inconsistent because of variability in cooking temperatures across the instrument and

from one instrument to the next. Recently research has shown that belt grills are an effective way to cook steaks and chops very rapidly with high repeatability. However, these belt grills are very expensive. The objective of this research was to compare the repeatability of WBS values from steaks that were grilled using a small kitchen clam-shell grill (GRILL), versus AMSA-recommended oven roasting (OVEN), or oven broiling (BROIL) cooking methods. These small, clam-shell grills cook by direct contact with the steaks on both sides, are inexpensive, and are readily available at department and discount stores. To test the effectiveness of these cooking methods, 12 no-roll boneless strip loins were cut into nine 2.5-cm-thick steaks starting from the anterior end. The steaks then were separated into groups of three: the three anterior steaks, the three middle steaks and the three posterior steaks. Each group of steaks was then randomly assigned one of the three cooking methods (OVEN, BROIL, OR GRILL). Steaks were cooked until they reached a final internal temperature of 71°C. Steaks cooked with the BROIL method were turned at 40°C. After cooling to less than 10°C, six 1.3-cm-diameter cores were removed parallel to the length of the muscle fiber and sheared once across the center using a WBS machine. Cooking time for the GRILL method (7.1 min) was shorter, and the OVEN method (22.8 min) was longer compared to the BROIL cooking method (17.5 min, $P < 0.001$). Percent cooking loss was higher ($P < 0.001$) for the BROIL method compared to either OVEN or GRILL cooking methods. However, final cooking temperatures and WBS values did not differ among cooking methods ($P > 0.25$). WBS values across all cooking methods ranged from 1.5 to 7.5 kg. Repeatability of WBS was relatively high for BROIL ($r = 0.83$), GRILL ($r = 0.88$) and OVEN ($r = 0.88$) cooking methods. These data indicate that, in addition to traditional broiling and oven roasting cooking methods, grilling beef loin steaks with an inexpensive clam-shell grill is an acceptable method for cooking steaks for research purposes.

Key Words: Cooking Method, WBS, Clam-shell Grill

1545 Sample location within muscle affects pork quality measurements. E.W. Mills*, S.L. Flowers, and B.M. Moser, Penn State University, University Park PA.

When collecting lean for quality measurements it is customary to take samples from several locations in a muscle cross-section and assume that they represent one population of samples. The purpose of the current work is to test that assumption by evaluating variation in pork quality measurements due to location within a muscle. In the first trial two 25 mm chops were removed from the longissimus thoracis at the tenth rib of 10 market hog carcasses at 24 h postmortem. Twenty-five and 13 mm cylindrical cores were removed near the medial and lateral edges of each chop. Water holding capacity measures were made on the cores - filter paper press method for 0.5g samples from the 13 mm cores and drip loss method for 25 mm cores. Lateral edge samples gave greater ($p < 0.01$) drip loss than medial edge samples after 24 h (5.02 vs. 1.87%) and after 48 h (6.08 vs. 2.63%). Filter paper press results indicated a similar trend in free water % for lateral and medial samples respectively (37.5 vs. 35.7%) but did not indicate a significant difference ($p > 0.30$). In a second trial cores were removed from medial, lateral, ventral and dorsal edges of 25 mm longissimus thoracis chops at 24 hours postmortem for 10 market hogs. In addition to water holding capacity measures as in trial 1, pH, color (L^* , a^* , b^*) and proximate composition were measured. Moisture, protein and fat did not vary significantly ($p > 0.30$) by location. Muscle pH was higher ($p < 0.02$) for medial vs. lateral and dorsal locations with no significant differences among lateral, dorsal and ventral locations. Redness, a^* value, and yellowness, b^* value, were significantly higher ($p < 0.01$) for lateral vs. each other location. Percent free water was highest for lateral and ventral locations but did not differ significantly ($p > 0.30$) among locations (lateral - 35.9%, ventral - 35.9, dorsal - 34.3 and medial - 33.4). Fluid loss after 48 h was greater ($p < 0.05$) for lateral (5.94%) vs. medial (4.52%) or dorsal (4.68%) locations. This work shows that muscle water holding capacity and color vary with location in the cross section of the longissimus thoracis and that drip loss measurement is more sensitive than free water (filter paper press) measurement for assessing meat water holding capacity.

Key Words: Water Holding Capacity, Drip Loss, Color

1546 Heat Penetration Patterns Of Biceps Femoris, Longissimus Lumborum And Semitendinosus Muscles Cooked By Electric Broiler, Electric Belt Grill, Or Forced-Air Convection Oven. E. Obuz, E. J. Yancey, T. E. Lawrence, D. A. King, and M. E. Dikeman, Kansas State University.

The objective of our study was to investigate heat penetration patterns of beef longissimus lumborum, biceps femoris, or semitendinosus muscles cooked by an electric broiler, belt grill, or forced-air convection oven. Subprimals (beef loin, boneless strip loin; beef round, bottom) from USDA Select carcasses were purchased and divided into the respective muscles. Muscles were vacuum packaged and held at 1C for 14 days and then frozen (-37C). Each frozen muscle was sawed into 2.54-cm thick steaks, vacuum packaged, and stored until cooking. Steaks were thawed and held at 4C for 24 h before cooking and were assigned to one of three cooking treatments: an electric belt grill at 163C, a forced-air convection oven at 163C, or an electric broiler (no temperature control). All steaks were cooked to 70C and the center temperature of steaks was monitored using copper-constantan thermocouples. A temperature recorder was used to follow the cooking pattern of steaks and data from the temperature recorder for each steak were retrieved and used to calculate the heat penetration rate for each muscle as min/C. Belt grill cookery gave the highest heat penetration rate for all muscles (three to seven times faster than the other two methods). Within any given temperature range, the semitendinosus required more heat than the other two muscles, which may be explained by its fiber orientation. Up to 40C, heat penetration rate was relatively slow for all muscles. However, heat penetration rate into all muscles decreased above 40C ($p < 0.05$), which likely was because of denaturation of contractile proteins starting at about 40C. The slowest heating rates occurred in the 60-70C interval and can be attributed to collagen shrinkage and protein denaturation. Heat penetration rate between 10 and 20C for the semitendinosus muscle cooked by either forced-air convection oven or electric broiler was almost three times faster than it was between 60 and 70C. Belt grill cookery did not allow us to detect muscle differences in any temperature range because heat transfer was very fast.

Key Words: Heat penetration, electric belt grill, forced-air convection oven

1547 Instruments differ in estimating lightness of fresh meat. C.P. Allison*, R.O. Bates, M.E. Doumit, and A.M. Booren, Michigan State University, East Lansing, MI.

There are many portable instruments available to measure lightness of meat, yet their equivalence is poorly understood. The objective of this study was to determine if differences exist between CIE L^* values determined by three instruments, the Minolta chromameter (M; illuminant D_{65} with a 2° observer), the Hunter Mini-scan spectrophotometer (H; illuminant D_{65} with a 10° observer) and the ColorTec (C; illuminant D_{65}). Color readings were taken on turkey *pectoralis superficialis* (major; $n=80$), pig *gluteus medius* ($n=60$), pig *gluteus accessorius* and *profundus* ($n=60$) muscles. Hunter mini-scan reported twice the variation in L^* values compared to the other two devices (23.13 vs. 12.5 in pig and 6.53 vs. 3.0 in turkey). Due to this heterogeneity of variance, data were normalized to a mean of 0 and a variance of 1. Normalized values were then used for all statistical analyses. The correlations (r) for L^* values of H versus M, M versus C, and H versus C were .90, .82 and .77, respectively and were different from zero ($P < .0001$). However, the r of H with M was higher than the r of M with C and the r of H with C ($P < .01$). The r of M with C was not different from the r of H with C ($P > .05$). We conclude that one instrument should be used to collect data for a given evaluation or experiment, since L^* readings from different devices are not equivalent.

Key Words: Instrument, L^*

1548 Effects of high protein/low carbohydrate swine diets during the final finishing phase on pork muscle quality. J.B. Bok*, D.M. Wulf, B.C. Shanks, B.A. Reuter, and R.J. Maddock, South Dakota State University, Brookings, SD.

The aim of this study was to lower the glycogen stores in pork muscle in order to improve pork muscle quality by feeding an ultra-high protein/low carbohydrate (HIPRO) diet. Fifty barrows (average live weight = 92 kg) were assigned across five treatments and two reps (five pigs per treatment by rep combination). All barrows were fed a control diet

(13.1% CP) until their assigned treatment began. A treatment was the number of days the barrows were fed the HIPRO diet prior to harvest (0, 2, 4, 7, and 14 d). The HIPRO diet (35.9% CP) was 97% extruded soybeans. Daily feed intake and weekly live weights were recorded for all barrows. At-death blood glucose levels were determined. Muscle pH, temperature and electrical impedance were measured in the longissimus lumborum and semimembranosus muscles at 45 min, 3 h and 24 h postmortem. Glycolytic potential, Minolta L*a*b* values, visual scores for color, firmness and marbling, water-holding capacity traits (drip loss, purge loss and cooking loss) and Warner-Bratzler shear force values were determined in the longissimus thoracis et lumborum. Weight gain per day decreased the longer the pigs were fed the HIPRO diet ($P < 0.05$). Daily feed intake decreased during the first week on the HIPRO diet, but returned to near-control levels during the second week, which when coupled with the continued decreases in daily gain, resulted in substantial decreases in feed efficiency during the second week on the HIPRO diet ($P < 0.05$). Blood glucose levels and glycolytic potentials were not lowered by feeding the HIPRO diet ($P > 0.05$); and therefore, no differences in rate of pH decline or ultimate pH among dietary treatments were found ($P > 0.05$). Likewise, there were no differences among dietary treatments in any of the measured meat quality attributes ($P > 0.05$). Feeding barrows the HIPRO diet for a time period prior to slaughter decreased feed intake, rate of gain, and feed efficiency, and was not effective at lowering glycolytic potential or improving pork muscle quality.

Key Words: Pork quality, muscle glycogen, Muscle pH

1549 Effect of supplemental fat on growth, quality, palatability, and fatty acid composition of beef from steers fed barley-potato product finishing diets. D. J. Marks^{*1}, J. R. Busboom¹, M. L. Nelson¹, J. D. Cronrath¹, L. Falen¹, A. E. Koepp¹, and P. S. Kuber¹, ¹Washington State University.

The objective was to evaluate the effects of supplemental fat in finishing diets on feedlot performance, carcass and shelf-life properties, and fatty acid composition of beef. One hundred sixty-eight crossbred steers (318 2.8 kg) were allotted within weight block (3) to a randomized complete block design with a 2 x 3 + 1 factorial arrangement of dietary treatments. Main effects were level of yellow grease (YG; 0, 3, and 6%), and level of alfalfa hay (3.5 and 7%) with the added treatment of 6% tallow and 7% alfalfa hay in barley-based diets containing 15% potato by-product and 7% supplement fed for 165 d. Growth and carcass data were determined on all steers, while longissimus muscle (LM) from four randomly selected animals per pen were used for shelf-life, trained panel and fatty acid analysis. Average daily gain linearly increased ($P < 0.05$) with YG from 1.5 to 1.6 0.16 kg/d and decreased ($P < 0.05$) feed-to-gain from 5.9 to 5.5 0.16. Level of alfalfa hay interacted with YG on backfat, marbling score, beef color score, and percentage choice. Backfat increased with 3.5%, but not 7% alfalfa diets. Marbling was maximized at 3.5% hay, but minimized at 7% hay with the 3% yellow grease diet. There were no effects of diet ($P > 0.1$) on color score, retail purge score, and L*, a* and b* values. Sensory panel initial tenderness scores increased quadratically ($P < 0.10$) with YG from 7.2 to 7.6 to 7.4 0.1, and decreased ($P < 0.10$) with alfalfa level. Diet did not affect total fatty acid (FA) content (DM basis) of LM (143 4.5 mg/g) or fat (958 9.3 mg/g). Level of yellow grease increased CLA quadratically ($P < 0.01$) in LM from 0.45 to 0.64 to 0.62 0.02 g/100g FA and fat from 0.61 to 0.835 to 0.825 0.02 g/100g FA. Yellow grease in the diet increased feedlot performance with no detrimental effects on shelf-life and increased CLA content of beef with no increase in total FA content.

Key Words: Barley, Yellow Grease, CLA

1550 Sensory evaluation of pork longissimus muscle from swine fed soybean meal from Roundup Ready[®] or conventional soybeans. C. L. Armstrong^{*}, W. B. Mikel, and G. L. Cromwell, University of Kentucky, Lexington, KY.

A study was conducted to evaluate the effects of feeding dehulled soybean meal (SBM) from genetically-modified, herbicide-tolerant soybeans containing the CP4 EPSPS protein (Roundup Ready[®] [RR]) or near-isogenic conventional (C) soybeans on sensory ratings, Warner Bratzler Shear (WBS) force, and cook loss of pork longissimus muscle (LM). Soybeans were grown in year 2000 under similar agronomic conditions, the RR soybeans were sprayed with Roundup[®], and both were processed at the same plant. Crossbred pigs (n=100) were fed fortified

corn-soy diets containing C- or RR-SBM from 24 to 111 kg BW. Loins (n=30) were obtained from 15 barrows/treatment (three replications of five pigs/replication). Fresh LM samples were removed at 24 h post-mortem and frozen until analysis for sensory and chemical traits. Three (2.54 cm thick) chops were cooked on a Farberware grill to an internal temperature of 71 C. An experienced sensory panel evaluated each chop for juiciness, tenderness, off flavor, flavor intensity, connective tissue and overall acceptance on a scale from 1 to 8, with 8 being the most desirable. Weights were recorded before and after cooking to determine cook loss. Three 1.26 cm cores were taken from each of the two remaining cooked chops for WBS force determination. Chemical analysis showed percentage of fat between chops from the two treatments tended to be slightly higher for the RR-SBM group (3.10 vs 2.74). Sensory analysis revealed that the C-SBM versus RR-SBM treatment groups were not different ($P > 0.05$) in juiciness (5.52 vs 5.58), tenderness (5.91 vs 6.10), off flavor (7.08 vs 7.18), flavor intensity (5.74 vs 5.95), connective tissue (6.54 vs 6.53) or overall acceptance (5.80 vs 6.05). Also, WBS force values (3.95 vs 3.58, kg) and cook loss (31.97 vs 30.28, %) were not different ($P > 0.05$) between the two treatment groups. Thus, these results indicate that type of soybean meal in feed had no effect on product quality.

Key Words: Pork, Sensory, Biotechnology

1551 Assessing Real Time Augmentation of USDA Yield Grade Application to Beef Carcasses Using Video Image Analysis (VIA) Instrumentation. R. Steiner^{*1}, A.M. Wyle², K.E. Belk¹, J.A. Scanga¹, J.W. Wise³, J.D. Tatum¹, and G.C. Smith¹, ¹Colorado State University, Fort Collins, CO/ USA, ²Research Management Systems, Fort Collins, CO/ USA, ³USDA AMS Branch, Washington, DC/ USA.

ABSTRACTword This study assessed the ability of two video image analysis (VIA) instruments, VIAscanTM and Canadian Vision System (CVSTM), to augment the assignment of USDA Yield Grades (YG) to beef carcasses, to the nearest tenth of a grade, under commercial operating conditions, and to test the accuracy of cutability predictions. Steer and heifer carcass sides (n = 290) were selected to vary in fatness, muscling and weight. Carcasses were assigned augmented YG (AYG), to the nearest tenth (i.e., YG 1.3, 2.6, 4.9), on an automated grading chain (360 head/hour) by each of the two VIA systems, and subsequently fabricated into closely-trimmed (.6 cm) subprimal cuts. Augmented YG that included line graders' estimates for adjusted PYG, and VIA measured ribeye area were highly correlated (r = .92 and .95 for VIAscanTM and CVSTM, respectively) with Gold Standard YG (committee of experts, at their leisure). Cutability prediction accuracy increased to levels near those achieved by expert whole YG, where VIAscanTM AYG, CVSTM AYG and expert whole YG accounted for 59, 60, and 62 percent of the variation in fabricated yields of closely-trimmed subprimal cuts, respectively. Video Image Analysis technology for use in the augmentation of USDA YG appears to be a useful tool for increasing the accuracy and objectivity of USDA YG application, as well as for improving the accuracy of prediction of subprimal yields. Augmentation of USDA YG through use of VIA instrumentation improves USDA line graders YG assignment accuracy. Assigning USDA YG to the nearest tenth would provide substantial economic benefit to the beef industry, allowing fabrication styles and inventories to be more closely managed. VIA instrumentation is a viable augmentation option for use by USDA line graders in assigning YG to the nearest tenth.

Key Words: Subprimal, Yield, Augmentation, Video Image Analysis

1552 Ozonation of animal wastewater to reduce environmental impact. J. K. Duke^{*}, L. W. Grimes, G. C. Skelley, and A. K. Greene, Clemson University.

Samples of wastewater from a confined animal feeding operation (CAFO) and a slaughter facility were ozonated and analyzed for reduction in biochemical oxygen demand (BOD₅), chemical oxygen demand (COD), coliform bacterial content, and aerobic bacterial content. Samples from the swine farm were collected from the flush pit of a 125 head swine-feeding floor. Subsamples were collected after 0.0, 0.5, and 1.0 hr of laboratory ozonation. At the cattle packing plant (500 head per day), samples were collected from the harvest floor and from the anaerobic lagoon discharge. After transport to the laboratory, samples were ozonated for 0.0, 0.25, 0.5, 0.75, and 1.0 hr. Ten-milliliter subsamples

were collected for analysis at each time interval. BOD₅ and COD determinations indicated reductions across all times on all samples. Coliform and aerobic bacterial content were measured using 3M Petrifilm[®]. Results indicated significant reduction ($P < 0.05$) in mean bacterial plate counts of 1 to 3 log for all samples over all times for both coliform and aerobic plate determinations.

Key Words: Wastewater, Ozonation, Environment

1553 Reducing airborne bacteria and molds using a germicidal air cleaning system. C.J. Cundith*, C.R. Kerth, W.R. Jones, T.A. McCaskey, and D.L. Kuhlers, *Auburn University, Auburn AL.*

The objectives of this study were to determine the effectiveness of a germicidal air cleaning system on the reduction of airborne molds and bacteria in a controlled environment and in a meat processing plant. Components of the cleaning unit were tested to determine their individual effectiveness. The UV light alone was capable of a 4.99 log reduction in Gram-positive bacteria (*Micrococcus luteus*) and a 5.76 log reduction in Gram-negative bacteria (*Serratia marcescens*). The filter alone, filter and electrically polarized, low-density media combined and the filter, electrically polarized, low-density media and UV light combined reduced ($P < 0.05$) *M. luteus* (84.0, 90.9, and 92.3% respectively) and *S. marcescens* (84.1, 87.3, and 90.2% respectively). The cleaning units were also examined for their effectiveness in reducing indigenous airborne bacteria and molds from ambient air in production conditions. Two types of cleaning units were used, a duct-mounted unit and wall-mounted console units. Testing was done at 3, 6, 9 and 24 hours after the duct-mount units were activated. The duct-mounted cleaning units reduced ($P < 0.05$) airborne molds by 66.8% in the heating, air conditioning and ventilation unit, and were found to be effective ($P < 0.05$) within 3 hours after activation. The console wall mounted units were tested under controlled conditions in the meat carcass chill cooler, processing room and carcass aging cooler using 1, 2, 3 or 4 cleaning units. Using 2, 3 or 4 units reduced ($P < 0.05$) airborne bacteria and molds. The console units then were tested in the processing room for their effectiveness in reducing airborne bacteria and molds in production conditions. Three and four cleaning units reduced airborne bacteria (21.6 to 61.4%) and molds (20.3 to 63.2%) during production in the processing room. Without the cleaning units in the processing room, both bacteria and mold counts increased ($P < 0.05$) from day 1 to day 4. These data indicate that germicidal air cleaning units containing UV light, filter, and low-density polarizing media are effective in reducing airborne bacteria and molds in a meat processing environment.

Key Words: Airborne, Bacteria, Mold

1554 Development of decontamination procedures for beef trimmings. C. S. Ebeling*, R. K. Miller, and G. R. Acuff, *Dept. Animal Sci., Texas A&M University, College Station, TX.*

Escherichia coli O157:H7 has become recognized as an important food-borne pathogen, with undercooked ground beef identified as the most frequent outbreak cause. Beef trimmings present a challenge to the meat industry due to a higher degree of bacterial contamination occurring in ground beef than in whole-muscle products because of extensive handling procedures during production. Interventions are needed to reduce microbiological levels on beef trimmings. Beef trimmings of 73/27 or 50/50 lean and fat content were obtained from a commercial plant. Trimmings were randomly assigned to four treatments: control, 4% lactic acid (LA), 4% lactic acid plus hot water (LA+HW), and 4% lactic acid plus 10% trisodium phosphate plus hot water (LA+TSP+HW). Meat color was evaluated on both trimming types before and after treatment and on ground beef chubs on days 0, 7, 14, 21, and 28 of storage. The L*, a*, and b* color space values were determined to measure objective color, and trained color panel was used to measure subjective color. After treatment, the lean color of all trimming types was darker ($P < 0.01$) or grayer ($P < 0.01$) in the LA+HW or LA+TSP+HW treated trimmings. Lean color of the ground beef was not noticeably darker ($P < 0.05$) due to treatment after grinding, but the LA treatment resulted in visually darker ($P < 0.01$) ground beef especially with subsequent storage time. A trained descriptive attribute panel evaluated flavor quality characteristics of the ground beef patties on each storage day. The LA treated patties had slightly lower levels of cooked beef/brothy ($P < 0.01$), cooked beef fat ($P < 0.01$), and grainy ($P <$

0.01) flavors. Total aerobic plate counts (APC) were measured on excised sample after treatment and on ground samples on each storage day. The LA+HW and LA+TSP+HW treatments reduced surface APC of trimmings by $1 \log_{10}$ CFU/cm². However, treating beef trimming with LA reduced the APCs of the ground beef by $1.3 \log_{10}$ CFU/g and lowered ($P < 0.01$) APCs on days 7, 14, and 21 compared to control and other treatments. These treatments, especially LA+HW would be an acceptable intervention step to be further examined to assist in decontamination of beef trimmings without adversely effecting shelf-life and flavor attributes.

Key Words: beef, decontamination

1555 Processing and product development of goat meat products: fermented cabrito snack stick and cabrito smoked sausage. G.H. Cosenza*, S.K. Williams, D.D. Johnson, and C. Sims, *University of Florida, Gainesville, FL.*

The production of high quality, value added goat meat products could increase the consumption, acceptability and marketability of goat meat. The objectives of this study were to develop a fermented cabrito snack stick and a cabrito smoked sausage containing different levels of soy protein concentrate in an effort to reduce their final product costs; conduct consumer acceptance, proximate analysis, pH, water activity and smoke-house yields and losses to evaluate and ensure quality and acceptance of these goat meat products; and to perform a comparative cost analysis to determine cost benefit of using soy protein concentrate in formulation of fermented cabrito snack stick and cabrito smoked sausage products. The levels of soy protein concentrate used to replace the goat meat were 0%, 1.75% and 3.50%. The trained panelists detected no significant "soy" off-flavor differences ($P > 0.05$) between the three formulation levels of soy protein concentrate for the fermented cabrito snack stick and cabrito smoked sausage. The consumer panelists detected no significant differences ($P > 0.05$) in the flavor, texture and overall acceptance attributes for the fermented cabrito snack sticks, and the cabrito smoked sausage products formulated with 0% and 3.50% soy protein concentrate. The fermented cabrito snack sticks formulated with 3.50% soy protein concentrate had a lower ($P < 0.05$) fat content than the 0% level. The fermented cabrito snack sticks formulated with 0% soy protein concentrate had the highest price of \$1.31, and the 3.50% level had the lowest price of \$1.25 per 42.61g serving size. There were no differences ($P > 0.05$) in moisture, fat and protein for the cabrito smoked sausage formulated with 0% and 3.50% soy protein concentrate. The addition of soy protein concentrate resulted in a \$1.30 per kg reduction in the price of the cabrito smoked sausage formulated with 3.50% soy protein concentrate (i.e., cost was \$13.49 per kg), when compared to the sausage formulated with 0% soy protein concentrate (i.e., cost was \$14.79 per kg). This project will enhance the marketability of goat meat and provide new and successful markets for Florida's goat industry.

Key Words: Goat Meat, Fermented Cabrito Snack Stick, Cabrito Smoked Sausage

1556 Use of sodium citrate to enhance tenderness and palatability of pre-rigor beef muscles. C. D. Perversi*¹, C. R. Calkins¹, and J. Velazco², ¹*University of Nebraska-Lincoln*, ²*Instituto Tecnológico de Estudios Superiores de Monterrey, Monterrey, Mexico.*

Previous research demonstrated glycolytic inhibition enhanced beef tenderness, despite causing substantial contraction by injection and tumbling of pre-rigor muscles. This project was designed to evaluate the effects of pre-rigor treatment with sodium citrate on the tenderness and palatability of beef muscles from the thoracic limb; the muscles were injected while maintaining skeletal restraints to contraction. Thoracic limbs from 14 steers were removed within 2 hr post-mortem and pumped to 10% of muscle weight with water, 200 mM, or 400 mM sodium citrate solutions. Controls remained on the carcass during chilling. Steaks (2.54 cm thick) were removed after 24 hours from the *Infraspinatus*, *Supraspinatus*, and *Triceps brachii* muscles and were either frozen immediately or aged for 6 more days. A consumer panel evaluated palatability (juiciness, tenderness, connective tissue amount, and flavor desirability) on *Infraspinatus* and *Triceps brachii* steaks using 9-point hedonic scales. Warner-Bratzler shear force values on 1.27 cm-diameter cores were determined on all muscles. Treatment with 400 mM sodium citrate improved shear force values over the control in all three muscles (3.32 vs. 3.61 kg and 2.79 vs. 3.50 kg for d1 and d 7 *Infraspinatus*

[$P < .10$]; 3.55 vs. 3.71 kg and 3.09 vs. 3.59 kg for d1 and d7 *Triceps brachii* [$P < .10$]; 4.19 vs. 5.30 kg and 4.03 vs. 4.78 kg for d1 and d7 *Supraspinatus* [$P < .05$], respectively). Tenderness ratings followed the same trend as shear force values. Flavor desirability ratings of beef treated with 200 or 400 mM sodium citrate were equal or superior control muscles. These data indicate that sodium citrate may be applied to pre-rigor beef muscles (constrained from contraction) to enhance tenderness and palatability.

Key Words: Beef, Tenderness, Palatability

1557 Mapping intramuscular tenderness variation in four major muscles of the beef round. B. J. Reuter*, D. M. Wulf, B. C. Shanks, J. M. Bok, and R. J. Maddock, *South Dakota State University, Brookings, SD.*

The objective of this project was to quantify intramuscular tenderness variation within four muscles from the beef round: biceps femoris (BF), semitendinosus (ST), semimembranosus (SM), and adductor (AD). At 48 h postmortem, the BF, ST, SM, and AD were dissected from either the left or right side of ten carcasses, vacuum packaged, and aged for an additional 8 d. Each muscle was then frozen and cut into 2.54-cm-thick steaks perpendicular to the long axis of the muscle. Steaks were broiled on electric broilers to an internal temperature of 71 C. Location-specific cores were obtained from each cooked steak and Warner-Bratzler shear force was evaluated. Definable intramuscular tenderness variation (SD = 0.56 kg) was almost twice as large as between-animal tenderness variation (SD = 0.29 kg) and 2.8 times as large as between-muscle variation (SD = 0.20 kg). The ranking of muscles from greatest to least definable intramuscular tenderness variation was BF, SM, ST, and AD (SD = 1.09, 0.72, 0.29, and 0.15 kg, respectively). The BF had its lowest shear force values at the origin (sirloin end), intermediate shear force values at the insertion, and its highest shear force values in a middle region 7 to 10 cm posterior the sirloin-round break point ($P < 0.05$). The BF had lower shear force values towards the ST side than towards the vastus lateralis side ($P < 0.05$). The ST had its lowest shear force values in a 10 cm region in the middle, and its highest shear force values towards each end ($P < 0.05$). The SM had its lowest shear force values in the first 10 cm from the ischial end (origin), and its highest shear force values in a 13 cm region at the insertion end ($P < 0.05$). Generally, shear force was lower towards the superficial (medial) side than towards the deep side of the SM ($P < 0.05$). There were no intramuscular differences in shear force values within the AD ($P < 0.05$). These data indicate that definable intramuscular tenderness variation is substantial and could be used to develop alternative fabrication and (or) merchandising methods for beef round muscles.

Key Words: Beef, Intramuscular, Tenderness

1558 Chemical characterization of beef inside and outside semimembranosus for improved color stability. LM Sammel*¹, MC Hunt¹, and DH Kropf¹, ¹*Kansas State University.*

The color instability of the beef semimembranosus (SM) has been troublesome to the meat industry and continues to be problematic in modified atmosphere packaging. The deep or inside portion of the SM (ISM) is lighter in color and discolors faster than the superficial or outside SM (OSM). The relationships of 5 assays for metmyoglobin reducing ability with color stability were determined at 5 and 14-days of storage. Combinations of cold or hot boning with and without electrical stimulation were used to create different postmortem declines in temperature and pH for the ISM and OSM to examine effects on chemical characteristics and initial color and stability. Aerobic reducing ability and reduction of nitric oxide metmyoglobin showed less activity in the ISM than OSM, and in tissue stored 14 compared to 5 days. The assay for total reducing activity and reduction of dichlorophenolindophenol showed more activity in muscles stored 5 compared to 14 days but showed few differences between the muscle portions. Reductions of horse and bovine metmyoglobins were inconsistent between muscle portions and storage times. Aerobic reducing ability correlated best with visual panel scores and metmyoglobin accumulation in the SM. Cold-boned ISM had a slower chill rate; faster pH decline; more denatured protein; less metmyoglobin reducing ability, oxygen consumption, and water-holding capacity; and a lighter, less stable color than the OSM. Cold-boned steaks were two-toned in color and discolored by day 3 of display. Hot-boned ISM and OSM chilled at the same rate and had similar pH declines, similar chemical characteristics, and acceptable color traits up to day 5 of display.

Myoglobin concentration, heme iron, nonheme iron, and lipid oxidation did not explain differences in color stability between the ISM and OSM. Methods that chill the ISM more rapidly should produce a more uniform, stable color by conserving reducing ability and protein integrity. Extending the color life of the ISM should reduce the need for reworking and discounting after only 2 days of retail display.

Key Words: Semimembranosus, Metmyoglobin, Color Stability

1559 Effects of cold shortening and cooking rate on tenderness, postmortem proteolysis, and cooking traits of beef longissimus and triceps brachii muscles. D.A. King*¹, M.E. Dikeman¹, T.L. Wheeler², C.L. Kastner¹, and M. Koochmariaie², ¹*Kansas State University, Manhattan, KS,* ²*Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, NE.*

Our study evaluated the effects of cold shortening and cooking rate on postmortem proteolysis, tenderness, and cooking traits of beef longissimus thoracis (LT) and triceps brachii, long head (TB) muscles. The LT and TB were removed at 45 min (left side) and 24 h (right side) postmortem from 12 carcasses and trimmed of fat. Muscles removed at 45 min were placed in an ice bath to induce cold shortening. At 24 h postmortem, muscles were cut into 2.54 cm steaks and assigned to aging (1 or 14d) and RAW and cooking (FAST or SLOW) treatments. Steaks were cooked at 260° C (FAST) or 93° C (SLOW). Cooking loss (CL), cooking time (CT), and Warner-Bratzler shear force (WBSF) were measured for cooked steaks. Sarcomere length (SL) and the extent of proteolysis of desmin were measured on all steaks. Rapid chilling resulted in shorter ($P \leq .05$) SL. TB steaks had longer ($P \leq .05$) SL than LD steaks. RAW steaks had longer ($P \leq .05$) SL than cooked steaks regardless of shortening. FAST cooking resulted in shorter ($P \leq .05$) SL than SLOW cooking in normal steaks, but cooking rate had no effect on shortened steaks. Generally, TB steaks required longer ($P \leq .05$) CT and had higher ($P \leq .05$) CL than LT steaks, and FAST cooked steaks had greater ($P \leq .05$) CL than SLOW cooked steaks. Shortened steaks had less ($P \leq .05$) degradation of desmin than normal steaks (31 vs. 41%, respectively). Aging for 14d increased ($P \leq .05$) desmin degradation. Cold shortening resulted in much higher ($P \leq .05$) and aging resulted in lower ($P \leq .05$) WBSF values. SLOW cooked TB steaks were more tender ($P \leq .05$) than FAST cooked TB and FAST and SLOW cooked LT steaks. These data indicate that shortened muscles undergo proteolysis, but at a slower rate than normal muscles. Cooking rate did not affect tenderness of LT steaks, but SLOW cooking resulted in lower WBSF values for TB muscles, presumably because of collagen solubilization.

Key Words: Beef Tenderness, Proteolysis, Cooking

1560 Relationships between mechanical tenderness measurements and trained sensory panel attributes of beef Longissimus lumborum muscle. T. S. Hively*¹, R. K. Miller¹, D. S. Hale¹, D. K. Lunt², T. L. Wheeler³, and M. Koochmariaie³, ¹*Dept. Animal Sci., Texas A&M University, College Station, TX,* ²*Texas Agriculture Experiment Station, McGregor, TX,* ³*Roman L. Hruska U. S. Meat Animal Research Center, Clay Center, NE.*

Mechanical assessment of beef tenderness is widely used. Varying methods have been reported in the scientific literature: Warner-Bratzler shear force (WB), Allo-Kramer shear force (AK), and slice shear force (SS). In addition, trained meat descriptive attribute sensory evaluation of myofibrillar tenderness (MT), connective tissue amount (CT) and overall tenderness (OT) are used to evaluate tenderness of beef. The objective of this research was to understand the relationships between these mechanical measures of tenderness and trained meat descriptive attribute sensory panel ratings of beef tenderness. Beef steers ($n = 63$) varying in live animal characteristics to induce variation in tenderness were slaughtered, electrically stimulated, and two strip loins (IMPS -180) were removed 48 h postmortem. Loins were subsequently vacuum-packaged, aged 14 d at 5C and then cut into 2.54 cm thick steaks. Within each animal, steaks were randomly assigned to one of four treatments: WB, AK, SS or trained sensory evaluation of MT, CT and OT using 8-point scales (1 = extremely tough, abundant and extremely tough; 8 = extremely tender, none, extremely tender, respectively). Steaks varied in tenderness across mechanical and sensory measures (2.4 to 7.4 kg for WB, 8.1 to 27.8 kg for AK, 7.0 to 42.4 kg for SS, 3.7 to 7.6 for MF, 4.7 to 7.9 for CT and 3.7 to 7.6 for OT). Mean measures for tenderness were 4.1 kg for WB, 13.6 kg for AK, 15.7 kg for SS, 6.3 for MT, 7.0 for CT and 6.3 for OT. The OT and WB values were correlated at -0.70 (P

< 0.01) whereas OT and AK were correlated at -0.61 ($P < 0.01$) and OT and SS at -0.70 ($P < 0.0001$). Respective correlation coefficients between MT and WB, AK and SS were -0.70, -0.59 and -0.60; while simple correlation coefficients between CT and WB, AK and SS were -0.66, -0.60 and -0.51, respectively. As expected, correlation coefficients among sensory measures were high (> 0.9 , $P < 0.01$). These data indicate that the common mechanical measurements of beef tenderness are highly correlated to each other and they are highly correlated to trained sensory measures of beef tenderness, although the apparent lower correlation between SS and OT as compare to WB and AK may be due to differences in cooking method (belt grill vs. electric grill).

Key Words: beef, shear force, tenderness

1561 Quality evaluation of case-ready beef steaks from various USDA grades. J. M. Behrends^{*1}, W. B. Mikel¹, C. L. Armstrong¹, Y. L. Xiong¹, and S. Harris², ¹University of Kentucky, ²Cryovac/Sealed Air Corporation.

Introduction of case-ready fresh meats to the marketplace has demonstrated a need to evaluate the benefits of this technology. The objectives of this study were to evaluate visual and chemical attributes of three different USDA quality grades (High Choice and above, Low Choice, Select) and three different muscles (semimembranosus, semitendinosus, and biceps femoris) of beef steaks encased in high-oxygen (80% O₂/20% CO₂) modified atmosphere packaging (MAP). Steaks from each treatment group (3 muscles, 3 grades, 2 packaging types) were displayed under retail conditions for 1, 3, 5, 7, and 10 d. Three steaks from each muscle-grade-package type combination were evaluated on each day by a five-member trained panel for visual color (lean color, discoloration, overall acceptability) and analyzed with a Minolta Chroma Meter CR-300 for L* a* b* values (lightness, redness, yellowness). Chemical analysis included percent metmyoglobin and lipid oxidation (TBARS). There were no grade x packaging interactions ($P > 0.05$) for lean color, discoloration, overall appearance, or L*, a* and b* values. However, the main effect of grades for these quality parameters was significant, with Low Choice and Select being higher than High Choice for L* values and Low Choice being more desirable than both High Choice and Select for lean color, discoloration, overall appearance, and a* and b* values. There were no grade x packaging interactions for percent metmyoglobin and TBARS values, however, grade had a main effect ($P < 0.05$) on percent metmyoglobin content, with High Choice being higher than both Low Choice and Select. TBARS values also differed ($P < 0.05$) among grades. These findings indicate quality grade has a major influence on color stability of high-oxygen packaged beef steaks. Regardless of muscle type and grade, however, whole muscle steaks from the round can achieve an extended shelf-life by use of novel MAP technology.

Key Words: Case-ready, Quality, Oxidation

1562 Diverse birth and rearing housing systems: effects on pig growth, meat quality and muscle fiber types. J. G. Gentry^{*}, J. R. Blanton, Jr., J. J. McGlone, and M. F. Miller, Texas Tech University, Lubbock.

The objective of this experiment was to examine the effects of diverse birth and rearing environments on pig growth, meat quality and muscle fiber types. Barrows (n=48, 6 pigs/pen) were randomly selected from a group of indoor-born and outdoor-born pigs at weaning and placed into an indoor or outdoor growing/finishing environment. The outdoor environment consisted of 4 pens (212 m²/pig) on alfalfa pasture. The 4 indoor pens (1.2 m²/pig) had concrete slatted flooring. Pigs were slaughtered at an average weight of 114 kg at a commercial facility. Fiber type samples were taken from the *longissimus* (LD) and *semimembranosus* (SM) muscles at 4 hr postmortem and stored at -80°C until analysis. Samples (12-m thick) were stained histochemically with ATPase after acid pre-incubation (pH= 4.3) to detect I, IIA and IIB fiber types. Boneless loins were collected following 24 hr chilling and aged for 14 d. Chops (2.54 cm thick) were cut for sensory and shear force analysis. Data were analyzed using the GLM procedures of SAS (1995) with pen as the experimental unit. Outdoor-born pigs grew faster than indoor-born pigs (ADG, kg/d: .81 vs .72 .03, $P < .05$). Outdoor reared pigs had more backfat, higher NPPC color scores and lower CIE L* values than the indoor reared pigs ($P < .05$). Sensory panel scores for pork flavor intensity were 6.07 and 6.48 .10 for the indoor and outdoor-born groups, respectively ($P < .05$). Shear force values were lower for the group finished outdoors (2.0 vs 2.2 kg .06, $P < .05$). LD and SM from

the outdoor reared group had a lower percentage of type IIB fibers (LD: 66.6% vs 73.2% 2.0, SM: 53.6% vs 65.1% 3.1; $P < .05$). Type I fibers in the SM represented 13.8% and 24.6% 3.1 for the indoor and outdoor reared pigs, respectively ($P < .05$). Outdoor rearing of pigs may improve pig growth, pork color and tenderness. Further studies should be conducted to link pork quality measures with muscle fiber types and environmental housing systems.

Key Words: Pigs, Housing systems, Pork quality

1563 Goat kids meat quality: artificial rearing and weight at slaughter effects. A. Arguello^{*1}, A. Marichal¹, J.F. Capote², and J.L. Lopez¹, ¹Animal Production Unit, Las Palmas de Gran Canaria University, Arucas, Spain., ²ICIA, La Laguna, Spain..

The objective of our study was to examine the effects of the rearing system and weight at slaughter on meat quality in young Canary Caprine Group kids. Forty twin, male kids were allotted to one of four groups based on feeding regimens: kids nursed by their dams (ND, n: 10), or kids fed a commercial milk replacer (23.7 percent CP and 22.8 percent fat) and controlled intake (CR, n: 10), and live weight at slaughter: 6 kg (WS6, n: 10), or 10 kg (WS10, n: 10). Immediately after slaughter, pH was measured on the Longissimus dorsi (LD). The carcasses were chilled at 4 C for 24 h, and pH, Warner-Brazler shear force (WBSF), color (Lightness, L, Chroma, C, Hue, H), water holding capacity (WHC), chemical composition (moisture, protein, fat, ash, collagen and his solubility), muscle fiber types proportions and their areas, were determined in the LD muscle. No interactions were observed in any parameter between rearing method and weight at slaughter. No statistic effect were founded in pH values, although the ND kids showed a higher pH values when the weight at slaughter increased, the evolution in CR kids were opposite. Compared with the WS10 kids, the LD muscle from WS6 kids had higher L ($P < .05$), but no differences were founded in Chroma or Hue. Rearing method and weight at slaughter did not affect to WBSF, but a relation between WBSF and solubility collagen may be observed. The meat from ND animals were more exudative than CR kids ($P < .001$), while no statistic effect was observed by weight at slaughter. The chemical composition changed lightly, reducing moisture percentage ($P < .001$) and increasing protein proportion ($P < .001$) in WS10, probably due to hypertrophy growth muscle fiber areas were higher. No effects were described in muscle fiber type population. The WS10 muscle fiber area was higher than WS6 ($P < .05$), but in opposite the rearing system did not show statistic effects. Thus, the results show that using milk replacers in goat kids and increasing the weight at slaughter did not affect negatively to meat quality.

Key Words: Kid meat quality, Rearing system, Weight at slaughter

1564 Comparison of breed and diet on factors associated with tenderness in two muscles. P. S. Kuber^{*1}, J. R. Busboom¹, S. K. Duckett², D. J. Marks¹, P. S. Mir³, Z. Mir³, R. G. McCormick⁴, C. T. Gaskins¹, J. D. Cronrath¹, and M. V. Dodson¹, ¹Washington State University, Pullman, WA, ²University of Idaho, Moscow, ID, ³Agriculture and Agri-food Canada, Lethbridge, AB, ⁴University of Wyoming, Laramie, WY.

The objective of this study was to evaluate attributes associated with tenderness in divergent breeds, Wagyu (**W n=12**), Limousin (**L n=12**) and F1-cross cattle (**WxL n=12**), fed two dietary treatments (either 0 or 6% sunflower oil). Data were analyzed using GLM procedures with breed and diet as main effects in a 2 x 3 factorial arrangement of treatments. Cattle were fed a barley-based diet for an average period of 259 d. Twenty-four hours post mortem (**PM**), steaks from the *longissimus* (**LD**) and *semitendinosus* (**ST**) were sliced, vacuum packed, aged (1, 3, 7, 14, 28 and 56 d **PM**) at 2°C and frozen (-40°C) until analyzed. Breed differences in Warner-Bratzler shear force (**WBS**) existed ($P < 0.05$) across aging times in LD. A WBS breed x day interaction existed in ST ($P < 0.05$) and tended to exist in LD ($P = .11$). On d 14, W LD ($P < 0.05$) required 0.77 kg less force to shear than L. Comparatively, W were more desirable in d 14 LD sensory panel sustained tenderness ($P < 0.05$) than L. In the ST, WxL ($P < 0.1$) required 0.60 kg less force to shear than L, but no difference ($P > 0.1$) in ST panel initial or sustained tenderness was evident. Wagyu LD and ST samples were slower ($P < 0.05$) in pH decline, and more rapid ($P < 0.05$) in temperature decline than L or WxL. Breed and diet did not affect ($P > 0.1$) free calcium (**FC**) over time (0, 1, 3, 7 and 14 d **PM**), 0 h calpastatin activity (**CA**), d 1 % collagen (**OH-Pro**), or d 1 collagen cross-linking (**HP**) in LD;

or d 1 OH-Pro and d 1 HP in ST. Western blot analysis for measuring the presence of the Troponin-T (Tn-T) 30kda fragment demonstrated more proteolysis in LD at d 3 in L than W or WxL. Breed differences in mechanical and sensory measures of tenderness existed (d 14 - LD and ST), but were not explained by FC, CA, OH-Pro, HP and Tn-T.

Key Words: Wagyu, Limousin, Beef Tenderness

1565 *In-vitro* oxidation of bovine oxymyoglobin as affected by 4-hydroxy-nonenal. A.L. Phillips*, S. Lee, L.K. Silbart, and C. Faustman, *University of Connecticut, Storrs, CT.*

Discoloration from the desirable cherry red to brown color in fresh meat is a result of oxidation of ferrous oxymyoglobin (OxyMb) to ferric metmyoglobin (MetMb). Lipid oxidation, among other factors, influences the rate of fresh meat discoloration. 4-Hydroxy-nonenal (HNE), a known product of ω -6 fatty acid oxidation, is very reactive toward protein and has been shown to accelerate equine cardiac OxyMb oxidation. Our objective was to determine the influence of HNE upon bovine skeletal OxyMb *in-vitro* under a variety of temperature (4, 25 and 37°C) and pH (5.6 and 7.4) conditions and to identify the adduction of HNE to OxyMb using Western Blots. Bovine skeletal muscle myoglobin (Mb) was purified from beef via ammonium sulfate fractionation and gel filtration

chromatography. OxyMb was prepared by hydrosulfite-mediated reduction and adjusted to physiologic or post-mortem pH via phosphate (pH 7.4) or citrate (pH 5.6) buffer dialysis, respectively. OxyMb (0.15 mM) was incubated with 1 mM HNE (OxyMb:HNE) at 4, 25 and 37°C; controls were aldehyde-free. Following incubation, samples were passed over a desalting column to remove unreacted HNE, scanned spectrophotometrically from 650 to 450 nm, and the percentage of MetMb calculated. Western Blot analysis was completed using control and OxyMb:HNE reacted at pH 7.4, 37°C for 2 hr. Identification of Mb bound HNE was visualized using a monoclonal antibody specific for HNE bound to histidine residues. Overall, MetMb formation increased with increasing temperatures and was greater at pH 5.6 than pH 7.4 ($P \leq 0.05$). At 37°C, a prooxidant effect of HNE was seen at pH 7.4 but not at pH 5.6 when compared to control ($P \leq 0.05$). At both 25 and 4°C, a prooxidant effect of HNE was seen at pH 7.4 and 5.6 relative to CON ($P \leq 0.05$). Western Blots revealed that OxyMb:HNE incubated at pH 7.4, 37°C yielded OxyMb:HNE adducts at histidine residues whereas control samples showed no reaction. This research suggests that HNE accelerates *in-vitro* bovine skeletal muscle OxyMb oxidation and appears to do so, in part, via covalent modification at histidine residues.

1566 Rheological Characterization of Butter Oil Obtained from Yogurt and Milk. Sevim Kaya* and Ahmet Kaya, *Gaziantep University.*

Butter oil, clarified butter or anhydrous milk fat is a widely consumed food product in southeast of Turkey. The aims of the study were to investigate and compare the rheological characters of butter oil from yogurt and milk using flow curve and oscillation frequency sweep tests at various temperatures. The steady shear flow data of the butter oil samples were investigated using a rheometer HAAKE RheoStress RS1 with a cone and plate system (d:35 mm, $\alpha :2^\circ$) and in combination with a Peltier/Plate TCP/P temperature control unit at temperature range of $35-70 \pm 0.05^\circ\text{C}$. Data were analyzed using a RheoWin Data Manager. The measurements were repeated three times, each time using a fresh sample and the average values were used to analyze data. Newtonian behavior was observed for the samples ($r^2 \geq 0.998$) at the temperature range studied. Increasing temperature decreased the viscosity. Activation energies of butter oil from yogurt and milk were 21.7 and 21.6 ± 0.2 kJ/mol, respectively showing that there was no difference between samples produced using different methods above the temperature 35°C . In addition to the temperature range studied above, another temperature range ($35-29 \pm 0.05^\circ\text{C}$) was studied to observe the structural conditions of the samples analyzed using an oscillation frequency sweep test. It was found that at low frequencies the viscous behavior reflected by loss modulus is dominant whereas at high frequencies the elastic behavior reflected by storage modulus is outweighing. This shows solid like behavior of samples at higher frequencies. When the log crossover point was plotted versus temperature, below 35°C samples made from yogurt and milk showed different characteristics due to different fatty acid composition of the samples.

Key Words: Butter oil, yogurt, rheology

1567 Acceptance of camel milk among elementary school students in Al Ain, UAE. Isameldin Hashim*, *United Arab Emirates University.*

Milk is an important food for children. Although camel is the dominant animal in the U.A.E., camel milk is not available commercially. The objectives of the study were to investigate: 1) consumption of milk and dairy products among elementary school students, 2) hedonic rating for sensory characteristics and overall acceptance of camel milk, and 3) acceptability of flavored camel milk. A questionnaire was designed to provide information on milk and dairy products consumption, milk flavor preference and willingness to participate on a milk tasting test. The questionnaire was distributed to 470 students (boys and girls, grades 4, 5 and 6) at elementary schools (public and private) in Al Ain. A panel of 173 students was selected to evaluate the milk samples (fresh cow milk, dried cow milk, fresh camel milk and chocolate-flavored camel milk). Seven-point hedonic scale (smiling faces) was used for rating the

color, aroma, taste, texture, and overall acceptance of the milk. Most of the students (93.2%) drink milk and only few (9.6%) drink camel milk. Most of the participants drink chocolate (43%) and strawberry-flavored (38.3%) milk. Beside the milk most of the participants consume other dairy products (yogurt, liquid yogurt, chesses and ice-cream). Camel milk had the lowest ratings for taste (3.2), aroma (4.1), and overall acceptance (3.8) compared to the fresh and dried cow milk (5.3 - 5.9). However, flavoring camel milk with chocolate enhanced the attributes of camel milk specially the taste (6.4), aroma (6.3) and overall acceptance (6.2).

Key Words: camel milk, acceptance, elementary school, UAE

1568 Effect of formulation and processing on emulsion stability of recombined sterilized milk. G. Prez-Hernandez, S. Bhatia, and R. L. Richter, *Texas A&M University, College Station, TX.*

The objectives were to determine the effect of product formulation and processing conditions on the composition of the milk fat globule membrane in recombined sterilized milk and to determine the effect of these changes on the emulsion stability. Samples contained casein to whey protein ratios of 80:20, 60:40, 40:60 and 0:100, and 0.5% monoglycerides, 0.5% lecithin, or a mixture of lecithin with monoglycerides. The protein and fat concentrations of the milk were 3%. Samples were homogenized at 20 and 90 MPa and sterilized at 121°C for 15 min. Emulsions were characterized by stability index, protein load, particle size distribution, and rheological parameters. Inclusion of monoglycerides in the samples caused the mean pH for all samples to decrease from 6.58 to 6.56 ($p \leq 0.0152$). Maximum viscosity occurred in samples with a casein to whey protein ratio of 0:100. This was caused by denaturation of whey protein during sterilization. There was a four fold increase in volume surface average diameter as the ratio of whey protein in the samples was increased from 80:20 ($0.4425\mu\text{m}$) to 0:100 ($1.7175\mu\text{m}$). The surface area of particles in all treatment increased as the homogenization pressure increased. Particle surface area increased when samples that had a casein to whey protein ratio of 0:100 were formulated with emulsifier. Emulsifiers did not affect the particle surface area in any other sample. The protein load increased as the ratio of whey protein in the samples increased. Inclusion of emulsifiers in the samples caused the protein load to decrease. Stability index increased as viscosity, particle surface area and relative distribution width increased and pH and protein load decreased.

Key Words: emulsion stability, recombined milk, sterilization

1569 Commercial whey protein concentrates: protein aggregation profile study. Samira Roufik*¹, Michel Britten², and Paul Paquin¹, ¹Centre de recherche en sciences et technologie du lait (STELA), Université Laval, Québec/Canada, ²Centre de recherche et de développement sur les aliments (CRDA), St-Hyacinthe, Québec/Canada.

Commercial whey protein concentrates (WPCs) exhibit different functional properties even when they have nearly the same total protein content. The aim of this study was to investigate the WPCs protein aggregation profiles to see if we can explain their functional variability through differences in their aggregated state. High performance size exclusion chromatography (HPSEC) technique using a TSK Gel[®] G-4000 PW XL column was performed to study the protein aggregation profiles of seven commercial WPCs. Results show for all WPCs under study the presence of two protein fractions, the aggregated protein fraction (APF) and the native protein fraction (NPF). The WPCs apparent APF proportion varies between 9.83% and 29.21% which reflect their variable level of aggregation. By performing centrifugation at 48 000 g during 45 min (25°C), we have separated these two protein fractions. Then, using HPSEC technique with a TSK Gel[®] G-3000 PW XL column we have characterized the NPF while the APF was characterized with electrophoretic techniques.

Key Words: Whey protein concentrates, Aggregation profile, Protein fractions

1570 Effect of drying methods on functional properties of tarhana, a wheat flour-yogurt mixture. Mehmet Hayta*¹, Mehmet Alpaslan¹, and Ahmet Baysar², ¹Inonu University, Department of Food Engineering, ²Inonu University, Department of Chemical Engineering.

Tarhana is a traditional product prepared by mixing wheat flour, yogurt, yeast and spices followed by fermentation for several days and drying after fermentation. The information on functional and sensory properties is essential for process design, quality control and consumer acceptability. In this study, the changes in functional and sensory properties of tarhana as affected by different drying methods were investigated. Tunnel-dried (TD) tarhana had significantly ($P < 0.05$) higher foaming capacity compared to freeze-dried (FD), home microwave oven-dried (HMD) and industrial microwave-dried (IMD) samples. FD tarhana had the highest protein solubility value ($P < 0.05$) and was followed by TD, IMD and HMD samples, respectively. All tarhana samples exhibited pseudoplastic behavior as apparent viscosity-rotational speed data fitted to a power law model. A significant ($P < 0.05$) decrease in oil absorption capacity was observed for TD tarhana compared to other drying methods. Water absorption capacity of each tarhana sample was significantly ($P < 0.005$) different. On the basis of soluble protein content, TD tarhana had the highest emulsion activity value. No significant differences were observed in odor and mouth-feel among the drying methods used. However, flavor of FD tarhana gruel was significantly ($p < 0.05$) different from other samples. IMD tarhana gruel had the highest overall rating and was followed by TD, HMD and FD, respectively. The lightness (L) value of FD sample was the highest and the HMD sample had the lowest L value. The L values for HMD and IMD samples were smaller than TD and FD samples. In contrast, b value was found to be higher for HMD and IMD samples.

Key Words: Tarhana, functional properties, sensory properties

1571 Effect of freezing process on the microstructure and stability of stabilized ice cream-type systems. K. Montoya and H. D. Goff*, University of Guelph, ON, Canada.

Ice cream model systems without fat and in the presence and absence of locust bean gum (LBG) and guar gum were frozen quiescently and in a scraped-surface freezer (dynamic freezing) with both low and high overrun. Samples were temperature cycled from -10 to -20°C for 15 and 50 cycles. Cryo-Scanning Electron Microscopy (Cryo-SEM) techniques and image analysis were used to determine structure and ice crystal size distributions. Results showed that microstructure of the two systems was different; dynamic samples showed discrete, block shaped crystals without connectivity and randomly dispersed in a system comprised of a continuous serum phase and air cells whereas quiescent samples showed a more continuous ice phase with irregularities on a dendritic type of crystal, or elongated crystals closely packed and separated just by the

serum. Stabilizers did not affect the initial size and distribution of ice crystals in either system. After temperature cycles, ice recrystallization occurred in the order of LBG < guar gum < no stabilizer only in quiescently frozen systems. For dynamic samples lower recrystallization rates were found compared to those of quiescent. In dynamic systems stabilizers did not exert a significant effect ($p < 0.05$) in retarding ice recrystallization, although there was a trend towards lower recrystallization in LBG samples with low overrun ($p < 0.10$). The mechanisms by which polysaccharide stabilizer may control ice recrystallization may have been affected by the freezing process. LBG effectiveness has been attributed to the formation of a gel matrix around the ice crystals enhanced by LBG-milk protein phase separation. The presence of shear during freezing in the scraped surface heat exchanger may have disrupted this microstructure. This provides further insight into stabilizer functionality and suggests caution in extrapolating the results from one process to the other.

Key Words: Ice cream, Polysaccharide stabilizer, Scanning electron microscopy

1572 Effect of Incubation Temperature and Homogenization on the Rheological Properties of Set Yogurt During Gelation Process. S.A. Ibrahim*¹, R.R. Shaker², B. Abu-Jdayil², and R.Y. Jumah², ¹North Carolina Agricultural and Technical State University, Greensboro, NC., ²Jordan University of Science and Technology, Irbid, Jordan..

Fresh raw milk was standardized (3% fat) and split into 2 portions. One portion was heated at 90°C for 3 min using a plate heat exchanger and homogenized at 13.79 Mpa. The second portion was heated at 90°C for 3 minutes without homogenization. Each portion was divided into 3 parts (450 ml each), inoculated with 3% yogurt starter culture (Joghurt 2 Type MK consisting of *Streptococcus thermophilus* and *Lactobacillus delbrückii sub. bulgaricus*) and incubated at 40, 45, and 48°C, respectively to determine the effect of incubation temperature and homogenization on the rheological properties of set yogurt during the gelation process using a cylindrical rotational viscometer. The optimum incubation temperature for acid development was observed at 45°C. The minimum viscosity was observed at 40°C while the maximum viscosity was at 48°C. The results indicated that incubation temperature affected yogurt viscosity during the gelation process while homogenization had no significant effect. The power law model was used to describe the flow behavior of set yogurt. Increasing the incubation temperature decreased the flow behavior index and increases the consistency coefficient. Homogenization increased the flow behavior index and decreased the consistency coefficient.

Key Words: Yogurt, Rheological properties, Homogenization

1573 The Effect of Salep and Locust Bean Gum Concentration on the Rheological Characteristics of a Turkish-type Ice-cream Mix. Sevim Kaya*¹, ¹Gaziantep University.

A traditional Turkish type ice cream is prepared from whole milk, sugar and salep. Salep, a natural polysaccharide, is used as a stabilizer. The effect of salep and locust bean gum concentration (0.2, 0.4, 0.78 and 1.00 g per 100 mL) on the flow behavior of the ice-cream mix has been investigated over a range of shear rates. The temperature dependency of the flow behavior of the mixes was also studied obtaining data at four different temperatures. The steady shear flow data of the ice-cream mixes were investigated using a rheometer HAAKE RheoStress RS1 with a cone and plate system (d:35 mm, $\alpha : 2^\circ$) and in combination with a Peltier/Plate TCP/P temperature control unit at temperature range of 5-30 $\pm 0.05^\circ\text{C}$. Data were analyzed using a RheoWin Data Manager and SigmaPlot for Windows. The measurements were repeated three times, each time using a fresh sample and the average values were used to analyze data. The empirical power law was observed to fit the shear stress-shear rate data ($r \leq 0.998$). Increasing stabilizer concentration decreased the power law index values which were in the range of 1.00-0.30 and 0.79-0.53 for 0.2-1.0 g salep per 100 mL mix and 0.2-0.78 g locust bean gum per 100 mL mix at 5°C, respectively. A gradual increase in salep concentration was found to alter the rheological characteristics of the mix from Newtonian to non-Newtonian. It was found that there was not any significant difference between apparent viscosity values of ice cream mixes containing 1 g of salep per 100 mL or 0.4 g locust bean gum per 100 mL ($p \leq 0.05$). The temperature-dependency of the

apparent viscosities of the samples with different salep and locust bean gum concentrations was also determined. It was observed that temperature effect were not significant on the apparent viscosity values of each concentration studied ($p \leq 0.05$) except 0.2 and 0.4 g per 100 mL salep concentration.

Key Words: salep, rheology, ice-cream

1574 Effect of double homogenization and whey protein concentrate on the texture of ice cream. P. R. Ruger*¹, R. J. Baer¹, and K. M. Kasperon¹, ¹*Dairy Science Department, South Dakota State University, Brookings, SD, USA.*

Ice cream was made with a mix composition of 11% milk fat, 11% milk solids-non-fat (MSNF), 13% sucrose, 3% corn syrup solids (36 dextrose equivalent), 0.28% stabilizer blend or 0.1% emulsifier and vanilla extract. Mixes were HTST pasteurized at 80°C for 35 s, homogenized at 141 kg/cm²-35 kg/cm² (2000 psi-500 psi), and cooled to 3°C. Six treatments were prepared from 4 batches of mix. Mix from batch one consisted of 0.1% emulsifier. Half of this batch, treatment 1 (T1), was cooled to 3°C and the other half, upon exiting the pasteurizer, was heated to 60°C, rehomogenized at 141 kg/cm²-35 kg/cm² (T2), and cooled to 3°C. Mix from batch two consisted of 0.28% stabilizer blend. Half of this batch was used as the control (T3), the other half, upon exiting the pasteurizer, was heated to 60°C, rehomogenized at 141 kg/cm²-35 kg/cm² (T4) and cooled to 3°C. Batch three consisted of 0.1% emulsifier and 1% whey protein concentrate (WPC) substituted for 1% MSNF. It was heated to 60°C, rehomogenized at 141 kg/cm²-35 kg/cm² (T5), and cooled to 3°C. Batch four consisted of 0.28% stabilizer blend and 1% WPC substituted for 1% MSNF. It was heated to 60°C, rehomogenized at 141 kg/cm²-35 kg/cm² (T6), and cooled to 3°C. Results showed no difference ($P > 0.05$) in mean ice crystal size between T3, T4, and T6, however T4 and T6 had a smaller mean ice crystal size than T1, T2, and T5. Mix viscosities were tested one day after manufacture. The viscosity of T3 was greater ($P < 0.05$) than all other treatments and the viscosities of T4 and T6 were greater than T1, T2, and T5. Milk fat and total solids of all treatment mixes were similar ($P > 0.05$).

Key Words: Ice cream, Homogenization, Whey protein concentrate

1575 Lack of effect of a specially designed yogurt for the eradication of *Helicobacter pylori* infection. L. Ozimek*¹, C. Wendakoon¹, S. Appelman², and A. Thomson², ¹*Department of Agricultural, Food & Nutritional Sc.*, ²*Division of Gastroenterology, University of Alberta.*

Helicobacter pylori infection is associated with an increased risk for the development of duodenal and gastric ulcers, chronic active gastritis, MALToma and gastric cancer. Various consensus guidelines have been developed to recommend when it is appropriate to test for and treat the presence of *H. pylori*. Standard treatment usually involves triple therapy with one two week course of antibiotics plus proton pump inhibitor. This regimen is approximately 85% effective, yet it is expensive, difficult to take and may be associated with the risk of development of diarrhea and enteric infection. Probiotics have been suggested as a possible therapeutic agent, and a specially designed yogurt derived from three strains of lactobacillus has been shown to be of a comparable inhibitory effect of *H. pylori* *in vitro* as compared with standard concentrations of amoxicillin and clarithromycin. Because the *in vitro* sensitivity of *H. pylori* may not necessarily predict its *in vivo* effect, we undertook an open study with 27 asymptomatic post-menopausal women positive for *H. pylori* on gastric biopsy, and administered 250 cc of yogurt three times a day for one month. Then, one month later, a ¹³C-urea breath test (UBT) was administered. In all 26 of 27 patients the UBT remained positive one month after a course of yogurt. In summary, the *in vitro* anti-*Helicobacter* effect of a mixture of specially designed yogurt does not predict the *in vivo* eradication of the infection.

Key Words: *Helicobacter pylori*, Probiotics, *In vitro* & *in vivo* studies

1576 Determination of B₁₂, biotin, and folic acid in infant formula by Biomolecular Interactive Assay. Thom Grace*¹, Deliang Cai², and Mingrui Guo², ¹*Biocore Inc. 384 Sam Webb Rd. Fairfax, VT. 05454.*, ²*Dept. of Nutrition and Food Sciences, University of Vermont, Burlington, VT 05405.*

The current methodologies for water soluble vitamin analysis are generally manipulative, and imprecise or insensitive. In this study, the precision and accuracy of the BIACORE Q system of biomolecular interaction analysis for the quantitative determination of B₁₂, biotin and folic acid in infant formula were evaluated. Two types (soy-based and milk-based) of commercial powdered infant formula were used for the analyses. Fifteen separate samples were prepared for each formula type and run singularly for reproducibility analysis. A single sample was also analyzed in replicates of 16 for the reproducibility of the instrument. The values of coefficient of variation (CV) for B₁₂, biotin, and folic acid were 6.2, 5.6, and 3.7%, respectively. Recovery test was also carried out by spiking with each vitamin at four different concentrations across each assay range of detection. The recovery rates were ranging from 96 to 105% for all the three assays. The results of this study show that the Biocore biomolecular interactive technology may be a good alternative for quantification of the water soluble vitamins, to the traditional methods

Key Words: Biomolecular interactive assay, infant formula, water soluble vitamin

1577 Microbial content and distribution in Turkish kefir grains. Z. B. Guzel-Seydim*, A. C. Seydim, J. T. Wyffels, and A. K. Greene, *Clemson University, Clemson, SC, USA.*

Kefir is a fermented dairy product made by addition of kefir grains into milk. In kefir grains, lactic acid bacteria and yeast symbiotically live in a slimy polysaccharide matrix known as kefiran. The objectives of this study were to determine the microbial content of grains and to observe the microbial distribution in Turkish kefir grains using scanning electron microscopy. Kefir grains had a ratio of 10⁶ cfu/g yeast to 10⁹ cfu/g lactic acid. Scanning electron microscopy indicated yeast colonization on the surface and middle of the kefir grain. Short, long and curved lactobacilli were throughout the grain. Lactococci were not observed under SEM; preparation of kefir grains for SEM may have caused removal of lactococci from the grains if they were lightly bound to the grains.

Key Words: kefir, fermented dairy products, scanning electron microscopy (SEM)

1578 Comparison of component interactions and mineral distribution in infant formulas prepared with organic or inorganic mineral salts. Casey R. Smith*¹, Mingrui Guo¹, Gregory M. Hendricks², and Robert S. Tyzbir¹, ¹*Dept. Nutrition and Food Sciences, University of Vermont.*, ²*Medical School, University of Massachusetts.*

Poor bioavailability of essential trace elements, such as copper, iron, and zinc, in commercial infant formula may be related to their low solubility, which may be affected by the forms of added mineral salts. Substituting organic for inorganic mineral salts may increase solubility and availability of minerals in infant formula. Ten 2.5 kg paired batches of whey-protein dominated liquid infant formula (40:60 casein to whey protein ratio) were processed in our university laboratory, with either organic or inorganic salts of Cu, Fe, and Zn. Organic formula (OF) and inorganic formula (IF) were heated to 55C, 60C, 65C, 70C, or 75C immediately preceding homogenization. Nitrogen (N) and mineral distribution were determined by measuring the contents of N and selected minerals in the fat, serum, and pellet fractions obtained on centrifuging the formula at 45,000Xg for 2 hours at 4C. Mineral levels were evaluated by inductively coupled plasma atomic emission spectroscopy, and nitrogen content was determined by the macro-Kjeldahl method. There were no notable differences in mineral and nitrogen distribution between unheated OF and IF. However, pre-homogenization heat treatment (PHT) seemed to have an impact on both nitrogen and mineral distributions in the experimental formulas. The level of iron in the serum was higher for OF at a PHT of 55C with 58.93% of total Fe in the serum fraction, compared to IF which was highest at 60C with a maximum of 49.64%. There was no significant difference detected in the percentage of copper in the serum fraction between OF and IF. Serum Zn was significantly higher ($p < .05$) in OF than IF (38.52% vs 30.65%) at PHT 55C. Percentage of N in the

serum fraction of both OF and IF was highest at a PHT of 60C. Total solids (TS), protein, and ash in the formulas were also analyzed. OF averaged slightly higher TS at 11.75%, whereas IF averaged 11.66%. Ash content in IF (0.33%) was slightly higher than that of OF (0.32%). The microstructures of both formulas were also examined. According to our results, organic mineral salts of Fe and Zn may be substituted for inorganic salts of Fe and Zn to enhance mineral solubility in infant formula, however, further research is needed to elucidate and verify methods to increase trace mineral solubility.

Key Words: Infant formula, component interaction, mineral distribution

1579 The effect of human milk pasteurization on the growth of Bifidobacteria. Luciana M. Borba¹, Celia L. L. F. Ferreira*¹, Sylvia C. Franceschini¹, and Tania Toledo¹, ¹Federal University of Viosa.

There is an increasing recognition of the importance of human milk banks. In such institutions, the donated milk is pasteurized to increase its safety. However little is known about the effect of heated milk upon the desirable microbiota of the newborn. In this work, pools of human milk (same age of maturity) were analyzed through addition of 4 different strains of Bifidobacteria, human origin. Isolates from *Bifidobacterium bifidum* (*B. bifidum*) ATCC 29521, *B. breve* ATCC 15700, *B. longum* ATCC 15707, and a newly isolate *B. breve* AJ 32 were inoculated in a whole pasteurized human milk (WPHM), and WPHM plus pasteurized human milk filtrate (35%) and plus unpasteurized human milk filtrate (35%). After a 24 hours incubation at 37°C, under anaerobic conditions, the contents of each treatment were plated in TPY agar (SCARDOVI, 1986), counted and compared with the counts of the initial time of incubation (time0). The difference between time 24 and 0, gives the degree of the stimulation or inhibition of the heated/unheated milk. The log average of the three repetitions of the CFU/mL of this difference were: -0,28/-0,18/+0,33 for ATCC 29521; -0,30/-0,26/+0,12 for ATCC 15700; -0,18/-0,22/+0,10 for ATCC 15707; and #0,25/-0,26/+0,17 for AJ 32, in the WPHM; WPHM + pasteurized filtrate; and WPHM + unpasteurized filtrate, in that order. The addition of the unpasteurized milk filtrate in the base (pasteurized) stimulate the growth of the 4 strains evaluated here in, and the difference of this treatment was statistically significant (p<0,05). This results indicate that the addition of Bifidobacteria of human origin to the pasteurized milk in the human banks could be beneficial to the newborn.

Key Words: Human milk, Pasteurization, Bifidobacteria

1580 Lactobacillus acidophilus translocation in rats feeding cholesterol rich diet. Dayse F. Machado¹, Celia L. L. F. Ferreira*¹, Neuza M. B. Costa¹, Lorena M. Ybarra¹, Eveline M. C. Azevedo¹, and Maria R. G. Cond¹, ¹Federal University of Viosa.

Probiotics are known as functional foods and individuals consuming a rich cholesterol diet are prone to consume such products. This work was devised to verify the effect of a cholesterol rich diet in translocation - the passage of microorganisms from intestinal environment to other organs and tissues, and rate of "clearing" of *Lactobacillus acidophilus* NCFM. One hundred and sixty weaned Wistar rats, divided in 4 groups and caged individually were used. The diets administered were: (1) standard (AIN-93G, "ad libitum"); (2) control (AIN-93G plus cholesterol and cholic acid); (3) control plus 0,1ml/day of Reconstituted Skimmed Milk (RSM) at 10%; (4) control plus 0,1ml/day of acidophilus concentrate at levels of 10¹⁰ CFU/ml, for 14 days. Translocation was evaluated in heart, kidney, liver and spleen of all animals at 0 and 28 days after the end of probiotic administration, through the screening for total count in MRS agar. Translocation was observed in all organs of group 4, but not in the others. The average translocation (\pm standard deviation) were 35(\pm 3,49)/ 16(\pm 2,28); 45(\pm 2,62)/ 27 (\pm 2,51); 26 (\pm 3,28)/ 11 (\pm 1,84); 68 (\pm 2,52)/ 22 (\pm 2,96) CFU/g from heart, kidney, liver and spleen, respectively at 0 and 28 days. The time required for the complete elimination of *Lactobacillus* from the organs was calculated according to adjusted regression models and corresponded to 48, 68, 48 and 41 days for heart, kidney, liver and spleen, respectively. Results from previous studies with rats receiving standard diet with RSM or *L. acidophilus* at the same levels and periods, showed initial average translocation number higher than in this work however the clearing time was shorter - 28, 26, 28 and 32 days. The current data indicated that cholesterol rich diet could increase the clearing rate of probiotic microorganisms. Since the implication of microbial translocation in the host is not known

especially in those with different degrees of debility, the translocation capacity and the rate of clearing are suggested to be important parameters for the selection of strains to be used as probiotics.

Key Words: *Lactobacillus acidophilus*, Translocation, Cholesterol diet

1581 A comparative study of the microstructure of caseins in dried milk products. B. S. Oommen*¹, D. J. McMahon¹, and W. R. McManus¹, ¹Utah State University.

Microstructure of caseins in non-fat dried milk, calcium caseinate, sodium caseinate, and calcium caseinate formed from acid casein dissolved using calcium hydroxide were studied using transmission electron microscopy. Solutions of all the dried products were made to a casein concentration of 2.4% and the pH of the solution adjusted to 6.7. The powders were hydrated at 40 °C, and allowed to stabilize for 4 h. These solutions were diluted 100 times and the casein micelles were adsorbed on to parlodion coated copper grids. These grids were stained using uranyl acetate and oxalic acid, quick frozen in liquefied Freon 22, and freeze dried so that whole casein micelles in a form as close to their native state was imaged. Images were photographed at 50,000 \times , 85,000 \times and 140,000 \times . Casein micelles in non-fat dried milk appeared to have lost its perfect spherical shape forming incomplete spherical shapes with some hollow spots inside the micelle. Calcium caseinate formed large micellar structures which were stained heavily. When acid casein was dissolved in water by the addition of calcium hydroxide, the structure of the calcium caseinate formed was different from the former. These formed smaller particles with irregular shapes. Sodium caseinate did not form any micelles. It formed a network very similar to a gel-like structure. The microstructural changes in caseins from different sources may be attributed to the processing conditions and can be used to correlate its functional properties.

Key Words: Casein Micelle, Microstructure, Dried Milk Products

1582 Effect of SCC on proteolysis and lipolysis of pasteurized fluid milk during shelf-life storage. M. V. Santos*¹, Y. Ma², and D. M. Barbano², ¹Universidade de Sao Paulo, Sao Paulo, SP, Brazil, ²Cornell University, Ithaca, NY.

The objectives of the study were to determine: (1) the time in days for a pasteurized (76°C for 30 s), homogenized 2% milk to develop off-flavor due to lipolysis and proteolysis caused by native milk enzymes associated with milks of different SCC (i.e., about 20,000, 210,000, 410,000, and 750,000 cells/ml) at 0.5 and 6.0°C, independent of microbiological spoilage of milk; (2) if fat content of milk (i.e., 1, 2, and 3.25%) influences the level of proteolysis or lipolysis caused by native milk enzymes; and (3) the number of days for 2% fat milk made from milks of differing SCC to develop off-flavor due to the combination of the action of native milk enzymes and microbial growth. Lipolysis was determined by the copper soap method. Proteolysis was by the Kjeldahl method using the decrease in casein as a percentage of true protein as an index of proteolysis during 61 d of storage. There was a significant effect of SCC and temperature of storage on fat and protein degradation by native milk enzymes in pasteurized 2% fat milk. Based on previous data for flavor and objective measures of lipolysis and proteolysis (JDS 83:264-274), the milk flavor in the present study would have been unacceptable at about 14 and 42 d for the high SCC milk and 49 and > 61 d for the low SCC milk, at 6 and 0.5°C, respectively. Fat concentration in milk had an impact on lipolysis, with both the level and rate of increase of FFA content increasing with increasing fat content. The combined effect of microbial growth plus native milk enzymes on lipolysis and proteolysis was larger at 6 than 0.5°C. Generally, low SCC milk spoiled due to microbial growth, not native milk enzyme action, by 26 days at 6°C, while high SCC milk had levels of proteolysis and lipolysis sufficient to produce off-flavor at about d 12, which was prior to microbial failure. At 0.5°C, the microbial counts were < 2000 cfu/ml at day 29 for both low and high SCC milk, but the proteolysis in the high SCC milk was just reaching the level that is sufficient to product off-flavor.

Key Words: pasteurized milk, somatic cell count, proteolysis and lipolysis

1583 Rheological properties of primary stabilizer/milk protein/ κ -carrageenan/sucrose systems simulating ice cream mix. S. Thaiudom* and H.D. Goff, *University of Guelph, Guelph, ON, Canada*.

The influence of primary stabilizers, preparation temperature and the concentration of κ -carrageenan on the rheological behaviour of aqueous systems simulating ice cream mix was studied using dynamic rheological techniques with a controlled stress rheometer. Three different primary stabilizers (locust bean gum (LBG), guar, and xanthan), two heat treatments (69°C/30min and 85°C/30min), and three concentrations of κ -carrageenan (0.0, 0.025, and 0.05% w/w) were fitted to a factorial experimental design. All samples were comprised of 12% (w/w) sucrose and were aged overnight at 4°C before rheological properties were measured at the same temperature. Flow behaviour of all samples with κ -carrageenan showed a thixotropic loop due to the interaction of κ -carrageenan and milk protein whereas samples without κ -carrageenan showed pseudoplastic behaviour. Phase separations were seen in all samples without κ -carrageenan due to depletion-flocculation of primary stabilizers and milk proteins. However, samples with LBG showed less phase separation than samples with guar or xanthan. Storage and loss moduli were governed by type of primary stabilizer, preparation temperature, concentration of κ -carrageenan, and the interactions of these main effects. Storage and loss moduli increased significantly with both increasing concentration of κ -carrageenan and/or preparation temperature at 85°C. This is presumably due to either the gelation of κ -carrageenan or the interaction between κ -carrageenan and milk proteins inducing solid-like characteristics. Samples comprised of xanthan with or without κ -carrageenan showed significantly higher storage moduli than the samples with guar or LBG, probably due to self-association of xanthan to form a weak gel in the system. However, loss moduli of samples comprised of xanthan with 0.025 or 0.05% (w/w) κ -carrageenan were very small, possibly due to κ -carrageenan gelation or enhanced self-association of xanthan, resulting in less liquid-like behaviour. Thus, we have concluded that the addition of κ -carrageenan has developed a more elastic in the aqueous solution.

Key Words: rheology, milk protein, κ -carrageenan

1584 Control of acidification of yogurt by microencapsulated bacteriocin. J. Y. Imm*¹, S. J. Oh², J. S. Kim¹, and S. H. Kim³, ¹*Korea Food Research Institute*, ²*Korea Yakult Co. Ltd.*, ³*Korea University*.

The purpose of this study was to examine the effect of microencapsulated bacteriocin to control excessive acidification of yogurt. *Lactococcus* sp. KU109, a bacteriocin producer was isolated from swiss cheese and crude bacteriocin was prepared by lyophilization of *Lactococcus* sp. KU109 culture grown in 10% skim milk containing 1% glucose. Bacteriocin powder was encapsulated with acid release coating material, Eudragit EPO by surface reforming method (hybridization). Yogurt was made by adding 0.02% (w/w) commercial starter to pasteurized 12% reconstituted milk either with (0.5, 1 and 1.5%, w/w) or without incorporation of encapsulated bacteriocin. The size and appearance of encapsulated bacteriocin was observed using scanning electron microscopy and the effect of incorporated bacteriocin on viable cells, pH and titratable acidity (TA) was monitored during incubation at 42°C for 24 h. The encapsulation with formulation ratio of 9:1 (bacteriocin:Eudragit EPO, w/w) formed sphere shaped particles of smooth surface with mean size of 25 μ m. The activity of 1.5% bacteriocin was 100 AU/mL. There was no substantial difference in time to reach pH 4.6 and the pH after 6 h incubation was ranged from 4.56 to 4.69. More than 6 h incubation, yogurt containing bacteriocin started showing difference in pH and the amount of acid production. The pH and TA of control yoghurt were 3.97 and 1.29% after 24 h whereas they were 4.25 and 1.16% in yogurt containing 1.5% encapsulated bacteriocin. The incorporation of bacteriocin in yogurt significantly inhibited the growth of *L. bulgaricus* and the extent of inhibition was increased as the concentration of bacteriocin increased. After 9 h incubation, growth of *L. bulgaricus* was resulted in 2 log reduction in the presence of 1.5% bacteriocin. However, the growth of *S. thermophilus* showed only 0.5 log reduction during incubation. The result suggests that the microencapsulated bacteriocin has potential to control excessive growth of *L. bulgaricus* caused by temperature abuse or post-acidification.

Key Words: bacteriocin, encapsulation, yogurt

1585 Consumer evaluation of "high-CLA dairy products" produced from cows fed fish oil. S. T. Franklin, L. J. Maynard, A. Pasley, and M. C. Newman, *University of Kentucky, Lexington, KY*.

Milk from cows fed fish oil contains high concentrations of conjugated linoleic acid (CLA) and increased n-3 fatty acids. Dairy products processed from this milk could provide substantial health benefits for consumers, however, questions exist as to the taste of dairy products produced from cows fed fish oil. Thus, eight Holstein cows in late lactation were assigned to treatments of a control (C) diet or a diet containing fish oil (FO) at 2% of dry matter in a 2 X 2 Latin square design. Cows were moved to a tie-stall barn 1 wk prior to the start of the trial to allow for acclimation. Each period consisted of 4 wk, with 2 wk for acclimation to the diets. Milk was collected from cows during the last 2 wk of each period and processed into butter, yogurt, and 2% milk. Products processed during the second period were allocated into individual samples for blind taste test by 111 consumers. Consumers also answered surveys concerning willingness-to-pay for products containing high CLA. Results of the consumer taste tests were that 34% of the consumers preferred the C milk, 21% preferred the FO milk, and 45% had no preference; with 60% of the consumers reporting that the taste of the FO milk was acceptable or better compared with 75% for the C milk. For the yogurt, 57% of the consumers reported that the taste of the FO yogurt was acceptable or better compared to 84% for the C yogurt. The flavor of the FO butter was rated as acceptable or better by 77% of the consumers compared to 96% for the C butter. Preference for the FO butter was 18% compared with a 42% preference for the C butter and 40% with no preference. No consumers reported a "fishy" flavor in any of the products. Willingness-to-pay for high-CLA products was correlated with the survey setting, the respondents' status as primary household shopper, gender, and priorities placed on price, fat content, and taste. In conclusion, dairy products made from milk from cows fed fish oil were found by the majority of the participants to be acceptable in flavor and high-CLA products could command a premium price.

Key Words: Conjugated linoleic acid, Dairy products, Fish oil

1586 Sensory and analytical analysis of milk formulations with sweet cream buttermilk. J. Powell*, S.E. Duncan, S.F. O'Keefe, and S.S. Sumner, *Virginia Polytechnic Institute and State University*.

The sensory and analytical characteristics of three dairy beverages were analyzed using two underutilized dairy products, liquid sweet cream buttermilk and dried sweet cream buttermilk, with skim to produce two lowfat (.5%) formulations. A hedonic test was used to measure the overall acceptability of these products as compared to skim milk, and the "just right" test was used to determine if there was a significant difference in flavor color and viscosity among the three samples. Sensory characteristics of nonfat milks were enhanced or changed by adding the liquid buttermilk and the dried buttermilk. The hedonic test showed that on an increasing scale from likes extremely to dislikes extremely, the skim milk scored a five, the liquid buttermilk formulation scored a 4, and the dried buttermilk formulation scored a nine. These results showed the liquid buttermilk formulation was more acceptable than the traditional skim or the dried buttermilk formulation. The average value for the "just right" test with 3 being "just right", showed that for the previously mentioned attributes, the cream and liquid buttermilk were "just right", and the dry buttermilk was evaluated above the "just right" score with a score of 4. Solid Phase Microextraction-Gas Chromatography/Mass Spectrometry was used to elucidate key flavor compound susceptible to light oxidation.

Key Words: Lowfat, Buttermilk, Sensory

1587 Use of Capillary Electrophoresis (CE) to determine metabolic organic acids in milk. Jesus M. Izco*¹, Monica Tormo¹, and Rafael Jimenez-Flores¹, ¹*Dairy Products Technology Center, Cal Poly*.

The aim of this work is to optimize a CE method for the simultaneous determination of eleven metabolically important organic acids (oxalic, citric, formic, succinic, orotic, uric, pyruvic, acetic, propionic, lactic and butyric). This method was tested to evaluate carbohydrate catabolism in lactic acid bacteria and *Bacillus* spp. Organic acids have little or no

UV absorbance, thus indirect UV detection is necessary. Also, a surfactant was used to avoid electroosmotic flow. The separation was carried out on an uncoated capillary (110 cm, 75 μ m I.D.) at 20kV for 18 min. Running buffer was tested at different pH values between 5.0 and 12.0. Addition of methanol was tested to improve the separation. Sterilized permeate obtained from skim milk, was inoculated with spores from 4 different strains (*B. licheniformis* 12759 and DPTC bacillus strains 14580, SL3 and CL6) and incubated at 40C in the BactiAlertTM System until detection by the sensor. Sample preparation consisted on treating 1 ml of permeate samples with sulfuric acid 4.5 mM, containing 15 ppm of boric acid as internal standard. Also, yogurt organic acids were analyzed in order to test the versatility of the technique. Good separation for all organic acids was achieved, except for pyruvic and acetic acids, which migrated as a single peak. Linearity was established between 2 and 100 ppm for most of them, with R² values between 0.97 and 0.99. Citric, succinic, orotic, pyruvic-acetic, propionic and lactic acids were detected and quantified in all of the permeate samples. Values of 85031, 557, 778, 783, 4810 and 1365 ppm respectively were found in sterilized permeate. Depending on the strain, different profiles have been defined. In the case of *B. licheniformis* 12759, the peak area of most organic acids was reduced, indicating a different metabolism. In yogurt, this test showed no presence of butyric acid, the lactic acid peak prevented quantification of propionic acid, and the rest of them were quantified successfully. The proposed method is useful to analyze the metabolism of different bacteria grown in milk substrates giving us a rapid tool to evaluate the quality of dairy products during manufacturing and storage.

Key Words: Organic acids, Capillary Electrophoresis, Dairy products

1588 Effect of addition of whey protein concentrate in the manufacturing of set yogurt. S. C. G. Lima, A. J. Petenate, and M. L. Gigante*, *State University of Campinas, Campinas, SP/Brazil.*

The increase in the level of milk solids used in the manufacturing of yogurt aims to improve the firmness and to reduce product syneresis. The object of this study was to compare the firmness, susceptibility to syneresis and pH of set yogurts manufactured with the addition of skim milk powder (SMP) or whey protein concentrate (WPC) in different concentrations. A Split-Plot design with tree replicate was used. The milk was divided into portions and five treatments were applied at random in the portions. The treatments were the following: without addition of solids and with addition of SMP or WPC in order to increase the level of solids to 13 and 15%. Set yogurts were stored in plastic container at 4°C and randomly chosen after 1, 8, 16 and 23 d. and analyzed for firmness, susceptibility to syneresis and pH. After the manufacturing, the set yogurts were analysed for total solids, protein, fat, lactose and ash. The set yogurts without the addition of solids, with the addition of SMP or WPC in order to increase the level of solids to 13 and 15% presented, respectively, 11.13, 13.01, 14.98, 13.04 and 15.04% of total solids. Set yogurts with SMP were significantly firmer and the firmness of all products increased significantly during storage. Set yogurts with WPC and 13% of total solids presented significant reduction of syneresis during storage, differing from the others which presented a significant increase of syneresis during storage. Products to which SMP or WPC were added in order to increase the level of solids to 15% presented, respectively, the greatest (29.86) and the smallest (9.13) percentage of increase of syneresis during storage. The treatment did not significantly influenced the post-acidification of the products, which was significantly influenced by storage duration. The substitution of SMP for WPC to increase the level of solids in milk used for the manufacturing of set yogurt resulted in less firm products, with less syneresis and no change in post-acidification.

Key Words: set yogurt, WPC, syneresis

1589 Texture Profiling of Skim Milk and Carrageenan Solutions. N.R. Pollen*¹ and C.R. Daubert¹, ¹*North Carolina State University.*

The texture profile of skim milk and carrageenan solution has been studied using rheological and sensory techniques. Three rheological properties were considered to characterize sensory properties of fluid foods: yield stress, steady shear viscosity at 50 s⁻¹, and extensional viscosity. All analyses were performed at 25°C on skim milk samples stabilized

with κ and λ - carrageenan blends of 50/50, 33/67, and 25/75 in addition 100% pure κ and λ -carrageenan. All solutions were tested between the concentration range of 0-0.20% (wt/wt), with 0% as pure skim milk. Steady shear viscosity as well as yield stress were determined using a Haake VT550 viscometer with a concentric cylinder or vane attachment, respectively. Shear rates were ramped from 0 to 100, then back to 0 s⁻¹. Extensional viscosity was measured using a specifically designed tube viscometer of expandable- length tubing, 5.08 cm in diameter. Fluids exited these vertically hanging tubes through small holes with a radius ranging from 0.5 to 10 mm. Pressure drop, flow rate, and strain rate at a constant entrance angle (90°) were measured for extensional flow calculations. As anticipated, results supported the direct relationships between carrageenan concentration and viscosity and yield stress. Also expected, κ -carrageenan formed the strongest gels at all concentrations. The extensional viscosity of solutions containing λ -carrageenan produced higher Trouton ratios, indicating the λ -carrageenan molecule was more readily extendible. Preliminary sensory results of mouthfeel viscosity and finger characterization of stringiness correspond with rheological testing; these correlations support the selection of the fundamental rheological parameters as predictors for sensory response for fluid food systems.

Key Words: Texture Profiling, Extensional Viscosity, Carrageenan

1590 Effect of sterilization on physical properties of recombined milk. G. Prez-Hernandez, B. Magaa-Ypez*, and R. L. Richter, *Texas A&M University, College Station, TX.*

The objective of this research was to determine the effect of retort sterilization on some physical characteristics of the emulsion and on particle size parameters of the emulsion. Emulsions containing casein to whey protein ratios of 80:20, 60:40, 40:60, 0:100, and 0.5% monoglycerides, 0.5% lecithin, or a mixture of lecithin with monoglycerides were homogenized at 20 and 90MPa. The protein and fat concentrations of the milk were 3%. Stability index, pH, viscosity and particle size distribution parameters were measured before and after sterilization at 121°C for 15 min. The heat treatment lowered the pH from 6.63 to 6.57 (p \leq 0.0001). Viscosity was affected by the interaction between the heat treatment and the casein:whey protein ratio (p \leq 0.0001). Viscosity increased from 2.62cp to 7.46cp for the sample that contained only whey protein, but differences in viscosity for other ratios of casein to whey protein were not found. The volume surface average diameter was affected by the interaction between heat treatment and casein:whey protein ratio. The volume surface average diameter increased from 0.4663 μ m before heating to 1.058 μ m after heating in the sample with casein to whey protein ratio of 40:60 (p \leq 0.06), and from 0.5309 μ m before heating to 1.7168 μ m after heating for the sample with 100% whey protein (p \leq 0.0003). The surface area of particles increased in the samples that contained 80 and 60% of the protein as casein during heating at both homogenization pressures, but decreased in the sample which had a casein to whey protein ratio of 40:60 homogenized at 90 MPa and with the sample that did not contain casein homogenized at 20 and 90MPa. Particle size surface area decreased after heat treatment in the samples with casein to whey protein ratios of 40:60 and 0:100 when the samples contained emulsifier. However, the decrease in surface area of the particles was significant only for the sample that contained no casein. The stability index increased after sterilization for all treatments containing emulsifiers.

Key Words: Recombined milk, Sterilization, Emulsion

1591 Selection of Cows Producing Fat of Low- and High-atherogenicity and the properties of butter and cheese made from their milk. She Chen¹, Shelly Zimmerman¹, Earl Hammond¹, Gene Freeman¹, David Kelley¹, Naomi Scott², Cindie Luhman², and Donald Beitz*¹, ¹*Iowa State University,* ²*Land O'Lakes/Farmland.*

Milk fat from approximately 330 cows from Iowa State University and Land O'Lakes/Farmland herds was analyzed for fatty acid composition. The index of atherogenicity (IA) of each fat sample was calculated by using the formula of Ulbricht and Southgate (Lancet 338:985, 1991): IA=[% lauric + 4(% myristic) + % palmitic] / % unsaturated acids. Milk fat ranged from 1.1 to 4.0 in IA. Four cows from both herds with highest and lowest IAs were selected. Milks from low-IA and high-IA cows and bulk tanks were pasteurized and converted into butter and Cheddar and provolone cheeses. Flavor notes of products were identified and scored by taste panels. Texture of butter and cheeses was

measured with a Texture Analyzer. Butters were achieved with low-IA (1.5), high-IA (2.3), and bulk tank-IA (1.9). Corresponding values for Cheddar were 2.1, 3.4, and 2.4 and for provolone 1.6, 2.6, and 2.1. Panels detected no differences in flavor notes for the three IA types of butter. For Cheddar, sour and bitter flavor notes approached but did not achieve significance at 0.05. Provolone showed differences in buttery flavor, with both high- and low-IA being significantly less than bulk tank. High-IA

butter was harder than low-IA butter as measured by penetration and creep. Similar differences were observed in the hardness of Cheddar and provolone cheeses, with high-IA being harder than low-IA. Seemingly, cows that give milk fat with a low IA will yield butter and cheeses with insignificant differences in flavor but slightly softer textures.

Key Words: Milk Fat, Butter, Cheese

ASAS/ADSA Physiology: General Physiology

1592 Influence of corticotropin-releasing hormone (CRH) on the expression of steroidogenic acute regulatory (StAR) protein in neonatal pigs derived by Caesarian section or natural birth. J.A. Carroll^{*1}, D. Alberts², D.J. Parzik², D.M. Stocco^{2,3}, and T.H. Welsh, Jr.^{2,3}, ¹*Animal Physiology Research Unit, ARS-USDA, Columbia, MO*, ²*Texas Tech University Health Science Center, Lubbock, TX*, ³*Texas A&M University, College Station, TX*.

We previously reported that pigs born by Caesarian section (C-section) have greater basal and CRH-induced cortisol (CS) secretion compared to natural birth pigs. This study evaluated potential differences in StAR protein and cytochrome P450 side-chain cleavage enzyme (P450scc) protein expression in C-section pigs which may have contributed to this altered CS secretion. Eight crossbred sows were selected for the study (n = 4 natural birth and n = 4 C-section). Gestation length did not differ between natural birth and C-section pigs (113.6 ± .1 and 113.2 ± .3 d, respectively). Blood and tissue samples from 38 pigs were collected at birth. Remaining pigs were sustained with natural birth sows until 2wk of age (n = 39). At 2wk of age, pigs were non-surgically cannulated for blood sample collection to assess pituitary-adrenal responsiveness to porcine CRH (10 µg/kg). Blood samples were collected at -30, -15, 0, 5, 10, 20, 40, 60, and 90 min, with CRH or saline given at Time 0. Total RNA was isolated from the pituitary and adrenal glands to evaluate mRNAs specific for pro-opiomelanocortin (POMC) and for the ACTH receptor. Adrenocortical samples were used in Western blot procedures to determine StAR and P450scc protein content. While basal serum concentration of CS was not different at birth (P = .86), adrenocortical expression of StAR protein was lower (P < 0.0001) in C-section pigs as compared to natural birth pigs. Interestingly, serum ACTH (P = 0.0008) and ACTH receptor mRNA (tendency; P < 0.06) were greater in C-section pigs, suggesting a compensational effect due to the reduced expression of StAR protein in these pigs. A developmental decrease was observed in serum CS (P < 0.0001) and ACTH (P < 0.044), while a developmental increase was observed in POMC mRNA (P < 0.0001). ACTH receptor mRNA expression tended (P < 0.07) to decrease with age. Both, serum concentration of CS and StAR protein expression were increased following the CRH challenge (P < .05) whereas no change was detected in P450scc protein expression. Type of birth, age, and CRH challenge each influenced the correlations among various components of the HPA axis. These data suggest an important role for StAR and P450scc adrenocortical proteins in mediating developmental- and hormonal-induced changes in CS synthesis and secretion in the young pig.

Key Words: StAR protein, Cortisol, Pigs

1593 Hepatic corticosteroid-binding globulin (CBG) mRNA expression and plasma CBG levels in pigs in response to social and heat stress. J. Heo^{*1}, H. G. Kattesh¹, M. P. Roberts¹, R. L. Matter², J. L. Morrow³, and J. W. Dailey³, ¹*University of Tennessee, Knoxville TN*, ²*ARS-USDA, Columbia MO*, ³*ARS-USDA, Lubbock TX*.

Plasma cortisol, CBG, hepatic CBG expression, and other physiological as well as behavioral measures of stress were studied in pigs in response to elevated temperature in conjunction with establishing social hierarchy. Twenty-four pigs (four pigs/litter) were weaned at 25 days of age and housed by litter for 2 wk at 23 ± 2°C. On d 0, animals were weighed and placed under general anesthesia for collection of blood (10 ml) and liver tissue (~100 mg). On d 1, three pigs of similar weight (23 ± .9 kg) but from different litters were allotted to eight nursery pens within two environmentally controlled rooms (12 animals/room). One room was maintained at 23 ± 2°C (CONT) and the other at 33 ± 2°C (HEAT). On d 8-14 both rooms were maintained at 23 ± 2°C (REC). Animals were videotaped for 72 h beginning on d 1 and 8 to document

behavioral changes in response to room temperature and to determine social order. Blood and liver tissue were collected again on d 7 and 14. Data was analyzed as a randomized complete block design using Proc Mixed procedure of SAS. Plasma haptoglobin increased (467.2 ± 122.5 vs 763.4 ± 112.9 ug/ml; d 0 vs d 7, P<.05) and cortisol and CBG decreased (9.92 vs 8.51 ± .83 ug/dl, 11.41 vs 9.93 ± 1.07 ug/ml; d 0 vs d 7, respectively, P<.05) in the HEAT group. Hepatic CBG mRNA level and neutrophil: lymphocyte ratio were not affected (P>.1) by treatment. HEAT pigs displayed increased (P<.01) drinking but reduced feeding (P<.01) and lying in contact with other pigs (P<.05) behaviors. ADG tended (P=.06) to be lower for HEAT (.64 ± .06 kg/d) compared to CONT (.82 ± .06 kg/d) pigs. During REC, HEAT pigs had similar (P>.1) ADG, plasma cortisol, CBG, haptoglobin, and drinking and feeding but increased (P<.01) lying with contact behaviors compared to CONT. Measured physiological and behavioral responses were not related to social status. These results indicate that reduced circulating levels of cortisol and CBG in pigs following 7-d exposure to elevated temperature may not be determined by hepatic CBG mRNA expression.

Key Words: Pig, Heat stress, CBG

1594 Cold-induced changes in brown adipose tissue (BAT) composition and iodothyronine 5'-deiodinase (5'D) activity in newborn Angus and Brahman calves. S.J. Falck^{*1}, G.E. Carstens¹, S. Kahl², S.R. Busch¹, L.J. Slay¹, C.D. Gilbert¹, and S.B. Smith¹, ¹*Texas A&M University, College Station, TX*, ²*USDA, Agricultural Research Service, Beltsville, MD*.

We previously found that newborn Brahman (BR) calves generate less heat from BAT in response to a norepinephrine challenge than Angus (AN) calves even though BAT 5'D activities (converts thyroxine, T₄ to triiodothyronine, T₃) were higher in BR calves. The aim of this study was to further characterize 5'D in newborn calves, and to examine breed effects on cold-induced changes in BAT composition, 5'D activity, and plasma T₃ and T₄ levels. AN (n = 15) and BR (n = 20) calves were each assigned to 1 of 3 postnatal treatments: newborn (N), cold (C) and warm (W) calves. Newborn calves were killed at 9 h of age, whereas, C and W calves were killed after 48 h of exposure to 4 and 20°C. Rectal temperature (RT) and blood samples were collected at 0, 12, 24 and 48 h, and plasma analyzed for T₃ and T₄. Deiodinating activity of BAT was determined by quantifying ¹²⁵I⁻ released from ¹²⁵I-labeled reverse-T₃ using assay conditions for type I (5'D-I) and type II (5'D-II). RT were higher (P < .01) in AN calves at time 0 (38.8 vs 38.1 ± .16°C, but were similar to BR calves thereafter. BR calves had higher plasma T₃ (61%; P < .001) and T₄ (31%; P < .05) levels than AN calves, but plasma T₃ increased more due to cold in BR (62%; P < .001) than AN (10%; P = .80). Overall, plasma T₄ levels were 31% higher (P < .001) in C than W calves. Compared to AN calves, BR had less (P < .05) BAT lipid at birth (2.12 vs 1.33) and after C (1.95 vs .63), but similar amounts after W treatment (2.32 vs 1.89 ± .28 g/kg BW). Cytochrome c oxidase activity (µmol/min/g BAT) was unaffected by breed and was 68% higher in C than W calves. BAT 5'D-I activity was higher (P < .001) in BR calves at birth (.53 vs .95 ± .01 nmol I/h/mg protein), but not after C or W treatment. Cold decreased (P < .01) 5'D-I activity 29% in BR calves, but numerically increased 5'D-I in AN calves. 5'D-II activity was higher (P < .001) in BR calves (.29 vs .94 ± .12 pmol I/h/mg), but was unaffected by postnatal treatment. The results suggest that although BR calves mobilize BAT lipid more rapidly during cold exposure, this substrate is not effectively used to support BAT thermogenesis.

Key Words: Brown Fat, 5'-Deiodinase, Thyroid Hormones

1595 Growth rates of Holstein heifers fed diets differing in amounts of protein, energy and protein:energy ratios and treated or not with bST. M. Liboni*, T.I. Belloso, M.S. Gulay, M.L. Schairer, M.J. Hayen, L.C. Teixeira, K.C. Bachman, and H.H. Head, *University of Florida*.

One hundred and twenty Holstein heifers were assigned to one of four diets (30/diet) and bST treatments in a 2x2x2 factorial arrangement of treatments beginning when they were 120 d of age. Diets were formulated to contain 14 or 19% CP with energy concentrations of 100% and 110% of daily requirements (NRC,1989) for each CP percentage. These diets were fed once daily in quantities to meet desired average daily weight gains (ADG) of 0.81 kg for diets with 14% CP and 1.09 kg for diets with 19% CP. The g of CP/Mcal ME for the four diets were held constant throughout the trial at 50, 55, 65 and 73, respectively. When heifers reached 341 Kg BW they then were transferred to the breeding herd. Heifers were raised in 8 groups of 10 heifers each and 2 groups of 20 heifers each. All heifers were weighed and height at withers measured when assigned to trial and then weekly thereafter. One-half of the heifers in each group was injected with bST (POSILAC[®], 500 mg bST/1.4 ml, Monsanto) biweekly in the following amounts: 0.2 ml up to 181 Kg BW, 0.3 ml between 182-273 Kg BW, and 0.4 ml above 273 Kg BW. These volumes provided about 5.1, 7.6 and 10.2 mg bST/d. Average daily weight gains (kg/d) of heifers on the four diets were 0.89, 0.01, 0.97, 0.01, 1.03, 0.01 and 1.02, 0.01. The ADG for the four diets differed ($P < 0.0001$). At 341 Kg BW the average ages of heifers fed the four diets were: 365, 4.63, 368, 4.00, 337, 4.00 and 356, 4.00 d. Difference in the average age to reach 341 Kg was significant ($P < 0.0003$). Average total height increases (AHI, cm) during the time period heifers were on experiment were 28.46, 0.69, 31.79, 0.70, 31.78, 0.70 and 34.62, 0.70, respectively. The AHI for the four diets differed ($P < 0.05$). Overall, there were significant positive effects of bST on ADG ($P < 0.0129$) and AHI ($P < 0.0898$) for heifers fed the four diets. Injections of bST reduced the number of days for heifers to reach 341Kg for the two high energy diets compared to uninjected heifers fed the same diets ($P < 0.0611$), but not for the lower energy diets. Considering the whole growth period, no significant effects of season of birth of heifers were detected on age to reach 341 Kg, ADG or AHI. No season of birth x bST interaction was detected for any growth measure.

Key Words: Heifer, Protein:energy, Growth

1596 Hepatic oxidative metabolism in lactating dairy cows is modulated by increasing doses of intravenous lipopolysaccharide. M. R. Waldron*¹, T. Nishida¹, B. J. Nonnecke², and T. R. Overton¹, ¹Cornell University, Ithaca, NY, ²National Animal Disease Center, USDA ARS, Ames, IA.

The effect of intravenous lipopolysaccharide (LPS; *E. coli* O11:B4) infusion on liver metabolism in twelve multiparous midlactation cows (150-220 DIM) was investigated. A covariate liver sample was obtained via percutaneous trochar biopsy 7 d prior to LPS infusion. Liver slices were used *in vitro* to determine hepatic capacities for conversion of [¹⁻¹⁴C]propionate, [¹⁻¹⁴C]alanine, and [¹⁻¹⁴C](L+)-lactate to CO₂. Hepatic capacities for conversion of [¹⁻¹⁴C]palmitate to CO₂, acid soluble products (a proxy for ketone body production), and stored esterified products also were determined. Seven days later, cows were intravenously infused with either 0 (n=6), 1.0 (n=4), or 2.0 (n=2) μg LPS/kg BW dissolved in 100 ml sterile physiological saline during a 100-min infusion. Saline infused cows were pair-fed with LPS-infused cows during the infusion period to eliminate effects of feed intake with LPS treatment. Liver was biopsied at 4.5 h after the beginning of infusion and metabolic incubations were conducted as described for covariate samples. Differences in the capacities of liver from control and LPS-infused cows to convert [¹⁻¹⁴C]palmitate to CO₂, acid soluble products, and stored esterified products were not significant ($P > 0.20$). However, LPS infusion tended to increase the capacity of liver to convert [¹⁻¹⁴C]propionate (4.19, 4.23, 6.07 μmol/h x g wet weight; $P < 0.12$) and [¹⁻¹⁴C](L+)-lactate (0.66, 0.98, 1.00 μmol/h x g wet weight; $P < 0.06$) to CO₂ for 0, 1.0, and 2.0 μg LPS/kg BW, respectively. Differences in hepatic capacity to convert [¹⁻¹⁴C]alanine to CO₂ were not significant ($P > 0.20$). These data suggest that aspects of hepatic carbohydrate metabolism in lactating dairy cows are affected by the inflammatory response elicited by LPS infusion; however, effects of the inflammatory

response on hepatic fatty acid metabolism in midlactation cows appear to be minimal.

Key Words: Liver Metabolism, Lipopolysaccharide, Immune System

1597 Circulating leukocyte populations, serum cytokines and plasma vitamins A and E in mid-lactation dairy cows infused with varied doses of lipopolysaccharide (LPS). B. J. Nonnecke¹, M. R. Waldron*², T. Nishida², T. R. Overton², and R. L. Horst¹, ¹National Animal Disease Center (NADC), USDA ARS, Ames, IA, ²Cornell University, Ithaca, NY.

Four multiparous lactating cows were used in 4 x 4 Latin square design to assess effects of LPS (serotype *E. coli* O11:B4 at 0.0, 0.5, 1.0, 1.5 μg/kg BW) on blood leukocyte populations, cytokines (TNF-α and IFN-γ) and vitamins [retinol,RRR-α-tocopherol and β-carotene (provitamin A)]. LPS, in 100 ml of physiological saline, was infused IV at 1 ml/min over 100 min. Blood was collected by jugular catheter immediately before infusion (0h) and at 2 (leukocytes not sampled at this time), 4, 6, 24 and 48h. Samples were shipped overnight to the NADC for analysis. Blood leukocytes were phenotyped by flow cytometry and the cytokines and vitamins were quantified by ELISA and reverse-phase HPLC, respectively. LPS infusion caused a marked leukopenia at 4 and 6 h that was characterized by a reduction in the number of T cells (CD3⁺, CD4⁺, CD8⁺ and γδTCR⁺ subsets), B cells, monocytes and cells expressing IL-2 receptors and MHC class II antigens. By ≥24h, values were comparable to preinfusion and control-cow values. Interestingly, percentages of B cells and γδTCR⁺, IL-2r⁺ and MHC class II antigen⁺ cells in leukocyte populations from LPS-treated cows were elevated at 4 and 6 h. Serum TNF-α was affected by infusion of LPS in a dose-dependent fashion, with maximal concentrations occurring at 2 h. TNF-α concentrations in these cows declined precipitously from 2 to 6 h and were not different from preinfusion values or those of control cows at ≥24h. Serum IFN-γ, extremely low throughout the experimental period, was unaffected by LPS. Plasma retinol, RRR-α-tocopherol, and β-carotene also were unaffected by LPS. These results and metabolic data presented in the companion poster suggest LPS-induced inflammation influences broad aspects of the immune system, affecting the metabolism of dairy cows.

Key Words: Lipopolysaccharide, Vitamins A and E, Immune Function

1598 Metabolic responses of lactating dairy cows to intravenous infusion of increasing amounts of lipopolysaccharide. M. R. Waldron*¹, T. Nishida¹, B. J. Nonnecke², and T. R. Overton¹, ¹Cornell University, Ithaca, NY, ²National Animal Disease Center, USDA ARS, Ames, IA.

Four multiparous lactating cows (175-220 DIM) were used in a 4x4 Latin square design to assess the effects of increasing doses (0.0, 0.5, 1.0, 1.5 μg/kg BW) of lipopolysaccharide (LPS; *E. coli* O11:B4) on performance and blood metabolites. Treatments were dissolved in 100 ml of sterile saline and infused intravenously over a period of 100 min. Milk production was decreased linearly for 24 h after LPS infusion (34.9, 22.4, 22.0, and 16.5 kg; $P < 0.001$) and generally returned to preinfusion levels by the sixth milking following LPS infusion. The DMI also was decreased linearly for 24 h following LPS infusion (21.2, 17.6, 15.5, and 10.9 kg; $P < 0.01$) and regained preinfusion levels 3 d following infusion. Blood was sampled immediately before infusion (0 h), at 60-min intervals for 8 h, and at 24 and 48 h postinfusion. Reported means for hormone and metabolite concentrations with treatment by time effects are at the 3 h timepoint. Plasma insulin (1.54, 1.64, 2.37, and 3.88 ng/ml), glucagon (80.6, 204.0, 249.3, and 326.3 pg/ml), and cortisol (0.14, 1.16, 1.51, and 1.79 ng/ml) concentrations increased linearly following LPS infusion (treatment by time, $P < 0.01$). Plasma (L+)-lactate concentrations (5.83, 7.43, 7.95, and 6.63 mg/dl) increased following LPS infusion (treatment, $P < 0.001$). There was a linear decrease (treatment by time, $P < 0.01$) for plasma BHBA (9.8, 5.3, 4.4, and 2.9 mg/dl) after infusion. Plasma NEFA were increased by the 1.5 μg LPS/kg BW treatment (204, 185, 198, and 260 mg/dl for 0.0, 0.5, 1.0, 1.5 μg LPS/kg BW, respectively; $P = 0.037$). There was no effect of LPS infusion on plasma glucose concentrations ($P > 0.2$). These data suggest that the inflammatory response elicited by LPS has dose-dependent metabolic consequences that may be important for metabolic health in dairy cows.

Key Words: Lipopolysaccharide, Hormones, Metabolites

1599 Propionibacteria as a direct fed microbial: effects on the insulin-like growth factor system and reproduction in early postpartum dairy cows. C. C. Francisco*, D. N. Waldner, C. S. Chamberlain, and L. J. Spicer, *Oklahoma State University, Stillwater, OK.*

This study was designed to investigate the effects of supplementing a direct fed microbial, Propionibacteria culture (*P. acidipropionici*) to the diets of postpartum cows on plasma IGF-I and IGF-I binding protein (IGFBP) concentrations and reproduction during the first 12 wk of lactation. Pluriparous Holstein cows (n=19) were individually fed a TMR and randomly assigned to either a control or treatment group. Each of the treated cows (n=9) received 17 g of Propionibacteria culture daily from -2 to 12 wk postpartum. In blood samples collected twice a week, plasma IGF-I and IGFBP concentrations did not differ between the two groups of cows, however, IGF-I concentrations increased (P<0.001) by fourfold from 1 to 12 wk postpartum. For both groups of cows, plasma IGFBP-3 concentrations at wk 1 were 14% and 15% lower (P<0.001) than at wk 6 and 12, respectively. Plasma IGFBP-2 concentrations at wk 6 and 12 were 19% and 27% greater, respectively, than wk 1, and plasma IGFBP-5 concentrations were 32% and 33% greater (P<0.001) at wk 6 and 12, respectively, than wk 1. Propionibacteria-treated and control cows had similar concentrations of progesterone peak and area under the progesterone curve during first and second postpartum estrous cycles. Interval to first and second postpartum ovulations did not differ between treated and control cows. Feeding Propionibacteria to early lactating cows did not affect the changes in the plasma profiles of IGF-I and IGFBP nor did it affect reproductive function.

Key Words: Propionibacteria, Insulin-like Growth Factors, Reproduction

1600 Propionibacteria as a direct fed microbial: effects on energy balance, milk production, milk components, metabolic hormones and metabolites in early postpartum dairy cows. C. C. Francisco, D. N. Waldner*, C. S. Chamberlain, R. P. Wettemann, and L. J. Spicer, *Oklahoma State University, Stillwater, OK.*

The objective of this study was to determine the effects of directly feeding Propionibacteria culture (*P. acidipropionici*) on energy balance (EB), milk yield, metabolic hormones and metabolites in early lactating cows. Pluriparous Holstein cows (n=19) were individually fed a TMR and randomly assigned to either a control or treatment group. Each of the treated cows (n=9) received 17 g of Propionibacteria culture daily from -2 to 12 wk postpartum. Calculated EB of cows supplemented with Propionibacteria (-7.3±1.5 Mcal/d) tended to be greater (P<0.10) than control cows (-11.4±1.5 Mcal/d) during wk 1 of lactation. Fat-corrected milk and DMI were not affected by treatment. BCS at wk 4 and 10 postpartum did not differ (P>0.50) between groups. Cows fed Propionibacteria had greater (P<0.05) percentages of milk protein (5.0±0.15% vs. 4.0±0.14%) and SNF (10.5±0.15% vs. 9.7±0.14%) than control cows during wk 1 of lactation. Percentages of milk fat and lactose were not influenced by treatment. In plasma samples collected twice a week, NEFA concentrations at wk 1 were greater (P<0.01) in treated than control cows. Plasma leptin concentrations tended to be greater (P<0.10) in cows fed Propionibacteria (8.1±1 ng/mL) compared with control cows (5.3±1 ng/mL) during the 12 wk study and did not change with week postpartum. Plasma cholesterol and glucose concentrations were not affected by supplemental feeding of Propionibacteria but both metabolites increased (P<0.05) with week postpartum. Concentrations of plasma insulin were also unaffected by treatment and increased by about twofold (P<0.05) between wk 1 and 12. In conclusion, feeding Propionibacteria culture to early lactating dairy cows increased milk protein and SNF content, and increased plasma NEFA and leptin levels.

1601 Administration of bST elevates phosphoenolpyruvate carboxykinase mRNA in lactating dairy cows. J.C. Velez* and S.S. Donkin, *Purdue University West Lafayette, IN.*

Somatotropin (bST) administration increases milk production and a corresponding increase in hepatic glucose output is necessary to meet increased needs for mammary metabolism and lactose synthesis. The objective of this study was to determine the effects of bST on expression of pyruvate carboxylase (PC) and phosphoenolpyruvate carboxykinase

(PEPCK), two enzymes that are critical to the synthesis of glucose in liver. Eighteen cows were randomly allocated to two treatment groups receiving either bST (Posilac®, Monsanto, St. Louis) or saline injections, over 14-day intervals during a 42-d period. Feed intake and milk production were recorded daily and milk composition was determined weekly. Liver biopsies and blood samples were obtained on day seven following the second and third injections. Blood samples were analyzed for non-esterified fatty acids (NEFA) and glucose. Total RNA was extracted from liver biopsy samples and used to determine the abundance of PC, PEPCK, and 18S mRNA using Northern blot analysis. Milk production and dry matter intake were increased (P<.05) for bST treated cows 38.6 vs. 33.8 1.4 kg/day and 27.2 vs. 25.8 0.5 kg/day, respectively. Plasma NEFA was increased due to bST treatment (111 vs. 170 14 μM). Plasma glucose was not affected by bST treatment (P >.05). Treatment with bST increased (P<.08) PEPCK mRNA but not PC mRNA expression. The effect of bST was accentuated with repeated injection cycles (time effect, P <.05). The relative abundance of PEPCK during the third injection interval was elevated 18% compared to control samples. The magnitude of increase in PEPCK mRNA and changes in milk production are of a similar magnitude. The data indicate a slight increase in PEPCK due to bST which may reflect a greater potential for hepatic glucose production.

Key Words: Somatotropin, liver, mRNA expression

1602 Pyruvate carboxylase 5' untranslated region mRNA variants are heterogeneously expressed within and among bovine tissues. C. Agca* and S.S. Donkin, *Department of Animal Sciences, Purdue University, West Lafayette, IN 47907.*

Pyruvate carboxylase (PC) catalyzes the first regulated reaction in the conversion of pyruvate to glucose in gluconeogenic tissue and the use of acetyl groups for fatty acid synthesis in adipose tissue. Multiple transcripts have been identified for rat and human PC mRNA that are the products of a single gene, encode the same protein, but differ with respect to translational efficiencies and exhibit tissue specific expression patterns. Two bovine PC variants containing different 5' untranslated regions (UTR) of the mRNA were previously identified and reported by our laboratory. The objective of this study was to determine the presence of additional variants of bovine PC mRNA and their distribution among bovine tissues. Total RNA was extracted from bovine liver and used in 5' rapid amplification of cDNA ends and reverse transcription (RT) -PCR. Four new 5'UTR variants were identified which share regions of similarity ranging from 68 to 185 bp. In total, six unique 5'UTR have been identified, cloned and sequenced. The 5'UTR clones are designated as bPC5'A, bPC5'B, bPC5'C, bPC5'D, bPC5'E, and bPC5'F and contain 68, 253, 178, 89, 227, and 162 bp respectively. Northern blot analysis indicates that PC mRNA is more abundant in perirenal fat, omental fat, kidney, mammary tissue, brain and liver than muscle, heart and lung. The profile of 5'UTR variants, determined using RT-PCR and primers for the 5' UTR indicates that bPC5'B, bPC5'C, bPC5'D, and bPC5'E are present all tissues although bPC5'D, and bPC5'E are found in reduced quantities in heart, lung and muscle. The variants bPC5'A and bPC5'F are detectable only in adipose tissue, kidney and liver. The data demonstrate the complexity of expression of PC mRNA 5'UTR variant profiles in liver and indicate PC variant expression that is tissue specific. The exclusivity of bPC5'A and bPC5'F suggests control of the PC gene expression that is unique to gluconeogenic and lipogenic tissues.

Key Words: Pyruvate carboxylase, 5'UTR

1603 Differential relationships of metabolic hormones to growth and reproductive development in performance-tested Angus, Brangus, and Brahman bulls. M.G. Thomas*¹, R.M. Enns², D.M. Hallford¹, D.H. Keisler³, B.S. Obeidat¹, C.D. Morrison³, J.A. Hernandez¹, W.D. Bryant¹, R. Flores¹, and R. Lopez-Ordaz¹, ¹New Mexico State University, ²University of Arizona, ³University of Missouri.

Understanding mechanisms that regulate growth and reproduction are important for improving selection strategies in cattle. In this study, Angus, Brangus, and Brahman bulls (n = 7 per breed) of similar age were randomly selected from a group of 65 weanlings. Bulls were then evaluated for 112 d for concentrations of metabolic hormones and metabolites and growth and reproductive traits. Performance data and serum were collected on d 0, 28, 56, 84, and 112. Serum was also collected on d 50

to 59 and 103 to 112. These time periods were titled 56D and 112D periods. Angus bulls were heavier ($P < 0.05$) than Brangus and Brahman bulls on d 56, 84, and 112. Initial and final BW for Angus, Brangus, and Brahman bulls were 292.7, 260.6, 230.4, and 468.3, 435.6, 350.7 kg. Conversely, Brahman bulls had greater hip height ($P < 0.05$) than Brangus with Brangus being taller ($P < .05$) than Angus. Angus bulls had the greatest ($P < 0.05$) scrotal circumference (SC) and Brahman bulls the least. Mean SC across days was 31.5, 29.7, 25.0 cm for the three breeds. Serum testosterone was greater ($P < 0.01$) in Angus and Brangus bulls (10.0 and 8.9 ng/mL) than in Brahman bulls (4.0 ng/mL) throughout the study. Serum concentrations of IGF-I and leptin were greater ($P \leq 0.059$) in Angus bulls on d 56, 84, and 112 than in Brangus and Brahman bulls. Serum concentrations of GH ($P < 0.08$) and glucose ($P < 0.03$) were greater in Brangus bulls relative to Angus and Brahman bulls throughout the study. Prediction analyses suggested that breed and serum concentration of leptin could be used to predict ($P \leq 0.08$) BW and SC ($R^2 > 0.82$) in the 56D and 112D periods. Leptin and breed were also useful in predicting ($P \leq 0.09$) serum concentration of GH and testosterone in the 112D period ($R^2 > 0.32$). Residual correlation with the effect of breed removed indicated that leptin was positively correlated ($r \geq 0.53$, $P < 0.05$) with both SC and serum testosterone. Angus and Brahman cattle differ in phenotype, level of adiposity, and rate of sexual maturity. Data herein suggest that these characteristics could be due to varying mechanisms by which metabolic hormones such as leptin, GH, and IGF-I are regulated. Work supported by NIH-SCORE GMO8136 and NMAES 180674.

1604 LH and leptin pulsatile secretions are independent in ewe lambs. S.E. Recabarren, A. Lobos, C.A. Vilches*, and P. Munoz, *University of Concepcion, Chillan, Chile.*

It has been proposed that leptin may be a metabolic signal regulating the onset of puberty in females and that stimulates also the secretion of GnRH from the hypothalamus. The objective of this work was to recognize if the secretion of leptin depends on the LH secretion in prepubertal sheep. Spring-born Suffolk ewe lambs of 20 weeks of age ($n=5$) received i.m. a long acting GnRH agonist (Decapeptyl®). Treatment was repeated at 24 and 28 weeks of age. Control lambs ($n=6$) received the vehicle. Pulsatility of LH and leptin was studied at 20 (before Decapeptyl injection), 26 and 30 weeks of age. For that, blood samples were collected at 10-min intervals for 6 hours. LH and leptin were measured in all samples by RIA and pulsatile hormone secretion characteristics assessed by the Cluster program. To further characterize the synchrony between LH and leptin pulses, GnRH (10 ng/kg BW) was injected at 60-min intervals for 6 times in other 5 ewe lambs of the same ages. The LH secretion was diminished in the Decapeptyl treated lambs (D) and was lower than in the control lambs (C) at 26 and 30 weeks of age. The transversal mean of plasma leptin concentrations (ng/mL/6h) did not change in the C lambs. In the D and in the GnRH lambs, mean leptin concentrations were higher ($P \leq 0.05$) at 30 weeks of age than at 20-weeks or 26-weeks. No difference in mean leptin concentrations was observed between groups at any age, except between the C and D lambs at 26-weeks (2.2 ± 0.12 vs 1.42 ± 0.11 ng/mL/6h, $P \leq 0.05$). Amplitude of leptin pulses was higher at 30 weeks of age than at 20 and 26-weeks in the D and GnRH lambs. Between groups, amplitude was higher in the C lambs than in the D lambs (2.6 ± 0.15 vs 1.8 ± 0.13 ng/mL, $P \leq 0.05$) at 26 weeks of age. No change in leptin pulse frequency was observed within and between groups. No coincidence between LH and leptin pulses was observed in any group. Data suggest that pulsatile leptin secretion is independent of LH secretion in ewe lambs. Supported by Fondecyt grant 1990389

1605 Effect of obesity and fasting on leptin secretion and message expression in ewes. J. A. Daniel*¹, B. K. Whitlock¹, J. A. Baker¹, B. Steele¹, C. D. Morrison², D. H. Keisler², T. H. Elsasser³, and J. L. Sartin¹, ¹Auburn University, Auburn, AL, ²University of Missouri, Columbia, MO, ³USDA, Beltsville, MD.

The study was designed to examine the production and secretion of leptin by fat. Ewes (thin to obese) were assigned to either fed (F) or short-term restricted (R) groups. In the first experiment, subcutaneous fat samples were collected from ewes under local anesthesia from just above the last rib. Samples were analyzed for leptin expression using

Northern blotting. In a second experiment, plasma samples were collected for leptin analysis from ewes every 15 min for 24 h beginning 48 h after initiation of feed restriction. Plasma concentrations of insulin, glucose, and NEFA were determined every 6 h. Fat thickness over the last rib was determined by ultrasound (0.025 to 2.18 cm). Expression of leptin mRNA did not differ in F vs. R ewes ($P > 0.14$). Profiles of plasma concentrations of leptin were episodic in nature, and did not differ in a diurnal manner. F ewes had greater leptin mean, area under the curve, number of peaks, peak height, and nadir than R ewes ($P < 0.05$), as determined by CLUSTER analysis. Additionally, F ewes had a shorter interval between peaks ($P < 0.054$). F ewes also had greater concentrations of insulin ($P < 0.01$) and glucose ($P < 0.01$) and lower concentrations of free fatty acids ($P < 0.01$) than R ewes. Fat thickness was correlated with leptin mean ($r = 0.73$, $P < 0.02$), area under the curve ($r = 0.73$, $P < 0.02$), peak height ($r = 0.71$, $P < 0.03$), and nadir ($r = 0.76$, $P < 0.02$) in F ewes and with leptin mean ($r = 0.89$, $P < 0.01$), area under the curve ($r = 0.89$, $P < 0.01$), number of peaks ($r = 0.69$, $P < 0.03$), peak height ($r = 0.87$, $P < 0.01$), and nadir ($r = 0.86$, $P < 0.01$) in R ewes. Fat thickness was also correlated with concentrations of insulin ($r = 0.88$, $P < 0.01$) in R ewes. At the 6-hour time points, leptin was correlated with insulin in F ewes ($r = 0.51$, $P < 0.01$) and in R ewes ($r = 0.59$, $P < 0.01$). These data provide evidence that profiles of plasma concentrations of leptin are episodic in nature and influenced by nutritive state and fat thickness.

1606 Intracerebroventricular melanin-concentrating hormone stimulates food intake in sheep. B.K. Whitlock*¹, L.A. Daniel¹, D.F. Buxton¹, F.C. Buonomo², C.J. Dyer², and J.L. Sartin¹, ¹Auburn University, ²Monsanto Company.

Melanin concentrating hormone (MCH) is a peptide that is present in the sheep hypothalamus and stimulates feeding when injected intracerebroventricularly (i.c.v.) into rat brains. To clarify its role as a regulator of food intake in ruminants, we investigated the effect of MCH injected i.c.v. in sheep. The doses of MCH used were derived from previous experiments in our lab with neuropeptide Y (NPY), a known appetite regulator in sheep. Six, castrate male sheep were satiated and then received one of six treatments [saline and either 0.243, 2.43 or 12.1 µg/kg MCH, or MCH + NPY (0.243 and 0.432 µg/kg, respectively)] injected i.c.v. over 30 s. Food intake was measured for 2 h before and at 2, 4, 6, 8, 12, and 24 h after i.c.v. injection. In the second experiment, the same sheep were satiated and received one of four treatments [saline, 0.243, or 2.43 µg/kg MCH, and NPY (0.432 µg/kg)] injected i.c.v. over 30 s, then infused i.c.v. hourly for 6 h (500 µl/h). Food intake was measured for 2 h before and at 2, 4, and 6 h. Serial blood samples were collected at 15-min intervals from 2 h to 6 h relative to i.c.v. injection. In the first experiment, all doses of MCH resulted in greater ($P < 0.05$) food intake than saline or NPY, while NPY did not ($P = 0.36$) affect food intake relative to controls. In the second experiment, food intake was increased ($P < 0.03$) in sheep given the higher dose of MCH and in NPY treated sheep. Concentrations of nonesterified fatty acids (NEFA) were not ($P = 0.47$) affected by treatment. We conclude that a single i.c.v. injection of MCH stimulates an increase in food intake in sheep. Moreover, i.c.v. infusion of both MCH and NPY increase food intake above saline but did not affect NEFA concentrations. Previous research has determined that MCH is present in food intake regulatory regions of the sheep hypothalamus and MCH can be altered by physiological states associated with appetite. In this study we found i.c.v. MCH to stimulate food intake in sheep. Hence we propose that MCH qualifies as an endogenous appetite regulator in sheep.

1607 GHRH-receptor is essential to the regulation of GH by GHS in cultured rat pituitary cells. Sang-gun Roh*¹, Chen Chen², Ki-choon Choi¹, Shin-ichi Sasaki¹, and Chang Yoon³, ¹Lab of Animal Molecular Physiology, Faculty of Agriculture, Shinshu University, Naganoken, JAPAN, ²Endocrine Cell Biology Group, Prince Henry's Institute of Medical Research, Melbourne, Australia, ³Dept of Animal Science, Iksan College, Iksan, Korea.

Growth hormone (GH) is secreted in a pulsatile manner from anterior pituitary glands. Secretion of GH is stimulated by GH-releasing hormone (GHRH) and inhibited by somatostatin. The cloning of receptor

for synthetic GH secretagogues (GHS) and the finding of endogenous ligand for GHS-receptor (GHS-R), ghrelin, strongly suggested the presence of another important regulator for the secretion of GH. To address the problem of specificity, we selectively inhibited GHRH-receptor (GHRH-R) and GHS-R gene expression using modified antisense oligonucleotides (ON). We hypothesized that selective inhibition of the GHRH-R and/or GHS-R would disturb the cross talk between GHRH and GHS. To test our hypothesis, we measured the secretion of GH induced by GHS and GHRH challenge (30 min) in cultured male rat pituitary cells in the presence of antisense 18mer phosphorothiate ON targeting on the initiation codon region of GHRH-R and GHS-R mRNA for 3 days. We found a significant decrease in GHRH-R and GHS-R mRNA levels in the corresponding antisense-treated groups compared with the control group and the sense-treated condition. Treatment with GHS-R antisense ON showed the normal GHRH-stimulated GH secretion compared with that in control, lipofectamine and sense-treated cells. In addition, GHRP-2 (peptide GHS)-induced GH secretion was not inhibited by GHS-R antisense ON treatment either. In the cultured cell exposed to the GHRH-R antisense ON, GHRH-stimulated GH secretion was significantly diminished. GHRP-2-induced GH secretion was, however, not affected by such an exposure to the GHRH-R antisense ON. These results indicate a critical importance of GHRH-R for the GH secretion induced by both GHRH and GHS whereas GHS-R is only responsible for the GHS-stimulated GH secretion in cultured rat pituitary cells.

Key Words: Growth hormone, Growth hormone secretagogues, Antisense oligonucleotide

1608 Effect of growth hormone releasing factor (GRF) on long form leptin receptor (Ob-Rl) expression in porcine anterior pituitary. J. Lin^{*1}, C. R. Barb², R. R. Kraeling², and G. B. Rampack¹, ¹University of Georgia, Athens, ²USDA-ARS, Athens, GA.

We previously demonstrated that the Ob-Rl is expressed in the hypothalamus and anterior pituitary of the pig. Moreover, leptin stimulated basal GH secretion, but suppressed the GH response to GRF in pig anterior pituitary cells in culture. Pituitary cells from six pigs, 180 to 200 days of age, were studied in primary culture to determine if GRF affects Ob-Rl expression. On day 4 of culture, 10^5 cells / well were challenged with either 10^{-6} , 10^{-7} or 10^{-8} M [Ala¹⁵]-hGRF-(1-29)NH₂. Secretion of GH into the media and pituitary Ob-Rl mRNA expression were determined at 4 h after treatment. Media were analyzed for GH by RIA and total RNA were isolated from cells for Ob-Rl expression by semi-quantitative RT-PCR. Basal GH secretion was 32 ± 2 ng/mL (n=6 pituitaries). Relative to control at 4 h, 10^{-6} , 10^{-7} and 10^{-8} M GRF increased (P<0.0001) GH secretion by 151%, 129% and 120% and decreased (P<0.05) Ob-Rl expression by 32%, 50% and 38%, respectively. These results indicate that GRF directly modulates Ob-Rl expression at the level of the pituitary and may play a role in regulating pituitary sensitivity to leptin.

Key Words: Pig, Leptin receptor, GRF

1609 Sequence and distribution of a single cDNA encoding growth hormone-releasing hormone-like peptide and pituitary adenylate cyclase activating polypeptide in channel catfish. B. Small* and D. Nonneman, *USDA/ARS Catfish Genetics Research Unit, Stoneville, MS.*

Significant advances have been made in channel catfish nutrition, reproduction and disease research over the past 30 years; however, the mechanisms controlling catfish growth have received little attention. Two neuropeptides which have been implicated in the regulation of fish growth are growth hormone-releasing hormone (GHRH) and pituitary adenylate cyclase activating polypeptide (PACAP). This study reports the sequence and tissue distribution of a single cDNA encoding both GHRH-like peptide (GHRHLP) and PACAP in channel catfish. The GHRHLP/PACAP precursor cDNA was cloned from catfish hypothalamic tissue and a brain cDNA library. Two cDNA variants of the gene were identified as a result of alternative splicing, a long form encoding both GHRHLP and PACAP, and a short form encoding only PACAP. The 110 bp deletion in the short precursor cDNA corresponds to the excision of exon 4, which encodes 71% of the GHRHLP sequence. The complete cDNA sequence was composed of 375 bp of 5-untranslated region containing a polymorphic compound microsatellite (CT-CA). The coding region covered nucleotides 376-900, containing a

signal peptide from 376-435 bp (aa 1-20), GHRHLP from 625-759 bp (aa 84-128) and PACAP from 765-879 bp (aa 130-168). The 3-untranslated region contained a compound microsatellite (GC-GA) beginning within the stop codon. The consensus polyadenylation signal was located from 1058-1063 bp. Catfish PACAP and GHRHLP sequences share 89.5 and 31.1% identity with human PACAP and GHRH, respectively. Catfish GHRHLP is 80% identical to carp native GHRHLP sequence. Both the long and short form of the GHRHLP/PACAP precursor cDNA were identified in catfish brain, pituitary, fat, gastrointestinal tract, muscle, ovary and testes by RT-PCR detection; however, neither variant was detected in gill, heart, kidney, liver, pancreas, skin or spleen. This is the first demonstration of mRNA expression for this gene in fat or skeletal muscle of fish. By characterizing the GHRHLP/PACAP gene and its distribution in channel catfish, we have developed essential tools to investigate the roles of these peptides in the regulation of catfish growth.

Key Words: Channel catfish, GHRH, PACAP

1610 Development of specific antibodies for the quantification of plasma insulin-like growth factor-binding protein-3 in cattle. R. Renaville^{*1}, C. Bertozzi¹, S. Hetzel¹, I. Parmentier¹, S. Fontaine¹, V. Haezebroeck¹, and D. Portetelle¹, ¹Gembloux Agricultural University, Animal and microbial biology unit, Gembloux, Belgium.

Insulin-like growth factor-I and -II (IGF-I, IGF-II) circulate in biological fluids bound to at least six different IGF-binding proteins that regulate IGF bioactivity. The IGF-binding protein-3 is regulated by growth hormone, and its concentration depends on nutrition and physiological state. Unavailable from commercial societies, bovine IGFBP-3 has been previously purified by acid precipitation, molecular filtration and affinity chromatography from pre-colostrum collected 3-5 days before parturition. This preparation has been used to produce specific mouse monoclonal and rabbit polyclonal antibodies and to develop a radioimmunoassay to quantify IGFBP-3 in bovine blood samples. Using the polyclonal antiserum, parallel displacement curves showed strong cross-reactivity with bovine, ovine, rabbit and human plasma protein and no cross-reactivity with porcine, rat, horse, dromedary or chicken plasma. Addition of IGF-I to a control pool of bovine plasma did not significantly alter control IGFBP-3 values in a radioimmunoassay. Nycthemeral periods, determined for three young bulls bled on two occasions were stable throughout the day; two or three samples were sufficient to characterize the animal. Heifers treated with recombinant bovine somatotropin (bST) had significantly higher serum levels of IGFBP-3 than did control animals. Likewise, plasma IGFBP-3 concentrations were decreased in growing bulls treated with clenbuterol (a β -agonist) while these concentrations increased after corticoid (dexamethasone) injection. Furthermore, IGFBP-3 levels were dramatically decreased during the first postpartum weeks. This radioimmunoassay for bovine IGFBP-3, which enables quantitative assessment of IGFBP-3 concentration in cattle, confirmed the previous observations using the less precise Western ligand blotting method. This research was supported by grants of the Belgian Ministry of Small Enterprises, Traders and Agriculture (grant 5736A) and Ministre de la Rgion Wallonne, subvention First Spin-Off (grant 991/3972).

1611 Responses of Holstein cows to low dose of somatotropin (bST) prepartum and postpartum. M. S. Gulay*, J. Hayden, and H. H. Head, *University of Florida, Gainesville, FL.*

Objectives were to evaluate effects of a low dose of bST injected pre- and postpartum on BCS, BW, MY and IGF-I, INS and metabolites in plasma during experiment carried out during two consecutive years. Holstein cows (194) were assigned randomly to one of two groups [Control (C)=99 vs. Injected (I)=95 cows/group]. Biweekly injections of bST (POSILAC[®]) were prepartum (starting 21 d before expected calving) and through 60 d postpartum (C vs. I; 0 vs. 10.2 mg bST/d). After 60 d, all cows received a full dose of bST. IGF-I, INS, NEFA and glucose were measured in plasma from 82 of the cows (yr1) and BCS and BW of 112 cows (yr2); no blood samples were collected (yr2). MY of all cows were merged and analyzed using mathematical models that included main effects of treatment (bST), calving month, the 2-way interaction, and cow nested in treatment-calving month as error term. bST prepartum resulted in higher mean concentrations of INS (C vs. I; 0.650.037 vs. 0.780.042 ng/ml, P<0.05) and numerically greater NEFA (236.916.4 vs.,

281.616.4 $\mu\text{eq/l}$, $P < 0.13$). bST postpartum did not affect mean concentrations of glucose (66.410.84 vs. 66.740.84 mg/dl) or IGF-I (165.94.5 vs. 168.04.5 ng/ml). Postpartum treatment resulted in increased concentrations of NEFA (331.2 21.2 vs 410.6 20.8 $\mu\text{eq/l}$, $P < 0.02$). No effects of bST treatment were observed on mean concentrations of INS (0.55 0.02 vs. 0.53 0.02 ng/ml), IGF-I (110.57.3 vs. 115.37.1 ng/ml), or glucose (66.131.68 vs. 64.451.65 mg/dl). Mean BCS did not differ prepartum, (3.730.02 vs. 3.760.02) around parturition (3.430.02 vs. 3.520.02), or postpartum (3.240.02 vs. 3.320.02). Although mean BW (kg) did not differ during prepartum (689.25.3 vs. 722.83.3, $P < 0.12$) and around calving (653.43.8 vs. 664.55.1, $P < 0.45$), bST injected group maintained BW better postpartum (618.53.6 vs. 645.83.3, $P < 0.07$). Greater MY was observed for bST-injected group during first 30-d (33.32 vs. 35.95 kg/d, $P < 0.06$), and 60-d (36.92 vs. 39.42 kg/d, $P < 0.07$) of lactation. No difference in MY was observed during the 100-d period (38.09 vs. 39.72 kg/d, $P < 0.22$), which included full dose of bST (60d-100d; 39.72 vs. 40.30 kg/d, $P < 0.70$). No adverse effects of bST treatment were observed during either the pre- or postpartum periods.

Key Words: Transition period, bST, Lactation

1612 Induction of lactation during winter and summer seasons in non-pregnant reproductive cull Holstein cows. M. Chahine^{*1}, W. J. Weber¹, J. K. Reneau¹, B. A. Crooker¹, T. H. Klusmeyer², M. F. McGrath², E. A. Reed², and J. L. Vicini², ¹University of Minnesota, St. Paul, ²Monsanto Animal Agriculture Group, St. Louis, MO.

Effect of season on induction of lactation was assessed with multiparous cows induced in February (FEB, n=15) or June (JUN, n=18). Treatments started on day 0 and consisted of twice daily injections of 17 β -estradiol (0.1 mg/kg BW/d) and progesterone (0.25 mg/kg BW/d) for 7 d, twice daily mammary massage (2-3 min/gland) for the next 6 d, and an injection of dexamethasone (0.05 mg/kg BW/d) on day 13 of study. Cows received POSILAC 1 STEP[®] (500 mg bST) on day 0, 10, 20, and 30 of study and at 14 d intervals thereafter. Milking (3x/d) commenced on day 14 of study and continued for 122 d. Samples from each milking on a single day in weeks 1, 2, 3, 4, 8, 12 and 16 of lactation were collected for analyses. Effect of season was determined using GLM of SAS. Cows were non-responsive and removed if they failed to produce ≥ 9.1 kg of milk on a single day by 24 d of lactation. Induction was successful if at least one daily total milk yield was ≥ 13.6 kg by 50 d of lactation. Two cows failed to respond in each season and one JUN cow responded but was removed for health reasons on day 12 of lactation. Thus, induction was successful in 13 of 15 (86.7%) FEB cows and 15 of 18 (83.3%) JUN cows. Of these cows, one FEB and two JUN cows were removed prior to day 70 of lactation for health reasons. Shape of the lactation curve was similar for both seasons. Total 122 d yields of actual milk (2966, 2729 kg), 3.5% FCM (3077, 2964 kg), and 4.0% SCM (2875, 2722 kg) did not differ between seasons. Daily yield per cow averaged 25.0 kg milk, 27.6 kg FCM, and 25.5 kg SCM. Milk composition did not differ between FEB and JUN cows and averaged 4.2% fat, 3.4% protein, 4.9% lactose and 174×10^3 SCC/ml. In this study, induction was successful in 85% of the cows and milk yield was not affected by season.

Key Words: Induced Lactation, bST, Season

1613 Reduced milk ejection as a consequence of chronic treatment with exogenous oxytocin in cows. R. M. Bruckmaier^{*}, Institute of Physiology, Techn. Univ. Munich-Weihenstephan, Freising, Germany.

Oxytocin (OT), released from the posterior pituitary in response to mechanical teat stimulation, causes myoepithelial contraction and hence alveolar milk ejection during milking. In dairy practice, exogenous OT is often administered before milking for therapy of disturbed milk ejection due to lacking or reduced OT release. The objective of this study was to test the hypothesis that chronic OT administration at each milking causes reduced milk ejection after withdrawal of exogenous OT. Experiments were performed with twenty-one healthy Brown Swiss dairy cows with normal milk ejection during machine milking at 5 a.m. and 4 p.m. One min before the start of each milking cows were injected i.m. either with 50 I.U. of synthetic OT (n = 7; OT-G) or with an equal volume of 0.9 % NaCl (n = 7; NaCl-G) for three weeks. Control animals (n = 7; CO-G) did not receive daily pre-milking injections. At evening milkings on d 0, 7, 14, and 21, no pre-milking injections were performed and residual milk was obtained by i.v. injection of 10 I.U.

OT at the end of milking. In addition, residual milk was obtained at the end of evening milking on d 1, 8, 15 and 22, when each group received a pre-milking injection of 50 I.U. OT i.m. Total milk yield as a sum of spontaneously removed milk (including stripping) and residual milk was set 100 %. On d 0, 952, 903 and 942 % of milk were spontaneously obtained before removal of residual milk in groups OT-G, NaCl-G and CO-G, resp. Spontaneously removed milk was reduced in OT-G on d 7, 14, and 21 ($p < 0.05$) to 825, 816 and 814 %, resp., but was not altered in NaCl-G and CO-G. Pre-milking OT injection on d 1 did not significantly increase the spontaneously removed milk fraction (961, 941 and 971 % in OT-G, NaCl-G and CO-G, resp.). Similar results as on d 1 were obtained on d 8, 15 and 22. In conclusion, chronic OT administration caused a rapid decline of spontaneous milk ejection. Repeated NaCl injection did not reduce milk ejection thus excluding stress effects of the injection procedure. As the response to exogenous OT remained unchanged throughout the experiment, the diminished milk ejection after chronic OT treatment is rather due to reduced OT release than to OT-receptor down regulation.

Key Words: Milk Ejection, Cow, Chronic Oxytocin Treatment

1614 Gene expression of immunologically relevant factors in blood cells, milk cells and mammary tissue of cows. R. M. Bruckmaier^{*}, S. L. Wittmann, H. H. D. Meyer, and M. W. Pfaffl, Institute of Physiology, Techn. Univ. Munich-Weihenstephan, Freising, Germany.

Tumor necrosis factor α (TNF α) and eicosanoids are involved in the mammary gland's immune response. Lactoferrin (Lf) has bacteriostatic effects. The goal of this study was to localize and quantify the synthesis of these factors in milk, blood and mammary tissue cells of cows exhibiting distinct levels of somatic cell counts (SCC) while lacking clinical signs of mastitis. mRNA expression of TNF α , Lf and key enzymes of leukotriene and prostaglandin synthesis, 5-lipoxygenase (5-LO) and cyclooxygenase (COX)-1 and COX-2, resp., was determined in Brown Swiss cows. Control animals (CTR; n=8) had $< 150,000$ cells/ml of milk in all quarters (CQ) while cows with partially elevated SCC (PE; n=7) had minimum one quarter $> 150,000$ (HQ) and one quarter $< 150,000$ cells/ml (LQ). Milk of one CQ of CTR and one HQ and LQ of PE was collected and a blood sample was taken. In addition, mammary tissue samples were obtained from the respective quarters. Total RNA was isolated, reverse transcription and quantitative real-time PCR were performed. TNF α and COX-2 were predominantly expressed in milk cells, 5-LO in blood cells whereas Lf was mainly found in mammary tissue. COX-1 was expressed at similar levels in all cell/tissue types tested. None of the parameters investigated was significantly different between CTR and PE in blood cells (TNF α : 1.00.3 and 0.90.3; COX-1: 0.80.3 and 1.00.3; COX-2: 0.60.2 and 1.91.1; 5-LO: 3.21.7 and 1.00.2; Lf: 0.10.05 and 0.20.1 molecules/cell, resp.). TNF α mRNA expression was elevated in HQ as compared to LQ in mammary tissue (1246 and 277 molecules/mg, resp.; $P < 0.05$). COX-2 mRNA expression was higher in milk cells of HQ than LQ (24.25.8 and 12.94.6 molecules/cell, resp.; $P < 0.05$). 5-LO expression tended to be elevated in milk cells and Lf in mammary tissue of HQ as compared to LQ. No difference was found between CQ and LQ in milk cells and in mammary tissue for any of the parameters tested. In conclusion, the immunological activity of the mammary gland is quarter specific. Besides mammary tissue, somatic milk cells seem to be an important source of factors involved in chemical signalling during immune response.

Key Words: Mammary Gland, Immunology, Chemical Signalling

1615 Effect of intramammary infusion of Escherichia coli endotoxin on ovulation in lactating dairy cows. A. M. Nugent, T. B. Hatler, S. H. Hayes, S. C. Kiggins, and W. J. Silvia^{*}, University of Kentucky, Lexington.

The purpose of this experiment was to determine if intramammary inflammation during the periovulatory period in lactating dairy cows affects the occurrence of ovulation. Ten lactating, cyclic, Holstein dairy cows received 2 injections of prostaglandin F_{2a}, at 11-day intervals, to synchronize luteolysis. The day of the second injection was designated as Day 0. Ovulation was anticipated on days 3-5. Beginning on day 1, cows received intramammary infusions of either Escherichia coli endotoxin (10 ug; n=5) or infusion vehicle (controls; n=5) into 2 quarters immediately after milking. The same quarters were infused after each milking through day 4. Venous blood samples were collected daily

from day -1 through 13 for determination of progesterone to monitor luteolysis and formation of the new corpus luteum. Samples were also collected at 4-h intervals (days -1 to 2), then at 2-h intervals (days 2 to 5) to measure concentrations of luteinizing hormone (LH). Ovaries were examined ultrasonographically on days -1 through 5 and on day 12 to monitor follicular growth and formation of the corpus luteum. Collectively, these observations were used to determine if and when ovulation occurred. Intramammary infusion of *E. coli* endotoxin induced an immediate increase in somatic cell numbers in treated quarters. However, this treatment had no effect on the occurrence or timing of ovulation. Four of 5 cows in each treatment group ovulated. Preovulatory surges of LH were detected within the intensive bleeding periods for 3 cows in each treatment group. The magnitude of the LH surge was reduced in cows receiving endotoxin. Supported by KABA/Select Sires and the KY Agr. Expt. Station.

Key Words: ovulation, luteinizing hormone, endotoxin

1616 Effects of N-nitro-arginine on blood flow and nutrient uptake in the mammary glands of dairy cows. T. G. Madsen^{*1}, D. R. Trout², S. Cieslar³, N. G. Purdie⁴, M. O. Nielsen¹, and J. P. Cant³, ¹*Department of Anatomy and Physiology, The Royal Veterinary and Agricultural University, Denmark*, ³*Department of Animal and Poultry Science, University of Guelph, Canada*, ²*Department of Clinical Studies, University of Guelph, Canada*, ⁴*School of Land and Food Sciences, University of Queensland, Australia*.

Nitric oxide (NO) has been shown to be a potent vasodilator in many tissues and previous research demonstrated that the arginine analogue N-nitro-arginine, which blocks NO synthesis from L-arginine, decreased mammary blood flow (MBF) in dairy goats. The objective of this study was to determine if N-nitro-arginine has the same effect on MBF in dairy cows and, if so, how changes in blood flow affect mammary metabolite uptakes, i.e. arterio-venous (AV) difference multiplied by MBF. Two multiparous Holstein cows in mid-lactation were fed and milked twice daily at 8:00 and 18:00 h. Between morning and evening milking on two consecutive days, saline or a mixture of amino acids (40 g/h) was infused for 9 h into the external iliac artery supplying one udder half. At 15:00 h N-nitro-arginine was added to the infusion at 25 mg/min for 60 min. Blood samples were taken approximately 25 min before and 10, 30, 50, 90 and 140 min after start of N-nitro-arginine infusion for estimation of MBF using the para-amino hippuric acid dilution technique. Blood flow decreased approximately 30 % during infusion of N-nitro-arginine and remained low for at least one hour after the infusion stopped. AV differences for acetate, β -hydroxy butyrate (BHB) and triacylglycerol (TAG) increased when the blood flow dropped; extraction efficiency increased 13, 38 and 14 %, respectively, for these three nutrients. Non-esterified fatty acid AV differences correlated negatively with AV differences of TAG. In conclusion, it is possible to decrease blood flow to the mammary glands of dairy cows by close arterial infusion of a NO synthesis blocker. The mammary glands compensated for the decreased nutrient supply resulting from the lowered blood flow by increasing the efficiency of nutrient extraction from blood.

Key Words: Blood flow, Nitric Oxide, Arginine analogue

1617 Effects of an induced mammogenesis and lactogenesis in sheep on the mRNA expression levels of immune globulin receptors (FcRn; pIGR) and zona occludens proteins (ZO1; ZO2; ZO3). MW Pfaffl^{*}, A Dzidic, P Rojas, RM Bruckmaier, and D Schams, *Institute of Physiology, Technical University of Munich, Freising-Weihenstephan, Germany*.

Mammary immune response is mediated mainly through phagocytotic leucocytes but to some extent by secreted immune globulins A (IGA) and G (IGG). Tight junction (TJ) barrier, built by zona occludens proteins 1-3 (ZO1-3), limit the movement of immunoactive leucocytes from the blood circulation into milk. During pregnancy TJs are leaky, undergoing a closure shortly before parturition to remain impermeable during lactation. IGG and IGA are transported transcellularly into secretion by IGG receptor (FcRn) and polymeric IG receptor (pIGR), respectively. Influence of steroids, dexamethason (DEX) and prolactin (PRL), to induce mammogenesis (MG) and lactogenesis (LG), and effects on the expression profile were investigated in sheep. MG was induced by a frequent estrogen and progesterone treatment (day 1-29), and LG via DEX and manual stimulation (day 30-37). In one group PRL secretion was inhibited by bromocriptin (BR+, n=4) and compared with

BR- (n=4) and a non treated control (K, n=4). Sheep were slaughtered (day 38) and mammary tissue was sampled for RNA extraction. Expression studies were done in real-time RT-PCR and each sample was normalised to internal ubiquitin expression. Relative expression levels of BR+ and BR- were compared with the control group (K=1). MG and LG could be induced and histology showed an alveolar development in BR- higher than in BR+, and a white secret could be retrieved by hand milking with physiological concentrations of fat, protein, lactose and somatic cells. PRL concentrations were successfully suppressed in BR+. Expression data showed no significant changes in pIGR, ZO1 and ZO3. FcRn and ZO2 expression were significantly elevated in BR+ and BR-. Only a trend of higher pIGR and ZO3 expression could be shown in BR- compared to BR+. In conclusion, the PRL inhibition and desired blockage of LG through BR had no effects in sheep. FcRn and ZO2 concentrations could be up-regulated, influenced by steroids and DEX, resulting in a higher IGG concentration in colostrum milk and impermeable TJ. No effects of BR treatment could be observed.

	FcRn	pIGR	ZO1	ZO2	ZO3
BR-	3.40±2.97 p=0.02	2.57±2.50 p=0.07	1.04±0.31 p=0.74	2.42±0.40 p≤0.001	2.17±1.45 p=0.07

1618 Effect of chromium-methionine level supplementation on immune response of bull calves recently arrived to feedlot. L. Almeida^{*1} and R. Barajas¹, ¹*FMVZ-Universidad Autonoma de Sinaloa*.

To determinate the effect of chromium-methionine level supplementation on immune response of calves recently arrived to feedlot, twenty bull calves (7/8 Brahman; 167 kg) were used in a 28 days complete randomized design experiment. After 300 km truck transportation the animals were randomized assigned (five by treatment) to receive one of four diets in that consist the treatments: 1)Diet 30:70 roughage:concentrate with 15% CP and 1.4 Mcal NEm/kg (control); 2)Diet similar to control, but supplemented with 0.4 ppm of chromium from chromium-methionine (Cr-Met; MicroplexTM, Zinpro, CO); 3)Diet supplemented with 0.7 ppm of Cr from Cr-Met; and 4)Diet supplemented with 1.0 ppm of Cr from Cr-Met. The animals were allocated in ground pens with central shade, fed twice a day with permanent access to fresh tap water. Next day to arrived, animals were dewormed, vaccinated again IBR, PI3, BRV,BVD, Clostridium, and Pasteurella; weighed, tagged, and ear hormone implanted. Blood samples were taken from jugular vein at start the experiment, and in days 7, 14 and 28. Cortisol, creatinin, glucose, globulin G, globulin M, and aspartate aminotransferase enzyme were determinate. After seven days, chromium supplementation tended (P<0.09) to diminished in 60% blood cortisol concentration (3.6 vs. 1.4 μ g/dL), and at 14 days 1.0 ppm of Cr reduce (P<0.04) cortisol (2.8 vs. 0.2 μ g/dL). Chromium 1.0 ppm increased (P<0.03) immunoglobulin G levels in days 14 and 28. Immunoglobulin M tended (P<0.14) to be increased by 1.0 ppm Cr supplement. Addition of 0.7 and 1.0 ppm of chromium tended (p<0.07) to increase glucose level in day 28. Aspartate aminotransferase enzyme concentrations tended to decrease (P<0.07) in day 7 with 1.0 ppm Cr treatment. Creatinin was not affected (P>0.20) by treatments. It is concluded that chromium-methionine supplementation improve the immune status of bull calves recently arrived to feedlot and that 1 ppm of Cr appears to be eligible level.

Key Words: Chromium, Supplementation, Bull calves

1619 The effect of equi-molar dietary betaine and choline additions on liver, plasma and gut of pig. K. Tiihonen^{*1}, S. Peuranen¹, H. Siljander-Rasi², and H.P. Simmins³, ¹*Danisco Cultor Innovation Center, Kantvik, Finland*, ²*Agricultural Research Centre of Finland, Hyvink, Finland*, ³*Finnfeeds International Ltd., Marlborough, Wilts, UK*.

The mode of action of dietary betaine and choline in pigs were studied. In broiler chicks dietary betaine is twice as efficient as equi-molar dietary

choline for increasing liver betaine levels but in pigs that has not been studied previously. Individually penned Finnish Landrace and Yorkshire pigs (30 kg; n=70) were fed basal diet with no added betaine or choline, the basal diet supplemented with 250, 500 or 1000 mg/kg of betaine (Betafin® S1), or with a similar molar amount of choline (578, 1155 or 2310 mg/kg of choline chloride). The net energy content of the maize-soybean meal basal diet was diluted with oat hull meal (100 g/kg) and it contained 8.55 MJ/kg NE, 155 g/kg crude protein and 7.4, 4.4 and 4.3 g/kg digestible lysine, threonine and methionine+cystine, respectively. The pigs were on restricted diet, 1.5-3.0 kg feed/d. The experiment lasted 75 days. Daily weight gain improved linearly ($p \leq 0.01$) with increasing dietary betaine. The liver betaine level increased linearly with dietary betaine addition ($p \leq 0.05$). The additives had no significant effect ($p \geq 0.10$) on plasma homocysteine levels. Addition of betaine tended to improve the tensile strength of the proximal ileum linearly ($p = 0.07$). Choline additions increased plasma carnitine linearly ($p \leq 0.01$) but had no effect on the pig performance, liver betaine or gut tensile strength. The results show that dietary betaine addition increased liver betaine and improved the daily weight gain of pigs on restricted diets with diluted energy concentration whereas choline addition increased plasma carnitine but had no effect on performance.

1620 Differences of autonomic nervous system activity in high and low body weight-selected chickens. A. Y. Kuo^{*1}, J. C. Lee², P. B. Siegel¹, and D. M. Denbow¹, ¹Virginia Tech, Blacksburg, ²VA-MD Regional Veterinary College, Blacksburg.

This study was to investigate whether there are differences in the autonomic nervous system (ANS) function of chickens from lines selected or high (HWS) or low body-weight (LWS). The cardiovascular response to pharmacological agents was used as an indicator of ANS response. Ten birds from each line and sex were used. Catheters were introduced into the left brachial artery and vein, and connected to a MP100-BIOPAC system to record blood pressure (BP) and heart rate (HR). Birds were injected with phenylephrine, atropine, propranolol, and tetraethylammonium chloride (TEAC). Data were analyzed using ANOVA; significant differences imply $P \leq .05$. The LWS birds exhibited a greater increase in BP and less increase in HR than the HWS birds following atropine. The response to atropine showed a line and sex interaction, in which male birds had a greater increase in HR than females, and LWS females had a lower increase in HR than the HWS females. Injection of phenylephrine following pretreatment with atropine caused a baroreceptor reflex in which males showed a greater decrease in HR than females. In response to the beta-adrenergic receptor blocker propranolol, females displayed a greater decrease in BP than males, and LWS birds had a greater decrease in HR than HWS birds. In response to the autonomic ganglionic blocker TEAC, BP and HR were decreased equally in both lines. The percentage of adrenal and sympathetic impact on regulation of HR showed that LWS females required greater adrenal activity than the other birds. While change in the HR to BP ratio in response to phenylephrine was different between lines, the response was not different when phenylephrine was given following atropine. These results suggest that a higher parasympathetic nervous system tone is present in the HWS, and a higher sympathetic nervous system tone is present in the LWS than HWS birds. It is suggested that differences between the lines could be at the level of the adrenal gland.

Key Words: Autonomic nervous system, Blood pressure, Chickens

1621 Hemodynamic Responses of Broiler Pulmonary Vasculature to Intravenously Infused Serotonin. M. E. Chapman* and R. F. Wideman, University of Arkansas, Fayetteville, AR, USA.

Serotonin (5-hydroxytryptamine, 5HT) is a potent pulmonary vasoconstrictor actively accumulated by mammalian platelets and avian thrombocytes, and released into the plasma during platelet or thrombocyte aggregation. 5HT has been implicated in the mechanisms responsible for pulmonary hypertension in several human and animal studies. However, the role of 5HT in pulmonary hypertension syndrome (PHS, ascites) in broilers previously had not been evaluated. In the present study we evaluated the pulmonary hemodynamic responses of broilers to intravenous infusions of 5HT dissolved in 2.5% mannitol solution (carrier vehicle).

Carrier vehicle infusion alone had no influence on any of the hemodynamic variables. 5HT infusion triggered rapid increases in pulmonary arterial pressure to approximately 50% above pre-infusion baseline values, accompanied by decreases in mean systemic arterial pressure and cardiac output. The peak pulmonary arterial pressure response occurred within approximately 70 s after the start of 5HT infusion, and remained elevated above baseline values over the course of a 10-minute infusion period. Pulmonary arterial pressure, mean systemic arterial pressure and cardiac output returned to pre-infusion baseline values upon cessation of 5HT infusion. Pulmonary hypertensive responses were associated with increased pulmonary vascular resistance (pulmonary vasoconstriction). The peak pulmonary arterial pressure attainable was inadequate to propel the normal cardiac output through the elevated pulmonary vascular resistance. Consequently, the impeded venous return to the left ventricle caused dependant reductions in stroke volume, cardiac output, and mean systemic arterial pressure. Reductions in cardiac output were associated with reductions in stroke volume but not heart rate. Any factor that reduces the pulmonary vascular capacity or increases the pulmonary vascular resistance theoretically can increase the incidence of PHS. The present study provides direct evidence that 5HT can trigger pulmonary vasoconstriction and pulmonary hypertension in broilers.

Key Words: Serotonin, Broiler, Hypertension

1622 Pulmonary Wedge Pressures Confirm Pulmonary Hypertension in Broilers is Initiated by an Excessive Pulmonary Arterial Resistance. M. E. Chapman* and R. F. Wideman, University of Arkansas, Fayetteville, AR, USA..

High retrograde pressure through the pulmonary venous system caused by failure of the left ventricle or left atrio-ventricular valve may result in the elevated pulmonary arterial pressure and right ventricular hypertrophy associated with pulmonary hypertension syndrome (PHS; ascites) in broilers. Unanaesthetized male broilers from an ascites-resistant line, the base population from which the resistant line was derived, and a separate unselected line were used to determine whether changes in wedge pressure are predictive of differences in the pulmonary arterial pressure of clinically healthy and pre-ascitic broilers. Venous, right atrial, right ventricular, pulmonary arterial, and wedge pressures were obtained by inserting a catheter into a wing vein and progressively advancing the catheter into a pulmonary branch artery until the catheter tip became wedged in and occluded the flow through a terminal artery. Mean right ventricular and pulmonary arterial pressures were lower in the resistant line than in the base population, but wedge pressures did not differ between the resistant, base, and unselected lines. Right:total ventricular weight ratios (RV:TV) and the percentage saturation of hemoglobin with oxygen in arterial blood ranged in value from 0.18 to 0.44 and 65 to 96%, respectively. Wedge pressure, however, remained similar when pre-ascitic broilers with high RV:TV values and low oximetry values were compared with clinically healthy broilers. In all birds, whether healthy or showing pre-ascitic characteristics, the wedge pressure was slightly

higher than the right atrial pressure, but substantially lower than pulmonary arterial pressure. These observations provide definitive proof that pulmonary hypertension is initiated as a consequence of excessive pulmonary arterial or arteriole resistance. Pulmonary venous pressure is estimated by measuring the pulmonary arterial wedge pressure, and high wedge pressures would be evident if pulmonary hypertension was caused by the elevated downstream resistances associated with left-sided heart failure.

Key Words: Ascites, Wedge Pressure, Broiler

1623 Cardiopulmonary and blood gas responses to cold exposure in broiler chickens. T.W. Odom*¹, M.A. Thompson¹, K.P. Floren¹, G.A. Ramirez¹, N. Puebla-Osorio¹, L.A. Martinez-Lemus², and J.S. Thomas³, ¹Department of Poultry Science, Texas Agricultural Experiment Station, ²Departments of Medical Physiology, ³Veterinary Pathobiology, Texas A&M University, College Station, TX 77483.

Cold exposure is a well-established cause of the development of pulmonary hypertension syndrome (PHS) in broiler chickens. Therefore, in this study we used cold exposure to induce PHS. Subsequently we measured venous blood acid-base balance and several cardiopulmonary parameters. Forty 1-day-old male broiler chickens, were equally divided in 2 environmental chambers and maintained at 25 C for one week. The temperature was not changed in one environmental chamber and the other environmental chamber was changed by a gradual step-down program until the chamber reached to 10 C and maintained at that point for an additional 3 weeks. Body weight (BW), heart rate (HR), right ventricular hypertrophy, venous blood gases, and plasma thrombin-antithrombin (TAT) complexes (a sensitive indicator of *in vivo* activation of the clotting cascade) were measured. Broiler chickens in the 10 C chamber had significantly ($P \leq 0.05$) reduced BW and HR, increased total venous CO₂ and HCO₃⁻, increased right ventricular hypertrophy, and increased plasma TAT complexes compared with the broiler chickens in 25 C chamber. This study suggests that cold exposure for 3 weeks results in an altered acid-base balance in the blood, a hypercoagulable state, and a cardiovascular dysfunctional circulation. Consequently, these results support that cold exposure produces stress on the cardiopulmonary system predisposing the broiler chicken to develop PHS.

Key Words: Broiler, Cold Stress, Blood Gas

1624 Thrombocyte aggregation does not correspond with nitric oxide and cardiovascular parameters in broiler chickens with pulmonary hypertension. A.R. Carpenter¹, L.A. Martinez-Lemus², J.S. Thomas³, and T.W. Odom*¹, ¹Department of Poultry Science, Texas Agricultural Experiment Station, ²Departments of Medical Physiology, ³Veterinary Pathobiology, Texas A&M University, College Station, TX 77843.

Pulmonary hypertension syndrome (PHS) is a multifactorial disease that affects predominantly the fast-growing broiler chicken. Research in mammalian models has suggested that platelet activity, thrombosis, and reduced synthesis of nitric oxide (NO) may be involved in pulmonary hypertension. Therefore, this study was designed to investigate the relationship thrombocyte aggregation may have with NO, and other cardiovascular parameters in PHS. Broilers were reared either under hypobaric conditions (HC) to induce PHS or under normobaric conditions (NC) for five weeks. Aggregation was measured in both whole blood and in thrombocyte-rich plasma. Whole blood aggregation was measured in order to assess thrombocyte function in a milieu similar to that *in vivo*. Thrombocyte-rich plasma provided an environment, which allowed for a more clear representation of thrombocyte activity unaltered by other blood cells. Body weights and cardiovascular parameters were compared in both experiments, and NO produced by a right pulmonary artery ring was measured. Compared with NC broilers, HC broilers had increased hematocrit levels, right ventricular hypertrophy, and PHS mortality. Right pulmonary artery rings from HC broilers also produced significantly less NO than NC broilers at 4 weeks of age. There were no consistent differences in thrombocyte aggregation between the NC and HC broilers. Also, thrombocyte aggregation did not correspond with

NO production by the right pulmonary artery ring or with PHS mortality. Thus, changes in thrombocyte aggregation may not be related with PHS in the broiler chickens.

Key Words: Broiler, Aggregation, Nitric Oxide

1625 Assessment of factor V, VII, and X activity, the key coagulant proteins of the tissue factor pathway in poultry plasma. A.E. Thomson*, E.J. Squires, and P.A. Gentry, University of Guelph, Guelph Ontario Canada.

Assay methods were developed for key components of the tissue factor pathway of coagulation, namely Factor V, Factor VII and Factor X. Using these assays, plasma from healthy laying hens, roosters and broilers was shown to contain functional and equivalent amounts of each of these clotting factors. The plasma activity for Factor V, Factor VII, and Factor X can only be accurately determined when chicken tissue factor is used to initiate the coagulation mechanism in poultry plasma. Neither human tissue factor nor rabbit tissue factor forms a fully functional enzyme reactive complex with chicken Factor VII. The overall Tissue Factor Pathway coagulation mechanism was evaluated in plasma from laying hens, roosters and broilers using the One-stage Prothrombin Time assay. As long a sufficient tissue factor was used, the overall clotting time results obtained with human recombinant tissue factor were not significantly different ($P > 0.05$) from those obtained with chicken tissue factor. We conclude that poultry plasma does possess a fully functional tissue factor coagulation mechanism, but homologous chicken tissue factor must be used for *in vitro* assays of the components of this pathway.

Key Words: Tissue Factor Pathway, Coagulant Proteins, One-Stage Prothrombin Time

1626 Establishing endocrine and behavioral indices for endocrine-disrupting chemicals in birds. M.A. Abdelnabi*, N. Thompson, and M.A. Ottinger, University of Maryland, College Park, MD USA.

Endocrine-disrupting chemicals (EDCs) would be expected to affect growth and reproduction. Japanese quail provide an avian model to establish endocrine and behavioral indices for EDC exposure. In these experiments, fertile eggs from the parents (P1) were injected at embryonic day 11 (E11) with estradiol benzoate (EB; 20 ug/egg), oil control (con), or uninjected. Chicks (F1) were raised to maturity and housed in pairs with all possible crosses (EB x con; EB x EB; and con x con) to assess fertility and productivity. A separate subset of EB and control F1 males were photoregressed, then implanted with testosterone and tested for sexual behavior one week later. In addition, eggs were collected from EB and control F1 pairs, then incubated. At embryonic day 11, eggs from the EB pairs were divided into two groups; the first was injected with EB (F2a) while the rest of the eggs from the EB pairs were not treated (F2b) the eggs from control pairs were not treated (F2c). After hatch, chicks (F2) were raised exactly as F1 chicks had been raised. F1 males were demasculinized by the EB treatment and when paired with EB females, fertility was severely reduced (35% vs 85%). F1 females showed erratic egg production (55% vs 90%). F2 birds that were embryonically treated with EB (F2a) also showed reproductive impairment, similar to that observed in the EB treated F1s. Fertility and productivity were 90 and 83%; 86 and 72% and 57 and 32% for the control, non-injected and EB injected, respectively. Interestingly, there appeared to be a carry over effect in the F2 offspring. This study provides evidence for long-term consequences of embryonic estrogen exposure to estrogen and suggests that these measures are potential indices for EDC exposure. Supported by EPA #R826134010 (MAO) and NSF #IBN-9817024 (MAO).

1627 Immunological effects of genistein exposure in chicks. Alexander Peterson¹, Haitao Li¹, and Wallace Berry*¹, ¹Auburn University Department of Poultry Science.

Exposure of chicks to high levels of sex steroids causes involution of the thymus and bursa with subsequent impairment of immune function.

Domestic poultry are exposed from hatching onward to potentially estrogenic isoflavones in soy based diets. Our previous work has demonstrated that the soy isoflavone genistein is estrogenic in chickens. The purpose of this study was to determine whether genistein would exert effects on thymus and bursa in a manner similar to that of estrogen and testosterone. Day old male chicks were assigned to 6 treatments as follows: chicks fed a typical soy based chick diet with daily subcutaneous injection of sesame oil vehicle (SV); soy-free diet and vehicle injection (V); daily injection of 0.5 mg diethylstilbestrol as a positive control (DES); 0.5 mg testosterone propionate as a positive control (TP); 1.0 mg genistein injection (G1); and 10.0 mg genistein (G 10). At 12 days of age, the chicks were weighed and testes and livers were excised and weighed. DES treatment significantly decreased bursa and thymus weight and increased liver weight. TP also decreased bursa and thymus weight and increased liver and testes weight. G 10 treatment significantly reduced both bursa and thymus weight and increased liver weight. These results demonstrate that genistein has effects similar to the sex steroids on immune tissues in chickens and may influence immunological development in poultry species. (Supported by the Alabama Agricultural Experiment Station and USDA AD-421 project S-289).

1628 Partial structural characterization of Bursal Anti-Steroidogenic Peptide (BASP) with structural homology to chicken histone H1. R.W. Moore^{1,2}, D.Y. Caldwell², T.E. Porter³, L.R. Berghman², F. Vandesande⁴, J.A. Byrd¹, and B.M. Hargis⁵, ¹USDA-ARS-SPARC, ²Texas A&M University, ³University of Maryland, ⁴University of Leuven, Belgium, ⁵University of Arkansas.

Previously, our laboratory has described a bursa of Fabricius-derived molecule that was named Bursal Anti-Steroidogenic Peptide (BASP) after its potent anti-steroidogenic activity. While the biological activity of BASP in several *in vitro* systems has been studied in our laboratory, until recently, molecular/structural characterization has remained elusive due to lack of substantial amounts of highly purified biologically active material useful for conventional sequencing. Presently, endopeptidase digestion, fragment purification, and conventional N-terminus sequencing of each of the two predominant bands (24 and 30 kDa) from SDS PAGE of highly purified biologically-active BASP were performed and six low level sequences were determined. Each of these short fragment sequences showed homology with the known sequence of chicken histone H1. A single partial sequence homologous with the structure of chicken histone H1 was also obtained utilizing Q-TOF analysis. In addition, a unidirectional cDNA library constructed from bursa of Fabricius mRNA was screened with polyclonal antibody probes constructed against highly purified biologically active BASP. Six expression proteins were identified, and nucleotide sequencing of the lambda phage inserts revealed 4 unique partial nucleotide sequences from the 6 sequenced cDNA inserts. One of these nucleotide sequences (two overlapping cDNA inserts) was 99% homologous with chicken histone H1. These observations may argue that BASP is either identical to, processed from, or shares homology with chicken histone H1. Purification of chicken histone H1 for bioassay has been initiated.

Key Words: Bursal Anti-Steroidogenic Peptide, Histone H1, Bursa of Fabricius

1629 Influence of broiler breeders age on villous and microvillous height in the embryo intestinal mucosa. Alex Maiorka¹, A.V. Fischer da Silva¹, E. Santin¹, L.O. Nakagui¹, and M. Macari¹, ¹FCAV - UNESP.

This study was carried out aiming to evaluate the effect of broiler breeders age (30 or 60 week) on embryo intestinal mucosa development. At 20th day of incubation, 8 embryos of each broiler breeder age were sacrificed and sample from different parts of the small intestine were collected (duodenum, jejunum and ileum) and submitted to morphometric studies under light microscopy using an image analysis system. The parameters studied were villous height (micrometer), crypt depth (micrometer) and microvillous height (micrometer) using transmission electron microscopy. The experimental design was completely randomized with two treatments and eight repetitions, with the data submitted to analysis of variance. At light microscopy analysis it was observed that intestinal mucosa of embryos from 30-wk broiler breeders showed smaller villous height when compared to those from 60-wk broiler breeders (77 vs 102; 40 vs 45 and 31 vs 41 for duodenum, jejunum and ileum, respectively)

and smaller crypt depth (44 vs 53 ; 31 vs 37 and 26 vs 31 for duodenum, jejunum and ileum, respectively). The results of the transmission electron microscopy analysis showed that the embryo from 30-wk broiler breeders had smaller jejunum microvillous height than that verified in jejunum of embryos from 60-wk broiler breeders (0.874 vs 1.090). These results indicate that broiler breeder age has an important role on intestinal mucosa embryo development. FAPESP Proc.98/11304-9

Key Words: Embryo, Intestinal mucosa development, Age of broiler breeders

1630 Effect of feed and/or water withdrawal on intestinal mucosa development in broiler chicks after hatching. Alex Maiorka¹, Elizabeth Santin¹, Fabiano Dahlke¹, and Marcos Macari¹, ¹FCAV-UNESP.

This study aimed to evaluate the effect of feed and/or water withdrawal on intestinal mucosa development in broiler chicks after hatching. In Trial I, 20 day-old broiler chicks, male, were used. After hatching, the birds were maintained in environmentally controlled room and divided in two groups and fed as follows: T1- water and feed ad libitum; T2 - water ad libitum and no feed. After 24 h of hatching samples from different segments of the small intestine were collected (duodenum, jejunum and ileum) which were submitted to morphometric studies using light microscopy using an image analysis system. The parameters studied were: villous weight and crypt depth. The results did not show difference between treatments in duodenum (P=0.434), jejunum (P = 0.699) and ileum (P = 0.060) for villous height and crypt depth in the duodenum (P = 0.434), jejunum (P = 0.825) and ileum (P = 0.246). In Trial II, 72 day-old broiler chicks, male, were divided into 4 treatments and fed as follows: T1- water and feed ad libitum; T2 -water ad libitum and no feed; T3 - no water and feed ad libitum and, T4 - no water and no feed. After 24, 48 and 72 hours post-hatching, 6 birds of each treatment were sacrificed and sampled from different parts of the intestine were collected (duodenum, jejunum and ileum) and submitted to scanning electron microscope studies to evaluate the villous density. The chicks fasted of feed and/or water showed greater number of the villous/area in all intestine mucosa segments, irrespective of the fasting period, than those in the birds not fasted. The results of this study suggest that not only feed is relevant to villous development in the mucosa of broiler chicks after hatching, but water, as nutrient, also play a important role in this mechanism. The findings also revealed that 24 h fasting is deleterious to intestine mucosa integrity. FAPESP Proc. 98/11304-9.

1631 Expression of selected hepatic genes related to lipid metabolism in broiler breeders. M.P. Richards¹, S.M. Poch¹, C.N. Coon², Y. Kirby², R.W. Rosebrough¹, C.M. Ashwell¹, and J.P. McMurtry¹, ¹USDA, ARS, Beltsville, MD, ²University of Arkansas, Fayetteville, AR.

Cobb 500 broiler breeder pullets were fed according to Cobb Breeder Management Guide specifications until they reached 21 weeks of age. At this time, half the birds were switched to *ad libitum* feeding (AL) while the remaining birds continued to be fed according to Cobb guidelines (CF). At 22 weeks all birds were photostimulated and maintained throughout a laying cycle ending at 36 weeks. Samples of liver and abdominal fat pad were collected at the following times: 1) just prior to photostimulation, 2) after photostimulation through first egg, and 3) at peak egg production. Reverse transcription polymerase chain reaction in conjunction with capillary electrophoresis and laser-induced fluorescence detection (RT-PCR/CE-LIF) was used to quantify hepatic expression of specific genes relative to that of β -actin in total RNA samples. Expression of fatty acid synthase (FAS), malic enzyme (ME), and acetyl-CoA carboxylase (ACC) genes in AL hens declined from their highest levels just prior to photostimulation to reduced levels as the birds came into and maintained egg production. In contrast, the CF hens displayed a dramatic increase in the expression of these genes following photostimulation through first egg with a subsequent decline in expression levels as these birds reached peak egg production. Expression of fatty acid binding protein (FABP) and apolipoprotein B (ApoB) genes increased in both AL and CF breeders following photostimulation. This is consistent with increased hepatic lipid transfer capacity during egg production. Abdominal fat pad weights were significantly higher in the AL as compared to CF hens following photostimulation.

Hepatic leptin receptor gene expression did not differ significantly for AL as compared to CF hens at any time. In conclusion, the AL and CF feeding regimes produced significantly different effects on hepatic gene expression related to lipid metabolism in broiler breeders. By analyzing the expression of specific hepatic genes involved in lipogenesis and lipid transport as well as other metabolic pathways, it may be possible to assess the potential metabolic impact of changes in feed consumption and other management practices on growth, body composition and performance of broiler breeders.

1632 Identification and expression of the turkey leptin receptor gene. M. P. Richards*, S. M. Poch, and C. M. Ashwell, *USDA, ARS, Beltsville, MD.*

Using reverse transcription polymerase chain reaction (RT-PCR) with total RNA isolated from whole brain tissue, we have sequenced 3976 bases of the turkey leptin receptor (Ob-R) gene corresponding to the complete coding sequence and portions of the 5'- and 3'-untranslated regions of the mRNA (GenBank accession no. AF321982). Turkey Ob-R showed greater than 90% sequence identity at both the nucleic acid and amino acid level with chicken Ob-R (GenBank accession nos. AB033383 and AF169827). The turkey Ob-R gene (long form) codes for a protein comprised of 1147 amino acids that displays a number of features similar to other leptin receptors including a signal peptide, a single trans-membrane domain and specific conserved motifs defining putative leptin binding and signal transduction regions of the protein. RT-PCR in conjunction with capillary electrophoresis and laser-induced fluorescence detection was used to quantify Ob-R expression relative to that of β -actin in total RNA samples isolated from various tissues. Ob-R expression was highest in brain, spleen and lung tissue obtained from 3 wk old poults with lower levels of expression in kidney, pancreas, duodenum, liver, fat, and breast muscle. Using a primer set specific for the long form of OB-R (Ob-RL), the highest levels of expression for this variant form were detected in brain, lung and spleen with lower levels in kidney, pancreas, fat and liver tissues. Ob-R expression in developing turkey embryos was highest in brain tissues and remained high throughout incubation (days 14-28). In contrast, expression of Ob-R in embryonic liver tissue peaked at day 16 and then declined toward hatching (day 28). Yolk sac expression of Ob-R declined from day 14 to day 20 and then increased toward hatching. These findings suggest differential regulation of Ob-R expression in turkeys during embryonic and post-hatch development. In conclusion, this is the first report of leptin receptor gene expression in turkeys.

1633 *Campylobacter* colonization of the crops of newly hatched chicks. R. L. Ziprin* and L. F. Kubena, *FFSRU/SPARC/ARS/USDA, College Station, TX/USA.*

It has been reported that up to sixty percent of the crops of market age birds contain *Campylobacter*. However, this number may not represent true colonization but only transient presence of the organism. In our present work we have studied colonization of crops in newly hatched chicks by wild-type and mutant strains of *C. jejuni*. Groups of 15 day-of-hatch Leghorn chicks were orally gavaged with 10^8 CFUs of the wild-type strain on day-of-hatch or with an equivalent number of mutant *C. jejuni*, which had been previously shown to be ineffective colonizers of the cecum. Three birds from each challenged group were killed by cervical dislocation on days 1,3,5,7, and 9 after inoculation. There was a 2-4 hour feed withdrawal period before sacrifice. Crops were aseptically removed, placed in individual plastic bags containing 5 ml of sterile water, and placed in a Stomacher device. The *C. jejuni* concentration in the resultant suspension was determined by standard plate count methods, using Campy-Cefex agar. We observed an initial rapid drop in *Campylobacter* concentrations present in the crop during the first 24 hrs after challenge, then a stable concentration of approximately 10^5 CFUs was established through days 7 to 9. Mutant strains lacking an ability to colonize cecum were found to persist in the crop. Concentrations of these mutant strains in the crop were usually below that of the wild-type, but were still between 10^3 to 10^5 CFUs. These results indicate that the bacterial factors necessary for colonization of the crop are not the same as those needed for colonization of the cecum.

1634 Heterogeneity of Ryanodine Receptors in Turkeys. Wen Chiang* and Gale Strasburg, *Michigan State University.*

Pale, soft, exudative (PSE) meat has been a serious quality problem in the turkey industry. Because of the striking similarity of development of PSE turkey to that of PSE pork, there could be a genetic basis for some of the incidence of PSE turkey. A point mutation (R615C) in the SR calcium channel protein or ryanodine receptor (RYR1) is associated with porcine malignant hyperthermia, and results in economic losses to producers from animal death by stress, and to processors by abnormalities in meat quality resulting from rapid postmortem glycolysis. Over 20 mutations in the primary structure of mammalian RYR1 have been associated with Malignant Hyperthermia (MH) and Central Core Disease (CCD) in human. At least 9 of these mutations cluster in the region of amino acid residues 35 to 614. We hypothesized that one or more mutations exist in the region of the turkey alpha-RYR (homologous to mammalian RYR1) which give rise to this problem. RNA was purified from genetically unimproved turkeys and from a commercial line intensively selected for muscle growth. alpha-RYR cDNA was amplified through RT-PCR and was cloned into a plasmid vector. Analysis of the alpha-RYR cDNA covering amino acids 376 to 647 (human sequence) reveals sequence diversity in the unimproved turkey population. One group is homologous to the commercial line and to mammalian RYR sequences. Another unimproved group shows a 27 amino-acid-residue deletion (residue numbers: 417-443). Another unimproved group shows heterogeneity of cDNA variants. The variants are characterized by the presence or absence of 81 bp, 193 bp, and 329 bp sequences. The exclusion of the 81 bp sequence results in the absence of amino acids corresponding to Ser-416 to Ser-443. The exclusion of the 193 and 329 bp sequences leads to frame shifts that introduce internal stop codons. Avian muscle fibers also express an additional RYR isoform, beta-RYR, which is homologous to the mammalian non-muscle isoform. Our ryanodine binding studies indicate that there is functional diversity of beta isoforms within the commercial turkey population. These results suggest that mutations may exist in either isoform or in both, which could predispose turkeys to yielding of PSE meat.

1635 Intestinal calcium uptake and reproductive hormones in three laying hen varieties after prolonged egg production. D. J. Franco*, K. K. Franzen¹, C. F. Toombs¹, and M. M. Beck¹, ¹*University of Nebraska.*

Hy-Line W-98, W-36, and Brown hens are among the most popular strains for commercial egg production around the world. Although hens of all three types lay approximately the same number of eggs/hen housed to 80 weeks, fewer eggs and more soft shelled or broken shell eggs are observed during prolonged egg production. Also, the increase in egg size with age brings, as a result, an insufficient calcium carbonate secretion, and consequently the thickness of the eggshell declines (R.J. Etches, 1996). As part of a larger study, hens of the three varieties were maintained under production longer than 100 weeks and hens of each strain were randomly selected for in vitro determination of calcium uptake (CaT) by duodenal cells. Blood samples were collected 4-6 hours prior to oviposition via brachial vein cannulation for plasma estrogen (E₂), luteinizing hormone (LH), and progesterone (P₄) determination. Hens were then euthanized by cervical dislocation and CaT determined. For W-36 hens, CaT was significantly greater than that found in Brown hens (P=0.042) while for W-98 there were no differences from W-36 or Brown strains (P=0.170 and 0.427), respectively. P₄ and LH concentrations were not significantly different in the three varieties of laying hens. E₂ concentration for Brown hens was significantly greater than that found in W-36 and W-98 hens (P=0.001 and 0.043, respectively), while for W-98 the E₂ concentration was significantly greater than that found in W-36 (P=0.083). Based on the higher CaT by duodenal cells and the lower plasma levels of E₂, these results suggest a higher efficacy of the W-36 hens in calcium regulation during the terminal phase of egg production (more than 100 weeks of age), compared to the Brown and W-98 hens. However, when specific gravity and thickness of shells were compared, the W-36 appeared to have no advantage over W-98 (P=0.460 and 0.684) or Brown (P=0.197 and 0.941) hens, respectively.

1636 Estrogen receptor populations in various calcium regulating tissues in laying hens at three ages. K. K. Franzen^{*1}, D. Clopton¹, N. Caceres², G. Sarath², and M.M. Beck¹, ¹Animal Sciences Dept., University of Nebraska, ²Biochemistry Dept., University of Nebraska.

Older hens in production lay larger but fewer eggs than younger birds and the incidence of soft and broken shells is greater in older hens than younger (Joyner et al., 1987). These changes are attributable at least in part to changing hormone profiles and diminished ability of the hen to process calcium at the duodenum (Al-Batshan et al., 1991; Hansen and Beck, 1997). However, in a recent study, duodenal cells from older birds (≥ 71 wk) were able to take up ⁴⁵Ca as well as hens at 26-29 wk of age despite reduced estrogen (E₂) and progesterone (P₄) concentrations (Franzen and Beck, 2000). In further exploration of this relationship, a study was conducted with three ages of Hy-Line W-36 birds: pre-lay pullets (PL; 19 wk, 0% production) peak-production hens (PP; 29 wk, 93% production), and late stage hens (LS; 71 wk, 80% production). Hens from the PP and LS groups were palpated for presence of an egg in the shell gland, and a blood sample for E₂, P₄ and luteinizing hormone (LH) determinations was drawn from the brachial vein of all birds 4-6h prior to expected oviposition. Hens were then euthanized and tissues (kidney, duodenum, shell gland, hypothalamus) were removed for quantification of estrogen receptor- α (ER α) populations via immunocytochemical and Western blot analyses. Plasma E₂ and P₄ were both lower in LS birds than in either PL or PP birds (P \leq 0.05), but LH did not differ across ages. ER α staining was not different among age groups in shell gland; however, in both kidney and duodenum, PL birds had fewer receptors than LS birds (P \leq 0.05), with PP birds being intermediate. When comparisons were made within age, only LS hens had differences between tissues: ER α staining was greater in duodenum than in kidney or shell gland (P=0.0016, 0.0427) with the least amount of staining in the kidney (P \leq 0.10), the primary site of E₂ action on calcium regulatory processes. PL and PP birds had no differences in ER α occurrence in the various tissues.

Key Words: Estrogen receptors, Laying hen, Aging

1637 Frequency of Preovulatory Luteinizing Surges in Turkey Hens and Egg Production Rate. H.-K. Liu, D.W. Long, and W.L. Bacon, *The Ohio State University, Wooster OH.*

Whether the interval between preovulatory surges of luteinizing hormone (LH) was different between lines of turkey hens with either poor (RBC3 line, peak at 55%) or excellent (Egg line, peak at 85%) rates of egg production was examined. Twelve laying hens of each line were cannulated and bled hourly (1.5 mL) for 10 d at peak of production. The hens were photostimulated with constant light (24 h light: 0 h dark d⁻¹) to avoid diurnal masking of innate circadian rhythms. Cannula patency was lost during serial bleeding in 5 of the RBC3 line hens and 1 of the Egg line hens, so they were removed from the study. The mean interval between preovulatory LH surges for the RBC3 line hens was longer than for the Egg line hens (39.5 h and 26.0 h, respectively; P < 0.001) and had a higher coefficient of variation (21.9% and 7.2%, respectively). Intersequence LH surges were found in some of the RBC3 line hens (2 of 7 hens), but none were found in the Egg line hens (0 of 11 hens). All preovulatory progesterone (P₄) surges (144 total) were coupled with preovulatory LH surges, but not all LH-P₄ surges were coupled with ovipositions; uncoupled LH-P₄ surges are referred to as blind LH-P₄ surges. The incidence of blind LH-P₄ surges was not different between RBC3 and Egg line hens (23% and 9% of all surges, respectively; P = 0.08). The baseline concentration of LH between surges was higher in the Egg line hens than in the RBC3 line hens (2.39 and 1.82 ng mL⁻¹, respectively P < 0.001), but the baseline and surge amplitude concentrations of P₄ were not different (P > 0.25) between lines, nor was the concentration of estradiol-17 β . It was concluded that the longer interval between LH-P₄ surges was the major factor tested that was associated with the difference in egg production rate between the RBC3 and Egg line turkey hens. A higher incidence of blind LH surges may be a second contributing source of lower egg production in the RBC3 line in comparison to the Egg line turkey hens.

Key Words: turkey hen, luteinizing hormone, egg production rate

1638 Changes in morphology of granulosa cells in heat-stressed laying hens. M. A. Alodan^{*1} and M. M. Beck¹, ¹University of Nebraska.

We know from previous experiments that heat stress (HS) reduces egg production in laying hens, in part at least through disruption of steroidogenesis. We also noted in several studies changes in the morphology of the granulosa cells (GC) at the level of lipid droplets (LD). It has been reported that HS increases lipid oxidation in the hen, and that normal lipid endocytosis is controlled by the amount of lipid in the cell. However, oxidized lipid receptors are not controlled, at least in human macrophages located in the endothelium of blood vessel walls, causing the formation of giant macrophage cells and leading to the formation of plaques in arteries. The aim of this study was to determine and describe the effect of HS on the morphology of LD in GC of the laying hen and the subsequent recovery to the pre-HS state. Two groups of hens were used; one group was subjected to 24C, 30%RH (control), the other to 36C, 60%RH for 24h (HS treatment). At the end of 24h, the F1 follicles were collected from both groups and the GC monolayers were isolated and fixed in 10% formalin for 24h. The monolayer was then stained using fat stain Oil Red O to localize LDs in the GC. In control GC, LDs were small and uniform in size and shape and they were randomly and evenly distributed in the cells. In contrast, the GC of the HS birds contained much larger LD of different sizes and shapes, and they were arranged neatly around the cell periphery. The percentage of cell area covered by LD in HS GC was significantly (P=0.000) greater than that of the control group. We hypothesize that, during HS, the reduction in activity of GC (steroid production) results in lipid accumulation in the cells. Alternatively, HS-induced lipid oxidation may lead to this accumulation via unregulated oxidized lipid receptors. Both of these are consistent with the recovery that occurs over time in these cells.

Key Words: Laying Hen, Granulosa cell, Lipid oxidation

1639 Active immunization against inhibin enhances reproductive measures in male broiler breeders. S. T. Pittman^{*}, D. G. Satterlee, and G. G. Cadd, *Louisiana State University, Baton Rouge, LA/USA.*

Inoculation of female Coturnix and broiler breeder hens with an inhibin-based immunogen (MBP-cINA₅₂₁) accelerates puberty and enhances egg production. MBP-cINA₅₂₁ is a fusion protein consisting of the *E. coli* Maltose Binding Protein (MBP) and a fragment of the alpha-subunit of chicken inhibin (cINA₅₂₁). Herein, the effect of this immunogen on male broiler breeder development was evaluated. At 13 wk, male breeders (n = 288; Cobb) were randomly assigned into one of four treatment groups based on a primary inoculation of 0 (control), 1, 3, or 5 mg of MBP-cINA₅₂₁ per bird. Booster vaccinations (one-half the primary dose) were given at 18 wk. At 24, 28, and 39 wk, one-third of the birds in each treatment were weighed (BWT), blood sampled and sacrificed. Testes were weighed (TWT) and plasma testosterone (T) levels were determined by RIA. At 24 wk, birds given the 5-mg dose had greater (P < 0.05) BWT and TWT than controls. BWT and TWT responses in birds of the two lowest dosages were intermediate between, but not different from, those of the control or high dose groups. Plasma T levels were higher (> 2-fold; P < 0.05) in birds given 5 mg than in either the control or 1 mg groups. T levels were also appreciably elevated in the 3-mg group but not different from control T responses. No treatment differences were detected in BWT, TWT and T levels at 28 wk. However, by 39 wk, although BWT remained similar in all treatment groups, TWT was greater in males given the 1-mg dose (43 %, P < 0.10) than in controls. TWTs in the 3- and 5-mg groups were also numerically elevated (30 and 37 %, respectively) over control values. Additionally, age-related decline in TWT between 28 and 39 wk was markedly less in all MBP-cINA₅₂₁-treated birds than in controls. Plasma T at 39 wk in the 1-, 3- and 5-mg groups were, respectively, 115, 74, and 67 % greater than those found in the controls. Fighting reduced bird numbers and likely precluded the finding of statistical differences between plasma T means at 39 wk. Mortality was similar in all treatment groups. Collectively, our data suggest that inoculation of male broiler breeders with MBP-cINA₅₂₁ enhanced early measures of puberty and diminished the expected decline in TWT and T levels associated with aging.

Key Words: Broiler breeder, Inhibin, Testes

1640 Dual labeling immunofluorescent staining demonstrates the presence of a protease-inhibiting protein (ovoinhibitor) in the chicken pituitary. C. M. Oubre*¹, K. E. Clements¹, F. Vandesande², and L.R. Berghman¹, ¹Texas A&M University, ²University of Leuven, Belgium.

Ovoinhibitor is a serine protease-inhibiting protein that specifically inhibits serine proteinases such as trypsin and chymotrypsin. During recent attempts to raise monoclonal antibodies (MABS) against chicken bursa of Fabricius proteins, one MAB was produced that specifically recognized chicken ovoinhibitor. This was the first demonstration of ovoinhibitor in an avian immune organ. Further immunocytochemical research revealed that in the pituitary and the brain of the chicken, some cells undeniably displayed immunoreactivity for ovoinhibitor. The present study was aimed at identifying the hypophysial hormone-producing cells that express ovoinhibitor immunoreactivity. Therefore, pituitary glands from 4-week old birds were fixed in phosphate-buffered paraformaldehyde (4% w/v) and 30- μ m vibratome sections were stained as floating sections in 12-well tissue culture plates. The mouse MAB

against Ovoinhibitor was used in conjunction with polyclonal antibodies against Luteinizing Hormone (LH), Growth Hormone (GH), Proopiomelanocortin (POMC) and Prolactin (PRL) and S-100, respectively. The mouse MAB was visualized with a rhodamine-conjugated secondary antibody, whereas the polyclonal rabbit antisera were detected with a biotinylated secondary antibody combined with FITC-conjugated streptavidin. This procedure stained ovoinhibitor-positive cells in red, while the pituitary hormone-positive cells were stained green; overlapping antigens were clearly visible in yellow. The results of these dual-staining experiments revealed partial co-localization of ovoinhibitor with GH, LH, and POMC, each time in a subset of the respective hormone producing cells. By contrast, no co-localization with PRL and S-100 could be demonstrated. Serine protease inhibitors from another family (the serpins) have recently been identified in rat brain and pituitary. In the latter, they have been suggested to play a role in the regulation of cell-extracellular matrix interactions .

Key Words: chicken, pituitary, ovoinhibitor

ASAS Nonruminant Nutrition: Vitamins, Minerals, and Energy

1641 The effect of genotype, parity and folic acid supplement on the expression of leptin, and its receptors in embryonic and endometrial tissues from pigs at 15 days of gestation. F. Guay¹, A. Giguere*², M.-F. Palin², C.L. Girard², J.J. Matte², and J.P. Laforest¹, ¹Laval University, Department of Animal Science, Qc, Canada, ²Dairy and Swine R & D Centre, Lennoxville, QC, Canada.

We have previously demonstrated mRNA expression of leptin (*Lep*) and its receptors (*Lepr* and the long form *Lepr-L*) in endometrium and embryos at 25 days of gestation in sow. We have also shown that expression levels of *Lep* and *Lepr-L* could be influenced by dietary supplement of folic acid (B9). *Lep* and its receptors may therefore have a direct role in the embryo-maternal dialogue. The objectives of this study were to compare the mRNA expression of leptin (*Lep*) in backfat tissue, and its receptors (*Lepr* and *Lepr-L*) in embryonic and endometrial tissues of sows in relation to the genotype, parity, and B9 supplement. Eleven nulliparous Yorkshire-Landrace (GT), 12 multiparous Landrace (LD) and 10 multiparous Meishan-Landrace (ML) sows were randomly assigned to 2 dietary treatments: 0 ppm or 15 ppm of B9 given from the estrous preceding mating up to slaughter, on d15 of gestation. Embryonic and endometrial tissues were collected to evaluate the mRNA expression of *Lepr* and *Lepr-L* while expression levels of *Lep* were assessed in backfat tissue. Blood samples were taken at mating and at slaughter to determine the concentration of circulating leptin; backfat thickness was also recorded. The embryonic *Lepr-L* transcript was barely detectable. Endometrial *Lepr* and *Lepr-L* and embryonic *Lepr* expression were higher in LD than in GT and ML sows ($P < .01$). No B9 effect was seen on *Lep* and its receptors; breed and parity did not influence *Lep* in backfat. Plasma leptin and backfat thickness were higher in ML than in LD and GT sows ($P < .01$). Circulating *Lep* was correlated with backfat thickness ($r = 0.54$, $P < 0.01$) but not with backfat expression levels of *Lep*. These results suggest a developmental regulation of leptin receptors (*Lepr* and *Lepr-L*) in early pregnancy. The effect of B9 on *Lep* gene expression may occur between d15 and d25. Furthermore, in early gestation, the circulating leptin concentration is related to adiposity.

Key Words: Leptin, Sow, Gestation

1642 The effect of genetic type and parity and folic acid supplement on homocysteine metabolism from sows on day 15 of gestation. F. Guay*¹, A. Giguere², M.-F. Palin², C.L. Girard², J.J. Matte², and J.-P. Laforest¹, ¹Laval University, Department of Animal Science, Qc Canada, ²Dairy and Swine R & D Centre, AAC, Qc Canada.

Supplements of folic acid (B9) have been shown to increase prolificacy in multiparous sows by increasing embryo survival. B9 supplement is also recognized to decrease the concentrations of homocysteine (HCY), which is known to be potentially teratogenic. The objective of this study was to compare the effects of B9 supplement on HCY metabolism in early gestating sows. Eleven nulliparous Yorkshire-Landrace (GT), 12 multiparous Landrace (LD) and 10 multiparous Meishan-Landrace (ML) sows were randomly assigned to 2 dietary treatments: 0 ppm or 15 ppm

of B9. Supplements were given from the estrous preceding mating up to slaughter on d15 of gestation. The uterine flushing was collected to evaluate the total content of HCY in the uterine lumen. Blood samples were taken at mating (d0), d5, d10 and d15 of gestation to determine the concentrations of circulating HCY. B9 supplementation had no significant effect on the concentration of circulating HCY, but it decreased ($P \leq .06$) HCY content of uterine flushing in LD (115 16 nmol vs 84 17 nmol) and GT sows (138 23 nmol vs 98 12 nmol) but not significantly in ML sows (117 30 nmol vs 102 30 nmol). ML (18.3 1.3 μ M) and GT (16.6 1.0 μ M) sows had lower ($P \leq .01$) concentrations of circulating HCY than LD sows (24.5 1.3 μ M). These results suggest that a decrease in the content of HCY in the uterine flushing may play an important role in the control of embryo survival by a supplement of B9.

Key Words: Folic acid, Homocysteine, Sow

1643 Phosphorus removal with and without phytase in finishing pigs. G.A. Apgar*¹, C.M. Peter², T.A. Guthrie¹, K.E. Griswold¹, and D.H. Baker², ¹Southern Illinois University, Carbondale, ²University of Illinois, Urbana.

Two trials were conducted using 171 crossbred pigs (53.3 +/- 1.4 kg) to evaluate the effects of removing the inorganic P from finishing diets with or without phytase. The finisher period was broken into two 28-d phases, with the early phase formulated to contain 0.82% lysine and the late phase 0.65% lysine. Dietary treatments (Trt) were: 1) control (early = 0.49% total P, 0.19% available P (aP); late = 0.43% total P, 0.15% aP); 2) control without inorganic P (early = 0.36% total P, 0.07% aP; late = 0.33% total P, 0.06% aP); and 3) diet 2 + 500 U/kg phytase. Pigs were given ad-libitum access to feed and water. Average daily gain, ADFI and G:F were calculated every 2 wks. Pigs were scanned via ultrasound at 98.9 +/- 1.1 kg for 10th rib backfat (BF) and loin eye area (LEA). One barrow and one gilt per pen were slaughtered (ave wt 108.4 +/- 1.4 kg) and metacarpals III and IV collected for bone ash determination. Data were analyzed using the GLM procedures of SAS (1999). The models included the effects of trial, dietary treatment, replicate and all pertinent interactions. There were no significant trial*treatment interactions. During both the early and late phases, pigs fed diet 3 had greater ($P < 0.05$) ADG than pigs fed diet 2. Pigs fed diet 3 also had greater ($P < 0.05$) daily feed intake during the late phase than pigs fed diet 2. Feed efficiency was not affected by dietary treatments. Loin eye area was greater for pigs fed Trt 1 ($P < 0.05$) than those fed Trt 2 and 3, or pigs fed Trt 3 ($P < 0.05$). Pigs fed Trt 1 tended to have greater ($P = .072$) ash content than pigs fed Trt 2 and 3. Removing P during the finishing phase did not alter BF, but reduced LEA and feed intake compared with animals fed a diet with supplemental P. Pigs fed supplemental phytase had improved ADG compared with non-supplemented pigs, but had lower LEA than control pigs.

Key Words: Pigs, Phytase, Finishing

1644 Effects of dietary chromium yeast supplementation on growth performance and carcass characteristics in growing-finishing pigs. C. Y. Liu*, J. N. Hsu, and L. C. Cheng, *Pig Research Institute Taiwan, ROC.*

Two experiments were conducted to evaluate the effects of chromium yeast on growth performance and carcass characteristics in growing-finishing pigs. In Exp. 1, 60 crossbred pigs (average 39.7 kg BW; 4 pigs/pen, 5 pens/treatment) were fed a corn-soybean meal diet (16% CP and .8% lysine) supplemented with 0, 200, or 400 ppb of Cr from chromium yeast (S.I. Lesaffre). Backfat and loin eye area were measured at termination from 2 pigs/pen with close BW. The addition of Cr increased ADG (788, 847, 857 g/d; $P < .05$) but did not affect ADFI (2.45, 2.56, 2.56 kg/d) or F/G ratio (3.13, 3.02, 2.98). Backfat was significantly reduced by Cr supplementation at 400 ppb level (2.73, 2.52, 2.29 cm; $P < .01$) without changes in loin eye area (45.2, 46.7, 47.3 cm²). In Exp. 2, 18 crossbred pigs (average 87.2 kg BW) were individually fed a basal diet (16% CP and .8% lysine) without or with 800 ppb of Cr for final 3 weeks. All pigs were slaughtered for determination of backfat and loin eye area. Dietary 800 ppb of Cr increased ADG (941 vs 1118 g/d; $P < .05$) and backfat (2.39 vs 2.77 cm; $P < .1$); however, ADFI (2.78 vs 3.27 kg/d), F/G (2.97 vs 2.91) or loin eye area (44.9 vs 47.4 cm²) were not significantly ($P > .1$) changed. The results of this study indicate that dietary Cr as chromium yeast is effective to improve performance and its effects are dependent on dietary level and feeding phase.

Key Words: Pigs, Chromium yeast, Performance

1645 Vitamin E and selenium improve pork stability in finishing pigs fed diets deleted of vitamin-mineral premix. S. C. Choi*¹, B. J. Chae, and In K. Han², ¹*Division of Animal Res. Sci., Kangwon National University,* ²*Dept. of Animal Sci. and Tech., Seoul National University, Suwon, Korea.*

Two feeding trials were conducted to determine the effect of inclusion levels, or deletion of vitamin-mineral (VM) premixes on growth performance and pork stability in finishing pigs. In expt. 1, a total of ninety-six pigs (L×Y×D, 85.09±3.12kg) were employed for a 4-week feeding trial. Treatments were 50% (Control), 100%, 150%, and 200% of NRC (1998) requirements for vitamins and trace minerals. In expt. 2, a total of 108 pigs (L×Y×D, 84.76±.58kg) were employed for a 4-week feeding trial. Treatments were 0% (Control), 200% VM, and 200% vitamin E and Se listed in NRC(1998) requirements. After feeding trials, four pigs/treatment were sacrificed for the analysis of pork quality. ADG and feeding/gain (F/G) were the best at 150% VM addition level (quadratic, $p < .05$) among treatments. Dressing percentage and backfat thickness in pigs were not affected by different addition levels of VM premixes. Pork stability in terms of TBARS was linearly ($p < .05$) improved as dietary VM premix was increased (expt. 1). ADG, F/G and pork stability (TBARS) were also reduced ($p < .05$) when VM premixes were deleted. However, adding vitamin E and Se improved ($p < .05$) ADG and pork stability in pigs fed diets deleted VM premix (expt. 2). It might be concluded that adding vitamin E and Se is necessary in finisher diets deleted VM premix for pork quality.

Key Words: Vitamin-mineral premix, Vitamin E, Se

1646 Effect of calcium to phosphorus ratio on grower-finisher pig performance and mineral excretion. J.J. Callan*¹, S.M. Brady¹, D. Cowan², M. McGrane³, and J.V. O' Doherty, ¹*University College Dublin,* ²*Novo Nordisk, Novo Nordisk S.A., Chesham, Bucks, UK* , ³*Trouw Nutrition, Leixlip, Co. Kildare, Ireland.*

Two experiments were conducted to evaluate the effects of phosphorus (P) level and Calcium (Ca): total P (tP) ratio on the efficacy of microbial phytase when added to diets containing barley, wheat and soya bean meal. In experiment 1, 48 entire male pigs were fed individually food containing (T1) 5.5 g/kg tP and 7.0 g/kg Ca, (T2) 5.5 g/kg tP and 7.0 g/kg Ca and 750 FYT/kg of *Peniophora lycii* (*Pen. lycii*) phytase, (T3) 4.3 g/kg tP and 7.0 g/kg Ca and (T4) 4.3 g/kg tP and 7.0 g/kg Ca and 750 FYT/kg of *Pen. lycii* phytase. In experiment 2, 48 entire male pigs were fed individually food containing (TT1) 4.3 g/kg tP and 7.0 g/kg Ca, (TT2) 4.3 g/kg tP and 7.0 g/kg Ca and 750 FYT/kg of *Pen. lycii* phytase, (TT3) 4.3 g/kg tP and 4.3 g/kg Ca and (TT4) 4.3 g/kg tP, 4.3 g/kg Ca and 750 FYT/kg of *Pen. lycii* phytase. In experiment 1, the pigs offered the low P diets had a lower P ($P < 0.001$) and Ca ($P <$

0.05) intake and a lower faecal P and Ca excretion ($P < 0.05$) than the pigs given the adequate P diets. These pigs also had a lower daily gain ($P < 0.01$), feed intake ($P < 0.05$) and feed conversion ratio (FCR) ($P < 0.05$). The inclusion of phytase to both the adequate and the low P diets increased energy and Ca digestibility ($P < 0.05$). In experiment 2, lowering the Ca: tP ratio from 1.6:1 to 1.0:1 increased the DE content of the diet ($P < 0.05$). The inclusion of phytase increased the digestibility of the N and Ca as well as the DE content ($P < 0.05$). There was a significant ratio by phytase interaction ($P < 0.5$) in P digestibility. The inclusion of phytase increased P digestibility when added to the 1.0:1 ratio diet, however phytase had no effect when added to the 1.6:1 ratio diet. The inclusion of phytase increased ($P < 0.05$) feed intake and weight gain. Lowering the Ca: tP ratio resulted in an improvement in FCR (2.3 v 2.4, s.e.m 0.03; $P < 0.05$). In conclusion the beneficial effects of phytase supplementation are adversely affected by a wide Ca: tP ratio.

Key Words: Pigs, Phytase, Ratio

1647 Determination of true phosphorus digestibility and the gastrointestinal endogenous phosphorus loss associated with soybean meal for growing-finishing pigs. A. Ajakaiye*, M. Z. Fan, T. Archbold, R. R. Hacker, C. W. Forsberg, and J. P. Phillips, *University of Guelph, Guelph, Ontario, Canada.*

A trial was conducted to determine true phosphorus digestibility and the gastrointestinal endogenous phosphorus loss associated with soybean meal fed to growing-finishing barrows. Four Yorkshire barrows, an average initial BW of 40 kg, were fed four diets according to a 4 x 4 Latin square design with four experimental periods. The diets were cornstarch-based containing four levels of phosphorus (0.09, 0.18, 0.27, and 0.36%, on as-fed basis) from solvent-extracted soybean meal. Chromic oxide (0.35%) was included as a digestibility marker. Each experimental period consisted of 8-d with 4-d adaptation and 4-d collection of representative fecal samples. Average feed intake was 2,500 g/d with free access to water. True fecal phosphorus digestibility value was determined by regression analysis technique. The true fecal phosphorus digestibility, corrected for the gastrointestinal endogenous phosphorus loss was determined to be 52.0±10.3% in soybean meal. The gastrointestinal endogenous phosphorus loss in feces was estimated to be 0.52±0.10 g/kg DM diet intake. The endogenous phosphorus loss is an inevitable component of total phosphorus requirement in the growing-finishing pigs. True phosphorus digestibility values in feed ingredients for growing-finishing pigs should be determined.

Key Words: Endogenous phosphorus, True phosphorus digestibility, Soybean meal for pigs

1648 Boron supplementation to pigs increases the production of tumor necrosis factor-alpha and interferon-gamma. T.A. Armstrong* and J.W. Spears, *North Carolina State University, Raleigh.*

Two experiments were conducted to determine the effects of dietary boron (B) on the production of cytokines following an endotoxin challenge. In both experiments pigs were obtained from litters generated from sows fed low B (control) or B-supplemented (5 mg/kg) diets. In experiment (Exp) 1 and 2, 28 and 35 pigs, respectively, (21 d old) remained with their littermates throughout a 49 d nursery phase and were maintained on either a control or B-supplemented diet. In Exp 1, 12 pigs/treatment were moved to individual pens at the completion of the nursery phase and maintained on their respective experimental diet. On d 99 of the study, pigs were injected with 150 µg phytohemagglutinin (PHA) to evaluate a local inflammatory response. Pigs receiving the B-supplemented diet had a decreased ($P < 0.01$) inflammatory response following PHA injection. Peripheral blood monocytes were isolated from 6 pigs/treatment on d 103 and cultured in the presence of lipopolysaccharide (LPS) to determine the effect of B upon tumor necrosis factor-α (TNF-α) production from monocytes. Isolated monocytes from B-supplemented pigs tended to have a higher production of TNF-α. In experiment 2, pigs were group housed with their littermates following the nursery phase for 43 d, after which 10 pigs/treatment were moved to individual pens. In Exp 1 and 2, pigs were randomly assigned within dietary treatment to receive either an i.m. injection of saline or LPS at d 117 and d 109, respectively. The dose of LPS in Exp 1 and 2 was 100 and 25 µg LPS/kg BW, respectively. In Exp 1, serum TNF-α was increased ($P < 0.01$) at 2 h and tended to be increased ($P < 0.11$) at 6

and 24 h post-injection by B; however, only numerical trends existed for a B-induced increase in TNF- α in Exp 2. Serum interferon- γ (IFN- γ) was increased ($P < 0.01$) at 6 h and tended to be increased ($P < 0.08$) at 24 h post-injection in Exp 1. In Exp 2, B also tended to increase IFN- γ . These data indicate that B supplementation increases the production of cytokines, which indicates a role of B in the immune system. However, these data do not explain the reduction in localized inflammation following an antigen challenge in pigs.

Key Words: Boron, Inflammation, Cytokines

1649 The effects of α -lipoic acid (LA) on performance and health of weaned neonatal pigs. K. R. Maddock^{*1}, E. P. Berg¹, C. A. Stahl¹, M. L. Linville¹, and J. A. Carroll², ¹University of Missouri, Columbia, ²ARS-USDA, Columbia, MO.

Two trials were conducted to evaluate the potential benefit of supplemental LA on growth, feed conversion, and health status of neonatal pigs. For both trials, gilts were weaned into individual pens at 21d of age, and treatments were administered orally for 11d. On d11, gilts were nonsurgically fitted with jugular cannulae. On d12, gilts received a dose of lipopolysaccharide (LPS; 150 μ g/kg) intravenously. Blood samples were collected at 15-min intervals for 30 min prior to, and 180 min after, LPS to monitor serum glucose, cortisol, tumor necrosis factor- α (TNF- α), and neutrophil and lymphocyte counts. Trial 1 consisted of 18 gilts (6.74 \pm 0.63 kg) allotted to three treatments: 1) no supplemental LA (CON, n=6); 2) LA1, 35 mg/kg BW daily (n=6); 3) LA2, 75 mg/kg BW daily (n=6). ADG ($P < 0.05$) and ADFI ($P < 0.05$) were greater in CON pigs compared to LA1 and LA2 pigs. There was no effect of LA on serum glucose, cortisol, TNF- α , % neutrophils, and % lymphocytes. LPS increased serum glucose, cortisol, TNF- α , and decreased % neutrophils and % lymphocytes ($P < 0.001$). A linear contrast of serum glucose showed a trend ($P < 0.1$) such that LA1 was lower than CON. Trial 2 consisted of 21 gilts (7.05 \pm 1.12 kg) allotted to three treatments: 1) no supplemental LA (CON, n=7); 2) LA3, 8 mg/kg BW daily (n=7); 3) LA4, 15 mg/kg BW daily (n=7). There were no LA effects on ADG, ADFI, cortisol, insulin, % neutrophils and % lymphocytes or lymphocyte counts. LPS increased serum glucose, cortisol, TNF- α , and decreased neutrophil counts and lymphocyte counts ($P < 0.001$). There was a time by LA effect in serum glucose ($P < 0.004$) where LA3 and LA4 were higher than CON. Time 0 neutrophil counts were higher ($P < 0.003$) in the LA3 and LA4 pigs compared to CON pigs. These results suggest that supplementing LA does have an effect on glucose during an LPS challenge, and an effect on neutrophil populations.

Key Words: α -Lipoic acid, Immune, Neonatal pig

1650 Effects of feeding different chelated copper and zinc sources on growth performance and their excretions in feces for weaning pigs. S. H. Lee^{*1}, S. C. Choi, W. T. Kim, B. J. Chae, and Y. K. Han², ¹Division of Animal Res. Sci., Kangwon National Univ., ²Feed Res. Inst., National Agri. Coop. Fed., Anyang, Korea.

Two feeding trials were conducted to study the effects of dietary Cu and Zn sources on performance and fecal excretions of Zn and Cu for weaning pigs. In Expt. 1, a total of 150 pigs (L \times Y \times D, 12.30 \pm 2.07kg) were randomly assigned to five treatments with three replicates (10 pigs/pen): 170 ppm Cu from CuSO₄, 85 ppm Cu from Cu-amino-chelate[®] (CAC), 170 ppm Cu from CAC, 85 ppm Cu from Cu-Lysine (CL), and 170 ppm Cu from CL. In Expt. 2, a total of 150 pigs (L \times Y \times D, 12.52 \pm 1.8kg) were randomly assigned to five treatments with three replicates (10 pigs/pen): 120 ppm Zn from ZnSO₄, 60 ppm Zn from Zn-amino-chelate[®] (ZAC), 120 ppm Zn from ZAC, 60 ppm Zn from Zn-Methionine (ZM), and 120 ppm Zn from ZM. Each expt. was conducted for 28 days. A metabolic study was also conducted to determine the fecal excretions of Cu and Zn in pigs fed the diets containing the above minerals sources. Fifteen pigs (13.51 \pm 1.6kg) were assigned to five treatments (3 pigs/treatment) in individual metabolic cages to collect feces. There was no difference ($p > .05$) in ADG and ADFI among treatments, but FCR was improved ($p < .05$) in pigs fed the 170 ppm CAC than 85 ppm CL (Expt. 1), and the ADG was higher ($p < .05$) in pigs fed the 120 ppm ZM than the 120 ppm inorganic and 60 ppm ZAC and ZM (Expt. 2). The fecal excretions of Cu and Zn were reduced ($p < .05$) when those minerals were chelated with amino acids. It might be concluded that the efficacy of the chelated Cu and Zn with amino acids or single amino acid are similar in terms

of performance, and fecal excretions of the minerals can be reduced in pigs fed chelated ones.

Key Words: Cu, Zn, Pig

1651 Dietary copper source and level increases pituitary growth hormone mRNA levels in weaning pigs. X. G. Luo^{*1}, X. Kuang¹, Q. H. Li¹, J. F. Li¹, T. D. Crenshaw², B. Liu¹, G. Z. Shao¹, and S. X. Yu¹, ¹Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China, ²University of Wisconsin, Madison, U. S. A..

An experiment was conducted with 30 crossbred (Landrace \times Large White) weaning barrows averaging 9.5 kg BW and 35 d to investigate the effects of dietary Cu source and level on growth, plasma growth hormone (GH) levels, tissue Cu contents, and pituitary GH mRNA levels. Pigs were randomly allotted by bodyweight and litter to one of three treatments in a randomized complete block design, and fed basal corn-soybean meal-whey diets supplemented with 15 (n=6) or 250 ppm Cu as Cu sulfate (n=12) or 250 ppm Cu as Cu-glycine (n=12), respectively. There were six pigs for the 15 ppm Cu treatment and 12 pigs for each of the two 250 ppm Cu treatments. Pigs were individually kept in fiber glass metabolism crates in a metabolism room for the duration of the 28-d experiment. Pigs were allowed free choice continuous access to feeds and tap water. Pigs were individually weighed and feed intake was recorded weekly. At the end of the trial, a blood sample was taken from each pig, and then all pigs were slaughtered for tissue sample collections. Pituitary gland samples were frozen in a liquid nitrogen immediately after taken, and pituitary GH mRNA levels were determined by RT-PCR procedure. Neither Cu source nor Cu level affected ($P > 0.10$) growth rate, feed intake, feed conversion ratio, plasma GH levels, or Cu contents in plasma, pancreas, kidney and spleen. However, pigs fed the diet with 250 ppm Cu added as Cu-glycine had higher ($P < 0.007$) pituitary GH mRNA levels than pigs fed diets with 15 or 250 ppm Cu as Cu sulfate. Pigs fed diets with 250 ppm Cu added from either Cu sulfate or Cu-glycine had increased ($P < 0.002$) Cu contents in brain, liver and heart compared to pigs fed the diet with 15 ppm Cu added from Cu sulfate. No differences ($P > 0.60$) were detected between the two Cu sources. These results indicate that Cu could enhance the growth of young pigs by promoting the pituitary GH gene expression; Pituitary GH mRNA levels might be more sensitive than conventional serum or plasma GH levels as a reflection of GH status in the body; And organic Cu-glycine was more effective than inorganic Cu sulfate in increasing pituitary GH mRNA levels in weaning pigs. Supported by the National Natural Science Foundation of China (Project No: 39600107).

Key Words: Copper, Pituitary GH mRNA, Weanling pigs

1652 Effects of long-chain polyunsaturated fatty acids (LCPUFA) on body composition and tissue accretion rates in the neonatal pig. S. A. Mathews^{*1}, R. J. Harrell¹, W. T. Oliver¹, J. A. Brown¹, O. Phillips¹, X. Lin¹, J. Odle¹, and D. A. Diersen-Schade², ¹North Carolina State University, Raleigh, ²Mead Johnson Nutritionals, Evansville, IN.

The effects of LCPUFA supplementation and source on body composition and tissue accretion rates were examined in the neonatal pig. Piglets had *ad libitum* access from d 1 to 16 of age to a skim milk-based formula with different fat sources added to provide 50% of the energy. Fat sources included LCPUFA as follows: single cell oil triglyceride (TG), egg phospholipid (EPL), TG with phospholipid and cholesterol added to match EPL (TG+PL), a control with no added LCPUFA (CTL), and an essential fatty acid deficient diet (EFAD). Formulas with LCPUFA provided 0.6% of fatty acids as arachidonic acid and 0.3% as docosahexaenoic acid. A group of 10 piglets remained on the sow for the duration of the study (Sow). An initial group of 10 piglets were taken at d 1 of age to serve as a reference group. Average daily gain was similar in all groups (320 \pm 20 g/d, $P > 0.1$). Average daily feed intake (1953 \pm 68 g/d) and feed efficiency (1.58 \pm 0.06) was similar across all treatments ($P > 0.1$). Whole body tissue accretion data are presented below. Protein accretion was greater in the TG, TG+PL and EPL fed piglets compared to the EFAD fed and sow-reared piglets ($P < 0.03$). Accretion of fat was greatest in the sow-reared piglets ($P < 0.0001$). TG fed piglets had greater fat accretion than the PL or the EFAD fed piglets ($P < 0.02$). Water accretion was greater in the TG, TG+PL, PL and CTL compared to the sow-reared and EFAD piglets ($P < 0.05$). These data demonstrate

that the source of LCPUFA increased protein and water accretion, but resulted in a decrease in the amount of fat accretion.

	CTL	EFAD	TG	TG+PL	PL	Sow	SEM
Protein, g/d	39.9 ^{a,b}	24.9 ^b	44.9 ^a	39.9 ^a	39.8 ^a	29.6 ^b	1.5
Ash, g/d	6.4 ^{a,b}	5.4 ^b	7.5 ^a	7.3 ^a	6.4 ^{a,b}	6.4 ^{a,b}	0.3
Water, g/d	208 ^a	178 ^b	229 ^a	215 ^a	201 ^a	161 ^b	6
Fat, g/d	28.4 ^{a,c,d}	24.5 ^c	32.6 ^d	30.6 ^{a,c,d}	24.7 ^{a,c}	47.6 ^b	1.4

1653 Utilization of energy and performance of piglets fed low protein diets. L. Le Bellego* and J. Noblet, *INRA, St Gilles, France.*

Eight blocks of five to six castrated male littermates were used to study the effect of reducing dietary CP level on performance and energy utilization in piglets. Four wheat - barley - corn - soybean meal diets (D1, D2, D3 and D4) providing 1.0 g of standardized digestible lysine per MJ NE were prepared. The reduction of CP was achieved by partial replacement of soybean meal by wheat, barley and corn; CP levels were 22.4, 20.4, 18.4, 16.9% and NE contents were 10.28, 10.33, 10.52, and 10.52 MJ/kg for D1, D2, D3 and D4, respectively. Diets were supplemented with industrial AA in order to maintain an optimal AA supply. One or two littermates per block were slaughtered at the beginning of the experiment (about 12 kg BW) to measure initial body composition, and the four remaining littermates were affected to the four diets. Pigs were penned individually with *ad libitum* access to feed and water and were slaughtered at about 27 kg. Gain of nutrients and energy were calculated according to the comparative slaughter technique. Reduction of dietary CP level resulted in higher ADFI ($P=0.05$) with D2, D3 and D4 (1049 g/d on average) than with D1 (959 g/d). However, ADG was not affected by diet composition (666 g/d on average). Adjustment of data for identical ME intakes (2.52 MJ/d/kg BW^{0.60}) revealed that BW gain and its composition were not affected by dietary CP level; mean daily gains of empty BW, water, protein and lipid were 100.0, 75.7, 18.9 and 13.0 g/kg BW^{0.60}, respectively; daily ash gain decreased ($P<0.05$) from D1 (3.0 g) to D4 (2.7 g). The partition of daily ME intake between energy gain and heat production was comparable for all diets (0.94 and 1.58 MJ/kg BW^{0.60}, respectively). The AA composition of gain (% of N x 6.25) was not affected by dietary CP level, except for histidine that was reduced ($P<0.05$) from D1 (2.95%) to D4 (2.40%). These results demonstrate that, at optimal AA supplies, dietary CP level in piglet feeds can be reduced to a large extent with no impact on performance, composition of gain and energy utilization in piglets; N excretion is then markedly reduced.

Key Words: Piglet, Dietary Protein, Energy Utilization

1654 Effects of feed processing methods on growth performance and ileal digestibility in weaning pigs. S. H. Ohh*¹, J. W. Joo, S. H. Lee, S. C. Choi, Y. H. Shim, K. N. Han, B. J. Chae, and In K. Han², ¹*Division of Animal Res. Sci., Kangwon National Univ., Chuncheon,* ²*Dept. of Animal Sci. and Tech., Seoul National Univ., Suwon, Korea.*

Two feeding trials were conducted to compare the processing effects of feeds in young pigs. In expt. 1, a total of 108 pigs (L×Y×D; 24-d old, 7.60±.5kg BW) were randomly allotted to three treatments (three replicates, 12 pigs/pen): Meal (M), simple pellet (SP), and expanded pellet (EP). In expt. 2, a total of 96 pigs (L×Y×D; 14-d old, 5.21±.77kg BW) were randomly allotted to three treatments (four replicates, 8 pigs/pen): M, EP, and expanded crumble (EPC). Each expt. was conducted for 14 days. Diets were pelleted with 2.8mm die in diameter at 40°C. For expanding, diets were expanded at 70°C, and then pelleted with 2.8mm die in diameter at 60°C, and crumbled, according to the designs. The ileal digestibilities of expanded whey powder (WP), spray-dried plasma protein (SDPP), and fish meal (FM) were determined with cannulated pigs (7.44±1.6kg) with different expanding temperatures: 100, 120, and 140°C, respectively. The ADG, ADFI and F/G of pigs fed a SP diet were better ($p<.05$) than those fed M or EP diets (expt. 1). In expt. 2, there was no difference ($p>.05$) in ADG, but feed intake was reduced, resulting in improved ($p<.05$) F/C in pigs fed EP and EPC as compared with those fed a M diet. The ileal digestibilities of histidine in WP, isoleucine

in SDPP, and valine in FM were reduced ($p<.05$) when the temperature was 140°C, but ileal digestibilities of most amino acids were not reduced when these ingredients were expanded at up to 120°C. It could be concluded that simple pelleting of diets containing highly palatable and digestible ingredients would be better than expanding and expander processing of the diets could reduce palatability and ileal digestibility in weaning pigs.

Key Words: Pelleting and expanding, Digestibility, Pig

1655 The effect of pelleting temperature on anti-*E. coli* F4 immunoglobulin activity in spray-dried egg and porcine plasma. M. D. Drew*, A. E. Estrada, and A. G. Van Kessel, *University of Saskatchewan, Saskatoon SK Canada.*

The effects of pelleting on the activity of chicken egg immunoglobulin (Ig) or porcine plasma Ig in feed was tested. Hyperimmune chicken egg Ig specific for *E. coli* F4 was produced by immunizing laying hens with an *E. coli* F4 bacterin. The immune eggs were spray-dried prior to use. Spray-dried porcine plasma (AP920, American Protein Corporation) and the spray-dried egg Ig were added to a barley and wheat based pig starter ration at a level of 5% of the diet. The diets were then pelleted at 80, 90 or 105°C (pellet temperature measured at the die outlet) through a die containing holes 5 mm in diameter. Anti-F4 titers of the unpelleted and pelleted feeds were measured using an enzyme-linked immunosorbent assay (ELISA). The feed samples were diluted 1:100 with phosphate buffered saline and shaken overnight. The solids were then allowed to settle and the supernatants were applied to ELISA plates coated with purified F4 antigen in a series of doubling dilutions. Endpoint titers were defined as the last dilution that produced an absorbance plus 3 standard deviations above background. The anti-F4 Ig titer of plasma was 1:1,600 in the pre-pelleted feed. This was reduced to 1:800, 1:400 and 1:200 by pelleting at 80, 90 or 105°C respectively. The anti-F4 Ig titer of the egg Ig was 1:6,400 in the unpelleted feed. Pelleting at any of the three temperatures used in this experiment completely destroyed anti-F4 Ig activity measured by ELISA. The results demonstrate that egg Igs are more sensitive to heat denaturation during pelleting than plasma Igs. Incorporation of egg Ig products into animal diets should be done after pelleting if diet temperatures of greater than 80°C are used. Porcine plasma Igs are more resistant to heat denaturation than egg Igs but temperatures of 80°C or higher reduce specific porcine Ig activity in pelleted feeds.

Key Words: Pelleting, Egg immunoglobulin, Plasma

1656 Solutein enhances piglet growth post weaning. H.M. Miller*¹ and P. Toplis², ¹*University of Leeds, Leeds, LS2 9JT, UK,* ²*Primary Diets Ltd, Ripon, HG4 5HT, UK.*

Piglets fed diets containing porcine plasma (PP) in wk1 post-weaning have better feed intakes and growth rates than piglets fed skim milk based starter diets. We aimed to determine whether similar improved piglet performance occurred when piglets received Solutein (soluble PP) in their water supply instead of in feed. We also investigated whether Solutein in water further improved performance of piglets receiving a PP based diet. One hundred and twenty eight 25.1d old (sd = 4.22) piglets (62.5% Large White, 25% Landrace, 12.5% Duroc) weighing 7.8kg (sd = 1.91) were weaned into fully slatted flat deck pens. Piglets were not creep fed pre-weaning. Each pen (1.37m x 1.43m) contained 8 pigs allocated on the basis of litter, liveweight and sex. Four treatments were fed until d14 post-weaning: A Control, no plasma, B plasma in water, C plasma in feed, D plasma in water and feed. Solutein was included in the water for 5d at 2.4%, then for 5d at 1.2% and for a further 4d at .7%. Four pens were randomly allocated to each treatment. Diets contained ZnO (Zn 2500 ppm) and were formulated to contain 16.3 MJ DE/kg, 1.65% total lysine. From d14 onwards all piglets received the same diet (15.0 MJ DE/kg, 1.5% total lysine) and no water supplementation. Pigs were individually weighed at 0, 7, 14 and 20d post-weaning. Food and water were provided *ad libitum* throughout the 20d trial. Data were analysed using the GLM procedure of Minitab 12.2. Growth rate, 184 v 117 14 g/d, and FCR, 0.98 v 1.50 0.07, were better for all PP supplemented pigs than control pigs in wk1, ($P<.05$). No additional benefit accrued from PP in both feed and water. End BWs of PP fed pigs were numerically greater than those of control pigs but this failed to reach significance (14.5 v 13.9 0.3 kg). Feed intake over the 20d trial was greater for C piglets than for any other treatment ($P<.05$). All 3 PP treatments were equally effective in stimulating piglet performance

during wk 1 of the trial. Therefore PP in water is as effective as in the diet. PP in both diet and water gave reduced feed intake in wk3.

Key Words: Piglet, Plasma, Growth

1657 Effect of weaning weight and diet on the post-weaning performance of pigs. P.G. Lawlor^{*1}, P.B. Lynch¹, J.V. O'Doherty², and P.J. Caffrey², ¹Teagasc, Moorepark Research Centre, Cork, Ireland, ²University College Dublin, Ireland.

The objective of this experiment was to assess the effect of weaning weight and post-weaning diet on the performance of weaned pigs. Pigs were weaned from 32 litters at 22 days of age. Four pigs (2 light and 2 heavy) were taken from each litter (n=128), blocked on sex, litter origin and weaning weight and individually assigned at random to 2 dietary treatments; (1) high density diet (230 g/kg wheat, 200 g/kg maize, 175 g/kg full-fat soya, 120 g/kg dried whey, 110 g/kg dried skim milk, 95 g/kg herring meal; 17.4 g/kg lysine and 16.1 MJ DE/kg) and (2) medium density diet (434 g/kg wheat, 100 g/kg maize, 210 g/kg full-fat soya, 75 g/kg dried whey, 50 g/kg dried skim milk, 100 g/kg herring meal; 15.7 g/kg lysine and 15.1 MJ DE/kg). The duration of the experiment was 26 days. There was no interaction between weaning weight and post-weaning diet. Weaning weight was 7.1 and 5.8 kg (s.e. 0.08; P<0.01) and pig weight at day 26 post-weaning was 17.5 and 15.4 kg (s.e. 0.23; P<0.01) for heavy and light weight categories, respectively. The differential in weaning weight was associated with a difference in birth weight, which was 1549 vs. 1379 g (s.e. 28; P<0.01) for heavy and light weight categories respectively. In the period from day 0 to 26 post-weaning, feed intake was 440 and 396 g/day (s.e. 8.0; P<0.01) and daily gain was 389 and 355 g/day (s.e. 8.0; P<0.01) for heavy and light weight categories, respectively. Weaning weight was found to be a good determinant of weight at day 26 when terms for litter origin were included (R²=0.67; P<0.001 for the high density diet and R²=0.77; P<0.001 for the low density diet). Intake from day 0 to 26 post-weaning was not affected by diet (P>0.05). However, daily gain was 384 vs. 360 g/day (s.e. 8.0; P<0.05) and FCE was 1.10 vs. 1.16 g/g (s.e. 0.014; P<0.01) for high density and low density diets respectively. Pig weight at day 26 was 16.8 vs. 16.0 kg (s.e. 0.22; P<0.05) for high density and low density diets respectively. It is concluded that a natural advantage in weaning weight was still evident at day 26 post-weaning. The high density diets improved post-weaning pig performance.

Key Words: Weaning weight, Post-weaning, Pigs

1658 Effect of pre-weaning management and post-weaning nutrition on the performance of weaned pigs. P.G. Lawlor¹, P.B. Lynch^{*1}, J.V. O'Doherty², and P.J. Caffrey², ¹Teagasc, Moorepark Research Centre, Cork, Ireland, ²University College Dublin, Ireland.

The objective of this experiment was to assess the effect of pre-weaning management designed to increase weaning weight and post-weaning (PW) nutrition on the performance of weaned pigs. Thirty litters with more than 10 live born pigs were selected. At 11 days of age, pigs of average weight for the litter were removed from 15 litters so that 8 pigs remained per sow. These litters were given access to creep feed (16.5 MJ DE/kg and 18.7 g/kg lysine) until weaned. The remaining litters were left intact and were not given creep feed. Pigs were weaned at 27 days of age and two mixed sex pairs of pigs were formed from each litter (n=54 pairs). Pairs were blocked on litter origin and weight and assigned to one of the following treatments; (1) 10 kg starter diet (17.4 g/kg lysine and 16.1 MJ DE/kg; 230 g/kg wheat, 200 g/kg maize, 175 g/kg full-fat soya, 120 g/kg dried whey, 110 g/kg dried skim milk, 95 g/kg herring meal) followed by link diet (15.0 g/kg lysine and 15.3 MJ DE/kg; 481 g/kg wheat, 81.5 g/kg maize, 220 g/kg full fat soya, 100 g/kg herring meal, 75 g/kg dried whey) to 27 days PW (high dietary regimen; HDR) or (2) 4 kg starter diet, 10 kg link diet and weaner diet (13.6 g/kg lysine and 14.0 MJ DE/kg; 542 g/kg wheat, 200 g/kg barley, 150 g/kg soya, 75 g/kg herring meal) to 27 days PW (low dietary regimen; LDR). Thereafter pigs were fed common diets to 156 days of age. Reducing litter size and creep feeding increased weaning weight from 7.9 to 8.5 kg (s.e. 0.14; P<0.05). This weight advantage was lost by day 14 PW (P>0.05). Daily gain from day 0 to 27 PW was 472 and 427 g/day (s.e. 12.8; P<0.05) and FCE from day 0 to 27 PW was 1.26 and 1.36 g/g (s.e. 0.026; P<0.01) for HDR and LDR, respectively. Feed intake and daily gain, were similar for both treatments in the period from weaning to day 129 PW (P > 0.05) and from day 27 to 129 PW (P>0.05) respectively.

In the period from day 27 to 50 PW, FCE was improved for LDR (1.66 vs. 1.72, s.e. 0.020; P<0.05). It is concluded that the advantage in weaning weight caused by better pre-weaning management was lost in the early post-weaning period. Feeding a HDR improved performance in the early post-weaning but did not benefit lifetime performance.

Key Words: Creep feed, Post-weaning, Pigs

1659 The effect of choice feeding complete diets on the performance of weaned pigs. P.G. Lawlor^{*1}, P.B. Lynch¹, J.V. O'Doherty², and P.J. Caffrey², ¹Teagasc, Moorepark Research Centre, Cork, Ireland, ²University College Dublin, Ireland.

Three experiments were undertaken to compare choice feeding and phase feeding for weaned pigs (19 to 24 days old). In Experiment 1, 24 mixed sex groups of 16 pigs were blocked on weaning weight and assigned to the following treatments; (A) starter diet (18.3 g/kg lysine and 16.6 MJ DE/kg) for 11 days followed by link diet (15.0 g/kg lysine and 15.3 MJ DE/kg) to 27 days, (B) starter diet and link diet offered free choice to 27 days and (C) starter diet and weaner diet (13.0 g/kg lysine and 14.3 MJ DE/kg) offered free choice to 27 days. In Experiment 2, 66 pigs, blocked as individuals on sex and weaning weight were assigned to treatments as in Experiment 1. In Experiment 3, 24 single sex groups of 16 pigs were blocked on sex and weaning weight and randomly assigned to treatments as in experiment 1 but with treatment C being; starter diet and link diet offered free choice to 26 days with feeder position rotated twice weekly. In Experiments 1 and 3, a weaner diet (14.1 g/kg lysine and 14.4 MJ DE/kg) was fed to all pigs following the experimental period. In Experiment 1, daily gain was 406, 410 and 397 g/day (s.e. 6.7; P>0.05), FCE was 1.25, 1.21 and 1.28 g/g (s.e. 0.01; P<0.01) and the proportion of intake as starter diet was 0.20, 0.50 and 0.47 (s.e. 0.023; P<0.01) during the period from day 0 to 27 for treatments A, B and C, respectively. In the period between day 27 and 57 there was no effect of treatment on pig performance (P>0.05). Within pen variation in pig weight was similar for all treatments at day 14, 27 and 56 (P>0.05). In Experiment 2, daily gain was 403, 436 and 394 g/day (s.e. 13.0; P=0.07), FCE was 1.20, 1.16 and 1.24 g/g (s.e. 0.02; P<0.05) and the proportion of intake as starter diet was 0.19, 0.57 and 0.53 (s.e. 0.024; P<0.01) during the period from day 0 to 26 for treatments A, B and C, respectively. In Experiment 3, daily gain was 465, 486 and 488 g/day (s.e. 9.4; P>0.05), FCE was 1.14, 1.10 and 1.07 g/g (s.e. 0.015; P<0.01) and the proportion of intake as starter diet was 0.21, 0.48 and 0.55 (s.e. 0.022; P<0.001) during the period from day 0 to 26 for treatments A, B and C, respectively. Pig weight at day 49 was 36.4, 37.1 and 37.3 kg (s.e. 0.27; P=0.09). In conclusion, choice feeding improved post-weaning pig performance.

Key Words: Choice feeding, Post-weaning, Pigs

1660 Effects of microencapsulation of natural antimicrobials on the secretory, microbiological and digestive processes in the small intestine of piglets. Z. Mroz^{*1} and W. Krasucki², ¹Institute for Animal Science and Health, ID-TNO Animal Nutrition, Lelystad, The Netherlands, ²Agricultural University of Lublin, Poland.

Ten weaning piglets of 9.5 kg initial BW were fitted with newly developed re-entrant catheters in the exocrine pancreatic duct and with ileal cannulas (SICV) to compare the effects of in-feed natural antimicrobials (bioactive proteins/peptides from milk) without and with a novel, beeswax-based microencapsulation on the pancreatic and mucin secretions, ileal morphology, microflora, and digestion of amino acids. The piglets were sib paired to form 2 blocks (no/yes microencapsulation), and each block was randomly allotted to 5 diets according to a 5 x 5 Latin square design. The diets were as follows: 1) a corn-SBM-based diet (BD)+0.1% placebo; 2) BD+0.1% bovine IgG; 3) BD+0.1% bovine lactoferrin and lactoperoxidase blend (LLB); 4) BD + 0.1% bovine lactoglobulins (LG); 5) BD+0.1% probiotic blend (PB). In each period of 7 d (5-d adaptation and 2-d sampling) piglets were given ad libitum access to feed and water. Exocrine pancreatic secretion (postprandial volume, protein, bicarbonate) were not affected by the diets or microencapsulation, whereas trypsin and chymotrypsin activities were greater (P<0.05) for all the microencapsulated additives. Feeding IgG, LLB, LG and PB in the microcapsules decreased (P<0.05) mucin production in the ileal digesta, with a tendency to improve morphological and histometrical characteristics in the terminal ileum. There was a positive effect (P< 0.05) of microencapsulation on the apparent ileal digestibility

of lysine (+1.5%), methionine (+1.9%), tyrosine (+2.1%) and arginine (+2.5%), irrespective of the additive. Also, due to this microencapsulation, we observed a greater ($P < 0.05$) population of Lactobacilli, whereas hemolytic E.coli counts were reduced ($P < 0.05$). These data imply that in-feed bioactive proteins/peptides addressed as antimicrobials instead of antibiotics should be preferably microencapsulated against their gastric hydrolysis and for enhancing their efficacy along the small intestine of piglets.

Key Words: Piglets, Microencapsulation, Antimicrobials

1661 Effects of dietary conjugated linoleic acid (CLA) on carcass characteristics and serum leptin and lipid profile of rabbits. C. Corino¹, V. Bontempo*², S. Magni¹, and G. Pastorelli¹, ¹University of Milan/Italy, ²University of Molise, Campobasso/Italy.

A study was conducted to determine the effect of conjugated linoleic acid (CLA) synthesized from sunflower oil on growth, carcass characteristics, serum leptin and lipid blood profile of rabbits. One hundred and eight NZW rabbits, half male and half female, averaging 1.80 kg LW, allotted within weight and sex to a randomised complete experimental design, were fed ad libitum conventional pelleted diets supplemented with different fat: 0.5 % sunflower oil (C), 0.25 % sunflower oil and 0.25 % CLA (T1), 0.5 % CLA (T2). CLA oil contained 65 % CLA isomers (Conlinco, Inc., Detroit Lakes, Minnesota 56502 USA). Thirty-six rabbits, 12 of each group, half males and half females, were slaughtered at three different slaughtering weight (age): 2.5 kg (76 d), 2.8 kg (90 d), and 3.1 kg (104 d). No effect of CLA supplementation was observed on ADG, FI, FE, dressing percentage, pH and meat colour. Perirenal fat weight decreased at the medium slaughtering weight ($P = 0.089$) and it increased at the higher slaughtering weight ($P = 0.01$). No effect was observed on interscapular fat. CLA supplementation reduced triglycerides and total cholesterol ($P < 0.05$), and increased serum leptin concentration (2.02, 2.67 and 2.35 ng/ml, respectively, SEM = 0.194, $P = 0.06$). A gender effect was observed on triglycerides with higher values in males than females ($P < 0.01$). A similar effect was also found on leptin, but higher values were measured on females (2.57 vs 2.13 ng/ml, $P = 0.06$).

PSA Nutrition: Feed Regimens, Digestion, and Gut Morphology

1663 Effects of protein levels on ostrich performance and carcass traits. I. Cormier*, M.R. Lefrançois, and R. Bergeron, Université Laval, Québec, Québec, Canada.

This study was conducted to assess the impact of a linear increase in dietary protein levels on performance, carcass quality and health of ostriches. Sixty-four unsexed crossed ostriches were raised in a greenhouse and fed ad libitum complete pelleted diets from 2 to 10 mo of age. Sixteen ostriches were randomly allotted four per pen to either one of four diets containing 18 to 23% CP for the starter (2 to 4 mo), 14 to 18% for grower (4 to 7 mo), and 12 to 15% for the finisher (7 to 10 mo). Except for protein levels, these diets supplied similar amounts of energy, fiber, lysine and methionine per kg of feed within each growing period. Body weight (BW), average daily gain (ADG), feed intake, feed efficiency (FE) were measured throughout the experiment. The ostriches' performance was recorded on a monthly basis. Carcass weight (CW) and yield (CY), viscera, heart and liver weights, meat cuts yields, and meat pH and color were also measured at the end of the trial. Carcasses were cut up into 12 meat parts according to the Canadian Ostrich Association chart and weighed. Meat pH was measured in the fan and inside the leg muscles 6 h post mortem. The Minolta color index (L, a*, b*) was used to assess meat color for these two carcass parts. Data were analyzed according to a complete block randomized design using protein level and body weight as the main factors. Mean live BW and CW were 95.15 ± 0.40 kg and 55.83 ± 1.35 kg, respectively. Cumulative ADG and FE were 310 ± 10 g and 0.160 ± 0.003 , respectively. Mean CY was $57.20 \pm 0.74\%$. Average meat pH was 6.27 ± 0.05 for the inside leg and 6.43 ± 0.06 for the fan. Total meat cuts yield was $40.56 \pm 0.53\%$ of the carcass. Besides the worst oyster cut yield ($P < 0.01$) for the third highest protein level, there was no significant differences ($P > 0.05$) between dietary treatments for the measured variables. There were no leg problems and mortality could not be associated with specific dietary treatments. Our results suggest

Our data suggest that conjugated linoleic acid reduce fatness and total serum cholesterol in rabbits. Our data are also consistent with the hypothesis that CLA has the potential to inhibit atherosclerosis.

Key Words: Dietary conjugated linoleic acid, Rabbit, Serum lipid profile

1662 Physiological adaptation to prolonged food restriction: a model study in growing rats. Ewa Furstenberg*¹, ¹Warsaw Agricultural University, Warsaw, Poland.

Organisms subjected to chronic food restriction attempt to mitigate the effects of deficiency by a series of physiological and behavioral responses, which are considered as adaptation to the low energy intake. Adaptation to energy restriction is expected to occur at different levels i.e. growth, rate, body size and composition, as well as energy metabolism. Whether the animals are able to economize on energy by reducing basal metabolism and whether it is an adaptive process per se resulting in decrease in metabolic rate beyond that predicted for the change in body size and/or composition or it is only secondary to changes in body weight and its components is, however, still controversial. The present study was carried out in 48 young growing female and male rats (RF group), which at different body weights (60, 75, 90, 105g) were subjected to food restriction (FR) by feeding constant stipulated rations (14.2, 15.9, 17.7, 19.4 g of standard laboratory diet, ME=1474kJ/100g, respectively) from ad libitum until maintenance level (i.e. constant body weight). Control group (C, n=24) was fed ad libitum throughout the experiment. During the experiment all rats were subjected to at least 2 measurements of resting metabolic rate (RMR). At the end, anatomical and chemical composition of animals was determined. Main results showed that the animals adapted to progressing energy deficit primarily by reducing final body weight and decreasing body fat and that female rats were more sensitive to food restriction than male rats. With respect to energy metabolism, when RF rats were compared with ad lib controls, RMR (in absolute values or relative to body weight and metabolic body weight) was significantly depressed in male rats, however, in females RMR was increased. Higher RMR in RF females than in female controls could be attributable in part to higher protein body mass. These results highlight some of the important differences between male and female rats in their mode of adaptation to restricted feeding.

Key Words: energy metabolism, food restriction, sex

that growing ostriches can perform equally well across a wide range of dietary protein levels without negative impacts on performance, carcass quality and health.

Key Words: Ostrich, Protein, Carcass

1664 Feeding program for broiler breeder hens based on the prediction equations of metabolizable energy requirements. N.K. Sakomura*, E.R. Freitas, C.B.V. Rabello, A.L. Santos, and O.M. Junqueira, ^{UNESP} Faculdade de Ciências Agrárias e Veterinárias de Jaboticabal - Sao Paulo - Brasil.

The purpose of this study was to evaluate feeding programs based on prediction equations of metabolizable energy requirements for broiler breeder after 55 weeks old. Seven hundred forty broiler breeder females Hubbard Hy-Yield and eighty males Peterson 55 wks of age, were distributed in a randomized design with 4 treatments and 5 replications of 37 birds. The feeding programs were: 1- Feeding according to the lineage recommendation, 2- Energy reduction 2 kcal/bird/day for each week, 3- Feeding according to UNESP (2000) equation: $ME = W^{0.75}(192.76 - 6.32T + 0.12T^2) + 7.62G + 2.40EM$, 4- Feeding according to NRC (1994) equation: $ME = W^{0.75}(173 - 1.95T) + 5.50G + 2.07EM$, where ME=energy requirement (kcal/bird/day), W=body weight (kg), T=temperature (C), G=weight gain (g) and EM=egg mass (g). The energy reduction program provided 417 kcal/bird/day, 181g of body weight gain (BWG) and 63.5 % of egg production from 55 to 66 wks of age. The feeding based on lineage recommendation provided 428 kcal/bird/day, 230 g BWG and 64.0 %. The equations UNESP and NRC promoted more energy intake (447 and 484 kcal/bird/day) consequently higher BWG (286 and 645g) and similar egg production 63,6% and 61,3%, respectively. The feeding programs did not affect the

reproductive performance. According to the results, the energy reduction program promoted a good performance being possible the reduction of 2 kcal/bird /day for each week in the broiler breeder feeding after 55 wks of age. The equations UNESP and NRC promoted higher energy intakes than the lineage recommendation probably because of the body weight of birds that were above than the recommended one for lineage, providing the highest energy requirements of maintenance. The UNESP (2000) equation promoted better adjustment than NRC (1994) in the energy feeding for broiler breeder hens.

Key Words: Broiler breeder, Energy prediction equation, Feeding program

1665 The effect of different energy and protein levels on the performance of W-36 Hy-Line laying hens . M. Shahnazari¹, M. Shivazad¹, A. Kamyab¹, and A. Nikkha¹, ¹University of Tehran, Animal Sci. Dept.

A factorial experiment was conducted to investigate the response of laying hens to various levels of dietary energy and protein. Varying levels of dietary energy (2700, 2800, and 2900 Kcal ME/Kg) each fed at four protein levels (14, 15, 16, and 17%) to 1152 laying hens at 27-32 and 32-40 week old. Birds were randomized into 8 cages, with each of the 12 experimental treatments consisting of 4 replicates. Egg production was not significantly affected by dietary energy, protein contents, or ME by protein interaction ($P > 0.05$). Even though, it tended to increase with increase in energy level. Dietary protein affected egg weight ($P < 0.01$), although there was no significant difference between protein levels. The egg weights with proteins ranging from 14, 15 and 17% was increased from 57.1 to 58.3 and 58.5 g, respectively. There was reduced FI as energy level of the diet was increased ($P < 0.05$). Daily FI was 2.5 g lower when dietary energy was raised ($P < 0.05$). Feed efficiency and feed per dozen eggs responded significantly to increasing dietary ME ($P < 0.05$). Financial returns were less for hens fed on 2900 Kcal ME/Kg and tended to decrease with increase in protein level. There was also energy effect ($P < 0.01$) on eggshell quality. Alterations in dietary ME concentration had no influence on body weight change, however, it was affected ($P < 0.01$) by protein levels. Dietary treatments did not exert any significant effects on the albumen index, cracked and soft-shell eggs and mortality ($P > 0.05$). Maximum hen-day egg production, FE, and lowest feed cost per Kg egg weight were obtained on the ration containing 2800 Kcal ME/Kg and 15% protein.

Key Words: Energy, Protein, Laying hens

1666 Effect of formulation density and feed moisture type additives on broiler performance. J.S. Moritz*, K.J. Wilson, K.R. Cramer, R.S. Beyer, L.J. McKinney, and W.B. Cavalcanti, Kansas State University, Manhattan, KS.

Past research has illustrated that moisture added to corn soybean-based diets at the mixer can improve pellet manufacturing parameters as well as improve adjusted broiler feed efficiencies. Feed efficiencies were adjusted due to moisture additions creating a dilution of nutrients in the diets. Diets with added moisture illustrated higher pellet durabilities and subsequently greater potentials for broilers to utilize feed energy for growth compared to diets without added moisture. The objective of the current study was to determine the effects of moisture additives, diets of different nutrient densities and their combination on broiler performance. Treatments consisted of diets containing different moisture type additives (water/surfactant solution vs. water) and diets of different nutrient densities (NRC density vs. adjusted -high density). Negative control diets, which consisted of the two diets of different nutrient densities without moisture additives were also fed. All diets were fed in a pelleted form. Each of the six diets were fed to ten replicate pens of 45 male Cobb-Vantress broilers during the (3-6) week grower period. Broilers fed diets of adjusted -high density that included moisture additives of either type had significantly higher live weight gains and feed efficiencies compared to broilers fed NRC diets with moisture additives. Adjusted -high density diets that included moisture produced broilers with higher live weight gains ($P = 0.0013$) compared to broilers fed either NRC or adjusted -high density control diets. Mortality percentages were not significantly effected due to diet type. These findings conclude that adding moisture to diets of adjusted -high density may

improve broiler performance above broilers fed diets formulated to NRC specifications with or without added moisture.

Key Words: Broiler Performance, Diet Density, Moisture

1667 Whole wheat feeding and influence of initial body weight on broiler performance. A. Golian*, L.D. Campbell, and W. Guenter, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2.

Two experiments were conducted to evaluate whole wheat feeding in broiler chicken production. Initial body weight (Exp1) and fortification of dietary additives (Exp 2) were assessed as treatment variables and the same whole wheat feeding regimen (substitution of whole wheat in the control diet at a rate of 5, 15 and 30% for the periods 10-20, 20-30 and 30-40 days-of-age, respectively) was used in both experiments. The first experiment was a 2*3 factorial design in which 5 replicate groups of 65 birds were fed a control diet or a whole wheat substituted diet and each diet included groups of chicks of low weight (40-44 g / bird), high weight (46-50 g / bird) or random weight. The second experiment was a completely randomized design in which 5 replicate groups of 65 birds were fed a control diet, a whole wheat substituted diet or a fortified whole wheat substituted diet. Whole wheat feeding affected chick body weight gain adversely in Exp 1 (1660 vs. 1945 g / bird) but not in Exp 2 (2405 vs. 2453 g / bird). Breast fillet, gizzard and abdominal fat pad weights as a percentage of body weight were adversely influenced by whole wheat feeding in both experiments. In Exp 1 feed intake and body weight were related to initial chick weight but initial chick weight did not affect chick uniformity (within 10% of the mean body weight) at 20 or 40 days-of-age. There was no interaction between diet type and chick weight groups. Overall feed intake was greater for birds in Exp 2 as compared to Exp 1 (101 vs. 88 g / bird) indicating that the beneficial effects of whole wheat feeding may be influenced by voluntary feed intake.

Key Words: Whole wheat, Initial body weight, broiler chicken

1668 The performance of broiler chickens during and following of different feed restriction methods at an early age. M. Houshmand¹, A. Kamyab², K. Yousefi³, and A. Taghipour Farshi*⁴, ¹University of Yasouj, ²University of Tehran, ³Mobarak Andish Co., ⁴Tehran Shaltouk Research Center.

Abstract. A total of 720 Ross chicks were grown in each of 24 separate floor pens until six weeks of age. In a completely randomized design experiment, the effects of energy and protein dilution, utilizing rice hull at 0, 10, 15, 20, 25, and 30%, during 6 to 12 days of age on broiler performance were examined. Metabolizable energy and crude protein content of the experimental diets were as follows: 3089, 2780, 2626, 2472, 2317, 2163 Kcal/Kg; and 21.45, 19.29, 18.23, 17.16, 15.02, and 16.1 percent, respectively. From 13 to 21 day of age a conventional starter and thereafter a finisher diet was used. During the period of study the chicks had free access to mash feed and water. The chicks were pens weighed periodically and feed intake were measured at the end of each phase feeding period on a pen basis as well. Between day 6 to 12, diet dilution increased feed consumption, reduced body weight gain, energy and protein intake ($P < 0.05$). Due to compensatory growth no significant differences ($P > 0.05$) among treatments in body weight were seen. Feed intake following feed restriction period was less for the birds received diluted diet as compared to control ($P > 0.05$). Meanwhile, FE was somewhat improved among the birds that were fed with diluted diets. Nevertheless, this difference was not statistically significant ($P > 0.05$). Diet dilution, had no significant effect ($P > 0.05$) on carcass composition, liver, and abdominal fat percentage at the slaughter age. In this experiment 20 and 25% dilution diets resulted in a slight increase in body weight gain and improved production efficiency.

Key Words: Diet Dilution, Broiler, Compensatory Growth

1669 The effects of early skip-a-day feeding regimen on the performance of Ross male broiler chicken. K. Yousefi¹, A. Kamyab², M. Houshmand³, and A. Taghipour Farshi*⁴, ¹Mobarak Andish, ²University of Tehran, ³University of Yasoudj, ⁴Telavang Co..

Abstract. This experiment was conducted to investigate the effects of an early skip-a-day feeding program on broiler chickens. The 720 day-old, mixed sex Ross chicks were fed a mash corn diet for the first 36 hrs and

then fed with a conventional starter diet (3089 Kcal ME/Kg and 21.45% CP) until 7 day of age. At this age, 4 floor pen of 30 birds each were randomly assigned to one of 6 dietary treatments. Treatment 1, control, involved in ad lib access to feed and the remaining treatments were subjected to a skip-a-day regimen from 7 to 13 days of age. During the restriction period, the restricted groups had access to water containing 2% sucrose. Starting day 14 to 21, chicks of 6 treatment groups were fed isocaloric diet containing of 20.45, 21.45, 25.27, or 31% CP. From 22 to 42 and 43 to 46 day of age all the treatments received commercial grower and finisher mash diet with 3090 Kcal ME/Kg, 19.32% CP and 3090 Kcal ME/Kg, 17.2% CP respectively. During the restriction period, weight gain of the restricted group was severely affected ($P < 0.05$). Body weight gain over the 33 day of realimentation, was faster for the 21.45% CP treatment that resulted in compensatory growth. As expected, chicks that were subjected to skip-a-day feeding consumed less feed ($P < 0.05$) compared with the control group. Likewise, their overall feed intake throughout the experimental period were also less than ad lib group ($P < 0.05$). The feed conversion ratio of restricted chicks was greater during skip-a-day feeding period than that of control. On the contrary, their FE were significantly better ($P < 0.05$) during the re-feeding period. Overall FE for skip-a-day group was not statistically different than ad-lib. group ($P > 0.05$). At the end of study, GI tract weights of restricted chicks were not different from those of control ($P > 0.05$). Mortality and leg abnormality in this experiment were little so, statistical analysis was not performed on these data.

Key Words: Skip-a-day, Broiler, Compensatory Growth

1670 The effect of dietary 1,4-diaminobutane (putrescine) on the performance and gastrointestinal development of broiler chicks. F.A. Santoyo* and T.K. Smith, *University of Guelph, Guelph, Ontario, Canada.*

The mammalian polyamines: putrescine, spermidine and spermine, are thought to be important promoters of cell division, protein synthesis and cell growth. Protein, DNA and protein:DNA ratio reflect cell size and development and can be used as an index of chick intestinal growth rate. A total of 216 six day-old broiler chicks were fed corn and soybean meal-based diets containing 0, 0.1, 0.2, 0.3, 0.4 and 0.5% supplemental dietary putrescine (6 pens of 6 birds per diet) for 21 days. Feed consumption and growth ratio were determined weekly. At the end of the experiment, 12 birds fed each diet were killed and intestinal sections, liver, spleen and pancreas were excised and weighed and intestinal concentration of soluble protein and DNA were determined. Increasing dietary putrescine resulted in a significant quadratic response in average daily gain, which peaked with the feeding of 0.1% putrescine. The feeding of 0.5% putrescine was clearly toxic. Relative organ weights were not affected by diet. There was a significant linear correlation between duodenal soluble protein concentration and dietary putrescine concentration. Intestinal DNA concentrations were not affected by diet. It was concluded that dietary putrescine supplemented may promote duodenal development in broiler chicks but causes increased growth only when 0.1% supplemented putrescine is fed.

Key Words: Putrescine, Gastrointestinal tract, Protein:DNA

1671 Effects of dietary supplemental Betaglucon on performance and blood components of broiler chicks. S. H. Kim*¹, S. J. Lee¹, K. H. Jung², D. J. Yu¹, S. Y. Park³, J. C. Na¹, and K. S. Ryu³, ¹National Livestock Research Institute of Rural Development Administration, Daejeon, ²Dawmajin biotech, Daejeon, ³Dept. of Animal Resources and Biotech., Chonbuk National University, Chonju, Republic of Korea .

An experiment was conducted to investigate the dietary supplemental betaglucon on performance and intestinal microflora of broiler chicks. Three hundred sixty one day old broiler chicks were randomly replaced into floor pen with four treatments. Four levels of betaglu^R (0, 0.05, 0.1, 0.2%) were added to basal diets. Weight gain, feed intake and feed conversion (FC) were measured for five weeks. Intestinal microflora was examined at third and fifth weeks old. Blood was collected from wing vein at three and five weeks old. Weight gain was no different for the first three weeks, but was significantly increased in 0.1 and 0.2% treatments for the rest two weeks compared to that of control ($P < 0.05$). Feed intake was no different of all treatments. FC of chicks fed 0.1 and 0.2% betaglu^R tended to improve but was not significantly different. No difference were found in *lactobacillus* spp., yeast, *salmonella* spp., *E. coli*

at three and five weeks old. Blood glucose, total protein, AST, ALT, cholesterol, urease, creatinin, Ca, Mg and P showed no difference of all treatments. Triglyceride, GPT, BUN, bilirubin and LDH were prone to increase in 0.1 and 0.2% betaglu^R treatments.

Key Words: Betaglucon, Broiler chicks, Blood components

1672 Influence of feeding *lactobacillus*, live yeast and its combination on the performance and intestinal microflora of laying hens. S. H. Kim*¹, S. J. Lee¹, D. J. Yu¹, S. Y. Park², J. C. Na¹, C. H. Choi¹, and K. S. Ryu², ¹National Livestock Research Institute of Rural Development Administration, Daejeon, ²Dept. of Animal Resources and Biotech., Chonbuk National University, Chonju, Republic of Korea.

A feeding trial was conducted to evaluate the influence of feeding *lactobacillus*, live yeast (Y) and its mixture (L+Y) on the performance and intestinal microflora of laying hens. Two hundred forty Isa brown hens were randomly allocated to six treatments. Control (no supplement), *Pichia farinosa* (Y), *lactobacillus crispatus* avihen1 (LC), *lactobacillus vaginalis* avihen2 (LV) isolated from hen's cecum, LC + Y, LV + Y were supplemented at 0.3% from 21 to 30 weeks of age (WOA). Viable microflora were added to meet 10^6 cfu *lactobacillus*/g Y and 10^7 cfu *lactobacillus*/g of feed. Egg production, egg weight, feed intake, feed conversion (FC) and egg qualities were periodically measured. Intestinal microflora and Fecal NH₃ emission were examined at the end of experiment. Egg production and daily egg mass of birds fed either of the microorganisms alone or in combination were significantly higher than control ($P < 0.05$). Egg production and daily egg mass was especially in birds fed the Y diet. Egg weight and feed intake were not significantly different between treatments. FC improved in Y, LC, Y + LC treatments significantly compared to that of other treatments ($P < 0.05$). Eggshell quality of all treatments was similar except Y treatment. Total *lactobacillus* spp. and anaerobes of ileum seemed to increase greater in LV, LV + Y, LC + Y than others. Total number of ileal and cecal yeast, anaerobes and *lactobacillus* spp. were constant from one to five WOA. Fecal NH₃ emission was significantly lower in LV, LV + Y and LC + Y than other treatments ($P < 0.05$).

Key Words: Laying hens, *Lactobacillus*, Yeast

1673 Influence of feeding various *lactobacillus* on performance and intestinal microflora of laying hens. S. J. Lee¹, S. H. Kim*¹, S. Y. Park², D. J. Yu¹, B. S. Kang¹, J. C. Na¹, C. H. Choi¹, and K. S. Ryu², ¹National Livestock Research Institute, Rural Development Administration, Daejeon, ²Dept. of Animal Resources and Biotechnology., Chonbuk National University, Chonju, Republic of Korea.

The objective of this experiment was to investigate the influence of feeding various *lactobacillus* on performance, intestinal microflora and fecal NH₃ gas emission of laying hens. Three hundred sixty Isa Brown hens were raised with nine treatments of four replicates from twenty one to thirty two weeks of age(WOA). Treatments consisted of control, *Lactobacillus crispatus* avibro1, *Lactobacillus reuteri* avibro2, *Lactobacillus crispatus* avihen1, *Lactobacillus vaginalis* avihen2 at the levels of 10^4 and 10^7 cfu/g diets. Egg production, feed intake, egg weight and feed conversion (FC) were measured every four weeks. Egg qualities, intestinal microflora and fecal NH₃ gas emission were examined at the end of experiment. All *Lactobacillus* supplementation increased egg production and daily egg mass significantly compared to those of control ($P < 0.05$), but were not statistically different between supplemental groups. Egg weight and feed intake also were not different between treatments. FC of birds fed *Lactobacillus* was significantly improved relative that of control ($P < 0.05$). Eggshell breaking strength, thickness, density and Haugh unit were not significantly different. Total number of *Lactobacillus* spp. in the *Lactobacillus* supplemented group was significantly higher than control ($P < 0.05$) in the ileum, but was not significantly different in the cecum. Total yeast and anaerobe numbers of both the ileum and cecum were not significantly different. Fecal NH₃ gas emission was significantly decreased in *Lactobacillus* supplemented groups ($P < 0.05$) and showed no significant difference between 10^7 and 10^4 cfu/g diets.

Key Words: Laying hens, *Lactobacillus*, Performance

1674 Influence of dietary supplemental live yeast on performance of laying hens. S. J. Lee*¹, S. H. Kim¹, S. Y. Park², D. J. Yu¹, J. C. Na¹, C. H. Choi¹, and K. S. Ryu², ¹National Livestock Research Institute, Rural Development Administration, Daejeon, ²Dept. of Animal Resources and Biotech., Chonbuk National University, Chonju, Republic of Korea.

A feeding trial was conducted to evaluate the influence of live yeast supplementation on performance and intestinal microflora of laying hens. One hundred sixty Isa brown hens were individually placed into wire cage with four replicates from twenty one to 30 weeks of age (WOA). Yeast was supplemented at 0, 0.1, 0.3, 0.5% corn-soy based diets containing 2800 kcal/kg ME and 16% CP. Egg production, egg weight, feed intake and feed conversion (FC) were measured. Egg qualities were examined at fifth and ninth weeks. Intestinal microflora, nutrient digestibility and fecal NH₃ were observed at the end of experiment. Egg production of birds fed 0.1 and 0.3% yeast was significantly higher than control and 0.5% yeast supplements (P<0.05). Daily egg mass of 0.3% supplemental groups was significantly increased compared to that of control (P<0.05). The average egg weight was not different. FC was significantly improved as dietary supplemental yeast increased (P<0.05). There were no significant differences in eggshell breaking strength, thickness, density and Haugh units at both 26 and 30 WOA. Viable *Lactobacillus* spp. in the ileum were significantly increased in supplemental yeast groups (P<0.05). However, total number of yeast and anaerobes were similar between the yeast supplemented and control groups. Total *Lactobacillus* spp. and yeast showed no difference in cecum of all treatments. Fecal NH₃ gas emission of birds fed yeast supplementation tended to decrease compared to that of control.

Key Words: Laying hens, Yeast, Performance

1675 Influence of dietary supplemental various *lactobacillus* on performance and fecal noxious gas of broiler chicks. S. H. Kim*, S. J. Lee, D. J. Yu, J. C. Na, S. Y. Park¹, C. H. Choi, and K. S. Ryu¹, National Livestock Research Institute, Rural Development Administration, Daejeon, ¹Dept. of Animal Resources and Biotech. Chonbuk National University Republic of Korea.

The objective of this study was to investigate the influence of feeding various *lactobacillus* isolated from broiler and laying hens on fecal noxious gas and performance of broiler chicks. One thousand eighty one day old male broiler chicks were fed control, *lactobacillus crispatus* avibro1(LCB), *lactobacillus reuteri* avibro2(LRB), *lactobacillus crispatus* avihen1(LCH) or *lactobacillus vaginalis* avihen2(LVH) at the level of 10⁴ and 10⁷ cfu/g diet for five weeks. There were four replicates with thirty chicks per pen. Diets contained 3,100 kcal ME/kg diet and 22.0 20.0% CP for starting and finishing periods, respectively. Weight gain, feed intake, feed conversion (FC), and intestinal microflora were measured weekly. Nutrient digestibility and fecal noxious gas were examined at the end of experiment. Weight gain of chicks fed *lactobacillus* tended to increase and were significantly higher than control at five weeks of age (P<0.05). Feed intake and FC were not statistically different between *lactobacillus* treatments and control. Total *lactobacillus* spp. of birds fed various *lactobacillus* was significantly increased in the ileum at five weeks of age (P<0.05), but was not different in the cecum. The number of total yeast began to increase significantly in cecum and ileum from three weeks (P<0.05), whereas total number of anaerobes tended to increase at both intestine from one weeks of age. Litter moisture of chicks fed *lactobacillus* was ranged from 27 to 30%, but was 38.3% in control. It decreased approximate 25% significantly in *lactobacillus* treatments compared to that of control (P<0.05). Fecal NH₃ gas emission was significantly decrease in *lactobacillus* treatments (P<0.05). Dry Matter(DM), protein and Ca digestibility tended to be higher in *lactobacillus* treatments than control. Ca and P digestibility of chicks fed LCH showed significantly higher than control (P<0.05). Crude ash and fat digestibility tended to improve in *lactobacillus* treatments. In conclusion, feeding various *lactobacillus* improved the performance and reduced fecal noxious gas. The results of this experiment indicated that optimum *lactobacillus* was thought to be more than 10⁴ cfu/g diet.

Key Words: Broiler Chicks, *Lactobacillus*, Performance

1676 A comparison of feeding *lactobacillus* and Virginiamycin influence on performance and intestinal microflora of broiler chicks. S. H. Kim*, S. J. Lee, S. Y. Park¹, D. J. Yu, B. S. Kang, C. H. Choi, and K. S. Ryu¹, National Livestock Research Institute, Rural Development Administration, Daejeon, ¹Dept. of Animal Resources and Biotechnology. Chonbuk National University, Chonju, Republic of Korea.

This experiment was conducted to investigate the effect of feeding two types of *lactobacilli* and Virginiamycin on performance, nutrients digestibility and intestinal microflora of broiler chicks. Seven hundred twenty one day old male broiler chicks (Abor Acres X Abor Acres) were randomly allocated into six treatments with four replications for five weeks. Control (no supplement), 0.5% Virginiamycin (VM), *lactobacillus crispatus* (LC), *lactobacillus reuteri* (LR), LC + 0.5% VM and LR + 0.5% VM were supplemented into basal diets, which contained ME 3,100 kcal/kg and CP 22.0, 20.0% for starting and finishing period, respectively. Weight gain, feed intake and feed conversion (FC) were weekly measured. Nutrients digestibility, intestinal microflora and fecal noxious gas were examined at the end of experiment. Weight gain of chicks fed *lactobacillus* or VM was significantly higher than control (P<0.05). Feed intake increased significantly in those supplemental groups (P<0.05). FC of chicks fed *lactobacillus* or VM was significantly lower than control (P<0.05). Digestibilities of crude protein, calcium, and phosphorus improved significantly in alone or combined *lactobacillus* treatments (P<0.05), Whereas DM, crude fat and ash digestibility were not statistically different. Feeding *lactobacilli* tended to increase the total *lactobacillus* spp. in ileum at one and three weeks of age (WOA) and showed significantly higher in cecum than control at 5 WOA. Total yeast were not shown difference at 1 and 3 WOA, but significantly increased at five WOA (P<0.05). The ileal and cecal anaerobes were started to increase from the first WOA. Fecal NH₃ gas tended to decrease in *lactobacillus* treatments compared to that of other treatments.

Key Words: Broiler Chicks, *Lactobacillus*, Virginiamycin

1677 Survivability of "pelletable" strain of lactic acid producing bacteria in the new direct-fed microbial, Avi-LutionTM, in broiler diets and resulting changes in intestinal and cecal microflora associated with enhanced performance. D. M. Hooge*¹, J. R. Corley², D. Spangler³, P. Brown³, M. D. Sims⁴, and G. F. Mathis⁵, ¹Hooge Consulting Service, Inc., Eagle Mountain, UT, ²Prince Agri Products, Inc., Quincy, IL, ³Agri-King, Inc., Fulton, IL, ⁴Virginia Scientific Research, Inc., Harrisonburg, VA, ⁵Southern Poultry Research, Inc., Athens, GA.

Four broiler chicken pen trials (see also Sims *et al.*, Poultry Sci. 79(Supplement 1):126 and Hooge *et al.*, 2001, abstract 38, IPSF, Atlanta) were conducted in which post-pelleting survivability of the steam heat-stable strain of lactic acid producing bacteria in Avi-LutionTM (AVN) was determined. Commercial broiler strains used were straight-run Ross x Ross 308 (trials 1-3), Ross x Cobb (trial 3 also), and Ross x Arbor Acres (trial 4). The built-up litter pen trials varied in length from a minimum of 42 days to a maximum of 56 days during several different seasons of the year. Stocking density in three broiler tests was 0.062 m²/bird (Virginia) and in the fourth study 0.086 m²/bird (Georgia). In experiments 1, 2, and 4, a basal-control (non-medicated basal diets), an antibiotic-control (bacitracin-md in one test, and virginiamycin in two others), and AVN treatments (0.025, 0.05, 0.075%, or combination step-down program) were examined. In trial 3 with two strains of broilers, only an antibiotic-control treatment (bacitracin-md, then oxytetracycline) was investigated vs AVN using the 0.075, 0.025, 0.025% three phase, step-down program. Improvements (P<0.05) in weight and feed conversion ratio were demonstrated with AVN vs basal-controls and in some instances vs antibiotic-control diets as well. By microbial analysis of lumen contents of market-age broiler intestines (4 trials) and ceca (1 trial), it was found that AVN treatments in one or more cases significantly (P<0.05) lowered coliforms, Campylobacter, Clostridia, and Salmonella, and raised lactic acid bacteria (log cfu/g dry matter) vs basal-control or antibiotic-control diets. The direct-fed microbial was added at the mixer, and all feeds were steam pelleted (starter crumbled). The AVN 0.05% level provided 330 million microbes/kg complete feed. Based on 28 different samples of feed from the trials, survivability of AVN microbes through pelleting was 95.94% (range, 74.67 to 136.97%) by averaging study sample percentages, or 94.68% by dividing overall average recovered microbes by average theoretical number added (x 100

for %). The AVN survived pelleting and beneficially influenced intestinal and cecal microflora populations, accompanied by improvements in broiler growth and feed conversion similar or higher in magnitude to those achieved with antibiotics.

Key Words: Avi-Lution, Direct-fed microbial, Intestinal microflora

1678 Effect of *Aspergillus* sp and bacterial phytase containing broiler diets on *Salmonella enteritidis* organ invasion in the broiler chick. G Nava*¹, N Ledesma¹, A Priego², C Priego², L Sutton³, and G Tellez¹, ¹Departamento de Produccion Animal: Aves, Facultad de Medicina Veterinaria y Zootecnia, UNAM-Mxico, ²Productos Quimicos-Agropecuarios S.A. de C.V. Mexico, ³PetAg Inc, Hampshire, IL 60140 USA.

In the mature broiler the intestinal microflora (IM) is active in reducing the potential for many intestinal diseases. In the neonatal broiler chick, the IM is not sufficiently developed to offer sufficient protection from potential pathogenic invasion. Both enzyme (bacterial phytase) and prebiotic (*Aspergillus* sp) have been used to improve the IM of the broiler and enhance performance. A trial was conducted to determine the effects of adding 0.2% prebiotic, 0.04% enzyme and the combination on *Salmonella enteritidis* (SE) organ invasion in the broiler chick. This experiment employed a completely randomized design. All of the sorghum plus soybean (S/S) diets were isocaloric and isonitrogenous and consisted of four diets with two replicates of 30 birds each (n = 240). The four experimental diets were: 1). Control S/S diet; 2). Control plus prebiotic; 3). Control plus enzyme; and 4). Control plus prebiotic and enzyme. On day 9 and 19, ten broiler chicks from each diet were challenged with 10⁸ CFU of SE. 24 hours post challenge liver and spleen tissues were collected aseptically and incubated for 24 hours at 37 C in tetrathionate enrichment broth. After incubation, the broth was streaked onto brilliant green agar plates, incubated for an additional 24 hours at 37 C, and examined for the presence of lactose-negative, SE colonies. The percentage of cecal tonsils invasion for SE at days 10 and 20 were virtually 100% confirming uniform inoculation with SE. The effects of the dietary additions (prebiotic and enzyme) significantly reduced subsequent liver and spleen SE invasion at days 10 and 20. The SE invasion of liver and spleen tissues in the 10 day-old chick was: 100, 55**, 60**and 80* percent for diet one through four, respectively (*P<0.05, **P<0.01). The SE invasion of liver and spleen tissues in the 10 day-old chick was: 80, 40**, 45**and 65* percent for diet one through four, respectively (*P<0.05, **P<0.01). The dietary addition of both the prebiotic and the enzyme demonstrated similar effects to "probiotics" in the improvement of the IM maturity to resist SE organ invasion in broiler chicks.

Key Words: Apeergillus meal, Phytase, Salmonella enteritidis

1679 Energy and lysine for broilers from 44 to 55 days of age. O. M. Junqueira*¹, L. F. Araujo¹, C. S. S. Araujo¹, D. E. Faria², and N. K. Sakomura¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal - SP - Brazil, ²Faculdade de Zootecnia e Engenharia de Alimentos - USP/ Pirassununga - SP - Brazil.

One experiment was conducted to evaluate the performance and carcass yield of broilers at 55 days of age fed diets with different levels of metabolizable energy and lysine. Data from performance were weight gain, feed intake, energy intake, lysine intake, caloric conversion and feed conversion. For carcass, it was used data from output carcass, breast weight, wings (wing and over wing), legs (thigh and drumstick), back, head + neck, foot and abdominal fat. The experimental design was a factorial 3x3, involving 3 levels of metabolizable energy (3,200; 3,400 and 3,600 kcal ME/kg and 3 lysine levels (0.95%; 1.05% and 1.15%). No interaction was found between the two factors. Nevertheless, increasing the levels of metabolizable energy resulted in improvement of weight gain (745g; 841 g and 910 g, respectively) and feed intake was found to be higher in broilers receiving the diets with 3,200 and 3,600 kcal ME/kg. Overall performance was not affected by the lysine levels. The feed conversion values were: 2.69, 2.42 and 2.14 from diets with 3,200, 3,400 and 3,600 kcal ME/kg, respectively. Carcass and breast yields were increased with the increment of energy and lysine in the diets. Acknowledgements: FAPESP for financial and technical support Proc. 97/03561-9.

Key Words: Broilers, Lysine, Metabolizable Energy

1680 Dietary supplementation of a blend of galactosidase, galactomannanase and amylase(Endopower[®]) improves energy utilization and intestinal development in broilers. C.W. Kang*¹, S.K. Kim¹, I.H. Chang¹, S.K. Kwan¹, and B.J. Jang², ¹Konkuk University, Department of Animal Science, ²College of Veterinary Medicine.

An experiment was conducted to investigate influences of a multi-enzyme complex compound(Endopower[®]) supplementation to corn-soybean meal diet on energy utilization and intestinal development in broiler chicks. Endopower[®] is a feed grade enzyme blend of α -galactosidase, galactomannanase and α -amylase designed for corn-soybean meal diet. Three hundred sixty 3 d old male broiler chicks(Ross) were randomly housed in 12 pens in an environmentally controlled room and assigned to 4 treatments applying a 2x2 factorial arrangement of two energy levels(3100 and 2980 kcal TME_n/kg diet) with 0 or 0.1% of Endopower[®] in the diet. There were no significant differences in feed intake or feed conversion among the treatments. The enzyme supplementation resulted in greater body weight gain(P<0.05) in the lower energy diet group, indicating the enzyme was very effective in improving energy utilization. However, the birds fed the high energy diet with 0.1% Endopower[®] did not produce additional weight gains compared to the birds fed the high energy without the enzyme diet. The enzyme supplementation reduced relative abdominal fat weights(% BW). The relative intestinal length(cm/BW) of the low energy without Endopower[®] diet group was lower than those of the others. Although the relative weights of jejunum and ileum(% BW) were similar, the duodenum weights(% BW) of the high energy groups were heavier than those of the low ones. The villi of birds fed the diets without Endopower[®] were shortened and thickened compared to those of 0.1% Endopower diet groups regardless of energy level. The results demonstrated that dietary Endopower[®] improved energy utilization and intestinal development and reduced abdominal fats in broiler chicks.

Key Words: Endopower[®] Enzyme, Energy, Intestinal Villus

1681 Effect of Kemzyme[®] on apparent metabolizable energy and ileal digestible energy of wheat and barley samples with differing AME values in broiler chickens. R. R. Carter*¹ and V. Ravindran², ¹Kemin Industries (Asia) Pte Limited, Hornsby, NSW, Australia, ²Massey University, Palmerston North, New Zealand.

This study assessed the impact of dose rate of a xylanase/ β -glucanase based liquid enzyme (Kemzyme[®]) on the apparent metabolizable energy (AME) and ileal digestible energy (IDE) of two wheat samples and two barley samples from different geographical origin during 1999/2000 harvest season. A total of 196 male Ross broiler chicks of uniform body weight were used and distributed into 48 groups (pens) of four birds each. Assay diets contained 95.9% of the test grain and were supplemented with 150 or 200 g/t of enzyme. Each diet was fed to four pens for seven days from day 25 post-hatching. Total collection of excreta was carried out for AME determinations and chromic oxide marker was used for the calculation of IDE. The AME of wheat A was increased from 12.55 MJ/kg DM to 13.56 (+8%) and 13.81 MJ/kg DM (+10%) with 150 g/t and 200 g/t of Kemzyme[®], respectively, while wheat B was increased from 10.8 MJ/kg DM to 13.48 (+25%) and 13.15 MJ/kg DM (+22%). The IDE of wheat A was increased from 12.01 MJ/kg DM to 12.93 (+8%) and 13.14 MJ/kg DM (+9%) with 150 and 200 g/t of Kemzyme[®], respectively, while wheat B was increased from 10.05 MJ/kg DM to 12.46 (+24%) and 12.48 MJ/kg DM (+24%). Significant effects were observed for grain origin (p<0.05) and enzyme addition (p<0.001). The AME of barley A was changed from 12.98 MJ/kg DM to 13.34 (+3%) and 12.91 MJ/kg DM for 150 and 200 g/t of Kemzyme[®], respectively, while barley B was increased from 10.92 MJ/kg DM to 12.17 (+11%) and 11.92 MJ/kg DM (+9%). The IDE of barley A was increased from 11.33 MJ/kg DM to 11.88 (+5%) and 11.83 MJ/kg DM (+4%) with 150 and 200 g/t of Kemzyme[®], respectively, while barley B was increased from 9.8 MJ/kg DM to 10.82 (+11%) and 10.79 MJ/kg DM (+10%). Significant effects were observed for grain origin (p<0.001) and enzyme addition (p<0.05). In summary, Kemzyme[®] significantly increased the cereal AME and IDE values with the greatest AME response associated with lower energy grains. No advantage was recorded from the higher enzyme dose rate.

Key Words: Digestibility, Enzyme, Small grains

1682 **Kemzyme C/S[®] brand for broilers supplementation and its effects on commercial broiler performance.** L. Lewis, A. Lamptey, M. Smith, J. Murphy, and P. A. Welch*, *Kemin Americas, Inc.*

This study evaluated the use of a corn/soybean meal enzyme product, KEMZYME C/S[®] brand for Broilers (KCS), on 49 day broiler performance and yield in a commercial setting. Twenty-eight hundred and eighty Cobb x Cobb male and female broiler chicks were randomly assigned and reared separately, in 48 floor pens. Chicks were allowed ad libitum access to feed and water. All birds received starter diets from d 1-15, grower diets from d 16-29, and withdrawal diets from d 30-49. Diets consisted of corn, soybean meal, meat and bone meal (5%), poultry fat, minerals, and vitamins to meet nutrient requirements for each stage of growth. Treatment diets were either unsupplemented control or KCS enzyme supplemented at 125g/tonne. Enzyme was applied using an AGR International (AGR) post-pelleting system. Dose post-pelleting was verified; however, final active concentration may have been affected by processing conditions. Birds and residual feed were weighed at 49 days and yield determinations were made the following day. No significant differences in weight (avg. 2.23 kg), feed conversion (avg. 1.84) or mortality (3.65%) were observed between enzyme supplemented and control treatments. A subpopulation of birds was randomly selected for yield determinations: liveweight (avg. 2.43 kg), front halves (avg. 37.26%), pectoralis major (avg. 14.51%), pectoralis minor (avg. 3.32%), and wings (avg. 7.93%) were not affected by treatment for either male or female birds. Combined and female WOG and hind half were not affected by enzyme supplementation. However, WOG and hind half yield was improved by 0.84% and 0.48%, respectively, for KCS supplemented male broilers. Although soybean meal concentration in diets was diluted by meat and bone meal, economically viable yield enhancements were detected due to supplementation with KEMZYME C/S[®] brand for Broilers .

Key Words: Enzyme, Corn Soy Diets, Meat Yield

1683 **Release of water insoluble arabinoxylans from rye bran by ferulic acid esterase and pancreatin.** Z. Zhang*, R. R. Marquardt, and W. Guenter, *Department of Animal Science, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2.*

Arabinoxylans crosslink with protein through ferulic acid (FA) to form a complex water insoluble structure of cell wall in rye or wheat grain. Many studies have indicated that the release of water insoluble arabinoxylans (WIA) by non-starch polysaccharide enzymes in the animal gut is associated with an enhanced digestibility of nutrients in the grains. The objectives of this study were to determine (1) if rye bran could be used as a model material for selecting enzymes that are able to open the cell wall structure, and (2) whether ferulic acid esterase (FAE) and pancreatin (PC), a preparation high in proteases, could release WIA from rye bran in vitro. Three studies were carried out. In the first study, rye bran was subjected to treatment with FAE and PC. The results demonstrated that these enzymes enhanced the release of total pentoses from rye bran. Moreover, the log viscosity of the extraction solutions was significantly increased following PC treatment (1.23 times, $P < 0.05$) but was significantly decreased by the FAE treatment (3 times, $P < 0.05$). This latter effect was attributed to the presence of xylanase activity in FAE preparation. The results also showed that the increased viscosity induced by PC could be dramatically reduced by xylanase, but not β -glucanase or PC, and that FAE enhanced the release of ferulic acid into the media. Overall, these studies demonstrated that (1) both arabinoxylans and FA were released by FAE, and (2) that arabinoxylans were also released by PC. Collectively, these results suggest that endogenous enzymes can interact synergistically with other exogenous enzymes to open the structure of the cell wall of cereal grains in the animal gut, thereby facilitating digestion of nutrients such as protein and starch. In addition, these studies also suggest that the bran of grains can be used in conjunction with certain specific enzymes as a model system for studying the mechanism by which enzymes digest cell wall material.

Key Words: Water Insoluble Arabinoxylans, Exogenous and Endogenous Enzymes, Rye Bran

1684 **Prediction of wheat viscosity by near infrared spectroscopy and development of AviNIR calibration.** J. V. Holm¹ and M. Hruby*², ¹*Danisco Cultor, Brabrand, Denmark,* ²*Finnfeeds Int. Ltd, Marlborough, Wiltshire, United Kingdom.*

Grain quality variation contributes greatly to increased variability in broiler performance. Previous research has shown that wheat viscosity, caused by soluble non-starch polysaccharides, correlates closely with wheat feeding quality in terms of AME and broiler performance. Additionally, carbohydrases (e.g. xylanases, beta-glucanases), through its action on soluble non-starch polysaccharides, reduce grain/diet viscosity. Timely and correct evaluation of wheat quality contributes to prediction of a specific enzyme amount (dose) required for a maximum economic return. Chemical viscosity evaluation method (Avicheck[®]) has been used for some time as a basis for wheat quality evaluation. However, the increase in near infrared spectroscopy (NIR) use in the milling and feeding industry and its potential for a rapid determination of chemical constituents of feed ingredients was a decisive factor to evaluate wheat viscosity also through NIR. In the current study, 700 samples of wheat, collected in Europe, North America and Australia during the harvest years of 1999 and 2000, were used to generate an NIR linear calibration equation for nutritive value of wheat measured through the grain viscosity evaluation. Prediction of viscosity was accurate. Coefficient of determination (r^2) was 0.75 for wheat viscosity. This NIR wheat viscosity calibration (AviNIR) covers wheat samples with viscosity of up to 14 cPs, which is more than 95% of all wheat samples screened by Finnfeeds Int. Ltd. during 1996 and 2000 through the chemical viscosity measurement method. On average, the standard deviation between chemical determination of viscosity and NIR was 1.3 cPs. It is concluded, that NIR can accurately estimate the viscosity value of wheat, which contributes greatly to the nutritive value of this grain.

Key Words: Reflectance Spectroscopy, Wheat, Viscosity

1685 **Cell wall polysaccharidase¹ and proteolytic² enzyme combinations may enhance the *in vitro* carbohydrate and protein hydrolysis from toasted and untoasted soybean meal.** I. Ouhida, J. Galobart*, J.F. Perez, and J. Gasa, *Universidad Autonoma de Barcelona.*

Water insolubles (WI) extracted from untoasted vs. toasted (85 and 125°C) soybean meals, were used as substrates to screen the carbohydrate activity of a number of cell wall degrading enzymes. Soybean meal WI yield was 44 vs. 61 and 68%DM⁻¹ of the original sample showing the decreasing solubility with the heat treatment of proteins (59 vs. 44 and 36%) and carbohydrates (41 vs. 28 and 22%, at 0, 85 and 125°C respectively). Incubations were performed at 40°C for 12h with cellulase, pectinase, and xylanase as single enzymes or each one combined with protease. Despite differences between substrate composition from toasting, no significant differences were observed on the enzymatic hydrolysis. Carbohydrate hydrolysis, measured as free monosaccharides, was significantly higher for pectinase (7-9%) and cellulase (9-12%) than xylanase (4-5%) or protease (2-3%). Simultaneous incubations of cell wall enzymes with protease interacted significantly with pectinase (20-22%) and cellulase (12-16%) but not xylanase (4-5%). Single incubations of pectinase and cellulase showed similar proteolytic activities than protease on toasted-85°C SBM (6.0 and 9.7% vs. 7.0% released amino acids, respectively) and higher than xylanase (1.8%). Simultaneous combination of pectinase or cellulase with protease showed an additive effect on protein hydrolysis (10.4 and 11.7%). *In vitro* results suggest an interesting potential of combining cell wall carbohydrases (pectinase and cellulase) and proteolytic enzymes on the hydrolysis of soybean cell wall polysaccharides and proteins. These findings should be confirmed *in vivo* by cell wall polysaccharidase supplementation. ¹Biopectinase NKP, Biocellulase A Con. and Bioxylanase 10P; ²Bioprotease 120P from Quest International Ireland.

Key Words: Soybean carbohydrates, Enzymes, *In vitro* activities

1686 **Effect of Kemzyme[®] on egg production and economics with prior adjustment of wheat and barley AME levels.** R.R. Carter*¹ and R.J. Hughes², ¹*Kemin Industries (Asia) Pte Limited, Hornsby, NSW, Australia,* ²*Pig and Poultry Production Institute, University of Adelaide, Roseworthy, Australia.*

This study evaluated a xylanase/ β -glucanase based dry enzyme included in a laying hen mash diet at 600 g/t. Hyline laying hens were housed at 5 birds per cage in a thermostatically controlled layer shed with a 16 hour light program. There were 12 replicates per treatment, i.e. 2 adjacent cages containing a total of 10 birds. Birds received the trial

diets from 42 to 50 weeks of age. The wheat and barley levels were fixed at 55% and 15% for both treatments. The wheat and barley AME values were each increased by 6% for the enzyme treated diet from control values of 12.7 and 11.6 MJ/kg DM, respectively. While the diet nutrient specifications for both diets remained the same, the effects of increasing the cereal AME values on the enzyme diet formulation compared with the control diet were: increased wheat brand/pollard from 2.99% to 6.24%, reduced tallow from 2.55% to 0.4%, reduced soybean meal from 7.25% to 6.63%, reduced meat meal from 8.3% to 7.8%, and reduced diet cost by A\$7.29 after including the enzyme cost. Prior feed formulation adjustment for the assumed energy utilization effect of the enzyme resulted in the following non-significant differences ($p \leq 0.05$) in production parameters over the 8 week period. The control versus enzyme treatment results were: 86.5% and 87.9% for eggs/100 hen days, 2.15 and 2.18 for g feed/g egg, 63.2 g and 62.6 g for egg weight. The economic impact on 100,000 laying hens over the 8 week period of the combined egg production (assuming a value of A\$1.20/dz eggs) and feed utilization advantages is A\$9,624.20 due to the inclusion of the enzyme.

Key Words: Enzyme, Small grains, Egg production

1687 Effect of diet metabolizable energy level on performance and energy metabolism of broilers. N.K. Sakomura*, C.B.V. Rabello, F.A. Longo, O.M. Junqueira, K. Watanabe, and K. Pelcia, *UNESP Faculdade de Ciências Agrárias e Veterinárias de Jaboticabal - Sao Paulo - Brasil*.

This study was conducted to evaluate the effect of diet energy level on performance, maintenance energy requirement and efficiency of energy utilization for protein and fat deposition. Two hundred-eighty-eight Ross male broilers aged 21 days were distributed at 3 levels metabolizable energy (ME) (3.050, 3.200 and 3.350 kcal/kg) and 3 feeding levels (*ad libitum*, 75% and 50% of *ad libitum* intake), with 4 replications of 8 birds each. Energy retention in carcass was determined based on body composition at the beginning and end of experimental period. The relationship of ME intake (MEI) and energy retained (ER) was used to determine maintenance energy requirements (MEM), energy efficiency above maintenance (k_g) and energy efficiency for protein (k_p) and fat retention (k_f). In order to determine the MEM and k_g were elaborated the following equations for each ME level: 3.350 ER=87.05+0.66.MEI ($R^2=0.97$), MEM=131.12kcal/kg^{0.75}/day, $k_g=0.66$; 3.200 ER=93.74+0.67.MEI ($R^2=0.97$), MEM=140.96kcal/kg^{0.75}/day, $k_g=0.67$; 3.050 ER=88.65+0.67.MEI ($R^2=0.96$), MEM=131.78kcal/kg^{0.75}/day, $k_g=0.67$. The k_p and k_f for each ME level were determined by the slope inversion of the equations: 3.350 MEI=81.34+0.816.REF+2.909.REP ($R^2=0.97$), $k_f=1.23$ and $k_p=0.34$; 3.200 MEI=147.15+1.443.REF+1.485.REP ($R^2=0.97$), $k_f=0.69$ and $k_p=0.67$; 3.050 MEI=128.17+1.233.REF + 1.799.REP ($R^2=0.96$), $k_f=0.81$ and $k_p=0.56$; The body weight gain (g) obtained were: 2058a, 2030ab and 1893b, feed conversion: 1.66a, 1.77ab and 1.88b, body fat composition (%): 38.92, 35.31 and 39.21 and breast yield (%): 33.7, 35.0 and 34.2, for 3350, 3200 and 3050 kcal ME, respectively. The 3200 kcal ME level promoted higher k_p and lower k_f and better performance and carcass quality than 3350 and 3050 ME levels of broiler diets from 21 to 42 days old.

Key Words: Energy efficiency, Energy level, Maintenance energy requirements

ASAS/ADSA Breeding and Genetics: Genetic Parameters and Breeding Strategies

1690 Utilization of ultrasound data from designed progeny testing programs for calculation of carcass trait expected progeny differences. D. J. Kemp*¹, W. O. Herring¹, and C. J. Kaiser², ¹University of Missouri, Columbia, ²Eli Lilly and Company, Indianapolis, IN.

Carcass measurements for weight (HCW), ribeye area (LMA), 12-13 rib fat thickness (FAT), and marbling score (MARB), as well as live animal measurements of weight at the time of ultrasound (YWT), ultrasound ribeye area (ULMA), ultrasound 12-13 rib fat thickness (UFAT), and ultrasound predicted percentage ether extract (UEE) were taken on 2855 Angus steers. The average ages for steers at the time of ultrasound and at slaughter were 391 and 443 d, respectively. Genetic and environmental parameters were estimated for all eight traits in a multivariate

1688 Effect of two sources of sodium on performance and electrolyte balance in broilers. Sultan Mahmood*, R. Ahmad, and S. Hassan Raza, *Dept. of Poultry Husbandry, University of Agriculture, Faisalabad, Pakistan*.

Traditionally, sodium chloride is used as source of sodium in poultry rations. Its supplementation demands great care because any imbalance may lead to depressed performance. This study was conducted to compare the effects of sodium chloride and sodium bicarbonate on broilers' performance, nutrient digestibility, chemical composition of meat and blood chemistry. Five experimental rations having 0,25,50,75 and 100 % supplementation from these two sources were prepared and fed to 150-day-old broiler chicks for 42 days in a completely randomized design. The data on feed intake, weight gain, water consumption, feed efficiency and blood chemistry were recorded. The analysis of data revealed that the use sodium chloride increased the water consumption significantly (201 10.5 vs. 179 10.4 ml/bird daily, $p < 0.05$) whereas sodium bicarbonate significantly increased the weight gain (48.14 5.23g/bird/day, $p < 0.05$), improved the efficiency of feed utilization and deposition of calcium and phosphorus in the broilers. The digestibility of protein was significantly better ($p < 0.05$) in the broilers using sodium bicarbonate than those of the groups fed rations supplemented with sodium chloride, however, dry matter and ether extract digestibility remained unaffected due to the treatments. Blood pH was found significantly higher ($p < 0.05$) in the broilers using rations supplemented with sodium bicarbonate. However, sodium and chloride contents of the blood were not affected. It was also observed that sodium bicarbonate favored the calcium deposition in the head of femur whereas the phosphorus contents deposition remained unaffected. None of the treatments exerted any effect on dressing percentage and breast and thigh meat yield.

Key Words: Broiler, Sodium feeding, Nutrient digestibility

1689 The effects of homocysteine on the avian macrophage *In Vitro*. F. McCorkle* and J. Paquette, *Central Michigan University*.

Homocysteine is an amino acid that has been linked with cardiovascular disease when found in high concentrations in the blood of man. This study looked at the effect of homocysteine on avian macrophage functions, using MQ-NCSU cells. All data was analyzed by one-way ANOVA and experiments were done in triplicate. Homocysteine was not toxic to macrophages at concentrations from 1×10^{-6} to 1×10^{-12} M. (88.9% for 10^{-6} M vs 90.4% for controls) Macrophages adherence was significantly reduced at all concentrations tested (130 cells at 10^{-12} M vs 290 cells for controls). The ability of MQ-NCSU macrophages to phagocytize sheep red blood cells (SRBC) and *Escherichia coli* (*E. coli*) was not affected by homocysteine (28.7% at 10^{-12} M vs 27.0% for controls). The average number of particles taken into the macrophages was not affected by homocysteine (1.26 *E. coli* at 10^{-8} M vs 1.24 for controls). Homocysteine was not cytotoxic and although does inhibit adherence, it does not affect phagocytosis of SRBC or *E. coli*.

Key Words: Homocysteine, Macrophage

animal model. In addition to a random animal effect, the model included a fixed effect for contemporary group and a covariate for measurement age. Heritabilities for HCW, LMA, FAT, MARB, YWT, ULMA, UFAT, and UEE were .48, .45, .35, .42, .55, .29, .39, and .51, respectively. Genetic correlations between LMA and ULMA, FAT and UFAT, MARB and UEE, and HCW and YWT were .69, .82, .90, and .96, respectively. Additional estimates were derived from a six trait multivariate animal model, which included all traits except those pertaining to weight. This model included a random animal effect, a fixed effect for contemporary group, as well as covariates for both measurement age and weight. Heritabilities for LMA, FAT, MARB, ULMA, UFAT, and UEE were .36, .39, .40, .17, .38, and .49, respectively. Genetic correlations between LMA and ULMA, FAT and UFAT, and MARB and UEE were .58, .86, and

.94, respectively. The high, positive genetic correlations between carcass and the corresponding real-time ultrasound (RTU) traits indicate that RTU imaging may be feasible as an alternative to carcass data collection in carcass progeny testing programs.

Key Words: Beef cattle, Ultrasound, Genetic parameters

1691 Genetic evaluations based on ultrasound of yearling beef cattle as related to carcass characteristics of commercially produced progeny. C.J.B. Devitt*¹ and J.W. Wilton², ¹Beef Improvement Ontario, Guelph, Canada, ²University of Guelph, Ontario, Canada.

The objective was to define relationships between carcass measures of commercially produced cattle and sire genetic evaluations based on carcass trait ultrasound. Ultrasound measurements of yearling bulls tested in Beef Improvement Ontario (BIO)'s bull evaluation program were used to obtain genetic evaluations in the form of across breed comparisons (ABCs) for longissimus dorsi area, backfat thickness, and intramuscular fat. The BIO-LINK program offered by Beef Improvement Ontario was used to track carcass weight, percent lean yield, and marbling grade on commercial progeny. The ABC and carcass data included 891 progeny from 85 sires of 10 breeds with an ABC for at least one of the following: longissimus dorsi area, backfat thickness, and intramuscular fat. Since intramuscular fat has been measured only more recently, 493 progeny from 58 sires with intramuscular fat ABC were available. All sires had more than 3 progeny with carcass records. Sire ABCs were calculated using a single trait animal model, expressed as an across breed expected progeny difference, on an age constant basis. Accuracy of ABCs averaged 53, 45, and 39, for longissimus dorsi area, backfat, and intramuscular fat, respectively. Correlation using unadjusted progeny carcass data showed that progeny marbling was positively correlated to sire intramuscular fat ABC, at 0.31. Correlations of progeny percent lean yield with sire longissimus dorsi area ABC and sire backfat ABC were .32 and -.40, respectively. Correlations of progeny carcass weight with sire longissimus dorsi area ABC and sire backfat ABC were .31 and -.24, respectively. Regression of progeny marbling on sire intramuscular fat ABC was significant ($P < .01$), as were regressions of progeny carcass weight and percent lean yield on sire longissimus dorsi area and backfat thickness ABC. These results show that carcass measures of commercially produced progeny are significantly related to sire genetic evaluations based on ultrasound.

Key Words: beef cattle, ultrasound, genetic evaluations

1692 Effects of amino acids and calcium levels on radiographic density and calcium excretion in broilers from 43 to 49 days of age. S. M. Baraldi-Artoni¹, C. S. S. Araujo*¹, L. F. Araujo¹, O. M. Junqueira¹, M. J. Q. Louzada², and N. K. Sakomura¹, ¹Universidade Estadual Paulista - UNESP/Jaboticabal, SP - Brazil, ²Universidade Estadual Paulista - UNESP/Araatuba, SP - Brazil.

Male broiler Avian Farms (n=540) were used from 43 to 49 days of age were subjected to a 3x2 factorial design consisting of three levels of dietary amino acids (100,125 and 150% NRC, 1994) and two levels of dietary calcium (75 and 100% NRC, 1994) with a total of 6 treatments replicated three times per treatment. Radiographic density (mm Aluminium equivalent), tibia variables (tibia weight, tibia length, compact bone thickness and spongy bone thickness) and Ca excretion were evaluate. The AA analyzed were methionine, lysine and threonine. Diets and water were available free choice. Experimental diets were comprised primarily of corn and soybean meal and were formulated to be isocaloric and isoproteic. Requirement levels for AA were accomplished when necessary by adding crystalline AA. Total fecal output was collected for 72 h from days 47 to 49 to determine the treatment effect on Ca excretion. Percentage Ca excretion was calculated as grams of Ca in feces divided by grams of Ca consumed in the 72-h period. At 49 days, two broilers from each pen were slaughtered and the tibia left of the birds were collected and analyzed according to radiographic density (mm Aluminium equivalent). The AA or Ca levels unaffected radiographic density, tibia variables and Ca excretion. There were found interactions between the two factors. Acknowledgements: FAPESP for financial and technical support.

1693 Genetic variation between two tropically adapted *Bos taurus* breeds, the Romosinuano and the Senepol . R. A. Breneman*¹, C. C. Chase, Jr.¹, T. A. Olson², D. G. Riley¹, and S. W. Coleman¹, ¹USDA, ARS, SubTropical Agricultural Research Station (STARS), Brooksville, FL, ²University of Florida, Gainesville.

Twenty-eight microsatellite loci were used to estimate parameters of genetic variation between two tropically adapted *Bos taurus* breeds, the Senepol (n = 47) and the Romosinuano (n = 47), under evaluation at STARS. The Senepol was developed on St. Croix, U. S. V. I., as a cross reported to be between the Red Poll from England and the N'Dama from Senegal. The STARS Senepol herd was acquired through the importation of animals from St. Croix in 1982. The Romosinuano is a criollo breed remnant from the cattle left by the early Spanish missionaries in Colombia. The STARS purebred Romosinuano herd was acquired via embryo importation from Venezuela in 1996. Phenotypically, both are medium-framed breeds, light to medium red in color, polled, and adapted to the hot humid tropical climate of the Caribbean region. Visual phenotypic variation significantly overlaps between the two breeds. Animals from the respective STARS herds were selected by pedigree and sampled as breed representatives. The DNA samples were extracted from isolated buffy coats, amplified by PCR, electrophoresed on 6% polyacrylamide gels, and visualized with silver stain. Allele sizes were estimated relative to a 25 bp DNA stepladder electrophoresed concurrently with the amplified PCR product. Analysis was performed using GENEPOP with alleles coded by three-digit fragment size. Exact Hardy Weinberg tests calculated across all loci support each population to be in Hardy Weinberg Equilibrium ($P < 0.001$). The genetic differentiation detected between the populations was highly significant ($P < 0.001$). The number of effective migrants between populations was negligible ($N_m = 0.325$). The mean frequency of private alleles between the two populations was 0.134. Nei's standard distance (Ds) calculated for the two populations across all loci was 0.825. These population statistics confirm that regardless of phenotypic similarities, these Romosinuano and Senepol populations are distinct and genetically diverse.

Key Words: Beef Breeds, Microsatellites, Genetic Distance

1694 Estimates of genetic and phenotypic parameters of calf birth weight and calving difficulty in Limousin cattle. Adolfo Prez Mrquez¹, Francisco Ponce Medina¹, Juan Rodriguez Garca¹, Fulgencio Bueno Fierro¹, Hctor Gonzlez Garca¹, Abelardo Correa Caldern¹, Juan Guerrero Cruz², and Jess Trejo Castillo³, ¹Universidad Autnoma de Baja California, ²University of California, Davis, Holtville, ³Universidad Autnoma de Ciudad Jurez.

Genetic parameters for birth weight and calving difficulty were evaluated in a herd, located in Samalayuca, a representative rangeland system in the desert region in northern Mexico. Progeny of 41 cows involving inheritance of Limousin (L) mated to sires Limousin were used. The objective was to estimate direct heritabilities for birth weight (BW) and calving difficulty (CD). Separate analyses for each trait used least squares mixed model, SAS (1989). The analytical model included: year of birth, age of dam, sex of the calf, with date of birth as a covariate to adjust a common age as fixed effects; sire and residual as random components. Mean birth weight was 37.97 kg. Birth weight ranged from 36 kg in heifers 29 months old at parturition to 41.4 kg in mature cows 57 months old at parturition. Calving difficulty was subjectively evaluated categorically using descriptive scores (i.e., 1=no difficulty, 2=little difficulty by hand, 3=little difficulty with jack, 4=slight difficulty with a calf jack, 5=moderate difficulty with calf jack, 6=major difficulty with jack, and 7=Caesarean birth presentation). Calving difficulty was greater ($P < .05$) in heifers (17%) than mature cows (9.38%). The sex of the calf was the major source ($P < .05$) of variation in levels of calving difficulty for both heifers and mature cows. The estimated heritability values for birth weight and calving difficulty were .29.07 and .05 .04, respectively. Breeders must consider birth weight and calving difficulty as important traits in their breeding programs.

Key Words: Birth weight, Calving Difficulty, Heritability

1695 Genetic parameters estimates for lean growth rate and its components in U.S. Yorkshire, Duroc, Hampshire, and Landrace pigs. P. Chen*, T.J. Baas, and J.W. Mabry, *Iowa State University, Ames, IA.*

Records on 361,300 Yorkshire, 154,833 Duroc, 99,311 Hampshire, and 71,097 Landrace pigs collected between 1985 and 1999 in herds on the National Swine Registry STAGES program were used to estimate additive genetic (animal), common environmental (litter) and residual variances and covariances for lean growth rate, days to 113 kg, backfat, and loin eye area. Analysis was by the REMLF90 program of I. Misztal using a multiple-trait animal model with fixed effects of contemporary group and sex and random effects of animal, litter, and residual. Estimates of heritabilities were 0.35, 0.40, 0.52, and 0.43 for lean growth rate, 0.43, 0.47, 0.57, and 0.46 for days to 113 kg, 0.35, 0.41, 0.55, and 0.49 for backfat, and 0.44, 0.43, 0.50, and 0.38 for loin eye area in Yorkshire, Duroc, Hampshire, and Landrace, respectively. Genetic correlations were -0.94, -0.86, -0.80, and -0.80 between lean growth rate and days to 113 kg, -0.32, -0.40, -0.25, and -0.41 between lean growth rate and backfat, and 0.40, 0.40, 0.36, and 0.36 between lean growth rate and loin eye area in Yorkshire, Duroc, Hampshire, and Landrace, respectively. Estimates for heritabilities and genetic correlations were consistent across breeds except for higher heritabilities for the Hampshire breed. Estimates for heritabilities across the four breeds for lean growth rate, days to 113 kg, backfat, and loin eye area were 0.43, 0.48, 0.45, and 0.44, respectively. Genetic correlations across the four breeds between lean growth rate and days to 113 kg, backfat, and loin eye area were -0.85, -0.35, and 0.38, respectively. Litter effects were generally small (< 0.1) except 0.12 for both days to 113 kg and loin eye area in the Yorkshire breed. The results indicate that lean growth rate should be used as an important selection criterion in genetic improvement of pigs.

Key Words: Lean Growth Rate, Heritability, Genetic Correlations

1696 Evaluation of Duroc vs. Pietrain sired progeny for meat quality. D. B. Edwards*, R. O. Bates, and W. N. Osburn, *Michigan State University, E. Lansing, MI/USA.*

Novel swine populations may contribute beneficial genes to U.S. swine production systems. Crossbred progeny sired by either Duroc or ryanodine receptor gene normal Pietrain were used in this study. Boars from each breed were mated to Yorkshire or F1 Yorkshire-Landrace females. A total of 162 offspring were evaluated for meat quality. Measurements were taken on animals representative of each litter. Data were analyzed using an animal model with fixed effects of breed of sire, breed of dam, gender, slaughter group, the interaction of breed of sire and gender, and random effect of animal. An additional term of pig was included in the model to fit the within pig variation from sample to sample. Shear force measurements had six samples per pig, while other meat quality measures had two samples per pig. Meat quality measures were not different or favored Duroc sired progeny. Duroc progeny had better subjective meat quality scores (1-5 scale) for color (2.540 vs. 2.354, $P < 0.05$), marbling (2.425 vs. 1.739, $P < 0.001$), and firmness (2.615 vs. 2.295, $P < 0.001$). Furthermore, Duroc progeny had higher 24-h pH (5.526 vs. 5.468, $P < 0.001$) and less percent drip loss (2.892 vs. 3.893, $P < 0.001$). No differences were detected between Duroc and Pietrain sired progeny for Minolta L* (54.764 vs. 55.307), a* (17.348 vs. 17.272), or b* (7.581 vs. 7.441) objective color scores, percent cooking loss (28.629 vs. 29.187), or Warner-Bratzler shear force (6.942 vs. 7.095 kg). Both Duroc and Pietrain populations merit further study into the genetic control of these meat quality traits.

Key Words: pig, meat quality, breeds

1697 Determining inbreeding levels for the Navajo-Churro sheep breed. A. Maiwashe*¹, B. Tseveenjav¹, B. Golden¹, and H. Blackburn², ¹Colorado State University, ²USDA/ARS.

Maintaining genetic diversity in breeds and specifically breeds of small population size requires understanding genetic relationships among animals within a breed. Not knowing such information reduces breeder and association ability to correct situations of genetic erosion and inbreeding. The Navajo Churro is a sheep breed with a small population size and at one time was considered a rare or endangered breed. Therefore, pedigree records from the Navajo Churro Sheep Association were evaluated to determine inbreeding level, rate of inbreeding and the number of flocks with inbreeding. The breed society was formed in 1988; records

collected by the association from 1988 to 1999 were analyzed. There were 2,654 registrations in the analysis. Inbreeding level was calculated using the Animal Breeders Tool Kit. Information concerning inbreeding level and flock size was used as layers in a GIS analysis of the data. Since the formation of the breed society, there have been four generations produced. The average inbreeding for the fourth generation was calculated at 4.6 vs 1.3% for the third generation. Third generation registrations were 360 vs 95 hd for the fourth generation. As the breed moved from the third to the fourth generation, it appears that the rate of inbreeding increased exponentially. Flock inbreeding levels were calculated and it was determined that 32% of the breeders with generation 3 and 4 animals had flock inbreeding levels ranging from 3.1 to 10.5%. Inbreeding levels are increasing among sheep registered with the Navajo-Churro Sheep Association. If inbreeding is left unchecked, and is not intentional, this could develop into a significant problem for this breed.

Key Words: Navajo Churro sheep, Inbreeding, Genetic diversity

1698 Genetic parameters for some growth traits of Local breed of goat in the United Arab Emirates. Salih Al-Shorepy*, Ghaleb Alhadrami, and Khalfan Abdulwahab, *United Arab Emirates University.*

The Local goat breed is the most common native breed of the United Arab Emirates and is adapted to its harsh environment. The data used in the present study was collected from the conservation flock at the Faculty of Agricultural Sciences Experimental Station. The traits recorded were body weights at birth (BWT), 30 days (WT30) and weaning (WWT), and average daily gains from birth to 30 days (ADG1), 30 to 90 days (ADG2) and birth to weaning (ADG3). Season of birth, type of birth or rearing, sex of kid and dam age at kidding were the environmental factors investigated. Genetic parameters and phenotypic and genetic correlations were estimated by REML procedures. By ignoring or including maternal genetic or environmental effects, four different models of analysis were fitted in order to determine the most effective model for each trait. Additive maternal effect was important ($P < 0.05$) for BWT, when compared with a model containing only additive direct effects. Inclusion of maternal permanent environmental effect provided a better fit ($P < 0.05$) for WT30, WWT and ADG1. Estimates of direct heritability from the most appropriate models were 0.18 for BWT, 0.16 for WT30, 0.32 for WWT, 0.11 for ADG1, 0.09 for ADG2 and 0.42 for ADG3. The estimates of genetic and phenotypic correlations were high and showed no genetic antagonisms among growth traits analyzed. It can be concluded that maternal effects have to be accounted for when estimating genetic parameters for BWT, WT30, WWT and ADG1.

1699 Estimation of heritability and repeatability for superovulatory responses of Japanese Holstein population. Y. Asada*¹ and Y. Terawaki², ¹The Graduate School of Dairy Science, Rakuno Gakuen University, ²Rakuno Gakuen University Dairy Science Institute.

The subjects of this study were to estimate repeatability and heritability for the yield of embryos and transferable embryos in Holstein population in Hokkaido, Japan. Data consisted of 306 MOET treatments on 224 Holstein cows from 1997 to 2000. Data were analyzed to investigate the factors affecting superovulatory responses of Japanese Holstein cows using maximum likelihood method and generalized linear model. Variance components for the superovulatory responses were estimated using REML employing animal model. The mean number of embryos and transferable embryos yielded per flush were 6.7 and 4.4, respectively. A good fit exhibited for negative binomial distribution of number of embryos and transferable embryos yielded. A lack of fit exhibited for Poisson and Binomial distribution of the number of embryos and transferable embryos yielded. Factors identified as importance in affecting superovulatory response were the areas (branch offices) and the donors estrus condition after superovulation for the number of embryos. And for the number of transferable embryos the characteristics of each donor was an important factor in addition to affecting factors for the number of embryos. The estimated heritability and repeatability for the yield of embryos were 0.02 and 0.38, and for the yield of transferable embryos were 0.05 and 0.28, respectively. These results showed that prior to carrying out MOET schemes, the consideration of affecting the areas and the donor's estrus condition after superovulation is need to be taken into account when using a computer simulation to predict the genetic gain

and the rate of inbreeding. The results also showed that it is indispensable to use repeatability of donor's superovulatory responses including the characteristics of each donor, so that the computer simulation can produce the more realistic results.

Key Words: Holstein, heritability, transferable embryo

1700 Genetic correlation between final scores over time in Holsteins. S. Tsuruta^{*1}, I. Misztal¹, L. Klei², and T. J. Lawlor², ¹University of Georgia, Athens, ²Holstein Association USA, Inc., Brattleboro, VT.

The goal of this study was to determine how the definition of final score changes in time. The first conformation final scores for cows born between 1951 and 1997 were obtained from Holstein Association USA Inc.; the number of cows born before 1970 was small. The model contained management group, age group, stage of lactation, and regressions on the year of birth as fixed effects; additive genetic random effects with random regressions on the year of birth using third order Legendre polynomials; and residual effects. Ten datasets, each having about 15,000 records, were randomly sampled from the original complete file (4,595,237 records). Estimates of additive genetic and residual variances were constant over the years (about 4.0 and 9.8, respectively). Genetic correlations between years of birth decreased from 1.0 to 0.7 as the distance between the years increased. These correlations between years 1997 and 1981 were .80 and between years 1951 and 1981 were 0.79; however, due to a small number of records in early years and/or low order polynomials, these correlations may have been under (or over)-estimated. The national genetic evaluation for final score may be more accurate if old scores are discarded or treated as separate traits.

Key Words: Holstein, Conformation final score, Random regression

1701 The genetic relationships among milk yield, herd life and productive life in Holstein cows in Hokkaido, Japan. T. Obayasi^{*1} and Y. Terawaki², ¹The Graduate School of Dairy Science, Rakuno Gakuen University, ²Rakuno Gakuen University Dairy Science Institute.

The objectives of this study were to estimate heritability for milk yield at first calving, lifetime milk yield, herd life and productive life of Holstein cows in Hokkaido, Japan. A total of 1,070,646 herds records of Holstein cows in Hokkaido, Japan, for animals born between 1963 and 1997 were classified into life span groups using three different criteria: less than 36 months; more than 36 months less than 72 months; and more than 72 months. These three groups were termed Group 1, Group 2 and Group 3, respectively. Milk yield at first calving, lifetime milk yield, herd life and productive life were all calculated for each animal. Analysis gave a mean for each trait for each group as follows: Group 1: 5531.3 kg, 2895.3 kg, 163.8 days, and 39.4 days; Group 2: 5506.7 kg, 13832.9 kg, 588.9 days, and 584.3 days; and Group 3: 5265.9 kg, 39149.6 kg, 1535.4 days, and 754.3 days, respectively. In Group 3, animals with a high milk yield at first calving showed a high lifetime milk yield, but herd life and productive life trend to be low. Next, we estimated heritability for each trait (milk yield at first calving, lifetime milk yield, herd life and productive life) in each group using REML F90. Heritability of each trait was estimated for a total number of 2,500 animals. In Group 1 heritability for each trait was found to be 0.32, 0.34, 0.08 and 0.22, respectively. In Group 2, heritability for each treat was found to be 0.34, 0.02, 0.20 and 0.19, respectively. And in Group 3, heritability for each trait was found to be 0.35, 0.01, 0.29 and 0.14, respectively. Animals with a high life span tend to show low heritabilities for lifetime milk yield and productive life. Heritability for herd life, however, was low. Animals with a low life span showed low heritability for herd life. Heritability for milk yield at first calving were similar in each group.

Key Words: Heritability, Longevity, Holstein

1702 Suitability of physiological traits of young cattle for the evaluation of their performance stability. L. Panicke^{*1}, R. Staufenbiel², and E. Fischer³, ¹Research Institute for the Biology of Farm Animals, Dummerstorf, Germany, ²Free University Berlin, Institute of Veterinary Physiology, Germany, ³University Rostock, Faculty of Agricultural and Environmental Sciences, Germany.

High milk performance connected with sound health regarding metabolism and sufficient fertility in dairy cows depends on a well balanced distribution of energy in the body. The concentration of glucose

in the blood is relatively constant. Enzymes, hormones, controlling proteins and transporters contribute to the enormous synthesis production of 3 to 4 kg glucose. These are capable of influencing the efficiency of glucose production and distribution. Glucose and growth hormone as "early predictors" are superior to other possible parameters such as free fat acids, urea, thyroxin, prolactin, somatropin and IGF-1 in comparing the relationship between physiological metabolic parameters and the performance of cows and sires. Insulin plays an outstanding role based on its central position in energy metabolism. The function of insulin may be recorded by means of the intravenous glucose tolerance test (GTT). The reaction of insulin and glucose was investigated after infusion of 1 g glucose per kg^{0.75} because of the probable genetic determination of the reactive ability. The coefficient of heritability was estimated as $h^2=0.28\pm 0.16$. The metabolic reaction for young cattle was the same for females and males as the GTT-parameters basic concentration of glucose was 4.0, 4.2 and 4.1 nmol/l plasma and the glucose half-life was 51.0, 49.2 and 50.3 minutes for heifers (n=22) and young sires (n=20, n=87), respectively. The differences of insulin and glucose show a contrary course and depend on the age under standardized feeding. The correlation between GTT and offspring breeding value (EBV) is also influenced by the age (in half-life years). The best correlation is read at the 3rd half-year. Three independent groups of 24 and 28 young sires and 12 heifers were involved in the investigation. The correlation coefficients between the glucose half-life (GHWZ) and the offspring breeding value (EBV) of about -0.4 to -0.5 are higher compared to the pedigree breeding value (PBV). If the so far achieved results are confirmed, an additional recommendation for the evaluation of breeding bulls before the start of the progeny test could be given. The test capacity could be extended or costs for testing bulls could be lowered.

Key Words: Cattle, Breeding Value, Physiology

1703 Influence of the quality of reproductive event data on heritability of gestation length in DHI herds. W. Zhang^{*} and G. E. Shook, University of Wisconsin, Madison.

Genetic evaluations for reproductive traits in dairy cattle are economically important. Accurate genetic evaluations for these traits depend on accurate recording of reproductive events; recording which is notoriously poor or inconsistent in many herds. In order to measure the quality of reproductive event data, gestation length (GL) was investigated in this study because of its biological consistency, having a standard deviation of 5.8 d and coefficient of variation of only 2% in these data. Although GL is not a trait of economic interest, it can be useful for measuring the accuracy of recording reproductive events in general. Data from Wisconsin Holstein herds during 1992 to 2000 were provided by AgSource Cooperative. Gestation length was calculated as days from last breeding to calving. Normal GL (NGL) was defined as 280 d \pm 21 d. Herds with 60 d non-return rate greater than 90% were excluded. Records that ended in abortion or had calculated GL outside the range 259 to 301 d were omitted. A basic data set with 3,906 herds including 244,222 parities was generated after the above editing. Several herd selection criteria based on within-herd percentage of NGL and/or within-herd standard deviation of GL (SDGL) were used to filter the basic data and eight data sets were created. REML estimation of the heritability (h^2) was performed through sire model for each data set. Heritabilities are in the table below. Compared with the basic data, estimates of h^2 based on selected data sets can be increased by at least 2%. The more stringent selection criteria resulted in higher h^2 . The effect of these data selection criteria on heritabilities for economically important reproductive measures are yet to be determined.

Data	Herd Selection Criteria	Records Retained(%)	Herds Retained(%)	h^2 (%)
1	Basic data set	100	100	13.9
2	SDGL<8 d	99	96	15.6
3	NGL>40%	96	92	16.3
4	SDGL<8 d and NGL>40%	95	88	15.9
5	SDGL<6 d	77	69	16.4
6	NGL>50%	73	64	16.6
7	SDGL<6 d and NGL>50%	59	47	17.3
8	SDGL<5 d and NGL>60%	9	10	20.8

Key Words: Gestation Length, Reproductive Data Quality, Dairy Cattle

1704 Heritabilities and genetic correlations between height, length, weight and body condition score of Holstein heifers in high producing Wisconsin dairy herds. C. D. Dechow*¹, N. C. Dorshorst², P. C. Hoffman², K. A. Weigel², J. Jensen³, and G. W. Rogers¹, ¹*Pennsylvania State University*, ²*University of Wisconsin-Madison*, ³*Danish Institute of Agricultural Research*.

The objectives of this study were to estimate genetic and phenotypic parameters for heifer growth in selected high producing Holstein herds. Height, length, heart girth circumference and body condition score (BCS) of heifers were recorded in 19 Wisconsin dairy herds with rolling herd averages greater than 13,500 kg. Each herd was visited one time. Therefore, measurements were recorded only once per heifer. Body weight was estimated from heart girth measurements. Sire information was available for 1163 heifers from 75 to 800 days old. Heifers were sired by 295 bulls. Heritabilities and correlations were estimated assuming a multiple-trait sire model using Average Information REML. All models included a fixed herd effect, linear and quadratic age covariables, and a random sire effect. Heritability estimates were 0.31, 0.26, 0.32 and 0.14 for height, length, weight and BCS respectively. Genetic correlations were 0.58 between height and length, 0.27 between height and weight, and 0.3 between length and weight. Residual correlations among height, length and weight ranged from 0.23 to 0.39. Genetic correlations between BCS and height, length and weight were -0.39, -0.23 and 0.1 respectively. Residual correlations between BCS and the growth measurements ranged from 0.22 to 0.41. Standard errors for all genetic correlations ranged from 0.22 to 0.4, while residual correlations ranged from 0.08 to 0.1. Heifers that were genetically inclined to grow more rapidly tended to have lower BCS. However, management and environmental conditions that increased growth rate also increased BCS.

Key Words: heifers, growth, heritability

1705 Accuracy of reported birth and calving dates of dairy cattle in the United States. H.D. Norman*, J.L. Edwards, and J.R. Wright, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD*.

Frequencies of births that were reported for specific days of the month were documented for US dairy cattle born since 1987 by birth year, herd size, and registry status and compared with calving frequencies for those dates. Because birth dates are expected to be random and uniformly distributed throughout each month, percentages of births on individual dates were expected to be equal (3.3% for d 1 through d 28, 3.2% for d 29, 3.0% for d 30, and 1.9% for d 31). However, percentages of reported birth dates for d 1, 2, 10, 15, and 20 were higher than expected. Percentage of reported births for d 1 was highest (5.3%) of all days of the month regardless of herd size or registry status. The nonuniform distribution of birth dates within month indicated that a substantial number of birth dates were unknown and that estimated birth dates had been reported. About 1.5% of birth dates overall appeared to have been estimated. The highest frequencies for birth dates on d 1 (5.9 to 7.4%) were found for registered cows during months that initiated age groupings for dairy shows (March, June, September, and December). Alteration of birth dates to gain an advantage in cattle shows is likely to have occurred. Birth dates for some registered cows were intentionally misreported as confirmed by comparison of birth dates of individual cows with calving dates of their dams. Reported calving dates appeared to be more accurate than reported births; the inflated frequency of recorded calvings on d 1 was only about 30% as large as the inflated frequency of recorded births. Because cow age is determined by birth date, proper reporting of birth dates is important to ensure the accuracy of standardized yield and fitness records and the genetic evaluations that are based on those records. When animals' recorded birth dates and their dams' calving dates differ, more credence should be given to the latter to improve accuracy.

Key Words: Birth date, Calving date, Accuracy

1706 Expected correlated responses for conformation traits, 48 month stayability and milk yield of Mexican Holstein cattle. M Valencia-Posadas¹, F Ruiz-Lopez*², J Moro-Mendez³, and H Montaldo-Valdenegro¹, ¹*Instituto de Ciencias Agrícolas. Universidad de Guanajuato. Guanajuato, Mexico.*, ²*Cent. Nal. de Invest. en Fisiología y Mejoramiento Animal. INIFAP-SAGARPA*, ³*Holstein de Mexico A.C.*

(Co)Variance components were estimated for mature equivalent first lactation milk yield (MY1), 48 month stayability (48ST) and 11 conformation traits: stature (ST), body depth (BD), rump angle (RA), thurl with (TW), foot angle (FA), rear legs side view (RS), bone quality (BQ), fore udder attachment (FU), front teat placement (FT), udder cleft (UC), udder depth (UD) and final score (FS). Mexican Holstein Association's pedigree information and classification system results were used on 3,409 cows. Derivative free REML was used to estimate (co)variance components under an animal model. Heritabilities for MY1 and 48ST were 0.25 and 0.01, respectively. Heritabilities for conformation traits ranged from 0.04 (UD) to 0.34 (ST). Genetic correlations among MY1 and the conformation traits ranged from -0.27 (UD) to 0.48 (UC) while those among 48ST and the conformation traits ranged from -0.30 (BD) to 0.69 (RS). Due to the high genetic correlations found specially between FT (0.40), FS (0.51), UD (0.52), and RS (0.69) with 48ST it could be recommended that these traits are used in selection programs to improve 48ST. Selecting for MY1 alone will improve UC, TW and to a lesser degree RA, since the genetic correlations were 0.48, 0.26, 0.10, respectively. When MY1, 48ST and FS were combined in an index, the optimum genetic advancement was obtained using a 3:1:1 ratio, which resulted in improvements of 739 kg, 0.40 % and 0.87 points per generation, respectively.

Key Words: Correlated responses, stayability, milk yield

1707 The relationship between the estrous situation of donor cows and genetic gain in Japanese Holstein MOET populations. Yoshinori Terawaki*¹ and Yohei Asada², ¹*Rakuno Gakuen University Dairy Science Institute*, ²*Rakuno Gakuen University*.

The relationship between the estrous situation of donor cows and genetic gain in Japanese Holstein MOET (multiple ovulation and embryo transfer) populations was examined using Monte Carlo simulation. The observed data (n = 306) used in this study were from an MOET program that has been carried out in Hokkaido, Japan. The data were divided into three parts, according to the degree of estrus (strong, normal or delicate) of donor cows. For each of those parts, the distribution of the number of transferable embryos collected per flush (NTECPF) was researched. Determination methods, using the Poisson and gamma (alpha = 1.0) distributions, were developed in order to generate the numbers fitting the distribution of NTECPF. The genetic gains and inbreeding coefficients in MOET populations with several different estrous situations were estimated using these determination methods. Four estrous situations, referred to as A, B, C and D, were assumed. Strong, normal and delicate estrus were assumed to occur in the ratio 7:2:1, 5:4:1, 3:6:1 and 1:8:1 in A, B, C and D, respectively. The base population was assumed to be 200 cattle. Ten males and 30 females were selected in each generation. The rates of strong, normal and delicate estrus in the observed data were 33, 58 and 9 %. The generated numbers were best fitted to the distributions on the observed data when beta of the gamma distribution was set at 7.6, 4.4 and 2.6 for strong, normal and delicate estrus, respectively. The mean NTECPF was highest (6.3) in A and lowest (4.6) in D. The frequencies of flushes that collected no transferable embryos were lowest (14.7%) in A and highest (18.7%) in D. For juvenile schemes, the largest genetic gain (5.4 genetic standard deviation unit) in the 10th generation was predicted to occur in C. The genetic gains in A and D were about 5.2 in the 10th generation, and these were the smallest. For adult schemes, the largest genetic gain (8.4) was predicted in A. The mean genetic gains increased as the ratio of strong estrus increased.

Key Words: Genetic gain, Estrous situation, Holstein MOET

1708 Economic weight and selection index with variance of milk yield, herd life, and depreciation cost . Y. Matsuoka*¹ and Y. Terawaki², ¹*The Graduate School of Dairy Science, Rakuno Gakuen Univ.*, ²*Rakuno Gakuen Univ. Dairy Science Institute.*

The goals of this study were to estimate the economic weight of the aggregate breeding value and to create a selection index from the point of view of milk yield and longevity. Aggregate breeding value was defined as $H = aMY \text{ GMY} + aHL \text{ GHL}$. Economic weights were aMY and aHL for milk yields and herd life, respectively. These values were estimated based on the partial derivatives of milk yield and herd life to the derived function which was calculated as the revenue minus cost per year per cow in Hokkaido, Japan. The relative economic weight of milk to herd life was calculated as aMY/aHL . Selection index traits were actual milk yield and four body traits—mammary system, angularity, rear udder height and udder support—for herd life at 48, 60, and 72 months. Therefore, the selection index was $I = bMY \text{ pMY} + bMS \text{ pMS} + bAG \text{ pAG} + bUH \text{ pUH} + bUS \text{ pUS}$. In these analyses, milk yield, herd life, and depreciation cost were changed from -60 to 60 percent. With change in the milk yields, aMY decreased, aHL increased to 6,400kg of milk, after which it showed a decrease. Both aMY and aHL decreased with the change in herd life, whereas they increased with the change in depreciation cost. The two curves of the relative economic weight of milk to adjusted herd life with the change in milk yield and the depreciation cost change were similar; the relative economic weight decreased within the range of approximately from 3 to 12 as the percentage increased. With the change in herd life, the tendency of the relative economic weight differed from the change in milk yields and depreciation cost change, while the relative economic weight increased within the range of approximately from 1 to 12. Each tendency of the weighting factors of the selection index regarding the changes in milk yield and herd life were similar in fluctuation: bMY and bMS increased, whereas bAG , bUH , and bUS decreased.

Key Words: Economic weight, Selection index

1709 Determining Weights in a Multiple Objective Programming Dairy Breeding Problem. Peter Tozer* and Jeffrey Stokes, *The Pennsylvania State University.*

A survey of animal breeding scientists and representatives from breeding companies provided two sets of information regarding the rankings and relative importance of three objectives in the breeding decision: maximizing net merit; minimizing inbreeding; and minimizing semen cost. Each group ranked the objectives in a slightly different order; net merit was the top objective for both groups, while each group ranked the other two objectives in opposite order. The scores were analyzed through an application of the analytic hierarchy process to determine the set of weights from each group for use in multi-criteria decision making (MCDM) models. The models were used to examine the impact the different rankings and weights had on the sire portfolio selected. Another aspect of the MCDM model tested was the sensitivity of the results to the degree of non-linearity of the function chosen. Linear programming models of the three single objectives were estimated to provide the ideal and anti-ideal values for use in the MCDM models. The single objective models were based on selecting sires for a representative group of 60 cows to be bred. Constraints were placed on the total number of semen units to be purchased in total and on the number of units from any one sire. The portfolios of sires selected by the MCDM models for each set of weights are similar, in that sires with high net merit were selected. This is not surprising given that the net merit weights were approximately 4 times greater than the next objective for each group. Minor differences in the portfolio selected occurred when the model was changed from a linear formulation to the quadratic form. However, a major difference in the portfolios selected occurred when the degree of non-linearity increased from the quadratic to the MINIMAX formulation. In the MINIMAX portfolios the levels of the second objective, either inbreeding or semen cost, were reduced by 27% and 23% when compared to the linear specification portfolios, however, these reductions came at a reduction in average net merit of the portfolios, 9% and 12%, respectively.

Key Words: analytic hierarchy process, breeding, multiple objective programming

1710 Relationships and inbreeding among young dairy bulls entering AI progeny test programs. K. A. Weigel*, *University of Wisconsin, Madison.*

Inbreeding is an expected but undesirable consequence of rapid genetic progress in modern breeding programs. Reproductive technologies allow rapid propagation of a few elite individuals and families, and this can increase inbreeding levels quickly. In a two-stage selection scheme, inbreeding is primarily a function of relationships between young bulls entering artificial insemination (AI) progeny test programs. Our objective was to examine the genetic diversity present within the young AI sire populations of the five major US dairy breeds. Assuming an inbreeding base year of 1960, young sires born in 1998-1999 were, on average, related to their respective breeds by 13.1% for Ayrshires, 11.6% for Brown Swiss, 11.8% for Guernseys, 10.1% for Holsteins, and 14.6% for Jerseys. Individual sires of sons were extremely influential. The percentages of these young bulls that were sired by the five most popular sires of sons were 100% for Ayrshires, 68% for Brown Swiss, 71% for Guernseys, 42% for Holsteins, and 76% for Jerseys. Genetic diversity is also limited on the maternal side of the pedigree. Among the current elite cows (top 5%) in the US, the percentages of cows that were offspring of the five most popular sires were 45% for Ayrshires, 46% for Brown Swiss, 51% for Guernseys, 17% for Holsteins, and 57% for Jerseys. Dairy cattle breeding is a global business, and it appears that the major dairy countries are all drawing from the same gene pool. Data from countries that currently participate in the Interbull dairy sire evaluations were also examined. Individual sires of sons were used very heavily internationally. The percentages of bulls born in 1995 that were sired by the ten most popular sires of sons were 54% for Ayrshires, 59% for Brown Swiss, 100% for Guernseys, 43% for Holsteins, and 66% for Guernseys. Strategies such as computerized mating programs can help reduce inbreeding in the next generation of replacement heifers, but long term maintenance of genetic diversity will require constraining the relationships between young AI bulls.

Key Words: inbreeding, dairy sires, progeny testing

1711 The use of fuzzy set to reduce inbreeding in MOET breeding schemes. Atsushi Nakamura*¹, Kenji Togashi², Naoyuki Yamamoto², and Akiko Nishiura², ¹*Japan Science and Technology Corporation*, ²*Hokkaido National Agricultural Experiment Station.*

Increased rates of inbreeding in multiple ovulation and embryo transfer (MOET) breeding schemes may have an important effect on genetic response to selection and reproductive ability through inbreeding depression and loss of genetic variability. The assumption of constant family size per donor has been assumed in earlier studies of mate selection to control inbreeding. However, the number of mates per donor will vary because the family size changes, depending on the number of embryos per donor. Therefore, the objective of this study was to examine mate selection using fuzzy set to control inbreeding on the assumption of a variable family size. Mate selection was carried out based on a selective mating criterion (FMC), which is an aggregated value of two fuzzy sets by algebraic product and trade-off parameters. These fuzzy sets were described as 'higher average breeding value of mate pair' and 'lower coancestry', respectively. The fuzzy membership functions were defined as logistic function. The value of the trade-off parameter between these two fuzzy sets was set to from 0 to 1. Stochastic simulation was used to study the effect of mate selection on rates of genetic response and inbreeding with a closed adult MOET nucleus breeding program. Milk production the the selected trait and heritability was 0.30. The number of embryos collected from a donor in one flush was sampled from a Poisson distribution. Hierarchical and factorial mating designs were examined. When the trade-off parameter changed from 0.25 to 0.75, the genetic response and inbreeding rates in the hierarchical mating design ranged respectively from 100 to 98% and from 64 to 47% of those in a hierarchical random mating design. The responses in the factorial mating design ranged from 102 to 95% and 57 to 40%, respectively. In conclusion, mate selection based on FMC does not guarantee optimum mate decision as does mate selection with a mathematical programming method. However, this mate selection criterion avoided mating of close relatives and reduced inbreeding on assumption of a variable family size.

ASAS/ADSA Ruminant Nutrition: By-Products, Fiber, and Silages

1712 Effect of feeding dairy cows with either BollGard[®], BollGard[®] II, Roundup Ready[®] or control cottonseeds on feed intake, milk yield and milk composition. A.R. Castillo^{*1}, M.R. Gallardo¹, M. Maciel¹, J.M. Giordano¹, G.A. Conti¹, M.C. Gaggiotti¹, O. Quaino¹, C. Gianni², and G.F. Hartnell², ¹Experimental Station Rafaela INTA, Argentina, ²Monsanto Co., St. Louis, MO.

This experiment evaluated the effect of feeding dairy cows with cottonseeds containing BollGard[®] (Cry1Ac) and BollGard[®] II (Cry1Ac and Cry2Ab), Roundup Ready[®] (CP4 EPSPS) and control non-transgenic cottonseed on dry matter intake, milk yield and milk composition. Twelve lactating multiparous Argentinean Holstein cows weighing 570 kg (BW) were used in a 4x4 Latin square design, with 3 squares each containing 4 cows, four 4-week periods and four treatments. The treatments were control cottonseed non-genetically modified (DP50), BollGard[®] (DP50B) that contains the Cry1Ac gene, BollGard[®] II (DP50BII) that contain both Cry1Ac and Cry2Ab genes and Roundup Ready[®] (DP50RR) that contain the CP4 EPSPS gene. All the cows received the same diet of corn silage, alfalfa hay, ground corn, soybean meal, minerals, vitamins. The individual cottonseeds were hand mixed in with the diet. There were no significant differences ($P>0.05$) in total dry matter intake (DMI) or cottonseed intakes, averaging 23.7 and 2.3 kgDM/cow/d respectively. Milk yield, milk composition (fat, protein, lactose, non-fat solids and urea) and body condition score (BCS) were comparable ($P<0.05$) among the treatments. Results of this study indicate that cottonseed of genetically modified varieties (BollGard[®], BollGard[®] II and Roundup Ready[®]) shown similar performance as control cottonseed.

1713 Effect of feeding dairy cows with cottonseeds containing Bollgard[®] and Roundup Ready[®] genes or control non-transgenic cottonseeds on feed intake, milk yield and milk composition. A.R. Castillo^{*1}, M.R. Gallardo¹, M. Maciel¹, J.M. Giordano¹, G.A. Conti¹, M.C. Gaggiotti¹, O. Quaino¹, C. Gianni², and G.F. Hartnell², ¹Experimental Station Rafaela, INTA, Argentina, ²Monsanto Co., St. Louis, MO.

The purpose of the experiment was to evaluate the effect of feeding dairy cows with cottonseed containing BollGard[®] (Cry1Ac) and Roundup Ready[®] (CP4 EPSPS) and control non-transgenic cottonseeds on feed intake, milk yield and milk composition. Twelve lactating multiparous Argentinean Holstein cows weighing 570 kg (BW) were used in a 4x4 Latin square design, with 3 squares each containing 4 cows, four 4-week periods and four treatments. The treatments were three non-transgenic cottonseeds from two commercial sources (Guazuncho and Pora), a parenteral line (Chaco520) and the genetically modified cottonseed (Chaco520BGRR). All the cows received the same diet of corn silage, alfalfa hay, ground corn, soybean meal, minerals and vitamins. The individual cottonseeds were hand mixed in with the diet. There were no significant differences ($P>0.05$) in total dry matter intake (DMI) or cottonseed intakes, averaging 22.9 and 2.3 kgDM/cow/d respectively. Milk yield, milk composition (fat, protein, lactose, non-fat solids and urea) and body condition score (BCS) were comparable ($P<0.05$) among the treatments. Results of this study indicate that cottonseed of genetically modified variety (BollGard[®] and Roundup Ready[®]) shown similar performance as control cottonseeds.

1714 Effect of chopped and ground roughage on ruminal parameters and voluntary feed intake of sheep. H. G. Gonzalez^{*1,3}, O. B. Ruiz², L. C. De la Vega², E. T. Rubio¹, O. R. Barrozo¹, N. E. Bujanda¹, N. A. Loya¹, E. S. Garcia¹, I. G. Ramos¹, and H. C. Hernandez⁴, ¹Medicina Veterinaria y Zootecnia-ICB, Universidad Autonoma de Ciudad Juarez, ²Universidad Autonoma de Chihuahua, ³Universidad Autonoma de Baja California, ⁴Universidad Autonoma de Baja California Sur.

Eight crossbred sheep (36 kg) with permanent rumen cannulas were used to evaluate if two different chop length: 2.5 cm (T1) and 10 cm (T2) of forage could affect ruminal parameters and voluntary feed intake. The animals were fed *ad libitum* with diets consisting of oat straw plus an alfalfa hay supplement (20 % of the diet). The supplement was offered once daily at 0800 h. Rumen fluid samples were collected of each animal at 0, 1.5, 3, 6, 9, 12, 16, and 24 h after meal and analyzed for pH, ammonia-nitrogen (NH₃-N) and volatile fatty acid (VFA) concentration. The analysis of data was using a crossover design. There were no differences ($P>.05$) in DMI (57.82 vs 58 g kg⁻¹W^{0.75}), pH (6.85 vs 6.93), NH₃-N(12.33 vs 12.27 mg 100ml⁻¹), propionic (14.87 vs 14.01 mM), butyric (5.64 vs 5.76 mM), and isobutyric (0.77 vs 0.77 mM) acids for T1 and T2, respectively. However, a significant difference was detected ($P<.08$) between T1 and T2 in concentration of acetic acid (78.22 vs 79.18 mM). The size of forage particle did not affect the DMI and ruminal parameters in sheep.

Key Words: Sheep, Ruminal parameters, Intake

1715 A comparison of methods used to measure eating and ruminating time in cattle. H. A. Lehman, P. J. Kononoff, and A. J. Heinrichs, *The Pennsylvania State University*.

Detailed knowledge of chewing and rumination activities are critical in order to fully understand the dietary factors affecting normal rumen function. An automatic system for the digital recording of the jaw movements in free-ranging grazing cattle has been described but its ability to measure chewing activity of cattle housed in confinement and fed total mixed rations has not yet been evaluated. The eating and ruminating behaviors of eight lactating dairy cows were recorded simultaneously by a wireless automatic system and by observation over 24 h periods. Data recorded by the automatic system were processed to identify periods of eating and ruminating in each of the cows. Mean total time eating and ruminating as measured by each method were compared using a paired sample t test. Results indicated both methods agreed on identification of eating and ruminating activities 99.1 % and 97.7%, respectively. Mean differences between methods for total time eating (31.0 min + 23.14) and ruminating (54.8 min + 19.13) were significantly different. The time recorded by observation in both eating and rumination was approximately 15% higher when compared to the automatic system. Disagreement between methods most likely indicates inaccuracies in the observational method itself. When different methods of measurements are used to approximate biological parameters such as salivary buffer flow or the amount of energy expended on chewing activity, overestimation was consistent when the observational method was employed. The

automatic system may prove useful in further studies examining eating and rumination activities in cattle.

Key Words: ruminating behavior, eating behavior, Graze software

1716 Effect of two particle sizes of forage on ruminal parameters and voluntary feed intake of steers fed a basal oat straw diet. H. G. Gonzalez^{1,3}, O. B. Ruiz², L. C. De la Vega², E. T. Rubio¹, O. R. Barrozo¹, N. E. Bujanda¹, N. A. Loya¹, I. G. Ramos¹, E. S. Garcia¹, and H. C. Hernandez⁴, ¹Medicina Veterinaria y Zootecnia-ICB, Universidad Autonoma de Ciudad Juarez, Mexico, ²Universidad Autonoma de Chihuahua, ³Universidad Autonoma de Baja California, ⁴Universidad Autonoma de Baja California Sur.

Four Hereford steers (300 kg) with permanent rumen cannulas were used to evaluate two chop lengths: 2.5 cm (T1) and 10 cm (T2) of forage on ruminal parameters and voluntary feed intake. The animals were fed *ad libitum* with a basal oat straw diet plus an alfalfa hay supplement (20 % of the diet). Alfalfa was offered once daily at 0800 h. Rumen fluid samples were collected from each animal at 0, 1.5, 3, 6, 9, 12, 16, and 24 h after meal and analyzed for pH, ammonia-nitrogen (NH₃-N) and volatile fatty acids (VFA) concentration. The analysis of data used a switch back design. A higher DMI was observed ($P < .09$) in T1 compared to T2 (78.64 vs 72.07 g kg⁻¹W^{.75}). No differences ($P > .05$) were found in pH (7.82 vs 7.56), NH₃-N (6.81 vs 6.91 mg 100ml⁻¹), and propionic acid (15.36 vs 14.98 mM) for T1 and T2, respectively. However there were significant differences ($P < .01$) between T1 and T2 in concentration of butyric (6.51 vs 4.89 mM), isobutyric (0.74 vs 0.4 mM), and acetic ($P < .07$; 77.39 vs 79.72 mM). The size of forage particle affected the VFA concentration and DMI.

Key Words: Steers, Ruminal parameters, Intake

1717 Feed Intake, Digestibility, and Growth of Spanish Goats Consuming Different Quality Diets. T. Wuliji, A.L. Goetsch, R. Puchala, S. Soto-Navarro*, R.C. Merkel, G. Detweiler, T.A. Gipson, and T. Sahlu, *E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK.*

Fifty-two Spanish kids (average initial BW = 13.5 ± 0.06 kg) were used in an experiment with two 9-wk phases. Three diets were used: prairie hay consumed *ad libitum* and supplemented with 0.125% BW (DM) of soybean meal (average = 21.4 g/d; H), dehydrated alfalfa pellets consumed *ad libitum* (A); and a 70% concentrate diet consumed *ad libitum* (C). Treatments were A in Phases 1 and 2 (AA), C in Phases 1 and 2 (CC), H in Phase 1 and A in Phase 2 (HA), H in Phase 1 and C in Phase 2 (HC), and A in Phase 1 and C in Phase 2 (AC). Dry matter intake in Phase 1 was lowest ($P < 0.05$) for HA and HC and greater ($P < 0.05$) for AA and AC than for CC (636, 502, 385, 352 and 634 g/d), and DMI in Phase 2 was 839, 629, 834, 636 and 805 g/d (SE = 12.6) for AA, CC, HA, HC, and AC, respectively. Average daily gain for AA, CC, HA, HC, and AC, respectively, was 81, 79, 0, 0 and 86 g (SE = 17.6) in Phase 1 and 73, 54, 112, 82, and 92 g (SE = 29.9) in Phase 2. Apparent total tract DM digestibility, determined at the end of the performance period with five animals per diet, ranked ($P < 0.05$) H < A < C (39, 54, and 66%, respectively). Likewise, ruminal pH was greatest for C and lowest for H ($P < 0.05$; 6.0, 6.5, and 6.8 for H, A, and C, respectively). The concentration of total VFA in ruminal fluid at 4 h after feeding was 35, 104, and 68 mmol/L for H, A, and C, respectively (SE = 3). In conclusion, dehydrated alfalfa pellets supported performance of Spanish kids as great or greater than that with a concentrate-based diet, when fed continuously and following consumption of a low-quality forage-based diet.

Key Words: Goats, Growth, Diet Quality

1718 Methane loss, nutrient digestibility, and net energy value of distiller's grains fed to steers or fermented *in vitro*. M. J. Jarosz*¹ and D. E. Johnson², ¹Purina Mills, St. Louis, MO, ²Colorado State University.

The nutrient digestibility, methane production, and net energy value of dried distiller's grains (DG) was measured with steers by concomitant 2-d respiration calorimetry and 7-d balance trial. Effects of the concentration of DG, dried brewer's grains (BG) or oil on methane production were determined by *in vitro* gas pressure technique. Six steers were fed

a 60% concentrate basal diet with 0, 20, or 40% DG and energy partitioning measured in a 3 x 3 Latin square design. Four *in vitro* trials evaluated 0, 20, 40, 60, 80, and 100% BG or DG replacing alfalfa, 0, 2, 4, 6, 8, and 10% corn oil replacing corn gluten feed (CGF), and normal and non-lipid BG and DG. Inclusion of DG in the diet fed to steers did not significantly decrease methane production (5.9%, versus 6.2% of GE for control diet). Successive DG additions to the alfalfa substrate, *in vitro*, first increased and then decreased methane production to 19% below control when 100% DG was fermented (cubic effect, $P < 0.01$). Methane production was also first increased and then decreased (quadratic, $P < 0.01$) when BG was successively added *in vitro*, reducing methane to 62% of control at 100% BG. *In vitro* additions of corn oil to corn gluten feed linearly ($P < 0.01$) decreased methane production over concentrations ranging from 0 to 10%, while removal of lipid from BG or DG did not alter methane production. When fed to steers, the distiller's grains additions of 20 and 40% did not significantly change DM digestibility, however, NDF digestibility increased ($P < 0.05$) by 17 and 30%, and %DE increased by 2 (N.S.) and 8% when compared to the control diet. Similarly, ME (Mcal/kg DM) content of the DG diets was 7% greater ($P < 0.05$) for each 20 percentage unit addition of DG to the diet. The heat production by the steers did not change with diet resulting in slightly greater (N.S.) partial efficiencies of ME use for maintenance and gain and a 10 and 19% improvement in NEm and NEg content of the 20 and 40% DG diets above control. Calculated by difference using the respiration calorimetry technique, the energy value of DG is; ME, 3.88, NEm, 2.92, and NEg, 2.42 Mcal/kg DM. Applying the slaughter balance derived conversion from ME to NE (NRC, 1996) provides estimates of 2.73 Mcal NEm and 1.95 Mcal NEg/kg DM, 25 to 30% above current tabular values.

Key Words: Distiller's grains, Methane, Net energy

1719 The effect of feeding a novel silage, consisting of liquid cheese whey and wheat straw, on production and digestibility characteristics of growing dairy heifers and beef steers. D.R. ZoBell*, K.C. Olson, R.D. Wiedmeier, and C.A. Stonecipher, *Utah State University, Logan, UT.*

A novel whey silage (WS) was produced in bunker silos at two separate locations. Liquid cheese whey (50% DM) was combined with wheat straw and wheat middlings at proportions of 63.1%, 28.9% and 8.0% (DMB) respectively. Nutrient and fermentation analysis of the WS (30d ensiling period) indicated approx. 44.8% DM, 14.3% CP, 1.87 Mcal/kg NEm, 1.23 Mcal/kg NEg, 4.3 pH, 10.5% lactic acid and 11.2% Total VFA (DMB). At location 1, 60 weaned beef steers were assigned either Control (C), Treatment 1 (T1) or Treatment 2 (T2). There were 5 steers per pen and 4 pens per treatment for this 56d trial. The C steers received 19.0% alfalfa hay (AH), 32.4% corn silage (CS), 39.9% rolled barley (RB), 5.6% SBM and 3.1% supplement and T1 and T2 steers 24.8% CS, 31.0% WS, 35.7% RB, 5.2% SBM and 3.3% supp or 65.5% WS, 31.3% RB and 3.2% supp respectively. All rations were isocaloric and isonitrogenous. Overall ADG (kg), DMI (kg) and FE for C, T1 and T2 steers were 1.18, 1.25, and 1.34 ($P = .09$); 7.09, 8.68 and 9.36 ($P = .0001$); 6.04, 7.01 and 7.07 ($P = .02$) respectively. *In vivo* DM and NDF digestibilities were similar when comparing C and T2 diets ($P > .05$). At location 2, 48 growing holstein heifers were assigned C or T diets with 8 heifers per pen and 3 pens per treatment for 56d. Control heifers received 16.8% AH, 46.2% CS, 36.9% wheat middlings and .1% supp. and T heifers 98.3% WS and 1.7% supp. The C and T rations were isocaloric and isonitrogenous. Overall ADG (kg), DMI (kg) and FE for C and T heifers were 1.14 and 1.07 ($P = .05$), 7.47 and 5.91 ($P = .001$) and 6.55 and 5.57 ($P = .028$) respectively. *In vitro* DM digestibility was improved with treatment ($P < .05$). Whey silage can be produced successfully and can increase production characteristics of growing holstein heifers but may not in growing beef steers.

Key Words: cheese whey, silage, growing steers and holstein heifers

1720 Selected fractionate digestibility coefficients of wheat middling and soybean hull mixtures amended with human food waste. P.M. Walker*, J.M. Dust, D.M. Finnigan, and S.B. Brown, *Illinois State University, Normal, IL USA.*

Suffolk wethers 6 - 7 months old and weighing 44.6 ± 4.8kg were used in two trials (T1 and T2) to determine the apparent digestible energy and digestibility coefficients of dietary DM, CP, ADF and ether extract (EE) of a dehydrated wheat middling (WM) and food waste mixture (DF) and

an extruded soybean hull (SBH) and food waste mixture (EF). In T1 WM and ground food waste originating from retail groceries were mixed in a 75: 25 ratio (DM basis), passed through a grinder/pelletizer and dehydrated. In T2 pulped plate waste (PW) obtained from university dining centers was mixed and extruded in a 40: 60 ratio (wet wt. basis) with an extruded combination of PW: SBH: rolled corn (40: 55: 5), on a wet wt. basis to provide a mixture containing 40.4% PW on a DM basis. In T1 and T2 28 lambs were randomly allotted to metabolism crates and were fed the extruded feed mixtures at 3.6% and 3.8% of body wt, respectively, for 30d with total fecal collection the last 7d. Gross energy was determined on all samples with an adiabatic bomb calorimeter. DF was found to contain 92.7 ± .4% DM, 20.9 ± 3.0% CP, 7.9 ± .6 ether extract (EE) and 11.2 ± .7% ADF. Apparent digestible energy of DF was determined to be 3.17 ± .24 Mcal/kg. DF apparent digestibility coefficients were 65.0 ± 4.8% DM, 75.0 ± 4.9% protein, 15.7 ± 10.8% ADF and 79.4 ± 5.1 EE. EF was found to contain 93.9 ± .9% DM, 17.7 ± 4.4% CP, 4.8 ± .7% EE and 32.2 ± 2.3% ADF. Apparent digestible energy of EF was determined to be 2.66 ± .18 Mcal/kg. EF apparent digestibility coefficients were 58.2 ± 4.2% DM, 62.5 ± 7.3% CP, 27.2 ± 7.8% ADF and 79.8 ± 6.7% EE. This study suggests amending WM and SBH with food waste is an acceptable method for including human food waste in livestock diets.

Key Words: Food Waste, Digestibility Coefficients

1721 Effects of feeding wheat middlings on performance of dairy cows in early lactation. G.D. Marx*, *University of Minnesota, Crookston, MN.*

Forty early lactation primiparous and multiparous Holstein cows were equally assigned to either a diet containing 10% wheat middlings (WM) or a control diet containing corn and soybean meal (CS) at equal ration DM content. The objective of the study was to determine the value of wheat middlings, an economic opportunity feed, using high producing cows. Performance of cows was determined on the two diets during a 12-wk study preceded by a 2-wk standardizing period. Total mixed rations were fed once daily to each group with the balance of the ration consisting of alfalfa haylage, corn silage, high-moisture corn, soybean meal, vitamins and minerals to meet NRC requirements for high producing cows. Cows were kept in individual tie stalls and fed to appetite plus 2.3 kg adjusted daily according to intake. Daily DMI and weigh-backs were measured on each individual cow. General linear models of SAS were utilized to determine statistical significance of the data. Daily milk production, milk fat and milk protein for cows fed WM were 36.9, 1.31 and 1.17 kg and cows fed CS were 38.0, 1.23 and 1.19 kg. Milk production and these milk components did not differ ($P>0.05$) between groups. Peak milk production was similar on each treatment. Average daily DMI did not differ between treatments and were 21.92 and 21.67 kg for the WM and CS fed cows. Average body condition scores were similar for both the WM and CS groups with scores of 3.18 and 3.12. Average daily BW gains of cows during the experimental period for the WM and CS were 0.32 and 0.21 kg. The SCC of milk with the WM treatment was slightly higher than the CS treatment group. Reproduction data indicated no difference in number of services and subsequent conception between treatments. No unusual health conditions or nutritional disorders occurred with any of the cows. Results of this feeding trial indicate that the wheat middlings byproduct feed was an acceptable and economical component at 10% of the ration DM for early lactation dairy cows.

Key Words: Wheat middlings, Early lactation, Dairy cow

1722 The prediction of potential nutrient supply to dairy cows from field pea (*Pisum sativum*) seeds pressure-toasted at various conditions. P. Yu*¹ and J.O. Goelema², ¹*Department of Animal and Poultry Science, University of Saskatchewan, Canada,* ²*Department of Animal Nutrition, Wageningen Agricultural University, The Netherlands.*

Field pea seeds (*Pisum sativum*, also called marrowfat pea, small blue pea, dry pea, arveja or muttar) have particularly high starch and protein contents (around 45% and 25%, respectively). However their rapid and extensive degradation of protein and starch by rumen microbes make them unsuitable and/or inefficient to be used in the unprocessed form in diets for high producing dairy cows. It is advantageous to have more starch and protein escape degradation in the rumen to provide a source of glucose and amino acid in the small intestine to achieve a higher milk

production. In this study, a systematic research was carried out on the effects of pressure toasting of field pea seeds at various conditions (100, 118 and 136C for 3, 7, 15 and 30 min) on rumen degradability and intestinal digestibility of protein and starch, as measured by in sacco nylon bag and mobile bag techniques in lactation dairy cows and on potential nutrient supply to dairy cows, as predicted by the DVE/OEB model. The results show that with increasing temperatures and times, pressure toasting increased ($P<0.01$) rumen bypass protein (BCP) from 58 to 149 g/kg DM and starch (BSt) from 158 to 248 g/kg DM without negatively affecting intestinal digestibilities, increased ($P<0.01$) intestinally absorbed rumen bypass protein (ABCP) from 54 to 145 g/kg DM and starch (ABSt) from 81 to 190 g/kg DM, increased ($P<0.01$) intestinally absorbable protein (DVE) from 115 to 189 g/kg DM and decreased ($P<0.01$) the degraded protein balance (OEB) from 88 to 25 g/kg DM. The highest increases of BCP, BSt, ABCP, ABSt and DVE were 156, 57, 169, 189 and 64%, respectively and the highest decrease of OEB was 72%, at 136C/15 min, over the raw seeds. The results indicate that the effects of pressure toasting on potential nutrient supply of field pea seeds to dairy cows were very much dependent on the conditions applied during processing. It was concluded that pressure toasting could be used as an effective treatment to increase potential nutrient supply to dairy cows by decreasing the OEB value and increasing the BCP, BSt, ABCP, ABSt and DVE values. The largest response was found after toasting for 15 min at 136C.

Key Words: Pressure toasted peas, DVE/OEB model, Cow

1723 Ruminal degradability of feather meal in tropical crossbred steers. J. Vergara-Lopez*¹, O. Araujo-Febres², Y. Troconis², and M. Lachmann³, ¹*Instituto Nacional de Investigaciones Agrícolas,* ²*Departamento de Zootecnia, Facultad de Agronomía, La Universidad del Zulia,* ³*Departamento de Producción Animal, Facultad de Ciencias Veterinarias, La Universidad del Zulia.*

An evaluation of ruminal degradability of feather meal (FM) was made using two crossbred tropical steers fitted with permanent rumen cannulae. Samples of FM (93.37 and 90.30% DM and OM), corn meal (CM; 92.12 and 87.88% DM and OM) and *Brachiaria humidicola* hay (HH, 92.86 and 87.63% DM and OM) were incubated in the rumen for 0, 1, 2, 4, 6, 12, 24, 36, 48, 60 and 72 h. Dry matter and OM degradabilities were calculated. Dry matter degradability of FM at 72h was 43.0 ± 0.86%, lower than ($P<0.01$) CM and HH (90.70 ± 3.11% and 63.37 ± 0.64, respectively). Organic matter degradability was similar (42.77 ± 0.86, 90.38 ± 3.28% and 62.22 ± 0.75% for FM, CM and HH respectively). Dry matter degradation rate of FM was 0.0115 ± 0.0022, lower than ($P<0.05$) CM 0.0261 ± 0.0048 and HH 0.035 ± 0.012. Organic matter degradation rate was similar (0.0124 ± 0.003, 0.0320 ± 0.009 and 0.0349 ± 0.0117 for HP, HM and HH respectively). Ruminal degradability of FM was lower than of CM and HH. These results suggest that FM may be an important by-product.

Key Words: Feather meal, Ruminal degradability, Tropics

1724 Effect of cull chickpeas variety on apparent digestibility of diets for sheep. G. Quevedo², J. F. Obregon*¹, R. Barajas¹, and A. Estrada¹, ¹*Universidad Autonoma de Sinaloa (Mexico),* ²*DGETA-SEP- Sinaloa (Mexico).*

To determine the effect of chickpeas variety on the apparent digestibility of diets for sheep, 4 lambs (Pelibuey, males, BW = 22.2 kg) were used in a Latin square design experiment. The treatments were: 1) 60% sorghum grain (control) 20:80 roughage:concentrate (13.7% CP and 3.41 Mcal of DE/kg of DM); 2) 30% sorghum and 30% chickpeas variety "Blanco Sinaloa"; 3) 30% chickpeas variety "Tubutama" and 30% sorghum; and 4) 30% chickpeas variety "Porquero" and 30% sorghum. The animals were housed in metabolic crates (1.2 x 0.6 m) and were fed twice a day (3.2% of BW). After 10 d of diet adaptation, samples of food and total feces production were collected for 4 d. Samples were oven dried (110°C 24 h), ashed and CP (N x 6.25; Kjeldhal) analyses were performed. Chickpeas variety had no effect ($P>0.10$) on dry matter digestibility (mean value = 79.5%). Organic matter digestibility was not affected ($P>0.10$) by treatments (mean value = 81.1%). CP digestibility of Porquero variety diet was 3% lower ($P<0.05$) than the other chickpeas varieties (77.48 vs. 79.81%). CP of sorghum diet was 7% less digestible ($P<0.01$) than chickpeas diets (73.33 vs. 79.03%). The DE of diets was not different ($P>0.10$) among treatments (mean value = 3.41 Mcal/kg). Observed/expected DE, was 3% lower ($P<0.05$) in chickpeas diets than

sorghum diet (0.97 vs 1.0) True digestibility of chickpeas crude protein was calculated to be 96% for Blanco Sinaloa and Tubutama varieties, while that for Porquero was estimated to be 89%. The DE content of cull chickpeas was estimated to be similar to sorghum grain (3.79 Mcal/kg). It is concluded that cull chickpeas varieties possess different value as a crude protein source for sheep, but their energy content is not impacted by variety.

Key Words: Chickpeas, Digestibility, Sheep

1725 Effect of feeding dairy cows with whey permeate on ruminal environment under alfalfa grazing conditions. M.C. Gaggiotti¹, M.R. Gallardo¹, A.A. Abdala¹, C. Arakaki², L. Burdisso¹, and A.R. Castillo*¹, ¹INTA-EEA Rafaela, ²INTA-CICV.

Whey permeate is an energetic byproduct resulting from the protein extraction of cheese whey (18% DM and 15% lactose) with a potential use in dairy cattle feeding. The objective was to determine the effects of whey permeate on the rumen environment of dairy cows grazing alfalfa. Six ruminally fistulated dairy cows (541 kg BW; 175 DIM; 15 kg of milk/cow/day) were used in a complete change-over design (2 treatments and two 4 wk periods). The treatments were a control diet (Tc) based on alfalfa pastures (strip-grazing) and 3.5 kg DM/cow/day of ground corn grain; and the whey permeate diet (Tp) where corn grain was replaced by 20 l/cow/day of whey permeate (3.6 kg DM/cow/day). Ground corn grain and whey permeate were supplied twice daily through the rumen cannula at the same time in both treatments (7 and 15 h). Ruminal fluid samples were collected at 6, 9, 12, 15, 18, 21 h and analyzed for pH, NH₃, VFA concentration and total count of amylolytic and cellulolytic bacteria. There were significant differences ($P < 0.05$) in NH₃ (Tc: 16.98 vs Tp: 11.26 mg%), pH (Tc: 6.55 vs Tp: 6.40), acetic acid (Tc: 68.6 vs Tp: 63.8 mM) and butyric acid (Tc: 11.4 vs Tp: 6.52 NMP $\times 10^9$ /ml). Although the whey permeate produced a different ruminal environment when it was compared with ground corn grain, this byproduct may be used as an energy source for dairy cows grazing alfalfa pasture.

Key Words: Whey permeate, Grazing dairy cows, Rumen environment

1726 Nutritional value of nonforage fiber sources used by feed industry in Costa Rica. M. Cruz¹, J. Ml. Sanchez*¹, and E. Vargas, ¹Universidad de Costa Rica, San Jose, Costa Rica.

A total of 40 samples of common nonforage fiber sources used in dairy cattle feeding in Costa Rica was taken to estimate their nutritional value. Crude protein, NDF, ADF, lignin, silica, ether extract and ash contents were analyzed. Protein was fractionated and energy content was estimated. Results of soybean hulls had 15.5, 20.3, 32.2, 23.6 and 8.4% of the A, B1, B2, B3 and C protein fractions, respectively. Likewise, palm kernel meal (solvent extracted) had 3.7, 5.8, 8.2, 66.2 and 16.1% of the fractions mentioned before. Rice hulls and corn cobs had low concentrations of CP and high proportions of C fraction, with 53.8 and 56.1%, respectively. Corn bran had the highest hemicellulose content (62.7%) and the lowest levels of lignin (1.1%) and silica (0.04%). Soybean hulls had similar characteristics, however its hemicellulose content was lower than in corn bran and cellulose was higher. Soybean hulls and corn bran had higher ($P < 0.05$) estimated energy values than the other products. In general, soybean hulls had the highest nutritional value because of its protein content and quality, and its energy content.

1727 Performance and apparent digestibility of ram lambs fed safflower silage. F.T. Sleiman*¹, O.D. Sayour¹, S.K. Yau¹, M.T. Farran¹, and M.G. Uwayjan¹, ¹American University of Beirut, Beirut, Lebanon.

Nine Awassi ram lambs averaging 43 kg BW were used in a 4-wk digestibility study with 1-wk collection period to determine the effect of feeding safflower silage (SFS) as the sole roughage or in a 1:1 ratio with barley silage (BS) on apparent digestibility and BW change of Awassi ram lambs. The experimental silage treatments were: 1) 100% SFS, 2) 100% BS, and 3) 1SFS: 1BS, mixed at feeding time. In addition to ad libitum silage feeding, each lamb consumed 0.7 kg DM/d concentrate (16.5% CP, on DM basis). All lambs gained weight by the end of the study with the 100% SFS fed lambs having the highest gain (156 g/d). BW change, however, was not significantly different ($P > 0.05$) among treatments. Furthermore, silage DMI was not significantly different ($P > 0.05$) and averaged 1.0 kg DM/d. Apparent digestibilities of DM (79.3, 75.3 and 77.8%) and EE (74.9, 89.2 and 79.8%) were not significantly different ($P > 0.05$) among the 100% SFS, 100% BS and the 1SFS: 1BS fed lambs, respectively. Lambs that received the 100% SFS manifested a significantly higher CP digestibility ($P < 0.05$) than those fed the 100% BS (77.8 vs. 67.9%); whereas CF digestibility was not different ($P > 0.05$) between these two silage groups (83.5 vs. 82.8%). This study indicates that SFS, when adequately prepared, is well accepted and efficiently digested by young ram lambs.

Key Words: Safflower silage, Digestibility, Performance of ram lambs

1728 Potential of apple pulp as silage for ram lambs. F.T. Sleiman*¹, R.A. Sarkis¹, M.G. Uwayjan¹, and M.T. Farran¹, ¹American University of Beirut, Beirut, Lebanon.

Silage characteristics, acceptability and apparent digestibility of ensiled apple pulp were studied using 12 Awassi ram lambs averaging 52 kg BW. The study consisted of a 4-wk trial with 1-wk collection period. The experimental treatments were: I) 100% apple pulp silage (APS), II) 100% barley-vetch silage (BVS), III) 70% APS + 30% ground yellow corn (GYC) and IV) 60% APS + 40% GYC. In addition to ad libitum silage feeding, each ram lamb was offered 1 kg concentrate (14% CP on DM basis). Changes in temperature of treatments containing the APS (I, II and IV) were not significantly different ($P > 0.05$) and averaged for the first 7d after ensiling 18.3, 18.4 and 19.2C, respectively. pH of treatment I was significantly lower ($P < 0.05$) than those of treatments III and IV by 7d after ensiling (3.3 vs. 3.5 and 3.8, respectively) and remained so until 16 d (3.4 vs. 3.5 and 3.9, respectively). Silage DMI was not different among treatments ($P > 0.05$) and averaged 0.4, 0.3, 0.4 and 0.6 kg/d, respectively. All lambs gained weight by the end of study with lambs on treatments I and IV having the highest gains (126 g/d), although changes in BW were not different ($P > 0.05$). Treatments apparent digestibilities of DM (72.3, 69.6, 73.9, and 74.9%), CP (62.9, 62.1, 59.5 and 62.8%) and CF (48.6, 47.3, 40.6 and 38.6%) were not different ($P > 0.05$). The EE digestibility of BVS (II) was significantly higher ($P < 0.05$) than those of treatments I and III (68.5 vs. 42.8 and 47.4%, respectively) but not different ($P > 0.05$) from that of treatment IV (67.1%). Results of this study indicate that apple pulp silage is acceptable and efficiently digested by ram lambs when properly prepared.

Key Words: Apple pulp silage, Apparent digestibility, Ram lambs

1729 Effect of substitution of common beans hay with Sudan grass hay on apparent digestibility of diets for sheep. R. Barajas*¹, J.F. Obregon¹, G. Quevedo², and A. Estrada¹, ¹Universidad Autonoma de Sinaloa, ²DGETA-SEP-Sinaloa.

To determine the effect of substitution of common beans hay (CBH) with Sudan grass hay (SGH) on apparent digestibility of diets for sheep, a digestion experiment was conducted. Four sheep (Pelibuey, males, BW=20.47 kg) were used in a crossover design. The treatments were: 1) Sudan grass hay 40% (11.24% CP and 2.96 Mcal DE/kg), canola meal 14%, sorghum grain 33.6%, sugar cane molasses 10%, urea 0.6%, and mineral premix 1.8%; and 2) A diet similar to control 40% of CBH instead of SGH. The animals were housed in metabolism crates (1.2 x 0.6 m) and were fed twice a day (3.1% of BW). After a 10 d adaptation period to the diet, samples of food and total fecal production were collected for 4 d. Samples were oven dried (110°C, 24 h), ashed and CP (N x 6.25; Kjeldhal) analyses were performed. Dry matter intake was

similar ($P > 0.10$) between treatments. Organic matter intake was higher ($P < 0.05$) in SGH. Intake of CP was higher ($P < 0.01$) in CBH (70.9 vs. 112 g/d). Fecal DM and OM were higher ($P < 0.01$) in SGH than in CBH. Fecal excretion of CP was not affected by treatments ($P > 0.10$). Common beans hay increased ($P < 0.01$) in 6% DM digestibility (69.9 vs. 73.4%). Digestibility of OM was improved ($P < 0.01$) in 9% by CBH. Apparent digestibility of CP was increased ($P < 0.01$) by 16% with the inclusion of CBH (69.1 vs. 80.1%). Observed/expected CP digestibility was not affected ($P > 0.10$) by type of hay supplied (1.12 vs. 1.09). Diet DE was increased ($P < 0.01$) by 10.6% with substitution of SGH for CBH (2.92 vs. 3.23 Mcal/kg). Observed/expected DE content of diets was higher ($P < 0.01$) for CBH than SGH (0.99 vs. 1.09). The DE content of CBH was calculated to be 3.2 Mcal/kg. It is concluded, that common beans hay can be used as ingredient in sheep feeding and that its DE content is approximately 3.2 Mcal/kg.

Key Words: Common beans, Digestibility, Sheep

1730 Ruminal degradation of crude protein of cull chickpeas using nylon bag technique in sheep. J.F. Obregon*¹ and R. Barajas¹, ¹Universidad Autonoma de Sinaloa.

The nylon bag technique was used to determine the ruminal degradation of crude protein of cull chickpeas in sheep. Three sheep (Pelibuey; males, BW=34 kg) were fitted with T cannulas in rumen. The animals were fed a diet containing sudan grass hay 18%, sorghum grain 30%, cull chickpeas 30%, canola meal 10.2%, sugar cane molasses 9%, urea 0.6%, and mineral premix 2.2% (17% CP and 3.34 Mcal DE/kg). Pairs of nylon bags (12 x 18 cm) containing five grams of ground chickpeas (CHP) or soybean meal (SBM) were placed in rumen, and incubated for 2, 4, 6, 8, 12, 16, 20, and 24 h. After removal from the rumen, residual CP content were determined. Solubility was obtained placing the bags in a 0.15 N NaCl solution. Kinetic parameters A, B, and C were calculated for CHP and SBM. Rate of passage of small protein particles (K) was estimated as 0.02 to calculate the effective degradability of CP in rumen. Residual CP values of CHP at 0, 12 and 24 incubation were used to obtain the rumen undegradable crude protein (UCP), taking as reference the value of 20% for SBM. Chickpeas CP was 79% more soluble ($P < 0.01$) than SBM-CP (26.3 vs. 14.6%). The CP disappearance from nylon bags was higher ($P < 0.05$) for CHP than SBM during the first 20 hours of incubation. CP degradability at 24 hours was similar ($P > 0.10$) for CHP and SBM (95.9 vs. 91.8%). The degradation rate of CHP-CP was 0.073 %/h ($R^2 = 0.96$). The effective CP degradation in rumen for CHP was estimated to be 93.7%. The calculated rumen UCP content of chickpeas was 6.5%. It is concluded, that CP of chickpeas is extensively degraded in rumen of sheep, and that its UCP content is close to 6.4%.

Key Words: Chickpeas, Crude protein, Sheep

1731 Ruminal fermentation, digestion kinetics, and nutrient flow in steers fed diets containing poultry manure and urea or blood meal as the main source of nitrogen. J. Mejia-Haro¹, O. Ruiz-Barrera², I. Mejia-Haro³, and J.A. Jimenez-Castro², ¹Universidad de Guanajuato, Mexico, ²Universidad Autonoma de Chihuahua, Mexico, ³CIGA-ITA de Aguascalientes, Mexico.

A study was carried out to evaluate the effects of two sources of nitrogen (poultry manure-urea, and blood meal) and levels of blood meal in diet on ruminal fermentation, digestion kinetics, and nutrient flow of beef steers. Four steers with ruminal and duodenal cannula were assigned to a Latin square design 4 X 4. The treatments were: T0, a control diet with RDP using a poultry manure-urea supplement; T150, a diet with a low level of RUDP, using blood meal (150 g/d); T300, a diet with an intermediate level RUDP (300 g/d); and T450, a diet with a high level of RUDP (450 g/d). The steers were fed twice a day. Before feeding, a chromic oxide bolus (6 g) was placed into the rumen. The experimental period lasted 12 d and the last 5 d, samples of feed, feces, and ruminal and duodenal contents were collected. Data were analyzed by ANOVA using the GLM of SAS (1993). No differences ($P > .05$) were found on the ruminal pH among treatments. T0 presented the highest concentration of ammonia nitrogen ($P < .05$). The total concentration of VFA and the molar proportion of butyric acid were not affected ($P > .05$). However, the molar proportion of acetic and propionic acids were affected ($P < .05$). In the kinetics of the liquid fraction, differences were not observed ($P > .05$) for dilution rate, ruminal volume, turnover time, fluid flow rate, and turnover per day. Similarly, in the kinetics of the

solid fraction, differences were not observed ($P > .05$) for low constant rate, fast constant rate, passage rate, mean retention time, mean retention time in the first compartment, mean retention time in the second compartment and total mean retention time. The duodenal flow of OM, total nitrogen, microbial N, NH₃-N, non-ammonia N and diet N was not affected ($P > .05$) by treatments. Similarly, no differences ($P > .05$) among treatments were found in the ruminal digestibility of OM, microbial and N efficiency. Total apparent digestibility of DM, OM, and N was not different among treatments ($P > .05$). However, the total apparent digestibility of ADF and NDF was affected by treatments ($P < .05$). The lowest value was observed in T0. In general, all the treatments presented a similar pattern in ruminal fermentation, liquid and solid kinetics and the outflow of nutrients to the duodenum.

Key Words: Fermentation, Rumen, Protein

1732 Comparison of nutrient digestibility between Roundup Ready® beets and pulp derived from Roundup Ready® beets and conventional beets and pulps. T. Hvelplund* and M.R. Weisbjerg, Danish Institute of Agricultural Sciences, Denmark.

Roundup Ready® (RR) sugar and fodder beets have been developed, which can tolerate Roundup® (glyphosate) herbicide treatment due to production of the 5-enolpyruvylshikimate-3-phosphate synthase protein (CP4 EPSPS) from *Agrobacterium sp.* strain CP4. The purpose of these experiments was to examine whether RR sugar and fodder beets or pulp derived from RR sugar beets were comparable to conventional (C) beets and pulps with respect to nutrient digestibility. Six varieties of sugar beets (5C+1RR), 5 varieties of fodder beets (4C+1RR) and 6 varieties of beet pulp (5C+1RR) were tested in 3 digestibility experiments with 7 sheep on each treatment. The daily dry matter intake was approx. 950 g (maintenance level), where hay with known digestibility and urea (assumed to be 100% digestible) was included in the diet in all experiments to obtain sufficient nitrogen and structural fiber. The digestibility was estimated for nutrients analyzed according to the Weende analysis, and for ADF, NDF and energy. The digestibility of organic matter varied between 91.8 and 94.6% for fodder beets, where RR variety showed the lowest value. For the sugar beets the variation was between 94.3 and 96.6%, with the RR variety resulting in a value of 94.4%. No significant difference was obtained between C or RR varieties for the main nutrients or energy in the sugar beet or fodder beet experiment. Organic matter digestibility for beet pulp varied between 84.7 and 89.5%, where the RR variety resulted in a value of 85.5%, and significant differences were found for main nutrients and energy digestibility between the highest and lowest C varieties. Organic matter digestibilities obtained for beets were slightly higher and for pulp slightly lower than tabulated values. From these experiments it is concluded that RR sugar and fodder beets, or pulp derived from RR sugar beets, have a nutrient digestibility which is within the range observed for conventional beets and pulps, indicating that feeding value is not influenced by genetic modification.

Key Words: Roundup Ready, Digestibility, Beets and pulp

1733 Growth performance of Xizhen cattle fed either urea or microbial treated rice straw. J. Luo¹, B. Wang*¹, X. F. Zhao², D. H. Tian¹, H. Y. Yang², and Q. Liu³, ¹Northwest Agricultural University, Yangling, Shaanxi, China, ²Animal husbandry bureau of Xixiang county, Xixiang, Shaanxi, China, ³Ankang Agricultural School, Ankang, Shaanxi, China.

In order to utilize the crop residues fully in the rural area of southern Shaanxi province in China, some processing methods were proposed to treat the low quality straw which could be used as animal feeds in dry winter season. The objectives of our study were to determine the nutritive values of microbial and urea treated rice straw, and investigate the growth performance of Xizhen cattle, a local cattle breed in Shaanxi province of China. Wheat bran (1%) was mixed with chopped rice straw (approximately 5 cm in length) before spreading urea and microbial cultures solution, treated mixture was pressed tightly into a square-shaped cement trench lined with a plastic film, after 20 days of fermentation, treated straw was used for feeding. 9 cows aged 1 to 1.5 year-old with 562 kg (± 28.8 kg) weighed BW were randomly divided into three groups: two groups received urea and microbial treated rice straw, the third group, as being the control, received untreated rice straw and 1% wheat bran supplement. The result showed that crude protein, fiber and fat percentage of urea and microbial treated rice straw were 5.5, 29.9, 1.54;

4.8, 30.0, 1.66% respectively; the average BW gain of cows in three groups was 1080, 1004, and 481 g/d in 88 days experimental period; cows fed urea treated rice straw had a greater ($P < 0.05$) BW gain than control, but was similar ($P > 0.05$) to cows fed microbial treated rice straw. The economic analysis suggested a higher profits for cows fed microbial treated rice straw. In conclusion, urea and microbial treated rice straw can be used as a basic diet for cattle during the winter feed deficiency.

Key Words: Urea or Microbial Treatment, Rice Straw, Nutritive Value

1734 Correlation between texture and *in situ* degradation of corn grain. C.E.S. Correa¹, R.D. Shaver², M.N. Pereira^{*1}, J.G. Lauer², and K. Kohn², ¹Universidade Federal de Lavras, Brazil, ²University of Wisconsin, Madison.

We hypothesized that corn kernel texture, measured as vitreousness and density, may be correlated with ruminal *in situ* degradation of corn kernel dry matter and starch. Fourteen American hybrids were harvested at half milk line, black layer, and mature (3-wk past black layer) stages and 5 Brazilian cultivars at maturity. Corn kernel samples were dried at 58 °C for 48 hours; vitreousness was determined by manual dissection of the vitreous endosperm and density was measured using a picnometer. Vitreousness ranged from 32.8 to 79.9 % of the endosperm and density from 1.124 to 1.292 g/cm³ of grain. The correlation between vitreousness and density was 0.87. A near infrared (NIR) curve generated from ground corn kernels had an RSD of 0.86 for vitreousness and 0.77 for density. The NIR technology may be useful for evaluating large corn data sets for differences in kernel texture. A sub-sample of 18 hybrids were ground through a 4 mm mesh screen and incubated *in situ* in 3 ruminally-cannulated Holstein cows in 3 separate non-concurrent trials. Ruminal degradation parameters were determined by non-linear regression for each cultivar. Effective dry matter (EFDM) and starch (EFST) degradation were estimated assuming a ruminal fractional passage rate of 8 %/h. For the 18 hybrids the correlation between kernel texture and effective degradation is reported. We conclude that corn kernel dry matter degradation is a good predictor of starch degradation, allowing for analytical cost savings. Kernel vitreousness and density were negatively associated with ruminal degradation within this corn population.

	Vitreousness	Density	EFDM
EFDM	-0.88	-0.83	
EFST	-0.91	-0.85	0.99

Key Words: Corn, Starch, Ruminal degradation

1735 Comparative dry matter degradation in rumen of cull chickpeas, soybean meal and sorghum grain using nylon bag technique in rumen of sheep. J.F. Obregon^{*1} and R. Barajas¹, ¹FMVZ- Universidad Autonoma de Sinaloa, Culiacan, Sinaloa Mexico..

To determinate the comparative dry matter degradation in rumen of cull chickpeas, soybean meal and sorghum grain using nylon bag technique in rumen of sheep, an experiment was conducted. Were used three sheep (Pelibuey, males; BW = 34 kg) fitted with canula in rumen. The animals were fed with a 17% CP and 3.34 Mcal DE/kg diet, containing sudan grass hay 18%, sorghum grain 30%, cull chickpeas 30%, canola meal 10.2%, sugar cane molasses 9%, urea 0.6%, and mineral premix 2.2%. Pairs of nylon bags (12 x 18 cm) containing five grams of ground chickpeas (CHP), soybean meal (SBM) or sorghum grain (SGG) were placed in rumen, and incubated by 2, 4, 6, 8, 12, 16, 20 and 24 hours. After removed from rumen, residual DM content was determinate. Solubility was obtained placing the bags in a 0.15 N NaCl solution. Kinetics parameters A, B and C were calculated. Rate of passage of small particles (K) was estimated as 0.02 to calculate the effective degradability of dry matter in rumen. Solubility of CHP-DM was 26% lower ($P < 0.01$) than SBM-DM (17.83 vs. 24.05%). While sorghum-DM solubility represented 6.9% of SBM-DM solubility (24.05 vs. 1.7%). At 12 hours incubation time, ruminal degradation of CHP-DM was 33% higher ($P < 0.01$) than SBM-DM (72.71 vs. 54.84%). Sorghum-DM degradation was 54% lower ($P < 0.01$) than CHP-DM (72.71 vs. 33.09%). After 24 hours incubation, CHP-DM was 43% more degraded in rumen ($P < 0.01$)

than SGG-DM (95.9 vs. 67.2). Effective degradation of chickpeas dry matter was calculate in 92.3%. Rate of disappearance of DM from nylon bags were: 0.083%/h ($R^2 = 0.98$), 0.027%/h ($R^2 = 0.99$) and 0.027%/h ($R^2 = 0.99$) for CHP, SBM and SGG, respectively. It is concluded, that chickpeas dry matter is highly degraded in rumen and that is disappearance rate is faster than soybean meal and sorghum grain dry matter in rumen of sheep.

Key Words: Chickpeas, Degradability, Sheep

1736 Ruminal *in situ* degradation was lower for Brazilian than United States corn grains. C.E.S. Correa¹, R.D. Shaver², M.N. Pereira^{*1}, J.G. Lauer², and K. Kohn², ¹Universidade Federal de Lavras, Brazil, ²University of Wisconsin, Madison.

Flint versus dent endosperm is predominant in Brazilian (BRA) versus United States (US) corn markets. We evaluated differences in corn kernel texture between countries and its effect on ruminal *in situ* starch degradation. Fourteen US and 5 BRA hybrids, cultivated in their respective countries and harvested at maturity, were ranked by vitreousness as measured by manual dissection of vitreous endosperm. Within each country three hybrids were chosen to represent the extremes of vitreousness. Mean vitreousness of US hybrids was 47.0% (42.3, 49.6 and 53.9%) and 73.2% (65.3, 68.7 and 78.3%) for BRA hybrids. Corn kernels were ground through a 4 mm mesh screen and incubated *in situ* in 3 ruminally cannulated Holstein cows. Ruminal starch degradation parameters were determined by non-linear regression. Effective starch (EFST) degradation was estimated assuming a fractional passage rate of 8 %/h. In a second *in situ* trial, two US hybrids of high (55.2%) or low (36.3%) vitreousness were harvested at half milk line, black layer, and mature (3-wk past black layer) stages. Average EFST was 78.7% for the low and 67.4% for the high vitreousness hybrids ($P < .001$). The hybrid with high vitreousness had a greater decrease in ruminal starch degradation with advancing maturity ($P < .01$ for the interaction between hybrid and maturity). Starch digestion may be a major concern in BRA hybrids, especially in situations of delayed harvest.

	US hybrids	BRA hybrids	P value
Fractional rate of starch degradation (%/h)	19.4	7.0	<.001
Rapidly degraded A fraction (% of starch)	31.0	6.1	<.001
EFST (% of starch)	77.4	48.5	<.001

Key Words: Corn, Starch, Ruminal degradation

1737 Evaluation of water powered liquid metering system to provide molasses for lactating dairy cattle on pasture. J.L. Amick*, L.D. Muller, D.R. Buckmaster, H.D. Karsten, T.W. Cassidy, and E.M. Seconi, *The Pennsylvania State University, University Park, PA.*

Grazing lactating dairy cattle were fed isoenergetic ratios of concentrate (C) or concentrate (minus 1.05 kg DM) + liquid molasses (1.05 kg DM/cow/day) (CM) to evaluate the effectiveness of a liquid metering system powered by pressurized water to deliver molasses to grazing dairy cattle. Fourteen Holstein cows (97 DIM, 44 kg milk/day, 567 kg BW, 2.6 BCS) grazed alfalfa (*Medicago sativa* L) (20.2% NDF, 28.4% CP, 67.2% IVDMD) in a single reversal design with 14 days/period. Cows grazed in a rotational grazing system with adjacent plots where the C received water and the CM received water containing the molasses. Water consumption was greater for CM than for C (79.4 vs. 62.5 L/cow/day. $P < 0.05$) and resulted in 1.05 kg/cow/d molasses DMI. Cows were milked twice daily and individually fed concentrate after each milking. Milk production (33 kg/d) and composition (2.6% fat, 2.8% protein, 13.8 mg/dl MUN) did not differ ($P > 0.05$) between groups. Feed intake, determined using Cr₂O₃, did not differ ($P > 0.05$) between treatments (22.8 kg/cow/d). Blood concentrations of urea nitrogen (16.7 mg/dl), glucose (66.1 mg/dl) and NEFA (207 µeq/L) were not different ($P > 0.05$). The water-powered liquid metering system increased water intake, provided molasses throughout the 24-hour grazing period, and effectively controlled liquid supplement intake. Milk production, milk

composition, DMI, and blood metabolites were not different when compared to feeding grazing cows a grain supplement without molasses.

Key Words: pasture, supplementation, molasses

1738 Effect of corn grain texture and maturity on ruminal *in situ* degradation. G.A. Caestine, M.N. Pereira*, R.G.S. Bruno, R.G. Von Pinho, and C.E.S. Correa, *Universidade Federal de Lavras, Brazil.*

Dent (AG 1051, AG 4051) and flint (AG 9012, Tork) corn cultivars were cultivated in five 7-m rows and harvested at early dent (ED), half milk line (HL), and black layer stages (BL). Each grain was frozen-cut into four pieces for ruminal incubation into 6 rumen-cannulated cows. The disappearance of dry matter over 24 hours (DEG24) and the residue of 72-hour (RES72) incubations were recorded. A sample was dried at 58 °C for 96 hours to determine dry matter content (DM) and vitreousness (Vitre) measured by manual dissection of vitreous endosperm. *In situ* data were analyzed within cow and least square means for each hybrid used to correlate *in situ* parameters with DM and Vitre. Linear and quadratic contrasts for maturity were evaluated. The quadratic decrease in ruminal digestion reflected a linear increase in Vitre and DM, factors beyond moisture and presence of hard endosperm may be involved in digestion responses. Correlation of DEG24 and DM was greater than with Vitre (-0.88 vs -0.61). However, correlations between Vitre and DEG24 were higher when performed within texture, and as high as with DM for dented corn. The harvesting window of flint corn is apparently shorter than for dented if starch digestion is a concern. Texture had a greater impact on ruminal digestion at the BL stage of growth.

	DEG24 (% of grain DM)	RES72 (% of grain DM)	Vitre (% of endosperm)	DM (% of grain)
Flint/ED	73.3	1.9	59.9	60.0
Flint/HL	65.0	3.7	67.0	64.5
Flint/BL	19.0	41.1	74.2	78.4
Dent/ED	86.2	1.2	38.2	54.5
Dent/HL	61.4	4.8	46.9	62.4
Dent/BL	42.3	16.9	47.9	74.2

1739 Optimal inclusion level of a raw soybean hull-corn steep liquor pellet in diets for lactating dairy cows. J. M. DeFrain*¹, J. E. Shirley¹, E. C. Titgemeyer¹, A. F. Park¹, and R. T. Ethington², ¹Kansas State University, Manhattan, ²Minnesota Corn Processors, Inc.

Forty multiparous Holstein cows (255 ± 135 DIM; 28 ± 6 kg/d milk) were used in a randomized block design to determine the optimal inclusion level of a raw soybean hull-corn steep liquor pellet (SHSL). Cows were blocked by pretreatment ECM, BW, and BCS and assigned to one of five diets: 0, 10, 20, 30, or 40% SHSL (DM basis). Diet CP averaged 17%. The 0% SHSL diet contained 30.2% alfalfa hay (AH), 15.2% corn silage (CS), 30.7% corn, 9.4% whole cottonseed, 6% soybean meal (SBM), 4% expeller SBM, 1% wet molasses, and 3.5% vitamin/minerals. SHSL incrementally replaced up to 12.5% AH, 7.1% CS, 12.7% corn, and 7.2% SBM. Cows were fed diets for 11 d. Milk yield (2-d average) and milk composition were measured prior to initiation of treatment for covariate analysis and at the end of the trial. Blood was collected on d 11. A quadratic response (P = 0.01) was observed for DMI with cows fed 30% SHSL consuming the least. A significant cubic effect (P < 0.05) was observed for ECM yield and efficiency as cows fed 10, 20, or 40% SHSL produced more ECM, more efficiently than cows fed diets containing 0 or 30% SHSL. Percent fat, protein, and SNF in milk were not affected by diet, but corresponding yields (kg/d) responded cubically (P < 0.01), similar to ECM. MUN was higher for cows fed 40% SHSL than those

fed other diets. Concentrations of glucose and urea in plasma were similar among diets, but quadratic responses (P < 0.05) were observed for plasma Lys, Leu, Trp, Tyr, total essential amino acids, and total amino acids, which were all higher for intermediate levels of SHSL. These data indicate SHSL up to 40% of diet DM is an acceptable feedstuff for lactating dairy cows during short term feeding periods. Longer term studies are warranted. Based on efficiency of ECM production, 20% of diet DM was the optimal inclusion level for SHSL in diets fed to lactating dairy cows.

1740 Corn crop residue grazing effects on soil physical properties and soybean production in a corn-soybean crop rotation. J. R. Russell¹, J. T. Clark*¹, D. L. Karlen², W. D. Busby¹, L. J. Secor¹, B. Peterson³, C. R. Olsen¹, and S. C. Shouse¹, ¹Iowa State University, ²National Soil Tilth Laboratory, ³USDA Natural Resource Conservation Service.

To evaluate the effects of crop residue grazing by beef cows on soil characteristics and soybean yields, a 19.4-ha field near Atlantic, IA and 14.6-ha field near Chariton, IA were divided into four blocks of 6 paddocks. Twelve beef cows were allotted to graze five of the paddocks at 28-d periods beginning on October 15 and November 29 at the Atlantic and Chariton sites. Twelve grazing exclosures were placed in two transects within each grazed paddock. Precipitation and soil temperature, bulk density, moisture content, penetration resistance, surface roughness, classification, topsoil depth, and crop residue cover were measured. Soil bulk density, moisture content, and penetration resistance in grazed paddocks were measured to a depth of 20.3 cm outside and inside grazing exclosures and expressed as the outside-to-inside ratio. In the subsequent growing season, soybeans were planted in replicate fields with disking or no tillage and yield determined at harvest. At the Atlantic site, the ratios of the soil bulk density outside to that inside grazing exclosures at a depth of 0 to 10.2 cm were greater (P < .06) in paddocks grazed in periods 1, 2, 3 and 5 and soil surface roughnesses were greater (P < .01) in paddocks grazed in period 5 than ungrazed paddocks. At the Chariton site, soil surface roughnesses (P < .01) were greater in paddocks grazed in periods 2, 3, and 4, ratios of penetration resistance to a depth of 10.2 cm outside to inside grazing exclosures were greater (P = .01) in periods 2, 4, and 5, and postgrazing residue covers were lower (P < .01) in all grazed paddocks than ungrazed paddocks. At both sites, soybean yields in the season following grazing did not differ between grazed and ungrazed paddocks. In stepwise multiple regressions using data from both sites, soybean yields (kg/ha) were predicted by soil clay % (y = 5672.65 - 112.73x; r² = .91).

1741 Dynamics of the nutrients in the gastrointestinal tract: Validation of the Cornell system for bovine fed with sugar cane based diets. E. S. Pereira*¹, A. C. Queiroz², S. C. Valadares Filho², L. F. Miranda³, and A. M. V. Arruda¹, ¹Universidade Estadual Oeste Paran, ²Universidade Federal Viosa, ³Universidade Federal Minas Gerais, Brazil.

The objective of this work was to validate the predictions with base in the estimates of the dynamic ruminal and post-ruminal parameters of the nutrients and of the microbial growth at the rumen level, using the equations that compose the submodel Cornell system relative to the gastrointestinal tract. Four Holstein-Zebu young bulls with average 300 kg LW, rumen and abomasal fistulated were allotted to 4 x 4 Latin square design in a 2 x 2 factorial arrangement. The animals were fed with sugar cane based, diets, supplemented with two nitrogen sources (urea or poultry litter) and two daily levels of *Sacharomyces cerevisiae* addition (0 or 10 g/animal). The indigestible neutral detergent fiber (NDF) and chromium mordant sugar-cane NDF were used as internal and external markers, to estimate the daily fecal production and the ruminal particle passage rates. The dynamics of the nutrients was based on the determinations of the total nitrogen flow and of the of abomasal nitrogen flow of microbial origin, of the total and NDF digested in the rumen. These variables were also predicted from the model described in the Cornell system, for validation of its estimates. The microbial yield was not influenced by the nitrogenous sources or by *Sacharomyces cerevisiae* addition. The simulation of the Cornell system resulted in overestimation of the total ruminal carbohydrates digestion (51%) and NDF degraded in the rumen (47%), the nitrogen flow of microbial origin (86%) and

underestimated the total nitrogen flow (73%). The CNCPS model did not present a realistic prediction of the dynamics of the nutrients in the gastrointestinal tract.

Key Words: Microbial efficiency, CNCPS system, Rate of passage

1742 Determination of the protein and carbohydrates fractions, and in vitro degradation rates of the sugar cane, poultry litter and cottonseed meal. E. S. Pereira^{*1}, A. C. Queiroz², S. C. Valadares Filho², L. F. Miranda³, and A. M. V. Arruda¹, ¹Universidade Estadual Oeste Parana, ²Universidade Federal Viosa, ³Universidade Federal Minas Gerais, Brazil.

The objective was to fractionate and examine the degradation kinetics of the nitrogenous compounds and the carbohydrates of the sugar cane, poultry litter and cottonseed meal. The non-protein nitrogenous compounds, soluble and insoluble nitrogen in borate-phosphate buffer, neutral detergent and in acid detergent insoluble protein nitrogen were analyzed for the determination of the nitrogen fractions. The degradation rates of the protein fractions were obtained from the in vitro incubation of the feeds with proteases isolated from ruminal fluid. The total carbohydrates, and the fractions C, B2 and the soluble neutral detergent components were calculated for the determination of the carbohydrates using the Cornell system. The potentially degradable (B2) and undegradable (C) fractions of the neutral detergent fiber, corrected for ash and protein, the lag dynamic rates, of degradation and of specific microbial growth, from the fraction B2, were determined. The coefficient of degradability and the NDF ruminal repletion effect of the feeds, were also determined. The values of 71.01; 45.80 and 71.66% of the fraction B2 of the nitrogenous compounds were observed for sugar cane, poultry litter and cottonseed meal, respectively. The poultry litter stood out for the highest B3 and C fraction (23.57 and 10.11%). The B3 fraction degradation rates were of 0.03; 0.031 and 0.09 h⁻¹ for sugarcane, poultry litter and cottonseed meal, respectively. The fraction C of the carbohydrates varied of 22.74; 28.00 and 32.64% for the three feeds, respectively. The sugar cane presented high soluble components fraction (35.99%), however presented low digestion of the potentially degradable fiber (3.41% h⁻¹) and a significant repletion effect (6.6 h⁻¹). The feeds, sugarcane and poultry litter present low nutritional value to meet the ruminal microorganisms and of the host requirements.

Key Words: Carbohydrate, Protein, Rumen

1743 Effect of whole or ground cottonseed on apparent digestibility of finishing diets for sheep. A. Estrada^{*1}, J.F. Obregon¹, R. Barajas¹, and B. Valenzuela¹, ¹FMVZ-Universidad Autonoma de Sinaloa (Mexico).

The objective of this study was to determine the apparent digestibility of whole or ground cottonseed in finishing diets of sheep. Four sheep (Pelibuey, males, BW=25.9 kg) were used in a crossover design experiment. The treatments were: 1) ground cottonseed 20%(GCS), sudan grass 12%, sorghum grain 50%, canola meal 5.2%, sugar cane molasses 10%, urea 0.8%, and mineral premix 2% (15.3% CP and 3.47 Mcal DE/kg); 2) A diet similar to control but containing whole cottonseed 20% (WCS) instead of ground cottonseed. The animals were housed in metabolic crates (1.2 x 0.6 m) and were fed twice daily (3.1% of BW). After a 10d dietary adaptation period, samples of food and total fecal production were collected across 4 d. Samples were oven dried (110 °C, 24 h), and DM and CP (N x 6.25; Kjeldhal) analyses were performed. Dry matter intake and crude protein intake were not affected (P>0.10) by treatment. Dry matter excreted in feces increased (P<0.04) in 14.7% with whole cottonseed treatment (170 vs. 195 g/day). Crude protein excreted in feces was not affected by treatments (P>0.10) with mean value of 22.3 g/day. The inclusion of whole cottonseed decreased (P>0.04) by 4.4% the apparent digestibility of diet dry matter (75.2 vs. 71.9%). Crude protein digestibility was not affected (P>0.10) by processing of cottonseed (P>0.10). The mean of experiment was 78.9%. DE of the diet was 4.4% lower (P<0.01) in whole cottonseed than in ground cottonseed diet (3.21 vs. 3.07 Mcal DE/kg). Observed/expected DE was lower (P<0.01) in WCS than in GCS diet (0.88 vs. 0.93). DE content of whole cottonseed was estimated to be 3.53 Mcal/kg. Whole cottonseed possesses a lower nutritional value than ground cottonseed for sheep fed finishing diets, and that WCS-DE content is near of 3.5 Mcal/kg.

Key Words: Cottonseed, Digestibility, Sheep

1744 Effect of feeding foliage of a multipurpose tree (*Enterolobium cyclocarpum*) on ciliate protozoa and ruminal fermentation in sheep. K. M. Koenig^{*1}, M. Ivan¹, B. Teferedenge², L. M. Rode¹, M. Ibrahim³, D. P. Morgavi¹, and C. J. Newbold², ¹Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB Canada, ²Rowett Research Institute, Aberdeen, Scotland, ³CATIE, Turrialba, Costa Rica.

The effect of feeding foliage of *Enterolobium cyclocarpum* on ciliate protozoal numbers and rumen fermentation was measured in three groups of five ruminally cannulated wethers with either no ruminal protozoa (fauna-free), a normal mixed protozoal population, or genera of *Entodinium* as a single species rumen fauna. Repeated measurements were made on the sheep in two periods of 28 d. The control diet was a total mixed ration composed (DM basis) of barley silage (60%), and a barley grain and soybean meal pelleted concentrate (40%). The diet was offered twice a day and feed was restricted to 85% of ad libitum intake from d 12 to 28. In the second period, 200 g (93.7% DM) of *E. cyclocarpum* was substituted for an equal amount of diet DM offered at the morning feeding, and fed from d 16 to 28. Rumen contents were collected at various times over the last 5 d of each period (d 9 to 13 of *E. cyclocarpum* feeding) for measurement of volatile fatty acids, NH₃-N, and protozoal numbers, and then averaged for statistical analysis. Total protozoal numbers were lower in sheep faunated with a normal mixed protozoal population compared to sheep monofaunated with *Entodinium spp.* Feeding the foliage of *E. cyclocarpum* tended (P = 0.065) to reduce protozoal numbers by 25%. Total volatile fatty acid concentration was higher and NH₃-N concentration lower in sheep fed *E. cyclocarpum* suggesting that ruminal digestion was not compromised and that the turnover of microbial protein in the rumen was reduced by the anti-protozoal effect of *E. cyclocarpum*. In a second experiment, eight ruminally cannulated sheep with a normal mixed ruminal protozoal population were fed the control diet or the control diet supplemented with 200 g *E. cyclocarpum* for a period of 42 d. Rumen contents were collected 2 h after feeding for protozoal enumeration to determine the persistence of the anti-protozoal effect of *E. cyclocarpum*. Protozoal numbers were reduced in sheep fed *E. cyclocarpum* from d 5 to 11, and then protozoal numbers recovered to the levels in the control animals. In conclusion, feeding the foliage of *E. cyclocarpum* reduced ruminal ciliate protozoal numbers, but the effect was transitory.

Key Words: protozoa, defaunation, ruminal fermentation

1745 Effect of subacute ruminal acidosis on in situ digestion of mixed hay in lactating dairy cows. J.C. Plaizier^{*1}, J.E. Keunen², J.-P. Walton², T.F. Duffield³, and B.W. McBride², ¹Department of Animal Science, University of Manitoba, ²Department of Animal and Poultry Science, University of Guelph, ³Ontario Veterinary College.

It is expected that subacute ruminal acidosis (SARA) reduces fiber digestion, since low rumen pH (< 6) reduces growth yield and increases maintenance requirements of fibrolytic microflora. Additionally, low rumen pH might reduce the effect of fibrolytic enzymes. Previous investigations on the effect of rumen pH on fiber digestion have been conducted in vitro. The extent of NDF digestion determined in situ is generally greater than that determined in vitro. Hence, results from earlier in vitro studies might not be fully indicative for the effect of SARA on ruminal digestibility. Using a previously developed nutritional model to induce low rumen pH, the effect of SARA on rumen DM and NDF degradability of mixed hay was determined. SARA was induced by replacing 25% of the ad libitum DM intake of total mixed ration (TMR) with grain pellets (50% wheat/50% barley). Rumen pH was measured continuously using in-dwelling probes. In situ degradability was determined by incubating nitrogen free polyester bags with a pore size of 50 microns containing 2 g of ground dried hay in the rumen for 3, 6, 12, 24, 48 and 72 h. The nutritional model resulted in a substantial drop in rumen pH. Rumen pH in control cows was lower than that normally observed in lactating dairy cows. This was most likely due to the absence of bicarbonate from the TMR. The model had a much larger effect on the time below pH 6 and time below pH 5.6, than on average daily rumen pH (see table below). Hence, the latter two measures are more indicative of SARA than average daily rumen pH. The model resulted in a large reduction of in situ degradability of DM and NDF. NDF degradability was more affected than DM degradability (see table below). This study suggests that induction of SARA by excess feeding

of wheat/barley pellets reduces the ruminal digestion of DM and NDF from mixed hay substantially.

	Treatment			
	SARA	Control	SE	P
Avg. rumen pH	5.87	6.08	0.04	< 0.05
Time < pH 6 (min/d)	916	547	63.4	< 0.005
Time < pH 5.6 (min/d)	353	152	31.9	< 0.001
DM 24 h degr. (%)	52.9	56.4	0.84	< 0.05
DM 48 h degr. (%)	59.6	64.1	0.46	< 0.01
NDF 24 h degr. (%)	21.8	27.2	1.32	< 0.05
NDF 48 h degr. (%)	30.9	39.5	1.05	< 0.01

Key Words: Sub-acute ruminal acidosis, Fiber digestibility, Dairy cows

1746 Diets with high non-fiber carbohydrate and different solubilities for Llamas (*Lama glama*): effects on digestive activity in compartment 1 of the digestive system. M. Sol Morales^{*1}, R. Cabrera¹, A. Lopez¹, C. Carvajal¹, J. Gutierrez¹, and M. Goic¹, ¹Facultad Ciencias Veterinarias y Pecuarias, Universidad de Chile, Santiago, Chile.

A 2x2 latin square experiment was used to characterize digestion of high carbohydrate diets in llamas. Two female llamas, cannulated in compartment 1 (C1), were fed diets containing 40% alfalfa hay; carbohydrate sources differed in solubility. Diet 1 (D1, high degradation rate): beet molasses and oats (12 and 48% of diet DM) and Diet 2 (D2, low degradation rate): dried beet pulp and corn grain (21.7 and 32.3% of diet DM). Both diets had 3.34 Mcal/kg of DE, and NFE/CF ratio of 3.46 to assure bacterial protein synthesis (Hagemeister et al, 1981). Contents of CP and NDF were 13.6 and 34.3, and 11.6 and 41.9 (%) for D1 and D2. The diets were ground (5mm) and fed for 2 h/day. Each experimental period consisted of 15 days as adaptation period, and sampling at days 16, 18 and 20. In sacco 24 h DM degradability (DMD) (Mehrez and Orskov, 1977) was determined simultaneously with sampling of C1 content at 0, 1, 2, 4, 8 and 12 h after feeding to measure pH, VFA and NH₄ concentrations. The DMD at 24 h (%) assessed by Orskov and MacDonald (1979) was 73.9 and 72.7, and the a, b and c parameters of the DMD curve were: 59.45, 22.44, 0.043 and 24.15, 55.59, 0.086 respectively for D1 and D2. The parameters of the C1 (D1 and D2, respectively), were: pH, 7.00 and 6.95; total VFA (mM), 54.0 and 49.4; acetate, 39.9 and 34.9; propionate, 8.5 and 7.0; butyrate, 7.6 and 5.9 and NH₄, 16.9 and 16.4 (mg/dl) were not affected (P>0.05) by the diets. Only pH and NH₄ were different (P<0.05) with hour after feeding. Although there were no differences in utilization of these carbohydrate sources by Llamas, the high buffer capacity of C1 was clearly shown by the pH values obtained (lowest values occurring at 2h after feeding were 6.6 and 6.9 for D1 and D2, respectively). Excessive foaming occurred in one llama fed with D1. These results extend the data base for digestion in llamas from that reported last year evaluating mixed forage diets in llamas. FONDECYT Project 1980-769

Key Words: Llamas, Rumen

1747 Improving the nutritional value of oat hulls for ruminant animals: Study of synergistic interaction between *Aspergillus ferulic acid esterase* and *Trichoderma xylanase* on release of hydroxycinnamic acids from oat hulls. P. Yu^{*1}, J.J. McKinnon¹, D.D. Maenz¹, V.J. Racz^{1,2}, and D.A. Christensen¹, ¹Department of Animal and Poultry Science, University of Saskatchewan, Canada, ²Prairie Feed Resource Centre Inc., Canada.

Oat hulls, a byproduct from the milling process, contain relatively high amounts of hydroxycinnamic acids, mainly *p*-coumaric (PCA: 4-hydroxy-cinnamic) and ferulic (FA: 4-hydroxy-3-methoxycinnamic) acids. These components are believed to be inhibitory to oat hull biodegradability by rumen microorganisms. Previous research has shown that release of FA and PCA by a novel enzyme - *Aspergillus ferulic acid esterase* (A-FAE) was dependent upon particle size ($\leq 250 \mu\text{m}$) of oat hulls and the presence of *Trichoderma xylanase* (T-XYL). In this paper, a further study of the synergistic interaction between A-FAE and T-XYL at different levels (A-FAE at 13 mU, 800 mU and 409.6 U/assay; T-XYL at 1 U, 256 U and 4096 U/assay) on the quantitative release of FA and PCA from oat hulls was carried out. Total alkali-extractable FA and PCA in the oat hulls used in this study were 3.83 $\mu\text{g}/\text{mg}$ and

5.21 $\mu\text{g}/\text{mg}$, respectively. The results indicated that relative to A-FAE alone, the synergistic action of A-FAE and T-XYL was superior in causing the release of FA, indicating that T-XYL is important in acting with A-FAE in the degradation of feruloyl-polysaccharides of oat hulls. Averaged across FAE concentrations, increasing T-XYL level from 1 U to 256 U to 4096 U/assay resulted in an increase (P<0.001) in FA release from 5.6 to 15.0 to 37.5% and PCA from 2.7 to 5.6 to 7.8%, respectively. In contrast, averaged across T-XYL concentrations, increasing A-FAE from 13 mU to 800 mU to 409.6 U/assay resulted in the release of FA and PCA being only slightly increased from 17.5 to 18.6 to 22.0% and from 4.6 to 5.0 to 6.6%, respectively. There was no extensive release of PCA by A-FAE in both the absence and presence of T-XYL, indicating a specificity of A-FAE which only efficiently releases FA and not PCA from oat hulls. Polynomial regression indicated that T-XYL had significant (P<0.001) linear and quadratic effects on FA release (R² 0.91 and 0.89, respectively). This study suggests that a low level of A-FAE (13 mU) with a high level of T-XYL (4096 U) is able to sufficiently break the ester linkage between FA and the attached sugar, releasing FA from oat hulls. This action which causes disruption of crosslinks has the potential to improve hydrolysis of the remaining polysaccharides by rumen micro-organisms which, in turn, would improve rumen degradability of oat hulls.

Key Words: Hydroxycinnamic acids, Ferulic acid esterase, Oat hulls

1748 Effect of supplementation on rate of neutral detergent fiber degradation in forages measured *in situ* and by rumen evacuation. M.R. Weisbjerg^{*}, P. Lund, and T. Hvelplund, Danish Institute of Agricultural Sciences, Denmark.

Forage neutral detergent fiber (NDF) digestibility is highly variable depending on type and maturity of forage and ration composition. The aim of these experiments was to estimate rate of degradation (k_d) for digestible NDF (dNDF) for different forages with and without concentrate supplementation, and to compare the *in situ* method with the rumen evacuation method (REM), as REM is believed to give true values. Four forages; early cut grass silage (ECGS), late cut grass silage (LCGS), whole crop barley silage (WCBS) and grass hay (GH) were compared in two 4x4 Latin squares using rumen, duodenal and ileal fistulated dairy cows. Forages were fed ad libitum, as the only feed in exp. 1, and in exp. 2 supplemented with low fiber concentrates (kg DM/d; 4.5 wheat flour and 1.3 soybean meal). *In situ* k_d of dNDF was estimated using a degradation model including lag time. k_d based on REM was calculated as rumen disappearance of dNDF divided by rumen dNDF pool. Rumen pool was the mean from three different evacuation times over the day. Neutral detergent fiber contents in forage DM were 47, 61, 47 and 65%, and potential NDF digestibilities (21 d rumen *in situ* incubation) were 90, 78, 72 and 80% for ECGS, LCGS, WCBS and GH, respectively. Concentrate supplementation reduced k_d for dNDF measured by REM from 5.4, 3.4, 2.8 and 2.9 ± 0.9 %/h to 3.0, 3.1, 1.8 and 2.3 ± 0.3 %/h for ECGS, LCGS, WCBS and GH, respectively. In contrast *in situ* k_d for dNDF increased by supplementation. The *in situ* method slightly overestimated k_d in unsupplemented diets compared to REM, and the *in situ* k_d overestimation thus became more pronounced in supplemented rations. The negative effect of supplementation on k_d for dNDF found using REM was supported by the reduction in total tract NDF digestibilities due to supplementation from 81, 64, 54 and 62 ± 3 % to 70, 63, 37 and 52 ± 4 % for ECGS, LCGS, WCBS and GH, respectively. This indicates that the REM method gives reliable results but the *in situ* method overestimates k_d for dNDF especially in supplemented rations.

Key Words: NDF, Degradation rate, Rumen evacuation

1749 Mean ruminal retention time of fiber measured using indigestible neutral detergent fiber or ytterbium-labelled feed. P. Lund^{*}, M.R. Weisbjerg, and T. Hvelplund, Danish Institute of Agricultural Sciences.

It is well known that a long mean ruminal retention time (MRT) improves digestibility of fiber. However this may also restrict feed intake. Six forages; early cut grass silage (ECGS), late cut grass silage (LCGS), whole crop barley silage (WCBS), grass hay (GH), maize silage (MS) and alfalfa hay (AH) were compared using fistulated dairy cows in 4 Latin square experiments (A,B,C,D). Forages were fed ad libitum as the only feed (A, C) or supplemented (B, D) with (kg DM/d; 4.5 wheat flour and 1.3 soybean meal). Mean ruminal retention time was determined based

either on rumen pool of indigestible NDF (INDF) divided by duodenal flow of INDF; or on duodenal concentration of ytterbium (Yb) fitted to a two compartment mathematical model with age-dependency in the first compartment (G3G1), subsequent to a pulse dose of Yb-labelled neutral detergent fiber (NDF) from the respective feeds. Supplementation seemed to decrease MRT based on Yb-labelled feeds, whereas the results were less conclusive based on INDF, where supplementation seemed to increase MRT for LCGS and WCBS. Though both methods predicted the highest MRT for unsupplemented GH and the lowest MRT for supplemented MS and AH, correlation between the two methods was moderate ($r=0.61$, 60 obs.). As INDF in contrary to NDF is an ideal nutritional entity, the INDF method is believed to give true values for MRT of INDF and also good estimates for MRT of NDF. Mean ruminal retention time calculated based on Yb-labelled feed was underestimated compared to MRT of INDF. This indicates a migration of Yb from the particulate matter to the liquid pool and from large to small particles in the rumen. Therefore, results from the Yb-method should not be used as absolute values, but are useful to describe the age-dependency of passage.

Method	INDF	INDF	Yb	Yb
Supplementation	No	Yes	No	Yes
Experiment	A (± 20)	B (± 10)	A (± 3)	B (± 3)
ECGS	85	70	46	40
LCGS	63	80	47	41
WCBS	55	73	42	44

Experiment	C (± 10)	D (± 4)	C (± 3)	D (± 2)
GH	90	80	49	40
MS	54	41	41	36
AH	70	53	44	32

1750 Effects of physically effective fiber on chewing activity and rumen fermentation of dairy cows fed barley-based diets. W. Z. Yang^{*1}, K. A. Beauchemin¹, and L. M. Rode², ¹Agriculture and Agri-Food Canada, ²Bioavance Technologies Inc.

Dietary factors that alter the intake of physically effective fiber (peNDF) were evaluated for their effects on chewing activity and rumen fermentation using a double 4 x 4 Quasi-Latin square design with a 2 x 3 factorial arrangement of treatments. The dietary factors were: kernel thickness of processed barley grain, coarse (1.60 mm) or flat (1.36 mm); forage to concentrate ratio (F:C), low (35:65) or high (55:45); and forage particle size, long (7.59 mm) or short (6.08 mm). Eight lactating cows were offered ad libitum access to a total mixed diet (TMR). The peNDF contents in the diets were measured as the total proportion of the sample retained on both sieves of the Penn State Particle Separator (PSPS) or as the proportion retained on a 1.18 mm screen as proposed by Mertens (1997; JDS 80:1463). The peNDF contents in the diets ranged from 9 to 14% using the PSPS, and were double using the 1.18 mm screen. Higher intakes of peNDF due to higher F:C or longer forage particle size increased chewing time. However, increased intake of peNDF due to grain processing had minimal effect on chewing time. Intakes of peNDF measured by both methods were correlated ($r^2=46$, $P<0.01$) to chewing activity. Mean ruminal pH was lower for cows fed flatly rolled barley than for cows fed coarsely rolled barley with no effect of F:C ratio or forage particle size. No correlation was observed between the intake of peNDF and ruminal pH regardless of the method used. Although contents of ruminal VFA were not affected by the dietary factors measured, the intake of peNDF was correlated positively to acetate proportion ($r^2=52$, $P<0.01$) and negatively to propionate proportion ($r^2=-42$, $P<0.02$). These results indicate that peNDF content of the diet is a reliable indicator of chewing activity and VFA profile but not a good indication of ruminal pH. Both methods (PSPS or 1.18 mm screen) can be used to accurately measure peNDF of feeds fed to dairy cows.

Key Words: Effective Fiber, Chewing Activity, Rumen Fermentation

1751 The effect of copper oxide bolus administration on forage fiber digestibility in growing steers. J. D. Arthington* and W. F. Brown, Range Cattle Research and Education Center, University of Florida, Ona.

The objective of this study was to evaluate the effect of an intra-ruminal bolus containing copper (Cu) oxide needles (Copasure; Animax Ltd.,

Columbus, OH) on forage fiber digestion. Eight steers were randomly assigned to receive either a single bolus of Cu containing 12.5 g of Cu oxide needles (B; n=4) or no bolus (NB; n=4). During the 39-d study all steers were individually offered ground limpgrass hay (8.6 ppm Cu) in quantities sufficient to ensure ad libitum access. On d12 (Period 1; P1) and d33 (Period 2; P2) steers were placed in metabolism crates and total forage offered, refused, and fecal production were collected for 7d. Compositated samples of forage offered, refused and feces for each steer at each period were analyzed for DM, OM, NDF, ADF, and CP. All digestibility results were calculated on an OM basis. Liver biopsy samples were collected on d12 and d33. Cu oxide bolus administration resulted in an increase ($P<0.03$) in liver Cu at the start of P1 (556 vs. 296 ppm) and P2 (640 vs. 327 ppm). Total tract OM digestibility and OM intake expressed as a percentage of BW was not different ($P>0.10$) between treatments for either period. Although total fecal ash production was not different, B steers had increased ($P<0.03$) fecal Cu during P1 (164 vs. 21 mg Cu/d) and P2 (79 vs. 23 mg Cu/d). Fecal aluminum, iron, manganese, and zinc were not different for either period. Intake of NDF and ADF did not differ between treatments for either period; however, digestibility of NDF and CP were higher ($P<0.04$) for NB steers in P2 (62.2 vs. 57.1 and 50.2 vs. 43.4 % for NDF and CP digestibility, respectively). Digestibility of ADF tended to be higher ($P=.092$) for NB steers in P2 (57.3 vs. 52.3 %). These data suggest that although Cu oxide boluses are effective in increasing tissue Cu stores, they may contribute to lower forage fiber digestibility.

Key Words: Copper oxide, Fiber digestion, Steer

1752 Effect of forage particle length on ruminal liquid fraction kinetics and straw degradability of steers fed an oat straw diet. H. G. Gonzalez^{*1,3}, O. B. Ruiz², M. L. De la Vega², A. E. Orozco², A. C. Correa³, A. M. Perez³, V. V. Gonzalez³, H. C. Hernandez⁴, E. T. Rubio¹, and L. B. Gerlach⁵, ¹Medicina Veterinaria y Zootecnia-ICB, Universidad Autonoma de Ciudad Juarez, Mexico, ²Universidad Autonoma de Chihuahua, ³Universidad Autonoma de Baja California, ⁴Universidad Autonoma de Baja California Sur, ⁵Universidad de Sonora.

Four Hereford steers (300 kg) fitted with permanent rumen cannulas were used to evaluate the effect of 2 forage chop lengths: 2.5 cm (T1) and 10 cm (T2) on the ruminal liquid fraction kinetics and straw degradability. The animals were fed a basal oat straw diet and they were provided an alfalfa hay supplement (20%). Alfalfa was offered twice daily at 0800 and 1700 h. The estimation of liquid kinetics was made by using a system of equations. A dose of Co-EDTA was infused into the rumen, and ruminal fluid samples were taken from each animal at 0, 1.5, 3, 6, 9, 12, 16, and 24 h post-infusion. The ruminal degradation of straw was estimated by using the nylon bag technique and a non-linear model. Data was analyzed as a switchback design. The feed intake was *ad libitum*. It was observed a higher DMI ($P<.05$) of T1 than T2 (79.7 vs 70.8 g $kg^{-1} W^{.75}$). No differences ($P>.05$) were detected in ruminal volume (79.93 vs 87.7 L) between diets. Nevertheless, steers fed T1 had a faster ($P<.01$) mean time (9.48 vs 16.02 h), dilution rate (7.08 vs 4.36 % h^{-1}), flow rate (5.64 vs 3.82 L h^{-1}), and turnover rate (1.7 vs 1.04 times d^{-1}) than steers fed T2. No differences were detected in degradation rate. No differences ($P>.05$) were detected in ruminal straw degradation to water soluble fraction (constant a; 19.94 vs 20.22 %), and degradation rate (.0258 vs .0255 % h^{-1}) for T1 and T2 treatments. A significant difference ($P<.05$) was detected in potential degradation of b constant (31.04 vs 33.27 %) between T1 and T2, respectively. These results suggest that size of forage affects the kinetic of liquid fraction and DMI.

Key Words: Steers, Kinetics, Degradability rate

1753 Models for describing kinetics of fiber digestion in the rumen. F. O. Carrete-Carreón*, C. E. Cole, J. H. Matis, W. C. Ellis, and C. Lowe, Texas A & M University.

The objective of this research was to evaluate alternate, non-exponential models for describing the expected distribution of lifetimes in the rumen of undigested, U, potentially digestible NDF and its constituent entities, cellulose and hemicellulose. Models having non-exponential distribution of lifetimes of U were emphasized because of the variable content and rate of digestion of entities that comprise NDF. Four classes of models were evaluated for fit to observed lifetimes for U in the rumen. Types of models included: 1) a single exponential distribution of lifetimes for U (G1), 2) a single distribution of gamma distributed, age-dependent

lifetimes for U (GN where $N \geq 2$), 3) simultaneous distribution of GN and G1 lifetimes for U (GN+G1 and G1+G1) and 4) a heterogeneous distribution of exponential, GN, and other non-exponential distributions of lifetimes (GX) for U. The U in ryegrass (*Lolium perenne* L.) hay, cotton seed hulls, CSH, and a mixed diet of 60% CSH ground to pass a 2 mm sieve was determined in triplicate as the U remaining after 0, 2, 6, 12, 18, 24, 36, 48, 60, 72, 96, 144 and 240 h. *in situ* in two rumen cannulated cattle. Discrete time delays statistically different from zero ($P < 0.05$) were frequently resolved by the G1 model. In contrast, inclusion of non-exponential distribution of lifetimes, GN, or simultaneous distributions of lifetime, G1+G1 and GN+G1, accounted for the spectrum of observed lifetimes of U without a discrete time delay and resulted in superior statistical fit ($P < 0.05$). Models assuming an intermediate age-dependency for a single distribution, G2, or two simultaneous distributions of lifetimes, G2+G1 and G3+G1 yielded mean rates of digestion and estimates of indigestible proportions that were of intermediate magnitude. Differences in mean rate of digestion for cellulose and hemicellulose that comprise NDF substantiate the need for non-exponential distributed models of NDF digestion. The G2+G1 or G3+G1 model were least sensitive to initial starting values and most reliable in achieving convergence and are recommended as better descriptors of the process of digestion of NDF in the rumen.

Key Words: Fiber, Digestion, Models

1754 Rumen fluid dilution rates in cattle grazing tropical pastures. M.K. Bowen^{1,2}, S.R. McLennan¹, and D.P. Poppi², ¹Queensland Beef Industry Institute, Yeerongpilly Australia, ²University of Queensland, St Lucia Australia.

Low rumen dilution rates may contribute to the low efficiencies of microbial crude protein (MCP) production sometimes reported with cattle on tropical pastures. Fractional outflow rates (FOR) were estimated in cattle across a range of tropical pasture types and seasonal conditions in south-eastern Queensland, Australia. Eight rumen-fistulated, *Bos indicus* steers (initial BW 329 ± 26 kg) grazed six tropical pastures over 12 months, including: a native pasture (major species C4 Black speargrass (*Heteropogon contortus*) and Forest bluegrass (*Bothriochloa bladhii*)) in the early wet season (NPEW), dry season (NPD) and wet/dry transitional period (NPT); an introduced C4 pasture species, Creeping bluegrass (*Bothriochloa insculpta* cv. *Bisset* (BB)) in the mid wet season; and the introduced tropical legumes Dolichos lablab (*LabLab purpureus* cv. *Highworth* (LL)) and Butterfly pea (*Clitoria ternatea* cv. *Milgarra* (BP)). The temperate annual ryegrass (*Lolium multiflorum* cv. *Tetila* (RG)) was included for comparison. A single dose of chromium-ethylenediamine tetracetic acid (Cr-EDTA; ca.2 g Cr) was injected into the rumen and nine rumen fluid samples were collected over the next 48 h. There was a three-fold variation in FOR across pasture types, representing a range in marker retention times from 8.6-22.9 h. FOR values for early to mid season C4 grasses were similar to those for C3 species (tropical legumes and ryegrass) but that for mature native C4 pasture (NPD) was very low in association with the very low availability of green leaf. Rumen volume did not show the same variation. The results indicate considerable scope to manipulate dilution rate and potentially the efficiency of MCP synthesis.

	NPEW	NPT	NPD	BB	LL	BP	RG

1755 The low forage feeding program, Totalac[®], increases milk production in high producing Holstein cows. P.A. Porter*, C.M. Luhman, and D.W. LaCount, Land O Lakes, Inc. and Cooperative Research Farms.

In 3 trials conducted over a 4-year period at one site, a low forage feeding program (25% of the ration DM) for high producing cows was evaluated; the trademarked name for the concentrate portion of these diets is Totalac[®]. The control rations were 50:50 forage: concentrate

ratio. The forage program in each trial was a 1:1 blend on a DM basis of corn silage and alfalfa silage; commercial applications of Totalac[®] have included hay. All treatments were fed to insure 10% feed refusal. Commercial applications have included hay. In Trial 1, a 4x4 Latin Square with 21-day periods, milk production was increased by 1.1 kg/d ($P < .05$) with the low forage program. Milk composition and DM intake were not different. In Trial 2, initiated at 100 DIM with a 15-week feeding period, the low forage program increased milk production by 3.7 kg/day, DM intake by 1.0 kg/day and milk crude protein content by .09% ($P < .05$). In Trial 3, initiated at day 1 of lactation with a 10-week feeding period, milk production and composition and DM intake were similar for control and low forage treatments. These data demonstrate that high producing dairy cows can be successfully fed low forage diets, even in early lactation. Long-term field usage (>300 days) has not indicated any adverse cow health effects. Totalac is registered trademark of Cooperative Research Farms.

1756 Growth rate of buffalo female calves on urea treated low quality roughages. Syed, H. Raza^{*1}, Shahid Mahboob², M.S. Khan¹, and Arshad Iqbal¹, ¹Faculty of Aniaml Husbandry, University of Agriculture, Faisalabad, Pakistan, ²Dept. Zoology, Govt. College, Faisalabad, Pakistan.

Eight buffalo female calves of almost similar age (5.20 ± 0.5 m) and weight (60.1 ± 1.5 Kg) were randomly allotted into two groups (A) and (B), each with four calves. The calves of group (A) were fed on ration containing untreated wheat straw (UWS) that served as control group. The group "B" was fed on ration containing 3% urea treated wheat straw (UTWS) for a period of six weeks in completely randomized design (CRD). The data on dry matter intake (DMI), daily live weight gain (DLWG), feed conversion ration (FCR) and digestibility of different nutrients viz., dry matter, (DM) crude protein (CP), crude fiber (CF), nitrogen free extract (NFE), other extracts (EE) and organic matter (OM) were recorded. The average values for DMI, DLWG, FCR and organic matter intake (OMI) were found to be 1.76 ± 0.65 and 2.63 ± 0.24 , 0.231 ± 0.04 and 0.332 ± 0.01 , 7.61 ± 0.32 and 7.92 ± 0.41 and 1.64 ± 0.06 and 2.42 ± 0.21 kg for treatments "A" and "B", respectively. The unit (%) increase in digestibility for urea treated wheat straw (UTWS) was found 9.51, 8.09, 13.68, 8.35, 12.46 and 10.35% for DM, CP, CF, NFE, EE and OM, respectively. Results suggested that urea treatment of wheat straw caused improvement in feed intake. The improvement in DMI and digestibility of various nutrients was due to the decrease in lignification, increase in N2 contents and more exposure of treated material for microbial attack for digestion breakdown.

1757 Utilization of gas production manometric system to estimate the rate of degradation of the dry matter (DM), neutral detergent fiber (NDF) and neutral detergent soluble fraction (NDS) of concentrate feeds by cattle, sheep and goat. J. C. Teixeira* and R. A. Santos, Universidade Federal de Lavras, Minas Gerais, Brazil.

The objective of this trial was to evaluate the degradation rate of the DM, NDF and NDS in ground corn, wheat, soybean and cotton meals, cottonseed and citrus pulp. The feeds were milled through 2.0 mm screen and the samples of 400 mg were incubated in vitro, in buffered rumen fluid obtained from 3 cows, 3 sheep and 3 goats. They were incubated whole sample, residue of neutral detergent. The gas production from NDS fraction was obtained by difference between the cumulative production of DM and NDF. The gas production (volume and pressure)

was measured after incubation time of 1, 2, 3, 4, 5, 6, 12, 18, 24, 30, 36, 48, 60 and 72 h, by manometric system. The volume of gas for all feeds was not different ($P < 0.01$) between cattle, sheep and goat (47.23; 52.18 and 49.56 ml respectively), and any interaction between species and fractions of the feeds was detected ($P > 0.05$). The colonization time of all feeds was not different ($P < 0.01$) between species (2.03; 2.32 and 2.93 h) too, but the NDF fraction had higher value ($P < 0.01$) than DM and NDS fractions (5.15; 1.14 and 0.99 h respectively). There was not difference ($P < 0.01$) between species to degradation rate of the tested feeds. However, the fraction NDS showed the best result ($P < 0.01$) for this variable; 10.54 versus 5.84 and 5.81 %/h to DM and NDF respectively. There was not interaction between fraction and feed ($P > 0.05$). This study shows that cattle, sheep and goat have the same behavior to degrade concentrate feeds. On the other hand, gas production technique is simple, fast and it can be used to estimate the degradation rate of feedstuffs, with success.

Key Words: Gas production, Degradation rate, Concentrate

1758 Comparison of the in vitro gas production and the nylon bag degradability techniques to measure degradation rate in cattle, sheep and goat. R. A. Santos and J. C. Teixeira*, *Universidade Federal de Lavras, Minas Gerais, Brazil.*

A study was conducted to compare in vitro gas production and nylon bag degradability techniques as methods of measuring degradation rate of ruminant feeds, and to determinate whether it is possible to predict in situ DM degradability with the gas production manometric technique. The samples of some roughage and concentrate feeds, were milled through 2.0 mm screen. They were utilized 3 animals of each specie to two techniques. The samples stayed incubated in the rumen for 72 h and the readings of in vitro cumulative gas production were made after incubation time of 1, 2, 3, 4, 5, 6, 12, 18, 24, 30, 36, 48, 60 and 72 h. The Pearson correlation coefficients between each pair of variables from in situ and gas production measurements were obtained using SAS. For all tested feeds there was significant ($P < 0.05$) correlation between in situ effective degradability and the volume of gas to all three species. Similarly, in situ DM disappearance was correlated ($P < 0.01$) with volume de gas. To sheep, the estimates of in situ effective degradability and DM disappearance were correlated ($P < 0.01$) with in vitro degradation rates. It can be concluded that the in vitro gas production is related to the degradation rate estimated by the in situ technique. Besides, the gas production technique with its simplicity of use and the possibility of processing a large number of samples in a short time, it will be important to find significant and valid correlation between in situ degradability and gas production parameters.

Key Words: Gas production, Degradation rates, In situ degradability

1759 The effect of rumen pH and forage type on in situ fiber hydrolysis in dairy heifers. C. Spackman*, R.L. Baldwin, E.J. DePeters, and M.L. Sweany, *University of California, Davis, CA.*

The objectives of this study were to determine the effects of rumen pH and forage type, on fiber hydrolysis in the rumens of Holstein heifers. Rumen and duodenal cannulated pregnant heifers (8) were sequentially fed four unbuffered diets, 100% oat hay (100%O), 40% oat hay:60% concentrate (40%O), 100% alfalfa hay (100%A), and 40% alfalfa:60% concentrate (40%A). Both oat hay (O) diets had a crude protein (CP) of 10% and both alfalfa hay (A) diets a CP of 20%. All animals were housed individually and fed twice a day at 8am and 6pm. After a 14d adjustment period to each diet, filter bags (ANKOM F57) containing samples of ground O or A to match the forage in that diet were incubated in the rumen. Bags were placed in the rumen at morning feeding and removed after 2,4,6,8,10,12,16, and 24h. After removal, bags were washed with water 6 times for 1 min in an ANKOM²⁰⁰ Fiber Analyzer at room temperature. Bags were then frozen until further analysis. Rumen pH was recorded every 15 min during the 24h incubation period by an indwelling pH probe inserted through the rumen cannula housed in the pocket of a harness worn by each heifer. Average pH values over the 24h for the four diets were 6.69, 6.38, 6.62 and 5.93 for 100%O, 40%O, and 100%A, 40%A respectively. A greater difference was seen between diets for range of pH values averaged across animals 5.99 to 7.21, 5.43 to 6.93 for 100%O and 40%O, and 5.88 to 7.11, and 5.13 to 6.79 for 100%A and 40%A. Dry matter (DM) loss from bags containing A incubated in

the rumen for 12h was reduced from 43.8% (100%A) to 33.3% (40%A) in response to concentrate. No difference was seen in the O bags with only 30% DM loss after 12h. Loss of DM from bags containing A rose to 54.9% on 100%A, and to 39.9% on 40%A after 24h. Increasing unbuffered concentrate in the diet resulted in a lower average rumen pH and a reduction in fiber hydrolysis for both forage types. Total fiber hydrolysis over 24hours was more reduced for A than O, suggesting that effect of rumen pH on fiber hydrolysis may vary with forage.

Key Words: pH, Rumen, Fiber

1760 Effects of Dietary Proportions of CP/Potentially Digestible NDF, PDF, upon Rates of Digestion, Turnover and Intake of PDF. C. A. Lowe*, W. C. Ellis, F. O. Carrete-Carreón, C. A. Marsh, and E. Moody, *Texas A & M University.*

It is hypothesized that insufficient yield proportions of rumen degraded CP, RDP, and potentially digestible NDF, PDF, limit the rate of digestion, ruminal turnover and intake of PDF. The objective of this experiment was to investigate effects of a wider range in CP/PDF than observed in previous studies. Three mature cattle with established rumen cannulae were fed mineral supplemented, mature bahia grass (*Paspalum notatum*) hay, *ad libitum*, with 0.0, 0.91, or 2.73 kg/d of cottonseed meal in a three by three Latin square design. Leaf and stem portions of the hay were separated, and labeled with different rare earth elements and consumed with a single meal in order to measure their ruminal turnover rate. Also, leaf and stem samples ground to pass a 2 mm screen were incubated in the rumen of the three cows during each period, for 0, 2, 6, 12, 18, 24, 36, 48, 60, 72, 96, 144 and 168 h *in situ* for determination of mean rate of digestion of PDF. The mean rate of digestion of PDF, PDFkd, was estimated by fitting a two-compartment age dependent, age-independent model to the profiles of undigested NDF *in situ*. PDFkd, for both leaf and stem, did not differ ($P = 0.14$), was unaffected by level of dietary protein and averaged 0.027/h. The mean of turnover rate, ke, did not differ for leaf and stem and was significantly ($P < 0.05$) and positively related to CP/PDF. Daily intake rate of PDF (g PDF/kg BW) was significantly and positively, $P < 0.05$, related to CP/PDF. Treatment means were 7.8^b, 8.6^{ab}, and 9.4^a g PDF/kg BW, for 0.0, 0.91, and 2.73 kg/d of cottonseed meal, respectively. Protein supplementation was not related to rate of *in situ* digestion. Thus, the hypothesized positive effects of dietary CP/PDF upon rates of ruminal turnover and intake of PDF were supported while the trend for positive effects on PDF was a non-significant ($P > 0.05$) trend.

Key Words: Rumen, Protein, Kinetics

1761 Effects of ensiling temperature and enzyme additives on the fermentation and in vitro rumen degradation of maize silage. D. Colombatto*¹, F. L. Mould¹, M. K. Bhat², R. H. Phipps¹, and E. Owen¹, ¹The University of Reading, UK, ²Institute of Food Research, Norwich, UK.

Forage maize (352, 447, 227 and 323 g/kg DM, NDF, ADF and starch, respectively) was ensiled in triplicate in 0.5 kg capacity silos, with or without addition of two enzyme preparations. Depol 40 (D, Biocatalyst Ltd, UK) and Liquicell 2500 (L, Specialty Enzymes and Biochemicals, USA) were added to provide relative xylanase activity levels of 7200, 14400, and 28800 units/kg forage DM. The silos were stored at room temperature (R, 15-20°C) for 120 d, or at 40°C for three weeks, then stored at R. Storage at 40°C decreased ($P < 0.05$) the mean pH of D-treated silages (3.71 vs. 3.47 for R and 40°C, respectively). No differences ($P > 0.05$) in the untreated silages (3.99 vs. 3.98) or in the L-treated silages (3.69 vs. 3.72). Starch contents were reduced ($P < 0.05$) by addition of D (252, 136, 102, and 82; 267, 190, 164, and 94 g/kg DM for control and D-treated silages at R or 40°C, respectively), in line with the high levels of α -amylase found in this preparation. NDF and ADF levels were increased ($P < 0.05$) as a result of starch hydrolysis, but this effect was only evident at R. NDF and ADF contents in L-treated silages were decreased ($P < 0.05$) (492 vs. 394, 249 vs. 198; and 489 vs. 392, 253 vs. 190 g/kg for NDF and ADF of control and L, at R or 40°C). As a result, L-treated silages showed an increase ($P < 0.05$) in starch (252 vs. 339 g/kg DM, and 267 vs. 347 g/kg DM for control and L-treated silages at R and 40°C). In vitro gas production and OMD dynamics were assessed using the Reading Pressure Technique. Rumen fluid was collected pre-feeding (0700 h) from two cows fed a maize silage-based TMR. Initial rates of gas production and OMD were decreased ($P < 0.05$)

in the D-treated silages, but were increased ($P < 0.05$) in the L treatments. End-point OMD was reduced ($P < 0.05$) in all D treatments at R, whereas no differences ($P > 0.05$) were observed at 40°C for any treatment. It is concluded that Liquicell 2500 shows potential to increase the rate of rumen degradation.

Key Words: Maize silage, Enzymes, Temperature

1762 Evaluation of a novel psychrophilic enzyme mixture as a potential additive for maize silage. D. Colombatto^{*1}, F. L. Mould¹, M. K. Bhat², G. Black³, and E. Owen¹, ¹The University of Reading, UK, ²Institute of Food Research, Norwich, UK, ³University of Sunderland, UK.

The fermentation characteristics and in vitro degradation of maize silages were examined to evaluate the effects of addition of a psychrophilic enzyme mixture at ensiling. The enzyme mixture (E) was a crude extract from the bacterium *Flavobacterium xylanivorum*, and contained mainly xylanase activity. Forage maize (335, 461, 219, 354 g/kg DM, NDF, ADF and starch, respectively) was ensiled in triplicate in minisilos, with or without enzyme addition at two levels (10 and 20 ml/kg forage DM, E1 and E2). The silos were stored at room temperature (15-20°C for 210 days. No effects ($P > 0.05$) on silage pH were observed (4.04, 4.13 and 3.96 for control, E1 and E2). NDF and ADF were numerically increased ($P > 0.05$) by E addition (417, 423 and 448 g/kg; 209, 216 and 240 g/kg of NDF and ADF for control, E1 and E2), whereas starch contents appeared to decrease with the highest level of addition (388 vs. 352 g/kg DM). In vitro gas production and OMD dynamics were assessed using the Reading Pressure Technique. Rumen fluid was collected pre-feeding (0700 h) from a cow fed on a maize silage-based TMR. Gas pressure measurements were taken 14 times over the incubation period, and sets of treatments were removed in triplicate after 6, 12, 19, 24, 48 and 96 h incubation, to determine OMD. No differences ($P > 0.05$) were detected in the rates of gas production, whereas initial OMD (6 h) was increased ($P < 0.05$) with E1 (174 vs. 202 g/kg for control and E1), but decreased ($P < 0.05$) with E2 (174 vs. 162 for control and E2). End-point OMD (96 h) was unaltered by E1 (774 vs. 480 g/kg for control and E1) but decreased ($P > 0.05$) by E2 (774 vs. 750 g/kg). If confirmed in vivo, the observed increased rate of silage OMD treated with this enzyme could lead to an increase in DM intake. However, over-treatment of silages may result in a decrease of the resultant nutritive value.

Key Words: Maize silage, Psychrophilic, Enzyme

1763 Effect of ensiling, storage time and inoculant use on amino acid composition of alfalfa silage preserved in silage bags. S. P. Crosby^{*1}, J. Zmich¹, R. A. Patton², M. J. Stevenson³, and R. T. Ward⁴, ¹Finger Lakes Nutrition, Genoa, NY/USA, ²Nittany Dairy Nutrition, Mifflinburg, PA/USA, ³Degussa-Huls Canada, Burlington, Ont/Canada, ⁴Cumberland Valley Analytical Services, Maudsenville, MD/USA.

Previous work had suggested that during ensiling of alfalfa lysine and arginine were destroyed to a larger degree than other amino acids. To investigate this, fresh alfalfa from two farms in New York state was sampled immediately before storing in silage bags. Ensiling management on these farms was excellent. Corresponding samples were obtained at feed out. A silage inoculant (Biotol Plus II, Biotol Inc) was added at the rate of 120,000 CFU per gram of wet forage. Sampling was based on field, day of cutting and inoculant use. Ten grab samples were mixed and a sub-sample sent to the laboratory for analysis. Nutrient analyses were performed and amino acid content was determined. In all 34 samples (14 inoculated) were analyzed. Effects of fermentation and correlation between wet and ensiled nutrients were evaluated using Proc GLM of SAS with farm and fermentation as factors. Effects of storage time and inoculation were evaluated using Proc Mixed of SAS with fresh values as covariate. Addition of silage inoculant resulted in statistically higher energy (TDN 59.4 vs 60.8, $P < .05$) because of lower fiber values (ADF 35.1 vs 33.3, $P < .02$) but had no effect on protein fractions except for preserving lysine (4.01 vs 4.38, $P < .08$) and arginine (2.08 vs 2.74, $P < .01$). Main effects (ls means) of ensiling on protein fractions is presented below. We conclude amino acid losses under conditions of good ensiling practice appear to be minimal with the exception of arginine.

1764 Effect of added degradable intake protein on *in situ* and *in vivo* digestibility of processed and unprocessed corn silage fed to beef steers. C.W. Hunt¹, L.R. Kennington^{*1}, G.T. Pritchard¹, J.I. Szasz¹, and W. Mahanna², ¹University of Idaho, Moscow, ²Pioneer Hybrid International, Des Moines, IA.

An experiment with a 2 x 2 factorial arrangement of treatments tested the main effects and interactions of mechanical processing (P+ or P-) of corn silage and DIP level as modified by urea (U+ or U-) on *in situ* and *in vivo* digestion. Treatments were evaluated using four ruminally and duodenally cannulated Angus steers in a 4 x 4 Latin square design. Diets contained 60% corn silage (DM basis) with the remainder being alfalfa hay; 0.5% urea replaced alfalfa in U+ treatments. The level of urea was determined using the 1996 Beef NRC Model to ensure adequate degradable intake protein. Steers were adjusted to silage-based diets for four weeks, then placed on treatment diets for 10-d followed by a 4 d collection period. Chromic oxide was used as an external digestibility marker. Ruminant NH₃ levels were higher ($P < .01$) for U+ than U- diets (13.2 vs. 8.9 mg/dL). Ruminant *in situ* incubations were for 24 and 72 h. No treatment differences ($P > .10$) were observed for OM intake or digestibility. Starch digestibility was greater ($P < .10$) for P+ than P- corn silage (98.6 vs. 96.5%). Urea increased NDF digestibility of P- diets (57.9 vs. 54.6%), but decreased NDF digestibility in P+ diets (53.4 and 56.5%; processing x urea, $P < .05$). Starch degradation *in situ* was greater ($P < .05$) at 24 h for P+ than P- silage (87.4 vs. 66.5%) with no differences ($P > .10$) observed at 72 h. Degradation of NDF was greater ($P < .05$) at 24 and 72 h for P- than P+ corn silage (22.1 vs. 28.4% and 47.8 vs. 50.7%, respectively). The increase in starch degradation in the first 24 h may partially explain the decreased NDF degradation in the P+ silage. Results indicate that improved ruminal starch degradability achieved from mechanical processing is detrimental to NDF degradation, and this effect is not corrected with additional DIP.

Key Words: Corn Silage, Digestibility, Starch

1765 Interactions of corn silage particle size and tallow supplementation on rumen fermentation and performance of dairy cows fed corn silage-based diets. S. G. Onetti^{*}, R. D. Shaver, and R. R. Grummer, *University of Wisconsin-Madison*.

In a previous study (Onetti et al., J. Dairy Sci. 83 (Suppl. 1):277) we showed that including 2% tallow in corn silage-based diets has negative effects on production and rumen fermentation of high producing dairy cows. The objective of this study was to determine if the length of chop of processed corn silage influences the impact of supplemental fat on rumen fermentation and performance of dairy cows. We hypothesized that increasing forage particle length may alleviate the interference of fat on rumen fermentation. Sixteen Holstein cows averaging 120 DIM were used in a replicated 4 x 4 Latin square design with 21d periods. Treatments were arranged in a 2 x 2 factorial design with 0% or 2% tallow (DM basis), and corn silage harvested at either 1.9 cm or 3.2 cm theoretical length of cut. The forage:concentrate ratio was 50:50, and diets were formulated to contain 18% CP and 32% NDF (DM basis). Cows were allowed ad libitum consumption of diets that were fed twice daily as a TMR. Fat supplemented cows had lower DMI and produced less milk fat relative to non-supplemented cows. No effect of silage particle

length was observed for DMI and milk fat production. Milk production tended to be higher for cows consuming short-cut silage without supplemental fat. Rumen pH was not affected by supplemental tallow, and tended to be higher for cows eating long-cut silage. No effect of treatments was observed for rumen ammonia concentration. In this study, tallow supplementation had a negative impact on performance of dairy cows regardless of the corn silage particle length.

1766 The effect of ensiling whole plant corn and wet corn gluten feed simultaneously on silage fermentation. J.A. Mills* and R.J. Grant, *University of Nebraska, Lincoln NE.*

The objective of this study was to evaluate the effect of corn silage combined with graded levels of wet corn gluten feed on silage fermentation in laboratory silos. Six combinations were ensiled in triplicate in micro silos for 37 d. Treatments were corn silage with wet corn gluten feed (WCGF) replacing 0, 20, 40, 60, 80, or 100% of the corn silage (DM basis). The treatment containing 0% wet corn gluten feed was designated as the control. Samples were collected before and after ensiling to determine ensiling characteristics and forage quality. The initial pH of control was highest ($P < 0.05$) at 6.02, and decreased with increasing levels of WCGF (3.91 for 100% WCGF). Packing density increased linearly with addition of WCGF (238 to 611kg/m³, DM basis). Prior to ensiling, water-soluble carbohydrate concentrations averaged 9.4% of DM for all treatments. Ammonia-nitrogen concentration increased (0.04, 0.06, 0.06, 0.09, 0.09, and 0.10% of DM) as did crude protein (9.1, 12.6, 12.8, 18.8, 21.1, and 22.5%) with increasing WCGF. The NDF percentage decreased with addition of WCGF (44.2, 39.2, 38.9, 38.1, 36.3, and 37.8% of DM) to corn silage. After ensiling, pH ranged from 3.87 (control) to 4.16 (40% WCGF). Water-soluble carbohydrates utilized during ensiling decreased with increasing amount of WCGF (8.8, 8.6, 8.4, 6.3, 3.2, and 1.9% of DM). Ammonia-nitrogen concentrations were lowest (0.085% of DM, $P < 0.05$) in the control silage; however, ammonia-nitrogen showed the greatest increase when compared with the initial concentration (50%). Dry matter recovery ranged from 86.7 (20% corn silage) to 96.2 (100% WCGF). In vitro NDF digestibility was greatest ($P < 0.05$) at 60% WCGF (60.7%) and lowest at either 100% WCGF (41.2%) or 100% corn silage (44.9%). Addition of wet corn gluten feed to whole plant corn at ensiling had no negative effects on corn silage fermentation and has the potential to be a suitable way to increase packing density in the silo for corn silage.

1767 Fermentation characteristics of alfalfa hay harvested at different stages of maturity and cutting times in continuous cultures of rumen contents. H. Han*¹, H. S. Hussein¹, J. P. Tanner¹, and H. F. Mayland², ¹University of Nevada-Reno, Reno, NV, ²USDA-ARS, Kimberly, ID.

This study was designed to investigate the ruminal fermentation characteristics of first harvest (1998) alfalfa hay as influenced by the stage of maturity and cutting time. Eight dual-flow continuous culture fermenters were used in an incomplete block design experiment. Nine alfalfa hay substrates were evaluated in four experimental periods (blocks; 8 d each with 5 d for adjustment and 3 d for sample collection) to allow for 3 replications for each treatment. The treatments were arranged as a 3 × 3 factorial. The main factors were 3 stages of maturity (i.e., vegetative, early bud, and 1/10 bloom) and 3 times of cutting (600, 1500, and 2100). The CP content averaged 23.3, 21.6, and 15.5 % (DM basis) for

the vegetative, early bud, and 1/10 bloom stages, respectively. No interactions ($P > .05$) were detected for any of the measurements evaluated. Cutting time did not affect ($P > .05$) OM digestion, N metabolism, or VFA concentrations. The following table summarizes the effects of stage of maturity on ruminal fermentation of the hay. Results suggested that time of cutting alfalfa had no effect ($P > .05$) on ruminal OM fermentation or N metabolism. Despite the highest ruminal degradation of alfalfa CP at the vegetative stage, results indicated greater amounts and higher efficiency of ruminal bacterial protein synthesis at this stage of maturity. Therefore, ruminants may utilize nutrients in alfalfa hay at higher efficiency if it is cut at earlier stages of maturity.

1768 High oil corn silage versus typical corn silage for cows early in lactation. J. G. Linn¹, D. G. Johnson¹, J. M. Akayezy¹, F. N. Owens*², D. W. Rice², B. L. Smith², and M. A. Hinds², ¹University of Minnesota, St. Paul, MN 55108, ²DuPont Specialty Grains, Des Moines, IA 50322.

To test effects of corn silage source on milk production and composition, 45 cows (24 multiparous and 21 primiparous) were fed one of three diets (46% corn silage) for 112 days starting 3 days after calving. Diets included 1) normal corn silage (C), 2) high oil corn silage (HO), and 3) C with 1.4% tallow added to the diet at feeding time (CT). Yield of dry matter (Mt/ha) was 45.9 for high oil corn silage and 38.1 for typical corn silage; starch was slightly less (18.2 vs 18.6% of DM) but ether extract was greater for the high oil corn silage (4.0 vs 3.1% of DM). Diet ether extract averaged 3.5, 3.9, and 4.8% of DM for C, HO, and CT diets. Dry matter intake was 11.1% greater for the HO diet. Apparent digestibility of most nutrients did not differ significantly between treatment groups, but fat digestibility was increased ($P = 0.10$) by adding tallow to C (77.2 vs 72.9%). Total milk yield and fat corrected milk production were numerically (2.2 and 5.0%), but not statistically, greatest for cows fed the HO diet (36.4, 38.3, and 36.8 kg FCM/d for C, HO, and CT diets). Fat concentration and yield both tended to be higher (3.7 and 6.5%) for cows fed HO; milk protein concentrations and yields were lowest for cows fed C (1.18, 1.23, and 1.23 kg protein/d with C, HO, and CT diets). Persistency of milk production, based on regression of milk production from day 60 to 105, tended to be greater for cows receiving more ether extract (monthly declines of 10.1, 7.3, and 7.4% for C, HO and CT diets). Compared with milkfat from cows fed CT, concentrations of short-chain fatty acids (C6 through C15) were higher in milkfat from cows fed the C and HO diets. Trans- and cis-18:1 levels were higher in milkfat from cows fed CT than for cows fed C. Milk fat produced by cows fed CT had more CLA (0.55, 0.64, and 0.84% CLA for C, HO, and CT diets). Feed intake and milk production persistency tended to be enhanced by substituting high oil corn silage for typical corn silage.

ASAS/ADSA Growth and Development

1769 Granular-secretory fraction of the bovine fetal cotyledons: I. Elution pattern and electrophoretic characterization. F.G. Rios¹ and F.A. Nuez², ¹FMVZ- Universidad Autonoma de Sinaloa, Culiacan, Sinaloa Mexico., ²FZ-Universidad Autonoma de Chihuahua..

To determine the elution pattern and electrophoretic characterization of granular-secretory fraction of the bovine fetal cotyledons, an experimental procedure was developed. A multi-proteic complex extract of the granular-secretory fraction of the bovine fetal cotyledons, was frozen at -20°C, then was centrifuged at 46,000 x g for 60 min at 4°C. After that, the supernatant was removed and saved by further use. The pellet was washed with a 0.05 M NH₄HCO₃ buffer solution at pH 7.8 and then was centrifuged at 46,000 x g at 4°C for 60 min, the supernatant also was removed. Both supernatants were mixed and suspended together, then recovered protein was quantified reading in spectrophotometer at 595 nm. The suspension was applied to a 5 x 70 cm column of Sphadex G-75. The protein was eluted with a pH 7.8 buffer solution of 0.05M NH₄HCO₃ at 4°C. From the elution peak observed in the elution pattern, aliquots were obtained for electrophoretic characterization. The fractions with MW, were divided in aliquots of 50 mL or less. 0.125g of sacarose were added for each aliquot. Then were frozen at -20 °C and lyophilized at -44 x 10⁻³ mBar. To characterize the electrophoretic pattern, SDS-PAGE with 12.5% gels were used. Protein recuperation of elution the process was 82.9%. The elution pattern showed three different peaks; the first one named peak A, has the 32.7% of the protein in 150 mL of eluent; in a second peak (B) 62% of protein was obtained in 165 mL of buffer; in a third peak (C), 4.8% of protein was obtained in 140 mL of eluent. The strip pattern of electrophoresis, produced three main regions, the first one grouped three proteins with the higher MW ranks from 42 to 95 kDa, and a second one constituted with proteins of intermediate MW (33.5 kDa); and third one grouping three proteins complex with the lower MW ranking from 20.5 to 28.5 kDa. It is concluded that the procedure described is able to produce partially purified placental bovine proteins usable in bioassays and ultrapurification process.

Key Words: Bovine, Placental , Protein Purification

1770 Granular-secretory fraction of the bovine fetal cotyledons: II. Effect on rate of growth of mice. F.G. Rios¹, F.A. Nuez², and R. Barajas¹, ¹FMVZ- Universidad Autonoma de Sinaloa. Culiacan, Sinaloa Mexico, ²FZ-Universidad Autonoma de Chihuahua.

There are many factors in animal tissues that promote animal growth. The mouse is an adequate animal model to carry out exploratory tests of these substances. Our objective was to determine if an extract of a granular-secretory fraction of bovine fetal cotyledons would promote rate of growth of mice. Sixty pre-pubertal 20-day-old mice (Balb/c strain; male and female; BW 11.4 g), were used in a complete randomized experiment. The animals were allocated individually in metabolic crates, with free access to feed and fresh water. After two days adaptation period, mice were divided into five groups (12 mice/group; six males and six females). The groups were randomly assigned to receive a daily intramuscular injection of various proteins. The treatments were: 1) No injection (control); 2) High Molecular Weight (42-95 kDa) placental protein isolate (HMWP); 3) Intermediate Molecular Weight (33.5 kDa) placental protein isolate (IMWP); 4) Low Molecular Weight (20-28.5 kDa) placental protein isolate (LMWP); and 5) Bovine somatotropin (bST). Body weight and feed intake were recorded daily for a 10 d experimental period. Rate of growth was calculated as average daily gain as percentage of final weight. Feed efficiency was calculated as weight gain divided by feed intake. The experiment was analyzed as a complete randomized design, with comparison of means performed by least significant difference. Feed intake, which averaged 4.12 g/d, was not affected (P>0.10) by treatments. The HMWP treatment improved (P<0.01) growth rate 10.6% (4.71 vs 4.26%/day). Feed efficiency was increased (P<0.01) 16.3% by HMWP (0.235 vs. 0.202 g of gain/g of feed). The other treatments had no effect (P>0.10). We conclude that high molecular weight proteins isolated from the granular-secretory fraction of the bovine fetal cotyledons improves growth in mice.

Key Words: Mice, Growth, Placental Proteins

1771 Tibial lesions in broiler chicks after feeding different dietary concentrations of calcium and ammonium chloride. I. B. Toure*, S. Weisbrode, and J. D. Latshaw, *The Ohio State University.*

Different concentrations of dietary calcium and ammonium chloride were used to influence the development of the tibial growth plate. Day-old male broiler chicks in battery pens were fed 1.0, 0.8 or 0.6% Ca and another diet of 1.0% Ca plus 0.5% NH₄Cl. All diets contained 0.47% NPP and 200 ICU of vitamin D per kg. At 10, 17 and 24 days, six chicks were randomly selected from each treatment. They were euthanized, and the left tibia was removed and cleaned of soft tissue. Calipers were used to measure the length of the bone and the diameter at mid-length. The metaphysis of each end was sectioned longitudinally to permit assessing the growth plate. Distance from growth plate to growth plate was recorded. The bones were fixed in 10% formalin, sectioned, and stained with hematoxylin and eosin. Prior to euthanasia at 24 days, blood was collected by heart puncture to provide plasma for blood chemistry profiles. Plasma from the 0.6% Ca chicks was significantly lower in Ca (8.2 mg/dL) than that of the other chicks (10.1 mg/dL). At 17 days, chicks fed 1.0% Ca had normal growth plates, tibial dyschondroplasia-like lesions (TDLL) were present in those fed 1.0% Ca + 0.5% NH₄Cl (6/6), 0.8% Ca chicks had TDLL (4/6), and 0.6% Ca chicks had rickets (3/6) or rickets at the distal end and TDLL at the proximal end (3/6). A marked proliferation of osteoprogenitor cells with the formation of spicules and congested vascular channels was noted in birds with the 1.0% Ca + 0.5% NH₄Cl treatment and was the predominant distinctive feature between lesions from that treatment and the 0.8% Ca treatment. We have hypothesized that the marked cellular proliferation could be due to bone morphogenic proteins that are released from bones under the influence of NH₄Cl induced acidosis.

Key Words: Calcium, Growth plate, Tibial dyschondroplasia

1772 Relationships between a single-point mutation in the chloride channel-1 gene and phenotypic responses in the Myotonic goat. B. L. Sayre*, S. Wildeus, M. P. L. Dismann, and J. R. Collins, *Virginia State University, Petersburg, VA.*

The Myotonic goat has congenital myotonia, a mutation in the chloride channel-1 (ClC-1) gene, often associated with muscle hypertrophy. This experiment determined relationships between the presence of a ClC-1 mutation and expression of myotonia in a herd of Myotonic goats. Myotonic does (n=63) were genotyped and phenotyped for presence of congenital myotonia. Spanish does (n=18) were used as negative controls. DNA was harvested from whole blood samples. A 177-bp ClC-1 fragment was amplified with PCR, and then digested with Mbo II. The presence of two (105 & 72 bp), three (72, 53, & 52 bp), or four (105, 72, 53, & 52 bp) fragments was used for classification of genotype as homozygous normal (NORM), homozygous mutated (MYO), or heterozygous (HET), respectively. Phenotype was determined as (1) the duration of muscle knots after a sharp strike with a percussion hammer (five repetitions; PH), (2) duration of myotonia (MD), and (3) severity of myotonia (Scored on a scale of 1-9; MS). After a 20 min rest, does had to jump over a step (approx. 45 cm), which induced myotonia in positive does for measurement of MD and MS. There was a positive correlation between genotype and phenotype (P<.001), and phenotypic measures were positively correlated to each other (P<.001). There were no differences (P>.1) in phenotypic measures between NORM and HET genotypes. MYO had greater (P<.001) MD (5.5 vs. 0.0 sec), MS (5.4 vs 1.0), and PH (4.0 vs.1.1 sec) than NORM and HET. Older MYO does (>2 yrs) had increased (P<.01) MD (6.8 vs. .9 sec), MS (6.6 vs. 1.8), and PH (4.8 vs. 1.5 sec) compared to younger does (<2 yrs). Myotonic goats homozygous for a mutated ClC-1 gene exhibited classic phenotypic responses for congenital myotonia, while heterozygous goats did not show signs of myotonia. In goats homozygous for the mutation, the phenotypic response is less apparent in younger animals than older animals. Future studies will link carcass characteristics to the genotype and phenotype relationships.

Key Words: Myotonic goat, Myotonia, Chloride Channel-1

1773 Effect of Somatostatin-14 (SS-14) and Passive Immunization Against SS-14 on Circulating Levels of Growth Hormone (GH) in Rainbow Trout (*Oncorhynchus mykiss*). B. C. Peterson*, P. R. Simpson, R. W. Hardy, T. L. Ott, A. Ahmadzadeh, and G. T. Schelling, ¹University of Idaho, Moscow, ID/USA.

Previous work indicated that rainbow trout (and other fish) exhibit a tremendous growth response when administered exogenous GH. However, regulation of growth hormone secretion in fish is not well characterized. The objectives of this study were to further examine endogenous GH secretion by determining (1) circulating concentrations of GH in resting fish, (2) the effect of SS-14 on GH release, and (3) the effect of passive immunization against SS-14 on GH release in rainbow trout. In the first study, 10 fish (665 g) were bled from the caudal vessel every 20 min for 4 h to assess the pattern of GH release. Any value of GH greater than 2 SD above the mean, followed by at least 2 values of lesser concentration, was considered a pulse. No pulses were detected in any of the 10 fish and serum GH averaged 4.0 ± 2.6 ng/ml. In the second study, 10 fish (550 g) were used to assess the effect of administration of SS-14 on GH release. Fish received an i.p. injection of 5 ng/g BW of SS-14 or saline. Serial blood samples were taken for 4 h starting 20 min pre-treatment. Results of the study indicated SS-14 decreased ($P = 0.09$) GH levels (1.9 ± 1.7 ng/ml vs 6.4 ± 1.5 ng/ml) compared to control fish. In the third study, 20 fish (450 g) were used to assess the effects of passive immunization against SS-14 on GH release. Fish were selected randomly to receive an i.p. injection of SS-14 anti-serum diluted 1:25 in saline or control serum diluted 1:25 in saline. Fish passively immunized against SS-14 increased ($P < 0.01$) GH levels (12.9 ± 1.0 ng/ml vs 4.9 ± 1.1 ng/ml) when compared to control fish. These results indicate GH in rainbow trout is released in an asynchronous fashion with no evidence of pulsatility and the hypothalamic hormone SS-14 apparently regulates GH secretion similarly in rainbow trout as it does in mammals. Elevation of GH by immunizing against SS-14 may provide another approach of increasing growth rates in rainbow trout.

Key Words: Somatostatin-14, GH, Rainbow Trout

1775 Growth and carcass quality of offspring in response to somatotropin (pST) treatment of sows during early gestation. G. Kuhn, C. Rehfeldt*, G. Nrnberg, and K. Ender, *Research Institute for the Biology of Farm Animals, Dummerstorf, Germany.*

The objective of this study (two experiments) was to investigate the influence of pST treatment of pregnant sows on live weight development, compositional characteristics, and meat quality of their offspring. Sixteen sows received daily i.m. injections of 6 mg pST from d 10 to 27 after artificial insemination (pST). Sixteen sows received a placebo (control). Three neonates of the highest (HW), middle (MW), and lowest (LW) birth weights were selected from each litter for dissection into body tissues followed by chemical analysis. The remaining piglets were allocated to the three birth weight classes (HW, MW, and LW) by the help of frequency distribution and reared up to 182 days of age. After slaughter, carcass composition and meat quality of the pigs were examined. All data were statistically analyzed using the mixed model of analysis of variance. The average birth weight of the piglets from treated sows was lower ($P = 0.11$) compared with control piglets with HW neonates being most different ($P = 0.01$). Treatment of sows with pST influenced the body composition of the newborn piglets by increasing the percentages of internal organs ($P = 0.01$) and skin ($P = 0.02$). No differences in protein and lipid content of the piglet body were apparent between the two groups. Postnatal daily gains during various growth phases were not significantly affected, although live weights were lower until d 49 of age due to pST treatment ($P < 0.05$). At slaughter, the percentage of internal organs (empty body basis) was higher in the offspring of treated sows than in corresponding controls ($P < 0.05$). In longissimus muscle, drip loss and intramuscular lipid content were increased due to pST ($P < 0.05$). Moreover, the pH₄₅-value and the brightness of longissimus muscle tended to be affected by pST treatment ($P = 0.08$) to an undesired direction. In conclusion, pST treatment of sows during

early pregnancy was not of advantage for postnatal growth and carcass quality in the offspring.

1776 Effect of oxytocin (OT) on hourly milk secretion in gilts with mastitis. R. S. Kensinger*, D. M. Sanzotti, A. L. Magliaro, A. C. W. Kauf, and L. C. Griel, Jr., *Penn State University.*

The objective of the study was to determine if OT treatment (20 IU given IM) on d 3, 5 and 7 of lactation would increase hourly milk yield (HMY) in gilts with intramammary inflammation. The goal is to improve baby pig performance. Gilts (176.4 kg BW; n = 15 in 5 groups of 3) farrowed, and pigs were cross-fostered to equalize litter size to 9.4. The experimental model was lactating Yorkshire crossbred gilts infused with 3.0 ug endotoxin/kg BW into 2 mammary glands at 0715 on each experimental day. The design was a 3X3 Latin Square Design. Litters were separated from dams between hourly weigh-suckle-weigh measurements (from 0800–1700) in order to assess HMY. Gilts were assigned to receive 0, 3, or 5 OT injections (0X, 3X, or 5X) at 0, 4, or 2 h intervals, respectively. Data were analyzed using the GLM option of SAS according to a mixed model design. Rectal temperature (RT) averaged 39.7 C at 0700, increased to 40.8 C at 1200 ($P < .01$), and returned to 39.9 C at 1700 h. Gilts on 3X and 5X had significantly increased RT compared to 0X ($P < .01$). Mean HMY was 100.7, 111.4 and 124.3 g on d 3, 5 and 7 of lactation, respectively ($P < .02$). Mean HMY by 0X gilts was 112.3 g. Mean HMY by 3X and 5X gilts averaged 80.9 g during nursings with no OT injection, and 160.1 g for nursings with OT treatment ($P < .01$). Response to OT treatment attenuated over time in the 5X group, as HMY averaged 173.5 g with first two injections, 137.6 g at third injection, but only 108.9 g at last two injections. The 3X group averaged 150.6, 233.6 and 182.5 g at 0800, 1200 and 1600, respectively. A treatment by time interaction was detected ($P < .01$). Mean HMY (for all nursings) for 0X, 3X and 5X treatment groups averaged 112.3, 117.6 and 106.5 g, respectively ($P > .10$); and there was no difference in 24-h litter weight gains. Results show OT injections improve milk yield at that nursing; but suggest that stress of injections may interfere with response. Data indicate a need for better methods of OT delivery.

Key Words: Porcine lactation, Oxytocin, Endotoxin

1777 Influence of long-term maternal nutrition on ovine fetal growth and development. SP Quigley*¹, DO Kleemann¹, SK Walker¹, JA Owens², PI Hynd², G Natrass¹, SR Barritt¹, and PA Speck¹, ¹South Australian Research and Development Institute, South Australia, ²University of Adelaide, South Australia.

Genetic and environmental factors during the pre-natal period affect the growth of the fetus and may set the potential for postnatal growth. The objective of this experiment was to investigate the effect of long-term nutritional manipulation of the pre-natal environment on fetal growth and muscle development in sheep. Mature age Merino ewes (n=119) were stratified on liveweight and randomly allocated to 2 nutritional treatments of 1.8 and 0.6 times maintenance requirements (High (H) n=60 and Low (L) n=59, respectively). Ewes were fed a pelleted diet (60% roughage: 40% grain plus additives) for 12 weeks prior to, and throughout pregnancy. Pregnant ewes from each treatment group were stratified on litter size, determined by ultrasonography on day 44, and liveweight and were randomly allocated to one of three sample points (day 50, 92 and 133 of gestation). Ewes were euthanased and the fetuses recovered, weighed and dissected and internal organ weights recorded. Samples of internal organs and longissimus dorsi, semitendinosus and supraspinatus muscles, were taken for gene expression analysis. H ewes were significantly heavier than L ewes ($p < 0.01$) at slaughter on day 50 (73.9±2.1 vs 54.8±2.3kg), day 92 (80.1±1.8 vs 57±3.4kg) and day 133 (86.1±2.5 vs 59.3±3.6kg) respectively. Nutrition had no significant effect on fetal weight and organ development during the first 50 and 92 days of pregnancy ($p=0.44$ and $p=0.26$ respectively). By day 133 fetal weight was significantly different between H (4.08±0.11kg) and L (3.57±0.15kg) fetuses ($p < 0.01$). Singleton fetuses were heavier (4.20±0.11kg) than twins (3.57±0.14kg) ($p < 0.01$), while males (4.0±0.13kg) tended to be heavier than females (3.78±0.11kg) ($p=0.18$). However, there were no significant interactions between level of nutrition, litter size and sex. Liver, lungs and kidneys were heavier in day 133 H than L fetuses ($p < 0.05$), while heart weight did not differ between treatments. These results indicate that the effect of nutrition, prior to and during gestation, on ovine

fetal growth and development are not evident until the last trimester of pregnancy. However, the interaction between pre-natal nutrition and the expression of specific genes and implications for postnatal growth are yet to be determined.

Key Words: Sheep, Maternal nutrition, Fetal growth

1778 Stereoselectivity of porcine beta-adrenergic receptors for ractopamine isomers. J.D. Kissel*¹, D.J. Smith², and S.E. Mills¹, ¹Purdue University, ²USDA-ARS Fargo, ND.

Ractopamine is a β -adrenergic receptor (β AR) ligand that enhances protein gain in animals. The commercial product is a mixture of four stereoisomers. In rats, the levorotatory RR isomer seemed to be responsible for the growth response of ractopamine, consistent with known requirements for biological AR-ligand activation. In order to determine the AR stereoselectivity for ractopamine stereoisomers, binding affinities and adenyl cyclase (AC) activation were determined using cloned porcine β 1- and β 2-AR. Chinese hamster ovary cells stably expressing the porcine β 1AR or β 2AR were grown to confluence and cell membranes collected by centrifugation from lysed cells. Dissociation constants (Kd) were determined by competitive displacement of [¹²⁵I]iodocyanopindolol binding by ractopamine isomers, and binding parameters were determined by non-linear regression. Membrane preparations were also used to quantify activation of AC; cAMP was measured by RIA after 10-min incubations with membranes and test ligands. Activation rates were expressed relative to isoproterenol. Experiments were replicated 3 to 5 times. The RR isomer had a high affinity for both β 1- and β 2AR (Kd of 25 and 29 nM, respectively); Kd estimates for the other stereoisomers were higher (RS = 463 and 78 nM, SR = 3,230 and 831 nM, SS = 16,600 and 3,530 nM for the β 1- and β 2-AR, respectively). Isoproterenol stimulated AC activity 600% relative to basal rates with both β AR subtypes. Ractopamine stereoisomers did not significantly stimulate AC through the β 1AR at moderate (near Kd) or high (10^{-4} M) concentrations. In contrast, the RR isomer increased AC activity 200 to 300% through the β 2AR at moderate and high concentrations; RS and SR isomers elicited a 50 to 75% increase in AC, but the SS isomer was ineffective at the β 2AR. The porcine β AR exhibited stereoselectivity towards ractopamine stereoisomers with the RR isomer exhibiting the highest affinity for β 1- and β 2-AR. In contrast, ractopamine stereoisomers seemed to be more effective at eliciting cAMP responses from β 2AR than β 1AR.

1779 Leptin in neonatal pigs: effects of oral versus intramuscular administration. N.C. Whitley¹, E.L. McFadin-Buff*², P.R. Buff², and D.H. Keisler², ¹University of Maryland-Eastern Shore, Princess Anne, MD, ²University of Maryland, Columbia, MO.

Leptin is found in milk and has been implicated in growth and development of neonates. Milk leptin levels are greatest during the first hours after parturition, then decline and remain low throughout the remainder of lactation. This observation indicates that leptin may influence the neonate if leptin absorption occurs with oral consumption of leptin. The objective of this study was to compare peripheral serum concentrations of leptin in neonatal pigs after oral or intramuscular administration leptin. Thirty-three pigs from 6 sows were used. Between 5 and 20 hours after birth, pigs were weighed, numbered, and treated with either a single intramuscular injection of sterile saline (C), or 2.5 mg/g BW ovine leptin, administered either orally (O) or intramuscularly (I). Pigs from each treatment were chosen for sacrifice at 2, 4, 6, or 8 h after treatment. At euthanasia, blood samples were collected for analysis of serum leptin levels. Liver tissue samples were collected and total liver RNA was used for determination of leptin receptor mRNA expression using porcine 28S and leptin receptor probes in a slot blot technique. There was no effect of time after treatment on either variable. Both oral ($P < .07$; tendency) and injected ($P < .001$) leptin increased serum concentrations of leptin over that of control pigs, with injection producing the highest serum leptin concentrations ($P < .001$). Serum leptin averaged 6.2 ± 4.9 , 19.5 ± 4.5 and 101.7 ± 5.4 ng/ml for controls, O and I pigs, respectively. Leptin receptor mRNA (leptin receptor mRNA:28S mRNA) was not influenced by treatment and averaged 7.7 ± 2.2 , 5.5 ± 2.1 and 6.3 ± 2.2 relative optical density units for C, O, and I treatments, respectively. Milk samples taken from sows soon after parturition were also analyzed for leptin and averaged 98.9 ng/ml. It is concluded that oral administration of leptin can be absorbed to influence peripheral leptin levels.

Leptin levels are highest in the milk of sheep and swine during the first 24 hours after parturition, and this study supports the hypothesis that leptin may play a role in the fetal to neonatal transition process.

Key Words: Leptin , pig, milk

1780 Endocrine response and fat metabolism change in finishing pigs treated with N-methyl-D,L-aspartate(NMA). Gang Xi*, Zirong Xu², and Ping Xiao², ¹University of Minnesota, St. Paul, MN, ²Zhejiang University, Hangzhou, China.

A trial was conducted to investigate the effect of the additional of NMA in diet on several growth related hormones and fat metabolism in finishing pigs. A total of 84 cross bred finishing pigs (average initial BW of 56 ± 0.37 kg) were divided into 6 pens, 14 pigs per pen (7 gilts and 7 barrows per pen). 3 pens of pigs were fed with control diet (corn-soybean meal) and the others were fed control diet addition with 50 mg/kg NMA. During trial, all pigs were given free access to feed and water. After 44 days trial, 8 pigs from each treatment (4 gilts and 4 barrows, weight similar to average group weight, 86.94 ± 0.71 kg for control group, 90.55 ± 1.51 kg for NMA treated group) were sacrificed to collect the sample of liver, longissimus muscle, subcutaneous fat (10th rib), and hypothalamus. Before the pigs were slaughtered, blood samples were collected and allowed to clot overnight at 4 °C. Serum was then harvested after centrifugation and stored at -20 °C until assayed. The addition of NMA in diet increased the IGF-I, Insulin, T₃, T₄ and TSH levels in serum with 50.68% ($p < .05$), 62.61% ($p < .02$), 123.33% ($p < .01$), 60.58% ($p < .03$) and 78.40% ($p < .02$), respectively. Meanwhile, cAMP level and IGF-I level in the liver were increased with 26.93% ($p < .01$) and 26% ($p < .03$) with addition of NMA. In contrast, cAMP level in the hypothalamus was decreased 21.89% ($p < .01$). The data from subcutaneous fat (10th rib) analysis showed that supplement of 50 mg/kg NMA decreased the total activities of malic dehydrogenase (MDH) by 20.54% ($p < .04$), glucose-6-phosphate dehydrogenase (G-6-DPH) by 16.97% ($p < .04$), and decreased the specific activities of MDH and G-6-DPH by 37.46% ($p < .001$) and 35.06% ($p < .01$), respectively. The hormone sensitive lipase (HSL) total activity was increased by 25.00% ($p < .02$) in NMA treated pigs. These results indicated that adding of 50 mg/kg NMA to diet can induce the endocrine dramatic change in finishing pigs, further, inhibit the fat synthesis through suppressing fat synthetases and promote the fat degradation by elevating HSL activity in finishing pigs.

Key Words: Endocrine Response, Fat Metabolism, NMA

1781 Studies on lipid metabolism in hepatocytes from growing pigs. T.J. Caperna*¹, I. Fernandez-Figares¹, A.E. Shannon¹, and D. Wray-Cahen², ¹USDA, ARS, Beltsville, MD, ²FDA, Rockville, MD.

Two *in vitro* assay systems were developed to elucidate the role of leptin in lipid oxidation (OX) and ketogenesis in pig liver. Glucagon (G): insulin (I) ratios of media were manipulated, to investigate interactions of leptin with I and G in hepatocyte monolayers. Hepatocytes were isolated from 30-70kg barrows and seeded into pig tail collagen-coated T25 flasks. Monolayers were established in medium containing fetal calf serum and switched after 24h to serum-free media containing dexamethasone (10^{-6} M) and 1% DMSO. To evaluate palmitate OX, a culture medium was formulated to maintain hepatocytes in an air environment (2:1 mixture of M199/HBSS and M199/EBSS containing 25mM HEPES). Cells were maintained in media containing 50ng/ml I, with G levels increasing from 20 to 500ng/ml. On day four, medium containing 0.23mM $1\text{-}^{13}\text{C}$ -palmitate was added to flasks and 6h gas samples were collected for determination of $^{13}\text{CO}_2$ by IRMS. As the ratio of G:I decreased from 10:1 to 0.4:1, palmitate OX increased by 13.5% ($P < 0.02$, $n=4$); chronic rh-leptin exposure (200ng/ml, 2.5d) had no apparent effect on palmitate OX under these conditions. For determination of ketogenesis, cells were maintained in DMEM/M199 containing both I and G between 1 and 100ng/ml with or without rh-leptin. Medium was collected on the fourth day, following a 24h incubation period and β -hydroxybutyrate (BHB) and acetoacetate (ACAC) were determined fluorometrically using a BHB-dehydrogenase-NADH coupled system. Ketone production was stimulated by G and inhibited by I; depending on the G:I ratio (0.01:1 to 100:1), total ketone production ranged between 100 and 400nmol/mg protein/24h. Addition of rh-leptin had no consistent effect on ketone production or BHB:ACAC ratio (0.98 control, 0.97 rh-leptin). These data suggest that while pig hepatocytes are indeed

sensitive to hormonal manipulation, chronic exposure to rh-leptin did not directly influence lipid OX and metabolism. Supported in part by a Spanish Ministry of Education fellowship (IF-F).

Key Words: Ketogenesis, Lipid oxidation, Leptin

1782 Recruitment and differentiation of intramuscular preadipocytes in stromal-vascular (S-V) cell cultures derived from fetal pig semitendinosus muscles. G.J. Hausman, R. Gaines, and S.P. Poulos, *USDA ARS, Athens, GA*.

Semitendinosus muscles in 105 day old fetuses contain a small number of intramuscular adipocytes. Therefore, we examined intramuscular preadipocyte development in S-V cell cultures derived from semitendinosus muscles from 105 day old fetuses. Both semitendinosus muscles were excised from 4-8 fetuses removed from each of four dams laparotomized at 105 days of gestation. All visible connective tissue was removed from the muscles prior to mincing and processing with a conventional collagenase digestion used to establish adipose tissue S-V cell cultures. Four muscle S-V cell cultures were established since muscles were pooled for each litter. After 1 hour in 10% fetal bovine serum (FBS) one-half of the muscle S-V cell cultures were rinsed to remove debris and insoluble muscle protein. Cultures were reacted for the AD-3 antibody, a preadipocyte marker, or stained for lipid. Preadipocytes (AD-3+) were randomly distributed and not clustered after 1 day in FBS. After 4-5 days in 10% FBS muscle S-V cell cultures reached confluence with large clusters of preadipocytes. Treatment with insulin + dexamethasone (DEX) for 5 days after confluence did not increase preadipocyte number ($P > .05$), but markedly increased preadipocyte size with no consistent change in lipid accretion. The proportion of large preadipocyte clusters (> 3 cells) was similar before and after DEX + insulin treatment ($75 \pm 12\%$ and $75 \pm 9\%$; respectively) but was reduced ($P < .05$) to $46 \pm 6\%$ in cultures treated with insulin alone. Muscle S-V cell cultures seeded on laminin coated dishes contained only preadipocytes whereas laminin coated dishes contained preadipocytes and earlier precursor cells in previous studies of adipose tissue S-V cell cultures. Thus, preadipocyte precursor cells are not present in fetal muscle.

Key Words: preadipocytes, pig muscle, differentiation

1783 The effect of LXR α ligands on adipocyte differentiation. T.D. Brandebourg* and C.Y. Hu, *Oregon State University, Corvallis*.

We recently demonstrated that ligand activation of LXR α , an orphan receptor expressed in adipose tissue, negatively regulated adipocyte differentiation. Administration of an LXR α agonist inhibited differentiation of 3T3-L1 cells while geranylgeraniol (GG), a metabolite of mevalonic acid that antagonizes LXR α , blunted the inhibitory effect of the LXR α agonist. The objective of this study was to extend those results by evaluating the effect of several LXR α ligands [22(R)-hydroxycholesterol (22R), 22(S)-hydroxycholesterol (22S), 20(S)-hydroxycholesterol (20S), 25-hydroxycholesterol (25OH),] on the differentiation of 3T3-L1 preadipocytes. Cells were grown to confluence (d -2) and differentiation was induced on d 0. Cells were treated with either ligand or carrier (ETOH) from d 0 to d 7. In separate experiments, either individual LXR α ligands or cholesterol (Chol), which neither activates nor binds LXR α , were administered at concentrations of 2.5, 5, 10, or 20 mM. Differentiation was evaluated by measuring sn-glycerol-3-phosphate dehydrogenase (GPDH; EC 1.1.1.8) activity on d 8. Independent experiments were performed on duplicate wells where $n=4$ for 22R, 20S, 25OH and Chol and $n=2$ for 22S. 25OH significantly decreased GPDH activity (nmol/(min*mg protein) versus controls by 42% at 2.5 mM ($p < .001$), 53% at 5 mM ($p < .01$), 61% at 10 mM ($p < .001$) and 66% at 20 mM ($p < .001$). Administration of 22R decreased GPDH activity by 9% at 2.5 mM ($p < .05$), 17% at 5 mM ($p < .001$), 35% at 10 mM ($p < .001$) and 41% at 20 mM. Administration of 20S decreased GPDH activity by 12% at 2.5 mM ($p < .001$), 20% at 5 mM ($p < .01$), 27% at 10 mM ($p < .01$) and 57% at 20 mM ($p < .001$). Conversely, administration of 22S, which is known to bind LXR α with high affinity, failed to significantly alter GPDH activity at any concentration. As expected, Chol did not affect GPDH activity at any concentration tested. These results further support a role for LXR α in the regulation of adipocyte differentiation. 25OH was most efficacious while 22R and 20S decreased GPDH activity with similar efficacies. Importantly, 22S represents a

potential LXR α antagonist that may prove useful in subsequent studies of the role of LXR α as a regulator of adipocyte differentiation.

1784 Hormonal regulation of postnatal chicken preadipocyte differentiation in vitro. T. G. Ramsay* and R. W. Rosebrough, *USDA-ARS, Beltsville, MD*.

The present study was designed to develop a chronic culture system from the stromal vascular fraction of chicken adipose tissue for use in identifying hormones or peptides that promote adipocyte formation. Abdominal adipose tissue was excised from 2-4 week old male broilers by sterile dissection. The stromal vascular cell fraction from the adipose tissue was isolated by collagenase digestion, filtration, and subsequent centrifugation. These preadipocytes were seeded in six well culture plates and proliferated to confluency in 10% fetal bovine serum in DMEM/F12 (50:50) medium. At confluency, experiments were initiated to determine hormonal requirements for differentiation in the presence of 2.5% or 10% chicken serum. Isobutylmethylxanthine (10 mM) in combination with 1 μ M dexamethasone could not promote differentiation, as determined by the expression of citrate lyase (CL) and sn-glycerol-3-phosphate dehydrogenase (GPDH) relative to lactate dehydrogenase. Insulin (100 nM) stimulated expression of CL and GPDH ($P < 0.05$) in the presence of 2.5% chicken serum, but not with 10% chicken serum. Triiodothyronine (1 nM) and IGF-I (100 ng/ml) had no effect on differentiation. Dexamethasone (1 μ M) stimulated differentiation in 2.5% or 10% chicken serum ($P < 0.05$). The combination of insulin and triiodothyronine stimulated differentiation ($P < 0.05$) but the effect was no greater than insulin alone in medium containing 2.5% chicken serum. Insulin, dexamethasone and 2.5% chicken serum synergistically stimulated differentiation and can replace 10% chicken serum in culture. Development of a culture system that only requires low serum concentrations for stimulating adipocyte formation may permit identification of important regulatory hormones for differentiation.

Key Words: Preadipocyte, Differentiation, Chicken

1785 Effects of dietary protein on the endogenous calpain/calpastatin proteolytic system in canine skeletal muscle. E. E. Helman*¹, E. H. Lonergan¹, S. M. Lonergan¹, and G. M. Davenport², ¹*Iowa State University, Ames, IA*, ²*The Iams Company, Lewisburg, OH*.

The cysteine proteinases μ - and m-calpain along with their inhibitor, calpastatin, and possibly skeletal muscle specific p94, have been hypothesized to play a role in skeletal muscle protein degradation. Previous studies have indicated a nutritional influence on calpastatin. Our working hypothesis is that protein nutrition can influence regulation of the calpain system in muscle. Our objectives were to determine the effects of dietary protein on the expression of calpastatin and p94 in canine skeletal muscle. A biopsy was taken from the semitendinosus of 56 dogs prior to and after 12 weeks on their respective diets. This experimental design allowed us to examine change within individual dogs. Our study consisted of 8 diets with 7 dogs per diet. Diets 1-4 were 12% total protein and contained ratios of chicken to corn gluten protein of 100:0, 67:33, 33:67, and 0:100%, respectively. Diets 5-8 were 28% total protein with identical protein ratios to diets 1-4. We examined these differences qualitatively using SDS-PAGE and immunoblotting, and quantitatively with densitometric analyses. Western blots were completed using an anti-calpastatin antibody (MA3945, Affinity Bioreagents). p94 blots were examined with an anti-p94 antibody (NCL-CALP-12A2, Novocastrol Labs). The majority of our calpastatin blots showed an expression of three distinct calpastatin bands, the uppermost appearing at approximately 110 kDa. Diet 5 resulted in an increase in the expression of the 110 kDa calpastatin band. A significant difference ($P < 0.05$) was obtained from comparison of the ratio of relative intensity in all three bands when comparing diet 5 (100:0) to diet 8 (0:100). Our results showed no treatment differences in detection of p94. Our calpastatin data suggest that dogs fed a diet containing a higher percentage of chicken protein may have a greater potential to regulate calpain-mediated degradation of muscle protein.

Key Words: p94, calpastatin, canine

1786 Growth of myoblasts derived from genetically different mice, pigs, and cattle. C. Rehfeldt^{*1}, G. Nürnberg¹, U.K. Zettl², E. Mix², M. Wittstock², U. Renne¹, H.J. Papstein¹, and K. Ender¹, ¹Research Institute for the Biology of Farm Animals, Dummerstorf, Germany, ²Rostock University, Rostock, Germany.

The objective of this study was to investigate the influence of long-term selection for different growth traits on intrinsic differences in myoblast proliferation activity and susceptibility to serum deprivation. Myoblasts were isolated from three lines of mice selected for more than 70 generations for 6-weeks body weight (DU-6), protein content (DU-6P), or an index from body weight and physical endurance fitness (DU-6+LB), and from a control line (DU-Ks); from wild-type (WP) or German Landrace domestic pigs (DP); and from Holstein Friesian (HF) or White Blue Belgium (WBB) cattle. During ten days of cultivation in DMEM with 8% FBS the cells of each selected mouse line accumulated more DNA and protein as compared to the control line ($P < 0.01$) with DU-6+LB > DU-6 > DU-6P ($P < 0.05$). Porcine myoblasts from *Semiteminosus* muscle of neonatal WP or DP were grown for six days in MEM α with 10% FBS. The cells from the highly selected DP accumulated less DNA than WP cells (1.06 vs 1.71 g/well, $P < 0.0001$). There were only small differences in the growth kinetics between HF and WBB myoblasts from *Biceps brachii* muscle of three month old fetuses grown for six days in DMEM with 10% FBS. The WBB myoblasts synthesized more protein than HF myoblasts from d 4 to 6 of cultivation (17 to 30%, $P < 0.0001$) whereas DNA levels did not clearly differ. Serum deprivation by changing to 1% FBS during exponential growth as examined in the murine cell lines caused significant decreases in DNA and protein levels ($P < 0.01$) with responses being higher in all long-term selected lines. In part, this was due to apoptosis as examined with DU-Ks and DU-6 cells. Higher percentages of apoptotic cells were found in cultures of DU-Ks ($P < 0.01$) and DU-6 ($P < 0.001$) cells cultivated in 1% as compared with 10% FBS. The results suggest that long-term growth selection is capable to induce intrinsic changes in myoblasts that determine muscle growth.

Key Words: Growth, Myoblast, Selection

1787 Solubilization and purification of a recombinant chicken myostatin expressed as inclusion bodies in *E. coli*. Y. S. Kim^{*1}, K. S. Baek², and M. A. Dunn¹, ¹University of Hawaii, Honolulu, HI, ²National Livestock Research Institute, Namwon, Korea.

The objective of this study was to solubilize and purify a recombinant chicken myostatin fragment expressed as inclusion bodies in *E. coli* culture. Plasmids containing a 369 bp C-terminal fragment of chicken myostatin were transformed into expression competent *E. coli*, followed by IPTG-induced protein expression. Inclusion bodies from the cells were isolated and washed to homogeneity. An average of 80 mg of inclusion body proteins was produced per L of culture. The myostatin inclusion bodies were solubilized in 50 mM Tris buffer containing 8 M urea, 5 mM EDTA, and 200 mM mercaptoethanol. The effect of buffer pH (8, 9, 10, and 11) and incubation condition (30 min boiling and overnight incubation at 25°C with mild shaking) on inclusion body solubilization and purification was investigated using a combination of centrifugation, gel filtration, and SDS-PAGE. When the extent of solubilization was examined by the formation of precipitates after centrifugation at 11,000 g for 10 min, all the above conditions solubilized inclusion bodies at 3 mg/mL. Significant breakdown of recombinant myostatin was observed during the solubilization at pH 10 and 11 in both incubation conditions, but not at pH 8 and 9. A significant proportion of recombinant myostatin stayed as heterogeneous multimer forms in the solubilized inclusion bodies, and increasing pH favored monomer formation. Thus, 30 min boiling or 25°C overnight incubation at pH 9 provided the optimum condition for inclusion body solubilization, and the proportion of monomer was approximately 50% in these conditions. Solubilized inclusion body proteins were refolded using a slow dialysis process by stepwise addition of Tris buffer containing no urea or mercaptoethanol. When the dialyzed inclusion body solutions were subjected to gel filtration, the myostatin monomer fraction was less than 1% of the total protein. This result demonstrates that heterogenous multimer formation had occurred during the dialysis process. Also, it was demonstrated that buffer pH and incubation conditions are important factors affecting solubilization of inclusion bodies.

Key Words: Myostatin, Inclusion body, Purification

1788 Stair-step compensatory growth regimen in dairy heifers and its effects on transition health. M.S. Laubach^{*1}, D.E. Schimek¹, D.B. Carlson¹, A.M. Encinias¹, J.L. Burton², J.W. Schroeder¹, W.L. Keller¹, and C.S. Park¹, ¹North Dakota State University, ²Michigan State University.

The objective of this study was to determine if a one stair-step gestational nutrition regime affects metabolic status and lactation potential of dairy heifers during the transition period. Nineteen Holstein heifers averaging 511 kg of body weight were randomly divided into two treatments. The treatments were imposed at 95 d of gestation. The control group (CON) was fed a diet containing 14% crude protein and 22.5 Mcal of metabolizable energy (ME) per d for the entire 180 d of the trial. The treatment group (TRT) was fed a diet containing 18.5% crude protein and 14.5 Mcal of ME per d until d 185 of gestation, then the diet was changed to 14% crude protein and 29.2 Mcal of ME per d for the realimentation period. Heifers were weighed for three consecutive d at the start, at 185 d of gestation and after calving. Body weights were not different at 185 d of gestation ($P = 0.3$), or at calving ($P = 0.71$). Blood was drawn from the heifers around parturition on d -13, -10, -7, -5, -3, -2, -1, 0 (within 3 hours of calving), 0.5, 1, 2, 3, 5, 7, 10, 13 to monitor various metabolites, white blood cell counts, and lymphocyte populations (CD3, CD4, CD8, and gamma/delta T-cells). Blood glucose levels before calving were higher in the TRT group ($P = 0.08$), but were not affected after calving. Insulin levels were increased in the TRT group before calving ($P = 0.03$), but they were not statistically different after calving. Triglycerides were increased before calving and after calving in the TRT group (before $P = 0.06$, after $P = 0.01$). There were no differences in non-esterified fatty acid concentrations before or after calving. White blood cell counts did not differ between treatments before or after parturition. The results support our hypothesis that compensatory growth during the last trimester of gestation improves metabolic status of prepartum heifers.

Key Words: Heifer, Transition, Compensatory growth, Blood metabolites

1789 Effects of added rumen undegraded protein and bovine somatotropin administration on skeletal growth rates in prepubertal dairy heifers. U. Moallem^{*1}, G. E. Dahl¹, E. K. Duffey-Tower¹, A. V. Capuco², and R. A. Erdman¹, ¹University of Maryland, College Park., ²USDA-ARS, Beltsville, MD.

The objective of this study was to test effects of added rumen undegraded protein (RUP) and recombinant bST administration on skeletal growth in dairy heifers from 90 days of age until onset of puberty. Fifty Holstein heifers (90 days of age) were used in the experiment and were randomly assigned to one of four treatment groups. Treatments consisted of added dietary RUP (+2%, DM basis) and 0.1 mg/kg BW/d recombinant bST applied in a 2 x 2 factorial design. Weekly blood progesterone concentrations, measured beginning at 180 d, were used to determine onset of puberty. Body weight (BW), wither height (WH), and hip height (HH) were measured every 2 weeks. Average age at puberty (314 ± 23 d) was not affected by treatment ($P > .05$). Daily growth rates for BW, WH and HH were increased by both RUP and bST alone while growth responses to the combination of RUP and bST (RUPbST) were additive. The combination of bST and RUP resulted in 42.8 kg, 2.9, and 2.9 cm increases, respectively in 315 d final BW, WH and HH as compared to Controls. Across treatments, average daily BW gain increased from 647 g/d at 105 d to 1330 g/d at 315 d of age while WH and HH rates decreased from 0.15 and 0.16 cm/d at 105 d to .13 and 0.13 cm/d at 315 d of age, respectively. After 200 to 210 d of age, the combination of bST and RUP was the only treatment that significantly increased rates of BW gain compared to Controls. Skeletal growth rates were increased by added dietary RUP between 90 and 200 d of age, but not later. Conversely, the effects of bST on skeletal growth rates were small at the early ages but increased as the heifers approached puberty. These results suggest that protein limited growth during the early post-weaning period, whereas circulating bST was more important during the time just prior to puberty.

1790 Effects of added rumen undegraded protein and bovine somatotropin administration on organ and tissue weights in prepubertal dairy heifers. U. Moallem¹, G. E. Dahl¹, A. V. Capuco², R. L. Baldwin², and R. A. Erdman¹, ¹University of Maryland, College Park, ²USDA-ARS, Beltsville, MD.

Twenty-four dairy heifers were used to determine the effects of added rumen undegraded protein (RUP) and recombinant bST administration from 3 to 10 months of age on organ and tissue weights. The heifers (90 days of age) were blocked randomly into 2X2 factorial trial, which consisted of added dietary RUP (+2%, DM basis) and 0.1mg/kg BW per day of recombinant bovine somatotropin (bST). Twelve heifers, 3 from each group were slaughtered at 5 mo of age and another twelve at 10 mo of age (estimated onset of puberty). Weights of rumen and intestinal tract components including digesta fill along with liver, heart, lungs, spleen and other organs at the time of slaughter. Body weight at 90 d of age was used as a covariate in the statistical analysis to adjust for differences in initial tissue weights. At 5 mo, bST increased the average liver weight by 28.4% compared to Controls and when expressed as a fraction of empty body weight (EBW) by 10% (*P* < 0.05). Rumen undegraded protein increased the empty rumen + reticulum and abomasum weights by 24.4% and 11.5% and as a fraction of EBW by 16% (*P* < 0.01) and 6% (*P* < 0.10) compared with controls, respectively. Rumen digesta fill was increased by 27.3% by added RUP (*P* < 0.05). This enlargement of the anterior digestive tract is consistent with the 10% increased DMI which was observed in the RUP group. At 10 month of age, bST increased the average weights of heart (28%, *P* < 0.01), kidney (22.3%, *P* < 0.01) and liver (17%, NS), and as the relative part of EBW by 15% (*P* < 0.05), 10% (NS), and 5% (NS), respectively. In addition, at 10 mo, omasum, small and large intestine were increased by 22.3%, 22.1% and 22.3%, respectively, by bST administration. These results indicate that administration of bST to growing heifers altered relative organ growth, in a manner that would support increased metabolic activity associated with partitioning of nutrients toward increased protein deposition. In comparison, the added RUP effects were shown only through increased mass of the digestive tract and digesta fill.

Key Words: bST, RUP, Organ weights

1791 Effects of added rumen undegraded protein and bovine somatotropin administration on body composition in prepubertal dairy heifers. U. Moallem¹, K. R. McLeod², A. V. Capuco², K. E. Duffey-Tower¹, G. E. Dahl¹, and R. A. Erdman¹, ¹University of Maryland, College Park, ²USDA-ARS, Beltsville, MD.

The objective of this study was to test effects of added rumen undegraded protein (RUP) and recombinant bST administration on body composition. In a companion growth experiment, added RUP increased rates of BW and skeletal growth early (<200 d age) while bST increased BW and skeletal growth rates at the end of the experiment (>200 d age). Twenty-four Holstein heifers housed and fed with animals in the

growth experiment were randomly assigned to 1 of 4 treatment groups beginning at 90 d of age. Treatments consisted of added dietary RUP (+2%, DM basis) and 0.1 mg/kg BW/d recombinant bST applied in a 2 x 2 factorial design. Twelve heifers, 3 from each treatment group, were slaughtered at 5 mo and another twelve at 10 mo of age. Body weight at 90 d of age was used as a covariate in the statistical analysis to adjust for differences in chemical composition. Across treatments, empty body fat and energy increased with age from 9.1% to 13.9%, and 1.87 to 2.31 mcal/kg at 5 and 10 mo of age (*P* < 0.0001), respectively. There were no significant effects of age on empty body ash and protein content. Across slaughter ages, bST increased ash (*P* < 0.06), tended to increase protein (*P* < 0.13) and decreased body fat content (*P* < 0.05). At 10 mo of age, EB weight was increased by bST, RUP, and bST plus RUP by 23.6, 11.3, and 20.8 kg, respectively. The amounts of body ash (*P* < 0.04) and protein (*P* < 0.07) were increased by bST whereas amounts of body fat were not changed at 10 mo of age. In summary, added RUP did not influence body chemical composition while bST altered body composition at 10 mo by redirecting increased growth towards skeletal development as shown by increased ash and protein deposition.

1792 Relationships between concentration of serum immunoglobulins and growth rate of dairy heifers. W. Jarmuz¹, I. Szlag², and R. Skrzypek², ¹IGiHZ PAN Jastrzebiec, ²Agricultural University of Poznan, Poland.

The study included 115 single-born crossbred Black-and-White heifers that were sampled at the age of 2, 21, 42, 90, 200, and 440 days. At sampling, the heifers were weighed, excepting the day 21 of birth. There were found numerous significant partial correlation coefficients between concentration of serum immunoglobulins and growth rate traits, that were most informative for immunoglobulins determined on the days 2 and 90 after birth. Serum immunoglobulin concentration measured on the day 2 was significantly correlated with body weight at the age of 200 days (*r* = 0.21; *P* ≤ 0.05), and body weight gains measured in different periods within the first 200 days of life (*r* from 0.21 to 0.24; *P* ≤ 0.05). All correlation coefficients between concentration of serum immunoglobulins determined at the age of 90 days and body weight gains measured beginning from the day 2 or 42 after birth were negative and greater than 0.4 (*P* ≤ 0.0001), ranging from -0.42 (42-200 days) to -0.56 (2-90 days). It is concluded, that in growing dairy heifers passive immunity is associated positively with body weight gains during the first 200 days after birth, and that growth rate is associated negatively with immunity acquired actively during the post-colostrum period of life.

Key Words: Heifers, Serum immunoglobulins, Growth rate

1793 Growth Performance, Metabolic and Endocrine Traits in Calves Pair-fed by Automate or by Bucket During the First Month of Life. H.M. Hammon*, A. Nussbaum, G. Schiessler, and J.W. Blum, University of Berne, Switzerland.

Amounts of colostrum (C) and milk intake greatly influence postnatal development of calves. However, as indicated by suckling calves in

natural cow-calf systems, feeding frequencies may also affect postnatal development. In this study growth performance and metabolic and endocrine traits in calves fed C (3 L on d 1, 4 L on d 2, and 5 L on d 3) and milk (5 - 11 L from d 4 up to d 28) by a computer-programmed automate that allowed frequent daily intakes (GrA; n = 7) were compared with calves twice daily pair-fed by bucket (GrB; n = 7). Blood samples were taken after birth on d 1, 2, 14, 21, and 28 before feed intake, on d 3 before and 1, 2, 4, 6 and 8 h after feed intake, and on d 7 every 20 min for 8 h. Plasma concentrations of total protein (TP), urea, glucose, and triglycerides (TG) were measured photometrically. Plasma concentrations of insulin, glucagon, growth hormone (GH), insulin-like growth factor (IGF-I) and thyroxine were measured by RIA. Data were evaluated by analysis of variance using a mixed model with different feeding frequencies and time as fixed effects and the individual calves as random effects. Weight gains did not differ between groups. Plasma TP was higher from d 14 to 28 in GrB than GrA. Plasma glucose increased postprandially (d 3 and 7) in GrB, remained unchanged in GrA, and was higher postprandially (on d 7) in GrA than GrB. Preprandial plasma TG (on d 7) were higher and mean postprandial concentrations (d 7) tended to be higher in GrA than GrB. Insulin concentrations (d 7) tended to be higher in GrA than GrB. During an 8-h period GH (d 7) was higher from 120 to 140 min, but was lower from 240 to 360 min after feeding in GrA than GrB. Plasma IGF-I was higher in GrA than GrB on d 7, 14 and 28. In conclusion, feeding at high frequency with an automate transiently changed some metabolic and endocrine traits, but had no significant effects on growth performance during the first 4 wk of life.

Key Words: Neonatal Calves, Feeding Frequency, Metabolites and Hormones

1794 Age-related changes of the somatotrophic axis in cloned Holstein calves. K.E. Govoni*, X.C. Tian, G.W. Kazmer, M. Taneja, B. Enright, A.L. Rivard, X. Yang, and S.A. Zinn, *University of Connecticut, Storrs, CT.*

Developmental anomalies, as well as high rates of fetal and post-natal mortality have been reported in somatic-cell cloned cattle. Our objective was to determine if the development of the somatotrophic axis in somatic clones (clones) was similar to AI produced heifers (controls). We compared the changes in Growth Hormone (GH), Insulin-like Growth Factor (IGF) -I and IGF Binding Proteins (BP) -2 and -3 of 4 clones generated from a 13-year-old cow with 4 age matched controls from 5 to 15 mo of age. Once a month for 7 mo, serum samples were collected every 30 min for 6 h. Animals were also challenged with GH Releasing Factor (GRF; 3 µg/100kg BW) and Somatostatin (SRIF; 1.87 and 5 µg/100kg BW) at mo 10. Concentrations of GH for clones and controls were compared with 4 post-pubertal heifers (PP; 11 mo of age). Averaged across all time points, concentrations of GH were not different between clones (7.29 ± .96 ng/mL) and controls (5.50 ± .89 ng/mL). However, there was a decline in GH over time in controls, but not in clones (p<.01). GH concentrations in PP animals were less than controls in mo 1 (p<.01) and less than clones in mo 2 (p=.05). When PP, clones and controls were compared at similar ages, concentrations of GH were not different between the three groups. GRF-induced GH secretion was greater in clones than controls (p<.02). SRIF (1.87 µg) inhibition of GRF-induced GH was less (p<.01) in clones than controls. IGF-I concentrations of clones and controls paralleled each other over time. However, overall concentrations of IGF-I were less in clones than controls (203.7 ± 13.8 vs 306.4 ± 13.1 ng/mL). BP-3 was greater in controls than clones (85 ± 3.7 vs 70 ± 3.7%), but did not change over time for either group. BP-2 did not change over time and average concentrations were not different between clones and controls. Although, there were some differences in measures of the somatotrophic axis between these clones and these age-matched controls, values of each variable measured were within reported ranges for cattle of similar ages, indicating that these clones have normal development, in terms of the somatotrophic axis. However, further studies are required using clones derived from different cell types and from different donor animals to validate this conclusion.

Key Words: Somatic Cell Derived Clones, Growth Hormone, Insulin-like Growth Factor-1

1795 Feed Intake Patterns, Metabolic and Endocrine Traits, and Growth Performance During the First Month of Life of Calves Provided Restricted or Unlimited Amounts of Colostrum and Milk with an Automate. J.W. Blum*, A. Nussbaum, G. Schiessler, and H.M. Hammon, *University of Berne, Switzerland.*

Amounts of colostrum (C) and milk intake greatly influence postnatal development of calves. Automatic feeding systems allow calves to drink high amounts of C and milk divided into several small portions per d. In this study growth performance and metabolic and endocrine traits were compared in calves fed by a computer-programmed automate either restricted amounts of C (GrR; n = 7) and milk or C and milk ad libitum (GrL; n = 7). Feed intake and meal frequencies were measured by the automate. Blood samples were taken after birth on d 1, 2, 14, 21, and 28 before feed intake and on d 3 and 7 before and 1, 2, 4, 6 and 8 h after feed intake. Plasma concentrations of total protein (TP), albumin, glucose, non-esterified fatty acids (NEFA), triglycerides and cholesterol were measured photometrically. Plasma concentrations of insulin, glucagon and insulin-like growth factor (IGF-I) were measured by RIA. Data were evaluated by analysis of variance using a mixed model with different feeding frequencies and time as fixed effects and the individual calves as random effects. There were group differences of dry matter intakes and meal sizes per visit (GrL > GrR) and total visits (with and without milk intake) at the automate (GrR > GrL). Feed intake in GrL increased from 1 to 4 d, then remained stable and was always higher than in GrR. Weight gain was greater in GrL than GrR in wk 1. There were significant group differences of plasma concentrations of TP (GrL > GrR; d 28), albumin (GrR > GrL; d 1 - 2), cholesterol (GrR > GrL; d 28), NEFA (GrR > GrL; d 1 - 2), insulin (GrL > GrR; d 1 - 2), and IGF-I (GrR > GrL; d 1 and 28). In conclusion, calves fed by automate ad libitum were capable of ingesting high amounts of C and milk already during wk 1 of life. High C and milk intakes in GrL were accompanied by moderate metabolic and endocrine changes. High weight gains in wk 1 could not be maintained up to 1 month.

Key Words: Feeding intensity, Growth performance, Metabolites and Hormones

1796 Glucose metabolism in Holstein and Jersey calves fed milk replacer once versus twice daily. C. M. Cheatham*¹, C. C. Williams¹, J. M. Fernandez¹, W. A. Nipper¹, H. G. Bateman, II¹, J. C. Lovejoy², D. T. Gantt¹, L. R. Gentry¹, and G.E. Goodier¹, ¹Louisiana State University Agricultural Center, Baton Rouge, LA, ²Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA.

Eighteen Holstein and fifteen Jersey heifer calves were fed milk replacer (MR) once (1x) or twice (2x) daily to determine effects of two feeding systems on glucose metabolism during the neonatal period. From birth to 5d of age all calves were fed colostrum or whole milk. From d5 to d6 of age, all calves were fed MR 2x. Beginning on d7 of age, calves fed 2x were offered 15g MR DM/kg birth weight reconstituted to 15% DM. Calves fed 1x were offered 15g MR DM/kg birth weight reconstituted to 21%DM. At 5 wk, MR was decreased by 50% for all calves followed by abrupt weaning at 6 wk. Calves were allowed free access to calf starter and water throughout the study. At weeks 3 and 6, Minimal Model intravenous glucose tolerance tests were performed to assess glucose effectiveness (S_G), an estimate of insulin-independent glucose disappearance; insulin sensitivity (S_I), an estimate of insulin-dependent glucose disappearance; and acute insulin response ($AIR_{glucose}$), insulin secretion relative to glucose administration. Of the three parameters measured, Jersey calves differed from Holsteins only by having greater S_I ($P < 0.05$). The S_I and S_G were similar for calves regardless of MR feeding frequency ($P > 0.10$). However, S_I decreased with age for all calves ($P < 0.05$) while $AIR_{glucose}$ increased with age ($P < 0.05$). In calves fed MR 2x, $AIR_{glucose}$ was greater than in calves fed MR1x ($P < 0.05$). These data suggest that feeding calves MR 1x versus 2x did not significantly affect glucose metabolism during the neonatal period.

Key Words: Calves, Glucose metabolism, Insulin sensitivity

1797 Evaluation of bovine or porcine plasma in calf milk replacers on mortality, morbidity, intake and growth of young dairy calves. J. D. Quigley, C. J. Kost, and T. M. Anspach*, APC Company, Inc., Ames, IA.

Replacement of a portion of the whey protein concentrate with spray-dried animal plasma in calf milk replacer (CMR) formulations can provide a source of immunologically active IgG without markedly affecting digestibility or intake. However, data indicating the importance of the species origin of animal plasma are lacking. In this study, Holstein bull calves (n = 120) at the APC Company Research Facility in Ames, IA were fed one of three CMR for 42 d. Experimental CMR were formulated to contain whey protein concentrate (WPC) as the primary protein source or WPC plus 5% spray-dried bovine plasma (SDBP) or WPC plus 5% heat stable porcine plasma (SDPP). Calves were also offered commercial calf starter and water for ad libitum consumption. Mortality was reduced from 25% to 7.5% and 5.0% when calves were fed CMR containing WPC, SDBP, or SDPP, respectively. Morbidity, measured as number of days that calves had diarrhea (scours) was reduced by 30% (P < 0.01) when SDBP or SDPP were fed. Mean number of days with scours were 6.1, 3.9 and 4.7 d for calves fed WPC, SDBP and SDPP, respectively. Fecal scores during the 42-d study tended to be reduced (P < 0.10) and feed efficiency tended (P < 0.10) to be improved when SDBP or SDPP was fed. Mean fecal scores (1 = normal feces to 4 = severe scours) were 1.66, 1.59 and 1.61 for calves fed CMR containing WPC, SDBP and SDPP, respectively. Mean feed efficiency was 170, 265 and 211 g of BW gain/kg DM intake, respectively. Calves fed SDPP tended (P < 0.10) to consume less starter, total DM and protein compared to calves fed SDBP and tended (P < 0.10) to have lower BW gain during the first 28-d of the study. Mean BW gain from d 0 to d 28 was 83, 119 and 80 g/d for calves fed WPC, SDBP and SDPP, respectively. There were no differences in BW gain after 28 d, and calves ended the study weighing 56.4, 58.2, and 56.8 kg, respectively. Both SDBP and SDPP were effective in reducing morbidity and mortality during the trial and may be effective adjuncts to a calf management program.

Key Words: calves, milk replacer, immunity

1798 Body composition of Piedmontese x Hereford and Wagyu x Hereford newborn calves. P.L. Greenwood*^{1,2}, H. Hearnshaw^{1,3}, D.W. Hennessy^{1,3}, J.M. Thompson^{1,4}, and G.S. Harper^{1,5}, ¹Cooperative Research Centre for Cattle and Beef Quality, Armidale, Australia, ²NSW Agriculture Beef Industry Centre, Armidale, Australia, ³NSW Agriculture Research and Advisory Station, Grafton, Australia, ⁴University of New England, Armidale, Australia, ⁵CSIRO Livestock Industries, Brisbane, Australia.

Newborn calves of extreme genotypes for marbling and muscle growth potential were studied to provide base-line data for studies aimed at elucidating the cellular basis and regulation of growth and development of carcass tissues. Female calves born to Hereford cows and sired by Piedmontese (PxH calves, LW range 31.4 to 42.0 kg, n = 10) or Wagyu (WxH calves, 27.6 to 35.4 kg, n = 8) bulls were slaughtered within 24 h of birth. Organs and selected muscles and body tissues were dissected out and weighed. Empty body weights were determined, and carcasses prepared to a standard before being Computer Tomography (CT)-Scanned. Carcass composition was determined by integration of cross-sectional tissue areas from serial CT body scans. As a proportion of empty body weight, PxH calves had (P < .05) higher dressing percentage than WxH calves (mean \pm SEM, 57.6 \pm .6% vs 54.9 \pm .5%, respectively), more carcass lean (75.1 \pm .4% vs 72.9 \pm .6%), less carcass fat (4.8 \pm .1% vs 5.2 \pm .1%) and bone (20.1 \pm .4% vs 21.9 \pm .5%), larger *M. semitendinosus* (.45 \pm .01% vs .38 \pm .01%) and *M. longissimus et lumborum* (.46 \pm .02% vs .39 \pm .02%), and lower combined weight of organs (9.0 \pm .1% vs 10.2 \pm .2%). PxH calves also tended to have less skin (11.5 \pm .3% vs 12.3 \pm .3%, P < .10) than their WxH counterparts, but there was no difference in the proportion of abdominal plus kidney fat (.55 \pm .04% vs .61 \pm .04%, P > .10). When adjusted for differences in empty body weight, significant effects (P < .05) remained for weight of fat in the carcass, weight of *M. semitendinosus* and combined weight of organs. The results demonstrate that differences in the distribution of body tissues between Wagyu x Hereford and Piedmontese x Hereford cattle are apparent at birth.

Key Words: Cattle, newborn, body composition

1799 Post-weaning growth of cattle destined for Japanese and Korean markets: Relationships between growth during backgrounding and intramuscular fat percentage (IMF%) at slaughter. M.J. McPhee^{1,2}, S. Harden^{1,3}, P.L. Greenwood*^{1,2}, and V.H. Oddy^{1,4}, ¹Cooperative Research Centre for Cattle and Beef Quality, Armidale, Australia, ²NSW Agriculture, Beef Industry Centre, University of New England, Armidale, NSW 2351, Australia, ³NSW Agriculture, Tamworth Centre for Crop Improvement, Tamworth, NSW 2340, Australia, ⁴Meat and Livestock Australia, 165 Walker Street, North Sydney, NSW 2060, Australia.

Effects of growth rate during backgrounding (weaning to commencement of finishing) on intramuscular fat percentage (IMF%) at slaughter of beef cattle destined for Japanese or Korean markets were assessed. Cattle were grazed on temperate perennial pastures on the Northern Tablelands of NSW, Australia (4 experimental years; years 1 to 4, n=329, 273, 290 and 107, respectively). Angus, Hereford, Murray Grey and Shorthorn steers were grown either without supplementation or with supplementary feeding of high protein pellets or with access to a forage crop to an overall group mean target LW of 400 kg. They were finished either on pasture or in the feedlot for Korean (average LW 520 kg) or Japanese (average LW 600 kg) market weights. IMF% was measured on a sample of *m. longissimus* at the 12/13th rib using near infrared spectroscopy. The variance in IMF% was analysed for each year by fitting a mixed linear model; the terms were market category, finishing system, market category x finishing system, breed, carcass weight and backgrounding growth rate. All terms contributed significantly to IMF% (P < .05). The proportions of total variation in IMF% accounted for across the years were: market (.9% to 22%), breed (7% to 14%), carcass weight (1% to 8%), market category x finishing system (.9% to 9%), finishing system (16% to 31%), backgrounding growth rate (.7% to 6.1%) and unexplained (residual) variation (30% to 63%). The results show that backgrounding growth rate had a small positive effect on IMF%, and that finishing system had a greater effect on IMF%. However, the high degree of unexplained variation supports the need for further investigations into factors affecting IMF% at different market weights.

Key Words: Cattle, growth rate, intramuscular fat

1800 Effect of Synovex-S[®] on pituitary-thyroid axis response to challenge with a combination of thyrotropin releasing hormone (TRH) and growth hormone releasing hormone (GHRH) in beef steers. S. Kahl*, T.S. Rumsey, and T.H. Elsasser, USDA, Agricultural Research Service, Beltsville, MD.

Thyroid status is an important regulator of growth. Studies have suggested that thyroid hormones may be involved in the mechanism of action of estrogen-based growth promoters in steers. This study evaluated the effect of Synovex-S[®] ear implants (SYN, 20 mg estradiol benzoate + 200 mg progesterone) on basal and TRH/GHRH-stimulated plasma concentrations of thyrotropin (TSH), thyroxine (T₄), and triiodothyronine (T₃), and on hepatic and pituitary 5'-deiodinase (5'D) activity. Sixteen crossbred steers (404 \pm 13 kg) were fed individually a 30:70 silage:concentrate diet (17.8% CP, 2.87 Mcal ME/kg DM) to gain 1.2 kg BW daily and assigned to no implantation (control) or implantation (n = 8). Two days before and 14, 28, 42, and 56 d after implantation, all steers were challenged (i.v.) with a combination of TRH + GHRH (1.0 + 0.1 μ g/kg BW, respectively). For each challenge jugular blood samples were obtained at 0, 10, 20, 30, 40, 60, 120, 240, and 360 min after challenge for TSH analysis and at 0, 1, 2, 4, 6, 8, 12, and 24 h after challenge for T₄ and T₃ analyses. Primary response to challenge was measured as area under the time x concentration curve (AUC). Liver and pituitary samples were collected at slaughter 5 d after the last challenge. Compared to control steers, SYN did not affect (P > 0.05): (a) basal plasma concentrations of TSH, T₄, and T₃, (b) TSH and T₃ responses to TRH + GHRH challenge at any time after implantation, and (c) 5'D activity in liver (type-I) and pituitary (type-II). However, SYN increased T₄ response to each TRH + GHRH challenge (742 vs 589 ng/mL x h, SEM = 52, P < 0.05). Results indicate that the primary action of SYN on the pituitary-thyroid axis in steers is greater sensitivity of the thyroid gland to TSH stimulation resulting in increased T₄ secretion.

Key Words: Growth promoters, Thyroid hormones, Thyrotropin

1801 Performance, carcass characteristics and plasma levels of thyroid hormones and insulin like growth factor-I in feedlot intact crossbred (*Bos taurus* × *Bos indicus*) Brazilian Superyoung System. L. A. L. Chardulo^{*1}, J. A. Ferro², A. C. Silveira¹, L. R. Furlan¹, M. D. B. Arrigoni¹, H. N. Oliveira¹, M. I. T. Ferro², and M. Macari², ¹UNESP - Botucatu, SP/Brazil, ²UNESP - Jaboticabal, SP/Brazil.

The objective of this study was to evaluate the performance, carcass characteristics and the levels of metabolic hormones in male and female young cattle of different genetic groups kept in feedlots and slaughtered at 12 months of age. Two-hundred male and female young cattle, crossbred from males of five breeds (Charolais, Gelbvieh, Aberdeen Angus, Hereford and Simmental) and Simmental × Nellore crossbred females, were weaned at seven months of age and kept in feedlots for 180 days in a completely randomized design. Diets were formulated according to the age (growth and finishing phases) and weight of animals. The performance was evaluated by weight gain and slaughter weight. The plasma levels of thyroid hormones were evaluated by EIA and the levels of IGF-1 by RIA. Hereford animals had a higher slaughter weight when compared to the other breeds ($p < .01$). Males had better performance than females for all characteristics evaluated ($p < .01$). Ultrasonography measurements showed a higher marbling rate in Aberdeen Angus animals, as well as lower hindlimb percentage and chilling losses, which resulted in a higher fat index in the carcass ($p < .01$). Aberdeen Angus animals had higher triiodothyronine (T_3) levels and higher IGF-1 levels during finishing phase as compared to the other breeds ($p < .01$). Correlations between T_3 and subcutaneous fat ($r = 0.76$, $p < .01$) and marbling ($r = 0.79$, $p < .01$) were significant as well as between IGF-1 and subcutaneous fat ($r = 0.67$, $p < .01$) and marbling ($r = 0.59$, $p < .01$). Among the breeds considered in this study, Aberdeen Angus seems to be the most adequate to be used in crossings for intensive meat production like the Brazilian Superyoung System.

Key Words: Crossbred cattle, Meat production, Plasma hormones

1802 Effects of estradiol administration and level of protein intake on nitrogen metabolism and insulin-like growth factor-1 (IGF-1) gene expression in muscle in growing steers. O Cheng^{*1}, W Knaus¹, M Boehm¹, and D Beermann^{1,2}, ¹Cornell University, ²University of Nebraska at Lincoln.

Modulation of IGF-1 expression in muscle was assessed using a ribonuclease assay developed to quantify the abundance of IGF-1 mRNA in ovine and bovine tissues. Four Holstein steers weighing 250 kg were fed a low-protein diet (7.6% CP) or a diet supplemented with urea to meet the ruminal requirement for N (12.2% CP) and administered twice-daily subcutaneous injections of estradiol-17 beta (500 micrograms at 12-hr intervals) or excipient using a 4 × 4 Latin Square design. Daily N retention increased from 10 to 18 g/d and plasma urea nitrogen (PUN) increased from 3.6 to 7.8 mg/dL (both $P < 0.05$) when the higher protein diet was fed. The higher level of protein intake increased IGF-1 mRNA abundance in the semimembranosus muscle to 189% of control levels ($P = 0.07$), and circulating IGF-1 concentration was not altered. Estradiol administration increased plasma estradiol 18-fold (2.4 to 48.5 pg/ml) but did not alter plasma PUN or IGF-1 gene expression in skeletal muscle (all $P > 0.1$). An interaction between protein intake and estradiol treatment was observed for IGF-1 mRNA abundance in skeletal muscle ($P = 0.11$). When the higher protein diet was fed estradiol treatment increased IGF-1 mRNA abundance in skeletal muscle 42% compared to excipient treatment. Results from this study indicate that skeletal muscle growth in steers may be controlled through autocrine or paracrine influence of IGF-1 mRNA abundance. The short-term twice-daily estradiol administration failed to enhance N balance, suggesting that either a longer treatment period or a higher level of protein intake is necessary for estradiol to exert its anabolic effect in growing Holstein steers.

Key Words: Muscle growth, IGF-1, estradiol

1803 Temporal effects of daily estradiol administration on nitrogen metabolism and insulin-like growth factor-1 (IGF-1) gene expression in liver and skeletal muscle in growing lambs. O Cheng^{*1}, M Boehm¹, and D Beermann^{1,2}, ¹Cornell University, ²University of Nebraska at Lincoln.

Twelve Suffolk-sired crossbred wether lambs weighing 23 kg were fed a diet containing 67% barley, 15% soy hulls and 13.5% soybean meal (15.6% CP). The objective was to assess the temporal effects of subcutaneous estradiol administration (175 micrograms at 12-h intervals) on plasma estradiol, urea nitrogen (N) and IGF-1 concentrations, on daily N balance, and IGF-1 gene expression in liver and skeletal muscle. A ribonuclease assay was developed to quantify IGF-1 mRNA abundance in muscle and liver RNA samples. Daily N balance and jugular blood samples were collected from all lambs over a 7-day control period. During the following 7-day estradiol treatment period two lambs were euthanized each day at 1, 2, 3, 4, 5, and 7 days for liver and muscle sample collection. Daily N balance samples were collected from each lamb until removed for tissue sample collection. Subcutaneous administration of estradiol increased plasma estradiol concentration 17-fold (from 50 to 450 pg/ml) within 15 min of injection and maintained concentrations at 300 pg/ml at 75 min and 150 pg/ml 300 min after administration ($P < 0.01$). Estradiol administration did not alter daily fecal and urinary N excretion, daily N balance, biological value, or PUN concentration (all $P > 0.05$). Likewise, circulating IGF-1 concentration, and liver, semitendinosus and longissimus muscle IGF-1 mRNA abundance were not altered at any of the treatment intervals (all $P > 0.05$). The lack of anabolic response to estradiol administration was unexpected. Control period variable means for N balance (11 g/d), biological value (0.59) and PUN concentrations (15 mg/dL) were higher than expected. These data suggest that the lambs were receiving adequate protein intake and may have been too close to their genetic potential for rate of protein gain, or that the treatment period was too short for a response to estradiol administration to be observed.

Key Words: Estradiol, N balance, IGF-1 expression

1804 Effects of immunization against LHRH on growth performance, sex characteristics, and meat quality of intact male pigs. C. Y. Liu^{*1}, L. C. Cheng¹, P. C. Yang¹, T. Y. Chang^{2,3}, M. Shen³, C. L. Finstad³, and C. Y. Wang^{2,3}, ¹Pig Research Institute Taiwan, ROC, ²United Biochemical, Inc., Asia, ROC, ³United Biochemical, Inc., USA.

Twenty-two young intact male pigs were used in an 18-week growth assay to determine the effects of immunization against LHRH on growth performance, sex characteristics, and meat quality. At 20 kg BW and 8 weeks later, control animals (C) were injected with vehicle only, and the remaining males were immunized with an anti-LHRH peptide vaccine at either 40 (L) or 100 (H) μ g per injection. Compared with control intact males, immunized pigs tended ($P < .1$) to have high ADG (for C, L, H; 698, 765, 837 g/d) and ADFI (1.78, 1.92, 2.14 kg/d) with no changes in F/G ratio (2.55, 2.55, 2.58). Greater backfat (2.17, 2.65, 2.91 cm) and loin eye area (45.9, 44.8, 56.2 cm²) were detected in pigs treated with anti-LHRH vaccine at 100 μ g level ($P < .05$). Tenderness and juiciness of longissimus muscle chops did not differ among groups by sensory panel evaluations, but chops from immunized animals had less off-flavor ($P < .01$) than intact controls. Genital tract weights (testes, epididymes, seminal vesicles, and prostate glands), measured at slaughter, were significantly ($P < .001$) decreased by immunization, and both doses of anti-LHRH vaccine had similar efficacy. Consistently, plasma testosterone concentrations were completely inhibited ($P < .001$) by anti-LHRH vaccine. The present results demonstrate that anti-LHRH immunization is an effective means to inhibit sexual development and to reduce incidence of boar taint for intact male pigs.

1805 The effects of zinc and thyroid hormone on the expression of growth hormone and thyroid stimulating hormone in primary rat anterior pituitary cells. A.L. Rivard^{*}, M.A. Shaller, H.C. Freake, and S.A. Zinn, University of Connecticut.

Chelation of zinc with DTPA (diethyltriaminepentaacetic acid) stimulates expression of growth hormone (GH) in tri-iodothyronine (T_3)-treated rat pituitary tumor (GH3) cells. To determine whether zinc chelation stimulates GH expression in rat anterior pituitary cells, 50 to

60 weanling CD rats (5 wk old; 75 g BW) were euthanized and anterior pituitary glands removed. Individual cells were dispersed with dispase and cells were maintained at 37C (humidified atmosphere; 95% air: 5% CO₂) in Dulbecco modified Eagle's medium for 24 h. Cells were then treated with one of the following (2 wells /treatment; replicated in 3 experiments): 1. controls; 2. 10 nM T₃; 3. 50 M DTPA; 4. 10 nM T₃ plus 50 M DTPA; and 5. 10 nM T₃, 50 M DTPA and 40 M zinc sulfate. Cells were incubated for 48 h prior to RNA extraction. Reverse transcription (RT) PCR, with specific primers for GH and thyroid stimulating hormone (TSH), was used to measure mRNA levels. Comparisons with control gene-specific primers RPL-32 and β -actin were used to calculate mRNA levels of expression for GH and TSH, respectively. To evaluate RT-PCR, preliminary experiments were performed with GH3 cells. Results with RT-PCR and the GH primer paralleled previous results using Northern analysis, showing that expression DTPA and T₃ stimulated GH mRNA expression. TSH was measured to confirm the viability of the anterior pituitary cells. As expected, T₃ inhibited TSH mRNA expression 50% compared to control cells. Expression of TSH mRNA was greater in DTPA treated cells compared with controls ($p < .01$), but was lowered by combination with T₃ and by combination with T₃ and zinc. These results confirm that the anterior pituitary cells are viable and responsive. In these same cells DTPA alone reduced GH mRNA levels by 25% ($p = .03$). However, in contrast to GH3 cells, DTPA did not stimulate GH mRNA levels in T₃-treated pituitary cells ($p = .18$). In conclusion, while zinc chelation increases TSH mRNA, in the presence or absence of T₃, it does not affect the GH mRNA in primary rat anterior pituitary cells in the same manner as GH3 cells.

Key Words: Rat, Growth hormone, Thyroid hormone

1806 Effects of dietary conjugated linoleic acid (CLA) on the composition and function of peripheral blood mononuclear leukocyte populations in heifer calves. J.M. Smith*¹, B.J. Nonnecke², M.E. Van Amburgh¹, B.A. Pesch², and J.A. Harp², ¹Cornell University, Ithaca, NY, ²National Animal Disease Center (NADC), USDA, ARS, Ames, IA.

At approximately 2.5 months of age, heifer calves, raised and housed at the Cornell University Dairy Teaching and Research Facility, began receiving a diet formulated to support 1 kg/d gain (controls, n = 6) or a diet containing protected CLA (treated, n = 6). Total CLA was included in the diet at 1% of DM intake. The CLA-supplemented diet was formulated to support the same levels of ME and MP allowable gain as the control diet. Peripheral blood was collected at the initiation of the study (100 kg BW) and at 6.5 (200 kg BW) and 9.5 (300 kg BW) months of age. Anti-coagulated blood was maintained at room temperature and shipped overnight to the NADC where the composition and function of circulating mononuclear leukocyte (PBML) populations were evaluated. The composition of PBML populations was evaluated by flow cytometry. The total number of PBML was unaffected ($P > 0.05$) by dietary treatment or age. Percentages of CD3+ T cells (and CD4+, CD8+, and $\gamma\delta$ T cell subsets) and B cells in the PBML population were unaffected ($P > 0.05$) by dietary CLA; however, the proportion of T cells did increase ($P < 0.01$) with age. Percentages of PBML expressing activation

antigens (i.e. MHC class II antigen and interleukin-2 receptor) were also unaffected by dietary CLA or age. Leukocyte function was evaluated in vitro by measuring interferon- γ (IFN- γ), nitric oxide, and tumor necrosis factor- α secretion in PBML cultures, both unstimulated and mitogen-stimulated (i.e. with pokeweed mitogen (PWM), concanavalin A, and phytohemagglutinin-P). In general, dietary CLA did not affect these functions. The only exception was greater IFN- γ secretion by PWM-stimulated cells from heifers supplemented with CLA. Although these data suggest dietary CLA had minimal effect on the composition and function of PBML from healthy calves, additional research is needed to determine if dietary CLA would benefit calves experimentally or naturally infected with pathogens causing significant morbidity or mortality in the field.

1807 Feeding conjugated linoleic acid to reduce the impact of an infectious disease challenge in growing swine. J.A. Brown*, G.W. Almond, S.A. Mathews, W.T. Oliver, and R.J. Harrell, North Carolina State University, Raleigh, NC.

Respiratory diseases, particularly in the grow-finish phase, account for considerable economic loss in the swine industry. Studies in chicks and rodents have shown dietary conjugated linoleic acid (CLA) reduced the catabolic effects of a noninfectious inflammatory challenge. Our objective was to maintain performance and/or reduce the duration of lower performance during an infectious disease challenge of porcine reproductive and respiratory syndrome virus (PRRSV) and *M. hyopneumoniae* (*M. hyo.*) by supplementing diets with CLA. Pigs were weaned from the sow at 12 days of age and reared in isolated facilities to ensure high health status. At 26.7 \pm 0.6 kg BW, 16 barrows were moved to metabolism cages and randomly assigned to a 2x2 factorial arrangement: diet (0 or 2% CLA-60) and disease challenge (uninfected or infected with PRRSV and *M. hyo.*). Pigs were allowed a 2 week adjustment period to their respective diet prior to infection. Pigs were then inoculated with PRRSV and *M. hyo.*, and control pigs were given sterile media. Blood samples were taken weekly, and total urine and feces were collected during the third week post infection. Pigs were euthanized at a constant BW of 63.4 \pm 1.1 kg. PRRSV titers were not present initially, and only infected pigs were positive at the conclusion of the trial. In addition, only infected pigs had lung lesions typical of *M. hyo.* No differences in average daily feed intake, efficiency of gain, N-retention, plasma urea nitrogen, or total blood protein were found ($P > 0.11$). Infected pigs had lower blood albumin ($P < 0.03$) and tended to have reduced ADG ($P < 0.06$) compared to uninfected pigs, but dietary CLA did not attenuate the reduced growth performance ($P > 0.20$). Results thus far suggest that CLA does not attenuate the reduced growth performance associated with an infectious disease challenge. However, beneficial effects of CLA may have been compromised by the lack of severity of the disease challenge.

Key Words: Swine, Conjugated linoleic acid, Disease

AMSA/ASAS Meat Science and Muscle Biology

1808 Prediction of the fat content of pork carcasses based on cross-sectional region analysis of dual energy X-ray absorptiometry scans. A. D. Mitchell*¹, A. M. Scholz², and V. G. Pursel¹, ¹USDA, Agricultural Research Service, Beltsville, MD, ²Ludwig Maximillians University-Munich, Oberschleissheim, Germany.

Dual energy X-ray absorptiometry (DXA) can be used to measure pork carcass composition by performing a total scan of the half-carcass. The scan can be analyzed for total or regional fat, lean, and bone mineral content, but is too slow for on-line slaughter application. The purpose of this study was to determine the feasibility of predicting carcass composition based on a single cross-sectional measurement. A total of 252 right half-carcasses (42.7 \pm 5.2 kg) were scanned by DXA. The DXA scans were analyzed for percentage fat in the entire half-carcass as well as the shoulder, ham, loin, and side regions. A total of 14 cross-sections (57.6 mm wide) were analyzed: 6 in the shoulder/thoracic region, 3 in the loin region, and 5 in the ham region. Regression analysis was used to compare the DXA fat percentage measurements in the total carcass with those of the various regions. The mean fat content of the half-

carcasses was 24.1 \pm 7.0%; shoulder region, 23.8 \pm 6.7%; ham region 22.9 \pm 6.7%; loin region, 23.7 \pm 7.6%; and the side region 27.9 \pm 7.6%. The correlation (R^2) between the fat content of a single cross-sectional slice and total fat content ranged from 0.908 to 0.976. The highest correlations were in the area of the last ribs. Based on previous results, it is estimated that a single slice could predict the percentage of carcass fat by chemical analysis with an R^2 of 0.80. The highest correlations between single cross-section and region analysis were: shoulder, 0.978; ham, 0.972; loin, 0.973; and side, 0.959. These results indicate that carcass fat percentage can be measured by performing a single-pass cross-sectional scan that would be compatible with on-line processing.

Key Words: Carcass Composition, DXA, Swine

1809 Effect of supplemental fat on growth performance and quality of beef from steers fed barley-potato product finishing diets I. Feedlot performance, carcass characteristics, and appearance. M. L. Nelson*, J. R. Busboom, D.J. Marks, L.F. Falen, and J.D. Cronrath, *Washington State University, Pullman, WA/USA*.

To measure effects of dietary fat on feedlot performance, carcass characteristics, and beef appearance, one hundred sixty-eight crossbred steers (318 ± 2.8 kg) were allotted within weight block (3) to a randomized complete block design with a $2 \times 3 + 1$ factorial arrangement of dietary treatments. Main effects were level of yellow grease (0, 3, or 6%) and level of alfalfa hay (3.5 or 7%) with the added treatment of 6% tallow and 7% alfalfa hay in barley-based diets containing 15% potato by-product and 7% supplement fed for 165 d. Dietary treatment did not affect ($P > .10$) DM intake ($8.2 \pm .17$ kg/d), ribeye area ($87.1 \pm .58$ cm²), beef brightness ($2.5 \pm .06$) on a 1 (very dull) to 5 (very bright) scale, or beef texture ($2.6 \pm .05$) on a 1 (very coarse) to 5 (very fine scale). Level of yellow grease linearly increased ($P < .05$) average daily gain from 1.5 to $1.6 \pm .16$ kg/d, diet NE_m from 2.4 to $2.6 \pm .06$ Mcal/kg, and diet NE_g from 1.7 to $1.9 \pm .04$ Mcal/kg, and kidney, pelvic and heart fat from 2.1 to $2.4 \pm .06\%$. Level of yellow grease linearly decreased ($P < .05$) feed-to-gain from 5.9 to $5.5 \pm .16$, beef firmness score from 3.0 to $2.8 \pm .07$ on a 1 (very soft) to 5 (very firm) scale, and fat luster score from 3.1 to $2.8 \pm .09$ on a 1 (very dull) to 5 (very lustrous) scale. Level of alfalfa hay by itself did not affect any of the measurements, however it interacted with level of yellow grease on backfat, marbling score, beef color score, and percentage USDA Choice. Backfat increased with yellow grease in 3.5% but not in 7% alfalfa diets. Marbling and beef color score were maximized in the 3.5% alfalfa hay diet but minimized in 7% alfalfa hay diet that contained 3% yellow grease. Steers fed tallow had lower ($P < .10$) marbling scores (272 vs 295 ± 5.54 where 300 was choice 0), percentage USDA Choice (21 vs $43 \pm 7.71\%$) but greater ($P < .10$) beef firmness score [3.0 vs $2.7 \pm .10$] on a 1 (very soft) to 5 (very firm) scale than those fed yellow grease. Therefore, yellow grease increased diet energy which improved gain, feed-to-gain, and slightly increased carcass fatness. Yellow grease also increased marbling and decreased beef firmness and fat luster.

Key Words: Barley, Yellow grease, Tallow

1810 Catalysis of meat tenderization during post-mortem aging by calpain 3 (p94). M. A. Ilian*, A. E. Bekhit, and R. Bickerstaffe, *Lincoln University*.

The biochemical basis of postmortem tenderisation of meat is the proteolysis of certain muscle structural proteins by the calpain proteolytic system. In mammalian skeletal muscle, calpains comprise the ubiquitous calpains 1 and 2 and the tissue-specific calpain 3 or p94. The results of our previous studies on the role of calpains in meat tenderization revealed, for the first time, a strong correlation between the variation in meat tenderness and the expression of calpain 3 at the mRNA and protein levels. Furthermore, it was observed that calpain 3 was terminally activated, like calpain 1, during postmortem storage. To investigate further the mechanism of meat tenderisation, we have determined the kinetics of; i) meat tenderisation, ii) myofibrillar fragmentation index (MFI), iii) proteolysis of nebulin and, iv) the activation of calpain 3 in the longissimus over a period of 7 days post slaughter. The results indicate there is agreement between the kinetics of tenderization and the kinetics of MFI, nebulin and the activation of calpain 3. The correlation coefficients between the kinetics of meat tenderization and the kinetics of MFI, nebulin and the activation of calpain 3 were 0.75 , -0.77 , and -0.86 respectively. These results support the statement that the biochemical basis of postmortem tenderisation of meat is the proteolysis of certain muscle structural proteins, such as nebulin, by the calpain proteolytic system. At this point in time, we can not be certain which calpain is rate limiting in postmortem tenderization, but the results support a potential role for calpain 3 in this process.

Key Words: Meat tenderization, proteolysis, calpain 3(p94)

1811 Effect of transport temperature and post-slaughter chilling on channel catfish fillet quality. B. G. Bosworth*¹, W. R. Wolters¹, J. Silva², and R. Chamul², ¹USDA-ARS, Stoneville, MS, ²Mississippi State University, Starkville, MS.

Objectives were to determine effects of transport water temperature and post-slaughter chilling on channel catfish fillet quality. Channel catfish (mean weight = 0.67 kg) were harvested from commercial ponds and transported in a 4-compartment trailer at a typical commercial transport density (440 kg fish/m³ water). Each compartment was assigned to one of four treatments with 3 replicate trials: Treatment 1 (T1) = transport water temperature 20°C , fillets chilled (typical industry practice); Treatment 2 (T2) = transport water temperature 20°C , carcasses chilled prior to filleting; Treatment 3 (T3) = transport water temperature 10°C , fillets chilled; and Treatment 4 (T4) = transport water temperature 1°C (slush ice), fillets chilled. After 3.5 h transport, 10 fish from T1, T2, and T3 were returned to pond water to simulate fish being rejected at the plant and returned to the producer. Remaining fish were stunned by electricity and processed. Fillet texture, color (CIE L*, a*, b*), purge-loss, and pH were measured. Mortality of fish returned to pond water was higher ($P < 0.05$) in T4 (97%) than in T1 (3%) and T3 (3%). Fillet texture (FTC Texture Meter) was not different ($P > 0.05$) among treatments. Purge-loss during 3 d iced-storage was highest ($P < 0.05$) in T1 (1.46%), but not different among T2 (1.08%), T3 (1.10%), and T4 (1.00%). Fillet L* values were higher ($P < 0.05$) for T1 (54.7) and T2 (53.8) than for T3 (51.6) and T4 (51.8). T3 fillets had lower a* values (-2.0) than T1 (-1.4), T2 (-1.6) or T4 (-1.6). Fillet b* values were highest for T1 (2.0), intermediate for T2 (1.0) and T4 (1.2), and lowest for T3 (0.4). Purge-loss was positively correlated with L*, a*, and b* values ($p < 0.001$). Ultimate pH of fillets was higher ($P > 0.05$) for T1 (7.00) and T2 (7.00) than for T3 (6.83) and T4 (6.84). We conclude that hauling catfish at 10°C and/or chilling carcasses prior to filleting could improve fillet quality. Cost/benefits of transport at 10°C or chilling carcasses before filleting need to be determined.

Key Words: catfish, fillet quality, transport

1812 Effects of pre-slaughter holding time on dressing-out percent and meat quality for bulls and steers. R. W. Purchas*, D. L. Burnham, and S. T. Morris, *Massey University, Palmerston North, New Zealand*.

Carcass and meat quality characteristics were compared for Angus and Angus-cross bulls ($n=58$) and steers ($n=59$) held at the meat plant for either 4h ($n=59$) or 28h ($n=58$) before slaughter. All cattle had been finished on pasture and the fasting time prior to arrival at the plant was c. 2h. At the plant cattle had access to water but not feed. Losses in live weight from farm to the time of slaughter were more than twice as high for the 28h group (46.8 vs 21.6 kg; $P < 0.001$), and the weight-adjusted dressing-out percent values based on on-farm weights were significantly lower for the 28h group (50.73 vs 51.99 ; $P < 0.001$). This indicated that the increased holding time led to a carcass weight loss that corresponded to 6.9 kg for an animal that weighed 550 kg on the farm. The extent of weight loss was similar for bulls and steers. Carcass composition and shape traits were unaffected by holding time. Meat quality was assessed on samples of longissimus thoracis muscle between ribs 6 and 12. Ultimate pH (pH_{ult}) was higher for the 28h group than the 4h group for the bulls (5.75 vs 5.57 ; $P < 0.05$) but not the steers (5.47 vs 5.46). Measures of sensory tenderness did not differ between the two holding-time groups either before or after adjustment for pH_{ult}, even though pH_{ult} had a significant effect on all measures of meat tenderness. Objective measures of tenderness by Warner-Bratzler shear or by MIRINZ tenderometer also did not differ between the two holding-time groups either with or without pH adjustment. Sensory juiciness scores were unaffected by holding time, but pH-adjusted cooking losses and expressed-juice values were lower for meat from the 28h-hold group suggesting some muscle dehydration. Increasing the holding time for cattle at the meat plant from 4 to 28 hours is likely to lead to carcass weight losses, but effects on meat quality are likely to be minimal provided high-pH beef is avoided.

Key Words: Beef Quality, Dressing-out Percent, Holding Time

1813 Instrumental and chemical characteristics, calpastatin mRNA genic expression and myofibrillar protein concentration in chilled meat of feedlot Brazilian Superyoung cattle *Bos taurus* × *Bos indicus* 24h postmortem. L. A. L. Chardulo*¹, J. A. Ferro², A. C. Silveira¹, L. R. Furlan¹, M. D. B. Arrigoni¹, H. N. Oliveira¹, M. I. T. Ferro², and C. Ludovico¹, ¹UNESP - Botucatu, SP/Brazil, ²UNESP - Jaboticabal, SP/Brazil.

Two hundred male and female crossbred animals were used. These were products of a cross between Aberdeen Angus, Charolais, Gelbvieh, Simmental and Hereford males and 1/2 Simmental × 1/2 Nellore crossbred females, weaned by creep-feeding method and kept in feedlots afterwards. The animals were slaughtered when weighed more than 440 kg (males) and 400 kg (females). One-gram samples of the Semitendinosus were collected for calpastatin mRNA expression analysis by dot blot and myofibrillar protein quantification by SDS-PAGE. Samples of the longissimus were collected between the 12th and 13th ribs for chemical and instrumental analysis of the meat. Experimental design was completely randomized. In chemical and compositional analysis of the meat, the Aberdeen Angus animals had higher subcutaneous and intramuscular fat ($p < .01$), as well as lower pH, ribeye area and shearing force ($p < .01$). Internal meat temperature 15h postmortem was higher for Aberdeen Angus animals ($p < .05$). Female showed higher fat deposition on the meat, pH and temperature ($p < .01$) but lower ribeye area ($p < .01$). No differences ($p > .05$) were observed for color characteristics, protein, humidity and losses during cooking for the different genetic groups, ages and sexes. There was also no differences ($p < .05$) in the quantity of calpastatin mRNA between the different breeds and sexes, although, Aberdeen Angus animals had lower myofibrillar protein levels ($p < .01$), denoting a higher postmortem proteolysis rate. The ability of Aberdeen Angus breed in producing tender meat in the Brazilian Superyoung System may be related to a higher fat deposition in carcass and meat, what consequently gives a better protection against the rapid cooling procedure studied herein.

Key Words: Young crossbred cattle, Calpastatin, Myofibrillar proteins

1814 Abundance and cellular distribution of the calpain proteolytic system proteins in the Longissimus of the ovine. R. Bickerstaffe*¹, M. Ilian¹, and H. Sorimachi², ¹Lincoln University, ²The University of Tokyo.

The calpain proteolytic system in mammalian skeletal muscle is a family of Ca²⁺-activated neutral thiol endopeptidases classified as ubiquitous (calpains 1 and 2) and tissue-specific (calpain 3 or p94). Calpains 1 and 2 are composed of 80 kDa catalytic subunits, which are products of separate genes, and a 30-kDa regulatory subunit, which is identical in both enzymes. The structure of calpain 3 differs from calpains 1 and 2 in the presence of 3 unique regions that are expected to convey functional specificity, and in the absence of the small subunit. Another distinguishing feature between the ubiquitous calpains and calpain 3 is that, unlike calpains 1 and 2, calpain 3 is not inhibited by calpastatin (a specific endogenous inhibitor protein). Several studies have indicated that the calpain proteolytic system plays major roles in muscle growth and development in health and disease. The challenge is that the physiological functions of the various muscle calpains remain unknown. As a step toward the elucidation of the specific function of the individual calpains in skeletal muscle we developed western assay to quantify the protein level of calpain 1, calpain 2, calpain 3 and calpastatin in ovine skeletal muscle. The method is based on constructing standard curves using predetermined amounts of pure calpain proteins. We used the above method to determine the abundance and cellular distribution of the calpain proteolytic system proteins in the longissimus (LD) of the ovine. The results (average ± SD, n = 4) revealed that the level (fmole/mg tissue) of calpain 1, 2, 3 and calpastatin in the LD was 309 ± 106, 846 ± 108, 4180 ± 322, and 487 ± 56, respectively. Cellular distribution of the calpains in the LD indicated that calpain 2 and calpastatin are present in the sarcoplasmic fraction but not in the myofibrillar fraction. However, calpains 1 and 3 are present in the sarcoplasm and at the myofibril at 71:29 and 18:82 ratios, respectively. Based on the pattern and level of expression, we infer that the calpains are performing different functions in the LD and that calpains 1 and 3 may be involved in the metabolism of myofibrillar proteins.

Key Words: Calpain, abundance, muscle

1815 Effects of marination on the processing parameters and palatability of bison top round. J.S. Dhanda*¹, R.B. Pegg¹, J.A.M. Janz², J.L. Aalhus³, and P.J. Shand¹, ¹University of Saskatchewan, Saskatoon, SK, Canada, ²University of Alberta, Edmonton, AB, Canada, ³Agriculture and Agri-Food Canada Research Centre, Lacombe, AB, Canada.

Injection of phosphate and salt containing marinades increases the palatability of a wide variety of meat products, but many of these studies have been based on domestic livestock species. The present study was conducted to investigate the effects of marination on the palatability of bison top round steaks/roasts cooked by two cooking methods (dry or moist-heat) and to two endpoint temperatures (71°C or 77°C). Twenty paired *semimembranosus* muscles were obtained from 10 male bison: each of these muscles was divided longitudinally into two sections. One section was injected to 110% of its original weight to contain 0.5% sodium chloride and 0.3% sodium tripolyphosphate, while the other was kept as a non-injected control. The steaks/roasts obtained from control and injected sides were used for color appraisal, tenderness evaluation and consumer acceptance studies. Bison steaks (stored at 31°C and under 975 Lux) held a bright red color for 2 days, but after that discoloration became evident. HunterLab a* (redness) values did not change significantly between treatments; however, injected steaks had lower L* (lightness) and b* (yellowness) values ($P < 0.01$) compared to control steaks. Cook yields for the steaks/roasts from the injected sections were significantly higher compared to those from control non-injected sections when cooked to either 71°C or 77°C. Injected steaks/roasts had significantly lower shear force values (63.9N) compared to controls (102.3N). Bison samples cooked by moist-heat (water bath) had significantly lower cooking losses and shear values compared to those cooked by dry-heat (oven broiling). As expected steaks/roasts were more tender and had better cook yields when processed to a lower temperature (71°C) compared to an internal temperature of 77°C. A panel of 80 consumers revealed that injected steaks had better acceptance in terms of tenderness, juiciness and flavor compared to non-injected ones. The findings of the present study suggest that marination by injection has a great deal of potential in improving the palatability of lesser value cuts of bison.

Key Words: Marination, Palatability, Bison top rounds

1816 Antihypertensive activities of enzymatic hydrolysates of porcine skeletal muscle proteins. Y Nakashima*, K Arihara, S Ishikawa, and M Itoh, *Kitasato University, Towada-shi, Japan.*

Inhibitors of angiotensin I-converting enzyme (ACE) have been shown to have antihypertensive activities and have been utilized for pharmaceuticals and physiologically functional foods. Several ACE inhibitory peptides, which have the antihypertensive activity, have been found in the enzymatic hydrolysates of foodstuffs, such as milk proteins. However, little is still known about the derivation of ACE-inhibitory and antihypertensive activities from meat proteins. The objective of this study was to investigate these activities of the enzymatic hydrolysates of porcine skeletal muscle proteins. Porcine skeletal muscle myosin was hydrolyzed by one of eight kinds of proteases. Among these hydrolysates, thermolysin digests showed the highest ACE inhibitory activity. The single oral administration of thermolysin digest of myosin to spontaneously hypertensive rats (SHR) significantly decreased their systolic blood pressure. Two ACE inhibitory peptides, named myopentapeptides A and B, Met-Asn-Pro-Pro-Lys and Ile-Thr-Thr-Asn-Pro, were purified from thermolysin hydrolysate of myosin by HPLC with reversed phase mode. Of the synthesized two myopentapeptides and six tripeptides, which have parts of the sequences of myopentapeptides, four peptides (myopentapeptides A and B, Met-Asn-Pro, Pro-Pro-Lys) demonstrated antihypertensive activities by their single oral administration in SHR significantly. Porcine skeletal muscle actomyosin and its thermolysin hydrolysate were tested for the activity of preventing hypertension by their long-term oral administration in SHR. The antihypertensive activity was demonstrated by the administration of thermolysin digest. This study demonstrated that ACE-inhibitory and antihypertensive activities can be generated from meat proteins by enzymatic hydrolysis. Utilization of enzymatic hydrolysates of meat proteins and corresponding peptides could lead to the development of new healthy meat products.

Key Words: Antihypertensive activity, Skeletal muscle proteins, Peptide

1817 Oxidative differentiation in muscle of small and large pig fetuses in late gestation. C. Ashton* and N. Stickland, *The Royal Veterinary College, London, UK, NW1 0TU.*

Muscle tissue consists of muscle fibres, which form in a biphasic manner. Initially, a myoblast population fuses to generate primary fibres, providing a surface on which a second population of myoblasts fuse to form secondary fibres. Secondaries are first observed at about 54 days in the pig. In the pig, muscle fibre hyperplasia is completed by about day 90 of gestation. The adult pig semitendinosus muscle is composed of a deep (oxidative rich) and a superficial (less oxidative) area. Prenatal differentiation in terms of contraction speed has been identified. However, oxidative (metabolic) differentiation has not been shown prenatally. The semitendinosus muscles from 11 pairs of the smallest and largest pig fetuses at 80-100 days gestation were removed. Succinic dehydrogenase (SDH) staining was performed on complete frozen transverse sections. Optical density measurements were recorded over the entire section from the most superficial to the deepest border. Although, there was no significant difference ($P > 0.05$) between the muscles of littermates, a significant difference ($P < 0.01$) between the superficial and deep portion of the muscle was observed. The results suggest that oxidative muscle differentiation does occur before birth. In fact the results imply that oxidative differentiation is occurring as early as day 80, prenatally. Both the deep (mean OD for small and large piglets = 190.188) and superficial (mean OD for small and large piglets = 193.945) portions of muscle were still very oxidative at this stage. However, the results have shown that some significant differentiation was occurring, within individual semitendinosus muscles, but not between littermates.

Key Words: Oxidative differentiation, Muscle, Prenatal

1818 Omega-3 fatty acids and meat lamb quality. F. Nicastro*¹, L. Zezza¹, and R. Gallo, *Department of Animal production, University of Bari, Bari, Italy.*

Nowadays meat is often seen as one of the factors that are responsible for a negative, unhealthy lipidic contribution. The composition of fatty acids in animals largely depends on the type of diet, especially the quality of dietary fat. We must use the omega-3 fatty acids for a more protective and healthier diet, to grant them the completion and physiological control of several functions of the organism. Twenty 30 d old Delle Langhe bred wether lambs were divided into two groups of 10 and housed indoors for eight weeks. The two groups received hay ad libitum and the first group was fed a basal diet of commercial concentrate (Control), while the second group received a diet supplemented with 3% fish oil (Omega 3). At the end of feeding, the lambs were fasted overnight and slaughtered. Hot carcass weight was measured at 45 minutes post mortem and carcasses chilled overnight. The right sides of the carcasses were weighted and cut into wholesale cuts. The weights were expressed as a percent of the cold carcass weight. The loin and leg cuts were separated in lean, bone and fat. Samples for meat quality investigations were removed from the longissimus thoracis for meat color and shear measurements. Meat color was taken using CIE methods (L, a, b) and the shear force was measured from the LT muscle raw and cooked. Objective measurements showed a significant ($P < .05$) increase in redness (a), in lambs fed fish oil whereas the control group was much lighter (L), than the group fed omega-3. The raw and cooked muscle of the lambs fed with omega-3 had significant ($P < .01$) effect on shear force (2.95 and 2.85 kg core for raw and cooked muscle respectively), so the loin tenderness was positively affected. In the leg the percentage of lean decreased with the omega-3, whereas fat markedly increased ($P < .05$). Lean and fat percentages of the loin are also influenced by the lamb's feeding, but with an opposite trend. In fact the lean goes up from 48.15 to 52.63% ($P < .05$), whereas the fat decreased. The omega-3 fatty acids, in the amount used in this study, have little influence in the cuts of carcasses.

Key Words: Lamb, Diet, Meat quality

1819 In Ovo Manipulation of Posthatch Growth in the Turkey. A. R. Somaiya* and N. C. Stickland, *Royal Veterinary College, London, UK.*

In fish, temperature has been successfully used to alter muscle tissue characteristics and postnatal growth. The main aim of these studies was to quantify the difference in muscle tissue parameters in turkey poults from eggs incubated at different temperatures, both higher and lower

than the optimum 37.5°C. Control eggs were set at 37.5°C for the duration of the 28 day incubation period. The time periods chosen to apply the experimental temperatures (38.5°C and 35.5°C) were for periods of four days, either 0-4, 5-8, 9-12, 13-16, 17-20, 21-24 and 25-28 days of incubation. Semitendinosus (ST) and pectoral muscles were taken and transverse sections were cut from the whole ST and a 1cm² sample of pectoral muscle at 16 days posthatch. The muscles were sectioned and stained to determine ST muscle area, total nuclei and fibre number and pectoral nuclei and fibre number densities. It was found that application of the lower temperature at the beginning of the incubation period (days 5-8) produced a decrease ($P < 0.05$) in ST weight (.50 vs .65), a decrease ($P < 0.05$) in total nuclei number per section (69,000 vs 76,500), but an increase ($P < 0.05$) in the total number of fibres (130,000 vs 110,000), compared to control. Conversely, application of the higher temperature during the same time period produced an increase ($P < 0.05$) in ST total nuclei number per section (100,000 vs 76,500), a decrease ($P < 0.05$) in total fibre number (90,000 vs 110,000), but also a decrease ($P < 0.05$) in ST weight (.50 vs .65), compared to control. These results suggest that even within the same strain there are different mechanisms of growth that can be employed, depending on the growth conditions available. Application of 35.5°C produced a relatively more hyperplastic growth (increase in fibre number), while 38.5°C a more hypertrophic growth (increase in fibre cross-sectional area). From studies on other species, it is known that a greater fibre number is often associated with better growth, greater feed conversion efficiency, leaner meat and also better meat quality. These results could therefore have implications for these parameters in turkeys.

Key Words: Fibre number, Meat quality, Posthatch growth

1820 Effect of supplemental fat on growth performance and quality of beef from steers fed barley-potato product finishing diets II. Beef appearance, shelf-life, and palatability. D. J. Marks, J. R. Busboom*, M. L. Nelson, J. D. Cronrath, L. Falen, and P. S. Kuber, *Washington State University.*

The objective of this study was to evaluate the effects of supplemental fat in finishing diets on moisture properties, shelf life measurements, and palatability of beef. One hundred sixty-eight crossbred steers (318 2.8 kg) were allotted within weight block (3) to a randomized complete block design with a 2 x 3 + 1 factorial arrangement of dietary treatments. Main effects were level of yellow grease (0, 3, and 6%), and level of alfalfa hay (3.5 and 7%) with the added treatment of 6% tallow and 7% alfalfa hay in barley-based diets containing 15% potato by-product and 7% supplement fed for 165 d. Longissimus muscle cuts from four randomly selected steers per pen were used for determination of moisture retention properties, L*, a*, and b* color values using a Hunter Miniscan[®], evaluation by a four person retail shelf-life panel and an eight member trained sensory panel (10 cm line scale). Diet did not affect ($P > 0.1$) pH (5.57 0.1) and wholesale purge (.5 0.1%). Shelf life measurements of color score, retail purge score, and L*, a* and b* values decreased with day ($P < 0.01$) with no dietary effects ($P > 0.1$). Diet did not affect drip (3 0.1%) or cook loss (28.8 2.5%). Initial tenderness was increased quadratically ($P < 0.10$) with yellow grease from 7.2 to 7.6 to 7.4 0.1, and decreased ($P < 0.10$) with alfalfa level in evaluation by the trained sensory panel. Diet did not affect initial juiciness (6.9 0.1), sustained juiciness (5.6 0.2), or beef flavor (5.3 0.1). There was an interaction of yellow grease by alfalfa detected for off flavor ($P < 0.05$), however all scores were less than 0.5 and were probably not biologically important. Supplemental fat did not affect most measurements of beef quality and palatability. However, supplemental fat increased initial tenderness for the sensory panel.

Key Words: Barley, Yellow Grease, Beef Palatability

1821 Effect of supplemental fat on growth performance and quality of beef from steers fed barley-potato product finishing diets III. Fatty acid composition of muscle and subcutaneous fat. D. J. Marks*, M. L. Nelson, J. R. Busboom, J. D. Cronrath, A. E. Koepp, and L. Falen, *Washington State University.*

One hundred sixty-eight crossbred steers (318 2.8 kg) were used to evaluate the effects of supplemental fat in finishing diets on fatty acid composition, including the c9,t11 isomer of conjugated linoleic acid (CLA) of longissimus muscle (LM) and subcutaneous fat. Animals were allotted within weight block (3) to a randomized complete block design with a 2

x 3 + 1 factorial arrangement of dietary treatments. Main effects were level of yellow grease (YG; 0, 3, and 6%), and level of alfalfa hay (3.5 and 7%) with the added treatment of 6% tallow (T) and 7% alfalfa hay in barley-based diets containing 15% potato by-product and 7% supplement fed for 165d. Fatty acids of LM and subcutaneous fat from four randomly selected steers per pen were quantified using gas chromatography after methylation with sodium methoxide. Dietary treatment did not affect total fatty acid (FA) content (DM basis) of LM (143 4.5 mg/g) or fat (958 9.3 mg/g). Palmitic acid decreased linearly ($P < 0.001$) with YG from 29.5 to 27.8 0.31 g/100g FA in fat. Stearic acid linearly increased ($P < 0.05$) with YG from 11.4 to 12.9 0.26 and from 10.0 to 12.0 0.34 g/100g FA in LM and fat, respectively, and oleic acid in fat from 42.1 to 43.5 0.44 g/100g FA. Steers fed 6% yellow grease compared to T had less ($P < 0.05$) stearic acid in LM (12.7 and 13.9 0.37 g/100g FA) and more oleic acid in fat (43.0 vs. 40.9 0.62 g/100g FA) and LM (42.7 vs. 40.3 0.53 g/100g FA). Level of yellow grease increased CLA quadratically ($P < 0.01$) in LM from 0.45 to 0.64 to 0.62 0.02 g/100g FA and fat from 0.61 to 0.835 to 0.825 0.02 g/100g FA. Conjugated linoleic acid was higher ($P < 0.1$) in LM (0.62 vs. 0.54 0.04 g/100g FA) and also higher ($P < 0.05$) in fat (0.81 vs. 0.69 0.04 g/100g FA) from steers fed yellow grease compared to T diets. Content of CLA in beef was increased without increasing total FA content by feeding yellow grease.

Key Words: Barley, Yellow Grease, CLA

1822 Market orientation: A possibility to improve consumers' acceptability of pork products. Charlotte Prestat* and M. Susan Brewer, *University of Illinois, Urbana-Champaign, IL.*

Pork producers have been confronted with increasing competition over the past few years, resulting in a renewed interest in developing food products with greater value added. However, since consumers are relatively closed to innovation, there is limited room for new product development. Understanding factors associated with purchase and consumption of pork will facilitate development of products and processes that promote pork utilization and increase market share. In this study, factors that may affect pork acceptability were evaluated by analyzing purchase and consumption behavior, as well as quality perception. A consumer survey ($n=200$) was conducted to qualitatively and quantitatively model the consumer choice process, to assess to what extent selected product characteristics impact consumers' quality evaluation and purchase intent, and to assess their weight relative to each other. Data were subjected to cluster analysis. Three clusters were separated. Cluster 1, representing 8.2% of the respondents, was primarily female (62.5%), over 40 years of age (68.8%). This group was concerned about health issues. The amount of visible fat accounted for 39% of the purchase decision while consumption acceptability depended essentially on the amount of fat in/on the product (51.5%). The second cluster (35.4% of the respondents) was primarily female (60.9%), between the ages of 18 and 40 (62.3%). The color (30%) and the amount of visible fat (21.5%) seemed to influence purchase intent for this cluster. Flavor and degree of doneness were equally important (27%) with respect to consumption acceptability. The third cluster (56.4% of the respondents) was primarily male (54.5%) between the ages of 18 and 55 (90%). Price was the most important factor (32%) during purchase, while sensory characteristics appeared to determine the experienced quality (flavor, 27.5%; tenderness, 22%; and juiciness, 18%). As the third cluster represents the majority of the respondents, particular attention should be paid to their behavior. These results suggest that enhancement of the sensory attributes of pork products along with a reduction of costs should be the priority of the pork industry.

Key Words: Pork product, Marketing Orientation, Consumer Purchase and Consumption Behavior

1823 Combined effects of pH and temperature on myoglobin in a model system. Liugen Zhu* and Susan Brewer, *University of Illinois at Urbana-Champaign.*

To understand the basic mechanism of the PSE phenomenon with respect to color abnormalities, the contributions of sarcoplasmic and myofibrillar protein denaturation under the combined influences of high temperature and low pH is of utmost importance. From a series of experiments heating metmyoglobin solutions at pH 5.0, 5.3, 5.6, 6.0, 6.5 and 7.0, the effects of temperature and pH on thermal stability of metmyoglobin were investigated. The percentage metmyoglobin denatured

at temperatures from 25 to 80°C was determined. pHs lower than 6.5 caused metmyoglobin denaturation at various temperatures from 25 to 80°C, but was particularly apparent when pH < 5.6. Metmyoglobin denaturation did not occur until 60°C at pHs from 5.3 to 7.0. It occurred at 55°C at pH 5. Thermal stability of metmyoglobin increased as pH increased. A slow heating rate (0.9°C/min) caused more thermal metmyoglobin denaturation than a fast heating rate (1.3°C/min) when the temperature was above 55 to 60°C. The denaturation caused by low pH alone was reversible, while that caused by high temperature was not.

Key Words: myoglobin, PSE pork, protein denaturation

1824 Development of photographing equipment for the cross section of carcass and prediction of Beef Color Standard number by using obtained image from that equipment. K. Kuchida*, M. Hasegawa, M. Suzuki, and S. Miyoshi, *Obihiro University of AVM, Obihiro-shi Japan.*

The first aim of this study was to develop photographing equipment, which is able to take a clear image of the cross section of carcass integrating the digital camera and the illumination device. The second aim was to predict the Japanese Beef Color Standard (BCS) number by using the obtained image from that equipment. BCS is the standard model and consists of 7 ranks for the shade of meat color. The photographing equipment was composed of a dome section, the ring illumination section, and a digital camera section. 570 white LEDs (Light Emitting Diode) were arranged upward at the bottom of the dome section like a ring, and 432 white LEDs were arranged in a downward direction on the ring illumination section. The bottom of the dome section contacted with the cross section of carcass, so that photographing from a perpendicular direction and a constant distance was possible. Images around the ribeye at 6th-7th rib cross-section were collected ($n=1,208$) at a meat processing plant in Hokkaido, Japan. BCS number assigned by grader was predicted by multiple regression analysis using image analysis traits. Digital images of 1,208 carcasses were taken by this equipment. As no sample with diffused reflection existed on the surface of the ribeye, clear and stable images were effectively taken by using this equipment. The correlation coefficients of R, G, B components and luminance from image with BCS number of the standard model of BCS were -0.98, -0.91, -0.82, and -0.99, respectively. These results indicated that the relationship between luminance and BCS number of standard model had highly linearity. However, the correlation coefficients between luminance and BCS number of actual carcass ($n=1,208$) were lower ($r=-0.66$) than that of the BCS standard model. Multiple regression equation with the BCS number assigned by grader as the dependent variable were obtained by a stepwise method starting with 108 independent covariates for image analysis traits. BCS number was predicted by using the multiple regression with five covariates selected by the stepwise method. The percentages of the difference between the assigned BMS and the predicted BMS being ± 0 and within ± 1 were 76.8% and 100.0%, respectively.

Key Words: Meat color, Digital image, Image analysis

1825 Effect of high oil corn and vitamin E supplementation on ground beef case-life properties. M.S. Eibs*, B.J. Johnson, D.M. Wulf, B.C. Shanks, and T.A. Wittig, *South Dakota State University.*

The objective of this experiment was to investigate the effects of high oil corn and vitamin E supplementation on ground beef case-life properties. Steers ($n = 84$) were fed a high concentrate diet consisting of either typical corn (C: 79.5% of ration) or high oil corn (HOC: 79.5% of ration) for 112 days with (+E) or without (-E) vitamin E supplementation during the last 50 d (1,000 IU/hd/d). Steaks were removed 24 h post-mortem from the 12th rib and trimmed. Steak trimmings were ground and formed into patties for retail display panel (RDP), thiobarbituric reactive substances determination (TBARS), and tocopherol analysis. Two storage treatments were used prior to RDP: 1) domestic chilled (DC), chilled storage for 13 d postmortem; and 2) export chilled (EC) chilled storage for 34 d postmortem. Patties were monitored for 9 d (d 0 to 8) under simulated retail meat display conditions by a 5-member panel and color was measured with a Minolta colorimeter. On d 8, TBARS of RDP samples were quantified. HOC grain contained greater ($P < 0.05$) α - and γ -tocopherol levels than C grain (14.62 and 84.90 vs 8.01 and 41.68 ppm). Ground beef concentrations of α - and γ -tocopherol were higher ($P < 0.05$) in HOC+E as compared to HOC-E, C+E, and C-E. Rate of discoloration, as appraised by RDP, was slower ($P < 0.05$)

for patties from HOC+E as compared to HOC-E, C+E, and C-E for EC storage treatment. Export chilled HOC+E patties maintained higher ($P < 0.05$) a* values from d 2 to 8 when compared to HOC-E, C+E, and C-E. Patties from DC storage treatment with +E had lower ($P < 0.01$) TBARS than -E patties. For EC ground beef, the reduction in TBARS for HOC+E vs HOC-E was twice the magnitude of the TBARS reduction for C+E vs C-E (corn type by vitamin E interaction, $P < 0.05$), indicating +E had greater effects on TBARS for HOC fed cattle than for C fed cattle. These data suggest that the supplementation of vitamin E while feeding high oil corn to finishing beef steers elevates tocopherol levels in ground beef and slows the rate of discoloration.

Key Words: High Oil Corn, Tocopherol, Ground Beef

1826 Increased calcineurin activity is associated with muscle hypertrophy in callipyge sheep. C. E. Carpenter* and N. E. Cockett, *Utah State University.*

Calcineurin (Cn; protein phosphatase 2B) is a calcium-activated phosphatase that provides central downstream signals regulating muscle growth and development. Presently, Cn is understood to play a central role in muscle hypertrophy and expansion of the slow fiber population in chronically overloaded muscle. It is known that muscle hypertrophy and increased predominance of fast fibers occur in the longissimus, but not the supraspinatus, of callipyge sheep after they reach about 5 weeks of age. We tested whether altered Cn activity accompanied these effects. Calcineurin activity was determined in muscle extracts of the hypertrophy-responsive longissimus dorsi (LD) and hypertrophy-nonresponsive supraspinatus (SS) from 2-week-old and 8-week-old lambs of the callipyge and normal genotype. Muscle type, age, and genotype had an interactive effect ($P < 0.05$) on Cn activity suggesting that the callipyge gene exerts its effects in muscle via Cn-mediated pathways. Calcineurin activity was greater ($P < 0.06$) in the hypertrophy responsive LD from 8-wk-old callipyge (1.6×10^{-3} units activity per gram protein) as compared to 8-wk-old normal lambs (1.2×10^{-3}) or 2-wk-old callipyge lambs (1.3×10^{-3}). There were no differences for similar comparisons of Cn activity in extracts of SS. These observations suggest an active role of Cn in mediating the hypertrophy and shift towards the fast phenotype that occurs in the LD of callipyge lambs. The callipyge model of muscle hypertrophy may provide a unique model to study Cn-mediated signaling in skeletal muscle.

Key Words: Callipyge, Calcineurin, Skeletal muscle

1827 Diets containing conventional corn, conventional corn and choice white grease, high oil corn, or high oleic, high oil corn will influence the fatty acid profile of fresh pork adipose tissue. C. A. Stahl*¹, M. L. Linville¹, K. R. Maddock¹, T. E. Sauber², G.L. Allee¹, and E. P. Berg¹, ¹*University of Missouri, Columbia, MO, 2*²*DuPont Specialty Grains, Des Moines, IA.*

The objective of this study was to evaluate the effect of corn type on the fatty acid profile of six distinct fat depots within the pork carcass. Gene Packer X EB barrows ($n = 196$, 26.6 kg) were blocked by weight and randomly allotted 28 pens (7 replications per pen). Each treatment group had ad libitum access to one of four corn-based diets consisting of conventional corn (CONV), conventional corn supplemented with choice white grease (CWG), high oil corn (HOC) or high oleic, high oil corn (HOHOC). Following 98d on test, two animals per pen ($n = 56$) representing the average pen weight (118 kg) were selected for harvest. A single slice (cranial) of the fresh belly, belly leaf fat, ham seam (star) fat, ham inner and outer subcutaneous (s.c.) fat layers, and loin inner and outer s.c. fat layers were collected at 24h postmortem. Individual samples were packaged and frozen for subsequent fatty acid profile analysis. The saturated fatty acids palmitic (C16:0) and stearic (C18:0) were higher ($P < .05$) in the CONV treatment. Furthermore, the CONV treatment possessed the lowest percentage of unsaturated fat in all six fat depots ($P < .05$). CWG exhibited the highest percentage ($P < .05$) of conjugated linoleic acid in fresh belly slices, belly leaf fat, ham seam and inner s.c. fats, and loin inner s.c. fat. HOC treated animals possessed the highest percentage ($P < .05$) of linoleic (C18:2cis) acid. Total unsaturated and polyunsaturated fatty acids expressed as a percent of total lipid were highest ($P < .05$) in the HOC treatment. Differences ($P < .05$) were found in the percentage of monounsaturated fatty acids within the HOHOC diet, with the concentration of oleic (C18:1cis) acid

greatest ($P < .05$) in all six fat depots. In conclusion, the level of saturated and unsaturated fatty acids within corn-based diets significantly affects the fatty acid profile of fresh pork adipose tissue.

Key Words: fatty acid, oleic acid, pork

1828 Genetic line effects on palatability, color and physical characteristics of fresh pork loin chops. J. M. Schlickau*¹, M. S. Brewer¹, A. Sosnicki², B. Field², and F.K. McKeith¹, ¹*University of Illinois, 2**PIC.*

The objective of this study was to characterize the sensory attributes, color and physical characteristics of pork from pigs of the following backgrounds: Duroc, Pietrain (Halothane negative, NN), Pietrain (Halothane positive, nn), Berkshire, Hampshire (rn), Hampshire (RN-), and a synthetic line. A trained panel evaluated visual appearance of uncooked lean and fat, and flavor and texture of cooked chops. L*, a*, and b* values, hue angle, cookloss and Warner-Bratzler shear force also were determined. Chops from Hampshire rn carcasses appeared more pink than those from Hampshire RN- carcasses. Chops from Duroc, Berkshire, Pietrain-nn, and the synthetic line had the lowest pink color intensity and were a minimum of 4 scale units lower than chops from Hampshire-rn carcasses. Chops from Berkshire carcasses appeared most marbled in the lean followed by those from Hampshires; chops from the synthetic line and from Pietrain-nn pigs appeared least marbled. Chops from Pietrain-nn and Hampshire-rn carcasses had the highest a* values; chops from Duroc, Pietrain-NN, and Hampshire-RN- carcasses had the lowest. Cook loss from chops from Duroc carcasses was lower than that from Hampshire, Pietrain-NN and synthetic line carcasses. The total cook loss range was 2.5% which could have significant economic implications. Warner-Bratzler shear force was highest for chops from Pietrain-nn and Hampshire-rn carcasses. Chops from Hampshire-RN- carcasses were most juicy followed by those from Hampshire-rn, Pietrain-NN, Berkshire and Duroc carcasses. Warner-Bratzler shear force was positively correlated with abnormal flavor intensity, metallic taste, and chewiness ($r = 0.72, 0.94, \text{ and } 0.69$, respectively), and negatively correlated with sweetness ($r = -0.73$). As shear force increased, off flavors, metallic flavors and chewiness increased while sweetness decreased suggesting that genetic background may have some indirect impact on flavor. Overall, genetic background had significant effects on many of the quality characteristics evaluated, however, no one genetic background resulted in high scores in all, or even most, traits. This indicates that different genetic lines have different quality attributes to contribute.

Key Words: genetic lines, cook loss, color

1829 Effect of enhancement of beef rounds on sensory and retail display characteristics. K.L. Robbins* and M.S. Brewer, *University of Illinois, Urbana-Champaign, IL.*

Beef round roasts from USDA Choice and Select beef carcasses were used to evaluate the potential for enhancing sensory and retail display characteristics by injecting a solution of sodium chloride and phosphate. Paired sides were fabricated and the semimembranosus was removed from each side. The right and left sides were randomly assigned to control or injected treatments (0.4% sodium chloride 0.4% phosphate solution pumped to 110% raw weight). Muscles were pumped at day 14 - 21 postmortem. Following equilibration (5 - 10 d), steaks from each section were sliced to 2.5 cm and used for either sensory evaluation or overwrapped and displayed in a coffin style display case at 4C for up to 6 days. Samples for sensory evaluation and Warner Bratzler shear were cooked to 72C in electric skillets. Data were analyzed using a paired-T procedure. The trained panel determined that the enhanced steaks were significantly ($P < 0.05$) more juicy and salty than the control steaks; however, tenderness and Warner Bratzler shear values did not differ. Enhancement had a detrimental effect on the color scores of the round steaks over display time. After two days in display, the enhanced steaks had significantly ($P < 0.05$) lower visual color scores indicating darkening and discoloration. By day 4, a* and b* values were significantly lower for the enhanced steaks indicating they were less red and yellow. The aerobic plate counts (APC) suggested that enhanced steaks were slightly more susceptible to microbiological growth during retail display; however, the difference was not significant. Further work is continuing to evaluate enhancement of lower quality grades of beef at

various times postmortem to improve sensory and retail display characteristics and to increase beef consistency and consumer acceptability.

Key Words: Beef, Enhancement, shelf life

1830 Effect of breed-type on the performance and carcass traits of hair-sheep. J. K. Apple¹, J. M. Burke², W. J. Roberts¹, J. S. Stephenson¹, and L. K. Rakes¹, ¹University of Arkansas, ²USDA-ARS Small Farms Research Center, Booneville, AR.

Live animal performance and carcass characteristics were measured for purebred Katahdin (K; n=15) and St. Croix (SC; n=8) lambs, as well as three-quarter St. Croix (SCX; n=8), Dorper × Romanov × St. Croix (DX; n=9), and Dorper × St. Croix (DXSC; n=7) lambs. After weaning, lambs were allowed 4 weeks to acclimate to a high concentrate finishing diet, which was fed for 120 to 127 d. Lambs were then transported to the University of Arkansas Red Meat Abattoir for harvest. At harvest, K, SC, SCX, DX and DXSC weighed 44.8, 43.7, 42.8, 49.6 and 56.4 kg, respectively. Carcass quality and cutability data were collected after a 7-d aging period at 2 C. From birth to weaning, K and DXSC lambs had higher (P<0.01) ADG than SC and SCX lambs; however, from weaning to harvest, DXSC had the highest (P<0.01) ADG, followed by DX, SC, SCX and K (253.7, 226.1, 204.9, 193.1 and 181.1 g/d, respectively). Carcasses from DXSC lambs were heavier (P<0.01) than all other breed-types; whereas, carcasses from K, SCX, DXSC and DX had greater (P<0.01) actual and adjusted fat thickness measurements, and resulting yield grades, than SC. Although fatter, carcasses from DXSC lambs had the largest (P<0.01), and SC and SCX lambs the smallest (P<0.01) longissimus muscle (LM) areas. Although kidney fat weights were similar (P>0.72), carcasses from SCX lambs tended (P<0.08) to have a higher percentage of internal fat than DX, DXSC and K lambs. Skeletal, lean and overall maturities were not different (P>0.26) among the breed-types; conversely, carcasses from SC lambs had lower (P<0.05) flank streaking scores than SCX, DXSC and K, with DX carcasses receiving intermediate scores. Conformation scores for DX and DXSC carcasses were substantially higher (P<0.01), resulting in higher (P<0.01) quality grades, than SC and SCX carcasses. Although L* values of the LM were similar (P>0.84), the LM from DX lambs was redder (P<0.01) and more yellow (P<0.01) than SC and DXSC. Results from this study indicate that improvements in ADG and carcass muscularity and quality can be achieved by using Dorper sires on purebred and crossbred St. Croix dams.

Key Words: Hair-sheep, Carcass quality, Cutability

1831 Relationship between porcine longissimus dorsi pH decline and μ -calpain activity/autolysis and protein degradation. L.J. Rowe, S.M. Lonergan, M.F. Rothschild, and E. Huff-Lonergan*, Iowa State University, Ames, IA.

Degradation of muscle proteins by μ -calpain has been hypothesized to affect meat tenderness and water-holding capacity. The rate and extent of pH decline in postmortem (PM) muscle tissue may affect μ -calpain activity and subsequently the rate and extent of muscle protein degradation. The objective of this study was to determine the relationship between PM muscle pH decline, μ -calpain autolysis and muscle protein degradation in pork. To achieve these objectives, 10 market weight pigs were harvested. The pH measures of the longissimus dorsi (LD) were taken at the last rib at 2 h and 24 h PM. Samples of the LD were taken at 2 h, 24 h, 72 h, 5 d, and 7 d PM. The LD samples were extracted in 5 vol of 50 mM HEPES, pH 7.6, 150 mM NaCl, 10% glycerol, 0.1% Triton X-100, 5 mM EDTA, 2 mM PMSF. After centrifugation, a portion of each supernatant was used for casein zymography to obtain a relative comparison of μ -calpain activity. The remainder of the supernatants and the pellets were used for immunoblotting with antibodies against μ -calpain 80-kDa subunit, desmin and troponin-T. Casein zymography revealed that a majority of the samples lost detectable μ -calpain activity between 24 and 72 h PM. Samples with the lowest pH at 2 h PM lost μ -calpain activity in the supernatant earlier than samples that had slower, limited pH decline. Immunoblotting of supernatants from all 2 h PM samples showed that the 80-kDa subunit of μ -calpain was intact. The 80-kDa subunit of μ -calpain was at least partially autolyzed in all samples by 24 h PM. Samples with higher pH values at 2 h and 24 h PM had the least extensive autolysis of the μ -calpain 80-kDa subunit in the supernatant 24 h PM. In all samples the 80-kDa subunit of μ -calpain was completely autolyzed by 72 h PM. Samples that had more extensive autolysis of μ -calpain at 24 h PM had earlier degradation of troponin-T

and desmin compared to samples that had less extensive autolysis of μ -calpain at 24 h PM. These data indicate that rate and extent of pH decline may affect autolysis and activity of μ -calpain.

Key Words: μ -Calpain, Pork, pH

1832 Potassium Lactate and Sodium Diacetate Affects on the Microbial, Sensory, Color and Chemical Characteristics of Vacuum-Packaged Beef Top Loin Steaks. T. A. Williams*, R. K. Miller, N. Anwar, L. M. Lucia, and G. R. Acuff, Texas A&M University, College Station, TX.

Non-meat ingredients to enhance shelf-life, visual attributes and sensory characteristics of steaks is of high interest in the beef industry. The objective of this study was to examine the effects of injected potassium lactate and sodium diacetate on shelf life, tenderness, taste and color of top loin steaks. Beef strip loins (n = 48) were assigned to eight treatments: controls (non-injected and injected with water and sodium tripolyphosphate), potassium lactate (1.5, 2.0, and 2.5%), sodium diacetate (0.1%), and combinations of the two (1.5 /0.1 and 2.0/0.1%). After injection (110% of raw weight), top loin steaks were vacuum-packaged and evaluated for aerobic plate count (APC), Minolta color space values, trained meat descriptive attribute panel color evaluation, 2-thiobarbituric acid values (TBA), pH, purge (%), cook yield (%), Warner-Bratzler shear force (kg), and trained meat descriptive attribute sensory evaluation after 0, 7, 14, 21, 28, 35, 42, and 49 days of vacuum-package storage at 4C. Addition of sodium diacetate either alone or in combination with potassium lactate was effective in lowering APC for up to 49 days (P < 0.05). Potassium lactate increased pH (P < 0.01) and cook yield (P < 0.01), and decreased purge (P < 0.05) and shear force values (P < 0.01). Steaks injected with potassium lactate were darker (P < 0.01), but color brightened when potassium lactate was used in combination with sodium diacetate. Steaks injected with either potassium lactate and/or sodium diacetate had more two-toned color (P < 0.01) than unpackaged controls. Potassium lactate improved muscle fiber tenderness (P < 0.01), connective tissue amount (P < 0.01), and overall tenderness (P < 0.01) as determined from trained meat descriptive attribute sensory evaluation. Sensory data showed that steaks injected with potassium lactate had more soda (P < 0.01), chemical flavor aromatics (P < 0.01), salt (P < 0.05), bitter tastes (P < 0.05), and soapy aftertaste (P < 0.01) compared to controls. To increase shelf life of vacuum-packaged beef top loin steaks at 4C, 2.0% potassium lactate with 0.1% sodium diacetate is recommended; however, two-toned color and off-flavor may result.

Key Words: Beef, Potassium lactate, Sodium diacetate

1833 The influence of diets containing conventional corn, conventional corn and choice white grease, high oil corn, or high oleic, high oil corn on belly/bacon quality. G. Rentfrow*¹, K.R. Maddock¹, C.A. Stahl¹, M.L. Linville¹, T.E. Sauber², G.L. Allee¹, and E.P. Berg¹, ¹University of Missouri, ²Dupont Specialty Grains.

The objective of this study was to evaluate the effect of corn type on belly firmness and bacon slicing yields. Crossbred barrows (n=196; 26.6 kg) were given ad libitum access to one of four corn-based diets consisting of conventional corn (CONV), CONV with choice white grease (CWG), high oil corn (HOC), or high oleic, high oil corn (HOHOC). Following 98 d on test, two animals representing the average pen weight (118 kg) were selected for harvest (n=56). Bellies were removed according to IMPS 408 specifications. Lateral and vertical flex tests were performed to determine the firmness of each belly. A higher lateral and a lower vertical flex indicated a firmer belly. Bellies were weighed prior to pumping and pumped to a target of 12% retention at a commercial packing plant. After pumping, bellies were re-weighed for actual pumping percentage, and cooked according to commercial protocol. Bacon slabs were pressed then sliced by a high-speed slicer at nine slices per 2.5-cm. Incomplete slices were removed from each end and weighed for determination of slicing yield. Each slab was divided into five equal sections. The first two slices from each section were used for fracture analysis and cooking evaluation, respectively. Bacon slices were cooked on a belt cooker targeting 40% of the original weight. Weight and length were determined on each slice before and after cooking to calculate cooking loss and shrink. No differences were observed between LSMEANS

across treatment for percentage pump retention, smokehouse yield, slicing yield, or slicing fractures ($P>0.05$). Also, no differences were observed for cooking loss or length of shrink. The CONV had the lowest vertical and the highest lateral flex, while the HOC possessed the highest vertical and the lowest lateral flex. Based on the results of this study, corn type influences belly flex but does not affect pump retention, slicing yields, or slicing fractures

Key Words: Bacon, Corn-type

1834 The effect of early weaning and intensive feeding on meat quality of beef cattle. PE Strydom* and EM Buys, *Animal Nutrition and Products Institute of the Agricultural Research Council.*

Twenty crossbred steer calves selected from the Sams Tender Beef Program[®] (STB) were compared to 20 conventionally raised steers (C). STB involves weaning at three months of age (instead of seven months or more), feedlot feeding for approximately 150 days (compared to 100 days conventional). Both groups were implanted with an anabolic growth promoter, fed a commercial feedlot diet and were slaughtered at the same carcass fat condition. The *M. longissimus* (LT) and *M. semitendinosus* (eye of silverside) (ST) of both sides of the carcass were sampled and aged for either 12 or 21 days and evaluated for sensory meat quality and shear force resistance. In addition, discoloration (metmyoglobin) of steaks displayed at 4 °C for a period of 4 days were measured for loins aged for 1, 12 and 21 days (0 - 2 °C). The STB procedure had a significant effect ($P<0.05$) on tenderness related characteristics of the LT and ST at both aging periods (Table 1). The effect of the STB procedure was less for the LT than for the ST muscle. The advantage of STB was emphasized by the fact that sensory tenderness scores tended to be higher for STB meat aged for 12 days compared to C meat aged for 21 days for both muscles. Prolonged aging (21 days) tended to reduce the advantage of STB over C. Although the STB treatment tended to discolor at a faster rate during retail display than C, neither treatment nor aging period had a significant effect on color shelf life (metmyoglobin accumulation). Furthermore, both treatments had metmyoglobin levels of < 14% after 4 days; well below the threshold level for consumer discrimination of 35%.

Aging period	Sams Tender Beef		Conventional		SEM*
	12 days	21 days	12 days	21 days	
First bite tenderness†	6.40 ^{bc}	6.64 ^c	5.46 ^a	6.03 ^b	0.119
Overall tenderness	6.53 ^{bc}	6.72 ^c	5.56 ^a	6.09 ^b	0.118
Residual connective tissue	6.24 ^{bc}	6.37 ^c	5.61 ^a	5.92 ^{ab}	0.090
Shear force Resistance (Newton)	87.2 ^{bc}	78.6 ^c	106.8 ^a	92.7 ^b	2.70

^{abc} Means for each characteristic with different letters differ significantly ($P<0.05$) * Standard error of mean † Worst for score 1, best for score 8

Key Words: Beef, Tenderness, Color shelf life

1835 The effect of dietary supplemental vitamin E and C on odors and color changes in irradiated pork. S. Ohene-Adjai*, T. Bertol, Y. Hyun, M. Ellis, S. Brewer, and F. K. McKeith, *University of Illinois at Urbana-Champaign.*

Pigs (n=8/dietary treatment), were fed 4 dietary treatments: a control (CD, vitamin E- 26mg/kg feed), vitamin E (vitE-200mg/kg feed), vitamin C (vitC-500mg/kg feed), or vitamin E and C (vitEC-200 and 500mg/kg feed respectively) diet. The vitE was fed for 6 wk and vitC for 5 d. The pigs were harvested and loin (LD) and ground pork (Gr) samples were prepared in duplicates. Paired samples from the sides of individual pigs were randomly assigned to irradiation (IR) (4.5 kGy) or no irradiation (NIR) treatment to evaluate the effect of the dietary antioxidants on post-IR odor, color, and lipid oxidation. Treated LD and Gr samples were PVC-overwrapped and held in display (4°C) for 8 (Gr) and 9d (LD) to evaluate the shelf life characteristics. Color (L*, a*, and b*) and TBARS were evaluated at 0, 2, 4, and 8 for Gr and 0, 3, 6, and 9 d after overwrap for LD. Discoloration (%) of the irradiated LD was not different across dietary treatment until after 6 d. Odor intensity

worsened with irradiation. Increasing storage time resulted in darker (L*), less red (a*) samples regardless of treatment. In the LD, change in L*, a* and b* were higher in the IR than the NIR. Also, yellowness (b*) decreased over time but was generally higher in the NIR than IR. In the Gr, % discoloration and odor intensity were ($P<0.001$) higher in IR than NIR. Gr-IR was darker (L*) compared to NIR. The NIR became less red with time (a*), and IR resulted in less yellow (b*). In the ground samples TBARS were significantly higher in the IR (4.2) than in the NIR (0.9) after 2 d storage. Compared to CD-IR treatment, vitE-IR resulted in lower TBARS by 4 d. Increased TBARS occurred in vitC-IR (9.71) compared CD-IR (5.1) by 4 d. The results suggest that irradiation resulted in color and odor changes; vitE reduced TBARS while vitC increased the TBARS compared to the CD-IR treatment.

Key Words: Vitamin E, Vitamin C, Irradiation

1836 Effect of the addition of electrolytes in drinking water and the chilling temperature on technological, physicochemical, and microbiological characteristics of pork. A. Alarcon-Rojo, S. Mendoza*, and A. Grado, *Universidad Autonoma de Chihuahua. Chihuahua, Chih. Mexico.*

With the objective of determining the effect of the addition of electrolytes in pig drinking water during resting and the effect of chilling temperature on technological, physicochemical and microbiological characteristics of pork, two experiment were carried out using 280 pigs from a technified farm of the central region of Mexico. The objective of experiment 1 was to evaluate the effect of electrolytes on meat quality. 80 pigs were offered electrolyte-containing water as the only drinking source during resting time, whereas the other 80 pigs were reared conventionally with only water as a drinking source. The objective of experiment 2 was to evaluate the effect of chilled carcass internal temperature (10 and 12 C) on meat quality, and the design consisted of two groups of 60 animals held at each temperature. The addition of electrolytes did not significantly ($P>.05$) affect drip loss, water holding capacity, carcass and leg yield, pH and temperature at 24 h post mortem, but improved ($P<.05$) meat color (L* = 39.74 0.42, a* = 2.82 0.19, and b* = 11.59 0.19 for the treated group versus L* = 42.40 0.42, a* = 2.26 0.19 and b* = 10.36 0.19 for the control group), increased pH at 45 min post mortem (6.53 0.02 versus 6.45 0.02), decreased temperature at 45 min post mortem (34.95 0.05 versus 35.69 0.05 C) and decreased electrical conductivity at 45 min (4.45 0.08 versus 5.23 0.08 mS/cm) and at 24 h post mortem (5.06 0.09 vs. 5.85 0.09 mS/cm). Carcasses with 10 C chilled carcass internal temperature showed higher ($P<.01$) cold carcass yield (2.55 0.15 versus 1.84 0.15%) but boned leg yield, water holding capacity, color, pH, temperature, electrical conductivity and bacterial counts of meat were not affected ($P>.05$). It is concluded that the addition of electrolytes in pig drinking water during resting improves physicochemical characteristics of meat, whereas having a chilled carcass internal temperature of 10 C improves cold carcass yield.

Key Words: electrolyte, pork quality, chilling temperature

1837 Relationship between a measure of troponin-T degradation and beef tenderness. L. J. Rowe, E. Huff-Lonergan, G. H. Rouse, D. E. Wilson, and S. M. Lonergan*, *Iowa State University.*

Development of beef tenderness during postmortem aging is believed to be due to degradation of muscle proteins, which results in a decrease in structural integrity of myofibrils. Observations of proteolysis of troponin-T and subsequent production of a 30-kDa protein product during postmortem aging have been widely reported in the literature. The objective of the current study was to determine the relationship between Warner-Bratzler shear (WBS) values and the presence of the 30-kDa band using densitometry. Angus bull calves (n=128) were used to meet this objective. Samples (2.54 cm and 0.5 cm thick) were removed from the 12th rib region of the right side of each carcass. Steaks (2.54 cm) were sliced, vacuum packaged, aged for 14 d at 1 C and frozen until WBS analysis. Steaks were cooked to an internal temperature of 71C and cooled to room temperature. Six cores (1.25 cm) from each steak were used to determine WBS. The 0.5 cm sample was vacuum packaged, aged for 7 d at 1C and frozen. These samples were used to monitor protein degradation by immunoblotting using an anti-troponin-T antibody. An extract from a reference sample (beef loin aged 7 d) was used on each membrane to serve as a reference across blots. Relative intensity of the 30 kDa bands was determined using the Kodak 1D 2.0 software and a

digital camera (Kodak DC120; Eastman Kodak, Rochester, NY). A ratio (relative intensity of 30-kDa band in the sample/intensity of 30-kDa band in the reference) was used as a measure of proteolysis. Samples were classified to 5 groups based on detection of the 30-kDa band (0 = no proteolysis, 4 = most proteolysis). WBS at 14 d postmortem was significantly negatively correlated (-.433) with the relative intensity of the 30 kDa band present at 7 d postmortem. Samples that showed no proteolysis after 7 days had the highest WBS of any group ($P < 0.01$). Samples classified in group 4 had a lower WBS than groups 0, 1 and 2. The results indicate that measures of troponin-T degradation may be useful in identifying sources of variation in tenderness of beef.

Key Words: Beef, Tenderness, Troponin-T

1838 Use of color and near-infrared reflectance analysis to predict Warner-Bratzler beef longissimus tenderness. C.E. Realini^{*1}, T.D. Pringle¹, W.R. Windham², B.G. Lyon², S.K. Duckett¹, and K.R. Smith¹, ¹The University of Georgia, Athens, ²USDA-ARS, Russell Research Center, Athens.

This research used Angus heifers ($n=9$) to determine the ability of muscle color and near infrared reflectance (NIR) to predict tenderness of longissimus lumborum steaks. Lipid content, Warner-Bratzler shear force (WBS), Hunter L*, a*, and b* values, and visible (VIS) and NIR spectra were measured after 2, 4, 8, 14, and 21 d of aging. Shear force values were higher ($P < 0.01$) at 2 d than at all other aging times (5.9, 4.8, 4.7, 4.5, and 3.9 kg for 2, 4, 8, 14, and 21 d, respectively), and lower at 21 d ($P < 0.01$) than at other aging times. Hunter L*, a*, and b* values increased with aging time indicating that steaks became lighter, redder and yellower during postmortem storage. Correlations of WBS with colorimeter data were higher than with lipid percent. Among the color measures, L* values had the highest correlations with WBS except at 2 d of aging. Day 2 L* values accounted for 28.0, 20.4, 4.0, 0.1, and 6.9% of the variation in WBS, while lipid percent accounted for 3.2, 0.6, 7.9, 8.2, and 15.2% at 2, 4, 8, 14, and 21 d, respectively. Partial least squares (PLS) regression was used to predict WBS from VIS and NIR spectra. Spectra from three regions (400-780 nm, VIS; 780-1850 nm, NIR; and 400-1850 nm, VIS/NIR) were used in PLS modeling of WBS. The SE of cross validation and R² were 0.65 kg and 0.36, 0.71 kg and 0.37; and 0.57 kg and 0.52 for the VIS, NIR, and VIS/NIR regions, respectively. The first principal component (PC) from the VIS/NIR spectra indicated variation in WBS values was due primarily to absorption in the VIS region. Protein and fat absorption peaks at 1138 and 1390 nm, respectively, were present in the second factor, with no absorption peaks in the visible region. The third PC indicated absorption in the VIS region, and protein and fat in the NIR region. The first 3 PC explained 61% of the variation in WBS, and suggest that this prediction is based on information in both the VIS and NIR spectra. It is not clear whether the information in the VIS/NIR spectra was sufficient for practical meat tenderness prediction, and samples with larger variation in WBS are needed to more accurately define this relationship.

Key Words: Beef, Tenderness, Near-infrared

1839 Effect of conjugated linoleic acid supplementation on pork quality and fatty acid profiles. M.W. Greene^{*1}, T.D. Pringle¹, M.J. Azain¹, M.H. Gillis¹, S.K. Duckett¹, G.J. Hausman², and C.R. Barb², ¹The University of Georgia, Athens, ²USDA-ARS, Russell Research Center, Athens.

This study was conducted to determine the effects of supplemental conjugated linoleic acid (CLA) on pork quality and fatty acid composition.

Crossbred gilts ($n=15$) were fed a corn/soybean ration containing 0, 0.5 or 2.0% CLA and humanely harvested at the University of Georgia Meat Science and Technology Center. Backfat samples were removed immediately after slaughter for determination of fatty acid composition. Following a 24-h chill, carcasses were ribbed and carcass data, including visual color and marbling scores, were collected. Longissimus L*, a*, and b* values were recorded and samples were removed for lipid determination. CLA supplementation had no effect ($P > 0.05$) on daily gain, feed intake or feed:gain. Tenth rib backfat (0.69, 0.60, and 0.63; SEM=0.55) and loin eye area (6.0, 5.8, and 5.3; SEM=0.3) were numerically lower in CLA treated pigs. Neither visual longissimus color scores nor Hunter L*, a*, and b* values differed across treatments. Marbling scores were numerically higher in the 2.0% CLA-treated pigs than the control and the 0.5% CLA-treated pigs (1.5 and 1.5 vs. 1.8; SEM=0.3); which was consistent with the longissimus lipid percentages across CLA treatments (2.8, 3.0, and 3.4; SEM=0.3). Fatty acid profiles showed that CLA percentage in the subcutaneous fat increased ($P < 0.01$) as CLA in the ration increased (c9t11; 0.2, 0.6, and 1.6; SEM=0.1; t10c12; 0.1, 0.4, and 1.8; SEM=0.1). As expected, the percentage of saturated fatty acids in the backfat increased ($P < 0.05$; 32.0, 33.7, and 37.7; SEM=1.3) and monounsaturated fatty acids decreased ($P < 0.01$) as CLA concentration in the ration increased (42.7, 39.1, and 37.2; SEM=0.9). These changes were due primarily to incremental increases in the percentage of C18:0 and decreases in the percentage of C18:1 as dietary CLA increased. Dietary CLA supplementation significantly alters fatty acid composition; however, more research is needed to document significant compositional changes at the carcass level.

Key Words: CLA, Pork, Fatty Acids

1840 Perimysium structure and collagen content change with muscle type and myostatin inheritance. R Taylor^{*1}, R Labas¹, P Berge¹, and J Culioli¹, Meat Research Station, INRA.

Previous studies have shown that collagen content and heat stability change with muscle type and/or age. Less well characterized is how changes in collagen are expressed structurally, as changes in perimysium. To investigate this we studied three different models in beef cattle which may have changes in collagen and perimysium. Comparison of muscle types *Pectoralis profundis* (Pp), *Gluteus biceps* (Gb) and *Semitendinosus* (St) showed that Pp has more perimysium, measured histologically as % muscle surface area and as length, than St and Gb. Qualitative evaluation showed that the form of the perimysium was clearly different in Pp compared to St and Gb, which were not different. As expected the collagen content and thermal properties varied with muscle type. In the second model myostatin -/- animals, with extensive muscle hypertrophy, were compared to normal animals, myostatin +/- animals. Myostatin -/- animals had less perimysium as % area and length, more soluble collagen and less total collagen (approx.-30%). In the third model *Semimembranosus* muscle was compared in cows from 2 contrasting breeds and production systems, i.e. Holstein (dairy) and Salers (meat, "rustic", raised in highlands), and finished in similar conditions. The hypothesis was that both breed and production system affect perimysium and collagen properties. However, no difference was found in perimysium distribution or collagen parameters comparing these breeds. We conclude that the major growth gene myostatin and muscle type, but not Holstein versus Salers breeds, have significant effects on perimysium organization.

ASAS Beef Species

1841 Pre-slaughter condition scoring of Zebu Cattle. O.T.F. Abanikannda^{*1}, A.O. Leigh¹, O.Y. Apena¹, and O. Olutogun², ¹Department of Zoology, Lagos State University, Ojo - Lagos, Nigeria, ²Department of Animal Science, University of Ibadan, Nigeria.

Condition scoring provides a quick, cheap and easy method of assessing an individual animal brought to the abattoir for slaughter. In this study, nine scores were used in which the three main conditions: fat (F), medium (M) and lean (L) were further subdivided into three categories: F+, F, F-; M+, M, M-; L+, L and L-. Four-hundred, fifty-four

cattle comprising 362 male and 92 female, 26 polled and 428 horned were evaluated. Of the three main categories, 54.85% were fat, 29.30% were medium and 15.85% were lean. However, the F+ had the highest frequency (40.16%) of the fat, the M+ had 64.66% of the medium while L- had the highest frequency (80.55%) of the lean. It is not surprising that over half of the cattle brought to the abattoir and lairage belong to the F class. This is because most of the cattle that are better priced are those that are visually appealing and which are expected to yield higher meat to bone ratio. Lagos, being of cosmopolitan nature, boasts the best or choice grade of cattle, despite the fact that these animals are

not bred within the state. The poorly conditioned cattle are lower priced and often rejected right from the farm. When farmers decide to market such animals, they often can not withstand the rigours associated with cattle transportation and handling and usually are dead before reaching the market. This study provides a means by which cattle from different farms under differing management systems can be quickly and cheaply appraised and assessed.

Key Words: Condition Scoring, Zebu, Nigeria

1842 Safety of moxidectin 1% nonaqueous injectable solution for cattle. K.L. Simkins*, R.L. DeLay, and T.W.J. Olchoway, *Fort Dodge Animal Health, Princeton, NJ.*

Moxidectin is used in cattle for controlling internal and external parasites. The objective of this study was to evaluate the safety of moxidectin 1% nonaqueous injectable solution administered subcutaneously to crossbred cattle (244 to 298 kg BW) at dosages of 0.2, 0.6 or 1.0 mg moxidectin/kg BW (1X, 3X or 5X the expected use level) given 3 times with 7 day intervals. There were 4 steers and 4 heifers in each of the following groups: A (saline control), B (1X), C (3X) and D (5X). Physical exams were conducted before and after treatment. All animals were observed daily for clinical signs following treatments. Hematology, serum chemistry, urinalysis and fecal analysis were conducted at 3 and 1 days prior to treatment and at 6 days after each treatment. All animals were necropsied 7 to 10 days after the third treatment and examined for gross pathology. Histopathology was conducted on approximately 40 tissues for each animal in Groups A and D. Physical exams showed no treatment related abnormalities. There were no apparent adverse clinical reactions following treatment. Hematology results showed that none of the treated groups were different from controls ($P > .10$) for red blood cell counts, hematocrit, platelets and activated partial thromboplastin time. Hemoglobin concentration for Group D was lower than Group A (10.04 vs 10.42 g/dL, $P < .10$). White blood cell counts for Groups C and D were higher than controls ($P < .10$). However, all hemoglobin and WBC counts were within normal ranges. Serum chemistry results showed that none of the treated groups were different from controls ($P > .10$) for glucose, phosphorus, sodium, chloride, potassium, total protein and total bilirubin. Serum iron was lower in all treated groups compared to controls ($P < .10$), but all iron concentrations were within normal ranges. Urine, feces, gross pathology and histopathology evaluations showed no treatment related abnormalities. The results of this study show that moxidectin 1% nonaqueous injectable solution is safe for cattle following administration of the expected use level of 0.2 mg moxidectin/kg BW or 3X and 5X this level at weekly intervals for 3 consecutive weeks.

Key Words: Moxidectin, Cattle, Safety

1843 Effect of supplemental energy source on growth and reproductive performance of virgin heifers consuming corn silage diets. C.M. Howlett*, E.S. Vanzant, L.H. Anderson, W.R. Burris, J. Randolph, and R.F. Bapst, *University of Kentucky.*

Ninety-six crossbred, virgin beef heifers (249 kg) were used in a randomized complete block design to determine the effects of source of supplemental nutrients on average daily gain (ADG) and reproductive performance. Heifers were randomly assigned within each of three weight blocks to 4 pens of 8 heifers each. The four pens within each block were assigned at random to one of four diets based on corn silage (CP=8.2%, TDN=63.5%) at 42% DMI with minerals supplied at 2% DMI. Treatments were: 1) corn and soybean meal (CSBM) at 56% DMI; 2) whole linted cottonseed at 15% DMI (COT); 3) whole raw soybeans at 15% DMI (SB); or 4) pelleted soyhulls at 30% DMI (SH). In diets 2 through 4, COT, SB, and SH replaced a portion of the corn and soybean meal. Diets were formulated to be isonitrogenous (13.7% CP) and were fed at approximately 2.2 X NEM to achieve target weights equal to 65% of expected mature body weight at the time of AI. Animals were weighed every 28 d for 112 d with weights obtained on two consecutive days at the beginning and end of the treatment period. After each weighing, feeding levels were adjusted for each pen to account for weight gain. Beginning on d 113, treatments were discontinued and all groups were fed a common diet at an appropriate level to maintain target gains. Serum was obtained for progesterone analysis on days 112 and 119. Heifers were considered to have initiated estrous cycles if progesterone concentrations exceeded .5 ng/ml in either sample. Heifers were synchronized with an MGA/PG system and bred by AI in response to detected heat on days

154 to 156 (beginning 48 h after PG administration). Since the energy value for SH was underestimated, cumulative ADG for SH (1.02 kg/d) was greater ($P \leq .03$) than for CSBM (.88 kg/d), COT (.87 kg/d), or SB (.86 kg/d). Number of estrous cycling heifers prior to synchronization for each treatment were: CSBM (n=13, 54%), COT (n=12, 50%), SB (n=16, 66%), SH (n=16, 66%). First-service conception rates were unaffected ($P > .10$) by treatment: CSBM 7:19 (37%); COT 8:21 (38%); SB 12:22 (55%); SH 8:19 (42%). Numerical trends suggest that SB may increase reproductive performance independent of energy supply in virgin heifers consuming a corn silage based diet.

Key Words: Energy, Supplementation, Conception

1844 Influence of Estrus Synchronization on Reproductive Performance of Cows Exposed to Natural Service. J. D. Rhinehart*, J. W. Wyles, and L. H. Anderson, *University of Kentucky.*

We tested the hypothesis that estrus synchronization would affect the interval to pregnancy and pregnancy rate in postpartum cows. In this experiment, crossbred postpartum cows (n = 84) and two-year-old heifers (n = 24) were randomly assigned to one of three treatments and balanced by age and calving date. The treatments consisted of 1) exposure to orally active melengestrol acetate (MGA, 5 mg/head/day as a top-dressed supplement to the basal diet) from D -7 to D -1 (D 0= first day of breeding season); 2) seven days of MGA exposure with administration of 25 mg of prostaglandin F₂α (Lutalyse, Pharmacia & UpJon, Kalamazoo, MI) on D -1 (MGA+PG); or 3) fed only the basal diet (CONT). On D 0, each group was exposed to natural service for 60 days (1 yearling bull per eight females). All bulls were subjected to, and passed, breeding soundness exams on D -30. Date of pregnancy was determined using rectal palpation on D 140. Pregnancy rates differed ($P = .08$) among cows in the CONT (86%), MGA (92%), and MGA+PG (100%) groups. Interval to pregnancy (number of days from onset of the breeding season to conception) was lower ($P < .05$) for cows in which estrus was synchronized (MGA, MGA+PG) than for cows which were not (CONT). Interval to pregnancy tended ($P = .13$) to differ between cows in MGA and MGA+PG groups. From these results we concluded that estrus synchronization, prior to natural service, improved reproductive performance in postpartum cows.

Key Words: Estrus Synchronization, MGA, Natural Service

1845 Influence of calving on body condition score in crossbred cows. Sarjan rao Kapa*¹, Dilipkumar Garikipati¹, and Kailash MM², ¹College of veterinary science, Tirupati, Angraui, ²University of Agricultural science, Bangalore.

A five-point body condition score technique based on visual, tactile or combined assessment of the amount of body condition carried by the cow was employed on 216 crossbred HF cows to study the postpartum changes in BCS. The BCS observed for all the first calvings and all other (2 through 4) calvings were 3.18 ± 0.39 and 3.52 ± 0.54 , respectively. The BCS at 60 days, 120 days and loss at 120 days of all lactations were 3.12 ± 0.79 , 3.06 ± 0.68 and 0.87 ± 0.62 , respectively were observed. The body condition loss ranged from 0.50 to 1.09 over the BCS range of 2.5 to 4.5 with an average of 0.27 points increase for every one unit higher initial BCS. The magnitude of condition loss depended primarily on score at calving and was greater for cows that calved with high BCS. After reaching the minimum score, cows gained the range of BCS from 0.18 to 0.27 and with an average gain of 0.04 points for every increase of one unit of BCS. The total amount of gain was mainly influenced by BCS at calving and by milk yield. The loss in BCS was low in comparison with gain in BCS. A quadratic relationship ($P < 0.0001$) existed between lactation number and BCS at calving with FCM production to 90 days in milk (DIM). The change in BCS from calving to 60 days vs 90 days FCM production was quadratically ($P < 0.0001$) related to lactation number which showed that lactation number accounted for most of variation in milk production. The BCS varied quadratically with days in milk and month in milk within each lactation. Mean BCS for 30 days lactation was significantly ($P < 0.05$) different at 241 to 270 days and ($P < 0.01$) at 90 to 120 days. All other 30 days of milk intervals and dry periods were not significantly different from respective adjacent 30 days lactation intervals. There was a significant difference in BCS between early dry cows and late dry cows.

Key Words: Body Condition Score, Days in Milk, Fat-corrected Milk

1846 Maternal performance of four biological types of Red Poll cows. B.A. Sandelin*¹, A.H. Brown, Jr.¹, Z.B. Johnson¹, A.M. Stelzleni¹, and C.F. Rosenkrans, Jr.¹, ¹University of Arkansas.

Maternal performance of four biological types of Red Poll cows born, reared and managed on Ozark Mountain range were evaluated. Growth curve parameters of mature weight (A) and maturing rate (k) were estimated for 59 Red Poll cows using the Brody Model. Cows were assigned to one of four biological types: large late maturing (LL, A > 455 kg, k < 0.0500%), large early maturing (LE, A > 455 kg, k > 0.0500%), small late maturing (SL, A < 455 kg, k < 0.0500%), and small early maturing (SE, A < 455 kg, k > 0.0500%). Weights for calves were recorded at birth, 120, 240, and 360 d. Distribution of calf weights by biological cow type included: LL (n = 99), LE (n = 37), SL (n = 24), and SE (n = 85). Age and age of dam adjusted calf weights were analyzed using a model that included terms for an overall mean, year, type, sire, sex, interactions of type x year and type x sex, and residual error. Year, type, and

sex were considered fixed effects and sire was considered a random effect. Year x type interactions were significant for weight at all ages, but sex x type interactions for weight were not significant at any age. Calves born to the four biological cow types had similar (P > 0.05) mean birth and 360 d weights. Small, early maturing cows had calves with smaller (P < 0.05) mean 120 d weights than calves of other biological types (135.5 vs 145.4, 147.5, 148.6 kg). Large and small, late maturing cows and LE cows produced calves with similar (P > 0.05) mean 240 d weights (217.4, 215.6, and 211.6 kg) and their calves were heavier (P < 0.05) than those of SE cows (197.4 kg). However, there was no difference (P > 0.05) in the 240 d weights between the LE and SE cow types. Mean weaning rates for LL, LE, SL, and SE cows were 85.5, 82.7, 76.8, and 83.4%, respectively. These data suggest that size and maturing rate of Red Poll cows managed with limited resources, influences preweaning calf performance, but may not affect weaning rate.

Key Words: Mature weight, Maturing rate, maternal performance

ASAS Goat Species and ASAS Companion Animal Species

1847 Evaluation of Corn Gluten Meal as a Protein Source in Canine Diets. R.M. Yamka*¹, S.E. Kitts¹, A.D. True¹, D.L. Harmon¹, and W.D. Schoenher², ¹Dept. of Animal Sciences, University of Kentucky, Lexington, 40546, ²Hill's Pet Nutrition, Topeka, KS 66617.

Ten mature dogs (19.0 kg + 0.4 kg) surgically fitted with ileal T-cannula were used in an experiment to determine the feeding value of corn gluten meal (CGM) in a complete diet fed to dogs. All diets contained 10% poultry meal and graded levels of CGM (0 to 32% DM) resulting in diets that were 10, 15, 20, 25 and 30% crude protein. Daily dry matter (DM) intake averaged 307 + 7 g/d. An increase in CGM resulted in an increase in fecal moisture from 51.6 to 57.5% (linear; P < 0.0001) and fecal DM output increased from 24.2 to 32.9 g/d (linear; P < 0.0001). Ileal DM flow increased from 34.8 to 51.3 g/d (linear; P < 0.0004). Small intestinal DM digestibility decreased from 88.9 to 83.4% (linear; P < 0.0002) and total tract DM digestibility decreased from 92.3 to 89.4% (linear; P < 0.0001) as CGM increased. Large intestinal digestibility (29.4% DM) was not affected by treatment. Crude protein (CP) fecal excretion increased from 5.6 to 8.1 g/d (linear; P < 0.0004) and ileal flow of CP increased from 9.4 to 16.9 g/d (linear; P < 0.002) as CGM increased. Small intestinal CP digestibility increased from 73.4 to 82.5% (linear; P < 0.002) with increasing CGM. Large intestinal CP digestibility was not affected by treatment (40.4% DM). Total tract CP digestibility increased from 84.5 to 91.1% (linear; P < 0.0001) as CGM increased. Disappearance of all amino acids (g/d) increased (linear; P < 0.0001) with increasing CGM. Glutamate had the highest disappearance ranging from 3.83 to 16.16 g/d. Histidine had the lowest disappearance ranging from 0.49 to 1.41 g/d. Arginine had the highest overall digestibility ranging from 86.2 to 87.6% whereas, threonine had the lowest digestibility ranging from 64.7 to 75.1%. These data indicate that CGM is a highly digestible protein source for canine diets with dietary inclusions of 8.4 to 32.2%.

Key Words: Corn Gluten Meal, Amino Acid, Canine

1848 The effects of an antioxidant system based on tocopherols and novel extracts from Rosemary on petfood shelf-life and acceptability by dogs and cats. C. G. Aldrich* and J. O. Mann, Kemin Americas, Inc., Des Moines, IA.

A study was conducted to determine the shelf life and palatability of extruded petfood stabilized with tocopherols and novel extracts from rosemary. The treatments included a negative control in which fat was not treated with an antioxidant, a positive control in which fat was treated with NaturoxTM at 3000ppm, and fat treated with an experimental formula, RX13, at 3000 ppm. NaturoxTM is a tocopherol-based antioxidant system, whereas RX13 is a blend of tocopherols and the novel extract of purpose-bred rosemary. Equal portions of fat were applied internally and externally during processing in an Extrutech E525 extruder run at a rate of 800 lb/hr. Diets consisted of corn (49.5%), chicken by-product meal (30%), chicken fat (10%), beet pulp (4%), egg (3%) and yeast (3%), as well as, minerals and vitamins to 100%. Processing conditions remained constant for the test runs. In the oxygen bomb analysis, an accelerated shelf-life method, an induction time of 3.85 h was recorded for

the negative control. This compared to 6.75 h for the positive control; petfood that contained tocopherol-based NaturoxTM. The experimental formula, RX13, had an 11.2% longer predicted shelf-life than the positive control with an induction time of 7.60 h. Crude extracts of rosemary contain compounds that impart a distinctive aroma to which dogs and cats have an aversion. It is necessary to remove these volatile compounds through the use of rolled-film evaporation. To verify that the negative aromas were removed, the NaturoxTM and RX13 diets were fed to 20 Beagle dogs and 20 American Shorthair cats in a 4 day split-plate palatability test. In dogs, first bite, a reflection of aroma, was not affected by treatment (1.00:1.11). Likewise, total consumption, an indication of flavor, was not different (1.30:1.00). In cats, a similar result was observed in that first bite was similar between treatments (1.59:1.00), as was total consumption (1.34:1.00). It was concluded from this study that the novel extract of purpose-bred rosemary and its subsequent deodorization was an effective component of an antioxidant system for the stabilization of fat in extruded pet foods.

Key Words: Rosemary extract, Shelf-life, Palatability

1849 The effect of hay and /or concentrate on performance, organ mass, blood metabolites and hormones in weaned kids. B. Kouakou*, S. Gelaye, G. Kannan, T. H. Terrill, E. A. Amoah, and S. Miller, Agricultural Research Station, Fort Valley State University.

Weaned kids (BW = 12.6 kg; n = 12) were used in an experiment to determine the effect of hay, concentrate, or concentrate following hay feeding on performance, organ mass, thyroid hormones and blood metabolites. Kids were stratified by BW and randomly assigned to dietary regimen. Chopped rhizoma peanut (*Arachis glabrata*) hay or an 18% CP concentrate diet were fed during the two periods of 60 d each. During the first period, two groups of kids (n = 4; total = 8) were fed hay alone, and one group (n = 4), the concentrate diet. During the second period, one of the hay-fed groups (n = 4) was switched to the concentrate, while the other groups remained on the previous diets (hay, n = 4; concentrate, n = 4). Dietary treatments were identified as HH (Hay, Hay), HC (Hay, Concentrate) and CC (Concentrate, Concentrate) to indicate hay or concentrate for first and second period, respectively. Weights, feed and blood samples were taken every 20 d. At the end of the second period (120 d), all animals were slaughtered and digestive tract (reticulo-rumen and intestines including digesta), liver and hot carcass weight were recorded. Blood samples were analyzed for BUN, NEFA, glucose, T₄ and T₃. In period one, T₄ and T₃ were higher (P < .05 and P < .01, respectively), BUN and NEFA were lower (24.9 vs 33.4 mg/dL and 159.9 vs 271.8 mEq/L, respectively) in concentrate-fed than in those fed hay. Glucose levels were similar (57.8 mg/dL) for hay or concentrate-fed kids but BW gain was greater (P < .01) for concentrate-fed than for hay-fed animals. During period two, gain was similar (3.25 vs 4.25 kg for HC and CC animals, respectively) and T₃ was highest (P < .01) in HC followed by CC and HH animals. Both groups of animals fed concentrate in period two had lower (P < .05) levels of NEFA (483 and 415.6 vs 1264 mEq/L) and higher levels of glucose (69.9 and 53.6 vs 43.5 mg/dL) than those fed hay. Overall gain was highest (P < .01) for CC (11 kg) followed by HC (5.5 kg) and HH (1 kg) animals. Liver

weights were similar (424 and 388.5 g) for CC and HC but greater ($P < .01$) than in HH (247 g) animals. Digestive tract as a percent of BW was higher ($P < .01$) for HH than HC and CC animals. These results suggest that concentrate feeding increases liver weight, level of T_3 and decreases digestive tract mass as a percent of BW.

Key Words: Goat, Hormones Metabolites, Organ mass

1850 Weight Gain In Beetal Goats Under Two Different Rearing Systems. S. H. Raza*, A. Iqbal, and M. Abdullah, *University of Agriculture, Faisalabad, PAKISTAN.*

Amongst the goat breeds of Pakistan "Beetal" goat is important due to its better production performance. Goats are reared under extensive to semi extensive systems. Their production under "zero" grazing has not been explored. In this study production potentials of Beetal male animals under "zero" grazing and "total" grazing systems were tested. 24 Beetal male animals were randomly allotted to 2 treatments viz., "A" and "B", having 12 animals each. Animals under treatment "A" were allowed grazing along with a supplement of 200 g of concentrate/head. The animals in group "B" were kept indoors under "zero" grazing and fed green fodder *ad libitum* along with concentrate as in case on "A". The animals were kept on treatments for 100 d including 7 d of adjustment period. The data on weekly weight gain were recorded to calculate daily weight gain. At the end of the experiment, 2 animals from each group were slaughtered and data on different carcass parameters were recorded. Data analysis revealed that weight gain in both the groups differed significantly. Animals in treatment "A" gained 0.0236g more weight/d than animals on "zero" grazing. The dressing (12.63±0.63, 11.25±0.52), head and trotters (3.05±0.35, 2.80±0.28) and pluck (1.45±0.07, 1.45±0.00) weights (Kg) were found to be non significant for "A" and "B". The dressing, head and trotters and pluck percentages were found to be 49.50 and 44.10; 11.43 and 10.95 and 5.70 and 5.75, respectively. The dressing % was almost 1.38 Kg more for group "A" with non-significant difference. The values for bone (33.00, 42.08) and fat (6.25, 6.65) percentage were also found to be, statistically, non significant for "A" and "B" but the lean meat weight (Kg) differed significantly ($P < 0.05$) in group "A" (44.65±0.85) than animals on zero grazing 40.75±0.25. It can be concluded that under prevailing conditions, for the rearing of this free ranging animal, extensive system is most suitable unless a reasonably longer adjustment period from the time of birth is not provided.

Key Words: Goat, grazing, carcass

1851 Preslaughter stress effects on physiological responses and meat quality characteristics in goats. G. Kannan*, B. Kouakou, T. H. Terrill, S. Gelaye, and E. A. Amoah, *Agricultural Research Station, Fort Valley State University, Fort Valley, GA.*

This experiment was conducted to determine the effects of transportation stress on physiological responses and meat quality characteristics in dairy goats of different age groups. The goats ($n = 28$) were classified as young (Y, 6 to 12 mo of age) and old (O, 24 to 30 mo of age) groups (AGE), feed deprived overnight, and slaughtered in three replicates. On the day of each replicate trial, one group was subjected to a two-hour transportation (T) to impose stress and the other group was held (H) in holding pens (treatment, TRT) prior to slaughter. Blood samples were collected from both T and H goats at 0, 1, and 2 h after beginning of transportation (TIME). Meat quality was assessed on Longissimus dorsi muscles. The data were analyzed as Split-Unit designs using MIXED procedures in SAS. The T goats had higher plasma cortisol concentrations than H goats ($P < 0.01$), however, plasma leptin, T_3 , and T_4 concentrations were not affected by TRT, TIME, or TRT x TIME. The initial (15 min postmortem) and ultimate (24 h postmortem) muscle pH were not influenced by TRT. Muscle glycogen concentrations were higher in H than in T animals ($P < 0.05$). Muscle glycogen was also higher in O compared to Y goats ($P < 0.01$), and the decline in glycogen over 24 h was not influenced by TRT or AGE. Water holding capacity and CIE $L^*a^*b^*$ color values, measured at 24 h postmortem, were not affected by TRT. The O group had lower L^* values ($P < 0.01$) and greater a^* ($P < 0.01$) and chroma ($P < 0.01$) values than the Y group. Cooking loss and Warner Bratzler shear (WBS) values of loin chops, vacuum packed and aged for different times (0, 6, and 12 d), were not influenced by TRT. Age of animal ($P < 0.01$) and meat aging time ($P < 0.01$) influenced WBS, as expected. The data indicate that short-term

preslaughter transport can cause significant changes in stress response and muscle metabolism in goats, although the overall meat quality may not be affected.

Key Words: Goats, Preslaughter stress, Meat quality

1852 Live weight changes in grazing goats supplemented with protein during the dry season. A.S. Juarez-Reyes, M.A. Cerrillo*, and G. Nevarez-Carrasco, *Universidad Juarez del Estado de Durango, Durango, Dgo. Mexico.*

Sixty criollo goats were arranged into four groups, fifteen animals each, according to a randomized block design to determine the effect of protein supplementation on weight loss during the dry season (January-June) in a semi-arid region of northern, Mexico. The supplementation requirements were determined by two protein systems named: Digestible Intestinal Protein (PDI) (Verite *et al.*, 1987) and Metabolizable Protein (Burroughs *et al.*, 1975). The protein supplements ($T_1 = 10$ g wheat hulls + 120 g cotton seed meal; $T_2 = 10$ g wheat hulls + 120 g poultry litter; $T_3 = 10$ g wheat hulls + 60 g cotton seed meal + 60 g poultry litter; $T_4 =$ control) were offered to the animals once a week. Statistical differences ($P < .05$) in weight loss were found between the animals fed the supplement and the control group 120 d from parturition. The effect was even more evident 150 d from parturition where the control group lost 13 kg (34% of the weight registered at parturition), whereas the supplemented animals lost from 7 to 8 kg ($T_1 = -7.9$; $T_2 = -7.4$; $T_3 = -8.1$), which corresponds to 20-22% of the weight at parturition. The results obtained in this study indicate that the weight loss in the control group makes the animals extremely vulnerable to the rough climatic conditions at the beginning of the rainy season, whereas the supplement guarantees the survival of the goats during the dry season.

Key Words: Goats, Grazing, Supplementation

1853 Determination of supplementation requirements of grazing goats utilizing two protein systems. A.S. Juarez-Reyes*, M.A. Cerrillo, and G. Nevarez-Carrasco, *Universidad Juarez del Estado de Durango, Durango, Dgo. Mexico.*

Three goats fitted with esophageal and ruminal cannulae (38 ± 1.7 kg BW) from a flock of 250 grazing animals, were used to estimate the intake of metabolizable protein (IMP) and content of metabolizable protein in the diet (DMP) utilizing two protein systems. Values from crude protein, *in situ* degradability of crude protein (48 h incubation) and content of TDN were incorporated into the Burroughs' Metabolizable Protein System (USA). The values used for the French Intestinal Digestible Protein System (IDP) were crude protein, *in situ* degradability of crude protein and organic matter fermented in rumen were utilized. Extrusa samples were collected twice a day (12:00 and 16:00) for two consecutive days per month. Two periods of sampling were evaluated, the dry season from February to June and the rainy season, from July to November. Data were analyzed in a completely randomized block design. Means obtained from MP system were 11.7%, 85 g/kg DM and 127 g/d for the CP, DMP and IMP respectively; whereas for the IDP System the data obtained were 11.7%, 74 g/kg MS and 110 g/d for CP, DMP and IMP respectively. To determine the ruminal nitrogen-energy balance in the MP system, the urea fermentation potential (UFP) was used, whereas for the French system, the difference between the intestinal digestible protein originated from nitrogen (NIDP) and energy (EIDP) was utilized. Data indicated that the UFP for the dry season was 5.2 g/kg DM suggesting the necessity to incorporate this amount of urea to the diet. The value of -14.4 g/kg DM for the rainy season indicates that no urea is required. The difference between NIDP and EIDP was 15 g/kg DM in favor of EIDP during the dry season; no difference was registered for the rainy season ($P > .05$). Results from both systems indicate that a source of degradable protein in the diet of grazing goats is required during the dry season to increase the amount of microbial metabolizable protein.

Key Words: Grazing goats, Metabolizable protein, Supplementation

1854 Effects of urea treatment of straw and dietary broiler litter on feed intake and digestion in Spanish wethers. G. Abebe¹, R. C. Merkel^{*2}, G. Anmut³, A. L. Goetsch², and T. Sahlu², ¹Awassa College of Agriculture, Debub University, Awassa, Ethiopia, ²E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK, ³Alemaya University, Dire Dawa, Ethiopia.

Eight Spanish wethers (29.3 ± 1.15 kg) were allocated to simultaneous 4 × 4 Latin squares to test effects on intake and digestion of urea treatment of wheat straw and supplementation with different levels of broiler litter (BL). Wheat straw, untreated (U, 0.41% N; DM basis) or treated with urea (T, 2.25% N), was consumed *ad libitum*; supplement treatments (ST) were C: corn-based (1.42% N, 0.64% BW); S: C + 0.25% BW soybean meal (3.10% N, 0.89% BW); L: C + 0.5% BW BL (2.97% N, 1.14% BW); and H: C + 1.0% BW BL (3.06% N, 1.64% BW). Chromic oxide was included in supplements to estimate apparent digestibilities. Straw type and ST did not interact in OM and N intakes and digestibilities. Straw OM intake was similar between U and T; total OM intake was greatest among ST (P < 0.05) for H and lowest (P < 0.05) for C (476, 566, 649, and 739 g/d for C, S, L, and H, respectively). Digestibility of OM was not influenced by straw type, but was lower (P < 0.10) for L and H than for C and S (67.9, 68.3, 61.9, and 60.7% for C, S, L and H, respectively; SE = 2.5). Digestible OM intake (DOMI) was greater (P < 0.05) for T than for U (436 vs 327 g/d); among ST DOMI was lowest (P < 0.05) for C and greater (P < 0.05) for H vs S (314, 377, 396, and 440 g/d for C, S, L, and H, respectively; SE = 19.6). Intake of straw N was greater (P < 0.05) in goats consuming T than U (9.7 vs 1.0 g/d) and greatest among ST for H (8.0, 13.6, 15.8, and 19.6 g/d for C, S, L, and H, respectively). Apparent N digestibility was not affected by straw type and was greatest among supplement treatments (P < 0.05) for S (51.5, 67.8, 51.4, and 46.4%, for C, S, L, and H, respectively). In conclusion, improvements in DOMI by supplementing a basal wheat straw diet with S or BL were not influenced by urea treatment. The increase in DOMI with a low level of BL (i.e., 0.5% BW) was comparable to that with S, and greater change occurred with 1.0% BW BL.

Key Words: goats, wheat straw, broiler litter

1855 Feed intake and growth by Spanish and Boer × Spanish doelings consuming diets with different levels of broiler litter. T. Negesse¹, R. C. Merkel², A. Tolera¹, A. L. Goetsch², T. Sahlu², R. Puchala², T. A. Gipson², and L. J. Dawson^{*2}, ¹Awassa College of Agriculture, Debub University, Awassa, Ethiopia, ²E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK.

Sixty Spanish (S) and 40 Boer × S (BS) doelings, 14.9 ± 3.8 and 21.9 ± 3.8 kg, respectively, were allocated to five treatments in an 84-d experiment (four 21-d periods) to test effects of dietary level of broiler litter (L) on feed intake and ADG. Six S and four BS doelings were assigned to two replicates per treatment. Treatments were OL: 20% chopped millet hay (H; 6.1% CP, DM basis) + 80% concentrate (11.9% CP); 20L: 20% H + 80% concentrate (12.9% CP) with 20% dietary L; 40L: 20% H + 80% concentrate (17.0% CP) with 40% dietary L; 60L: 20% H + 80% concentrate (21.0% CP) with 60% dietary L; and 80F: 80% H + 20% concentrate (24.4% CP). Diets were consumed *ad libitum*, group feed intake was determined daily, and BW was measured at 21-d intervals. DMI differed (P < 0.05) among all treatments in period 1 (772, 620, 683, 371, and 468 g/d; SE = 12.6) and 2 (816, 657, 748, 347, and 579 g/d; SE = 11.1) for 0L, 20L, 40L, 60L, and 80F, respectively. Goats consuming 0L had greatest and 60L lowest (P < 0.05) DMI in period 3 (938, 825, 859, 557, and 832 g/d; SE = 15.9) while in period 4, DMI was greatest for 0L and 40L and lowest (P < 0.05) for 60L (1,007, 933, 1,007, 682, and 905 g/d; SE = 19.9) for 0L, 20L, 40L, 60L, and 80F, respectively. ADG was similar between S and BS with 60L but greater (P < 0.05) for BS with other diets, and the difference between genotypes in ADG was greatest among treatments with 0L (interaction, P < 0.05). ADG of S was 108, 81, 71, 9, and 37 g/d (SE = 8.7), and that of BS was 177, 118, 105, 12, and 58 g/d (SE = 10.6) for 0L, 20L, 40L, 60L, and 80F, respectively. In conclusion, S and BS doelings can be fed diets with up to 40% L for growth comparable to or greater than that with a low quality forage-based diet, and diets with moderate to high levels of L or based on low quality forage may lessen differences in ADG between S and BS compared with concentrate-based diets.

Key Words: goats, broiler litter, growth rate

1856 Comparison of goats raised intensively versus pasture raised. N.C. Beckford^{*}, J.M. Dzakuma, E. Risch, C.O. Smith, P.M. Johnson, and L.C. Nuti, *Prairie View A&M University, Prairie View, TX, USA.*

After weaning at 70±7 days of age 72 kids of Tennessee Stiff-legged (TS), Spanish (SP) and Boer (BR) breeds were individually fed an 18% CP and 65% TDN diet. These breeds represent goats with small, intermediate and large mature sizes (TS, SP, and BR). An equal number of offspring randomly selected from both sexes (36 Females and 36 Males) were used. They were divided into three groups of 8 per breed. The first group was fed *ad libitum*. The second and third groups were fed at 85% and 70% levels of the *ad libitum* diet. An equal number of kids born of the same breeds were maintained on pasture and run with their dams. One half the population of kids were creep fed and the other half were not. After weaning, both creep and non-creep fed goats were randomly assigned to pasture only and pasture with supplementation (corn). Goats in stalls were weighed biweekly and those on pasture monthly. All kids were slaughtered at approximately 6 mo of age. Birth weights were similar for BR and SP breeds (3.47 and 3.30 kg) and differed significantly (P<.05) from TS breed (2.75 kg). On goats fed the formulated ration at weaning, however, the BR breed (23.5 kg) was significantly heavier (P<.001) than the TS breed (14.76 kg) which also differed from the SP breed (11.81 kg). On pasture, the BR weighed 21.8 kg and was significantly heavier (P<.001) than the TS and SP breeds which were similar and weighed 13.7 and 14.45 kg, respectively. Kids from all 3 breeds that were creep fed were only slightly heavier (P<.17) than those that were not (17.4 vs 16.0 kg). Prior to slaughter, goats that had been creep fed were significantly heavier (P<.05) than those that had not (25.1 vs 21.8 kg). Within each breed, goats that were supplemented on pasture showed increases in weight (P ranging from P=.08 to P=.11) compared to those not supplemented. On the average, goats that had been raised intensively (BR 32.7; SP 16.3 and TS 21.1 kg) were heavier than those raised on pasture (BR 26.4; SP 24.4 and TS 19.6 kg). The cost benefit of raising goats intensively versus pasture raised will be evaluated. The study suggests supplementing pasture raised goats.

Key Words: Tennessee Stiff-legged, Spanish, Boer, Goats, Pasture, Intensive

1857 Survey of goat meat sales in New Jersey. James Lechner^{*}, James Wohlt, Ramu Govindasamy, and Patricia Schoknecht, *Rutgers, The State University of New Jersey, New Brunswick, NJ.*

Goat meat may be a potential specialty product for farmers in the Eastern U.S., due to the large ethnic populations within this region and their consumer preference for this product. To determine the potential market for goats, 368 butcher shops in the state of NJ (listed in the yellow pages) were surveyed. Surveys were initially conducted by phone establishing that shops sold goat meat. Then in-person surveys with the butchers were conducted, using a translator when necessary, to record data on both supply source and consumer preference for goat meat. A total of 65 shops (18%) sold goat meat year-round, with an additional 34 shops (9%) willing to order goat meat when requested. A majority of the butchers, 42% acquired goat meat from a distributor, with 28% of the meat obtained from a distributor being imported. Butcher shops in northern NJ sold most of their goat to either a European or Muslim consumer, while in southern NJ the consumers were primarily Caribbean. European and Muslims preferred carcasses or select cuts, while Caribbean's preferred cubed meat. All meat purchased by butchers averaged \$3.72/kg, with an average sale price of \$6.14/kg for carcasses, \$6.16/kg for legs and \$5.61/kg for cubed meat. Shops sold an average of 145 kg/wk. Findings indicate that the NJ goat market is very price sensitive. Over 55% of the shops indicated that the consumer would not pay more for a higher quality product and 75% indicated that the consumer base would not be broadened if a higher quality product were available. The major source of goat meat sold in NJ is either goat trucked in live from Texas and sold for \$40/head or meat imported from Australia and New Zealand which sold for an average of \$3.39/kg. Our data suggests that NJ butcher shops would not have a market for a higher quality, higher priced product, making it difficult for eastern goat producers to compete with the established supply channels.

Key Words: Goat meat, Butcher shops, Marketing

1858 Extension of the Cashmere Growth Period in Spanish Goats with Melatonin. T. Wuliji*¹, A. Litherland², A.L. Goetsch¹, T. Sahl¹, R. Puchala¹, T.A. Gipson, and L.J. Dawson¹, ¹*E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK*, ²*AgResearch, Grasslands Research Centre, Palmerston, New Zealand*.

Melatonin suppresses blood prolactin levels, and the prolactin surge in fur animals is usually associated with fiber shedding. Therefore, use of melatonin to induce out-of-season breeding could affect the seasonal pattern of cashmere fiber growth in goats by extending the active, anagen phase. Eighty 80 female Spanish goats (15 2 yr of age and 65 doelings) were used to determine influences of spring melatonin treatment on cashmere fiber growth. Treatments were control (C); melatonin implant (18 mg; Regulin, Shering Pty. Ltd.) without (I) and with three bromocryptine mesylate (215 mg) implants (IB) (Innovative Research of American, Sarasota, FL); and oral administration of melatonin (3 mg/d for 5 wk) (Sigma Chemical Co., St. Louis, MO) without (O) or with bromocryptine mesylate (OB). Melatonin treatments started 5 wk before breeding. Cashmere growth was examined by clipping fiber regrowth in a 10 x 10 cm area on the mid-side each month. Mean daily clean fiber growth rate (mg/d) estimated by mid-side patch clipping was greater ($P < 0.05$) for melatonin-treated groups compared with C in April (44.7, 82.9, 77.5, 80.6 and 71.5 mg/d) and May (39.6, 69.8, 81.4, 63.9 and 63.5 mg/d); in the overall 12-mo period fiber growth was greatest ($P < 0.05$) among treatments for I and IB (12.5, 15.9, 15.3, 13.1, and 12.9 g for C, I, IB, O, and OB, respectively). Mean cashmere fiber diameter was greater ($P < 0.05$) for I, IB, O and OB compared with C (17.4, 18.7, 18.9, 18.4, and 18.1 microns) in a pooled sample for February, March, and April, while in May, June, and July diameter for C was lowest ($P < 0.05$) among treatments (16.8, 18.6, 18.7, 18.4, and 18.8 microns for C, I, IB, O, and OB, respectively). In conclusion, spring melatonin treatment for out-of-season breeding appeared to extend the period of cashmere fiber growth, and the lack of effect of bromocryptine mesylate suggests no additive effect to melatonin treatment. Oral administration of melatonin had effects on cashmere fiber growth measured by mid-side patch similar to those of an implant early in the experiment, but over the entire 12-mo period fiber growth was not influenced.

Key Words: Goats, Cashmere fiber, Melatonin

1859 Milk yield, body weight and some physiological traits of Baladi goats and their crosses with Damascus and Anglo-Nubian breeds in Egypt. A. Hassan, M. Samak, A. Elkomy*, and M. Anwar, *Fac. of Agric. Alex. ElShatby, Egypt*.

Thirty lactating goats (10Baladi, B, (10BaladixDamascus, BxD) and (10BaladixAnglo-Nubian, BxA-N), one week post partum were used in this study to evaluate lactation performance and some blood parameters. Milk and blood were sampled biweekly intervals. Results showed that milk yield, total solids and fat percentages were significantly ($P < 0.01$) affected by breed. These values were 1.17kg, 14.54 and 4.83%, respectively which were higher in (BxD) cross than (BxA-N) or (B) goats. Parity had significant effect on milk yield and protein % ($P < 0.01$) and fat % and lactose % ($P < 0.05$). In the second parity milk yield and fat % were higher, while lactose and protein percentages were higher in the first one. Throughout the duration of lactation, only milk yield, TS % and fat % were significantly affected ($P < 0.01$). Counts of (RBC) and (WBC) and (PCV%), but not (HB%) were significantly affected ($P < 0.01$) by breed. Parity had significant effect ($P < 0.01$) on RBC counts and PCV% only. Regarding blood composition, breed had a significant effect on percentages of glucose, total lipids, albumin, A:G ratio, calcium (Ca), inorganic phosphorous (P), Ca:P ratio and Got and Gpt. Results indicated that parity affected, significantly, all the biochemical parameters studied, except albumin and (P). Kid's body weight was significantly affected by breed, sex and type of birth, but not parity.

Key Words: Milk, Blood, Goats

1860 Differences in growth and carcass characteristics in young goats of different genotypes. R. Kraig Peel*¹ and W. Shawn Ramsey², ¹*Sam Houston State University*, ²*Texas A&M University*.

Boer-Spanish (BxS), Boer-Angora (BxA), Angora-Spanish (AxS), Spanish (S), Angora (A), and 12 Boer-Spanish intact males (BxSi) were used to compare ($n=175$) genotypic effects on performance and carcass quality

in pasture and feedlot. Feedlot goats were fed ad libitum diets containing 64 % TDN and 14% CP. Using 20 d adjustment, weights were taken at 14 d intervals for 154 d with refusals taken every 3 d. Pasture goats were grazed on native Texas range and weighed at 14 d intervals. BxS had the highest ($P < .05$) AGD followed by the BxA and S (143 g/d, 119 g/d and 116 g/d). Angora and SxA had the lowest ($P < .05$) ADG (81g/d and 91 g/d). Feed efficiency and intake followed the same trend as ADG with BxS consuming the most feed (1.15 kg/hd/d) and A consuming the least (.89 kg/hd/d). BxS were the most efficient ($P < .05$), A were least efficient ($P < .05$) (7.55 kg/kg vs. 11.70 kg/kg). Generally, BxS had the heaviest carcasses, least fat at the 12th rib, largest loin eye area, largest leg circumference, highest percent kidney and pelvic fat (KP), and produced the longest carcasses. Generally A observations were the lowest for all attributes considered. The BxA goats did deposit more ($P < .05$) body wall fat over the 12th rib (1.91 cm vs .16 cm- all breed avg.). No differences were observed due to breed type in pasture goats. Fed goats gained faster and produced fatter, heavier muscled carcasses than pasture goats. Castration increased feed efficiency, percent hindsaddle, body wall thickness and percent KP, ($P > .05$).

Key Words: Goat, Carcass

1861 Effects of insulin administered to a perfused area of skin in Angora goats. R. Puchala*¹, S.G. Pierzynowski², T. Wuliji¹, A.L. Goetsch¹, and T. Sahl¹, ¹*E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK 73050*, ²*Department of Zoophysiology, Lund University, Lund, Sweden*.

The effect of insulin infusion on mohair growth of Angora goats was investigated using a skin perfusion technique. Six Angora wethers (average BW 32 4 kg) were implanted bilaterally with silicon catheters into the superficial branches of the deep circumflex iliac artery and vein. For the first 14 d of the experiment, 2.4 mL/h of saline solution was infused into the deep circumflex iliac arteries. The infusate for one side contained insulin, delivered at 48 mU/h and estimated to triple the blood insulin concentration in the perfused region. The area of skin supplied by the deep circumflex iliac artery was approximately 250 cm². An area of 100 cm² within the perfused region was used to determine mohair growth. Two weeks after cessation of infusions, perfused areas were shorn. Greasy and clean mohair production from the perfused region was not affected by insulin infusion compared with the side infused with saline (4.57 vs 4.69 and 3.67 vs 3.74 g/100 cm²/28 d for greasy and clean mohair, respectively; $P > 0.10$). Similarly, insulin did not change mohair fiber diameter or length ($P > 0.10$). Plasma glucose concentration was lower ($P < 0.05$) in blood from the deep circumflex iliac vein on the side infused with insulin (57.2 vs 63.4 mg/dL). Blood flow and plasma concentrations of amino acids were not different between treatments ($P > 0.10$). The lack of an insulin effect on mohair fiber growth may be due to insufficient supply of amino acids or, similar to IGF-1, insulin may have limited effects on fiber-producing follicles.

Key Words: Skin Perfusion, Insulin, Mohair

1862 Effects of Preweaning Concentrate Supplementation on Performance of Meat Goats. A. L. Goetsch*, G. Detweiler, and T. Sahl, *E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK*.

Sixty-four Spanish does with 112 Boer x Spanish or Spanish kids (16 singles and 96 twins) were used to determine effects of preweaning feeding of a concentrate-based supplement on preweaning and early postweaning growth. In mid-April, from approximately 6 to 14 wk after birth, animals grazed wheat forage (Phase 1), followed by 5 wk on native grass pasture (Phase 2) and an 8-wk postweaning period with a moderate level of supplemental concentrate (Phase 3). Treatments were no supplementation in Phases 1 and 2 (C), *ad libitum* consumption of a concentrate-based supplement in Phases 1 and 2 (A), no supplementation in Phase 1 and *ad libitum* consumption of supplement in Phase 2 (A-2), and limit feeding of supplement (approximately 1% of live weight, DM) in Phases 1 and 2 (L). Supplement intake averaged 30, 74, 90, 157, and 158 g/d for L and 36, 87, 192, 240, and 229 g/d for A in wk 2-4, 5-6, and 7-8 of Phase 1 and wk 1-2 and 3-5 of Phase 2, respectively; supplement intake for A-2 averaged 171 and 249 g/d in wk 1-2 and 3-5 of Phase 2, respectively. Forage DM mass was 2,474, 2,062, 1,315, 1,434, 2,245, 1,405, and 1,161 kg/ha in wk 1, 3, 5, and 7 of Phase 1 and wk 1, 3, and 5 of Phase 2, respectively. Kid live weight gain was similar among treatments in Phase 1 (108, 131, 119, and 113 g/d), lower ($P <$

0.05) for A than for C and A-2 and lower for L than for C ($P < 0.05$) and A-2 ($P = 0.09$) in Phase 2 (73, 21, 15, and 60 g/d), and lower ($P < 0.05$) for C than for A and A-2 in Phase 3 (44, 67, 90, and 83 g/d for C, L, A, and A-2, respectively). In conclusion, under conditions of this experiment preweaning feeding of a concentrate-based supplement did not enhance kid growth preweaning but generally improved early postweaning growth.

Key Words: Goats, Growth, Supplement

1863 Optimum herd size of small goat holders in Qinba Mountain district in China. J. Luo¹, H. Yao*¹, X. F. Zhao², and H. Y. Yang², ¹Northwest Agricultural University, Yangling, Shaanxi, China, ²Animal husbandry bureau of Xixiang county, Xixiang, Shaanxi, China.

Our objective was to optimize the production and herd size for goat holders in Qinba Mountain district of China using a linear programming technique. The capital input, goat herd structure, grassland condition and economic profit were surveyed on 15 typical small goat holders in 15 locations within Xixiang county of Qinba mountain area, China. Using these survey data from goat holders, resource allocation and management factors were analyzed to identify 12 variables which exhibited a close relationship with goat production at these locations, such as number of bucks, base breeding does, replacement doelings, fattening kids, shed space, grassland area, fertilizer costs, veterinary costs, amount of crop residues and silage, amount of concentrate supplement, labor cost and farm investment in goat production. Parameters of each variable was defined, thereafter, considering net profit as an objective function, applying a linear programming technique to simulate an optimum herd size of small goat holders under differing condition of investment, labor and grazing land. Results suggested that the amount of investment was a major determining factor of herd size under the specific circumstances of Qinba Mountain district, with an average investment, small goat holders possessed approximately 7 hectare pasture could attain the maximum profit if they keep a herd with 20 to 40 does and 1 to 2 bucks. The herd size under two other similar management regimens including bred by either artificial insemination or natural mating in goat herd were also analyzed, the mean profit of investment for three identified conditions were 73.9%, 72.9% and 139.8%, respectively.

Key Words: Optimum Herd Size, Goat Holder, Linear Programming

1864 Growth and survival of kids of three goat breeds during different seasons. S. Wildeus* and T. A. Gipson, Virginia State University, Petersburg, VA.

This experiment evaluated pre-weaning growth and survival in Myotonic, Nubian, and Spanish kids born either in May, December or August. Dams were managed either on a high forage base (HI: moderate stocking rate, rotational grazing), or restricted forage base (LO: high stocking rate, drylot hay feeding). Kids were born on pasture with limited assistance and weaned at 10 wk of age. Seasonal kiddings were replicated and a total of 875 records analyzed in a model that included kidding season, breed, forage base, birth type and sex as main effects. Kids born in August were lighter ($P < .001$) than in May and December (2.31, 2.56 and 2.59 kg, respectively), and Myotonic were lighter ($P < .001$) than Nubian and Spanish (2.31, 2.72 and 2.76 kg, respectively). Myotonic kid birth weights in LO were heavier than in HI, while the other breeds were not different (season x breed interaction: $P < .001$). Birth weights were heavier in HI than LO in May and December, but not August (season x forage base interaction: $P < .001$). Kid survival at birth was higher ($P < .05$) in August than May and December (98.5, 95.3, and 93.8%, respectively). Pre-weaning ADG was higher ($P < .001$) in December (119 g/d), than in May and August (107 g/d), as a result of higher ADG in Myotonic and Spanish, but not Nubian (season x breed interaction: $P < .001$). Pre-weaning ADG was not different between seasons in LO (103 g/d), but higher in December (133 g/d) than May and August (114 g/d) in HI (season x forage base interaction: $P < .05$). Adjusted weaning weights (60 d) reflected pre-weaning ADG and were heavier ($P < .001$) in December than May and August (9.85, 9.07 and 8.79 kg, respectively). Survival to weaning was lower ($P < .001$) in August than May and December (60.4, 76.6 and 70.5%, respectively), and lower ($P < .001$) in Nubian than Myotonic and Spanish (53.8, 73.4 and 79.9%). Data indicate that 'early season' kids born in December

performed similar to spring-born (May) kids, whereas birth weights and survival to weaning was depressed in 'late season' (August) kids.

Key Words: meat goat, season, kid performance

1865 Differences in intake, growth rate and carcass characteristics in young males of three hair sheep and meat goat breeds. S. Wildeus*¹, M. B. Solomon², A. D. Mitchell², J. S. Eastridge², and J. R. Collins¹, ¹Virginia State University, Petersburg, VA, ²Beltsville Agricultural Research Center, USDA, Beltsville, MD.

There is still limited information available on hair sheep (HS) and meat goat (MG) carcass traits. In this experiment 36 postweaning males, representing HS (Barbados Blackbelly: BB, Katahdin: KA, St. Croix: SX) and MG breeds (F₂ Boer Cross: BX, Myotonic: MY, Spanish: SP), were weaned at 9 wk of age, and either left intact or castrated. Animals were allocated to 6 pens by species, stratified by breed and sex class, at 4 mo of age, and fed a diet of moderate quality grass hay *ad libitum* and a corn/whole cottonseed-based concentrate (16% CP) at 2% of BW. Pen intake was measured on d 1-5, d 50-55, d 105-110, and d 148-153 of the trial. At 160 d animals were slaughtered, and carcass characteristics and body composition, using dual energy X-ray absorptiometry, recorded. Data were analyzed in a model with species, breed within species, and sex class as main effects. Forage intake was higher ($P < .001$) in HS than MG (20.8 vs. 16.5 g/kg BW/d). Average daily gain was higher ($P < .001$) in HS than MG (97 vs. 66 g/d), but was not affected by sex class. Within species, ADG was higher ($P < .001$) in KA than SX and BB (129, 85 and 76 g/d, respectively), but was not different in MG breeds. Dressing percent (DP; includes hide), REA and KPH was higher ($P < .05$) in HS than MG (55.9 vs. 54.2%, 10.5 vs. 8.3 cm², and 0.98 vs. 0.66%, respectively), however, weight-adjusted REA and back fat thickness (BF) was not different between species. Within species, KA had higher ($P < .05$) BF and body fat content than BB and SX. In MG, MY had a higher ($P < .001$) DP than BX and SP (56.1, 53.3 and 53.2%, respectively), and a similar KPH in intact and castrate males, while sex classes were different in BX and SP (breed x sex class: $P < .05$). These results confirm differences in growth and carcass characteristics between HS and MG, and point to unique differences in KA and MY within their species.

Key Words: meat goats, hair sheep, carcass traits

1866 Modeling extended lactation curves in dairy goats using grafted polynomials. T.A. Gipson*¹ and G.R. Wiggans², ¹E (Kika) de la Garza Institute for Goat Research, Langston University, Langston, OK, ²Agricultural Research Service, USDA, Beltsville, MD.

Some dairy goat producers milk their does for an extended period before rebreeding and drying off, but little information is available about the shape of extended lactation curves for goats. To examine the effect of extending lactations upon the shape of the lactation curve, test-day records ($n = 7425$) of 469 does with extended lactations were obtained from USDA/AIPL. Range for days in milk was 419d to 696d with an average of 530d. Number of test days ranged from 12 to 20 with an average of 16 per lactation. Lactations from six breed types (Alpine, LaMancha, Nubian, Saanen, Toggenburg and Experimental) and four parities (first, second, third and fourth or greater) were included. Non-linear regression analysis using several grafted polynomial models was conducted for each animal. The models used were quadratic-linear (QL), quadratic-quadratic (QQ), quadratic-quadratic-linear (QQL), quadratic-quadratic-quadratic (QQQ), quadratic-quadratic-quadratic-linear (QQQL), quadratic-linear-quadratic-quadratic (QLQQ), and quadratic-linear-quadratic-quadratic-linear (QLQQL). The most appropriate model was selected by testing for significant ($P < .05$) reduction in error sums of squares relative to the QL model for each individual animal. A significantly ($P < .01$) higher percentage of selected models were QL than were QQQ, (64% vs. 22%), respectively. The selection of other models was 6% for QQQL, and 3%, 3%, and 2% for, QLQQ, QQ, and QQL, respectively. The QLQQL model was not selected. There were no significant ($P > .10$) breed or parity effects on the distribution of selected models. The median joint point was 300 for QL, and 348 for QQ. Points were 193 and 343 for QQQ; 87 and 147 for QQL; 445, 331, 131 for QQQL; and 287, 185, 57 for QLQQ. A QL grafted polynomial model appears sufficient to model the majority of extended lactation curves in dairy goats.

ASAS Sheep Species

1867 Evaluation of resistance to *H. contortus* in Pelibuey sheep. Antonio Figueroa, Danilo Mendez*, Manuel Berruecos, Rogelio Alonso, and Hugo Perez, *Facultad de Medicina Veterinaria y Zootecnia. Universidad Nacional Autonoma de Mexico.*

The objective of this study was to identify Pelibuey sheep resistant to *H. contortus*. The resistance criterion used was fecal egg counts during an experimental infection of 42 days. Fifty-three Pelibuey lambs of 5 months of age (22 males and 31 females), free of nematodes, were infected with 3,000 larvae of *H. contortus*. Lambs were monitored every week for fecal egg counts (FEC), hematocrit value (HV), plasma protein level (PP), eosinophil counts (EC) and total weight gain (TWG). On day 42 post-infection, lambs were drenched and then evaluated every 28 days for a year under natural infection conditions. The degree of resistance was determined using the average of the last four egg counts during the experimental infection. Data was normalized by a log₁₀ transformation. Statistical analysis of the data was carried out through an analysis of variance. The classification criterion used was the transformed mean minus one standard deviation (criteria equivalent in actual count=1,200 egg counts for males and 1,161 for females). Animals with an average FEC above the criterion were classified susceptible and animals below the criterion were classified resistant. Results showed that 45% of the males and 42% of the females were resistant. Resistant males had an average FEC, HV, PP, EC, and TWG of 752125, 27.6.7, 6.7.1, 2913, and 331.2 kg, respectively. Susceptible males had an average FEC, HV, PP, EC, and TWG of 1072368, 26.2.4, 6.8.1, 23532, and 322.4 kg, respectively. However, no significant differences were found for any these parameters with the exception of FEC ($P < .05$). Resistant females had significantly lower FEC compared to susceptible females (33342 vs 89397, respectively, $P < .05$). No other significant differences were found between resistant and susceptible females. Values for the studied parameters for resistant and susceptible females were: HV, 26.9.5 vs 26.7.5; PP, 7.2.3 vs 6.8.3; EC, 310106 vs 34430; and TWG, 9.6.4 vs 11.85.4, respectively. These data suggest that while variability in FEC exists in Pelibuey, this variability is not strongly associated with differences in HV, PP, EC, or TWG in resistant vs susceptible lambs.

Key Words: *H. contortus*, Resistance, Sheep

1868 Pre-mating nutrition affects the onset and synchrony of oestrus in Merino ewes treated with progesterone CIDR dispensers. SP Quigley*¹, SK Walker¹, PA Speck¹, SR Barritt¹, and DO Kleemann¹, ¹*South Australian Research and Development Institute, South Australia.*

Nutrition is a key factor controlling reproductive performance of the ewe. This study examined the effect of long term nutritional manipulation prior to insemination on the timing and incidence of oestrus in Merino ewes synchronised with controlled internal drug release (CIDR) devices containing 0.3g progesterone. Mature age Merino ewes (n=119) were stratified on liveweight and randomly allocated to 2 nutritional treatments of 1.8 and 0.6 times maintenance requirements (High (H) n=60 and Low (L) n=59, respectively). Ewes were fed a pelleted diet (60% roughage: 40% grain plus additives) for 12 weeks prior to joining. CIDR devices were inserted for 14 days with oestrus observations commencing 24 h after CIDR removal. Oestrus was recorded three times daily (08:00h; 12:00h; 16:00h) on three consecutive days. Ewes were inseminated via laparoscopy using fresh semen collected from a single Poll Dorset ram. Ewe liveweight and condition score between the treatment groups diverged significantly from 8 weeks prior to joining and throughout pregnancy ($p < 0.01$). Low level of nutrition significantly delayed onset of oestrus ($p < 0.01$); oestrus was detected 57 ± 1.8 and 41 ± 1.6 h after CIDR withdrawal in L and H ewes respectively. Better synchronisation of oestrus was observed in H ewes, with 72% of ewes detected in oestrus between 24-48 h after CIDR withdrawal, compared with 23% of L ewes. The percentage of H ewes detected in oestrus over three days tended to be higher (95%) than L ewes (81%) ($p = 0.08$). For ewes detected in oestrus and inseminated, pregnancy rate tended to be higher in H ewes (72.7%) than in L ewes (51.1%) ($p = 0.08$). Litter size did not differ between H (1.55 ± 0.08 fetuses/ pregnancy) and L ewes (1.36 ± 0.1). These results indicate that long term nutritional status of the ewe flock

prior to a artificial insemination/ embryo transfer program has important implications for achieving satisfactory synchronisation of oestrus and ewe fertility.

Key Words: Sheep, Nutrition, Oestrus synchrony

1869 The effects of offering grass or maize silages with a flat rate of concentrate supplementation to pregnant ewes on ewe and lamb performance. T.F. Crosby*, J.V. O'Doherty, P.J. Quinn, J.J. Callan, B. Flynn, D. Cunningham, P. Reilly, and E Massey, *University College Dublin, Belfield, Dublin 4, IRELAND.*

Individually fed twin-bearing ewes (n=64) were offered either grass silage (T1) or maize silage (T2) ad libitum and supplemented with a daily flat rate of 400g concentrates from day 92 of pregnancy until lambing, in order to evaluate pregnant ewe and lamb performance and colostrum yield and quality. Overall daily forage DM intake was lower in the ewes fed grass silage (0.95 vs 1.11kg/ewe; SEM. 0.041; $P < 0.05$) and this was directly reflected in lower ($P < 0.05$) metabolizable energy intake, although these ewes had a higher daily crude protein intake (178 vs 169g/ewe/d; SEM. 3.2; $P < 0.05$). The ewes in T1 gained less liveweight (10.93kg vs 12.90kg; $P < 0.05$), lost more body condition (0.22 vs 0.08; SEM. 0.043; $P < 0.05$) and had a longer gestation length (148.1 v. 146.4 days; S.E.M. 0.34; $P < 0.001$) than the ewes offered maize silage. Despite the difference in gestation length between the two forage types there was no difference in terms of total litter weight (9.87kg vs 9.53kg; SEM. 0.237kg; $P > 0.05$). The type of forage fed had no effect on colostrum yield at 1, 10 or 18 hours post-lambing or on total yield at 18 hours post-lambing ($P > 0.05$). The ewes on the grass silage based diet produced colostrum at 1 hour with a lower total solids concentration than the ewes fed maize silage (410.4 vs 465.1g/l; SEM. 16.39g/l; $P < 0.05$). The forage treatment had no effect on the yield of colostrum total solids, crude protein, IgG concentrations or IgG yield ($P > 0.05$); lamb serum IgG concentration; or the efficiency of IgG absorption in the first 24 h. The type of forage fed to the ewes had no effect on lamb birth weight, lamb weight at five weeks or average daily gain from birth to five weeks ($P > 0.05$). In conclusion the balance of advantages favours the use of maize silage for pregnant ewes especially in relation to ewe weight and body score changes but these advantages did not reflect themselves in colostrum or any of the lamb parameter data measured.

Key Words: Sheep, Silage, Lamb

1870 An evaluation of production systems for early season lamb production. T.F. Crosby, J.V. O'Doherty, P.J. Quinn, J.J. Callan, B. Flynn, and D. O'Shea, *University College Dublin, Belfield, Dublin 4, IRELAND.*

Following lambing, estrus synchronised ewes (n=137) and their lambs (n=239) were divided into four treatment groups and offered diets based on grass (T1), mixed brassica crop (swede/kale mixture) (T2), grass silage (T3), and maize silage (T4) in order to evaluate growth rate and carcass parameters. These forage-based diets were supplemented with concentrates in early lactation. The lambs had access to concentrates from the age of fourteen days and were selected for slaughter between 36 and 42 kg live weight. Concentrate creep consumption was 59.5, 44.9, 55.7, and 59.4 kg for T1-T4, respectively. Lamb growth rate (g/day) from birth until slaughter was 351, 335, 340, and 356 (SEM 9.7) for T1-T4, respectively, with lambs on maize silage growing faster than those on brassicas ($P < 0.05$). Similarly, lamb age at slaughter for T1-T4, respectively, was 98.6, 101.5, 99.9, and 95.0 days (SEM 2.49) with lambs on the maize silage-based diet slaughtered earlier than lambs on either the brassica crop or the grass silage ($P < 0.05$). Mean lamb live weight at slaughter ranged from 38.7 to 40.1 kg with lambs on the brassica treatment being lighter than all other treatments ($P < 0.01$). Carcass weight (kg) for T1-T4 was 18.4, 18.7, 18.6, and 19.0, with dressing percentages of 46.8, 47.5, 47.3, and 48.2 (SEM 0.45), respectively. Lambs on maize silage (T4) had a higher dressing percentage than those on grass (T1) ($P < 0.01$) and grass silage (T3) ($P < 0.05$). Treatment had few significant effects on conformation, fat score, fat colour, or fat hardness. Lambs in T1 and T4 were sold earlier than in other treatments ($P < 0.05$). Ewes offered the maize silage-based treatment had higher DM intakes and lost less weight and body condition ($P < 0.05$). These results show the considerable superiority of maize silage over grass silage for suckling ewes

and their lambs but, in relation to lamb growth rate, the outdoor grass-based system (T1) was equally good. The lower creep intake of the lambs on the brassica-based treatment (T2) was probably a reflection of the highly succulent nature of this crop.

Key Words: Ewe, Lamb, Growth

1871 Feedlot performance, wool production, and carcass characteristics of Merino/Rambouillet wether lambs as affected by breed and dietary forage to concentrate ratios. S. L. Lake*, H. S. Hussein, H. A. Glimp, B. D. Kindred, T. P. Ringkob, and D. W. Holcombe, *University of Nevada - Reno*.

The objective of this study was to determine the effects of sheep breed and finishing diet on feedlot performance, wool production, and carcass characteristics of lambs. Forty lambs (initial BW = 42.47 kg) from two breed (Merino [M]/Rambouillet [R]) combinations (20 each) were assigned at random to 2 dietary treatments in a completely randomized design experiment. Treatments were arranged as a 2 × 2 factorial. The main factors were 2 breed combinations (.5 M-.5 R or .875 M-.125 R) and 2 dietary forage (alfalfa pellets) to concentrate (cracked corn) ratios (i.e., high forage [HF; containing 60% alfalfa] and high concentrate [HC; containing 80% corn]). The diets contained 14.2 and 11.1% CP on DM basis, respectively. The lambs were housed in individual pens in a temperature-controlled room, had ad libitum access to feed, water, and salt blocks, and were harvested at 55.2 kg of BW. No interactions ($P > .05$) between lamb breed and diet were detected for any of the measurements evaluated. Therefore, results of the main factors were summarized. Feedlot performance and wool production were not affected ($P > .05$) by lamb breed but they were influenced ($P < .05$) by diet. Lambs fed the HF diet consumed more DM (1.69 vs 1.38 kg/d), gained faster (.29 vs .21 kg/d), and had higher gain/feed ratio (.171 vs .147). The wool data were derived from evaluation of wool produced in 10 cm × 10 cm midrib patches that were shorn at the beginning of the study. Lambs fed the HF diet produced less grease (8.1 vs 9.9 g) and clean (5.1 vs 6.4 g) wool. Carcass characteristics were not altered ($P > .05$) by the treatments. The only exceptions were less ($P < .05$) kidney, pelvic, and heart fat (2.6 vs 4.0%) and a tendency ($P=.199$) for better yield grade (1.77 vs 1.99) when lambs consumed the HF diet. Results suggest that finishing M/R wether lambs on HF diets (provided by alfalfa pellets) may be beneficial in reducing days on feed, improving efficiency, and producing carcasses with higher yield of boneless cuts. Increasing M genetics from .5 to .875 did not negatively affect lamb

performance. Compared with recommended requirements (NRC, 1985), lambs were either consuming 30% more (HF) or 17% less (HC) CP. It appears that CP requirements of M/R lambs must be equal to or higher than those recommended (NRC, 1985).

Key Words: Sheep, Carcass characteristics, Finishing diet

1872 Comparison of carcass data and ultrasound measures using both cattle and swine standoffs for loin eye area, loin eye depth and external fat in lambs. B.D. Banks*, M.E. Benson, J.D. Cowley, G.C. Good, M.T. Shane, and T.M. Villumsen, *Michigan State University, East Lansing, MI/USA*.

The objectives of this study were to determine accuracy of ultrasound measures for loin eye area (LEA), loin eye depth (LED) and external fat at the 12th rib (BF). Data were collected by real-time ultrasound (Pie 200 SLC, Pie Medical, Tequesta, FL) with cattle (USC) and/or swine (USS) standoffs. Ultrasound measures were compared to carcass measures. Commercial ewe and wether lambs (n=120) born in 1999 and 2000 were harvested at an average weight of 59.36.0 kg. Post-harvest LEA, LED and BF were measured on the carcasses. Actual carcass LEA averaged 17.74 cm² (n=120), USC LEA averaged 18.39 cm² (n=119), and USS LEA averaged 17.87 cm² (n=56). The range in standard deviations across all measurements was 1.94 to 2.26 cm². Actual carcass LED averaged 3.23 cm (n=68), USC LED averaged 2.97 cm (n=68), and USS LED averaged 3.12 cm (n=30). Standard deviations ranged from 0.18 to 0.30 cm. Mean carcass BF was 0.69 cm (n=120), average USC BF was 0.48 cm (n=119), and average USS BF was 0.51 cm (n=56). Standard deviations ranged from 0.13 to 0.25 cm. Correlations between carcass LEA and ultrasound measurements were .30 and .57 for USC LEA and USS LEA, respectively. The correlations between carcass LED and ultrasound measurements were .52 and .68 for USC LED and USS LED, respectively. Carcass BF was correlated with USC BF (0.69) and USS BF (0.78). The linear regression coefficients for carcass LEA on USC LEA and USS LEA were 0.278 ($P<0.01$) and 0.550 ($P<0.01$), respectively. The regression of carcass LEA on USC LED and USS LED were 1.963 ($P<0.01$) and 2.737 ($P<0.01$), respectively. Carcass BF linear regressions on USC BF and USS BF were 1.348 ($P<0.01$) and 1.369 ($P<0.01$), respectively. Both standoffs overestimated the average carcass LEA and underestimated carcass BF. The swine standoff predicted carcass LEA, LED and BF closer to carcass estimates.

ASAS Swine Species

1873 Lysine requirement of growing (35.1 to 60.5 kg) pigs, when formulated on ideal protein basis. I. Moreira*, M. Kutschenko, A.C. Furlan, A.E. Murakami, E.N. Martins, and C. Scapinello, *Universidade Estadual de Maringá, Maringá-PR, BRAZIL*.

An experiment was performed to determine the optimum lysine (total) level in the diet of the growing pigs when formulated on ideal protein basis. A corn-soybean meal basal diet contained 13% crude protein, 3.4 Mcal of digestible energy/kg and 0.75 % lysine. Treatment diets were supplemented with .15, .30, .45% of lysine to attain dietary concentration of .90, 1.05 and 1.20% lysine (total). Crystalline methionine, threonine and tryptophan were added in all diets to maintain constant ratios of these essential amino acids to the lysine content in each treatment diet. All other nutrients met or exceeded NRC (1998) nutrient requirement of pigs. Thirty-two crossbred pigs with an average body weight of 35.1 kg were blocked by weight and randomly assigned to the four experimental diets for a 28-d growth study. The experiment was a randomized complete design and was conducted in four replicates, with two pigs per experimental unit (pen). Pigs had access to their treatment diets on an ad libitum basis. Pigs were weighed, pen feed intakes determined and individual pig blood samples taken every 14 days. Plasma urea nitrogen (PUN) was determined. Backfat thickness (BF) was obtained using ultrasound on live pigs at the end of the growing phase. Gain:feed and backfat thickness were not affected by lysine levels. The regression models estimated the total lysine (%) requirement to be .90, .89 and 1.03% when average daily feed intake, average daily gain and PUN, are the measurement criteria respectively.

Key Words: Amino Acid Requirement, Ideal Protein, Pigs

1874 Substitution of Corn to Coffee Hulls in a Isoenergetic Diets for Growing and Finishing Pigs. E. T. Fialho*^{UFLA}, V. Oliveira^{UFLA}, J. A. F. Lima^{UFLA}, and R.T. Freitas^{UFLA}, ¹*Universidade Federal de Lavras - UFLA/BRAZIL*.

A metabolism assay and a performance trial were carried out at the University of Lavras (UFLA) in Brazil in order to evaluate the technical and economical viability of substitution of corn with Coffee Hulls (DM 86.7%; CP 10.2%; FDN 55.0% and 2500Kcal DE/Kg) in isoenergetic growing and finishing pig diets. The metabolism assay was conducted utilizing 24 crossbred (LDxLW) barrows with 12 in the growing phase (34.8 Kg) and 12 in the finishing phase (60.7 Kg) which were randomly assigned to a metabolism cage with six replicates per phase. In the performance trial a total of 96 crossbred (LDxLW) barrows and gilts with mean initial weight of 34.4 Kg were utilized. The experiment was in a randomized block design with four treatments and six replicates with pigs distributed in a pen with four pigs (2 barrows and 2 gilts). The treatments consisted of the inclusion of Coffee Hulls (CH) at 0.0;5.0;10.0 and 15.0%, replacing corn in isoenergetic diets (16% and 14% CP and 3350 Kcal DE/Kg) for growing and finishing phases, respectively. Increasing the level of CH decreased linearly ($P<0.01$) the digestibilities of nutrients as well as energetic values (DE and ME) of the diets. The performance assay showed that weight gain decreased linearly ($Y=876.3-13.17R=0.932$) and feed intake decreased linearly ($Y=2.685-34.26R=0.899$) with increasing CH. Considering the price of corn and CH in January/2001 the use of Coffee Hulls was technically

and economically viable at levels up to 5% in growing and finishing pig diets.

Key Words: pigs, metabolism assay, alternative feedstuffs

1875 Effect of deletion of vitamin and trace mineral premixes from diets on daily gain, feed:gain ratio, backfat thickness, red blood cell count in finishing pigs. S. C. Lee^{*1}, C. E. Lee², and K. I. Kim¹, ¹*Cheju National University, Cheju, Rep. of Korea*, ²*Cheju Agr. Exp. Station, RDA, Cheju, Rep. of Korea*.

A study was done to determine the effect of deletion of vitamin and trace mineral premixes from diets on growth and feed:gain ratio, hemoglobin content, hematocrit and red blood cell count in finishing pigs. Three replicates of 5 pigs each (average weight, 70 kg) were assigned to a control (with complete premixes), 50% or 100% deletion of the premixes and fed to market weight. They had free access to feed and water. Average daily gain \pm SEM was 0.78 ± 0.04 , 0.73 ± 0.03 and 0.74 ± 0.05 kg for control, 50% deletion and 100% deletion over a 7-week feeding period, respectively. Feed:gain ratio, and carcass backfat thickness (mm) were 3.86 ± 0.05 , 3.90 ± 0.20 and 3.96 ± 0.05 , and 23.7 ± 2.49 24.5 ± 4.68 and 25.3 ± 4.86 for control, 50% deletion and 100% deletion, respectively. Hemoglobin content (g/100 mL blood); hematocrit (volume %); and red blood cell count (millions/mL) were 14.2 ± 0.7 , 13.4 ± 1.1 and 13.7 ± 1.3 ; 44.5 ± 2.0 , 42.6 ± 3.6 and 44.2 ± 4.0 ; and 734 ± 42 , 697 ± 79 and 719 ± 69 for control, 50% deletion and 100% deletion, respectively. All of these measurements were not different ($P > 0.05$) among the dietary groups. These findings together with others' clearly demonstrate that supplementary vitamins and trace minerals are not necessary for finishing pig diets.

1876 Fatty acid polyunsaturation of boar semen: Positive effects on gilt reproduction. P.C Penny^{*1}, R.C Noble¹, and A. Maldjian¹, ¹*JSR Healthbred Ltd, Southburn, Driffield, YO25 9ED, UK*.

The major differentiated regions of the spermatozoan cell, display their own unique lipid compositions involving a high degree of polyunsaturation. Idealisation of the polyunsaturation profile of boar spermatozoa by nutritional supplementation (ProsperrmTM), has demonstrated highly beneficial effects on spermatozoa characteristics. The aim of this study was to determine if gilts inseminated with spermatozoa from boars with enhanced polyunsaturated spermatozoa composition would enhance female reproductive output beyond standard boar spermatozoa. Thirty five boars were allocated to the study, with four hundred and seventy eight gilts (JSR Genepacker) being randomly allocated to two insemination treatments, either standard or optimised polyunsaturated semen (post eight week spermatozoa synthesis). All gilts were artificially inseminated twice (75ml, 2.5 billion spermatozoa. Insemination timing schedule (days) either d1+2, d2+3 and d3+4 was balanced between semen treatments. Significant positive effects were observed for conception rate (90 vs. 83 %, $P < .05$), born alive (10.6 vs. 10.2, s.e.d. 0.19, $P < .05$) and overall fecundity, number of piglets born alive per 100 services (954 vs. 846, s.e.d. 19.5, $P < .001$) in those gilts inseminated with enhanced polyunsaturated spermatozoa. Polyunsaturated fatty acids which are concentrated in the cell membrane and tail region of spermatozoa, have been shown to play a pivotal role in both spermatozoa capacitation and the interaction between spermatozoa cell membrane and uterine surface. The increased female reproductive efficiency demonstrated here by utilising enhanced polyunsaturated spermatozoa, can be associated with improved spermatozoa characteristics and survivability properties during the critical time window from semen insemination to fertilisation.

Key Words: Boar, Polyunsaturation, Spermatozoa

1877 Effect of docosahexaenoic acid (DHA) and cryopreservation on boar spermatozoa. A Maldjian¹, P.C Penny^{*1}, S Cerolini², and R.C Noble¹, ¹*JSR Healthbred Ltd, Southburn, Driffield, YO25 9ED, UK*, ²*Istituto Zootecnico, Via Celoria 10, 20133 Milano, Italy*.

Lipids present within boar spermatozoa play a key role in physiological and structural formation. Cryopreservation of boar semen is not routinely used due to variable spermatozoa survival rates. Changing specific fatty acids within the spermatozoa could deliver both fresh and frozen

benefits. The aim of this study was to investigate the effect of providing a supplement containing docosahexaenoic fatty acid (DHA) plus antioxidants (PropsermTM) on the fresh quality of boar spermatozoa and subsequent cryopreservation of such derived spermatozoa. Fourteen boars were randomly allocated to either a standard boar diet or standard diet + nutritional supplement (ProsperrmTM), for 16 weeks. Both fresh and thawed samples of normal and DHA manipulated spermatozoa were assessed for motility and viability. Ejaculate concentration and fatty acid profile were assessed on fresh spermatozoa only. Samples were frozen using the Westendorf procedure (1975). The level of DHA increased from 28.1 % to 43.3 % of total fatty acids ($P < .01$) in spermatozoa from supplemented boars. Sperm concentration was also significantly higher (571 vs. 695 million per ml; $P < .05$) in boars receiving the supplement. Following cryopreservation and thawing sperm quality parameters were similar for normal and DHA manipulated spermatozoa. DHA supplementation of boars provided a major benefit for improving fresh spermatozoa quality. Altering other fatty acids in-conjunction with DHA may be required to improve cryopreservation of boar spermatozoa.

Key Words: Boar, Docosahexaenoic, Spermatozoa

1878 Response of weaned pigs housed in large groups to alternative feeding strategies. P.C Penny^{*1} and S Tibble², ¹*JSR Healthbred Ltd, Southburn, Driffield, YO25 9ED, UK*, ²*SCA Iberica S.A., Mequinenza, Spain*.

The uptake by pig producers of large group (LG) weaning systems provides complex nutritional challenges. Defining an appropriate nutritional strategy to accommodate the extensive weaning weight variation within LG is not easy. The aim of this study was to investigate specific nutritional feeding regimes to maximise the overall performance of weaned pigs housed in LG. A total of 1300 weaned piglets were used in a randomised block design involving two treatments (group size 130). 1. Fixed feeding regime of four diets, each offered for a specific number of days (FX). 2. Choice feeding regime, same four diets but offered in paired combinations over time (CH). Feeder allocation, feeder type and water availability were standardised. All pigs were weighed individually at weaning, d 7, 14, 21, 28 and 35. Average daily gain (ADG) during d0-7 was significantly reduced for FX compared to CH, 0.117 vs. 0.143 kg ($P < 0.01$). From d8-14 ADG for FX was significantly higher than CH, 0.340 vs. 0.315 kg ($P < 0.01$). Live weight at d35 was significantly lower for FX compared to CH, 19.9 vs. 20.7 kg ($P < 0.01$). Pigs on CH showed clear evidence of being able to choose between diets offered. This study demonstrates positive nutritional solutions for improving the performance of weaned pigs in LG. Further work is necessary to synergistically combine specific attributes from both FX and CH feeding strategies.

Key Words: Large group, Nutrition, Pig

1879 Increased progeny performance by elevating nutrient intake to sows during gestation. P.C Penny^{*1}, M.A Varley², and S Tibble³, ¹*JSR Healthbred Ltd, Southburn, Driffield, YO25 9ED, UK*, ²*SCA Nutrition Ltd, Thirsk, UK*, ³*SCA Iberica S.A., Mequinenza, Spain*.

Previous work has demonstrated a positive effect on progeny performance from increasing nutrient intake to sows between d 28-56 of gestation. This first in-field experiment was undertaken with limited numbers and although results obtained were positive, further data is necessary to deliver producer acceptance. The aim of this study was to extrapolate and confirm the effectiveness of implementing increased nutrients d28-56 and the effect of offering two diets to derived progeny during the growth phase (2x2 factorial design). Forty eight multiparous sows were randomly allocated between two treatments, Standard (ST) 2.5 kg/d or Elevated (EL) 5.0 kg/d. Pigs from each sow were housed in groups of twelve, received identical nutrition and were weighed on d 57, 85, 127 and 157. Two diets differing in lysine content (1.05 vs. 1.25 %) were offered to ST and EL progeny during d85-127. Quantity of feed consumed during gestation was lower ($P < 0.01$) for ST than EL. ST progeny produced a significantly lower average daily gain from d 85-127 ($P < .05$) compared to EL progeny (0.866 vs. 0.910 kg). This was also evident for both diets. Food conversion for ST progeny was substantially increased (2.201 vs. 2.060, $P < .05$) compared to EL, again represented by both dietary treatments. These results confirm that increased maternal

nutrients, d28-56, provides enhanced progeny performance and suggests the possibility of reducing the nutrient density of the diet offered.

Key Words: Sow, Gestation, Performance

1880 Effect of storage and pelleting temperature on the activity of bacterial alkaline endoprotease (E.C. 3.4.21.14), Alpha D-(1,4) amylase (E.C. 3.2.1.1) and combination of both enzymes. I Prez-Portabella¹, J Sol, and E Roura*, ¹Lucta, s.a.

The objective of this study was to examine the ability of bacterial alkaline endoprotease (E.C.3.4.21.14), Alpha D-(1,4) amylase (E.C.3.2.1.1) and the combination of both enzymes (Luctazyme Pro-Pig[®]) to withstand storage and exposure to moist heat. In experiment 1 enzymes were incubated in a water bath at different temperatures for 1 minute simulating pelleting heat conditions (table). In experiment 2 protease stability in the combined product at a three different storage conditions (5C, 22C and 40C) was assessed. Enzyme activities were determined using the methods developed by Lucta, s.a. after modification of previously published laboratory procedures. One unit of amylase activity is defined as the amount of enzyme which liberates 1 mmole of reducing sugars from potato starch per minute at pH 7 and 40C. One unit of protease activity is the amount of enzyme which liberates 1.5 mg/ml of L-tyrosine from casein per minute at pH 7 and 37C. The effect of different heat treatments on protease and amylase activity are shown in table 1 and 2.

Both, the endoprotease and the alpha-amylase, are highly stable even at 80C when assayed separately (84% and 90.5% of residual activity respectively) and in combination (80% and 84%). Loss of endoprotease activity in combination with alpha-amylase after 6 month storage was 18% at 40C, 4.5% at 22C and 3% at 5C. It is concluded that the combination of endo-protease and alpha-amylase is stable to moist heat and a 6 month storage at 40, 22 and 5C.

% protease activity	50 C	60 C	70 C	80 C
Bacterial alkaline endoprotease	99.0	1.0	95.5	2.5
Combination of both enzymes	99.0	1.0	96.0	1.5
% amylase activity	99.0	1.0	94.0	2.0
Alpha D-(1,4)amylase	99.0	1.0	94.0	2.0
Combination of both enzymes	98.0	2.0	92.0	1.0

Key Words: Alkaline endoprotease, Alpha-amylase, Stability

1881 *Saccharomyces cerevisiae* for breeding sows in a Parvoviral challenge. V. G. Perez¹, M. L. Angeles², A. M. Anaya², and J. A. Cuaron², ¹FES-C, UNAM, ²C. N. I. Fisiología y Mejoramiento Animal, INIFAP. Queretaro, Mexico.

A total of 94 sows were challenged by a management induction of a parvoviral outbreak in 50% of the herd at breeding. Parvovirus surviving piglets are weaker and more susceptible to secondary infection; therefore the disease was used as a challenge to possible protective effects on productivity by a live yeast strain. Starting at d-30 of gestation sows were randomized to 2 treatments: Control (CTR) and the addition of 3 kg/ton of feed of live *Saccharomyces cerevisiae*, strain 47 (S47); treatments identity was conserved upon weaning. Parity (first litter gilts, mature sows, 2-5, and old 6+ farrowings) was included in a factorial arrangement. Parvovirus infection was confirmed by clinical signs, including number of piglets born alive. Challenged sows farrowed 7.6 live pigs and weaned 5.5 piglets vs. 10.7 and 9.1 in healthy animals (P<.01). Litter size effects were those expected and no interaction was detected (P>.23) with S47 addition or parity. Feed intake during lactation was 5.2 kg/d (P>.32), but yeast addition resulted in heavier litters at weaning (P<.01): 53.6 vs. 46.5 kg, for a mean litter size of 7.3 piglets after a lactation period of 24-d. Sow parity and S47 interacted (P<.11) in sow lactation wt. loss: first litter gilts in S47 lost 20.4, while CTR gilts 6.9 kg; sows in all treatment combinations lost 16.7 kg. Milk protein and fat was analyzed at d-10 of lactation and mean composition was similar: CP, 9.7 and fat, 7.3% (P>0.8). However, total milk CP and ME yield was calculated higher in S47 fed sows (P<.05). No differences (P>.25) were observed in subsequent reproductive performance, including pigs at parturition. The effect of S47 was the induction of greater

(by 15%) litter weaning weight; live yeast in the dam's diet did not protect piglets from Parvovirus side effects, but may be favoring a better metabolic response for milk synthesis.

Key Words: Yeast, Lactating sows, Parvovirus

1882 *Saccharomyces cerevisiae* for lactating sows in a septic environment. V. G. Perez¹, S. Solorio², A. Juarez³, J. Becerri³, E. O. Castaneda-Silva⁴, and J. A. Cuaron⁵, ¹FES-C, UNAM, ²PAIEPEME, A.C., ³Grupo Delta, S.A., ⁴Nutrimentos Concentra, S.A. de C.V., ⁵C. N. I. Fisiología y Mejoramiento Animal, INIFAP. Queretaro, Mexico.

In a commercial farm suffering several infectious diseases (among others PRRS), a total of 322 sows were used to conduct an experiment in two phases. Phase 1 was supervised feeding to ensure *ad libitum* intake, while in Phase 2, feeding was done by laborers applying the feeding method as a routine. Treatments were the addition or not of 2 kg/ton of a live culture of *Saccharomyces cerevisiae* strain SC47 (S47), to the lactation diet. Productive performance was measured during lactation and re-breeding. Experimental lactation diets were offered from gestation d-100, at 2 kg/sow/d. From farrowing sows' feed allowance was increased by .5 kg/d until *ad libitum* intake. Sows' parity group (1st, 2nd, 3rd and greater than 5 parities) was included in the model as a factor. Overall, number of piglets born alive was 10. In Phase 1, S47 fed sows had greater (P<.08) daily feed intake (5.72 vs. 5.45 kg) during the 16-d lactation period. Sows fed S47 weaned heavier (P<.02) litters (45.84 vs. 42.71 kg) and exhibited less (P<.01) piglet mortality (7.01 vs. 12.83%). Sow wt. change during lactation was similar (P>.25) between dietary treatments (mean of -3.5 kg). In Phase 2, mean daily feed intake was similar (P>.8) between dietary treatments, but differences in litter wt. at weaning were maintained (P<.05; 44.9 vs. 42.8 kg), resulting in greater (P<.01) sow wt. loss: 6.77 vs. 2.53 kg. In both phases, sow parity and S47 showed (P>.2) no interactions for any of the response criteria. Days to 1st estrus, conception rate and prolificacy to the following farrowing were unaffected (P>.7). It is inferred that the greater litter wt. gain in yeast fed animals was a consequence of a better metabolic status, possibly by enhancing immune responsiveness of the sows to acute sub-clinical challenges.

Key Words: Yeast, Lactating sows, Health status

1883 *Saccharomyces cerevisiae* for growing-finishing pigs in a septic environment. V. G. Perez¹, S. Solorio², A. M. M. Martinez³, E. O. Castaneda-Silva⁴, and J. A. Cuaron⁵, ¹FES-C, UNAM, ²PAIEPEME, A.C., ³CNID-Microbiología, INIFAP, ⁴Nutrimentos Concentra, S.A. de C.V., ⁵C. N. I. Fisiología y Mejoramiento Animal, INIFAP. Queretaro, Mexico..

A total of 630 growing-finishing barrows and gilts (mixed in similar proportions) of an avg. initial wt. of 41.7±7 kg (a covariable) were used in a single experiment in which pigs were weaned and raised to initial wt. from sows fed diets containing 2 kg/ton of a live culture of *Saccharomyces cerevisiae*, strain SC47 (S47). In three treatments, S47 was kept in the diets to starting wt. (W40), up to 70 kg BW (W70) or to market wt. (105±6 kg), no withdrawal (NOW). The experiment was a RCB, being blocks 2 identical open front buildings in which pigs were housed in pens of 21 head. There were 10 pen replications per treatment. In all cases, antibiotics were used in feed up to 70 kg BW, as recommended by the resident veterinarian. Feed intake was measured daily and body wt. gain by weighing pens every 14-d. Real time ultrasound measurements (backfat and muscle depth at P2) were recorded initially and in 28-d intervals. Clinical observations were recorded and animals losing BW in two consecutive weighings were removed and counted as mortality. Average feed intake was 2.42 kg/d and no differences were noted (P>.7) between treatments. However, BW gain showed differences (P<.07): W40, .718 < W70, .747 and NOW, .762 kg/d and gain:feed was: W40, .29 < W70, .31 and NOW, .32 (P<.03). Noted differences (P<.05) in carcass composition were on P2 backfat at the last rib, which paralleled daily BW gain: W40, 15.4 < W70, 16.4 < NOW, 17.6 mm. During the experiment an outbreak of complicated mycoplasmosis resulted in high mortality during a 2 week span, starting at about d-125 of age. Final mortality rate was: W40, 6.54 > W70, 3.64 and NOW, 2.32% (P<.08). Live S47 yeast in feed possibly conferred better resistance to disease, provided that the culture was present in the diet at time of challenge.

Key Words: Yeast, Growing pigs, Health status

1884 Molecular typing of hemolytic *Escherichia coli* isolated from swine. D. Parrott*¹, T. Rehberger¹, and M. Holt², ¹Agtech Products, Inc., Waukesha, WI, ²Varied Industries Corporation, Mason City, IA.

E. coli is known to cause edema disease and coliform gastroenteritis in swine leading to an important economic loss and mortality between weaning and market. Understanding the genetic diversity between isolates is an important aspect when trying to prevent and treat this disease. Forty-eight hemolytic *E. coli* isolates were obtained from animal diagnostic laboratories in Iowa, Oklahoma, Arkansas, Georgia, Indiana, and Texas as a causative agent in infected swine herds presenting with diarrhea or edema disease. All isolates were biochemically tested to confirm their identification. The isolates were genetically analyzed using pulse-field gel electrophoresis (PFGE) and random amplified polymorphic DNA analysis (RAPD). PFGE was performed using chromosomal DNA embedded in agarose beads and digested with *Xba* I. PFGE analysis classified isolates into 22 genotypes with no genotype containing more than four isolates. RAPD was performed using two 10-base pair oligonucleotide primers. RAPD analysis with the first primer classified isolates into 15 genotypes with no genotype containing more than five isolates. RAPD analysis with the second primer classified isolates into 10 genotypes with no genotype containing more than eight isolates. The classifying of swine *E. coli* into 10-22 different genotypes demonstrates the genetic variability within hemolytic *E. coli* isolated from infected swine herds. Both PFGE and RAPD analysis are useful techniques for isolate typing, with PFGE being the more discriminatory method.

Key Words: Swine *E. coli*, Pulsed-field gel electrophoresis, Random amplified polymorphic DNA analysis

1885 Effect of three dietary growth promoting additives on performance of nursery pigs. B. P. Corrigan*¹, B. F. Wolter¹, M. Ellis¹, and S. Moreland², ¹University of Illinois, Urbana, IL/USA, ²Braes Feed Ingredients, Wheeling, IL/USA.

This study was carried out over a 4-wk period to investigate the impact of dietary additions of 3 growth-promoting agents on growth performance of nursery pigs. A randomized-block design was used with four treatments and fifteen replicates per treatment, blocked by weaning date. The treatments were: 1) Control (no additive); 2) Zinc oxide (to provide 3000 ppm added zinc); 3) Antibiotic CSP 250[®] (at 0.25% of the diet to provide 110 mg of chlortetracycline, 110 mg of sulfamethazine, and 55 mg of penicillin per kg); 4) ApexTM 3050 (at 0.10% of the diet). ApexTM 3050 is a blend of specific plant extracts, mixed herbs, essential oils and AllinexTM, a natural form of alliin. A total of 360 crossbred pigs were weaned at 21 ± 1.2 d of age and allotted to treatment groups (mixed-sex) of 6 pigs on the basis of weaning weight, sex, and litter. Pigs were given ad libitum access to feed and water. A two-phase feeding regimen was used with the Phase I diet (3438 kcal/kg ME, 23.8% CP, 1.63% lysine) fed as a pellet for the first two weeks and the Phase II diet (3421 kcal/kg ME, 22.68% CP, 1.46% lysine) fed as a meal in weeks 3 and 4. Morbidity (pigs removed due to poor health or lameness) was higher for the control compared to the other treatments (17.7 vs 5.6 vs 3.3 vs 3.3 %, for the Control, Zinc oxide, CSP 250[®], and ApexTM 3050, treatments, resp., P<0.01). Two pens of pigs on the control treatment were removed from the study because of high levels of morbidity and the data from these pens were not included in the growth performance analysis. Over the 4-week study period, ADG (229 vs 324 vs 277 vs 259 g, SE 7.8 g, resp., P < 0.05), ADFI (392 vs 469 vs 430 vs 408 SE 10.8 g, resp., P<0.05), and G:F (0.66 vs 0.76 vs 0.72 vs 0.71 SE 0.015 g/g, resp., P<0.05) were lowest for the control and highest for the Zinc oxide treatment, with the other two treatments generally being similar and intermediate for these traits. These results suggest the growth promoting additives evaluated in pigs weaned at 21 d of age were effective in reducing morbidity and increasing growth performance for 4-wk post-weaning.

Key Words: Pigs, Weanling, Growth

1886 Effect of iron supplementation and dietary iron source and level on bioavailability of iron in weanling pigs. B. K. Anderson*¹, N. R. Augspurger¹, M. Ellis¹, and D. E. Nuzback², ¹University of Illinois at Urbana-Champaign, ²Albion Laboratories, Inc.

The effect of iron (Fe) supplementation and dietary Fe source on Fe bioavailability was determined by hemoglobin (Hb) depletion and use of a slope-ratio assay. Ninety Fe-deprived piglets (Hb 5.17 ± 1.21 g/dL) from 11 litters were used in a 2 × 3 × 5 factorial design, the factors being Fe supplementation level, dietary Fe source and dietary Fe concentration. Piglets were randomly allotted at birth to one of two Fe supplementation levels, 0 or 30 mg Fe via Fe dextran. Injections were administered on d1 with all piglets receiving either 1 ml saline or 1 ml Fe dextran 30 mg Fe/ml. At weaning, pigs were blocked by Fe supplementation level, then randomly allotted across 13 dietary treatments comprised of 4 levels of 3 dietary Fe sources and a common control. Diets were based on a common basal diet employing dried skim milk and corn to yield 27 mg/kg of iron. Twelve diets were formulated from aliquots of the basal diet to contain 25, 50, 75, and 100 mg Fe/kg iron from either ferrous sulfate, an Fe-amino acid chelate or a combination of ferrous sulfate and chelated product mixed in a 70:30 ratio (Fe concentration). Performance measures (ADG, ADFI, and G:F) were recorded individually for all piglets. Blood Hb concentration was determined at the start and end of the 3-wk feeding period during which pigs were offered feed and water ad libitum. Estimates for Fe bioavailability of both Fe chelate and ferrous sulfate/chelate combination were based on the ratio of the regression slopes of blood Hb levels on dietary Fe intake for both sources vs. ferrous sulfate. Those values were calculated to be 98.5% for the chelated product and 107.6% for the ferrous sulfate/chelate combination. These values are generally higher than previously reported for iron complexes.

Key Words: pigs, iron, bioavailability

1887 The response of starting pigs to increasing levels of dietary lysine, when formulated on ideal protein basis. I. Moreira*, A.L. Fraga, A.C. Furlan, A.O. Bastos, R.P. Oliveira, and D. Paiano, *Universidade Estadual de Maringa, Maringa-PR Brazil.*

A trial was carried out to evaluate the effect of increasing lysine levels (LYS) in the diet of starting pigs when formulated on ideal protein basis. A corn-soybean meal basal diet contained 13.1% crude protein, 3.4 Mcal of digestible energy/kg and 0.80% lysine. Treatment diets were supplemented with .2, .4, or .6% lysine to attain dietary concentrations of 1.0, 1.2 and 1.4% lysine (total). Crystalline methionine, threonine and tryptophan were added in all diets to maintain a constant ratio of these essential amino acids to the lysine content. All other nutrients met or exceeded NRC (1998) nutrient requirements of pigs. Sixty-four crossbred pigs with an average body weight of 15.3 kg were blocked by weight and randomly assigned to the four experimental diets for a 26-d growth study. The experiment was a randomized complete block design and was conducted in eight replicates with two pigs per pen (experimental unit). Pigs had access to their treatment diets on an ad libitum basis. Pigs were weighed, pen feed intakes determined and individual pig blood samples taken at 14 days and at the end of experimental period. Plasma urea nitrogen (PUN) was determined. Neither PUN nor average weight gain was altered (P≥.05) by lysine levels. Increasing lysine levels resulted in linear (P≤.05) responses in average feed intake (AFI = 1.378331 - .1905×LYS) and feed:gain (F:G = 2.16182 - .174625×LYS).

Key Words: Ideal Protein, Plasma Urea Nitrogen, Starting Pig

1888 Effect of a GnRH-analogue at estrus on reproductive performance of gilts. J.A. Romo*¹, R. Barajas¹, and M.A. Luque¹, ¹FMVZ-Universidad Autonoma de Sinaloa (Mexico).

With the objective of determining the effect of the application of an analogue of gonadotropin releasing hormone (GnRH-A) at estrus on reproductive performance of gilts, two experiments were carried out. Experiment 1. One hundred seventy four hybrid gilts (YLHD; 1-5 parities) that had shown estrus between December and February (cool season) were used in a randomized design experiment. Gilts were designated to receive one of two experimental treatments: 1) Injection (im) of 50 µg of GnRH-A at first acceptance of a boar (GnRH-A; n=84); or 2) Injection of 2 mL of water (control; n=84). Experiment 2. One hundred thirty two hybrid gilts (YLHD; 1-5 parities) having shown estrus between June

and September (hot season) were used in a randomized design experiment, and received similar treatments as in experiment 1 (GnRH-A, n=70; and control, n=62). In experiment 1, farrowing was between March and June. GnRH-A application had no effect on the number of total piglets born (11.35 vs. 11.44) or the number of liveborn piglets (10.73 vs. 10.78). Fertility was similar (P>0.10) across treatments (90% vs. 85.71%). In experiment 2, farrowing was between October and January. GnRH-A injection had no effect (P>0.10) on the num-

ber of total piglets born (11.25 vs 11.20) or number liveborn (10.14 vs 10.22). Fertility of gilts receiving GnRH-A (91.43%, 64/70) and control gilts (85.48%, 53/62) was not different (P>0.10). It is concluded that injection of GnRH-A at service time does not affect the reproductive performance of gilts.

Key Words: GnRH, Reproduction, Gilts

ASAS Horse Species

1889 Temporal variables of the flat walk of the Tennessee Walking Horse weanling. K.M. Holt*¹ and M.C. Nicodemus¹, ¹Mississippi State University, Mississippi State, MS/USA.

Limited research has been done on gaited horses, particularly concerning gaited weanlings. During the first few years, proper gait development for the gaited horse is very critical. This study describes the stride variables of the flat walk for 4 Tennessee Walking Horse weanlings. Frame-by-frame analysis was done to measure the following stride variables: stride duration, fore and hind stance durations, diagonal and lateral step intervals, and percentage of limb support. Four strides of a natural, consistent flat walk were measured for each weanling. The flat walk was determined to be a symmetrical, four-beat stepping gait that alternated between periods of tripod and bipedal limb support. The majority of the stride was spent in a stance phase with a similar percent of stance for both the fore and hind limbs. Weanlings 3 and 4 had a longer diagonal than lateral step interval and longer lateral than diagonal bipedal support indicating these gaits had an irregular rhythm with lateral couplets. Weanling 2 had the most even gait by demonstrating similar lateral and diagonal step intervals, lateral and diagonal bipedal supports and fore and hind stance durations. These stride variables will assist in the better understanding of how the gaits of the gaited horse develop with age. The temporal variables of these weanlings will be measured throughout aging and training to track the development of the flat walk.

Table 1. Mean values (SD) for the stride variables in the individual weanlings and group mean (SD) values.

	Wean-ling 1	Wean-ling 2	Wean-ling 3	Wean-ling 4	Ave.
Stride Duration (ms)	908(42)	1133(96)	1150(72)	1133(64)	1081(121)
Fore Stance (ms)	542(42)	696(40)	708(57)	688(61)	659(78)

1890 In vitro fermentation characteristics of vegetative and mature grasses by equine fecal inoculum. H. S. Hussein*, H. Han, J. P. Tanner, and A. A. Cirelli, University of Nevada - Reno.

The objective of this study was to determine the effects of forage species and stage of maturity on digestibility of DM and OM and on VFA production after in vitro incubation of .5 g DM of each substrate with equine fecal inoculum. Three horses (replications) were maintained on a diet containing oat-alfalfa cubes (i.e., 70% alfalfa hay and 30% oat hay) and were used as donors of fecal inocula for the in vitro fermentation. In a completely randomized design, the treatments were arranged as a 4 × 2 × 4 factorial. The main factors were 4 forage species (bromegrass [BG; *Bromus inermis*], orchardgrass [OG; *Dactylis glomerata*], ryegrass [RG; *Lolium perenne*], and tall fescue [TF; *Festuca arundinacea*]), 2 stages of maturity (vegetative [V] or mature [M]), and 4 incubation times (i.e., 6, 12, 24, and 48 h). Interactions (P < .05) were only detected between forage species and stage of maturity for DM and OM digestibilities. Digestibility of DM (across incubation times) was highest (35.0%; P < .05) for OG-V and lowest (29.9%; P < .05) for RG-M. Digestibility of OM (across incubation times) was highest (41.0%; P < .05) for BG-V and lowest (33.3%; P < .05) for RG-M. With the exception of acetate, forage species had no effect (P > .05) on individual or total VFA concentrations. Acetate concentration was highest (9.32 mM; P < .05) for RG and lowest (8.03 mM; P < .05) for TF. Concentrations of acetate, propionate, butyrate, and total VFA were higher (P < .05) for vegetative (9.14, 2.64, .50, and 12.98 mM, respectively) than for mature (8.13, 2.25, .30, and 11.26 mM, respectively) forages. Evaluation of the 4 forage species indicated that OM digestibility was lowest (P < .05) for RG than for BG, OG, or TF (36.4, 39.8, 39.6, and 38.5%, respectively). The corresponding values for total VFA (12.7, 11.7, 12.7, and 11.5 mM, respectively), however, were not different (P > .05). Therefore, horses may be able to utilize BG, OG, and TF more efficiently than RG.

Key Words: Horses, Forages, In vitro digestibility

1891 Environmental factors affecting racing time in Brazilian Thoroughbred horses in Cristal hippodrome. Rodrigo Taveira* and Marcilio Mota, ^{Unesp}Universidade Estadual Paulista.

The aim was to study environmental factors that affect the racing time of Thoroughbred that won races in the classical calendar at the Cristal hippodrome, State of Rio Grande do Sul, Brazil. The data used in this study were provided by the Study Book from the Brazilian Association of Race Horse Breeders (ABCCC) and included 1139 finishing times from 420 animals that won 100 different kinds of races taken place from 1974 to 1998. The analyses of information was carried out using the GLM procedure of the Statistical Analyses Systems (SAS, 1996). Race year (1974 to 1998), track condition, grade (5 levels), condition (sex and age combination) and distance (700 to 3000 meters) were the fixed effects considered in the linear model. The fastest time have been provided by the animals that was running on light turf and group I (the most important of the grades). There are not significant difference between the different kinds of sex and age combination and year of race. The quadratic regression of time on distance has shown decrease in average speed of 0.92 m/s, when racing distance goes from 1000 m (16.69 m/s) to 2000 m (15.77 m/s), and 0.49 m/s from 2000 m to 3000 m (15.28 m/s).

Key Words: Thoroughbred, Race, Time

1892 Environmental factors affecting the racing time of Quarter Horses in Brazil. Marcilio Mota and Rodrigo Taveira*, *Unesp Universidade Estadual Paulista.*

The aim of this paper was to study the environmental factors affecting the racing time of Quarter Horses which participated in races held in Sorocaba and Ribeirao Preto racetracks, Sao Paulo state, Brazil. The data consisted of 4684 performances evaluated based on the 1428 animals final time (630 females and 798 males) that have run from 1983 to 1997. The analytical methods involved the GLM procedure of the Statistical Analysis System, SAS (1996). Age of animals (2,3,4 e >4 Years), jockey's weight (44-62 Kg), race year (1983-1997), sex (male, female), origin (national, imported), racetracks (Sorocaba and Ribeirao Preto) and distance (301,320, 365,402 and 503 meters) were the fixed effects considered in the linear model. Racetrack and origin have presented no significant effects (p>0,05). Animal age equal or over 4 years old and

jockey's weight at 59 Kg were the fastest (p<0,001), while those at 2 years old and jockeys at 62 Kg have shown the worst performances. Males and females had no significant difference (p>0,05). The linear regression of the time on the race year has pointed out an animal decrease annual next to 0,16 second, about 2 seconds in the studied period. The decrease occurred, may be, in part, due to improvements in veterinary, nutritional and training features as well as gains obtained by selection. The quadratic regression of the time on distance ($y = -0,077 + 0,0617X - 11E-6X^2$) has shown that when the 402 and 301 distances (101 meters difference) have been compared, a 0,31 m/s increase in the animal speed has occurred (17,51 m/s and 17,2 m/s respectively). In the same way when 503 and 402 distances have been compared (also 101 m difference), a lightly higher increase in the 0,34 m/s speed has been observed.

Key Words: Quarter Horse, race, time

ASAS/ADSA Forages and Pastures: Grazing and Alternative Forages

1893 Growth performance of stocker calves backgrounded on sod-seeded winter annuals or hay and grain. K. P. Coffey*¹, W. K. Coblenz¹, T. G. Montgomery², J. D. Shockey², K. J. Bryant², P. B. Francis², and C. F. Rosenkrans, Jr.¹, ¹University of Arkansas, Fayetteville, AR, USA, ²Univ. of Ar. SE Research and Extension Center, Monticello, AR, USA.

Winter annual forages have the potential to provide a lower-cost, rapid-gain option for retaining ownership of fall-weaned calves. A study was conducted during the winters of 1998, 1999, and 2000 using 180 crossbred calves (261 kg BW) to compare winter backgrounding programs in southeastern Arkansas. Calves were fed bermudagrass hay (ad libitum) and a grain sorghum-based supplement (1% of BW) in drylot (HS) or were grazed on pastures of bermudagrass/dallisgrass overseeded with 1) annual ryegrass (RG), 2) wheat and RG (WRG), or 3) rye and RG (RRG). Calves grazed from mid-December until mid-April, but were fed hay during times of low available forage. During the first two years, calves fed HS gained less (P < 0.05) BW (73.2 kg) than calves that grazed winter annual forages (113.9 kg); gains did not differ (P > 0.10) among RG, RRG, and WRG (121.4, 111.3, and 109.0 kg, respectively). During the third year, undesirable environmental conditions limited growth of the winter annual forages; total gain did not differ (P > 0.10) among the four treatments (65.7, 58.3, 57.0, and 55.0 kg for HS, RG, RRG, and WRG, respectively). Mean CP and IVDMD concentrations were 19.0 and 71.1%, respectively across sampling dates and winter annual forages, but three-way interactions among forage treatments, year, and sampling date were detected (P < 0.01) for available forage, and concentrations of CP, NDF, and IVDMD. Available forage did not differ (P > 0.10) among RG, RRG, or WRG on any sampling date. The IVDMD of RRG was greater (P < 0.05) than that of RG in the 1999. A treatment by sampling date interaction was detected for forage CP in 1998 (P < 0.05) and 1999 (P = 0.05) but not in 2000 (P > 0.10). Winter annual forages offer potential to provide high quality forage for calves retained until spring, but consistent forage production is a concern when sod-seeding techniques are used.

Key Words: Stocker cattle, Winter annuals, Forage quality

1894 Steer grazing behavior on endophyte-free, toxic endophyte-infected, and non-toxic endophyte-infected (Max QTM) tall fescue. J. A. Bondurant*, M. A. McCann, J. S. McCann, J. H. Bouton, C. S. Hoveland, R. H. Watson, and J. G. Andrae, *The University of Georgia, Athens, GA.*

Fescue toxicosis decreases grazing time and depresses performance in cattle as they alter grazing behavior to cope with the toxicosis. In an attempt to capitalize on improved animal performance and health as well as agronomic benefits, non-toxic endophytes that enhance plant persistence have been inserted into tall fescue. The objectives of the present study were to assess grazing behavior in stocker steers grazing non-toxic endophyte-infected (MaxQTM) Jesup tall fescue versus endophyte-free (EF) and toxic endophyte-infected (EI) Jesup tall fescue. Hereford steers weighing approximately 270 kg were stocked at 3.71 hd/ha on replicated (n=2) .809-ha tall fescue paddocks at the Central GA Branch Station for 69 days commencing October 11, 2000. Computerized grazing behavior recorders and jaw movement sensors were fitted to 12 steers for two 5-d collection periods from October 11-16

and December 4-9. Jaw movement data was collected for a minimum of 20 h/hd/d and was analyzed with GRAZETM software. Mean available forage was approximately 3100 kg DM/ha. Steers on all treatments spent less (P<.05) time grazing, a similar (P>.05) amount of time ruminating, and more (P<.05) time in other activities in October. Numbers of grass boli swallowed/h were not different (P>.05) among treatments or periods. Fewer (P<.05) mastications/h and fewer (P<.05) prehensions/h were observed during October versus December. In addition to the period differences, treatments affected grazing behavior. On the toxic EI paddocks, steers had more (P<.05) mastications/h than the cattle on the EF and MaxQTM treatments during October. In December the number of prehensions/h were lower (P≤.05) on the toxic EI paddocks. Time spent neither grazing nor ruminating was lower for cattle on MaxQTM paddocks in December than for cattle on toxic EI or EF treatments. Data from two cool-season periods demonstrates no adverse effects of MaxQTM tall fescue on steer grazing behavior.

Key Words: grazing behavior, tall fescue, MaxQTM

1895 Use of *Ascophyllum nodosum* for alleviation of fescue toxicosis in cattle. J.E. Williams*¹, A. Rodriquez², E. Navarro¹, and D.P. Colling³, ¹University of Missouri, Columbia, MO, ²University of Puerto Rico, Mayaguez, PR, ³Land O'Lakes Farmland Feed, Kansas City, MO.

Cattle grazing endophyte-infected tall fescue (EIF) sprayed with seaweed extract *Ascophyllum nodosum* show reduced fescue toxicosis and improved immune function as compared to untreated animals. In order to evaluate the impact of Tascotm seaweed extract (SWE) and Tascotm seaweed meal (SWM) on fescue toxicosis, a feedlot study was conducted with measures of ADG, DM intake, rectal temperature, and respiration rate. Eighty continental crossbred yearling steers (avg. 291 kg) were assigned to one of four treatments (5 pens per treatment and 4 steers per pen): 1) endophyte-free tall fescue (EFF) seed; 2) EIF seed; 3) EIF seed + 2.0 % SWM; 4) EIF seed + 0.5 % SWE. The EIF seed provided 10 ug ergovaline / kg BW. The EFF seed, EIF seed, and EIF seed with SWE or SWM were fed daily prior to the morning feeding. The SWE and SWM were fed from 0 to 14 d, while the EFF seed and EIF seed were fed from 0 to 42 d. The diet consisted of cottonseed hulls and cracked corn based diet to provide 0.92 Mcal/ kg Neg and 11.2 % CP. Rectal temperatures were recorded 7 times while respiration rates were recorded 13 times throughout the 42 d study. The air temperature (Ta) and % relative humidity (RH) were recorded continuously. During 0 to 14 d, the average Ta was 27.1 C and RH was 71%; for d 14 to 42, the Ta was 27.5 C and RH was 66.7%. During the first 14 d and 14 to 42 d period, respiration rates were not affected (P > 0.30) by treatment. During the first 14 d period, there was a treatment X time (P = 0.10) interaction for respiration rates. Rectal temperature was not affected (P > 0.50) by treatment for either period. ADG, DM intake, and feed / gain ratio were not affected (P > 0.40) by treatment. The moderate Ta conditions were responsible for the lack of an effect of SWE and SWM on reducing respiration rates and rectal temperatures in cattle. Additional studies are warranted to determine the effects of SWE and SWM on reducing signs of fescue toxicosis in cattle.

1896 The effects of grazing a brown midrib vs a conventional sorghum x sudan hybrid on animal performance and gain/ha. J. B. Banta*, F. T. McCollum, III, and L. W. Greene, *Texas A & M University System, Amarillo.*

Abstract: An experiment was conducted to determine animal performance and gain/ha of beef steers (mean initial wt.: 241 kg) grazing a conventional sorghum x sudan hybrid (C) versus its near isogenic brown midrib (BMR) variety. The experiment was conducted during the summers of 1999 and 2000 in the Texas Panhandle. During both summers 8 pasture plots (2.2 ha) were blocked by location and randomly assigned either C or BMR. Fertilization and irrigation were similar for both varieties. Data were analyzed using a model containing year, block, forage type, and year by forage type. The interactions were not significant. Pastures were grazed using put and take stocking for an average of 41 and 58.5 d at an average stocking rate of 6.71 and 5.10 head/ha for years 1999 and 2000, respectively. Head d/ha, gain/ha, and ADG were determined. Steers grazing BMR tended ($P = .0651$) to gain more rapidly (1.33 kg/d) than steers grazing the C hybrid (1.19 kg/d). Gain/ha (361.5 kg, $P = .12$) and head d/ha (286.9, $P = .98$) were not different. BMR varieties are known for less lignin content, which should result in improved digestibility and thus increased ADG.

Key Words: Beef Cattle, Forage, Digestibility

1897 Use of temperature data loggers to measure body temperature in cows grazing toxic or non-toxic tall fescue. R.H. Watson*, M.A. McCann, J.A. Bondurant, J.G. Andrae, and L.L. Hawkins, *The University of Georgia, Athens, GA.*

Cattle grazing toxic tall fescue often suffer from thermoregulatory dysfunction. Elevated body temperature (BT) is often used as an indication of fescue toxicosis. To better understand the affect of grazing toxic tall fescue on BT, it is necessary to take multiple diurnal measurements while the animal is grazing, which is not possible using hand-held thermometers. Cattle ($n=10$) were randomly selected from herds grazing either toxic or non-toxic tall fescue. Equipment consisted of a temperature data logger (TDL) with 61-cm thermistor cable, housed in a plastic case. A halter was placed on the animal with the TDL attached to the neck strap so that the subcase sat comfortably behind the poll. The thermocouple end of the thermistor was coated with anti-biotic ointment and inserted into the ear canal until it met resistance at a 45° turn near the tympanic membrane. A foam block was molded into the outer ear to hold the cable in place, and insulate the ear canal from the external environment. The ear was wrapped in vet-wrap and elastic tape to secure the foam block. The TDL was programmed to record BT every 15 minutes. After 14 grazing days, the TDL was removed and the data downloaded onto computer. Rectal temperature was recorded at 1200h on the last day of grazing by hand-held thermometer. BT was significantly different between cattle grazing toxic and non-toxic fescue only when environmental temperatures were high ($>23^{\circ}\text{C}$) or low ($<12^{\circ}\text{C}$). There was no significant difference in rectal temperature between toxic and non-toxic cattle (39.4°C and 39.2°C respectively). TDL results showed that BT in cattle grazing toxic fescue is influenced by environmental temperature. The TDL method allowed measurement of BT in grazing animals across a range of environmental conditions, and sampling times.

recorded	Environmental Temp. recorded ($^{\circ}\text{C}$)	Body Temp. ($^{\circ}\text{C}$)	
		Toxic	Non-toxic
0600	9.9	38.2 ^a	38.7 ^b
1200	23.4	38.7	38.9
1800	25.5	40.2 ^a	39.6 ^b
2400	14.7	39.1	38.9

^{a,b}Mean body temperatures in a row are different ($P < .05$)

1898 Effects on forage quality and animal performance of steers grazing smooth brome pastures interseeded with legumes. M. D. Ullerich*, B. E. Anderson, T. J. Klopfenstein, and M. A. Trammell, *University of Nebraska-Lincoln.*

A trial was conducted to evaluate the effects of interseeding legumes into smooth brome (*Bromus inermis*) pastures on animal performance and forage quality compared to a smooth brome control. Forty-eight

steers (254 ± 16 kg BW) were assigned randomly to one of four treatments consisting of smooth brome pastures interseeded with 1) alfalfa (ALF; *Medicago sativa*), 2) birdsfoot trefoil (BFT; *Lotus corniculatus*), 3) kura clover (KC; *Trifolium ambiguum*), or 4) fertilized with 56 kg N/ha (CON). Steers rotationally grazed during four 36-day periods (May 2 to September 22). In addition, four ruminally fistulated steers were assigned to one of the four treatments in a 4 x 4 Latin square design. Diet and omasal samples were collected. Forage diet samples contained (DM basis) 62.1% in vitro digestible dry matter (IVDMD), 16.80% CP, and 1.48% undegradable intake protein (UIP; % DM) for ALF; 62.9% IVDMD, 16.30% CP, and 1.45% UIP for BFT; 70.8% IVDMD, 17.40% CP, and 1.46% UIP for KC; and 62.6% IVDMD, 16.10% CP, and 1.39% UIP for CON. The UIP contents of the diets across treatments were not statistically different. Undegradable intake protein content of omasal samples were similar to diet samples. Animal gains on legume/brome treatments were higher ($P < .05$) than the control (0.89 kg/d vs. 0.78 kg/d) with KC gaining the most (0.93 kg/d). The IVDMD were higher ($P < .10$) for the legume/brome treatments than the control with KC being the most digestible. Therefore, the increases in gain may be attributed to the increased energy of the legume/grass diets and not a protein (UIP) response when compared to a smooth brome control.

Key Words: Undegradable Intake Protein, Grazing Cattle, Legumes

1899 Tall fescue based forage systems for developing beef replacement heifers. J.C. Waller*¹, F.N. Schrick¹, M.C. Dixon³, A.E. Fisher¹, A.M. Saxton¹, and H.A. Fribourg², ¹Department of Animal Science, University of Tennessee, ²Department of Plant and Soil Sciences, University of Tennessee, ³Ames Plantation, Grand Junction, TN.

Effects of *Neotyphodium coenophialum* infested (E+) tall fescue (*Festuca arundinacea*) based forage systems on heifer growth and reproductive competence were evaluated. Each year, 36 fall-born heifers were weaned in mid-June and randomly allotted to one of four triplicate pasture treatments: (1) E+ tall fescue; (2) E+ tall fescue with ladino white (*Trifolium repens*) and red clover (*T. pratense*); (3) endophyte free (E-) tall fescue; (4) E- tall fescue with clovers. Each 1.2 ha pasture was stocked with 3 heifers. Weaned heifers grazed from mid-June to mid-November. All heifers were removed from experimental pastures, estrus was synchronized, bred artificially, and exposed to a bull. At 30 and 60 d after insemination, pregnancy was diagnosed by ultrasonography. Bred heifers were re-allotted to the same pasture treatment grazed as weaned heifers. Grazing occurred from early March until the end of calving season in December. A mixed model (SAS) blocked on year (1995-2000) was used to test fescue, clover, calf sex, and weaned/bred fixed effects. Quadratic regression for repeated measures over weigh dates was used to estimate average daily gain (ADG). Heifers (weaned and bred) grazing E- tall fescue had higher ($P < 0.05$) ADG than heifers grazing E+ tall fescue, 0.59 and 0.46 kg d⁻¹ respectively. The presence of clover improved ($P = 0.05$) performance of heifers grazing E+ and E- tall fescue. Once confirmed pregnant, no differences in fetal losses of heifers grazing either E+ or E- tall fescue were observed. Calf birth weight was lower ($P < 0.05$) when dams grazed E+ tall fescue than when dams grazed E- tall fescue, 24.5 and 31.7 kg, respectively. Bull calves weighed more ($P < 0.05$) than heifer calves at birth on E+ and E- tall fescue systems. The difference in calf birth weight may be explained by decreased ADG of bred heifers grazing E+ tall fescue.

Key Words: tall fescue, replacement heifers, *Neotyphodium*

1900 Effect of grain supplementation on methane production of grazing steers. D. A. Boadi*¹, K. M. Wittenberg¹, and W. P. McCaughey², ¹University of Manitoba, Winnipeg, Manitoba Canada, ²Agriculture and Agri-Food Canada, Brandon, Manitoba Canada.

The objective of the study was to examine the effects of supplemental grain on methane (CH₄) production of grazing steers. Eight beef steers (344.6 ± 6.4 kg) were assigned to legume- grass pastures (CON; $n = 4$) or legume-grass pastures and a rolled barley supplement (SUP; $n = 4$). In a completely randomized design with repeated measures, CH₄ production was measured for 2-24 hr periods using the SF₆ tracer gas technique as steers entered and exited paddocks. Two, 4 and 4 kg of rolled barley was fed to SUP steers during the Early (June 17-25 1998), Mid (July 20-29 1998) and Late (Aug. 12-21 1998) period of the grazing season, respectively. Supplementation reduced forage DMI by 11%

($P = 0.03$), and increased total digestible OMI (TDOMI) by 20% ($P = 0.001$) of SUP steers. Daily CH_4 production was similar for CON (310.5 25.9 Ld^{-1}) and SUP (331.2 24.6 Ld^{-1}) steers ($P = 0.58$). Methane, % of total gross energy intake (TGEI) ranged from 4.7 to 8.4% (mean 6.5 0.3%) during the grazing season, and there was no difference between SUP (6.4 0.6%) and CON (6.7 0.6%) steers ($P = 0.71$). There was a diet x period interaction in the grazing season ($P < 0.05$), where (LCH_4 , $\text{kg}^{-1}\text{TDOMI}$) was lowered by 29% with grain supplementation only during the Mid period ($P < 0.05$). The lower (CH_4) loss observed during the Mid period was however 38% lower ($P < 0.05$) than losses occurring during the Early period without supplementation. It can be concluded that there were marginal effects of supplementation on CH_4 production and the study implies that pasture quality plays a major role on the extent to which CH_4 production can be lowered with grain supplementation in grazing animals.

Key Words: Methane production, Grazing steers, Grain supplementation

1901 Effect of infusing protein post-rotationally and graded levels of ruminally available protein on the utilization of low-quality prairie hay by beef steers. T. A. Wickersham*, R. C. Cochran, E. C. Titgemeyer, C. G. Farmer, E. A. Klevesahl, and J. I. Arroquo, *Kansas State University, Manhattan.*

An experiment was conducted to evaluate the effect of infusing post-ruminal protein (P) with graded levels of supplemental ruminally available protein (R) on low-quality prairie hay utilization. Twelve ruminally fistulated steers (BW = 361 kg) were used in a 12-treatment, 2-period, crossover design. Steers were subjected to a 17-d depletion period (ad libitum access to hay only) before onset of the trial. Each period had 5 intervals: 1) 10-d adaptation to treatments; 2) 7-d measurement of intake and digestibility; 3) 3-d ruminal sampling; 4) 10-d ad libitum access to hay only; 5) 7-d measurement of intake. Steers were given ad libitum access to prairie hay and supplemented in a 2×6 factorial arrangement of treatments. For the first factor, steers were abomasally infused once daily with one of two levels of sodium caseinate (0 and 0.087% of initial BW; P) via anchored infusion lines into the abomasum. For the second factor, steers were ruminally dosed once daily with one of six levels of sodium caseinate powder (0, 0.029, 0.058, 0.087, 0.116, and 0.145% of initial BW; R). Provision of R linearly increased total OM intake, total digestible OM intake (TDOMI), and OM digestibility ($P \leq 0.03$). Infusion of P increased hay OM intake ($P = 0.06$). Additionally, P increased total OM intake, TDOMI, and OM digestibility ($P \leq 0.01$). In the absence of supplemental R, P-supplemented steers consumed 50% more TDOMI than those receiving no P. However, as R supplementation increased the additional benefit from P decreased. Addition of P at 0.087% of BW with no R increased TDOMI 65% as much as R at the same level. In conclusion, both R and P improved forage utilization; however, the response to direct ruminal protein provision was greater. Improvements in forage utilization in response to P are likely dependent on N recycling.

Key Words: Beef Cattle, Forage, Protein

1902 Soybean genotypes for grain and stover in smallholder crop-livestock systems in West Africa. Asamoah Larbi*¹, Baffour Asafo-Adjei², Olayinka Yusuf³, and Adekunle Isiaka⁴, ^{1,3}*International Livestock Research Institute (ILRI), West Africa, Ibadan, Nigeria*, ²*International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria*, ⁴*Federal University of Agriculture, Abeokuta, Nigeria.*

Soybean (*Glycine max* (L) Merrill) stover has potential as feed for ruminants, but information on feed value of the stover is limited in sub-Saharan Africa where production is expanding, crop residues are important dry season livestock feed, and source of income. The extent of variation in grain and stover yields and stover quality among 19 early-, 20 medium- and 20 late-maturing soybean genotypes was determined, and genotypes with potential for higher grain and quality stover yields were identified. Stover and grain yields, and stover quality (crude protein, neutral detergent fibre and 48-hour dry matter disappearance) varied ($P < 0.01$) among genotypes for all maturity types. Grain and stover yields were positively correlated (early: $r = 0.79$, medium, $r = 0.85$; late, $r = 0.78$). Genotypes (early: TGX 1878-30E, TGX 1880-3E; medium: TGX 1873-6E, TGX1869-14E; late TGX 1869-13E, TGX 1440E) with potential for higher yields of both grain and stover, and better stover

quality were identified based on the agronomic and stover quality attributes. The results suggest that stover and grain yield characteristics can be combined in breeding programs to select dual-purpose genotypes for smallholder crop-livestock systems in the northern Guinea savanna zone of west and central Africa.

Key Words: Soybean, Stover and Grain, Stover quality

1903 Yield and fodder quality of dual-purpose groundnut genotypes fed to West African Dwarf sheep. I. Etela¹, A. Larbi*², P.E. Olorunju³, D.D. Dung⁴, and U.I. Oji⁵, ¹*Department of Animal Science, University of Benin, Benin City, Nigeria*, ²*International Livestock Research Institute (ILRI), Ibadan, Nigeria*, ³*Institute of Agricultural Research, Samaru, Nigeria*, ⁴*National Animal Production Research Institute, Shika, Nigeria*, ⁵*Department of Animal Science, University of Science and Technology, Port Harcourt, Nigeria.*

Smallholder farmers in the subhumid zone of West and Central Africa grow groundnut (*Arachis hypogaea* L.) for both seed for humans and fodder for livestock. Genotypes with potential for higher grain and quality fodder yields (dual-purpose genotypes) have recently been selected for smallholder crop-livestock systems in the region, but data on the fodder quality of the dual-purpose genotypes in terms of animal output is scanty. The objective of this study was to compare fodder and seed yields and fodder quality of six dual-purpose genotypes (M170-80I; M554-76; M572-80I; RMP-12; UGA-2; UGA-5). Fodder and seed yields were determined over a 2-year period. Sun-dried fodder of the genotypes was fed as a sole diet to West African Dwarf sheep using a randomized block design with six animals per genotype to determine nutrient intake and digestibility, nitrogen balance, and daily weight changes. Genotype had significant ($P < 0.05$) effect on fodder and seed yields, fodder crude protein (85 - 89 g/kg), neutral detergent fiber (519 - 586 g/kg), lignin (105 - 148 g/kg) concentrations, dry matter (DM) intake (range: 65 - 80 g/kg BW), DM digestibility (33 - 50 g/kg), nitrogen retention (1.2 - 4.3 g/day), and liveweight changes (range: - 6 - 46 g/day). Genotypes M170-80I and UGA-5 had greater potential for higher yields of seed and quality fodder.

Key Words: Fodder, seed, Chemical composition, Liveweight

1904 Grazing method effects on growth rate of St. Croix White hair sheep lambs on a tropical grass-shrub legume over-story. E. Valencia* and R.W. Godfrey, *University of the Virgin Islands, Agricultural Experiment Station, St. Croix VI USA.*

In the seasonally dry eastern Caribbean islands, growing small ruminants are sensitive to availability of high quality tropical grasses. The potential for improved weight gains by growing hair sheep and dry season yield of guineagrass (*Panicum maximum* Jacq.)-Leucaena (*Leucaena leucocephala* Lam de. Wit) was investigated. St Croix White hair lambs (4 mo. of age) were utilized to compare two different grazing systems, with three replicates within each treatment. In the continuous grazing system (CS) each replicate of lambs ($n = 5$) grazed guineagrass-leucaena (10-15% over-story) pastures (.14 ha) at a stocking rate of 650 kg BW/ha/d for a period of 98 d. In the rotational grazing system (RS) each replicate of lambs ($n = 5$) grazed guineagrass-leucaena (10-15% over-story) pastures (.14 ha) at 650 kg BW/ha/d for 126 d. In the RS, each .14 ha pasture was subdivided into 3 equal paddocks and lambs were moved every 14 d which allowed each paddock a 28-d rest period. Lambs were weighed weekly throughout the trial. Forage dry matter yield was estimated in five .25m² areas in each paddock. Pastures were sampled every 28 d in CS and every 14 d in RS. All data were analyzed using GLM procedures of SAS. There was a trend ($P = .09$) for higher average daily gain for sheep on CS (68 ± 3.7 g/d) compared to those on RS (46 ± 3.7 g/d). However, seasonal forage yield was favored ($P < .05$) by RS ($3.5 \pm .4$ Mg/ha) compared to CS ($1.8 \pm .4$ Mg/ha). At season-end, sheep on CS had to be supplemented with leucaena on a cut-carry system (1.6 kg DM/d) as regrowth of leucaena was affected. Grazing selectivity increased under CS, but also favored encroachment of the low-quality hurricane grass (*Bothriocloa pertusa*). These results suggest that weight gains are slightly better under CS, but will require supplementation during the dry season. Forage yield during the dry season is better under RS and may favor the grass-legume over-story in the long-term.

Key Words: Tropical Grasses, Hair Sheep, Weight Gain

ASAS/ADSA Physiology: Reproductive Physiology

1905 Use of ECP in a timed insemination program.

S. M. Pancarci^{*1}, C. A. Risco¹, F. L. Lopes¹, F. Moreira¹, E. R. Jordan², and W. W. Thatcher¹, ¹University of Florida, Gainesville, FL, ²Texas A&M University, College Station, TX.

Experiment 1 evaluated pregnancy rates (PRs) when estradiol cypionate (ECP) replaced the second GnRH injection of a timed artificial insemination (TAI) protocol for lactating dairy cows. Cows were pre-synchronized with two injections of PGF_{2α} (Lutalyse[®], Pharmacia Corp., 25 mg; i.m.) given to multiparous cows (n=170) at 40 ± 3 and 54 ± 3 d postpartum (dpp) and to primiparous cows (n=201) at 62 ± 3 and 76 ± 3 dpp. The TAI protocol consisted of an injection of GnRH (Cystorelin[®]; Merial Ltd., 100 µg, i.m.) at 68 ± 3 and 90 ± 3 dpp for multiparous and primiparous cows, respectively, followed by PGF_{2α} 7 d later. Cows were injected with GnRH (Treatment I: Ovsynch, n=179) 48 h after PGF_{2α} and inseminated 16 h later. In Treatment 2 (ECP-synch; n=192), ECP[®] (Pharmacia Corp., 1 mg, i.m.) was injected 24 h after PGF_{2α}, and cows were inseminated 48 h later. Pregnancy was determined at 46 ± 3 d after TAI. For primiparous and multiparous cows, PRs for Ovsynch were 43.5 ± 6.9 and 30.6 ± 7.2 % compared to 50.7 ± 6.3 and 19.4 ± 6.5 % for ECP-synch. Effects of parity (P<0.01) and parity by treatment (P<0.10) were detected on PRs. In Experiment 2, onset of estrus and time of ovulation were determined in lactating dairy cows submitted to the ECP-synch protocol as described in Experiment 1. Estrus was detected by HeatWatch[®] and ovulation time determined by ultrasound at 8-h intervals beginning 18 h after onset of estrus or at 48 h after ECP injection. Frequencies of detected estrus and ovulation were 75.7 % (28/37) and 89.2 % (33/37), respectively. Mean intervals to ovulation were 58.5 ± 4.0 h (n=33) after ECP and 27.1 ± 1.1 h (n=28) after onset of estrus. Estrus occurred at 33.6 ± 4.4 h (n=27) after ECP. Percent cows ovulating at an optimal interval of ≥42 h to ≤70 h after ECP was 75.8 % (n=25/33). Synchronization of ovulation and fertility results indicated that ECP can be utilized to induce ovulation for a timed insemination.

Key Words: Timed artificial insemination, ECP, Ovulation

1906 Determining the effect of gonadotropin releasing hormone to synchronize returns to estrus in dairy heifer.

K.S. Rosenkrans^{*1}, D.K. Hardin¹, M.C. Lucy¹, J.W. Tyler¹, and R.L. Larson¹, ¹University of Missouri, Columbia, MO/USA.

This study evaluated the efficacy of gonadotropin releasing hormone (GnRH) administered on day 21 post breeding to synchronize returns to estrus. One hundred-twenty-two Holstein heifers were initially synchronized using 2 injections of prostaglandin F_{2α} (PG). Twenty-five mg PG were administered im on days 0 and 11. HeatWatch[®] transmitters were applied on day 11 and monitored estrus activity for the remainder of the trial. The heifers were bred by fixed-timed artificial insemination on day 14 and randomized into two groups (treatment and control). On day 35, the treatment group received 100 µg GnRH im and the control group received 2 ml saline im. Pregnancy status was determined on day 42 using transrectal ultrasonography. Heifers that were not pregnant (n=85) were given a 25 mg injection of PG im and estrus activity was monitored until day 48. There was no difference in median time to estrus between treatment groups. Data on heifers that returned to estrus (n=56) were analyzed using a Fischer's exact test. Data cells were collapsed into groups that expressed estrus at <60 hrs post PG and >60 hrs post PG. The GnRH group had significantly greater synchrony (p<0.05) than the saline group. More heifers in the GnRH group expressed estrus in the first 60 hrs following PG administration as compared to the saline group. Eighty five percent of the GnRH group expressed estrus between 36-60 hrs after PG administration compared to 55% of the saline group. In this study, GnRH was not efficacious in synchronizing returns to estrus when administered 21 days post breeding because of the large number of heifers that did not return to estrus. However, heifers that did return to estrus had greater synchrony if treated with GnRH compared to saline.

Variable	GnRH	Saline
n	41	44
Observed in estrus	27	29
Median time to estrus (hrs)	45	57
<36 hrs	1 (4%)	2 (7%)
36-60 hrs	23 (85%)	16 (55%)
>60 hrs	3 (11%)	11 (38%)

Key Words: Heifer, Synchronization, GnRH

1907 Efficacy of using Ovsynch to initiate artificial insemination at the onset of the breeding season in lactating dairy cows managed for seasonal calving in a grazing based dairy system.

M.C. Cordoba^{*} and P.M. Fricke, University of Wisconsin-Madison, Department of Dairy Science.

Lactating dairy cows (n=226) were subjected to a 21 d artificial insemination (AI) breeding period beginning at the onset of the breeding season (Day 0) followed by introduction of natural service sires. Throughout the AI breeding period, cows received AI based on tail paint removal, which was evaluated twice daily at milking. Beginning 10 d before the breeding season, cows were randomly assigned to receive synchronization of ovulation (50 mg GnRH, Day -10; 25 mg PGF_{2α}, Day -3; 50 mg GnRH, Day -1) and fixed-time AI (Day 0) followed by estrus detection and AI for the remainder of the AI breeding period (Ovsynch; n=114), or estrus detection and AI for the duration of the AI breeding period (Control; n=112). Blood samples collected on Day -20, -10, -3, and -1 were classified based on serum progesterone (P) concentrations as High (≥0.5 ng/ml) or Low (<0.5 ng/ml). Overall, the proportion of anestrus cows (Low P on Day -20 and -10) was 14% (31/220) and did not differ between treatment groups. Although days to first AI was greater (P<0.01) for Control vs. Ovsynch cows (12.0 vs. 0.0, respectively) and the 21-d AI service rate was greater for Ovsynch vs. Control cows (100%, 114/114 vs. 86%, 96/112, respectively), conception rate to first AI service was greater (P<0.01) for Control vs. Ovsynch cows (47%, 43/91 vs. 27%, 30/100, respectively). Only 61% (69/114) of Ovsynch cows underwent luteolysis (50% reduction in P from Day -3 to Day -1) after PGF_{2α} administration. No Control cows received a second AI service during the AI breeding period, compared to 47% (51/108) of Ovsynch cows (mean d to second AI = 17.58). Conception rate to second AI service was 43% (22/51), which did not differ from that of Control cows at first AI service. Cumulative pregnancy rate for Control and Ovsynch cows was similar at Day 49 (47%, 43/91 vs. 46%, 50/108, respectively) and Day 179 (80%, 66/82 vs. 83%, 80/96, respectively). Ovsynch failed to synchronize lactating dairy cows managed in a grazing based dairy system thereby resulting in lower first service conception rates than AI to spontaneous estrus. Tail paint is an effective reproductive management tool for conducting AI in grazing based dairies. Supported by Hatch project WIS04222

Key Words: Ovsynch, TAI, Grazing

1908 Ovulation synchronization protocols affect early postpartum reproductive efficiency in crossbred dairy cows.

J.L.M. Vasconcelos^{*}, R.L. Valarelli, R.L.A. Cerri, A.H. Souza, and M. Meneghetti, FMVZ-UNESP, Botucatu, SP/Brazil.

Crossbred Holstein-Gir cows have lactation curves with low persistence and high incidence of postpartum anestrus, which negatively impact profitability. Objectives of this study were to evaluate three ovulation synchronization protocols and their impacts on reproductive efficiency. The study was conducted between March and December of 2000 in Brazil. Cows were randomly assigned to one of the four treatments: 1) Control (n=118), which consisted of estrus detection and prostaglandin injections in cows with a palpable corpus luteum (CL) every 14 d; 2) GnRH (Cystorelin[®], 50mcg, im)-6d-PGF_{2α} (Lutalyse[®], 25mg, im)-2d-GnRH-16 to 18h-AI (n=133); 3) GnRH-5d-GnRH-6d-PGF_{2α}-2d-GnRH-16 to 18h-AI (n=132); and 4) CIDR + GnRH-6d-PGF_{2α} + CIDR removal-2d-GnRH-16 to 18h-AI (n=129). PGF_{2α} injection on day 6 after the first GnRH aimed to optimize ovulation synchronization after the last GnRH injection. Treatment with two GnRH injections 5d apart intended to increase the proportion of cows with a responsive CL when PGF_{2α} was used. Use of CIDR in conjunction with GnRH aimed to minimize the incidence of short luteal phases in cows that might not

respond to the first GnRH. Interval from the end of the VWP to conception and days open were analyzed by ANOVA. Interval from the end of the VWP and conception were affected by treatment ($P < 0.01$) and averaged 49.1 ± 5.5 , 34.8 ± 4.8 , 31.9 ± 5.1 , and 28.1 ± 5.1 days for treatments 1, 2, 3, and 4, respectively. Similarly, days open were affected by treatment ($P < 0.01$) and averaged 127.7 ± 5.5 , 114.0 ± 4.8 , 110.6 ± 5.1 , and 107.1 ± 5.1 days, respectively. An interaction between parity and treatment was detected ($P < 0.05$) for the interval between the end of the VWP and conception. This interval was reduced in primiparous cows receiving treatments 2, 3, and 4 compared with those on treatment 1, indicating that ovulation synchronization protocols might induce cyclicity. Reproductive protocols that synchronize ovulation reduced the interval from the end of the VWP to conception and days open when compared with regular prostaglandin treatments.

Key Words: lactating dairy cows, synchronization, anestrous

1909 Administration of hCG during estrus and its effect on corpus luteum size and progesterone production. J.A. Bartolome, S.M. Pancarci*, T. Dickerson, L.F. Archbald, and W.W. Thatcher, *University of Florida, Gainesville, FL.*

Progesterone (P4) production by the corpus luteum (CL) influences establishment and maintenance of pregnancy in cattle. Human Chorionic Gonadotropin (hCG) has LH-like activity, binds LH-receptors in luteal tissue and stimulates luteinization. The objective of this study was to evaluate the ability of hCG to enhance CL development and increase production of P4 when injected at estrus to supplement the natural LH surge. Twenty-three cows were treated with GnRH (100 ug, im, Cystorelin®) and PGF_{2α} (25 mg, im, 2 doses 8 hs apart, Lutalyse®), 7 d later. Seventeen cows that showed estrus (according to Heat Watch®) between 2 and 3 d after PGF_{2α} were randomly assigned to receive either hCG (3,000 IU, im, Chorulon®, n=9) or saline (n=8) 8 to 10 h after the onset of heat. Blood samples were collected every 12 h and ovarian ultrasound examination was done every three days to evaluate plasma P4 concentration, number of follicular waves and CL size during 23 days after treatment. Data for plasma P4 concentration and CL size were evaluated using repeated measures ANOVA for mixed models, and the number of follicular waves were compared using Fisher exact test. There was no difference in the number of follicular waves between cows treated with hCG (78% of cows with 2 waves) and control cows (75% of cows with 2 waves). Plasma P4 concentration was lower in cows treated with hCG (6.46 ng/ml) than in control cows (7.89 ng/ml; $P < 0.05$), with major differences detected between days 14 and 16. In addition, on day 16, CL tended to be smaller ($P < 0.08$) in cows treated with hCG compared to control cows. It was concluded that the administration of hCG during the spontaneous LH surge may have produced an excess of LH and LH-like activity and negatively affected CL differentiation and development.

Key Words: hCG, corpus luteum, progesterone

1910 Follicular dynamics in postpartum cows after treatment with either GnRH or Estradiol benzoate (EB) at the initiation of a 7 d controlled intravaginal progesterone-releasing device (CIDR). MK. V. Dahms*, C. R. Barthle, E. A. Hiers, G. E. Portillo, and J. V. Yelich, *University of Florida, Gainesville.*

Crossbred (*Bos indicus* X *Bos taurus*) lactating cows averaging 56 d (range 23-77 d) postpartum were used to characterize follicular dynamics after treatment with either EB or GnRH at the initiation of a 7 d CIDR (Eazi-Breed™ CIDR®; day of insertion = d 0). Cows were allotted to treatments by cycling status and size of the largest follicle present on the ovaries on d 0 of experiment as determined by ultrasonography (US). At d 0, treatments 1 (n = 7; USGCIDR) and 3 (n = 8; GCIDR) were administered 100 µg GnRH i.m. (Fertagyl) and treatments 2 (n = 7; USEBCIDR) and 4 (n = 5; EBCIDR) were administered 2 mg EB i.m. On d 7 of the experiment, CIDRs were removed and all cows received 25 mg PGF_{2α} i.m. (Lutalyse). In the USGCIDR and USEBCIDR cows, ovaries were examined via US daily from d 0 until observed estrus, and 7 d after estrus or d 14 of experiment if estrus was not observed. Ovaries were examined in the GCIDR and EBCIDR cows on d 0 and 7 of the experiment, and 7 d after estrus or d 14 of experiment if estrus was not observed. Estrus was detected using Heat Watch®. Response to treatment on d 0 in USGCIDR was defined as ovulation to GnRH (71.4%), and as turnover of the largest follicle to EB (100%) in USEBCIDR cows. Of cows responding to treatment, day of emergence of the next follicular

wave occurred earlier ($P > 0.10$) in USGCIDR (3.3 ± 0.6 d) compared to USEBCIDR (4.1 ± 0.6 d). Diameter of the newly emerged follicle(s) on d 7, 8 and 9 of the experiment were similar ($P > 0.10$) between USGCIDR (10.3, 11.1 and 13.0 mm; respectively) and USEBCIDR (9.9, 11.0 and 11.4 mm; respectively) cows. Estrus expression was influenced by US as fewer ($P < 0.05$) USGCIDR and USEBCIDR (7/14 = 50%) cows exhibited estrus than GCIDR and EBCIDR (12/13 = 93%) cows. Interval to the onset of estrus was similar ($P > 0.05$) within the US and non-US treatments, but the US (65.5 ± 13.1 h) cows had a shorter ($P < 0.05$) interval than non-US (84.7 ± 9.3 h) cows. Diameter of the ovulatory follicle was similar for USGCIDR (15.0 mm) and USEBCIDR (14.7 mm). These results suggest that there is no significant difference in follicular development between the GCIDR and EBCIDR treatments, although daily US significantly affected estrus behavior after CIDR removal.

Key Words: CIDR, Estrogen, GnRH

1911 Resynchronization of Ovulation and Timed Insemination in Beef Cattle. S Lares*¹, G Dominguez¹, N Formia², C Scena³, O Rambeaud⁴, and R.L. de la Sota¹, ¹Instituto de Teriogenologia, Fac. Cs. Veterinarias-UNLP, ²Escuela M.C. y M. Inchausti-UNLP, ³Intervet Argentina SA, ⁴INTA-Brandsen.

A field trial was conducted to evaluate the effectiveness of Resynch, a resynchronization protocol for prompt insemination of cows diagnosed open at d 25 post AI. Postpartum suckled beef cows with BCS >3 (scale 1-5) were randomly allocated to one of four treatments: 1) Norgestomet implant d0-9, 400IU PMSG d9, timed AI (TAI) d11 (n=21; NOR-TAI); 2) same as 1 plus heat detection (HD)+AI d9-10, TAI d11 of remaining cows (n=21; NOR-IDH); 3) 8ug GnRH (Buserelin) d0, 25mg of PG (cloprostenol) d7, 8ug GnRH+TAI d9 (n=19; COS-TAI) and 4) same as 3 plus HD+AI d7-8, 8ug GnRH+TAI d9 (n=20, COS-IDH). Calves did not suckle for 48 h (NOR protocols, d9-11; COS protocols, d7-9). The Resynch protocol was: 8ug GnRH d18, pregnancy diagnosis with ultrasonography d25, and open cows were injected with 25mg of PG on d25 and 8ug GnRH+TAI on d27. Calves did not suckle for 48 h (d25-27). Pregnancy diagnosis was repeated at d25 after the 2nd AI to evaluate the PR to the Resynch protocol and the early embryonic death. The CATMOD procedure in SAS was used to analyze the data. First AI pregnancy rate (PR) were not different between the NOR groups (43 [TAI] vs. 43%[IDH]) and between the COS group [47[TAI] vs. 40% [IDH]]. The PR for cows diagnosed open and resynchronized were not different between the NOR groups (46[TAI] vs. 58%[IDH]) and between the COS groups (20[TAI] vs. 25%[IDH]). Furthermore, the accumulated PR for both AI were also not different between the NOR (67[TAI] vs. 76%[IDH]) and the COS groups (58[TAI] vs. 55%[IDH]). Hence, data were pooled into two groups (cows synchronized with NOR vs. COS) and were reanalyzed. Although PR were not different in the 1st AI (43 vs. 44%), the PR was higher in the NOR group compared to the COS group in the resynchronized cows (52 vs. 23%; $p < 0.05$) and the accumulated PR for both rounds of AI (71 vs. 56%; $p < 0.05$). The early embryonic death rate was 4% (2/46). In conclusion, the Resynch protocol successfully resynchronized open cows for TAI but the PR depended on the type of protocol used for the 1st AI. Cows 1st synchronized with a progestin had a 29% higher PR in the 2nd AI compared to those synchronized with GnRH. Also they had a 15% higher accumulated PR. Supported with grants BID AR/OC 08-04360 and UNLP-V11/107 to RLS.

Key Words: Timed insemination, Resynchronization, Early pregnancy diagnosis

1912 Luteolysis after PGF_{2/alpha} on day 6 or 7 of the estrous cycle in Angus and Angus x Brahman heifers. G. E. Portillo*, E. A. Hiers, C. R. Barthle, MK. V. Dahms, W. W. Thatcher, and J.V. Yelich, *University of Florida, Gainesville, Florida.*

Cycling Angus and crossbred Brahman heifers (5/8 Angus x 3/8 Brahman and 3/8 Angus x 5/8 Brahman) were used to evaluate the effectiveness of a single injection of PGF_{2/alpha} administered during the early estrous cycle to initiate corpus luteum (CL) regression (CLREG) as measured by progesterone concentrations. Estrous response (ESTRES), interval from PGF_{2/alpha} to the onset of estrus (INTEST), duration of estrus (ESTDUR), and total number of mounts received (TMTS) during the duration of estrus were also evaluated. Heifers were pre-synchronized with a modified two-injection PGF_{2/alpha} (Lutalyse) protocol (25 mg

i.m. on d 14 and 12.5 mg i.m. on d 3 and 2 of the experiment). Estrus was designated as d 0 of experiment. On d 6 or 7 of the subsequent estrous cycle, heifers were injected with 25 mg $\text{PGF}_{2/\alpha}$ i.m. Estrus was monitored using HeatWatch[®] for the pretreatment synchronization and treatment phase of the experiment. The experiment was replicated twice using the same pre-synchronization and treatment protocols and heifers. There were no replication or replication by breed effects ($P \geq 0.10$) so data were pooled. CLREG was greater ($P \leq 0.05$) for Angus (25/26 = 96.2%) than for crossbred (25/31 = 80.6%) heifers. The ESTRES was similar ($P \geq 0.10$) between Angus (15/26 = 57.7%) and crossbred (21/31 = 67.7%) heifers. INTEST and ESTDUR were similar ($P \geq 0.10$) between Angus (51.5 \pm 3.8; 10.6 \pm 1.4 d, respectively) and crossbred (52.4 \pm 3.1; 12.9 \pm 1.1 d, respectively). Crossbred heifers had more ($P \leq 0.05$) TMTS than Angus (51.1 \pm 7.1 vs. 28.9 \pm 9.2, respectively). In conclusion, breed had a significant effect on the ability of $\text{PGF}_{2/\alpha}$ to regress the early (d 6 or 7) developing CL as more Angus than crossbred heifers had CL regression.

Key Words: *Bos indicus*, $\text{PGF}_{2/\alpha}$, Corpus luteum Regression

1913 Reproductive performance of beef heifers following administration of an oral progestogen or GnRH. H. E. Blackmon*¹, M. E. Hockett¹, T. M. Towns¹, N. R. Rohrbach¹, R. B. Simpson¹, A. M. Saxton¹, and F. N. Schrick¹, ¹Department of Animal Science, University of Tennessee, Knoxville.

Oral progestogen or GnRH was administered to beef heifers 60 days prior to the breeding season to examine effects on reproductive performance. During a 3 year replicated study, 222 beef heifers were allotted by weight (320 \pm 3 kg), age (11 to 13 mo), and breed (Angus, n = 198; Hereford, n = 24) to one of three treatments: 1) 2 mL saline (CON, n = 74), 2) 2 mL GnRH (GnRH, n = 74), and 3) 2 mL saline and 0.75 mg/(hd) melengestrol acetate for 14 days (MGA, n = 74). Control and GnRH heifers were fed non-MGA pellets for 14 days. Blood samples were collected twice 10 d prior to the start of the study (Period 1) and before the breeding season (Period 2) to determine cyclicity (progesterone > 1.0 ng/mL). Estrus was synchronized and heifers inseminated (AI) following visual estrus. Heifers not exhibiting estrus were time-inseminated at 48 h after implant removal. Following AI, heifers were exposed to bulls through the breeding season. Pregnancy was determined at 30 and 150 d following AI. A SAS based mixed model and Chi square were utilized for analysis of data. Fifty-two percent of heifers were prepubertal prior to initial treatments (Period 1), and exhibited an increased cyclicity prior to the breeding season (Period 2) after administration of MGA (59%) compared to CON (26%; $P = 0.02$), with GnRH (37%) intermediate. However, AI pregnancy rates did not differ (MGA, 41; GnRH, 35; and CON, 37%). In heifers cycling prior to the study (48%), AI pregnancy rates were higher in MGA (67%) and GnRH (65%) heifers compared to CON (43%; $P = 0.06$). Overall AI pregnancy rates were increased in MGA (55%) heifers than CON (40%; $P = 0.07$); whereas, GnRH (46%) heifers were intermediate. In conclusion, administration of MGA to prepubertal heifers 60 days prior to breeding increased cyclicity at initiation of the breeding season, but did not improve AI pregnancy rates. Treatment with MGA and GnRH increased pregnancy rates in heifers that had attained puberty prior to study.

Key Words: Progestogen, Puberty, Pregnancy

1914 A comparison of three progestin-GnRH-prostaglandin $\text{F}_{2\alpha}$ (PG) based protocols for estrus synchronization of beef cows. J. E. Stegner*, J. F. Bader, F. N. Kojima, M. F. Smith, and D. J. Patterson, University of Missouri, Columbia, MO.

This experiment was designed to compare three progestin-GnRH-PG based protocols for estrus synchronization in beef cows. Primi- and multiparous cycling crossbred cows were assigned to one of three treatments. Cows assigned to treatment 1 (T1) were fed melengestrol acetate (MGA; .5mg \cdot hd⁻¹ \cdot d⁻¹) for 14 d followed by an injection of GnRH (100 μ g Cystorelin[®]) on d 26 and PG (25 mg Lutalyse[®]) on d 33. Cows assigned to Treatment 2 (T2) were fed MGA for 17 d followed by GnRH on d 19, and PG on d 26. Cows assigned to Treatment 3 (7-11 Synch; T3) received MGA for 7 d followed by PG on d 7 of MGA, GnRH on d 11, and PG on d 18. Transrectal ultrasonography was performed daily on all cows to monitor follicular dynamics during the MGA feeding period and through the synchronized period after PG. Response to GnRH,

determined by ovulation of the dominant follicle at the time GnRH was administered, was as follows: 8/9 (88 %), 6/9 (66 %), and 8/8 (100 %) for cows assigned to T1, T 2, and T3, respectively ($P > .10$). Beginning 48 h after PG, ultrasonography was performed every 12 h until ovulation occurred. Cows were observed for signs of behavioral estrus for 7 d after PG. Estrus response for cows assigned to each treatment was as follows: 9/9 (100 %), 7/9 (77 %), and 8/8 (100 %) for cows assigned to T1, T2, and T3, respectively ($P > .10$). Two of 9 cows (22 %) in T2 exhibited estrus 24 h before PG. Mean interval to estrus was shorter ($P < .01$) for cows assigned to T2 (46 \pm 4.6 h), and T3 (52 \pm 4.2 h), than in cows assigned to T1 (79 \pm 7.8 h). The range in estrus response was 48-126, 24-54, and 24-60 h for cows assigned to T1, T2 and T3, respectively. Synchrony of estrus after PG did not differ among treatments. Follicular diameter at GnRH, PG, or 24-72 h after PG did not differ ($P > .10$) among treatments. Characterization of follicular dynamics and timing of estrus from these data will support development of protocols that facilitate fixed-time AI in beef cattle. (Supported by USDA-NRI grant 2000-02163)

1915 Evaluation of a fixed-time AI protocol for postpartum beef cows. G. A. Perry*, J. F. Bader, M. F. Smith, and D. J. Patterson, University of Missouri, Columbia, MO.

Treatment with the oral progestin, melengestrol acetate (MGA) prior to GnRH and $\text{PGF}_{2\alpha}$ effectively synchronizes estrus and maintains high fertility in postpartum beef cows. The objective of this experiment was to determine whether treatment with MGA prior to a GnRH- $\text{PGF}_{2\alpha}$ -GnRH protocol would improve pregnancy rates resulting from fixed-time AI. Multiparous crossbred cows at two University of Missouri farms (n=90 and n=137) were assigned by age and days postpartum (dpp) to one of two treatments: Cows were fed carrier (1.8-kg \cdot hd⁻¹ \cdot d⁻¹) with or without MGA (0.278-mg \cdot kg⁻¹) for 14 d. GnRH (100 μ g Cystorelin) was administered to all cows 12 d after MGA or carrier withdrawal and 7 d before $\text{PGF}_{2\alpha}$ (25 mg Lutalyse) injection. All cows received a second injection of GnRH and AI 72 h after $\text{PGF}_{2\alpha}$. Mean dpp for MGA and Control cows at the initiation of treatment were 39.6 and 38.9 for herd 1; and 51.9 and 50.9 for herd 2, respectively ($P > 0.05$ within herds). Blood samples were collected from all cows 10 d before and the day before MGA or carrier began, and at the time GnRH and $\text{PGF}_{2\alpha}$ were administered. Concentrations of P_4 in serum at the initiation of treatment were elevated (>1ng/ml) in 0% of MGA and 7% of Control cows in herd 1, and 54% of MGA and 49% of Control cows in herd 2 ($P > 0.05$ within herds). Pregnancy rates to fixed-time AI were determined by ultrasound 50 d after AI. Pregnancy rates in herd 1 were 58% (26/45) and 51% (23/45) for MGA-treated and Control cows, respectively ($P = 0.52$); and 63% (44/70) and 45% (30/67) for MGA-treated and Control cows in herd 2, respectively ($P < 0.03$). Differences in pregnancy rates to fixed-time AI remained significant ($P < 0.05$) when data from the two herds were combined [MGA=70/115 (61%); Control=53/112 (47%)]. There was no difference ($P > 0.2$) in final pregnancy rate between treatments, within herds, or combined. In summary, pregnancy rates resulting from fixed-time AI may be improved with treatment of MGA prior to a GnRH- $\text{PGF}_{2\alpha}$ -GnRH protocol. (Supported by grants from Select Sires, Inc. and USDA-NRI 2000-02163).

1916 Stage of cycle effects on response to different GnRH + prostaglandin $\text{F}_{2\alpha}$ (PG) treatments in *Bos indicus* x *Bos taurus* cows. E. A. Hiers*, C. R. Barthle, J. K. Fullenwider, G. E. Portillo, MK. V. Dahms, J. M. Kramer, and J. V. Yelich, University of Florida.

Synchronization rate was evaluated using three different GnRH/PG protocols initiated on different days of the estrous cycle in *Bos indicus* x *Bos taurus* cows. Cows were presynchronized with a modified two-injection PG protocol (Lutalyse; 25 mg on d -14 and 12.5 mg on d -3 and -2 of experiment). Estrus was detected with HeatWatch[®]. After expression of estrus, cows were allotted to four groups based on day of the estrous cycle, d 2 (n = 15), 5 (n = 13), 12 (n = 12) and 18 (n = 13), when injected with GnRH (100 μ g i.m.; Fertagyl). At GnRH injection, cows within each day were randomly subdivided into one of three PG treatments 7 d later: 1) PG (25 mg i.m.; Lutalyse; n = 16); 2) split-PG (12.5 mg i.m. on d 7 and 8; Lutalyse; n = 18); and 3) cloprostenol (500 μ g i.m.; Estrumate; n = 19). At PG injection and every 48 h until

estrus and/or ovulation, a blood sample was collected and ovaries were examined by ultrasound. Cows treated with GnRH on d 18 tended ($P = 0.10$) to have a decreased 5-d estrous response (54%) compared with d 2, 5 or 12 (80, 77, and 92%, respectively). Interval from PG injection to onset of estrus was greater ($P \leq 0.05$) for d 18 (101 ± 15 h) compared with d 2, 5 or 12 (87 ± 12 , 82 ± 13 , 62 ± 12 h, respectively). Percentage of cows ovulating after PG was decreased ($P \leq 0.05$) for d 18 (38%) compared with d 2, 5 and 12 (100, 100, and 100%, respectively). The PG, split-PG, and cloprostenol treatments had similar ($P \geq 0.10$) 5-d estrous response (63, 89, and 74%, respectively) and percentage of cows with corpus luteum (CL) regression (81, 88, and 95%, respectively). Interval from PG injection to onset of estrus was similar for PG, split-PG and cloprostenol (90 ± 13 , 81 ± 11 , and 77 ± 11 h; respectively). In conclusion, stage of the estrous cycle when GnRH was administered affected response to PG. Although not significant, split-PG and cloprostenol treatments resulted in increased CL regression and estrous response in *Bos indicus* x *Bos taurus* cows.

Key Words: *Bos indicus*, estrus, GnRH

1917 Effects of exogenous GnRH infusion and steroid replacement on gonadotropins in ovariectomized nutritionally anovulatory cows. J.A. Vizcarra*¹ and R.P. Wettemann¹, ¹*Animal Science Department, Oklahoma Agricultural Experiment Station.*

Twenty-four nutritionally induced anovulatory ovariectomized cows were used to determine the effect of estradiol, progesterone, and exogenous GnRH pulses on LH and FSH in serum. Cows were randomly assigned to four 6 x 6 Latin Squares (LS). Control cows in LS 1 received a sham progesterone and estradiol vaginal insert. Cows in LS 2 were treated with a vaginal estradiol insert (E2), while cows in LS 3 received a progesterone insert (P4). Cows in LS 4 received an estradiol and progesterone vaginal insert (E2P4). Within each LS, cows were randomly assigned to six treatments in a 2 x 3 factorial. Doses of GnRH (0, 2 or 4 g) in 2 mL were infused at frequencies of once every h or once every fourth h for 2 d. Blood samples obtained every 10 min for 8 h on d 1 and d 2 and were analyzed for LH and FSH by RIA. In addition, blood samples were taken daily to evaluate progesterone and estradiol concentrations. Estradiol was increased from 0.1 0.1 pg/mL in control cows to 1.6 .1 pg/mL in the E2 insert treatment, and progesterone was increased from 0.1 0.1ng/mL to 2.3 0.1 ng/mL with the P4 insert. In the absence of exogenous GnRH, concentrations of LH were increased (39% greater than control; $P < 0.001$) while concentrations of FSH were reduced (34% less than control; $P < 0.01$) when ovariectomized nutritionally anovulatory cows were treated with E2, P4 or E2P4 inserts. Cows treated with a E2 and E2P4 insert had increased ($P < 0.03$) LH concentrations when either 2 or 4 g of GnRH was infused, compared with control cows. The GnRH-induced LH secretion was not increased when pulses were given every fourth h. Cows treated with a E2, P4, and E2P4 insert had decreased ($P < 0.04$) FSH concentrations when GnRH (2 g) was infused compared with control cows. However, only cows treated with a E2 and E2P4 insert had decreased ($P < 0.1$) FSH concentrations when GnRH (4 g) was infused compared with control cows. We concluded that estradiol, progesterone and GnRH pulses differentially regulate secretion of LH and FSH from the pituitary of beef cows.

1918 Vaginal electrical conductance for determining the timing of ovulation is also effective for monitoring rates of uterine involution in the postpartum dairy cow. S.D. Bowers*¹, B.S. Gandy¹, J. Spencer¹, K.B. Graves¹, A.B. Moore¹, and S.T. Willard¹, ¹*Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS.*

The principle behind vaginal electrical conductance measurements (VEC) is that a change in the ionic balance of vaginal and cervical mucus occurs in response to cyclical changes in reproductive hormones. The objective of this study was to determine the efficacy of using VEC for monitoring not only follicular development and ovulation, but also uterine involution (UI) in dairy cattle postpartum (PP). In Experiment I, the applications of VEC for monitoring follicular development and ovulation using the Ovatest meter (Animark Inc.) were verified. Jersey cows ($n = 16$) were administered prostaglandin (PG; d 0) and sampled at 12 h intervals for 7 d post-PG. At each sampling period VEC

measurements (relative units; RU) were obtained, ultrasonography was used to measure follicular diameters, and serum samples collected for quantification of estradiol (E2) by RIA. Nine of the 16 cows that responded to PG ovulated within 7 d (56%) and were retained for further analysis. Ovulatory follicle size did not differ ($P \geq .10$) from PG to ovulation but increased (on average) 5.9 mm in size during this interval. While 2 of the 9 cows that ovulated exhibited variable E2 profiles post-PG, serum E2 decreased ($P \leq .01$) $3.1 \pm .84$ pg/ml in relation to ovulation ($n = 7$). Moreover, VEC measurements decreased ($P \leq .001$) 20.5 ± 4.5 RU between PG and ovulation. In summary for Experiment I, VEC decreased prior to ovulation and patterned, though not significantly, follicular growth and serum E2 through ovulation. In Experiment II, Jersey cows ($n = 11$) were sampled 2X/week from 1 to 60 d PP to assess the use of VEC for monitoring UI. On test days, VEC was recorded (Ovatest), follicular sizes and cross-sectional area of the pregnant vs. non-pregnant uterine horns captured (ultrasonography), and uterine tone scores assigned (UTS; rectal palpation). Uterine horn size differences were negatively correlated with UTS ($r = -.52$; $P \leq .001$) and VEC ($r = -.52$; $P \leq .001$); as uterine horn differences decreased over time PP, UTS and VEC measurements increased. Finally, UTS was also positively correlated ($r = .44$; $P \leq .01$) with VEC. These data suggest that VEC may be used as an objective tool for quantifying UI in dairy cattle.

Key Words: Vaginal electrical conductance, Uterine involution, Dairy cattle

1919 Pregnancy rates of lactating beef cows losing body weight during the breeding season. T. M. Towns*¹, M. D. Davis¹, M. E. Hockett¹, N. R. Rohrbach¹, and F. N. Schrick¹, ¹*Department of Animal Science, University of Tennessee, Knoxville.*

Effect of weight loss during the breeding season on reproductive performance was assessed in 150 beef cows. Cows were sorted by calving date, body condition (BCS; mean = 5.5), BW (mean = 510 ± 8 kg), age, and breed. Restricted (RES) cows were fed to lose 5% BW from d-30 to d 0 (start of breeding season), and an additional 10% BW from d 0 to d 60 (end of breeding season). Control (CON) cows were fed to maintain BW. All cows reinitiated cyclicity (progesterone ≥ 1 ng/mL) prior to start of the breeding season. Estrus was synchronized and cows were inseminated at estrus and 12 h later. Bulls were placed with each group after the synchronization period through the breeding season. Pregnancy was determined at d-30, 60, and 150. Measurements for BW, BCS, and blood samples for progesterone, insulin, nonesterified fatty acids (NEFA), and urea nitrogen (BUN) were collected weekly from d 30 to d 60. Body weight of RES cows decreased 56.9 kg; whereas, CON cows increased 10.8 kg from d-30 to d 60. Insulin decreased throughout the experimental period in RES cows (d-30, 0.33 ± 0.02 ng/mL; d 60, 0.24 ± 0.02 ng/mL; $P < 0.05$); however, NEFA (d -30, 0.77 ± 0.12 mEq/dL; d 60, 0.95 ± 0.12 mEq/dL; $P < 0.05$) and BUN (d -30, 20.4 ± 0.9 mg/dL; d 60, 29.1 ± 0.9 mg/dL; $P < 0.05$) increased. Neither estrous response (86.3 vs. 88.3%) nor conception rates (68.3 vs. 76.5%) differed between RES and CON cows, respectively. Pregnancy rates did not differ on d 30 (58.9 vs. 67.5%), d 60 (89.0 vs. 93.5%), or d 150 (91.8 vs. 96.1%) between RES and CON cows, respectively. Calves from RES cows had lower BW than CON at the end of the breeding season (145.4 ± 2.9 vs. 176.8 ± 2.9 kg; $P < 0.05$). In conclusion, cows which had reinitiated estrous cyclicity but were losing weight during the breeding season did not have reduced reproductive performance. These results suggest lower pregnancy rates associated with poor nutrition may be more related to failure of animals to reinitiate postpartum cyclicity rather than inability to establish and maintain pregnancy.

Key Words: Nutrition, Body weight, Pregnancy

1920 Use of doppler ultrasonography to estimate fetal age and monitor fetal heart rate and uterine artery pulse rate in dairy cattle. S. Willard¹, A. Webb*¹, S. Bowers¹, and B. Gandy¹, ¹*Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS 39762.*

The objective of the present study was to evaluate the use of Doppler ultrasonography (US) to monitor both uterine blood flow and fetal heart rate (FHR) during pregnancy in dairy cattle. Possible applications of Doppler US include the monitoring of fetal distress when a pregnancy becomes compromised, or as a method for estimating fetal age through changes in FHR during gestation. In this study, 30 pregnant Holstein

heifers were sampled repeatedly between 54 to 262 d post-breeding. On test days, transrectal Doppler US (Medata Systems) was performed to quantify FHR and dam uterine artery pulse rates (UAP). Following Doppler US, B-mode US was performed to obtain placentome diameter measurements as an additional measure of pregnancy stage. For the 104 total individual tests, 48 FHR, 101 UAP and 78 placentome measurements were obtained. Doppler US was also linked to a PowerLab Chart Recorder (ADI Instruments) to record FHR and UAP wave-forms for analysis. Data were analyzed using correlation and regression analysis relative to stage of gestation. Fetal heart rate was negatively correlated ($r = -.61, P \leq .01$) with d of gestation. Fetuses that were ≤ 140 d of age had higher ($P \leq .01$) FHR (155.8 ± 3.2 beats per minute; BPM) than fetuses ≥ 140 d of age (142.8 ± 2.4 BPM). As expected, average placentome size was positively correlated ($r = .83; P \leq .01$) with d of gestation. However, UAP of the dam did not change ($r = .16; P \geq .10$) relative to d of gestation (mean: 74.1 ± 1.0 pulses per minute). Of the 104 attempts at Doppler US, FHR were determined 46% of the time and UAP found 97.1% of the time. Using the PowerLab, FHR wave-forms (gestation d 140 to 145) varied 808.0 ± 13.9 mV in amplitude from baseline (62.9 ± 5.9 mV), at a frequency of 150 BPM. In contrast, UAP signatures were not different ($P \geq .10$) from background levels (81.2 ± 3.2 MAX mV; 44.8 ± 3.1 MIN mV). In summary, transrectal Doppler US is effective for estimating fetal age in the bovine and for monitoring FHR characteristics. However, assessments of uterine blood flow using standard transrectal Doppler US will require additional investigation to detect changes in uterine blood flow under varied conditions. [This project was part of an undergraduate directed individual study program].

Key Words: Doppler ultrasonography, Fetal heart rate, Dairy cattle

1921 Factors affecting temporal relationships between estrus, ovulation and insemination in a commercial sow herd. B. A. Belstra*, W. L. Flowers, K. J. Rozeboom, and M. T. See, *North Carolina State University, Raleigh, NC.*

Our objective was to examine the effect of genotype (A, B, C), lactation length (11 to 20 d), parity (1, 2, ≥ 3), weaning-to-estrus interval (WEI; 3, 4, 5, ≥ 6 d) and season (spring, summer) on the estrus, ovulation and subsequent fertility characteristics of sows. Duration of estrus and time of ovulation were estimated via boar exposure and transabdominal real-time ultrasonography, respectively, every 6 h from 2 to 10 d postweaning in 174 sows (87/season). The mean and range of duration of estrus (DE) and onset of estrus-to-ovulation interval (EOI) was 58.1 h, 24 to 84 h and 44.1 h, 12 to 90 h, respectively. Genotype, lactation length and parity did not affect DE or EOI ($P > .18$). There was a stepwise decrease in DE as WEI increased from 3 to 5 d ($P < .03$) but not 5 to ≥ 6 d ($P > .3$). Sows weaned in the spring compared to the summer had a shorter DE (53.1 vs. 60.8 h, $P < .001$) and a shorter EOI (38.1 vs. 48.5 h, $P < .001$). Sows were inseminated on an 8 am d 1 of estrus, 8 am and 3 pm d 2 of estrus schedule. Variation in WEI, DE and EOI resulted in insemination-to-ovulation intervals with a mean and range of 35.9 h, 87 to - 3 h; 12.0 h, 63 to - 27 h and 4.8 h, 56 to - 34 h, for services 1, 2 and 3, respectively. Only season affected insemination-to-ovulation intervals ($P < .001$) but there was no difference in spring vs. summer number of inseminations within 24 h prior to ovulation (1.3 vs. 1.3, $P > .9$), conception rate (94.6 vs. 90.5%, $P > .3$), farrowing rate (91.9 vs. 86.5%, $P > .3$) or pigs born alive (11.0 vs. 10.9, $P > .9$). Sows that received 0 vs. 1 or 2 inseminations within 24 h prior to ovulation had a similar conception and farrowing rate ($P > .7$) but tended to have fewer pigs born alive (9.5 vs. 11.3, $P < .09$). In this particular herd, season and weaning-to-estrus interval altered duration of estrus and time of ovulation. However, these changes were not large enough to affect sow fertility because the multiple insemination schedule in place ensured that at least one insemination occurred near ovulation.

Key Words: Estrus, Ovulation, Sow

1922 Hormonal Changes After Manual Rupture of Follicular Cysts. Ahmet Gumen* and Milo C. Wiltbank, *Department of Dairy Science, University of Wisconsin-Madison.*

Follicular cysts are commonly treated by manual rupture. In this study, we induced follicular cysts by causing a GnRH/LH surge with 5 mg estradiol benzoate (EB; produces circulating estradiol = 67 pg/ml) at a time when a dominant follicle was not present on the ovary (Day 0).

After treatment 8 of 20 (40%) cows developed a large follicle anovulatory condition similar to follicular cysts. On Day 10, cows were again challenged with EB. Six of 8 cows had no detectable LH surge but 2 cows had some LH increase (8 and 3 ng/ml) after EB. At Day 50, cows were randomized into 2 groups: Manual Rupture (MR; n=4), Control (n=4). MR cows had all follicles ≥ 15 mm removed by exerting pressure through the rectum similar to what is done routinely in the field. Prior to treatment all cows had periodic (every 15-25 d) development of large anovulatory follicles and corresponding increases in circulating estradiol. At MR, 2 cows had elevated estradiol (12 and 29 pg/ml) that decreased to basal concentrations after MR. There was a subsequent surge in FSH and emergence of a new follicular wave. Two MR cows had basal estradiol and a follicular wave was emerging at the time of MR. There was no FSH surge in these cows following MR. Two cows (one control and one MR) had a spontaneous double ovulation at Days 56 and 57. These ovulating cows were the same 2 cows that had an LH increase in response to EB at Day 10. The remaining 6 cows were challenged with EB on Day 71. Two of the cows (one control and one MR) had an LH surge and ovulation in response to EB; while 4 had no LH surge and no ovulation. The non-ovulating cows were treated for 7 d with progesterone (CIDR on Days 78-85) followed by EB on Day 86. All four cows had an LH surge and ovulation in response to EB. Thus, MR can remove functional large anovulatory follicles and start a new follicular wave. However, MR does not appear to resolve the underlying physiological problem that cystic cows do not have an LH surge following high circulating estradiol. Progesterone treatment can resolve this physiological problem.

Key Words: Follicular Cysts, Manual Rupture, Estradiol

1923 Pregnancy rates in lactating dairy cows following timed embryo transfer under heat stress conditions. Y.M. Al-Katanani*¹, M. Drost¹, R.L. Monson², J.J. Rutledge², C.E. Kringer III¹, J. Block¹, and P.J. Hansen, ¹University of Florida, Gainesville, FL/USA, ²University of Wisconsin, Madison, WI/USA.

Timed embryo transfer (TET) using in vitro-produced (IVP) embryos without estrus detection can be used to reduce adverse effects of heat stress on fertility. One limitation is the poor survival of IVP embryos to cryopreservation. Objectives were to 1) confirm beneficial effects of TET on pregnancy rate during heat stress as compared to timed artificial insemination (TAI) and 2) determine the efficacy of vitrification as a method for cryopreservation. For vitrified embryos (TETV), vitrification and thawing procedures, using excellent and good quality d 7 Holstein blastocysts, were as described (Theriogenology 50:129). For fresh embryos (TETF), Holstein oocytes were shipped from Wisconsin to Florida overnight, fertilized and embryos cultured in modified KSOM for 7 d using the method for production of vitrified embryos. Excellent and good quality blastocysts on d 7 were transported to the cooperating dairy in a portable incubator. Non-pregnant, lactating Holsteins (n=155) were injected with GnRH (100 μ g, im), followed 7 d later by PGF_{2 α} (25 mg, im) and GnRH (100 μ g) on d 9. Cows in the TAI group (n=68) were inseminated the next day with semen from a single bull that was also used to produce embryos. Cows in the other groups (n=33 for TETF and 54 for TETV) received an embryo on d 7 after anticipated ovulation (d 8 after second GnRH). The proportion of cows that responded to synchronization (plasma progesterone ≤ 1.5 ng/ml on d 0 and ≤ 1.5 ng/ml on d 8 after GnRH) was 67.7%. Pregnancy rate for all cows at d 45 was higher ($p < 0.05$) in the TETF group than for the TAI and TETV groups (19.0 \pm 5.0%, 6.2 \pm 3.6%, and 6.5 \pm 4.1%). For cows responding to synchronization, pregnancy rate was higher ($p < 0.05$) for TETF than for other groups (26.7 \pm 6.4%, 5.0 \pm 4.3%, and 7.4 \pm 4.7%). In conclusion, ET of fresh IVP embryos can improve pregnancy rate under heat stress conditions but pregnancy rate following transfer of vitrified embryos was no better than TAI.

Key Words: Heat stress, Embryo transfer, Vitrification

1924 Factors affecting the time intervals between estrus, LH surge and ovulation in high-yield dairy cows. A. Bloch*¹, D. Wolfenson¹, M. Kaim², Z. Roth¹, R. Braw-Tal², and Y. Folman², ¹Faculty of Agriculture, Hebrew University, Rehovot, Israel, ²Agricultural Research Organization, Bet-Dagan, Israel.

The short fertile lives of the male and female gametes in the female tract necessitate accurate timing of insemination. We examined the effects of season, parity, milk yield, body condition, and concentrations of steroids

and LH surge prior to estrus, on the intervals: estrus-ovulation (E-O), estrus-LH surge (E-LH), and LH surge-ovulation (LH-O), and on post-O progesterone curves. Holstein cows (n=74) in first-fifth lactation, yielding 35-57 kg milk/day (d), were examined at 60-80 d postpartum. After synchronization, cows were examined around subsequent spontaneous E. Blood samples were taken every 2 d in cycles before and after E, and every 3 to 8 h around E and expected O. Cows were watched for E continuously for 5 d from the expected time of E. From 20 h after standing E, time of O was checked by ultrasound every 4 h. For most cows (73%), with E-O<30 h, E-O, E-LH and LH-O intervals were 27±0.3, 2.3±0.4 and 24±0.4 h, respectively (normal interval; meansem); 17% of cows had a 31-35 h E-O (long interval) and 10% (n=7) ovulated 35 to >50 h after E (43±2.6 h; very long interval). E-O, E-LH and LH-O intervals were not affected by season, parity, milk yield, milk composition or body condition. LH surge amplitude in very-long interval group reached 40% of those in other groups (P<0.01). Concentrations of estradiol prior to LH surge tended to be lower (P<0.08), and those of progesterone prior to E were lower (P<0.03) in the very-long than in the other two groups. Post-O progesterone curves were lower in long and very-long than in normal interval group (P<0.03). The data show a subgroup of cows with extended E-O interval, associated with low plasma steroid concentrations and low LH surge prior to O, and with low post-O progesterone, which may result in non-optimal timing of insemination, lowering fertilization rate and leading to low fertility.

Key Words: Estrus, Ovulation, LH surge

1925 Hormonal induction of enhanced removal of impaired follicles improved oocyte quality in the autumn in previously heat-stressed cows. Z. Roth*¹, A. Arav², A. Bor², R. Braw-Tal², and D. Wolfenson¹, ¹Faculty of Agriculture, Hebrew University, Rehovot, Israel, ²Agricultural Research Organization, Bet Dagan, Israel.

The autumn conception rate of dairy cattle is low although cows are relieved from summer heat stress. Previously, frequent follicular aspirations in the autumn improved oocyte quality, therefore, the present study examined different hormonal approaches to oocyte quality improvement in autumn by enhanced removal of follicles damaged in the previous summer. In two experiments intended to examine different hormonal treatments, follicles (3-8 mm) were aspirated in the autumn from lactating Holstein cows on day (d) 4 of each cycle by the ovum pick up procedure. Oocytes were morphologically examined, matured in vitro, activated and cultured for 8 d. In the first experiment, recombinant bovine somatotropin (500 mg; bST, Sometribove) was injected into cows (n=8) every 14 d, during 4 estrous cycles. Before bST treatment (cycle 1) percentages of grade-I and cleaved oocytes did not differ between control (n=8) and bST groups, and parthenogenetic blastocysts were nil. Treatment with bST increased grade-I oocyte percentages, compared with control cows (P<0.05), particularly in cycle 2 (72 vs. 26%), less so in cycles 3 and 4 (55 vs. 42%). Cleavage and blastocyst rates gradually rose in cycles 3 and 4, but did not differ between groups. In the second autumn experiment, two doses of FSH (2x200 mg; Follotropin V) were injected at 12-h interval (FSH; n=3) on d 5 and on d 11 of cycle 1. In cycle 1 (before FSH injection), grade-I oocyte (52%) and cleavage (24%) rates did not differ between control (n=4) and FSH groups. In the next cycle, grade-I oocyte and cleavage rates were higher in FSH than in control group (89 vs. 51% and 85 vs. 31%, respectively; P<0.05). Results indicate that a short treatment with bST or FSH in the autumn improved oocyte quality; perhaps recruitment of more growing follicles into follicular waves enhanced the removal of follicles damaged in the previous summer.

Key Words: bST, FSH, Oocyte

1926 Follicular dynamics and concentrations of steroids and gonadotropins in lactating cows and nulliparous heifers. G. Inbar¹, D. Wolfenson*¹, Z. Roth¹, M. Kaim², A. Bloch¹, and R. Braw-Tal², ¹Faculty of Agriculture, Hebrew University, Rehovot, Israel, ²Agricultural Research Organization, Bet Dagan, Israel.

Differences between lactating cows (C) and nulliparous heifers (H) in follicular development and circulating hormone concentrations, that may relate to differences in fertility between the groups, were examined. Multiparous Holstein C (n=19) at 77±7 (meansem) days (d) post-partum,

yielding 49±2.4 kg milk/d and H (n=20), 13.3±1 months old, were examined in 2 replicates during 1 estrous cycle, by ultrasound monitoring every 2 d and daily blood samples. Fifteen C (79%) and 14 H (70%) had 2-follicular-wave cycles, 4 C and 5 H had 3-wave cycles and 1 H had a 4-wave cycle. Cycle length was shorter in H than in C, and in 2- than in 3- and 4-wave cycles, both by 2.5 d (P<0.02). Size of ovulatory follicle (F) and number of large Fs in the follicular phase were smaller in H than in C (13.1±3 vs. 16.5±5 mm; P<.001; and 1.0.1 vs. 1.9.1 Fs; P<.01), in both wave cycles. Emergence of preovulatory F was earlier in H than in C (10.2±.7 vs. 12.5±.5 d; P<.01), in 2-wave cycles, and similar (17.1±.8) in 3-wave cycles. Dominance duration of ovulatory F was longer in 2-wave than in 3-wave cycles (7.0±.5 vs. 4.6±.8 d; P<.01), similar in C and H in replicate 1, but shorter in H than in C in replicate 2 (5.1±1.0 vs. 9.1±1.5 d; P<.05). Estradiol concentrations were higher around estrus in H than in C, peaking at 10.1±.7 vs. 7.1±.8 pg/ml (P<.01). Progesterone concentrations were higher in H than in C from d 2 to d 16 of cycle (P<.01). LH surges were higher and wider in H than in C, peaking at 19.0±4.2 vs. 8.6±1.8 ng/ml (P<.01). The timing of FSH surge concentrations corresponded well to the emergence of follicular waves in both H and C. Basal and peak surge values of FSH were 15 to 20% lower in H than in C (P<0.05). Results show differences in ovarian functions and gonadotropins secretion that may account for the differences in fertility between nulliparous heifers and multiparous lactating cows.

Key Words: Follicular dynamics, Cows, Heifers

1927 Effects of fertilizing bovine oocytes with sperm aged post-thaw. J.A. Miller*, F.N. Schrick, A.M. Saxton, and J.L. Edwards, *The University of Tennessee, Knoxville, TN, USA.*

The present study examined development of bovine embryos derived from oocytes fertilized with aged sperm. Cumulus oocyte complexes were matured 22.5 h and fertilized with percoll-purified sperm (750,000 sperm/mL). Before percoll-purification, sperm was treated in the following manner: prepared within 1 h post-thaw (control), aged for 8 or 14 h post-thaw at 34.4°C in a H₂O bath, or aged 23 h post-thaw at 4°C in a refrigerator. Spermatozoa from nine bulls, representing various breeds, were evaluated. Proportion of motile sperm was assessed after aging and following percoll-purification. Number of putative zygotes (PZ) that cleaved and developed to blastocyst was evaluated on d 3 and 8 post-fertilization, respectively. Data were arranged in a randomized block design and analyzed using mixed models of SAS. Aging sperm in a H₂O bath for 14 h at 34.4°C or in a refrigerator for 23 h at 4°C reduced proportion of motile sperm when compared to control or sperm aged in a H₂O bath for 8 h post-thaw at 34.4°C (42.1 and 56.8% vs 69.2 and 64.9%, respectively; P < 0.0001; SEM = 4.1). Overall, proportion of motile sperm increased after percoll-purification (53.0 vs 64.6%; P < 0.03; SEM = 5.1) but remained lower for sperm aged at 34.4°C for 14 h (77.3 and 69.3% for control and refrigerated sperm, respectively vs 48.9%; P < 0.07; SEM = 8.8). Fertilization of oocytes with sperm aged for 14 h at 34.4°C reduced proportion of PZ that cleaved, but did not alter ability of embryos to develop to 8-16-cell or blastocyst (Table). Although reducing number of motile sperm is a negative effect of aging post-thaw, results demonstrate that developmentally competent embryos can be obtained. Aging is of concern but inevitable when attempting to manipulate sperm post-thaw after fertilization.

Treatments	Reps	# PZ	Cleaved	8-16-Cell*	Blastocyst*
Control	9	310	76.8 ^a	89.7	30.1
34.4°C, 8 h	4	106	74.8 ^{ab}	85.2	30.6
34.4°C, 14 h	8	317	63.7 ^b	81.1	41.1

1928 Evaluation of the fertility potential of extended cooled equine spermatozoa using the resazurin reduction test and NADH₂. W. T. Campbell*, S. A. Ericsson, J. S. Pendergraft, K. K. Korth, and J. A. Pitchford, *Sul Ross State University, Alpine, Texas.*

The objective of this study was to determine if the fertility potential of extended cooled equine semen samples could be assessed using the resazurin reduction test supplemented with NADH₂. Semen samples (n=30) from 7 mature stallions were collected using a Missouri style artificial vagina with the gel-free fraction of each sample being evaluated microscopically (250X) with a Makler counting chamber. Samples that contained at least the minimal concentration (20 X 10⁶/mL), total number motile (10 X 10⁶/mL), and number of progressively motile (5 X 10⁶/mL) spermatozoa recommended for a 50 mL insemination dose were extended (1:4 ratio) in Kenney's skim milk with Gentamicin Sulfate to 50 mL and cooled to 5°C. At 32, 56, and 80 h post-extension, 7 (1 mL) aliquots were removed and allowed to warm at 23°C for 30 min. One aliquot was analyzed microscopically to determine if the sample retained the recommended sperm numbers. The remaining aliquots were divided equally into control aliquots (no NADH₂) and treatment aliquots (0.5 mg NADH₂/aliquot). Resazurin (50 µL of a 6.77 µM solution) was added to each of the aliquots and the time of reduction of resazurin (blue) to resorufin (pink) was recorded up to a maximum of 30 min. Diagnostic statistics were utilized to assess the accuracies of the two groups. None of the control aliquots reduced resazurin (30 min) at 32, 56, and 80 h. The treatment aliquots at 32 h reduced resazurin at 20.5 min with a 75% sensitivity (Sen), 96% specificity (Spec), 75% positive (PPV) and 96% negative (NPV) predictive values, and 93% overall accuracy (ACC). Resazurin was reduced by the 56 h treatment aliquots at 17.5 min with a 46% Sen, 94% Spec, 86% PPV, 70% NPV, and 73% ACC. The 80 h treatment aliquots reduced resazurin at 16.5 min with a 69% Sen, 100% Spec, 100% PPV, 81% NPV, and 87% ACC. These results suggest that the resazurin reduction test supplemented with NADH₂ can accurately assess the fertility potential of extended cooled equine semen.

Key Words: Spermatozoa, Resazurin, NADH₂

1929 Motility of frozen-thawed bovine sperm after aging for extended time periods. M.N. Malone*, J.A. Miller, A.M. Saxton, and J.L. Edwards, *The University of Tennessee, Knoxville, TN, USA.*

The objective of the present study was to evaluate effects of aging frozen-thawed bovine sperm. Specifically, sperm motility was evaluated after aging frozen-thawed sperm for an extended time period in nine bulls representing Charolais, Holstein, and Senepol breeds (n = 3 bulls/breed). Straws of frozen sperm were thawed and maintained in a water bath at 34.5°C. Sperm motility was assessed at 0, 5, 7, 9, 11, 13, and 15 h post-thaw. Spermatozoa were diluted 1:20 in Sperm-TALP containing 6.0 mg/mL BSA, 1.0 mM sodium pyruvate, 50 U/mL of penicillin, and 50 µg/mL of streptomycin. Motility of sperm was assessed independently by two individuals. The experiment was replicated three times. Statistical models were fit to include effects of breed, individual bulls, and time as either a class or regression variable. Motility of frozen-thawed sperm decreased from 68.3% immediately post-thaw to 34.7% 15 h later (SEM = 2.5; P < 0.0001). Averaged over time, sperm motility was lowest in Charolais bulls (41.1%) compared to Holstein (51.9%) and Senepol (55.3%; SEM = 2.1; P < 0.0001). Ability of sperm to withstand stress of aging post-thaw differed according to breed. Regressing over time, motility of frozen-thawed sperm from Charolais and Holstein bulls decreased more rapidly (slope = -2.8 and -2.5% per hour, respectively) than for Senepol bulls (slope = -1.4% per hour; SEM = 0.4; P < 0.0002). The rate of decline in motility of aged sperm was very similar for three Senepol bulls examined (slope = -1.7, -1.3 and -1.2% per hour; SEM = 0.4; P > 0.7). In contrast, large amounts of variation among individual bulls were noted in Holsteins (slope = -4.2 and -3.0% versus -0.6% per hour; SEM = 0.4; P < 0.0001) and Charolais (-3.8% versus -2.6 and -2.1% per hour; SEM = 0.4; P < 0.02). Results demonstrated motility of sperm of individual bulls within a breed differed in ability to handle stress of aging. Future efforts will focus on determining if ability of sperm to withstand stress can be used as an indicator of fertility.

Key Words: Sperm, Motility, Aging

1930 Effects of growth hormone (GH) and IGF-I on development of in vitro derived bovine embryos. F. Moreira, F. F. Paula-Lopes, P. J. Hansen, L. Badinga, and W. W. Thatcher, *University of Florida.*

Objectives were to determine if addition of GH to maturation medium and GH or IGF-I during embryo culture affects development of bovine embryos. Cumulus oocyte complexes (COCs) from slaughterhouse ovaries were matured in 50 µL drops of serum-free TCM-199 medium containing FSH (20 µg/ml) and estradiol (2 µg/ml) in groups of 10 oocytes per drop. During maturation, COCs were treated with 100 or 0 ng/ml of GH. COCs were inseminated, denuded, and transferred to 25 µL drops of serum-free KSOM medium containing essentially fatty acid-free bovine serum albumin (2 mg/ml) in groups of 10 presumptive embryos per drop for culture (d 0). Beginning at d 0, the following treatments were added to medium: 1) non-specific IgG (raised to heat shock protein 65 of *Mycobacterium bovis*; 10 µg/ml), 2) GH (100 ng/ml) plus IgG (10 µg/ml; GH/IgG), 3) IGF-I (100 ng/ml) plus IgG (10 µg/ml; IGF/IgG), 4) antibody to IGF-I (10 µg/ml; anti-IGF), 5) GH (100 ng/ml) plus anti-IGF (10 µg/ml; GH/anti-IGF), 6) IGF-I (100 ng/ml) plus anti-IGF (10 µg/ml; IGF/anti-IGF), or 7) no further additions (control). Embryos were observed at d 3 for cleavage and at d 7 and 8 for blastocyst development. The experiment was replicated on 6 occasions. Addition of GH to the maturation medium increased cleavage rates at d 3 compared to control (87.3 ± 1.2 % > 83.9 ± 1.2 %; P < 0.05) but had no effects on blastocyst development at d 7 and 8. Blastocyst development was greater (P < 0.1) for GH/IgG (16.2 ± 1.8 %) and IGF/IgG (16.5 ± 1.8 %) than for IgG (8.7 ± 1.5 %) at d 7. At d 8, blastocyst development was greater (P < 0.01) for GH/IgG (24.8 ± 2.5 %) and IGF/IgG (33.7 ± 2.5 %) than for IgG (16.1 ± 2.1 %) and greater for IGF/IgG than for GH/IgG (P < 0.02). Blastocyst development at d 8 did not differ between anti-IGF (20.4 ± 1.8 %) compared to GH/anti-IGF (24.1 ± 1.9 %) and IGF/anti-IGF (17.7 ± 1.9 %), but it was greater for GH/anti-IGF than for IGF/anti-IGF (P < 0.05). Both GH and IGF-I stimulated embryonic development and GH effects seem to be independent from IGF-I.

1931 Nuclear progression of bovine oocytes maintained at germinal vesicle stage up to 66 hours using roscovitine. A.M. Clarke*, L.M. McCann, and J.L. Edwards, *The University of Tennessee, Knoxville, TN, USA.*

The objective of this study was to determine effectiveness of roscovitine (inhibitor of p34^{cdc2}/cyclin B kinase) to maintain bovine oocytes at germinal vesicle (GV) stage for 21, 42 or 66 h after removal from follicles without compromising subsequent progression to metaphase II (MII). Cumulus oocyte complexes were cultured with 50 µM roscovitine for 21, 42, or 66 h in 5.5% CO₂ at 38.5°C in M199 containing 10% fetal bovine serum, 1 X nucleosides, 2 mM L-glutamine, 1 X nonessential amino acids, 0.1 mM β-mercaptoethanol, 50 U/mL penicillin, and 50 µg/mL streptomycin. After 21, 42, or 66 h, oocytes were divided within treatment: nuclear status was determined in approximately half while those remaining were washed of roscovitine and cultured for an additional 24 h in medium containing 0.3 µg/mL LH and 5.0 µg/mL FSH. Nuclear status of oocytes was evaluated using Hoechst staining. Number of oocytes with a GV, metaphase I (MI), anaphase I, telophase I, or MII configuration was recorded. Data were arranged in a randomized block design and analyzed using mixed models of SAS. Culture of oocytes with roscovitine, up to 66 h after removal from follicles, maintained >90% at GV stage (Table). Moreover, culture of oocytes with roscovitine for 21 or 42 h after removal from follicles, did not alter proportion progressing to metaphase II after placement in gonadotropins (Table). Inhibiting resumption of meiosis for extended time periods in oocytes after removal from follicles will be important for development of culture systems allowing for the study of immature oocytes.

Time in Roscovitine (h)	Oocytes*		Matured Oocytes**		Reps	GV (%)	MI (%)	MII (%)
	Reps	Oocytes*	GV (%)	Oocytes**

1932 Postweaning growth and puberty of Angus and Romosinuano bulls in Florida. C. C. Chase, Jr.*¹, R. E. Larsen², P. C. Sheerin², M. J. Williams¹, A. C. Hammond³, T. A. Olson², and S. W. Coleman¹, ¹USDA, ARS, Brooksville, FL, ²University of Florida, Gainesville, ³USDA, ARS, Athens, GA.

Postweaning growth and puberty were determined from two consecutive calf crops using Angus (A; yr 1: n = 17, 254±15.9 d, 214±6.6 kg; yr 2: n = 12, 264±7.3 d, 221±11.4 kg) and Romosinuano (R; yr 1: n = 18, 259±15.4 d, 222±6.4 kg; yr 2: n = 24, 232±5.1 d, 182±8.0 kg) bull calves. Following weaning and preconditioning, bulls were managed as a single group on mixed bahiagrass and perennial peanut pastures (and hay) and fed 4.5 kg/d concentrate for 357 to 358 d. At the start of the study and at 28-d intervals, BW, hip height (HH), and scrotal circumference (SC) were measured. Concurrently, when the SC of a bull reached 23 cm, semen collection was attempted by electroejaculation. Ejaculates were evaluated for presence of first spermatozoa (FS), 50 million sperm with at least 10% motility (PU), and 500 million sperm with at least 50% motility (PP). In yr 1, R gained more BW (P < 0.05; 308±7.8 vs 281±8.1 kg), HH (P < 0.05; 26±0.9 vs 23±0.9 cm), and SC (P < 0.10; 13.0±0.6 vs 11.5±0.6 cm) than A bulls. In yr 2 when R were (P < 0.05) younger, lighter, and had smaller SC at the start of the study than A bulls, gains in BW and HH did not differ between R vs A (264±7.5 vs 283±10.7 kg and 22±1.0 vs 21±1.4 cm); however, R had greater (P < 0.001) gains in SC (14.5±0.4 vs 10.9±0.6 cm). In yr 1, breed (R vs A) did not affect (P > 0.10) age at FS (336±18.6 vs 306±19.2 d), PU (357±19.6 vs 339±20.2 d), or PP (397±19.4 vs 362±19.9 d); however, R were heavier (313±10.6 vs 267±11.0, 336±11.2 vs 297±11.6, and 378±11.4 vs 320±11.7 kg) and taller than A at FS, PU, and PP, respectively. Breed did not affect SC at FS and PU, but R tended (P < 0.10) to have a larger SC at PP (30.2±0.5 vs 28.9±0.5 cm). In yr 2, R tended (P < 0.10) to be older than A at FS (356±10.2 vs 325±14.6 d), but not (P > 0.10) at PU (378±10.5 vs 352±15.0 d) and PP (408±11.8 vs 408±16.7 d). In yr 2, breed did not affect BW at FS (250±7.4 vs 258±10.5 kg) or PU (266±9.4 vs 283±13.3 kg), but R tended (P < 0.10) to be lighter than A at PP (291±11.0 vs 328±15.7 kg), and R were taller (P < 0.001) than A at FS, PU, and PP. Romosinuano had smaller (P < 0.05) SC than A at FS and PP, but similar SC at PU (25.7±0.4 vs 26.7±0.6 cm). In conclusion, the tropically adapted R bulls reached puberty at similar ages as A bulls when reared in the subtropics.

1933 Concentrations of LH and testosterone in serum of sexually mature boars treated with naloxone. M.J. Estienne*¹, A.F. Harper¹, J.W. Knight¹, G.B. Rampacek², and C.R. Barb³, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²University of Georgia, Athens, ³USDA-ARS, Athens, GA.

Treatment of gilts and sows with naloxone, an endogenous opioid receptor antagonist, increases LH secretion, presumably as a consequence of increased GnRH release (Barb et al., 1991; *Domest. Anim. Endocrinol.* 8:15-27). The objective of the current study was to determine the effects of naloxone on circulating concentrations of LH and testosterone in sexually mature boars. Five littermate boars (Landrace x Yorkshire; 186.9 ± 8.3 kg BW and 289 d of age), fitted with indwelling jugular vein catheters, were used. Beginning 24 h after catheterization, blood samples were collected at 15-min intervals for three hours. Two h after initiation of blood sampling, boars received an i.v. challenge of naloxone hydrochloride (Sigma Chemical Co., St. Louis, MO; 1 mg/kg BW; n = 2) or .9% saline (n = 3). Twenty-four h later the experiment was repeated, but boars that previously received naloxone received .9% saline and vice versa. Serum concentrations of LH and testosterone were not affected by day of experiment (P > .1). Prior to i.v. injections, LH concentrations in serum were similar (P > .1) between groups and averaged 0.56 ± 0.03 ng/mL. Naloxone increased (P < 0.01) LH concentrations, with peak values of 1.75 ± 0.22 ng/mL occurring 45 min after treatment. Injection of .9% saline had no effect (P > 0.1) on LH secretion. Serum testosterone concentrations averaged 1.94 ± 0.23 ng/mL prior to naloxone and increased (P < 0.01) to 3.06 ± 0.23 ng/mL by 1 h after treatment. Testosterone levels averaged 3.24 ± .23 ng/mL before .9% saline and decreased (P < .04) to 2.52 ± 0.23 ng/mL by 1 h after

injection. In summary, naloxone increased serum LH and testosterone concentrations. Our results are consistent with the theory that endogenous opioid peptides suppress LH secretion in sexually mature boars.

Key Words: LH, testosterone, boars

1934 Early postnatal concentrations of plasma testicular steroid hormones as indicators of boar taint in market weight pigs. P.A. Sinclair*, E.J. Squires, and J.I. Raeside, University of Guelph, Guelph, Ontario, Canada.

If a relationship existed between levels of testicular steroids present in early postnatal pigs, and those present at market weight, then plasma steroid concentrations in young pigs could be used as an indicator of boar taint at market weight. Blood samples were taken from 75 Yorkshire boars at days 14, 21, and again at a market weight of 110 kg. Positive correlations were found between the concentrations of fat androstenone at market weight and the concentrations of plasma androstenone (r = 0.46; P < 0.01), estrone sulfate (r = 0.42; P < 0.01), and testosterone (r = 0.26; P < 0.05) at market weight. Significant correlations were observed between plasma testosterone concentrations at market weight and plasma concentrations of androstenone (r = 0.57; P < 0.05), and estrone sulfate (r = 0.49; P < 0.05) in early postnatal animals. However, concentrations of androstenone in fat of market weight animals were not correlated with plasma concentrations of estrone sulfate, androstenone or testosterone in early postnatal animals. This suggests that early postnatal plasma steroid production has no relationship with levels of market weight testicular steroids and cannot be used to predict the potential for boar taint. Additional findings of this study revealed that in market weight animals, a negative correlation (r = - 0.57; P < 0.01) between backfat thickness and concentrations of androstenone in fat was present. Animals were subsequently sorted according to backfat thickness into lean and fat groups of animals. There was a strong, negative correlation between backfat thickness and androstenone concentrations in fat (r = - 0.80; P < 0.01), as well as a positive correlation between plasma androstenone and concentrations of androstenone in fat (r = 0.42; P < 0.05) among the lean group of animals. This suggests that the accumulation of androstenone from plasma into fat may be affected by other factors than the hydrophobicity of androstenone, such as carcass leanness.

Key Words: Boar taint, Androstenone, Postnatal

1935 Vitamin supplements and reproductive performance in boars. I. Audet*¹, J. -P. Laforest², G. -P. Martineau³, and J. J. Matte¹, ¹Agriculture and Agri-Food Canada, Lennoxville, QC, Canada, ²Laval University, QC, Canada, ³cole Vtrinaire de Toulouse, France.

The aim of the present study was to determine the effects of dietary supplements of vitamins, on vitamin status, libido and semen characteristics in young boars under normal and intensive semen collection. Sixty boars were randomly allocated from 8 to 15 months of age to one of the following diets: (B, n=15) basal diet (commercial formulation for boars) for minerals and vitamins; (B+C, n=15) B diet supplemented with vitamin C (1 g daily); (B+F, n=15) B diet supplemented with fat-soluble vitamins (3 times for D and 5 times for A, E, K higher than B); (B+W, n=15) B diet supplemented with water-soluble vitamins (10 times higher than B). After puberty (10 months of age), semen was collected at a regular frequency (3 times every 2 weeks) during 2 months. Thereafter, all boars were intensively collected (daily during 2 weeks). A resting period of 10 weeks followed. Sperm quality and quantity were recorded as well as boar libido, on all animals. Blood and seminal plasma samples were taken during this experiment to monitor vitamin status. Semen production was higher during the intensive collection period, for boars supplemented in the B+W group (P≤.06) and B+F group (P≤.1). During the resting period, the percentage of motile sperm was higher in B+W boars (P≤.03) and, in a lesser extent, in B+F boars (P≤.1), as compared to control boars. Sperm morphology and libido were not affected by treatments (P≥.15). High concentrations of B6 (P≤.05) and folic acid (P≤.01) were observed in blood plasma of B+W boars while higher concentrations of vitamin E (P≤.01) were obtained in B+F boars. In seminal plasma, an increase in folic acid concentrations was noted in B+W boars (P≤.01). In conclusion, dietary supplements of water-soluble and fat-soluble vitamins appear to increase semen production in response to stress conditions such as an intensive semen collection.

The transfer of vitamins from the blood plasma into the seminal plasma seems rather limited.

1936 Laying hen response to molt induction by either pelleted alfalfa or alfalfa meal. K Medvedev*¹, C Woodward¹, X Li¹, L Berghman¹, L Kubena², D Nisbet², and S Ricke¹, ¹Texas A&M University, Department of Poultry Science, ²USDA-ARS, Food and Feed Safety Unit.

Molting is a process commonly utilized by commercial laying facilities to extend and improve the productivity of a flock. This practice usually involves the deprivation of feed for a period of several days in order to rejuvenate the reproductive system. Due to food safety and consumer awareness factors, alternatives to this approach are being investigated. Feeding alfalfa as an insoluble fiber source with the purpose of inducing molt is one such alternative. In this study, 118 hens were fed one of four diets: Layer Ration, Alfalfa Meal, Alfalfa Pellets, and Feed Deprivation. Hen weights were monitored 5 times during the trial to assess weight loss throughout the molting phase. During the trial, 8 hens per treatment were assessed for stress level using a tonic immobility technique. At the end of the trial, 58 hens from respective diet groups were sacrificed, and ovary weights were obtained to monitor regression of the reproductive system after a completed molting cycle. The diets correlated to the final hen weight with a p value ≤ 0.05 where feed deprivation birds lost 22.55%, alfalfa meal birds lost 16.85%, alfalfa pellet birds lost 13.03%, while birds kept on layer ration gained 2.31%. Ovary weights correlated to diet with a p value ≤ 0.05 where feed deprivation birds had a mean ovary weight of 6.37g, alfalfa meal birds had 5.08g, alfalfa pellet birds had 5.73g, and layer ration birds had 35.72g. No significant differences in stress response were noted in birds from these studies. Based on layer hen response, it appears that alfalfa can induce molt with the same efficiency as feed deprivation.

Key Words: Alfalfa, Hen Response, Molt

1937 Interleukin-1 β (IL-1 β) reduces the activity of 3 β -hydroxysteroid dehydrogenase (3 β -HSD) in granulosa cells of laying hens. M. A. Alodan*¹ and M. M. Beck¹, ¹University of Nebraska.

It is known that high environmental temperature (heat stress, HS) significantly reduces egg production, in part at least through disruption of reproductive hormones, progesterone (P₄), luteinizing hormone (LH), and estrogen (E₂). There are many well documented systemic effects of HS that may affect these hormones, but very little is known about local mechanisms through which HS acts. Interleukin-1 is increased by stress, including HS, and recently, in mammals, it has been shown that cytokines interleukin-1 α and IL-1 β play a role in ovarian function. The role(s) of cytokines in the bird remain unclear. The aim of this study was to determine the effect of HS and IL-1 β on the activity of 3 β -HSD, one of the major enzymes involved in steroidogenesis, in the granulosa cells (GC) of the laying hen. Two groups of hens were used in this study; one group was subjected to 24C, 30%RH (control), the other group to 36C, 60%RH (HS treatment). At the end of HS, the F1 follicles were collected from both groups and the GC dispersed enzymatically. The GC preparation from the control group was divided into three aliquots. One served as a control for the HS treatment; the other two were incubated with 100ng/ml IL-1 β or without IL-1 β (IL control) for 5h at 39C. Approximately 10,000 viable GC from each treatment were incubated in 1.5 ml of medium (PBS, pregnenolone, NAD, and nitroblue tetrazolium, pH 7.4) using 24-well flat-bottom plates at 39C for 90 min. After the incubation period, wells were examined with inverted microscope for dark blue formazan precipitate. A total of at least 100 cells per sample were examined to determine the percentage of cells that stained positive for 3 β -HSD (dark blue cells). Both HS and IL-1 β significantly reduced the percentage of 3 β -HSD positive cells ($P=0.000$, 0.053 , respectively). We hypothesize that HS reduces the activity of 3 β -HSD in the granulosa, and that reduction may be in part, at least, mediated through IL-1 β .

Key Words: Heat stress, Progesterone, 3 β -HSD

1938 Expression of the activin type II receptors and the inhibin/activin subunits during follicular development in broiler breeder hens. A. J. Davis* and S. N. Slaphey, University of Georgia.

There are two known activin type II receptors (ActRII and ActRIIB). An activin type II receptor must bind with an activin type I receptor to form a complex that can bind activin and then elicit downstream signaling by phosphorylation of proteins. The expression of mRNA for ActRII, ActRIIB, follistatin and inhibin/activin subunits was investigated in the follicles of broiler breeder hens. Total RNA was isolated from individual granulosa and theca layers of the F₁ through F₅ follicles, a pool of the F₆-F₇ follicles, the small yellow follicles (5-12 mm) and from the combined granulosa and theca layers of the large white follicles (2-5 mm) from 6 birds. 40 μ g of total RNA per sample was run on a 1.5% agarose/formaldehyde gel and then transferred to nylon membrane for Northern analysis with chicken cDNA probes for the activin type II receptors, follistatin, the inhibin/activin subunits and GAPDH (control). Two ActRII mRNA transcripts of 6.5 and 3.7 kb were detected in all of the theca and granulosa samples. Both transcripts were equally expressed in granulosa samples, but in theca samples expression of the 3.7 kb transcript was significantly greater than the 6.5 kb transcript. ActRIIB was not detected by Northern analysis in any of the samples. Expression of the mRNA for the activin/inhibin binding protein, follistatin was detected in both theca and granulosa samples with the greatest expression found in small yellow follicle samples for both cell layers. Expression of the inhibin α -subunit was detected in the granulosa layer of all the follicles. Expression of the inhibin α -subunit was highest in the F₆-F₇ granulosa layer. Granulosa layers from large hierarchical follicles expressed the most inhibin/activin β -A-subunit, while expression of the inhibin/activin β -B-subunit was highest in nonhierarchical follicles. This is the first report, to our knowledge, of the detection of activin type II receptor mRNA in the hen ovary, and characterization of the expression pattern of the inhibin family in both the theca and granulosa layers throughout follicular development. The presence of activin receptor and follistatin mRNA in both the theca and granulosa layers of the small developing follicles suggests that locally produced activin might have a vital role in early follicular development.

Key Words: Activin receptors, Chicken

1939 Immunization of male broiler breeders against mammalian Gonadotropin Releasing Hormone. J.A. Vizcarra*¹, M.L. Rhoads¹, C.C. Hsu¹, J. Washington¹, J.L.M. Morgan¹, J. Yang¹, H. Tang¹, K. Shaffer¹, and J.D. Kirby¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, AR 72701.

Twenty broiler breeder males were used to evaluate the effect of immunization against mGnRH on the development of antibody titers, adult testis weight, pulsatile LH and FSH secretion, and expression of mRNA for FSH-beta in the pituitary and LH receptors in testis. A mGnRH-fimbriae antigen (Intervet International) was emulsified in Freund's incomplete adjuvant and DEAE. At 10 wk of age (WOA), males were randomly assigned to two treatments, and received a primary immunization against mGnRH (50 g), or were not immunized. Booster immunizations (total of 60 g) were given at 3, 6 and 14 wk after the primary immunization. Weekly plasma samples were obtained from 10 WOA until the end of the experiment to evaluate titers against mGnRH and concentrations of testosterone by RIA. At 28 WOA, a jugular cannula was inserted, and blood samples (1 ml) were collected at 10-min intervals for 8 h. Plasma was stored at -20 C and analyzed for LH and FSH concentrations. At the end of the 8 h acute sampling period, males were killed. Pituitaries were removed to evaluate the expression of mRNA for FSH-beta subunit, and testes were obtained to evaluate daily sperm production (DSP), and expression of mRNA for LH receptors. There was a remarkable variation in titers between birds immunized against mGnRH. Only 2 of 10 birds had titers greater than 50% after the second booster immunization, and 4 of 10 birds had titers greater than 20%. Titers of 4 of 10 birds were

slightly above control (7%). Testosterone concentrations were decreased only in birds with titers greater than 20%. Testis weights and expression of mRNA for FSH-beta were significantly reduced in immunized birds. Concentrations of LH, FSH, DSP, and expression of LH receptor mRNA were not affected by treatment. Despite a significant variation in the response to the p-fimbriae antigen, immunization against mGnRH decreased testis weight and FSH-beta expression in adult broiler breeder males.

Key Words: GnRH, LH and FSH, mRNA

1940 Thyroid hormone and prolactin profiles in male and female turkeys following photostimulation: Validation of an ELISA for turkey prolactin. J. A. Proudman^{*1}, T. D. Siopes², F. Vandesande³, and L. R. Berghman⁴, ¹*Germplasm & Gamete Physiology Lab, ARS, USDA, Beltsville, MD 20705*, ²*Department of Poultry Science, North Carolina State University, Raleigh, NC 27695*, ³*Lab of Neuroendocrinology and Immunological Biotechnology, Catholic University of Leuven, Belgium*, ⁴*Poultry Science Department, Texas A&M University, College Station, TX 77843*.

Reproduction in turkeys is controlled by photoperiod and is a balance between two physiological states, photosensitive and photorefractory (PR). The hen requires a period of short day lengths to establish photosensitivity while the tom does not. Further, the hen and tom are known to express the PR response differently. The PR response is thought to be programmed by the presence of thyroxine (T4) during the early wk following photostimulation (PS). The sex difference in PR response of turkeys is not known to exist in other species, and provides an opportunity to differentiate hormonal influences on programming of PR. Our objective was to compare the early, post-lighting hormone profiles in hens and toms of three hormones, T4, triiodothyronine (T3), and prolactin (PRL). In addition, PRL was measured by both radioimmunoassay and a new homologous sandwich ELISA technique that uses a monoclonal capture antibody and a polyclonal detection antibody, permitting measurement without use of radioactivity. Results showed no significant difference in T4 levels of hens and toms measured at weekly intervals for 8 wks following PS, and at 10, 12, 16, and 22 wks. The T3 levels of toms were lower than those of hens at PS, and subsequently increased, while T3 levels of hens declined. PRL levels increased markedly following PS in hens, but remained very low throughout reproduction in toms. A high correlation ($r=0.94$) was observed between RIA and ELISA measurements of PRL levels in hens, but absolute PRL values measured by ELISA were lower ($P<0.001$) than those measured by RIA. We conclude that there are post-lighting sex differences in hormone profiles for PRL and T3 but not T4.

Key Words: photorefractoriness, hormones, turkey

1941 Dietary Manipulation of Rooster Sperm. Denise C. Bongalhardo^{*1} and Mary M. Buhr¹, ¹*University of Guelph*.

Lipid composition of sperm has been related to sperm quality and it can be modified by dietary means. Two experiments were conducted to monitor sperm quality of birds fed diets with different lipid composition. In the first trial, 20 White Leghorn roosters were randomly allocated in one of four treatments: control diet, diet containing corn oil, fish oil or flax seed as lipid source. The birds were ejaculated at 35, 36, 37, 38, 45, 46, 47, and 50 weeks of age. From 35 to 37 and 48 to 50 weeks of age, all birds were fed the control diet. From 38 to 47 weeks, they were fed the experimental diets. Semen was collected twice a week by abdominal massage, and the semen of the second collection was analyzed for concentration (estimated by spectrophotometer), motility (subjective microscopic analysis), viability (SYBR-14/PI fluorescent staining), and volume. In the second trial, 64 White Leghorn roosters were randomly allocated in one of the 4 treatments previously described. In the first (20 and 21 weeks of age) and in the last two weeks (27 and 28 weeks of age) of experiment, all birds were fed the control diet. From 22 to 26 weeks, they were fed the experimental diets. The semen was evaluated by concentration (spectrophotometer), motility (computer-assisted analysis), viability (flow cytometer), and volume. Repeated measures design was used to analyze the normalized data. The effect of diet was not significant ($P>0.05$) for any trait analyzed in the older birds in the first trial. In the second trial, diets didn't change concentration, viability or motility values ($P>0.05$), but diets containing corn and fish oil increased ($P<0.0123$) the volume ejaculated (0.60 0.22 and 0.65 ml

0.22, respectively) vs. control or flaxseed diets (0.50 0.23 and 0.51 0.24 ml). Lipid composition of diets affects semen parameters.

Key Words: Sperm, Diet, Lipids

1942 Sperm mobility phenotype influences duration of fertility in turkeys after insemination at 0 or 24 hour *in vitro* storage of sperm. A. M. Donoghue¹, D. P. Froman², Y. K. Kirby^{*1}, D. J. Donoghue³, and J. D. Kirby³, ¹*PPPSR, ARS, USDA, Fayetteville, AR*, ²*Oregon State University, Corvallis, OR*, ³*University of Arkansas, Fayetteville, AR*.

Sperm motility phenotype is based upon the ability of sub-populations of sperm to penetrate a solution of Accudenz (a viscous, inert non-toxic medium) at body temperature from a sperm suspension overlay. Repeatedly, we have demonstrated that sperm mobility phenotype correlates with fertility and can be used to predict the reproductive fitness of toms or roosters. The objectives of this study were to: 1) determine if duration of fertility is different between toms of good or poor phenotype; 2) determine if mixing semen from good and poor phenotype toms influences duration of fertility; and 3) evaluate whether storing semen of high and low phenotype at 4C for 24 h influences fertility outcomes. Toms ($n=57$) were assessed for sperm mobility on 3 occasions and ranked. Toms with the highest mobility scores and lowest mobility scores were identified as Good or Poor, $n=6$ /group. Equal amounts of semen from each group was pooled for the Mixed group. Hens ($n=20$ /group) were inseminated 2 days apart with Good, Mixed or Poor semen within 1 h of collection (0 time) or after 24 h of *in vitro* storage at 4C. Duration of fertility was assessed for 50 days following the final insemination. Fertility was higher in the Good (57.84.3, 23.15.2) and Mixed (53.26.1, 25.14.3) groups compared to the Poor (42.86.6, 13.72.9) group at both 0 and 24 h storage times, respectively ($P<0.05$). Interestingly for all groups at the 0 time insemination and the Good group at 24 h, the level of fertility remained constant for 14 days before a daily decline in % fertile eggs was observed. However, the 24 h *in vitro* stored semen from the Mixed and Poor groups demonstrated an immediate decline in % fertility. These data suggests that sperm quality, as determined by mobility influences fertility possibly by altering the storage capability of sperm in the hen. Supported in part by the U.S. Poultry and Egg Association (#340).[®]

1943 Demonstration of ovoinhibitor, a serine-protease inhibiting protein, in the chicken brain. L.R. Berghman^{*1}, E. D'Hondt², R.W. Moore³, B.M. Hargis⁴, C.M. Oubre¹, and F. Vandesande², ¹*Texas A&M University, College Station TX*, ²*University of Leuven, Belgium*, ³*USDA-ARS, College Station TX*, ⁴*University of Arkansas, Fayetteville AR*.

As suggested by its name, ovoinhibitor is a protease inhibitor that was originally purified from egg whites about 50 years ago. It is a 56 kDa protein that specifically inhibits serine proteases such as trypsin and chymotrypsin. Anti-ovoinhibitor monoclonal antibodies (MABs) were unexpectedly obtained as a side-product during the production of MABS against purified chicken bursa of Fabricius protein preparations. This event led to the first demonstration of ovoinhibitor in an avian immune organ. More recently, further immunocytochemical research also revealed ovoinhibitor-immunoreactivity in subsets of chicken pituitary cells (see companion communication) and, as described in the present report, in the brain of the chicken. Seven- μ m paraffin sections of Bouin-Hollande sublimate fixed chicken brain tissue were used throughout this study. Upon standard dewaxing and rehydration, sections were incubated overnight with the MAB and detection was performed with a peroxidase-labeled secondary antibody combined with diaminobenzidine and hydrogen peroxide. Both in 18-day old embryos and in 4-week old chickens, immunopositive cells were observed surrounding the lateral ventricles, the pallial commissure and the third ventricle (i.e. paraventricularly). Interestingly, in the embryo labelled cells were also found in the cerebellum, surrounding the fourth ventricle. In line with the above observation of specifically stained cells in several circumventricular areas, cerebrospinal fluid (CSF)-contacting nerve endings were prominent around the lateral ventricles, especially in the embryo. It is tempting to speculate that ovoinhibitor may be secreted into the CSF where it could play a role in inhibiting proteolytic breakdown of regulatory peptides or proteins. Serine protease inhibitors from a different family have

recently been shown to be involved in neuronal plasticity and neuroprotective mechanisms. The precise function of ovinhibitor in the brain will be a topic for further research.

Key Words: chicken, ovinhibitor, brain

1944 Vasotocin receptor mRNA expression in the brain and pituitary of broiler breeder hens. K. Shaffer*¹, J.A. Vizcarra¹, C.C. Hsu¹, J.Y. Yang¹, M.L. Rhoads¹, L.E. Cornett², D. Baeyens³, N. Ali³, and J.D. Kirby¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, AR, ²Department of Physiology, University of Arkansas for Medical Sciences, ³Department of Biology, University of Arkansas Little Rock, Little Rock, AR.

Vasotocin receptors (VTR) are members of the seven trans-membrane spanning G-protein associated receptor superfamily. Several members of the vasopressin-oxytocin-mesotocin receptor family have been characterized in vertebrates. We have previously shown that VTR-1 expression occurs primarily in the brain while VTR-2 expression occurs mainly in the pituitary. Our goal was to evaluate the expression of VTR-1 and VTR-2 mRNA in known sites of expression over the ovulatory cycle of

hens. In order to study potential changes in VTR-1 and VTR-2 expression, birds (n=4-5 per time point) were killed at 3 hour intervals relative to oviposition over a 24 hour period. Blood samples were drawn within 2 minutes of handling, prior to cervical dislocation. Brain, pituitary, shell gland, and kidney were immediately removed and frozen in liquid nitrogen. Plasma was stored at -20 C prior to determination of corticosterone levels by RIA. Isolated total RNA from the brains and the pituitaries was transferred to nylon membranes for analysis of receptor steady state mRNA levels by slot blot analysis. Full length cDNAs for VTR-1, VTR-2 and 28-S rRNA were used to make random primed cDNA probes. VTR-1 and VTR-2 mRNA expression levels were normalized relative to 28-S expression for each sample. Corticosterone levels were significantly increased at nine hours post oviposition relative to all other times. Neither VTR-1 nor VTR-2 mRNA levels showed any significant variation over the 24 h cycle, in the brain or pituitary, respectively. Based on these results, we conclude that VTR-1 and VTR-2 steady state mRNA levels do not fluctuate dramatically over the ovulatory cycle of broiler breeder hens. Further work on circadian variations in membrane bound receptor concentrations in the brain and pituitary are currently underway.

Key Words: Vasotocin Receptor, Pituitary and Brain, Corticosterone

ASAS Nonruminant Nutrition: Feed Ingredients and Enzymes

1945 Effect of lactic acid and lactosucrose supplementation in diets for nursery pigs. Acie Murry*¹, Susan Sanchez¹, and Parshall Bush¹, ¹The University of Georgia, Athens.

Swine producers have been adding organic acids to feed for several years. Acidified feed lower the pH of the pig's stomach, inhibit certain pathogenic bacteria, increases nutrient digestibility and results in faster weight gain and more efficient feed conversion. Lactosucrose is considered a nondigestible trisaccharide produced from lactosucrose and sucrose and may be used as a substrate by intestinal bacteria in humans. The influence of these factors has not been documented in nursery pigs. The objective of this study was to evaluate the effects of lactic acid and lactosucrose supplementation in pig's diet on growth performance, feed efficiency and nutrient digestibility. Two experiments with twenty cross bred nursery pigs, average initial body weight 9.6 kg and age 28 days were conducted. All pigs were fed a corn-soybean meal basal diet (18% CP) for a 7-d adjustment period. On day seven after the adjustment period, ten pigs were randomly assigned to receive the basal diet supplemented with either lactic acid (1.8%) or lactosucrose (0.2%) for a 14-d experimental period. Daily feed intake was held constant at 5% of body weight for all pigs in an attempt to reduce the effects of different levels of feed intake on nutrient digestibility. Pigs were weighed every three days and feeding was adjusted according to the pig's individual weight. Pigs fed the lactosucrose diet were heavier (P < 0.04) at d 21 (15.40 vs 14.95 kg), but there was no effect of treatment (P > 0.50) on average daily gain (0.45 vs 0.43 kg), average daily feed (0.57 vs 0.56 kg), or gain:feed ratio (0.80 vs 0.78 kg) for lactosucrose and lactic acid, respectively. Treatment had no effect (P > 0.20) on apparent digestibility of DM (80.96 vs 82.46%), EE (77.45 vs 79.50%), CP (72.30 vs 74.45%), or GE (69.69 vs 69.33%) for lactosucrose and lactic acid, respectively. However, ash digestibility was greater (P < 0.05) for pigs fed the lactic acid diet than for those fed lactosucrose (50.43 vs 43.15%). The results from this study show that growth performance was better in pigs fed the lactosucrose diet, but ash digestibility was lower when compared with pigs fed the lactic acid.

Key Words: Lactosucrose, Lactic Acid, Digestibility, Pigs

1946 The potential for egg by-products to replace spray-dried porcine plasma in early-weaned piglet diets. L.D. Schmidt*, C.M. Nyachoti, D. Boros, and B.A. Slominski, University of Manitoba Winnipeg, MB, Canada.

Egg-breaking facilities produce substantial quantities of egg by-products each year that are unsuitable for human consumption. Due to the excellent amino acid profile, the potential for spray-dried egg proteins to replace spray-dried porcine plasma (SDPP) in early-weaned pig diets was investigated in two 3-week performance trials. In both experiments, 5 pens containing four piglets (17 ± 1d old) stratified by sex were assigned to the experimental diets in a completely randomized design. Experiment 1 comprised of four corn-soy diets containing 7% of either SDPP,

spray-dried technical albumen (SDTA), heat treated SDTA (hot room storage at 70°C for 72h) or spray-dried whole egg (SDWE). Average daily gain (ADG), average daily feed intake (ADFI) and feed conversion ratios (FCR) were determined. In addition, five piglets per treatment were euthanized to determine ileal amino acid and energy digestibilities. Relative to the SDPP diet, ADG (266, 219, 199, 194 g/d), ADFI (323, 304, 277, 278 g/d) and FCR (1.22, 1.38, 1.46, 1.44) were poorer (P<0.05) for SDTA, heat treated SDTA and SDWE, respectively. The SDTA diet had numerically better performance parameters than the other diets containing egg proteins. Apparent ileal digestibility of methionine, lysine and threonine in SDPP and SDTA diets ranged from 80-90% and was generally higher (P<0.05) than in the SDWE diet. Ileal digestible energy content was similar (P<0.05) in all diets (3.1-3.2 Mcal/kg). In the second experiment, the effect of substituting SDPP with 25 or 50% SDTA was investigated. Pig performance was not affected by dietary substitution of SDTA for SDPP as values for control (7% SDPP) and the two SDTA diets were similar (P<0.05) for ADFI (380, 402, 376 g/d), ADG (275, 284, 265 g/d) and FCR (1.38, 1.42, 1.45), respectively. The results suggest that technical albumen can replace 25% of SDPP in early-weaned pig diets without compromising performance.

Key Words: Egg by-products, Nutritive Value, Early-weaned pigs

1947 Comparison of edible grade whey, granular whey, and Dairylac 800 as lactose sources for nursery pig diets. J.M. DeRouchey*, M.D. Tokach, J.L. Nelssen, R.D. Goodband, S.S. Dritz, J.C. Woodworth, and B.W. James, Kansas State University, Manhattan, KS.

A total of 210 pigs (BW of 5.6 kg and 18 d of age) were used in a 14-d growth assay to determine the ability of granular whey or Dairylac 80[®] to replace a high quality, edible grade whey in nursery diets. Pigs were blocked by weight and allotted to one of seven dietary treatments. Treatments included a negative control without lactose and a 2 x 3 factorial consisting of two lactose levels (9 and 18%) and three lactose sources (Edible whey, Land O' Lakes; Granular whey, International Ingredient Corp.; and Dairylac 80[®], International Ingredient Corp.). There were five pigs/pen and six pens/treatment. All diets were pelleted and contained 3% animal plasma and 2% select menhaden fish meal and were formulated to 1.60% lysine. Either edible whey or granular whey (12.5 and 25%) replaced corn and soybean meal in the control diet. Diets containing Dairylac 80[®] were formulated to replace the lactose provided in the dried whey diets. Fish meal replaced the amino acids provided by dried whey to maintain a constant soybean meal level. Pigs fed additional lactose from d 0 to 14 had greater ADG (P<.04) and ADFI (P<.07) compared to pigs fed no supplemental lactose. Pigs fed edible whey had greater ADFI (quadratic, P<.05) and ADG (linear, P<.06) with increasing lactose from 9 to 18%. As granular whey level increased, ADG and ADFI increased (linear, P<.02) over the control diet from d

0 to 7, but not overall. For pigs fed DairyLac 80[®], ADG and ADFI were greater (quadratic, $P < .01$) compared to pigs fed the negative control, while gain/feed improved (linear, $P < .02$) as the lactose level was increased from 9 to 18%. Pigs fed 9% granular whey and DairyLac 80[®] had similar performance to pigs fed 18% edible whey. In conclusion, there were no differences in growth performance between sources of lactose used in this study.

Item	Control		Edible		Granular		DairyLac 80 [®]		SEM
	Lactose, %	0	9	18	9	18	9	18	
Day 0 to 14

1948 Productive performance and carcass characteristics of growing and finishing pigs fed different level of oat groats with and without enzymatic compound. F. Salvador, C. Rodriguez*, F. Nunez, J. Jimenez, O. Ruiz, and A. Alarcon, *Universidad Autonoma de Chihuahua, Chihuahua, Chih. Mexico.*

An experiment was carried out to determine the optimum level of oat groats and the effect of the addition of the enzymatic compound Allzyme Vegpro[®] in growing and finishing pig rations on the productive response and carcass characteristics. Thirty two Yorkshire X Landrace-Duroc pigs distributed in individual metabolic cages with a completely randomized design of a 4x2x2 factorial arrangement were used. Pigs were fed a ration containing 0, 15, 30 and 45% oat groats during the growing (26.0 to 54.5 kg of BW) and finishing period (54.5 to 84.7 kg of BW), with and without one kg Allzyme Vegpro[®] per ton of feed. A tendency to improve ($P < .01$) feed conversion during the whole feeding period by including oat groats in the ration (3.73, 3.46, 3.32 and 3.17 for 0, 15, 30 and 45% oat groats in the ration, respectively) was observed, with a reduction up to 17.9% with the highest oat groats level in the diet. Males showed higher feed intake (9.1%) and daily weight gain (6.3%) than females. Multivariate analysis showed a true effect during the last phase of the finishing period, with a decrease in pig feed intake of up to 250 g/d and an extra daily weight gain of 21 g per pig in animals fed 45% oat groats plus enzymatic compound rations. A tendency to improve cold carcass yield was detected as the ration oat groat level increased but only when the enzyme was added. Males showed 4 mm higher dorsal fat than females. Those animals eating diets with the enzymatic compound showed 3 mm higher dorsal fat than those without enzyme. With higher levels of oat groats in the ration there was a tendency to decrease ($P < .05$) the fat content in muscle. It was concluded that the addition of oat groats to diet of growing and finishing pigs improves the animal productive response showing an increase of up to 9.5% in economic return for every 15% addition of oat groats.

Key Words: Pigs, Oat groats, Enzymes

1949 The effects of pretreating soybean meal with fiber-degrading enzymes on ileal and total tract digestibility by growing pigs. K. L. Saddoris*, M. R. Smiricky, D. M. Albin, V. M. Gabert, and M. R. Murphy, *University of Illinois, Urbana.*

Soybean meal (SBM) contains fibrous components that are poorly digested by pigs. Pigs do not produce the endogenous enzymes necessary to digest the fibrous components of SBM, so fiber-degrading enzymes such as arabinase, cellulase, alpha-galactosidase, hemicellulase, pectinase, and xylanase can be used in an attempt to degrade these components. Four barrows (avg. BW = 75 kg) were surgically fitted with a prececal simple-T cannula and randomly assigned to a 2 x 2 crossover design to evaluate the influence of pretreating SBM with fiber-degrading enzymes on nutrient digestibility. The cornstarch-soybean meal-based diets were formulated to contain 17% CP. Chromic oxide (0.3%) was added as an indigestible marker for determination of nutrient digestibilities. A control cornstarch-soybean meal diet was compared to a diet containing SBM pretreated with enzymes. The pretreatment consisted of dilution with deionized, distilled water at a 1:4 ratio and incubation at 50C, pH 5 for 18 hr with 8.5 g each of the following enzymes/kg of SBM: arabinase, cellulase, alpha-galactosidase, hemicellulase, pectinase,

and xylanase. Pigs were fed 2.28 and 2.44 kg/d for periods 1 and 2, respectively, in 2 equal feedings at 0800 and 2000 h. The experimental period lasted 7 d, with 5 d of diet adaptation, fecal collection on d 6, and ileal digesta collection on d 7. Diets, feces, and digesta samples were analyzed for DM, OM, CP, AA, and chromic oxide concentrations. Enzyme pretreatment increased ($P < 0.08$) ileal digestibility of DM, OM, Asp, Glu, Lys, and total tract digestibility of OM, N, Asp, Thr, Ser, Gly, Val, Phe, His, Lys, Ile, and Tyr. Enzyme pretreatment tended ($P < 0.15$) to increase ileal digestibility of Pro, Val, Ile, Leu, and total tract digestibility of DM, Glu, Pro, and Leu. In conclusion, enzyme pretreatment of SBM increased DM and AA digestibilities of cornstarch-soybean meal diets fed to growing pigs.

Key Words: Pigs, Enzymes, Soybean meal

1950 Evaluation of a carbohydrase combination on performance in growing-finishing pigs. M. D. Lindemann¹, G. A. Apgar², T. Guthrie*², G. L. Cromwell¹, H. J. Monegue¹, K. E. Griswold², and N. Inocencio¹, ¹University of Kentucky, Lexington, ²Southern Illinois University, Carbondale.

Arabinoxylans increase digesta viscosity and decrease digestibility. A bacterial enzyme product which contained endo-1,4- β -xylanase and β -glucanase (105 and 50 IU/g) was used to evaluate its potential for improvement of performance of growing-finishing pigs fed a fortified corn-soy diet (which typically contains 4-5% arabinoxylans). A total of 192 pigs were used in two experiments (Exp. 1: SIU, n=112 crossbred pigs, 45.6 kg BW; Exp. 2: UK, n=80 crossbred pigs, 34.7 kg BW) to evaluate graded levels of the product (0, 80, 100, and 120 mg/kg) on growth performance and carcass characteristics to a market weight of 112.8 kg. Pigs were housed seven/pen at SIU for a total of four replicates and four/pen at UK for a total of five replicates. The diet was formulated to 0.86% lysine; lysine levels were reduced to 0.68% and 0.55% at 58 and 82 kg, respectively. Diets were fed in meal form. All pigs were scanned by real-time ultrasound at 110 kg. There were no experiment x diet interactions for any criteria ($P = .20$). Performance for the initial grower period was improved (linear, $P < .02$) for ADG (940, 982, 962, and 1,022 g) but not ($P = .10$) for ADFI (2.24, 2.26, 2.31, and 2.31 kg) or F/G (2.37, 2.30, 2.39, and 2.26). For the total study, ADG (856, 896, 866, and 875 g), ADFI (2.67, 2.77, 2.74, 2.74 kg), and F/G (3.12, 3.10, 3.16, and 3.13) did not differ ($P = .10$) due to enzyme inclusion. Carcass characteristics (adjusted to 104 kg) did not differ ($P = .10$) with regard to backfat depth (20.8, 21.8, 21.1, and 20.8 mm), longissimus area (39.7, 40.6, 40.6, and 40.2 cm²), or scanned lean (52.4, 51.8, 52.4, and 52.5%). Lean gain (352, 360, 356, and 359 g/d) did not differ ($P = .10$) among dietary treatments. The greatest potential for a product directed at arabinoxylans would appear to be in the earlier stages of the grow-finish period.

Key Words: Pigs, Performance, Enzymes

1951 Amino acids ileal digestibility of hullless barley, barley and sorghum grains in growing pigs. G. Mariscal-Landin*¹ and J. E. Rodriguez², ¹C. N. I. Fisiologia y Mejoramiento Animal, INIFAP, ²Nutrientes Basicos de Monterrey, S.A. de C.V. NL, Mexico.

Nutritive value of grain sorghum, barley and hullless barley was assessed in 2 experiments. In Exp. 1, 4 barrows of initial BW of 40 kg were fitted with simple T cannulae at the terminal ileum. In a 4x4 Latin square arrangement, pigs were fed 4 diets formulated to 16% CP: corn-starch+soybean meal (SBM); sorghum+SBM (SSB); hullless barley+SBM (HBS) and barley+SBM (BAS). Amino acids apparent digestibility was measured using the difference method. A 6-d adaptation period was followed by a 48-h phase, sampling digesta in 2-h intervals. Pigs were fed in 2 meals (0800 and 1700 h) at 2.5x their DE maintenance requirement (110 Kcal of DE/kg^{.75}). Lys apparent digestibility was greater ($P < .05$) for SBM, 86.3 > SSB, 51.6 = HBS, 49.7 and BAS, 55%. Similar differences were found for Thr, SBM, 80.2 > SSB, 55.5 = HBS, 55.5 and BAS, 54.8%; Met, SBM, 87.9 > SSB, 64.6 = HBS, 70.0 and BAS, 66.9% and for most of the amino acids. Experiment 2 was a growth performance trial, in which sorghum grain was substituted by hullless barley at 0, 34, 66 and 100% of the total cereal grains in the diet (*i.e.*, 4 experimental diets). Initial weight of the pigs was 39.3 \pm 4.8 kg and the observation period was of 77-d. Barrows ate more ($P < .001$) than gilts: 2.57 vs 2.31 kg/d. Avg. of daily gain was similar ($P > .05$), a mean response of .751 kg, but gain:feed ratio was progressively improved

as hullless barley substituted sorghum: .293, .299, .316 and .328 kg. Differences in gain:feed between sexes were a direct response to feed intake. Lean eye area resulted in an diet x sex interaction ($P < .05$): barrows fed the higher concentration of sorghum (0 and 34% hullless barley) showed the lowest values: 20 and 23 cm², while the rest had a mean value of 28 cm². Considering apparent amino acid digestibility, sorghum and hullless barley are of similar nutritive value, but performance in response to hullless barley could be explained in terms of the better amino acid profile and the ME value.

Key Words: Sorghum grain, Barley grains, Amino acids digestibility

1952 Effects of Fibrozyme[®] supplementation on ileal and total tract digestion of nitrogen and energy by finishing pigs fed diets containing a fibrous soy co-product. M. R. Smiricky^{*1}, D. M. Albin¹, V. M. Gabert¹, H. Yang², and R. Dvorak³, ¹University of Illinois, Urbana, IL, ²ADM Feed Products Group, Quincy, IL, ³Alltech, Inc., Nicholasville, KY.

Fibrous components in swine diets are incompletely digested and are poorly utilized energy sources. Pigs do not produce the enzymes necessary to hydrolytically digest fibrous components of the diet. Fiber-degrading enzymes, such as Fibrozyme[®], have been used in an attempt to degrade these components. Four barrows (avg. initial BW = 85 kg) were surgically fitted with a prececal simple T-cannula and randomly assigned to a 2x2 crossover design to evaluate the influence of Fibrozyme[®] on nutrient digestibility. The corn-soybean meal-based diets were formulated to contain 12.5% CP, and a fibrous soy co-product containing 27% NDF (as-fed basis), was included at a level of 10% to test the effectiveness of the enzyme source. Chromic oxide was added as an indigestible marker for determination of nutrient digestibilities. The 2 treatments were a control diet and a diet containing 0.022% Fibrozyme[®] (as-fed basis), an enzyme supplement containing a minimum of 100 xylanase units/g, added at the expense of corn. The pigs were fed twice daily (0800 and 2000 h, 1.5 kg/meal). The experimental period lasted 7 d, with 5 d diet adaptation, fecal collection on d 6, and ileal digesta collection on d 7. Diets, feces, and digesta samples were analyzed for DM, OM, CP, GE, and chromic oxide concentrations. Dietary treatment did not significantly affect apparent ileal or total tract digestibilities of any of the parameters measured. However, there was a numerical increase in apparent ileal and total tract digestibilities when Fibrozyme[®] was added to the control diet. The increase in digestibility ranged from approximately 0.3 to 5 percentage units. In conclusion, Fibrozyme[®] numerically improved apparent ileal digestibilities of DM, OM, N, and GE of pigs fed a corn-soybean meal diet containing a fibrous soybean co-product.

Key Words: Pigs, Enzymes, Digestibility

1953 Effects of dietary supplementation of crude inulin extract on the emission of volatile sulfides from manure slurry of growing-finishing pigs fed corn and soybean meal-based diets. T.C. Rideout¹, M.Z. Fan¹, Y. Gao¹, C. Wagner-Riddle¹, J.P. Cant¹, P. Stonehouse¹, G. Sheffrin², R. Cook², B. Raines², and R.R. Hacker¹, ¹University of Guelph, ²Qtf Foods, Inc..

A balanced two-period changeover experiment was conducted with 6 Yorkshire barrows, average initial BW of 30 kg, to determine the effect of crude inulin, extracted from Ontario grown chicory, on the emission of volatile sulfides from swine manure slurry. Two corn and soybean meal (SBM)-based dietary treatments, a control diet containing no inulin extract and a treatment diet containing 5% crude inulin at the expense of cornstarch, were formulated to contain 16% CP from corn (51%) and SBM (29%). Each period lasted for 14d with 10-d adaptation and 4-d collection of total urine and representative fecal samples. At the end of each period, fresh manure slurry was prepared by mixing the collected feces and urine at a ratio of 1:2.5 (wt/wt). Accumulative sulfide emission was measured over a 7-d period in an in vitro system that trapped the emitted sulfide gas in a cadmium sulfate-based solution. Samples of the trapping solution were taken at specified time points (0, 4, 19, 24, 48, 96, 144, 168 h, respectively) over the 7-d emission period at room temperature. The amount of total sulfides trapped in the solution was determined in hydrogen sulfide unit through a spectrophotometric-based procedure. Inclusion of the inulin at 5% reduced ($P < 0.01$) the 168-h cumulative hydrogen sulfide emission rate by 36.4% in comparison with the control (14.96 vs. 22.69 mg H₂S/kg DM slurry/h). In conclusion, dietary supplementation of the crude inulin extract at a 5% dietary level

is effective in reducing the emission of odour-causing volatile sulfides into the environment.

Key Words: Inulin, Sulfide emission, Growing-finishing pigs

1954 Efficacy of mannan oligosaccharide (Bio-Mos[®]) addition with two levels of copper sulfate in the diets of growing-finishing pigs. M. E. Davis^{*1}, C. V. Maxwell¹, B. Z. de Rodas², D. C. Brown¹, Z. B. Johnson¹, and R. A. Dvorak³, ¹University of Arkansas, Fayetteville, ²Land O'Lakes Inc., Fort Dodge, IA, ³Alltech, Nicholasville, KY.

An experiment involving 144 crossbred barrows and gilts was conducted to determine the efficacy of Bio-Mos[®] in improving performance of growing-finishing pigs fed diets devoid of antibiotics and with and without growth promoting levels of CuSO₄. Pigs were moved from a nursery facility, sorted by BW and divided into six weight groups with 24 pigs in each group. Pigs within each group were allotted into four pens (6 pigs/pen) and stratified based on sex and litter. Treatments were randomly assigned to pens within each weight group (6 pens/treatment). Dietary treatments were fed throughout the starter (20 to 32 kg BW), grower (32 to 68 kg BW), and finisher (68 to 106 kg BW) phases. Diets consisted of two levels of CuSO₄ (10 ppm in starter, grower, and finisher diets vs. 175 ppm in starter and grower diets and 125 ppm in finisher diets) with and without Bio-Mos[®] (0 vs. 0.2% in starter, 0.1% in grower, and 0.05% in finisher). Average daily gain and gain:feed (G/F) improved ($P < 0.02$) in the starter phase when pigs were fed diets containing 175 ppm CuSO₄ compared to pigs fed 10 ppm CuSO₄. Gain:feed was greater ($P < 0.02$) in the grower phase when pigs were fed 175 ppm CuSO₄ compared to pigs fed 10 ppm CuSO₄. During the finisher phase, ADG improved with the addition of Bio-Mos[®] when pigs were fed 10 ppm CuSO₄, but decreased when Bio-Mos[®] was supplemented in diets containing 175 ppm CuSO₄ (interaction, $P < 0.04$). In the overall experiment (20 to 106 kg BW), ADG and G/F improved ($P < 0.03$) when pigs were fed diets supplemented with 175 ppm CuSO₄ when compared to pigs fed diets containing 10 ppm CuSO₄. The results of this experiment indicate that CuSO₄ supplemented in growing-finishing diets improves gain and efficiency. Additionally, Bio-Mos[®] improves gain when supplemented in growing-finishing diets without antibiotic addition, although the magnitude of response is not as great as that observed with CuSO₄ addition.

Key Words: Swine, Mannan oligosaccharide, Copper

1955 Dietary fiber level and xylanase affects nutrient digestibility and waste production in grower pigs. A.J. Moeser^{*} and T.A.T.G. van Kempen, North Carolina State University.

An experiment was conducted with twelve grower pigs to determine if lowering dietary NDF, through selection of available feedstuffs or dietary addition of xylanase, can provide an effective and practical approach for reducing nutrient excretion in pigs. Four diets were formulated, using least cost ration principles, to contain equal digestible lysine to ME ratios and three levels of dietary NDF: 1) control corn soybean meal diet (10.3% NDF), 2) low NDF diet (2.6% NDF) based on degermed, dehulled corn (79%), corn gluten meal (11.5%), meat and bone meal (5%), and blood meal (2.5%), 3) high NDF diet (18.4% NDF) based on corn and soybean meal with 20% soybean hulls, and 4) diet 3 + 0.2% xylanase. Diets were tested in a balance experiment using a 4X4 Latin square design in which each experimental period consisted of a 4-d dietary adaptation period followed by a 3-d data collection period. Lowering dietary NDF increased the digestibility of DM and GE (by 5 and 4%, respectively) but did not affect the digestibility of nitrogen (N) compared to the control diet ($P < 0.01$). Increasing dietary NDF reduced the digestibility of DM by 8%, GE by 8%, and N by 13% compared to the control ($P < 0.01$). Addition of xylanase improved the digestibility of DM and GE by 2 and 3%, respectively ($P < 0.01$) while a trend for improved digestibility of N was observed. Lowering dietary NDF reduced fecal production by 35% compared to the control ($P < 0.01$). Increasing dietary NDF increased fecal production by 36% compared to the control ($P < 0.01$). Addition of xylanase reduced fecal production by 10% in high NDF diets ($P < 0.01$). In conclusion, lowering dietary NDF level and dietary inclusion of xylanase may offer relatively practical and easy methods for reducing waste production in pigs.

Diet	Control	Low NDF	High NDF	High NDF + xylanase	SE
Digestibility, %					
Dry matter	88.2 ^b	92.3 ^a	81.6 ^d	83.5 ^c	0.63
Gross energy	87.6 ^b	91.3 ^a	80.4 ^d	82.5 ^c	0.65
Nitrogen	86.6 ^a	85.6 ^a	75.4 ^b	77.5 ^b	0.95
Fecal production, % of DMI	11.8 ^c	7.7 ^d	18.4 ^a	16.5 ^b	0.63

1956 Wheat specific weight or added enzyme did not affect weaner performance. H.M. Miller¹, P. Toplis², and P. Blanchard³, ¹University of Leeds, School of Biology, Leeds, LS2 9JT, ²Primary Diets Ltd., Melmerby, HG4 5HP, UK, ³Frank Wright Ltd., Ashbourne, DE6 1HA, UK.

Livestock industries in many countries use specific weight to indicate nutritive value of grain. The aim of this experiment was to compare 2 specific weights of Riband wheat (64 vs 78 kg/hl) when fed to weaned piglets with or without xylanase enzyme. To amplify possible differences wheats were uncooked and included in the test diets at an atypically high level. We hypothesised that 78 kg/hl specific weight would outperform 64kg/hl specific weight and that enzyme supplementation would improve performance of both wheats. One hundred and twenty eight 21 0.2d old piglets (62.5% Large White, 25% Landrace, 12.5% Duroc) were weaned at 6.3 0.2 kg liveweight into fully slatted flat deck pens. Piglets received no creep feed pre-weaning. Eight piglets were allocated to each pen (1.37 m x 1.43 m) on the basis of litter, liveweight and sex. The experiment was a 2 x 2 factorial design with Riband fed at 2 specific weights, 64 and 78 kg/hl, with or without enzyme. Four pens were randomly allocated to each of the 4 treatments. All diets contained ZnO (Zn 2500 ppm) and were formulated to contain 50% wheat, 16.25 MJ DE/kg, 1.63% total lysine. Enzyme was added to provide 5,500 xylanase units/kg feed and 600 β -glucanase units/kg feed. Piglets were individually weighed at 0, 7, 14 and 20d post-weaning. Food and water were provided ad libitum throughout the 20d trial. Data were analysed using the GLM procedure of Minitab 12.2. Growth rate (282 11 g/d), feed intake (291 10 g/d) and feed conversion ratio (1.04 .02) were similar for all treatments throughout the trial. End weight after 20d was not different between treatments (11.9 .24 kg). The low bushel weight wheat did not reduce piglet performance, neither did enzyme inclusion improve it. Despite the high inclusion of wheat, piglet performance was typical for the experimental unit. Use of specific weight as an indicator of nutritive value is questioned.

Key Words: Specific weight, Piglets, Wheat

1957 Efficacy of Allzyme Vegpro in swine diets. L. J. Johnston¹, H. G. Jung², J. A. Wilson¹, and J. E. Pettigrew³, ¹University of Minnesota, Morris, ²USDA-ARS, St. Paul, ³Pettigrew Consulting International, Louisiana, MO.

A growth performance (Exp. 1) and a digestibility (Exp. 2) experiment were conducted to determine the efficacy of an enzyme preparation, Allzyme Vegpro[®], in diets for nursery pigs containing soybean meal (SM; 44% CP) or dehulled SM (DSM; 47% CP). Vegpro contains protease, cellulase, pentosanase, α -galactosidase, and amylase activity. Pigs (n = 200) were weaned at about 19 d of age for Exp. 1. After consuming a common phase 1 diet for 12 d, pigs were blocked by weight and allotted to 20 pens. Pens were assigned randomly within block to one of four diets in a 2 x 2 factorial arrangement of treatments. Main effects were inclusion of Vegpro (-V or +V) and type of SM. Vegpro was included in phase 2 and 3 diets at .14 and .17%, respectively. Pigs had ad libitum access to phase 2 (1.2% lysine) and 3 (1.1% lysine) diets that were marginal in lysine concentration for 2 and 3 wk, respectively. Pigs fed DSM grew faster (P < .05) than those fed SM regardless of Vegpro inclusion (.529 vs .475 kg/d; SE = .019). An interaction (P < .01) between Vegpro addition and SM type was observed for feed efficiency (1.724, 1.774, 1.692, 1.608 for -V/SM, +V/SM, -V/DSM, and +V/DSM, respectively). In Exp. 2, barrows (n = 20) were weaned at about 18 d and housed individually in stainless steel cages. Pigs received a common phase 1 diet for 14 d then were assigned randomly within litter to the same phase 2 diets as used in Exp. 1. A 7-d adjustment period preceded a 5-d total collection period to determine energy and nitrogen balance.

Nitrogen retention (91.23, 92.04, 89.47, 91.81%; SE = .014) and ME (91.52, 91.44, 90.58, 90.96% of GE; SE = .71) were not influenced by diet. Addition of Vegpro tended to reduce (P < .10) digestibility of total dietary fiber polysaccharide (72.6, 66.9, 70.5, 65.8%; SE = 2.72). Addition of Allzyme Vegpro to corn-soybean meal based diets did not improve growth performance of nursery pigs or digestibility of dietary energy or nitrogen.

Key Words: Swine, Enzymes, Digestibility

1958 Beneficial effect of using a blend of flavoring substances in promoting appetite and growth performance in weaned piglets. A. Piva¹, M. Morlacchini², F. Galvano³, and A. Prandini⁴, ¹University of Bologna, Ozzano Emilia, Italy, ²CERZOO, Piacenza, Italy, ³University of Reggio Calabria, Reggio Calabria, Italy, ⁴Universita' Cattolica del S. Cuore, Piacenza, Italy.

The ban on the use of certain antibiotic feed supplements instituted or planned in several countries has renewed the interest in exploring alternatives to the use of antibiotic growth promoters. The aim of the present study was to investigate a blend of natural and natural identical flavoring substances in promoting appetite and growth performance in weaned piglets. The trial was conducted using 40 weaned piglets (9.31.60 kg BW) divided in 2 homogenous groups and fed the experimental diets for 56 days. The control group received a conventional diet containing 500 g/ton of formic acid and 1500g/ton of lactic acid (CTR diet); the experimental group was fed the CTR diet containing 2 kg/ton of HerBioticTM HB (HB diet). Feed intake was recorded and pigs were individually weighed at 14, 35, and 56 d after the study commenced. Differences between the dietary treatments were already observed after 14 days of the trial in terms of average daily gain (ADG: 218 vs 268 g/d for CTR and HB, respectively; +22.9%; P<0.05) and live weight (12.4 vs 13.1 kg; P<0.05). During the study, ADG was improved by HB (378 vs 439 g/d; +16.1%; P<0.01) with a noticeable increase in ADG in the period 36-56 d (440 vs 525 g/d for CTR and HB, respectively +19.3%; P<0.05). The feed intake was higher in HB than in CTR fed animals in the periods 0-14 and 0-35 days by 20.7% (P<0.01) and by 12% (P<0.01), respectively, with no statistical difference thereafter. The feed efficiency was higher only in the period 36-56 days of the trial in HB fed animals (1.68 vs 1.91 kg feed/kg weight gain; P<0.05). Overall there was a substantial decrease in time to reach 30 kg l.w. (-8 days) in animals fed the HB diet. In conclusion, compared to the control group fed an acidified diet animals fed HerBioticTM HB displayed improved feed intake and growth performance.

Key Words: Additive, Botanical, Pig

1959 Effect of plant extracts on the performance and lower gut microflora of early weaned piglets. E.G. Manzanilla¹, F. Baucells¹, C. Kamel², J. Morales¹, J.F. Perez¹, and J. Gasa¹, ¹Universidad Autonoma de Barcelona, ²AXISS France, S.A.S. Archamps, France.

Two hundred and forty early (20±2.0 d) weaned piglets (5.4±0.4 kg LW) were randomly distributed in 24 replicates to carry out a 3x2 experimental design. Three diets were formulated with the same proportion of cereals (42%), milk by-products (25%), and porcine plasma (4%) but differing in crude protein (CP) level and source: FM-18 (18% CP, LT fish meal 10%); partially replaced (SBM-18; FM 5% plus SBM 9%) or supplemented (SBM-20; FM 10% plus SBM 6.3%) with full fat SBM. Diets were supplemented with or without 200 ppm of XTRACTTM, a commercial product based on plant extracts, and with chromium oxide (0.15%) as a digestibility marker. After a 14 days production experiment, the feeding cycle followed a 4-day adjustment period of piglets on ad-libitum feeding half an hour over a one hour and a half periods from 8:00 am to 8:00 pm, and *ad-libitum* over the remainder of the day; on day 5 eight piglets per treatment were slaughtered and jejunum digesta, *enterobacteria* and *lactobacilli* counted (log₁₀/g fresh weight content). Feed Intake (FI, g/d), Average Daily Gain (ADG, g/d) and Organic Matter Digestibility (OMD) were unaffected by diet (p≥0.10). However, FM-18 showed lower Gain to Feed (G/F) ratios (0.67 vs 0.76 or 0.77, p=0.01) and SBM-20 higher CP digestibility (0.849 or 0.861 vs 0.876, p=0.08). Supplementation of XTRACTTM did not affect significantly FI (243.0 vs 248.5), ADG (179.8 vs 178.6), G/F (0.74 vs 0.72) and OM (0.888 vs 0.890) or CP (0.864 vs 0.860) digestibilities. The microbial counts were unaffected by the diet but XTRACTTM promoted a slight but not significant decrease in *enterobacteria* (6.52 vs 6.29,

$p=0.51$) coupled with a significant increase in *Lactobacilli* (5.69 vs 6.26, $p=0.02$). Differences were specially pronounced with the low CP diets (FM-18, SBM-18). It is speculated that microbial differences could improve the digestive stability of the animals and affect performance in a longer time or with stronger stress conditions.

Key Words: Plant extracts, Weaned piglets, *Lactobacilli*

1960 Limiting amino acids in wheat for growing pigs. M. Cervantes*¹, A. Pichardo², M. Cuca², M. Cervantes¹, A.B. Araiza¹, and N. Torrentera¹, ¹Universidad Autónoma de Baja California, Mexicali, Mxico, ²Colegio de Postgraduados, Montecillos, Mxico.

An experiment was conducted to determine the order of the first limiting amino acids (AA) in wheat for growing pigs. Thirty crossbred (Landrace x Yorkshire x Duroc) pigs (22.5 kg initial body weight) were assigned to 5 dietary treatments according to a randomized complete block design. Wheat was the sole source of dietary protein and energy in the test diets. Treatments were: T1) 97.1% wheat, basal diet, T2) + .46% L-lysine, T3) + .46% L-lysine + .14% L-threonine, T4) +.46% L-lysine + .14% L-threonine + .05% DL-methionine, T5) control, wheat-soybean meal diet formulated to contain .83% lysine. Crystalline lysine, threonine and methionine were added, at the expenses of corn starch, to rise their dietary content to .83, .54 and .25% (.54% methionine+cystine), respectively. Vitamins and minerals were added to meet or exceed the requirements for the 50-80 kg pigs. Feed and water were provided ad libitum. Daily gain, feed intake, feed/gain ratio, and intakes of lysine, threonine and methionine were: 241, 430, 598, 615, 513 g/d; 1.24, 1.75, 1.85, 1.93, 1.80 kg/d; 5.29, 4.35, 3.07, 3.18, 3.53; 4.6, 14.6, 15.3, 16.0, g/d; 4.7, 6.7, 9.6, 10.3, g/d; 2.6, 3.7, 3.9, 5.2, g/d, respectively. Lysine addition to the basal diet increased ($P<.05$) daily gain, and intake of feed, lysine, threonine, and methionine; it also improved ($P<.05$) feed/gain ratio. Threonine addition to the lysine-added basal diet resulted in a further increment of growth rate and threonine intake, and improved ($P<.05$) feed/gain ratio. Further addition of methionine increased methionine intake, but the performance of the pigs was not additionally improved. However, the growth rate tended to increase ($P<.15$) as a result of methionine addition. The performance of pigs fed the control, wheat-soybean meal diet was similar to that of pigs fed the lysine-threonine-added diet. These data indicate that lysine and threonine are the first and second limiting AA, respectively, in wheat for growing pigs. Methionine appears to be marginal in wheat-diets for growing pigs.

Key Words: Pigs, Wheat, Limiting amino acids

1961 Comparative nutritional value of wheat, grain sorghum and corn in diets for finishing pigs. A.B. Araiza, M. Cervantes*, S. Espinoza, N. Torrentera, and M. Cervantes, Universidad Autónoma de Baja California, Mexicali, Mxico.

Two experiments, involving 60 crossbred pigs, were conducted to evaluate the comparative nutritional value of three cereal grains (wheat, grain sorghum, and corn) in diets for finishing pigs, under two different weather conditions. Thirty finishing pigs were used in each experiment (59.6 and 53.2 kg initial body weight, respectively), according to a complete randomized block design. Dietary treatments, in both experiments, were as follows: T1) wheat-soybean meal, T2) grain sorghum-soybean meal, and T3) corn-soybean meal; there were five 2-pig replicates per treatment. All diets were formulated to meet the lysine requirement of pigs between the 50-80 kg range weight; vitamins and minerals were added to meet or exceed the requirement. Exp. 1 was conducted during late fall (11.9 and 24.3°C, average low and high, respectively), whereas Exp. 2 was conducted in early summer (19.4 and 38.3°C, average low and high, respectively). Feed and water were provided ad libitum. In Exp. 1, daily gain, feed intake, feed/gain, lysine intake, threonine intake, gain/lysine intake, and gain/threonine intake were: 858, 874, 837 g/d; 2.54, 2.59, 2.67 kg/d; 3.02, 2.99, 3.30; 16.5, 16.8, 17.4 g/d; 13.7, 14.0, 13.6 g/d; 52.2, 53.5, 48.7 g/g; 62.8, 64.4, 62.1 g/g, respectively. There was no difference ($P>.10$) in daily gain, feed intake, feed/gain ratio, lysine intake and threonine intakes, and gain/lysine and gain/threonine ratios, between pigs fed either the wheat-, the grain sorghum- or the corn-based diets, during the winter time. In Exp. 2, ADG, feed intake, feed/gain, lysine and threonine intakes, gain/lysine intake, and gain/threonine intake were: 718, 706, 775 g/d; 2.23, 2.40, 2.42 kg/d; 3.19, 3.42, 3.17; 14.5, 15.6, 15.8 g/d; 12.1, 12.9, 12.4 g/d; 50.3, 45.5, 50.0 g/g; 60.5, 54.8, 63.7 g/g, respectively. As in

Exp. 1, the performance of pigs in this study was not affected ($P>.10$) by the type of cereal grain used in the diet. In average, daily weight gain was higher ($P<.05$) and the feed/gain ratio was better ($P<.05$) during the winter as compared with the summer season. No difference was observed in gain/lysine or gain/threonine ratios between seasons. These data indicate that pigs fed wheat-based diets containing around 50% less soybean meal can perform as well as those fed grain sorghum- or corn-based diets.

1962 Time response effects of cornstarch and raw potatoe starch on the whole-tract digestibility and digestive tract adaptation in growing (20-60 kg) pigs. D. Martinez-Puig¹, J. Morales*¹, J.F. Perez¹, S.M. Martin-Orue¹, and M.D. Baucells¹, ¹Universidad Autónoma de Barcelona.

Twelve growing pigs (Landrace, initial BW 26±3.6) were fed on two diets (6 animals /each) based on ground barley (29%), soybean meal (33%) and purified starch (25%), obtained from either corn (diet C) or raw potatoe (diet P), and characterized by their different content in resistant starch (52g/kg, diet C; 143g/kg, diet P). Diets were offered twice daily at 90% of the predicted voluntary intake. Chromium oxide (0.15%) was incorporated as a flow marker for OM digestibility (OMD) measurements. The experiment lasted 38d reaching the animals an average final weight of 54 kg (55.5 v. 52.9 kg for diet C and P, $P=0.11$). Faecal samples were obtained at day 7, 14, 21 and 38 for the estimation of the whole-tract OMD. On day 27, single doses of Co-EDTA and Cr mordanted wheat bran were administered and the total tract mean retention time (TMRT) was estimated from the faecal marker excretion. On day 38, animals were slaughtered, the whole gut excised, and the stomach, small intestine, caecum and colon ligated, removed and weighed. Whole tract OMD was significantly higher ($P\leq 0.01$) for diet C than diet P on d7 (0.835 v. 0.778) and d14 (0.864 v. 0.790). However, a progressive increase was observed on the diet P digestibility on day 21 ($P=0.08$) and 38, reaching a value on d38 lower but not significantly different from corn (0.861 v. 0.842, $P=0.18$). Hindgut adaptation to diet P was also evidenced by the significant heavier weight of the full digestive tract (7031 v. 8115g, $P\leq 0.05$), full colon (2267 v. 3255g, $P\leq 0.001$), colon digesta (1230 v. 1990g, $P\leq 0.001$) and colon length (3.44 v. 4.12m, $P\leq 0.05$). Despite these results, no significant differences were observed on the TMRT of Cr and Co between diets (Cr, 37.5 v. 42.2h; and Co, 35.9 v. 40.3h for Diet C and P, respectively). It is concluded that a long term period appears necessary to the growing pigs for hindgut adaptation to ferment resistant starch.

Key Words: Resistant starch, Digestive adaptation, Growing pig

1963 Performance and caecal microbial activity of growing rabbits fed different starch levels. A. M. V. Arruda*¹, R. D. Carregal², R. G. Ferreira², and E. S. Pereira¹, ¹Universidade Estadual Oeste Parana, ²Universidade Estadual de Sao Paulo, Brazil.

To evaluate the influence of dietary starch levels on the performance and caecal microbial activity in growing rabbits, four experimental diets were formulated to contain increasing corn starch levels (23, 28, 33 and 38 % total starch levels on a DM basis). White New Zealand rabbits (n=32) were used in a randomized block design. The results showed a decreasing linear effect ($P<0.01$) on food intake and food conversion, where the better rate (108.67 g/d and 3.216, respectively) were obtained with 38% total starch level. However, differences for weight gain and carcass yield were not observed. Regarding caecal microbial activity, pH and VFA production were not significantly affected by the treatments, but the propionic acid concentration showed a decreasing linear effect ($P<0.05$) with the higher molar proportion (12.06 %) observed in the rabbits fed the 23% total starch level. It can be concluded that the starch of corn grain has a higher influence on the caecal microbial activity than purified maize starch, but without significant changes on the performance and carcass yield.

Key Words: Rabbits, Starch, Volatile fatty acids

1964 Apparent digestibility of diets with different starch levels to growing rabbits. A. M. V. Arruda*¹, R. D. Carregal², R. G. Ferreira², and E. S. Pereira¹, ¹Universidade Estadual Oeste Parana, ²Universidade Estadual de Sao Paulo, Brazil.

To evaluate the influence of dietetic starch level on the nutrients apparent digestibility in young rabbits, four experimental diets were formulated to contain increasing corn starch levels (23, 28, 33 and 38 %, total starch levels in dry matter basis). For the digestibility trial, it was used 20 White New Zealand rabbits, assigned to metabolism cages, following a complete randomized design. The results showed a crescent linear effect ($P < 0.01$) to the coefficients of apparent digestibility for DM, OM, NDF and Starch, while that increased dietetic starch level in the experimental diets, where it was verified that the best digestibility (87.26%) was obtained with the 38% of dietetic starch level. It was not observed significant differences to the coefficients of apparent digestibility for CP, CE and ADF by the different starch levels in the experimental diets. However, the best digestibility of fat (89.46 %) was verified with the animals receiving 23% of dietetic starch level. Through this study, it can be concluded that rabbits were efficient in digesting purified starch maize, when this ingredient have a high participation in total carbohydrate fraction of the diets.

1965 Studying the effect of protein sources on meat quality of pigs using discriminant analyses. Cs. Szabo¹, A.J.M. Jansman², L. Babinszky*¹, E. Kanis³, and M.W.A. Verstegen³, ¹University of Kaposvr, Department of Animal Nutrition, Kaposvar, Hungary, ²ID-TNO Animal Nutrition, Lelystad, The Netherlands, ³Wageningen Institute of Animal Sciences (WIAS), Wageningen, The Netherlands.

Effect of four protein sources (soybean meal, sunflower meal, pea and fish meal as the main protein source) in pig diets on meat quality traits were investigated. A total of 96 individually housed animals (24 per treatment in equal number of barrows and gilts) received the diets from 30 to 105 kg live weight at a level of 3.0 times maintenance requirements of energy. The diets were formulated based on ileal digestible amino acid and ideal protein concepts. At slaughter (105 kg) the traits were determined: lean meat percentage, intramuscular fat content, pH at 45 min and 24 h after slaughter, water loss, meat color (CIELAB) measured 24 h and 4 d after slaughter. The statistical analyses were carried out with GLM and DISCRIM procedures of SAS. Significant difference was not found between protein source treatments regard to ADG, FCR and meat quality. After eliminating the variables having multicollinearity ($r > 0.8$) seven variables remained for discriminant analysis (lean meat percentage, pH₄₅, pH₂₄, WL, L₂₄, Hue₄, IMF). If observations were classified by chance, a 25% accuracy would be expected for the four protein source groups. The animals classified with a 42-74% accuracy to the right treatment based on the traits used. The value of Wilks' lambda (0.77) show a good discrimination, however, it was not significant ($P = 0.38$). These results indicate that although no significant differences could be detected regarding individual variables, an overall effect of protein sources on meat quality probably exists. Similar fattening performance can be expected if protein sources are substituted on the basis of ileal digestible amino acid content and ideal protein concept.

Key Words: Meat quality, Pigs, Protein sources

1966 Feeding value in broiler chicken diets of a potato expressing a β -glucanase from *Fibrobacter succinogenes*. J. Baah*¹, T. A. McAllister¹, T. A. Scott², L. M. Kawchuk¹, J. D. Armstrong³, L. B. Selinger⁴, and K.-J. Cheng⁵, ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, ²Pacific Agri-Food Research Centre, Agassiz, BC, ³Pacific Agri-Food Research Centre, Summerland, BC, ⁴University of Lethbridge, Lethbridge, AB, ⁵Academia Sinica, Taipei, Taiwan.

A transgenic potato cultivar was evaluated as a source of glucanase in barley-based diets for broiler chickens. Six broiler bioassay diets were formulated from each of two barley cultivars, CDC Silky and Falcon. Diets were unsupplemented (control), supplemented with a commercial poultry enzyme (Avizyme), or had 0.6 or 1.2 kg/tonne of the barley replaced with equal amounts of normal potato (NP) or with potato that expressed a β -glucanase from *Fibrobacter succinogenes* (FSEP). Hubbard High Yield broiler chicks were randomly assigned to the 12 diets

(10 birds/cage; 2 cages/diet). After 3 d on a common broiler starter diet, chicks were given ad libitum access to experimental diets for 14 d. Growth and feed conversion ratios (FCR) were determined by cage. All birds were euthanized on d 17 and viscosity of digesta from the upper portion of the intestine (DV) was determined. On the control diets, growth performance was generally better with Falcon than with CDC Silky. Replacing 0.6 kg/t of barley with FSEP improved ($P < 0.05$) FCR with CDC Silky (1.87 vs 2.05) but not with Falcon; FCR on Avizyme diets was best (1.56; $P < 0.05$). Digesta viscosity was lower ($P < 0.05$) with 1.2 kg/t FSEP in CDC Silky diet than with control (152.3 vs 260.5 cP), but was still much higher ($P < 0.05$) than with Avizyme (31.8 cP). Apparent metabolizable energy (AME) of the diets, based on ileal digesta, was not affected ($P > 0.05$) by NP with either cultivar. With Falcon diets, AME was slightly higher (by 16 and 13%, $P > 0.05$) when 0.6 or 1.2 kg/t FSEP were included, than with no potato (2375.7 kcal/kg). Transformed potato may have potential as a supplementary source of enzyme in barley-based diets for broiler chickens.

1967 Effect of protein fluctuations and space allocation on performance of growing-finishing pigs. M. S. Edmonds*¹ and D. H. Baker², ¹Kent Feeds, Inc., Muscatine, IA, ²University of Illinois, Urbana, IL.

Two trials with growing-finishing pigs (PIC line 356 x Camborough 22) were conducted to evaluate the effects of CP levels and/or space allocation on performance and carcass traits. In trial 1, three CP regimens were used with 216 growing-finishing pigs (mixed sex). Average initial weight of pigs was 31 kg. The CP regimens consisted of 1) control (18% CP wk 0-4; 15% CP wk 4-12), 2) moderate CP variations (MCPV = 19.5% CP wk 0-2; 16.5% CP wk 2-6; 13.5% CP wk 6-8; 16.5% CP wk 8-10; 13.5% CP wk 10-12) and 3) extreme CP variations (ECPV = 21% CP wk 0-2; 15% CP wk 2-4; 18% CP wk 4-6; 12% CP wk 6-8; 18% CP wk 8-10; 12% CP wk 10-12). There were six replications (pens) per treatment with 12 pigs per pen (0.93 m²). During wk 8-12, pigs on the ECPV had improved ($P \leq 0.01$) gain and feed efficiency compared to those on the control regimen. Overall (wk 0-12), there were no treatment differences ($P \geq 0.05$) for gain, feed intake, gain/feed, or percent lean. Trial 2 involved 360 finishing pigs (mixed sex) in a 3 x 2 factorial (three CP regimens, two levels of space). Average initial weight of pigs was 49 kg. The diets consisted of 1) control (16% CP wk 0-4; 15% CP wk 4-8; 14% CP wk 8-12), 2) moderate CP variations (MCPV = 17.5% CP wk 0-2; 14.5% CP wk 2-4; 16.5% CP wk 4-6; 13.5% CP wk 6-8; 15.5% CP wk 8-10; 12.5% CP wk 10-12), and 3) extreme CP variations (ECPV = 19% CP wk 0-2; 13% CP wk 2-4; 18% CP wk 4-6; 12% CP wk 6-8; 17% CP wk 8-10; 11% CP wk 10-12). Pigs were provided with either 1.12 m² (5 pigs/pen) or 0.56 m² (10 pigs/pen). Overall (0-12 wk), crowded pigs had depressed ($P \leq 0.05$) gains (9.8%) and feed intakes (8.3%) compared to uncrowded pigs. A control vs. ECPV x space interaction for overall gain ($P \leq 0.05$) and gain/feed ratio ($P \leq 0.08$) occurred. Thus, uncrowded pigs fed ECPV performed better than controls, but crowded pigs did not. No treatment differences occurred for percent lean. The data suggest that uncrowded, but not crowded pigs, respond positively to up-and-down levels of dietary CP.

1968 Pelleting stability of Ronozyme™ P CT phytase in commercial feedmills. N.E. Ward* and J.W. Wilson, Roche Vitamins Inc..

Ronozyme P™ CT (RCT), a phytase, was developed for improved heat stability for pelleted feeds to avoid the need for liquid phytase application. The patented, thin lipid coating of the beadlet reduces enzyme exposure to moisture, one of the two major destabilizing factors for phytase during pelleting. Retention tests were completed in 12 randomly chosen integrated U.S. poultry commercial feedmills. In each case, a total of 0.4 to 0.6 lbs (181 to 272 grams; no carrier) was added per 2000 lbs (907 kg) of feed. A total of 10-20 samples of mash feed were taken as the feed exited the mixer, while 10-20 samples of pelleted feed were obtained at the cooler. Samples were taken at equal-time intervals based on feed flow rate. The percent RCT phytase remaining was 68 to 90% across pellet temperatures of 163°F to 210°F (73°C to 99°C). RCT retention tended to plateau at 70-80%, even at the highest temperatures tested. The mean mixing coefficient of variation (%CV) for phytase was 14.2% in mash, but 12.6% in pelleted feed, an improvement of about 11% in %CV. Mixing during augering and cooling likely accounts for the improved %CV in pelleted feed. RCT phytase retention is no less than about 70% across typical pelleting temperatures, thus serves as a viable, economically attractive alternative to liquid phytase in pelleted feeds. Conditioned mash was 16-17% moisture across mills, and may be the factor that limits RCT phytase destruction at the higher temperatures.

Feedmill #	1	2	3	4	5	6	7	8	9	10	11
Pellet temp., °C	73	80	81	82	89	89	90	91	93	97	99
Pellet temp., °F	163	176	177	180	193	193	194	195	200	207	210
Condition time, sec	20	30	20	35	20	20	25	20	25	20	20
Retention, %	90	82	82	70	72	75	78	80	68	80	75

Retention is percent phytase remaining in pellets relative to starting level in mash; CV = Coefficient of variation

1969 Comparison of Ronozyme P™ CT, Ronozyme P™ Liquid and Natuphos® Liquid in a commercial broiler pelleted feed. N.E. Ward*¹, J.W. Wilson¹, and J. McNaughton², ¹Roche Vitamins Inc., Parsippany NJ, ²Solutions BioSciences Inc., Salisbury MD.

Ronozyme P™ CT (RCT), Ronozyme P™ Liquid (RL) and Natuphos® Liquid (NL) were compared in a male broiler floorpen study with feed pelleted at 210°F(99°C)/20 sec by a commercial broiler feedmill. Eight (8) treatments were fed, including positive (POS) and negative (NEG) controls. Final targeted "feed trough" phytase levels were as noted. RCT: 500, 750, 1000 FYT/kg; RL: 500, 750 FYT/kg; NL: 500 FTU/kg. Eight (8) reps/trt were fed for 21 days in floorpens with 50 birds/pen. The feed was a basic commercial corn/SBM diet. Earlier observations indicated a 72-75% retention of RCT when pelleted at 210°F(99°C)/20 sec conditioning, thus RCT was added to the NEG mash at a rate to compensate for expected retention due to pelleting. Liquid phytases were sprayed onto pelleted NEG feed. The right tibia was ashed from 10 birds/pen on day 21.

Total P analysis was 0.57% for NEG and 0.72% for POS control. Average phytase retention across RCT diets was 76%, thus met targeted values. In addition, phytase analysis confirmed targeted values for liquid phytase addition. Body weights were generally improved ($P < .05$) over NEG with phytase addition. F/G and bone ash improved ($P < 0.05$) with increased phytase levels, but no difference in F/G existed across phytase sources at 500 units/kg. RCT and NL at 500 units/kg were equivalent across all variables tested, whereas bone ash for RL (500 FYT/kg) was higher ($P < .05$) than that for NL at 500 units/kg. These results find that RCT can be added to feed prior to pelleting, and retain sufficient quantities to support bird performance that is equivalent to liquid phytases of similar units/kg, and applied post-pelleting.

Trt	Final phytase, units/kg	Total P, %	Body wt., g	F/G	Mortality, %	Bone ash, % DM
POS	68	0.72	692abc	1.379e	1.0ab	38.95c
NEG	21	0.57	677c	1.403f	1.7ab	37.34d

1970 Comparison of a solid-state fermentation produced phytase with a traditional liquid-fermented phytase in broiler chicks. J Pierce*¹, J Driver², and J Harter-Dennis³, ¹Alltech, Nicholasville, KY, ²University of Pretoria, South Africa, ³University of Maryland Eastern Shore, Princess Anne.

Enzyme preparations produced in solid-state fermentation contain measurable amounts of protease, xylanase, and cellulase, in addition to phytase. An experiment was conducted to compare the efficacy of phytase produced by solid state fermentation (SSF) with a phytase produced by liquid fermentation (LF) containing no measurable enzymatic side activities. One hundred seventy-five 4-d old broiler chicks were used in a randomized block design with 5 dietary treatments and 5 replications of 7 birds/cage for 14 d. Dietary treatments 1-3 contained 0.25, 0.30 or 0.35% available P (aP), respectively. Diets 4 and 5 contained 0.25% aP + SSF or LF phytase (300 PU/kg). All diets were formulated to meet or exceed NRC requirements for all nutrients except P. The corn-soybean meal based mash diets contained 1.0% Ca, 1.26% lys, .97% TSAA, and 3200 kcal ME/kg. Total gain for the five treatments was 336, 363, 365, 362, 352g and gain:feed was 0.70, 0.69, 0.67, 0.69, 0.68. Both forms of phytase improved gain over the control ($P = 0.06$). Tibia ash percentages were 42.7, 46.3, 49.5, 48.2, and 48.1 for treatments 1-5, respectively. In addition, there was a linear improvement in tibia ash percent as P was increased ($P < 0.01$). Similar responses in bone traits were found in tibia strength and toe ash. Based on regression of Treatments 1-3 on tibia ash, it was found that 300 PU/kg of phytase is equivalent to 0.11% of dietary P. The SSF phytase was more effective at reducing fecal P than LF phytase (29 vs 20%, $P = .05$). The results of this experiment indicate that phytase produced by SSF may have advantages over LF phytase in terms of animal performance and P excretion.

Key Words: Chicken, Phytase, Phosphorus

1971 Efficacy of Allzyme Phytase® produced by solid-state fermentation in improving the phosphorus availability of wheat-soybean meal diets for broilers. Y.B. Wu¹, V Ravindran¹, D.T. Thomas¹, B.J. Camden¹, P.C.H. Morel¹, W.H. Hendriks¹, and J. Pierce*², ¹Massey University, Palmerston North, New Zealand, ²Alltech, Nicholasville, KY.

Allzyme Phytase® is an enzyme complex produced by solid-state fermentation, which contains several side-enzyme activities in addition to phytase. The influence of this phytase product on the performance and toe ash contents of male and female broilers fed a wheat-soybean meal diet was investigated in a 6-wk trial. Dietary treatments were: 1) negative control (0.30 and 0.20% nonphytate P during wks 1-3 and 4-6, respectively), 2-4) treatment 1 + 0.06, 0.12, or 0.18% nonphytate P as monocalcium phosphate, and 5-8) treatment 1 + 500, 1000, 1500, or 2000 PU/kg phytase as powder. A 1.4:1 Ca:P ratio was maintained. Diets were cold pelleted (65°C) and, within sex, each diet was fed to 5 pens of 8 birds each. In both sexes, weight gains ($P < 0.05$ to 0.001), gain/feed ($P < 0.05$ to 0.001) and toe ash contents ($P < 0.001$) were increased as the P or phytase was added to the low-P diet. The magnitude of increment in all parameters was greatest for the first addition

of P or phytase and then tended to plateau with further additions. Toe ash contents of birds fed the low-P diet with 500 PU phytase/ kg of diet were comparable to those of birds fed adequate-P diets. Unexpectedly, the birds receiving the low-P diet plus 1000 PU phytase/kg had a similar weight gain and better ($P < .05$) feed efficiency compared to those receiving P-adequate diets. Equations based on performance responses to graded additions of supplemental nonphytate P and phytase estimated the P equivalency of 1000 PU Allzyme[®] phytase/kg of diet to exceed 0.22%. These equivalency values may reflect enzyme activity above that accounted for by phytase activity alone. Thus, the secondary enzymes may have played a part in improving the availability of nutrients from wheat other than P alone.

Key Words: Phytase, Phosphorus, Wheat

1972 Effect of phytase on reduced available phosphorous levels in broiler diets. S. Parhizcar*, A. Kamyab, M. Shivazad, and R. Ashtiani, *University of Tehran, Animal Science Dept..*

A study was conducted to determine the effects of a commercially produced phytase enzyme on feed intake, body weight gain, feed conversion, toe ash, mortality, leg abnormality and blood calcium (Ca) and phosphorous (P) of broilers. This experiment was conducted in a completely randomized design. All of the five diets were isocaloric and isonitrogenous, consisting of five replicates, in which 25 mixed sex day old birds were housed. The experimental diets consisted of: A) basal control diet, B) control diet, but consisting of 85% recommended available phosphorous level plus phytase, C) control diet, but consisting of 85% of the recommended available phosphorous level without phytase, D) control diet, but consisting of 65% of the recommended available phosphorous level plus phytase, and E) control diet, but consisting of 65% of the recommended available phosphorous level without phytase addition. At the end of study, diet D resulted in heavier weight gain and better feed conversion which was statistically significant ($P < 0.05$). At the same age, diet B resulted in higher toe ash and phosphorus serum ($P < 0.05$). Likewise, birds which received diet C had significantly ($P < 0.05$) higher Ca level in their blood. No statistically significant differences were found between carcass quality, mortality and leg abnormalities in the dietary treatments ($P > 0.05$).

Key Words: Phytase, Broiler, Toe ash

1973 Effects of microbial phytase on apparent ileal digestibility of amino acids in broiler chicks fed a corn-soybean meal diet formulated on an ideal protein basis. D. R. Ledoux*, J. N. Broomhead, and J. D. Firman, *University of Missouri Columbia, MO USA.*

A 21-day battery study using 400 day-old male broiler chicks was conducted to determine the effects of microbial phytase on apparent ileal digestibility of nitrogen and amino acids and on apparent metabolizable energy (AME). The 2 X 4 factorial arrangement of treatments included a 100% ideal protein (IP) diet (20% CP) and a 90% IP diet, supplemented with four levels of microbial phytase (0, 250, 500, or 1000 FTU/kg diet) supplied by Natuphos[®]. Ten replicate pens of five chicks were assigned to each dietary treatment. There was no effect ($P > 0.05$) of phytase or IP on feed intake or body weight gain. There was also no effect ($P > 0.05$) of phytase on feed conversion, AME, or nitrogen digestibility. However, chicks fed the 90% IP diet were less efficient ($P < 0.05$) in converting feed to gain, but digested more ($P < 0.05$) nitrogen and utilized more energy (AME) compared with chicks fed the 100% IP diet. Significant ($P < 0.05$) phytase by IP interactions were observed for the dietary essential amino acids threonine, valine, methionine, isoleucine, leucine, phenylalanine, and histidine. Significant ($P < 0.05$) phytase by IP interactions were also observed for the dietary nonessential amino acids aspartic acid, serine, proline, glycine, alanine and cystine. The interactions indicated a benefit for supplementing diets with phytase in chicks fed 90% IP but no benefit for supplementing diets with phytase in chicks fed 100% IP. In addition to the phytase by IP interactions, there was a significant ($P < 0.05$) IP main effect observed for all of the dietary essential amino acids (except for methionine), and most of the dietary nonessential amino acids (exceptions serine and glutamic acid), with chicks consuming the 90% IP having higher digestibilities compared with those consuming the 100% IP diet. Phytase supplementation of a

90% IP diet was effective in increasing apparent ileal digestibility of several amino acids.

Key Words: Chicks, Phytase, Amino acid digestibility

1974 The effect of a non-GMO phytase on the performance of broilers fed diets containing different concentrations of phosphorus. Ruedi Hadorn¹, Hans Wiedmer¹, Samuel Nydegger², and Peter Spring*², ¹*Swiss Poultry Husbandry School, Zollikofen, Switzerland*, ²*Swiss College for Agriculture, Zollikofen, Switzerland.*

The aim of the present study was to determine the effect of a non-GMO phytase on performance of broilers fed diets containing different concentrations of phosphorus. The trial was conducted as a 2x2 factorial design with phytase (E) (0 vs. 1 kg/t) and available phosphorus concentrations (2.65 vs. 3.65 g/kg) as experimental factors. The trial included 4,500 chicks (Ross PM3). Birds were assigned to 20 pens (225 birds per pen) with 16-m² surface each. The sex ratio was 1 to 1 in each pen. Broilers were housed on litter. All animals received the same pre-starter diet for nine days. They received grower diets (13.2 MJ UE, 20.7% CP) from day 10 through 35 and the finisher diet from day 36 through 41 *ad libitum*. The following parameters were determined: Life weight, feed intake, feed conversion, mortality (d10, 21, 35, 41) as well as litter quality, carcass grade and bone breaking strength at day 41. Effects of experimental factors as well as interactions were analyzed by ANOVA. In addition, mean values were compared with the test of Bonferroni ($p < 0.05$). Overall average daily feed intake was increased by phytase addition (90.8 g vs. 93.5 g; $P < 0.05$). The increase in feed intake led to a significant increase in life weight (d41) (2118 vs. 2197g) when phytase was included in the diets. Mean feed conversion was 1.79 and was not affected by treatment. Average mortality over the entire trial period was generally low (1.5%) and not affected by treatment. The production index was significantly higher (279 vs. 290) with the addition of phytase, due to improved weight gain and feed intake. The reduction in dietary phosphorus levels from 3.65 to 2.65 g/kg had no significant effect on animal performance at day 41. There was no statistical difference in litter quality and group uniformity between treatments. Phytase addition tended to improve carcass yield (65.2 vs. 66.0%). Tibia breaking strength (measured as kg/bone) was numerically affected by treatment: high P: - E (44.82 kg) +E (47.30 kg); low P -E (43.27 kg) +E(45.68 kg), however, differences were not significant. This data indicate that non-GMO phytase has the potential to significantly improve animal performance.

Key Words: Phytase, Non-GMO, Broiler

1975 Evaluation of a high coefficient of variation (CV) of phytase consumption on the performance of broilers from 21-42 days of age. J. M. Harter-Dennis*¹, J. Timmons¹, and A. E. Sefton², ¹*University of Maryland Eastern Shore, Princess Anne, MD*, ²*Alltech, Inc., Guelph, Canada.*

A trial was conducted to determine the effects of a high coefficient of variation (CV) of phytase consumption on the performance of commercial broilers during the 21-42 day of age finisher phase. All birds were fed a commercial starter ration from 0-21 days of age that met or exceeded NRC requirements for all nutrients. On day-21 birds were allotted in a RCB design to 4 treatments with 6 reps/treatment and 5 male broilers/rep. Treatments consisted of T1: basal diet (B) containing 3200 kcal/kg ME, 20%CP, 0.9% Ca and 0.15% available phosphorus (AP), T2: B + the recommended level of phytase (11,500 PTU/kg ALLZYME[®], Alltech, Inc) daily, T3: B + 2X the recommended phytase level (23,000 PTU/kg) every-other-day and B on alternate days and T4: B + .20% AP. The CV of phytase consumption of T2 was 0% and that of T3 was 103%. The diets were adequate in all other nutrients. The addition of phytase (T2 and T3) sig. improved tibia bone breaking strength (BBS) and % tibia ash (TA) when compared to the phosphorus deficient diet (T1). Birds fed the AP adequate diet (T4) had tibia BBS and % TA values sig. higher than those fed T1, T2 and T3. There were no significant differences in these parameters due to the %CV of phytase consumption (T2 vs T3). These results confirm that phytase increases dietary phosphorus availability and suggests that older birds from 21-42 days of age may tolerate the high CV's of phytase application often experienced with post-pellet spray systems. These results also confirm similar findings with starter broilers from 0-21 days of age.

Treatment	Gain(g)	G/F	BBS(kg)	%TA
T1	829 ^b	.353	24.2 ^c	45.5 ^c
T2	899 ^{ab}	.393	32.2 ^b	49.2 ^b
T3	942 ^{ab}	.411	31.6 ^b	48.6 ^b
T4	1027 ^a	.417	40.5 ^a	53.5 ^a
ANOVA	P≤.05	NS	P≤.01	P≤.01

Key Words: Phytase, Broilers, Phosphorus

1976 Influence of Allzyme (Phytase) supplementation on Bovans hens. H. Anwar Ahmad^{*1}, S. S. Yadalam², and David A Roland, Sr.², ¹Tuskegee University, ²Auburn University.

A 2x3 factorial experiment to determine the efficacy of supplemental phytase was conducted using 960 40 wks old Bovan hens. Experimental diets were formulated based on two lysine levels, 0.83 and 0.92%. Within each lysine level, a positive control diet containing 0.4% available Phosphorus, a negative control Phosphorus deficient diet containing 0.1% available Phosphorus and the negative control diet supplemented with 11,400 PTU/kg Phytase (Allzyme) were formulated. Performance criteria evaluated were egg production, egg weights, egg specific gravity, and feed consumption. Reducing the lysine level from 0.92 to 0.83% significantly reduced the egg weight and feed consumption but did not drop egg production. Reducing the available Phosphorus level from 0.4 to 0.1% reduced the egg production, egg weight, and feed consumption. Supplying 11,400 PTU/kg phytase (Allzyme) to the negative control Phosphorus deficient diets (0.1%) significantly improved the egg production, egg weight, and feed consumption comparable to those of positive control diets that contained 0.4% available Phosphorus. Feed efficiency of phytase supplemented negative control diets (0.1%) was even better than the positive control diet of 0.4% available Phosphorus. Phytase (Allzyme) supplementation reversed the adverse effects of Phosphorus deficiency and further improved the feed efficiency.

Key Words: Allzyme, Bovans hens, Performance criteria

1977 Effects of dietary supplemental microbial phytase and nonphytate phosphorus on performance, nutrient digestibility and egg quality of laying hens. S. H. Kim^{*1}, W. J. Lee², S. J. Lee¹, D. J. Yu¹, S. Y. Park³, B.S. Kang¹, J. C. Na¹, and K. S. Ryu³, ¹National Livestock Research Institute of Rural Development Administration, Daejeon, ²Daesung Microbiology Co., LTD, ³Department of Animal Resources and Biotechnology, Chonbuk National University.

A total of six hundred forty Hyline brown laying hens were assigned into sixteen treatments to investigate the effect of dietary supplemental microbial phytase and non-phytate phosphorus (NPP) on nutrient digestibility and performance of laying hens. Phytase(Transpos^R) was supplemented at 0, 300, 500 or 1,000 DPU/kg diet. NPP levels were adjusted with tricalcium phosphate(TCP) to be 0 (0.11% NPP), 0.5% (0.20% NPP), 1.0% (0.29% NPP) and 1.5% (0.38% NPP) of diets. Dietary ME, CP and Ca were maintained at 2,800 kcal/kg, 16% and 3.5%, respectively. Egg production, egg weight, feed intake, feed conversion (FC), egg qualities and nutrient digestibility were measured from 21 to 32 weeks of age (WOA). Egg production of birds fed phytase was significantly increased compared to that of non supplemental phytase groups (P<0.05). TCP supplements also significantly improved egg production and daily egg mass up to 0.5% (P<0.05). Egg weight was not different between treatment groups. Feed intake was not statistically different among phytase supplemental groups, however, it was significantly increased with TCP supplementation (P<0.05). FC was significantly improved with phytase supplements (P<0.05), but was not different from FC of those fed TCP supplements. All nutrient digestibilities tended to improve with phytase and TCP supplement, but was not different at various phytase supplementation. The effect of phytase supplement was greater in low phosphorus diets compared to that of NRC recommended levels. Eggshell breaking strength and thickness also improved significantly in phytase supplemental groups (P<0.05). Tibial ash and P content were slightly increased with phytase supplements. However, Ca content was significantly higher in phytase supplemental groups than without phytase groups (P<0.05). As a result, dietary supplemental phytase decreased the level of NPP supplementation necessary. The optimum Transpos^R of diets were estimated to be approximately 300 DPU/kg diets. The results of this laying hen experiment showed that

phytase supplementation improved performance, nutrient digestibility and bone development of birds fed low phosphorus diets.

Key Words: Microbial phytase, TCP, Laying hens

1978 The response of laying hens to phytase added to corn-soybean meal-based diets containing two levels of available phosphorus. 2. Phytate phosphorus utilization. M.A Kamberi¹, H.M. Edwards², G.M. Pesti^{*2}, S. Muratovic³, S. Muji¹, and R.I. Bakalli², ¹University of Prishtina, Prishtina, Kosova, ²The University of Georgia, Athens, GA 30602-2772, ³University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

A trial was conducted to determine the effects of adding phytase (Natuphos[®], BASF) to corn-soybean laying hen diets for 8 weeks with different available phosphorus (AP) levels. After a 14-d adjustment on a common layer diet, 144 Hysex Brown hens were allotted using a randomized complete block design, to four treatments in a factorial arrangement of two AP levels (0.12 or 0.42%) and two phytase levels (0 or 600 FTU/kg). Each treatment was assigned to 3 replicates of 12 hens. Body weight, feed consumption, egg weight, egg specific gravity, and egg shell weights were measured biweekly. Egg production was recorded daily. Total excreta were collected each day and approximately 10% were dried in a forced draft oven. Excreta were pooled by 2-week periods for phytate phosphorus analysis. As reported earlier, the performance of hens fed 0.12% AP + phytase and 0.44% AP without phytase were very similar for egg production (96±2 vs 93±3%), egg weight (63±1 vs 63±1 g), egg shell weight (6.3±0.1 vs 6.4±0.1 g) and feed intake (106±1 vs 105±4 g). Hens fed the diets containing 0.12 and 0.44% AP utilized only 10.6±1.86 and 7.95±0.38% of the phytate phosphorus fed, respectively. When 600 FTU phytase per kg was added to the diets, phytate phosphorus utilization increased to 41.02±1.11 and 33.45±2.95%, respectively. Both the level of AP (P=0.024) and phytase (P<.0001) significantly affected phytate phosphorus utilization (their interaction was not significant, P=0.219). It is concluded that corn and soybean meal diets contain 0.18 to 0.22% phytate phosphorus that can be made partially available by adding phytase to the diet.

Key Words: Available phosphorus, Laying hens, Egg production

1979 Effects of Roche Ronozyme CT on Hy-Line W-98 laying hen performance when fed low phosphorus diets. S. E. Scheideler^{*1}, N. Ward², and M. Jalal¹, ¹University of Nebraska, ²Roche Vitamins.

A 4 X 3 factorial arrangement of 4 levels of Ronozyme CT (phytase) (0, 350, 450, or 550 IU/kg phytase) and 3 levels of nonphytate phosphorus (NPP) (.10, .20 or .30) were fed to Hy-Line W-98 laying hens from 18 to 35 weeks of age. An additional control diet of .45% NPP was also fed. Each of the 13 diets were assigned to 8 replicate cages with 7 hens per cage (56 hens/diet) in a randomized complete block design. Diets consisted primarily of corn-soybean meal with added fat. Daily egg production (EP) and feed intake (FI) were measured. Egg weight (EW) was measured on one day's production weekly and biweekly, 2 eggs/cage were measured for specific gravity, Haugh units and egg components (yolk, albumen and shell). Tibia ash was measured on tibias from 8 hens/diet at the end of the study. Level of NPP and inclusion of phytase significantly affected EP. EP increased with phytase addition at all 3 low levels of NPP and 350 IU/kg phytase was adequate to increase EP at low NPP levels. Low NPP had a negative effect on feed intake which was reversed by the addition of phytase. Tibia ash significantly increased as NPP increased and as phytase was added to low NPP diets. Increasing level of phytase showed some beneficial effects on increasing tibia ash. Diet treatments had no significant effect on EW, but did have a slight effect on albumen content. Increasing NPP decreased proportion of albumen in the egg and egg albumen quality as measured by Haugh units. Proportion of yolk in the egg increased as phytase was supplemented to low NPP diets. Diet effects on % shell and specific gravity were not significant. In summary, Roche Ronozyme CT phytase supplementation of low NPP diets results in equal or better egg laying performance in the Hy-Line W-98 laying hen to a control .45% NPP diet.

Key Words: Phytase, Laying hen, Phosphorus

1980 The evaluation of Ronozyme™ P CT in layer diets. R.D. Miles¹, N.E. Ward*², J.W. Wilson², and D. Ledoux³, ¹University of Florida, Gainesville FL, ²Roche Vitamins Inc., Parsippany NJ, ³University of Missouri, Columbia MO.

This study was conducted to evaluate Ronozyme™ P CT (RCT) and Natuphos® G (NG) for phosphorus (P) replacement in layer diets. A total of 455 HyLine W-36 hens (47 weeks of age) were individually housed. Seven treatments were formulated from a corn/SBM basal diet and replicated 13 times (one rep consisted of five individually-housed hens). RCT was fed at 300, 450 and 600 FYT/kg, while NG was fed at 300 FTU/kg diet. Diets 1, 2 and 3 were formulated to contain 0.1, 0.2 and 0.3% available P (AP). All phytase treatments were added to the 0.1% AP diet. Production data were collected over a 12 week period. The right tibia was removed from 20 actively laying hens/trt for ash determination. Phytase analysis was in agreement with formulated values for phytase. No differences (P>.05) existed across trts for hen-day egg production, although the 0.1% AP diet began to experience lower production by week 4. RCT numerically improved egg production for 0.1% AP trt. From week 4, feed intake was lowest (P<.05) for 0.1% AP trt, but was corrected (P<.05) with added phytase. Hens fed either source of phytase in 0.1% AP diets had equivalent bone ash to hens receiving up to 0.3% AP. An in vitro P release determination found no difference (P<.05) between either source of phytase added at 300 units/kg.

Trt	Phytase units/kg	Egg Prod %	Feed intake g/bird/d	F/G, kg feed/12 eggs	Egg wt. g	Bone ash, % dry matter
0.1% AP	–	74.8	86.5 ^b	1.4	62.0	58.9 ^c
0.2% AP	–	79.0	93.4 ^a	1.43	62.4	59.5 ^{bc}
0.3% AP	–	77.2	93.0 ^a	1.46	62.6	60.5 ^{abc}

1981 Effects of 25-Hydroxyvitamin D₃, vitamin D₃, low phytic acid corn, and phytase on phosphorus utilization by turkey poults fed dietary treatments from hatch to six weeks of age. G. M. Owens and D. R. Ledoux*, University of Missouri Columbia, MO USA.

A floor pen study was conducted to compare the efficacy of 25-hydroxyvitamin D₃ (25-OH-D₃) and vitamin D₃ (V-D₃), on phosphorus (P) utilization by turkeys fed wild-type (NC) or low phytic acid corn (LPC), with or without supplemental phytase. A completely randomized design was used with six dietary treatments and five replicate pens of 10 poults allotted to each dietary treatment from day 1 to 42. Dietary treatments included: (A) NC diet containing 0.60% available P (aP) and 1.2% calcium (Ca), supplemented with 3650 ICU vitamin D₃/kg diet; (B) NC diet as in A, but supplemented with 90 mg 25-OH-D₃ (Hy.D®)/ton instead of V-D₃; (C) NC diet containing 0.44% aP, 1.1% Ca, and supplemented with 600 FTU phytase (Natuphos® 600) and 3650 ICU V-D₃/kg diet; (D) NC diet as in C but, supplemented with 90 mg 25-OH-D₃/ton diet instead of V-D₃; (E) LPC diet containing 0.44% aP, 1.1% Ca, 600 FTU phytase and 3650 ICU V-D₃/kg diet; (F) LPC diet as in E, but supplemented with 90 mg 25-OH-D₃/ton diet instead of V-D₃. Compared with turkeys fed diet A, turkeys fed diet B had similar feed intake (FI) and feed conversion (FC; P > 0.05) but lower body weight gain (BWG; P < 0.05). There were no differences (P > 0.05) in FI, BWG, or FC between turkeys fed diet C and diet D or diet E and diet F. There were no differences in percent toe ash (P > 0.05) among dietary treatments. There were also no differences in percent tibia ash or bone breaking strength (P > 0.05) between turkeys fed diets A and B, diets C and D, or diets E and F. There were no differences in litter P (P > 0.05) between turkeys fed diets A and B, diets C and D, or diets E and F. Litter P was reduced (P < 0.05) in turkeys fed diets containing phytase and lower P levels. Results of this study suggest that 25-OH-D₃ may be as effective as V-D₃ in providing the benefits of vitamin D, and

that phytase was effective in improving phytate P utilization. Results also indicated that LPC contained more available P than NC.

Key Words: Vitamin D, 25-OH-D₃, Turkeys, Low Phytate Corn

1982 Effect of dietary tea polyphenols or daidzein and copper on cholesterol oxide formation in egg yolk powders. Guang-Hai Qi*, Jing-Dong Yin, Qi-Yu Diao, Jun-Jie Zheng, and Qi-Guang Huo, Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China.

Two trials were carried out to examine the effect of dietary tea polyphenols (TP) or daidzein (DA) and Copper (Cu) on lowering egg cholesterol content and cholesterol oxides formation in heated egg yolk powders. A layer diet based on corn-soybean meal-cottonseed meal was used in both trials. One hundred and twenty, 60-wk-old, Hisex laying hens were allocated to one of the 4 treatments of 30 birds with 5 replicates each in each trial. In trial 1, a 2x2 factorial design of TP (0, 40mg/kg diet) and Cu (4, 125 mg/kg diet) was used. A 2x2 factorial design of DA (0, 10mg/kg diet) and Cu (4, 125 mg/kg diet) was also used in trial 2. Both trials lasted 8 weeks. Three eggs were randomly sampled from each replicate and the egg yolks were separated. The three separated egg yolks from each replicate were combined and put in a microwave oven at medium-high temperature for 3 min to make one heated sample. The results showed that dietary supplementation of TP and DA inhibited the formation of 7-keto-cholesterone and total cholesterol oxides (p<0.01). The interactions between TP or DA and Cu on cholesterol formation were not significant (p>0.05). 7-Keto-cholesterone can be used as a marker in measuring egg yolk oxidation or cholesterol oxides formation because of their convenience of detecting and high correlative to total cholesterol oxides. Dietary supplementation of TP, DA and Cu decreased egg cholesterol and triglyceride content (p<0.05), and increased stability of egg lipids by 16.2% (p<0.05), 12.3% (p>0.05) and 5.7% (p>0.05), respectively. Although the interaction between DA and Cu was not significant (p>0.05), the interaction between TP and Cu was significant on reducing egg yolk cholesterol content (p<0.05). Dietary supplementation of TP, DA and Cu significantly reduced total cholesterol and low-density-lipoprotein cholesterol levels in the plasma (p<0.01). This study indicates that dietary supplementation of TP, DA and Cu could improve the healthy quality of egg yolk.

Key Words: Tea Polyphenols, Daidzein, Cholesterol Oxide

1983 Influence of atorvastatin on select indices of lipid metabolism in normolipidemic and hereditary hyperlipidemic chickens. R. G. Elkin*¹, Y. Zhong², S. S. Donkin², C. R. Thomas², E. Hengstschlager-Ottina³, and W. J. Schneider³, ¹The Pennsylvania State University, University Park, PA, ²Purdue University, West Lafayette, IN, ³Biocenter and University of Vienna, Vienna, Austria.

We have previously shown that atorvastatin (AT), a potent 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGR) inhibitor, is an effective plasma- and egg cholesterol (CHOL)-lowering agent when fed to normolipidemic (NL) laying hens. In the present study, we extended our sample population to include a unique strain of non-egg laying White Leghorn hens with hereditary hyperlipidemia, the so-called restricted ovulator (RO) chickens, and comparatively examined the effect of AT on select indices of lipid metabolism. NL and RO hens, each 82 wk old and sired by a heterozygous RO carrier rooster, were fed a layer ration supplemented (at 0.06 g/100 g diet) with either microcrystalline cellulose or AT. On d 20, 8 NL and 7 RO hens/diet were weighed and blood samples were obtained; the birds were then euthanized and their livers were excised, weighed, and sectioned for subsequent microsome preparation, mRNA extraction, and lipid, crude protein (CP), and moisture analyses. Compared to NL hens, RO birds were heavier, had markedly larger livers, and exhibited greatly elevated baseline plasma total CHOL and triglyceride (TG) concentrations (156 vs. 455 mg/dL and 3,070 vs. 13,837 mg/dL, respectively). AT attenuated plasma total CHOL concentrations in NL and RO hens by 60.3% and 45.1% respectively, and lowered plasma TG levels in these two groups by 71.0% and 34.3%, respectively. Within each genotype, AT reduced liver total CHOL and fat contents, while levels of phospholipids, CP, and moisture were elevated. AT tended to suppress expression of several key genes involved in hepatic very-low density lipoprotein assembly/secretion (apolipoprotein B, microsomal triglyceride transfer protein, and protein disulfide isomerase) while liver HMGR mRNA levels were elevated by AT in both NL and

RO birds, albeit more so in the former group. AT-associated increases in hepatic HMGR immunoreactive protein levels were noted only in NL birds. Down-regulation of HMGR gene expression by higher baseline levels of circulating CHOL may explain why RO birds, compared to NL hens, responded less robustly to AT administration.

Key Words: Atorvastatin, Lipid metabolism, Restricted ovulator

1984 Modification of the lipid profile of eggs yolks by feeding laying hens different sources of fatty acids. Douglas Faria*¹, Monica Mazalli¹, Daniely Salvador¹, Samir Correa¹, and Diogo Ito¹, *Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brasil.*

Three hundred and ninety Hy-Line W-36 commercial laying hens 46 weeks of age were fed diets containing different fatty acids sources (3% canola oil, 3% sunflower oil, 3% flaxseed oil, 3% fish oil, a mixture of 1.5% flaxseed oil plus 1.5% fish oil and 9% ground flaxseed), two levels of vitamin E (12 and 100 IU/kg) and a control diet in a factorial arrangement with five replicates of six hens each. Performance and internal and external egg quality characteristics were measured. Concentrations of saturated, monounsaturated and polyunsaturated fatty acids, cholesterol, vitamin E and sensory analysis of the eggs were measured. The results showed no influence of the factors studied on the performance, egg internal quality and egg flavor characteristics. Vitamin E concentration in eggs was related to its dietary levels. Eggshell percent and specific gravity were reduced when 100 IU of vitamin E/kg of the diet was fed. Cholesterol content was slightly reduced by inclusion of greater quantities of unsaturated fatty acids in the diet. The lipid profile in the yolk was modified by fatty acids sources. These findings indicate that it is possible to improve the eggs lipid profile, increase vitamin E content, and use flaxseed as a means of increasing the egg linolenic acid (C18:3n-3) content. The inclusion of flaxseed in the diet induced also the production of eggs with higher concentrations of docosahexanoic acid (C22:6n-3).

Key Words: Cholesterol, Fatty acids, Sensory evaluation

1985 Relationship between objective and subjective measurement of egg yolk colour. X. Rincon-Carruyo¹, R. Sala¹, B. Vila², J. Galobart*¹, and J. Gasa¹, ¹*Universidad Autonoma de Barcelona*, ²*Industrial Tecnica Pecuaria S.A. (ITPSA), R&D Dep., Barcelona Spain.*

An experiment was conducted to evaluate the objective (HunterLab MiniScan Colorimeter; Hunter scale L -lightness-, a -redness- and b -yellowness-, illuminant D65, 10° standard observer) and subjective (Roche Yolk Colour Fan, RYCF) measurement of egg yolk colour, on eggs laid by hens fed 20 different feed treatments obtained as a 4 × 5 factorial design: 4 levels (2.25, 4.50, 6.75 and 9.00 ppm) of natural yellow xanthophylls (CEBSNT, stabilized natural pigment from marigold flowers) and 5 levels (1.125, 2.250, 4.500, 9.000 and 18.000 ppm) of natural red xanthophylls (CFSNT, stabilized natural pigment from paprika). Two-hundred forty Lohmann laying hens, 58 wk old at the beginning of the experiment, were distributed in 40 replicates (6 birds in 2 cages), and 2 replicates were randomly assigned to each treatment. Ten eggs per treatment and day were collected the last 3 days of the 3rd and 4th experimental weeks and evaluated for several quality parameters including egg yolk colour. Performance parameters were also determined for the whole 4-wk experimental period. No significant differences were observed in any parameter but colour measurements of egg yolk. A significant interaction on CEBSNT and CFSNT levels in the diet was observed for all the colour measurements, explained by a significant effect of CEBSNT level at low levels of CFSNT (up to 4.5 ppm), not registered at higher levels. Redness was the best correlated variable with RYCF (r=0.962; n=1034); L and b also showed good negative correlation with RYCF (r=-0.884, and r=-0.876 respectively). The egg yolk colour can be expressed in RYCF units while using the colorimeter for the colour determination, by means of the regression of L a b variables. The equation obtained from this trial (RYCF=5.90+0.396×a-0.205×b+0.051×L; R²=0.929; n=1034) allows an objective measurement of egg yolk colour, independent of light conditions and observer.

Key Words: Egg Yolk Colour, Natural Pigments, Colorimeter

1986 Comparison of inert markers in poultry digestibility studies. P. R. Ferket*, A. D. Israel, and E. B. Morris, *NC State University, Raleigh, NC USA.*

The use of inert markers added to diets in digestibility studies eliminates the need to estimate the total amount of feed intake and fecal excretion. Analysis of chromium from chromic oxide, the most popular digestibility marker, is tedious, time consuming, and hazardous. The objective of this study was to evaluate the use of two alternative inert markers: titanium dioxide (TiO₂) and acid insoluble ash from Celite™, a diatomite product (Celite Corp., Lompoc, CA). Day-old Nicholas male turkeys were randomly assigned to 45 cages containing groups of 10 poults each and allowed to consume one of 9 experimental diets ad libitum until 17 days of age. The experimental diets consisted of a soy-bean meal-basal diet containing corn-based positive control diet and 8 test diets containing wheat in place of corn. These 8 wheat-based dietary treatment were a factorial arrangement of 4 wheat sources (A, B, C, and D) and 2 enzyme supplementation levels. Each diet included .5% TiO₂ and .8% Celite™ (w/w). Pooled fecal collections were made 11-14 d were acidified to pH 5.4 with .1N H₂ SO₄ prior to freezing. Diet and excreta were analyzed for Ti and acid insoluble ash contents, respectively, and AME and apparent N retention (ANR) was determined for each dietary treatment using each digestibility marker. Significant wheat source and enzyme main effects were observed on AME and ANR using TiO₂ as the inert marker, but only significant enzyme effects were observed when Celite™ was used. In comparison to the TiO₂ method, the Celite™ method resulted in higher mean ± SE for AME (2217 ± 47 versus 2346 ± 40 kcal/kg, P<.05) and higher mean ± SE for ANR (34.1 ± 1.2 versus 38.2 ± 1.1, P<.05). Although the Celite™ method is less expensive and easier to perform than the TiO₂ method, it requires bigger sample sizes (10 g versus .1 g) and 2 more replicate samples (i.e. 8 versus 10 replicates) to detect equivalent statistical differences in nutrient digestibility.

Key Words: Digestibility, AME, Nitrogen retention

1987 Additivity of amino acid and energy digestibility in barley and canola meal for ducks. D Hong*¹, D Ragland², and O Adeola¹, ¹*Department of Animal Sciences*, ²*Department of Veterinary Clinical Sciences, Purdue University.*

The additivity of amino acid digestibility and metabolizable energy values in barley and canola meal for White Pekin ducks was investigated in an experiment. The difference between the observed value for a complete barley-canola meal diet and the value predicted from measurements determined for individual ingredients was used to test additivity. Six ducks were assigned to each of the following dietary treatments: 1) barley, canola meal, 2) the complete diet and 3) dextrose. Dextrose-fed ducks were used for estimation of endogenous losses for calculation of true amino acid digestibility (TD). Observed values for the apparent amino acid digestibility (AD) and TD in the complete diet were higher than those predicted from individual ingredients. Observed AD for lysine, histidine, tryptophan, alanine and aspartate were higher (P < 0.05) than predicted values indicating that digestibilities of these amino acids were not additive. The mean of AD in canola meal (77.29 %) was higher (P < 0.05) than the observed values of barley (52.2 %) and the complete diet (64.55 %). For TD values, the differences between observed and predicted were significant (P < 0.05) for lysine, histidine and tryptophan. The mean of TD in canola meal, barley and the complete diet were 85.88, 80.87 and 81.33%, respectively. The AME, TME, AMEn and TMEn in barley and canola meal were all additive. Numerically, the respective AME, TME, AMEn, and TMEn values observed in the complete diet were 0.065, 0.083, 0.016 and 0.023 kcal/g higher than predicted values. These differences between observed and predicted values were not significant (P > 0.05). The AMEn in barley, canola meal and complete diet were 3.205, 2.764 and 3.042 kcal/g, respectively. The experiment provided new information about amino acid and energy utilization in barley and canola meal for ducks and indicated that AME, TME, AMEn and TMEn in barley and canola meal are all additive in the complete diet but that the digestibility of some amino acids are not additive.

Key Words: Barley, Canola Meal, Energy, Amino Acid, Ducks, Additivity

1988 Utilization of various starch sources as affected by age in the chick. A.B. Batal* and C.M. Parsons, *University of Illinois, Urbana, IL USA.*

Two experiments were conducted to determine if age affects utilization of different carbohydrate sources or high-carbohydrate ingredients fed to New Hampshire x Columbian male chicks. Five pens of eight chicks were fed carbohydrate-soybean meal (SBM) diets (23% CP) containing one of 17 different carbohydrate sources from 0 to 21 days of age. Carbohydrate sources evaluated in Experiment 1 were dextrose, conventional cornstarch, dextrinized cornstarch, corn-syrup solids, pregelatinized unmodified cornstarch, pregelatinized tapioca starch, pregelatinized unmodified waxy corn starch, tapioca dextrin, high amylose starch, and polycose. Carbohydrate sources evaluated in Experiment 2 were conventional corn, waxy corn, high-oil corn, cornflour, riceflour, and dextrose. In Experiment 1, the effects of carbohydrate sources on weight gain at the end of Week 1 were as follows (actual weight gains in parentheses): dextrose (88g), polycose (80g), dextrinized cornstarch (79g), tapioca dextrin (78g), corn-syrup solids (74g), cornstarch (70g), pregelatinized tapioca starch (69g), high amylose starch (60g), pregelatinized unmodified cornstarch (41g), and pregelatinized unmodified waxy corn starch (11g) (pooled SEM = 3.8g). Similar relative results were observed for the 0 to 3 week period except that feeding the corn-syrup solids, pregelatinized unmodified cornstarch and polycose were discontinued after Week 1 due to diet texture problems. In Experiment 2, there were no significant differences ($P > 0.05$) in performance during the first week among chicks fed the various corns and flours; however, chicks fed waxy corn, high-oil corn, or dextrose had numerically higher weight gains. By three weeks of age, chicks fed waxy corn, high-oil corn, or dextrose-SBM diets had significantly ($P < 0.05$) higher growth performance than chicks fed conventional corn, cornflour, or riceflour. These results suggest some potential benefits of feeding dextrose, polycose, dextrinized starches, waxy corn, or high-oil corn during the first 1 to 3 weeks posthatching.

Key Words: Chicks, Starch, Carbohydrates

1989 Dietary protein and thyroid interactions broiler chickens. R. W. Rosebrough, *ARS, Beltsville, MD, USA.*

The thyroid axis is one of the more controversial areas in growth and metabolism of the broiler chicken. Although chemical hypothyroidism decreased growth, artificial changes in thyroid hormone levels did not always change growth predictably. While dietary T_3 and T_4 decreased body weight and feed efficiency of chickens, daily injections of thyroid releasing hormone (TRH) improved growth and increased plasma thyroid hormone concentrations. What is lacking from previous studies is any information concerning recovery from inhibition of T_4 production. Male broiler chickens were fed diets containing 12, 18 or 24% protein 1 mg methimazole/kg diet from 7 to 28 d of age and then a diet containing 180 g protein/kg from 28 to 49 d of age. Birds were killed at 28 and 49 days to 1) determine effects of treatments at 28 d and 2) determine carry over effects of these treatments. In vitro lipogenesis was inversely related to dietary protein levels in control birds at 28 d ($P < 0.01$). Dietary methimazole attenuated this effect, resulting in a common rate similar to that attained in the birds fed the highest level of protein without methimazole. In contrast, birds fed methimazole from 7 to 28 d had greater lipogenic ($P < 0.01$) rates at 49 d than did their control counterparts. It is unclear at this time if observations noted at 28 d can be traced to reduced feed intake or to changes in thyroid status. Previous pair-feeding studies from this laboratory confirmed that differences in metabolic parameters caused by differences in dietary protein were not attenuated by limit feeding. Observations at 49 d suggest that permutations in the thyroid of the young bird may substantially change metabolism in later life.

Key Words: Thyroid, Metabolism, Lipogenesis

1990 Dietary protein level and stage of development affect expression of the intestinal peptide transporter (cPepT1) in chickens. H. Chen*, Y-X. Pan, E. A. Wong, and K. E. Webb, Jr., *Virginia Tech, Blacksburg, VA, USA.*

The purpose of this study was to evaluate the expression of chicken intestinal peptide transporter (cPepT1) mRNA as influenced by development and dietary protein level. Straight Cobb chicks (317) obtained from a commercial hatchery were used in this study. Ten were sampled

at incubation day 18 (E 18). After hatch but before feeding, ten more chicks were sampled (d 0). The rest of the chicks were randomly assigned to one of three floor pens. Diets containing 12, 18, or 24% protein were randomly assigned to be fed to the birds in a pen. Feed intake of the birds fed diets containing 18 or 24% protein were restricted to the intake of birds fed 12% protein. Eleven chicks from each group were sacrificed on d 1, 3, 5, 7, 10, 14, 21, 28, and 35. The duodenum, jejunum, and ileum were removed from each bird and were stored at -80°C until total RNA was extracted and quantified by spectrophotometry. Abundance of cPepT1 mRNA was quantified densitometrically from northern blots that were prepared using our full-length cPepT1 cDNA as the probe. An 18s-rRNA cDNA probe was used as an internal control to evaluate the amount of RNA loaded and transferred. At E 18, expression of cPepT1 mRNA in the small intestine was barely detectable. By the time of hatch (d 0), there was an approximately 50-fold increase in cPepT1 mRNA abundance in all three sections of small intestine. In birds fed the 12% protein, a decrease in cPepT1 mRNA abundance was observed in the three sections of small intestine during d 5 to d 10. Afterwards, cPepT1 mRNA abundance remained low throughout the rest of the feeding period. In contrast, both 18 and 24% protein groups showed an increase in cPepT1 mRNA abundance with time in all three sections of the small intestine. Most of the increase occurred during d 5 to d 10. Our results indicate that expression of cPepT1 mRNA in broilers is regulated by both level of dietary protein and stage of development.

1991 The effect of early nutrition and refeeding on satellite cell mitotic activity. P. E. Mozdziaik*¹, T. J. Walsh², and D. W. McCoy¹, ¹North Carolina State University, ²Novus International, Inc.

Myofiber growth is dependent upon the contribution of new nuclei from the mitotically active satellite cell population. The objective of this study was to examine satellite cell mitotic activity, in conjunction with different nutritional paradigms, during the early post-hatch period. Turkey poults were either provided a standard turkey starter diet, the starter diet plus a low fat, high protein hydrated nutritional supplement known as Oasis[®] Hatchling Supplement (Novus International, Inc. St. Louis, MO), the starter diet plus Solka-flok-dyed green, or no food for the first 3 days post-hatch. A standard starter diet was provided to all birds between 3 and 9 days of age. Bromodeoxyuridine (BrdU) was continuously infused into all groups (n=5 all groups) between hatch and 3 days of age. A second group of identically treated poults was continuously infused with BrdU between 2 and 9 days of age. Mitotically active satellite cells were identified in the *Pectoralis thoracicus* and quantitated using BrdU immunohistochemistry in combination with computer-based image analysis. Satellite cell mitotic activity was significantly higher ($P < 0.05$) in the birds fed a standard starter diet compared to all other treatments at 3 days post-hatch. However, there were no ($P > 0.05$) differences in satellite cell mitotic activity between all treatments at 9 days post-hatch. The *Pectoralis thoracicus* weight, and the *Pectoralis thoracicus* weight to body weight ratio were significantly higher ($P < 0.05$) in the birds fed Oasis[®] compared to all other treatments at 3 days post-hatch with the fastest birds having the significantly ($P < 0.05$) lowest *Pectoralis thoracicus* weight overall. The larger muscle size observed in the Oasis[®] treated birds at 3 days post-hatch may result from an increase in the amount of protein per nucleus.

Key Words: Turkey, Oasis[®] Hatchling Supplement, Skeletal muscle

1992 Incorporation of n-6 and n-3 fatty acids into selected meat portions from male and female broilers fed sardine oil. Rosa Ma. Castillo Domnguez¹, Silvia Carrillo Domnguez*¹, Ernesto Avila Gonzalez², Benjamin Fuente Martnez², and Fernando Prez-Gil Romo¹, ¹Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, ²Fac de Medicina Veterinaria y Zootecnia. Universidad Nacional Autonoma de Mexico.

The objective of this study was to compare the incorporation of n-6 and n-3 fatty acids (FA) into leg/thigh and breast muscles lipids of male and female poultry fed sardine oil (SO). 432 one-day-old broiler chicks (males and females) were randomly distributed among four treatments: 0%SO, 0.5%SO, 1.5%SO and 3.0%SO. Feed and water were provided ad libitum. At the end of the trial (6 wk), 3 males and 3 females, randomly selected from each treatment, were killed and legs/thighs and breasts were removed. n-6 (LA,AA) and n-3 (ALA,EPA,DHA) fatty

acids of total lipids were determined by gas chromatography. The results showed that birds supplemented with 1.5%SO and 3%SO had significantly ($P < 0.05$) higher levels of n-3 (25.27, 50.62 mg/100g) than control group (5.65 mg/100g) into breasts. With regard to leg/thigh the higher incorporations of EPA and DHA were obtained with 1.5%SO (20.68, 24.64 mg/100g) and 3%SO (49.17, 43.37). The n-6/n-3 ratios obtained in each treatment were: breast 16.4, 4.7, 3.1, 1.8 and for leg/thigh 16.6, 9.6, 5.4, 2.1. There were not changes induced by the sex ($P > 0.05$). Under conditions of the present study, it is concluded that SO could be used to increase the EPA and DHA content in tissue lipids of poultry, that there is higher incorporation of FA into leg/thigh than in the breast and, than the sex no affect the deposition of FA in the muscle of the birds.

1993 Changes of magnesium and calcium contents and adenosine triphosphatase activity of shell gland mucosa during eggshell formation in Brown Tsaiya ducks and White Leghorn hens. W. L. Chen and T. F. Shen*, *National Taiwan University, Taipei, Taiwan.*

The changes of magnesium and calcium contents, adenosine triphosphatase (ATPase) activity of shell gland mucosa during various stages of eggshell formation in brown Tsaiya ducks and white Leghorn hens

were investigated. Ducks and hens containing an egg in the shell gland were sacrificed at 6, 10, 15, 20 and 22 hours after oviposition, respectively. The whole shell gland lumen was flushed immediately by 50 mL 10 mM Tris-buffer (pH 7.4) for analyzing the amounts of Mg and Ca and their shell gland mucosa were scraped off to determine Mg, Ca contents and ATPase activity. Calcium content in eggshell gland mucosa of both birds decreased to lowest level at 10 hours after oviposition and the data in ducks were lower than hens after active eggshell formation. Total flushed Ca content in uterus lumen of duck or hen were rapidly increased from initial to active stages of eggshell formation. Magnesium content in duck shell gland mucosa was significantly higher ($p < 0.05$) than those in hens from 6 to 20 hours after oviposition. Total flushed Mg content in whole shell gland lumen of chicken was higher than duck after 15-hr stage. The specific activities of Ca^{2+} -, Mg^{2+} - or Ca^{2+} - Mg^{2+} -ATPase in shell gland mucosa were only minor changes ($p > 0.05$) during eggshell formation in both birds. Mg^{2+} added to incubation medium improved uterus mucosa ATPase activity of Leghorn hens, but not in Tsaiya duck. It was concluded that brown Tsaiya ducks could retain higher Mg and lower Ca contents in shell gland mucosa, and secrete less Mg and more Ca to shell gland lumen for depositing in eggshell. The Mg transport mechanism of shell gland mucosa in brown Tsaiya duck is worthy to be further studied.

Key Words: Shell Gland Mucosa, Magnesium, Adenosine Triphosphatase

Dairy Foods Undergraduate Paper Presentations

1994 Drinking reduced-fat milk may reduce heart disease risk. C.M. Opsahl*¹, ¹*University of Minnesota-St. Paul.*

Cardiovascular disease (CVD) is the major cause of mortality in the U.S. There are multiple risk factors for CVD including genetics, gender, race, age, tobacco use, exercise, diabetes, obesity, hypercholesterolemia, high blood pressure, elevated triglyceride, and high levels of homocysteine (a by-product of protein metabolism). Recent studies have shown that drinking at least four glasses of reduced-fat milk (<2% fat) may significantly reduce the risk of CVD. The exact mechanism of this relationship is not known but there are several possibilities. The dietary calcium from milk has been shown to reduce blood pressure in individuals susceptible to hypertension. Milk drinkers tend to be leaner, have higher levels of good or HDL (high-density lipoproteins) cholesterol, and lower incidence rates of diabetes. Finally, dairy products reduce artery-damaging homocystenine. Don't pass up the milk, drink to your health!

Key Words: Cardiovascular disease, Reduced fat milk

1995 Improving calcium availability with dairy foods and inulin. R. L. Blades*¹, ¹*Louisiana State University.*

Osteoporosis affects millions of Americans each year. This disease, resulting from inadequate calcium bioavailability, is of particular concern to the elderly but may begin during childhood. Only 30% to 40% of the calcium consumed is absorbed by the body, so new methods must be developed for increasing the bioavailability of this important mineral. One way to improve calcium availability is to increase intake of products high in calcium, particularly dairy foods. Another alternative would be to increase calcium absorption from foods. Inulin, an oligosaccharide derived primarily from the chicory root, has been shown to have numerous positive effects on human health. One benefit of this substance is its effect on intestinal flora. This product enhances growth of favorable bacteria while retarding growth of harmful bacteria. One of the most promising aspects of inulin is its ability to increase the intestinal

absorption of calcium. Inulin additive research has been proven to enhance calcium absorption without increasing caloric intake. One study has shown a 20% increase in calcium absorption from yogurt and fermented dairy beverages with only half of the normal usage level. With new technology and the added benefits of inulin, bone loss could be a major concern of the past, and a minor concern for the future.

Key Words: calcium, dairy foods, inulin

1996 Conjugated linoleic acid: Cancer prevention from dairy products. B. E. Dixon*, *University of Kentucky, Lexington, KY.*

Conjugated linoleic acids (CLA) are fatty acids produced by ruminants that are found in meat and dairy products. After the discovery of CLA in meat, a synthetic form of CLA was developed to use in initial research on laboratory animals. In rodents where cancer was induced, consumption of a diet with high levels of this synthetic CLA reduced the incidence of breast, colon, prostate and skin cancer in the order of 50%. Approximately 40% of synthetic CLA are found as the *cis-9, trans-11* form, the isomer responsible for its anti-carcinogenic effects. In natural dairy products, however, at least 90% of CLA are found as the *cis-9, trans-11* isomer. Recent studies feeding butter with high CLA levels to rodents have indicated a similar decrease in cancer incidence and severity. Butter with high concentrations of CLA decreased mammary cancer in one study with rats and colon cancer in another rat model. Similar effects on humans consuming a diet high in CLA can be expected; thus, CLA have great potential in the diet as an anti-carcinogen. Dairy products that include milk fat with increased levels of CLA have a broad potential market. Milk with increased CLA content can be processed with little effect on CLA levels or anti-carcinogenic benefits. Taste tests have shown that butter and milk with high CLA content are considered acceptable by a majority of samplers. Based on a survey, these consumers

were willing to pay more for products containing increased CLA. Future research may lead to the development of a variety of designer dairy products with enhanced, natural, anti-carcinogenic activity for humans.

Key Words: CLA, Cancer, Conjugated linoleic acid

1997 Biotechnology as a means of modifying milk composition. A.E. Lager*¹, ¹*Virginia Polytechnic Institute.*

The dairy industry is reaching a point where the advertising of calcium-laden milk may not be enough to sustain a profitable market for dairy products. Over the past decade, consumers have flocked toward alternative foods, other than milk products, to fulfill their nutritional requirements. Consequently, the time is now for our industry to look for new, improved, and more accelerated ways to modify the composition of milk and provide alternative uses for milk that increase sales. Traditional methods of dairy cattle breeding do not allow for rapid genetic change

Dairy Production Undergraduate Paper Presentations

1998 The importance of biosecurity measures in dairy herds. D.D. Leuty*¹, *Washington State University, Pullman, WA.*

Biosecurity is preventing the introduction of new diseases into a herd by taking some basic precautionary measures. The importance of biosecurity to the dairy industry rises with the increasing prevalence of herds purchasing cattle. Cattle entering the herd can carry contagious diseases from several outside sources. Johne's disease, Bovine Viral Diarrhea (BVD), and Leptospirosis are just a few of the diseases that can be controlled through proper biosecurity. An outbreak of Johne's will decrease the herds production at least five percent and BVD will result in an estimated loss of \$500.00 per cow. One component of biosecurity is isolation of all potential carriers. Such a program includes quarantining all new animals for at least 21 days, testing for highly contagious diseases such as BVD and Johne's, and establishing an aggressive vaccination program. Other measures include increasing herd resistance to disease by reducing stressors, using aggressive colostrum management and limiting access to dairy facilities from outside visitors. The use of biosecurity measures will prevent the spread of disease, decrease the loss of animals, and increase production of the herd.

Key Words: Biosecurity, contagious

1999 Increasing cow milkability. Jana Edwards*¹, ¹*Virginia Tech.*

Milking parlor efficiency is a limiting factor for many dairies. If a parlor is being fully utilized, increasing the amount of milk produced per hour is one alternative to building new facilities or expanding the existing parlor in order to become more profitable. The principle behind good milking technique is that the milking machine should remove the available milk from the udder gently, quickly, and completely with little irritation to the udder. This definition can be used to describe the essential characteristics of good milkability. Good milkability is when the unit is attached and milk flow is apparent immediately after the last teat cup is attached. The cow milks out quickly and completely with a steady milk flow. When the cow is finished milking, milk flow suddenly slows down and the unit is promptly removed from the cow. One way to increase good milkability on a dairy herd is through the implementation of automatic take-off settings. This can be done with an automatic recording system. In order to increase the amount of milk being produced per hour, dairymen must limit the maximum unit-on-time of the milking machine. The typical cow should yield twenty-five pounds in the first three minutes and then eight pounds per minute after that. Once a dairy has no cows milking longer than seven to eight minutes, parlor flow is dramatically more consistent, and the time spent in the holding area is decreased. However, an automatic milking machine is not all automatic. Cows must be properly prepped in order to increase milkability. Cows, with poor preparation, have a longer unit-on-time, which results in a decrease in cows per hour. Cows also tend to have a slower milk let down and a decrease in average flow rates. In conclusion, the time a cow takes to milk out is very important for total time spent in the milking parlor, udder health, and parlor flow. However, proper preparation before milking and properly functional takeoffs must be in

to significantly change milk composition. Milk component modifications can provide for health benefits for the consumer. Researchers have been investigating ways to develop transgenic animals that would produce milk with modified components. Proposed modifications presently being investigated for the benefit of humans include altering protein and fat content, increasing production efficiency, improving food safety, and "humanizing" milk where human proteins would be substituted for bovine proteins in bovine milk. There are several factors currently delaying product availability. These include costliness and inefficiency of transgenic animal production, lack of understanding of mammary gland physiology, and the possibility of milk component interactions. Industry leaders will also have to plan for specialized, separate processing plants for these novel products and be prepared to face potential problems with consumer acceptance of genetically modified products. However, the anticipated benefits will outweigh the current hurdles when the development and follow through of this technology are complete.

Key Words: Biotechnology, Milk, Composition

place for these results to take place. Once the cows are accustomed to being milked properly and efficiently, they will respond by standing quietly, have healthier teat ends, and milk out faster.

2000 The effects of heat stress on conception rates and early embryonic development. I. A. Norris*¹, ¹*Louisiana State University.*

In today's intense dairy industry, the time between freshening and conception is of ever-growing concern. Management during this time plays a role not only in milk production but also in farm efficiency. Simply stated, the sooner dairymen can get heifers and high producing cows pregnant, the more profitable they are as milking units on the dairy. Heat stress in dairy cattle has been associated with negative effects on cyclicity, conception, embryonic development, maternal recognition, and gestation. As the spring and summer rapidly approaches, dairymen in the southern United States must make the decision whether or not to breed heifers and cows during the months of May through September. In studies conducted at the University of Florida, conception rates during summer months commonly drop below 15%. As seasonal temperatures rise, maternal hyperthermia may potentially contribute to uterine heat load. The decreased availability of water and nutrients, along with a decline in metabolic activity needed for proper uterine function and embryonic development, places embryos at higher risk of inadequate growth and potential death. The manner in which dairy cattle are managed during summer months (and other periods of heat stress) may significantly influence reproductive performance. The use of fans, sprinklers, cooling ponds, and shades has been shown to potentially increase conception rates and aid in maintaining pregnancy throughout periods of elevated heat stress.

Key Words: heat stress, conception rates, embryonic development

2001 Agroterrorism: is it a possibility? J.L. Flinchbaugh*¹, ¹*Pennsylvania State University.*

Agricultural biological warfare, or "agroterrorism" as it is known, poses an alarming threat to our society. Agroterrorism may include any activity intended to introduce pathogens into livestock, crops, or directly into processed food products. Currently, the British Ministry of Agriculture is probing the idea that a terrorist group may have planted hoof and mouth disease in an attempt to discredit farming practices. If agroterrorism were truly the cause of this devastating disease outbreak, this act could foreshadow a similar shock to the US dairy and beef industries. The motivation behind most acts of agricultural terrorism is the allure of economic or political gains, with the ease and relatively risk-free nature of agroterrorism serving as added incentives. The ramifications of an act of agroterrorism would be far-reaching, extending beyond the immediate agricultural community to the rest of society. The consequences of agroterrorism are not about food per se, but about the effects on the economic and socio-political infrastructure. Economic destabilization of the agriculture sector would be one of the more immediate effects, followed by a degree of social instability and a loss of confidence in the government. The USDA is taking an active role in the fight against

agroterrorism through such actions as the establishment of the Counterterrorism Policy Council and the Plum Island Animal Disease Center. The development of a national defense strategy against agroterrorism is a necessity if the safety and stability of American agriculture are to be ensured.

Key Words: Agroterrorism

2002 The Advantages and Disadvantages of Accelerated Heifer Growth. M.H. London*, *University of Kentucky Dairy Club.*

Accelerating the growth rate of heifers can help decrease the age at first calving, but this objective must be accomplished without compromising first-lactation or lifetime milk production. Many classical studies done prior to 1990 showed that prepubertal heifers severely overfed energy had decreased amounts of ductal tissue, which resulted in decreased first-lactation milk yields. Studies have shown that heifers from 3 to 12 months of age fed to gain up to 1000 g/d did not result in excessive fattening. However, other research demonstrated a decrease in milk

production of 7.1% when heifers were fed to gain 1000 g/d in comparison to 700 g/d with the accelerated-growth heifers reaching puberty 32 days earlier. Using data present in the literature, VandeHaar concluded that 61% of variation in mammary impairments was attributed to the protein to energy ratio being fed. In another study, feeding a diet with a crude protein to metabolizable energy ratio of 50:1 compared to 61:1 g/Mcal improved feed efficiency, increased structural and overall growth rates, and decreased body condition scores in heifers from 28 to 48 weeks of age. More recent studies also have seen decreases in actual first-lactation milk yield in heifers reared on diets formulated for 1000 g/d gain prepartum. After breeding, all heifers were fed a common diet ad libitum and heifers fed to gain 680 g/d prepubertally showed compensatory gain after puberty with no difference in body condition at calving. These changes in growth after puberty explained most of the differences seen in milk production between the prepartum treatments. Therefore, prepubertal gain may only explain part of the decreases seen in first-lactation milk production. More research needs to be conducted to develop feeding and management programs, which allow for early calving and optimum milk production.

Original Research/Independent Study Undergraduate Paper Presentations

2003 Genetic relationships among electrical conductivity of milk, somatic cell scores and mastitis. R.C. Goodling*¹, G.W. Rogers¹, J.B. Cooper¹, and B. Rune², ¹*Pennsylvania State University*, ²*SAE Afikim, Kibbutz Afikim, Israel.*

Electrical conductivity of milk (EC) increases during mastitis and can be routinely measured during each milking of dairy cattle. The objectives of the study were to examine the relationships among EC, somatic cell scores and mastitis. The Afikim computerized milking and management system measures composite EC in millimho (mmho) during milking and records daily averages for EC. Analyses were performed on 3503 cows sired by 259 bulls in eight herds. Heritabilities for EC were determined using the PROC MIXED procedure of SAS[®] with a model that included herd-year-season, age at calving, and sire. Heritabilities for lactation 1 ranged from .27 to .39; lactation 2 ranged from .21 to .23. Regression of daughter EC on sire PTASCS were all highly significant (.80 for lactation 1 and .67 in lactation 2). Genetic correlations among EC and clinical mastitis incidence were also estimated using a subset of the data where clinical mastitis was present. Bulls with higher PTASCS had daughters with significantly higher EC. The positive regressions and moderate heritabilities from this study indicate that EC might be useful in selecting for mastitis resistance in dairy cattle.

Key Words: Conductivity of Milk, Heritability, Mastitis Resistance

2004 Effects of Propylene Glycol or Fat Drench on Plasma Metabolites and Liver Composition of Transition Dairy Cows. M. M. Pickett*, M. S. Piepenbrink, and T. R. Overton, *Cornell University, Ithaca, NY.*

Forty eight Holstein cows were used to test the effects of short-term oral drenching of propylene glycol (PG) and EnerG II (Ca soaps of

palm oil fatty acids, Bioproducts Inc., Fairlawn, OH) on milk production, blood metabolites, and liver triglyceride composition during the first three weeks of lactation. Treatments (2 X 2 factorial arrangement) given orally once daily for the first three days postcalving were water (Control), 500 ml PG, 454 g EnerG II (Fat), or 500 ml PG plus 454 g Fat brought to a volume of 2.5 L, using warm water. Concentrations of non-esterified fatty acids (NEFA) in plasma tended (P = 0.11) to decrease from day 2 through 7 in cows treated with PG (694.0, 570.7, 684.8, 582.4 μ E/L for control, PG, Fat and PG + Fat, respectively). Concentrations of β -hydroxybutyrate (BHB) in plasma tended (P = 0.09) to decrease from day 2 through 7 in cows treated with PG (10.1, 8.3, 8.9, 8.1 mg/dl). There was a tendency for an interaction of PG and Fat for plasma glucose concentrations (P = 0.07) for days 2 through 7 (36.3, 38.3, 39.4, 37.1 mg/dl), such that concentrations were greater for PG and Fat compared with the control or PG + Fat. Concentrations of triglyceride in liver on d 7 postcalving were not affected by treatment (P > 0.15; 10.82, 6.10, 10.01, 9.96%). Cows drenched with Fat tended to have lower DMI (P = 0.13; 38.0, 39.6, 37.3, 34.9 kg/d) and milk yield (P = 0.13; 36.5, 36.1, 32.5, 34.8 kg/d) during the first 21 d of lactation. There was no effect of treatment on milk composition. There was an interaction of PG and Fat for milk fat yield (P = 0.14; 1.7, 1.5, 1.5, 1.6 kg/d) which led to a trend (P = 0.15) in 3.5% fat corrected milk yield (42.9, 40.3, 38.1, 41.6 kg), such that yields were higher in the control and PG + Fat treatments compared with the other two treatments. Short term drenching of PG as described in this experiment has a slight beneficial effect on concentrations of NEFA and BHB while fat drenches appear to not affect concentrations of these metabolites in early postpartum cows.

Key Words: Propylene Glycol, Fat, Transition Cow

Meat Thermoprocessing: Products and Processes

2005 Thermal Processing of Meat Products. Romeo Toledo*¹, ¹*University of Georgia.*

Meat products are heated to eliminate the bloody red color, set the cured meat color, heat set proteins to form a gel and develop the texture, and thermally inactivate pathogenic and spoilage microorganisms. A number of RTE meat products are water cooked in a flexible film package, cooled, and then the covering is stripped followed by reheating to develop a roast and/or smoked flavor and color. Heating rates must be optimized to maximize color development and minimize purge. Too slow a heating rate will slow down production and may result in excessive shrink. A very fast heating rate will overcook the outer sections before the center reaches the endpoint temperature and results in excessive purge on cooling. Heat transfer mechanisms of conduction, convection, and radiation govern heating rates and different mechanisms predominate in a particular equipment. Surface heat transfer coefficients play a

major role in heating but when the Biot number gets too high, the effect is more on the surface than the interior where conduction becomes the rate limiting mechanism. Radiant heating systems have extremely high surface heat transfer coefficients and are effective for controlling purge and shrink in a post-processing pasteurization process.

2006 Effect of potato-processing waste in finishing diets on meat quality from yearling heifers. A. E. Radunz*, M. L. Bauer, G. P. Lardy, M. J. Marchello, and E. R. Loe, *North Dakota State University, Fargo, ND.*

Inclusion of potato-processing waste (PW) was evaluated in high-grain finishing diets fed to one hundred twenty-five crossbred yearling heifers (365.5 ± 0.3 kg initial weight). Heifers were fed for 84 and 105 d. Heifers were blocked by weight and allotted randomly to one of five dietary treatments (5 pens/treatment). PW replaced 0, 10, 20, 30, and 40% of corn and concentrated separator by-product in the diet. As the beginning of the trial, heifers were implanted with estradiol/trenbolone acetate. At harvest, a portion of the shortloin was removed from carcasses in the heaviest four blocks (n=20) and aged for 16 d. After aging, 3 steaks (2.54 cm) were cut from the shortloin, vacuum packaged and

frozen. Color meter readings were taken on the longissimus muscle and subcutaneous fat when the steaks were processed. One steak per heifer was broiled at 185°C to an internal temperature of 70°C and cooled to room temperature. Warner-Bratzler shear force was measured on six cores (1.27 cm). No effect ($P > 0.4$) was observed on fat and muscle color characteristics (L^* , a^* , and b^*) with inclusion of PW. Inclusion of PW did not affect thawing and cooking losses ($P > 0.2$). No difference ($P > 0.2$) was observed for shear force for 0, 10, 20, and 30% levels (3.10, 3.02, 3.11, 3.27 ± 0.15 kg, respectively); however, 40% PW (2.75 ± 0.15 kg) replacement reduced ($P = 0.5$) shear force compared with other levels of PW. Inclusion of PW in a finishing diet does not affect muscle or fat color, cooking characteristics or tenderness; however, inclusion of 40% PW may improve tenderness.

Meat Thermoprocessing: Products and Processes

2007 Discussion on which ingredients play key roles to food safety and product quality. Dennis Seman*¹, ¹Oscar Mayer Foods Division/Kraft Foods.

Providing food products for consumers that are safe and of a high quality are two pillars upon which meat companies build their businesses. Within the past few years, after the occurrence of a few serious food illness outbreaks in ready-to-eat prepackaged meat products, consumer confidence in the safety of the food supply may have eroded. Several

strategies may provide processors the ability to create secondary barriers for potential pathogenic bacterial growth by the incorporation of additional ingredients including naturally occurring antimicrobial ingredients as well as sodium diacetate and sodium and/or potassium lactate. The use of these ingredients by themselves and in combination with other treatments suggest that they assist in providing a product in which listeria growth is inhibited.

Key Words: Listeria, Sodium diacetate, Lactate
