to one of two dietary treatments: control or betaine supplemented (1.25 g Betain®/ per kg of feed). The experimental diets were maize and soybean meal-based. Diets were aimed to be limiting in energy content and sufficient in protein. The experiment consisted of a 3-wk adaptation and a 3-wk experimental period. Initial BW was 46 kg during the experimental period, when each group of pigs was housed in a climate respiration chamber. During the experimental period, pigs were offered changed diets, which were diluted with 10% oat hulls. Pigs were fed at 2.5 times the energy requirements for maintenance. During the experimental period, heat production, energy and nitrogen balances were measured weekly. The metabolizable energy intake was unaffected by dietary betaine supplementation (P > 0.10). Averaged over the experimental period, betaine supplementation reduced heat production (5 kJ·kg⁻₀·₇₅·d⁻¹, P < 0.05). Moreover, this difference between diets increased with time within the experimental period (P < 0.05). Averaged over the 3-wk period, energy retention was increased (P < 0.10) and energy requirements for maintenance were decreased (P < 0.10) in pigs fed the betaine supplemented diet. However, the effect of betaine on the energy requirements for maintenance changed with time (P < 0.05). Maintenance requirements were similar in Week 1 and were reduced by betaine supplementation by 5.5% during Week 3 (477 vs. 452 kJ·kg⁻₀·₇₅·d⁻¹). The current results showed that betaine supplementation affected energy partitioning of growing pigs. This effect was not due to a methionine sparing effect of betaine, because betaines were formulated to be sufficient in amino acid as well as choline.

The effect of dietary betaine supplementation on energy partitioning in pigs was studied. Six groups of 14 group-housed barrows were assigned to two dietary treatments: control or betaine supplemented (1.25 g Betain®/ per kg of feed). The experimental diets were maize and soybean meal-based. Diets were aimed to be limiting in energy content and sufficient in protein. The experiment consisted of a 3-wk adaptation and a 3-wk experimental period. Initial BW was 46 kg during the experimental period, when each group of pigs was housed in a climate respiration chamber. During the experimental period, pigs were offered changed diets, which were diluted with 10% oat hulls. Pigs were fed at 2.5 times the energy requirements for maintenance. During the experimental period, heat production, energy and nitrogen balances were measured weekly. The metabolizable energy intake was unaffected by dietary betaine supplementation (P > 0.10). Averaged over the experimental period, betaine supplementation reduced heat production (5 kJ·kg⁻₀·₇₅·d⁻¹, P < 0.05). Moreover, this difference between diets increased with time within the experimental period (P < 0.05). Averaged over the 3-wk period, energy retention was increased (P < 0.10) and energy requirements for maintenance were decreased (P < 0.10) in pigs fed the betaine supplemented diet. 763 A comparison of methods of editing and adjusting feed intake data from electronic swine feeders. D.S. Casey1* and J.C.M. Dekkers, Iowa State University, Ames, Iowa.

Data from electronic swine feeders contain errors that must be identified, edited, and replaced. The objective of this study was to compare the accuracy of six methods of editing and replacing missing data to estimate daily DFI and average daily feed intake (ADF1) in short and long test periods. Data from FIRE73® feeders on 591 pigs from the National Pork Producers Council’s Maternal Line Genetic Evaluation Program were used. Errors in each visit were identified using 16 criteria. To create an error-free data set as a basis for comparison, data from 124 pigs with few errors were selected and visits with errors were replaced by error-free visits from the same pig. Resulting DFI and ADF1 were assumed to be the true trait values. Error visits were then introduced to create long test period data (average 12 weeks), representative of real data. The last 4 weeks per pig were used to create short test period data. Data were edited using 6 methods (EM1-6). For EM1, a DFI record was deleted if DFI<1000g or >4500g. For EM2-6, the 16 criteria were used to identify errors in each visit. For EM2 and 3, all DFI records with ≥1 and ≥2 errors were deleted. For EM4-6, DFI was obtained by summing feed intake over error-free visits. For EM5 and 6, DFI records were then adjusted for the effects of presence of error visits on unadjusted DFI, which were estimated from a linear model analysis of the complete data set (591 pigs) for EM5 or from the data sets being edited (124 pigs) for EM6. For EM1-4, missing DFI records were replaced by linear or quadratic regression estimates of DFI on test day for each pig. DFI and ADF1 from the edited data sets were correlated to true values. Correlations were high (r ≥ 0.99) for both traits for all editing methods except EM1. EM6 had the highest correlations for DFI in both test periods (r ≥ 0.96). EM2 and EM6 had the highest correlations for ADF1 (r ≥ 0.96). EM1 had the lowest correlations for both traits and test periods (r ≤ 0.76 to 0.94). Results indicate that editing methods affect the accuracy of data from electronic feeders. EM6 is recommended for maximum accuracy.

764 Effects of piglet birth weight and liquid milk replacer feeding during lactation on pig performance to slaughter weight. B. F. Wolter*, M. Ellis, B. P. Corrigan, and J. M. DeDecker, University of Illinois, Urbana, IL.

The effects of piglet birth weight and liquid milk replacer feeding during lactation on growth performance to slaughter was evaluated in a study
carried out with thirty-two sows (PIC C-22) and their piglets (n=384, PIC Line 337 sires). A randomized block design with a 2 × 2 factorial arrangement of treatments was used. Treatments were birth weight (Heavy and Light) and liquid milk replacer (Supplemented or Unsupplemented). The study was divided into 2 periods. In period 1 (birth to weaning), pigs were assigned at birth to either a heavy or light (1.83 vs 1.32, SE = 0.01 kg; P < 0.001) litter of 12 pigs and one-half the litters were given ad libitum access to supplemental milk replacer (Land O’Lakes, Inc., Fort Dodge, IA) from d 3 of lactation to weaning. In period 2 (from weaning at 21 d of age to slaughter at 110 kg), a total of 308 randomly selected pigs were allocated at weaning within previous treatment group and sex to pens of 4 pigs. Pigs were given ad libitum access to feed, and diets were formulated to meet or exceeded NRC recommendations. Heavy litters were heavier at weaning (6.58 vs. 5.72, SE = 0.14 kg; P < 0.001), tended to have more pigs weaned (11.4 vs. 10.9, SE = 0.21 pigs; P = 0.10), had greater post-weaning ADG (850 vs. 800, SE = 6.7 g; P < 0.001) and ADFI (1866 vs. 1783, SE = 17.6 g; P < 0.001), similar G:F (0.46 vs. 0.45, SE = 0.003; P > 0.10), and required 7 fewer d (P < 0.001) to reach slaughter. Feeding supplemental milk replacer during lactation produced heavier pigs at weaning (6.60 vs. 5.69, SE = 0.14 kg; P < 0.001), tended to increase pigs weaned (11.4 vs. 10.9, SE = 0.21 pigs; P = 0.10), but had no effect (P > 0.10) on growth performance from weaning to slaughter; however, milk replacer fed pigs required 3 fewer d (P < 0.01) to reach slaughter weight. Sow feed intake and BW loss during lactation was not affected (P > 0.10) by either birth weight or milk replacer treatment. In conclusion, pigs with heavier weaning weights resulting from increased birth weight or from feeding of milk replacer required less time to reach market weight.

765 Effect of initial stocking rate and weighing frequency on pig performance in wean-to-finish pens. B.F. Wolter1, M. Ellis2, S.E. Curtis3, M.E. Parr2, and D.M. Webel2, 1 University of Illinois, Urbana, IL/USA, 2 United Feeds, Inc., Sheridan, IN/USA.

Crossbred pigs (n = 1,560) were used in a randomized-block design with a 2 × 2 factorial arrangement of treatments to determine the effects of initial stocking rate (Single [52 pigs/pen] vs. Double [104 pigs/pen]) and weighing frequency (High [every 2 wk during the study] vs. Low [3 times during the study]) on pig performance from weaning (5.8 ± 0.43 kg BW; 17 d of age) to slaughter (114 kg BW). Floor and feeder space allowances per pig were 0.650 m² and 4 cm and 0.325 m² and 2 cm for Single- and Double-stocked pens, respectively. Drinker allocation (13 pigs/drinker) was the same for all treatments. At the end of wk 10 post-weaning, Double-stocked pens were divided into 2 equal-sized groups with similar mean BW and CV of BW, and pigs in one of the groups were moved to a different location in the same house. Pigs had free access to feed and water throughout. In the 1st wk 10 post-weaning, Double compared to Single stocking resulted in lighter pigs (39.7 vs. 42.6 kg; P < 0.001) and lower ADG (8%; P < 0.001) and ADFI (7%; P < 0.001), but similar G:F (P > 0.10). From wk 10 to slaughter, pigs that previously had been on the Double- compared to the Single-stocking-rate treatment had similar ADG and ADFI (P > 0.10), but greater G:F (4%; P < 0.01). Double-stocked pigs required 2 additional days to reach slaughter BW (P < 0.05), but had similar (P > 0.10) carcass backfat and loin depths. Double-stocked pigs moved at the end of 10 wk had similar (P > 0.10) growth performance to those that stayed in the original pen. Growth rate was not affected (P > 0.10) by frequency of weighing. Mortality and morbidity were similar (P > 0.10). From wk 10 to slaughter, double-stocked pigs increased their growth rate from 10 wk post-weaning and increased days to reach slaughter BW, but increased subsequent feed efficiency.

Key Words: Pigs, Stocking Rate, Wean-to-Finish

766 Effect of feeder-trough space on pig growth performance in double-stocked wean-to-finish pens. B.F. Wolter4, M. Ellis5, S.E. Curtis5, E.N. Parr2, and D.M. Webel2, 1 University of Illinois Urbana, IL/USA, 2 United Feeds, Inc., Sheridan, IN/USA.

Previous research has shown that double-stocked compared to single-stocked pigs in wean-to-finish pens reduced growth performance from weaning to 10 wk post-weaning. The objective of the present experiment was to evaluate the effect of doubling feeder-trough space (4 cm/pig [Double] vs. 2 cm/pig [Control/Standard]) on pig performance from weaning to 8 wk after weaning. In a randomized-block design, crossbred pigs (n = 1,728) were randomly allocated at weaning (5.4 ± 0.23 kg BW; 16 d of age) to mixed-sex pens of 108 pigs/pen on the basis of weight and sex. Floor-space allowance (0.30 m²/pig) and drinker allocation (14 pigs/drinker) were the same for both treatments. Two six place (35 cm/place) feeders (Jumbo Wean-to-Finish, Farmweld, Teutopolis, IL) positioned together in the center of each pen were accessible from both sides. However, only one feeder contained feed in pens on the Control trough-space treatment. Pigs had free access to feed and water. Pigs were weighed and feed disappearance was recorded every 2 wk throughout. Doubling feeder-trough space (P < 0.10) pig growth rate from weaning to the end of wk 6 after weaning. Pigs on the Double compared to those on the Control trough-space treatment had higher ADG (669 vs. 634 g; P < 0.05) from wk 6 to 8 and were heavier (31.7 vs 30.9 kg; P < 0.05) at the end of wk 8, although ADFI and G:F did not differ (P > 0.10). These results suggest that pigs double-stocked in wean-to-finish pens for longer than 6 wk post-weaning need additional feeder-trough space to maintain growth performance.

767 Carcass and meat quality of halothane gene carriers and negative pigs. Jorge Galindo-Garcia6, David A. Villagomez*, and David R. Sanchez-Chipres, Centro Universitario de Ciencias Biologicas y Agropecuarias, Universidad de Guadalajara, Mexico.

Among the major genes identified in swine, the halothane gene, perhaps, is the most economically relevant due to its detrimental effects on technology and carcass yield parameters (Enfalt, 1997). Differences in gene penetrance are expected when the same genotypes are exposed to different environments, (Falconer, 1989) we carried out this investigation to evaluate the halothane gene effects on carcass quality and technological traits of pork from commercial hybrids pigs (F1 York/Landrace X synthetic hybrids), which were carriers (Nn) or negative (NN) for the Hal mutation. A total of forty three (22 females and 21 castrates) pigs, fatted in conventional housing and management, were slaughtered at 100 Kg of live weight. PCR and restriction enzyme analysis allowed Hal genotyping of pigs. For statistical analysis, the animals were grouped according to sex and halothane genotype in a 2X2 factorial array, the size of each group being nearly equal (11 animals). Carriers had shorter carcass length (P < 0.05) and increased days to reach slaughter BW, pigs that previously had been on the Double compared to those on the Control had lower carcass backfat and loin depths. Double-stocked pigs moved at the end of 10 wk had similar (P > 0.10) growth performance to those that stayed in the original pen. Growth rate was not affected (P > 0.10) by frequency of weighing. Mortality and morbidity were similar (P > 0.10). From wk 10 to slaughter, double-stocked pigs increased their growth rate from 10 wk post-weaning and increased days to reach slaughter BW, but increased subsequent feed efficiency.

768 Test performance of halothane gene homozygous and heterozygous pigs under no controlled climate. D.R. Sanchez-Chipres, D.A.F. Villagomez*, and J. Galindo-Garcia, Centro Universitario de Ciencias Biologicas y Agropecuarias, Universidad de Guadalajara.

Porcine Stress Syndrome (PSS) is a genetic disorder that mainly affects fast growing. Sudden death or pale, soft, and exudative (PSE) pork at slaughter may occur. At present, it is well known that FSS, PSE and Malignant Hyperthermia (MH) are associated with the same mutation of a ryanodine receptor gene (O’Brien, et. al.,1990; Fujii, et. al.,1991). The halothane gene (after challenging to halothane anesthesia; Archibald and Imlah, 1985) genotype of an animal is identifiable by PCR and restricted enzyme analysis. The present investigation was conducted to evaluate the productive performance of halothane negative (NN) and carrier (Nn) pigs reared individually at a test station without climate manipulation. Forty four pigs (22 females; 22 males) from commercial genetic lines (F1 York/Landrace X synthetic hybrids) were evaluated. The test started when the animals averaged a weight of 25 Kg and finished when they reached 100 Kg. The feed consumption, body weight, back fat and loin area (ultrasound) was measured during the time of the test. A frequency of 61.4% (27 animals) and 38.6% (17 animals) of the pigs were either NN or Nn, respectively. Better daily live weight gain was shown (P < 0.05) by homozygous (NN) pigs than...

771 Evaluation of three genetic populations of pigs
for response to four levels of ractopamine. A. P. Schinkel1, C. T. Herr1, B. T. Richert1, and M. E. Einstein2, Purdue University.

Gilts (n = 300; BW = 83.5 kg) were allotted to pens (n = 60) by weight
in a 3 x 4 factorial arrangement of treatments in a randomized com-plete block design (n = 5) with three genotypes (G) and four ractopamine
levels (RL): 1) control, 0 ppm; 2) 5 ppm; 3) 10 ppm; and 4) 20 ppm
RAC to evaluate the effects of ractopamine (RAC) on growth perform-
ance in a four week trial. All pigs were fed an 18.6% CP, 1.1% lysine
diet. The weekly pen data were fitted to numerous linear, nonlinear and
biphasic equations of ractopamine level (RL), and either duration of
time (DRAC, midweek days on RAC), or weight gain (WTGRAC,
kg) on RAC. The values of DRAC and WTGRAC were set to zero for the
color treatement. The RAC response was also divided into two
phases: (1) RL1, 0 for control and 5 for all other RAC treatments, and
(2) RL2, (RL-RL1) for RAC treatments 2, 3, and 4. For ADG (kg/d),
the equations included the fixed effects of block, G and week on test
(p < .01) and either a biphasic [0.0186 RL1 + .0272 (RL2)
linear function (.113 [1 - exp (-.713 RL)]) of RL level. For gain-feed
(G:F), the models included the fixed effects of week (p < .01) and ei-
ther a biphasic linear (.0084 RL1 + .0013 RL2) or nonlinear function
(.0513 [1 - exp (-.717 RL)]). The partial sums of squares accounted for
by the biphasic functions were 4.4 and 8.9% greater than the nonlinear
functions for the ADG and G:F, respectively. For daily feed intake (ADFI,
kg/d), the equation with the lowest RSD included the fixed effects of
block, G, week, and -.0068 RL2 (p < .01). The change in the RAC re-
sponse with WTGRAC were not significant (p > .50) for any variable. The
predicted linear change in RAC response to DRAC were small for
ADG (-.0035, p = .19), G:F (-.0008, p = .49), and ADFI (-.0026, p = .33).
The regression analyses indicated that the three variables respond
nonlinearly and differently to increasing RL. The biphasic and nonlinear functions of RL resulted in different predicted RAC responses. The RAC response did not significantly change over the duration of the 28-day feeding trial.

772 Parenteral vitamin E for prevention of retained
placenta in dairy cows. S. LeBlanc, K. Leslie*, T. Duffield, K.
Bateman, J. Ten Hag, and J. Wallace, University of Guelph, Guelph,
Ontario, Canada.

Immune function is suppressed, and the risk of infectious and metabolic
disease is increased in periparturient dairy cows. Several studies have
shown improved immune function and decreased risk of RP or mastitis
in transition cows supplemented with vitamin E in feed and/or parenterally. However, these benefits are not universally reproducible and may depend on baseline vitamin E and selenium status of animals, and other factors. Additionally, a fraction of animals will demonstrate hypersensitive reactions to parenterally administered vitamin E. The objective
of this study was to investigate the effect of vitamin E administered subcutaneously to prepartum cows on the incidence of periparturient health problems. A total of 1184 cows in 20 herds were randomly
allocated to receive either a single SC injection of 3000 IU vitamin E (d-α
tocopherol) or placebo approximately one week prior to expected calv-
ing date. Incidence of peripartum disease (retained placenta, milk fever,
metritis, ketosis, displaced abomasum, clinical mastitis, and lameness) was recorded. Data were analyzed in SAS using the GENMOD pro-
dure including herd as a random effect. The risk factors for RP and the effect of vitamin E on RP were different between primiparous and mul-
tiparous cows. Therefore, these parity groups were modeled separately. Occurrence of dystocia was offered to the models but was not a signifi-

A Sustainable Pork (SP) Research and Demonstration Farm was de-
veloped based on past research and the following conditions. The ob-
jectives of the SP Farm were to develop a precisely defined production
technology. Acceptable criteria include that the farm does not use waste
landfills, owns no more land than a conventional indoor production sys-
tem and should have no negative impact on the land. The farm may
use no more labor than a conventional system and must be economically
competitive. Neither may the farm have an offensive odor. It must be
viewed as a positive member of the rural community. Plants used as
groundcover must uptake the nutrients the animals add to the soil and
recycle them by retaining carbon, nitrogen and other nutrients in a solid
form. Finally, the farm should contribute healthy meat to the segment
of consumers who wish to protect the environment, the animals and the
workers. This niche market may be available in the United States now.
