T257 Ruminal degradation of dry matter of raw cull chop suey beans (*Vigna radiata* L., Wilzeck) in sheep. J.F. Obregon*, J.C. Robles, R. Barajas, A. Estrada-Angulo, and M. Valdez, *FMVZ-Universidad Autonoma de Sinaloa (Mexico)*.

This study was designed to determine the ruminal degradation of dry matter (DM) of raw cull chop suey beans (*Vigna radiata* L., Wilzeck) in sheep. Two Pelibuey sheep (31.5 kg) fitted with ruminal cannulas were used. The animals were fed with a diet 25:75 roughage:concentrate, containing 20% of raw cull chopsuey beans. Nylon bags (10 x 18 cm) containing 5 g of raw cull chop suey beans (CCB) or soybean meal (SBM) were randomly designated to be incubated in rumen of sheep for 3, 6, 9, 12, 18, 24, and 36 hours. After the incubation was completed, the bags were washed with tap water and DM was determined. DM degradability at 3 hours was similar ($P=0.19$) for SBM and CCB (39% vs. 42.82%, respectively), the ruminal degradation of CCB-DM was greater than SBM-DM ($P<0.02$) at 18 hours incubation time (92.87 vs. 83.02%, respectively). After 36 hours of rumen incubation, there were no differences ($P>0.63$) between CCB-DM and SBM-DM degradation (95.32 vs. 93.75%, respectively). Soluble fraction (a), degradable fraction (b) and rate of degradation (c) of CCB-DM were 25.58%, 70.95%, and 0.134%/hour, respectively. While values of 27.68%, 77.09%, and 0.076%/hour for fraction a, b, and c, respectively, were obtained for SB-DM. The effective dry matter of CCB degraded in rumen was calculated in 87.03%. It is concluded that dry matter of raw cull chopsuey beans is highly degradable and rapid degraded in rumen of sheep.

Key Words: Chop Suey Beans, Rumen Degradability, Sheep

T258 Ruminant degradation of dry matter of overcooked sesame meal using nylon bag technique in sheep. J. F. Obregon*, H. Castro, R. Barajas, A. Estrada-Angulo, G. Telles, and Y. Peraza, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

The nylon bag technique was used to determine the ruminal degradation of sesame meal dry matter in sheep. Three sheep (Pelibuey males, BW=32 kg) were fitted with rumen cannula. The animals were fed a diet containing corn straw 13%, corn grain 55.5%, soybean meal 20%, sugar cane molasses 9%, and mineral premix 2.5% (16.5% CP and 3.55 Mcal DE/kg). Nylon bags (10x18 cm) containing 5 g of sesame meal (SM) or soybean meal (SBM) were randomly designated to be incubated in rumen of sheep for 3, 6, 9, 12, 18, 24, 36, or 48 hours. After removal from the rumen the bags were washed with tap water and DM was determined. The DM disappearance from nylon bags was higher ($P<0.01$) for soybean meal than sesame meal for all times of incubation, DM degradability was 35.05% vs. 30% at 3 hours, 67.8% vs. 46.05% at 12 hours, 87.36% vs. 53.05% at 24 hours and 97.4% vs. 63.9% at 48 hours for soybean meal and sesame meal respectively. Soluble fraction (a), degradable fraction (b) and rate of degradation (c) were 25.46%, 40.70% and 0.054%/h for SM, respectively. While values of 19.37%, 82.47%, and 0.067%/h for fraction a, b, and c, respectively, were obtained for SBM. The effective dry matter of SM degraded in rumen was calculated in 55.7%. It is concluded that dry matter of sesame meal is less degradable by and more slowly degraded in the rumen of sheep.

Key Words: Sesame Meal, Rumen Degradability, Sheep

T259 Genetic resistance to *Eimeria* infections in Merinoland sheep and relationships among oocyst count, *E. ovinoidalis* antibody level and live weight. M. Gauly*¹, J. Reeg², C. Bauer³, H. Brandt², C. Mertens⁴, H. Zahner³, and G. Erhardt², ¹*Institute of Animal Breeding and Genetics, University of Göttingen, Göttingen, Germany*, ²*Department of Animal Breeding and Genetics, University of Giessen, Giessen, Germany*, ³*Institute of Parasitology, University of Giessen, Giessen, Germany*, ⁴*Intervet Innovation GmbH Zur Propstei, Schwabenheim, Germany*.

Genetic parameters in resistance to *Eimeria* infections were studied in Merinoland sheep lambs (n = 222) descending from 179 ewes and sired by 10 rams, using *Eimeria* oocyst counts (oocysts per gram of faeces,

OpG) and *E. ovinoidalis* antibody level index (Ab) as marker traits. Faecal samples were taken individually in all lambs beginning at an age of 17 until an age of 40 days every third and afterwards every sixth day, respectively. The presence and number of oocysts were determined (OpG) using the modified McMaster method with saturated NaCl as the flotation fluid, which allowed the detection of a minimum of 100 OpG (MAFF, 1986). Blood samples were taken from all lambs at an age of 7, 40 and 80 days to measure antibody level using a Sandwich-ELISA (Nolan et al., 1986). Based on that Ab was calculated (Zahner et al., 1981). All lambs were individually weighed at birth and at 21, 40, 80, 120 and 150 days of age. Male lambs were slaughtered with a weight of 42 kg and females with 39 kg. OpG and Ab were transformed as the decimal logarithm or logarithm to correct for heterogeneity of variance and to produce approximately normally distributed data. 1714 samples (33.6 %) were oocyst negative while 3392 samples (66.4 %) were positive. Every lamb shed at least once oocysts. Even animals with high oocyst counts did not show any visible signs of sickness. Heritabilities of decimal log OpG were between 0.00 and 0.79 (s.e. 0.27). Mean log Ab was decreasing from a level of 0.33 (s.d. 0.13) at day 7 to a level of 0.13 (s.d. 0.07) at day 40 before the value increased again to 0.25 (s.d. 0.13) at day 80, respectively. The estimated heritabilities for log Ab measured at days 7, 40 and 80 were between 0.00 and 0.02 (s.e. 0.06), respectively. Phenotypic correlations among log OpG and body weight ranged between $r = -0.07$ ($p > 0.05$) and $r = -0.25$ ($p < 0.01$), respectively. The corresponding correlations between log Ab at various ages and body weight averaged between $r = -0.09$ ($p > 0.05$) and $r = 0.27$ ($p < 0.05$), respectively

Key Words: *Eimeria* Resistance, Antibody Level, Oocyst

T260 Phenotypic correlations between body measurements and production performance of six sheep breeds at north-central México: exploratory trial. M. A. Gallegos-Acevedo, N. Nieves-Herrera, C. F. Arechiga, J. I. Aguilera, M. A. Castillo-Pecina, and M. A. Lopez-Carlos*, *Universidad Autonoma de Zacatecas, Zacatecas, Mexico*.

Body measurements of 72 young rams (4 to 6 months of age) of different breeds (Rambouillet n=17, Suffolk n=5, Blackbelly n=8, Dorper n=8, Kathadin n=21 and Pelibuey n=14) were correlated with their production performance. Seventeen parameters, scrotal circumference (SC), body weight (BW), body length (BL), shoulder height (SH), shoulder width (SW), hindquarter height (HH), hindquarter width (HW), heart girth (HG), abdominal girth (AG), metacarpus circumference (MCC), metatarsus circumference (MTC), knee circumference (KC), neck circumference (NC), shoulder width (SW), wide of the back (WB), average daily gain (ADG) and feed conversion (FC) were measured 90 days apart (two times during the trial), as an exploratory test to develop a simple "on farm" ram selection method, and selection indexes for these breeds on local production conditions. Highest phenotypic correlations of 0.90 - 0.91 were found between BW and HG, for all breeds except for Dorper where a correlation of 0.34 was found. Some authors have found high relations between BW and BL, but in this trial medium values were obtained (0.45 - 0.62). Correlations between BW, HH, NC, KC and WB obtained high values (0.72 - 0.85). The measurements of the bone mass, MCC and the MTC, obtained high values of correlation (0.75 - 0.82) with BW, HG and AG. SC had low (0.20) to medium (0.40 - 0.50) correlations with other parameters measured. ADG obtain intermediate correlations with bone measurements MCC and MTC (0.45 - 0.53) and FC a low relationship (-0.02-0.015) with all parameters measured except with BW (0.73). Different correlation values were found for different breeds included in this trial, demonstrating that these measurements are related to the breed body shape and size. This exploratory trial could help us to develop a simple "on farm" method for selection of rams.

Key Words: Sheep, Phenotype, Genetic Traits

T261 Effect of breed type, finishing treatment, and dietary supplements on carcass characteristics and tenderness in hair sheep. M. Fisher¹, S. Duckett*¹, and S. Wildeus², ¹*The University of Georgia, Athens*, ²*Virginia State University, Petersburg*.

Thirty-six lambs were used to determine the effects of breed, finishing diet, and CP level of supplement on carcass quality and tenderness. Lambs from three hair sheep breeds (Barbados Blackbelly [BB];

Katahdin [K]; and St. Croix [STX]) were assigned to two finishing diets (pen [PEN] vs. pasture [PAST]) and supplemented with 12% (LOW) or 18% (HIGH) CP. Lambs finished in PEN received chopped, moderate quality grass hay; whereas lambs finished on PAST were allowed to graze native, predominantly fescue pasture. Lambs were harvested, and carcass data and loin samples collected at 24 h postmortem. Loin were aged at 4°C for 14 d and frozen for subsequent Warner-Bratzler shear force (WBS) measurement. Data were analyzed as a 3 x 2 x 2 factorial design to evaluate the effects of breed, finishing diet, supplemental CP level, and all possible interactions. Hot carcass weight (HCW) and ribeye area (REA) were greater ($P < 0.05$) for K than BB or STX. Carcasses from STX had heavier ($P < 0.05$) HCW but smaller ($P < 0.05$) REA than BB. Flank streaking was greater ($P < 0.05$) for K and STX than BB. Leg scores and quality grades were greater ($P < 0.05$) for K than BB or STX, which were similar. Body wall thickness was greater ($P < 0.05$) for K and STX than BB. The three-way interaction between breed, finishing diet and CP supplementation was significant ($P < 0.05$) for fat thickness. Fat thickness was higher ($P < 0.05$) for K fed HIGH on PAST than K-PAST-LOW, K-PEN, or STX and BB regardless of finishing diet and CP level. Fat thickness was lower ($P < 0.05$) for BB fed HIGH on PAST than K-PAST regardless of CP level or K-PEN-LOW. For WBS, HIGH increased ($P < 0.10$) WBS in BB but CP supplementation level did not alter WBS for STX or K. Hair sheep breed influenced carcass quality with K having heavier HCW and greater quality grades. Finishing diet and CP supplementation only influenced fat thickness levels but did not alter other carcass variables.

Key Words: Lamb, Hair sheep, Tenderness

T262 Characterizing exfoliative vaginal cytology (ECV) in ewes from 60 d of age through parturition. G. Solis, J. I. Aguilera, R. M. Rincon, R. Bañuelos, and C. F. Arechiga*, *Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

Present work try to characterize exfoliative vaginal cytology (EVC) from 60 d of age through parturition of Border-Leicester X Rambouillet lamb ewes from Mexican highlands of Zacatecas (22° 58' of north latitude and 102° 31' of west latitude above 2,153 m above the sea level). Vaginal smears (n=967), were obtained from ewes (n=8), from d 60 of age until parturition through different developmental stages: Pre-puberty, Puberty, Estrous Cyclicity, Pregnancy, Parturition. Papanicolau staining was performed to identify cellular types on vaginal smears. During the Pre-pubertal stage of ewe lambs (n=541 smears), basal (B) cells were mainly predominant followed by intermediate (I) and superficial (S) cells (B=84.62%; I=14.52%; S=0.41%). At the beginning of Puberty (n=8 smears), superficial cells were mainly predominant (B=1%; I=4%; S=84%), however, during the Estrous Cyclicity stage, (n=263), intermediate cells predominate with considerable populations of basal and superficial cells (B=23.1%; I=49.9%; S=26.62%). During Pregnancy (n=148 smears), there was an increase of intermediate cells (B=8.77%;

I=77.57%; S=11.95%). At Parturition (n=7), there was tendency to decrease intermediate cells and increase superficial cells (B=19%; I=38%; S=38.86%). Thus, we can conclude that in the Pre-pubertal stage there is a high population of basal cells. At the beginning of Puberty, there is high proportion of superficial cells (estrogen influence). During Estrous cyclicity there is a double amount of intermediate cells in comparison with basal and superficial cells (progesterone dominance). During Pregnancy, there is a high dominance of intermediate cells (high progesterone influence) and finally, at Parturition, there is a tendency to decrease intermediate cells (decreased progesterone) and to increase superficial cells (increased estrogens), until both cell types reach similar ratios.

Key Words: Ewe, Cytology, Vaginal Smears

T263 Sexual behavior and interaction of hair rams as an auxiliary aid for estrus detection in bovine females. C. F. Arechiga*, M. G. Magallanes¹, N. Nazarala¹, R. M. Rincon¹, J. A. Piña¹, M. A. Lopez¹, and J. Valencia², ¹*Universidad Autonoma de Zacatecas, Zacatecas, Mexico,* ²*Universidad Nacional Autonoma de Mexico, Mexico.*

Sexual behavior of hair rams (Black-belly, n=2) expressed by interaction with bovine females was evaluated as a possible auxiliary for visual estrus detection of cows included in artificial insemination programs. Bovine females (n=8), were dairy cows (n=3) and beef heifers (n=5). Sexual behavior of hair rams was evaluated on response to bovine-ovine interaction, to be used as ovine-teasers on estrus detection of bovine females, based on a previous adaptation period of 120 d. Then, bovine females were induced in estrus by a prostaglandin injection. 56 h post-administration of prostaglandins, hair rams were introduced into a pen with bovine females. Sexual behavior and interactions were recorded among both species by video-camera films. 100% of bovine females (8/8) were induced in estrus by 72.84 ± 5.12 h after prostaglandin injection. Estrus duration was 11.91 ± 5.64, bovine females performed 77 mounts, received 74 mounts, showed 12 anxiety signs and 6 cases of presence of vaginal mucus. In contrast, 42.9% of females (3 of 7), showed natural estrus 20.6 d after induced estrus. Performing 45 mounts, receiving 30 mounts, and 2 cases of presence of mucus without showing anxiety signs. Sexual behavior of hair rams in both types of estrus was: 20 courtships, 13 followings, 9 sniffings, 5 Flehmen reflexes, 3 territory markings, 2 masturbations and 2 homosexual mounts within male rams (adult and young rams). In conclusion, a hair ram is capable of showing sexual interest to bovine females in estrus. Such type of behavior, could help to visually detect bovine females in early estrus, independently of age (cows and heifers) or type (dairy and beef). Sexual behavior of rams seems to be acquired by a previous adaptation period of 120 d of interaction with bovine females.

Key Words: Estrus Detection, Sexual Behavior, Hair Sheep

T264 Financial performance of dairies in Florida and Georgia in 2002. A. deVries¹, R. Giesy¹, L. O. Ely*², A. deAraujo¹, A. Andreasen¹, B. Broadus¹, S. Eubanks¹, D. Mayo¹, P. Miller¹, T. Seawright¹, and C. Vann¹, ¹*University of Florida, Gainesville,* ²*University of Georgia, Athens.*

The Dairy Business Analysis Project (DBAP) includes an annual survey of the financial performance of dairies primarily located in Florida and Georgia. Its objective is to document the dairies financial success using standardized, accrual accounting methods in order to calculate benchmarks and provide feedback on the dairies financial strengths and weaknesses. Twenty-nine dairies submitted financial data in 2002. Twenty-seven dairies were included in the summary results. Of these, 18 were located in Florida, 8 in Georgia and one in Alabama. The average herd size was 1,168 cows and 583 heifers with 16,810 lbs. milk sold per cow. The average culling rate was 34%. There was an average of 20 FTE workers per farm and 1,010,000 lbs milk sold per FTE worker. Total revenue per cwt. was \$17.67 / cwt with \$16.05 / cwt milk income. The average total expense was \$17.88 / cwt. The largest expense items were purchased feed (\$7.00 / cwt), labor (\$2.88 / cwt), and livestock (\$1.04 / cwt). Net farm income from operations was on average \$-.21 / cwt and net farm income was \$-.10 / cwt. The debt to equity ratio was 1.10, the rate of return on assets was -0.02, the rate of return on equity

was -0.08, the operating profit margin was ratio was -0.03. There was no clear association between income, expenses or returns with herd size in 2002. Milk price / cwt was lowest for <500 cows (\$15.81) but other income was highest (42.25 / cwt) resulting in the highest total income (\$19.24 / cwt) and net farm income \$0.57 / cwt. Milk price, total income, total expenses increased with production level. net farm income was highest for medium production level.

Key Words: Dairy, Financial, Management

T265 Factors affecting death losses in DHI holstein herds. L. O. Ely* and J. W. Smith, *University of Georgia, Athens.*

Dairy cow death losses are a significant economic loss for U. S. dairy farmers. This study examines the effect of several factors (yr, region, month of the yr, herd milk production level, and herd size) and the interaction of these factors on death losses in DHI Holstein herds. DHI herd summary records for the years 1999 through 2002 were sorted and classified by yr, region (Northeast, Midwest, Midsouth, South), month, milk production level (low[5443 to 7258 kg], medium [7258 to 9072] and high [>9072]), and herd size (small[<100 cows], low medium [100 to 149], high medium [150 to 299] and large [>300]). Monthly death loss

percent (MDL) was calculated as the number of cows reported died per month / total cows in the herd per month *100. Least squares means for MDL were compared by the Tukey option of SAS PROC GLM. The level of significance used was $P < 0.05$. MDL significantly increased each yr from .56 (1999) to .63 (2002). MDL differed significantly across regions with the lowest value in the Northeast (.47) and the highest value in the South (.67). MDL was lowest for high producing herds (.50) and highest for low producing herds (.67). MDL increased significantly from small size (.55) to large size herds (.67). MDL was highest during July to September across all regions. MDL was $< .70$ during all mo in the Northeast. MDL was $> .70$ during Aug and Sept in the Mid-south, ; $> .70$ during Jul, Aug, Sept in the Midwest, and $> .70$ during Aug, Sept, Oct, Nov, Dec, and Jan in the South. The South not only had the highest values but also the longest duration of high death loss. #8805#8804#8805#8804#8805#8805#8805#8805#8805#8805

T266 SoutheastDairyExtension.org - An Internet-Based Dairy Website for Southeast US and Beyond. G. W. Rogers*, E. L. Tipton, K. M. Hill, and J. B. Cooper, *The University of Tennessee, Knoxville*.

Dairy Extension personnel in the southern United States need fast access to pertinent dairy-related articles on the Internet. A website, www.SoutheastDairyExtension.org, sponsored by The University of Tennessee Dairy Extension program and the UT Department of Animal Science currently is providing this to dairy producers, Extension personnel, researchers and 4-Her's throughout the Southeast US. This is a database-driven website designed in Microsoft Access as a portal to the vast amount of web-based dairy industry information. Many prominent and information-rich links are being collected and key information from these are stored as database fields. Fields include the title of the information source, URL, author, state/country, year and a brief excerpt. Keywords, topic and subtopics (also fields) are assigned to each link. Topics pertinent to the Southeast, such as heat stress and heifer raising are featured. Other current topics include economics/marketing, facilities, genetics, grazing systems, health, mastitis/milking, nutrition, reproduction, waste management, and youth. Links include published dairy science papers, popular press articles, Internet-only information, and industry publications. Dairy statistics are available for twelve southern states as well as contact information for Dairy Extension personnel. Tip of the Month and Spotlight are two features on the home

Teaching/Undergraduate and Graduate Education: Teaching

T268 Comparison of evaluation methods for placement in a freshman equitation course. K. Bennett-Wimbush* and S. Porr, *Ohio State University, Agricultural Technical Institute, Wooster*.

The skill level of students enrolling in college riding courses is varied. It is often necessary to evaluate and rate students based on their reported previous riding experience and observed skills in order to place them in an appropriate riding group. This insures a more homogenous student group which should facilitate learning and skill development. The objectives of this study were to gather information on past riding experiences of college students enrolled in an equine science major and compare an instructor evaluation method of riding skills to a student self-evaluation method. One hundred and fifteen students were surveyed and evaluated over a three year period. Students completed a three page questionnaire with the last question asking them to rate their riding skills (SE) as one of the following: Pre-Beginner (1), Beginner (2), Advanced Beginner (3), Intermediate (4), Advanced-Intermediate (5), Advanced (6) or Professional (7). The course instructor then performed a mounted evaluation (IE) of each student using the same evaluation levels without knowledge of the SE. Differences in ratings between SE and IE were determined by Chi square analysis. Additionally the difference in means was analyzed using Proc Means, SAS. Students reported having an average of 7.9 years of riding experience. SE ratings were higher ($p < .01$) than IE. More students rated themselves Advanced-Intermediate (34.86%) while the most common rating from IE was Intermediate (29.36%). SE yielded .92% (1), 8.26% (2), 11.92% (3), 25.69% (4), 34.86% (5) and 11.93% (6). The SE and IE were in agreement for approximately 38% of the students, while 45% of the surveyed students overrated their riding ability compared to the IE, 11% of the students underrated their ability and 6%

page that are updated regularly. A fast-results keyword search is embedded in this application. To keep the site up-to-date, visitors can suggest new links by clicking the "Suggest Link" button that is on each page. T267 Association between bulk tank milk urea nitrogen and DHI production variables in California dairy herds. G. E. Higginbotham*¹, W. R. VerBoort², and J. E. P. Santos³, ¹*University of California Cooperative Extension Fresno/Madera Counties, CA*, ²*California DHIA Fresno, CA*, ³*School of Veterinary Medicine, University of California, Davis, Tulare*.

A retrospective study from January, 2001 to December, 2003 was conducted using data from DHI monthly tests to investigate the relationship between daily bulk tank milk urea nitrogen (MUN) concentration and selected DHI production variables from selected Holstein (N=40) and Jersey (N=31) herds located in the central valley of California. Average herd size and rolling herd average (RHA) for milk were 1,123 cows and 10,106 kg, respectively, for Holstein herds, and 730 cows and 7,412 kg, respectively, for Jersey herds. Data were analyzed using regression analyses and the MIXED procedure of the SAS (2001) program. Concentrations of MUN averaged 12.2 and 12.1 for Holsteins and Jerseys ($P=0.34$). Concentrations of MUN were negatively correlated with percentage of casein and true protein ($P < 0.001$) in milk for Holsteins and Jerseys, but the relationships were weak ($r^2 < 0.036$). Bulk tank MUN was not associated with average milk yield per cow ($P=0.11$). However, MUN was negatively correlated with true protein ($r^2=0.0033$; $P < 0.001$) and casein ($r^2=0.0034$; $P < 0.001$) in milk of Holsteins and Jerseys ($r^2=0.027$; $P < 0.001$). Time of season effected concentrations of MUN being significantly ($P < 0.001$) lower during the winter for both Holstein and Jersey herds and significantly ($P < 0.001$) higher during months of heat stress. Test day somatic cell count (SCC) as mean SCC and as linear score showed a negative non-linear relationship with MUN for both breeds.

Key Words: MUN, DHI, Dairy

of the students failed to rate their skills. This supports the use of instructor evaluations of student self-evaluations for proper placement in riding classes.

T269 Integrating leadership, communications, and service learning education to prepare future leaders in the animal sciences. D. R. Brink*, L. D. Moody, and B. S. VanDeWalle, *University of Nebraska, Lincoln*.

Leadership and communications are very beneficial areas of study for Animal Science students. These areas have been included in a program at the University of Nebraska called the Animal Science Leadership Academy (ALA). The program is lead by a professor of Agricultural Leadership Education and Communication and a professor of Animal Science with the assistance of a graduate student. In ALA, there are many different activities for students to obtain leadership experience in business and industry. In the first semester of ALA, students shadow professionals in three different career options, develop a professional presentation and a portfolio of their professional development. Furthermore, as freshmen, ALA students attend the ASAS and ADSA Midwestern Sectional Scientific Sessions. During the second semester, ALA students learn about service learning and develop individual and group service-learning projects. During the third and fourth semesters of ALA, students implement their service learning proposals while also attending sessions focusing on internships and leadership development plans for the remainder of their undergraduate study. In four, 1-credit hour courses a variety of methods are used. Class projects and papers

are designed to build experience for future careers and to create network contacts for future opportunities. Ideas and projects are developed in groups to build communication and interpersonal skills, helpful in a future work environment. Guest speakers provide business and industry perspectives on leadership and communications topics. A survey of ALA students indicated job shadowing was the most beneficial activity of ALA and students agreed they were able to demonstrate leadership

within their classes and student organizations. The partnership of faculty from different departments, business and industry professionals, and students in ALA provides a unique opportunity for Animal Science students to be prepared for leadership positions.

Dairy Foods: Chemistry

T270 Storage stability of lutein in cheddar cheese. S. T. Jones*, K. J. Aryana, and J. N. Losso, *Louisiana State University, Baton Rouge.*

The etiology of age-related macular degeneration (AMD) is complex; however, risk factors include genetic and environmental stimulus. As standard therapies for macular degeneration are limited, costly, and often associated with undesirable pathological side effects, the role of nutrition in protecting against AMD is intensively under scientific consideration. Lutein (3,3-dihydroxy- α -carotene) has been identified as a dietary strategy that can delay the onset of AMD. However, available food sources of lutein contain small amounts of lutein. Food fortification with lutein extract has been identified as a low budget prescription to prevent the onset and/or progression of AMD. The objectives of this study were to 1) incorporate various amounts of lutein into cheddar cheese; 2) analyze the stability of lutein during the cheese aging process; and 3) examine the color, pH, and microbiological profile of the cheddar cheese during storage. Lutein, extracted from corn was added to cheddar cheese in quantities of 1 mg, 3 mg, and 6 mg. Measurements of the lutein stability were carried out by HPLC using a YMC C₃₀ carotenoids column. Microbiological analyses of cheese samples included counts using SPC, Coliform, and Y/M Petrifilm. The attributes studied on the cheese were color and pH. The color attribute a* ($p < 0.05$) was significantly different among the treatment and control groups; however no significant difference were observed in L*, b*, and pH values. A significant difference ($p < 0.05$) among 1 mg, 3 mg, and 6 mg treatments were observed in the SPC with respect to the control. The cheese samples were found not to have any coliforms (<10 cfu/g) and Y/M (<10 cfu/g). HPLC data showed quantitative recovery of lutein during the storage period and no lutein degradation products were identified. These results indicate that lutein, a functional food with purported ability to prevent or reduce the onset of macular degeneration; can be added to cheese as a value-added product.

Key Words: Lutein, Cheese, Age-Related Macular Degeneration

T271 Physical properties of κ -casein stabilized emulsions. R. Richter, P. Ungkuraphinunt*, A. Gerung, and G. Perez-Hernandez, *Texas A&M University, College Station.*

The objective of this study was to determine the physical properties of emulsions stabilized with κ -casein. κ -casein was separated from acid casein using ion-exchange separation (Cayot et al. 1992). Emulsions containing 0.3% κ -casein and 3% butteroil were heated to 65°C and homogenized at 20, 60 and 100 MPa. Particle size distribution, rheological properties, heat stability, and the effect of rennet on the coagulation properties of the emulsions were studied. Storage stability was determined by measuring the particle size at the top and bottom of emulsions after 1, 7 and 14 days of storage. Particle sizes (dvs) of the emulsions were 0.738, 0.291 and 0.115 μ m for emulsions homogenized at 20, 60 and 100 MPa respectively. The homogenization pressure did not affect the viscosity of the emulsions, the average viscosity was 1.20 cP and emulsions had a Newtonian behavior. The addition of rennet caused the mean viscosity to increase from 1.20 to 3.74 cP. Significant differences in particle size were not found in the emulsions after heating. Emulsions homogenized at 100 MPa were more stable than emulsions homogenized at 20 and 60 MPa during the storage period. κ -casein can be used to prepare stable emulsion with butteroil.

Key Words: κ -Casein, Emulsion Stability, Physical Properties

T272 Probiotic, fiber fortified, fat free plain yogurt. K. J. Aryana*, *Louisiana State University Agricultural Center, Baton Rouge.*

Probiotic bacteria exert benefits on the gastrointestinal health. High fiber intakes lower the risk of coronary heart disease and certain cancers. The objective was to determine whether or not the incorporation of a combination of probiotic bacteria and fibers impact the physico-chemical and sensory characteristics of fat free plain yogurt. Six different fibers namely Fibergum, Fibersol, Benefiber, Hydrobind, QC-40 and Inulin (ST-Gel) were incorporated at the rate of 1% w/v separately in the yogurt mixes. The total solids were kept constant in the control with non fat dry milk. Yogurt mixes were homogenized, batch pasteurized, cooled and yogurt culture (*Lactobacillus bulgaricus* and *Streptococcus thermophilus*) was added. This was immediately followed by further inoculation of the mix with a probiotic culture containing *Lactobacillus acidophilus*, *Bifidobacterium*, and *Lactobacillus casei*. The inoculation rates with probiotic bacteria were 0, 0.02% v/v mix. The yogurt attributes studied were syneresis, viscosity, pH, color (L*, a*, b*), sensory flavor, body and texture and appearance. Yogurts manufactured with Hydrobind exhibited significantly ($p < 0.05$) the least amount of syneresis (released whey) followed by Benefiber. The use of the remaining fibers resulted in syneresis which were not significantly different from the control. Yogurt manufactured with Hydrobind was significantly ($p < 0.05$) the most viscous compared to the control yogurt and yogurts with other fibers. The pH of the yogurts were not significantly ($p < 0.05$) impacted by the incorporation of the above mentioned fibers. Yogurts with Fibersol, Benefiber and QC-40 had significantly ($p < 0.05$) higher L* (Lightness) values compared to the other yogurts. Significantly highest a* and b* values were recorded for yogurts manufactured with Hydrobind and Benefiber respectively. Flavor and body and texture scores for yogurts with ST-Gel, QC-40 and Fibersol were not significantly ($p < 0.05$) different from the control. The appearance scores of yogurts with Fibergum and ST-Gel were high and did not differ significantly ($p < 0.05$) from the control. Probiotics along with different fibers favorably impacted different attributes of fat free yogurts.

Key Words: Health, Fermented, Dairy

T273 Fat free plain set yogurts fortified with minerals. K. Achanta*¹, K. J. Aryana², and C. Boeneke², ¹*Louisiana State University*, ²*Louisiana State University Agricultural Center.*

The health benefits of various minerals are well documented in literature. Whether or not the incorporation of various minerals impacts the physico-chemical characteristics of yogurt is not clearly understood. Seven different minerals namely, iron, magnesium, zinc manganese, molybdenum, chromium and selenium were incorporated separately into the yogurt mixes at 25% of their respective recommended dietary allowances. The various attributes studied on the yogurts were viscosity, color (L*, a*, b*), pH, syneresis, flavor, body, texture and appearance. No significant difference was observed in viscosity, color (L*, a*, b*), pH, syneresis, body, texture and appearance for yogurts fortified with minerals when compared to the control yogurt. The flavor scores of selenium fortified yogurt were significantly lower from that of the control yogurt. Fortification of yogurts with the above mentioned minerals can be accomplished without adversely affecting the product characteristics.

Key Words: Health, Dairy, Fermented

T274 Effect of emulsifying salts on texture of pasteurized process Cheddar cheese. N. Shirashoji^{*1,2}, J. J. Jaeggi², and J. A. Lucey², ¹*Food Research & Development Laboratory, Morinaga Milk Industry Co., Japan*, ²*University of Wisconsin, Madison*.

A detailed understanding of the influence of various emulsifying salts (ES) on process cheese functionality is important to control product quality and its end-use application. Model process cheeses were made in preliminary trials from 3-4 months old Cheddar cheese with trisodium citrate (TSC), tetrasodium pyrophosphate (TSPP) or polyphosphate salts (1-3%) that was heated at 80°C for 2 min using a bench top blender. Hot melted cheese was poured into pouches and stored at 3-5°C for 7 d. Small amplitude oscillatory rheology (SAOR) was used to study the rheological properties using a temperature sweep (frequency 0.08 Hz, strain 0.5%) from 5-85°C at a heating rate of 1°C/min. Melting properties of process cheese were measured by UW-Meltprofler. Uniaxial compression of cheese was determined by compression to 20% of original height. Acid-base titration method was used to determine the concentration of residual insoluble calcium phosphate. Initial results from these model cheeses indicated that the storage moduli values between 40 to 85°C of cheese made with polyphosphate were higher than those with TSC, which had excellent meltability. A low concentration of TSPP resulted in cheese that had greatly reduced melt. Uniaxial compression showed that cheese with added polyphosphate had higher hardness and lower adhesiveness values than cheese made with TSC. Titration curves of process cheese made with TSC resulted in a reduction in the buffering peak at pH 4.8 as the concentration of ES increased. The buffering peak at pH 4.8 is caused by residual insoluble calcium phosphate. This buffering peak shifted to a lower pH value (pH 4.04.2) as the concentration of added polyphosphate increased. Currently pilot plant scale cheese trials with these ES and various heat treatments are being performed and will be reported.

T275 Probiotic, fat free, no sugar added ice cream. M. Summers^{*} and K. J. Aryana, *Louisiana State University Agricultural Center, Baton Rouge*.

Probiotic bacteria exert benefits on the gastrointestinal health. The objective was to determine whether or not the incorporation of probiotic bacteria impacts the physico-chemical and sensory characteristics of fat free no sugar added ice cream. A fat free, no sugar added ice cream mix was homogenized, vat pasteurized, cooled, and aged. Prior to freezing, vanilla flavor was added. The mix was inoculated with a probiotic culture containing *Lactobacillus acidophilus*, *Bifidobacterium* and *Lactobacillus casei*. Mixes were inoculated at rates of 0, 0.002, 0.02 and 0.2 %v/v. Immediately after inoculation the mixes were frozen. The attributes studied on the mixes were viscosity and pH. Attributes studied on the ice creams were color, meltdown time for first 15 ml, meltdown ml after 60 minutes, and sensory flavor, body and texture. The probiotic ice creams had significantly higher L* and b* values compared to the control. The a* values for the probiotic ice creams were significantly lower than the control. There were no differences in L*, a*, and b* values among the probiotic ice creams. The pH of the control was significantly lower compared to the probiotic ice creams. There were no significant differences in pH among the probiotic ice creams. There was no significant difference in the meltdown time for first 15 ml, meltdown ml after 60 minutes, sensory flavor, and body and texture of the ice creams. Incorporation of probiotic bacteria impacted some of the physico-chemical characteristics of fat free no sugar added ice cream.

T276 Effect of insoluble calcium phosphate on cheese functionality. J. Choi^{*1}, D. S. Horne², M. E. Johnson¹, and J. A. Lucey, ¹*University of Wisconsin, Madison*, ²*Charis Food Research, Scotland*.

We hypothesized that loss of insoluble Ca from casein could be responsible for softening and flow of cheese. To test this hypothesis, skim milk was directly acidified with lactic acid to pH 6.0, 5.8, 5.6 and 5.4. In another trial, EDTA (0, 2, 4, and 6 mM) was added to skim milk, and milk was directly acidified to pH 6.0. Both types of milks were processed into cheese. The proportion of insoluble Ca was determined by acid-base titration method. Dynamic low amplitude oscillatory rheology was used

to measure the viscoelastic properties of cheese during heating from 5 to 80°C. To reduce the effect of proteolysis, viscoelastic properties were measured 10 h after pressing. The moisture content in all the cheeses was the same (55%), as cheesemaking procedures were modified to obtain similar moistures. The loss tangent maximum (MaxTan) increased (i.e. more flow) during heating, and for cheese made from milk preacidified to pH 6.0, 5.8, 5.6, and 5.4 it was 1.5, 2.9, 4.0, and 4.8, respectively. MaxTan of cheese made from milk with 0, 2, 4, and 6 mM EDTA were 1.5, 1.9, 2.5, and 3.4, respectively. The cheese pH was 5.7, 5.6, 5.4, and 5.3 for cheeses made with milk acidified to pH 6.0, 5.8, 5.6, and 5.4, respectively, and all cheeses from EDTA trials had the same pH (5.7). When the proportion of insoluble Ca in cheese made from milk acidified to pH 6.0 was set as 100%, there was 85, 71, 63% residual insoluble Ca in cheese made at pH 5.8, 5.6, and 5.4, and 96, 83, 80% for 2, 4, and 6 mM EDTA cheese, respectively. Preacidification of milk resulted in a reduction in total Ca and decreased the proportion of insoluble Ca and both could contribute to the increased softening and flow observed in lower preacidification cheeses. Addition of EDTA reduced the proportion of insoluble Ca while there was a only slight reduction in total Ca and pH was constant. The greatly increased melt with higher levels of EDTA was due to the reduction in insoluble Ca.

Key Words: Insoluble Calcium Phosphate, Cheese Functionality, Loss Tangent

T277 Texture and microstructure of full fat and low fat Cheddar cheeses fortified with chitosan. K. J. Aryana^{*} and M. C. Beck, *Louisiana State University Agricultural Center, Baton Rouge*.

Chitosan is a fat absorbing fiber. Adding chitosan to full fat and low fat Cheddar cheeses could make it possible to enjoy the advantages of fat (texture, flavor, mouthfeel) and avoid the disadvantage by preventing fat absorption in the intestine. The objective was to elucidate whether or not incorporation of chitosan in full fat and low fat Cheddar cheeses influences the texture and microstructure of cheese. Two types of chitosan namely granular and 90% high density were incorporated during cheese making at 0, 0.5 and 1.5% w/w fat in cheese. Texture was determined using a TA.XT plus texture analyzer and the microstructure was determined by scanning electron microscopy. The fracture stress and strain of the full fat and low fat control cheeses were significantly (p<0.05) higher compared to the cheeses with chitosan. Incorporation of chitosans at the highest concentrations resulted in cheeses with compact surface microstructures compared to the control. Chitosan incorporation in cheese at 1.5% w/w fat impacted the texture and microstructure of full and low fat Cheddar cheeses.

Key Words: Fat, Dairy, Health

T278 Quantification of volatile flavor compounds in fresh and different off-flavor lowfat milks. L. L. Francis, D. H. Chambers, I. J. Jeon, and K. A. Schmidt^{*}, *Kansas State University, Manhattan*.

Various chemical compounds contribute to the naturally pleasant flavor of milk, however with time and unwanted reactions, flavor loss is inevitable. This study was done to quantify and compare chemical compounds in "various flavors" of lowfat milk for identification of critical compounds that contribute to fresh milk flavor. Fresh milk (2d) was used to purposely prepare altered milks such as light oxidized and high acid. Lacks freshness was a 2 wk prior production milk maintained at 4°C in the dark. For SPME analysis, 75µm Carboxen/PDMS fiber sampling at 60°C for 30 min was used to collect volatile compounds in the milk headspaces which were subsequently analyzed by GC-FID for quantification. In addition all milks were analyzed for compositional contents and microbial counts. This experiment was replicated twice. Results from this study provide evidence that fresh milk flavor cannot be defined by the concentration of pentanal, hexanal, 2-heptanal, benzaldehyde, 2-butanone, and octanal only. Trends showed that light oxidized milk had a lower concentration of octanal and a higher concentration of hexanal than did fresh milk. When comparing oxidized milks exposed to light (200 ft candles) at various times (1 and 3 h), pentanal and 2-butanone concentrations increased as light exposure time increased. High acid milk possessed higher concentrations of benzaldehyde and 2-butanone, but had a lower concentration of octanal than did fresh milk. Lacks freshness milk had a higher concentration of pentanal and a lower concentration of octanal than did the fresh milk. All milks had similar

fat, total solids, and viscosity values. The lacks freshness and high acid milk had higher total plate counts than did the other milks which were considered equivalent. For this study fresh milk had a higher octanal concentration than did the off-flavored lowfat milks, which may suggest that octanal or a defined ratio of octanal to another compound is an important contributor to fresh milk flavor and, thus deserves further study.

Key Words: Milk, Flavor, Compounds

T279 Serving temperature effects on milk flavor, milk aftertaste, and volatile compound quantification in nonfat and whole milk. L. L. Francis, S. H. Kong, D. H. Chambers, I. J. Jeon, and K. A. Schmidt*, *Kansas State University, Manhattan.*

Teenagers find the flavor and aftertaste of milk more acceptable when milk is served cold. However, describing the flavor and aftertaste of milk and correlating it to its chemical composition have not been reported. The objectives of this study were to describe the flavor and aftertaste of milk, and quantify the headspace volatiles of nonfat and whole milk as a function of serving temperature (4, 10, and 15°C). The descriptive panel results indicated that as serving temperature increased milk flavor was described as more flat or more astringent. Nonfat milk flavor was rated as having greater sour aromatics, and being more chalky, cardboard, flat, bitter, and metallic but less sweet than the whole milk flavor. Characterizing milk aftertaste at 15 s after swallowing indicated that nonfat milk had more sour, cardboard, and cooked traits than did the aftertaste of whole milk. Characterizing milk aftertaste at 90 s after swallowing indicated that the nonfat milk was less sweet, but had more cardboard and cooked traits than whole milk. With time, aftertaste ratings decreased for sweet, cooked, and fat whereas cardboard and processed aftertaste ratings remained similar. The sour aromatics aftertaste ratings were no longer significant at 90 s. Headspace volatile compounds of milk samples served at 4 and 15°C were quantified using SPME analysis, 75 µm Carboxen/PDMS fiber sampling, done at 60°C for 30 min and then analyzed by GC-FID for quantification. Serving temperature was not significant, but nonfat milks had a higher concentration of hexanal but lower concentrations of 2-heptanone, heptanal, and benzaldehyde than did the whole milk. Correlating the headspace compounds with flavor descriptors, hexanal, which has been associated with cardboard flavors, was higher in the nonfat milk. These data provide evidence that the fat contributes to the flavor and aftertaste traits of milk. For this study milk composition was more influential to milk aftertaste as opposed to serving temperature.

Key Words: Aftertaste, Milk, Flavor

T280 Evaluation of pH stability in different types of heat-treated fluid and manufactured milk products during refrigerated storage. C. O. Maduko*¹, R. Shewfelt¹, J. Frank¹, and Y. W. Park², ¹University of Georgia, Athens, ²Fort Valley State University Agricultural Research Station, Fort Valley, GA.

Heat-induced changes in pH due to shifts in the milk salt equilibrium are largely reversible, while the re-establishment of the equilibrium on cooling is slow. Heat treatment reduces the concentrations of soluble phosphates as well as soluble and ionic calcium. Heat treatment causes the precipitation of soluble calcium to colloidal calcium phosphate, which greatly influences the stability of pH and casein micelle structure in the milk. Ten different types of commercial milk products: pasteurized cow fluid (PCF), cow evaporated (CE), cow skim fluid (CSF), cow skim powdered (CSP), cow whey (CW), pasteurized goat fluid (PGF), goat evaporated (GE), goat milk protein concentrates (GPC), soy fluid (SF) and soy powdered (SP) milks were purchased to study the pH stabilities of the milk products during two weeks storage at 4 and 13°C refrigeration and 22°C room temperature. Evaporated and powdered milks were reconstituted by adding 50 and 87.5% (v/v) deionized water to the products, respectively. All milk groups were divided into three subgroups as heat treated by pasteurization (63°C for 30 min), sterilization (121°C for 20 min), and 22°C room temperature, then pHs were determined. The range of initial pHs for PCF and CE were 6.8-6.9 and 6.4-6.5, then decreased to 6.50-6.75 and 5.97-6.16 after heat treatment at 1st day refrigerated storage. This may be attributable to heat-induced acid production from lactose degradation and precipitation of tricalcium phosphate. From day 3 to 7, there were gradual increases in pH for PCF, CE, PGF and GE by 0.05-0.67 for bovine and 0.03-0.29 for caprine products. The lowest pH reached at day 9 for fluid milks,

where a more drastic pH declines were observed in the milks stored at 4°C compared to those stored at 13°C. The pH stabilities of CE, SCP, SCP, CW, GE were better than the corresponding fluid milks. The SF and SP showed the highest pHs (above 7.0), while the GPC revealed the lowest values. Heat-treated fluid milks had better pH stability at 13°C storage than at 4°C due to the minimized effect of casein dephosphorylation and changes in phosphate equilibrium which would occur at lower temperature.

Key Words: pH Stability, Milk Products, Heat Treatment

T281 Use of long-chain polyphosphates for shelf-life extension of processed cheese spreads. L. Varga* and S. Orbán, *Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.*

The effect of a food-grade long-chain polyphosphate mixture (JOHA HBS sodium polyphosphate glassy, 69±1% P₂O₅) on the growth and survival of spoilage microorganisms during storage in an experimental processed cheese spread formulation containing 55% moisture and 57% fat in dry matter was evaluated. The emulsifying salt was added to the cheese blend at a concentration of 0.5% or 1.0%. A control product was also manufactured, which contained monophosphate instead of polyphosphate as emulsifying salt, with all other ingredients being identical to those in the experimental processed cheese spread. The finished products were subjected to either accelerated shelf-life testing at 37°C for 10 d or refrigerated storage at 4°C for 120 d. Microbiological analyses (enumeration of viable cell counts, sulfite-reducing clostridia, coliforms, yeasts, and molds), acidity measurements, and sensory tests were performed at regular intervals. The results obtained showed that polyphosphates had a beneficial effect on the shelf life of the processed cheese spread tested in that they significantly reduced (*P* < 0.05) the growth or survival rate of spoilage microorganisms, especially of sulfite-reducing clostridia. Polyphosphates also beneficially influenced the sensory, including textural properties of the experimental processed cheese spread. All the samples containing less than 1% polyphosphate showed signs of butyric blowing significantly earlier (*P* < 0.05) during both accelerated shelf-life tests and regular refrigerated storage than did products fortified with 1% polyphosphate. In conclusion, the suitability of the long-chain polyphosphate formulation tested for shelf-life extension of pasteurized processed cheese spreads was demonstrated.

Key Words: Polyphosphate, Processed Cheese, Shelf Life

T282 Seasonal variations in chemical composition of water buffalo milk. F. Lee*¹, J. Page², S. Gokavi¹, and M. Guo¹, ¹University of Vermont, Burlington, ²Page & Pedersen International, Ltd., Hopkinton, MA.

Production of water buffalo milk yogurt, fresh Mozzarella and other products was established in Vermont and is projected to increase steadily in the next several years. However, information on chemical composition and its seasonal variation of year-round bulk-collected water buffalo milk is limited. The objective of this study was to analyze the chemical composition of commingled raw water buffalo milk from the creamy for 12 months to provide fundamental information for yogurt and cheese manufacture. The breeds of the water buffalos were mostly Riverine, with a mix of Murrah, Nili-Rivi and Jafrabadi, and their diet included a mixture of corn silage, baylage and palletized supplements. Samples were collected on the second week of each month, beginning in November, 2002, and analyzed for total solids, fat, lactose, crude protein, ash, specific gravity, minerals and pH. Chemical composition and pH of the water buffalo milk varied slightly during the period. The contents of total solids, fat, lactose, crude protein, ash, and specific gravity were 17.86 ± 0.74, 7.20 ± 0.50, 4.61 ± 0.04, 5.02 ± 0.12, 0.92 ± 0.01, and 1.0339 ± 0.0017 %, respectively. Ranges for these composition were 16.39-18.39, 6.57-7.99, 4.49-4.74, 4.59-5.37, 0.91-0.92 and 1.0317-1.0380, respectively. Mineral contents of Ca, P, K, Mg, Na and Zn were 1798.89 ± 286.97, 1216.76 ± 199.03, 843.72 ± 141.87, 337.20 ± 80.92 and 7.48 ± 3.11 mg/kg, respectively, and remained steady throughout the year. Value of pH was 6.85 ± 0.06, with a range of 6.76-6.98. Content of total solids was higher in the months of November thru March (18.46 ± 0.19 %) when compared to April thru October (17.34 ± 0.62 %). Fat content was higher in the months of September thru January (7.66 ± 0.27 %) compared with February through August (6.80 ± 0.20 %). Crude protein level was higher from November to May (5.14 ± 0.18

%). The data showed that variations in the chemical composition of the bulk water buffalo milk occurred during the period of this study.

Key Words: Buffalo, Milk, Composition

T283 Relationship between cholesterol and fat contents of commercial dairy products. Á. Kovács¹, L. Varga*², R. Dulicsek¹, J. Szigeti², and Z. Herpai², ¹PharmaFood Inc., Pécs, Hungary, ²Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.

The aims of this study were to determine the cholesterol and fat contents of a wide range of dairy products, and to find a relationship between these two compositional attributes. Thirty-three varieties of commercial fluid milks, hard and semi-hard cheeses, condensed and dried milks, cream products, butters, buttercreams, and fermented milks were purchased from food stores located in the western part of Hungary and were then analyzed for fat and cholesterol using the Roese-Gottlieb method and the direct saponification-gas chromatographic method, respectively. Cholesterol-to-fat ratios were also calculated from the values obtained. A high correlation ($r = 0.983$) was found between cholesterol and fat concentrations. Butters and buttercreams had the highest fat and cholesterol levels of the 33 varieties of dairy products tested. The nonfat varieties of dried, fermented, and fluid milks showed largely increased cholesterol-to-fat ratios as compared with the other products, which must have been due to the mechanical damage caused by cream separation to fat globule membranes because the membrane-bound cholesterol thus released remained in skim milk at a higher proportion than fat did. The results of this study can be used for various purposes such as quality control of milk products, food labeling, consumer information, and development of new dairy foods. They may also be needed when assessing fat and cholesterol intakes in epidemiological studies aimed at investigating the relation between diet and health, when formulating diets for population groups with special requirements, or when establishing dietary guidelines for the general public according to health concerns.

Key Words: Cholesterol, Fat, Dairy Product

T284 Development of technology for manufacturing lactose-free fermented milks. J. Szigeti, Á. Krász, and L. Varga*, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.

Lactose intolerance is common in adult populations worldwide except for peoples with a northern European genetic background. We have developed a technology for production of lactose-free fermented dairy products. The protein content of the process milk was increased whereas its lactose level was decreased by addition of milk protein concentrate. The raw material was then inoculated with the starter cultures selected (*Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* or *S. thermophilus* and *L. acidophilus*), and the lactic acid produced during the initial stages of fermentation was neutralized using a proper mixture of sodium hydroxide and potassium hydroxide. Thereafter fermentation was run according to normal commercial practice. The lactose and glucose levels of the fermented milks thus produced were negligible and their galactose content was moderately or highly reduced, depending on the starter organisms used. The finished products did not differ in texture or flavor from regular fermented milks.

Key Words: Fermented Milk, Lactose, Galactose

T285 Rheological and light scattering properties of cottage cheese-type gels made under different gelation rates. M. Castillo*^{1,2}, J. A. Lucey¹, and F. A. Payne², ¹Department of Food Science, University of Wisconsin, Madison, ²Department of Biosystems and Agricultural Engineering, University of Kentucky, Lexington.

The study of milk coagulation by a combination of acidification and rennet (i.e. mixed gels) has received very little attention when compared to rennet-induced coagulation. In cottage cheese, for example, a little rennet is sometimes added to alter the gelation characteristics. Monitoring coagulation by an objective device when cheese is made by many different manufacturing conditions would be useful to control the consistency at cutting and thereby improve the quality of cottage cheese. Gels made at different gelation rates were investigated by a randomized factorial design. Gels were made with a low rennet concentration at three

different temperatures and three different starter concentrations. Gel formation was monitored using infrared light (880 nm) backscatter and dynamic small amplitude oscillatory rheology. Increasing incubation temperature or inoculum concentration enhanced the rate of pH reduction resulting in faster network formation. When coagulation rate increased, the gels became more viscous (i.e. higher loss tangent) and less stiff (i.e. lower storage modulus). The backscatter parameter, t_{min2} , and the rheologically-determined gelation time were highly correlated ($r = 0.992$, $P < 0.0001$) but not significantly different ($P > 0.36$), suggesting that they corresponded to the beginning of gel firming. Activation energy of network formation estimated by light backscatter decreased significantly with increasing starter concentration, which could be related to a reduction in the energy barrier against aggregation caused by enhanced acidification rate.

Key Words: Rheology, Light Backscatter, Cottage Cheese

T286 Influence of natural cheese characteristics on process cheese functionality: Unmelted and melted properties. A. C. Biswas*¹, R. Kapoor², P. Upreti², L. Metzger², and K. Muthukumarappan¹, ¹Department of Ag. & Bio. Engr., South Dakota State University, Brookings, ²Department of Food Science and Nutrition, University of Minnesota, St. Paul.

Four treatments of Cheddar cheese with two levels (high and low) of calcium (Ca) and phosphorus (P), and two levels (high and low) of residual lactose were manufactured. Each treatment was subsequently split prior to the salting step of cheese manufacture and salted at two levels (high and low) for a total of eight treatments. The eight treatments included: High Ca and P, High lactose, High S/M (HHH); High Ca and P, High lactose, Low S/M (HHL); High Ca and P, Low lactose, High S/M (HLH); High Ca and P, Low lactose, Low S/M (HLL); Low Ca and P, High lactose, High S/M (LHH); Low Ca and P, High lactose, Low S/M (LHL); Low Ca and P, Low lactose, High S/M (LLH); and Low Ca and P, Low lactose, Low S/M (LLL). At two months of ripening each treatment was used to manufacture process cheese food using a twin-screw Blentech process cheese cooker. All of the process cheese food formulations were balanced for moisture, fat, and salt. Texture and melting characteristics of the process cheese were evaluated with several techniques including the modified Schreiber test, melt profile test, and texture profile analysis (TPA). There was a significant ($P < 0.05$) decrease in melt area and softening rate and an increase in softening temp and TPA-hardness in the high Ca and P treatments (HHL, HLH, HHL, and HHH) as compared to the low Ca and P treatments (LHH, LHL, LLH, and LLL). Additionally, a significant ($P < 0.05$) decrease in melt area and softening rate and an increase in softening temp and TPA-hardness was observed when the high salt treatments (HLH, HHH, LHH, and LLH) were compared to the low salt treatments (HLL, HHL, LHL, and LLL). No significant ($P > 0.05$) difference was observed in the melt characteristics and hardness of the high lactose treatments (HHH, LHH, HHL, and LHL) as compared to the low lactose treatments (HLH, LLH, HLL, and LLL). This study demonstrates that the characteristics of natural cheese (calcium and phosphorus content and salt/moisture ratio) used in process cheese manufacture have a significant impact on process cheese functionality.

Key Words: Process Cheese, Calcium, Melt

T287 Effect of aging on the proteolytic and rheological properties of Mennonite-style cheeses from Chihuahua, Mexico. D. L. Van Hekken*¹, M. H. Tunick¹, P. M. Tomasula¹, F. J. Molina-Corral², and A. A. Gardea², ¹USDA, ARS, ERRC, Wyndmoor, PA, ²CIAD, Cuauhtemoc, Chihuahua, Mexico.

The proteolytic and rheological properties of semi-hard Mennonite-style cheeses, made from raw or pasteurized milk, were measured over 16 wk of 4°C storage to evaluate the changes that occurred during aging. Samples, obtained from four different Chihuahua cheese manufacturers (two used raw milk and two used pasteurized milk), were collected within days of manufacture and stored. Degree of proteolysis (SDS-PAGE) and rheological (small amplitude oscillatory strain, torsion, and texture profile analyses) properties of the cheeses were measured at 4 wk intervals. Over the 16 wk of storage, cheeses made with raw milk produced sufficient gas to disrupt the cheese matrix and severely limit shelf life. The loss of textural integrity in raw milk cheeses was reflected in the greater rate of proteolysis (decrease in α_{S1} - and β -casein with concomitant increase of casein fragments with molecular mass of 22-18

kDa and <14 kDa) and the decrease in shear strain at the point of fracture (ability to withstand deformation). Shear strain of the pasteurized milk cheeses increased with age. While the hardness, cohesiveness, chewiness, and shear stress and shear rigidity at the point of fracture of all cheeses decreased over time, these properties decreased more rapidly and tended to be lower for the raw milk cheeses than the pasteurized milk cheeses. Results indicate that proteolysis and shear strain are good indicators of differences in the cheese matrix between the aging raw milk and pasteurized milk cheeses.

Key Words: Hispanic-Style Cheese, Aging, Rheology

T288 Influence of natural cheese characteristics on process cheese functionality: Dynamic viscoelastic properties. A. C. Biswas*¹, R. Kapoor², P. Upreti², L. Metzger², and K. Muthukumarappan¹, ¹Department of Agricultural & Biosystems Engr., South Dakota State University, Brookings, ²Department of Food Science & Nutrition, University of Minnesota, St. Paul.

Four treatments of Cheddar cheese with two levels (high and low) of calcium (Ca) and phosphorus (P), and two levels (high and low) of residual lactose were manufactured. Each treatment was subsequently split prior to the salting step of cheese manufacture and salted at two levels (high and low) for a total of eight treatments. The eight treatments included: High Ca and P, High lactose, High S/M (HHH); High Ca and P, High lactose, Low S/M (HHL); High Ca and P, Low lactose, High S/M (HLH); High Ca and P, Low lactose, Low S/M (HLL); Low Ca and P, High lactose, High S/M (LHH); Low Ca and P, High lactose, Low S/M (LHL); Low Ca and P, Low lactose, High S/M (LLH); and Low Ca and P, Low lactose, Low S/M (LLL). At two months of ripening each treatment was used to manufacture process cheese food using a twin-screw Blentech process cheese cooker. All of the process cheese food formulations were balanced for moisture, fat, and salt. Dynamic viscoelastic (G' and G'' at $\tan \delta = 1$) characteristics of the process cheese were evaluated using a Viscoanalyzer at 1Hz and 0.5% strain level. There was a significant ($P < 0.05$) increase in both G' and G'' values in the high Ca and P treatments (HHH, HHL, HLH, and HHH) as compared to the low Ca and P treatments (LHH, LHL, LLH, and LLL). Additionally, an increase in G' and G'' values was observed when the high salt treatments (HLH, HHH, LHH, and LLH) were compared to the low salt treatments (HLL, HHL, LHL, and LLL). In the high Ca and P treatments with high lactose (HHL and HHH) a significant ($P < 0.05$) increase in G' and G'' was observed relative to the low lactose treatments (HLL and HLH), whereas in the low Ca and P treatments high lactose significantly ($P < 0.05$) decreased G' and G'' in the high salt treatments and had no effect ($P > 0.05$) in the low salt treatments. This study demonstrates that the characteristics of natural cheese (calcium and phosphorus content, lactose, and salt/moisture ratio) used in process cheese manufacture have a significant impact on process cheese rheological characteristics.

Key Words: Process Cheese, Calcium, Rheology

T289 Quantitative evaluation of light-oxidized off-flavors in reduced fat milk using sensory evaluation and the electronic nose. H.-Y. Chung*¹, J. A. Partridge², and B. R. Harte¹, ¹School of Packaging, Michigan State University, East Lansing, ²Food Science and Human Nutrition, Michigan State University, East Lansing.

Light-oxidized off-flavors in milk can occur when exposed to fluorescent light in retail dairy cases. Photosensitized oxidation of milk proteins and lipids can be initiated by light activation of riboflavin which results in generation of sulfur and carbonyl volatiles. An electronic nose equipped with 12 metal-oxide semiconductor sensors was used to analyze headspace volatiles. Reduced fat (2%) milk in glass bottles was exposed to 0, 2, 4, 8, 12, 24, 36 and 48 hours of fluorescent light (1000 lx) at 5°C. Milk in various packaging (HDPE, HDPE-TiO₂ and PET bottles and paper cartons) was also exposed to fluorescent light for 12 hours. Sensor responses (max dR/R₀) from the electronic nose were correlated to ADSA sensory scores from a trained taste panel, using partial least square (PLS) or multilayer perceptrons (MLP) techniques. Sensory scores of 2% milk in glass bottles decreased continually with increase in light exposure to 24 hours. Milk stored in the better light barriers, i.e. paper cartons and HDPE-TiO₂ bottles, had slightly higher sensory scores than the others, but the differences were not statistically significant. A PLS model based on a 95°C headspace sampler technique had the lowest root mean square error (RMSE) and was a

better fit than 45°C and 70°C, as well as all MLP model temperatures. The PLS approach was to find latent component(s) from electronic nose sensor responses that were also relevant to sensory scores. It was well defined for light-oxidized milk in glass bottles, since higher light-oxidized volatiles gave higher sensor responses and lower sensory scores. Alternatively, MLP was a better model for milk stored in the other packages and exposed to light. The electronic nose has potential to be used to determine light-oxidized off-flavors in packaged milk quantitatively.

Key Words: Electronic Nose, Milk, Light Oxidation

T290 Effect of pre-storage and sterilization on physico-chemical properties of goat milk during storage. A. C. Biswas*¹, A. K. Bandyopadhyay², P. K. Ghatak², and K. Muthukumarappan¹, ¹Dept. of Agricultural & Biosystems Engr., South Dakota State University, Brookings, ²Dept. of Dairy Chemistry, Faculty of Dairy Technology, West Bengal University of Animal & Fishery Sciences, Kolkata, India.

Effect of pre-storage and sterilization (121°C / 1.05 Kgf/cm² pressure for 10 min) on goat milk was determined during cold (5°C) and warm (30°C) temperature storage by evaluating changes in its physico-chemical properties. Three different sterilization treatments, T1 (sterilized on the same day of milking), T2 (stored at 5°C for 24 h and then sterilized) and T3 (stored at 5°C for 48 h and then sterilized) were applied to the goat milk. The sterilized goat milk was then equally stored at 5°C and 30°C respectively and physico-chemical properties, viz. viscosity, surface tension (ST), titratable acidity (TA), pH, free fatty acid (FFA), Tyrosine value (TV), non-protein nitrogen (NPN), and hydroxymethyl furfural (HMF) values were monitored on 0, 15, 30, 45 and 60 days. The experiment revealed significant increase in viscosity, TA, FFA, TV, NPN, and HMF during storage at 5°C and 30°C. In addition, significant difference ($P < 0.01$) in all physico-chemical properties was observed between the treatments (T3 showed significantly higher values compared to T2 and T1), and also for different storage duration. This study elucidated that the increase in pre-storage time at 5°C before sterilization have a significant effect on the physico-chemical properties during storage at different temperatures.

Key Words: Goat Milk, Sterilization, Physico-Chemical Properties

T291 Development of Cheddar cheese for lowering blood cholesterol by phytosterol ester. H. S. Kwak*, H. J. Ahn, S. J. Lee, and J. Ahn, *Sejong University, Seoul, Korea.*

This study was carried out to investigate the effect of phytosterol ester addition on lowering blood cholesterol in cholesterol-reduced Cheddar cheese, which was manufactured with the milk combined with cholesterol-reduced cream and skim milk. After cholesterol reduction process by beta-CD treatment, the cholesterol removal rate was in the range of 91.2 to 92.1%. Amount of short-chain free fatty acid and free amino acids increased with an increase of phytosterol ester addition, and those were significantly different from that of control in all ripening periods. Among neutral volatile compounds, more acetaldehyde and ethanol were produced in control than other compounds in phytosterol ester-added groups. All texture values increased with an increase of phytosterol ester amount during ripening period. In sensory analysis, the scores of rancid, bitterness, Cheddar flavor and off-flavor intensities increased significantly, while texture was decreased during ripening in phytosterol ester-added groups. In animal study, total blood cholesterol lowered 18% with 8% phytosterol ester-added Cheddar cheese, which was significantly different to that of control. The present study indicated that phytosterol ester showed the lowering effect of blood cholesterol when it was added in cholesterol-reduced Cheddar cheese.

Key Words: Phytosterol Ester, Blood Cholesterol, Cheddar Cheese

T292 Crosslinking of beta-cyclodextrin and the optimizing of cholesterol removal in milk by using the crosslinkage. S. H. Kim*, E. M. Han, J. Ahn, and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study was performed to crosslink beta-cyclodextrin (beta-CD) and to find the optimum conditions of cholesterol removal using the crosslinked beta-CD in milk. Two different methods were tested using 2.3 mL epichlorohydrin and 2.5 g of adipic acid, and added into containing 250 g of crosslinked beta-CD in NaOH solution. After 24

hr magnetic stirring, the pH of solution raised to 10. The solution was washed with distilled water, and dried for 24 hrs. In a subsequent study, two different crosslinked beta-CDs were used to find the optimum conditions for cholesterol removal in milk. In both, the optimum conditions were 1% beta-CD addition, 10 min stirring time, and 800 rpm stirring speed. The rates of cholesterol removal were 80 and 75% in epichlorohydrin and adipic acid, respectively. In conclusion, the present study showed the possibility of crosslinked beta-CD development and the application to cholesterol removal process in milk.

Key Words: Crosslinking, Beta-Cyclodextrin, Cholesterol Removal

T293 Simple immobilization of beta-cyclodextrin to remove cholesterol in milk and recycling. H. S. Kwak*, S. H. Kim, J. H. Kim, H. J. Choi, and J. Kang, *Sejong University, Seoul, Korea.*

This study was designed to determine the optimum conditions of three different factors (mixing time, mixing temperature, and tube size) in reduction of cholesterol in milk using immobilized beta-CD beads. Immobilized beta-CD glass beads were prepared at different conditions of silanization and beta-CD immobilization reactions. In result, the glass beads (diameter 1 mm) at 20 mM 3-isocyanatopropyltriethoxysilane and 30 mM beta-CD without base showed the highest cholesterol removal rate as 52%. Using above immobilized beta-CD glass beads, the cholesterol removal rate was 51.2% with 6 hrs of mixing time in 7 mm diameter tube at 10°C. After cholesterol removal from milk, the glass beads were washed for cholesterol dissociation and reused. For recycling study, the cholesterol removal rate was 52%, which was mostly same as that using new glass beads. These results indicated that cholesterol removal rate was 52% with beta-CD immobilized glass beads, however, the recycling efficiency was almost 100%.

Key Words: Beta-CD Immobilization, Cholesterol Removal, Recycling

T294 Effects of microencapsulated chitoooligosaccharide addition on cholesterol-reduced milk. H. J. Choi*, J. Ahn, J. H. Hwang, and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study was designed to develop microencapsulated chitoooligosaccharide that could be added into cholesterol-reduced milk, and to examine the changes of physical and sensory properties during storage. Coating material was polyglycerol monostearate (PGMS). The efficiency of microencapsulation was 80.08% with 10:1 ratio (w/w) as coating to core materials. When even 0.5% microencapsulated chitoooligosaccharide was added, the L, a, b values and viscosity were significantly different from that of control (uncapsulated chitoooligosaccharide added). In stability measurement of microcapsules, the releases of chitoooligosaccharide were 1.33% and 1.25% in distilled water and cholesterol-reduced milk for 15 day storage at 4°C, respectively. In a sensory analysis, the values of astringency, bitterness, and color were significantly different between control and encapsulated chitoooligosaccharide-added cholesterol-reduced milk for 7 days of storage. The present study indicated that the microencapsulated chitoooligosaccharide showed a high stability, and could be an effective means for addition in cholesterol-reduced milk.

Key Words: Chitoooligosaccharide, Microencapsulation, Milk

T295 Functional properties of cholesterol-removed whipping cream treated by beta-cyclodextrin. S. Y. Shim, J. Ahn, and H. S. Kwak*, *Sejong University, Seoul, Korea.*

The present study was carried out to examine the changes in functional properties of cholesterol-removed whipping cream by beta-CD treatment. The cholesterol removal rate reached over 90% in cream before whipping with in all conditions (different stirring time and speed) applied. The apparent viscosity of beta-CD treated cream after whipping increased with increased stirring time and speed. Comparatively, the overrun percentage reached to 150%, and foam instability was measured as 2.5 mL deformed cream with lower stirring time (10 min) and speed (400 rpm). The TBA value of cholesterol-removed whipping cream increased from 0.08 to 0.14 stored at 4°C during 4 wk, however, no difference was found compared to that of control. Above results indicated that beta-CD treatment process for cholesterol removal did not show a profound adverse effect on functional properties of cream after whipping.

Key Words: Cholesterol Removal, Beta-Cyclodextrin, Whipping Cream

T296 Development of functional properties of water buffalo milk yogurt beverage. J. R. Huck, F. L. Lee, and M. Guo*, *University of Vermont, Burlington.*

A prototype yogurt beverage was developed using regional water buffalo milk, probiotic cultures and inulin. Water buffalo milk is considered to be more nutritious because it contains higher levels of calcium, fat, protein and antioxidants than cows milk. Probiotic bacteria such as *L. acidophilus*, *L. casei* and *Bifidobacteria* have shown to have beneficial effects to human intestinal health and are commonly added to commercial yogurt products. Inulin and oligofructose have been documented as prebiotics to provide fermentative stimulation to probiotic cultures and direct health benefits as non-digestible dietary fiber. Three trials of prototype yogurt beverages were prepared by adding whey protein concentrate and a probiotic yogurt culture mixture to pasteurized, homogenized water buffalo milk and incubating for 5.5 h. The cooled yogurt bases were then blended with a stabilizer mixture of water, sucrose, inulin, and pectin. A flavor and an acidulant were added prior to second homogenization process and bottling. Sensory evaluation by semi-trained panelists revealed acceptable textural and taste attributes of the yogurt beverage after 24 h in refrigerated storage of 3°C. Mean chemical composition of the product consisted of 11.2% carbohydrates, 2.7% fat, 1.8% protein, 0.3% ash and pH 3.65. Visual inspection and digital photographs showed the beverage remained stable up to twelve weeks. Survivability enumeration of probiotic cultures showed only levels of *L. casei* and *Bifidobacteria* to be above 10⁶ CFU/g at week 5. Therefore, a post-fermentation fortification of *L. acidophilus* to the yogurt beverage is recommended in order to maintain functional probiotic levels above 10⁶ CFU/g during refrigerated storage. In conclusion, symbiotic water buffalo yogurt beverage can be developed with probiotic cultures and functional prebiotic ingredients.

Key Words: Water Buffalo Milk, Symbiotic, Yogurt Beverage

T297 Effect of cheddaring temperature on moisture retention, rheological properties and proteolysis in model cheese systems. P. J. Watkinson, C. J. Coker, C. C. Dodds, S. Hewson, B. Kuhn-Sherlock, N. J. White, and L. K. Creamer*, *Fonterra Research Centre, Fonterra Co-operative Group Limited, Palmerston North, New Zealand.*

Removal of water from the rennet coagulum is important in cheese manufacture. Cheddaring is one of the ways that can be used to control the moisture content of a cheese. A series of model cheeses were prepared using a range of cheddaring temperatures to give cheeses with different moisture contents in order to determine the effect of cheese moisture on the development of certain rheological properties. Milk with a protein:fat ratio of 1.4:1 was acidified with acetic acid to a pH of about 6.1 and then coagulated with rennet (3.0 mL/100L). Each coagulum was cut and cooked (40°C), drained and then mixed with a measured quantity of glucono- δ -lactone (GDL). It was then cheddared in jacketed vats controlled between 10 and 60°C. The curd was then salted, hooped, pressed, wrapped, and stored at 5°C. The cheeses were sampled after storage from 2 to 184 days and then the rheological and compositional properties and intact casein were measured. Moisture contents of the cheeses were between 40 and 48% (average value over the storage time). The Hencky fracture strain (resistance to crumbling) increased with the moisture content of the cheeses and the effect was greater in the more mature cheeses. The adhesion area (adhesiveness) was similar but the modulus of deformability (stiffness) diminished with increasing moisture content and cheese maturity had a small and variable effect. The content of intact α_{s1} -casein decreased with increased moisture content, except for the two-day samples, which were assumed to contain 100% intact protein. The pHs of all cheeses were between 5.76 and 5.80. A second study used a set of cheeses with moisture contents between 34 and 39% (pHs between 5.51 and 5.54) and showed similar but slightly more complex trends. There was an apparent correlation between moisture content and the extent of proteolysis and some of the rheological properties. The relationship between moisture content and proteolysis may be indirectly responsible for the changes in rheological properties being correlated with moisture content.

Key Words: Model Cheese, Cheddaring Temperature, Rheological Parameters

T298 Effects of fat content on physico-chemical and sensory properties of buffalo milk dahi (yogurt). N. Pandya*¹, S. Kanawjia¹, and R. Dave², ¹*Dairy Technology Department, National Dairy Research Institute, Karnal, India*, ²*Dairy Science Department, South Dakota State University, Brookings.*

The use of fermented milks dates back to many centuries and dahi is one such fermented milk product occupying an important place in Indian diet satisfying the palate and nutritional requirements of human beings. Commercial production of dahi is still in infancy stage in India and very few studies are available on the effects of ingredients on physico-chemical and sensory properties of dahi made from buffalo milk. This study was aimed to optimize the fat content in buffalo milk dahi. Fat levels studied were 1.5, 3.0 and 4.5% with solids not fat maintained at 9.5% level in all the samples. It was observed that during the first 12 h of incubation, the rate of drop in pH and the rate of increase in acidity were faster in milk with 1.5 and 3.0 % fat as compared to the milk with 4.5% fat. However, after 12 h of incubation, the rate of change in pH and acidity became almost similar at all fat levels studied. Also, the optimum set time increased up to 2.5 h with the increase in fat content from 1.5 to 4.5%. Rheology and sensory properties improved significantly ($P < 0.05$) with increasing fat content. With the increase in fat content from 1.5 to 4.5%, the average increase in viscosity was 22.5%, wheying off reduced by 31% and curd tension improved by 10%. Also, with increase in fat content from 1.5 to 4.5 % in dahi, the flavor scores improved from 40.7 to 48.3 out of 50, the body & texture scores improved from 35 to 38.8 out of 40.0, and there was no significant difference ($P < 0.05$) in appearance scores. Keeping in view the overall sensory characteristics and different rheological properties of dahi, fat level of 4.5% was suggested for the commercial production of dahi.

Key Words: Buffalo Milk, Fat, Dahi

T299 Understanding the role of proteolysis in reduced calcium Mozzarella cheese. P. R. Thakur* and R. I. Dave, *Dairy Science Department, South Dakota State University, Brookings.*

Calcium content plays an important role in the functional properties of cheese. Recent study showed that reduced calcium Mozzarella cheeses not only had improved softening, melting and flow characteristics, but also had higher proteolysis. The objectives of this study were to characterize the proteolysis in Mozzarella cheese at various storage periods, correlate the melt properties to the proteolysis and also study the effects of coagulants (chymosin and Sure Curd[®]) on the proteolysis of reduced calcium Mozzarella cheese. Mozzarella cheeses were made by direct acidification using Glucono- δ -Lactone. The milk was pre-acidified using citric acid and acetic acid to a pH of 5.9 to lower the level of calcium. No alteration in the calcium content of control cheeses was made. The composition of cheeses were kept as uniform as possible by adjusting the processing conditions. The samples were analyzed on day 1, 7, 15 and 30 for various study parameters. Proteolysis as measured by water-soluble nitrogen (WSN), TCA - soluble nitrogen and PTA - soluble nitrogen was higher in reduced calcium cheeses. The water-soluble nitrogen for reduced calcium cheeses was almost double than the control cheeses on day 1. WSN changed only a little throughout the storage period in control cheeses, but it increased in reduced calcium cheeses during storage. TCA -soluble nitrogen increased over the storage period in reduced calcium cheese while the increase in PTA - soluble nitrogen was very little. Also, the proteolysis was higher in cheeses manufactured using sure curd in comparison to the cheeses manufactured using Chymosin. The melt area for reduced calcium cheeses was 2.1 times higher than the control cheeses. Control cheeses had higher expressible serum than the reduced calcium cheese throughout the storage, which shows higher water-holding capacity of reduced calcium cheeses. The fluorescence microscopic images showed better distribution of fat within the protein matrix of reduced calcium cheeses.

Key Words: Reduced Calcium Mozzarella Cheese, Proteolysis, Coagulant

T300 Milk from cows fed potato by-products indistinguishable from whole milk. M. L. Nelson*, M. J. Costello, M. F. Morrison, and S. Clark, *Washington State University, Pullman.*

Four multiparous Holstein cows (761 ± 18 kg body weight; 119 ± 2 d in milk) were randomly assigned to a 4x4 Latin Square to determine effects of type of potato by-product in a TMR on milk production, composition, and quality. Periods were 28d (21d for adaptation, 7d for milk

collection). Cows were fed a TMR with none or 15% replacement of the grain portion with a potato by-product (filter cake, potato peels, or screen solids). Daily feed intake and milk production were quantified. Weekly milk subsamples were analyzed for milk composition. Total milk, from each cow, was collected at both milkings on d 22, pasteurized, homogenized, and cooled. Milk was evaluated by a 9 member trained sensory panel and a 40 member consumer panel in each period. Cows fed potato byproduct containing diets consumed less ($P < 0.05$) DMI (26.6 vs. 20.8 ± 0.65 kg) with no effects ($P > 0.05$) on milk production (41.6 ± 0.54 kg/d), milk fat (3.5 ± 0.10 %), or weight change (0.3 ± 0.1 kg/d). No differences ($P > 0.05$) due to diet were detected in 17 milk attributes by the trained sensory panel. Consumer panels paired milk samples from potato peel-fed cows and screen solid-fed cows more than by chance (63.7 ± 14.2 %, 59.7 ± 11.8 %), which was not due to milk composition or sensory attributes identified by the trained sensory panel. Potato byproducts, by replacing grain in a TMR, resulted in reduced DMI without affecting milk production, composition or sensory attributes.

Key Words: Milk, Potato By-Product, Sensory Evaluation

T301 Microstructure of pasteurized Process cheese manufactured from vacuum condensed and ultrafiltered milk. V. V. Mistry*, A. N. Hassan, and M. R. Acharya, *MN-SD Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

Milk concentrated by ultrafiltration (UF) or vacuum condensing (CM) to two levels of protein: 4.5% (UF1 and CM1) and 6.0% (UF2 and CM2) or Control (C) with 3.2% protein was used for manufacturing Cheddar cheese (Acharya et al. 2001. *J. Dairy Sci.* 84 (Suppl.1):306). Pasteurized Process cheeses were manufactured using a 1:1 blend of 18-week and 30-week Cheddar cheese (Acharya et al. 2002. *J. Dairy Sci.* 85: (Suppl. 1):357). The moisture content of the Process cheeses ranged from 39.3 to 40.2%. Fat content was the highest in C (35.0%) and the lowest in UF2 (31.6%). The microstructure of cheeses was evaluated using cryo-scanning electron microscopy and fluorescence microscopy. Process cheeses with the highest meltability (Control) demonstrated a structure in which fat globules of varying size were uniformly distributed in a porous protein matrix. The porosity of the protein matrix decreased with decreasing meltability (UF2, CM1 and CM2). Cheeses with minimal porosity were the hardest; UF cheeses (8.45 kg-UF1 and 9.90 kg-UF2) followed by CM cheeses (6.27 kg-CM1 and 9.13 kg-CM2) and C (3.94 kg). Similarly, viscosity of molten cheese at 80°C correlated to this structural feature and was higher in 6.0% protein treatments (1043 cp-UF2 and 1208 cp-CM2) than in 4.5% protein treatments (855 cp-UF1 and 867 cp-CM1) and in C (557 cp). It was also interesting to note that the fat globules in control cheeses were surrounded by greater void space relative to the other cheeses. The application of concentrated milks for Cheddar cheese-making influences Process cheese functionality and structure.

Key Words: Process Cheese, Concentrated Milk, Microstructure

T302 Flavor and stability of pasteurized milk with elevated levels of conjugated linoleic acid and vaccenic acid. J. M. Lynch¹, A. L. Lock², D. A. Dwyer², R. Norbaksh³, D. M. Barbano*¹, and D. E. Bauman², ¹*Northeast Dairy Foods Research Center, Department of Food Science, Cornell University, Ithaca, NY*, ²*Department of Animal Science, Cornell University, Ithaca, NY*, ³*Institute of Standards and Industrial Research, Mashhad, Iran.*

The objectives in this study were to determine if flavor differences between 2% fat pasteurized milks with and without elevated vaccenic acid (VA) and cis-9, trans-11 CLA levels could be detected over the commercial shelf life of the product and to determine if milk with elevated VA and cis-9, trans-11 CLA levels was more susceptible to light-induced oxidative flavor defects. Cows were fed either a control diet ("control" diet) or the same ration supplemented with 2% soybean oil and 1% fish oil ("CLA" diet). Control and CLA raw milks were collected and separated into cream and skim. The skim and cream from each treatment were combined to achieve 2% fat milk. The milks were pasteurized, homogenized and stored in commercial clear plastic milk containers at 4°C. Oxidation was induced by exposing half of the containers to fluorescent light. Testing was conducted at 1, 7 and 14 days post-pasteurization. Average cis-9, trans-11 CLA content of the control and CLA milks was 0.52 and 4.74 g/100g fatty acids, respectively (812% increase). Average

VA content of the control and CLA milks was 1.43 and 12.06 g/100 g fatty acids, respectively (743% increase). There was no effect of light exposure on fatty acid composition either initially or over the 14-day storage period. Although VA, cis-9, trans-11 CLA and degree of unsaturation were significantly elevated in the CLA milk, untrained panelists were unable to detect flavor differences either initially or over time in 15 out of 16 triangle test evaluations. Similarly, sensory results indicated no difference in susceptibility to the development of oxidized off flavor between the control and CLA milks, even when oxidation was induced by light exposure.

Key Words: CLA, Fluid Milk, Flavor

T303 Evaluation of long term frozen-storage effect on chemical changes in soft and semi-hard goat milk cheeses. J. H. Lee*, Y. W. Park, and B. L. Gadiyaram, *Fort Valley State University, Fort Valley, GA.*

Freezing cheese is not common practice in dairy industries due to the high production costs and possible adverse effects on physico-chemical, rheological, and sensory qualities of the frozen products. However, frozen-storage of cheese as a food technological approach may be essential for extending marketability of caprine milk products. Three lots of plain soft (PS) goat cheeses were purchased, and 3 lots of Monterey Jack (MJ) goat cheeses were manufactured at the University dairy plant to study changes in chemical parameters such as pH, acid degree value (ADV), water soluble nitrogen (WSN) profiles during 6 months of extended frozen and refrigerated storage. Each cheese variety was subdivided into 4 equal portions, and stored at 4°C for 4 weeks (0, 14, 28 days) as the unfrozen control, and the other three subsamples were frozen (-20°C) and stored for 0, 3 and 6 months, then immediately thawed the next day at 4°C, followed by aging at 4°C for 4 wks. For PS cheese, ADVs were increased ($P < 0.05$) with frozen storage time (0.5 to 0.7) and subsequent refrigeration time (0.5 to 0.7). However, the levels of WSN were only influenced by subsequent refrigeration time (9.2 to 10.5). The pH (4.0 to 4.1) was not affected by freezing and subsequent refrigeration. Both proteolysis and lipolysis properties of PS cheese were affected by freezing and subsequent refrigeration. For MJ cheese, neither pH nor ADV was affected by freezing/subsequent refrigeration in MJ sample. The pH was ranged from 5.8 to 6.1 during the experimental period; the ADV was varied from 1.2 to 1.5. WSN contents of MJ were significantly decreased against frozen storage time from 0 to 6 mo (16.6 to 15.3), whereas subsequent refrigeration did not influence to the WSN. Increasing frozen storage time may influence the protein degradation in MJ. Frozen storage time and subsequent refrigeration impacted on flavor compounds and protein degradation, but not on the chemical properties related to lipolysis (ADV) and pH.

Key Words: Goat Cheese, Long Term Frozen-Storage, Chemical Changes

T304 Feasibility study of forming a California cheese aging cooperative. B. A. Reed*, *University of California Cooperative Extension, Orland.*

California artisan cheesemakers were contacted to assess their interest in the development of a cheese aging cooperative and collect information on the scope of services desired. Twelve cheesemakers agreed to

participate in the survey. Average cheese production was 41681 kg/yr with a range of 5443 to 145150kg/yr. Facilities made an average of 6 cheese varieties with a range of 1 to 12. The collective volume of cheese aged <60 d, 2-5 mo, 6-12 mo, 13-23 mo and >2yr was 179750, 141657, 155002, 42547 and 2132 kg respectively. Cheese shipped from the plant cut and wrapped versus whole wheels was 34.2% and 65.8% respectively. Cheese makers reported primary barriers to expansion as lack of storage or processing space (4), or the cost of space (1), cash flow (3), milk supply (1), expertise in aging (1), and distribution (1). Secondary barriers identified were, processing space (2), storage space (1), labor (2) and housing costs for labor (1), freight costs (1), (unspecified) problems with distribution (2), lack of cross docking and drop points to improve distribution (1), risk and cost of expansion (1), and cash flow (1). For the producers interested in using a facility, features/services offered by a facility ranked in importance on a 10 point scale from highest to lowest were, retain ownership and identity (8.8), added storage space (8.5), assistance with aging (7.2), cash advance for cheese (6.3), marketing and distribution assistance (6.2), better risk protection (5.0) and unique marketing identity (4.7). Financial analyses developed from the survey information showed an average cost for aging cheeses in a cooperative at \$1.37, \$0.95 and \$0.95/kg for years 1, 2 and 3 respectively with 5 initial member/owners and a rolling monthly inventory of 11340 kg. The charge needs to drop to \$0.44/kg for the aging cost not to exceed the price differential for an aged cheese.

Key Words: Cheese Aging, Costs, Cooperative

T305 Release of antioxidants from biodegradable films into dry milk products and food simulating liquids. M. van Aardt¹, S. E. Duncan*¹, J. E. Marcy¹, T. E. Long², S. F. O'Keefe¹, and S. R. Sims³, ¹*Food Science and Technology, Virginia Tech, Blacksburg,* ²*Chemistry, Virginia Tech, Blacksburg,* ³*Eastman Chemical Company, Kingsport, TN.*

Poly(lactide-co-glycolide) (50:50) films loaded with antioxidants (i) 2% α -tocopherol, and (ii) a combination of 1% butylated hydroxytoluene (BHT) and 1% butylated hydroxyanisole (BHA), were used in an antioxidant release study in water and Miglyol 812[®] at 4°C and 25°C, as well as a study on the effect of these films on dry whole milk and dry buttermilk stability. BHT was released through the hydrolytic degradation of the polymer when stored in water at room temperature for eight weeks. As expected, polymer degradation did not take place when antioxidant-loaded films were stored in whole milk powder (3.01% moisture) and buttermilk powder (4.60% moisture). However, α -tocopherol, BHA, and BHT were released through diffusion from 0 mg/kg to 21.9, 60.0, 192.0 mg/kg milkfat, respectively, in whole milk powder after four weeks of storage at 25°C. Buttermilk powder did not show increasing antioxidant content, which might be due to a much lower fat content (2.35%), as compared to whole milk powder (24.48%). Milkfat stability was measured by determining hexanal, pentanal, and heptanal content. Although limited reductions were observed in these volatiles in control- and antioxidant-treated powders, pentanal content was significantly decreased for the first three weeks of storage when buttermilk powders were packaged in contact with BHA/BHT-loaded PLGA films.

SYMPOSIA AND ORAL SESSIONS

* Author Presenting Paper

Bioethics: Symposium-Ethics and the Cost of Food: What is the Impact of Lessening Food Prices on Citizens, Producers, Animals and the Environment?

347 Cheap food and its impact upon health, safety and security of supply. J. Hodges*, *European Association of Animal Production, Mittersill, Austria.*

During the 2nd half of the 20th century, the pursuit of cheap food has been the prime strategy of animal and agricultural scientists in Western society. Intellectual and organizational resources are shaped to serve this objective. These include disciplinary research in the biosciences, management systems, mechanisms to maximize scale, recycling of waste and by-products, increased capitalization, reduced labor, and the relocation of production sites nationally and internationally. Alternatives are often dismissed as inefficient and unrealistic in the age of Homo economicus. Some non-monetary values have recently appeared in the equation: human health, food safety, gustatory food quality, animal welfare and quality of rural life challenging the monolithic dominance of the cheap food movement. But mainstream Western agriculture, fuelled by the powerful engine of science allied to business, still dominates by seeking ever cheaper food. I argue that this mainstream ideology will not change while the unseen external costs remain hidden and apparently painless. Nevertheless informed people know that the mainstream system is unsustainable in terms of biological resources, the environment, the quality of human life and in the civilized values for treatment of other people and of animals. In this paper, some options are explored by which these hidden costs might be factored into the visible costs of the food chain. Globalization of food production is built upon the cheap food Western model of intensification, capitalization and specialization. But the history and current experience of food in the West finds national governments as major players in regulating health, safety and providing economic support. The prospect of major global food supplies responding solely to market forces holds threats of instability and unsustainability with food shortages, disruption of family farms and rural societies in the developing countries plus health and safety issues outside regulatory control. The paper concludes that food deserves more

care nationally and internationally than the fate of being driven into the 21st century solely by the ideology of low cost.

Key Words: Cost, Safety, Sustainability

348 Considerations of the relationship between food prices and animal welfare. M. C. Appleby*, *The Humane Society of the United States, Washington, DC.*

The proportion of income spent on food has been in steady decline. Most people could readily pay more for food. Indeed, most consumers already pay more than necessary, by buying specialist products or convenience foods. But there are costs associated with cheap food produced from animals that reach well beyond the dollars paid by citizens at the checkout register of a supermarket or fast food restaurant. A morally significant effect of pressure for cheap food production has been modifications to production methods that may have impacts on animal welfare; for example by decreased space allowances. Cheaper food for humans sometimes involves greater pain and suffering for food animals. Yet improvements, possibly even major improvements, in welfare could be achieved with only small increases in price to the consumer. The obstacle to change is in part economic inertia - producers resist change because buyers expect low prices. Deployment of public subsidies and gradual change could avoid these short-term effects, although protection is needed against imports from countries with even lower welfare consideration and environmental standards. From the viewpoint of doing what is appropriate for animal welfare and the environment, free market competition should no longer be the sole determinant of food prices. Animal scientists can serve the long-term interests of animal agriculture by combining efforts to do the right thing for welfare of animals with more traditional goals.

Key Words: Animal Welfare, Economic Competition, Food Prices

349 Interrelationships of animal agriculture, the environment and rural communities. M. G. Hogberg*¹, F. L. Kirschenmann², S. L. Fales³, M. S. Honeyman¹, and J. A. Miranowski⁴. ¹Department of Animal Science, Iowa State University, Ames, ²Leopold Center for Sustainable Agriculture, Iowa State University, Ames, ³Department of Agronomy, Iowa State University, Ames, ⁴Department of Economics, Iowa State University, Ames.

Animal agriculture has an obvious, close interrelationship with both the natural environment and also with human systems such as the rural community. Accordingly, changes in animal agriculture can have broad ranging consequences to other areas. Tremendous change in animal agriculture has occurred during the past 50 years. In general this has involved an increase in size of production units, greater reliance on technology, a corresponding decrease in labor, increased animal confinement, and a general trend toward monoculture or specialized production systems. At least in part these changes were brought about by animal science research in nutrition, breeding, reproduction, growth, etc. A long-term goal of animal scientists has been to increase biological efficiency of production, and the success in reaching this goal could be said to be remarkable with the time to market, growth rates, milk and egg production, etc. per animal increasing as much as 2 to 3 times in the 50 years. The increase in the efficiency has brought about a parallel decline in food prices. But while animal science in one sense has been very successful, new questions or issues have emerged. The scale of animal systems today sometimes concentrates large numbers of animals into areas smaller than can easily handle the animal waste. Stream and ground water pollution is increasingly a concern in some regions. Odor is a nuisance problem that increasingly places urban growth in conflict with confinement animal systems. Possibly one of the biggest issues can be stated in terms of sustainability; i.e., are all current food animal production systems ones that can continue as they currently exist. Additionally, the decline in numbers of producers has impacted the sociology of rural communities and in some cases brought about the closure of small towns. Animal scientists typically contend that they serve the interests of producers and strive to promote practices that are environmentally sound. Bringing about a discussion among animal scientists

Lactation Biology: Symposia: Molecular Mechanisms Governing Mammary Development

351 Emerging genomic technologies for studying mammary development and mammary cancer. D. Porter*^{1,2} and K. Polyak^{1,2}. ¹Dana-Farber Cancer Institute, Boston, MA, ²Harvard Medical School, Boston, MA.

The breast cancer genetics lab at the Dana-Farber Cancer Institute is currently using genomic approaches to understand the biology of the mammary gland and breast tumorigenesis. This work has involved global gene expression profiling of normal and cancerous mammary tissue to identify diagnostic, prognostic, and therapeutic targets in breast cancer as well as follow-up experiments on candidate genes to more fully characterize gene expression and physiological function. SAGE (Serial Analysis of Gene Expression) is an expression profiling method that allows for global, unbiased, and quantitative characterization of transcriptomes. The expression of thousands of genes can be analyzed simultaneously without prior knowledge of their sequence, thus leading to the discovery of novel transcripts. Importantly, this makes SAGE a particularly useful tool for use in species with incompletely characterized genomes like the dairy cow. We have used SAGE to characterize normal and malignant gene expression patterns in the human breast, and we have identified genes involved in mammary epithelial cell differentiation, proliferation, and survival that may be involved in the initiation and/or progression of breast cancer in humans. In addition, we have combined immuno-magnetic cell sorting and SAGE to describe the comprehensive gene expression profiles of individual cell types composing breast tissue thus providing a molecular portrait of potential autocrine and/or paracrine interactions among cell types in the mammary gland. The application of these technologies in the dairy cow will lead to the discovery of important new genes and has the potential to yield important insights into the molecular basis of developmental processes in the mammary gland.

Key Words: Genomics, Mammary, SAGE

as to whether these goals are always met, or could be better met, is considered to be a worthwhile endeavor.

Key Words: Animal Agriculture, Food Prices, Environment

350 Ethics and low-priced meat, milk and eggs: Too much of a good thing? R. J. Burkhardt*, University of Florida, Gainesville.

There can be little doubt that decreases in food prices are generally thought to be in consumers best interests. If we wish to base judgments about the ethical soundness of practices designed to reduce food prices on a human welfare-optimization, or utilitarian, ethical norm, then those practices are seemingly right. One assumption that has to be made in this regard is that prices are high enough to keep producers in business. Assuming that is true, one question that arises is whether lower prices are ethically sound for all foodstuffs. It could be argued, for example, that low wheat or corn or rice or vegetable prices are ethically sound because these are food staples, and in some form consumed by people from every socioeconomic and demographic category, both domestically and around the world. When we consider food from animals, the argument is not so easily made. It could be, for example, that lower meat, milk and egg prices means that more ostensibly "free" resources such as water are being consumed by the respective industry, and additional animal wastes are being introduced into the environment. These "hidden costs" are not to be ignored in a long-run utilitarian assessment of the ethics of lower animal-based food prices. However, the more significant ethical concern is whether lower prices encourage more consumption, and given connections between animal fats and risks to human health, should additional meat, milk and egg consumption be encouraged? This is made all the more important when we think about what economists call "substitution effects": will lower prices for animal products encourage the substitution of meat, milk and eggs for other food products, also essential to human well-being?

Key Words: Applied Ethics, Animal Agriculture, Food Costs

352 Hormonal regulation of mammary growth, morphogenesis, and breast cancer. R. C. Hovey* and J. F. Trott, University of Vermont, Burlington.

Mammary development in all species is regulated by a complex interplay of hormones that reflects the reproductive state of a female, ultimately in preparation for lactation. These changes translate to phases of ductal development with associated branching and lobulogenesis, alveologenesis, secretory activation, and subsequent involution. Separately, breast cancer can arise as a function of dysregulated growth by normal mammary epithelial cells. Notably, these changes occur in a tissue microenvironment that can act as a site of local mediation for hormonal cues. Our lab has addressed questions concerning the hormonal regulation of normal mammary gland development and the local changes that mediate this input during processes associated with cell proliferation, morphogenesis and breast cancer. In particular, we have addressed the combinatorial regulation that occurs with alterations in the pituitary-ovarian axis in several species. Our data demonstrates that hormonal cross-talk and its local mediation by autocrine and paracrine factors is a key determinant of specific proliferative and morphogenic events. It also serves to regulate changes in supporting tissues such as the vascular endothelium and surrounding stromal. Currently we are delineating some of the transcriptional mechanisms underlying these changes with the objective of defining key pathways downstream of hormonal regulation during mammary development and breast cancer progression.

353 Developmental and nutritional regulation of steroid receptor mRNA expression and epithelial cell proliferation in the prepubertal bovine mammary gland. M. J. Meyer^{*1}, A. V. Capuco², A. Hummel², E. E. Connor², Y. R. Boisclair¹, and M. E. Van Amburgh¹, ¹Cornell University, Ithaca, NY, ²USDA-ARS, Beltsville, MD.

Estrogen and its alpha receptor (ER α) are thought to mediate the ovaries influence on prepubertal mammary epithelial cell proliferation (MEP) in the bovine. The ER beta isoform (ER β) and the estrogen-related receptor α 1 (ERR α 1) may also play a role in estrogen mediated MEP. To better understand these relationships, the developmental and nutritional regulation of ER α , ER β , and ERR α 1 mRNA abundance was determined in prepubertal bovine mammary parenchyma (PAR) and fat pad (FP) by real-time RT-PCR. Holstein heifers (n = 72) were fed to grow at 950 (E) and 650 (R) g/d from birth to slaughter at 50kg increments between 100 to 350kg BW. MEP was assessed by BrdU labeling and estrogen responsiveness by quantity of progesterone receptor (PR) transcript. ER β mRNA abundance was exceedingly low and appeared unregulated. E-heifers tended to have greater abundance of ER α , ERR α 1, and PR mRNA in PAR (P < 0.10) and greater ER α mRNA abundance in FP (P < 0.05) than R-heifers. Furthermore, expression of ER α was localized to FP fibroblasts by immunohistochemistry. ER α , ERR α 1, and PR mRNA abundance decreased linearly (P < 0.08) with increasing BW in PAR but not in FP. At 100kg, E- had greater MEP than R-heifers (P < 0.05). Beyond 100kg, MEP decreased rapidly with increasing BW and was similar between treatments. Among all heifers, MEP and PAR PR mRNA were positively correlated with PAR ER α mRNA abundance (r = 0.42 and 0.80, respectively, P < 0.05). Data suggest that expression of ER α , ERR α 1 and PR are developmentally regulated within PAR but not FP, implying tissue specific regulation of

these genes. Energy intake appears to increase PAR expression of these transcripts, but has no effect on MEP.

354 Estrogen and progesterone response networks in the mouse mammary gland. D. J. Jerry^{*}, S. Lu, A. L. Roberts, and K. A. Dunphy, *Department of Veterinary & Animal Sciences, University of Massachusetts, Amherst.*

A majority of mammary gland development occurs post-natally and is controlled by many environmental factors including nutrition, exposure to environmental compounds and endogenous hormone status. The complement of signals not only influence milk yield in subsequent lactations in livestock, but have a striking effect on subsequent risk of breast cancer in humans. The p53 tumor suppressor protein senses cellular stresses and arbitrates the decision of whether a cell should undergo arrest, senescence or apoptosis. Given the gravity of these decisions, it would be expected that levels of p53 activity should be constrained within physiological limits so that cells are not removed inappropriately resulting in loss of secretory epithelium. Nor should levels of p53 be impaired excessively as cells bearing genetic alterations would be allowed to survive raising the risk of cancer. The physiologic role of p53 in the mammary gland is most evident in the fact that impaired p53 function results in delayed involution in rodents. Similarly, activity of p53 is enhanced by estrogen and progesterone, presumably to enforce heightened surveillance of cells undergoing replication to ensure that genomic integrity is maintained. Therefore, we undertook a series of experiments to map the transcriptional responses initiated by these hormones that are crucial to both growth and development of the mammary epithelium as well as suppression of mammary tumorigenesis.

Ruminant Nutrition: Science of Ruminant Nitrogen Metabolism and Its Application to Feeding Cows

355 What is the true supply of amino acids? H. Lapierre^{*1}, D. Pacheco¹, R. Berthiaume¹, D. R. Ouellet¹, C. G. Schwab², G. Holtrop³, and G. E. Lobley³, ¹Lennoxville Research Centre, AAFC, Lennoxville, QC, Canada, ²University of New Hampshire, Durham, ³BIOSS, Rowett Research Institute, Aberdeen, UK.

Improving the prediction of milk protein yield relies on knowledge of both protein supply and requirement. Definition of protein/amino acid (AA) supply in ruminants is a challenging task, due to feedstuff variety and variability, and to the remodeling of nutrient intake by the rumen microflora. So, how and where should we measure the real supply of AA in the dairy cow? This review will follow the downstream flow of AA from duodenum to peripheral tissue delivery, with a glance at the efficiency of transfer into milk protein. Duodenal AA flow comprises rumen undegradable feed, microbial protein, and endogenous secretions. Most attention has been directed towards definition of the first two contributions, but the latter fraction can represent up to 20% of flow and more information is needed on what factors affect its magnitude and overall impact. Once digested, AA are absorbed into the portal vein. The ratio of portal absorption to small intestinal apparent digestion varies among AA, from 0.50 (threonine) to 0.85 (histidine), due to pre-duodenal endogenous secretions, non-reabsorption of intestinal endogenous secretions and gut oxidation of AA. Few data are available on these phenomena in dairy cows, but the evidence indicates that they alter the profile of AA available for anabolic purposes. Recent comparisons of estimated duodenal flux and measured portal flux have prompted a revisit of the NRC (2001) approach to estimate AA flows at the duodenum. New equations are proposed that yield predictions that better fit the current knowledge of AA metabolism across the gut. Absorbed AA flow first to the liver, where substantial and differential net removal occurs, varying from zero for the branched-chain AA to 0.50 of portal absorption for phenylalanine. This process alters the pattern of net supply to the mammary gland. Overall, intermediary metabolism of AA between the duodenum and the mammary gland biologically explains the decreased efficiency of the transfer of absorbed AA into milk protein as maximal yield is approached. Therefore, variable, rather than fixed factors for transfer efficiencies, must be incorporated into future predictive models.

356 Impacts of the source and amount of crude protein on the intestinal supply of nitrogen fractions and performance of lactating dairy cows. J. H. Clark^{*} and I. R. Ipharraguerre, *Department of Animal Sciences, University of Illinois, Urbana.*

At the onset of a new century, increasing cow productivity and concerns about the environment and safety of food for human and animal consumption in combination with shrinking profits of dairy producers have renewed the challenge first faced by scientists almost 100 years ago. That is, it is fundamental to establish the minimum amount of protein required by today's high-producing dairy cows for achieving optimal milk production. In addition, it is important to identify protein sources that will accomplish that goal with maximum efficiency from a nutritional and economical standpoint. The main objective of this paper is to review and summarize the impacts of the source and amount of dietary crude protein on the supply of nitrogen fractions to the small intestine and the consequential performance of lactating dairy cows. An attempt will be made to quantitatively integrate literature data into a summary that will contribute to our understanding of the flow of protein fractions from the rumen of dairy cows and their effects on dietary protein requirements. Specifically, this approach will focus on providing estimates of the magnitude and significance of documented alterations in the supply of nitrogen fractions to the lower gastrointestinal tract and performance of dairy cows in response to manipulations of the amount and source of dietary crude protein. The ultimate goal of this review is to provide information that may be helpful for identifying areas where further research is required, for comparing new research outcomes, or for evaluating parameterization of computer-based models currently used for predicting the response of lactating cows to the feeding of different diets.

357 Nitrogen Supply to the Lower Gut and Its Relationship to Animal Performance in Beef Cattle. T. J. Klopfenstein^{*} and G. E. Erickson, *University of Nebraska, Lincoln.*

Beef cattle require amino acids for maintenance and growth. The amino acids are supplied to the lower gut as microbial protein and undegraded

intake protein (UIP). The balance of amino acids depends upon the proportion of UIP and the amino acid spectrum of the UIP. Therefore, it is absolutely essential to measure or predict the relative amounts of MP (metabolizable protein) from microbes and UIP in any given feeding scenario. Both the production potential of the beef animal and microbial protein synthesis are driven by energy. It is impossible to predict MP supplied to the lower gut and MP needs of the animal without having accurate estimates of energy needs, energy supplies and ruminal energy availability. While there are many variations on beef production systems, most are based on high grain (finishing) diets or high forage diets. Forage contains little UIP and that UIP appears to be poorly digested (<50%). Without supplements, essentially all of the MP in forage feeding situations is supplied by microbes. Site of carbohydrate digestion (NDF) is relatively predictable and methodology for measuring forage protein degradation is relatively precise (NDF-N). Degradable intake protein (DIP) may be deficient in some situations. Microbial protein synthesis efficiency decreases as diet TDN decreases from 60% down to 45 to 50%. Low microbial production and low forage UIP create MP deficiencies in many forage feeding situations. On high grain diets, energy supply is high but microbial efficiency is limited by low ruminal pH. Site of carbohydrate digestion (starch) varies with grain type and processing. Estimation of ruminal degradation of grain (starch and protein) is not precise. DIP is usually required. Byproducts reduce starch, raise pH and add protein (maybe DIP or UIP depending on byproduct). Corn is high in UIP and the UIP is highly digested (>90%). Therefore feedlot cattle generally have adequate supplies of MP. It is difficult to produce an amino acid deficiency in feedlot cattle. Growing cattle can be deficient in specific amino acids depending upon the amino acid balance in the UIP.

Swine Species Symposium. Improving Sow Productivity: Recent Developments in Gilt and Lactation Management

359 Increasing weaning age improves pig performance and profitability in a multi-site production system. R. G. Main*, S. S. Dritz, M. D. Tokach, R. D. Goodband, and J. L. Nelssen, *Kansas State University, Manhattan.*

Two trials were conducted to determine the effects of weaning age on growing pig biologic and economic performance in a multi-site production system. Trial 2 also evaluated the effects of modifying nursery feed budgets according to weaning age. In trial 1 (2,272 pigs), treatments included weaning litters at 12, 15, 18, or 21 d of age. In trial 2 (3,456 pigs), litters were weaned at 15, 16, 18, 19, 21, or 22 d of age and categorized into three treatments (15.5, 18.5, or 21.5 d of age). In trial 2, pigs in each age group were fed a nursery feed budget classified as more or less complex. Since feed budget did not affect ($P > 0.27$) performance, only weaning age effects are presented. Each trial was conducted as a randomized complete block design with four blocks of linked nursery and finishing sites (6 and 10 reps/block in trials 1 and 2, respectively). All wean age treatments were weaned from a 7,300-head sow farm on the same day into the same nursery. Each block remained intact as pigs moved from nursery to finishing site. Costs and revenue were measured for each pen. Increasing weaning age (12, 15, 18, or 21; and 15.5, 18.5, or 21.5 in trials 1 and 2, respectively) improved (linear, $P < 0.03$) wean-to-finish ADG (580, 616, 637, 687 ± 8 g/d; 676, 697, 722 ± 6 g/d), mortality rate (9.4, 7.9, 6.8, 3.6 ± 0.95 %; 3.9, 3.4, 2.5 ± 0.5 %), weight sold per pig weaned (94.1, 100.5, 104.4, 113.1 ± 1.3 kg, 107.6, 111.6, 116.2 ± 1.1 kg), income over costs (\$2.00, 5.11, 7.12, 11.19 ± 0.52 /pig; \$7.99, 10.04, 12.46 ± 0.46 /pig), and cost per hundred kg sold (\$86.19, 83.24, 81.49, 78.36 ± 0.46 ; \$80.80, 79.25, 77.50 ± 0.32). The improvements in growth and mortality largely occurred in the initial 42 d after weaning, with smaller growth improvements in finishing. These studies indicate that increasing weaning age up to 21.5 d predictably improves grow-finish throughput (1.80 ± 0.12 kg sold/pig/d of age) and profitability ($\$0.89 \pm 0.05$ /pig/d of age) within this multi-site production system.

Key Words: Weaning Age, Pigs, Economics

358 Mathematical models used to determine ruminant protein requirements and availabilities. R. A. Kohn*¹ and M. D. Hanigan², ¹*University of Maryland, College Park,* ²*Land O' Lakes/Farmland Feeds, LLC, St. Louis, MO.*

The objective of this presentation is to review the functional differences between mathematical models that are used to formulate diets for beef and dairy cattle with respect to protein and amino acid requirements. An ideal model for diet formulation would require minimal data input to accurately predict the amount and form of protein required by the animal and supplied by available feedstuffs. Where appropriate, there should be a means to incorporate feed analysis results into the model to improve predictions. All current models divide dietary crude protein into two parts: that required by ruminal microbes and that required at the small intestine as true feed protein that has not been digested by ruminal microbes. The most recent models have established specific requirements and availabilities of the first limiting amino acids (e.g. lys, met). The Cornell model (CNCPS) also formulates for required amino acid and peptide protein (as opposed to non-protein nitrogen) for rumen fermentation. The 2001 NRC can incorporate soluble protein information, and the CNCPS can use protein solubility in buffers and detergents as indicators of protein degradation. When several models (NRC, 1989; CNCPS, CPM Dairy) were compared for their ability to predict protein flows to the small intestine for typical diets and cows, there were no obvious advantages for any one model. However, the NRC, 1989 was best able to predict losses in milk production due to underfeeding of protein to dairy cows. The 2001 NRC increased both RDP and RUP requirements for dairy cows without affecting the supply. As a result, the total CP recommended in diets increased for the 2001 NRC compared to the 1989 version. However, the amount recommended in the 1989 NRC was adequate. The various models that currently are available differ substantially in their level of complexity and the number and type of feed analyses that can be used. But, there is little evidence that this increased complexity has improved the accuracy of model predictions for typical farm conditions.

360 Behavior of sows during lactation. J. McGlone*, *Pork Industry Institute, Texas Tech University, Lubbock.*

Sow behavior is influenced by their genes and by their environment. During lactation, sows undergo significant changes in physiology that cause large behavioral changes. The objective of this review is to summarize the literature on sow behavior during lactation and the effects of management practices (such as weaning age and housing system) on sow behavior. Also, this review will summarize sow behaviors that lead to problems with the lactating sow or piglets. Sows undergo four major phases of behavior in the peri-lactation phase. First, prior to farrowing, sows undergo nest-building behavior that may involve building of an actual nest if sows are given building materials or expression of phantom nest-building behaviors in the absence of building materials. The second phase involves the establishment of the maternal-neonatal bond. This phase requires 12 to 24 h and is critical for piglet survival and growth. Maternal pheromones are secreted and the piglet is able to suckle in the presence of maternal pheromones. The piglet also is able to recognize its mother by her odor signature. The third phase is the lactation phase in which sows and piglets organize suckling with an interval of 40 to 50 min between nursing bouts. As piglets become larger, they will have larger, but less frequent meals - this trend continues from birth through market age. If given the opportunity, sows will spend less time with piglets as lactation progresses. The fourth phase is the weaning phase which can be gradual or abrupt and includes weaning and the weaning to estrus interval. Natural weaning by the sow can take place at any time from 3 d to 6 months of age. Sow genotype and the housing system can have major impacts on pig behavior during each phase. Weaning age will significantly impact phase 3 and 4 sow behaviors. Sow welfare including stress-related behaviors, wounds, scratches, injuries, weight loss and body condition are influenced by the behavior sows express as a result of their genotype, housing system and management practices.

361 Field experience with gilt age and lactation length. L. V. Himmelberg*, *Danbred North America, Seward, NE.*

The objective of this presentation will be to relate field experiences regarding the impact of gilt age and lactation length on sow productivity. Over time the largest percentage of females to farrow within a herd are parity one and therefore overall herd productivity is greatly influenced by the results achieved by them. Gilt age and weight at first service have a direct impact on these results. Field observations show that increasing gilt age and weight by approximately 30 days and 20 kilograms respectively, over traditional targets of 210 days and 125 kilograms can improve first parity born alive by as much as .75 pig per litter. Early

weaning programs designed to increase sow productivity and improve health have driven weaning averages below 21 days of age. Many producers have noted that weaning this early has a negative impact on subsequent parity born alive. To explore this, commercial production herds containing Danish genetics were examined. Born alive per litter was treated as a dependent variable and previous lactation length as an independent variable within each herd. The results of this analysis showed an average decrease in subsequent parity born alive of .12 pig per day for each day decrease in weaning average between 21 and 15.

Breeding and Genetics: Genetics Methodology 2

362 Pedigraph 2.0: A software tool for the graphing and analysis of large complex pedigrees. J. R. Garbe* and Y. Da, *Department of Animal Science, University of Minnesota, St. Paul.*

Pedigree graphing and analysis are important tasks in animal breeding and genetics. However, pedigree graphing and analysis are difficult for large complex pedigrees. Pedigraph version 2.0 provides rapid graphical visualization and analysis of large, complex pedigrees with a variety of options and features. The program produces artistic pedigree drawings with options to draw the full pedigree, a summarized pedigree with three options, or an extracted pedigree for a selected individual. The user has control over drawing style, fill color, line color, page size, pedigree size, title of the pedigree, gap between two generations, display of trait status, genotype, or inbreeding coefficient, and the minimal number of offspring required for a family to be included in the pedigree. The program can also calculate inbreeding coefficients for all individuals and the coefficient of coancestry between each pair of individuals. The program has been tested using two large and complex populations for its capability of pedigree graphing and its computational feasibility to calculate inbreeding and coancestry coefficients. The program has not encountered limitations in sample size or complexity of the pedigree. The only limitation encountered so far is the ability to print a potentially huge pedigree drawing. These tests plus over a years trial indicate that Pedigraph could be a versatile and capable tool for pedigree visualization and analysis.

363 Multiple-breed genetic inference using a heavy-tailed structural model for heterogeneous residual variances. F. F. Cardoso, G. J. M. Rosa, and R. J. Tempelman*, *Michigan State University, East Lansing.*

Multiple-breed genetic models have been recently demonstrated to effectively specify the heterogeneous genetic variances that exist between different beef cattle breed groups. We extend these models to allow for heterogeneous residual variances that may be a function of fixed effects (e.g. sex, breed proportion, or breed group heterozygosity) and random effects such as contemporary groups (CG). We additionally specify the residual distributions to be either Gaussian or based on a heavy tailed alternative such as the Student t , in order to distinguish potential outliers from individuals in high variance environments. For either of these two distributions and their homoskedastic counterparts, we analyzed 22,717 post weaning gain records from a Nelore-Hereford population based on a Markov chain Monte Carlo animal model implementation. The heteroskedastic Student t error model (with estimated degrees of freedom 7.33 ± 0.48) was clearly the best fitting model based on a Pseudo-Bayes factor criterion. Sex and breed group heterozygosity, but not breed proportion, appeared to be marginally important sources of residual heteroskedasticity. Specifically, the male residual variance was estimated to be 1.13 ± 0.09 times that for females whereas, for example, the residual variance in F_1 animals was estimated to be 0.70 ± 0.16 times that for purebreds. The CG effects were important random sources of residual heteroskedasticity; that is, the standard deviation of ratios of CG-specific residual variances relative to the baseline average was estimated to be 0.72 ± 0.06 . Purebred Nelores were estimated to have a larger genetic variance ($124.87 \pm 21.75 \text{kg}^2$) compared to Herefords ($40.89 \pm 6.70 \text{kg}^2$) under the heteroskedastic Student t error model; however, the converse was observed from results based on a homoskedastic Student t error model ($46.24 \pm 10.90 \text{kg}^2$ and 60.11 ± 8.54

kg^2 , respectively). These results naturally have important implications for multiple breed genetic evaluations.

Key Words: Bayesian Inference, Genetic Predictions, Outlier Robustness

364 Genetic evaluation of male fertility using a threshold model with emphasis on accurate estimation of conception rate. G. Abdel-Azim*¹, S. Schnell¹, G. Gelbert¹, and H. Rycroft², ¹*Genex Cooperative, Inc., Shawano, WI*, ²*Cooperative Resources International, Shawano, WI.*

A threshold model for male fertility evaluation was applied to a data set of size 2,233,377 records. The model included herd, year-season, bull age, cow parity, as fixed factors, and service bull, inseminated cow, and inseminator as random factors. Variance components estimated as ratios of the total phenotypic variance were 2.8, 11.1, and 5.2% for service bull, cow and inseminator, respectively. The main objective of the study was to transform bull solutions into percentages of conception rates, a more interpretable value to indicate male fertility. The transformation implemented avoids problems arising when linear combinations of estimates are used in a nonlinear parametric function, a practice that is currently in use to report national calving ease evaluations estimated by a threshold model. The transformation we implemented takes into account the accuracy of estimating breeding values and other factors in the model, hence, current practices that do not take accuracy into account were shown to consistently overestimate the probability of success in the binomial setting studied.

Key Words: Fertility, Conception Rate, Genetic Evaluation

365 Application of a random regression model to gene expression profiling. S. L. Rodriguez-Zas*, J. J. Looor, J. K. Drackley, and H. A. Lewin, *University of Illinois, Urbana.*

The patterns of gene expression recorded on individuals over a period can be studied using discrete or continuous representations of time. Within the later representation, the profile of expression can be modeled using common (fixed) and individual (random) polynomial coefficients in time. We evaluated the potential of random regression models to describe the fluctuations in the gene transcription levels recorded at successive time points. The data consisted of fluorescence intensities on more than 6000 unique genes recorded using spotted cDNA microarray technology. Liver samples were obtained at -65 d, -30d, -14d, +1d, +14d, +28d and +49d relative to calving on 8 Holstein cows. A reference design was implemented with each cow-day sample represented in two reverse-dye microarrays and each gene double spotted on each microarray. Fluorescence intensity measurements on 106 microarrays were filtered for weak signals and were normalized using a log2 transformation on the loess-adjusted values. The random regression model included linear to quartic polynomials on days and accounted for heteroscedasticity between days. Three percent of the genes had at least one significant ($P < 0.0001$) regression coefficient in days. The majority of these genes had significant quadratic trends alone or in combination with a significant quartic trend. Hierarchical and disjoint clustering of these coefficient estimates indicated the presence of 5 clusters. Four of these clusters were approximately characterized by significant (positive and negative) quadratic regression coefficients in combination with significant (positive and negative) quartic regression coefficient within each signed quadratic group. The last cluster was characterized by significant linear and cubic regression coefficients. Results from this study

indicate that random regression models are flexible to accommodate the variation in patterns that can be observed in genomic studies.

366 Evaluation of three statistical methods for QTL analysis. J. Xu*, J. R. Garbe, N. R. London, Y. Mao, and Y. Da, *Department of Animal Science, University of Minnesota, St. Paul.*

Three statistical methods are widely used in QTL analysis: mixture model (MM) likelihood analysis, regression on genotypic probabilities (RGP) and the least squares method (LS). We evaluated these three methods for statistical power in QTL detection and for accuracy in parameter estimation using simulations. Additive and dominance effects were simulated separately under each method. Three significance levels were used for QTL detection under LS. Critical values for QTL detection under MM and RGP were determined by empirical type-I errors that are equivalent to those under the LS method to ensure fair comparison. Statistical power was measured by the percentage of significant results. Accuracy of parameter estimation was measured by the mean squared error (MSE) of the estimates. For detecting additive effect, LS had the highest power when the heritability of the trait is <0.1 , and the three methods had similar power for higher heritabilities. For detecting dominance effect, MM and RGP had the same higher power and LS had the lowest power. For estimating marker-QTL recombination frequency based on the testing for additive effect, LS had the best accuracy (smallest MSE), followed by RGP, with MM having the worst accuracy. For estimating marker-QTL recombination frequency based on the testing for dominance effect, RGP had the best accuracy and MM had the worst accuracy when dominance heritability <0.1 . The three methods had similar accuracy when dominance heritability is >0.1 . For estimating additive effect, LS had the best accuracy followed by RGP. MM had the same accuracy as RGP when heritability is >0.1 but its accuracy rapidly worsens as heritability decreases. For estimating dominance effect, the three methods had similar performance when dominance heritability is >0.1 but the accuracy of MM rapidly worsens as dominance heritability decreases. These results suggest that each of the three methods has its own strength and that the three methods could be used jointly to complement each others strength.

367 Relationship between the choice of a random regression model and the possible shapes of the resulting variance function. S. D. Kachman*, *Department of Statistics, University of Nebraska, Lincoln.*

Random regression models provide a flexible means of modeling a trait, measured at variable points in time, using a relatively small number of covariance parameters. Random regression models have been applied in a variety of settings, including modeling lactation curves and growth curves. Within the class of random regression models, models using polynomials have proven to be very popular. The variance as a function of time can be obtained using the variance function, a linear transformation of a set of component variance functions. The component variance functions are not dependent on the variance components. In the case of polynomials the component variance functions are polynomials in time. An examination of the component variance functions, along with the restriction that a covariance matrix for the random regression coefficients must be positive semidefinite, results in the variance function having a lower bound formed by polynomials of even power. This results in a tendency for the variance to grow rapidly for extreme time points. For growth curve models without a fixed endpoint, a major consequence is large genetic and environmental variances for extreme ages. A secondary consequence is the tendency for variance functions to display a rounded wave pattern at intermediate time points. Regardless of the type of function used in a random regression model, the shapes of the component variance functions will determine the possible shapes of the variance function. Understating the component variance functions is important both in determining the suitability of a random regression model and in interpreting the resulting covariance matrices.

368 Weighting of information when predicting breeding values using the standard or marker-based inverse of the numerator relationship matrix. A. Maiwashe*, D. J. Garrick, and R. M. Enns, *Colorado State University, Fort Collins.*

Best linear unbiased prediction uses information from relatives when evaluating the genetic merit of an animal by accounting for additive genetic relationships among animals. Relationships among animals are usually computed using pedigree information (A_p). Relationships among animals can now be computed using genetic markers (A_m). The objective of this study was to derive weights for an individual and its relatives when the A_p or A_m numerator relationship matrices were inverted and used in the mixed model equations. A hypothetical data set for a trait measured on females included one grandsire with half sib sons. The grandsire and his sons had several hundred daughters with yield deviations (DYD). Estimated breeding values (EBV) were obtained using a sire model. The EBV for each son was expressed as a linear function of his DYD if available and EBV of his relatives. The weights for a half-sib bull using A_p were always zero except for his DYD and the grandsire. The relative emphasis on the DYD increased as the number of daughters increased. The zero weight on half-sibs was a feature of the inverse of the A_p . In any non-inbred population, the A_p uses a relationship of 0.25 between all half-sibs. A bull with no daughters was evaluated as half its sires EBV. Its reliability is limited because there can be no accounting for Mendelian sampling. In contrast, the relationship between half sibs can vary from 0 to 0.5 in A_m . That resulted in an inverse with more non-zero coefficients than existed when A_p was used. Accordingly, the evaluation of any particular half-sib had non-zero weights for all half-sibs with the weight on each half-sib varying with the proportions of alleles shared in common. A bull with no daughters could be more reliably assessed using A_m rather than A_p if he had half sibs with daughters because the inferiority or superiority of his Mendelian sampling could be assessed to some extent. The use of relationships based on markers may be advantageous for young bulls.

369 A practical longitudinal model for evaluating growth in Gelbvieh cattle. K. R. Robbins*, I. Misztal, J. K. Bertrand, A. Legarra, and S. Tsuruta, *University of Georgia, Athens.*

Using Gelbvieh records spanning 1972-2001, the practicality of using a longitudinal model to evaluate growth in beef cattle was examined by subjecting the data to multiple-trait (MT) and random regression (RR) analysis. Approximately 15% of the animals in the dataset had at least one record measured outside of the accepted MT age ranges for weaning weight (WW) and yearling weight (YW). Fourteen percent of WW records and 19% of YW records were measured outside of the accepted ranges for MT analysis. This suggested that a longitudinal model could provide additional information for breeding value (BV) prediction. Three RR evaluations were performed using cubic Legendre Polynomials. The first (RR1), included only records measured within MT ranges. The second (RR2), used records as in RR1, but ages were set to 205 days and 365 days for WW and YW respectively. This was done to determine the extent to which the spread in days at weighing affected the predicted BVs. Finally, the third evaluation (RR3) utilized all available records. Due to convergence problems the random regression parameters were diagonalized via eigenvalue decomposition. After diagonalization, it was found that all models converged in a similar number of iterations. Correlations were computed between model predictions for fixed, direct, maternal, and maternal permanent environmental effects. Correlations between the MT, RR1, and RR2 evaluations were high for all effects. Correlations of MT with RR1 and RR2 for the direct effect were $\#8805$.99 for all three traits, leading to the conclusion that both models were equivalent when predicting BVs from data containing records measured within the MT age ranges. Correlations between MT and RR3 were .992, .958, and .951 for BW, WW, and YW. These correlations show that the added information does affect BV prediction. The results of this study indicate that the RR model has increased capability at a cost similar to MT.

Companion Animals

370 Effect of breed and size of dog on body composition. C. J. Cupp, DVM, MS* and G. Czarnecki-Maulden, PhD, Nestle Purina Research, St. Louis, MO.

The objective of this study was to evaluate body composition in small breeds of dogs as compared with larger breeds. Body composition by Dual Energy X-ray Absorptiometry (DEXA) was performed in 34 adult small and toy breed dogs. Results were compared with data obtained from 41 Beagles and 6 Labrador retrievers. Body weight, bone density, total calcium, fat grams, lean grams and bone mineral content were significantly lower in small dogs than in larger breed dogs, which were directly related to their body size. However, small dogs showed a higher percentage of bone and lean tissue, and lower percentage of fat tissue relative to larger breed dogs. Age, gender and reproductive status may influence the differences seen in these parameters and warrants further study.

Key Words: Dog, Body Composition

371 Influence of age on flatulence in dogs. C. Apanavicius*¹ and G. Czarnecki-Maulden², ¹University of Illinois, Urbana, ²Nestle Purina Research, St. Joseph, MO.

Digestive function is thought to decline in elderly animals. One indicator of digestive function is flatus production. The objective of this trial was to determine the effect of aging on flatulence in the dog. Twenty young adult (15 years old, mean age 2.6 years) and twenty elderly adult (8-14 years old, mean age 12.2 years) beagle dogs were used in the trial. All dogs were fed a nutritionally complete extruded dog food. Three hours after meal consumption, a hydrogen sulfide (H₂S) monitor was placed in a vest worn by the dog. Hydrogen sulfide is the main component of flatulence in dogs. Hydrogen sulfide concentration (ppm) was measured by the monitor at 4-second intervals. There was no statistically significant ($P>0.05$) difference in number of flatulence events, peak H₂S, or average H₂S per event in young adult vs. elderly dogs. Therefore, flatulence, as measured by H₂S expulsion, was not affected by aging in beagle dogs. Further research is needed to determine whether other indicators of digestive function are influenced by aging in the dog.

Key Words: Dog, Digestion, Aging

372 Management of canine food intake to reduce obesity. D. Mattsson* and L. Deffenbaugh, Kemin Nutrisurance, Inc., Des Moines, IA.

Obesity in pets is a significant veterinary health issue that manifests in over 40% of dogs and cats that are seen by veterinarians. Most obesity is due to over feeding at mealtime and to owners providing unnecessary snacks to their pets. Unfortunately, veterinarians estimate that they have been successful in treating obesity in only about 10% of cases. One reason for the lack of success might be the difficulty that pet owners have with compliance to a strict feeding program. Pet owners that wish to help their pet lose weight might find a dietary supplement that impacts food intake very helpful in achieving their goal. Cholecystokinin (CCK) is a gastrointestinal peptide hormone that is released from the digestive tract into the circulatory system after consuming food and acts to control short-term food intake. Release of CCK from the digestive tract is stimulated by protein and inhibited by endogenous proteases such as trypsin. Normally, following a meal, the human circulating CCK level can reach 8 pmol/L then decline to a pre-meal level after about 40 minutes. In the absence of proteases, an endogenous releasing factor interacts with cells that produce CCK resulting in stimulation of CCK release. Canine digestive physiology is very similar to humans, particularly with respect to CCK release and serum levels after food consumption. The canine basal CCK level is about 2 pmol/L which rises to a peak of 5-11 pmol/L within 30-45 minutes of the start of food consumption. The serum CCK level then declines to the basal level about 120 minutes after the start of feeding. While exogenous CCK delays gastric emptying, it is not clear whether the increased serum level of CCK following feeding is sufficient to induce satiety. A canine dietary supplement that might temporarily impact short-term food intake may provide pet owners with a means to help their pet consume less food.

Key Words: Canine, Obesity, CCK

373 Meeting the challenge of stabilizing weight management petfood diets. L. B. Deffenbaugh*, Kemin Nutrisurance, Inc.

Weight management diets designed to counter the epidemic of obesity in companion animals abound. For many years, petfood diets for weight reduction have been reduced calorie, reduced fat and / or increased fiber. When fat content is reduced in a petfood diet, special attention must be given to ensure that the limited fat in the formulation meets fatty acid profile requirements. Not surprisingly, the low carbohydrate (high fat and protein) trend in human dietary regimes is also making an appearance in petfoods. In this case, higher fat diets also beg for manipulation of the fatty acid profile to avoid unhealthy excesses of saturated fats. Thus, weight management diets are carefully formulated for not only the amount of fat but also the types of fat. Regardless of the formulation approach for weight reduction diets, whether low or high fat, the ratio of healthy, unsaturated fats will be increased at the expense of unhealthy, saturated fats. Unsaturated fats, especially vegetable and marine oils, are notoriously difficult to protect against autoxidation, and oxidized lipids will cause more harm than the best of intentions for meeting an ideal fatty acid profile. Low fat diets also pose the seeming paradox of being more difficult to stabilize than medium or high fat diets. The chief consideration with increased use of unsaturated fats is selection of the appropriate antioxidant. Recent research has shown that rosemary extract is uniquely suited for highly unsaturated diets, and especially diets relatively low in total fat. For example, the shelf-life stability of a diet with only 8% total fat in which most of the fat was from highly unsaturated menhaden oil was more than doubled by treating the oil with rosemary extract compared to equivalent actives from mixed tocopherols, the most commonly used natural antioxidant. Further, rosemary extract has positive consumer appeal equivalent to the perceptions of fresh, healthy, natural and holistic diets. Proper selection of antioxidants and other strategies to ensure oxidative stability of weight management diets throughout the entire shelf-life will be detailed.

Key Words: Rosemary Extract, Unsaturated Oils, Shelf-Life

374 Diet and age affect canine small intestinal and colonic gut morphology. K. N. Kuzmuk*, K. S. Swanson, L. B. Schook, and G. C. Fahey, Jr., University of Illinois, Urbana.

The objective of this experiment was to determine the effects of diet and age on gut morphology in healthy dogs. Small intestinal villus width, height, and area, and small intestinal and colonic crypt depth were measured. Twelve senior (age = 12 yr old; 6 M, 6 F) and 12 young adult (age = 1 yr old; 6 M, 6 F) beagles were randomly assigned to one of two dietary treatments: an animal product-based diet (APB) and a plant product-based diet (PPB). The APB diet was primarily composed of highly digestible, animal-derived ingredients and was formulated to contain 30% crude protein and 20% fat. The PPB diet was primarily composed of plant-derived ingredients and was formulated to contain 22% crude protein and 8% fat. In addition to dietary protein and fat differences, total dietary fiber was greater in the PPB diet (15.2%) compared to the APB diet (4.8%). Diets were fed for one year. Intestinal sections were collected from the duodenum, jejunum, ileum, and colon and placed in formalin for preservation. Tissues were embedded in paraffin and cut into 3 mm sections, and placed on glass slides. Digital images of tissues were taken using a Nikon Optiphot-2 microscope (Nikon, Melville, NY). Height and width measurements, a minimum of 15 per section, were taken using Image Pro Plus[®] software. Jejunal and ileal villus height, and duodenal villus width were greater ($P<0.05$) for dogs consuming the PPB diet. Age also affected gut morphology as young dogs had greater ($P<0.05$) jejunal villus height while senior dogs had greater ($P<0.001$) colonic crypt depth. Thus, both diet and age affect small intestinal and colonic morphology of the dog. This research was supported by Pyxis Genomics, Inc.

Key Words: Dog, Gut Morphology, Aging

375 Evaluation of glycylysarcosine and cefadroxil as substrates for non-invasive determination of canine small intestine PepT1 capacity and demonstration that maximal cefadroxil absorption occurs when consumed 4 h after meal ingestion. B. M. Zanghi*¹, G. L. Sipe¹, G. M. Davenport², and J. C. Matthews¹, ¹Department of Animal Science, University of Kentucky, Lexington, ²The IAMS Company, Lewisburg.

Glycylysarcosine (GlySar) and cefadroxil (Cef) are reputedly poorly-metabolized substrates of PepT1, the low affinity, H⁺-coupled, peptide cotransporter expressed in the apical membranes of enterocytes. To non-invasively study PepT1 functional capacity in dogs, 50 μ Ci of GlySar (12.5 nmols) or Cef (50 nmols) was orally bolused in a gel capsule to adult, intact female, mongrel dogs to characterize the amount, form, and time required for ³H appearance in blood, urine, and feces. A pilot study (n = 3) demonstrated that GlySar was well absorbed (97.6 versus 2.4% of total ³H was recovered within 24 h after bolusing in plasma versus feces, respectively), but GlySar accounted for only 11.5 \pm 7.8% of serum ³H and 161 \pm 9 d was required for clearance of ³H from plasma (17.3 d half-life). In contrast, Cef was poorly metabolized, and cleared from plasma, urine, and feces within 27 d. Therefore, a 4 x 4 Latin Square experimental design with 35 d periods was performed using dogs (n = 4; BW = 21.3 \pm 2.5 kg) to evaluate the influence of time of Cef bolusing after meal ingestion (0-, 2-, 4-, 6-h) on appearance, metabolism, and clearance of bolused Cef as an indicator of relative PepT1 absorption capacity. Plasma content of Cef (pmol) from 1.5 through 12 h was 530 to 43% greater (P < 0.10) for the 4-h treatment than for the 0-h. Quantitatively, the 4-h after meal ingestion treatment also was 111 to 22% and 60 to 9.4% greater than the 2- or 6-h treatments, respectively. For all bolus treatments, 89 to 95% of serum ³H was in the form of Cef within 1.5 h after dosing. No treatment effect was observed for plasma or urine ³H clearance, and the mean plasma ³H half-life was 6.3 d. These data demonstrate that Cef is a useful marker to evaluate in vivo PepT1 functional capacity and is maximally absorbed when consumed 4-h after ingestion.

376 Digestibility of dry dog kibble containing spray dried animal plasma. C. J. Hammer, J. D. Quigley, J. C. Campbell, J. D. Crenshaw*, and L. E. Russell, APC, Inc., Ankeny, IA.

Addition of spray dried animal plasma (SDAP) to diets of farm animals improves feed efficiency; however, there are few data with companion animals. Objective of this study was to determine effects of SDAP on intake and digestibility in dogs. Nine adult Beagle dogs (initial BW = 11.7 kg) were used in a replicated 3 x 3 Latin Square design with 10-d periods. The final five days of each period were used for measurement of intake and fecal collection. A dry dog kibble was prepared and SDAP was added at 1% of the mixture either by blending with other ingredients prior to extrusion, or by blending with fat and applying on the outside of the kibble. Intake and apparent digestibility of nutrients were determined. Addition of SDAP did not markedly affect chemical composition of diets. Intake of dog food was unaffected by treatment; however, intake of DM tended to be reduced (P = 0.09) by 9 g/d when SDAP was added to the diet. Digestibility of DM was improved (P = 0.02) when SDAP was included in the diet. Crude protein digestibility was improved (P < 0.01) by 4.6 and 3.8% when SDAP was added to the kibble pre- or post-extrusion, respectively. Digestion of ash also was improved (P < 0.01) by 11.0 and 10.9% when SDAP was added to the kibble pre- or post-extrusion, respectively. Digestibility of energy tended to be increased (P = 0.07) when SDAP was included in the diet. Digestibility of total dietary fiber was decreased (P < 0.01) by 3.5% when SDAP was applied pre-extrusion and decreased by 9.4% when SDAP was included post extrusion. Although digestibility of total dietary fiber was decreased, fecal weight was reduced an average of 23 g/d and fecal DM excretion was reduced an average 18.5% when SDAP was added to the kibble. In conclusion, spray-dried animal plasma was an acceptable ingredient in this dry dog food preparation and improved digestion and reduced fecal output.

Key Words: Canine, Plasma, Digestibility

377 Chemical composition, bioavailability, palatability, and digestibility of alternative protein sources for dogs. J. M. Dust*¹, C. M. Grieshop¹, C. M. Parsons¹, N. R. Merchen¹, J. D. Quigley, III², and G. C. Fahey, Jr¹, ¹University of Illinois, Urbana, ²American Protein Corp. Inc., Ankeny, IA.

Eleven proteinaceous ingredients (chicken protein sources, blood protein sources, enzyme hydrolyzed fish protein concentrate (EHFPC), soybean meal (SBM), and spray dried pork liver (SDPL)) were analyzed for chemical composition and biological availability. Chicken protein sources ranged in concentrations of CP, acid hydrolyzed fat, and total amino acids (TAA) by 20, 31, and 24%, respectively, and GE by 1.7 kcal/g. Blood proteins ranged in concentrations of CP and TAA by 11 and 8%, respectively. Protein solubility differences within chicken and blood protein source categories averaged 57 and 69%, respectively. Protein solubility of EHFPC, SBM, and SDPL was 53, 67, and 26%, respectively. Calculated lysine digestibility (using immobilized digestive enzyme assay) ranged approximately 16 and 24% for blood and chicken protein sources, respectively. Lysine digestibility values for SBM and SDPL were 89 and 77%, respectively. A chick protein efficiency ratio (PER) assay indicated that chicken protein sources, EHFPC, SBM, and SDPL were highly available (PER value > 2.8) and blood protein sources were poorly available (PER values < 1.5). An experiment to determine palatability and digestibility of a diet supplemented with 0 or 3% processed red blood cells (PRBC) fed to canines was conducted. Palatability data indicated an intake ratio of 0.34 for the 3% PRBC diet. Total tract nutrient digestibilities of DM, OM, and acid hydrolyzed fat were not different (P > 0.05). Digestibility of CP was higher (P < 0.05) for dogs consuming the 0% PRBC diet than the 3% PRBC diet. These data suggest that chemical composition and bioavailability of alternative protein sources differ greatly among ingredients within the same category. The feeding study data suggest that a PRBC-containing diet is not highly palatable and elicits somewhat of a decrease in protein digestion.

Key Words: Bioavailability, Digestibility, Dog

378 Evaluation of preference and acceptability of 2-hydroxy-4 methylthio butanoic acid (HMTBA) and DL-methionine (DLM) by canine and feline animals. M. Vazquez-Anon*¹ and L. R. Prewitt², ¹Novus International, Inc., St. Louis, MO, ²Prewitt Global Consulting Services, Balwin, MO.

This study was designed to evaluate the preferences and acceptability of an 88% solution of HMTBA (Alimet Feed Supplement, Novus International, Inc.) and DLM (dry 99%) in pet food diets. Three levels of HMTBA (0.05, 0.10, 0.15% in canine and 0.2, 0.25, 0.30 % in feline diets) and two levels of DLM supplementation (0.10, 0.15% in canine and 0.25, 0.30 % in feline diets) were added to a basal diet deficient in methionine (M). The first and second level in canine and the third level of supplementation in feline diets represent commercial levels of supplementation. In a three day preference tests, canine and feline animals preferred (P 0.05) diets containing either of the M sources over the control. Canine gram-intake ratios for M compared to control were 2.07:1, 5.58:1, and 5.13:1 for 0.05, 0.1, and 0.15% HMTBA and 5.32:1 and 4.95:1 for 0.1 and 0.15% DLM concentrations. Feline gram-intake ratios for M compared to the basal diet were 1.67:1, 1.91:1, and 1.85:1 for 0.20, 0.25, and 0.30 % HMTBA and 1.87:1 and 1.63:1 for 0.2 and 0.25% DLM. No differences were found between the M sources at 0.10% and 0.25 % for canine and felines, respectively. Canines preferred DLM 2.5:1 times (P 0.05) over HMTBA when over-supplemented at 0.15 % and felines preferred 1.24:1 times (P 0.05) HMTBA over DLM when fed at 0.3 %. Consumption over a 7-day period with no choice demonstrated no significant differences between basal, 0.1 % HMTBA and 0.1 % DLM in canines. In felines, higher consumption (P 0.05) was observed for 0.25 % DLM (69a g) followed by 0.25% HMTBA (62b g), and control (60b g). Addition of HMTBA or DLM to a canine or feline M deficient diet improves palatability and had no detrimental effect on food consumption.

Key Words: Canine, Feline, Methionine

379 Beneficial effects of mannan oligosaccharide on diet component digestibility and fermentation characteristics in the dog. L. C. Kappel¹, Y. Zhang¹, Y. Marcum¹, W. H. Taylor¹, W. G. Henk¹, P. Jowett¹, C. Hedlund¹, K. E. Newman², H-P. Healy³, and A. Kocher*³, ¹*School of Veterinary Medicine, Louisiana State University, Baton Rouge*, ²*Venture Laboratories, Lexington, KY*, ³*Alltech Inc., Nicholasville, KY*.

Adult Beagles (36) and mixed-strain hounds (4), in 8 groups of 5 dogs each, were used to evaluate organic matter digestibility of 4 diets having no fibrous ingredient (CON), beet pulp (BP), soybean hulls (SH), or cellulose (CEL), with or without 0.11% mannan oligosaccharide (MOS; Bio-Mos[®], Alltech, Inc., Nicholasville, KY). Analyzed total (and soluble) fiber percents, respectively, were: 8.1 (2.4), 15.3 (3.7), 16.7 (1.5), and 15.6 (1.7). The study conducted 6 times involved a 21-d adaptation period and a 5-d total fecal collection period. Insoluble fiber digestibility was greatest for SH diet whereas CON, BP, and CEL diets were similar. Insoluble fiber of SH was about 25% more fermentable than that of BP though nonsignificant. Soluble fiber digestibility was variable and not significantly different among fiber sources. The MOS increased soluble fiber digestibility across all fiber sources ($P < 0.05$; 72.9 vs 61.5%, on average), indicating a strong beneficial effect on microbial metabolism due to increased proliferation of the fermentation microbe population. In vitro fermentation of starch, BP, SH, or CEL was evaluated using inocula from feces of 12 dogs (3 from each of the CON and BP diets with and without MOS). Organic matter digestibility of BP and SH was improved with BP + MOS diet but not CON + MOS diet fecal inoculum, indicating that some adaptation period was required for MOS to lead to changes in microbial metabolism. However, fecal inoculum from dogs fed BP + MOS diet decreased acetate, propionate, and total volatile fatty acids using BP or SH substrates and fecal inoculum from dogs fed CON + MOS diet increased acetate and total volatile fatty acids using starch. Histology revealed the number of colonic mucous secreting goblet cells was greater for BP and SH than CON and CEL diets in response to amount of fermentation not fiber per se. Addition of MOS to dry dog food improved fiber digestibility and altered intestinal fermentation patterns.

Key Words: Canine, Fiber, Manno-Oligosaccharide

380 Effect of Bioplex organic trace minerals on copper, manganese, and zinc status of the canine. L. C. Kappel¹, J. F. Williams¹, G. R. Pettifer¹, H-P. Healy*², and A. Kocher², ¹*School of Veterinary Medicine, Louisiana State University, Baton Rouge*, ²*Alltech, Inc., Nicholasville, KY*.

A 24-wk study was conducted with 20 adult, mixed-strain hounds from five litters, housed two dogs per pen, to compare Cu, Mn, and Zn in serum, liver, and hair when feeding a control (CON) diet with an inorganic trace mineral premix or a diet supplemented with an organic trace mineral premix (OTM; Bioplex[®], Alltech, Inc., Nicholasville, KY) at equal mineral inclusion levels. One dog was removed from the OTM group for non-nutritional causes. Dogs used in this experiment were mature with low mineral requirements and adequate mineral status prior to the study. By analysis, the commercial dry basal diet (Animal Nutrition, Ogden, UT) had 10 ppm Cu, 29 ppm Mn, and 56 ppm Zn. Typical industry levels of 8 ppm Cu, 10 ppm Mn, and 140 ppm Zn were added in sulfate form to the CON diet or in proteinate form to the OTM diet. These mineral concentrations were probably above the dogs' mineral requirements. Jugular blood samples (8 mL) were taken at 0, 2, 8, 12, 16, and 24 wk two hours before feeding for serum mineral analysis (stored frozen). Liver samples (15-25 mg) were obtained by liver biopsy at 0, 12, and 24 weeks on test (stored frozen). Two 10 x 10 cm areas on the left side were closely clipped initially, and from one location hair was clipped at the skin at 4, 8, and 12 wk and from the other site hair was sampled at 12 and 24 wk. Over 24 wk, serum and liver mineral concentrations did not differ between diets and were in normal ranges for dogs. Although hair Zn levels did not differ significantly by dietary treatments, the OTM supplemented diet increased hair Cu ($P < 0.05$; 1-4 wk, 17.9 vs 12.9, and 9-12 wk, 11.1 vs 7.2 mcg/g) and Mn (main effect $P < 0.10$; 12.6 vs 9.7 mcg/g) in 4-wk interval hair samples, indicating better Cu- and Mn-proteinate uptake, utilization, different distribution in the body or a combination of the three than Cu and Mn sulfates in the CON diet. Trace mineral availabilities may be more easily demonstrated with growing dogs or those previously deficient, or when using supraoptimal trace mineral inclusion rates.

Key Words: Bioplexes, Canine, Trace Minerals

Extension Education - Dairy Science

381 Impact of conducting a dairy herdsman short-course in California. G. E. Higginbotham*¹, J. H. Kirk², C. C. Collar⁵, A. R. Castillo⁶, S. L. Berry³, B. A. Reed⁷, and J. D. Robison⁴, ¹*University of California Cooperative Extension, Fresno/Madera Counties*, ²*Veterinary Medicine Extension, University of California, Davis*, ³*Department of Animal Science, University of California, Davis*, ⁴*California State University, Fresno*, ⁵*University of California Cooperative Extension, Kings County*, ⁶*University of California Cooperative Extension, Merced County*, ⁷*University of California Cooperative Extension, Glenn County*.

Since 2001, University of California Cooperative Extension (UCCE) has conducted four 18-hour training programs at three different locations for dairy farm employees in the central valley of California. The program consists of classroom and hands-on teaching sessions. Session topics include raising replacement heifers, reproductive management, milking management, nutrition, hoof care, labor management and herd health. Material is presented in English with simultaneous translation for Spanish attendees. Over 120 dairymen, dairy workers and dairy industry representatives have attended the courses. To assess impact of materials taught, a survey was mailed to attendees (N=95) who attended one of the first three herdsman shortcourses and who were thought to have been currently employed on a dairy. Time since attendees attended the shortcourse ranged from 8 - 24 months. The survey was provided in both English and Spanish. Thirty-two former attendees returned the survey (34%). Of those responding, English was the first language for 63%. Of the twelve who indicated Spanish was their first language, only ten used the Spanish questionnaire version. All of the respondents indicated that the course met their expectations (33% strongly agreed; 66% agreed). All but one indicated that they would recommend the course to other herdsman. Nearly 66% of the respondents indicated that Spanish translation of presentations helped in their understanding of the materials. The previous dairy experience of those responding was 0-5 years, 45%; 6-10 years, 22%; and over 10 years, 32%. Overall, 41% of the attendees

indicated that they had begun to apply information they had learned in the classes. Hands-on laboratory exercises were found to be useful to most of the past attendees (calf necropsy, 94%; reproductive tracts, 91%; use of CMT, 91%; cow health, 97%; and foot trimming, 88%). Results from this survey demonstrate the need for a dairy herdsman shortcourse in order for dairy employees to improve their practical dairy skills.

Key Words: Herdsman, Training, Dairy

382 Assessing the Occupational Profiles of Senior- and Middle-level Dairy Managers. R. Stup*, L. Holden, and J. Hyde, *Pennsylvania State University, University Park*.

To effectively prepare dairy managers, educators must have a clear understanding of the competencies that lead to success. A competency is a knowledge or skill that an individual can apply to the successful completion of a task. The first objective of this project was to develop comprehensive sets of job competencies for middle managers and senior managers. These can subsequently be used for developing and updating dairy education curricula. The second objective was to assess the level of proficiency in each of the competencies among the current workforce to prioritize training needs.

Highly successful senior- and middle-level dairy managers were identified by Cooperative Extension educators and dairy industry personnel. These successful managers participated in focus groups with the objective of identifying, describing, and categorizing the competencies that lead to success. Four focus groups were conducted, two senior manager groups with a total of 17 people and two middle manager groups with a total of 12 people. Focus groups were professionally facilitated. The focus groups used a computer aided process known as a Customized Occupational Profile (COP) to identify general competency areas and the specific tasks that must be accomplished within those areas. The data resulting from the focus group processes were combined into comprehensive sets of job competencies for each respective manager position.

A survey was developed to assess the proficiency of existing middle and senior managers, relative to the identified competencies, within the framework of a gap analysis. The survey was distributed to dairy managers and the overall response rate was 37.2%. Respondents were asked to assess their own ability in each of the general competency areas. Competency-based research of this nature is widely used in other industries, but it is rare in dairy. Dairy educators in both Cooperative Extension and resident education will be able to use this information to update and improve educational programs.

Key Words: Dairy, Manager, Competency

383 The evolution of an extension education website - Dairy beef: Maximizing quality and profits. J.C. Dalton*¹, D.A. Moore², J. Kirk², M. Poe², and H. Sullivan³, ¹University of Idaho, Caldwell, ²University of California, Davis, ³New Mexico State University, Las Cruces.

In response to food safety and quality concerns in dairy market cattle, a 7-western state collaborative educational project was developed to create a distance-learning program for dairy producers, Cooperative Extension advisors, and dairy veterinarians to provide a consistent message about dairy beef food safety and quality. Faculty at the University of California, Davis, designed the program with input from dairy and meats scientists, veterinarians, and media specialists from Arizona, Colorado, Idaho, New Mexico, Oregon, and Washington. Individuals are encouraged, but not required, to register to view the website program materials. Between February 2003 and March 2004, 93 individuals registered for the course. According to FlashStats, the monthly page hit totals for March to December 2003 range from 8,904 to 27,412 hits. Following publication of an article about the development of the Dairy beef educational program in the *Journal of Dairy Science*, there were over 8,000 page hits in the first week of January 2004. The curriculum modular format complements the role of Cooperative Extension faculty through flexible delivery via the Internet or by CD ROM. The curriculum also has the versatility to be used in a workshop setting by a veterinarian, or even a dairy owner. Furthermore, the modular format allows for flexibility when adding, changing, or marketing new segments to users. When BSE was found in a dairy cow in Washington, project members were quickly able to assess the situation, find useful, existing links to educate dairy producers and veterinarians, and add new information to the Dairy beef website. In response to suggestions from in-residence programs and website course evaluations, the project team is producing training modules for Spanish speaking dairy employees. Dairy beef: Maximizing Quality and Profits (<http://dairybeef.ucdavis.edu>) is a flexible distance education tool to educate dairy and allied industry personnel about dairy beef food safety and quality.

Key Words: Dairy Beef, Food Safety

384 Businessense: Teaching dairy producers best management practices in business and information management. B. J. Hilty* and L. A. Holden, *Pennsylvania State University, University Park.*

Operating a dairy business involves considerable risk. Financial risk can be managed through sound decision-making. Accurate information concerning business performance is needed for sound decision making. An educational program, Businessense, was developed to improve decision making skills of Pennsylvania dairy producers through the adoption of best management practices in business and information management. This program was an interactive three-session workshop consisting of lectures, hands-on business analysis exercises and group discussions. Forty-five producers participated in the program. Each producer was required to submit data to complete a comprehensive business analysis. Participants also used an Excel spreadsheet, DairyCOPS (Cost of Production System), to calculate their production costs per hundred pounds of milk. Data from both analyses was summarized and presented to participants so they could see where their operation ranked among the sample of farms. Group discussions addressed issues such as investment management, cost control and production efficiency, which were previously addressed in lectures. Five key financial ratios for evaluating business performance and five key production indicators for evaluating herd performance were identified. Participants were given a pre and post test to identify these ten indicators. Less than 10 percent of participants were able to identify more than one correct financial ratio, while less than 20 percent were able to identify more than two key production indicators

on the pre-test. On the post-test over 70 percent of participants correctly identified four to five financial indicators and 98 percent correctly identified four to five production indicators. Businessense effectively taught producers how to implement best management practices in business and information management. Regular analysis of key indicators will positively impact dairies over time through better decisions.

Key Words: Dairy, Business, Management

385 Minnesota 4-H Gopher Dairy Camp: A Youth Learning Experience. B. J. Heins*, L. B. Hansen, and A. J. Seykora, *University of Minnesota, St. Paul.*

The Gopher Dairy Camp provided an exceptional 3-day opportunity for 4-H and FFA youth to participate in dairy showmanship, dairy judging, dairy workshops, and to interact with other youth participants. The camp provided four educational workshops consisting of artificial insemination, dairy heifer nutrition, corrective mating of dairy animals, and linear classification and scoring of dairy cows. The workshops were followed by a 'mock' dairy auction where youth purchased dairy heifers to prepare for the showmanship contests the next day. On the second day, professional dairy fitters were brought in to help teach and assist the campers about the basics of fitting a heifer and dairy showmanship. In the afternoon the youth participated in an ethics training seminar and a showmanship contest followed. A fun evening activity was planned where youth could interact and relax. The evening activity in 2003 was a Minnesota Twins game. The third day involved dairy leaders presenting dairy judging workshops, teaching the basics of dairy judging, which was followed by a dairy judging contest with 3 classes. Program evaluation by youth indicated that the camp was highly successful (4.6 on a 5-point scale). Group Fitting demonstrations (4.5), Activity Night (4.8) and Gopher Gold Auction (4.4) were also highlights among the participants. Approximately 50% of the costs were provided by various dairy industry sponsors and 4-H foundations. Seventy-four youth were registered for the camp and the participants paid a registration fee of \$75. Many alumni and industry professionals made the camp a huge success. Based on the high ratings received, the planning committee decided to continue with the camp into the future. The results indicated the Gopher Dairy Camp was enjoyed by all.

Key Words: 4-H, Youth, Dairy

386 Western integrated nutrition and nutrient management education (WIN²ME) for the nutrition and nutrient management professional. J. H. Harrison*¹, L. M. VanWieringen¹, R. L. Kincaid¹, A. Hristov², R. Sheffield², M. Gamroth³, P. French³, and T. Downing³, ¹Washington State University, Puyallup, ²University of Idaho, Moscow, ³Oregon State University, Corvallis.

The US EPA released new guidelines for Concentrated Animal Feeding Operations and Animal Feeding Operations in 2003. Under the new guidelines, CAFO/AFOs are required to develop a Nutrient Management Plan. One form of a Nutrient Management Plan is a Comprehensive Nutrient Management Plan and is defined in the Natural Resources Conservation Service National Planning Procedures Handbook. There are six components of a CNMP: 1) Feed Management, 2) Manure and Wastewater Handling and Storage, 3) Nutrient Management, 4) Land Treatment, 5) Record Keeping, and 6) Other Manure and Wastewater Utilization Options. Feed represents the largest import of nutrients to the farm, followed by commercial fertilizer. Feeding Management opportunities currently exist to reduce imports of nutrients, particularly nitrogen and phosphorus. The technologies and approaches to achieve these reductions vary in their degree of economic feasibility and environmental impact. Agricultural professionals need to understand the probable impact of changes in feeding management both from an economic and an environmental standpoint. The intended audience is staff of the NRCS, Conservation Districts, Nutrient Management Consultants, Nutrition-Management Consultants, and designated Nutrient Management Specialists of large animal operations. Specific objectives are: 1) provide training to Ag Professionals in feed management concepts and practices that minimize the import of nutrients to the farm and provide economic and environmental sustainability, 2) provide training in the use of computer models and software for strategic ration balancing, whole farm nutrient balance, and whole farm economics, and 3) develop educational materials that are specific to the Pacific Northwest regional

animal industries while utilizing national curriculum developed to address nutrition in the context of nutrient management. The curriculum has been developed using a 101 and 201 level approach.

Key Words: Extension, Nutrient Management, Environmental

387 Use of a dairy whole farm phosphorus balance education tool (dairy WFPBET) to teach dairy producers and their advisers nutrient management concepts at the whole-farm level. J. H. Harrison*¹, T. Nennich¹, and A. Rotz², ¹Washington State University, Puyallup, ²USDA/ARS, University Park, PA.

All dairy farms in the state of Washington are now required by law to have a certified nutrient management plan. These plans are nitrogen based; however, in early 2003, EPA released new CAFO guidelines to require that nutrient management plans consider phosphorus (P) as well. The objective is to encourage producers to actively use their nutrient management plans as a part of their overall farm management. To better prepare producers for this change, a spreadsheet based education tool was developed in Excel to demonstrate whole farm concepts related to nutrient balance with a focus on P. The goals in developing the tool were: 1) to use a simple interface viewed on a single page (worksheet), 2) to use input information readily available on most dairy farms, and 3) to use terminology and calculations consistent with a program developed by NRCS that is used in writing nutrient management plans for Washington dairy farms. The inputs required to determine a farm balance are herd milk production, number of milking cows, dry cows, and heifers, DMI of lactating cows, P content of lactating cow rations, fertilizer import, land in forage crops, yield and P content of forage crops, and estimated availability of P in manure. Output of the analysis includes the manure P available to crops and the whole farm balance of P. This educational tool is used to demonstrate the effects of management changes such as reduction in diet P, level of milk production, custom raising of heifers, forage yield and type, and the use of winter cover crops.

Key Words: Nutrient Management, Environment, Phosphorus

Forages and Pastures: Forages in Dairy Production

389 Grazing behavior of late lactating dairy cows under continuous stocking. H. Z. H. Taweel*, B. M. Tas, J. Dijkstra, and S. Tamminga, *Department of Animal Sciences, Animal Nutrition Group, Wageningen University, Wageningen, The Netherlands.*

This experiment aimed at studying the behavioral strategies grazing dairy cows employ to satisfy their nutritional needs as the day progresses. For this purpose the day was divided into three main periods (6:00 to 12:00 h, 12:00 to 18:00 h and 18:00 to 24:00 h) where the three main grazing bouts (dawn, afternoon and dusk) of dairy cows usually occur. Four late lactating rumen-cannulated dairy cows were used in a repeated measures design, with the grazing bout as the within subjects factor. The cows had access to a 1-ha grass sward under a continuous stocking system, which assured ad libitum herbage allowance. To estimate dry matter intake (DMI), bite rate, bite mass (BM) and intake rate at the three bouts, cows were rumen-evacuated at 6:00, 12:00, 18:00 and 24:00 h and jaw recorders were fitted to the cows between these time points. Time spent eating by dairy cows at the dusk grazing bout was much longer ($P < 0.05$) than that at the other two grazing bouts and made about 40 % of the daily total eating time. Total grazing jaw movements (TGJM) rate was constant during the day at around 75/min. Bite rate increased ($P < 0.05$) from 54 to 61/min, but chewing rate decreased ($P < 0.05$) from 20 to 16/min as the day progressed. BM (mg DM/bite) increased ($P < 0.05$) from 400 to 563 as the day progressed, but that was not due to increased bite dimensions, rather it was due to increased DM content of the grass at dusk time, which increased from 19 to 25%. Consequently, both intake rate and DMI increased ($P < 0.05$) from 22 to 34 (g DM/min) and from 3 to 7 (kg/bout) during the dawn and dusk grazing bouts, respectively. Therefore, it could be concluded that the main behavioral strategies dairy cows employ to satisfy their nutritional needs under continuous stocking include manipulating

388 The feeding of dietary phosphorus on dairy farms in the Lake Champlain Basin. K. W. Cotanch*¹, C. S. Ballard¹, W. C. Emerich¹, C. J. Sniffen², and E. D. Thomas¹, ¹W.H. Miner Agricultural Research Institute, Chazy, NY, ²Fencrest LLC, Holderness, NH.

Nutrient balance on dairy farms is critical in efforts to maintain and improve water quality in the Lake Champlain Basin. Reducing dietary phosphorus (P) levels to dairy cattle will reduce phosphorus loading of cropland from manure application. A survey of feed consultants operating in Vermont showed recommended P levels for cows producing 30 kg/d varied: 0.48 to 0.55% from five feed company consultants; 0.44% from an independent consultant; and 0.37% from the University of Vermont nutritionist. At current feeding rates, P is being fed in excess of requirements (0.32 to 0.38%). The objective of the study was to obtain baseline information about current P feeding practices on farms; farmers understanding of the nutritional requirements for P; and their attitudes about the economic and environmental importance of P reduction on dairy farms in the region. Thirty farms located in the Champlain Basin were randomly selected with weight given to farm size and facility design. Farms varied in size (100-1000 cows), facility structures and management styles from both New York and Vermont (15 per state). A 10 question survey indicated that farmers were agreeable to reducing dietary phosphorus levels, but not fully aware of the new NRC 2001 P recommendations. Only 50% of the producers claimed to know the level of P they were currently feeding. Nutritionists dietary P formulations were compared with wet chemistry analyses of diets. Only 21% of diets formulated for lactating cows were balanced for <0.40% P with ranges from 0.36-0.50%. Analyzed TMRs found that 38% of rations were <0.40% P, ranging from 0.28-0.57%. The wide variation between P levels balanced for and that actually being fed may be attributed to imprecise measurements of P in forages on the farm and feeds sold to the farm. Grain components used to manufacture feeds vary greatly in P levels and may not be accurately accounted for in ration formulation. Farm size was a critical factor in the frequency of forage testing and overall nutrient management. Larger farms had forages analyzed more than twice as often as smaller farms and were more positive to the economic savings of reducing dietary P levels.

Key Words: Phosphorus, Nutrient Management, Dairy Cattle

their eating time, biting rate and chewing rate, with little control over TGJM rate and BM.

Key Words: Grazing Behavior, Intake Rate, Bite Mass

390 Modeling pasture-based split-calving dairy systems using a whole farm model. P. C. Beukes*¹, B. S. Thorrold¹, M. E. Wastney¹, C. C. Palliser¹, J. A. S. Lancaster¹, C. F. Folkers¹, G. L. Levy¹, M. Neal^{2,1}, and M. J. Auld³, ¹Dexcel Ltd., Hamilton, New Zealand, ²University of Sydney, Sydney, Australia, ³Department of Primary Industries, Ellinbank, Australia.

Traditional New Zealand dairy systems are based on spring calving with drying off in autumn to match cow demand with pasture growth. Split-calving involves a proportion of the herd calving out-of-season (e.g. in autumn) with the aims of coping better with dry summers, reducing wastage in cows which fail to get in calf on a 12-month cycle and to benefit from a winter milk premium. A farm systems modeling approach was used to investigate feed flow and economic impacts of split calving. The first step was to calibrate the predicted lactation curves of a computer model (the Whole Farm Model; WFM) against observed data from a trial where different herds were calved in winter, spring, summer and autumn over a three-year period. Introducing a photoperiod effect on lactation hormone levels into the cow component of the model (known as "Molly"), significantly ($P < 0.01$) reduced the average prediction error for milk yields (before adjustment = 4.52, SD 1.598 kg; after adjustment = 2.77, SD 0.749 kg). The WFM was then used to compare milk fat and protein (milksolids; MS) production, silage conservation and feeding and economics (in NZ\$) between a spring-calving (July) system and a 50:50 spring-autumn (May) split-calving system over five different climate years (1998-2002). At a similar stocking rate the split-calving herd produced 9.4 kg MS/cow and 28.8 kg MS/ha more ($P < 0.001$) than the spring-calving herd, but with no significant difference in silage

costs (\$146/ha, SD \$43 vs \$144/ha, SD \$35). The winter milk premium of \$180/ha (@ \$0.8/kg MS) for the split-calving herd contributed to a significantly ($P < 0.001$) higher economic farm surplus (\$2602/ha, SD \$253) compared to the spring-calving herd (\$2370/ha, SD \$236).

Key Words: Model, Farm Systems, Economics

391 Effects of feeding legume silage with differing tannin levels on lactating dairy cattle. U. C. Hymes-Fecht*, G. A. Broderick, R. E. Muck, and J. D. Graber, *U.S Dairy Forage Research Center, Madison, WI.*

Silages made from Birdsfoot trefoil (BFT) containing three different levels of condensed tannins (CT) were compared to alfalfa (ALF) and red clover (RC) silages as forage sources. Twenty-five lactating Holstein cows (5 fitted with ruminal cannulae) were randomly assigned to incomplete 5X5 Latin squares to assess the effects on milk production and N utilization. Diets contained (DM basis) 50% of ALF, RC or one the 3 BFT that contained low (LTBFT), normal (NTBFT) or high (HTBFT) concentrations of CT. There were differences in CP among silages: ALF and LTBFT were highest, NTBFT and HTBFT intermediate, and RC lowest. The levels of NDF were higher in RC and ALF than in the BFT silages. There were no differences in DM intake or in milk composition due to silage source. However, yield of milk and FCM was higher on NTBFT and HTBFT than LTBFT, which was higher than that on ALF and RC. Fat yield was 0.19 kg/d higher on NTBFT than on ALF, with the other 3 diets being intermediate. Protein yield on all 3 BFT diets, regardless of CT level, was higher than on ALF and RC, despite the fact that the BFT diets contained about 1% less CP. MUN was lower on NTBFT and HTBFT than on LTBFT, ALF and RC. Differences in milk yield may have been confounded by the BFT diets being lower in fiber (27% NDF) than the ALF and RC diets (29% NDF). However, these results suggest CT concentration was directly related to improved utilization of CP in BFT silages.

Item	ALF	RC	LTBFT	NTBFT	HTBFT	SE	P value

392 Protective coatings for the edible covering of bunker silos. L. L. Berger* and J. R. Sewell, *University of Illinois, Urbana.*

The objective of this research was to develop a protective coating for the edible starch/salt matrix (SSM) covering for silage. Since the SSM is semi permeable to moisture, an external coating is needed to prevent erosion. A control (6-mil polyethylene plastic covering) was evaluated against three test coatings, sprayable paraffin wax emulsion (SW), molten paraffin wax (MW) and a wax paper (WP; Georgia-Pacific Paper Company, Clatskanie, OR). Eight 2.14 X 7.32 m bunker silos with a packed limestone base and plywood walls were used. Approximately 9695 kg of chopped whole corn plant (39.1% DM) was packed into each silo. The silos were sealed on September 11, 2003 and opened after 117 d of ensiling. Upon opening, the SSM was removed from the surface of the silage and was fed at 2.5% of a corn-corn silage diet for growing steers without refusal. Samples of ensiled forage were collected from depths of 0-15.24, 15.25-30.48 and 30.48-45.72 cm and analyzed for percent sodium content. As seen in previous trials the sodium levels help preserve the silage immediately under the covering. Data were analyzed with proc GLM model in SAS. The percent sodium for the three depths under the control treatment yielded values of 0.02, 0.01, and 0.01%. The sodium values for the SSM with SW, MW, and WP covering were 1.18, 0.80, and 0.44%; 2.18, 1.36, and 0.46%; 0.77, 0.51, and 0.29% at each depth, respectively. The concentration of sodium for the SW, MW, and

WP were significantly different than the control ($P < .05$). The salt aids in the preservation of the silage under the covering, but external coating over the SSM improves preservation. The DM fed for the control, SW, MW and WP treatments were 2497, 1990, 2664, and 2497 kg/silo, respectively. Less DM was fed from control silos than from MW silos ($P < .05$). Less DM was fed from the SW than WP silos ($P < .05$).

Key Words: Corn Silage, Edible Covering, Salt/Starch Matrix

393 Effect of corn cutting height on digestibility and nutrient composition of silage-only and dual-purpose corn hybrids. K. W. Cotanch*¹, E. D. Thomas¹, H. M. Wolford¹, C. S. Ballard¹, R. J. Grant¹, P. Mandevu¹, M. Suekawa², T. Sato², and Y. Yabuuchi², ¹W.H. Miner Agricultural Research Institute, Chazy, NY, ²Zen-Noh National Federation of Agricultural Co-operative Associations, Tokyo, Japan.

Previous research has found that when cutting height was increased from 15 to 45 cm, milk yield per tonne increased by 9.8% and milk yield per hectare increased by 3.3% (MILK2000 spreadsheet). The objective of this study was to evaluate the effect of corn cutting height on forage quality parameters of silage-only and dual purpose hybrids. Two 95-d relative maturity corn hybrids were selected and planted in a replicated 4-row strip trial: Pioneer 38T27, a dual-purpose hybrid and Mycogen TMF 2450, a silage-only hybrid containing the leafy and Bt genes. Within five field plots, ten plants per plot were selected randomly and harvested 15 cm above the ground. Within plots, each plant had two 15-cm sections of the stalk cut and pooled by stalk section. Samples were chopped to a particle length of 6 to 8 cm and dried at 60°C. Nutrient composition and digestibility were determined and MILK2000 was used to estimate milk yield. Corn silage harvested at 30 and 45 cm had significantly higher milk production potential at the expense of milk production per hectare. The silage-only hybrid gained the most potential milk yield from increasing cutting height from 15 to 45 cm (1777, 1841 kg/tonne) compared with the dual-purpose hybrid (1812, 1851 kg/tonne).

394 Effect of harvest date and brown midrib gene on in situ disappearance of sorghum x Sudangrass hybrids. P. A. Beck*¹, J. M. Phillips¹, S. Hutchison², T. Losi³, C. B. Stewart¹, P. K. Capps¹, and S. A. Gunter¹, ¹Southwest Research & Extension Center, University of Arkansas, Center Hope, ²Dept. of Animal Science, University of Arkansas, Fayetteville, ³Universidade Estadual Paulista Faculdade de Medicina Veterinaria e Zootecnia, Botucatu, SP, Brazil.

Three sorghum x sudangrass hybrids were planted in 12 - 0.2 ha plots to test the effect of date of harvest and the presence of the Brown Midrib (BMR) gene on in situ DM and fiber disappearance. Sweet Sunny Sue, a non-BMR hybrid, and the BMR hybrids Nutri + Plus BMR and MS505DS were planted at 22.4 kg/ha using a no-till drill. Plants in ten 0.5 m² quadrants per plot were hand-clipped to 2.5 cm height at weekly intervals beginning 34 d after planting. Samples were dried at 50° C, ground to pass a 2 mm screen, and samples from d 34, 48 and 63 were composited within plot for determination of N, NDF, ADF, and in situ disappearance of DM, NDF, and ADF. The in situ disappearance study was conducted using three ruminally cannulated steers (BW = 584 kg ± 10.4) in a 3 x 3 Latin-square design. Samples from each harvest date were incubated for 6, 12, 24, 36, 48, 72, 96, and 120 h in a single steer during each period of the Latin square. Disappearance

kinetics were analyzed using PROC NLIN in SAS the resulting data was analyzed as a Latin-square design using PROC MIXED in SAS. Forage quality was analyzed as a completely random design using PROC GLM in SAS. The BMR varieties were lower ($P < 0.01$) in ADF and NDF at all harvest dates, while N concentrations were not affected ($P > 0.41$) by variety. The A fraction of DM and NDF was higher ($P < 0.01$) and the C fraction of DM, NDF, and ADF was lower ($P < 0.01$) for BMR than non-BMR. The B fraction of DM was not affected ($P = 0.15$) by variety, while the B fraction of ADF was higher ($P < 0.01$) in BMR than non-BMR. The B fraction of NDF was not different ($P = 0.28$) on d 34, but was higher ($P < 0.01$) on d 48 and 63 for BMR than non-BMR. The A fraction of DM and ADF was higher ($P < 0.01$) and B fraction of ADF was lower ($P < 0.01$) for MS505 DS compared to Nutri + Plus BMR. Rates of DM and NDF disappearance were higher for BMR than non-BMR for all harvest dates ($P < 0.01$). Disappearance of ADF was faster ($P < 0.01$) with BMR than non-BMR on d 48 and 63. Effective degradability of DM, NDF, and ADF was higher ($P < 0.02$) for BMR than non-BMR at all harvest dates.

Key Words: Sorghum x Sudangrass Hybrids, Forage, In Situ Disappearance

395 Effect of genotype and maturity on ensiling characteristics and chemical composition of millet forage. F. Hassanat*, A. Mustafa, and P. Seguin, *McGill University, Ste-Anne-de-Bellevue, QC, Canada.*

A study was conducted to determine the effects of genotype and stage of maturity at harvest on ensiling characteristics, microbial population, and chemical composition of forage millet. Regular (RM) and brown midrib (BM) millet were harvested at vegetative (VS) or heading stage (HS), then ensiled in mini-silos for 0, 2, 4, 8, 16, and 45d in triplicates. Both millet types were well ensiled and had a pH less than 4.2 after 45d of ensiling. Both RM and BM millet harvested at HS had more ($P < 0.05$) water soluble carbohydrates (16.08 and 17.82%) than when harvested at VS (11.13 and 12.25% respectively). This was reflected in lower pH in BM silage harvested at HS compared with those harvested at VS ($P < 0.05$) at any day of ensiling. Most proteolysis occurred between 0d and 8d of ensiling, where 40-50% of true protein (TP) was lost to non-protein nitrogen (NPN) for the two millet types at any stage of maturity. Changes in the microbial population during ensiling were similar for the four treatments. There was an increase in the lactic acid bacteria population in the first 2d of ensiling. Enterobacteria population decreased as ensiling progressed and were not detected after d 8 of ensiling. Yeast and mold populations followed the same trend, but stayed at detectable level up to d45 post-ensiling. Silage made from millet harvested at VS had more yeast at d45 (2.9 log cfu/g) than that harvested at HS (< 2.0 log cfu/g). Silage (45d) made from BM contained less NDF, (55.0 vs 59.2%), ADF (29.1 vs. 31.3%), ADL (1.1 vs. 1.6%) and more CP (8.5% vs. 7.2%) than silage made from RM ($P < 0.05$). For the two millet genotypes, silages harvested at HS contained more ADF and ADL and less CP than silages harvested at VS ($P < 0.05$). It was concluded that silages produced from RM and BM millet at VS and HS of maturity were well preserved as indicated by low pH. Genotype and stage of maturity had significant effects on the chemical composition of forage millet silage. It is concluded that brown midrib millet provides better quality forage than regular millet.

Key Words: Forage Millet, Brown Midrib, Chemical Composition

396 Effect of inoculation on ensiling characteristics and chemical composition of regular and brown midrib millet. F. Hassanat*, A. Mustafa, and P. Seguin, *McGill University, Ste-Anne-de-Bellevue, QC, Canada.*

A study was conducted to determine the effects of inoculation and genotype on ensiling characteristics and chemical composition of two millet types in a 2x2 factorial design. Regular (RM) and brown midrib (BM) millet were treated with commercial inoculum (PIONEER[®] 1129) or left untreated. Forages were ensiled in mini silos for d 0, 2, 4, 8, 16, and 45 in triplicates. For the two millet types, pH at d 2, 4 and 8 was lower ($P < 0.05$) for inoculated than untreated ensiled forages. Lactic acid concentration was higher ($P < 0.05$) in inoculated silage compared to the untreated one at any day of ensiling. At d 45, inoculated BM millet silage had a lower ($P < 0.05$) pH (3.5) than untreated BM (3.7). However, pH of RM silage at 45d was not affected by inoculation. Level of non protein nitrogen at each ensiling time was similar for inoculated and untreated ensiled forage, suggesting minimal effect of inoculation on proteolysis. Inoculation had no effect on the chemical composition of the d 45 silage made from any millet type, except in RM TP% level which was higher ($P < 0.05$) in inoculated (42.42%) than the untreated silage (39.70%). Levels of NPN% and TP% were similar between inoculated treated and untreated BM silage. The RM silage contained lower NPN (54.5 vs. 57.3% CP) and higher true protein (41.1 vs. 38.4 %CP), acid detergent fiber (30.8 vs. 27.8%), and acid detergent lignin (2.1 vs. 1.0%) than BM silage ($P < 0.05$). Both silages had similar CP%. We concluded that inoculation produced a rapid decline in pH and an increase in lactic acid of ensiled forage millet. The d 45 silages were not affected by inoculation, and were all well preserved. Inoculation had minimal effect on chemical composition RM and BM silages.

Key Words: Millet, Brown Midrib, Inoculation

397 Lignin concentration of whole plants and stems of Bt corn hybrids. H. G. Jung*^{1,2} and C. C. Sheaffer², ¹USDA - Agricultural Research Service, ²University of Minnesota, St. Paul.

There have been inconsistent reports regarding whether corn (*Zea mays*) hybrids with the *Bacillus thuringiensis* (Bt) *cry1 Ab* transgene contain more lignin than non-Bt hybrids of similar genetic background. Our objective was to evaluate the potential impact of the *cry1 Ab* transgene on lignin concentration (using three different assays), yield, and forage quality traits of corn silage. Replicated trials were conducted at four locations in Minnesota with 12 commercial hybrids (three MON810 and three Bt11 *cry1 Ab* transgene event hybrids, and respective near-isogenic controls). Whole plants and the fourth elongated, above-ground internodes were harvested at silage maturity. Samples were analyzed for crude protein, starch, neutral detergent fiber (NDF), acid detergent fiber, 24- and 96-h in vitro ruminal NDF digestibility, and lignin (acid detergent, Klason, and acetyl bromide). European corn borers (*Ostrinia nubilalis*) were not controlled and plant damage from this source was limited to the non-Bt hybrids, averaging 1.5 internodes per plant with tunnels. Growth environment impacted all measures of corn hybrid performance and quality, as evidenced by significant location effects. Comparisons of non-Bt/Bt hybrid pairs, for both whole plants and internodes, found no consistent differences in yield, nutrient content, in vitro ruminal NDF digestibility, or lignin concentration. Differences in lignin concentration (for all three analysis methods) were infrequent, small in magnitude, and limited to a few non-Bt/Bt hybrid pairs at individual locations. Bt hybrids were both higher and lower in lignin concentration than their non-Bt counterparts. Two non-Bt/Bt hybrid pairs did not differ in lignin concentration at any location. Contrary to some earlier reports, presence of the *cry1 Ab* transgene did not alter lignin concentration or other forage quality traits of corn stover in commercial maize hybrids.

ASAS Growth and Development I

398 Muscle fiber characteristics are important in the relationship between birth weight and carcass quality in pigs. C. Rehfeldt*, G. Kuhn, I. Fiedler, and K. Ender, *Dept Muscle Biology and Growth, Research Institute for the Biology of Farm Animals, Dummerstorf, Germany.*

It is commonly recognized that low birth weight in piglets correlates with decreased survival and lower postnatal growth rates. The aim of this

study was to investigate the relationships between birth weight, carcass quality and skeletal muscle fiber characteristics. At birth, three piglets (lightest, but > 800 g; middle-weight; heaviest) were selected from each of 16 litters. The lightest piglets exhibited the smallest percentages of

meat, total protein, total fat, the lowest *Semitendinosus* muscle (ST) weight and total fiber number, whereas the percentages of internal organs, skin, bone, and total water were highest. The remaining piglets were grown up at *ad libitum* feeding. Differences in daily gains paralleled the differences in birth weights ($P=0.07$). At day 182 of age 58 pigs were randomly selected for slaughter. They were assigned to one of three birth weight classes (25% low; 50% middle; 25% heavy). The pigs of low birth weight had lower live weights ($P<0.05$), smaller meat percentages ($P=0.09$) and loin areas ($P=0.08$) compared to pigs of high birth weight, whereas the percentage of internal adipose tissue tended to be higher ($P=0.11$). In addition, pigs of low birth weight exhibited lower relative heart weights ($P=0.02$) and a higher drip loss ($P=0.08$) in *Longissimus* muscle (LD). The pigs of low birth weight exhibited the lowest muscle fiber numbers, the largest fiber size, the highest myonuclear number per fiber, and the highest percentages of abnormal giant fibers in ST and LD muscles ($P<0.05$). The results suggest that the deficiency in muscle fibers by genetic or maternal reasons in low birth weight piglets cannot be equalized by accelerated fibre hypertrophy and that in these pigs extremely large fibers may be one of the reasons for poor carcass quality at slaughter.

Key Words: Growth, Body Composition, Intrauterine Growth Retardation

399 Nutrition of Wagyu- and Piedmontese-sired fetuses alters newborn *longissimus* muscle cellular characteristics. P. L. Greenwood^{1,2}, H. Hearnshaw^{1,4}, G. Kelly^{1,3}, and D. W. Hennessy^{1,4}, ¹CRC for Cattle and Beef Quality, Armidale, NSW, Australia, ²NSW Agriculture, Armidale, NSW, Australia, ³University of New England, Armidale, NSW, Australia, ⁴NSW Agriculture, Grafton, NSW, Australia.

Longissimus lumborum muscle was studied in low and high birth weight Wagyu- (mean \pm SEM birth weights 27.3 ± 1.1 kg, $n=8$ [WL] vs 33.4 ± 1.4 kg, $n=8$ [WH]) and Piedmontese-sired (27.4 ± 1.9 , $n=7$ [PL] vs 40.2 ± 1.5 kg, $n=8$ [PH]) female calves following low or high nutrition of their Hereford dams during pregnancy. Muscle weight was greater ($P<0.05$) in Piedmontese-sired and high birth weight newborns (WL, WH, PL, PH means; pooled SE: 84, 101, 91, 150; 7g, respectively). Number of satellite cells relative to myofibre-related nuclei (6.7, 8.8, 8.3, 9.1; 0.8%) and myofibres (29.9, 36.8, 35.6, 41.8; 3.6 per 1,000 myofibres) tended ($P<0.10$) to be greater in high birth weight calves. Mass of muscle DNA (53.9, 52.5, 63.5, 78.8; 4.1 mg), RNA (229, 259, 267, 390; 26 mg) and protein (13.0, 16.1, 14.0, 23.7; 1.4 g) were greater in Piedmontese-sired calves, and mass of protein was greater in high birth weight calves who also tended to have more RNA. Apparent number of myofibres (29.8, 29.8, 32.2, 30.4; 2.5×10^5 myofibres) did not differ ($P>0.10$) due to genotype or prenatal nutrition. Percentage of type 1 myofibres was higher in Wagyu-sired and high birth weight calves (19.5, 25.0, 14.9, 21.6; 1.6%), and percentage type 2A myofibres (28.5, 23.1, 27.8, 23.9; 2.1%) and the ratio of fast to slow myofibres (4.4, 3.0, 6.9, 3.9; 0.8) increased with lower prenatal nutrition and tended to be greater in Piedmontese-sired calves. Cross-sectional area of type 2B myofibres was reduced by low birth weight (666, 751, 679, 910; $74 \mu\text{m}^2$) which also tended to influence average cross-sectional area of myofibres (507, 573, 505, 668; $56 \mu\text{m}^2$). The results demonstrate that maternal nutrition and low birth weight can impact on size, contractile and metabolic properties of myofibres in newborn cattle and may affect relative numbers of myosatellite cells. It remains to be established whether nutritionally altered cellular characteristics in muscle of newborn heifers with high muscle growth (Piedmontese-sired) or high marbling (Wagyu-sired) potentially have long-term consequences for growth, body composition and eating quality.

400 High energetic costs of stereotyped behaviour in preruminant calves. J. J. G. C. van den Borne*, S. J. F. M. van der Heijden, H. Oorsprong, E. A. M. Bokkers, J. E. Bolhuis, and W. J. J. Gerrits, *Animal Sciences Group, Wageningen University and Research Centre, Wageningen, The Netherlands.*

High energetic costs for standing versus lying ($130 \text{ kJ/kg}^{0.75}/\text{d}$) in preruminant calves were mentioned in several experiments. Behaviour, and particularly stereotyped behaviour, can be an important reason for these high estimations. It was hypothesized that calves spend a considerable part of their time on stereotyped behaviour and that energetic costs of

stereotyped behaviour are high. In this study (originally not designed to study behaviour) energy expenditure related to stereotyped behaviour was quantified in individually housed preruminant calves. Eighteen preruminant calves (on average 120 kg BW) were used, in two experimental periods of 9 days each. Heat production was measured by indirect calorimetry in 6-min intervals. Physical activity was recorded by a radar-Doppler device and posture was recorded by infrared beam interruption. Energy expenditure related to activity was estimated. Behavioural observations were made of each calf for two days per period, 13 hours per day, using 6-min scan-sampling. Five and 47% of the time spent standing and lying, respectively, was spent idling. Main activities during standing were manipulating bucket (37%) and (other) objects (24%), and tongue playing (10%). Main activities during lying were tongue playing (15%) and self-licking (8%). The sum of these repetitive activities, except self-licking, was considered total stereotyped behaviour. Stereotyped behaviour during standing increased energy expenditure almost threefold ($+74 \text{ kJ/kg}^{0.75}/\text{d}$) compared to standing idle ($39 \text{ kJ/kg}^{0.75}/\text{d}$), while tongue playing during lying was energetically more expensive ($+25 \text{ kJ/kg}^{0.75}/\text{d}$) than lying idle ($1 \text{ kJ/kg}^{0.75}/\text{d}$). It can be concluded, that energetic costs for stereotyped behaviour are considerable, and account for up to 8 (lying) and up to 15% (standing) of the energy expenditure for maintenance. As stereotyped behaviour is more frequently shown in standing as opposed to lying calves, this affects estimation of posture-related energy expenditure.

Key Words: Calves, Behaviour, Energy Expenditure

401 Relationships between serum constituents at weaning and subsequent carcass characteristics of beef calves. J. May¹, M. Looper², C. Golden¹, M. Nihsen¹, K. May³, and C. Rosenkrans Jr.*¹, ¹Department of Animal Science, University of Arkansas, Fayetteville, ²USDA-ARS, Dale Bumpers Small Farms Research Center, Booneville, AR, ³Caldwell Farms, Rosebud, AR.

Fall born Brangus-crossbred calves ($n = 112$; BW = 224 ± 12 kg) were used to determine the relationship between serum constituents at weaning and carcass characteristics. At weaning, calves were weighed, blood samples collected, and bull calves castrated two days later. After the stocker phase (145 d), calves were weighed and then finished in a commercial feedlot. Serum samples were analyzed for lactate dehydrogenase (LDH) activities, hemoglobin, protein, creatinine, prolactin, triiodothyronine (T_3), thyroxine, cortisol, testosterone, and insulin-like growth factor-I (IGF-I). After harvest, *longissimus* muscle and ribfat thickness were measured. In addition, USDA quality and yield grades were assigned to each carcass. A retrospective ANOVA was conducted with quality grade, yield grade, and calf gender in the model as independent variables and serum constituents as dependent variables. At harvest, 65% of the carcasses were assigned USDA Choice grade. Carcass distributions among USDA yield grade were 22, 48, and 29%, respectively for yield grade 1, 2, and 3. Heifers had higher ($P < 0.05$) concentrations of cortisol and T_3 than bulls at weaning (32 vs 20 ng/mL cortisol; 4.0 vs 3.5 ng/mL T_3), and less ($P < 0.001$) testosterone (0.5 vs 3.2 ng/mL). Serum LDH activity, when corrected for hemoglobin concentration, was lower ($P < 0.05$) in calves that ultimately graded USDA Choice when compared with animals that resulted in USDA Select carcasses. Serum concentrations of IGF-I and cortisol at weaning were associated with an interaction ($P < 0.1$) of quality grade and yield grade. Yield grade was associated ($P < 0.1$) with weaning LDH activity, and testosterone concentrations. These data support previous studies indicating that serum LDH activity could be used as an early indicator of a calf's probability to grade USDA Choice or better.

Key Words: Cattle, Lactate Dehydrogenase

402 Physiological indicators of growth are influenced by supplementation and steroid implantation in steers. M. L. Looper*¹, C. F. Rosenkrans, Jr.², R. Flores², G. E. Aiken³, and S. E. Duke⁴, ¹USDA-ARS, Dale Bumpers Small Farms Research Center, Booneville, AR, ²University of Arkansas, Fayetteville, ³USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY, ⁴USDA-SPA, College Station, TX.

Forty-five crossbred steers (BW = 246 ± 5.4 kg) were utilized to determine the effects of timing of steroid implantation and supplementation on average daily gain, prolactin, triiodothyronine (T_3), thyroxine (T_4), cortisol, and insulin-like growth factor-I (IGF-I). All steers grazed bermudagrass paddocks (1 steer/0.8 ha). Each steer received either no

supplementation (n = 30) or 1.4 kg/d per steer of a corn-soybean meal supplement (n = 15; 12% crude protein). Within supplementation strategy, steers were assigned to either no implant, one implant at d 0 and one implant at d 56 (EI), or one implant at d 56 (LI). Steers were weighed at the initiation and termination of experiment to determine average daily gain (ADG). Blood samples were collected on d 0, 62, and 108, and blood metabolites were quantified. Supplemented steers had greater (P < 0.0001) ADG than non-supplemented steers (0.93 ± 0.05 vs 0.57 ± 0.04 kg/d, respectively). Implanted steers (EI and LI) tended to have increased (P = 0.13) ADG compared with non-implanted steers. Concentrations of prolactin and T₄ were decreased (implant x time; P < 0.05) in control and LI (one steroid implant) steers but not EI (two steroid implants) steers at 108 d compared to d-62 concentrations. Cortisol was influenced by a supplement x implant interaction (P < 0.05). Supplemented EI steers had increased cortisol compared to supplemented LI steers (58.8 ± 10.0 vs 35.3 ± 9.2 ng/mL for EI and LI steers, respectively). However, non-supplemented LI steers had increased concentrations of cortisol compared with non-supplemented EI steers (56.8 ± 6.6 vs 42.2 ± 6.4 ng/mL for LI and EI steers, respectively). Supplemented steers, independent of timing of implantation, had increased (P < 0.001) concentrations of IGF-I compared with non-supplemented steers (211.5 ± 19.9 vs 122.7 ± 11.8 ng/mL, respectively). Concentrations of T₄ at d-0 were positively correlated (P < 0.05; r = 0.33) with ADG of steers. Management strategies may alter animal physiology, and those strategies should be considered when using physiological markers for the prediction or selection of animal growth.

403 A mechanistic nutrition model to evaluate beef cow efficiency. L. O. Tedeschi¹*, D. G. Fox¹, M. J. Baker¹, and K. L. Long², ¹Cornell University, Ithaca, NY, ²Bell Ranch, Solano, NM.

The beef cattle seedstock industry is searching for ways to select for improved beef cow efficiency. Most selection indexes for efficiency have a

Nonruminant Nutrition: Minerals

404 Mineral and chromium supplementation to diets of finishing pigs. B. V. Lawrence*, D. Overend, S. A. Hansen, J. D. Hahn, and J. Hedges, Hubbard Feeds Inc., Mankato, MN.

A total of 765 terminal Duroc cross barrows and gilts (Compart Boar Store Line 442 X D100; 29.8 ± 1.2 kg) were used to compare three treatments: corn-soybean meal control (CTRL), CTRL diet for 63 d with Yield Pak (a blend of vitamins and trace minerals) added from 63 to 91 d (CTRL/YPC), or CTRL/YPC diet supplemented with 200 ppb Cr from chromium propionate from d 0 to 63 (Cr/YPC). Pigs (12 pens/treatment) were weighed on d 0, 63 and 91. Growth performance was similar across treatments (P > 0.10) from d 0 - 63. Day 63 to 91 gain (P < 0.05) and gain:feed (P < 0.01) were lower for the CTRL pigs. At 111.6 ± 7.3 kg, 36 gilts per treatment were tagged, tattooed, and weighed. After 8 h transit to a commercial abattoir, hot carcass weights (HCW) were obtained (84.3 ± 1.8 kg). The HCW and yield [(HCW/liveweight)*100] were different (P < 0.01) between treatments. Fat or muscle depth, lean percentage, and ham and loin pH measured at 1 and 22 h post-mortem were not different (P > 0.10) across treatments. At 22 h, a 40 - 50 g loin core was taken between the 7th and 8th ribs and held for 7 d for drip loss determination. Although there was no difference in 22-h pH or rate of 22-h pH decline, the Cr/YPC pigs had a higher (P < 0.10) drip loss than other treatments (4.78 vs. 3.43%). The NPPC measures of loin color, and firmness, as well as ColorTec L*, A*, and B* values were not different (P > 0.10) across treatments. Loin marbling was higher (P < 0.05) for the CTRL/YPC pigs than for the CTRL or Cr/YPC pigs (2.80 vs. 2.46). Forty gilts per treatment (live weight of 115.6 ± 6.1 kg) fed the CTRL or CTRL/YPC diet at the commercial finisher were processed as described previously. There was a trend (P < 0.10) for the CTRL/YPC pigs to have a higher yield (75.5 vs. 74.9%). The higher yield corresponded with a trend (P < 0.10) toward a reduction in loin drip loss (4.03 vs. 5.30%) and a numerical (P < 0.20) reduction in rate of 22-h ham pH decline (0.55 vs. 0.67 units). These results indicate that addition of YPC in late finishing may improve some meat quality characteristics of fresh pork.

Key Words: Minerals, Pigs, Meat Quality

goal of using less resource while obtaining the same outcome in a sustainable environment. However, the inputs required to determine individual beef cow feed efficiency are not readily available in practical conditions. A mathematical model was developed to use inputs readily available in each production situation to estimate the ratio of cow ME required to calf-weaning weight (WW) for computing an energy efficiency index (EEI). This model ranks EEI estimates and compares individual cow EEI with the range of expected EEI using Monte Carlo (MC) methods to identify the upper and lower cutoff values. It uses the 2000 Beef NRC recommendations as implemented in the Cornell Net Carbohydrate and Protein System for energy requirements for maintenance, lactation, and pregnancy. Data containing varying levels of milk and forage intake of individual calves during the first 200 d after birth was used to develop a submodel to estimate calf forage and peak milk intake (PKM) based on calf BW and forage composition. A database collected from the Bell Ranch, NM (N = 182) was used to evaluate the ranking from most to least efficient cows. The simulation indicated that as peak milk (PKM) increases, WW increases almost linearly, the difference in the calf WW between small and large cows tended to increase, and EEI estimates improve exponentially. As PKM increased, the EEI difference between small- and large-size cows decreased. The model-predicted least efficient cows were in agreement with culling decisions made prior to evaluating the EEI ranking. The MC simulation based on the distribution, mean, and variability of cow BW, PKM, and forage quality indicated that cows having EEI lower than 30.6 or higher than 38 Mcal/kg are within the 10% more and less efficient cows, respectively. Our analysis suggested this model could assist beef producers in identifying the most and least efficient cows for their resource, and can be used to simulate different production scenarios to identify the best match of cow type to alternative management systems.

405 Performance effects of potassium and chloride levels in swine finisher diets. B. V. Lawrence*, J. D. Hahn, and S. A. Hansen, Hubbard Feeds Inc., Mankato, MN.

Two trials with terminal cross Duroc sired pigs were conducted to evaluate the effect of K or Cl levels in corn-soya-synthetic amino acid diets on growth and carcass parameters. In Exp 1, 512 pigs (38.7 ± 1.1 kg) were assigned to either a Control diet (0.22% Na, 0.41% Cl, and 0.73% K), or the Control diet supplemented with 0.10% (Low), 0.20% (Med), or 0.30% (High) K supplied as KCl. Constant Na and Cl levels were maintained by altering the level of dietary NaCl and NaPO₄. Pens (n = 6) were weighed on d-0, 21, 42, 63, and 85. In Exp 2, 512 pigs (32.9 ± 0.8 kg) were fed one of four diets. The Control diet was similar to that in Exp 1. The remaining 3 treatments were formulated to 0.94% K and 0.22% Na and either 0.60% (High Cl), 0.47% (Med Cl) or 0.33% (Low Cl) chloride. The Cl levels were achieved by altering inclusion level of NaPO₄ and NaCl. Pens (n = 6) were weighed on d-0, 21, 42, 63, 85 and 96. At the end of both experiments, real-time ultrasound (RTU) measurements of tenth rib loineye area (LEA) and backfat (TRF) as well as last rib fat (LRF) were obtained on 40 barrows and 40 gilts per treatment. Yield, fat depth, loin depth, and lean percentage were obtained on 40 barrows and 40 gilts per treatment at a commercial abattoir. Data was analyzed using the GLM procedures of SAS with pen the experimental unit for gain, intake and feed conversion and individual pig the experimental unit for RTU and abattoir analysis. During Exp. 1, pigs fed the K supplemented diets had numerically higher gains, however, there were no significant (P>0.10) differences in gain, intake, or feed conversion. K supplementation had no influence on RTU or abattoir carcass parameters. In Exp. 2, pigs fed the Med Cl diets tended to have the highest (P<0.10) gain. There was no diet effect (P>0.10) on intake or feed conversion. RTU and abattoir carcass measurements were not different (P>0.10) across treatments. Yield was lowest (P<0.05) for the Low Cl fed pigs. These results suggest that K supplementation may improve growth, while the appropriate Cl level may influence gain and yield.

Key Words: Electrolytes, Growth, Pigs

406 Comparisons of inorganic and organic trace mineral supplementation for grow-finish swine. J. L. Burkett^{*1}, K. J. Stalder¹, C. R. Schwab¹, T. J. Baas¹, D. W. Newcom¹, J. L. Pierce², W. J. Powers¹, and J. W. Mabry¹, ¹Dept. of Animal Science, Iowa State University, Ames, ²Alltech Inc., Nicholasville, KY.

A study was conducted to investigate the effect of inorganic and organic mineral supplementation on the growth and ultrasonically measured carcass characteristics of swine. In each of the two replications, 264 pigs were used in a completely randomized design with four dietary treatments and 10 - 12 pigs per pen (n = 24) throughout the grow-finish period. A commercial line of barrows and gilts were penned by sex, and randomly assigned to one of the four treatments at approximately 27 kg. Treatment 1 (control) contained a common trace mineral supplement (Kent Feeds, Muscatine, IA), while treatments 2, 3, and 4 contained Alltech's Bioplex products at 100%, 75%, and 50% of the common trace mineral supplemental levels, respectively. Individual tenth rib backfat (BF) and loin muscle area (LMA) measurements were evaluated ultrasonically on all pigs prior to marketing (118 kg). Average daily gain and average daily lean growth on test (LGOT) were calculated from the data collected on individuals. Pen feed intake was calculated by feed weigh-back to determine ADFI, feed efficiency (FE), and efficiency of lean gain (LE). Pen was the experimental unit of measurement in this study. Data from this study were analyzed using a mixed linear model with fixed effects of replication, treatment, and sex and the interaction of sex by treatment. Pen nested within treatment was included as a random effect for the evaluation. Off test weight was included as a covariate for the analyses of BF and LMA. On test weight was included as a covariate in the analyses of ADG, LGOT, ADFI, FE, and LE. Replication and sex effects were significant sources of variation for BF, LMA, ADG, LGOT, and ADFI. Pigs fed the control diet consumed less (P < 0.05) feed per day than pigs fed the three experimental diets. This study revealed no differences (P > 0.05) among the treatment means for BF, LMA, ADG, LGOT, and LE.

Key Words: Pigs, Mineral Supplementation, Ultrasound Measurements

407 The effects of high phytase levels on nutrient digestibility, growth performance and bone characteristics in growing pigs. M. J. Azain^{*1} and M. R. Bedford², ¹University of Georgia, Athens, ²Zymetrics, Golden Valley, MN.

Phytase is typically supplemented at less than 1000 U/kg diet. The objective of this study was to look at the effects of higher levels of phytase supplementation in the growing pig. A total of 144 pigs (initial wt = 13 kg) were randomly assigned to one of six dietary treatments with 3 barrows or 3 gilts per pen and a total of 48 pens in 2 trials. A corn-soy diet (20% CP, 1.12% lysine) was used. Diet 1 was the positive control and contained 0.90% Ca and calculated total and available P of 0.55 and 0.28%, respectively. Diets 2-6 had less dicalcium phosphate added and contained 0.70% Ca and 0.40 and 0.13% total and available P. Diet 2 was the negative control and diets 3-6 were supplemented with 100-12,500 U/kg feed of a novel *E. coli* Phytase expressed in *Pichia pastoris*. Diets were fed for 28 d. Apparent nutrient digestibility was determined using chromic oxide as a marker during the last week of the trial. Pigs were euthanized and metatarsal bone isolated for determination of bone strength and mineral content. Pigs fed the P deficient diet had reduced growth and efficiency as well as decreased bone weight and strength. Phytase addition improved growth rate and bone parameters. Ca and P digestibility were improved with phytase, but there was no significant effect on protein or energy digestibility. Bone Ca and P content were not affected by dietary treatment. However, bone Mg was decreased and K increased on the P deficient diet. Both were normalized with the addition of phytase to the diet. Pigs fed diets with 12,500 U Phytase/kg had growth rates, nutrient digestibilities and bone characteristics that were superior to the pigs fed the positive control diet. This effect may be accounted for by the removal of the anti-nutritional effects of phytate.

408 Shifting the pH profile of *Aspergillus niger* PhyA phytase improves its efficacy in pig diets. S. U. Rice, T. G. Ko, T. W. Kim, K. R. Roneker, and X. G. Lei^{*}, Cornell University, Ithaca, NY.

Aspergillus niger PhyA phytase is widely used in swine diets, but its pH optimum (5.5) is too high for an effective hydrolysis of phytate-P under the acidic condition in the pig stomach. Using site-directed mutagenesis, we have developed two mutants (TK10 and TK228) with lower pH optima than the wild-type (WT) of PhyA. The objective of this experiment was to compare the effectiveness of TK10 and TK224 with that of WT in improving dietary phytate-P availability to pigs. A total of 24 weanling pigs (8.41 ± 0.49 kg BW) were divided into three groups (n = 8), and fed a low-P, corn-soybean meal basal diet supplemented with the WT, TK10, or TK228 phytases at 250 units/kg of feed for five weeks. Growth performance, plasma inorganic P concentration, and plasma alkaline phosphatase activity of individual pigs were recorded or measured weekly. The overall daily gain of pigs fed the TK228 mutant phytase was 13% higher (509 vs 451 g, P < 0.05) than that of those fed the WT enzyme. Pigs fed TK228 also had higher (P < 0.05) plasma inorganic P concentrations at weeks 2-5, but lower (P < 0.05) plasma alkaline phosphatase activity at weeks 3-5 than those fed the WT enzyme. Feeding pigs with the TK10 mutant enzyme resulted in growth performance or plasma measures similar to those fed the WT enzyme. In conclusion, the shift of pH optimum in the TK228 mutant PhyA phytase enhanced its efficacy in the corn-soybean meal diets for weanling pigs. However, the similar shift in the TK10 mutant rendered no benefit over the WT enzyme.

Key Words: Phytase, Pigs, Phosphorus

409 Phosphorus excretion of pigs fed conventional or low-phytate corn-soybean meal diets without or with phytase. E. G. Xavier, L. A. Pettey, G. L. Cromwell^{*}, and M. D. Lindemann, University of Kentucky, Lexington.

Two 5-d balance experiments were conducted to assess diets containing normal (N) corn and N soybean meal (SBM) or low-phytate (LP) corn and LP, low-oligosaccharide SBM without or with phytase (Natuphos[®], BASF; 750 units/kg) on total and soluble P excretion in pigs. The LP-corn and LP-SBM were provided by Pioneer Hi-Bred International. The N-corn, LP-corn, N-SBM and LP-SBM contained 0.32, 0.26, 0.66, and 0.77% total P and 0.06, 0.17, 0.21, and 0.55% non-phytate P with estimated P bioavailabilities of 20, 75, 25, and 50%, respectively. Twelve pigs (52 kg) in metabolism crates were fed four diets (0.90% lysine) during two periods. Feeding level was equalized within replications and averaged 96% of ad libitum intake. Diets were (1) N-corn + N-SBM, 0.57% P; (2) N-corn + N-SBM + phytase, 0.47% P; (3) LP-corn + LP-SBM, 0.39% P; and (4) LP-corn + LP-SBM + phytase, 0.35% P. Diet 4 contained no added inorganic P. Ca was reduced from 0.58% in Diets 1 and 3 to 0.53% in Diets 2 and 4. All diets had the same levels of non-phytate P (0.28%) and bioavailable P (0.27%), assuming that phytase released one-third of the unavailable P. Daily feed and P intake averaged 1.91, 1.92, 1.96, 1.96 kg/d and 9.95, 8.05, 7.65, 6.88 g/d for Diets 1 to 4, respectively. Apparent P digestibility was increased by feeding the LP- vs N-diets and by phytase addition (37, 56, 66, 78%; P < 0.05). Total P in feces and urine was 3.09, 1.89, 1.58, 0.95% of DM (P < 0.05) and 21, 29, 36, 48 mg/L. Daily P excretion in feces, urine, and both

were affected by diet (6.24, 3.58, 2.62, 1.51 g/d, $P < 0.05$; 0.07, 0.13, 0.19, 0.20 g/d; 6.31, 3.71, 2.81, 1.71 g/d, $P < 0.05$), as were absorbed P (3.71, 4.46, 5.03, 5.36 g/d; $P < 0.05$) and retained P (3.63, 4.34, 4.84, 5.16 g/d; $P < 0.05$). Total P excretion decreased by 41% when phytase was added to the N-diet, by 55% when the LP-diet was fed, and by 73% when phytase was included in the LP-diet. Soluble P in excreta, expressed as % of total P, increased ($P < 0.05$) with the LP-diet and with phytase (2.0, 4.4, 7.1, 12.8%), but daily soluble P excretion was not affected ($P > 0.50$) by diet (0.13, 0.17, 0.23, 0.23 g/d).

Key Words: Pigs, Phosphorus, Phytase

410 Estimation of Ca and P retention in bone, fat-free soft tissue, and other whole body and carcass components in growing-finishing pigs from 18 to 109 kg. L. A. Pettey*, G. L. Cromwell, and M. D. Lindemann, *University of Kentucky, Lexington*.

The distribution of Ca and P in carcass bone, carcass fat-free soft tissue (FFST), and viscera (empty)-head-blood-skin (VHBS) was determined in 50 pigs from 18 to 109 kg BW to develop equations describing the retention rates of Ca and P. Ca and P in hair and hooves was inconsequential. Data were combined from two studies in which pigs were killed at 18, 27, 36, 45, 54, 73, 91, and 109 kg. Pigs were fed fortified corn-soy diets (four phases) that exceeded NRC standards for lysine, Ca, and P by 0.1%. Carcasses were split with the right half physically separated into soft tissue, bone, and skin. Chemical analysis was conducted on each body tissue. Carcass bone represented 10.0, 9.5, 9.0, 8.2, 8.3, 8.1, 7.4, and 7.5% of BW for the eight weight groups, respectively. Bone Ca represented 98.8% of the Ca in the carcass and was constant from 18 to 109 kg BW. Carcass P contributed by bone was constant from 18 to 54 kg (71.9%), but increased linearly ($P < 0.01$) to 75.1% from 54 to 109 kg BW. In fresh bone, protein, lipid, ash, Ca, and P concentrations increased linearly ($P < 0.01$) with increasing BW, while water concentration decreased linearly ($P < 0.01$). Ca and P concentrations in fresh bone were 4.2, 4.8, 5.2, 5.9, 5.7, 6.6, 6.9, and 7.4%; and 2.3, 2.5, 2.8, 3.1, 3.1, 3.3, 3.6, and 3.7%, respectively. In bone ash, Ca and P averaged 33.8 and 17.7% across all BW groups. FFST was constant (45% of BW) across BW groups. Ca and P concentrations in FFST were unchanged with BW and averaged 0.012 and 0.210%, respectively. Based on days from 18 to 36, 36 to 54, 54 to 73, 73 to 91, and 91 to 109 kg BW, the retention rates of Ca and P were calculated for bone, FFST, and VHBS. The predicted Ca retention rates for 27, 45, 64, 82, and 100 kg pigs (means of the five BW ranges) were 4.03, 5.68, 6.71, 7.03, and 6.70 g/d ($Y = 0.34 + 0.1635X - 0.001X^2$), and predicted P retention rates were 3.06, 4.16, 4.79, 4.88, and 4.47 g/d ($Y = 0.49 + 0.1158X - 0.00076X^2$). When combined with Ca and P needs for maintenance, a net requirement for Ca and P can be estimated for pigs from 20 to 110 kg BW with this model.

Key Words: Pigs, Bone, Phosphorus

411 Endogenous excretion of phosphorus and calcium in growing pigs fed two varieties of soybean meal. R. N. Dilger* and O. Adeola, *Purdue University, West Lafayette, IN*.

Using the regression approach, whole body endogenous excretion of phosphorus and calcium were measured in growing pigs fed diets containing conventional or high available phosphorus (HAP) soybean meals (SBM) as the primary phosphorus and calcium source. Semipurified cornstarch-based diets contained four graded levels of each soybean meal; thereby creating a linear dietary intake of phosphorus (0.7, 1.3, 2.0 and 2.7 g/kg DM) and calcium (0.5, 0.9, 1.4 and 1.8 g/kg DM). Chromic oxide (3.0 g/kg diet, as-fed) was used as an indigestible index and pigs were fed at a rate of $0.09 \times BW^{0.75}$ kg according to individual weekly BW. Sixteen barrows (average initial BW of 17.7 kg) were fitted with simple T-cannula at the distal ileum and fed the diets according to a replicated 8 X 8 Latin square design. Experimental periods were 7 d in length with 5 d diet acclimation, sampling of feces on d 5 and 12-h collection of ileal digesta on each of d 6 and 7. Apparent pre-cecal phosphorus and calcium digestibilities exhibited a linear relationship to dietary mineral intake for conventional ($P < 0.01$) but not HAP SBM ($P > 0.10$). Conversely, apparent total tract phosphorus and calcium digestibilities increased linearly to dietary mineral intake for HAP ($P < 0.02$) but not conventional SBM ($P > 0.10$). Endogenous outputs

of phosphorus in ileal digesta were different between SBM sources ($P < 0.01$; 7.9 vs. 4.2 g/kg DMI for conventional and HAP SBM, respectively) but not when determined in the feces ($P > 0.10$; 0.02 vs. 0.09 g/kg DMI for conventional and HAP SBM, respectively). True pre-cecal and total tract digestibilities of phosphorus and calcium were higher for HAP SBM compared with conventional SBM ($P < 0.01$). This was due in part to the 34- and 47-fold reductions ($P < 0.01$) in endogenous phosphorus output (DMI basis) between the ileal and fecal collection sites for conventional and HAP SBM, respectively. These data suggest the regression approach may be used to estimate whole body endogenous mineral output though an inherently high degree of variability seems to exist with this methodology.

Key Words: Endogenous, Minerals, Pigs

412 A novel procedure for measuring endogenous phosphorus losses and true phosphorus digestibility by growing pigs. G. I. Petersen* and H. H. Stein, *South Dakota State University, Brookings*.

A novel procedure was developed to estimate endogenous losses of phosphorus by growing pigs. A P-free diet was formulated using mainly cornstarch, dextrose, gelatin, and crystalline AA. In Exp. 1, two P-free diets were formulated using gelatin of either porcine or bovine origin. The apparent (AID) and standardized (SID) ileal digestibility coefficients of AA in these two diets were compared to the AID and SID in soybean meal (SBM). Results of this experiment showed that there were no differences in AID or SID for any of the indispensable AA except for trp between the three feed ingredients when fed to growing pigs. In Exp. 2, a P-free diet based on gelatin of porcine origin was used to measure the apparent (ATTD) and true (TTTD) total tract digestibility of three sources of inorganic phosphorus. In addition to the P-free diet, three other diets were formulated based on the P-diet, but each of these diets were supplemented with either monosodium phosphate (MSP), purified monocalcium phosphate (MCP) or dicalcium phosphate (DCP). The inorganic phosphate sources were added to the P-free diet to reach a total P-content in the diets of 0.2%. Each of the four diets was fed to 7 pigs for 12 d. Fecal material was collected for five d using the marker to marker procedure. Results of the experiment showed that the ATTD in DCP was lower ($P \leq 0.05$) than in MCP (81.49 vs. 91.88%), while the ATTD in MCP (87.96%) was similar to the other two sources. The endogenous losses of P were calculated based on the P-concentration in the fecal samples from pigs fed the P-free diet and averaged 0.139 g P per kg DMI. By correcting the ATTD for the endogenous losses, the TTTD were calculated. For DCP, MCP, and MSP, the TTTD was 88.41, 94.93, and 98.20%, respectively. The value for MSP was higher ($P \leq 0.05$) than the value for DCP, while the TTTD for MCP was not different from the other two sources. The two experiments showed that the P-free diet provides a way of estimating endogenous losses of P in pigs and can be used to calculate ATTD and TTTD in feed phosphates.

Key Words: Endogenous Loss of P, P-Free Diet, True Digestibility of P

413 Evaluation of the bioavailability of phosphorus in distillers dried grains with solubles (DDGS) when fed to pigs. R. W. Fent*¹, T. S. Torrance², B. W. Ratliff¹, S. X. Fu¹, G. L. Allee¹, D. M. Weibel², and J. D. Spencer², ¹*University of Missouri, Columbia*, ²*United Feeds, Inc., Sheridan, IN*.

A slope ratio assay was conducted to estimate the bioavailability of phosphorus (P) in distillers dried grains with solubles (DDGS). Seventy-two barrows (initial wt = 15.0 kg) were individually penned and allotted by weight to one of nine dietary treatments in a randomized complete block design. All diets were cornstarch-soybean meal based. Treatments 1-7 comprised the slope ratio assay consisting of a basal diet (0.25% P, 1.25% TID Lys) and diets containing 0.075, 0.150, and 0.225% additional P from either monosodium phosphate (MSP) or DDGS. The two additional diets consisted of the 0.225% P DDGS + 500 FTU/kg phytase (Optiphos#8482; Phytex, LLC) and the basal diet + 500 FTU/kg to assess the possible further liberation of phosphorus. Pigs were allowed ad libitum access to feed and water. After a 28-d feeding period, all pigs were weighed, sacrificed, and right fibulas collected for analysis of bone breaking load and bone ash content. The standard curve (MSP) and the DDGS titration both resulted in linear improvements ($P < 0.01$) in ADG, ADFI, gain:feed, fibula breaking load, and fibula bone ash content. The bioavailability estimate of the phosphorus contained in DDGS was estimated as the ratio of the slopes of the DDGS

curve to the standard curve. The resulting P bioavailability estimates for DDGS relative to MSP were 84.3% and 85.3% for fibula breaking load and fibula bone ash, respectively. The basal diet + 500 FTU/kg phytase resulted in greater fibula breaking load (18.7 vs 13.7 kg force) and bone ash (1.049 vs 0.896 g) as compared with the basal diet, resulting in calculated P release of 0.082 and 0.064%, respectively. The 0.225% P DDGS + 500 FTU/kg phytase also resulted in greater fibula breaking load (31.9 vs 24.6 kg force) and bone ash (1.681 vs 1.389 g)

as compared with the 0.225% P DDGS diet. Taking into consideration the response from soybean meal, phytase supplementation resulted in complete P bioavailability from DDGS. These results indicate that the bioavailability of phosphorus in DDGS is approximately 85% with the remaining phosphorus liberated with additional phytase.

Physiology and Endocrinology: Strategies for Appointment Breeding of Beef and Dairy Cattle

414 Comparison of EAZI-BREED CIDR inserts with melengestrol acetate in progestin-based protocols to synchronize estrus in beef cows. D. J. Schafer*, J. F. Bader, D. C. Busch, F. N. Kojima, M. R. Ellersieck, M. C. Lucy, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

Follicular dynamics and timing of estrus and ovulation were compared in 48 nonsuckled, estrous cycling beef cows using EAZI-BREED CIDR inserts (CIDR) or melengestrol acetate (MGA) in progestin-based protocols to synchronize estrus. Cows were assigned equally (n=12) to one of four treatments (T1 to T4) by age and body condition. Cows in T1 were fed MGA (0.5mg·hd⁻¹·d⁻¹) for 14 d, GnRH (100 µg Cystorelin) was injected on d 26, and PGF_{2α} (PG; 25 mg Lutalyse) on d 33. Cows in T2 had CIDRs (1.38g progesterone) inserted for 14 d, GnRH was injected on d 23, and PG on d 30. Cows in T3 were fed MGA for 7 d, injected with PG on d 7, GnRH on d 11, and PG on d 18. Cows in T4 had CIDRs inserted for 7 d, were injected with PG on d 7, GnRH on d 9, and PG on d 16. Transrectal ultrasonography was performed daily to monitor follicular dynamics from GnRH to estrus after PG; and every 4 h from 20 h after the onset of estrus until ovulation was confirmed. Estrus detection was performed with HeatWatch. Emergence of a new follicular wave after GnRH, and estrus after PG did not differ (P>.10) among treatments: T1, 11/12; T2, 9/12; T3, 11/12; T4, 9/12. Mean interval to estrus (h) was shorter (P<.05) for cows in T3 and T4 than cows in T1 and T2 (T1, 62 ± 2.1; T2, 59 ± 2.4; T3, 51 ± 2.1; T4, 52 ± 2.4). Follicle diameter (mm) at GnRH did not differ (P>.10) among treatments; differed at PG (P<.05) between T2 and all other treatments (T1, 12.2 ± .5; T2, 10.7 ± .5; T3, 13.0 ± .5; T4, 12.9 ± .5); and differed (P<.05) 20 h after the onset of estrus between T1 and T2. Progesterone (ng/mL) at PG was greater (P<.001) for cows in T1 and T2 than T3 and T4 (T1, 3.7 ± .4; T2, 3.9 ± .4; T3, 1.8 ± .4; T4, 1.7 ± .4). Interval from estrus to ovulation (h) was shorter (P<.05) for cows in T4 than T3 (T1, 30 ± 1.2; T2, 30 ± 1.4; T3, 31 ± 1.2; T4, 27 ± 1.4). These data demonstrate the flexibility in using MGA or CIDR inserts in progestin-based protocols to synchronize estrus in beef cows. (Supported by USDA-NRI grant 2000-02163).

Key Words: Progestin, Beef Cows, Estrus Synchronization

415 Substituting EAZI-BREED CIDR inserts (CIDR) for melengestrol acetate (MGA) in the MGA Select protocol in beef heifers. F. N. Kojima*, J. F. Bader¹, J. E. Stegner¹, D. J. Schafer¹, J. C. Clement², R. L. Eakins¹, M. F. Smith¹, and D. J. Patterson¹, ¹University of Missouri, Columbia, ²Cow Calf Research and Consulting, Mandan, ND.

This study was designed to compare estrous response, timing of AI and pregnancy rate resulting from AI among beef heifers that were presynchronized with MGA or the CIDR insert prior to GnRH and PGF_{2α} (PG). Heifers (n = 353) at three locations (location 1, n = 154; 2, n = 113; and 3, n = 85) were assigned randomly to one of two treatments by age and weight. The MGA Select-treated heifers (MGA; n = 175) were fed MGA (0.5 mg·hd⁻¹·d⁻¹) for 14 d, GnRH (100 µg i.m. Cystorelin) was injected 12 d after MGA withdrawal, and PG (25 mg i.m. Lutalyse) was administered 7 d after GnRH. CIDRs (CIDR; n = 177) were inserted in heifers for 14 d, GnRH was injected 9 d after CIDR removal, and PG was administered 7 d after GnRH. CIDR-treated heifers received carrier without MGA on days that coincided with MGA feeding. Heifers were monitored for signs of behavioral estrus beginning the day PG was administered. AI was performed 12 h after onset of estrus and recorded as day of AI (Day 0 = PG). Pregnancy rate to AI was determined by ultrasonography 40 d after AI. Quantitative data were analyzed by ANOVA and qualitative data were compared by Chi-square analysis. Distribution of AI was analyzed by ratio of variance (F-test) for mean interval to AI. No interactions between locations and treatments were detected;

therefore, data were pooled for analyses. Estrous response did not differ (P > 0.10) between treatments. Peak AI occurred on Day 3 for heifers in both treatments (CIDR 122/177, 69%; MGA 93/175, 53%), and distribution of AI was more highly synchronized (P < 0.05) among CIDR- than MGA-treated heifers. Pregnancy rate to AI was greater (P < 0.01) in CIDR- (112/177, 63%) than MGA-treated heifers (83/175, 47%), however, final pregnancy rate did not differ (P > 0.10) between treatments. In summary, replacing feeding of MGA with CIDR inserts improved synchrony of estrus and pregnancy rate resulting from AI in replacement beef heifers.

416 MGA and CIDR based timed AI protocols in postpartum beef cows. D. Kreider*, N. Post, R. Rorie, T. Lester, and E. French, *University of Arkansas, Fayetteville.*

An experiment was conducted to compare two timed AI, estrus synchronization protocols in postpartum beef cows. Straight bred Angus cows (n = 125) in herds 1 (n = 54) and 2 (n=71) were sorted by BW and body condition score (BCS); then randomly assigned to treatments. Treatments were: MPGG: MGA (.5mg/hd/d) for 14 d followed by 25mg Lutalyse (PG) 17 d after MGA withdrawal and GnRH (100 µg Fertagyl) 48 h after PG; and CIDR: 100 µg GnRH plus Eazi-Breed CIDR for 7 d, then PG followed in 48 h by GnRH. All cows were inseminated 18 h after GnRH, and then placed with a fertile bull at 10 d after AI. Conception rate (CR) was determined by ultrasound at 30 d post AI and pregnancy rate (PR) was determined by palpation 55 d after bull removal. Serum was collected and analyzed for progesterone (P4) on d -6, 1 and 31 of MGA treatment for MPGG and on d -6, 1 and 7 for CIDR. Cows were assumed to be cycling if P4 was ≥ 1 ng/ml on d -6 or 1 and were considered to have a functional CL if P4 was ≥ 1 ng/ml on d 31 (MPGG) or d 7 (CIDR). BW and BCS, d postpartum at the start of treatment and CR to AI were all different between herds (P < 0.01), but treatments did not differ in initial BW, initial BCS and days postpartum, either within herd (P > 0.14) or for the combined data (P > 0.10). Percent of cows cycling at the start of treatments differed (P = 0.001) between herds (35% vs 92% for herds 1 and 2 respectively), and between MPGG and CIDR in herd 1 (18% vs 54%, respectively; P = 0.006). Conception rate to AI was 25% in MPGG vs 46% in CIDR in herd 1 (P = 0.09) and overall pregnancy rate was 79% in MPGG vs 69% in CIDR (P = 0.86). In herd 2, percent cycling at the start of treatment, and conception rate to AI did not differ between MPGG and CIDR (89% vs 94%, P = 0.35; and 53% vs 65%, P = 0.19; respectively). For the combined data, percent cycling at the start of treatment and conception rate to AI differed between MPGG and CIDR (58% vs 76%, P = 0.03; and 57% vs 41%, respectively, P = 0.04). Under the conditions observed in this study, conception rates to timed AI using an MGA based protocol tend to be lower than those obtained with a CIDR based protocol in postpartum beef cows.

Key Words: Timed AI, Estrus Synchronization, Beef Cows

417 Effect of timing of insemination and estrous synchronization method on AI pregnancy rates in beef heifers. B. R. Dorsey*, J. B. Hall, W. D. Whittier, and W. S. Swecker, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objectives of this experiment were to evaluate time of insemination relative to estrus and synchronization with melengestrol acetate with PG (MGA-PG) or an intervaginal progesterone insert with PG (CIDR-PG) on AI pregnancy rate in beef heifers. Crossbred heifers were blocked by weight and assigned to MGA-PG (n = 176) or CIDR (n = 173). The MGA-PG group received MGA (0.5 mg/hd/d for 14 d) followed by PG (25 mg Lutalyse, Pfizer) 19 d after last feeding of MGA. The CIDRs

were inserted for seven days and PG administered 1 d before CIDR removal. Heifers were fitted with HeatWatch (HW) transmitters (n = 200) or heat detection aid (K-mar). Estrus was monitored by HW or thrice daily visual estrous detection. Heifers detected in estrus (n = 270) were randomly bred AI (EAI) once daily beginning at 0900. Heifers not detected in estrus by 96 h after PG (n = 79) were bred by fixed-time AI (TAI) and received GnRH (100 µg Cystorelin, Meriel) at TAI. Pregnancy status was determined via ultrasonography at 60d post AI. Overall AI, EAI and TAI pregnancy rates were analyzed by Chi Square using CAT-MOD procedures of SAS. A majority of heifers (77.4%) were bred AI following estrus. Estrous synchronization method did not (P > 0.5) affect overall, EAI or TAI pregnancy rates. Pregnancy rates for MGA-PG versus CIDR-PG heifers were 53.4% vs. 54.9%; 59.9% vs. 63.3%; 26.5% vs. 31.1% for overall AI, EAI, and TAI, respectively. Data were pooled across estrous synchronization method to determine effect of timing of AI relative to estrus (n = 247). Heifers were grouped by 4 h periods relative to first estrual mount. Time of AI relative to estrus did not (P = 0.30) affect EAI pregnancy rate. Pregnancy rates for heifers bred AI at 0-4, 4-8, 8-12, 12-16, 16-20, 20-24, and > 24 h after estrus were 62.5%, 56.7%, 79.3%, 63.2%, 53.8%, 65.7%, 60.6%, respectively. We conclude that MGA-PG and CIDR-PG are equally effective for synchronizing beef heifers, and that time from estrus to AI, up to 24h, did not affect AI pregnancy rate.

Key Words: Heifers, Estrous Synchronization, AI

418 Factorial analysis of timed AI (TAI) protocols for synchronization of first and second insemination in dairy cattle. J. P. Meyer*, R. P. Radcliff, M. L. Rhoads, J. F. Bader, C. N. Murphy, and M. C. Lucy, *University of Missouri, Columbia.*

The PGPG TAI protocol uses a series of prostaglandin F_{2α} (PGF) and GnRH injections to synchronize ovulation for TAI. We examined the utility of the first PGF and GnRH injections within PGPG by testing a factorial treatment arrangement within a single study conducted on a large commercial dairy. The PGPG cows were treated with PGF (25 mg Lutalyse), 3 d, GnRH (100 µg Cystorelin), 8 d, PGF, 2 d, GnRH and TAI (n=131). Other treatments were PPG (PGF, 11 d, PGF, 2 d, GnRH and TAI; n=149), GPG (GnRH, 8 d, PGF, 2 d, GnRH and TAI; n=158), PG (PGF, 2 d, GnRH and TAI; n=160) and Ovsynch (GnRH, 7 d, PGF, 2 d, GnRH and TAI; positive control; n=138). The TAI were done within 6 h of the last GnRH. The efficacy of the first PGF injection and the first GnRH injection could be estimated by comparing PGPG/PPG with GPG/PG and by comparing PGPG/GPG with PPG/PG, respectively. Pregnancy was determined by ultrasonography on days 28 and 42 after TAI. The 28 d pregnancy rate (26.0, 31.8, 32.8, 29.3, and 40.3%), 42 d pregnancy rate (22.1, 24.8, 27.2, 23.8, and 32.6%), and embryonic loss rate (28 to 42 d; 15.6, 15.9, 18.8, 18.2, and 20.0%) were similar for PGPG, PPG, GPG, PG, and Ovsynch, respectively. There was no effect of the first PGF or the first GnRH on pregnancy rate. Cows were randomly assigned to receive either GnRH or control (no injection) on d 22 after TAI. Cows diagnosed nonpregnant on d 28 were then treated with PGF on d 29, GnRH on d 31 and TAI. The random pretreatment with GnRH on d 22 enabled a test of two resynchronization TAI protocols [Ovsynch (GnRH, 7 d, PGF, 2 d, GnRH and TAI) versus PG (PGF, 2 d, GnRH and TAI)]. The percentage of cows with corpora lutea on d 28 (pregnancy exam before resynchronization) and the 42 d pregnancy rate following resynchronization were similar for Ovsynch [131/154 (85.1%) and 38/154 [24.6%]] and PG [132/163 (81.0%) and 39/163 (23.9%)]. We conclude that a simple TAI protocol (PGF, 2 d, GnRH and TAI; Rapid synchronization) may be an effective method for TAI in large commercial dairies.

Key Words: Dairy, Cow, AI

419 Effects of CIDR inserts on first service pregnancy rates of lactating dairy cows submitted to a presynch program and on re-synchronization of second service in Mexico. F. Moreira*, R. Flores, J. Boucher, and J. Chenault, *Pfizer Animal Health.*

Objectives were to evaluate if EAZI-BREED CIDR Cattle Inserts (CIDR) increase first service pregnancy rate (FSP) of a Presynch program and if CIDR would affect second service estrus detection (EDR) and pregnancy rates (PR). The single-site study was conducted in Central Mexico. Within barns (n=3), parity, and week of enrolment, cows

were assigned to either Presynch or Presynch-CIDR for their first service. Presynch was initiated at 25±3 days postpartum with 25 mg of PGF_{2α} (5 mL, i.m.; LUTALYSE Sterile Solution) and a second PGF_{2α} 14 days later. At 14 days later, cows received 100 µg of GnRH (2 mL, i.m.; CYSTORELIN), PGF_{2α} 7 days later, GnRH 48 hours later, and timed insemination (TI) 12 to 20 hours later. Presynch-CIDR cows also received a CIDR Insert (1.38 g of progesterone) which was administered at first GnRH and removed 7 days later. Presynch and Presynch-CIDR cows were assigned to receive a CIDR insert at 14 days after first service for a 7-day period (Resynch) or no additional treatments (Control). Resynch cows were observed for estrus and inseminated between days 22 and 26 after TI. Control cows were observed for estrus and inseminated between days 4 and 26 after TI. Thus, there were 4 treatments: Presynch/Control (n=415), Presynch/Resynch (n=406), Presynch-CIDR/Control (n=414), and Presynch-CIDR/Resynch (n=403). Cows were palpated for pregnancy 45 to 60 days after insemination. Presynch-CIDR cows had increased PR compared to Presynch (43% and 37%, respectively; P=0.021). EDR did not differ between Resynch and Control (51% and 51%, respectively). In primiparous cows, PR was decreased for Resynch compared to Control (18% and 26%, respectively; P=0.045). In multiparous cows from the Presynch-CIDR group, PR was increased for Resynch compared to Control (21% and 11%, respectively; P=0.034). CIDR increased FSP of lactating cows submitted to Presynch. Resynch had no effect on EDR, negative effects on PR of primiparous cows, but positive effects on PR of multiparous cows.

Key Words: CIDR, Presynch, Re-Synchronization

420 Resynchronization of ovulation in Holsteins after not pregnant diagnosis. J. S. Stevenson* and S. M. Tiffany, *Department of Animal Sciences, Kansas State University, Manhattan.*

We compared outcomes of 2 protocols used to resynchronize estrus and ovulation in not pregnant females. Nulliparous heifers and lactating cows in which AI occurred 41 ± 0.7 d (range: 26 to 200 [91% between d 27 and 53]) earlier were presented every 2 to 3 wk for pregnancy diagnosis using ultrasonography. Ovaries were scanned, follicles mapped and sized, presence of corpus luteum noted, and 100 mcg of GnRH injected. Seven days later, 25 mg of PGF was injected and females were assigned randomly to receive a second GnRH injection 48 h (Ovsynch; n = 224) or 1 mg of estradiol cypionate (ECP) 24 h after PGF (Heatsynch; n = 230). Those detected in estrus since diagnosis were inseminated, whereas the remainder received a timed AI (TAI) between 65 and 74 h after PGF. Based on ovarian scans and blood collected before injections for progesterone analysis, 4 groups were classified: anestrus; cystic; cycling, and unknown. Few females (n = 23; 5.1%) were detected in estrus between pregnancy diagnosis and through the day of ECP injection. On the day following ECP injection through the day of TAI, more (P<0.01) ECP- than GnRH-treated females were inseminated based on estrus (33 vs. 13%). Overall, more (P<0.01) Ovsynch than Heatsynch females were TAI (82 vs. 62%). Pregnancy rates were greater (P<0.01) for females inseminated after estrus (34%) than after TAI (24%), but differences were greater between estrus and TAI for Heatsynch (38 vs. 21%) than Ovsynch (33 vs. 27%) females. Pregnancy rates for groups were: anestrus (9%; n = 23); follicular cysts (25%; n = 12); luteal cysts (33%; n = 12); unknown (25%; n = 63); and cycling (28%; n = 344). Pregnancy rates did not differ among parities, but tended (interaction: P = 0.12) to differ between Heatsynch and Ovsynch within parity, respectively: heifers (50% [n = 20] vs. 30% [n = 20]); first lactation (27% [n = 108] vs. 22% [n = 92]), and 2+ lactations (23% [n = 102] vs. 30% [n = 112]). We conclude that little difference occurred in pregnancy outcomes after either the Ovsynch and Heatsynch protocols when applied to dairy females after a not pregnant diagnosis.

Key Words: Ovsynch, Heatsynch, Resynchronization

421 Variations in the Ovsynch protocol after presynchronization of estrous cycles alter pregnancy rates in lactating dairy cows. M. A. Portaluppi* and J. S. Stevenson, *Department of Animal Science, Kansas State University, Manhattan.*

Our objectives were to determine pregnancy rates after altering times of the second GnRH injection and AI in the Ovsynch protocol to accommodate AI once daily while cows were locked up at the feed bunk. Cows (n = 654) from 2 dairy herds in northeastern Kansas were studied. Cows ranged from 24 to 44 DIM at the start of the Presynch protocol

consisting of two injections of PGF 14 d apart with the second given 12 d before initiating treatments. Cows were blocked by lactation number and assigned randomly to 3 treatments consisting of variations of the Ovsynch protocol. Cows in Cosynch-48 and Ovsynch received injections of GnRH 7 d before and 48 h after a PGF injection. Fixed-time inseminations (TAI) were made at the time of the second GnRH injection (0 h; Cosynch-48) or 24 h (Ovsynch). Those in Cosynch-72 received the second GnRH injection at 72 h after PGF and were inseminated at the same time. Pregnancy was diagnosed by palpation on d 40 or 41 after TAI. Pregnancy rates in both herds were consistently greater ($P < 0.05$) for Cosynch-72 than for Cosynch-48 and Cosynch-72 vs. Cosynch-48 + Ovsynch. First-lactation cows ($n = 263$) had greater ($P < 0.05$) pregnancy rates (32 vs. 27%) than older cows ($n = 391$). The BCS at TAI ranged from 1.0 to 4.0. Cows having BCS #8805 2.25 ($n = 469$) had greater ($P < 0.05$) pregnancy rates than those having BCS < 2.25 ($n = 185$): 31% vs. 24%, respectively. For each 10-d increase in DIM at the first Presynch PGF injection, pregnancy rates increased ($P < 0.05$) by $9 \pm 4\%$. We concluded that pregnancy rates for cows in which estrous cycles were presynchronized before the Cosynch-72 protocol were greater than those treated with the Cosynch-48 and Ovsynch protocols. Table 1. Pregnancy Rates at 40-41 Days after First Insemination

Herd	Cosynch-48	Ovsynch	Cosynch-72	Total
1	17 (78)	19 (78)	25 (72)	20 (228)
2	27 (139)	34 (134)	41 (143)	34* (426)
Total	23 (217)	29 (212)	35** (215)	29 (654)

* Different ($P < 0.01$) from herd 1.

** Different ($P < 0.05$) from Cosynch-48 and Ovsynch.

Key Words: Pregnancy Rates, Presynchronization, Ovsynch

422 The effect of deep intrauterine placement of semen on conception rate in dairy cows. M. G. Diskin^{*1}, J. R. Pursley², D. A. Kenny³, J. F. Mee⁴, and J. M. Sreenan¹, ¹Teagasc, Atheryn, Co. Galway, Ireland, ²Michigan State University, East Lansing, ³University College Dublin, Belfield, Dublin, Ireland, ⁴Teagasc, Fermoy, Co. Cork, Ireland.

The reported results of the effect of deep intra-uterine horn insemination on conception rate (CR) in cattle is equivocal. Some reports indicate an improvement while others report no improvement in CR. The objective of this study was to determine the effect of bi-lateral uterine horn artificial insemination (AI) on CR in dairy cows. This study was carried out over two years involving 6 commercial inseminators in each year, 4 of which were involved in both years. All inseminators were trained prior to the start of the experiment in each year. Each alternate cow presented for AI in co-operating herds was inseminated by placing all of the inseminate in the body of the uterus (Body) or by placing 50% of the inseminate beyond the curvature in each uterine horn (Horn). Data was collected on a total of 1860 inseminations in 37 herds in 2002 and on 1586 inseminations in 24 herds in 2003. Pregnancy diagnosis was performed using ultrasonography at 28 to 60 days post AI. Data were

analyzed using PROC CATMOD with terms for AI treatment, year, inseminator, and their interactions included in the model. There was no effect (>0.05) of AI treatment x inseminator x year, treatment x year or inseminator x year on CR. There was a significant effect ($P < 0.02$) of AI treatment x inseminator on CR, with evidence of either an increase (+11.4%; $P < 0.05$), decrease (-4 to -6%; $P < 0.05$) or no effect ($P > 0.05$) of Horn AI on CR for individual inseminators. A retrospective analysis of the data for all 61 herds showed that the improvement in CR following Horn insemination was most evident in herds with lowest CR following Body AI. This study indicates that the effect of uterine horn AI on CR is not uniform and is inseminator dependent and may be ameliorated by the inherent level of herd fertility. Further studies are required to investigate the technique x inseminator interaction before any general recommendation could be made.

Key Words: Semen, Placement, Conception

423 The association between ultrasound reproductive tract scoring and commonly used veterinary therapeutics with pregnancy rates in spring-calving Holstein-Friesian cows. F. Buckley*, J. F. Mee, and P. Dillon, Teagasc, Dairy Production Research Centre, Moorepark, Fermoy, Co. Cork, Ireland.

The objectives of this study were to investigate if ultrasound reproductive tract scores (URTS) recorded prior to first service reflected subsequent fertility performance, and to discern if commonly used veterinary therapeutic regimes (VTR) administered post ultrasound examination led to improved reproductive efficiency. In total, 6,477 URT scores were analysed from 5,734 Holstein-Friesian cows in 61 spring-calving herds over 2 yr (1999 and 2000). In brief: URTS 1 was assigned to cows with a normal uterus that had recommenced ovulation post partum. A cow with URTS 2 had almost completed involution, had a small volume of mixed echogenic fluid in the uterine lumen, and was ovulatory. Cows with URTS 3 had partially completed involution, had a moderate volume of mixed echogenic fluid in the uterine lumen, and were ovulatory. Cows with URTS 4 were anovulatory, had partially completed involution with a small or moderate volume of mixed echogenic fluid in the uterine lumen. URTS 5 was pyometra. Cows with URTS 6 had completed uterine involution but were anovulatory. A lower pregnancy rate to first service (PREG1) was observed with URTS 2 (51%), 3 (36%), 5 (17%) and 6 (46%) when compared to URTS 1 (57%) ($P < \text{or} = 0.01$). VTR resulted in a lower PREG1 with URTS 1 (-6%, $P = 0.054$) (predominantly a prostaglandin (PG) regime) and URTS 6 (-12%, $P < 0.05$) (predominantly progesterone supplementation), when compared to cows with the same URTS receiving no VTR. Intervention with URTS 2 (predominantly washout (WO) +/- a PG regime) and URTS 4 (predominantly progesterone supplementation and a WO) had no significant effect on PREG1. A positive response to VTR was observed with URTS 3 (+17%, $P < 0.05$) and URTS 5 (+25%, $P < 0.05$), (predominantly a WO +/- PG and an intensive hormonal regime including a WO, respectively). In conclusion, URTS recorded prior to first service did reflect subsequent reproductive performance. However, the level of routine VTR being administered in these herds was unjustified.

Production, Management and the Environment: Reproduction and Behavior

424 Minimum temperature and maximum humidity: Predictors for conception of crossbred Holstein cows in Thailand. V. Punyapornwithaya¹, K. Kreausukon^{*1}, S. Theepatimakorn², and W. Suriyasathaporn¹, ¹Clinic of Ruminant, Faculty of Veterinary Medicine, Chiangmai University, Chiang Mai Province, Thailand, ²Chiangmai AI Center, Department of Livestock, Chiang Mai Province, Thailand.

In general, weather influences reproductive performance in dairy cattle. The objective of this study was to determine the effects of temperature and humidity on conception rate in small holder crossbred Holstein dairy herds in the tropics. Data from primiparous and multiparous dairy cows from 513 herds in northern part of Thailand, during January 2001 to November 2002, were used. Monthly average weather data, includ-

ing minimum and maximum of both temperature and humidity, were collected from Thai Meteorological department. Data were analyzed by creating generalized estimating equation (GEE) using PROC GENMOD (SAS version 8). The final data included 8,096 observations from 3,425 cows. For univariate analysis, all weather data except for the maximum temperature factor were negatively related to the risk of conception ($P < 0.01$). The final model included minimum daily temperature ($P < 0.01$) and maximum daily humidity ($P = 0.09$). The increasing of either minimum temperature or maximum humidity caused decreasing conception occurrence. Based on monthly average weather data, we concluded that cows have the lowest conception rate during June to August in Thailand.

Key Words: Temperature and Humidity, Conception, Dairy Cows

425 Diameter of head of tail as a negative energy balance indicator in relation to reproductive performance in dairy cows. K. Kreausukon*, V. Punyapornwithaya, W. Posuya, and W. Suriyasathaporn, *Clinic of Ruminant, Faculty of Veterinary Medicine, Chiang Mai University, Chiang Mai Province, Thailand.*

Body Condition Scoring has been used as a management tool for evaluating negative energy balance in dairy cows. However, the efficiency of the scoring is based on each practitioner. The objective of this study was to determine the use of diameter of head of tail (DHT) parameter in relation to body weight (BW), body condition score (BCS), and reproductive performance in dairy cows. Data from sixty-five crossbred Holstein-Friesian cows calving during July to November 2003 from 31 farms in Mae-On sub-district, Chiangmai province were used. The DHT were measured at the 1st coccygeal by using vernier calipers. Data of DHT, BW, and BCS were collected before and after parturition, and data on calving date and first insemination date were recorded for calculated day to first service. The maximum losses of DHT, BCS, and BW, were found at 6 weeks after parturition. Subsequently the data at 6 weeks was used and analyzed by Pearson Correlation Coefficients. Results showed that loss of DHT was positively related to loss of BCS, loss of BW, and day to first service ($P < 0.01$). In conclusion, measuring DHT before and after parturition can be used as a management tool in dairy farms.

Key Words: Diameter of Head of Tail, Day to First Service, Dairy Cows

426 Can acceptable pregnancy rates be achieved using exclusive timed artificial insemination for first service? M. B. Capel*¹, D. V. Nydam², and R. Saltman³, ¹*Perry Veterinary Clinic*, ²*NYS College of Veterinary Medicine*, ³*Pfizer Animal Health.*

The goal of this study was to determine if acceptable pregnancy rates can be achieved using exclusive timed artificial insemination for first service. The study was conducted on a commercial dairy milking 1,900 cows. Rolling herd average, heat detection rate, and pregnancy rate (defined as the proportion of cows open and eligible for breeding that become pregnant per 21-day period) were 11,200 kg, 67%, and 20% for the previous year, respectively. The breeding program for the past two years was a prostaglandin (PGF₂α) injection at 30-36 days in milk (DIM) and 14 days later (Pre-Synch). All cows not bred by natural heat detection after a 46 day voluntary waiting period (vwp) were given GnRH at 57-63 DIM, PGF₂ α 7 days later, GnRH 2 days later, and bred 12-16 hours later (Ov-Synch). This program served as the control group for the trial. The treatment program was a Pre-Synch, Ov-Synch program with no natural heat detection on first service that started at 9-15 DIM. The treatment group also had a 46 day vwp, and 100% of the treatment group cows were bred by 52 DIM. All cows present on the farm at 9-15 DIM were enrolled in the study. Cows in both groups found open at pregnancy examination were placed on Ov-Synch either the same day if a corpus luteum was detected by rectal palpation, or in one week if one was not detected. The sample size for the study was 1049 cows. Pregnancy rates for both groups presented in the following table indicate that it is biologically possible to achieve high pregnancy rates using exclusive timed artificial insemination for first service beginning at 46 DIM.

DIM	Treatment Group	95% Confidence Interval	Control Group	95% Confidence Interval
	Pregnancy Rate		Pregnancy Rate	
46-66	30	25.9-34.5	20	16.7-23.1
67-87	18	14.1-21.5	28	24.2-32.3
88-108	25	20.6-30.2	21	16.4-25.5
109-129	21	15.5-27.4	23	17.6-29.5
Total	25	22.1-27.2	23	20.5-25.4

Key Words: OvSynch, Pregnancy Rate, Breeding

427 System for in vitro production with sexed sperm in commercial dairy herds. R. D. Wilson*¹, K. A. Weigel¹, P. M. Fricke¹, M. L. Leibfried-Rutledge², D. L. Matthews¹, V. R. Schutzkus¹, and J. J. Rutledge^{1,2}, ¹*University of Wisconsin, Madison*, ²*BOMED Inc., Madison, WI.*

Our objective was to research a system exploiting the synergy among ovulation (estrus) control, sexed sperm and in vitro production for replacement heifers production on commercial farms. Holstein cull cows (n=104) were selected by herd owners for use as donors, and ovaries were collected via colpotomy or at slaughter. Oocytes (n=4542) were aspirated from the ovaries and used to produce embryos in vitro using sex-sorted sperm from 3 Holstein sires. Seven Wisconsin herds participated and 365 embryos were produced (3.5 ± 0.4 transferable embryos per donor) although only 272 embryos were transferred (fresh) due to limited availability of recipients. Embryos were transferred into recipients 6, 7, or 8 d after recipients either expressed estrus or ovulation occurred (i.e. Ovsynch synchronization). Recipients cows that showed standing estrus had a conception rate of 16.3 %, while those resulting from a synchronization program had a mean conception rate of 20.0%. Recipient heifers (all in standing estrus) had conception rate of 34.2%. Conception rates for female in vitro produced embryos were lower ($P < 0.005$) than timed artificial insemination in cows and heifers (24.3% and 36.1% respectively). For the last 124 embryo transfers, GnRH (100μg, IM) was randomly administered recipients immediately after embryo transfer. Farm, GnRH, embryo sire, and season had significant effects on conception rate. To date 28 full term calves have been born; 89% were female. Mean lifetime net merit of donor cows was $\$122 \pm 17$, while that of recipients was $\$130 \pm 13$. Therefore, additional replacement heifers can be produced using selected cull cows as donors, with little or no adverse effect on genetic merit of the herd. These results suggest that in vitro production has promise as an early system for utilizing sexed semen in dairy cattle breeding programs. However models of implementation should continually be investigated, a working model will be beneficial to the dairy industry.

Key Words: Sex-Sorted Sperm, In Vitro Production, Holstein Cattle

428 Effect of clinical mastitis and other diseases on reproductive performance of Holstein cows. F. Frago¹, A. Ahmadzadeh*¹, B. Shafii¹, J. C. Dalton², M. A. McGuire¹, and W. J. Price¹, ¹*University of Idaho, Moscow*, ²*University of Idaho, Caldwell Research & Extension Center, Caldwell.*

This study investigated the effect of clinical mastitis and its interaction with other diseases on reproductive performance of lactating Holstein cattle. Data were collected from cows that calved between June 2001 and October 2003. Retrospectively, cows (n=963) were divided into four groups: clinical mastitis with other diseases (group 1), clinical mastitis only (group 2), other diseases only (group 3), and healthy cows (group 4). Days in milk at first service (DIMFS), services per conception (S/C), days open (DO), and proportion of cows that remained open by 220 DIM were analyzed. Groups 1 and 2 had higher ($P < 0.05$) S/C compared to group 4 (2.8 ± 0.4 and 2.1 ± 0.1 vs. 1.6 ± 0.1 , respectively). Moreover, groups 1 and 2 had higher ($P < 0.05$) DO compared to group 4 (155 ± 15 and 107 ± 5 vs. 88 ± 2 , respectively). Based on non-linear exponential decay model, the rate by which animals became pregnant over time was lower ($P < 0.05$) for groups 1, 2, and 3 compared to group 4. Moreover, the proportion of cows that remained open by 220 DIM was higher ($P < 0.05$) in groups 1, 2, and 3 compared to group 4. There was no difference in DIMFS among groups possibly due to programmed breeding. Mastitis affected ($P < 0.05$) S/C and DO only when clinical mastitis occurred after 105 DIM. Time of mastitis occurrence had no effect on DIMFS. Results suggest that reproductive efficiency was decreased by the presence of clinical mastitis in that a greater proportion of cows with mastitis remained non-pregnant over time. Furthermore, the negative effects were exacerbated when cows experienced both clinical mastitis and other diseases.

Key Words: Clinical Mastitis and Other Diseases, Reproductive Performance, Dairy Cow

429 Use of audible Doppler and B Mode ultrasonography to monitor fetal heart rate of hair sheep in the tropics. R. W. Godfrey*¹, L. Larsen¹, A. J. Weis¹, and S. T. Willard², ¹University of the Virgin Islands, Agricultural Experiment Station, Kingshill, VI, ²Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State.

There is little information available on the fetal development of hair sheep in a tropical environment. The objective of this study was to compare measurements of crown-rump length (CRL) and fetal heart rate (FHR) throughout gestation using B-mode and Doppler ultrasonography in hair sheep. St Croix White, Barbados Blackbelly and Dorper X St. Croix White ewes (n = 54) were bred to St Croix White, Dorper, Barbados Blackbelly and Dorper X St. Croix White rams. Fetal measurements were collected weekly starting 28 d after a successful mating. Linear array B-mode ultrasonography (5 and 7.5 mHz) was used to measure CRL and visual FHR and Doppler ultrasonography was used to measure audio FHR. Due to the size of the fetus CRL was not measurable after 42 d of gestation and visual FHR was not measurable after 70 d. Audio FHR was not consistently measurable before 35 d but could be measured through 140 d of gestation. There was no effect ($P > 0.10$) of breed of dam or sire on CRL or FHR. Single lambs had higher CRL ($P < 0.01$) than twin or triplet lambs at d 35 and 42 of gestation. There was no difference ($P > 0.10$) in visual or audio FHR between single, twin and triplet lambs. Visual FHR was higher ($P < 0.09$) than audio FHR at 28, 42 and 49 d of gestation. Audio FHR and days of gestation of singles, twins and triplets had a linear relationship ($y = 255.44 - 0.392(x)$, $r^2 = 0.15$). Crown-rump length and days of gestation of singles, twins and triplets had a linear relationship ($y = -3.43 + 0.17(x)$, $r^2 = 0.59$). The relationship between days of gestation and visual FHR of single, twin and triplet lambs was best described by a cubic equation ($y = -531.19 + 39.56(x) - 0.62(x^2) + 0.002(x^3)$, $r^2 = 0.37$). These results indicate that FHR can be monitored using Doppler ultrasonography for a longer period of time during gestation in hair sheep than either visual FHR or CRL measured by B-mode ultrasonography.

Key Words: Sheep, Ultrasound, Fetus

430 Effect of time of feed delivery on the feeding and lying behavior of lactating dairy cows. T. J. DeVries* and M. A. G. von Keyserlingk, *The University of British Columbia, Vancouver, BC, Canada.*

Feeding activity of group-housed dairy cows is highest during the day, with peak feeding times occurring in the morning and late afternoon immediately after milking and delivery of fresh feed. What is unclear is whether it is the return from milking or delivery of fresh feed that has the greatest effect on stimulating cows to feed. The objectives of this experiment were to determine: 1) which of these management practices has the greater ability to stimulate dairy cattle to go to the feed alley, and 2) the effect of moving the time of feed delivery away from milking on the feeding and lying behavior of dairy cows. These objectives were tested by separating feeding and milking times, and monitoring the changes in feeding and lying behavior of free stall housed cows. Forty-eight lactating Holstein cows were subjected to each of two treatments in a 2 x 2 cross-over design replicated over time. The treatments were: 1) milking and feeding time coinciding, and 2) feeding 6 h post milking. Cows were milked twice daily at 0500 h and 1700 h. Time-lapse video was used to quantify the lying time of the cows and an electronic feed alley monitoring system was used to monitor the feeding behavior of the cows. When animals were fed 6 h post milking, they increased ($P = 0.02$) their daily feeding time by 12.5%. This change was predominantly driven by a 26% decrease ($P = 0.006$) in the feeding time during the first hour post-milking and a 82% increase ($P = 0.007$) in feeding time during the 60 min following the delivery of fresh feed. Feeding 6 h post milking did not change the daily lying time of the cows ($P = 0.9$), however, cows that did not have fresh feed upon return from milking lay down 20 min sooner ($P < 0.001$) after the return from milking. These results indicate that the delivery of fresh feed has a greater impact on stimulating cows to go to the feed alley than does the return from milking. Additionally, these results indicate that feeding and lying behavior of dairy cows are affected by changes in feeding management.

Key Words: Feeding Time, Feeding Behavior, Dairy Cows

431 Impacts of grouping and space during gestation on body-condition and lesion scores and performance of sows. J. L. Salak-Johnson*, S. R. Neikamp, S. E. Curtis, and S. L. Rodriguez-Zas, *Department of Animal Sciences, University of Illinois, Urbana.*

Knowledge of impacts of grouping and floor space treatment during gestation on sow state-of-being and performance is limited. Objectives were to determine effects of individual (crate) vs group (pen) housing and optimal space allowance for grouped dry sows based on state-of-being and performance. At d27 of gestation, 5 sows per treatment were allocated to crate or group pen. Space in 3 pen treatments was 15, 25, or 35 ft²/sow, respectively. Sows in 6 replicates over 2 parities (n=120) were evaluated. Body condition (BCS) and lesions (LS) scores, health/injury, and lameness were assessed every 3 d the first 3 wk then weekly, thereafter. Productive performance was based on BW gain, backfat (BF) and farrowing data. Many significant treatment, day, parity, and interaction effects on performance occurred, but only treatment effects and linear and quadratic contrasts are reported. Overall, treatment affected BCS and LS ($P < 0.0001$); BCS was highest ($P < 0.0001$) in crated sows. Crated sows also had lower ($P < 0.0001$) LS regardless of body location. In grouped sows, there were many significant linear and quadratic contrasts. Grouped sows at 15 ft²/sow had higher ($P < 0.001$) LS at ears, head, neck, shoulder, back, rear, perineum-vulva, side than sows grouped at 25 or 35 ft²/sow that typically did not differ. Sows grouped at 35 ft²/sow had higher ($P < 0.001$) BCS than those at 15ft²/sow. Overall, treatment affected BW and BF ($P < 0.0001$); grouped sows at 25 and 35 ft²/sow were heavier and had deeper BF than other sows. Crated sows weaned fewer ($P < 0.02$) pigs than did grouped sows at 35 ft²/sow. There were no overall treatment effects on total pigs born and born alive, or various litter performance measures, but there were quadratic trends among pen treatments ($P = 0.05$). Sows at 25 ft²/sow had smaller litters, pigs of lower birth wt and fewer weaned than those at 35 ft²/sow. So, both grouping sows and space allowance during gestation influenced numerous measures of sow and litter performance.

Key Words: Sow, Gestation, Housing

432 Relationships between measures of temperament and carcass traits in feedlot steers. R. C. Vann*¹, J. C. Paschal², and R. D. Randel³, ¹MAFES-Brown Loam Experiment Station, Raymond, MS, ²TAMU-Cooperative Extension Service, Corpus Christi, TX, ³TAMU-Texas Agricultural Research and Extension Center, Overton, TX.

The objectives of this study were to evaluate effects of exit velocity (EV, m/s), chute temperament score (CS; 1=calm, no movement to 5=jumping and rearing; highly agitated) and pen temperament score (PS; 1=non-aggressive, not excited by humans to 5=aggressive, runs into fences and at humans if approached) and measure relationships between EV, CS and PS taken at two times near weaning (T1=21 d after weaning and T2=90 d later) with carcass traits and Warner-Bratzler shear force (WBS) values in feedlot steers. Crossbred steers (n=58) were assigned a PS, calves were weighed and assigned a CS, restrained in a cattle restraint chute then released and time recorded to travel 1.83 m. Sire consisted of one Brangus and several Angus sires. Least square means were obtained from PROC Mixed with main effects of sire breed, harvest date and age of dam. Sire breed was not a significant source of variation for EV, PS, CS, or carcass traits of longissimus muscle area (LMA), and back fat (BF); however, Brangus-sired steers had greater intramuscular fat (IMF; $P < 0.06$) at weaning and greater carcass longissimus muscle area per hundred weight (LMACWT; $P = 0.03$) and a higher USDA Yield grade ($P < 0.05$). The r between EV and PS at T2 was 0.61 ($P < 0.001$). The r between EV at T1 and WBS was 0.28 ($P < 0.03$) and EV at T2 and WBS was 0.34 ($P < 0.0095$). The r between EV and CS at T2 was 0.43 ($P < 0.008$). The r between PS at T1 and WBS was 0.24 ($P < 0.07$) and at T2 was 0.35 ($P < 0.008$). The regression coefficients between EV and WBS at T1 was 0.37 ($P < 0.04$) and at T2 was 0.57 ($P < 0.0095$) and PS and WBS at T1 was 0.39 ($P < 0.07$) and at T2 was 0.47 ($P < 0.008$). In conclusion, sire breed was not a significant source of variation in exit velocity. As exit velocity and pen score increased WBS values also increased.

Key Words: Feedlot Steers, Temperament, Carcass

433 Temperament alters adrenal response to exogenous ACTH in Brahman heifers. K. O. Curley, Jr.^{1,2}, D. A. Neuendorff², A. W. Lewis², J. J. Cleere², T. H. Welsh, Jr.¹, and R. D. Randel², ¹Texas Agricultural Experiment Station, College Station, ²Texas Agricultural Experiment Station, Overton.

The objective of this study was to compare adrenal responsiveness to stimulation with exogenous ACTH, in calm and temperamental heifers. Two-year old, spring born Brahman heifers comprised the two temperament groups that were selected using exit velocity (EV). The calm (C) and temperamental (T) groups consisted of the 6 slowest (EV=1.05±.05 m/sec) and 6 fastest (EV=3.14±0.22 m/sec) two-year old heifers within the herd. Blood samples were collected via indwelling jugular cannula for 6h pre- and 6h post- administration of ACTH (0.1 IU/kg BW). Sampling intervals were 15min throughout the 12h except for the final 180min; when the sampling intervals were 30min. Serum cortisol (CS) concentrations were determined via RIA. Pearson correlation coefficients and ANOVA were used for statistical comparisons. Basal CS, determined as the mean concentration (ng/mL) within the 1h period prior

to ACTH challenge, was correlated to EV (r=.87; P<.001) and differed (P<.001) between temperament groups (C=4.5±.7 and T=18.7±2.9). Following ACTH challenge, both peak CS and time to reach peak CS did not differ between temperament groups. Temperament influenced (P<.001) the increase, induced by the ACTH challenge, from basal CS (C=1375±215 and T=310±94%). A negative correlation was found between EV and % increase in CS (r=-.83; P<.001) increase. Time to return to basal CS was also influenced (P<.001) by temperament group as C took longer than T heifers (C=268±10 and T=154±18min). The area under the curve following the return to basal CS was not influenced by temperament (C=7548±644 and T=8464±428ng*min/mL), indicating that the CS concentrations in the temperamental heifers continued to decrease below basal concentrations. As poor temperament relates to increased basal adrenal activity and muted responsiveness to pharmacological stimulus, temperament does affect stress mechanisms. Exit velocity can be used as an indicator of temperament and predictor of adrenal response to ACTH.

Key Words: Temperament, ACTH Challenge, Exit Velocity

PSA - Environment and Management: Layer Management

434 The impact of layer dietary threonine levels on egg component yield, composition, and functionality. P. R. Niemeier*, C. D. Coufal, and J. B. Carey, Texas A&M University, College Station.

Over 20 weeks, one hundred 35 week old Single Comb White Leghorn laying hens were housed individually in an open sided laying facility with groups of 5 hens sharing access to a common feed trough. A typical layer diet (diet A) containing 0.56% threonine was fed to control hens. Four experimental diets containing additional levels of threonine were fed for 18 weeks. Diets B, C, D, E, contained threonine at levels of 0.66%, 0.76%, 0.86%, and 0.96% respectively. Egg samples were analyzed for egg weight, shell strength, and yolk and albumen yield, protein content, solids, and functionality. Albumen and yolk were kept separate and pooled by nutritional treatment, homogenized and analyzed for protein content and solids. Eggs were sampled at weeks 3, 10, and 16 for angel and sponge cake. Yolk and albumen were separated and pooled by nutritional treatment to make three replicates each of sponge and angel food cakes. Results were recorded by rapeseed displacement. Cake samples were cored, five cores per cake and subjected to double compression on the Instron Universal Testing machine. Cakes were measured for hardness, cohesiveness, springiness, gumminess, and chewiness. Yolk protein content was found to be significantly higher in diets C, D, and E, when compared to diets A and B. Yolk solids showed no significant differences over the dietary treatments. Sponge cake rapeseed displacement yielded no differences among diets. Albumen protein content was found to be significant higher in diets C and E when compared to the other diets. Diet E was found to have significantly higher albumen solids and angel cake rapeseed displacement when compared to the other dietary treatments. These data clearly indicate a potentially important impact of threonine nutrition of laying hens on LE yield, composition, and functionality.

Key Words: Threonine, Liquid Eggs, Egg Composition

435 Single and combined effects of yeast cell wall residue and Sel-Plex® on production and egg quality of laying hens. V. G. Stanley*¹, W. F. Krueger², and A. E. Sefton³, ¹Prairie View A&M University, Prairie View, ²Texas A&M University, College Station, ³Alltech, Guelph, ON, Canada.

The objectives of the study were to examine the effects of yeast cell wall residue (Bio-Mos) and Sel-Plex, single and combined on egg production and egg quality from 37-wk-old White Leghorn hens for 4 wk in a completely randomized designed experiment. Hens were reared in cages, 2 hens per cage, and fed the same corn-soybean based layer diet, supplemented with either Bio-Mos (2 kg/ton) or Sel-Plex (1 lb/kg) and combined with 16% CP, 2,800 kcal ME/kg, 3.5% Ca and .6% P. Hen-day egg production from the Sel-Plex-fed hens was significantly higher (P<.05) than the control (88 vs 81%) and Bio-Mos (83.2%). Egg production of the Bio-Mos plus Sel-Plex-fed hens was also significantly higher (90%) than the control (81.4%). Eggs from the Sel-Plex-fed hens weighed significantly more (68.13 g), had heavier yolks (31.9 g) and albumen (59.8 g), compared to the control [63.20%, 18.12 g (28.7%),

and 35.03 g (55.4%), respectively]. Sel-Plex plus Bio-Mos-fed hens produced yolk (20.68 g) and albumen (39.02 g) significantly heavier than control (18.12% and 35.51%, respectively). Eggs from the Bio-Mos-fed hens were significantly heavier than the control (65.41g vs 63.21g). However, yolk and albumen weights from the Bio-Mos-fed hens [19.42g (29.7%) and 35.91g(54.9%), respectively] did not differ significantly from the control [18.12g (28.7%) and 35.51g (56.2%), respectively]. Hens fed Bio-Mos supplemented-feed had significantly larger eggs (65.41g), yolk [19.38 g (29.6%)] and albumen weight [35.93g (54.93%)] compared to the control [63.14g, 18.07g (28.62%), 35.47g (56.18%), respectively]. Cholesterol concentration per gram of whole egg was significantly lower for the Sel-Plex-fed hens (193.2 mg/dL) compared to the control (236.1 mg/dL). Egg cholesterol concentration from the Bio-Mos plus Sel-Plex-fed hens was also significantly lower (211.2 mg/dL) than the control (236.1 mg/dL). The results suggested that Sel-Plex had beneficial effects on egg production, egg size, and egg cholesterol concentration and there appears to be a synergistic effect of Bio-Mos and Sel-Plex on egg production.

Key Words: Sel-Plex, Bio-Mos, Laying hens

436 Beak trimming of Leghorn pullets 2: Healing and beak re-growth. C. B. Annett*, K. Schwean-Lardner, and H. L. Classen, Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.

Beak trimming of White Leghorn pullets is performed in an attempt to reduce cannibalism and improve performance in the flock. This procedure, when optimally performed, removes the rostral portion of the beak, including the epidermis, innervated and vascularized dermis and bone of the maxilla and mandible. The objective of this study was to observe histological healing and neuroma formation and measure re-growth of beaks from two strains of pullets that had been beak trimmed at the hatchery, or trimmed on farm at 10d or 35d of age. Six beaks (2 trimmed of each strain and 1 each of untrimmed) were collected at 1d, 10d, 30d and 210d post trim and placed in 10% buffered formalin. Following fixation, beaks were trimmed sagittally and the medial aspect trimmed to 3-5 mm, mounted and stained with haematoxylin & eosin for histological examination. Healing was rated on a graded scale of 1 (no healing) to 7 (no lesions). At 2d, 86d and 43 wk of age, Vernier calipers were used to measure beak length from the rostral nares to the beak tip in 40 birds per treatment per strain. Data were analyzed as a 2 X 4 factorial analysis, with Duncans Multiple Range Test separating means when ANOVA was significant. No healing was seen in any of the treatment groups at 1d post trim. At 10d post-trim, beaks of pullets trimmed at the hatchery had a significantly improved healing score (4.25) compared to pullets that had been beak trimmed at 10d (1.25) and 35d (1.00) of age, however, by 30d post-trim healing between groups was not different (5.75, 5.50 and 5.00, respectively). Beaks were considered healed at 210d post-trim (6.00, 6.00, 6.00). Neuromas were not identified in any of the beaks examined. There were significant differences in beak length between all groups (untrimmed: 17.7 mm; 0d: 13.5 mm; 10d: 11.7; and 35d: 16.1mm) when measured at 43 wk of

age. In conclusion, there is faster healing and less re-growth of beaks when pullets are beak-trimmed at 0d or 10d of age compared to pullets beak-trimmed at 35d of age.

Key Words: Beak Trimming, Neuroma, Age

437 Ammonia emissions of commercial broilers from 0-42 days of age. L. Mitran*¹, J. Harter-Dennis¹, J. Meisinger², and J. Timmons¹, *Department of Agriculture and Natural Sciences, University of Maryland Eastern Shore, Princess Anne, ²USDA-ARS.*

An experiment was conducted to quantify the rate of ammonia (NH₃) emission from commercial broilers. This research is a part of a larger project to determine the total N budget of broilers. Six environmentally controlled chambers (37.2 m²) equipped with automatic feeding and watering systems were used. Pooled used wood shaving/sawdust litter was thoroughly mixed, weighed and equally distributed into the chambers. Five hundred one-day old birds (250 males, 250 females) were placed per chamber and raised for 42 days. Samples of litter, feed and birds were collected at the beginning, the end and at every feed change during the trial to determine the nitrogen content. A known percentage of the exhausted air was circulated through a weak acid solution to collect ammonia which was later determined using a QuikChem[®] 8000 Automated Ion Analyzer (QuikChem[®] Method 10-107-06-2-J). Ventilation rates were accurately estimated using an Alnor Electronic Balometer. Mean daily ammonia emissions ranged from 0.13 to 0.77g (NH₃-N)/b/d, with a mean of 0.36g NH₃-N/b/d and a coefficient of variation (CV) of 7.6%. Ammonia emissions were relatively constant (<.25 g/b/d) during the early growth period (0-17 days) followed by a linear increase from 18-42 days of age. The majority of NH₃-N(81%) was emitted from 18-42 days of age. This data may aid in the formulation of meaningful regulations and future research will also aid in the development of new management practices to reduce the emission of ammonia.

Key Words: Broilers, Nitrogen, Ammonia

438 Beak Trimming of Leghorn Pullets 3: Behaviour and welfare effects. K. Schwan-Lardner*, H. L. Classen, and C. B. Annett, *Department of Animal and Poultry Science, University of Saskatchewan.*

Beak trimming is controversial because of the beneficial reduction in cannibalism and the proposed detrimental pain associated with the procedure. The objective of this study was to determine if age at trimming had an effect on welfare as judged by behaviour or associated traits. White Leghorn pullets (2 strains - 480 each) were assigned to four treatments: untrimmed (C), hatchery trim (0d), or farm trimmed 10d or 35d of age. Pullets were housed in floor pens (40 per pen) to 17 wks of age. Behaviour was monitored (scan samples) at 0, 7, 14, 21 and 28d post trim (PT). At 16wk of age, tonic immobility was tested on 8 pullets per strain x treatment. Adult birds were housed in cages (6 replications of 15 birds per strain x treatment), and behaviour was monitored (focal birds) at 34 wk of age. Feather cover was scored at 58 wk of age. A 2 x 2 factorial analysis was used to analyze pullet behaviour data, and a 2 x 4 factorial analysis used for all other data. 0d birds pecked less at 1d PT, had fewer birds at the feeder 21d PT, and had more birds performing inactive standing 28d PT than C birds. Birds trimmed at 10d differed from C birds with more inactive standing (0, 7, and 21d PT), less time at the feeder (14, 21d PT), and less litter pecking (7, 14d PT). As compared to C birds, 35d trimmed birds were rested more (0d PT), spent more time inactive standing and less time feeding (0,7, 14d PT), with fewer birds at the drinkers and preening (0d PT). At 28d PT, C showed higher frequency of aggressive pecking compared to 35d. Adult birds behaved similarly. Pullets trimmed at 10d and 35d of age behaved differently for a longer period of time but did not show evidence of chronic pain. Tonic immobility comparisons (apriori contrasts) of 0d and 10d vs C showed longer latency to upright in C (P=0.09), suggesting a higher fear level. Feather cover was best on 0d and 10d and poorest on C. Trimming at 0, 10 or 35d caused no long term effect on welfare, but because of speed of beak healing and efficacy of trim, 0 and 10d may be preferable.

Key Words: Behaviour, Fear, Feather Cover

439 Effects of bill-trimming on the welfare of muscovy ducks. L. Gustafson*¹, H.-W. Cheng², E. Pajor², and J. Mench¹, ¹*University of California, Davis,* ²*Purdue University, West Lafayette, IN.*

Studies have shown that beak-trimmed chickens may show behavioral and physiological indicators of pain post-trim, but there is little information on the effects of bill-trimming on ducks. Muscovy ducks (N=96) were housed in mixed-sex pens containing 16 birds (8 per sex), with three replicate pens per treatment. One half of the birds were trimmed (TRIM) using secateurs at 20 days post-hatch, while the other half were untrimmed controls (CONT). The average length removed from the upper bill was .51cm, or 21.1% of the bill length from nares to tip. Two ducks/sex/treatment were randomly selected as focal birds for behavioral observations, which were conducted immediately post-trim and then at 3-day intervals. The frequency and duration of all behaviors was recorded using 15-min focal animal samples until age 68 days; all birds were weighed weekly. Two observation sessions/pen/week were conducted between 0900-1100 and 1200-1500. In the days immediately post-trim, CON ducks spent 33% of their time performing bill-related behaviors (preening, feeding, drinking, exploratory pecking), whereas TRIM ducks spent only 19% of their time performing such behaviors, a marginally significant difference (p=.063). This difference decreased by one week post-trim (CON 36.5%, TRIM 26.5%; p=0.14). There were no sex differences in behavior. By 4 days post-trim there were no significant (p=0.24) differences in weight between treatments; the average weights of CON and TRIM males were 900g and 640g, respectively, while those of CON and TRIM females were 760g and 720g. By 67 days, the lower bill of TRIM was on average only 11.9% longer than the top bill and there was also evidence of feather pecking, indicating substantial bill re-growth. Our behavioral data suggest that there is probably acute pain associated with trimming, but that it is not sufficiently severe to have marked effects on feed intake. The heads of the focal birds were collected during processing for morphological analysis of the bills. TRIM ducks had scar tissue near the beak stump; bills are currently being examined for evidence of neuromas, which are considered indicators of chronic pain.

Key Words: Bill-Trimming, Welfare

440 Effects of top-dressing recycled broiler litter on nitrogen mass balance. C. D. Coufal*, C. Chavez, P. L. Niemeyer, and J. B. Carey, *Texas A&M University, College Station.*

An experiment was conducted to access the effects of top-dressing recycled broiler on the nitrogen mass balance of a broiler grow-out facility. Six pens were used to rear five (flocks 10-14) consecutive flocks of broilers to 6 weeks of age. The bedding material in the pens was recycled rice hull broiler litter which had been used previously for 9 consecutive broiler flocks. Three pens received no litter treatment (control), while three pens were top-dressed (treated) with a thin layer (1-2 cm) of new rice hulls before each flock of birds was placed. A total of 840 broilers were used for each flock (420 bds/trmt.). Total nitrogen content of day-old chicks and all feeds was calculated as the total mass of nitrogen entering the facility. Nitrogen not accounted for from analysis of litter, caked litter, broiler carcasses and mortality was assumed to be lost from the facility (volatilized). Seasonal effects were observed regarding percent nitrogen loss from the facility when treatment was not considered. Nitrogen loss was significantly (P<0.05) higher in flocks 13 and 14 (warmer months), 26.0 and 35.5%, respectively, compared to flocks 10, 11 and 12 (cooler months), 16.7, 8.8 and 17.7%, respectively. Percent of total nitrogen partitioned into the caked litter for all flocks was significant less for the treated (4.1%) versus control (7.7%) pens due to decreased caked litter production in the treated pens. Percent of total nitrogen lost due to volatilization (ammonia) was significantly greater for treated pens compared to the controls in flocks 10 and 12, but was lower flocks 11 and 13. However, the difference in nitrogen loss in flocks 10 and 12 was of greater magnitude than flocks 11 and 13. Carbon analysis of litter samples showed increased C:N for top-dressed pens for all flocks, with flocks 10, 12 and 13 being significantly greater. Results of this experiment show that seasonality greatly influences nitrogen loss from the broiler rearing facility and that top-dressing of litter can increase the C:N in litter, which tends to increase nitrogen loss.

Key Words: Broilers, Nitrogen, Mass Balance

441 In house composting of layer manure for pest control. G. P. Martin*, P. H. Patterson, and C. A. B. Meyers, *The Pennsylvania State University, University Park.*

An experiment was conducted to determine the effects of mechanical pile turning/mixing with the addition of hardwood shavings to manure in deep pit layer housing. A commercial six row deep-pit poultry house were assigned treatments of : two rows each with 357.5 kg shavings base-mixed (treatment A), two rows each with 725.9 kg shavings-mixed (B), one row mixed without added shavings (T), and one row without mixing or added shavings (NT). Each treatment row was 21m long with mixing of designated rows by a belt stacking composter every 3d (approximately). Additional manure was added by the mature layers over the 51d observational period. Temperature levels in the manure were significantly greater for all treatments that were mixed with averages over the period of 50.9°C (A), 51.0 (B), 50.2 (T), 41.7 (NT). Percent moisture ranges at 51d were: 37.0(T), 37.1(B), 42.0(A), 48.3(NT). The practice of in house composting with mechanical manipulation of the pit manure may serve as a main component to an IPM program in commercial poultry housing.

Key Words: IPM, Manure, Mechanical Composting

977 Beak trimming of Leghorn pullets 1: Production effects. K. Schwan-Lardner*, H. L. Classen, and C. B. Annett, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

Strains of White Leghorn pullets are available for commercial production that may benefit from beak trimming with regards to a reduction

in cannibalism and or an improvement in feed efficiency. The objective of this work was to study the impact of age of mild beak trimming on pullet growth and hen performance. Pullets (120 of each of two strains) were designated to one of four trimming treatments: control or untrimmed (C), trim at commercial hatchery using a Zoo-Technique Robotics Machine (0d), or trim on farm at 10d or at 35d of age. Hens (90 per strain x treatment) were housed in battery cages at 17 wk of age, and photostimulated at 18wk (6 replications per strain x treatment group with 5 cages of 3 birds or 15 hens per replication). Data were analyzed as a 2 x 4 factorial analysis, with Duncans Multiple Range Test separating means when ANOVA was significant. Birds trimmed at 10 and 35d were lighter at 57d than control pullets (kg: C=0.649^A, 0d=0.647^{AB}, 10d=0.632^C, 35d=0.635^{BC}). By 85d of age and through to the termination of the experiment, body weights of all pullets were not different. Total hen day production was lower (P=0.0629) for C birds (%: C=82.3, 0d 83.3, 10d 83.7, 35d 84.4), but hen housed production did not differ. Feed intake was not affected by trimming treatments (g/hen/d: C=110.3, 0d=108.0, 10d=107.7, 35d=108.5) but because of the higher egg production and the numeric difference in feed intake, feed efficiency was poorer for untrimmed birds (TFEM: C=2.27^A, 0d=2.20^B, 10d=2.19^B, 35d=2.20^B; TFDE: C=1.61^A, 0d=1.56^B, 10d=1.54^B, 35d=1.54^B). Mortality was not different due to treatment (%: C=2.22, 0d=3.89, 10d=3.89, 35d=5.00). Cannibalism was only found in untrimmed birds, but levels were not significantly different from trimmed birds (C=0.56, 0d=0, 10d=0, 35d=0). Trimming the beaks of pullets at a young age (0, 10 or 35d) had minor effects on pullet growth and improved feed efficiency and egg production in White Leghorn birds.

442 Direct and correlated response from selection for phytate phosphorus bioavailability in a randombred chicken population. W. Zhang, S. E. Aggrey*, R. I. Bakalli, G. M. Pesti, and H. M. Edwards, Jr., *University of Georgia, Athens.*

This study was undertaken to evaluate the direct and correlated response to a 3 generation divergent selection for phytate phosphorus bioavailability (PBA). Individual 4-week body weight (BW), BW gain (BWG), feed consumption (FC) during a 3 d period, and feed conversion ratio (FCR) were studied as correlated responses to directed selection for PBA in Athens-Canadian randombred population. There was a significant difference between the high (H) and low (L) lines for PBA. The phenotypic difference in BW between the high and low lines at generation 3 was 26 g (P<0.01). The chickens in the low line had higher BW than the high line. There were significant (P<0.05) correlated responses in BWG, FC and FCR. The line differences in the correlated traits were due primarily to changes in the H line than the L line. The correlated responses in BW, BWG and FC were mainly due to the genetic change that had occurred in H line, and little genetic change occurred in L line across generations. The mixed model procedure with an animal model was used to separate environmental effects from genetic effects in order to establish a genetic trend for the correlated traits across the generations. Comparison between phenotypic and genetic trends indicated that, the selection experiment was influenced by environmental variation in the first two generation. It was thought that changes in PBA could be related to an internal homeostatic mechanism that limits genetic progress in the L line. There is a lower threshold of phosphorus in the diet that has to be met for chicks to feed. This provides an indication that utilization of phytate phosphorus will be limited in the L line, and as a result changes in correlated traits in this line would also be limited.

Key Words: Selection, Phytate Phosphorus Bioavailability, Chicken

443 Allele frequencies of genes associated with feed efficiency traits in selected and unselected population in a commercial broiler line. P. Sharma*, W. Bottje, and R. Okimoto, *University of Arkansas, Fayetteville.*

Various polymorphisms were identified in coding and noncoding region of genes studied in association with the feed efficiency traits. These genes included Uncoupling protein gene (UCP), Melanocortin 4 receptor (MC4R), Melanocortin 3 receptor (MC3R), and proopiomelanocortin gene (POMC). A PCR-RFLP test was developed to type the Ala118Val

polymorphism in UCP gene. Similar PCR-RFLP tests were developed for Ser76Leu polymorphism in MC4R gene and Pro61Leu polymorphism in POMC gene. UCP Val 118 allele was found to be associated with the higher feed efficiency and MC4R Leu 76 was found to be associated with the higher body weight in the selected population studied. Two populations from the same line were tested for above polymorphisms. The birds that are typed for feed efficiency are a selected population. Individuals selected based on several defined traits pass into feed efficiency trials. The population of 400 birds chosen prior to the feed efficiency selection process was screened to study the distribution and frequency of the detected polymorphisms and alleles in the unselected population. The Val118 UCP allele was found at a frequency of 0.1 among 44 birds of the selected population and at the same frequency of 0.1 in the unselected population of 400 birds. A difference in the frequency of Leu76 MC4R allele was found with the frequency of 0.435 among the selected 44 birds and 0.359 in the unselected 100 birds tested so far but the difference was not found to be significant.

Key Words: Feed Efficiency, Polymorphism, Allele Frequency

444 Quantitative trait loci affecting bone mineral density in the chicken. M. A. Schreiweis*, P. Y. Hester, and D. E. Moody, *Purdue University, West Lafayette, IN.*

Osteoporosis is a significant problem in egg-laying strains of hens. Bone fractures caused by the loss of structural bone have resulted in a loss of markets for the spent hens and created welfare concerns. The objective of the current study was to identify quantitative trait loci (QTL) associated with bone mineral density (BMD) in a chicken resource population. Layer (White Leghorn hens) and broiler (Cobb roosters) lines were crossed to generate an F2 population of 509 hens over seven hatches. Phenotypic data collected from hens in the resource population included BW at 6, 35, and 55 wk of age as well as the BMD of the left humerus and tibia at 35 and 55 wk of age. The BMD was determined using a Norland pDexa X-ray bone densitometer. Genotypes of 25 microsatellite markers were determined on chromosomes 1 and 3 using the ABI3700 and ABI Prism Genotyper software. A preliminary regression analysis was conducted using QTL Express. The statistical model included hatch as a fixed effect and additive and dominance effects for putative QTL were fit to a linear model using least squares. Chromosome-wide significance thresholds were empirically determined following 10,000 permutations. Chromosome 1 contained a QTL for humeral BMD at 35

wk of age located at 15cM ($P < 0.05$) expressing significant dominance effects ($P < 0.01$). Chromosome 3 potentially contained two QTL for tibial BMD at 35 wk of age located at 84 and 143cM ($P < 0.01$) and one QTL for 35 wk BW at 147cM ($P < 0.05$). All three QTL on chromosome 3 expressed significant additive effects ($P < 0.01$). The QTL located on chromosomes 1 and 3 explained 2.7 and 4.0% of the residual phenotypic variation for BMD of the humerus and tibia at 35 wk of age, respectively. No QTL were identified on chromosomes 1 and 3 for other traits in the analysis. Identification of additional QTL associated with BMD may facilitate selection of birds for improved bone strength through marker assisted selection. Research supported by Midwest Poultry Consortium and NRI Competitive Grants Program / USDA No. 2002-03394.

445 Molecular characterization of chicken SOCS2 gene. G. Y. Zhou* and F. C. Leung, *Department of Zoology, The University of Hong Kong, Hong Kong, China.*

Suppressor of cytokine signaling 2 (SOCS2) has been demonstrated to involve in postnatal growth in mouse, negatively regulating a wide variety of cytokine signaling like growth hormone and interleukin-6 through the JAK-STAT pathway. In Chicken, using alternative transcriptional starting sites, two transcripts of SOCS2 named variant 1 and variant 2 were discovered by 5' RACE assay. Besides, two SOCS2 proteins encoded by the variants were identified and they are composed of 156 aa and 207 aa, respectively. In order to illustrate its genomic structure, a chicken BAC clone containing the SOCS2 gene was characterized by sequencing. It was found that chicken SOCS2 gene comprises only two exons and one intron, while in human or in mouse, SOCS2 gene consists of three exons and two introns. These differences may reveal the evolutionary relationship between mammals and birds. On the other hand, RT-PCR showed that the two SOCS2 mRNAs were distributed widely in both male and female adult chicken, but the expression levels of them varied from organ to organ. In summary, chicken SOCS2 gene may modulate somatic growth of chicken as shown in mouse and

447 Relative toxicity of gossypol isomers in laying hens. M. M. Lordelo*¹, A. J. Davis¹, M. C. Calhoun², and N. M. Dale¹, ¹*Poultry Science Department, University of Georgia, Athens,* ²*Texas A&M University Research Center, San Angelo.*

Cottonseed meal has been proposed as a protein source for poultry diets, but concern over the presence of the potentially toxic factor, gossypol, has limited its use. Gossypol is a polyphenolic compound that exists as either a positive (+) or negative (-) isomer. An experiment was conducted to determine the relative toxicity of each gossypol isomer in laying hens. Twenty-five individually caged Hy-Line W36 43 wk-old layers were fed a corn/soy diet supplemented with either 0, 200 (+), 400 (+), 200(-) or 400 (-) mg/kg of pure gossypol isomer for 20 d (5 pens /treatment). Feed intake, egg production and egg weight were monitored daily. Birds were weighed on d 1 and d 20. All eggs were individually opened and scored for yolk discoloration using a scale of 0 (no discoloration) through 10 (complete discoloration). Subsequently, yolks were separated for gossypol analysis. At the end of the experiment, tissue samples were collected for determination of gossypol isomer levels. Total egg production was equivalent for birds fed either the control or the (-) isomer diets. Birds fed the (+) isomer, however, had lower ($P < 0.05$) total egg production. After d 10, egg weight was significantly decreased from birds fed either level of the (+) isomer when compared to the control-fed birds. Eggs produced by the layers fed the (+) isomer had severe yolk discoloration. Although average egg yolk discoloration scores were equivalent between birds fed either the control diet or the diets supplemented with the (-) isomer, there were a few eggs with a score of 3 detected for the (-) isomer treatment but not for control treatment. Total feed intake was lower for birds consuming the 400 mg/kg level of (+) isomer when compared to the birds on the other treatments. Final body weights were not different between the controls and the other treatments. Tissue and yolk accumulation of the (+) gossypol isomer was higher than the (-) isomer. Additionally, there was no racemization of the isomers in the tissues and yolks of the laying hens. The results

the physiological relevance among the two isoforms of SOCS2 requires further investigation.

Key Words: SOCS2, Variants, Growth Hormone

446 Molecular cloning and characterization of a broiler small intestine Type IIb sodium phosphate cotransporter gene. F. Yan^{1,4}, C. Ashwell*^{2,3}, and R. Angel¹, ¹*Department of Animal and Avian Sciences, University of Maryland, College Park,* ²*Growth Biology Lab., Animal and Natural Resources Institute, USDA-ARS, Beltsville, MD,* ³*Department of Poultry Science, North Carolina State University, Raleigh,* ⁴*Department of Poultry Science, University of Arkansas, Fayetteville.*

Intestinal absorption and renal resorption play a critical role in overall homeostasis of phosphorus in chickens. Using RNase-Ligase-Mediated Rapid Amplification of cDNA Ends (RLM-RACE) PCR, we have obtained a cDNA from the broiler small intestine, that encodes a type IIb sodium-dependent phosphate transporter. The cDNA has an open reading frame of 2022 base pairs and predicts a protein of 674 amino acids with the calculated molecular mass of approximately 74 kDa. Amino acid hydrophathy predicts eight transmembrane domains, with intracellular NH₂ and COOH termini. The Na/Pi IIb cotransporter has high homology with other type II Na/Pi cotransporters, but low homology with the type I or type III Na/Pi cotransporters. The Na/Pi IIb transporter is located on chicken chromosome 4 at 73.61 Mb where a gene was predicted by the Ensemble database. A microsatellite marker is present within intron 5 of the genomic structure. Northern blot analysis demonstrated the presence of a single mRNA transcript present predominantly in the small intestine with the highest expression in the duodenum, followed by the jejunum and ileum. In situ hybridization indicated that the Na/Pi cotransporter mRNA is expressed throughout the vertical crypt-villus axis of the small intestine. Further study is needed to elucidate its physiological role in the intestinal absorption of phosphate in chickens.

Key Words: Small Intestine, Phosphorus, Absorption

indicate that the (+) gossypol isomer is responsible for the negative impacts associated with feeding cottonseed meal to laying hens.

448 Effect of increased heat processing on phosphorus (P) bioavailability in corn distiller dried grains with solubles (DDGS). C. Martinez Amezcua*, L. E. Markovic, and C. M. Parsons, *Department of Animal Sciences, University of Illinois, Urbana.*

A few previous studies have shown that heat processing may increase the bioavailability of phytate-P in some foodstuffs. Therefore, two chick experiments were conducted to determine the effect of various increased heat processing treatments on bioavailability of P in DDGS. In addition, two precision-fed cecectomized rooster assays were conducted to evaluate the effects of the heat treatments on amino acid digestibility, particularly lysine. For the chick assays, a P-deficient cornstarch-dextrose-soybean meal basal diet containing 0.10% nonphytate phosphorus was formulated. A standard curve was then constructed by adding 0.0, 0.05 and 0.10% P from KH₂PO₄ to the basal diet. For the DDGS treatments, a commercial sample of DDGS was obtained and then subjected to increased heat processing by autoclaving at 124 kPa and 121C or by heating in a drying oven at 121C. The various DDGS samples were then added to the P-deficient basal diet at levels of 7 to 14%. New Hampshire x Columbian male chicks were fed the experimental diets from Day 8 to 22 post-hatch, and growth performance and tibia ash were measured. Bioavailability of P was estimated using the slope-ratio method, where tibia ash was regressed on P intake from KH₂PO₄ or DDGS. In the first experiment, bioavailability of P in DDGS (% of total) was increased ($P < 0.05$) from 75 to 87% by autoclaving for 75 min. In the second chick assay, P bioavailability was significantly increased ($P < 0.05$) by autoclaving for 60 and 80 min, but not for 40 min. The effects of oven drying on P bioavailability were inconsistent. Lysine digestibility of DDGS determined by the cecectomized rooster assay was substantially decreased

by the heat treatments, particularly for autoclaving, which caused large reductions. The results of this study indicated that increased heat processing may increase P bioavailability in DDGS but will likely reduce amino acid digestibility, particularly for lysine.

Key Words: DDGS, Phosphorus, Lysine

449 High protein corn distiller dried grains as a feed ingredient. C. Abe*¹, N. J. Nagle², C. Parsons³, J. Brannon¹, and S. L. Noll¹, ¹University of Minnesota, St. Paul, ²National Bioenergy Center, Golden, CO, ³University of Illinois, Urbana.

Hydrolyzed distillers dried grains (HDG) were obtained from the National Renewable Energy Laboratory. The sample was submitted for determination of proximate components, sugar, starch, amino acid, and minerals. For digestible amino acid determination, cecatomized chicken roosters were used. Growing turkeys were used for the determination of TMEn. HDG was evaluated for feeding value by inclusion into a basal diet at 0, 5, 10, 15, and 20%. The corn-soybean meal based turkey starter diet was formulated to provide similar levels of ME, digestible lysine (lys) and methionine (met), calcium, and phosphorus. Male poult (Large White) were fed a commercial starter diet until 3 d of age. At 3 d of age, they were weighed and assigned into cages such that there was an equivalent cage body weight. Poults were fed the experimental diets to 18 d of age (Ten replicate cages/seven poults/cage). At the end of the trial, two poults per pen were randomly selected, euthanized, and internal organs (spleen, heart, liver, gastrointestinal tract, bursa) weighed. Results (as fed) for ash, DM, fat, fiber, protein, starch and sugars were 1.43, 95.9, 10.7, 3.9, 57.8, 1.6, and 2.0%, respectively. Lys, arginine (arg), tryptophan (trp), threonine (thr), cystine (cys) and met content as % of protein were 1.99, 2.63, 0.34, 3.14, and 2.1%, respectively. Digestibility coefficients of lys, arg, trp, thr, cys and met were 68.1, 79, 64, 75.2, 78.3 and 85.9% respectively. TMEn was 2692±78 kcal/kg as is. There was significant linear decrease ($P<0.01$) at 11 day of age in average daily gain (ADG) and feed intake as HDG level was increased and a cubic effect ($P<0.02$) in ADG during 11 to 18 days. In conclusion, up to 10% of HDG can be included in turkey starter diets although higher levels may be possible after two weeks of age.

450 Mucin dynamics in the chicken gastrointestinal tract. A. Smirnov*, Z. Uni, and D. Sklan, *Hebrew University, Rehovot, Israel.*

The absorptive surface of the small intestine is covered by a layer of mucus secreted by goblet cells which acts a barrier influencing transport between luminal content and epithelial cells. Bacterial lipopolysaccharide, growth-factors, nutrients and nutritional conditions participate in regulation of mucin biosynthesis. Mucin glycoproteins modulate adherence of different bacterial species that have a role in gut health. In this study methods of analysis of mucin dynamics were established and the influence of nutritional manipulations on mucin function in chicks investigated in two different nutritional settings. In the first experiment chicks were starved for 48 hr, and in the second chicks were fed with diets with added antibiotic or probiotic. Mucin mRNA expression, mucin glycoprotein concentration, mucus adherent layer thickness and goblet cell size and numbers were measured in the jejunum. A 371-bp cDNA fragment of the chick small intestine mucin gene was isolated and was 60% homologous to human mucin MUC5AC. Mucin mRNA expression was analyzed by semi-quantitative RT-PCR. mRNA expression increased by 480% and mucin glycoprotein by 216% in the jejunum of starved chicks. Goblet cell size was increased by starvation by 100% in the jejunum. Measuring the thickness of the mucus adherent layer revealed that increased protein synthesis did not result in a thicker mucus layer. On the contrary, the mucus adherent layer exhibited a 36% decrease in jejunum of the starved chicks. This may be explained by a higher rate of mucus layer degradation in starved chicks or by changes in mucin secretion from goblet cells. Feeding antibiotic and probiotic additives changed mucin dynamics, goblet cell morphology, mucin gene expression and mucin glycoprotein concentrations. These changes may be due to alterations in the intestinal microflora. This study has indicated that regulation of mucin production, secretion and turnover in

the chick small intestine is altered by nutritional manipulations. These changes influence mucosal function and defense.

Key Words: Chick, Small Intestine, Mucin

451 Diurnal variations and quantitative determination of the generation of carboxylic acids by microbial fermentation in the crop of the domestic turkey. S. A. Johannsen*¹, M. J. Hensley³, M. A. Rasmussen⁴, R. Griffith³, and C. G. Scanes^{1,2}, ¹Department of Animal Science, Iowa State University, Ames, ²Biomedical Sciences, Iowa State University, Ames, ³Veterinary Microbiology and Preventive Medicine, Iowa State University, Ames, ⁴National Animal Disease Center, Animal Science, Iowa State University, Ames.

The roles of avian crop include storage of ingesta but it may allow fermentation. It has been shown recently in the chicken that carcass contamination can be attributed to bacterial colonization of the crop tissue when the organ ruptures during evisceration. The present studies examine intra-luminal fermentation in the crop of young turkey poults. The following carboxylic acids were detected in the crop contents: formic, acetic, butyric, lactic, valeric, caproic, oxalic, phenyl acetic, succinic and fumaric acids. Unexpectedly, propionic, isobutyric and isovaleric acids were not detectable. At the beginning of the scotophase, there were considerable ingesta in the crop of turkey poults. During the scotophase, there were changes in the amount and characteristics (pH and carboxylic acid concentrations) of the crop contents. A progressive reduction in the contents was observed. Increases in the numbers of lactobacilli during the period of subjective night were observed. The pH of the contents decreased; for example declining from 5.9 one hour after the onset of the scotophase to 5.0 nine hours after the onset of the scotophase in control turkey poults. During the scotophase, there were linear increases the concentration of lactic, valeric and caproic acids (approximately 7 fold increases over 8 hours). There were decreases in the crop concentrations of formic, oxalic and succinic acids during the scotophase. Chronic addition of lactose or *Lactobacillus* sp. to the diet exerted modest effects on the carboxylic acid concentration in the crop contents. These data indicate the importance of microbial fermentation in the crop of poults and provide evidence of diurnal variation. These factors may have an impact upon metabolism and nutrition of the turkey and poultry in general.

Key Words: Turkey, Fermentation, Crop

452 Effects of delayed placement on Villus characteristics and barrier functions of the small intestine of the newly hatched turkey. L. P. Potturi*, J. Patterson, and T. J. Applegate, *Department of Animal Sciences, Purdue University, West Lafayette, IN.*

The objectives of the research were to determine the effect of delayed access to feed, on villus development, bacterial translocation and salmonella attachment potential in turkey poults during the first wk after hatching. Poults were either given ad libitum access to water and feed immediately after hatch (FED), or delayed access to water and feed for 48 h (DLY). In the first study, the FED poults had 50 μ m longer villi, 6.8 μ m wider villi and 5.9 μ m deeper crypts when compared to the DLY poults at 5 d post-feeding ($P<0.05$). The DLY poults had fewer goblet cells per villus when compared to FED poults on 5 d post-feeding ($P=0.016$). The FED poults had a significant increase in the number of proliferating enterocytes in the villus, when compared to DLY poults, on 1, 2, and 5 d post-feeding. Apoptotic labeling was higher in DLY group compared to the FED group on 1, 2 and 5 d post-feeding. In the second study, the DLY poults had higher numbers of aerobic bacteria in the ileal digesta and ileal tissue, when compared to the FED poults on 1 d post-feeding ($P<0.05$). The number of aerobic bacteria translocated to the spleen by 5 d post-feeding was less when compared to 1 d post-feeding ($P\leq 0.05$). The FED and DLY poults challenged with salmonella were not significantly different in the number of salmonella isolated from the ileal tissue. Higher numbers of salmonella were isolated from both the treatment groups on 5 d post-feeding relative to 1 d post-feeding ($P=0.0006$). In conclusion, early access to ad libitum feed in poults stimulated the growth and development of small intestinal villi and their absorptive surface while delayed access to feed resulted in

delayed enterocyte proliferation and greater enterocyte apoptosis during the first wk post-hatch. Delayed placement increased the numbers of aerobic bacteria in the small intestine of poult shortly after hatch.

Key Words: Poult, Delayed Placement, Intestinal Development

453 Effect of dietary amino acid content on intestinal populations of *Clostridium perfringens* in broiler chickens fed high-crude protein diets. D. C. Wilkie*, A. G. Van Kessel, L. J. White, and M. D. Drew, *Dept. of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

Necrotic enteritis is a disease affecting poultry caused by *Clostridium perfringens* and is a concern to producers worldwide. Previous studies have reported that dietary protein has a significant effect on gut *C. perfringens* populations. Thus, a better understanding of the relationship between dietary protein and gut *C. perfringens* populations may result in improved control of this disease. An experiment was performed to examine the effect of dietary amino acid content on intestinal levels of *C. perfringens*. Broiler chickens (N = 192) were fed a non-medicated starter diet (31.5% crude protein) for 14 days after hatching and were orally challenged with 1 mL per day of an overnight culture of *C. perfringens* on days 14-21. On days 14-28 the 2 pens of 12 birds each were fed 1 of 7 diets containing 40% crude protein with fish meal, meat/bone meal, feather meal, corn gluten meal, soy protein concentrate, pea protein concentrate, or potato protein concentrate as the primary protein source. An eighth diet containing 23% crude protein was fed as a control. No clinical necrotic enteritis was observed, however the birds fed fish meal, meat/bone meal, feather meal and potato protein concentrate had significantly higher cecal *C. perfringens* counts than the birds fed corn gluten meal, soy or pea protein concentrates or the control diet (P < 0.05). In the ileum, *C. perfringens* counts in the birds fed fish meal, meat/bone meal and feather meal were significantly higher than in the birds fed corn gluten meal, soy or pea protein concentrates or the control diet (P < 0.05). Correlation analysis was done between the amino acid content of the diets and *C. perfringens* numbers in ileum and cecum. The glycine content of the diets was significantly correlated with *C. perfringens* numbers in ileum (r = 0.923; P < 0.05) and cecum (r = 0.840; P < 0.05). No other significant correlations were observed. The results suggest that the glycine content of diets is an important factor predisposing broilers to the intestinal overgrowth of *C. perfringens* and clinical necrotic enteritis.

Key Words: Clostridium Perfringens, Broiler Chicken, Amino Acid

454 Molecular tracking of *Bifidobacterium animalis* colonization in the gastrointestinal tract of broiler chickens using quantitative real time PCR (qPCR). S. A. Briggs*¹, T. J. Dumonceaux¹, B.G. Goldade¹, J. K. Marshall¹, J.E. Hill², S. M. Hemmingsen², and A. G. Van Kessel¹, ¹University of Saskatchewan, Saskatoon, SK, Canada, ²National Research Council, Saskatoon, SK, Canada.

To evaluate molecular quantification of specific bacteria in the intestine a qPCR assay was developed to enumerate *Bifidobacterium animalis* (ATCC 27536) using PCR primers designed on chaperonin 60 gene sequence, SYBR Green fluorescence detection of PCR product accumulation and a standard curve based on genomic DNA extracted from pure *B. animalis* culture. Primer specificity was confirmed with standard PCR and a panel of genomic DNA from 30 bacterial species, including 7 *Bifidobacterium* spp. Specific amplification of *B. animalis* in a complex background was confirmed by sequencing of PCR products generated from cecal contents. To test the assay in vivo, 216 broiler chickens were arranged in a 2X3 factorial design, such that birds (6 birds/pen) were fed a corn-soy starter diet (CP 20.8% AME 3.1 kcal/g) containing 0, 1.5 or 3% guar gum (GG) and orally gavaged with 10⁸ cells of *B. animalis* or water on days 1, 3, 5, 7 and 9 after hatch. Bifidobacteria(BA), coliforms(CO) and *B. animalis* genomes were enumerated using Beerens agar, MacConkeys agar and the qPCR assay, respectively in ileal and cecal contents collected on days 7, 14 and 21 after hatch. Addition of 1.5 and 3.0 % GG to diets increased (P<0.05) BA in ileum on day 14 and increased BA, CO and *B. animalis* genomes in cecum on all sampling days. Gavage increased (P<0.05) *B. animalis* genomes detected in ileum on day 21 but not days 7 or 14. In cecum, gavage increased (P<0.05) BA detected in all diets on day 7 and in the 0% GG diet on day 21, however, gavage did not affect the number of CO or *B. animalis* genomes in cecum. DNA extracted from only 1 of 15 colonies isolated

from pooled cecal contents cultured on Beerens agar could be amplified with *B. animalis* specific primers. Results demonstrate that qPCR assays can be used to enumerate bacteria in intestinal contents of poultry and offer markedly improved specificity vs. culture-based analysis.

Key Words: Poultry, qPCR, Bifidobacterium

455 The effect of glutamine on growth performance and the development of the gastrointestinal tract and immune system of broilers. S. M. Bartell* and A. B. Batal, *University of Georgia, Athens.*

Two experiments were conducted to evaluate the effect of glutamine (Gln) on growth performance, development of the gastrointestinal tract and immune system. Immediately after hatch six replicate pens of six chicks were randomly assigned to one of the seven (Experiment 1) or five (Experiment 2) dietary treatments for 21 d. On Day 0, 4, 7, 14, and 21 twelve chicks per treatment were sacrificed for thymus, spleen, bursa, duodenum, jejunum, ileum, bile, and blood sample collections and/or weights. In Experiment 1, the effect of 1 or 4% Gln addition to the feed, water, or both was compared to a corn-soybean meal (SBM) control diet. All diets were formulated to be isocaloric and isonitrogenous. Weight gain was significantly (P < 0.05) improved at 4, 14, and 21 d of age when chicks were fed diets with 1% Gln as compared to chicks fed the corn-SBM control (10% average improvement). The addition of 4% Gln to the water depressed (P < 0.05) growth performance through out the 21 d study and appeared to be toxic. There was an advantage of 1% Gln in the feed and water on the spleen and thymus weights. The addition of 4% Gln in the feed resulted in heavier duodenum and jejunum weights but a depression in weight gain. From experiment 1, 1% Gln supplementation to the diet was determined to be ample and most practical. Thus in experiment 2, 1% Gln was fed for 4, 7, 14, or 21 d after which time chicks were fed the corn-SBM control diet. Weight gain was significantly (P < 0.05) improved when chicks were fed 1% Gln as compared to chicks fed the corn-SBM control. The best performance was observed when the chicks were fed the diet with 1% Gln through out the 21 d study. The relative thymus weight of chicks fed diets with 1% Gln was higher than that of chicks fed the corn-SBM diet. In both experiments, concentrations of bile and plasma IgA were increased in the chicks fed diets with 1% Gln for 21 d. Our results indicate that the addition of Gln to the diet of broiler chicks improves growth performance and may stimulate development of the gastrointestinal tract and immune system.

Key Words: Glutamine, Gastrointestinal Tract, Broiler Chicks

456 Feeding a semi-purified diet induced early gut development in young turkey poults. Y. O. Fasina*¹, J. D. Garlich², H. L. Classen³, Z. Uni⁴, P. R. Ferket², and S. R. Mckee¹, ¹Auburn University, Auburn, AL, ²North Carolina State University, Raleigh, ³University of Saskatchewan, Saskatoon, SK, Canada, ⁴Faculty of Agriculture, Hebrew University, Rehovot, Israel.

Delayed access of newly hatched poultry to feed is known to result in higher poult mortality, sub-optimal intestinal development, and subsequent reduction in market weight. Sub-optimal functional maturation of the intestine early in the brooding period is one of the main constraints to optimal early growth of precocial birds (Konarzewski et al., 1990; Ricklefs et al., 1998). We propose that providing a diet that is capable of inducing intestinal maturation early in newly hatched poults is one way of improving early poult performance. Thus, an experiment was conducted to compare the ability of a corn starch-casein-based semi-purified diet (PD) and a conventional corn-soybean meal diet (SBD) to induce early intestinal development and growth in young poults. Each experimental diet contained 0.5 % titanium dioxide as an indigestible marker and was fed to 56 poults in four replicate pens (14 poults per pen) from 0 to 14 days of age. Body weight gain and feed efficiency of birds were recorded on days 7 and 14. Intestinal maturation was assessed by measuring the levels of brush border enzymes (maltase and alkaline phosphatase) on days 7 and 14. Fecal samples were collected during days 5 to 7 and days 12 to 14 of the experiment to evaluate nutrient digestibility. On day 7, although poults fed the SBD digested fat better (p < 0.05) than poults fed the PD, the latter poults had higher (p < 0.05) weight gain, feed efficiency and brush border enzyme levels. However, by day 14, the performance of poults fed the SBD improved such that the SBD treatment was similar or better to the PD treatment in all parameters assessed. It is concluded that the PD is superior to the

SBD in inducing early intestinal development in poults, but this benefit is significantly realized only during the first week of poult life.

457 Dietary lysine response by broilers in two photoperiods. O. C. Aimuwu* and M. S. Lilburn, *The Ohio State University/OARDC, Wooster.*

Within the broiler industry there is a move toward producing heavy broilers for the production of deboned breast meat. The management of heavy broilers typically involves some degree of photoperiod restriction to minimize the incidence of growth related anomalies (i.e. ascites). An experiment was conducted to establish a lysine response range for commercial broilers between 6 and 8 weeks of age. Diets were formulated to contain 0.70 (Control), 0.82, 0.94 and 1.06 percent total lysine. Acid insoluble ash (celite) was included in each diet to allow for ileal digestible lysine determination. Each diet was fed to broilers in four replicate floor pens (n=15 birds per pen) in each of two rooms. The birds in Room A had a 16 hour photoperiod beginning at 4 days of age whereas the birds in Room B had a 22 hour daily photoperiod. In each room, half the birds in each treatment were weighed and processed on days 15 and 16 of the experiment. In addition to body weight and feed conversion (pen basis), the weights of the pectoralis major and minor breast muscles were also recorded. The maximal response to lysine (body weight, breast muscle weight) occurred at 0.94 % total lysine (88% digestible lysine; $P < 0.05$). At the highest level of lysine (1.06 % total lysine, 92% digestible lysine) weight gain declined. There was a significant increase in lysine digestibility as dietary total lysine increased (Dig. Lysine = $60.5 + 29.9 \times (\text{total lysine})$; $r^2 = 0.72$; $P < .0001$). This was most likely due to the increasing proportion of synthetic lysine added as dietary total lysine increased. There were no significant photoperiod effects or diet by photoperiod interactions.

Key Words: Broilers, Digestibility, Lysine

458 A comparison of amino acid digestibility coefficients between chickens and turkeys. O. C. Aimuwu*¹, C. M. Parsons², and M. S. Lilburn¹, ¹*The Ohio State University/OARDC, Wooster*, ²*University of Illinois, Urbana.*

There is a paucity of information on comparative amino acid digestibility coefficients in chickens and turkeys. An ileal digestibility study with turkeys was conducted with five week-old turkey toms. Semi-purified diets were formulated with corn, wheat, soybean meal, meat and bone meal, feathermeal, and fishmeal as the sole sources of dietary protein. Toms were reared in litter floor pens until the beginning of the experiment (35 days) when they were moved into Petersime growing battery cages (3 toms per cage). Each diet was fed to three replicate pens and the experimental period was five days. Birds were killed by cervical dislocation on day 5 and ileal digesta was collected between Meckels diverticulum and the ileal caecal junction. Samples of each of the experimental diets were sent to the University of Illinois for true amino acid digestibility determination using cecectomized adult roosters. The coefficients for the essential amino acids (EAA) lysine, methionine, and arginine in corn were fairly similar between the species but threonine digestibility was considerably lower in turkeys (72%) than roosters (88.5%). The digestibility coefficients for arginine, lysine, and methionine in soybean meal were 4 to 6% higher in roosters and the threonine differences were similar to what was observed for corn. Some of these differences could be due to the measurement of apparent digestibility in turkeys versus true digestibility in roosters. There was good similarity between the species for most of the EAA in meat and bone meal whereas in fishmeal, EAA digestibility was consistently higher in roosters than in turkeys.

Key Words: Digestibility, Roosters, Turkey

459 Valine needs of broilers from 21 to 42 days of age. S. A. Thornton*, S. J. Barber, A. Corzo, and M. T. Kidd, *Mississippi State University, Mississippi State.*

Valine is typically considered the fifth limiting amino acid in commercial broiler diets based on corn and soybean meal (CS). Three experiments

were conducted to evaluate Val needs for growth and carcass responses in Ross 508 broilers (d 21 to 42). All birds received a common diet from d 1 to 20. Experiment (Exp) 1 was a Val-test-diet validation experiment conducted with males randomly allocated across 30 battery pens (5 birds/pen). Dietary treatments for Exp 1 included: a test diet containing 0.72% Val (0.64% digestible (dig)) or 0.82% Val (0.73% dig) as achieved via L-Val supplementation, and a CS control diet containing 0.82% Val (0.73% dig) equaling NRC (1994) Val. Both Exp 2 and 3 were Val dose responses in male and female broilers, respectively. In Exp 2 and 3, birds were randomly distributed across 48 floor pens per Exp (12 birds/pen) and fed Val graduations (0.64 to 0.87% in 0.045% increments). In Exp 1, growth measurements were not affected ($P > 0.05$) by dietary treatments. Fat and carcass weight, and carcass yield did not differ ($P > 0.05$), but percentage fat was increased ($P \leq 0.05$) in birds fed low Val (15.6% CP) compared to birds fed the CS diet (18.0% CP). Because differences in BW gain ($P = 0.16$; 0.72% Val, 1.34 kg; 0.82% Val, 1.41 kg; and 0.82% Val in the CS control, 1.40 kg) did not occur, the test diet used to titrate Val in Exp 2 and 3 was decreased to 0.64% Val (0.57% dig). Quadratic responses in Exp 2 and 3 did not occur. Linear responses to increasing Val were observed for BW gain and feed conversion ($P \leq 0.05$) in males, and breast meat yield ($P = 0.07$) in females. Increasing Val to 0.73% (0.65% dig) improved ($P \leq 0.05$) BW gain and feed conversion in males, but not females, over broilers fed 0.64% Val (0.57% dig). Results indicate that diets based on CS containing 0.73% Val (0.65% dig) should support good live performance and processing traits for 21 to 42 d old males, but females may need less. The 21 to 42 d NRC (1994) Val recommendation of 0.82% is safe, but may be overestimated.

Key Words: Amino Acid, Broiler, Valine

460 Changes in the digestible lysine and sulfur amino acid needs of broiler chicks during the first 21 days posthatching. A. R. Garcia*, T. D. Troutman, and A. B. Batal, *University of Georgia, Athens.*

Two experiments were conducted to study the digestible lysine (DL) and sulfur amino acids (DSAA) requirements of broilers during the first wk of age, and to evaluate how the requirements change during the first 21 d. Male broiler chicks were randomly assigned to 5 replicate pens of 6 chicks per treatment from 0 to 21 d. The experimental diets, based on corn, soybean meal, and corn gluten meal (experiment 1), were formulated to be isocaloric and isonitrogenous, varying only in the level of the amino acid being tested. In experiment 1, the levels of DL used were 0.92, 1.02, 1.12, 1.22, 1.32%. In experiment 2, the levels of DSAA were: 0.65, 0.75, 0.85, 0.95 and 1.05%. Body weights and feed intake were recorded at d 4, 7 and 21, and body weight gain (BWG) and gain:feed ratio (GF) were calculated for each period. The digestible amino acid requirements were estimated by broken-line methodology, fitting the data to a quadratic curve (90%) and determining the first point at which the quadratic response curve intersects the plateau of the one slope broken-line. Estimated requirements reported herein are based on results of the broken-line analysis. In experiment 1, the DL requirement based on BWG and GF increased slightly with age, 1.02% at d 4 to 1.05% at d 7 and 1.12% at d 4 to 1.14% at d 7, respectively, with little to no change thereafter. The DL requirement based on BWG was lower than the estimated requirement based on GF. In experiment 2, the estimated DSAA requirement based on BWG gradually decreased from 4 to 21 d (0.85, 0.84 and 0.80% at 4, 7 and 21 d, respectively), whereas the requirement based on GF did not change during the first wk, but increased slightly from 7 to 21 d of age (0.75% at d 4 and 7 and 0.78% at d 21). Results from these studies suggest there is little change in the DL requirement during the first three wk posthatch. The observed decrease in the DSAA requirement during the first 21 d does not match the expected increase needed for feathering. Studies conducted to date do not support the

hypothesis that the amino acid needs of broilers are high immediately after hatch.

461 Broiler growth in response to increased lysine in the first week post hatching. S. Pophal*, S. L. Vieira, A. M. Kessler, A. R. Ebert, and B. B. Gallo, *UFRGS*.

Recent research has demonstrated an influence of early starvation on the growth of broilers leading to a permanent loss in the breast muscle synthesis. This loss seems to be related to myonuclei accretion from satellite cells. Broiler responses at a late age may also be related to malnutrition. Since Lys is very important to the synthesis of breast muscle protein, its deficiency may also be involved. In this study, male broiler chicks of two strain crosses (A and B) were fed diets with increased Lys levels (0.82%, 0.99%, 1.16% and 1.33% dig Lys) from hatching to 7 days. Feeds were based on corn and soybean meal and formulated to contain 2,950 ME kcal/kg and to be ideally balanced for essential amino acids. All other nutrients met or exceed NRC recommendations (1994). Each treatment had 5 replicates with 50 birds per pen at the beginning. Birds of all treatments received common commercial feeds from 8 days to 7 weeks. One bird per replicate was slaughtered weekly and its weight and the weight of its digestive organs, abdominal fat, feathers and commercial cuts were evaluated. Results showed that strain crosses exhibited different growth patterns with strain cross A being heavier through the first 5 weeks, but strain B being heavier at 6 and 7 weeks. Differences between strains also included a better feed conversion for strain cross B through all the experiment. A faster development of feathers was seen for birds of the strain cross A at 2 and 3 weeks of age. A positive linear relationship was observed between increasing Lys levels in the first week and body weight, body weight gain, carcass weight, and breast muscle mass to 6 weeks of age; however, this trend did not remain in the following week. No effect of Lys on organ weight, feather growth, and on the yield of the carcass and commercial cuts were detected. Lys deficiency in the first week leads to losses in meat production of broilers grown to body weights targeting most of the market needs.

463 Development of a whole cell sensor – green fluorescent protein based method for estimating lysine bioavailability in poultry feed proteins. V. I. Chalova*, W. K. Kim, I. B. Zabala-Díaz, C. L. Woodward, and S. C. Ricke, *Texas A&M University, College Station*.

Lysine can be one of the more limiting amino acids in protein sources for animals. Therefore, an accurate pre-determination of bioavailable lysine in feedstuffs is important. An optical density (OD) based microbiological assay for lysine determination using *E. coli* lysine auxotroph has been previously developed. However, because the assay is based on bacterial growth response to extracellular lysine measured as OD, it can be relatively time consuming (10-12h). Therefore, more rapid assays are needed. The purpose of our study was 1) to develop a whole cell fluorescent biosensor for lysine by introducing *gfpmut3* into the genome of an *E. coli* Δ LysA::bla, a deletion mutant lysine auxotroph, and 2) to compare lysine availability values of the bacterial assay with an in vivo chick growth assay. The fluorescent signal emitted by GFPmut3 was used to construct a standard curve as a function of lysine concentration to estimate the quantity of lysine available in respective poultry feed protein samples. Based on the fluorescence emitted by GFPmut3 we constructed a standard curve after 6 hour growth of the strain. Using the newly developed lysine fluorescent whole cell sensor we determined the total as well as the bioavailable amount of lysine in casein. The lysine recoveries were $97 \pm 1.65\%$ and $103.9 \pm 4.66\%$ respectively for the two levels ($12 \mu\text{g/ml}$ and $30 \mu\text{g/ml}$) of casein acid hydrolysate. We also determined the amount of bioavailable lysine in three feed samples (soybean, cotton seed meal, meat and bone meal) and compared with the data obtained from the chick bioassay. The bioavailable lysine as estimated by in vitro microbial assay was $3.09 \pm 0.74\%$ for soybean, $1.17 \pm 0.16\%$ for cotton seed meal and $1.74 \pm 0.06\%$ for meat and bone meal and $2.47 \pm 0.022\%$,

$1.28 \pm 0.049\%$ and $1.64 \pm 0.067\%$ respectively determined by chick bioassay. When the data obtained by microbial and animal assays were compared statistically, a correlation of 99% was observed. The results suggest that microbial assay using GFP fluorescence is highly comparable to conventional chick assays for estimating lysine bioavailability from these typical poultry feed protein sources.

464 The effect of several oligosaccharides on true amino acid digestibility in cecectomized and intact roosters. P. E. Biggs* and C. M. Parsons, *Department of Animal Sciences, University of Illinois, Urbana*.

Prebiotics, such as indigestible oligosaccharides, are considered to be possible dietary alternatives to antibiotic growth promoters in poultry. The effects of indigestible oligosaccharides on nutrient digestibility in poultry are largely unknown. Therefore, an experiment was conducted to evaluate the effects of several oligosaccharides on amino acid digestibility in roosters. The dietary treatments consisted of a corn-soybean meal control diet or that diet supplemented with 4 or 8 g/kg of inulin (IN), oligofructose (OF), mannanoligosaccharide (MOS), short-chain fructooligosaccharide (SCFOS), or trans-galactooligosaccharide (TOS). Each of the 11 diets was tube-fed (30 g) to four cecectomized and four intact Single Comb White Leghorn roosters that had been fasted for 24 h. Excreta were then collected for the following 48 h, freeze-dried, and analyzed for amino acid content. The digestibility of lysine and valine was increased ($P < 0.05$) in cecectomized roosters fed 8 g/kg MOS or TOS when compared to roosters fed the control diet. In addition, methionine digestibility was improved ($P < 0.05$) in cecectomized roosters fed 4 g/kg MOS or SCFOS and 8 g/kg OF or TOS. The true digestibility of isoleucine was increased ($P < 0.05$) in cecectomized roosters fed 8 g/kg MOS or 4 or 8 g/kg TOS. The magnitude of the increases in amino acid digestibility coefficients for cecectomized roosters ranged from 3 to 9 percentage units. Feeding either 4 or 8 g/kg IN to intact roosters decreased ($P < 0.05$) the true digestibility of methionine. The amino acid digestibility coefficients for all other dietary treatments were not significantly different from the control treatment. The results of this study indicated that the indigestible oligosaccharides had no significant effect on the digestibility of most amino acids in a corn-soybean meal diet. The digestibility of a few amino acids, however, was increased by some oligosaccharides in cecectomized roosters but not in intact roosters.

Key Words: Amino Acid Digestibility, Oligosaccharide, Cecectomized Rooster

465 Zinc-Methionine enhances the intestine development and functionality in the late term embryos and chicks. E. Tako*¹, P. R. Ferket², and Z. Uni¹, ¹*Department of Animal Sciences, Faculty of Agriculture, Hebrew University, Rehovot, Israel*, ²*Department of Poultry Science, College of Agriculture and Life Sciences, North Carolina State University, Raleigh*.

Early function of the digestive tract is crucial for achieving the maximal growth and development of broilers. Studies in mammals, demonstrated the importance of zinc to intestinal crypt cell production & restitution. Although zinc is essential in almost all aspects of metabolism, its influence on the intestine has never been investigated in chicken. The Zinc-Methionine (ZnMet), an organic form of zinc feeding additive was used in this study. This research examined the effect of In Ovo feeding (IO) solutions, containing ZnMet on the broiler embryos and chicks intestine functionality & development from 17d of incubation till 7d posthatch. At 17d of incubation, 100 fertile eggs per group were injected into the amnion, 1ml IO of .4% saline solutions containing either ZnMet (.05%) or ZnMet (.05%) plus carbohydrates (3% Maltose, 3% Sucrose, 12% Dextrin) and β -hydroxy- β -methylbutyrate (.1% HMB). The control group was injected with 1ml of .4% saline. Results showed that both IO-fed groups, exhibit increased villus surface area compare to control (elevation of 70% at 19d of incubation & 60% at 7d). At hatch the IO-fed groups had higher brush border activity levels of Sucrase-Isomaltase (SI) & leucine-Aminopeptidase (AP) (.2 mM glucose/g & 18mM pnitroalilide/g respectively, as compare to .15 mM glucose/g & 10mM pnitroalilide/g in controls). Also at hatch, all the IO-fed birds exhibited higher ($P < 0.05$) mRNA levels of SI, AP, Sodium-glucose cotransporter (SGLT1) & ATPase genes compare to controls. Use of RTPCR isolated & sequenced fragment (303bp) of chicken ZnT1 zinc transporter, revealed 2 fold increase in mRNA levels of ZnT1 at

hatch in the IO groups compare to controls. In conclusion, birds IO-fed ZnMet, had an improved digestive & absorptive capacity. However, the IO solution contained ZnMet added to carbohydrates & HMB had a long term effect on intestinal morphological development, expression and activity of brush border enzymes and transporters.

Key Words: Broiler, Intestine, Zinc-Methionine

466 Effect of vitamin D source on broiler production and carcass composition. J. L. Saunders-Blades* and D. R. Korver, *University of Alberta, Edmonton, AB, Canada.*

The effect of vitamin D source and time of feeding 25-OH vitamin D₃ (HyD[®]) on broiler production efficiency and carcass composition was studied. The first hydroxylation of vitamin D in the liver results in 25-OH vitamin D₃ (25-OHD₃); providing dietary 25-OHD₃ to the bird reduces the need for this hydroxylation, potentially allowing for a more efficient use of vitamin D. The dietary treatments differed only in supplemental vitamin D source: the Control diet contained 3,000 IU/kg of vitamin D₃, the 25-OHD₃ diet contained 69 µg/kg of 25-OHD₃. Four dietary treatments were fed: Control (Control diet from 1-41 d), 25-OHD₃ (25-OHD₃ diet from 1-41 d), 25-OHD₃ Early (25-OHD₃ diet from 1-28

d, Control diet from 29-41 d), or 25-OHD₃ Late (Control diet from 1-28 d, 25-OHD₃ diet from 29-41 d). Birds were reared sex separately in 32 pens, with 4 replicates per treatment within each sex. Feed consumption and BW were measured at 0, 10, 28 and 41 d. At 42 d, 80 birds from each male pen were randomly selected for carcass and portion yield analysis. Birds in the 25-OHD₃ and 25-OHD₃ Early groups had a greater BW gain than the Control and 25-OHD₃ Late groups from 11-28 d, gaining 55 and 55 vs 53 and 53g·bird⁻¹·d⁻¹, respectively (P<0.05). By 42 d, birds fed the 25-OHD₃ treatment were heavier than those fed the Control and 25-OHD₃ Late treatments (2301 vs 2233 and 2234 g, respectively; P<0.05). All treatment groups maintained similar feed conversion efficiencies (P>0.05). Starved and eviscerated BW and absolute weight of the pectoralis major, wings and drums were greater for the 25-OHD₃ fed birds than those fed the Control and 25-OHD₃ Late treatments (P<0.05). Overall, the 25-OHD₃ treatment supported a faster BW gain, and greater breast and leg portions. All groups in this study developed field rickets around 11 d, however symptoms subsided and no treatment was administered. The results of this study are therefore confounded by the rickets, but may indicate that 25-OHD₃ helped to lessen the effects of rickets as shown by the greater growth rate.

Key Words: Broiler Production, Vitamin D, 25-OH-vitamin D₃

Ruminant Nutrition: Beef - Minerals & Vitamins

467 Effects of trace mineral source and feeding method on the productivity of grazing Braford cows. J. D. Arthington*¹ and C. K. Larson², ¹*Range Cattle Research and Education Center, University of Florida, Ona,* ²*Zinpro Corporation, Eden Prairie, MN.*

Braford cows (n = 160) were used to evaluate the effects of trace mineral source and feeding method on cowherd productivity over 3 yr. In yr 1, cows were stratified by age and randomly allocated to one of eight groups (n = 20 cows/group). Cows were allotted to eight of 16 bahiagrass pastures (8.0 ha each, one empty pasture between groups) and were rotated each week. Cow groups remained intact throughout the study with the exception of culled cows, which were replaced with 3-yr-old pregnant heifers. Cows were offered 2.27 kg of liquid molasses daily from early November until middle of April. One mature Braford bull was placed into each cow group starting in early January, remaining for 90 d. Bulls were rotated through cow groups each week. Two main factors were randomly applied to groups in a 2 x 2 factorial arrangement (two groups/treatment), consisting of 1) trace mineral source; inorganic vs organic, and 2) mineral feeding method; free-choice vs control-fed in a molasses supplement. Cow BW, body condition score (BCS), pregnancy rate, calving interval, and calf BW at weaning were obtained. Mineral intake was measured each week in pastures provided free-choice mineral. In yr 1 and 2, liver biopsy collections, for the determination of mineral status, were conducted at the start and end of winter supplementation on the same six randomly chosen cows/group. Cows assigned to free-choice treatments consumed 23% less (P < 0.001) mineral compared to control-fed cows, resulting in a greater (P < 0.05) decrease in liver Zn (yr 1) and liver Cu (yr 2) concentration compared with control-fed cows. Mineral source and feeding method had no effect on cow BW, cow BCS, and calf BW at weaning. Young cows (3 and 4 yr of age) consuming organic minerals had a greater pregnancy rate during yr 2 (P < 0.05) and 3 (P = 0.15) and a lesser (P < 0.05) calving interval in yr 1 and 3, compared to cows consuming inorganic minerals. The supplementation of organic minerals (Cu, Zn, Mn, and Co) appears to increase the reproductive performance of young, but not mature, grazing Braford beef cows consuming molasses-based supplements.

Key Words: Cattle, Mineral, Molasses

468 Effects of Tri-Basic Copper Chloride Vs Copper Sulfate on Measures of Copper Status and Forage Intake in Growing Beef Heifers. J. D. Arthington* and F. M. Pate, *Range Cattle Research and Education Center, University of Florida, Ona.*

Previous research indicates that growing beef cattle may experience increased DMI when supplemented with tri-basic copper chloride (TBCC) vs an organic Cu source. The objective of this study was to investigate the effect of supplemental TBCC vs Cu sulfate on the Cu status and DMI of growing heifers fed forage-based diets. Twenty-four crossbred heifers were stratified by BW (355 ± 10.4 kg) and randomly allotted to

individual pens. Heifers were provided free-choice access to ground grass hay (8.0 and 54.0% CP and TDN, respectively) and 1.75 kg/d of a corn-cottonseed meal supplement. Three treatments were randomly allocated to pens, providing; 1) 100 mg/d Cu from Cu sulfate, 2) 100 mg/d Cu from TBCC, or 3) 0 mg Cu/d (Control). Forage DMI was measured daily. Individual heifer BW, jugular blood, and liver biopsy samples were collected on d 0, 30, 60 and 90. Heifer ADG was not affected (P = 0.83) by Cu treatment (average = 0.22 ± 0.07 kg). Change in liver Cu and plasma ceruloplasmin (Cp) concentration did not differ (P > 0.16) among Cu sources (120 vs. 77 ppm liver Cu, and -6.0 vs. 3.5 mg/dL Cp for Cu sulfate and TBCC supplemented heifers, respectively; SEM = 20.6 and 3.1). Heifers fed no supplemental Cu experienced a lesser (P < 0.001) accumulation of liver Cu and a greater decrease (P < 0.04) in Cp concentration over the 90-d supplementation period (-34.4 ± 20.6 ppm liver Cu and -4.1 ± 3.1 mg/dL Cp) compared to both Cu sulfate and TBCC supplemented heifers. Forage DMI did not differ among Cu sources, however, heifers provided no supplemental Cu had lower (P < 0.05) forage DMI compared to both Cu sulfate and TBCC supplemented heifers (average forage DMI = 4.9 and 5.3 kg/d for Control and Cu supplemented heifers, respectively; SEM = 0.14). These data indicate that Cu sulfate and TBCC are of similar availability when offered to growing beef heifers in corn-cottonseed meal supplements. As well, these data indicate that the lack of supplemental Cu may decrease forage DMI in growing beef heifers.

469 Effect of chromium supplementation and copper status on glucose metabolism in beef cows. H. S. Stahlhut*, C. S. Whisnant, K. E. Lloyd, E. J. Baird, L. R. Legleiter, S. L. Hansen, and J. W. Spears, *North Carolina State University, Raleigh.*

Pregnant Angus (n=83) and Simmental (n=69) cows were blocked by age and assigned to one of two free choice mineral supplements to determine the effect of dietary Cr and Cu status on glucose metabolism. Supplements consisted of: 1) control (no supplemental Cr) and 2) 40 mg Cr /kg (from Cr picolinate). Mineral supplements were formulated to contain all minerals typically supplemented to cattle diets with the exception of Cu. At the beginning of the study (75 d prepartum) one-half of cows in each treatment received a 25 g Cu oxide needle bolus. Blood was collected from 35 cows on d 28, 58, 97 (20 d postpartum), and 155 for plasma glucose. Plasma glucose concentrations were affected by time (P< 0.01), breed x Cu bolus (P< 0.05), and Cr x time (P< 0.05). In non-Cu supplemented cows, plasma glucose was higher (P< 0.05) in Angus than in Simmental. In animals receiving a Cu bolus, plasma glucose was similar in both breeds. On d 97, plasma glucose levels were lower (P< 0.01) in cows receiving Cr relative to controls. Plasma glucose was not affected by Cr at other sampling d. At approximately 1 mo prepartum and 1 mo postpartum, 12 cows were cannulated and glucose tolerance tests (GTT) were conducted. Plasma glucose concentrations

following the GTT conducted prepartum were lower ($P < 0.01$) in Cr-supplemented than in control cows (86.3 vs 91.8 mg/dL), but glucose clearance rates were not significantly affected by treatment. In postpartum GTT, plasma glucose was affected by an interaction between Cr-supplementation and Cu status. Chromium-supplemented animals that received a Cu bolus had higher ($P < 0.001$) plasma glucose (92.2 vs 69.2 mg/dL) than cows not supplemented with Cu after glucose administration. No significant difference in plasma glucose was observed between control cows regardless of Cu status. Results of this study indicate that plasma glucose is lower in cows receiving supplemental Cr and that an interaction between Cr and Cu status may alter glucose metabolism.

Key Words: Chromium, Copper, Glucose, Cattle

470 Growth, reproductive performance, and manganese status of heifers fed varying concentrations of manganese. S. L. Hansen*, C. S. Whisnant, K. E. Lloyd, E. J. Baird, L. R. Legleiter, H. S. Stahlhut, and J. W. Spears, *Department of Animal Science, North Carolina State University, Raleigh.*

Eighty Angus ($n = 40$) and Simmental ($n = 40$) heifers, averaging 10 mo of age and 245 kg in BW, were used to determine the effects of dietary Mn on performance, reproduction, and Mn status of heifers. Heifers were stratified by age within a breed and randomly assigned to treatments consisting of a control diet (analyzed 20 mg Mn/kg DM) supplemented with 0, 10, 30 or 50 mg Mn/kg DM. Diets were offered ad libitum using Calan gate feeders. Blood samples were taken on d 0, 63, and 98 for plasma cholesterol and Mn analysis. Liver biopsies were taken on d 0 and 98. Average daily gain, DMI and G:F for the 140-d period were not affected by Mn. Initial liver Mn was not affected by breed. Liver Mn concentrations on d 98 were affected by a treatment by breed ($P < 0.05$) interaction. Simmental heifers supplemented with 30 or 50 mg Mn/kg diet had higher ($P < 0.05$) liver Mn than controls. Liver Mn in Angus heifers was not affected by dietary Mn. Plasma cholesterol was higher ($P < 0.05$) in Angus compared to Simmental heifers, especially on d 0. On d 63 control heifers had lower ($P < 0.07$) plasma cholesterol (151 vs 196 mg/dL) than heifers supplemented with 50 mg Mn/kg DM. Plasma cholesterol was not affected by Mn treatment on d 98. Cholesterol values across treatments increased ($P < 0.01$) over time. Based on serum progesterone concentrations at or greater than 1 ng/mL, 40% of control heifers were cycling at approximately 12 mo of age compared to 50% of Mn-supplemented heifers. At approximately 13 mo of age 40% of control heifers exhibited signs of estrus, in response to a two-shot Lutalyse synchronization protocol, compared to 50% of those supplemented with 50 mg Mn/kg DM. The percentage of heifers cycling at 12 or 13 mo of age was not significantly affected by treatment. Results of this study indicate that 20 mg Mn/kg diet DM is adequate for growth of heifers, but may be inadequate for maximum reproductive performance.

Key Words: Manganese, Heifers, Reproduction

471 Influence of dietary manganese on performance and serum glucose concentrations in growing steers. L. R. Legleiter*, K. E. Lloyd, and J. W. Spears, *Department of Animal Science, North Carolina State University, Raleigh.*

Manganese requirements of beef cattle are poorly defined. This study was conducted to determine the effect of dietary Mn on performance and serum glucose concentrations of growing cattle. One hundred twenty Angus cross steers were bunk fed a corn silage-based diet for 84 d in a confined feeding facility with slatted concrete floors. Steers were blocked by weight and randomly assigned to one of six treatments (four blocks, 24 pens, 5 head/pen) providing increasing levels of Mn in the form of manganese sulfate. The 12.9% CP basal diet, provided ad libitum, consisted of corn silage (78%), corn gluten feed (18%), urea, trace minerals and vitamins. Treatments consisted of 0, 10, 20, 30, 120 and 240 mg supplemental Mn/kg DM. The control diet without supplemental Mn analyzed at 30.2 mg Mn/kg DM. Steers were weighed every 28 d. Blood samples were taken 2 h post feeding from eight steers per treatment on day 56. Data were analyzed as a completely randomized block design using the GLM procedure of SAS. Initial weight (247.5 ± 1.2 kg) and final weight (354.2 ± 6.3 kg) were not different ($P > 0.05$) between treatments. Average daily gain was similar ($P > 0.05$) among all treatments and averaged 1.27 kg/d. Likewise, DMI and feed efficiency were similar ($P > 0.05$) across treatments averaging 6.68 kg/d and 0.19 (G:F, kg/kg), respectively. Additionally, serum glucose concentrations averaging 80

mg/dL were not different ($P > 0.05$) between treatments. These data suggest that a corn silage-based growing diet containing Mn at 30 mg/kg DM adequately meets the growing requirements of steers in confinement.

Key Words: Manganese, Cattle, Glucose

472 Selenium in tissues of calves supplemented with selenium yeast. C. J. Richards*, H. M. Blalock, L. C. Miller, and H. D. Loveday, *The University of Tennessee, Knoxville.*

An experiment was conducted to evaluate supplementation of Se yeast (Sel-Plex[®]; Alltech Inc, Nicholasville, KY) in a finishing diet balanced to contain adequate Se from feedstuffs. Forty Angus and Angus crossbred steers and heifers (20 steers, 20 heifers) were blocked by sex and randomly allotted to eight pens (5 hd/pen). Calves were acclimated to grain using common diets varying in Se concentration, but always supplemented with 0.2 mg Se/kg diet (DM) from sodium selenite. After adaptation, pens were randomly assigned, within sex, to a basal finishing diet containing adequate Se from cracked corn, alfalfa pellets, corn gluten pellets, molasses and a Se free vitamin/mineral supplement (CON) or the basal finishing diet plus 0.27 mg Se/kg diet (DM) from Se yeast (SUP). Two pens of each sex received each treatment for 130 d with weights and blood samples taken at 28 d intervals and prior to shipping. Calves were shipped overnight to a commercial harvesting facility where hot carcass weights were recorded and samples of each liver lobe collected. After a 48 hr chill, yield grade, quality grade, back fat, and KPH were determined and a loin muscle sample obtained. The CON and SUP diets contained an average of 0.15 and 0.43 mg Se/kg diet (DM), respectively. No difference ($P > 0.01$) in calf weights, ADG, feed intake, feed efficiency or any carcass measures were detected. Serum Se had a treatment by time interaction ($P < 0.01$) where initial serum Se concentrations were similar (0.09 mg/mL). Thereafter, CON calves had lower ($P < 0.01$; average = 0.08 mg/mL) serum Se concentrations than SUP calves (average = 0.11 mg/mL). Loin Se concentrations were lower ($P < 0.01$) for CON than SUP calves (0.135 and 0.258 mg Se/kg as-is tissue, respectively). Liver Se concentration increased ($P < 0.01$) from 0.426 to 0.831 mg Se/kg as-is tissue with SUP. Results of this experiment indicate that supplementing 0.27 mg Se/kg diet (DM) from Se yeast in a feedlot diet containing adequate Se does not increase animal performance, but does result in increased Se tissue concentrations that do not exceed the FDA limit.

Key Words: Ruminant, Selenium, Beef

473 Determining the route and amount of P excreted from cattle consuming finishing diets. B. G Geisert*, G. E Erickson, T. J. Klopfenstein, M. K. Luebke, and J. C MacDonald, *University of Nebraska, Lincoln.*

Determining the amount and the route of phosphorus (P) excretion is important due to the increasing pressure to manage P in animal waste. This experiment was designed to determine the amount and the route of P excreted from cattle fed a high energy finishing diet with different amounts of P. Five ruminally fistulated crossbred steers were used in a 5x5 latin square design. Diets consisted of 3 brewers grit based diets formulated for 0.12% P (LOWP) with monosodium phosphate added to increase P level to 0.27 (MEDP) and 0.42% P (HIGHP). They consisted of 50% course brewers grits, 20% dry rolled corn (DRC), 15% corn bran, 5% grass hay, 5% molasses, and 5% supplement. The other 2 diets were a DRC based diet (CORN), and a dry distillers grain diet (DDGS, 57% DRC, 30% DDGS, 5% grass hay, 5% molasses, and 3% supplement). Diets contained 0.12, 0.27, 0.42, 0.30, 0.36 % P (DM basis) for LOWP, MEDP, HIGHP, CORN, DDGS, respectively. Steers were adapted to diets for 16 days with a 5-day collection period. Chronic oxide was dosed at 5 grams every 12 hours for the last 8 days of each period. Total urine was collected and analyzed for P concentration. Fecal samples were taken 3 times daily, composited by day and analyzed for P and chromium concentrations. There were no significant differences in DMI ($P > 0.05$). P intakes were 10.5, 26.7, 37.9, 29.5, 34.6 g/d for LOWP, MEDP, HIGHP, CORN, DDGS, respectively. P excretion was related to P intake and was lower ($P < 0.05$) for LOWP. Route of excretion whether feces or urine, was also affected by dietary P intake. Steers fed LOWP excreted very little P in urine (0.50 g/d). However, if diet P was $> 0.20\%$ more P was excreted in urine (2.1 g/d), but was not different across diets and was variable among animals. P retention

was lower (2.0 vs. 13.8 g/d) for LOWP than other diets, suggesting that cattle fed 0.12% P were deficient and excreting 85.3 % of the P fed.

Key Words: Excretion, Phosphorus, Cattle

474 Effects of dietary supplemental vitamin A concentration on growth, intake, and marbling in yearling feedlot steers. T. C. Bryant^{*1,3}, J. J. Wagner², T. E. Engle³, K. L. Dorton³, P. D. Burns³, and M. L. Galyean^{4,1}, ¹ContiBeef LLC, Boulder, CO, ²Continental Beef Research, Lamar, CO, ³Colorado State University, Fort Collins, ⁴Texas Tech University, Lubbock.

Recent research has shown a negative correlation between marbling and serum retinol concentration in Japanese Black cattle. Three hundred sixty single-source black, yearling steers (average initial BW = 316 ± 9.1 kg) fed a 91 % concentrate (steam-flaked corn base) diet were used to evaluate the effects of supplemental vitamin A concentration on performance, DMI, and carcass traits. Steers were blocked into eight weight replicates and assigned randomly to pens (n = 9/pen) and to diets containing 0, 1,103, 2,205 4,410, or 8,820 IU of supplemental vitamin A/kg DM. Daily DMI, ADG, and feed:gain ratio were determined for each 28-d period and for the overall 142-d trial. Final BW (586, 580, 590, 584, and 584 kg for 0, 1,103, 2,205 4,410, and 8,820 IU vitamin A/kg DM, respectively) did not differ (P > 0.10) among treatments. Feed efficiency, ADG, and daily DMI also did not differ (P > 0.10) among treatments within each 28-d period or for the overall trial. From d57 to harvest, average DMI (10.33, 10.28, 10.57, 9.75, and 10.22 kg/steer daily for 0, 1,103, 2,205, 4,410, and 8,820 IU vitamin A/kg DM, respectively) was lower (P < 0.02) for steers receiving 4,410 IU vitamin A/kg DM than for steers in other treatments, and DMI was greater (P = 0.06) for the 2,205 IU vitamin A/kg DM treatment than for the 8,810 IU/kg DM treatment. Marbling score, hot carcass weight, longissimus muscle area, and 12th rib fat thickness did not differ (P > 0.10) among treatments. Similarly, the number of carcasses grading ≥ Choice (62.6, 52.8, 64.0, 58.4, and 58.4 % for 0, 1,103, 2,205, 4,410, and 8,820 IU vitamin A/kg DM, respectively), Select, or ≤ Standard did not differ (P > 0.10) among treatments. Results of this trial suggest that vitamin A supplementation up to twice the NRC-suggested concentration has little effect on performance or marbling in typical yearling feedlot steers.

Key Words: Cattle, Marbling, Vitamin A

Ruminant Nutrition: Dairy - Lactation, Health & Gut Physiology

476 Effect of dietary cation-anion difference and crude protein on milk yield and blood metabolites of lactating dairy cows. C. D. Wildman^{*}, J. W. West, and J. K. Bernard, *The University of Georgia, Tifton.*

Eight ruminally cannulated lactating Holstein cows averaging 47 ± 10 DIM were used in a 12 wk replicated 4 x 4 Latin Square trial to determine the relationship between dietary cation-anion difference (DCAD) and dietary crude protein (CP) concentration. The study was conducted from March 28 through June 19. Treatments were arranged as a 2 x 2 factorial to provide 15 or 17% CP and DCAD of 25 or 50 meq/100 g DM (Na+K-Cl). As DCAD increased from 25 to 50, increases (P < 0.01) in DMI (17.8 to 19.1 kg/d), yield of 3.5% fat-corrected milk (20.2 to 23.7 kg/d), energy-corrected milk (20.5 to 23.8 kg/d), fat (0.6 to 0.8 kg/d) and protein (0.7 to 0.8 kg/d) were observed. Blood Na and bicarbonate (P < 0.05, P < 0.01) were greater for DCAD 50 (144 and 24.5 mmol/L) compared with 25 (143 and 22.3 mmol/L). Blood Mg decreased (P < 0.01) as DCAD increased from 25 to 50 (2.5 to 2.2 mg/dl). An increase (P < 0.01) in blood pH (7.46 to 7.50) was also noted with increasing DCAD. Urinary bicarbonate:creatinine ratio was higher (P < 0.01) for DCAD 50 (2.6) versus 25 (0.6). Greater microbial crude protein production, indicated by uric acid:creatinine ratio, was noted with increasing DCAD at low CP compared to that observed with high CP, resulting in an interaction (P < 0.05). Fractional excretion of K was greater (P < 0.01) for DCAD 50 (78.8) compared to DCAD 25 (38.3) whereas fractional excretion of Mg (P < 0.05) was reduced for high DCAD (9.6) relative to low DCAD (13.0). A DCAD x CP interaction (P < 0.05) was observed for fractional excretion of Na with an increase in DCAD resulting in increased excretion of Na at both high and low CP. The magnitude of the increase was greater at low CP compared to that observed

475 Effects of feeding a polyclonal antibody preparation against *Streptococcus bovis* or *Fusobacterium necrophorum* on performance and carcass characteristics of feedlot steers. C. R. Dahlen², N. DiLorenzo^{*1}, A. DiCostanzo¹, G. C. Lamb², and L. J. Smith¹, ¹Department of Animal Science, University of Minnesota, St. Paul, ²North West Research and Outreach Center, Crookston, MN, ³North Central Research and Outreach Center, Grand Rapids, MN.

Steer calves (n = 226; 272 kg), stratified by weight and housed in 16 pens, were used to evaluate effects of feeding a polyclonal antibody preparation (Ab; sprayed onto a soyhull pellet) against *Streptococcus bovis* (AbSb) or *Fusobacterium necrophorum* (AbFn) on performance and carcass characteristics for 153 d. Pens were randomly assigned to one of four dietary treatments resulting from a 2 X 2 factorial arrangement that included AbSb or AbFn. Diets (1.39 Mcal NEg/kg DM, 12.5% CP, 0.7% Ca, and 0.35% P) were formulated with high-moisture corn and dry ground corn (50:50 mix, DM basis), corn silage, and supplement. Interaction terms for final and carcass-adjusted final weight, gain and carcass-adjusted gain were significant (P < 0.05). Steers receiving AbSb or AbFn had heavier (P < 0.05) final BW resulting from faster (P < 0.05) daily gains. Adjusted-final weights of steers fed AbSb were heavier (P < 0.05) than those fed both or no Ab. Only AbSb was effective (P = 0.08) at enhancing carcass-adjusted daily gain. Interestingly, steers receiving both Ab gained similarly (P > 0.05) as steers fed no Ab. Interaction terms were significant (P < 0.05) for feed efficiency (analyzed as gain-to-feed), and tended (P < 0.08) to be significant for carcass-adjusted feed efficiency. Steers receiving AbSb were more efficient (P < 0.06) than those receiving both or no Ab. Steers receiving AbSb were more efficient (carcass-adjusted; P < 0.09) than those receiving both or no Ab. Steers supplemented with AbSb had heavier carcasses (P < 0.05), which accounted for greater (P < 0.05) subcutaneous fat, and greater (P < 0.05) yield grades than those of steers fed both or no Ab. These results demonstrate that feeding a polyclonal antibody preparation against *Streptococcus bovis* or *Fusobacterium necrophorum* influences performance and carcass characteristics of feedlot cattle fed high-grain diets.

Key Words: *Streptococcus bovis*, *Fusobacterium necrophorum*, Steers

at high CP. Results indicate that increasing DCAD improves intake and performance, which suggests improved N utilization on lower CP diets.

Key Words: Dietary Cation-Anion Difference, Dietary Crude Protein

477 Effect of dietary cation-anion difference and dietary crude protein degradability on milk yield and blood metabolites of lactating dairy cows. C. D. Wildman^{*}, J. W. West, and J. K. Bernard, *The University of Georgia, Tifton.*

Eight ruminally cannulated lactating Holstein cows averaging 180 ± 10 DIM were used in a 12 wk replicated 4 x 4 Latin Square trial to determine the relationship between dietary cation-anion difference (DCAD) and protein degradability (UIP). The study was conducted from August 8 through November 6. Diets were formulated to provide 15% dietary crude protein (CP) across all treatments. Treatments were arranged as a 2 x 2 factorial to provide DCAD of 25 or 50 meq/100 g DM (Na+K-Cl) and 33 or 42% of CP as UIP. Increasing DCAD from 25 to 50 increased (P < 0.01) DMI (17.0 to 18.0 kg/d), 3.5% fat-corrected milk (19.1 to 20.0 kg/d), fat (0.6 to 0.7 kg/d), and energy-corrected milk (19.5 to 20.4 kg/d) yield. A significant DCAD x degradability interaction (P < 0.01) was observed for each of these parameters with the magnitude of the DCAD effect much greater at 42% UIP compared with 33% UIP, where no difference was observed. Blood bicarbonate (22.5 to 24.4 mmol/L) and pH (7.41 to 7.43) increased (P < 0.01) as DCAD increased from 25 to 50, respectively. Urinary bicarbonate increased (P < 0.01) at DCAD 50 (69.1 mmol/L) over that observed at DCAD 25 (20.3 mmol/L). A DCAD x UIP interaction (P < 0.05) was observed for uric acid:creatinine ratio, an indicator of microbial crude protein production, because a decrease was observed with DCAD 50 versus 25 at 33%UIP (0.5 to 0.4) but no differences were observed between DCAD for 42%

UIP. Fractional excretion of Na (0.3 to 0.9), K (35.8 to 61.6), Cl (0.26 to 0.76), and bicarbonate (1.07 to 5.65) increased while Mg (11.54 to 7.36) and Ca (1.4 to 0.3) decreased ($P < 0.01$) as DCAD increased from 25 to 50, respectively. No interactions were noted for fractional excretion of minerals or blood parameters. Results of this trial indicate that increasing DCAD in diets with high concentrations of UIP can improve intake and performance of lactating dairy cows by improving dietary protein utilization.

Key Words: Dietary Cation-Anion Difference, Protein Degradability

478 Maternal undernutrition from early- to mid-gestation versus throughout gestation: Effects on visceral organs of ewes and their fetuses. B. W. Hess^{*1}, K. A. Vonnahme², E. J. Scholljegerdes¹, S. L. Lake¹, J. D. C. Molle¹, V. Nayigihugu¹, R. L. Atkinson¹, P. A. Ludden¹, L. R. Miller¹, and S. P. Ford¹, ¹Department of Animal Sciences, University of Wyoming, Laramie, ²Department of Animal and Range Sciences, North Dakota State University, Fargo.

Twenty-one multiparous ewes were used to determine the influence of maternal nutrient restriction on visceral tissues of the ewe and fetus. Control (CON) ewes (n = 4 singles; n = 4 twins) were fed pelleted beet pulp fortified with vitamins and minerals to meet requirements. From d 28 to 78 of gestation, the remaining ewes were fed 50% of CON. Beginning on d 78 of gestation, nine undernourished ewes were fed CON (UC, n = 4 singles; n = 5 twins) whereas four undernourished ewes continued to be fed 50% of CON until d 135 of gestation (UU, n = 2 singles; n = 2 twins). Rations were adjusted weekly for BW changes throughout the experiment. All ewes were slaughtered on d 135 of gestation, and ewe visceral tissues and fetal digestive tracts were measured. Eviscerated BW (EBW; $P = 0.02$) and weights of the lungs ($P = 0.03$) and heart ($P = 0.07$) were reduced in UU ewes. Total digestive tract weights were less ($P = 0.06$) for UU ewes because of reduced ($P = 0.10$) weights of the stomach, small intestine, and colon. However, the pancreas, liver, and heart of UU ewes were greater ($P = 0.11$; % of EBW) than CON or UC ewes. The weights of fetal digestive tracts were less ($P = 0.09$) for UU fetuses due to reduced ($P = 0.04$) stomach weights. Because of reduced ($P = 0.03$) EBW for UU fetuses, fetal digestive tract components (% of EBW) were not affected ($P = 0.18$ to 0.95) by dietary treatment. Twin fetuses had lighter ($P = 0.11$) EBW, but heavier ($P = 0.01$) stomach weights (% of EBW) than single fetuses. Undernourishment during gestation will decrease maternal and fetal digestive tract weights in a manner proportional to decreased BW. The ability of ewes and their fetuses to maintain equal or greater relative weights of visceral organs (% of EBW) despite being undernourished may be necessary to ensure proper physiological function.

Key Words: Ewes, Fetus, Visceral Organs

479 Energy requirement of close-up dairy cows grazing pasture. J. R. Roche^{*1}, E. S. Kolver¹, and J. K. Kay^{1,2}, ¹Dexel, Hamilton, New Zealand, ²University of Arizona, Tucson.

Fifty-two multiparous grazing dairy cows (BW:442±65.2kg) were randomly allocated to four levels of pasture DMI for 27±9.6 days precalving. Cow DMI was 1.3, 2.0, 2.3 and 2.6% of BW of fresh pasture. Following calving, all cows were grazed together and offered pasture to appetite. Daily milk yields were recorded postcalving and fat, protein and lactose concentrations determined on 2 days each wk for 5 wk. Blood was sampled 17 d precalving, on the day of calving and on d 1, 2, 3, 4, 7, 14, 28 and 35 postcalving. Loss of BW precalving was linearly ($P < 0.001$) related to precalving feeding level and only cows consuming 2.6% BW gained BW at a rate that suggested a positive energy balance. This was supported by a quadratic decrease ($P < 0.001$) in plasma NEFA and BHBA, a linear decrease ($P < 0.05$) in growth hormone (GH), and a corresponding quadratic increase in IGF-1 ($P < 0.001$), leptin ($P < 0.1$) and glucose ($P < 0.05$), as precalving DMI increased. Apart from GH and IGF-1, where differences in plasma concentrations remained during the colostrum period, precalving DMI did not change postcalving plasma concentrations of these metabolites. Similarly, precalving DMI did not affect milk yield or the yield of fat, protein or lactose in milk, although BW loss increased ($P < 0.001$) postcalving with increasing precalving level of feeding. Based on changes in BW, these results indicate that 6.0 Mcal ME/100kg BW was required precalving to maintain cow energy balance, considerably more than is currently recommended.

However, precalving DMI did not affect milk production. Further research is required to determine if an interaction exists between pre- and postcalving level of feeding.

Variable	Pre- calving DMI (% BW)				SED	P- value	
	1.3	2.0	2.3	2.6		DMI	L
ME Intake (Mcal/100 kg BW)	3.3	5.1	5.8	6.4	0.51	<0.001	<0.001
Milk yield, kg/d	19.7	21.1	19.3	20.6	1.48	0.85	0.45
Fat, %	4.79	4.81	5.10	5.05	0.238	0.75	0.48
Protein, %	3.72	3.79	3.77	3.77	0.078	0.55	0.30
Postcalving DMI, %BW	3.0	3.0	2.8	2.6	0.227	0.26	0.06
BW at calving, kg	424	441	458	468	8.1	<0.001	<0.001
BW change precalving, kg/d	-1.2	-0.1	0.5	0.9	0.41	<0.001	<0.001
BW change postcalving, kg/d	-1.0	-1.3	-1.6	-2.0	0.27	<0.001	<0.001

480 Potential for dairy feeds to harbor an invasive mold (*Aspergillus fumigatus*): Implications to herd health. S. B. Puntenney^{*}, Y. Wang, and N. E. Forsberg, Oregon State University, Corvallis.

Ruminant animals are susceptible to mycotic infections. The most-frequently encountered mycotic infections include *A. fumigatus* and *Candida albicans*. The most common sites for infection are the GI tract (omasum, abomasum and Peyer's Patches) and the lung. Symptoms of mycoses include coagulopathies and death. Factors which increase susceptibility to mycoses include immunosuppression, acidosis, anti-microbials, BVD and stress. At present, the significance of mycotic infections to dairy production is not certain. Dairy feeds, especially silages and commodities which are poorly managed, have potential to support growth of pathogenic molds. *A. fumigatus* is a thermotolerant, ubiquitous mold which prefers an acidic environment. It requires oxygen, a food source and moisture for growth. Poor handling of commodities and silages increases the possibility of mold growth. In this study we surveyed the prevalence of *A. fumigatus* in common dairy feeds. A quantitative Sybr-Green real-time PCR assay was developed to assess concentrations of *A. fumigatus* DNA. Seventy-three samples were obtained from dairies in Oregon. Feed samples were dried and ground and then DNA was extracted for Sybr-Green PCR analysis. Mean concentrations of *A. fumigatus* (spores/g) were: corn (11,286), corn/barley mix (33,156), SBM (158), beet pulp (26,966), whole cottonseed (15,363), distillers dried grains (11,516), wheat mill run (6,480), grass silage (9,304), corn silage (14,785) and spoiled silage (1,300,000). We conclude that dairy cows will be continually exposed to *A. fumigatus* and that spoiled silages harbor the highest concentrations of this invasive mold. Additional factors (e.g., stress or acidosis) are likely required to permit mycoses to develop in an individual animal. Healthy humans are resistant to *A. fumigatus* infection. Immunosuppression increases susceptibility of an individual to infection. It is possible that stress and immunosuppression in ruminants similarly predispose to mycotic infection.

Key Words: *A. Fumigatus*, Dairy Feeds, Immunosuppression

481 Is ruminal acidosis related to high diet fermentability or low buffer recycling? D. Sauvant^{*1} and D. Mertens², ¹Département Des Sciences Animales, Institut National Agronomique Paris Grignon, Paris, France, ²US Dairy Forage Research Center, West Madison, WI.

Rumen pH is the outcome of the balance between organic acids produced by diet fermentation and buffer recycling through salivation and chewing. The aim was to elucidate if one of these factors is more important than the other in ruminal acidosis. A database was compiled from 102 published experiments (nexp) containing 264 treatments. To be included in the database, an experiment must have variation in dietary

proportion of concentrate or NDF (NDF = 39.5 ± 13.7 % DM) and provide data on ruminal pH (pH = 6.21 ± 0.34), liquid outflow rate (LOR = 12.1 ± 4.0 L/kg DM), and ruminally digested OM (rdOM = 39.5 ± 10.3 % DM). The LOR is an index of buffer recycling/kg DMI and rdOM is an index of VFA production/kg DMI. The compiled data also included dry matter intake (DMI = $2.81 \pm .87$ % LW) and Acetate/Propionate ratio (A/P = 3.18 ± 0.89). Data were analyzed using GLM procedure to separate variances among and within experiment. On 52 experiments and 132 treatments when ruminal pH was compared to rdOM, there was no significant relationship among or within the diets. In contrast, the small regression standard deviation (rsd) indicated that ruminal pH was fairly accurately explained within diets by LOR: pH = $4.90 + 0.15(\text{LOR}) - 0.003(\text{LOR}^2)$; n = 86, nexp = 35, rsd = 0.09. With the A/P ratio, another index of ruminal perturbation, there was a curvilinear relationship with rdOM: A/P = $-0.59 + 0.50(\text{rdOM}) - 0.011(\text{rdOM}^2)$; n = 79, nexp = 32, rsd = 0.46. However, the corresponding relationship was more accurate with LOR: A/P = $-0.57 + 0.52(\text{LOR}) - 0.014(\text{LOR}^2)$; (n = 75, nexp = 30, rsd = 0.30). In conclusion, this summary of published research indicates that perturbations in ruminal pH and A/P are related more to LOR, which is linked to diet fibrosity indexes and chewing activity, than to differences in dietary variation linked to rdOM.

Key Words: Acidosis, Ruminal Digestibility, Ruminal pH Turnover

482 Design of a bovine metabolism gene array. B. E. Etchebarne*, W. Nobis, M. S. Allen, and M. J. VandeHaar, *Michigan State University, East Lansing.*

First generation microarrays employing extensive cDNA libraries have allowed high numbers of both known and unidentified genes to be surveyed. Many of these arrays have only one spot per gene, leaving no margin for measurement error and giving no information on variance of replication. The Human Genome Project has provided extensively annotated databases, such as Locuslink, the Kyoto Encyclopedia of Genes and Genomes (KEGG), The Institute for Genomics Research (TIGR), and BioCarta. These publicly available resources, paired with recent price reductions in oligonucleotide synthesis, allow researchers to feasibly design and produce microarrays with gene sets tailored to specific research areas. Using these databases, we identified approximately 2000 bovine genes representing enzymes of metabolic pathways, metabolic regulators and receptors, transport and binding proteins, intracellular signaling cascades, and cell cycle and apoptotic pathways. Three individual 70mer oligonucleotide probes per gene were designed for triplicate spotting onto glass slides, giving nine spots per gene. Each oligonucleotide was designed within specific parameters to standardize hybridization behavior. Use of multiple oligonucleotides per gene improves representation of the expressed fraction of each gene, including splice variants. High spot replication improves within-array quality control and increases the statistical power of detecting small changes in

expression at a lower cost than slide replication. Statistical power is especially important for metabolic research, in which changes in gene expression are often subtle. In addition, our focus on only those genes that are relevant to metabolism improves downstream bioinformatics and data analysis for integration of metabolic gene networks. Because all genes included in this design are annotated with corresponding human homologs, the design can be applied to other species to promote our understanding of comparative metabolism. In conclusion, our design of a focused oligonucleotide microarray with multiple spots per gene will facilitate research in the metabolic genomics of cattle and can be easily applied to other species and disciplines.

Key Words: Microarray, Metabolism, Statistical Power

483 Effect of increasing ruminal valerate, caproate, and heptanoate on splanchnic metabolism of VFA absorbed from the washed reticulorumen of steers. N. B. Kristensen*¹ and D. L. Harmon², ¹*Danish Institute of Agricultural Sciences, Tjele, Denmark,* ²*University of Kentucky, Lexington.*

Four steers fitted with a ruminal cannula and chronic indwelling catheters in the mesenteric artery, mesenteric vein, hepatic portal vein, hepatic vein, as well as in the right ruminal vein were used to study the absorption and metabolism of VFA from bicarbonate buffers incubated in the temporarily emptied and washed reticulorumen. Each treatment was incubation of a bicarbonate buffer in the rumen for 90 min and continuous infusion of ruminal infusate to maintain a constant rate of VFA disappearance. Treatments were control (VFA mixture) or added valerate (VAL), caproate (CAP) or heptanoate (HEP). With the control the ruminal disappearance rates were 585 ± 24 , 257 ± 10 , 12 ± 0.4 , 118 ± 3 , and 17 ± 1 mmol/h of acetate, propionate, isobutyrate, butyrate, and valerate, respectively. With VAL, the valerate disappearance increased to 99 ± 1 mmol/h. Ruminal disappearance of caproate and heptanoate were 57 ± 1 and 60 ± 0.4 mmol/h with CAP and HEP, respectively. Net portal flux (68 vs. 39 ± 2 mmol/h) and splanchnic flux (22 vs. 10 ± 1 mmol/h) of butyrate increased ($P = 0.01$) with VAL compared with control. The concentration difference of butyrate between artery and ruminal vein increased ($P = 0.01$; 0.242 vs. 0.120 ± 0.007 mmol/kg blood) with VAL compared with control indicating that butyrate metabolism by the ruminal epithelium was inhibited by the increased valerate. Net portal flux of caproate and heptanoate accounted for 54 and 43% of the ruminal disappearance, respectively. The splanchnic flux of caproate and heptanoate accounted for less than 2% of the ruminal disappearance rate indicating complete metabolism by the splanchnic-drained viscera. Caproate and heptanoate affected rumen epithelial butyrate metabolism less than the increased valerate.

Key Words: Cattle, Energy Metabolism, Volatile Fatty Acids

ALPHARMA Beef Cattle Symposium: Factors Affecting Feedlot Profitability

484 Assessing the cost of beef quality. J. D. Lawrence*, C. Forristall, and G. May, *Iowa State University, Ames.*

The number of U.S. fed cattle marketed through a value-based or grid marketing system is increasing dramatically. Most grids reward Choice or better quality grades and some pay premiums for yield grades. The Choice-Select (C-S) price spread increased 55 percent, over \$3/cwt during the 1990s. However, there is a cost associated with pursuing these carcass premiums both in the feedlot and the cowherd. Correlations between carcass and performance traits resulted in economic tradeoffs that change across input costs and quality grade premiums and discounts. Feedlot profitability was largely determined by marbling, carcass weight, and feed efficiency. Carcass weight was most important at a low C-S spread but give way to marbling at average and higher quality premiums. Data suggests that cow size and marling score are negatively correlated. The current trend toward wider C-S spreads places greater emphasis on marbling ability of calves. These correlations and results suggest that higher marbling is associated with lower cost cows to maintain.

Key Words: Beef, Feedlot Profits, Grid Marketing

485 The effect of cattle health on performance, production costs, and carcass value. R. L. Larson*, *College of Veterinary Medicine, Commercial Agriculture Program, University of Missouri, Columbia.*

Bovine respiratory disease (BRD) and possibly other diseases may detrimentally affect weight gain, carcass weight, rib eye area, marbling, and meat tenderness of feedlot cattle. Gardner et al. (1999) found steers with lung lesions had lighter hot carcass weights, lower dressing percentage, less internal fat, and lower marbling scores than steers without lesions. Steers with lung lesions also tended to have less external fat and smaller longissimus muscle area than healthy counterparts.

A clear mechanistic pathway linking disease to changes in growth and carcass traits has not been described. In their review of feedlot cattle growth, Owens et al. (1995) summarized that rate and composition of tissue accretion may be controlled by chronological age, physiological age, energy intake, hormonal status, relative turnover of tissues, cell number, and cell activity. Disease could conceivably impact all of these control processes except chronological age. There are three possible mechanisms by which disease may impact growth and carcass traits. First, metabolic signals such as cytokines and cortisol could have an effect on carcass composition through modification of hypothalamic secretions of thyrotropin-releasing hormone, by inhibition of IGF-I and insulin actions on muscle and fat tissues, and by direct protein catabolism

and lipolysis. Second, disease-induced anorexia could decrease serum IGF-I and increase serum GH which causes irreversible change in the partitioning of nutrients for tissue deposition. Ward et al. (1992) found that fasted cattle have higher serum cortisol concentrations than do fed cattle. Cortisol may be involved in anorexia-associated decreases in carcass weight and fatness through decreased thyroid hormone activity and increased protein catabolism. Third, cytokines and endotoxin induce various behavioral symptoms of sickness including lethargy, adipisia, and reduced social interactions. The result may be an indirect effect of anorexia on growth and carcass traits in that sick cattle are effectively on feed for fewer days than healthy penmates.

Key Words: Respiratory Disease, Cattle, Carcass Value

486 Effects of nutrition and management on carcass value and profitability. L. L. Berger* and N. A. Pyatt, *University of Illinois, Urbana.*

As increasing numbers of cattle are being marketed on a grid basis, carcass value rather than live weight is becoming the primary determinant of profitability. Carcass value is determined by weight, quality grade, yield grade, choice-select spread, and premiums and discounts. Early-weaned steers (n = 192, Simmental or greater) of known genetics were individually fed in a four-year study to determine performance and carcass factors explaining variation in carcass value and profitability. Steers were weaned at 88.0 ± 1.1 d and fed a high concentrate diet

(\$108.99/T) for 84.5 ± 0.4 d prior to allotment. Steers consumed a 90% concentrate diet (\$98.93/T), consisting primarily of whole shelled corn and corn silage, for 249.7 ± 0.7 d and harvested at 423.3 ± 1.4 d of age. Five-year price data were collected for feedstuffs, dressed beef, and grid premiums and discounts. Average dressed beef price was \$110.67/45.4 kg. Premiums (\$/45.4 kg) were given for Prime (\$5.62), premium Choice (\$1.50), yield grades (YG) 1 (\$2.46), 2A (\$1.31) and 2B (\$1.11). Discounts (\$/45.4 kg) were given for Standard (-\$17.72), Select (-\$8.90), YG 3A (-\$0.12), 3B (-\$0.19), 4 (-\$14.16) and 5 (-\$19.56), and hot carcass weight (HCW) extremes (409-431 kg, -\$0.64; 432-454 kg -\$11.39; > 454 kg, -\$19.71). Input costs included annual cow costs (\$327.77), veterinary/medical and labor (\$35/hd), feed markup (\$22/T), yardage (\$0.25/hd/d) and interest (10%). Dependant variables were carcass value and profit per steer. Independent variables were yearling weight EPD, marbling EPD, daily DMI, ADG, feed efficiency, HCW, 12th rib fat, calculated YG and marbling score (MS). Carcass value was correlated ($P < 0.05$) with yearling weight and marbling EPD, DMI, ADG, feed efficiency, HCW and MS. Carcass weight, MS and YG accounted for over 79% of the variation in carcass value among steers; explaining 57, 12 and 10%, respectively. Profit was correlated ($P < 0.05$) with DMI, ADG, feed efficiency, HCW and MS. Marbling score, DMI, ADG, YG and HCW accounted for over 77% of the variation in profit among steers; explaining 30, 14, 12, 12 and 9%, respectively

Companion Animal Symposium

487 Nutritional management of obese animals. G. D. Sunvold*, *The Iams Company Research and Development, Lewisburg, OH.*

Being overweight or obese is the single most common nutritional disease in companion animals. Traditional weight management technology involves diluting dietary calories with fiber. The potential side effects of high fiber diets will be noted in the presentation. An alternative weight management strategy, managing the underlying physiological changes that occur in overweight animals or put these animals at risk for obesity, will be discussed. The close relationship between obesity and glycemia makes it important to study glucose and insulin metabolism in order to effectively treat obesity. This metabolic association will be discussed. The role of several nutrients for use in weight management has been examined and will be an important aspect of this presentation.

Key Words: Dogs, Cats, Obesity

488 Humans and companion animals: hand-in-paw towards aging and obesity. B. T. Larson*, D. F. Lawler, Y. Pan, and J. R. Jackson, *Nestle Purina PetCare Co.*

The effects of aging are relentless. In response to aging, living organisms make functional, physiological and zoometric adaptations. Beyond these seemingly pre-ordained genetic and physiological adaptations, there are

increasing adverse effects upon aging mediated through obesity. The relative abundance of inexpensive, entertaining, and delectable food energy sources combined with a lack of immediacy or initiative to use calories through physical activity has caused an epidemic of obesity. Statistics regarding obesity in humans and companion animals compels science to explore available options. Scientific knowledge surrounding obesity and aging is growing at a remarkable rate. New revelations have been made of adipose tissue's regulatory effects on whole-body physiology (insulin resistance, ex.). In addition, obesity is related to chronic disease development (osteoarthritis, organ function, cancers, ex.) through insulin sensitivity. These new developments have opened new venues in the science of aging and obesity. Additionally, the aging-related loss of lean tissue mass physiologically intersects with age-associated fat tissue deposition to multiply downstream physiological effects. Unfortunately, this exponential knowledge growth exceeds population implementation rate. How companion animal science approaches these issues is critical to implementation. What is the science component in the aging and obesity implementation equation? Given, that science agrees to disagree about mechanistic theories, how is interim credibility preserved with partners outside science? Who are sciences potential partners in the aging and obesity implementation equation? What might this partnership look like in order to curb the acceleration of obesity in aging companion animals?

Key Words: Companion Animals, Aging, Obesity

Dairy Foods and Human Nutrition

489 Fortification in dairy products. C. Boeneke*, *Louisiana State University Agricultural Center, Baton Rouge.*

Webster's dictionary defines fortification as the act or process of adding materials to for strengthening or enriching. Fortification of dairy products is not a new idea. The process of fortification of milk with vitamin D dates back to the 1930's. The acceptance of this practice led to additions of vitamin A and minerals in the 1940's. No vitamin content levels were specified by the Milk Ordinance and Code until 1953 when a level of at least 400 International units (IU) per quart was established for vitamin D. In 1965, the Milk Ordinance and Code became the Grade A Pasteurized Milk Ordinance or PMO. This PMO defined low fat milk but gave no provisions for its fortification. An increase in consumption of the lower fat products led to nutritional concerns over vitamin A. The content of vitamin A, a fat-soluble vitamin, is smaller in the lower fat product. The 1978 PMO required fortification of these lower fat products at levels of not less than 2000 IU per quart for vitamin A. Vitamin D

fortification was still optional and could be added at 400 IU per quart. Consumers are demanding products that taste good and have health benefits. Dairy products are already rich in nutrients like potassium, riboflavin, calcium and vitamins A, D, and B-12. Fortification has the potential to improve them further. Dairy products fortified with added calcium, whey proteins, beneficial bacteria, and isoflavonoids are already on the shelves. Other ingredient additions such as vitamin C and E, lactoferrin, lutein, and others are available. Fortification poses unique problems to scientists and manufacturers involved with dairy products. Interactions with the ingredients used in fortification can cause product improvement or product detriment. More research must be conducted to examine the results of fortification in dairy products.

Key Words: Fortification, Dairy

490 Consumer attitudes toward dairy foods. C. M. Bruhn, *University of California, Davis.*

Taste is the number one reason for selecting food, but interest in nutritional content and special health benefits is also important. Consumers respond positively to the taste of many dairy products, but perceptions of health benefits are not as positive as they could be, perhaps because of the strong association of dairy with high fat. An increasing number of consumers are aware that food can provide special health promoting nutrients. Both traditional nutrients, like calcium, and nutrient components of emerging importance, like probiotics, can increase the appeal of dairy foods. Consumers are aware that dairy products help protect against osteoporosis, and many recognize that they do not get enough calcium, however young and middle aged people incorrectly believed they do not have to guard against this disease until they were older. People are not aware of other benefits of dairy products, such as the potential protection provided by calcium against certain cancers and lowering of blood pressure. Furthermore, people have not heard that diets that include dairy result in faster weight loss. While yogurt is generally perceived as a healthy product, consumers are not aware of the numerous potential benefits that probiotic cultures may provide. Although parents expect children to consume dairy product, modeling this behavior by parents is lacking in many home. Label statements may help alert consumers to a fuller range of dairy advantages. Promotion programs that emphasize the number of servings needed at each stage in the life cycle would provide information not generally known by the public today.

Key Words: Consumer, Calcium, Probiotic

491 Probiotics in health: Their immunomodulatory potential against allergic disorders. Z. Ustunol* and J. J. Pestka, *Michigan State University, East Lansing.*

Prevalence of allergic disease such as asthma, food allergies hay fever and eczema is rising with most rapid increases are observed in developed countries. In the U.S., today, one in every four children and one third of the adult population are reported to have allergies. Although the reason for this increase are not completely known, over the past 20 - 30 years changes in food processing, sanitation, disease eradication and extensive use of antibiotics have been suggest to have altered postnatal immune function and development favoring allergic immune profiles. While the primary reason for atopic diseases may be genetic susceptibility, gastrointestinal microflora is recognized to modulate the local immunological environment and influence systemic immunological events, thus, response to allergens. Probiotic ingestion may alter the gastrointestinal microflora by providing bacterial cells to this ecosystem and have been suggested as potential candidates for immunomodulation and for ameliorating allergic diseases. The major mechanism by which probiotics influence the immune system may relate to their ability to differentially modulate expression of cytokines and co-stimulatory molecules. Probiotic administration can also enhance IgA production, which is thought to be important in clearing of allergens. Although,

the etiology of allergies is complex and the exact mechanisms by which probiotics may affect these diseases are still speculative and mechanistic details are yet to be elucidated, probiotics are already being explored with increasing interest for their therapeutic potential in the management and even primary prevention of allergic disorders. Clinical and epidemiological studies indicate that probiotics potentially may be a viable option for management and prevention of allergies.

492 Nutritional properties of whey proteins. K. J. Burrington*, *Wisconsin Center for Dairy Research, Madison.*

Whey proteins have long been recognized for their functional properties and broad application in foods. Only recently, has interest developed in the nutritional properties of whey-derived food ingredients. Body builders were some of the first consumers to recognize the nutritional value of whey proteins as dietary supplements. Though the body builders' main interest is the muscle repair and building ability of the branched chain amino acids found in whey products, there are many other nutritional benefits associated with selected whey proteins. For example, alpha-lactalbumin, lactoferrin, glycomacropeptide and other whey peptides have been shown to manifest unique nutritional bioactivities. This presentation will review the current knowledge detailing the nutritional properties of whey proteins.

Key Words: Whey Proteins, Nutrition, Bioactivity, Peptides

493 The beneficial role of dairy foods on weight and body fat loss: Where we are and where we are going. D. B. DiRienzo*, *National Dairy Council, Rosemont, IL.*

Obesity has been classified as an epidemic in the U.S. A growing body of evidence indicates that dairy products may be part of the solution, not part of the problem for weight and body fat management. Several studies have indicated an inverse relationship between calcium/dairy product intake and weight/body fat in men, women and children. Animal and in-vitro studies have provided a plausible mechanism on how dairy foods may exert a beneficial effect. Clinical studies have demonstrated that the inclusion of at least three servings of milk, yogurt, or cheese per day can augment weight and body fat loss which occurs from reduced energy intake. Moreover, the impact of dairy foods is greater than calcium supplements or low calcium diets suggesting dairy foods contain additional components, beyond calcium, which impact weight. Additional research is underway or planned to further expand the beneficial impact of dairy foods on weight management. Industry and consumer communication efforts on this relationship have been initiated and expand in 2004 and 2005. This presentation will review the science and communication activities associated this newest benefit of consuming 3+ servings of milk, yogurt or cheese products per day.

Growth and Development: ADSA - Mammary Development - The Role of Progenitor Cells and Nutritional Modulation on Lactation

494 Bovine mammary progenitor cells. S. Ellis*, *Clemson University, Clemson, SC.*

Dairy profitability is dependent on the cyclic development and differentiation of the mammary gland. As in other somatic tissues, a resident population of mammary stem cells is thought to be responsible for supporting the development of the mammary parenchyma. While there is general agreement regarding the existence of mammary stem cells, little else about this important cell population is known. There is a particular lack of information about stem cells in the bovine mammary gland. Data from a number of experimental models suggest that mammary stem cells are scattered throughout the mammary parenchyma and are resistant to stimuli that would promote differentiation. Investigations of prepubertal mammosgenesis in heifers indicate that a histologically distinct population of lightly staining epithelial cells are the primary proliferative cell population in mammary parenchyma. The so-called

light cells have been described in mammary parenchyma of all species examined to date. Unfortunately, the nomenclature relating to these putative mammary stem cells is inconsistent and classification of the cell staining is very subjective. Much of the confusion around mammary stem cells relates to epithelial cells being mistaken for wandering lymphocytes and to the differences between progenitor cells and true stem cells. However, recent ultrastructural studies have clearly shown that light cells do indeed possess epithelial characteristics, and molecular analyses are beginning to identify potential markers that will help identify stem cells in situ. The application of refined embedding, microtomy, and staining techniques for histologic examination with the light microscope has helped to facilitate investigations of putative mammary stem cells, but the experiments are still time-consuming, relatively subjective, and difficult to perform on a large number of tissue samples. Critical needs for future studies of bovine mammary stem cell physiology include: the development of genomic and proteomic information for

bovine model systems; investigations of the ontogeny of mammary stem cell formation, activity, and senescence; and integration of in vitro, genomic, and proteomic information into histologic analyses of mammary development and function.

495 Characterization of gene expression patterns in bovine mammary epithelial cells isolated using laser capture microdissection. B.E. Etchebarne*, M. Kiupel, and M.J. VanDeHaar, *Michigan State University, East Lansing.*

Molecular examination of specific cell populations in primary tissues is necessary to elucidate the mechanisms underlying cellular responses to cytokine and hormonal signals. The inherent heterogeneity of tissues with varying mixtures of reactive cell populations can decrease the sensitivity and accuracy of molecular studies of gene expression. Technological advances in microdissection have allowed for the isolation of homogeneous, morphologically identified cell populations from prepared tissues. When used in conjunction with sensitive analytical techniques, such as quantitative reverse transcriptase polymerase chain reaction (qRT-PCR), microdissection allows precise in vivo examination of gene regulation within the cell population of interest. Using procedures developed in human breast cancer studies, we employed laser capture microdissection (LCM) to study the gene expression profile of epithelial cells in bovine mammary tissues treated with IGF-I and leptin. Our study was performed using frozen samples of bovine mammary parenchyma embedded in OCT compound and sectioned at 8 μ m. Following a brief hematoxylin staining and sequential dehydration, cell sections were air-dried and immediately isolated using the Arcturus Pix-Cell laser capture microscope. Using the SYBR Green-based detection method of qRT-PCR, transcripts for leptin receptor, beta-actin, and forkhead transcription factor FOXO3A were detected in as little as a 1:100 dilution of RNA (equivalent to 10 cells) isolated from a single LCM cap and subsequent cDNA synthesis. Ongoing studies are focusing on characterizing and quantifying relative gene expression between LCM versus whole tissue preparations of specific genes of interest for both epithelial and stromal bovine mammary cell populations.

Key Words: Laser Capture Microdissection, Gene Expression, Mammary

496 Phenotypic and ultrastructural characterization of the developmental pathway of bovine mammary gland progenitor cells. M. S. Holland*¹, L. D. Griffin¹, J. A. Stasko², and R. E. Holland*³, ¹*Veterinary Microbiology and Preventive Medicine, Iowa State University, Ames*, ²*National Animal Disease Center, USDA-ARS*, ³*Veterinary Diagnostic and Production Animal Medicine, Iowa State University.*

A model system that scaled down the mammary gland to its most essential components was developed. Bovine mammary gland progenitor cells (BMGPC) were isolated from the mammary parenchyma by biopsy and collagenase digestion. The isolation process confirmed the parenchyma as one site within the mammary gland that contained mammary stem/progenitor cells. Cell culture techniques were used to purify the BMGPC from other cell types in the mammary gland. Based on ultrastructural analysis, BMGPC were divided into two populations. An undifferentiated population exhibited minimal absorption of osmium tetroxide while the differentiated population exhibited efficient absorption of osmium tetroxide. The two populations also differed in the number and type of cellular organelles. Undifferentiated BMGPC had mitochondria and tonofilaments. Depending on the stage of differentiation, differentiated BMGPC contained mitochondria, tonofilaments, rough endoplasmic reticulum, free ribosomes, golgi apparatus, protein-filled vesicles, etc. The differentiation process in BMGPC appeared to be controlled by the complex cellular microenvironment as indicated by the response of BMGPC to signals from hormones and the extracellular matrix. Our results indicated that components in extracellular matrix elicited a range of responses. While matrigel induced undifferentiated BMGPC to differentiate, laminin, collagen I and IV induced minimal differentiation. Signals from hormones and growth factors were also key in inducing differentiation. In conclusion, we produced a cell line for functional studies of the mammary gland.

Key Words: Progenitor Cells, Differentiation, Ultrastructure

497 Effects of energy intake and time to puberty on mammary growth of prepubertal Holstein heifers. M. J. Meyer*¹, A. V. Capuco², and M. E. Van Amburgh¹, ¹*Cornell University, Ithaca, NY*, ²*USDA-ARS, Beltsville, MD.*

In the bovine, early postnatal mammary growth is thought to occur at an allometric rate and return to an isometric rate after puberty. Elevated energy intake prior to puberty has been shown to retard mammary parenchymal (PAR) DNA content at puberty, however, a causative relationship between PAR DNA at puberty and future milk yield has yet to be substantiated. Our objectives were to describe effects of increased energy intake from shortly after birth on 1) total PAR and fat pad (FP) DNA, 2) PAR DNA accretion rates, and 3) timing of the prepubertal allometric growth phase. Holstein heifers (n = 78) were fed from 45kg either elevated (E) or restricted (R) levels of energy to achieve divergent rates of gain (E 950 g/d; R 650 g/d). Six heifers per treatment (TRT) were slaughtered at 50kg increments from 100 to 350kg. Six were slaughtered at 46kg, at which time PAR was difficult to discern and present as a small cord of tissue. FP weights were similar between TRT up to 200kg but were heavier from 250 through 350kg in E-heifers (P < 0.05). However, FP DNA content was similar between TRT until 350kg, at which point FP DNA was greater in E- than R-heifers (P < 0.05). PAR DNA was similar between TRT up to 200kg. From 250 through 350kg, R- had more PAR DNA than E-heifers (P < 0.05). Interestingly, daily PAR DNA accretion rates, calculated between consecutive slaughter points, were not influenced by energy intake (P = 0.98). This rate reached a peak of 5.4 mg PAR DNA per day between 200 and 250kg and declined precipitously during the peripubescent period. A plot of the log BW vs. log PAR DNA indicates that mammary growth rate, independent of TRT, was allometric by 100kg BW and became isometric shortly before puberty (puberty occurred at 280kg independent of TRT). These data demonstrate that reductions in mammary PAR DNA associated with elevated rates of gain result from a reduction in time to puberty rather than impairment of epithelial cell proliferation and PAR DNA accretion.

Key Words: Heifer, Mammary Development, Puberty

498 Nutritionally directed compensatory growth affects mammary cell proliferation and apoptosis. C. S. Park*, *North Dakota State University, Fargo.*

The proper application of a time-dependent and closely controlled nutrition regimen during different growth stages prior to first parturition can affect mammary development and subsequent lactation potential. We have developed a compensatory growth nutrition regimen which is a combination of dietary energy restriction and realimentation phases designed to regulate mammary development. The basic concept of this nutrition regimen is to exploit the biological nature of the energy restriction and compensatory growth phenomenon in concert with one or more hormone-sensitive allometric phases of mammary development (i.e., peripuberty through gestation). We have examined various models for developing dairy and beef heifers, gilts, and rats. General observations are that compensatory growth regimens have positive effects on mammogenesis and lifetime lactation performance. The synergistic interaction of nutritionally induced compensatory mammary growth with developmentally related allometric growth causes a cascade of up-regulation of various genes which affect cellular activity and regulate the cell cycle. Compensatory growth causes permanent hyperplasia and hypertrophy of mammary alveolar epithelial cells, thereby stimulating mammary development and differentiation as evidenced by increased expression of ornithine decarboxylase and β -casein. The decrease in epithelial cell death in compensatory mammary tissue may be closely related to an increase in the expression of insulin-like growth factor-I which affects both cell cycle progression and apoptosis. Our recent studies with expression profiling by gene array analysis reveal that compensatory mammary growth modulates genes associated with a broad range of metabolic pathways or physiological functions (i.e., proliferation, differentiation, secretion, cellular communication, apoptosis, lipogenic and myogenic pathways, and tissue remodeling). By altering the expression of cell cycle genes, compensatory mammary growth provides a potential means to manipulate mammary function and lactation.

Key Words: Compensatory Growth, Mammary Cell Proliferation, Apoptosis

499 Effects of a high rate of gain for increasing lengths of time on body and mammary growth in prepubertal dairy heifers. L. E. Davis*, M. S. Weber Nielsen, L. T. Chapin, J. S. Liesman, and M. J. VandeHaar, *Michigan State University, East Lansing.*

A high rate of gain in dairy heifers for #8805 3 mo is detrimental to prepubertal mammary growth and subsequent milk yield. However, the effects of a high rate of gain for shorter periods have not been reported. Our objective was to compare effects of high (1200 g/d) and low (600 g/d) rates of gain over different lengths of time (0, 3, 6, 12 wk) on body and mammary growth. Heifers (age = 11 wk, n = 64, BW = 107 kg, SE = 1.0) were randomly assigned to 1 of 4 treatments: H0 (low diet fed for 12 wk); H3 (low diet fed for 9 wk followed by high diet for 3 wk); H6 (low diet fed for 6 wk followed by high diet for 6 wk); and H12 (high diet fed for 12 wk). Animals were slaughtered at 23 wk of age. Statistical analysis used the GLM procedure of SAS and tested multiple comparisons using the Bonferroni test. Statistical significance was declared at $P < 0.05$. Average daily gain and final live weights were different for all comparisons except H0 versus H3 (H0 = 662, H3 = 660, H6 = 848, H12 = 1124 g/d, SE = 12; H0 = 165, H3 = 166, H6 = 181, H12 = 203 kg, SE = 1). Final withers height was greater for H6 and H12 (H0 = 100, H3 = 100, H6 = 102, H12 = 104 cm; SE = 0.3). Carcass wt were different for all comparisons (H0 = 77, H3 = 82, H6 = 92, H12 = 107 kg; SE = 1). Mammary hemigland mass increased with time on high diet (H0 = 529, H3 = 591, H6 = 768, H12 = 864 g/100 kg carcass wt; SE = 43). Mass of perirenal fat also increased with time on the high diet (H0 = 900, H3 = 1181, H6 = 1608, H12 = 1794 g/100 kg carcass wt; SE = 105). Short-term changes in diet altered growth of body and mammary tissues. Composition analysis of carcass and mammary tissues are ongoing.

Key Words: Growth, Heifer, Mammary

500 Long days that hasten puberty do not reduce lean body growth in heifers. A. G. Rius*¹, P. E. Kendall¹, T. L. Auchtung¹, A. V. Capuco², E. E. Connor², and G. E. Dahl¹, ¹*University of Illinois, Urbana,* ²*USDA-ARS, BGFL, Beltsville, MD.*

Photoperiod affects growth and development in many species with long day photoperiod (LDPP; 16L:8D) hastening the onset of puberty and enhancing lean growth in cattle. Appropriate body scale is crucial in heifers at first parturition. However, accelerating prepubertal growth may diminish mammary parenchymal growth. Nutritional factors including metabolizable protein also affect the onset of puberty, body and mammary growth in heifers. Our objective was to determine if LDPP hastens the onset of puberty without limiting skeletal growth, (i.e. height). We also sought to determine if the response to LDPP is limited by protein availability. Holstein heifers (n = 32) were assigned to 1 of 4 treatments in a randomized complete block design and a 2x2 factorial arrangement to assess effects of photoperiod and dietary bypass protein on the onset of puberty and body growth. Treatments were LDPP, short day photoperiod (SDPP; 8L:16D), high or low dietary bypass protein. Blood samples were analyzed for PRL concentration to confirm a photoperiodic response and for progesterone to determine puberty. Body weight (BW), withers height (WH), hip height (HH), and heart girth (HG) were measured every two weeks. After puberty, heifers were housed under natural photoperiod and body measurements were continued to evaluate body growth postpubertally. Heifers exposed to LDPP reached ($P < 0.02$) puberty 20 d earlier than animals on SDPP. Increasing dietary bypass protein did not affect growth of heifers (BW, WH, HH or HG) on either photoperiod treatment. However, heifers previously exposed to SDPP gained 22 kg more ($P < 0.05$) of BW after puberty than did heifers previously exposed to LDPP. These data support the use of photoperiod as a non-invasive technique to hasten skeletal without limiting lean growth and development in heifers.

Key Words: Photoperiod, Growth, Heifer

PSA World Poultry Science Lecture

501 Reducing the carriage of foodborne pathogens by livestock and poultry. M. P. Doyle*, *Center for Food Safety, University of Georgia, Athens.*

Livestock and poultry are frequently asymptomatic carriers of human enteric pathogens. Salmonella, Campylobacter and Escherichia coli O157:H7 can reside in the animal's gastrointestinal tract and be shed in feces that subsequently contaminates food and water. Practical, effective on-farm interventions are needed to provide greater protection of the environment and the food supply. Progress is being made on several

fronts in developing useful strategies for pathogen control in animals. Examples include competitive exclusion microorganisms, vaccines, bacteriophages, water/feed treatments, and husbandry practices. Reducing pathogen carriage by animals on the farm can have a major impact on reducing contamination of the environment, water and food, thereby providing greater public health protection.

Key Words: Foodborne Pathogens, Competitive Exclusion, Preharvest Interventions

Animal Behavior & Well Being II

502 Correlating spatial learning, social recognition and aggression in young pigs. J. M. Siegford*, A. S. Souza, J. Jansen, and A. J. Zanella, *Department of Animal Science, Michigan State University, East Lansing.*

We examined cognitive abilities and agonistic behavior in young female pigs to determine whether spatial learning (SL) was correlated with social recognition (SR) and post-mixing aggression. SL and SR require activation of the hippocampus, thus they may be correlated. Therefore, pigs performing well in SL should remember other pigs more easily in SR and might use information of previous social encounters to avoid fights when mixed. SL of pigs was tested twice (d13 and d14) using a modified water maze (WM) in which pigs in a pool of opaque water locate a submerged platform (5 exposures per pig separated by 10min). Good (GP; n=23) and poor performers (PP; n=24) were selected based on latencies from previous WM results for pigs of this age. Using average latencies from exposures 2-5 on both days, criterion for GP was <55s and criterion for PP was >70s. Animals were familiarized at d20 and d21 in arenas divided by flexible netting. SR testing was subsequently carried out at d21 and d22. At d23, all pigs were weaned. On d24, piglets were retested in the WM. Latency continued to decrease, suggesting weaning did not disrupt memory of the WM task, but no difference in latency was seen between GP and PP ($F_{1,47}=0.04$; $p=0.84$). At d25, pigs were mixed in groups of 6 GPs (n=4) or PPs (n=4) and duration and number of fights were monitored for 1 day. Pre-mixing familiarization led to a decrease

in post-mixing fights ($F_{1,43}=4.75$; $p=0.03$; 7.26 ± 1.49 vs. 4.46 ± 0.69). In the first 3 hours post-mixing, unfamiliar PPs fought more than other groups ($F_{1,43}=14.33$; $p < 0.001$; 13.67 ± 2.32 vs. 5.22 ± 2.22), suggesting a correlation between SL and post-mixing aggression. Duration of fights was affected by interaction of day with familiarity ($F_{1,43}=4.61$; $p=0.04$) and time of day with WM performance ($F_{1,43}=4.41$; $p=0.04$). Additional animals are being tested to strengthen findings, which suggest familiar pigs and possibly GP fight less. Protocols could be developed to familiarize litters to reduce post-mixing aggression in production.

Key Words: Behavior, Welfare, Learning

503 Acute stress impairs spatial learning and social recognition in early-weaned pigs. A. S. Souza*, K. Laughlin, J. M. Siegford, and A. J. Zanella, *Department of Animal Science, Michigan State University, East Lansing.*

We investigated whether weaning age and social isolation disrupt spatial learning (SL) and/or social recognition (SR) in newly-weaned pigs. Female pigs were early-weaned at d11-12 (EW; n=48) or conventional-weaned at d23 (CW; n=48) and social isolation (SI) for 15 minutes occurred immediately before testing each pig once in either SL or SR. We assessed SL using a modified water maze, in which pigs in a pool of opaque water and must locate a submerged platform. The latency to reach the platform from a pre-determined release point was recorded

over 7 exposures (separated by 10 minutes). A decrease in latency across exposures has been validated as a measure of SL. For SR, 2 litters at time were habituated to each other for 8h in an arena divided by netting, preventing mixing and fighting. The day following habituation pairs of pigs from habituated litters were re-habituated for 20min, then pigs were exposed to a familiar or an unfamiliar conspecific for 3min to test SR. Duration of social investigation is a valid measure of SR as familiar conspecifics spend less time in social investigation than unfamiliar animals. Social isolation of pigs caused significant impairment in SL (GLM; $F_{1,48}=18.59$, $p=0.0001$) and interaction of weaning age and SI (GLM; $F_{1,48}=11.14$, $p<0.0018$), with EW pigs showing no decrease in latency following isolation. A significant interaction existed between weaning age and SI during SR between familiar animals (GLM; $F_{1,17}=23.13$, $p=0.0002$). Socially isolated EW pigs investigated familiar animals more than non-SI EW animals ($66.57s\pm 5.92$ vs. $14.28s\pm 3.54$, $p<0.0001$), SI CW ($18.60s\pm 5.92$, $p<0.0001$) or non-SI ($20.80s\pm 7.26$, $p<0.0001$) CW pigs. The amount of social investigation did not differ in unfamiliar animals. The observed deficits in SL and SR with EW and SI suggest potential cognitive disruption and may be affected by age at which the developing brain is exposed to increases in stress hormones, such as those accompanying weaning. Possible neural mechanisms for this disruption are being investigated.

Key Words: Welfare, Behavior, Stress

504 Relationships among pre- and post-weaning oral-nasal behaviors and growth rates in newly weaned pigs. S. Torrey* and T. M. Widowski, *Department of Animal and Poultry Sciences, University of Guelph, Guelph, ON, Canada.*

Previous studies have found large differences in the amounts of time that individual piglets spend belly-nosing in the first few weeks post weaning, but the individual characteristics that predispose some pigs to perform oral vices are not known. The objectives of this experiment were to discern whether piglets that perform the most nursing behaviors during and in-between nursing bouts pre-weaning also perform the most belly-nosing and pig-directed behaviors post-weaning and to determine any relationships between these behaviors and growth rates. Sixty-six pigs from seven litters of Yorkshire pigs were individually identified and observed for nursing-related behaviors during and in between three nursing bouts on each of three days pre-weaning (days 7, 12, 17 of age) and weaned at 21 days. Pigs were penned with littermates post-weaning and behaviors were scan sampled from video-recordings for 21 days. In addition, individual piglets were weighed at birth, at days 7, 12 and 17 of age, at weaning and at days 7, 14 and 21 post-weaning. Pearson partial correlations were performed on individual pig data with litter used as a partial covariate. The performance of nursing behaviors during a nursing bout tended to be negatively related to belly-nosing post-weaning ($P = 0.07$; $r^2 = -0.22$). Birth weight ($P < 0.05$; $r^2 = -0.26$) and post-weaning average daily gain ($P < 0.01$; $r^2 = -0.35$) were also negatively related to belly-nosing. Alternatively, there were positive relationships between nosing behavior directed onto objects post-weaning and pre-weaning ($P < 0.001$; $r^2 = 0.45$) and post-weaning ($P < 0.05$; $r^2 = 0.29$) average daily gains. Pre-weaning behaviors and growth rates are related to the performance of oral-nasal behaviors post-weaning, with the low birth weight, slower-growing piglets performing the most belly-nosing.

Key Words: Belly-Nosing, Nursing, Weaning

505 Effects of induced mixing and pen size on performance and serum concentration of acute phase proteins in growing pigs. C Piñero*¹, J Morales¹, M Piñero*¹, F Lampreave², and G.G Mateos³, ¹PigCHAMP Pro Europa, S.A., Spain, ²U. de Zaragoza, Spain, ³UP. de Madrid, Spain.

There is a growing interest to assess the response to stressors in pigs. The objective of this study was to determine the response of serum levels of two acute-phase proteins (APP's) (Pig-MAP; MAP and haptoglobin; HPT) and performance due to mixing and pen size at the entry at the fattening unit. A total of 240 pigs (LW x LW-LD) 20.2 ± 0.9 kg BW was randomly distributed in 24 pens in a $2 \times 2 \times 2$ factorial that included the effects of mixing (mixing or same piglets than in nursery), pen size (8 or 12 pigs per pen), and sex. Piglets were controlled every 14 d from 60 to 116 d of age to determine ADG, FC and FI). Blood samples were taken at d 1, 5, 14, 28, and 42 d of the study. Mixing affected APP's concentration. The day following placement at the fattening barn, mixed pigs had higher MAP values (2.07 vs 1.36 mg/mL;

$P=0.0006$) than not-mixed pigs and the differences were still significant 5 d after placement (1.18 vs 0.90 mg/mL; $P=0.04$). At d 14, mixed pigs tended to have higher MAP values (0.69 vs 0.54 mg/mL; $P=0.07$) than non-mixed pigs but the difference disappeared thereafter. No consistent pattern was observed for HPT, but the concentration was always higher for mixed pigs and in fact the effect was significant at d 14 (1.83 vs 1.31 mg/mL; $P=0.05$). The differences in APP's concentrations correlated with differences in productive performance and from 74 to 88 d of life non-mixed pigs showed a higher ADG than mixed pigs (667 vs 624 g/d; $P=0.02$). Pen size did not have any effect on APP serum concentrations but ADG were higher for pigs kept in groups of 8 than in pigs kept in groups of 12 (736 vs 712 g/d; $P=0.03$, respectively). Boars were more sensitive to both stressors than females and showed higher MAP concentration ($P<0.05$) and lower growth ($P<0.05$) than females. We conclude that mixing of pigs at the start of the fattening period induces stress independently of pen size and that serum concentration of APP's can be used to detect the intensity of the stress.

Key Words: Pigs, Stress, Acute-Phase Proteins

506 Gestation induced changes in behavior and autonomic regulation of cardiac activity in gilts. R. M. Marchant-Forde* and J. N. Marchant-Forde, *USDA-ARS, West Lafayette, IN.*

Gestation in mammals is a time of considerable physical, physiological and behavioral change necessary for the continuance of the pregnancy. Gestating pigs are often used in behavior and well-being studies yet there is little published data describing how gestation affects normal behaviour and patterns of autonomic regulatory control of cardiac activity. The objective of this work was to evaluate gestation induced modifications in the longitudinal dynamics of behavior and autonomic regulation of cardiac activity using heart rate variability parameters in primiparous pigs. The behavior and cardiac activity of ten gilts were recorded at fixed time points over gestation as follows: 1 weeks before oestrus and mating (week 1), 14 days post-mating (week 2), day 30 (week 4), day 44 (week 6), day 65 (week 9), day 79 (week 11), day 93 (week 13) and day 107 (week 15) of pregnancy. Temporal changes in behavior patterns were present in all gilts over the course of gestation. Pre-test levels of general activity progressively declined between weeks -1 and 15 as indicated by a decrease in the proportion of observations spent rooting ($p<0.001$), walking ($p<0.001$) and standing ($p<0.001$). There was a corresponding increase in inactivity ($p<0.001$) and the proportion of time spent sleeping, as opposed to lying alert, increased also ($p<0.001$). Apart from RR-min and its corresponding HR-max indices, all time domain parameters of cardiac activity were substantially influenced by stage of gestation. Specifically, mean HR increased ($p<0.001$) whereas RMSSD and SD decreased ($p<0.001$). Pregnancy further impacted on frequency domain measures of heart rate variability. From week 1 to week 15 the absolute magnitude of Total power ($p<0.001$) decreased, HF power decreased, ($p<0.001$) and LF power increased ($p=0.004$). In conclusion, pregnancy induced widespread changes in behavior and in sympathovagal regulation of cardiac activity in pigs that were reflected in both time and frequency domain indices of heart rate variability analysis.

Key Words: Gestation, Behavior, Heart Rate Variability

507 Circadian rhythmicity in behaviour and cardiac activity of gilts and heifers. R. M. Marchant-Forde*¹, J. N. Marchant-Forde*¹, and R. Hofman², ¹USDA-ARS, West Lafayette, IN, ²Institute of Animal Husbandry and Welfare, University of Veterinary Medicine, Vienna, Austria.

Biological rhythms are of universal occurrence in animals and it is usually easy to demonstrate adaptive explanations for them. The aim of this work was to examine circadian patterns of behavior and cardiac activity in gilts and heifers, to determine if any rhythms present followed general sleep/wake cycles and the degree to which they were influenced by activity levels. Continuous behavior and cardiac data were simultaneously recorded in non-gravid gilts and heifers over a 24h period. Scan sample were used to extract behavior data from videotapes and hourly means for all behaviors, as well as the proportion of time spent active or inactive, were determined. Cardiac data was processed for error before undergoing heart rate variability (HRV) analysis. Hourly means for all cardiac indices were also calculated. Cosinor analysis was used to evaluate circadian rhythms from which the MESOR, amplitude, acrophase, and Pearsons correlation coefficient were determined. Results

found that gilts and heifers differed largely in their 24h behavioral time budgets. Heifers were considerably more active ($p < 0.01$), spent more time standing ($p < 0.01$) and less time investigating their surroundings ($p < 0.01$) than gilts. Gilts showed more circadian rhythmicity in behavior and HRV indices than heifers. Circadian patterns in time domain indices were generally similar, but with gilts demonstrating higher correlation coefficients than heifers in all bar one parameter. Relative to the sleep/wake cycle, rhythms in cardiac activity in gilts were closely associated with the sleep/wake cycle with mean HR being highest and parasympathetic indicators lowest at the end of the sleep period. While heifers demonstrated little circadian rhythmicity in behavior, rhythms in cardiac activity followed obvious circadian patterns, though their rhythmicity was still considerable lower than those in gilts. In summary, gilts showed strong circadian patterns in behavioral and HRV parameters, which were strongly interrelated, whereas heifers showed much weaker evidence of behavioral circadian patterns, but exhibited surprisingly strong circadian rhythmicity in HRV measures.

Key Words: Circadian Rhythms, Behavior, Heart Rate Variability

508 Behavior and heart rate of crated gestating sows given an ICV CRH or a CRH receptor antagonist. L. E. Hulbert^{*1}, J. M. Hellman¹, J. W. Dailey², J. L. Morrow², and J. J. McGlone¹, ¹*Pork Industry Institute, Texas Tech University, Lubbock*, ²*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX*.

Third-parity, crated Camborough-28 (PIC USA) sows ($n=3$) were used to determine the effects of intracerebroventricular (icv) corticotropin releasing hormone (CRH) or a CRH antagonist (Astressin, AST) on sow behavior and heart rate. Specifically, we sought to determine if oral-nasal-facial (ONF) stereotyped behaviors were caused by elevations in central CRH. Sows were surgically fit with an icv canulae in the lateral ventricle during mid gestation. Following an 8-d recovery period, sows were fed and then 30 min later given icv saline (SAL), CRH or AST. Heart rates (Polar 610 IR) and sow behavior were recorded for 48 h after icv injection. Behaviors included sitting, standing, feeding, drinking, sham chewing, ONF directed towards the bars, floor, or feeder and total ONF duration and frequency. Central CRH increased ($P < 0.01$) ONF directed towards the bars and the floor and total ONF compared with icv SAL. AST did not ($P > 0.10$) change ONF or general activity. Total ONF duration was 187.8, 2,253.1 and 203.1 s for SAL, CRH and AST, respectively ($P < 0.001$; SE = 117.8). Lying down duration was lower for CRH-treated sows than for sows in the other treatments (3,261, 1,153, 3,175 s for SAL, CRH and AST, respectively, $P < 0.001$; SE = 127). Heart rate was increased among CRH-treated sows compared with the other treatment groups (75, 114 and 86 bpm; $P < 0.01$; SE = 5.8). Increasing central CRH dramatically increased ONF, general activity and heart rate. Central AST did not reduce (or increase) ONF or heart rate. We conclude that elevated basal levels of CRH among crated sows does not cause ONF behaviors (because AST did not reduce this behavior). However, elevated central CRH increases both ONF behaviors and heart rate. Sow bar-biting behaviors, at the levels observed in crated sows, is not caused by elevated central CRH.

Key Words: Pigs, CRH, Welfare

509 Behavioural description of cannibalism in fattening pig production. D. Saffray^{*1}, I. Madec¹, C. Lafont¹, J.-F. Gabarrou², and P. Pageat¹, ¹*Pherosynthese, Saint Saturnin d'Apt, France*, ²*ESA-Purpan, Toulouse, France*.

Cannibalism in fattening pigs' production refers to a special behavioural problem characterised by repeated bites between pen-mates, leading to wounds of variable severity. Stress and infections following these bites generate decrease of growth rate, emergency slaughter and carcass rejection at the abattoir. Cannibalism is at once a health, welfare and economic problem. Many solutions have been suggested but treatments showed a variable efficiency. A major reason of this situation is that the true causes of cannibalism are still unknown. To find out these causes, an accurate behavioural description is essential to establish if different types of individuals with particular behavioural patterns exist. From a list of 137 pig farms with cannibalism historical records, 12 farms were selected. Inclusion criteria were type of production, performance, genetic, type of cannibalism, type of buildings, feeding parameters, breeding methods and health status. Consequently, the selected farms were similar, allowing the constitution of a single database, with enough data for statistical analysis. In each pig farm, 2 to 4 pens were

filmed. For each pen, we realized 2 sequences of 30 minutes of video recording. Video recordings were analysed by means of a reading grid, focused on the bite act. We recorded wound status, bite type, motor act before the bite and motor act after the bite (for both the biter and the victim). With the resulting database, we carried out both a single variable descriptive analysis and a Multiple Correspondence Analysis. The part of the population involved in at least one bite is substantial (70 %) and is divided into four categories of individuals: biters who bite different body parts, biters who always bite the same body part, victims showing loss of tissue and individuals who are both biter and victim. Depending on the fattening pen in question, all or some of these categories are present, leading to suppose that we observed either different types of disorders or different stages of the same disorder. To settle this point, we need to carry out a study on cannibalism evolution in a same pen.

Key Words: Cannibalism, Description, Pig

510 Maternal pheromone application before and(or) after weaning: effects on pig behavior and performance. N. Krebs^{*} and J. J. McGlone, *Pork Industry Institute, Texas Tech University, Lubbock*.

Weaning is a stressful event for piglets. A synthetic maternal pheromone was studied to determine its effects on behavior and performance of groups of weaned piglets when applied either before and(or) after weaning. Ninety-six 4-wk-old piglets from 30 litters were randomly assigned to 4 treatments arranged factorially with pheromone (PH) treatment (1 mL per pig Suiience; Ceva Sante Animale) or control (CO) in the pre-weaning farrowing environment and PH treatment (1 mL) or CO in the nursery. Each block contained 32 pigs (1 castrated male and 1 female from 4 litters per treatment). Observers recorded live pig behavior pre-weaning using a 10-min scan sample for 40 min before treatment and 80-min after treatment. Prior to weaning, Suiience was applied on sows' teats (or not), to test the hypothesis that the maternal pheromone may increase teat-contact behavior and post weaning feeding behavior. Pigs were weaned into pens that contained either nothing or the maternal pheromone while being video taped in time lapse for 48 h. Pigs were weighed at weaning and each week for 4 wk. Feed disappearance was recorded and feed efficiency was calculated. The maternal pheromone applied in farrowing environment decreased piglet-teat contact behavior (16.2 vs. 8.5 %, SE = 1.91, $P = 0.047$, for CO and PH, respectively). The farrowing treatment by period effect was significant ($P = 0.03$) for post-weaning agonistic behavior; CO pigs had higher % time engaged in agonistic behavior than PH pigs during the first 8 h and 20 to 24 h after weaning. Pigs given PH in the nursery environment had a higher ($P = 0.02$) % of observations standing close to the feeder than CO piglets. There were no significant differences among treatments in pig weaning weights, post-weaning gain or feed intake. In conclusion, the application of PH on the sows' teats before weaning did not increase piglet-teat contact but PH reduced post-weaning agonistic behaviors and increased piglet time spent near the feeder.

Key Words: Pigs, Pheromone, Behavior

511 Pig behavioral responses to biologically relevant and non-relevant odors. N. Krebs^{*} and J. J. McGlone, *Pork Industry Institute, Texas Tech University, Lubbock*.

Pigs use olfaction to detect biologically-relevant odors including pheromones. The objective of this study was to quantify pig behavioral responses to biologically-relevant and non-relevant odors. Pigs were evaluated for their behavioral type. High responder pigs (HR) showed 3 or more escapes in a back test; low responder (LR) piglets showed 2 or less escape attempts in a back test; medium responders (MR) were not consistently LR or HR. Sixty 14-d old piglets (30 castrated males and 30 females) were assigned to randomly experience one odor treatment (isopropyl alcohol [ISO], n-butanol [NB], amyl acetate [AA], maternal feces [MF], synthetic maternal pheromone [MP] and the boar pheromone androstenone [AN]) with the odor applied once in liquid and once in aerosol form. The aerosol was out of reach of the pigs' touch. Piglets displayed the same behaviors regardless of the form of the odors (liquid or aerosol). Piglets oriented their snout away from AA compared to ISO ($P = 0.04$). There was a treatment by back test effect ($P < 0.01$) for lying behavior (indicator of general activity), parallel-facing the fan (PFF; $P < 0.01$) and parallel orienting away from the odor source (PAF; $P < 0.01$). MR pigs spent more time lying down

when experiencing MP than all other treatments. LR pigs did not differ in lying time among odor treatments. HR piglets exposed to AA, NB or MF had decreased lying time compared with ISO. MR pigs spent more time PFF (interested in the odor) when exposed to MF or NB compared with ISO. LR pigs showed similar PFF when exposed to each odor. HR piglets showed more PFF when exposed to MF than ISO. MR piglets showed more PAF (avoided the odor) when exposed to MP and AA than ISO-exposed piglets. LR and HR did not differ in their PAF behaviors among odors. These experiments demonstrated that pig behavioral type interacted with piglet behavioral responses to relevant and non-relevant biological odors.

Key Words: Pigs, Odors, Backtest

512 Effects of mixing stress on plasma cortisol, corticosteroid-binding globulin and free cortisol index in prenatally-stressed pigs. D. C. Lay Jr^{*1}, H. G. Kattesh², M. P. Roberts², M. J. Toscano¹, and K. A. McMunn¹, ¹USDA-ARS Livestock Behavior Research Unit, West Lafayette, IN, ²University of Tennessee, Knoxville.

Exposing a pregnant sow to stress has been shown to have negative effects on her resulting offspring. However, little knowledge exists regarding the mechanisms of this process or the effects of specific stressful events. Our objective was to determine if exposing a sow to stress altered the response of her offspring to mixing stress at 4 mo of age. Sow

treatments consisted of i.v. injections of adrenocorticotrophin (ACTH, 1 IU/kg BW) (ACTH), exposure to rough handling for a 10-minute duration (ROU), or no treatment (CONT) once a week during d 42 to 77 of gestation. At 4 mo of age, one pig from each litter (n = 14, 14, 15) was taken from its home pen and placed in a pen of unfamiliar pigs. Blood samples were collected three times per week for two weeks and then once a week for four more weeks. Blood samples were analyzed for cortisol and corticosteroid-binding globulin (CBG), and a free cortisol index (FCI; total cortisol/CBG) was calculated. In response to treatments, ACTH sows had greater concentrations of cortisol than did ROU sows, which had greater concentrations than CONT sows (77.1, 46.0 and 32.1 ng/mL, P < .004). CBG concentrations in pigs from CONT sows tended to be lower (P < .06) than pigs from ROU sows and was lower (P < .008) than pigs from ACTH sows (4.75 ± .10, 5.2 ± .12, and 5.51 ± .13 mg/L, respectively). An effect of gender was also detected with females having greater (P < .001) concentrations of CBG than males. No treatment differences (P < .10) were found for either plasma cortisol concentrations or FCI. A treatment by repetition (P < .02) and repetition effect (P < .04) were noted for both plasma cortisol and FCI. Prenatal stress, induced either artificially with injections of ACTH, or via rough handling, changes CBG responses compared to controls but does not alter either FCI or plasma cortisol concentrations. The degree to which effects of prenatal stress are induced in production livestock needs to be sought.

Key Words: Swine, Prenatal Stress, Corticosteroid Binding Globulin

Animal Health: Dairy Cattle Health – Transition Cows and Mastitis

513 Negative energy balance during the periparturient period is associated with uterine health disorders and fever in Holstein cows. D. S. Hammon^{*1}, I. M. Evjen¹, T. R. Dhiman¹, and J. P. Goff², ¹Utah State University, Logan, ²USDA, National Animal Disease Center, Ames, IA.

Eighty-three multiparous Holstein cows were used to investigate the association between periparturient energy balance and uterine health disorders and fever. Blood samples were collected weekly from wk -2 to wk 5 postpartum for serum nonesterified fatty acids (NEFA) and Beta-hydroxybutyrate (BHB) Feed dry matter intake (DMI) was determined daily from wk -2 to wk 5 postpartum. Cows were examined at wk 3 for clinical endometritis (purulent cervical discharge on vaginal examination) and at wk 4 for subclinical (SC) endometritis (presence of neutrophils on endometrial cytological exam). Retained placentae (RP) were determined by visual and vaginal speculum examination on d 1 postpartum. Rectal temperatures were recorded from day 1-10 postpartum. Fever was defined as a rectal temperature #8805103°F for #88052 d. Differences in measurements were determined using a repeated measures of ANOVA. Of 83 cows total, 14 developed RP, 13 developed clinical endometritis, 61 developed SC endometritis, and 18 developed fever. Cows with RP had significantly (P < 0.001) lower DMI beginning 1 wk before calving and for the first 3 wk of lactation compared to cows without RP. Cows with SC endometritis had significantly (P = 0.01) lower DMI from wk -1 to wk 5, significantly (P = 0.01) higher NEFA from wk -2 to wk 4, and significantly higher (P < 0.04) BHBA from wk 1 to wk 4, compared to cows without subclinical endometritis. Cows with fever had significantly (P = 0.05) lower DMI from wk 1 to wk 4, significantly (P = 0.03) higher NEFA from wk -1 to wk 4, and significantly (P < 0.03) higher BHBA wk 1 to wk 4, compared to cows without fever. DMI, NEFA, and BHBA were similar for cows with or without clinical endometritis. From these data, we suggest that some uterine health disorders and fever are preceded by negative energy balance that begins prior to calving and extends into early lactation.

Key Words: Periparturient Dairy Cow, Endometritis, Negative Energy Balance

514 The relationship between the incidence of production-limiting disease and return over feed in Ontario dairy herds. C. McLaren^{*1}, K. Lissimore¹, T. Duffield¹, K. Leslie¹, D. Kelton¹, and B. Grexton², ¹Department of Population Medicine, University of Guelph, Guelph, ON, Canada, ²Ontario Dairy Herd Improvement Corporation, Ontario, Canada.

Production-limiting diseases are some of the most prevalent and costly conditions in the dairy industry. Displaced abomasum (DA), retained

placenta (RP), lameness, milk fever, mastitis and ketosis have a large economic impact on the individual animal. However, there are few studies that quantify their effect on herd economics. The objectives of this research were to examine the relationship between profitability as measured by the Ontario Dairy Herd Improvement (DHI) Corporation's Return over Feed herd profit index (ROF), and production-limiting disease. Clinical disease incidence risk of DA, lameness, RP, milk fever, mastitis and ketosis were calculated from participant submissions. For the determination of subclinical mastitis and ketosis cumulative incidence, the California Mastitis Test (>0) and the KetoTest[®] Beta-hydroxybutyrate (greater than or equal to 100 umol/l) milk test were used weekly in early postpartum cows (1-14 days). Producers were identified through the Ontario DHI Corporation ROF groups. The ROF was calculated from the difference between milk revenue and feed cost each month. Feed cost was determined from herd level dry matter intakes at each operation multiplied by fixed market prices for each feed ingredient. Revenue was calculated based on the Dairy Farmers of Ontario multiple component pricing formula for milk. There were 48 producers that submitted ROF, postpartum monitoring and clinical disease data for the period January 1st, 2002 and January 31st, 2003. Using linear regression modeling, no significant association (p>0.05) was detected for subclinical and clinical mastitis, RP, lameness and milk fever herd incidence with ROF.

Disease	Mean Herd	Coefficient ¹	p-value
	Incidence Risk (%)	(\$/cow/day)	
Subclinical Ketosis	61.0	-0.015	0.0239
Clinical Ketosis	2.1	0.12	0.0030
DA	3.4	0.11	0.0085

¹Baseline ROF (Intercept)=\$13.13/cow/day, r²=0.33

Key Words: Return Over Feed, Production-Limiting Disease

515 An evaluation of rumen-protected choline and monensin controlled release capsule on milk production, health and metabolic function of periparturient dairy cows. L. Zahra^{*1}, S. LeBlanc¹, K. Leslie¹, T. Duffield¹, T. Overton², and D. Putnam³, ¹Department of Population Medicine, University of Guelph, Guelph, ON, Canada, ²Department of Animal Science, Cornell University, Ithaca, NY, ³Balchem Corporation, New Hampton, NY.

Three weeks prior calving, 185 Holstein cows were randomly assigned to receive one of the following: a monensin CRC, a daily top-dress of

56g rumen-protected choline (RPC; Reashure choline, Balchem Encapsulates, New Hampton, NY) until 28 days post-calving, both supplements (RPC+CRC), or neither (CON). Blood samples were collected at enrollment, one week pre-calving, and in the first and second weeks post-calving. Daily DMI from enrollment until 30 DIM, and daily milk weights up to 60 DIM were measured. Adjusting for parity and BCS at enrollment, beta-hydroxybutyric acid (BHBA) concentrations in the first week post-calving were lower in the CRC and RPC+CRC groups than controls (990, 1140 and 1553 $\mu\text{mol/L}$ respectively, $P<0.05$). NEFA concentrations in the first week post-calving were lower in the CRC group compared to control (0.51 and 0.70 mEq/L, respectively, $P<0.01$). In both the first week pre-calving and the first week post-calving, the concentrations of serum urea were higher in the CRC group (4.03 & 4.54mmol/L, respectively) and RPC+CRC group (4.12 & 4.51 mmol/L, respectively) in comparison to the CON group (3.67 & 4.02 mmol/L, respectively) ($P<0.05$). During the first week post-calving higher serum glucose concentrations were observed in both the CRC and RPC+CRC groups in comparison to the CON group (2.76, 2.72 and 2.43mmol/L, respectively, $P<0.05$). There was no treatment effect on DMI pre or post-calving. There was no interaction between CRC and RPC on milk production, and no significant main effects of CRC on milk production. Data were pooled into two groups, cows receiving RPC and cows not receiving RPC. Adjusting for treatment, parity, BCS at enrollment, week of lactation and average post-calving DMI there was a tendency ($P=0.06$) for the RPC group to produce more milk in the first 60 DIM compared to cows that did not receive RPC (32.6 vs 31.7 kg/d respectively). According to the results from this study thus far, the mechanism by which RPC enhances milk production remains unclear.

Key Words: Dairy, Choline, Monensin

516 Effect of the method of delivery of monensin on serum insulin and cortisol concentrations in transition dairy cows. C. S. Petersson^{*1}, K. E. Leslie², T. F. Duffield², T. M. Osborne², B. W. McBride³, R. Bagg⁴, and P. Dick⁴. ¹Department of Animal Sciences, Ohio State University, Columbus, ²Department of Population Medicine, University of Guelph, Guelph, ON, Canada, ³Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, ⁴Elanco Animal Health, a Division of Eli Lilly, Inc., Research Park Centre, Guelph, ON, Canada.

An investigation was conducted to compare the effects of the monensin controlled-release capsule (CRC), the monensin premix and a negative control group on serum insulin and cortisol concentrations in a randomized and blinded clinical trial. A total of 136 Holstein cows and heifers from the Elora Dairy Research Centre were enrolled at three weeks prior to expected calving date. At enrolment, each animal was randomly assigned to receive a monensin CRC, monensin premix in the TMR or no treatment. Blood samples were obtained at enrolment, at one week prior to expected calving date, at calving, and at one and two weeks postpartum. The serum from these samples was analyzed for insulin and cortisol concentrations. Monensin had no effect on serum insulin concentration over the study period. However, serum insulin concentrations were higher prior to calving as compared to the postpartum period. Additionally, the serum concentration of insulin in heifers was significantly increased compared to multiparous animals. A seasonal effect found that the serum concentration of insulin was lowest in the summer as compared to the spring, winter and fall seasons. Monensin administration had no effect on serum cortisol concentration throughout the study period. However, statistical variation over time was observed; the highest concentrations occurred at calving.

Key Words: *Escherichia coli*, Mastitis, Vaccination

517 Determination of the test characteristics of a rapid, on-site serum NEFA test. L. Gooijer, K. Leslie*, T. Duffield, S. LeBlanc, N. Perkins, and E. Vernooy, University of Guelph, Guelph, ON, Canada.

Excessive or prolonged periparturient negative energy balance (NEB) may be associated with increased risk of clinical disease and losses from impaired production and reproductive performance. Monitoring the incidence of subclinical ketosis has been the recommended method of surveillance. It has been found that affected cows commonly have elevated circulating levels of non-esterified fatty acids (NEFA) in the prepartum period. However, measuring NEFA has traditionally involved submission of serum to a diagnostic laboratory. The objective of this

study was to determine the test characteristics of a new, rapid, on-site test for NEFA in serum (DVM NEFA, Veterinary Diagnostics LLC, Newburg, Wisconsin, USA). Cows were enrolled between 7 and 4 days prior to their expected calving date. Blood was collected by coccygeal venapuncture and serum was harvested. Cows were re-sampled twice weekly until calving. NEFA concentration was measured using the DVM NEFA test, and an aliquot was submitted to the Animal Health Laboratory (AHL) of the University of Guelph for analysis by a Hitachi 911 automated analyzer (Roche, Laval, Quebec). The AHL NEFA concentration was considered the gold standard for this evaluation. Serum NEFA greater than or equal to 0.4 mEq/L NEFA has been proposed to identify excessive prepartum NEB. A total of 491 samples from 256 different cows on eight farms in the Guelph, Ontario area were utilized in this study. The Pearson correlation coefficient between the DVM NEFA and the AHL NEFA determination was 0.75. Using 350 samples drawn within 14 d prepartum and NEFA greater than or equal to 0.4 mEq/L from the AHL test as the gold standard, the sensitivity and specificity of the DVM NEFA test were 84% and 96%, respectively. It is noteworthy that changing the NEFA cut off level to greater than or equal to 0.5 mEq/L resulted in a similar sensitivity and specificity of 85% and 97%, respectively. It was concluded that the DVM NEFA test characteristics were satisfactory for detection of cows with elevated prepartum NEFA.

Key Words: Non-Esterified Fatty Acid, Negative Energy Balance, Test

518 DCAD affects responsiveness of cows to parathyroid hormone -how anion supplementation prevents milk fever. J. P. Goff* and R. L. Horst, USDA-ARS, National Animal Disease Center, Ames, IA.

How adjusting dietary cation-anion difference (DCAD) reduces milk fever incidence remains debatable. Our hypothesis is that DCAD affects acid-base status of the cow altering the action of parathyroid hormone (PTH) on its target tissues, primarily bone and kidney. PTH normally stimulates renal synthesis of 1,25-dihydroxyvitamin D (1,25- vit D) and the effects of 1,25-vit D on intestine, and PTH on bone, cause a rapid rise in plasma Ca concentration. To test this hypothesis, Jersey cows in late gestation were fed a Low DCAD (N=8) or a High DCAD diet (N=8) for 2 wks. Urine pH averaged 5.7 in Low DCAD and 8.3 in High DCAD cows indicating the diets did affect acid-base status. Baseline blood samples were collected from each cow. Then 0.5 mg PTH 1-34 was administered IM, with additional injections of 3.3 mg PTH given every 3 h for 48 h. Blood samples were obtained every 3 h during PTH treatment and plasma Ca and 1,25-vit D concentrations were determined. Repeated measures ANOVA demonstrated significant time by diet effects on both plasma Ca and 1,25- vit D. Cows fed Low DCAD had a significant increase in plasma Ca from baseline at 6 h of PTH treatment and plasma Ca continued to increase with PTH treatment. In High DCAD cows plasma Ca did not increase from baseline until 21 h and continued to increase with PTH treatment. Plasma 1,25- vit D was above baseline in Low DCAD cows at 6 h of PTH treatment, peaked at 24 h of PTH treatment and remained elevated. In high DCAD cows there was a small but significant spike in plasma 1,25-vit D concentration at 6 h of PTH treatment but values at 9 and 12 h of PTH treatment were not significantly elevated from baseline. Plasma 1,25- vitD concentration rose above baseline at 15, 24, 30 and 33 h of PTH treatment but were similar to baseline at 18, 21 and 27 h of PTH treatment. These data demonstrate that High DCAD causes a pseudohypoparathyroid state in which tissues are less responsive to PTH stimulation, which impairs Ca homeostasis to cause milk fever. Low DCAD diets restore tissue PTH sensitivity, preventing milk fever.

Key Words: DCAD, Milk Fever, Parathyroid Hormone

519 Impact of participation in somatic cell count testing on herd average somatic cell score. H. D. Norman, A. H. Sanders*, R. H. Miller, and R. L. Powell, Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.

Mastitis results in substantial loss for dairy producers through lost milk and cow treatment or replacement. Test day data for somatic cell score (SCS) is stored in the national database at the Animal Improvement Programs Laboratory (AIPL). Since 1995, national herd average SCS has increased slightly. Also in that time, emphasis on SCS in the Net Merit index was increased from 6 to 9%, recognizing the value of improving udder health. To examine the impact of participation in official

somatic cell count (SCC) testing, herd mean SCS for 692,993 test days in 15,869 herds that began SCC testing between July 1995 and February 2004, having at least 6 mo on SCC testing, were analyzed for within herd effects of months on test. Herds were assumed to have stopped testing if no test was reported for >6 mo. Significant seasonal effects were accounted for by including month of test in the model; SCS was highest in August and lowest in November. Herd effect was nested in time of first test (month and year). Overall, mean first SCS test was 2.99; however, herds beginning SCC testing more recently had lower first SCS test (regression of first SCS on time of first test of -0.03). From the first to the second month on testing, SCS decreased by 0.14 ($P = 0.05$), but returned to starting level by 6 mo, and continued to increase over the subsequent 42 mo. Conversely, milk production increased significantly from the first to the second month of SCC testing, but decreased as SCC increased. These results were more pronounced in herds not previously on official milk testing. Increasing herd size was associated with a reduction in SCS, but including number of cows on test day produced similar results for effects of time on test. Frequency of testing did not significantly affect results. The national average of herd SCC and percentage of herd SCC exceeding 750,000 cells/ml have been increasing, the results of this study indicate that somatic cell testing can provide information valuable in reducing herd SCC, but producers may not fully utilize this information.

Key Words: Somatic Cell Score, Mastitis, DHIA

520 Dairy herd characteristics, management practices and mastitis prevalence data from farm visits to improve milk quality in New York and surrounding states. D. Wilson*, R. Gonzalez, G. Bennett, H. Schulte, J. Spatz, L. Tikofsky, F. Welcome, and Y. Schukken, *Quality Milk Production Services, Cornell University, Ithaca, NY.*

From January through November, 2003 the Quality Milk Production Services made 1294 herd visits and collected 76,346 aseptic milk culture samples from those visits in New York, Pennsylvania, Massachusetts, and Vermont. These visits were made either to monitor and maintain milk quality, or because of concerns about elevated bulk tank SCC. Mean SCC for herds monitoring milk quality was 384,000/ml. Herd size averaged 92 lactating plus dry cows, range 5-1648 cows. The smallest 400 herds had fewer cows than the largest 10 herds. Milk production 305-d mean was 14,903 lb with 90th percentile 22,000 lb. 1.5% of herds sold 50,000-710,000 lb/day, 2.5% sold <300 lb/day. Holstein breed was most common, with Holstein crosses also more common than any other breed. Tiestalls were most common housing type but freestalls were increasing. Dry cows were housed with lactating cows (45%) or a variety of other housing types. Milking systems included pipeline (67%), parlor (21%), and bucket (as only milking system, 12%). Parlor usage was increasing. Predip (63%), udder wash (24%), postdip (85%), dry cow therapy (all cows 84%, selected 7%) were practices increasing in adoption. Closed herds (53%) are decreasing. Trends toward fewer larger herds, freestalls, adoption of milk quality practices, and associated improved milk quality are evident. Some effective mastitis control methods still are not adopted by a substantial fraction of dairy farms, including large operations.

Key Words: Mastitis, Milk Quality

521 Efficacy of intramuscular ceftiofur combined with intramammary pirlimycin or cephalixin for treatment of systemically mild clinical mastitis in dairy cattle. J. R. Wenz*, R. Elia, D. Pruna, F. B. Garry, and R. P. Dinsmore, *Integrated Livestock Management, Colorado State University, Fort Collins.*

The objective of this study was to evaluate the impact of IM ceftiofur on important outcomes of systemically mild clinical mastitis. Cows from a 1500 cow dairy with clinical mastitis were randomly assigned to a treatment group: M1-intramammary (IMM) pirlimycin (n=35), M2-IMM pirlimycin and ceftiofur (n=36), M3-IMM cephalixin (n=40), M4-IMM cephalixin and ceftiofur (n=33). Pirlimycin was administered as labeled. Cephalixin was administered twice a day for three days. Ceftiofur was administered IM (2mg/kg) once a day for 3 days. Milk was cultured at initial identification (0hr), on exit from sick pen and 7 days post-exit. Cows with abnormal milk 3 days after the end of initial IMM treatment were re-treated. Recurrent clinical mastitis was diagnosed in cows with a subsequent clinical mastitis episode in the same quarter within 3 months. Bacteriologic cure was defined as no growth or growth

different from 0 hr culture results on both exit and 7 day post-exit cultures in cows that did not require re-treatment. Effects of treatment (IMM and IM) on outcomes were analyzed by logistic regression accounting for Gram staining characteristics (GRAM) of 0 hr bacterial culture result (SAS, PROC LOGISTIC). Sixty-nine, 22 and 9 % of 0hr cultures were Gram negative, Gram positive and mixed, respectively. There was a significant difference in bacteriologic cure of ceftiofur treated cows (75%) compared to IMM only treated cows (50%) controlling for IMM treatment and GRAM ($P=0.048$). However, there was no difference in re-treatment or recurrence rate comparing treatment group or ceftiofur treatment alone ($P>0.40$). Treatment had no effect on the number of dried quarters, cows sold for or dying from mastitis or sick pen days. The results of this limited study in one herd, with a predominance of Gram negative clinical mastitis, suggest IM ceftiofur treatment has no beneficial effects on the outcome of systemically mild clinical mastitis.

Key Words: Mastitis, Treatment, Ceftiofur

522 The effects of two *Escherichia coli* J5 immunization protocols on milk production, dry matter feed intake, antibody response and intramammary infection in dairy cattle. C. S. Petersson*¹, K. E. Leslie², D. F. Kelton², B. A. Mallard³, and S. W. Martin², ¹Department of Animal Sciences, Ohio State University, Columbus, ²Department of Population Medicine, University of Guelph, Guelph, ON, Canada, ³Department of Pathobiology, University of Guelph, Guelph, ON, Canada.

An investigation was conducted to compare the effects of two *Escherichia coli* J5 immunization protocols (Standard and Experimental) in 198 animals from two herds. Each immunization included the *E. coli* J5 bacterin and a naïve marker antigen, ovalbumin (OVA). The Standard Group was immunized at drying-off, three weeks before expected calving and 3-9 days postpartum. The Experimental Group was immunized at two weeks before drying-off, at drying-off and at three weeks before expected calving. Immunization protocol did not effect milk production for 14 days prior to drying-off, or to 60 days in milk. To evaluate the physiologic effects of immunization, dry matter feed intake values were collected for the 24 hours before the third immunization in the Standard Group, as well as the 24, 48 and 72 hours after. The intake values were also collected for the same dates in the non-immunized Experimental Group. Dry matter feed intake was not affected by immunization in the postpartum period. Serum antibody to *E. coli* J5 did not increase following immunization in either group. Animals showed significant response to OVA, however, total peripartum antibody to OVA did not differ between the two groups. The risk of culturing a gram-negative pathogen at calving and the risk of gram-negative clinical mastitis was not different between the two protocols.

Key Words: Insulin, Cortisol, Parturition

523 Tunnel ventilation cooling for lactating dairy cows during hot weather: Comparison to cooling with shade and fans. T. R. Smith*¹, A. M. Chapa¹, D. O. Pouge², T. O. Riley², R. J. Williams¹, J. Crouch¹, and H. Wilson¹, ¹The Department of Animal & Dairy Science, Mississippi State University, Mississippi State, ²The Dairy Research Unit, Mississippi Branch Experiment Station, Holly Springs, MS.

The objective of this study was to characterize the ability of tunnel ventilation cooling to alleviate symptoms of heat stress in lactating dairy cows. Fans and evaporative "cooling" cells were used to cool the model, 20-cow tunnel ventilation facility, constructed at the Dairy Research Unit in Holly Springs, MS. The 10-week trial, which began June 2, 2003, compared two groups of 10 cows housed in the tunnel ventilation barn with two similar groups, housed in an adjacent "traditional" freestall barn, which was cooled by shade and fans alone. The effect of tunnel ventilation cooling was to decrease exposure to moderate heat stress conditions by 4.3 ± 0.26 hours/d when compared to conditions in the traditional freestall barns. In response, cows housed in the tunnel barn had dramatically lower peak body temperatures (0.67 ± 0.02 °C) and respiration rates (15.7 ± 0.54 breaths/min) than cows housed in the "outside" freestall barn ($P<.001$). This increment in cooling improved feed consumption within the tunnel barn an average of 1.8 ± 0.81 kg/hd/d over the 10-week study. In addition, over the 10-week trial, cows cooled by tunnel ventilation averaged 2.8 ± 0.7 kg/hd/d greater milk production ($P<.0001$) than cows cooled with shade and fans alone. These results demonstrate that tunnel ventilation cooling can be used

to mitigate the effects of heat stress on lactating dairy cattle in the southeastern US.

Key Words: Tunnel Ventilation, Dairy, Heat Stress

Breeding and Genetics: Dairy Crossbreeding and Breeding Objectives

524 Comparison of first-parity Holstein, Normande-Holstein crossbred, Montbeliarde-Holstein crossbred and Scandinavian-Holstein crossbred cows for dystocia and stillbirths. B. J. Heins*, L. B. Hansen, and A. J. Seykora, *University of Minnesota, St. Paul.*

First-parity Holstein (H), Normande-Holstein (NxH) crossbred, Montbeliarde-Holstein (MxH) crossbred and Scandinavian-Holstein (SxH) crossbred cows calving from June 2001 to December 2003 were compared for dystocia and stillbirths from seven California herds. Dystocia scores ranging from 1 (no assistance) to 5 (hard pull) and stillbirths (1 for alive and 0 for dead) were recorded for 1695 Holstein cows, 205 Normande-Holstein cows, 157 Montbeliarde-Holstein cows and 110 Scandinavian-Holstein cows. Cows were bred to Brown Swiss, Holstein, Jersey, Normande, Montbeliarde and Scandinavian sires. Investigated were effects of calf sex, breed composition of cow, age at calving, breed of service sire, calving year and herd. For dystocia, sex of calf, calving year, breed of dam, breed of service sire and herd were significantly different ($P < .05$). The least squares mean for calf sex were 1.55 for males and 1.19 for females. Mean scores for dystocia for breed of dam were 1.59 (H), 1.44 (NxH), 1.26 (MxH) and 1.19 (SxH). Holstein sired calves (1.52) differed significantly ($P < .05$) from Jersey sires (1.11), and Holstein sires differed ($P < .01$) from Scandinavian sires (1.30). For stillbirths, sex of calf, calving year, breed of dam, breed of service sire and herd were significantly different ($P < .01$). Male calves (12%) had higher stillbirths than females (2%). Mean scores for stillbirths for breed of dam were 12% (H), 8% (NxH), 3% (MxH) and 5% (SxH). Holstein sires had the highest rate of stillbirths (12%), and rates for the other breeds of sires were 10% for Brown Swiss, 3% for Jersey, 7% for Montbeliarde, 4% for Normande, and 5% for Scandinavian sires. Holstein sires differed significantly from Jersey ($P < .05$) and Scandinavian sires ($P < .01$). Brown Swiss differed significantly from Scandinavian sires ($P < .05$).

Key Words: Crossbreeding, Dystocia, Stillbirths

525 Comparison of the fertility of pure Holstein sires and F1 Jersey x Holstein sires mated to pure Holstein cows in an experimental herd. K. Weigel* and C. Maltecca, *Department of Dairy Science, University of Wisconsin, Madison.*

The objective of this study was to compare the male fertility of pure Holstein service sires and crossbred F1 Jersey x Holstein service sires in artificial insemination (AI) matings to pure Holstein cows. Approximately 60% of matings involving Holstein cows in the University of Wisconsin Experimental Herd were randomly allocated to F1 Jersey x Holstein young sires ($N=7$) from Alta Genetics, Select Sires, ABS Global, and Accelerated Genetics. The remaining matings were allocated to pure Holstein young sires ($N=52$) from seven commercial AI companies. Our analysis included 429 inseminations (166 cows) to crossbred sires and 288 inseminations (124 cows) to Holstein sires between February 3, 2003 and January 28, 2004. Pregnancy status was determined by ultrasound at 28 to 33 d after breeding. All pregnant cows were re-checked twice, at approximately 63 d and 100 d after breeding. Mean conception rates were 29.2% (84/288) for matings to pure Holstein sires and 30.3% (130/429) for matings to F1 Jersey x Holstein sires. Conception rates for individual crossbred sires were 27.4%, 27.6%, 30.7%, 29.1%, 34.7%, 35.4%, and 0.0% based on 73, 69, 75, 55, 45, 99, and 9 matings, respectively. Abortion rates (after a positive ultrasound at 28-33 d) were 7.1% (6/84) for pregnancies from Holstein sires and 14.6% (19/130) for pregnancies from crossbred sires. Based on Chi-Squared test statistics, corrected for days in milk and year-month of insemination, neither differences in conception rates nor differences in abortion rates between purebred and crossbred sires were statistically significant ($P < 0.05$). Based on the results of this study, it does not appear that crossbred Jersey x Holstein sires can provide a significant improvement in male fertility relative to their pure Holstein contemporaries.

Key Words: Male Fertility, Crossbreeding

526 A comparison of reproductive efficiency in four breeds of dairy cow and two cross breeds under seasonal grass-based production systems in Ireland. F. Buckley*, J. F. Mee, N. Byrne, M. Herlihy, and P. Dillon, *Teagasc, Dairy Production Research Centre, Moorepark, Fermoy, Co. Cork, Ireland.*

The objective of this study was to compare the reproductive performance of four dairy cow breeds, and two cross breeds; Holstein-Friesian (HF), French Montbeliarde (MB), MBxHF, French Normande (NM), NMxHF, and Norwegian Red (NRF), over a three year period, on two seasonal grass-based milk production systems. The study included a total of 402 cows: 95 HF, 72 MB, 63 MBxHF, 36 NM, 58 NMxHF, and 78 NRF. The mean calving date was February 18. In mid-April each year cows were assigned (within breed) to a low level of concentrate supplementation (LC: 650kg/cow/lactation) or a high level of concentrate supplementation (HC: 1,250kg/cow/lactation) based on calving date and pre-experimental milk yield. Breeding started in late April and lasted 13 weeks (all AI). No difference in the interval to commencement of luteal activity (as determined by thrice weekly milk progesterone measurement), submission rate in the first 24 days of breeding, or number of services per cow were observed between the groups investigated. Significant differences in pregnancy rate to first service (PREG1), pregnancy rate after 42 days of breeding (PR42) and calving to conception interval (CCI) were observed. Overall, the highest reproductive efficiency was observed with the NRF breed (PREG1 = 59%, PR42 = 75% and CCI = 88 days). The lowest reproductive performance was observed with the HF breed (PREG1 = 42%, PR42 = 56% and CCI = 96 days). The reproductive performance of both the MBxHF and the NMxHF was higher than the average of the respective parent breed groups. Feeding system had no influence on any of the fertility traits investigated. In conclusion, the results of the current study highlight the benefit of the NRF breeding program where improved health and fertility have been selection criteria since the early 1970's. The results also suggest that dairy crossbreeding will lead to improved reproductive performance through hybrid vigour.

Key Words: Dairy Breeds, Fertility, Hybrid Vigour

527 Effect of Holstein females carrying Holstein versus Jersey sired calves on subsequent MEMilk, days open and involuntary culling. A. J. Seykora*, B. J. Heins, L. B. Hansen, J. G. Linn, D. G. Johnson, and W. P. Hansen, *University of Minnesota, St. Paul.*

From September 2001 to June 2003, 163 Holstein and 180 Jersey-Holstein crossbred calves were born at the University of Minnesota research herds at the St. Paul campus and at the West Central Research and Outreach Center, Morris. Cows and heifers had been randomly assigned to either Holstein or Jersey service sires. Dystocia was scored with a range of 1 (no assistance) to 5 (hard pull). Independent variables for analysis were herd, parity (1st, 2nd and 3rd and greater), sex of calf, and breed of sire. Differences between Holstein and Jersey sires were significant for dystocia score, calf weight, and retained placenta ($P < .05$). Least squares means for Holstein and Jersey sires, respectively, were dystocia score, 1.97 versus 1.36; calf weight, 43.6 kg versus 35.7 kg; and retained placenta, 8.2% versus 3.6%. Stillbirth rate was 7.2% for Holstein sires and 5.2% for Jersey sires, but not significantly different ($P > .05$). There were no significant differences in the subsequent MEMilk, days open or chance of early culling (culled less than 100 days into lactation) for cows having Holstein versus Jersey sired calves. For all cows, cows that had been bred to Holsteins averaged 10,430 \pm 158 kg MEMilk versus 10156 \pm 155 kg for cows bred to Jerseys. Days open also favored the cows that had had Holstein sired calves: 138 \pm 8 days versus 143 \pm 8 days. Relative to early culling, 16.6 \pm 3.9% of cows having Holstein calves were culled vs. 14.1 \pm 3.7% of cows having Jersey sired calves. The analysis was repeated for just the first lactation cows.

Again breed of calf did not significantly affect MEMilk, days open, or chance of early culling.

Key Words: Crossbreeding, Dystocia, Fertility

528 Overview of different breeding objectives in various countries for Holsteins. F. Miglior*, *Agriculture and Agri-Food Canada - Canadian Dairy Network, Guelph, ON, Canada.*

For many years, most Holstein breeding schemes worldwide focused exclusively towards increasing milk production. In the last five years selection goals have evolved worldwide, shifting the focus on production to a more balanced selection goal of improving production, especially protein yield and percentage, as well as longevity, udder health, functional conformation and fertility. Selection indexes and top bull listings from 15 countries were compared. Average relative emphasis for Production, Durability and Health & Fertility, across all countries, was 59.5%, 27.9% and 12.6%, respectively. The largest difference was the relative emphasis on Production in various countries. Overall, the Danish S-Index appeared to be the most balanced across the three components, with 34% emphasis on Production, 29% on Durability and 37% on Health and Fertility. The broadening of selection goals through recent changes to selection indexes had a clear effect on decreasing the similarities of top bull listings in various countries.

Key Words: Dairy Cattle, Breeding Objective, Selection Index

529 Effect of inbreeding on female reproduction in Jerseys. J. P. Cassady*, J. C. Wilk, B. T. McDaniel, and S. P. Washburn, *North Carolina State University, Raleigh.*

The objective was to determine effects of inbreeding in Jerseys on age at first calving, days to first observed estrus, days to first insemination, conception rate, services to conception, days open, and survival to second lactation. Inbreeding has been increasing rapidly in U.S. Jerseys as documented by the Animal Improvement Programs Laboratory (<http://www.aipl.arsusda.gov/eval.htm>). Inbreeding in Jerseys has more than doubled from 3.4% in 1990 to 7.1% in 2003. Experimental data included first lactation records between 1970 and 1993 of 900 Jersey females raised in the North Carolina State Randleigh herd. These animals were from two selection experiments. One experimental line used only highly proven sires and the second experimental line used pedigree selected young sires. As a result, cows studied were daughters of popular Jersey sires. Thus, results are expected to be relevant to commercial Jersey herds. For statistical analyses, calculated inbreeding values for each animal were rounded to the nearest whole percentage. Data were adjusted for effects of selection line, birth year of the dam, calving month, calving year, MEMilk, and MEFat. Inbreeding did not significantly affect age at first calving, days to first observed estrus, days to first insemination, or survival to second lactation. However, increased inbreeding had significant, deleterious effects on first service conception rate, services to conception, and days open. A 1% increase in inbreeding reduced 1st service conception rate by 2 percentage points, increased services to conception by 0.05 services, and increased days open by 1.8 days. Jersey breeders should implement a selection program that increases productivity and minimizes inbreeding. Effective mating programs to guide Jersey breeders in accomplishing these goals are recommended.

Key Words: Dairy, Inbreeding, Reproduction

530 Effect of synchronization protocols on days open and pregnancy rate at 120 days in dairy cattle. R. C. Goodling*¹, G. E. Shook¹, K. A. Weigel¹, N. R. Zwald¹, and R. D. Welper², *¹University of Wisconsin, Madison, ²Alta Genetics, Inc., Balzac, AB, Canada.*

Data were from herds in an AI progeny testing program that were utilizing Dairy Comp 305 and had at least 75% of recorded breeding events classified as standing heat or synchronized. A total of 16,374 records from 64 herds were analyzed. Data subsets were based on individual cow synchronization categories and herd management categories. Statistical models for days open (DO) included herd-year-season, age at calving, and parity as fixed effects, and sire or animal and residual as random effects. The pregnancy rate at 120 days (PR120) data were analyzed with a threshold sire model with similar fixed and random effects to DO. Models including a fixed effect for synchronization and a

random interaction for sire by herd management also were investigated. Producers who used synchronization, 47 herds in these data, were applying it selectively to problem cows. Records synchronized after the first breeding (later-synchronized) had 71 d longer DO and 24% lower PR120 than records synchronized at first breeding (first-synchronized). First synchronized records had 23 d longer DO and 10% lower PR120 than non-synchronized records. The 11 herds adhering strictly to synchronized first inseminations had 17 fewer DO and 10% higher PR120 than other herd management groups. Heritabilities ranged from 0.03 to 0.07 for DO and 0.10 to 0.26 for PR120. Sire variance was 40% lower for DO and 25% lower for PR120 in first synchronized records than either later-synchronized or non-synchronized records. Residual variances for DO varied by 3% between cow treatment categories and 14% for herd management categories. Including a fixed effect for synchronization in the DO model reduced sire variance by 33% and residual variance by 10%. Sire by herd management interaction accounted for less than 1% of the total variance for DO and 2% of the total variance for PR120. Synchronization had important, but similar, effects on sire and residual variances with only modest effect on heritability.

531 Level of metabolic trait of glucose by young bulls and cows. L. Panicke*¹, E. Fischer², B. Fischer³, H. Behn⁴, and R. Staufenbiel⁴, *¹Research Institute for the Biology of Farm Animals, Dummerstorf, Germany, ²Agric. and Environmental Faculty of the University Rostock, Rostock, Germany, ³Institute of Agriculture and Horticulture of Sachsen-Anhalt, Iden, Germany, ⁴Free University Berlin, Clinic of Cattle and Pigs, Berlin, Germany.*

The breeders are interested in premature information about the evaluation of growing young bulls. The common contemplation of genetic and physiological aspects is offered. In the lactation, the milk performance influences the demand for glucose. Insulin has a central position in the regulation of the energy metabolism of cattle. Methodically, the insulin function can be measured using the glucose tolerance test (GTT, Reinicke,1993). 58 cows in the stage of partus to 15 weeks post parturition was compared with 392 young bulls in the third life half-year. The goal of the examination was, to establish a comparable test level for cows and growing young cattle. By an infusion of 1g glucose per kg^{0.75} of metabolic body weight in the GTT was kept the urine threshold of Burkert (1998) and Reinicke (1993). By the constant glucose base concentration (G₀), the glucose half-life (G_{HWZ}) of the young bulls at 48 min is comparable with the eighth week of the lactation of the cow (see Tab.). Exactly in this time period has been proved by Cassel (2001) the highest genetic correlation between energy balance and yield r_g = -0.84 and the highest heritability for the energy balance h² = 0.20. Thus, by the infusion quantity and the expelled test time under performance the young bulls imitate the genetic equipment of their daughters for the metabolism capability.

Results of the Glucose Tolerance Test (GTT) in young bulls according to test in the third life half year and cows by partus and later 4, 8 and 15 weeks

532 Heterosis and breed differences for daughter pregnancy rate of crossbred dairy cows. P. M. VanRaden, M. E. Tooker*, and J. B. Cole, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Fertility of crossbred and purebred dairy cows was compared based on daughter pregnancy rate (DPR) as defined and introduced in February 2003 by the USDA. Heterosis and breed differences were estimated from first parity records of 11,708 F1 crossbred cows and 195,123 purebred contemporaries born after 1987 in 5775 herds. A second analysis for parities 1 through 5 included 485,297 records. Lactations were required to be >250 days in milk. Records with >250 days open were set to 250 days open and records with <50 days open were set to 50 days open. Numbers of purebred contemporaries were 1,679 Ayrshires (AY), 1,259 Brown Swiss (BS), 1,926 Guernseys (GU), 191,872 Holsteins (HO), 8,812 Jerseys (JE), and 396 Milking Shorthorns (MS). The most numerous F1 cross was 5,563 progeny of JE sires mated to HO dams. Days open records were converted to DPR by the linear approximation $DPR = .25$ (233 days open). To compare base cows born in 2000, sire predicted transmitting abilities for DPR were adjusted to the 2000 genetic base and subtracted from DPR records. The model for adjusted DPR included age at first calving, herd-year-season of calving with three seasons per year, parity, heterosis, and breed effects as compared to purebred HO. Estimates of heterosis for DPR were $+2.4 \pm 0.6$ for first parity and $+1.8 \pm 0.5$ for all parities. Within herd-year-season estimates of breed differences and standard errors were AY $+0.9 \pm 0.9$, BS $+0.9 \pm 0.8$, GU $+2.2 \pm 1.2$, JE $+3.9 \pm 0.5$, MS $+4.5 \pm 1.8$ for first parities and AY $+1.8 \pm 0.5$, BS $+0.1 \pm 0.4$, GU $+2.0 \pm 0.7$, JE $+4.6 \pm 0.3$, MS $+4.3 \pm 1.0$ for all parities. Those estimates were similar to differences obtained from national breed averages for first parity DPR, which were AY 22.8, BS 21.9, GU 21.3, HO 22.3, JE 27.0, and MS 26.0 for cows born in 2000. JE x HO crossbreds are as fertile as purebred JE, and heterosis for DPR is about 10% of mean DPR. Crossbred cows have significant advantages over their purebred parents for daughter fertility.

Key Words: Crossbreeding, Heterosis, Fertility

533 Calving difficulty in Holsteins and Jerseys and their crossbreeds. S. McClintock*^{1,2}, B. Kevin^{3,2}, M. Wells², and G. Michael^{1,2}, ¹University of Melbourne, Melbourne, Australia, ²Primary Industries Research Victoria, ³Australian Dairy Herd Improvement Scheme.

Calving traits for frequently used dairy breeds and crossbreeds were investigated for primiparous and multiparous calvings, using 402,116 calving records collected in Australia for a period of 18 years. The incidence of dystocia was highest for Holstein-Friesian primiparous cows, and Jersey-Holstein crosses had the least dystocia. There was a strong interaction between calf sex and breed: male calves from Holstein-Friesian cows resulted in more dystocia and greater calf mortality than female calves, whereas male and female Jersey-sired calves with cross bred or Holstein dams had less difference in dystocia and calf mortality between the sexes. There was no significant difference between sexes in dystocia in Jersey calves. Logit transformation of proportion suffering dystocia reduced but failed to eliminate these significant interactions. Incidence of dystocia in Holsteins was influenced by the season (gestation lengths were longer in winter, resulting in larger calves and more dystocia) and by the age of the cow, but these fixed effects were not apparent in Jersey calvings, and less noticeable in Jersey cross calvings. Though there was a major breed difference for calving ease between Jersey and Holstein bulls, the bull standard deviations of the two breeds for this trait were sufficiently large, relative to the breed differences, that there will be a small percentage of Holstein bulls that may be as easy calving as many Jersey bulls.

Key Words: Dystocia, Crossbreed, Sex

534 Early results of Holstein-Jersey crossbreeding at Virginia Tech and Kentucky. B. G. Cassell*¹, K. E. Getzewich¹, R. L. Nebel¹, R. E. Pearson¹, S. T. Franklin², and A. J. McAllister², ¹Virginia Polytechnic Institute and State University, Blacksburg, ²University of Kentucky, Lexington.

The joint Virginia Tech - Kentucky crossbreeding project produced 88 calves at Virginia Tech and 18 at Kentucky by mid-February 2004. Limited data from Kentucky precluded its use here, but data from both

institutions will be combined in coming months. The project was initiated using a heterospermic insemination trial, whereby females were inseminated with a mixture of semen from one Holstein and one Jersey bull in a single straw. Dams were purebred Holsteins and Jerseys, ranging in age from heifers through fifth lactation cows when bred. Six sets of twins (excluded from analysis) were among the first 88 births, including three sets of mixed sex (females all freemartin), two sets of heifers, and one set of bulls. Five of the twins were stillborn or died by 24 hrs, and only two reproductively sound females survived. Dystocia scores (1-5) were recorded at birth. Calf mortality included stillbirths and calves dead by 48 hours. Calf weights were recorded periodically, but only birth weights are reported here. Breed combinations (HH, HJ, JH, and JJ, sire first) included 30, 21, 11, and 14 calves respectively. Over 80% of births were unassisted, dystocia score 1, with an average score of 1.42. Death losses were 6.7% for the 76 single births. A fixed model including effects of sex of calf, breed group, and lactation number of the dam evaluated dystocia, calf mortality, and birth weight. No significant differences existed for any effects for dystocia or calf mortality. Thus, we found no difference in dystocia for Holstein sired calves born to Jersey dams or Jersey sired calves born to Holstein dams. Birth weight differed significantly ($P < 0.05$) for sex (males heavier than females by 2.6 kg) and breed combination (HH calves heavier by 15.3 kg, HJ by 6.7 kg, and JH by 8.2 kg than JJ calves). Calves born to first calf heifers were 3.7 kg lighter than calves born to third and later lactation cows. The project is designed to produce 40 females per breed group at Virginia Tech and an additional 20 animals per breed group at Kentucky. To date, the Virginia Tech project has produced 16 HH, 8 HJ, 8 JH, and 8 JJ females after death and freemartin losses.

535 Normande-Holstein crossbreds versus pure Holsteins for conception, days open, calving interval and survival. B. J. Heins*, L. B. Hansen, and A. J. Seykora, *University of Minnesota, St. Paul.*

Normande-Holstein first parity crossbreds ($n=32$) were compared to pure Holsteins ($n=161$) for first service conception rate, services per conception, days open and survival to second lactation. Cows were housed in five commercial dairies in California and calved in a six-month period from June 2002 through November 2002. All cows in the study had A.I. sires and maternal grandsires. Cows having Days open greater than 270 days were truncated to 270 days. Independent variables were breed (Holstein, Normande-Holstein crossbred), age at calving (linear, months) and herd (5). Normande-Holstein crossbreds had a higher first service conception rate ($34\% \pm 8$) compared to Holsteins ($20\% \pm 4$). Holstein cows had more days open (135 ± 8) compared to Normande-Holstein crossbreds (109 ± 14). One-hundred percent of the Normande-Holstein crossbreds became pregnant and 97% of the Holsteins became pregnant. Of the cows that became pregnant, Normande-Holstein crossbreds had fewer services per conception compared to Holsteins. Least squares means were $2.52 \pm .32$ (Normande-Holstein) and $2.91 \pm .18$ (Holstein). For the cows that calved a second time, least squares means for calving interval were $383\text{-d} \pm 17$ (Normande-Holstein) and $419\text{-d} \pm 10$ (Holstein). Sixteen Holstein cows and one Normande-Holstein crossbred cow were culled during first lactation.

Key Words: Crossbreeding, Fertility, Days Open

536 Breed composition codes for crossbred dairy cattle in the United States. J. Cole*, M. Tooker, P. VanRaden, and J. Megonigal, Jr., *Animal Improvement Programs Laboratory, Agricultural research Service, USDA, Beltsville, MD.*

Crossbred animals in the US dairy cattle population do not currently receive genetic evaluations. A system for storing breed composition data was developed and the software implemented. Crossbreds are animals whose sire and dam breeds are known but different. Two ways that crossbred animals may be handled in an evaluation are: they may be included in the breed-of-sire evaluation, or all animals may be combined into a single evaluation. For each crossbred cow ($n=431,432$) the database stores animal identification, breed of animal registry, breed fractions for 18 dairy breeds and an unknown category, a four-generation breed stack, a sire breed stack, and a heterosis value. Standard two-letter breed codes are used in the breed stacks. Breed fractions were calculated from pedigree information in the USDA database as far back as data were available. As a result, the crossbred table includes >70,000 crosses that

occurred >4 generations back in pedigrees, resulting in one breed with a very large contribution (e.g. 96.9% HO) to the breed composition and the other with a very small contribution (e.g. 3.1% JE). To avoid confusion the data may be reformatted for presentation (e.g. 97HO3JE), which would involve a small loss of precision. When purebred sires are used, the sire breed stack completely describes the mating system and may be used to identify rotational breeding programs. If crossbred sires are used, a four-generation breed stack is needed to identify reciprocal crosses that cannot be denoted by the breed composition alone. Consider a purebred Holstein sire mated to a purebred Jersey cow. Breed composition of a daughter would be 50HO50JE with a sire breed stack of HOJE and heterosis of 1.0. If that daughter were backcrossed to a Jersey bull, the resulting calf would have a breed composition of 75JE25HO, a sire breed stack of JEHOJE, and heterosis of 0.50. This system is necessary to facilitate implementation of across-breed genetic evaluations.

537 Effect of strain of Holstein-Friesian cow and grass based feeding systems on milk production, body weight, body condition score and reproductive performance. P. Dillon^{*1}, B. Horan^{1,2}, F. Buckley¹, J. Mee¹, and M. Rath², ¹Teagasc, Moorepark Research Centre, Fermoy, Co. Cork, Ireland, ²Faculty of Agriculture, University College Dublin, Dublin, Ireland.

The objective of this study was to assess the biological efficiency of three strains of Holstein-Friesian (HF) cows in three grass-based systems. For

this purpose, 39 High production (HP) North American Holsteins, 39 High durability (HD) North American Holsteins, and 39 New Zealand (NZ) Holsteins were used in three consecutive years. Each strain was allocated to one of three feed systems (FS); high milk output per cow (MP), high concentrate (HC), and high milk output per unit area (HS). Concentrate supplementation averaged 384, 384 and 1,455 kg per cow for MP, HS and HC, respectively. Milk yields were recorded on five days per week, milk composition was determined in one successive morning and evening sample each week. Body weight (BW) was recorded weekly and body condition scores (BCS) every three weeks. Cows were inseminated using AI, over a 13-week period. Milk production, BW, BCS and reproductive data were analysed as a split-plot design, using statistical procedures of SAS. There was a significant strain of HF by FS interaction for milk ($P < 0.01$), fat ($P < 0.01$), protein ($P < 0.01$) and lactose ($P < 0.001$) yields. Milk yield response to increased concentrate supplementation was greater with the HP strain. The NZ strain maintained the highest BCS and lowest BW. The HD strain had similar BW to the HP strain, while the BCS of the HD strain was higher than the HP strain ($P < 0.05$). Interaction between strain of HF and FS was not significant for the reproductive variables. The HP strain had greater number of services, lower conception rate to first service, and overall pregnancy rate, than both the NZ and HD. The NZ strain had higher conception rate to first and second service, and 6-week in-calf rate than both the HP and HD, while the HD was higher than the HP strain. FS had no effect on reproductive variables. The results indicate that the optimum system of milk production will vary with strain of HF.

Dairy Foods: Cheese

538 Use of reverse osmosis concentrated milk for the manufacture of Cheddar and Colby cheese: Impact on Ca equilibrium and functional properties. M.-R. Lee^{*}, J. A. Lucey, and M. E. Johnson, *University of Wisconsin, Madison.*

The physical characteristics of cheese are governed by proteolysis and electrostatic and hydrophobic interactions as influenced by pH and casein bound Ca (INSOL CA). The objective of this study was to study of the role of Ca equilibrium and pH on functionality changes that occur during ripening. Reverse osmosis (RO) of milk was performed before cheese making which increased the total solids content of cheesemilk by 2%. The additional lactose (0.5%) in RO milk, if fermented, could greatly decrease cheese pH and increase solubilization of Ca. Cheddar and washed curd Colby cheeses were made from RO and non-RO milk with different renneting and draining pH to vary total Ca content of cheeses. Changes in INSOL CA were determined by titration and cheese juice methods. Rheological properties were determined by small amplitude oscillatory rheometry during heating from 5 to 80°C and meltability from UW-Melt Profiler test where the degree of flow at 60°C was determined. The texture of RO Cheddar cheese with low renneting and draining pH was very crumbly (pH dropped to #88044.7). The INSOL CA in cheese decreased during aging in all cheeses. INSOL CA in cheese was positively correlated with cheese pH in both RO ($r = 0.89$) and non-RO ($r = 0.83$) trials. Above pH 4.95, changes in INSOL CA in cheese during ripening were negatively correlated with the maximum loss tangent value (i.e., point when cheese was most fluid-like) ($r = -0.54$) and with degree of flow ($r = -0.56$). Below pH 4.95, there was no significant relation between melting and INSOL CA. These results suggest that for cheese at pH < 4.95, melt was limited and loss of insoluble Ca in cheese during ripening could not improve melt due to dominant effects of low pH on the casein network. In cheeses with pH > 4.95, the reduction of INSOL CA in cheese during ripening contributed to increased meltability.

Key Words: Insoluble Ca, Meltability, Rheology

539 A comparison of three different methods for measuring intact casein in cheese. P. Lehtola^{*} and L. E. Metzger, *MN-SD Dairy Foods Research Center, University of Minnesota, St. Paul.*

Intact casein is a fundamental constituent in process cheese because it has important emulsifying properties that significantly affect the texture, stability and melt characteristics of the final product. In the traditional method for measuring intact casein 0.75g of cheese is extracted

twice with 25ml of a pH 4.6 buffer. The cheese is dispersed with a high shear mixer, extracted at room temperature for 30 min, and centrifuged. The supernatant obtained is then analyzed for soluble protein using the Kjeldahl method. Intact casein is determined by subtracting the amount of soluble protein from the total protein. The objective of this study was to develop two alternative procedures for measuring intact casein in cheese. In the first new method, 2.5 g of cheese is extracted once with 15 ml of pH 4.6 buffer. As in the traditional procedure, the cheese is dispersed using a high shear mixer, extracted for 30 minutes and centrifuged. Subsequently the supernatant and fat plug is removed and the amount of insoluble protein in the pellet is determined using the Dumas combustion method. In the second new method, .17 g of cheese is extracted once with 1 ml of pH 4.6 buffer. The extraction was performed in a micro centrifuge tube and the cheese was dispersed with a bead blaster. Following centrifugation the pellet was first washed with 1ml of a methanol/acetone solution (75:25) and then washed with 1 ml of acetone. The pellet was then dried in a heating block at 50°C for 1 hr. The final weight of the pellet was determined and used as a measure of insoluble protein. To compare the three methods eight samples of Cheddar cheese were analyzed at 2 wk, 2 months, and 4 months of ripening using each method. Each sample at each ripening time was analyzed in duplicate using each method. All methods observed a significant ($P < .05$) increase in soluble protein and a significant decrease ($P < .05$) in insoluble protein in all samples during ripening. The results of all three methods were highly correlated (>.90). This research has developed two alternative procedures for measuring intact casein in cheese.

540 Vatless manufacture of mozzarella cheese from 8X concentrated microfiltration retentate. A. V. Ardisson^{*} and S. S. H. Rizvi, *Department of Food Science, Cornell University, Ithaca, NY.*

The objective was to compare the functional and viscoelastic properties of low-moisture part-skim LMPS Mozzarella cheeses made by direct acidification with glucono- δ -lactone (GDL) and with starter culture. Both made by a continuous cheese-making process from concentration factor (CF) 8, pH 6.0 skim milk microfiltration retentate (MFR). Pasteurized skim milk was microfiltered to CF 8 at 50C using a 0.1 μ m nominal pore diameter microfiltration (MF) membrane unit with a total area of 9.2m². The system was equipped to maintain a uniform transmembrane pressure (UTMP) of 88.7 KPa. The milk was gradually acidified during MF to pH 6.0 using GDL (1.6g/kg skim milk) to adjust the calcium to casein ratio in the final retentate. The MFR was standardized with cream (40% fat) to produce a cheesemilk (CM) with

a casein to fat ratio of 1.1. GDL (1.7% w/w) or starter culture (1.3% w/w) was added followed by single strength rennet (80 μ /kg CM). CM was converted into cheese curd in an Alcurd continuous coagulator. The resulting curd was then cooked and stretched. The analyses performed on skim milk, retentate, CM and cheeses included total solids, protein (total N, non-protein N and non-casein N), fat and calcium. The cheeses made from MFR were compared to a control for compositional characteristics at day 1, and for functional (meltability and stretchability) and viscoelastic properties at 7, 30 and 60 days of age. All experiments were performed in triplicate.

The fat, moisture and protein contents of the cheeses produced from MFR showed no statistical difference ($p>0.05$) when compared to the control. Viscoelastic parameters (G and G) showed significant differences among the treatments at 7 days of age. However, at 30 days of age, the G and G values for the three treatments coincided at 14.1 kPa and 5.54 kPa, respectively. These trends were similar to those observed for meltability and stretchability, which were different ($p<0.05$) at day 7 but showed no difference at day 30. These results suggest that LMPS Mozzarella cheese can be continuously manufactured from microfiltration retentates and achieve compositional and textural characteristics similar to commercial LMPS.

Key Words: Microfiltration, Mozzarella

541 Influence of calcium, phosphorus, residual lactose, and salt-to-moisture ratio on cheese quality: manufacture and composition. P. Upreti*, R. Kapoor, S. K. G. Purna, and L. E. Metzger, *Department of Food Science and Nutrition, MN-SD Dairy Food Research Center.*

Four treatments of Cheddar cheese with two levels (high and low) of calcium (Ca) and phosphorus (P), and two levels (high and low) of residual lactose were manufactured. Each treatment was subsequently split in half and salted at two levels (high and low) for a total of 8 treatments. The 8 treatments included High Ca and P, High lactose, High S/M (HHH); High Ca and P, High lactose, Low S/M (HHL); High Ca and P, Low lactose, High S/M (HLH); High Ca and P, Low lactose, Low S/M (HLL); Low Ca and P, High lactose, High S/M (LHH); Low Ca and P, High lactose, Low S/M (LHL); Low Ca and P, Low lactose, High S/M (LLH); and Low Ca and P, Low lactose, Low S/M (LLL). All cheeses were made using stirred-curd procedure and were replicated three times. Treatments with a high level of Ca and P (HHH, HHL, HLH, HLL) were produced by cutting and drawing the whey at high pH (6.6 and 6.3 respectively), as compared to the treatments with a low level of Ca and P (LHH, LHL, LLH, LLL) (pH of 6.1 and 5.7 respectively). The lactose content in cheeses were varied by adding lactose (2.5% by weight of milk) to the cheese milk for high lactose cheeses (HHH, HHL, LHH, LHL), and washing the curd for low lactose cheeses (HLH, HLL, LLH, LLL). The difference in S/M was obtained by dividing the curds to be salted into two halves, weighing each half, and salting at 3.5 and 2.25% of the weight of the curd for high (HHH, HLH, LHH, LLH) and low S/M cheeses (HHL, HLL, LHL, LLL) respectively. All cheeses were salted at a pH of 5.4. The moisture and fat content of the cheeses ranged from 32.07 to 37.57%, and 33.32 to 35.93%, respectively. The total Ca and P in high Ca and P cheeses was on an average 0.67 and 0.47% Vs 0.53 and 0.39% for low Ca and P cheeses. The amount of residual lactose on the day after manufacture was significantly higher ($P<0.05$) for the high lactose treatments as compared to low lactose cheeses. The S/M for high and low salt cheeses was 6.68 and 4.77% respectively. The manufacturing conditions used in the study produced Cheddar cheeses with desired levels of Ca and P, residual lactose, and S/M.

542 Proteolysis and yield of Cheddar cheeses manufactured from milks with different serum protein contents. B. K. Nelson* and D. M. Barbano, *Northeast Dairy Foods Research Center.*

Our objective was to determine the impact of undenatured serum protein (SP) concentration in milk on proteolysis during Cheddar cheese aging. There were three treatments: control (0.52% SP), reduced SP (0.18%) and increased SP (0.69%). Skim milk was microfiltered (0.1- μ m pore size) to 3X in the first stage and then diafiltered twice to 3X using permeate from the UF of permeate from the MF as the diafilterant. The 3X MF retentate after the second diafiltration was diluted to the same casein content as the control milk with the UF permeate that was used as the diafilterant. The increased SP milk was produced by adding SP concentrate from the UF to skim milk. Cream was added to

all three milks to achieve a casein-to-fat ratio of about 0.7 and weights were determined for a mass balance of milk components. All manufacturing conditions were held constant for the three treatments and three replicates. The calcium content of the three treatment milks and cheeses were not different, indicating that using UF permeate as a diafilterant and diluent kept the calcium content at the same level as skim milk. There was no difference detected in initial cheese composition among the three treatments. Cheese make time was not affected by the milk SP content. The reduced SP treatment had a higher fat recovery in the cheese than the control or increased SP treatment and this resulted in a higher cheese yield efficiency for the reduced SP treatment. The rate of pH 4.6 soluble nitrogen (SN) production, expressed as a percentage of total nitrogen, was higher (indicating more primary proteolysis) in the cheese made from the reduced SP milk than control or increased SP, but 12% TCA SN was not affected by milk SP content. The ratio of α_s and β -CN to para- κ -CN was lower (17 h of pressing and at 30, 90, and 180 d of aging) in the cheese from low SP content milk. The lower ratio indicated that more CN had been proteolyzed. SP can be removed prior to cheese making without any detrimental impact on cheese composition or proteolysis.

Key Words: Cheddar, Microfiltration, Proteolysis

543 Gel microstructure, permeability and syneresis kinetics of cottage cheese-type gels made under different gelation rates. M. Castillo*^{1,2}, J. A. Lucey¹, W. Tao¹, and F. A. Payne², ¹*Department of Food Science, University of Wisconsin, Madison*, ²*Department of Biosystems and Agricultural Engineering, University of Kentucky, Lexington.*

Very little is known about syneresis in acid gels or in milk gels made by the combined action of acid and rennet (mixed gels), such as is sometimes used for cottage cheese manufacture. A factorial two-factor experiment with three replications was conducted to study the syneresis kinetics and the relationship between milk coagulation and syneresis at different coagulation rates. Effects of coagulation temperature and inoculum concentration on the microstructure and permeability of these mixed gels were also investigated. Coagulation parameters were concurrently monitored using rheology tests and near infrared light backscatter. Coagulation factors, such as inoculum level and temperature, had a direct effect on the development of the casein matrix, which impacted the physical characteristic of gels (e.g. particle rearrangement, permeability coefficient). These physical characteristics affected the extent and kinetics of the syneresis process. Whey drainage and curd shrinkage in mixed gels followed a first order kinetic reaction. The effect of temperature on kinetic rate constant for whey drainage allowed us to estimate both the thermal coefficient and the activation energy. A strong correlation was observed between syneresis parameters and those parameters characterizing acidification and network formation, which showed that coagulation kinetics played an important role in the syneresis process of mixed gels. Whey expulsion with time was predicted using a model that consisted of temperature and light backscatter parameters with an R^2 of 0.96. This suggests that it may be possible to develop a sensor capable of monitoring both coagulation and syneresis process, which could lead to greater control of the curd moisture content and an improvement of the final cheese homogeneity and quality.

Key Words: Syneresis Kinetics, Permeability, Cottage Cheese

544 Sensory differences among Pecorino Siciliano cheeses by geographic origin. J. Horne¹, S. Carpino*¹, S. Mallia¹, A. Difalco¹, G. Tumino¹, and G. Licitra^{1,2}, ¹*CoRFiLaC, Regione Siciliana, Ragusa, Italy*, ²*D.A.C.P.A. Catania University, Catania, Italy.*

Pecorino Siciliano is a PDO ewes' milk cheese produced in Sicily. The current study was undertaken to determine if location of production affects sensory properties of the cheese. Four months' ripened cheeses, respecting the traditional shape, were obtained from 15 farms from throughout Sicily that were classed into four groups by geography. Sensory characteristics were measured using a MS-based Electronic Nose (EN) and by a trained sensory panel. EN data were collected from a SPME extraction of volatile organic components from each cheese and from five sterile processed cheese blanks. A MS-based Electronic Nose (SMartNose) was used to detect volatiles in the mass-to-charge (m/z) range of 10 to 130 amu. Stepwise discriminant analyses followed by discriminant factor analyses on standardized data sets with and without five air samples found a group of mid-range masses that efficiently

separated cheeses by area of production along east-west axes. A few high-range masses were also important discriminators. Sensory panelists were likewise able to discriminate between cheeses produced in different areas of Sicily: western cheeses had stronger floral, fruity and mushroom/earthy aromas and eastern cheeses had stronger aroma intensities, butyric and spicy aromas. Eastern cheeses were also saltier, harder and less moist. Principal components analysis on the sensory data separated cheeses by area with an east-west axis on PC1 (58%) and a separation between northeastern and southeastern Sicily on PC2 (17%). Both EN and traditional sensory analysis found similar differences among cheeses. While EN technology is simpler and faster to use, especially if there are a lot of samples, the human nose is probably still superior in detecting subtle differences.

Key Words: Pecorino Siciliano, Electronic Nose, Sensory Analysis

545 Differences between milled curd and stirred curd Cheddar cheese manufactured with different culture/enzyme systems. S. Rehman^{*1}, N. Farkye¹, and M.A. Drake², ¹Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo, ²Southeast Dairy Foods Research Center, North Carolina State University, Raleigh.

The quality of Cheddar cheese made by stirred or milled curd methods are presumably different. This study was undertaken to minimize quality differences in Cheddar cheese due to method of manufacture by evaluating the effects of culture and ripening temperature on Cheddar cheese. Three replicate experimental cheesemaking trials (by both milled and stirred curd methods) were conducted using specific culture systems supplied by four commercial culture companies. On each cheesemaking day, two 625 kg lots of milk were made into Cheddar cheese with one culture system by each method. Cheese curds in 18.2kg blocks were pressed overnight in a vacuum chamber with 24 mmHg for first 60 min. Cheeses were ripened at 2 or 8°C and sampled at intervals for starter and non-starter lactic acid bacteria (NSLAB), and proteolysis. Sensory analysis was done at 3, 6 and 9 months by a panel (n=6) and 12 industry graders. Growth of starter or NSLAB was not effected by the method of manufacture (P>0.01). Proteolysis and the sensory attributes diacetyl, sour and salty were influenced by method of manufacture. The culture system affected cell density of NSLAB and the sensory attributes cooked, whey, sulfur, brothy, milkfat, umami and bitter while only brothy flavor was influenced by storage temperature.

Key Words: Cheddar Cheese, Milled and Stirred Curd, Culture

546 Influence of brine concentration, brine temperature, and presalting on early gas defects in raw milk pasta filata cheese. C. Melilli^{*1}, D. M. Barbanò², M. Caccamo¹, M. A. Calvo¹, G. Schembari¹, and G. Licitra¹, ¹CoRFiLaC, Regione Siciliana, Ragusa, Italy, ²Northeast Dairy Food Research Center, Department of Food Science, Cornell University, Ithaca, NY.

Thirty one 3.8-kg experimental blocks of Ragusano cheese were made on each of 6 days. On days 1, 3, and 5 cheeses were not presalted while on days 2, 4, and 6 cheeses were presalted. One block was analyzed prior to brine salting. Blocks (15) were placed in 18% brine and the other 15 into saturated brine. For the 15 blocks within each of the two brine concentrations (BC), 5 blocks were placed in a brine at 12°C, 5 at 15°C, and 5 at 18°C. One block was removed from each brine tank after 1, 4, 8, 16, and 24 d, weighed, sampled, and analyzed for composition, coliform count, and gas production. Presalting the curd with 2% salt before stretching reduced the coliform count in the cheese by 1.41 log and made a major reduction in early gas formation. Gas production was measured by image analysis of cheese slices to determine the percent of the surface area of the slice occupied by gas holes. Across all treatments the largest reduction in gas formation (ca. 75%) was due to presalting. Reducing brine temperature (BT) had the second largest impact on reducing gas production, but did not reduce the coliform count in the cheese. Reducing BT from 18 to 12°C made a larger reduction in gas formation in cheeses that were not presalted (from 6.8 to 1.8% gas holes, respectively) than in cheeses that were presalted (from 1.9 to 0.5% gas holes, respectively). To achieve the same absolute level of gas production in the cheese that was not presalted, as was achieved by the combination of presalting and 18°C brine, the BT had to be lowered from 18 to 12°C. Reducing BC, while it improved salt penetration, did not have any impact on coliform count and had minimal impact on

reducing gas production. Reducing BC, while it improved salt penetration, did not have any impact on coliform count. BC did not affect gas production at BT of 12 and 15°C. The amount of gas holes were not different from 0 to 16 d but were higher at 24d in saturated brine at 18°C than in 18%B at 18°C.

Key Words: Early Gas, Coliform, Presalting

547 Direct acidification and cream homogenization for Mozzarella cheese manufacture. K. J. Ottman and L. E. Metzger^{*}, Department of Food Science and Nutrition, MN-SD Dairy Food Research Center, University of Minnesota, St. Paul.

The effect of direct acidification, cream homogenization and non-fat dry milk addition on Mozzarella cheese composition and functionality were determined. Four vats (16 kg of milk per vat) of cheese were made with no direct acidification (control), direct acidification with acetic acid (DA), direct acidification with acetic acid and homogenized cream (DH), and direct acidification with acetic acid, homogenized cream and addition of non-fat dry milk (DHNF). Cheese curd produced in the direct acidification treatments was stretched in a process cheese twin screw cooker to 70°C whereas the control was stretched by hand in a hot brine solution to a temperature of 60°C. Cheese manufacture was replicated three times on different days. The direct acidification treatments had a significantly (P<.05) lower calcium content as compared to the control. The DA treatment had significantly higher (P<.05) fat losses as compared to the control. However, when cream homogenization was used in conjunction with direct acidification (DH and DHNF), the cheese produced had a similar (P>.05) fat content and fat recovery as compared to the control. Non-fat dry milk addition (DHNF) resulted in the highest actual and adjusted yield. The control treatment had a significantly higher level of pH 4.6 and 12% TCA soluble nitrogen throughout 90 d of refrigerated storage as compared to the direct acidification treatments (DA, DH and DHNF), which remained relatively stable. The direct acidification treatments had less proteolysis due to the lack of starter culture and higher stretching temperature. The control had an increase in meltability during the first 30 d and then remained stable throughout refrigerated storage whereas the direct acidification treatments remained stable throughout storage. The DA treatment had the greatest meltability and the DHNF treatment had the least meltability at 30, 60, and 90 d of refrigerated storage. This study demonstrates that direct acidification in conjunction with cream homogenization and a high temperature during stretching can be used to produce Mozzarella cheese with targeted functionality immediately after manufacture and throughout 90 d of refrigerated storage.

548 Effects of 6 month extended frozen-storage on changes in organic acid profiles of plain soft and Monterey Jack goat milk cheeses. Y. W. Park^{*}, J. H. Lee, and I. C. Blackman, Fort Valley State University, Fort Valley, GA.

Maturation processes of cheeses are not well understood for most varieties because of the heterogenous nature of the product. Although organic acid composition is greatly related to the acceptability of goat milk cheeses, few reports are available on this premise. Three lots of plain soft (PS) goat cheeses were purchased, and 3 lots of Monterey Jack (MJ) goat cheeses were manufactured at the University dairy plant to study changes in organic acid profiles during 6 months of extended frozen and refrigerated storage. Each cheese variety was subdivided into 4 equal portions. One portion was stored at 4°C for 4 weeks (0, 14, 28 days) as the unfrozen control (UFC), and the other three subsamples were frozen (-20°C) and stored for 0, 3 and 6 months (FZC, 3FZ and 6FZ), then immediately thawed the next day at 4°C, followed by aging at 4°C for 4 wks. Organic acids were assayed using a HPLC (Hewlett Packard; LC-1100 Series) equipped with auto sampler and diode array UV detector. The column was reverse phase Hewlett Packard ODS Hypersil 5µm (125 X 4 mm), and solvent was 0.5% (wt/vol) (NH₄)₂HPO₄. Differences in organic acid contents between soft and MJ cheeses were significant (P<0.01 or 0.001) for all acids except citric and lactic acid. Lot effect was significant (P<0.01) for most of the known acids, indicating that some variations might have occurred in milk composition and manufacturing processes. Effects of storage treatments (UFC, FZC, 3FZ and 6FZ) were highly significant (P<0.01 or 0.001) for most organic acids, except for orotic and a few unidentified acids. Aging at 4°C for 4 weeks had little influence on all organic acids except butyric acid. Concentrations of butyric, lactic, propionic, tartaric and uric acids were significantly (P<0.01) elevated as the frozen-storage period advanced.

Although several organic acid levels were elevated in the goat cheeses, prolonged frozen-storage upto 6 months may be feasible because no apparent deterioration in sensory scores were observed in other companion studies.

Key Words: Goat Cheese, Frozen-Storage, Organic Acids

549 Interaction of emulsifying salts with milk proteins. R. Mizuno^{1,2} and J. A. Lucey², ¹*Food Research & Development Laboratory, Morinaga Milk Industry Co., Japan*, ²*Department of Food Science, University of Wisconsin, Madison*.

Emulsifying salts (ES) are used for process cheese production, however, it is not completely understood how ES influence the physical and chemical properties of process cheese. The purpose of this study was to understand the interactions between ES and milk proteins using a simple model system. In this system, milk protein concentrates (MPC) solution was used as the source of milk protein and the effects of addition of ES upon milk protein were estimated by measuring the area of acid-base titration curves, turbidities, and the amount of soluble calcium. Various concentrations (0 to 0.7% (w/w)) of ES (trisodium citrate or sodium phosphates (ortho-, pyro-, or poly-)) were added to MPC solution (5% (w/w) solids). The pH of all solution was adjusted to 5.8 using hydrochloric acid after addition of ES (to be in the typical pH range of process cheese). The area of the titration curves was measured using the acid-base buffering method to observe changes in the amount and type of colloidal calcium phosphates (CCP). Turbidity measurements were made at 600 nm and the amount of soluble calcium was determined by measuring the calcium concentration that was ultrafilterable. An increase in the concentration of trisodium citrate brought about a decrease in the buffering capacity contributed by CCP, a decrease in the turbidity, and an increase in the amount of soluble calcium. Orthophosphates had little effect on the titration curves, turbidity, and the amount of soluble calcium. With increasing addition of pyrophosphates, the buffering capacity, turbidity, and amount of soluble calcium decreased. With the addition of a small amount polyphosphates, the effects were similar to those of pyrophosphates but when excessive amounts were added, there was a shift in the pH where the peak of the titration curve caused by CCP occurred, and an increase in the amount of soluble calcium. These results suggest that each ES influences milk proteins with different mechanisms.

Key Words: Emulsifying Salt, Milk Protein, Colloidal Calcium Phosphates

550 Impact of type of concentrated sweet cream buttermilk on the manufacture and functionality of pizza cheese. T. Y. Lin¹, S. Govindasamy-Lucey², J. J. Jaeggi², C. J. Martinelli², M. E. Johnson², and J. A. Lucey¹, ¹*Department of Food Science, University of Wisconsin, Madison*, ²*Wisconsin Center for Dairy Research, University of Wisconsin, Madison*.

Sweet cream buttermilk (SCB), a by-product of buttermaking, is a rich source of phospholipids, which could assist in fat emulsification. Most SCB is sold concentrated and it is not clear how the different concentration processes affect the behavior of SCB as an ingredient in cheese. SCB was concentrated by cold (<7C) ultrafiltration (UF), cold reverse osmosis (RO) or evaporation (EVAP). A washed, stirred-curd cheese was manufactured from the three different types of concentrated SCB. Cheesemilks of CN:fat ratio of 1.1 and final CN content 2.7% were obtained by blending UF-SCB retentate (19.5% TS), RO-SCB retentate (22.0% TS) or EVAP-SCB retentate (37.6% TS) with partially-skimmed

milk. Control cheese was made with partially-skimmed milk (11.3% TS). Cheese functionality was assessed using dynamic low-amplitude oscillatory rheology (DLAOR), UW Melt Profiler (extent of flow after heating to 60C) and on pizza. Initial trials with SCB fortified cheeses resulted in 4% higher moisture (51-52%) than control cheese (46-47%). In subsequent trials procedures were altered to obtain similar moisture content in all cheeses. Fat recoveries in cheeses were lower with SCB fortified milks than with control milks. Nitrogen recoveries in cheeses made with control milks were slightly higher than in cheeses with RO-SCB and EVAP-SCB milks; but lower than UF-SCB milk cheeses. Total phospholipids recovered in SCB-cheeses (28-34%) were lower than control (42%). From DLAOR test, the loss tangent curves at temperatures > 40°C increased as cheese aged up to a month and were lower in SCB-cheeses than control. Extent of flow was higher for control cheese than SCB-cheese and as cheese ripened, it increased for all cheeses. TCA-soluble nitrogen levels were slightly lower in SCB fortified cheese than control. On baked pizza, UF-SCB fortified cheese had lowest amount of free oil but flavor attributes of all cheeses were similar. Addition of concentrated SCB to standardize cheesemilk for pizza cheese lowers free oil without adversely affecting functional properties of cheese but could increase cheese moisture, unless corrected.

Key Words: Sweet Cream Buttermilk, Pizza Cheese, Melt

551 Effect of fat content on rheological and melting properties of Mozzarella cheese. C. Udayarajan* and J. Lucey, *Department of Food Science, University of Wisconsin, Madison*.

Melting properties of Mozzarella cheese are influenced greatly by its chemical composition. The objective of this study was to evaluate the influence of various fat levels on rheological and melting properties of Mozzarella while maintaining similar moisture content. Mozzarella cheeses with low (30%), medium (40%) and high (50%) fat in dry matter (FDM) were manufactured. Cheeses properties were analyzed on day 2, 7, 14, 21 and 28. Rheological properties were studied using Fourier Transform Mechanical Spectroscopy (FTMS), which is a type of small amplitude oscillatory rheometry. Using FTMS the data for a wide range of frequencies (0.08-8 Hz) were collected in real time while cheese sample was heated over a temperature range from 10 to 90°C at 1°C/min. Storage modulus (*G'*) and loss modulus (*G''*) increased with frequency for all cheeses and the differences between frequencies were more evident at higher temperatures. Both *G'* and *G''* were lower with an increase in fat content and their values at high temperatures decreased with increasing cheese age. During heating all three cheeses exhibited a maximum in loss tangent (*Max_{tan}*) and the value of *Max_{tan}* decreased as the frequency increased. *Max_{tan}* increased with an increase in fat content and ripening period. Melting properties like extent of flow at 60°C and melt area were analyzed using UW Melt profiler and Schreiber test, respectively. Meltability improved as the fat content increased. Extent of flow increased for all cheeses from day 2 to 21 and then hardly changed. There was a significant correlation between extent of flow and *Max_{tan}*. Melt area was higher for medium and high FDM cheeses compared to low FDM cheese. Melt area increased with age for medium and high FDM cheeses up to day 14 and then declined. Melt area did not change during ripening for low FDM cheese. Rheological results correlated well with the pizza bake test in which the low FDM cheese blistered and blackened and did not flow. Excessively strong protein interactions in the high protein (low FDM) cheese were responsible for its poor meltability. Strategies are needed to reduce the strength of protein interactions if improved meltability is required.

Key Words: Mozzarella, Rheology, Melt

Extension Education - Animal Science

552 Beef development costs. W. Ellis*, *Southeast Missouri State University, Cape Girardeau*.

The objective of the study was to determine the cost of beef heifer development from weaning to her first parturition. The study was conducted at Southeast Missouri State University Farm. Data were obtained from thirty-one Angus or Angus cross heifers born in the fall of 2000. Heifers were weaned in April of 2001, bred in November of 2001, and calved in fall of 2002. Heifer development followed the guidelines of the Missouri Show-Me-Select Replacement Heifer Program, which is an educational program involving comprehensive guidelines for beef replacement heifer

development and marketing. Program development included pasture, feeds, labor, vaccinations, pre-breeding reproductive tract score, estrus synchronization, artificial insemination (AI), clean-up bull, pregnancy testing, and cost of open heifers. Mean weight and age (Mean SE) of heifers at weaning and at beginning of the breeding season were 203.7 ± 2.9 kg, 205.6 ± 3.2 days, 370.4 ± 4.9 kg, and 405.6 ± 3.2 days, respectively. Mean pre-breeding reproductive tract score was 4.9 ± .04 indicated 31/31 (100%) of the heifers reached puberty and cycling before breeding season. First AI service pregnancy rate following estrus synchronization treatment was 22/31 (71%) and pregnancy rate after

the breeding season (AI and clean-up) was 29/31 (94%). The cost of the development program was \$400.23 per beef heifer. The worthiness of this cost is acceptable based on heifer sale price from the Show-Me-Select sale. The average sale price per heifer for nine of the 29 pregnant was \$1125. The remaining 20 pregnant heifers were retained in the herd. The combination of the development cost and heifer value at weaning yields a cost of \$889.32. The net profit of the heifers was \$235.68 per heifer sold.

553 Elements influencing cattle buyers to participate in preconditioned certified calf sales. M. D. Corro*, D. Lalman, J. D. White, R.P. Wettemann, and J. P. Key, *Oklahoma State University, Stillwater.*

The Oklahoma Quality Beef Network (OQBN) was organized in 2001 with the primary objective of adding value to weaned calves and capturing a portion of this value for both the cattle producer and the cattle buyer. The OQBN provides a process verification system relative to management practices applied to beef calves around the time of weaning. The fundamental concept is that by reducing costs associated with sickness, improving animal performance; and improving beef product quality, additional value can be achieved in beef cattle production. Livestock market owners cooperate with producers by assembling OQBN process verified calves and marketing them in certified calf sales. Survey data were collected from OQBN participants during the fall of 2001 and 2002 to determine elements which influenced cattle buyers to participate in certified preconditioned calf sales. A total of 291 stakeholders that either bought or sold cattle through the OQBN during the fall of 2001 and 2002 were identified. One hundred eighteen stakeholders (40.5 %) responded to the survey. The chi-square test was used to evaluate differences between groups of stakeholders. Livestock market operators, Cooperative Extension and OCA meetings were the most frequent source of awareness for buyers regarding the OQBN program and sponsored auctions. The majority of buyers (86%) that responded to the survey purchased the cattle for their own operation. A total of 72% of buyers indicated they normally purchased more than 500 head annually. The majority (85%) of buyers in 2002 indicated that they had to treat less than 10% of the cattle they purchased, while 33% of 2001 buyers indicated less than 10% treatment or pull rate. The percentage of buyers paying a premium price of \$4 cwt. or more above the regular market, was greater ($p < 0.05$) in 2001 than in 2002. No statistical difference ($P > 0.05$) was found among the perceived premium price received by producers and the perceived premium price paid by buyers. The benefits related to preconditioned cattle, convenience, and other benefits were the main elements for buyers purchasing cattle in certified calf sales.

Key Words: Preconditioning, Certified Calf Sales, Beef Cattle

554 Selected management practices of beef cows on cow-calf operations in Oklahoma. M.D. Corro*, D. L. Lalman, K. Barnes, and J. L. Evans, *Oklahoma State University, Stillwater.*

A total of 3000 cow-calf operators were identified by the Oklahoma Cooperative Extension Services in the Northeast District of Oklahoma. A sample of 323 cow-calf operators participated in a study to describe selected management practices that may influence cow-calf operators to adopt preconditioning practices. Information was gathered on demographic characteristics preferred calving season, perceived return over costs needed for applying preconditioning management, perceived costs of running beef cows, perceived limiting factors for preconditioning practices and major obstacles to profitability. The chi-square test was used to evaluate differences between groups of cow-calf producers. A total of 69.7 % of the operators had more than 15 years in the beef business. A majority (68.5%) of operators had less than 100 cows. Only a portion (13 %) of cow-calf producers indicated they currently apply preconditioning practices. Almost half (49.3 %) of producers indicated they would accept less than \$30 profit per head for preconditioning. Similarly, half of the operators indicated they had \$350 annual costs for running a beef cow. Among the elements that limiting the use of preconditioning practices, 51.2 % of operators ranked time and labor as the major limiting factor for preconditioning; facilities (fences, pens, etc) were ranked as the second most limiting factor, and know-how as the third limiting factor. Collectively, these management practices, higher production costs, and lower market price were indicated as the major

obstacles for profitability that may contribute to a lower adoption of preconditioning practices among cow-calf operators.

Key Words: Beef Cattle, Management Practices, Preconditioning

555 Maximizing extension efforts by multi-county horse programs. O. F. Harper*, J. Hall, J. Goddard, J. Rhea, and B. Slinger, *University of Tennessee, Knoxville.*

In the fall of 2001, a major focus on Extension education adult horse programs was initiated in the Smoky Mountain Extension District, which encompasses 24 counties in Eastern Tennessee. In 2001, one multi-county adult horse program was conducted in the district. This was expanded to seven multi-county horse programs in 2002 and eight in 2003. Two new programs, Horse Ownership Course and a Horse Round Table, were initiated and additional programs expanded in two key metropolitan areas, the centers of program focus. Extension agents in the Knox-Metro area and upper East Tennessee and Southwest Virginia counties joined the horse specialist in forming leadership teams in coordinating the programs in these two metro-areas. The programs include Horse Management Courses, Horse Ownership Courses and Horse Round Tables. All programs are multi-county and the Horse Management and Horse Ownership Courses are fee-based programs. The Horse Ownership Courses provide 10-hours of continuing education meeting one-night per week (2 hours) for five weeks, focusing on basic topics of ownership: facilities, feeding, management, health care and selection. The Horse Management Courses are also one night for five weeks (10-hours of continuing education); however, topics are generated from exit-evaluations from the previous years attendees plus input from the Extension agent and horse specialist. Other major differences are the Ownership Courses have a limited enrollment of 30-35; whereas, Management Courses are limited only by available facilities. Ownership Courses are designed as a one-time course while participants are encouraged to attend the Management Courses each year. The Horse Round Table is a one night with five to six 15-20 minute current topic presentations are followed by a question and answer session. In the fall/winter of 2002/2003, 318 individuals attended seven programs. The average program rating was 4.7 out of 5 with 99 percent stating they would attend another Extension horse program and 99.7 percent would recommend these programs. Pre and post-test from six programs showed a 39 percent increase in knowledge.

Key Words: Horse, Multi-County Outreach, Extension Programs

556 Expanding extension horse programs by the internet. O. F. Harper* and E. L. Tipton, *University of Tennessee, Knoxville.*

New scientific information and technology transfer is the mission of the Extension Service. Rapid advance of the Internet provides an innovative and challenging methodology to reach new, broader and often diverse audiences. It provides an opportunity to showcase impacting research, field data and specific focused Extension programs. The web site highlights seven Extension species programs: Beef, Dairy, Horse, Poultry, Sheep and Swine, in addition to 4-H programs. The Department's horse web page (<http://animalscience.ag.utk.edu/horses/horse.htm>) has been used to augment, broaden awareness and provide articles while marketing new educational horse programs. The horse page begins with Hot Topics and Events. This area marquee: video releases, Extension Horse Course and a West Nile Virus (WNV) Information web page. The 4-H Horse Program, Publications and Educational Materials, News Letter (Tennessee Horse Express), Horse Links and Calendar of Events rounds out the directory. The occurrence of WNV promoted the posting of periodic reports of WNV positive horse and bird activity during the year and the development of an interactive state map showing the number of positive horses and birds by county. Listing of varied educational horse programs is a marketing initiative and industry promotional effort. This user-friendly site is easily navigated from current issues and programs to relevant educational materials. Web-based publications include 23 fact sheets and Horse Information Series which are categorized as Genetic, Health Care, Management, Nutrition or Reproduction. Articles appear in more than one category to assist one-time users. Reviews of Extension horse programs and activities aid in marketing future programs, documents the department's educational horse impact and provides recognition for involved Extension agents. E-mails, telephone calls and letter requesting additional information indicates the web page is viewed by

horse owners, breeders, agribusiness, government agencies and the general public. Agricultural/equine press usage of articles from the web site indicates the value of these materials and its easy and rapid access.

557 Holey Cow—The inside story of why cows eat grass—a model for youth agricultural education. D. J. R. Cherney*, B. Berggren-Thomas, and A. W. Bell, *Cornell University, Ithaca, NY.*

Less than 2% of the U.S. population is currently involved in agriculture and many young people have little or no experience with farm animals. We need young people to continue to chose agricultural careers, but also, as adult consumers, to make intelligent choices and policies about issues involving the use of animals for food and fiber. We have developed a program that begins with a PowerPoint slide show describing ruminant animals. The Powerpoint includes images of a variety of ruminant animals that the students may have seen on television or in zoos. We describe how a ruminant is able to use grass with the aid of slides and other props. The presentation is geared to the level and experience of the youth group. These groups range in age from 6 to 18 years and from no animal experience to farm youth. Because these audiences learn best from hands-on experiences, they are invited to handle a rumen-fistulated cow, offer her feed, and explore the rumen. The youth are given lab coats and gloves and can place their arm inside the cow. The program includes the use of a microscope for viewing rumen microflora and a feed demonstration. In this way, participants can see, feel and smell what we have talked about, reinforcing their learning experience. When appropriate, the program also includes discussion of possible careers in animal biology and production. Last year 10 demonstrations were conducted for approximately 350 young people and their chaperones. The program has Institutional Animal Care and Use Committee Approval. Many of the groups bring new students each year. The cow is a critical component of the success of this program.

558 Healthy farms—healthy agriculture: A new approach to biosecurity education. J. M. Smith*, *University of Vermont, Burlington.*

The University of Vermont entered into a special cooperative agreement with the United States Department of Agriculture's Animal and Plant Health Inspection Service in 2002 to distribute biosecurity materials relevant to ruminant livestock production. The original objectives were to develop, produce, and distribute information on (1) biosecurity measures that all personnel, salespeople, consultants, and visitors should follow when entering farm animal premises and (2) measures to follow when bringing animals, especially those of unknown origins, onto existing farms. These objectives were modified during the planning process involving various stakeholders. The stakeholders helped identify our target audiences and the types of information they needed. We concluded that farm owners are responsible for the biosecurity measures practiced on their farms by themselves and their employees, as well as by the agri-service personnel, salespeople, and others who enter the premises. So the materials were designed to be distributed to and used by farmers. In addition to biosecurity procedures for people and

new or returning animals, we decided to cover measures to reduce the biosecurity risks posed by wildlife. The title was chosen so as to not be alarming. The main outputs of the project were a professionally-printed, 3-ring binder with about 100 pages of information, a compact disk of the same information adhered inside the back cover, and a web site (www.uvm.edu/~ascibios/) where the information was posted. Tabbed dividers were labeled introduction, assessment, new animals, visitors, wildlife, biosecure practices, diseases, and appendix. Our goal was a well-organized collection of existing information, reformatted to make it easy for farmers to understand and apply. Sixteen reviewers, who included veterinarians, extension faculty, agri-service personnel, and farmers, made comments on drafts of the materials. The finished binder was distributed to all ruminant and dairy farms listed with the Vermont Agency of Agriculture, Food, and Markets in fall of 2003. A video was also planned but not completed by the end of the one-year project period.

Key Words: Biosecurity, Extension

559 An environmental assessment tool for poultry farms developed as part of environmental management systems. P. H. Patterson*¹, L. E. Lanyon², and A. H. Mende³, ¹*Department of Poultry Science, The Pennsylvania State University, University Park,* ²*Department of Crop and Soil Sciences, The Pennsylvania State University, University Park,* ³*PennAg Industries Association, Harrisburg, PA.*

Environmental Management Systems (EMS) for the poultry industry address environmental policy with continuous improvement to ultimately achieve regulatory compliance and pollution prevention. As part of the 9-state Partnership for Livestock Environmental Management Systems project, a team of industry, government and university stakeholders developed an assessment tool for the commercial layer, broiler and turkey industries in Pennsylvania (PA). The goal of the tool was to set environmental priorities, to evaluate environmental protection measures, and to communicate and monitor environmental performance. It was adapted from national and existing PA Farm*A*Syst materials, and field-tested on 10 layer, 10 broiler and 10 turkey farms. Eleven priority areas were evaluated for risk on a scale from 1-low to 4-high risk including: drinking water supply, septic design and operation, run-off issues, mortality management, farm nutrient balance, emergency action planning and more. Example average scores for drinking water supply were: 1.7 layers, 1.7 broilers, 1.4 turkeys, however, the range of scores were 1-2.3, 1-4 and 1-4, respectively, indicating improvement opportunities. Other opportunities were identified for pest, odor and dust management (broilers), mortality management (turkeys) and farm nutrient balance (layers). Survey responses by producers indicated the tool was helpful to their operation, the experience raised awareness, 75% preferred the 3rd party assessment to self-assessment, and 1/3 were interested in pursuing an EMS. An important lesson from the pilot was that producers have little time and a concise, timely assessment was essential. The tool was effective in documenting performance and identifying opportunities. It has been proposed for adoption as the poultry component of PEACCE, a state-wide certificate program for environmental excellence and stewardship in animal agriculture.

Forages and Pastures: Harvesting and Grazing Management of Forages

560 The effects of total non-structural carbohydrates (TNC) on voluntary intake of goats and digestibility of gamagrass (GG) harvested in the morning (AM) or afternoon (PM). A. Sauve*¹, G. Huntington¹, and J. Burns^{1,2}, ¹*North Carolina State University, Raleigh,* ²*USDA, ARS.*

The objective was to evaluate the differences in TNC of Iuka GG (*Tripasacum dactyloides L.*) harvested at 0530 (AM) or 1730 (PM), and to measure how TNC concentration and CP supplement affect the voluntary DMI and digestible DMI (DDMI) of GG field-cured and stored in square bales. Boer X Spanish wethers (24 ± 3 kg) were randomly assigned to supplement (SP, 31% CP, fed at 11% of DMI, 14 goats) or no supplement (14 goats). Within SP or no SP, goats were randomly assigned to a crossover design of AM GG (7 goats) or PM GG (7 goats). Goats were individually housed in metabolism crates with free access

to water and mineral blocks. They were fed twice daily, with SP being offered once a day 30 min before morning feedings. After a 7-d adaptation, voluntary intake (goats were fed 110% of previous days intake) was measured for 14 d, followed by a 4-d adjustment (to equalize DM offered between periods) and a 5-d digestion trial to measure DM digestibility (DMD). After Period 1 the goats were switched to their new diets, and the protocol was repeated. GG concentrations are g/kg DM and intakes are g/d. Means differ at $P < 0.03$. Compared to AM, the PM harvest had greater TNC (72.5 vs. 59.1), monosaccharides (37.3 vs. 27.5), and di- and polysaccharides (15.4 vs. 13.3). The DMD was greater for PM vs. AM (56.0 vs. 53.6%) and for SP vs no SP (57.0 vs. 52.7%). Crude protein (92) and starch (19.1) were similar ($P = 0.98$) for PM and AM. Compared to no SP, SP increased total DDMI (DMI times DMD from the digestion trial) during the voluntary intake phase (344 vs. 305) and

digestion trial (337 vs. 292). However, GG DMI was not affected ($P > 0.17$) by SP during the voluntary intake phase (531 vs. 571) or digestion trial (522 vs. 554). Voluntary GG DMI (552 vs. 551, $P < 0.89$) and voluntary total DDMI (331 vs. 318, $P < 0.15$) were similar for PM and AM; however, total DDMI during the digestion trial was greater for PM vs. AM (325 vs. 304). We conclude that PM GG had a greater DMD and DDMI than AM GG due to increased TNC and not due to differences in intake by the goats. Supplementation had small effects on DMI and DMD of GG.

Key Words: Gamagrass, Meat Goats, Carbohydrates

561 Afternoon harvest increases readily fermentable carbohydrate (CHO) concentration and voluntary intake of gamagrass (GG) and switchgrass (SG) baleage fed to beef steers. G. Huntington*¹ and J. Burns^{1,2}, ¹North Carolina State University, Raleigh, ²USDA,ARS.

Our objective was to determine if AM (0600) vs. PM (1800) harvest affects CHO composition and voluntary intake of GG or SG stored as baleage. Iuka GG (*Tripsacum dactyloides* L.) and Alamo SG (*Panicum virgatum* L.) were direct-cut and stored as baleage in round bales wrapped in plastic. Black steers (260 ± 16 kg BW) were assigned (5 steers per treatment) to GG/AM harvest, GG/PM harvest, SG/AM harvest, or SG/PM harvest. Steers were group-housed in covered, outdoor pens with individual feeding gates. After adaptation to the facility and 14 d standardization, ad libitum intake was measured for 21d (7 d adjustment and 14 d intake estimate) followed by a 5-d digestion trial in indoor digestion crates. Silage concentrations are g/kg DM. Means differ at ($P < 0.05$). Compared to AM harvest, PM harvest had more starch (9.3 vs. 4.7), total nonstructural CHO (30 vs. 19), and monosaccharides (17 vs. 11). Compared to AM harvest, PM harvest had less acetate (13 vs. 18) and propionate (0.29 vs. 0.82), and tended ($P = 0.12$) to have less lactate (2.9 vs. 3.5) and butyrate (3.9 vs. 5.1). Compared to SG, GG had more starch (9.4 vs. 4.7), total nonstructural CHO (34 vs. 15), and monosaccharides (21 vs. 7.4). Compared to GG, SG had higher pH (5.79 vs. 5.32) and more ethanol (27 vs. 19), acetate (19 vs. 12), propionate (1.11 vs. 0.00), and butyrate (8.4 vs. 0.6), but less DM (242 vs. 324 g/kg silage), and DM concentrations of CP (97 vs. 114) and lactate (1.6 vs. 4.8). Daily DMI (2.16 vs. 1.83 % BW) and digestible DMI (1.15 vs. 0.95 % BW) were greater for PM vs. AM harvest. Serum urea N concentrations at the end of the intake phase were greater for AM (3.91 mM) than for PM harvest (2.31 mM) and tended ($P < 0.09$) to be greater for GG (3.51 mM) than for SG (2.71 mM). We conclude that increased soluble CHO content of these grasses stored as baleage caused increased voluntary intake by beef steers. Decreased serum urea N is consistent with improved retention of dietary N for PM vs. AM harvest.

562 Digestion characteristics of perennial ryegrass (*Lolium perenne* L.) at different stages of maturity. A. V. Chaves¹, G. C. Waghorn*², and I. M. Brookes¹, ¹Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, ²Dexel Limited, Hamilton, New Zealand.

In vitro and *in sacco* digestion offers a rapid and inexpensive method for evaluating nutritive value of ruminant feedstuffs. The hypothesis to be tested here was that ryegrass maturation will alter rates of degradation and products of digestion and these changes will be affected by initial cutting dates (ICD) of the sward. Ryegrass pasture was mown at three dates in Spring and samples of 2 kg were harvested at 7-14 day intervals for chemical analyses and *in vitro* and *in sacco* incubations by cutting to 5 cm above soil level. An important aspect of this experiment was the use of the fresh mincing procedure to provide material for *in vitro* and *in sacco* incubations which mimicked cow digesta. Comparison of ICD showed minor effects on the rate of change in chemical composition. This affected fibre but not CP or NSC content. Protein degradation was not affected by maturation (mean $k=0.12h^{-1} \pm 0.08$), but a higher proportion was released into the soluble (A) fraction with mature grass (A=52 to 72%). This appeared to indicate more extensive cell rupture of mature grass and is likely to reflect the *in vivo* situation where more extensive chewing is needed to swallow mature, compared to succulent forages. In contrast to protein, fibre degradation rate was halved as ryegrass matured ($k=0.14$ to $0.03h^{-1}$), probably as a result of cross linkages between fibre components and lignification. Estimated

ME values for ryegrass were reduced from about 12.8 to 8.8 MJ/kg DM as ryegrass became mature. The ammonia production *in vitro* was a function of grass CP content, extent of release into the soluble fraction and microbial utilisation. One effect of maturation was a brief period of ammonia surplus followed by insufficiency for microbial growth, but the rate and amounts of VFA produced were not affected by forage CP content or ammonia concentration. Maturation had little effect on proportions of VFA. The hypothesis was proven in part; maturation did alter rates of degradation but products of digestion were less affected by maturation and the proportion of N degraded was similar for all maturities.

Key Words: Forage Maturity, Ryegrass, Nutritive Value

563 Effects of beef cow grazing management on sediment and phosphorus losses from smooth brome grass pastures. M. Haan*¹, J. Russell¹, W. Powers¹, S. Mickelson², R. Schultz³, and J. Kovar⁴, ¹Department of Animal Science, Iowa State University, Ames, ²Department of Agricultural and Biosystems Engineering, Iowa State University, Ames, ³Department of Natural Resource and Environmental Management, Iowa State University, Ames, ⁴USDA-National Soil Tilth Laboratory, Ames, IA.

To determine the impacts of grazing management on phosphorus (P) and sediment loss to surface waters five-pasture management systems were evaluated. For 3 yr, three smooth brome grass pastures with slopes of up to 15° were divided into five 0.4-ha paddocks that were grazed by Angus cows (mean BW 632 kg). Grazing treatments included: an ungrazed control (U), summer hay harvest with winter stockpile grazing to a residual sward height of 5 cm (HS), continuous stocking to a residual sward height of 5 cm (5C), rotational stocking to a residual sward height of 5 cm (5R), and rotational stocking to a residual sward height of 10 cm (10R). In the late spring, mid-summer, autumn and early the subsequent spring of each year, rainfall simulations were conducted at 6 sites within each paddock, 3 at high slopes (7.5 to 15.0°) and 3 at low slopes (0 to 7.5°). Rainfall simulators dripped at a rate of 7.1 cm/hour over a 0.5-m² area for a period of 1.5 hours. Runoff was collected and analyzed for total sediment, total P, and total soluble P. Simultaneous to each rainfall simulation, measurements were taken of ground cover, penetration resistance, surface roughness, slope, soil P, soil moisture, sward height and forage mass. There was no difference in the amount of sediment in runoff across treatments. Of the variables measured, amount of sediment in the runoff was most highly correlated with percent ground cover ($r^2 = 0.16$). The 5R and 5C treatments contributed the greatest amount of total and soluble P ($p < 0.05$) to runoff, the 10R and HS treatments were intermediate, and the U treatment contributed the smallest amounts. High slope areas had greater surface runoff ($p < 0.05$) and greater sediment flow ($p < 0.05$) than did low slope areas. Forage management practices that leave greater forage residue on the pasture will reduce the amount of P potentially lost to surface waters in runoff. Pastures with high slopes are more sensitive to losses of sediment in runoff and may need to be stocked less intensively than pastures with low slopes.

Key Words: Grazing, Phosphorus, Water Quality

564 Apparent nutrient digestibility and ruminal alterations in beef steers consuming bermudagrass hay and supplemented with soybean hulls and/or corn. J. C. Henley*, A. I. Orr, and B. J. Rude, Mississippi State University, Mississippi State.

Six ruminally fistulated steers (initial BW = 266 ± 36.9 kg) were utilized in a digestion trial to evaluate the performance of steers consuming soybean hulls and/or corn while consuming bermudagrass hay. The steers were randomly allotted to one of three supplement groups: 1) soybean hulls (SBH); 2) 75% SBH + 25% corn (MIX); 3) corn (CORN). There were three collection periods of five days each. Prior to each 5-day collection, steers were adapted to their diets for 14 days, and were adapted to their individual stalls for an additional three days. Steers were housed in stalls for ten days per period (3 day adaptation, 5 day collection, 2 day in situ collection). All steers were fed their respective supplement at 1.5% BW at approximately 0800 each day and had ad libitum access to bermudagrass hay throughout the trial. There were no differences ($P > 0.05$) among treatments for dry matter, organic matter, or crude protein apparent digestibilities. However, steers consuming SBH and MIX had greater ($P < 0.05$) apparent digestibility of NDF (64.9 and

62.7%, respectively), ADF (65.4 and 63.2%, respectively), and hemicellulose (64.0 and 61.8%, respectively) compared to steers fed corn (51.9, 48.7, and 55.0%, respectively). No differences ($P > 0.05$) were found for total VFA or individual VFA concentrations among treatments. However, isobutyrate and isovalerate as a percentage of total VFA decreased ($P < 0.05$) with time after steers consumed their supplement. Valerate concentrations increased ($P < 0.05$) for approximately 6 hours after consuming supplements, and then decreased by 8 hours post consumption. Ruminal pH decreased ($P < 0.05$) from 6.93, 6.85, and 6.80 for CORN, SBH, and MIX, respectively to 6.30, 6.11, and 6.05, respectively. Supplementing steers with soybean hulls was not affected by addition of corn. However, supplementing with corn decreased fiber digestion. Use of soybean hulls as a supplement may improve animal fiber utilization compared to corn only when consuming hay.

Key Words: Soybean Hulls, Supplementation, Digestibility

565 Evaluation of different backgrounding programs for weaned beef calves. K. H. Hunter*, A. M. M. Shank, R. K. Shanklin, W. S. Swecker, J. P. Fontenot, G. Scaglia, and C. L. Pickworth, *Virginia Polytechnic Institute and State University, Blacksburg.*

Sixteen trials were conducted during 4 yr with 716 animals (552 steers and 164 heifers) (approximately 200 kg) to evaluate the effects of various regimens on performance and health during the backgrounding period (42 d) from weaning to stockering. Thirteen trials were conducted on pasture and three in drylot. All trials had a minimum of two replicates. Grazing trials were on stockpiled fescue-based pastures, and fescue hay was fed in the drylot trials. Grazing calves were fed different supplements with CP levels of 15, 16, 17.4, and 30% at rates of 0, 0.5, and 1.0% BW in different trials. Supplements included corn + SBM, soy hulls + SBM, corn gluten feed + soy hulls, alfalfa pellets, and a 50% hay mixture. Data for all trials were analyzed using the GLM procedure for analysis of variance for a completely randomized block design. Tukey's one way analysis of variance test was used to compare treatment and forage type effects and interactions. Usually, supplemented calves had higher ADG ($P < 0.05$) than unsupplemented calves. Similar ADG were observed when supplementation was provided at 0.5 and 1.0% BW ($P > 0.05$), suggesting that supplementation of calves at more than 0.5% BW is not advantageous. Similar gains were observed across all grazing trials with supplementation at 15, 16, 17.4, and 30% CP levels. Cattle supplemented with by-product feedstuffs (corn gluten feed + soy hulls and soy hulls + SBM) performed comparably to those supplemented with corn + SBM ($P > 0.05$). There were no differences in ADG between unsupplemented animals grazing either fescue pastures or fescue-alfalfa pastures. In drylot, animals supplemented with concentrate had higher ADG ($P < 0.05$) than unsupplemented animals. Low levels of protein supplementation improves performance of calves grazing stockpiled forage.

Key Words: Beef Cattle, Forages, Backgrounding

566 Impact of stocking rate and stocking strategy on gain per animal and gain per hectare of steers grazing rotational or continuous stocked rye-ryegrass pasture. J.J. Cleere*², F.M. Rouquette, Jr.¹, and G.M. Clary^{2, 1} *Texas Agricultural Experiment Station, Overton, 2Texas Cooperative Extension, Overton.*

Selecting appropriate stocking rates for winter annual pastures used for stocker cattle requires knowledge about the environment and forage growth attributes as well as management experience. Sod-seeded Maton rye and TAM 90 annual ryegrass pastures were grazed by Bonsmara x Beefmaster steers from December 18, 2002 to May 14, 2003 to quantify effects of stocking rate (SR), stocking method (SM), and stocking strategy (SS) on gain per animal and gain per hectare. Replicate pastures ($n = 2$) with ($n = 4$) steers each were used for each of the following treatments: 1) Stocking Rates; Low (LO, 2.5-238 kg steers/ha initially) and Medium (ME, 4.9-238 kg steers/ha initially). 2) Stocking Methods; Continuous (CN) and eight-paddock Rotation (RT, 2-d residence and 14-d rest). 3) Stocking Strategies; Fixed SR (FX, SR was fixed during the entire grazing period) and Variable SR (VR, initial SR were fixed until early March and then both LO and ME SR were increased to 7.4 hd/ha until termination). Animal ADG ranged from 1.22 to 1.28 kg/d for all low stocked pastures with no differences across SM or SS. Effects of stocking treatments on ADG became more apparent at ME stocking rate with the RTVR exhibiting 0.17 kg lower ADG (P

$= 0.02$) than the CNFX steers (CNFX = 1.18, CNVR = 1.14, RTFX = 1.05, and RTVR = 1.01 kg/d). The slight decline in ADG with VR strategy compared to FX was likely due to reduced forage availability in late spring. Differences in gain per animal were not detected between FX and VR at any one stocking rate with the exception of a difference in the ME-CNFX and ME-RTVR (152 vs 129 kg; $P = 0.02$). This may indicate that increased stocking via VR strategy in early March increased forage utilization with little negative impact on gain per animal. Gain per hectare ranged from 426 kg/ha on the LO-FX for both CN and RT to 884 kg/ha on ME-CNVR and 853 kg/ha on LO-CNVR. The opportunity to increase stocking rate on the rye-ryegrass pastures during spring increased forage growth can double the gain per hectare.

Key Words: Stocking Rate, Pasture, Animal Gain

567 Accuracy of intake measurements for cows grazing grass/legume pastures using the alkane marker technique. G. C. Waghorn*, S. L. Woodward, and D. A. Clark, *Dexcel Limited, Hamilton, New Zealand.*

Measurement of feed intakes of individual cows grazing perennial ryegrass (*Lolium perenne* L.) based pastures in New Zealand has favored use of alkane markers, in part because forage digestibility is not required for intake calculation. Estimates of DMI are based on recovery of odd chain length (C31 and C33) plant cuticular waxes (alkanes) in conjunction with twice daily administration of a synthetic even chain (C32) alkane marker. However some researchers have expressed concern over the accuracy of intake estimates. Implicit in this methodology is an equal recovery of all alkanes used in calculations of intake. Results of indoor trials with lactating cows and some supporting data from sheep are presented to demonstrate unequal recoveries of individual alkanes from faeces. Intake calculations presented here use pasture C31 and twice daily doses of C32 to estimate intakes. In a trial with 16 cows fed pasture and given a C32 marker, mean actual daily DM intake (y) $10.7 \text{ kg} \pm 1.09$ (mean \pm SD) was lower than predicted from alkanes (x) $11.2 \text{ kg} \pm 1.37$; where $y = 0.66x + 3.28$, $r^2=0.68$. The mean actual daily DM intake (y) of 15 cows in a separate trial (Trial 2) fed fresh pasture indoors with total faecal collection was $12.0 \text{ kg} \pm 1.19$ compared to predicted (x) values of $10.35 \text{ kg} \pm 1.06$; where $y = 0.77x + 1.15$; $r^2=0.75$). Recovery (% of intake) of C31, C32 and C33 from total collection of faeces in Trial 2 differed, averaging 89 ± 10.5 , 101 ± 10.6 and 97 ± 15.2 respectively. Comparable values from total collection of faeces from separate groups of six sheep were 92 ± 7.1 , 80 ± 6.6 and 83 ± 8.1 for pasture diets; 100 ± 7.5 , 106 ± 10.3 and 90 ± 9.2 for alfalfa diets and 73 ± 12.5 , 95 ± 14.8 and 57 ± 12.3 for white clover diets. The differences between faecal recovery of specific alkanes preclude an accurate prediction of intake and the standard deviations demonstrate large variations in recovery between animals. Inconsistent and contrasting alkane recovery will limit their use for estimating intakes of cattle grazing pastures.

Key Words: Alkane Markers, Pasture, Intake

568 Developing consistent relationships among fiber fractions for uniform alfalfa hay quality guidelines. D. R. Mertens*¹ and J. E. Getz^{2, 1} *US Dairy Forage Research Center, Madison, WI, 2USDA-Agricultural Marketing Service, Moses Lake, WA.*

Objective and uniform hay quality guidelines for market reporters are essential to ensure that hay prices are reported accurately, i.e., Good quality hay should be similar throughout the US. Our goals were to determine if relationships between ADF and NDF are consistent enough among laboratories from different regions of the US to derive a uniform equation. Fiber concentrations of alfalfa were obtained from laboratories in 15 states (ST), which provided a full range of values. To obtain a data set that was balanced, values were ranked by ADF and every nth sample was selected to obtain 40 to 50 samples per ST ($n = 625$). Residuals $< 3 \times \text{RMSE}$ of regression were removed as outliers ($n = 5$). The GLM Model: $Y = ST + b \cdot (X \cdot ST)$ for $Y = \text{ADF}$ with $X = \text{NDF}$ and $Y = \text{NDF}$ with $X = \text{ADF}$ was used to identify the ST with median geometric slope. Slopes of other ST were compared to the median and those ST not different ($P > .05$) were identified and used to generate pooled slopes. All ST with different slopes were compared to the pooled slope. Only one ST (CO) had slopes of ADF on NDF and NDF on ADF that differed ($P < .05$) from pooled slopes and this data was removed. The ST with

the median intercept was identified using the pooled slopes and compared to all other ST intercepts. Seven ST were not different ($P > .05$) from the median intercept with an average geometric intercept (GI) of 0.20 (AZ, CA, KA, MN, OR, PA, WA). Three ST had a higher average GI of 1.00 (UT, ID, NE), two ST had a lower GI of 0.95 (IL, NY) and two ST had the lowest GI of 3.08. Average GI weighted for the observations in each group was .19. The slope of ADF versus NDF appears constant throughout the US and variation in intercepts is more likely related to laboratory differences rather than to regional differences in alfalfa. In conclusion, it is possible to identify a geometric relationship between ADF and NDF that can be used to develop uniform alfalfa hay quality guidelines for the US: $ADF = -.19 + .80 \times NDF$; $n=605$, $R^2=.90$, and $RMSE=1.7$.

Key Words: Fiber, Forage Quality, Alfalfa

569 Effects of purified fiber energy supplementation on digestion and ruminal parameters of steers fed cool season grass hay. H. M. Blalock* and C. J. Richards, *The University of Tennessee, Knoxville.*

Six ruminally and duodenally cannulated steers were arranged in a replicated 3 x 3 Latin square. Steers had free choice access to cool season grass hay and were supplemented with 0 (NO), 0.25 (LO) or 0.50% (HI) BW of purified fiber (60% solka floc, 40% oat fiber) prior to AM hay

feeding. Periods were 18 d. On d 7 to 17, steers were intra-ruminally dosed with Cr_2O_3 followed by total fecal collection from d 12 to 17 and duodenal digesta sampling at 10 hr intervals on d 13 to 17. On d 17, Co-EDTA was ruminally dosed and rumen fluid collected at 0, 3, 6, 9, 12 and 24 hr post-dosing. On d 18, ruminal contents were evacuated, weighed and subsamples retained for bacterial separation. Forage intake and total N intake were not affected by supplementation. Total intake of DM, NDF, ADF and OM were increased ($P < 0.05$) with increased supplementation. Quantities and percentages of total tract DM, NDF, ADF and OM digestion were increased ($P < 0.05$) by supplementation. Ruminal and total tract nitrogen digestion were not affected by supplementation. Ruminal acetate and propionate concentrations were not affected ($P > 0.10$) while butyrate concentrations increased ($P < 0.01$) with supplementation. Isobutyrate, valerate and isovalerate concentrations decreased ($P < 0.01$) with supplementation. However, isobutyrate was not different between HI and LO. Ruminal pH was greatest ($P < 0.01$) for HI. Ruminal NH_3-N concentrations were decreased ($P < 0.01$) by supplementation. A TRT x Time interaction existed ($P < 0.01$) for NH_3-N due to the concentration of NO remaining relatively constant throughout the 24 hr period. Total N flow at the duodenum was not affected by supplementation. This data indicates that supplementing steers consuming cool season grass hay with fibrous energy can increase ruminal and total tract fiber digestion without affecting forage intake.

Nonruminant Nutrition: Amino Acids

570 The optimal true ileal digestible lysine and total sulfur amino acid requirement for nursery pigs between 10 and 20 kg. J. D. Schneider*, M. D. Tokach, S. S. Dritz, R. D. Goodband, J. L. Nelssen, J. M. DeRouchey, C. W. Hastad, N. A. Lenehan, N. Z. Frantz, B. W. James, K. R. Lawrence, C. N. Groesbeck, R. O. Gottlob, and M. G. Young, *Kansas State University, Manhattan.*

An experiment involving 360 pigs (avg BW = 10.3 kg) was conducted to determine the appropriate true ileal digestible (TID) lysine and total sulfur amino acid (TSAA) requirement of nursery pigs, and consequently to determine the optimal TSAA:lysine ratio. This trial was organized as a combination of two separate experiments with one set of diets consisting of five treatments with increasing TID lysine (0.9, 1.0, 1.1, 1.2, and 1.3%) and the second set of diets consisting of five treatments with increasing TID TSAA (0.56, 0.62, 0.68, 0.74, and 0.81%). The highest level of both lysine and TSAA (1.3 and 0.81%, respectively) served as a positive control and this diet was combined as one treatment to give a total of nine treatments. Pigs were randomly allotted to 8 replications with 5 pigs per pen based on BW. Average daily gain increased (linear, $P < 0.01$), while ADFI decreased (linear, $P < 0.06$) to 1.3% TID lysine. Increasing TID lysine from 0.9 to 1.3% also improved (linear, $P < 0.01$; and quadratic $P < 0.05$, respectively) gain:feed. Increasing TID TSAA from 0.56 to 0.81% increased (linear, $P < 0.02$) ADG and improved (linear, $P < 0.01$) gain:feed. Regression analysis of the response surface resulted in an estimated TID TSAA to lysine ratio ranging from 55 to 61% for ADG and 57 to 61% for gain/feed.

Item	TID Lysine, %					SED	Linear	Quadratic
	0.9	1.0	1.1	1.2	1.3			
ADG, g	494	524	525	519	549	17.306	0.01	0.51

571 The optimal true ileal digestible lysine and threonine requirement for nursery pigs between 10 and 20 kg. N. A. Lenehan¹, M. D. Tokach¹, S. S. Dritz¹, R. D. Goodband¹, J. L. Nelssen¹, J. L. Usry², J. M. DeRouchey¹, and N. Z. Frantz*¹, ¹*Kansas State University, Manhattan*, ²*Ajinomoto Heartland LLC, Chicago, IL.*

A total of 360 pigs (Genetiporc; initially 10.7 kg and 34 d of age) were used in a 17-d growth assay. This trial was conducted as a combination of two separate trials in order to simultaneously examine both the true ileal digestible (TID) lysine and threonine requirements, and determine the appropriate threonine to lysine ratio. The first part of the trial consisted of five treatments with increasing TID lysine (0.9, 1.0, 1.1, 1.2, and 1.3%). The second part consisted of five treatments with increasing TID threonine (0.60, 0.66, 0.73, 0.79, and 0.85%). The highest level of both lysine and threonine (1.3 and 0.85%, respectively) served as a positive control and this diet was combined as one treatment to give a total of nine treatments. There were 8 replications with 5 pigs per pen. Both ADG and gain/feed (G/F) increased (quadratic, $P < 0.02$) to 1.2% TID lysine. For threonine, ADG (linear, $P < 0.03$) and G/F (quadratic, $P < 0.04$) increased to 0.79% TID threonine. Using 0.79% TID threonine and 1.2% TID lysine as the requirements yields a TID threonine to lysine ratio of 66% for both ADG and G/F. In summary, these results suggest a TID threonine to lysine ratio of approximately 66% for 10 to 20 kg pigs.

Item	TID Lysine, %					SED	Linear	Quadratic
	0.9	1.0	1.1	1.2	1.3			
ADG, g	532	541	587	599	582	19	< 0.01	0.02

Key Words: Threonine, Lysine, Nursery Pigs

572 Assessment of the methionine requirement of pigs in the weight range 11 to 20 kg. Patrick B. Lynch^{*1}, Meike Rademacher², and Peadar G. Lawlor¹, ¹Teagasc, Moorepark, Fermoy, Co. Cork, Ireland, ²Degussa AG., Feed Additives, Hanau, Germany.

The objective of this trial was to determine the optimum ratio of Methionine (Met) to Lysine (Lys) for nursery pigs in the weight range 11 to 23 kg. A total of 192 pigs were used, with a pair of pigs of the same sex penned together (n = 96 pairs) as the experimental unit in a randomized complete block design. Pigs were fed a commercial starter diet for 11 d after weaning at 26 to 28 d of age and fed the test diets for 24 d. The basal diet contained (g/kg): wheat, 231; barley, 120; heated full fat soybeans, 200; field peas, 240; corn starch, 120; soy oil, 25; L-Lys HCl, 3.5; L-threonine, 2.0; L-tryptophan, 0.5; L-valine, 0.5; L-isoleucine, 0.5; minerals and vitamins, 57. The digestible energy content of the diet was 14.9 MJ/kg, crude protein was 166 g/kg, total Lys was 12.0 g/kg, and true ileal digestible (TID) Lys was 10.0 g/kg. The basal diet (2.2 g/kg total Met) was supplemented with DL-Met in increments of 0.4 g/kg to give seven diets ranging from 2.2 to 4.6 g/kg total Met. The ratio of total Met:total Lys varied from 0.183 to 0.383 and TID Met:TID Lys from 0.17 to 0.37. Total sulphur amino acids:Lys ranged from 0.41 to 0.61. Met supplementation increased the average daily feed intake (748, 734, 775, 840, 775, 829, and 707 g/d; quadratic, P < 0.01) and average daily gain (297, 372, 453, 457, 507, 515, and 459 g/d; linear, P < 0.01; quadratic, P < 0.01) and improved feed to gain ratio (2.55, 2.00, 1.74, 1.75, 1.54, 1.60, and 1.55; linear, P < 0.01; quadratic, P < 0.01). Exponential response curves were fitted and showed the optimum level of Met (95% of the asymptote) to be 4.1 g/kg for daily gain and 3.7 g/kg for feed:gain. It is concluded that the optimum ratio of Met:Lys is 0.31 for feed:gain and 0.34 for average daily gain.

Key Words: Nursery Pig, Methionine, Lysine

573 Evaluation of the true ileal digestible (TID) lysine requirement for 11 to 29 kg pigs. S. X. Fu^{*1}, A. M. Gaines¹, B. W. Ratliff¹, P. Srichana¹, G. L. Allee¹, and J. L. Ustry², ¹University of Missouri, Columbia, ²Ajinomoto Heartland LLC, Chicago, IL.

The objective of this research was to evaluate the true ileal digestible (TID) lysine requirement for 11 to 29 kg pigs. For this experiment, a total of 769 pigs (TR-4 × C22; 11.1 ± 0.2 kg) were allotted to one of six dietary treatments in a completely randomized design with 6 replicate pens/treatment. Dietary treatments included six TID lysine concentrations of 1.05, 1.14, 1.23, 1.32, 1.41, and 1.50%. Diets were formulated to be isocaloric and contained the same amount of soybean meal (34.25%). The dietary lysine content was increased by adding L-lysine-HCl with additional synthetic amino acids supplied as necessary to meet the minimum amino acid profile. Growth performance data were collected for 28 d. Body weights and feed intakes were recorded on d 0, 14, and 28. From d 0 to 14, increasing dietary lysine increased (linear, P < 0.01) ADG (505, 523, 546, 556, 554, and 550 g/d) and improved (linear, P < 0.001; quadratic, P = 0.01) G/F (0.631, 0.674, 0.691, 0.705, 0.710, and 0.711). At d 14, pigs were weighing an average of 19 kg. From d 0 to 28, increasing dietary lysine improved (linear, P = 0.03) ADG (614, 624, 633, 646, 639, and 646 g/d) and improved (linear, P < 0.001; quadratic, P = 0.01) G/F (0.621, 0.651, 0.657, 0.676, 0.670, and 0.669). At d 28, pigs were weighing an average of 29.0 kg. Based on the biological and economic data, the TID lysine level that maximized return over feed cost was 1.32%, regardless of weight range (11 to 19 or 11 to 29 kg). Results from this experiment indicate that the late nursery pig diet should contain at least 1.32% TID lysine.

Key Words: Lysine, Pigs, Growth

574 Estimation of the true ileal digestible sulfur amino acid requirement for nursery pigs weighing 13 to 25 kilograms by using Alimet[®] feed supplement. A. M. Gaines¹, G. F. Yi^{*2}, B. W. Ratliff¹, P. Srichana¹, G. L. Allee¹, C. D. Knight², and K. R. Perryman², ¹University of Missouri, Columbia, ²Novus International, Inc., St. Louis, MO.

The objective of this research was to estimate the true ileal digestible (TID) sulfur amino acid (SAA) requirement of 13 to 25 kg pigs reared under commercial conditions. A total of 1,303 pigs (TR-4 × C22; 12.7 ± 0.1 kg) were allotted to one of five dietary treatments in a randomized complete block design with twelve replicate pens (22 pigs/pen) per

treatment. Dietary treatments included five TID SAA levels that corresponded to concentrations of 0.63, 0.70, 0.77, 0.83, and 0.90%, respectively. Experimental diets were corn-soybean meal based and formulated to contain 1.40% TID lysine. Dietary SAA content was increased by adding Alimet[®] feed supplement (88% L-methionine activity) at concentrations of 0.00, 0.08, 0.15, 0.23, and 0.31%, respectively. Increasing dietary TID SAA increased (linear, P < 0.07; quadratic, P < 0.01) ADG (586, 611, 620, 604, and 608 g/d) and improved (linear, P < 0.001; quadratic, P < 0.01) G/F (0.638, 0.667, 0.676, 0.688, and 0.687). Based on the biological and economic data, the TID SAA that maximized return over feed cost was 0.77%. Using the relatively conservative two-slope broken line method, the TID SAA requirement was estimated to be 0.73 and 0.80% for ADG and G/F, respectively. These values were then used to determine the point at which the quadratic curve intersected the plateau of the broken line, which provided another objective estimate of the SAA requirement. The point at which the quadratic curve first intersected the plateau of the broken line occurred at 0.77 and 0.83% for ADG and G/F, respectively. Based on the current study, it can be concluded that the TID SAA requirement for 13-25 kg pigs are 0.73-0.77% for maximal ADG and 0.80-0.83% for optimal feed efficiency. Key Words: Sulfur Amino Acids, Growth, Nursery Pigs

575 Effect of L-lysine-HCl level and true digestible lysine:crude protein ratio on late nursery pig performance. B. W. Ratliff^{*1}, A. M. Gaines¹, P. Srichana¹, R. W. Fent¹, G. L. Allee¹, J. L. Ustry², and R. D. Boyd³, ¹University of Missouri, Columbia, ²Ajinomoto Heartland LLC, Chicago, IL, ³The Hanor Company, Franklin, KY.

At a commercial research site, 792 pigs (TR-4 × C22; 13.0 kg) were used to evaluate the effect of L-lysineHCl level and true digestible (TID) lysine:crude protein (Lys:CP) ratio on nursery pig performance from 13 to 26 kg BW. Pigs were allotted to one of six dietary treatments with 6 replicate pens/treatment and 22 pigs/pen. Dietary treatments included five levels of L-lysineHCl that corresponded to concentrations of 0.30, 0.40, 0.50, 0.60, and 0.70% lysine, respectively. With increasing L-lysineHCl inclusion, the CP concentration decreased (21.8, 20.7, 19.6, 18.5 and 17.5%, respectively) and the TID Lys:CP ratio increased (5.96, 6.28, 6.62, 7.00 and 7.45%, respectively). To evaluate the effect of Lys:CP ratio, a 0.70% L-lysineHCl diet was formulated to contain 18.5% CP and a Lys:CP ratio of 7.00% using a 50:50 blend of L-glutamine and L-glycine. All diets were formulated at a 1.30% TID lysine and minimum ideal protein ratios were maintained (Thr, 65%; Met+Cys, 60%; Trp, 16.7%; Iso, 58%; and Val, 65%). Growth performance data were collected for 21 d. Results indicated a decrease (Linear, P < 0.01; Quadratic, P = 0.10) in ADG (631, 634, 639, 611 and 598 g, respectively) and reduced (Linear, P < 0.01; Quadratic, P = 0.06) G/F (0.684, 0.680, 0.679, 0.666 and 0.643, respectively) with increasing levels of L-lysineHCl inclusion. Feed intake was not affected (P > 0.73). Furthermore, for diets containing 0.70% L-lysineHCl, lowering the Lys:CP ratio to 7.00% increased (P < 0.03) ADG (630 vs. 598 g) and improved (P < 0.03) G:F (0.667 vs. 0.643). Two slope broken line analysis indicated a maximum L-lysineHCl inclusion of 0.50% for ADG and 0.55% for G:F. Collectively, these data indicate that up to 0.50% inclusion of L-lysineHCl has no negative effect on nursery pig performance and inclusion of 0.70% L-lysineHCl addition is possible when the Lys:CP is kept at or below 7.00%.

Key Words: Lysine, Crude Protein, Pigs

576 Estimation of the true ileal digestible sulfur amino acid:lysine ratio for growing pigs weighing 29 to 45 kilograms. A. M. Gaines^{*1}, G. F. Yi², B. W. Ratliff¹, P. Srichana¹, G. L. Allee¹, C. D. Knight², and K. R. Perryman², ¹University of Missouri, Columbia, ²Novus International, Inc., St. Louis, MO.

The objective of this research was to evaluate the optimum true ileal digestible (TID) sulfur amino acid:lysine (SAA:LYS) ratio for growing pigs weighing 29 to 45 kg reared under commercial conditions. A total of 2,208 growing pigs (TR4 × C22; 29.0 ± 0.1 kg) were allotted within sex (barrows and gilts) to one of six dietary treatments in a randomized complete block design with eight replicate pens (23 pigs/pen) per treatment/sex. Dietary treatments included five levels of TID SAA:LYS

ratios (49.5, 54.5, 59.5, 64.5, and 69.5%, respectively). Diets were formulated at a 0.90% TID lysine and contained 0.40% L-lysine-HCl. Dietary SAA content was increased by adding Alimet[®] feed supplement (88% L-methionine activity) with additional synthetic amino acids to meet the minimum amino acid profile. To evaluate the effect of 0.40% L-lysine-HCl supplemented low-protein amino acid fortified (LPAA) diets, a 0.15% L-lysine-HCl supplemented corn-soybean meal diet (high protein control) was also formulated (64.5% TID SAA:LYS ratio). Growth performance data were collected for 17 d. Increasing the TID SAA:LYS ratio increased (linear, $P < 0.001$; quadratic, $P < 0.01$) ADG (916, 951, 953, 958, and 956 g/d) and improved (linear, $P < 0.001$; quadratic, $P < 0.001$) gain:feed (0.459, 0.470, 0.477, 0.479, and 0.475). There were no differences in feed intake with increasing TID SAA:LYS ratios. However, feed intake was higher ($P < 0.01$) in pigs fed the LPAA diet compared to pigs fed the high protein control diet at 64.5% TID SAA:lysine ratio, which resulted in decreased ($P < 0.01$) gain:feed. Based on biological and economic data, the optimum TID SAA:LYS ratio that maximized return over feed cost was a 59.5%. This is in good agreement with estimates using the two slope broken line model, which indicated the optimum TID SAA:LYS ratio to be 59.7 and 61.1% for ADG and gain:feed, respectively. Key Words: Sulfur Amino Acid, Growth, Growing Pigs

577 Estimation of the true ileal digestible sulfur amino acid:lysine ratio for early finishing gilts weighing 45 to 68 kilograms. A. M. Gaines^{*1}, G. F. Yi², B. W. Ratliff¹, P. Srichana¹, G. L. Allee¹, C. D. Knight², and K. R. Perryman², ¹University of Missouri, Columbia, ²Novus International, Inc., St. Louis, MO.

The objective of this research was to evaluate the optimum true ileal digestible (TID) sulfur amino acid:lysine (SAA:LYS) ratio for early finishing gilts weighing 45 to 68 kg reared under commercial conditions. A total of 827 finisher gilts (TR4 × C22; 44.7 ± 0.3 kg) were allotted to one of six dietary treatments in a randomized complete block design with six replicate pens (23 pigs/pen) per treatment. Dietary treatments included five levels of TID SAA:LYS ratios (50.2, 55.2, 60.2, 65.2, and 70.2%, respectively). Diets were formulated at a 0.85% TID lysine and contained 0.40% L-lysine-HCl. Dietary sulfur amino acid content was increased by adding Alimet[®] feed supplement (88% L-methionine activity) with additional synthetic amino acids supplied to meet the minimum amino acid profile. To evaluate the effect of 0.40% L-lysine-HCl supplemented low-protein amino acid fortified (LPAA) diets, a 0.15% L-lysine-HCl supplemented corn-soybean meal diet (high protein control) was also formulated (65.2% SAA:LYS ratio). Growth performance data were collected for 21 d. Increasing the TID SAA:LYS ratio increased (linear, $P < 0.09$; quadratic, $P < 0.09$) ADG (1,044, 1,056, 1,089, 1,084, and 1,069 g/d) and improved (quadratic, $P < 0.02$) gain:feed (0.416, 0.428, 0.429, 0.427, and 0.424). There were no differences in feed intake with increasing TID SAA:LYS ratios. However, feed intake tended to be higher ($P < 0.10$) in pigs fed the LPAA diet compared to pigs fed the high protein control diet, which resulted in lower ($P < 0.10$) gain:feed. Based on biological and economic data, the optimum TID SAA:LYS ratio that maximized return over feed cost was a 60.2%. This is in good agreement with estimates using the two slope broken line model, which indicated the optimum TID SAA:LYS ratio to be 62.0% for maximal ADG. ([®]ALIMET is a trademark of Novus International, Inc., and is registered in the United States and other countries.)

Key Words: Sulfur Amino Acids, Growth, Early Finishing Gilts

578 Evaluation of the true ileal digestible (TID) lysine requirement for 80-100 kg barrows and gilts. P. Srichana^{*1}, A. M. Gaines¹, B. W. Ratliff¹, G. L. Allee¹, and J. L. Usry², ¹University of Missouri, Columbia, ²Ajinomoto Heartland LLC, Chicago, IL.

Two experiments were conducted at a commercial research site in order to evaluate the true ileal digestible (TID) lysine requirement for 80 to 100 kg barrows and gilts. In Exp.1, a total of 865 barrows (TR-4 × C22; 83.0 ± 0.3 kg) were used in a completely randomized design with 7 replicate pens/treatment. In Exp. 2, a total of 884 gilts (TR-4 × C22; 79.6 ± 0.4 kg) were used in a completely randomized design with 7 replicate pens/treatment. Pigs used in both experiments were allotted to one of six dietary treatments containing 0.50, 0.60, 0.70, 0.80, 0.90,

and 1.00% TID lysine. Diets used in the experiments were corn-soybean meal based diets and contained 0.15% L-lysine HCl. Dietary lysine content was increased by altering the corn:soybean meal ratio. Growth performance data were collected for 14 and 21 d, respectively, for Exp.1 and 2. For Exp. 1, increasing dietary lysine increased (quadratic, $P < 0.01$) ADG (907, 985, 983, 982, 961, and 957 g/d) and improved (linear, $P = 0.07$; quadratic, $P = 0.06$) G:F (0.294, 0.303, 0.314, 0.309, 0.310, and 0.308). For Exp. 2, increasing dietary lysine increased (linear, $P < 0.001$; quadratic, $P < 0.001$) ADG (898, 986, 1,000, 1,000, 969, and 1,004 g/d) and improved (linear, $P < 0.001$; quadratic, $P < 0.001$) G:F (0.317, 0.348, 0.346, 0.374, 0.354, and 0.358). Furthermore, increasing dietary lysine resulted in a linear decrease ($P = 0.05$) in ADFI (2,834, 2,830, 2,890, 2,807, 2,732, and 2,802 g/d). Using segmented regression procedures, the TID lysine requirement was estimated to be 0.61 and 0.68% for ADG and G/F, respectively, in barrows. The TID lysine requirement was estimated to be 0.61 and 0.77% for ADG and G/F, respectively, in gilts. These data indicate that from 80 to 100 kg BW, the optimum TID lysine requirement for barrows and gilts of this genotype is at least 0.60%.

Key Words: Lysine, Pigs, Growth

579 Effect of low-protein amino acid supplemented diets on performance and indicators of enteric health in early-weaned pigs. C. M. Nyachoti^{*1}, O. F. Omogbenigun¹, M. Rademacher², and G. Blank¹, ¹University of Manitoba, Winnipeg, MB, Canada, ²Degussa AG, Germany.

Previous research suggests that high dietary protein may encourage proliferation of intestinal pathogenic bacteria leading to post-weaning diarrhea in pigs. We used 96 pigs weaned at 18 d to study the effect of low-protein amino acid (AA) supplemented diets on performance, and intestinal microbial population and fermentation activities in a 3-wk trial. Four corn-wheat and soybean meal-based diets were assigned at random to six pens each with 4 pigs balanced for initial body weight and sex. The diets were a control containing 23% CP or the same diet but with CP reduced to 21%, 19% and 17% and supplemented with Lys, Thr, Trp, and Ile to equal that of the control. Diets were formulated to similar nutrient levels and provided for ad libitum intake. Blood was sampled on d 0, 7, 14, and 21 for determining plasma urea nitrogen (PUN). ADFI, ADG, and gain:feed (G:F) were determined weekly. On d 21, two pigs per pen selected at random, were sacrificed to determine intestinal histology, digesta pH, ammonia levels, volatile fatty acids (VFA), and luminal microbial counts. ADFI, ADG, and G:F were not affected ($P > 0.05$) by reducing CP by 2 percentage units but a reduction of 4 or more percentage units reduced ($P < 0.05$) ADFI and ADG over the 3-wk study period. Ileal digesta pH was lower ($P = 0.01$) in pigs fed low-protein diets compared with control. Ammonia nitrogen in ileal digesta, and PUN were reduced linearly ($P < 0.01$) as CP was reduced. With the exception of valeric acid, VFA levels in ileal digesta of piglets fed low-protein diets were generally lower ($P < 0.05$) compared with control. Diet had no effect on intestinal microbial counts ($P > 0.1$). The results show that when CP is reduced by four or more percentage units other AA may become limiting and support the hypothesis that low CP AA supplemented diets may help maintain enteric health in pigs by lowering microbial metabolites with toxic effects.

Key Words: Amino Acid Supplementation, Early-Weaned Pigs, Intestinal Health

580 The tryptophan requirement of growing and finishing barrows. J. L. Shelton^{*1}, A. C. Guzik¹, L. L. Southern¹, B. J. Kerr², and T. D. Bidner, ¹LSU Agricultural Center, Baton Rouge, LA, ²USDA-ARS-SOMMRU, National Swine Research and Information Center, Ames, IA.

Five experiments were conducted to determine the true digestible Trp (dTrp) requirement of growing and finishing barrows. Treatments were replicated with three or four replications of three or four barrows per pen. Broken line regression was used to estimate the dTrp requirement in all experiments. Experiment 1 was conducted with 27 barrows (initial and final BW of 78.3 and 109.8 kg, respectively) to validate whether a corn-feather meal (C-FM) Trp-deficient diet, with added crystalline L-Trp, would result in growth performance and carcass traits similar to a corn-soybean meal (C-SBM) diet. Barrows fed the C-FM diet without L-Trp addition had decreased growth performance and carcass traits, and an increased plasma urea N (PUN) concentration ($P < 0.01$). Adding

L-Trp to the C-FM diet resulted in similar growth performance and carcass traits as barrows fed the C-SBM diet ($P > 0.10$). In Exp. 2, 60 barrows (initial and final BW of 74.6 and 104.5 kg, respectively) were used to estimate the dTrp requirement. The levels of dTrp used in Exp. 2 were 0.06, 0.08, 0.10, 0.12, or 0.14%. Response variables were growth performance, PUN concentrations, carcass traits, and pork quality. The dTrp requirement was estimated to be 0.102%. In Exp. 3, 4, and 5, barrows ($n = 60, 60, \text{ or } 80$, respectively) were allotted to five dietary treatments supplemented with crystalline L-Trp, and PUN concentration was the response variable. The levels of dTrp in Exp. 3 (BW was 30.9 kg) were 0.13, 0.15, 0.17, 0.19, or 0.21%. The dTrp requirement was estimated to be 0.167%. The levels of dTrp in Exp 4 (BW was 51.3 kg) were 0.09, 0.11, 0.13, 0.15, or 0.17%. The dTrp requirement was estimated to be 0.134%. The levels of dTrp in Exp. 5 (BW was 69.4 kg) were 0.07, 0.09, 0.11, 0.13, or 0.15%. The dTrp requirement was estimated to be 0.096%. These data indicate that the dTrp requirements of barrows weighing 30.9, 51.3, 69.4, and 74.6 to 104.5 are 0.167, 0.134, 0.096, and 0.102%, respectively.

Key Words: Barrows, Requirement, Tryptophan

581 The isoleucine requirement of 80- to 120-kilogram barrows. D. W. Dean^{*1}, L. L. Southern¹, B. J. Kerr², and T. D. Bidner¹, ¹LSU Agricultural Center, Baton Rouge, LA, ²USDA-ARS-MWA-SOMMRU, Ames, IA.

Three experiments were conducted to validate an Ile deficient diet and then to determine the Ile requirement of 80- to 120-kg barrows. Cross-bred barrows ($n = 60, 80, \text{ or } 80$ with initial BW of 93, 82, and 85 kg, respectively) were used in each experiment. In Exp. 1, five replications with four pigs per pen were fed diets containing either a corn-soybean meal diet (C-SBM) or a corn-based diet containing 5% blood cells (BC) with or without 0.26% supplemental Ile (C-BC+Ile or C-BC) in a 28-d growth assay. On d 14, pigs receiving the C-BC diet were taken off experiment due to a severe depression in feed intake. Growth performance was not different for pigs fed C-SBM or C-BC+Ile ($P = 0.36$) over the 28-d experiment. In Exp. 2, four replications with four pigs per pen were fed the C-BC diet containing 0.24, 0.26, 0.28, 0.30, or 0.32% true digestible (TD) Ile. The experiment lasted 7 d and was an attempt to estimate the Ile requirement using plasma urea nitrogen (PUN) as the response variable. Because of dramatic incremental increases in ADFI as TD Ile was increased, PUN could not be used to estimate the Ile requirement. In Exp. 3, five replications with four pigs per pen were fed the C-BC diet containing 0.28, 0.30, 0.32, 0.34, or 0.36% TD Ile. Three pigs per pen were slaughtered on d 33 or 61 for determination of carcass lean and fat measurements (117.8 kg average final BW). Daily gain, ADFI, and gain:feed were increased linearly ($P = 0.007$) as Ile was increased in the diet. There were no effects of TD Ile level on 10th rib fat depth or loin muscle area; however, kilograms of lean was increased linearly ($P < .001$) as TD Ile level increased. In summary, the Ile deficiency of a C-BC diet can be corrected by the addition of supplemental Ile, and the PUN method is not suitable when assessing Ile requirement due to dramatic changes in ADFI. The TD Ile requirement for 80- to 120-kg barrows for maximizing feed intake, growth, and kilograms of lean is not less than 0.36%.

Key Words: Isoleucine, Pig, Plasma Urea Nitrogen

582 Determination of the optimum threonine:lysine ratio for prolific lactating sows. A. M. Gaines^{*1}, N. H. Williams², M. E. Johnston³, C. Zier², G. L. Allee¹, J. L. Usry⁴, and R. D. Boyd³, ¹University of Missouri, Columbia, ²Pig Improvement Company, Franklin, KY, ³The Hanor Company, Inc., Franklin, KY, ⁴Ajinomoto Heartland LLC, Chicago, IL.

This study was conducted to determine the optimum threonine:lysine ratio for prolific lactating sows. A total of 269 PIC product sows (parities

1-6) were allocated by parity to four dietary threonine concentrations, 0.51, 0.58, 0.64, and 0.70%. Diets were formulated to contain 0.90% total lysine which, based on expected litter growth rate (2.35 kg/d), would have been below requirement. The four concentrations of threonine corresponded to total threonine:lysine ratios of 0.57, 0.64, 0.71, and 0.78, respectively. Experimental diets were corn-soybean meal based diets and contained 0.29% L-lysine-HCl. Soybean meal was held constant and dietary threonine was increased by adding L-threonine with additional synthetic amino acids supplied as necessary to meet the minimum amino acid profile. Sows were fed ad libitum from d 112 of gestation through a 19 d lactation period. Litter size was standardized by 24 h post-farrowing (avg. 11.5 pigs/litter). There was no treatment difference ($P > 0.41$) in sow feed intake (avg. 6.3 kg/d). Sow weight loss during lactation ranged from 11.4-17.5 kg and was not affected by threonine:lysine ratio ($P > 0.15$). Increasing the threonine:lysine ratio improved litter weight gain (quadratic, $P < 0.06$), litter weaning weight ($P < 0.05$), and the number of pigs weaned (quadratic, $P < 0.06$). The highest threonine:lysine ratio (0.78) was detrimental to both piglet livability (88.6 vs. 91.2%) and litter growth rate (2.10 vs. 2.34 kg/d). A threonine:lysine ratio of 0.64 appears to optimize milk production and pigs weaned for high producing lactating sows nursing large litters. This estimate was the same for both younger (parity 1-2) and older sows (parity 3-6).

Key Words: Threonine, Lactation, Sows

583 The valine requirement of lactating sows. M. Etienne^{*1}, J. Y. Dourmad¹, J. Noblet¹, L. Le Bellego², and C. Relandeau², ¹INRA-UMRVP, Saint-Gilles, France, ²Ajinomoto Eurolysine sas, Paris, France.

This study was undertaken to determine the effects of the valine:lysine ratio in the lactation diet on sow and piglet performance, milk and piglet compositions, and nitrogen balance of sows. A basal diet with barley, wheat, peas and soybean meal containing 135 g/kg CP was fortified with crystalline amino acids to reach an optimal balance between essential amino acids except for valine. The lysine level was limiting (7.6 g/kg), and crystalline L-valine was added so that the valine:lysine ratio was below (0.70, diet L), met (0.89, diet M) or exceeded (1.28, diet H) estimated requirements (INRA, 1991). Twelve replicates of three Landrace x Large White sows (mean parity, 2.5) were fed the experimental diets during a 25-d lactation. Litters were equalized to 13.7 piglets after farrowing. They did not have access to creep feed. Sow feed intake increased progressively up to 6 kg/d within 5 d and then remained constant. Feces and urine of sows were collected from 5 to 25 d of lactation. Body composition of two piglets/litter sacrificed at weaning was determined. Weight and backfat depth losses during lactation (26.7 kg and 2.8 mm, respectively) did not differ between groups. The mean number of piglets nursed (12.6) or weaned (12.1) was not affected by treatments. Mean piglet (6.47 kg) and litter weight at weaning (78.3 kg) and average daily gain of piglets (194 g/d) and litters (2.29 kg/d) were similar in the three groups. No significant effect of diet was found on milk composition determined at 5, 15 and 25 d of lactation. Mean dry matter, nitrogen, and energy output in milk estimated through growth rate and composition of body weight gain of the piglets were also unaffected (1.53 kg, 63.6 g, and 41.9 MJ/d, respectively). Piglets in the L group had more dry matter and fat and less nitrogen ($P < 0.05$) in their body than those in groups M and H. The N retention coefficient in sows did not differ between groups. It is concluded that there is no advantage to increase the valine:lysine ratio in the lactation diet of sows beyond 0.90.

Key Words: Sows, Valine, Lactation

Physiology and Endocrinology: Nutritional Regulation of Reproduction

584 Energy balance, dry matter intake, and hormone profiles of cows with ovulatory and non-ovulatory follicles during the first postpartum follicle wave. S. T. Butler^{*} and W. R. Butler^{*}, Cornell University, Ithaca, NY.

An early resumption of ovulatory activity following parturition is positively associated with subsequent measures of reproductive success.

Postpartum energy balance (EB) affects ovarian follicle development and likelihood of ovulation. This study was carried out to assess whether differences in transition period EB (pre- and postpartum) also contribute to differences in postpartum follicular activity (study period = d -21 to d 30 relative to parturition). First wave follicle development was fol-

lowed via ultrasound in fifty-five mature Holstein cows, and the follicle waves were retrospectively categorized as being ovulatory (O; n=17), non-ovulatory high E2 (NH; n=6), non-ovulatory low E2 (NL; n=24), or cystic (n=8). The cystic cows were excluded, and the remaining data were analyzed by ANOVA and repeated measures ANOVA. Peak plasma estradiol (E2) concentrations were similar in O and NH cows (5.8 ± 0.7 vs. 6.0 ± 1.1 pg/ml; $P=0.8$), and were higher in both groups ($P<0.001$) than NL cows (1.2 ± 0.5 pg/ml). Energy balance in the NL cows during the pre- and postpartum periods (10.8 ± 0.4 and -12.2 ± 0.6 Mcal/d) were less favorable than in either the O (13.6 ± 0.5 and -8.3 ± 0.8 Mcal/d; both $P<0.001$) or NH cows (15.8 ± 0.8 and -9.0 ± 1.2 Mcal/d; $P<0.001$ and $P<0.05$). Divergence between groups in EB started as early as d -21 and continued through d 30. There were no differences between groups in milk yield ($P>0.2$), and differences in EB were paralleled by differences in DMI. In accordance with the EB results, NL cows had lower insulin and glucose and higher NEFA than O cows (all $P<0.001$) and NH cows ($P<0.05$, $P=0.16$ and $P<0.06$, respectively). The NL cows had a more severe negative EB nadir compared with O ($P<0.08$) and NH cows ($P<0.05$). In conclusion, EB was least favorable in NL cows. This status commenced up to 3 weeks prior to parturition and carried over through the postpartum follicular wave. Conversely, NH cows had a similar EB profile to O cows and produced similar levels of E2, but failed to ovulate.

Key Words: Energy Balance, Ovulation, Estradiol

585 Effects of feeding menhaden fish meal or Ca salts of fish oil fatty acids on uterine fatty acids composition, COX-2 level and PGF_{2α} production in early lactating cows. A. Heravi Moussavi¹, R. O. Gilbert², T. R. Overton², D. E. Bauman², and W. R. Butler², ¹Dept. of Animal Science, Ferdowsi University, Mashhad, Iran, ²Cornell University, Ithaca, NY.

The study was designed to test the effects of dietary fatty acid supplementation on uterine fatty acid composition, cyclooxygenase-2 (COX-2) level, and PGF_{2α} production in early lactating cows. From d 5-50 postpartum, cows (n = 30; 6/treatment) were fed diets that were isonitrogenous, isoenergetic and isolipid containing 0 (Control), 1.25, 2.5 or 5 % menhaden fish meal (FM) or 2.3% Ca salts of fish oil fatty acids (CaFOFA). At day 23 postpartum, cows were induced to a synchronized ovulatory cycle with an i.m. injection of 100 μg of GnRH followed after 7 days by i.m. administration of 30 mg of PGF_{2α} and a second injection of GnRH 48 h later. On d 15 after second GnRH injection, cows were injected with 100 IU oxytocin (i.v.) at 11.00 h. Blood samples were collected at 15-min intervals from 1 h before to 3 h after the oxytocin injection and at 30-min intervals from 3 to 4 h after oxytocin injection to monitor uterine secretion of PGF_{2α} measured as 13,14-dihydro 15-keto PGF_{2α} (PGFM). After completion of blood sampling, uterine endometrium biopsy samples were taken for fatty acid analysis and Western blot for COX-2 concentration. The uterine fatty acid composition of eicosapentaenoic acid (EPA, C20:5, n-3) and docosahexaenoic acid (DHA, C22:6, n-3) were significantly ($P<0.0001$) increased by supplementation with fish meal and CaFOFA to as much as 3-fold. Arachidonic acid (AA, C20:4, n-6) was decreased by adding 5 % FM ($P<0.05$). The uterine level of COX-2 protein and PGFM area under curve after administration of oxytocin were not significantly different among diets. Results from this experiment demonstrate that dietary fatty acid supplementation significantly increases uterine omega-3 fatty acid concentration with no apparent effect on COX-2 level and PGF_{2α} production after oxytocin challenge in early lactation dairy cows.

Key Words: Fish meal, COX-2, PGF_{2α}

586 Effect of fat sources differing in fatty acid profile on fertilization rate and embryo quality in lactating dairy cows. R. L. A. Cerri¹, R. G. S. Bruno¹, R. C. Chebel¹, K. N. Galvao¹, H. Rutigliano¹, S. O. Juchem¹, W. W. Thatcher², D. Luchini³, and J. E. P. Santos¹, ¹University of California, Davis, ²University of Florida, Gainesville, ³Bioproducts, Inc..

Holstein cows, 154, were randomly assigned to one of two treatments consisting of either a Ca salt of linoleic and trans fatty acids (LTFA) or of palm oil (PO). Cows consumed 250 and 350 g/d of the supplemental fats during the last 25 d of gestation and first 60 d in milk (DIM), respectively. Cows were pre-synchronized with a CIDR and GnRH at 30 DIM, followed 7 d later by PGF_{2α} and CIDR removal. The Ovsynch protocol was initiated 2 d after CIDR removal and all cows were timed AI by the

same person 12 h after the last GnRH. Blood samples were collected at all injections in the Ovsynch and then at d 1, 3 and 5 d after AI for P4 analysis. Ovaries were examined by ultrasound throughout the synchronization protocol, and cows were flushed at 5.5 d after timed AI. Structures were evaluated visually and using vital staining with propidium iodine followed by Hoescht. Continuous, binomial, and count data were analyzed using the GLM, GENMOD, and LOGISTIC procedures of SAS (2001), respectively. Ovulation to the first and second GnRH and double ovulation to the second GnRH of the Ovsynch were similar ($P>0.25$) across treatments and averaged, respectively, 83.7, 86.4, 19.1%. Diameter of the ovulatory follicle at the second GnRH of the Ovsynch and of the CL at embryo collection were similar ($P>0.80$) across treatments and averaged, respectively, 18.6 and 22.2 mm. A total of 86 structures were recovered (41 LTFA and 45 PO), and recovery rate (structure/CL) was similar for LTFA and PO (51.9 vs 54.9%; $P>0.15$). Fertilization rate (87.2 vs 73.3%; $P=0.11$), number of total cells (19.4 vs 14; $P=0.13$), and percentage of live cells (94.2 vs 85.3%; $P=0.09$) all tended to be higher for LTFA than PO. Similarly, the percentage of high quality embryos (grades 1 and 2) were higher for LTFA compared with PO (73.5 vs 51.5%; $P=0.06$), and number of accessory sperm cells attached to the zona pelucida/structure were higher (34.3 vs 21.5; $P<0.001$) for LTFA than PO. These results suggest that feeding Ca salts of LTFA improve fertilization rate and embryo quality in lactating dairy cows. Supported by NRI/USDA Grant 2003-02742.

Key Words: Embryo, Fatty Acids, Dairy Cows

587 Expression of growth hormone receptor and IGF-I mRNA in the reproductive tissues of early postpartum dairy cows. M. L. Rhoads*, J. P. Meyer, S. J. Kolath, W. R. Lamberson, and M. C. Lucy, University of Missouri, Columbia.

The growth hormone (GH)/IGF-I system plays a critical metabolic role in dairy cattle. In liver, GH receptor (GHR) and IGF-I are dynamically regulated by lactation and energy balance. Less is known about the regulation of GHR and IGF-I mRNA in reproductive tissues. The objective of this study was to measure total GHR (tGHR) and IGF-I mRNA expression in the liver, uterus, corpus luteum (CL) and follicle in Holstein cows (n=21) sampled three times during early lactation. GnRH was administered within 15 d postpartum to induce first ovulation. Nine d after ovulation (23 ± 1 d postpartum) the liver, uterus, CL and first wave dominant follicle (DF; follicular fluid aspiration for granulosa cell collection) were sampled. PGF_{2α} and GnRH were injected 7 and 9 d after sample collection to synchronize the second (41 ± 1 d postpartum) and third (60 ± 1 d postpartum) tissue collections. Total RNA was isolated and used for mRNA analysis by real-time quantitative PCR. Uterus, CL and DF expressed less tGHR (0.1 ± 0.8 , 8.3 ± 0.9 and 1.4 ± 0.9 AU, respectively; $P<0.01$) and IGF-I (4.3 ± 2.7 , 12.0 ± 2.9 and 6.4 ± 3.1 AU, respectively; $P<0.01$) than liver (24.4 ± 0.8 and 47.2 ± 2.7 AU, respectively). GHR1A mRNA in liver and tGHR and IGF-I mRNA in liver and reproductive tissues were unaffected by stage of lactation ($P>0.10$). The tGHR mRNA was correlated with IGF-I mRNA in liver ($r=0.42$; $P<0.01$), uterus ($r=0.78$; $P<0.01$) and CL ($r=0.40$; $P<0.01$), but not DF. Liver IGF-I mRNA ($r=0.33$; $P<0.01$) and plasma IGF-I concentrations ($r=0.31$; $P<0.02$) were correlated with body condition score (BCS) from calving to sample collection. The effects of BCS loss on reproductive tissues were opposite to that observed in liver. The tGHR mRNA in CL ($r=0.37$; $P<0.01$) and the IGF-I mRNA in DF ($r=0.31$; $P<0.05$) increased with greater BCS loss. The metabolic control of tGHR and IGF-I differed between liver and reproductive tissues. Reproductive tissues may compensate for low BCS with localized synthesis of tGHR and IGF-I.

588 Influence of postpartum nutrition of primiparous beef cows on insulin-like growth factor binding proteins in follicular fluid and plasma. I. Rubio*, F. J. White, N. H. Ciccioli, R. P. Wettemann, and L. J. Spicer, Oklahoma Agricultural Experiment Station, Oklahoma State University, Stillwater.

Effect of postpartum nutrient intake on insulin-like growth factor binding proteins (IGFBPs) in dominant follicles (DF) and plasma was evaluated at 56 ± 9 d postpartum in anovulatory primiparous Angus x Hereford cows. Body condition score (BCS) at calving was 4.8 ± 0.2 . Cows (n=28) were blocked based on BCS and randomly assigned to one of two nutritional treatments at calving; moderate (M), 2.3 kg/d of a 40

% CP supplement and ad libitum hay, or high (H), ad libitum access to a 12% CP-50 % concentrate diet and hay. Blood samples were collected twice a week starting at 30 d postpartum. Ovarian follicles were evaluated daily by ultrasonography commencing at 42 d postpartum. When growth of DF plateaued, follicular fluid (FF) was obtained by transvaginal ultrasound-guided follicular aspiration. Data were analyzed using the MIXED procedure of SAS and Pearson correlation coefficients. Concentrations of IGF-I in FF were greater ($P < 0.01$) for H (34.0 ± 10.7 ng/ml) than M (23.6 ± 8.5 ng/ml) cows, but concentrations of progesterone, androstenedione, and estradiol in FF were not influenced ($P > 0.10$) by treatment. Concentrations of IGFBP-4 and -5 in plasma were 30% greater ($P < 0.01$) in H than in L cows. Concentrations of IGFBP-4 and -5 in FF were 68 and 48%, respectively, greater ($P < 0.05$) for H than M cows. Concentrations of IGFBP-2 and -3 in plasma and FF were not influenced by treatment. Concentration of IGFBP-2 and -5 in plasma at follicular aspiration were positively correlated with follicle size ($P < 0.05$) and IGFBP-2 in FF was correlated with follicle size. BCS at calving was positively correlated with IGFBP-2, -4 and -5 in plasma at aspiration of follicles. Concentration of IGF-I in plasma at aspiration and in FF were positively correlated with IGFBP-3 and -4 in FF. Although concentrations of IGFbps in FF were not correlated with IGFbps in plasma, similar increases in both systemic and intrafollicular IGFBP-4 and -5 in cows with greater nutrient intake, indicate that these two IGFbps may be regulated by the same nutritionally driven endocrine or metabolic changes.

Key Words: Insulin-like Growth Factor Binding Proteins, Nutrition Postpartum, Cow

589 Reproductive performance of primiparous and multiparous cows fed whole soybeans before breeding. N. M. Long^{*2}, G. M. Hill¹, J. F. Baker¹, W. M. Graves², M. A. Froetschel², B. G. Mullinix, Jr.¹, and D. H. Keisler³, ¹University of Georgia, Tifton, ²University of Georgia, Athens, ³University of Missouri, Columbus.

Effects of supplemental energy before breeding on primiparous (PC; 508.84 ± 35.8 kg BW) and multiparous (MC 581.4 ± 66.57 kg BW) reproductive performance were determined using Angus (A; PC=17; MC=36) and Polled Hereford (PH; PC=12, MC=11) beef cows. Parity (P), breed, cow and calf initial BW, and calf age were used to rank cows before random assignment to control (C; no supplementation, PC = 15, MC= 25) or soybean (S; cracked whole soybeans 2.26 kg/cow daily, PC=14; MC=24) treatments (T) during a pre-breeding period (Feb 11 to Apr 11). The breeding interval began April 14, estrual activity was monitored visually and by Heatwatch[®] system, and cows were bred A.I.(d 1 to d 44), or natural service (fertile bulls, d 45 to d 71). Cow blood serum (Feb 11 and Apr 11) was analyzed for triglyceride, cholesterol, low and high density lipids, and leptin (TRIG, CHO, LDL, HDL, LEP, mg/dl). Calf ADG (kg) from Feb 11 to end of breeding season, with birthweight as a covariate was affected ($P < 0.10$) by P (PC and MC within C and S, respectively, were : 0.91, 0.95, 0.93, 0.98, SE = 0.023). Pregnancy rate (%) on Sep 17, for PC and MC within C and S, respectively, were: 66.7, 85.0, 62.5, 58.3, SE = 8.2, and it was unaffected by T and P. Initial values for CHO, LDL, HDL and TRIG were unaffected ($P > 0.10$) by T or P, but all increased by Apr 11, resulting in differences (adjusted using Feb 11 data) shown in the table. Leptin values increased from Feb 11 to Apr 11 for all treatments except PC-C. Feeding S to PC cows resulted in increased LEP ($P = 0.05$), and elevated TRIG, CHO, LDL, and HDL of PC-S to levels comparable with MC.

Item	Control (C)		Soybeans (S)		SE	T	P	TxP

590 Recombinant oleptin does not acutely accelerate the frequency of LH pulses at any developmental stage in normal and growth-restricted heifers. D. A. Zieba^{1,2}, M. Amstalden^{1,2}, S. Morton^{1,2}, D. H. Keisler³, and G. L. Williams^{*1,2}, ¹Animal Reproduction Laboratory, Texas A&M University Agricultural Research Station, Beeville, TX, ²Department of Animal Science and Center for Animal Biotechnology and Genomics, College Station, TX, ³Department of Animal Science, University of Missouri, Columbia.

Leptin plays critical roles in communicating nutritional status to the central reproductive axis in mammals and is necessary for sexual maturation. However, there is an emerging consensus that leptin may serve merely as a permissive signal for puberty. This is supported by the fact that chronic treatment of well-fed heifers with recombinant ovine leptin (oleptin) fails to accelerate the timing of puberty. Nonetheless, oleptin acutely stimulates gonadotropin secretion during nutritional stress in cows, and prevents fasting mediated reductions in frequency of LH pulses in peripubertal heifers. Therefore, objectives herein were to determine whether leptin could act to accelerate acutely the frequency of LH, and putatively GnRH, pulses at some critical point(s) of development in heifers fed normal or growth-restricted diets Ten-month old prepubertal heifers were assigned randomly to one of two dietary groups: 1) Normal Growth (a BW gain of 0.68 kg/d; and 2) Restricted Growth (a BW gain of 0.3 kg/d). Every 5 wk, each heifer received in random order on each day of a 2-d experiment, three hourly injections of either saline or oleptin (0.2 µg/kg BW i.v.). Blood samples were collected every 10-min for 5 h during each experimental period. The experiment ended when all normal-growth heifers had reached puberty. None of the restricted-growth heifers reached puberty during the study. Mean circulating concentrations of leptin were approximately 70% lower ($P < 0.001$) in restricted- compared to normal-growth heifers. Mean plasma LH and amplitude of LH pulses in restricted-growth heifers were less ($P < 0.01$) than in normal-growth heifers. Leptin treatment acutely increased ($P < 0.002$) mean circulating leptin 1.7- to 2.0-fold and slightly but significantly ($P < 0.02$) increased mean concentrations of LH over all periods, regardless of diet. Neither frequency nor individual characteristics of LH pulses were altered acutely by leptin treatment at any age. We conclude that changes in sensitivity of the hypothalamic-hypophyseal axis to leptin do not occur as a function of sexual maturation (USDA-NRI 00-35203-9132).

Key Words: Heifer, Leptin, LH

591 Effect of prenatal nutrition on plasma glucose at birth and weaning. D. W. Kastner^{*}, I. Rubio, F. J. White, N. H. Ciccioli, and R. P. Wettemann, Oklahoma Agricultural Experiment Station, Stillwater, OK.

Two experiments (Expt) were conducted to determine the effect of high (H) or low (L) energy and protein diets of cows during gestation on

plasma concentrations of glucose in calves at birth and after weaning. In Expt 1, mature Angus x Hereford cows received a 12% CP - 50% concentrate diet ad libitum (H, n=12), or grazed dry prairie grass and received 0.45 kg/d of a 40% CP supplement (L, n=10) from approximately 118 to 202 d of gestation. Calves were born between February 12 and April 3. H cows gained 143 ± 6 kg and 2.1 ± 0.2 body condition scores (BCS; 1=emaciated, 9=obese) and L cows gained 31 ± 7 kg and 0.2 ± 0.2 BCS. In Expt. 2, H cows (n=10) received a 50% concentrate diet ad libitum and L cows (n=9) received 4 kg/d of prairie hay and 0.45 kg/d of a 20% CP supplement from approximately 78 to 174 d of gestation. H cows gained 138 ± 4 kg and 1.7 ± 0.2 BCS and L cows gained 7 ± 4 kg and lost 0.3 ± 0.1 BCS. Cows calved between March 13 and April 29. Birth weights of calves were not influenced by diet that cows received during mid-gestation. Weaning weights were greater for calves from H than L cows in Expt 1 ($P < 0.06$) and 2 ($P < 0.01$). At 30 d of treatment (Expt 2), H cows had greater ($P < 0.05$) concentrations of glucose, thyroxine and NEFA in plasma than L cows. Concentrations of glucose in plasma of calves at birth were not influenced by treatment in either experiment. At weaning (Expt 1), concentrations of glucose were greater ($P < 0.05$) in H than L cows but NEFA and IGF-I levels were not influenced by treatment. H and L calves (Expt 2) responded differently to a glucose tolerance test after weaning. Concentrations of glucose with time after infusion were greater ($P < 0.01$) at 3 wk after weaning for H than L calves and tended to be greater ($P < 0.10$) for H than for L calves at 3.5 mo after weaning. We conclude that exposure of cows to high energy diets that cause increased glucose in plasma during mid-gestation, may influence regulation of concentrations of glucose in plasma of calves after weaning.

Key Words: Calf, Glucose, Prenatal

592 The role of food intake on estrous cyclicity and reproductive potential in white-tailed deer (*Odocoileus virginianus*). E. L. Monaco^{*1}, R. L. Stanko¹, and D. G. Hewitt², ¹Department of Animal and Wildlife Sciences, Texas A&M University, Kingsville, ²Caesar Kleberg wildlife Research Institute, Texas A&M University, Kingsville.

Nutritional status at the time of breeding can influence reproduction of cervids, but specific effects on timing of reproduction are not fully understood. We studied the effects of a non-restricted diet versus a restricted diet on deer reproduction. Baseline data were collected in Year 1 when penned does (n=16) were feed a high quality pellet (18% CP, 36% CF, Moormans[®] 6193) and alfalfa hay ad libitum. In Year 2, does were allocated randomly to feed restriction treatments which occurred from September (week 1) through early December (Early, E; n=8) or mid-January (Late, L; n=8). A ration of a 50:50 mix of high quality:low quality pellet (16% CP, 55% CF, Purina[®] 34A7) and sudan hay was fed. Amount fed per day was calculated as 80% of average DMI from companions of similar size (n=8). Blood was taken via jugular venipuncture on weeks 1, 4, 7 through 26, and 30 and body weights (BW) were recorded. Serum was analyzed for progesterone, triiodothyronine (T₃), and thyroxine (T₄). Estrous cyclicity and reproductive outcome was recorded for both years. Feed restriction decreased ($P < .01$) BW, T₃, and T₄. Serum T₄ was lower ($P < .05$) in L than E does. However, BW and T₃ were similar ($P > .1$) between treatments. Between years, feed restriction delayed ($P < .01$) onset of estrous cyclicity and increased ($P < .01$) the number of estrous cycles before conception. Week of first estrous cycle and week of conception were delayed ($P < .01$) in L does. Data suggest that white-tailed does consuming a low quality diet prior to the breeding season can successfully reproduce if high quality food becomes available.

593 Performance and semen quality of yearling bulls grazing tall fescue pastures. G. M. Schuenemann^{*1}, J. C. Waller¹, F. M. Hopkins², H. S. Adair², N. R. Rohrbach¹, F. N. Scenna¹, D. I. Bryant¹, A. M. Saxton¹, J. W. Oliver³, J. C. Riggins⁴, and F. N. Schrick¹, ¹Department of Animal Science, University of Tennessee, Knoxville, ²Department of Large Animal Clinical Sciences, University of Tennessee, Knoxville, ³Department of Comparative Medicine, University of Tennessee, Memphis, ⁴Highland Rim Experiment Station, University of Tennessee, Springfield.

During a two-year study, performance and semen quality of yearling beef bulls grazing Kentucky 31 tall fescue (*Festuca arundinacea* Schreb.) infected with *Neotyphodium coenophialum*, an ergot alkaloid-producing fungal endophyte (E+; n = 20/yr); E+ plus ladino (*Trifolium repens*) and red (*T. pratense*) clovers (E+Cl; n = 10/yr); or Jesup tall fescue with the non-ergot alkaloid-producing endophyte strain MaxQ#8482 (MaxQ; n = 10/yr) were determined. Bulls were grouped by scrotal circumference (SC; 28 ± 1.6 cm); BW (303 ± 13.5 kg), breed composites, and age (296 ± 20.2 d) to graze E+, E+Cl, or MaxQ tall fescue pastures from November to July (224 d). Blood samples, ADG, SC and rectal temperatures (RT) were collected every 14 d. Scrotal temperatures (ST) were obtained by thermography before semen collection in May and June. Semen samples were immediately evaluated for motility and normal morphology. A mixed model procedure that included treatment, time, year, pasture (treatment), and all interactions as fixed effects was used to compare differences among treatment. Bulls grazing E+ and E+Cl pastures had increased RT (39.1 ± 0.04 and 39.0 ± 0.04 vs $38.7 \pm 0.06^\circ\text{C}$; $P < 0.0001$) and decreased prolactin (28.5 ± 4.3 and 39.5 ± 6.2 vs 102.5 ± 6.2 ng/mL; $P < 0.0001$) compared to bulls grazing MaxQ pastures. However, bulls grazing E+ had lower ST (32.7 ± 0.2 vs 33.1 ± 0.2 and $33.5 \pm 0.2^\circ\text{C}$; $P = 0.05$) and decreased ADG (0.6 ± 0.02 vs 0.85 ± 0.03 and 0.8 ± 0.03 kg/d; $P < 0.0001$) compared to bulls grazing E+Cl and MaxQ pastures. Testosterone, SC, and semen motility and morphology did not differ between treatments. In conclusion, motility and gross morphology of semen were not altered in bulls grazing E+ tall fescue pastures. Addition of clover to E+ pastures reduces the adverse effects on growth performance and scrotal temperature associated with fescue toxicosis.

Key Words: Tall Fescue, Bull, Fertility

594 Effects of P.G. 600 treatment at weaning on reproductive performance of sows limit-fed during lactation. B. R. Horsley^{*}, M. J. Estienne, A. F. Harper, and J. W. Knight, Virginia Polytechnic Institute and State University, Blacksburg.

The objective was to determine whether treatment with 400 I.U. PMSG and 200 I.U. hCG (P.G. 600; Intervet America, Inc.; Millsboro, DE) at weaning would improve reproductive performance of sows limit-fed during lactation. First- and second-parity, crossbred sows (213.3 ± 2.4 kg BW and 17.2 ± 0.5 mm last-rib backfat thickness) nursing 10.0 ± 0.3 pigs each were allowed ad libitum access to feed (AL; n = 18) or were limited to 3.2 kg of feed/d (L; n = 35) during an 18-d lactation. AL sows consumed more feed ($P < 0.01$) than did L sows (5.3 vs. 3.1 kg/d; SE = 0.05). L sows lost more ($P < 0.01$) BW (22.2 vs. 2.6 kg; SE = 2.4) and backfat (3.1 vs. 0.6 mm; SE = 0.6) compared to AL sows. There was no effect ($P = 0.99$) of feeding level on pigs weaned ($88.7 \pm 3.0\%$), but pig BW at weaning was greater ($P < 0.01$) for AL sows compared to L sows (6.3 vs. 5.6 kg; SE = 0.2). At weaning, L sows received i.m. treatment with P.G. 600 (L + P.G. 600; n = 16) or saline (L + saline; n = 19) and AL sows received saline (AL + saline; n = 18). Sows in estrus by d 7 post-weaning was greater ($P < 0.05$) for AL + saline sows (94.4%) compared to L + saline sows (68.4%), with L + P.G. 600 sows having an intermediate value (87.5%) that was not different ($P > 0.05$) from the other two groups. The weaning to estrus interval (5.2 ± 0.1 d) and sows pregnant at d 30 post-mating (84.1%) were not different among groups ($P > 0.1$). Following slaughter at d 30 of gestation, the number of corpora lutea (17.8 ± 0.6), number of live embryos (10.6 ± 0.6), embryonic survival ($61.1 \pm 3.5\%$), and embryo weight (1.56 ± 0.07 g) and crown-rump length (27.3 ± 0.4 mm) were not different ($P > 0.1$) among groups. In summary, low feed intake during lactation decreased the percentage of sows that displayed estrus within 7 d after weaning, an effect partially remediated by gonadotropin treatment. Pregnancy rate and litter size at day 30 of gestation were similar for AL and L sows and not affected by P.G. 600 in L sows.

Key Words: Gonadotropin, Estrus, Sow

595 Effect of acetate to propionate ratio on clearance of progesterone in the ovid. D. L. Smith*, B. A. Costine, and M. E. Wilson, *West Virginia University, Morgantown.*

The objective of these experiments was to determine if a change in the ratio of acetate to propionate (A:P ratio) in hepatic portal blood, draining the gastrointestinal tract, can alter the metabolism of progesterone by the liver. Experiment 1; 4 crossbred, ewe lambs (BW 45.5 + 2.5 kg) were fed for maintenance and given a once daily oral bolus (0.146 Mcal/d) of acetate (0.7 moles) or propionate (0.4 moles) for 11 d. A portal-vein catheter was inserted 14 d prior to collection. Portal and jugular venous blood were simultaneously collected (-0.17, 0.17, .33, 0.5, .66, .83, 1, 1.17, 1.33, 1.5, 1.66, 1.83, 2, 2.33, 2.66, 3, 4, 5, 6, 7 h with respect to feeding and VFA bolus) and serum was analyzed for concentrations of VFA by GLC. Experiment 2; 30 crossbred ewe-lambs, (BW 45.2 + 1.9 kg) were blocked by BW and fed for maintenance for 11 d. On d 12, each lamb was randomly assigned to one of two treatments, and given an oral bolus (0.146 Mcal/d) of acetate (0.7 moles) or propionate

(0.4 moles). Animals received (i.m.) 20 mg progesterone (P₄) in corn oil. Plasma samples were collected (-0.5, 0.5, 1, 2, 3, 4, 5, 6, 8 h relative to feeding, VFA bolus, and P₄ injection) via jugular venipuncture and circulating concentrations of P₄ were determined by P₄-RIA. An oral bolus of acetate or propionate caused a mark change in the A:P ratio for at least 4 h. By 24 h after the oral bolus, the A:P ratio returned to baseline. Plasma concentrations of P₄ after the oral bolus of either acetate or propionate began to diverge as early 0.5 h and were different ($P < 0.05$) by 3-h (1.09 + 0.09 ng/ml vs. 2.04 + 0.48 ng/ml) and 4-h (1.20 + 0.09 ng/ml vs. 1.95 + 0.41 ng/ml) for ewe lambs bolused with acetate and propionate, respectively. By 5 h, coincident with the return to baseline A:P ratios seen in Experiment 1, circulating concentrations of P₄ were not different. Changes in the A:P ratio altered the circulating concentrations of P₄ by reducing the metabolic clearance of P₄ when the A:P ratio was decreased.

Key Words: Acetate, Propionate, Progesterone

Production, Management and the Environment: Heat Stress and Environment

596 Response of heat stressed dairy cattle to low-pressure soaking or high-pressure misting heat abatement systems. M. J. Brouk*¹, J. P. Harner, III², J. F. Smith¹, W. F. Miller¹, and B. Cvetkovic¹, ¹*Department of Animal Sciences and Industry, Kansas State University,* ²*Department of Agricultural and Biological Engineering, Kansas State University.*

Eight lactating Holstein cows (4 primiparous and 4 multiparous) were arranged in a replicated 4x4 Latin square design to evaluate the effect of three different heat abatement systems. Respiration rate and surface temperature (right shoulder, left shoulder and rear udder) were measured and recorded at 5-min intervals during the study. Surface temperatures were measured with an infrared thermometer. Body temperature was recorded with a vaginal probe once per min and averaged by 5 min intervals prior to data analysis. Animals were housed in freestall barns and milked 2x. During testing, cattle were moved to a tiestall barn for a period of 2 hr starting at 14:00 hr on 4 days of intense heat stress. Treatments were control (C), low-pressure soaking applied for 1 min on 5 min intervals (LPS), continuous high-pressure misting with 2 (6.4 L/hr) nozzles (HP-2) or continuous high-pressure misting with 4 (6.4 L/hr) nozzles (HP-4). In addition to water application, all cooling treatments had supplemental airflow (215 m/min). Cows cooled by the LPS or HP-4 system became soaked during the 85 min the cooling treatments were applied. Respiration rates were lowered ($P < 0.05$) when cows were cooled (114.4, 98.2, 89.3 and 82.5 breaths per min for C, HP-2, HP-4 and LPS treatments, respectively). Cows cooled with either LPS or HP-4 had lower ($P < 0.05$) respiration rates than those cooled by HP-2. Surface temperatures of the right and left shoulders were lower ($P < 0.05$) for cooled cows as compared to controls. Cows cooled by HP-4 had lower ($P < 0.05$) shoulder surface temperatures than those cooled by HP-2 or LPS. Rear udder surface temperature was also lower ($P < 0.05$) for cows cooled by either HP-4 or LPS as compared to controls. Respiration rates were decreased by 14, 37 and 48% for HP-2, HP-4 and LPS cooling systems, respectively, during the 85 min evaluation period. The combination of cooled respiratory air and surface soaking of the HP-4 treatment was more effective in reducing shoulder surface temperature than LPS. These data suggest that soaking of cattle with either the LPS or HP-4 treatment provided superior heat abatement as compared to HP-2 or C.

597 Impact of air velocity and direction of flow upon respiration rate, body surface temperature and body temperature of heat stressed dairy cattle. M. J. Brouk*¹, J. P. Harner, III², J. F. Smith¹, W. F. Miller¹, and B. Cvetkovic¹, ¹*Department of Animal Sciences and Industry, Kansas State University,* ²*Department of Agricultural and Biological Engineering, Kansas State University.*

Seven heat stressed, mid-lactation Holstein cows averaging 250 days in milk and producing an average of 38.3 kg of milk were arranged in a 7x7 Latin square design to determine the effects of air velocity and direction of flow on cow cooling. Animals were housed in freestall barns and milked 2x. Cows were moved to a tiestall barn for a period of 2 hr at

14:00 hr each afternoon of testing. Respiration rate and surface temperatures were measured and recorded at 5-min intervals during the 2 hr testing period. Surface temperatures were determined with an infrared thermometer and body temperature was measured and recorded once per min with a data logger and vaginal probe and subsequently averaged by 5-min intervals prior to data analysis. Treatments were control (C) or one of six different cooling treatments. All cooling treatments included a low-pressure soaker system which soaked the cows for 1 min on 5-min intervals. Supplemental airflow was provided by axial flow fans at one of three flow rates; 183 (1), 229 (2) or 275 (3) m/min. Airflow was either from the front to rear (FRT) or from the right side (SIDE) of the animal. Cooling treatments were FRT-1, FRT-2, FRT-3, SIDE-1, SIDE-2 or SIDE-3. Respiration rates were lowered ($P < 0.01$) by all cooling treatments as compared to controls. Cows cooled with SIDE-3 had lower ($P < 0.01$) respiration rates than cows cooled with FRT-1 or SIDE-2. Rear udder surface temperature was lowered ($P < 0.05$) when cows were cooled by FRT-3, SIDE-2 or SIDE-3 as compared to the controls. Right shoulder temperature was reduced more compared to left shoulder temperature when the airflow was from the right side as opposed from the front. The impact of air velocity on surface temperature was variable, but more predictable when from the front as opposed to the side of the animal. These data indicate that the velocity and direction of supplemental airflow elicit different responses from heat stressed dairy cows. Airflow from the front to the rear of the animal may result in greater cooling than air directed at the side of the animal.

Key Words: Heat Abatement, Facilities, Cow Cooling

598 Impact of soaking cows housed in a tunnel ventilated barn equipped with evaporative pads located in Thailand. D. V. Armstrong¹, J. F. Smith*², M. J. Brouk², V. Wuthironarith³, and J. P. Harner, III², ¹*University of Arizona, Tucson,* ²*Kansas State University, Manhattan,* ³*Charoen Pokphanol Group Co., LTD, Bangkok, Thailand.*

Ten lactating Holstein cows (10 multiparous) were arranged in a replicated 5 x 5 Latin Square design to evaluate the effect of soaking frequency and volume of water per soaking on lactating cows housed in tunnel ventilated and evaporative cooled freestall barn. Rectal temperature, respiration rate and body surface temperature (shoulder, thurl and rear udder) were measured every 5 minutes. Treatments were control (C), soaking every 5 min with 1L (5+1) or 2L (5+2), and soaking every 10 min with 1L (10+1) or 2L (10+2). Average ambient temperature and humidity were 30.3°C and 68% and 26.9°C at 86% in the barn. Water was applied manually from the shoulder to the tail and had a temperature of 27°C. Treatments were applied after 3 initial measurements were taken. Seventeen measurements were taken during treatment application and 5 measurements were taken after the treatments were stopped. Air velocity over the shoulder of the cows was 110 m/min. Respiration rate and body surface temperature for all treatments were lower than the control except for rear udder surface temperature of 1+10. Rectal temperature for 1+5, 2+5, and 2+10 were lower than the control. Respiration rate for 1+5 and 2+5 were lower than 1+10. These data suggests that soaking can be used in combination with tunnel ventilation and evaporative pads to reduce heat stress.

Treatments	C	1 + 5	2 + 5	1 + 10	2 + 10	SE
Respiration rate, Breaths/min.	72.8 ^a	51.0 ^c	51.6 ^c	59.3 ^b	55.6 ^{b,c}	2.03
Rectal Temperature, °C	38.5 ^a	38.2 ^b	38.2 ^b	38.3 ^{ab}	38.2 ^b	0.12
Body Surface Temperature, °C						
Thurl	34.4 ^a	32.0 ^c	31.8 ^c	32.6 ^b	32.3 ^b	0.38

599 Effects of shade, sprinklers, and stocking density on performance, behavior, physiology, and environmental impact of Holstein heifers in drylot pens. N. M. Marcillac*, P. H. Robinson, J. G. Fadel, and F. M. Mitloehner, *University of California, Davis*.

The objective of the study was to measure the effects of shade, sprinklers, and stocking density on performance, behavior, physiology, and environmental impact of 40 Holstein heifers, housed in dirt-floored drylot pens during summer. Experimental design was a 4 x 4 Latin square, using 21-d periods and treatments: 1) shade, no sprinklers, normal (100%) stocking density; 2) no shade, sprinklers, normal stocking density; 3) shade, no sprinklers, increased (130%) stocking density; and 4) no shade, sprinklers, increased stocking density. Performance measures included DMI, ADG, and gain:feed. Ethologic measures were laying, standing, walking, feeding, drinking, bulling, agonistic, urination, and defecation behavior. Physiological measures were rectal temperature, respiration rate, urinary urea nitrogen (UUN), blood urea nitrogen (BUN), fecal carbon and energy. Environmental measures were manure composition, surface temperature, surface moisture, particulate matter #8804 10 or 2.5 μm (PM10 and PM2.5, respectively), and surface flux chamber ammonia concentrations. Shaded vs sprinkled heifers tended to have increased DMI ($P = 0.07$), decreased gain:feed ($P < 0.05$), but similar ADG, while stocking density had no effect on performance. Heifers spent most time and showed highest frequency of daytime elimination behaviors in either the shaded ($P < 0.05$) or sprinkled areas ($P < 0.05$) of their pens. Heifers in pens with normal vs increased stocking density showed increased bulling and standing behavior ($P < 0.05$). Respiration rate was decreased ($P < 0.01$) in shaded vs sprinkled heifers, but rectal temperature, BUN, UUN, and fecal carbon was similar across treatments. Shaded or sprinkled areas within each pen had highest surface moisture ($P < 0.05$), and lowest surface temperature ($P < 0.05$). Shaded vs sprinkled pens showed decreased ammonia ($P < 0.05$), increased PM10 ($P < 0.05$) and similar PM2.5 concentrations. In conclusion, only shade improved heifer performance, and both shade and sprinkling inversely affected ammonia and PM10 emissions from drylot pens.

Key Words: Heat Stress, Environment, Cattle

600 The effect of fiber characteristics on production, physiological and behavioral traits in heat stressed dairy cows. A. Arieli*¹, A. Rubinstein¹, Y. Ahroni², U. Moallem², and I. Halachmi², ¹Fac. of Agric., Hebrew University of Jerusalem, Rehovot, Israel, ²Agricultural Research Organization, The Volcani Center, Bet Dagan, Israel.

A trial was conducted using 40 mid-lactating (141 DIM) cows to evaluate the effect of fiber characteristics on production, physiological and behavioral traits in heat stressed dairy cows. The trial was conducted during summer 2003, in Bet Dagan, Israel. The mean, and maximal ambient temperature, relative humidity and thermal humidity index prevailing throughout the trial were: 26 and 31°C, 63 and 92%, and 75 and 82, respectively. Cows had 3 showers/d in the milking waiting yard; each lasting for 20 min. Cows were individually fed, receiving a low CP diet (15% CP), 33% RUP (% of CP), 33% NDF. The cows were blocked into 2 dietary treatments: Control (CON) and treatment (TRT) groups received 18% and 12% NDF in the DM from forage sources. In the TRT

group 2 kg of wheat hay was replaced by the same amount of soyhulls. Milk yield and composition were measured daily, and every 2 wks. Feed intake was measured continuously by a computerized system. The heart rate was measured in ten cows per group during a 3 d period, and energy expenditure was estimated by calibrating heart rate with oxygen consumption by applying the open mask method. In both groups the initial DM intake was 25 kg/d, and decreased by 80 g/d. Mean meal size was 1.7 kg of DM/meal in both groups, but feeding time was higher (14 min) in CON than in TRT (12 min, $P < 0.001$). Initial milk yield was 37 kg/d in both groups; milk yield decreased by 120 g/d in both groups. Concentrations of milk protein and lactose were 3.08 and 4.80% in both groups, whereas fat concentration was 3.30% in TRT and 3.02% in CON ($P < 0.05$). Mean energy expenditure was 1025 kJ/MBW-d in both groups. Energy expenditure varied during the day, being highest at 1900h (1063 and kJ/MBW-d) and lowest at 0800h (996 and kJ/MBW-d, $P < 0.05$). It was concluded that replacing forage NDF with NDF from non forage source, like soyhulls, is not an efficient means to reduce metabolic heat production in heat stressed cows.

601 Changes in the diurnal rhythm of rectal temperature of cattle exposed to prolonged heat stress, and cooled with warm salt water. J. Gaughan*¹ and S. Holt², ¹The University of Queensland, Gatton, Australia, ²South Dakota State University, Brookings.

This study was undertaken in a controlled climate facility using 6 Angus steers in individual stalls. This study investigated changes in rectal temperature (RT) in cattle exposed to thermoneutral conditions (TN) for 4 d and hot conditions (HOT) for 11 d. During HOT cattle were wetted for approximately 60 s when RR equalled or exceeded 120 breath per minute using a hose. Warm (30 °C) salt water (3% NaCl) was used. Individual RT was measured every 60 s. Dry bulb temperature, wet bulb temperature, relative humidity and air movement were recorded every 10 min. For all steers mean daily RT were lower ($P < 0.01$) on days 1 to 4 than for 5 to 15. During HOT, individual mean daily RT on day 5 were lower than mean daily RT for days 6 to 15. Rectal temperatures increased over the first 4 d and then decreased slightly. Individual rectal temperatures varied over a 24-hour period, but remained fairly constant (± 0.1 °C variation) for up to 6 h each day. During HOT, small incremental rises in RT were additive. There was no consistency in the rise, with daily increases of 0.5 °C followed the next day with a 0.01 °C increase. Decreases in RT also occurred but at no time did RT return to levels of TN. Minimum RT is an important measure. Clear diurnal patterns were seen for RT over the first 8 to 9 d of HOT but not on days 10 and 11. There is also evidence of reduced diurnal movement (day 8, 10 and 11) suggesting that the cattle were not dumping their heat load, and may be an indicator of failure to cope. Diurnal patterns seen in previous studies were usually associated with significant diurnal changes in climatic conditions. It is possible that cattle accumulate heat during the hotter parts of the day and then dissipate this heat when conditions are cooler. These data suggest that cattle will use this mechanism even where diurnal variations in climatic conditions are small or non-existent but will reach a point where the mechanism fails largely because the ambient conditions do not alleviate.

Key Words: Heat Stress, Rectal Temperature, Beef Cattle

602 Emissions of atmospheric ammonia and a nitrogen mass balance for a dairy. B. P. Rumburg*¹, G. H. Mount¹, J. M. Filipy¹, B. K. Lamb¹, R. L. Kincaid², and K. A. Johnson², ¹Laboratory for Atmospheric Research, Department of Civil & Environmental Engineering, Washington State University, Pullman, ²Department of Animal Sciences, Washington State University, Pullman.

Atmospheric ammonia (NH₃) emissions have many impacts on the environment and human health. The global emissions of NH₃ are estimated to be 45 Tg N yr⁻¹ (Dentener and Crutzen, 1994). Most emissions come from domestic animals with the largest per animal emission coming from dairy cows at 3 times the beef cow rate. The main sources of emission from US dairies are the cow stalls where urea and manure react to form NH₃, the storage lagoons where NH₃ is the end product of microbial degradation and waste disposal. Numerous studies of NH₃ emissions performed in Europe do not apply to the US due to differences in farming practices. We have been studying the NH₃ emissions from the WSU

dairy for four years to develop a detailed emission model from each dairy source for use in a Pacific Northwest regional air quality model. NH₃ concentrations are measured using open path differential optical absorption spectroscopy in the mid- ultraviolet where NH₃ photoabsorbs near 220 nm. The instrument consists of a Xe lamp, a sending and receiving telescope, retro reflectors and a multiplexing spectrograph and data acquisition hardware (Mount et al., 2002). The method is self calibrating and avoids inlet wall adherence which is a major source of error in NH₃ measurements. An SF₆ tracer technique has been used to convert measured NH₃ concentrations to fluxes from the three main dairy emission sources. The SF₆ is released at a measured rate upwind of the source and both the tracer and NH₃ are measured downwind. A ratio of the SF₆ and NH₃ concentrations and the SF₆ flux along with a stability and area factor gives the NH₃ flux.

NH₃ fluxes from the dairy cow stalls area average 0.4 mg m⁻² s⁻¹ and the flux from the dairy lagoon averages 50 ug m⁻² s⁻¹. Waste application with a "Big Gun" sprinkler resulted in 17% volatilization from the sprinkler alone. Total NH₃ emissions from the WSU dairy are 170 ± 50 kg cow⁻¹ yr⁻¹ while current EPA estimates are 40 kg cow⁻¹ yr⁻¹. Emission rates will be compared in detail to a nitrogen mass balance of the feed inputs and milk and animal outputs at the dairy.

Key Words: Ammonia, Dairy, Emission

603 Effects of dietary crude protein level on nitrogen balance and emissions. H. A. Rachuonyo*, S. E. Curtis, E. O. Castaneda, and M. Ellis, *University of Illinois, Urbana.*

Two studies were conducted; one in dynamic air flow chambers (DAFC; exposure zone 64 ft³), the other using metabolic crates, to determine amounts of N losses and evaluate N digestibility and excretion using growing pigs fed either 14.5 (LCP) or 18.5% (HCP) CP diets (similar levels of digestible lysine-0.83%). In *Study 1*, 8 barrows (initial mean BW 17.9±0.97 kg) were randomly assigned in pairs to 4 DAFC and diets; with 3 replicates over time. Air in chambers was kept under positive static pressure at 0.32 inches H₂O with constant ventilation rate of 30 cfm. Feed and water were provided *ad libitum*. Pigs were acclimated for 7 d, followed by a 2-wk sampling period. Pigs and feeders were weighed weekly. In *Study 2*, twelve barrows/diet (initial mean BW 17.7±1.32 kg) were randomly assigned to individual crates and diets, and were fed at 90 % of *ad libitum* intake. Acclimation for 5-d was followed by 5-d collection of feces and urine (analyzed for N). In *Study 1*, BW, ADFI, ADG, gain:feed, water usage, odor threshold, and hydrogen sulfide levels did not differ between diets (P>0.05); however, slurry pH (6.1 vs. 6.8, SEM=0.05) and ammonia concentrations (0.4 vs. 1.8 ppm; 0.03) as well as ammonia emission rate (2.8x10⁻⁴ vs. 1.2x10⁻³ g/min; 1.73x10⁻⁵) were higher (P<0.05) for HCP than LCP diet. In *Study 2*, there were no differences in BW, ADG, ADFI, or urine output due to diet. Nitrogen in feed, feces, and urine and N intake were higher (P<0.05) for HCP than LCP diet (2.3 vs. 3.5%, 0.02; 3.0 vs. 3.7%, 0.16; 0.1 vs. 0.2 g/100 ml, 0.01; and 16.0 vs. 24.5%, 0.25, respectively). Total N excreted, retained, and balance also were higher (P<0.05) for HCP than LCP (6.7 vs. 12.0 g/d, 0.25; 41.8 vs. 49.2%, 1.28; 9.4 vs. 12.5 g/d, 0.31, respectively); however net protein utilization and biological value were greater (P<0.05) for LCP than HCP diet (58.2 vs. 50.9%, 1.29 and 71.8 vs. 59.7%, 1.33, respectively). Results indicate that CP level in diet influences N excretion, retention, utilization as well as slurry pH and N emissions.

Key Words: Crude Protein, Nitrogen Balance, Ammonia Emission

604 Calcium clinoptilolite zeolite added to the diet to reduce nitrogen losses from feedlot lagoons and composted manure. K. S Eng*¹, R. Bectel², and D. P. Hutcheson³, ¹Eng, Inc., San Antonio, TX, ²Advance Agricultural Testing, Baden, ON, Canada, ³Animal-Agricultural Consulting, Inc., Amarillo, TX.

Rapid nitrogen (N) loss and ammonia emissions from feedlot manure and lagoons represent a loss in fertilizer value and a potential environmental problem. Composting feedlot manure may reduce odors, but additional N is lost during the composting process. Previous research has shown that Biolite (BLT) a specific calcium clinoptilolite zeolite (CZ) added to feedlot diets can reduce manure N losses. The study was designed to compare a high concentrate steam flaked corn-wet gluten corn silage finishing diet with or without 1.2% CZ (DMB) fed to feedlot steers on concrete floors. The CZ was added in place of an equivalent amount of grain. In the lagoon study 20 gallons of fresh liquid manure adjusted to

a 10% dry matter content was added to 100 gallon sealed vertical plastic containers. Ammonia content of the trapped air was measured each day, after which the air was evacuated and the container re-sealed. No additional manure was added to the system. The ammonia concentration measured would be daily not accumulated ammonia production. Ammonia production was greater and increased more rapidly in the control compared to the CZ treatment. In both treatments, ammonia production peaked at nine days and was 110 and 57 ppm for the control and CZ treatments, respectively. Ammonia production for each treatment appeared to increase with increasing ambient temperatures. Composted treatments consisted of wet manure collect for four days from the control and CZ diets, mixed with 1/3 sawdust and composted for ten weeks. Samples from each treatment were obtained on day one and at one to two week intervals thereafter and analyzed for moisture, N and phosphorus (P). N loss from the compost was reduced in the CZ treatment and the N: P ratio increased. Compost N loss at weeks 6 and 7 was 27.3% for the control compared to 14.7% for the CZ treatment. The results indicate 1.2% CZ added to a feedlot finishing diet significantly reduces lagoon ammonia and composted manure N losses, Table1.

Treatment	Time	Dry Matter %	N	% Lost	P	N:P
Control	Day 1	35.1	2.05		1.00	2.05
Control	Week 2-3	37.8	1.95	-4.88	0.95	2.05

605 Combination of a urease inhibitor and a plant essential oil for control of fecal coliforms and emissions of odor and ammonia from cattle waste. V. H. Varela*, J. E. Wells, and D. N. Miller, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

A 2002 report from the National Research Council of the National Academies ranked ammonia and odor as their highest concerns for emissions from confined animal feeding operations. Most of the ammonia emissions in livestock wastes originates from hydrolysis of urea, whereas odor emissions originate from microbial production of VFA from waste organic matter. The objectives of this work were to evaluate urea hydrolysis, VFA production (odor), and fecal coliforms in cattle waste slurries after a urease inhibitor N-(n-butyl) thiophosphoric triamide (NBPT) and a plant oil (thymol) were added. Feces, urine and distilled water in the ratio 50:35:15 were blended for 1 min. Triplicate aliquots of 750 ml were amended with chemical additives and rebled for 1 min, and were poured into 1.6 L wide-mouth jars covered 90% with a lid. After 56 days, thymol (2000 mg/kg waste) in combination with NBPT (80 mg/kg waste) retained 5.2 g of an initial 8 g of urea in cattle waste slurries, compared to less than 1 g of urea retained when NBPT was the only additive (P < 0.05). Thymol by itself had no inhibitory effect (P > 0.05) on urea disappearance. However, thymol or thymol in combination with NBPT reduced VFA production (P < 0.01), but NBPT had no effect (P < 0.05) on VFA production. Thymol and thymol with NBPT also eliminated all fecal coliforms after one day. Fecal coliforms disappeared in the no addition treatment after 8 days; however, they were viable at 6.6 × 10⁴ cfu/g waste beyond 35 days in the NBPT treatment. These results indicate thymol has an additive effect to NBPT by further inhibiting hydrolysis of urea in cattle waste slurries and increasing nitrogen retention in the waste. Also NBPT appears to interfere with the normal eradication of fecal coliforms in cattle waste slurries.

Key Words: Plant Oils, Urease Inhibitor, Cattle Waste

606 Evaluation of factors affecting phosphorus solubility in feces of lactating cows. T. D. Nennich*¹, J. H. Harrison¹, Z. Dou², L. Johnson VanWieringen¹, R. L. Kincaid³, and D. L. Davidson¹, ¹Washington State University, Puyallup, ²University of Pennsylvania, Kennet Square, ³Washington State University, Pullman.

Solubility of fecal P is associated with potential movement of P to surface waters after field application. The objective of this study was to evaluate factors affecting total and soluble P excretion by lactating dairy cows. Fecal samples (n = 121) were from total collection metabolism studies that used multiparous Holstein cows. These samples were analyzed for water soluble P by extraction (0.3 g + 100 ml deionized water) and P soluble in dilute acid (0.3 g + 100 ml 0.1% HCl). Variables evaluated in regression equations included P intake, dietary P concentration, Ca:P ratio, Ca intake, and other animal and dietary factors. Regression analysis performed using the PROC MIXED procedure of SAS included study as a random variable. Total P and HCl soluble P excretion were predicted using dietary P concentration, whereas dietary P concentration was not a significant variable for predicting water soluble P. Water-soluble P in the feces was affected by P intake and the concentration of Ca in the diet. Increased ratios of dietary Ca:P decreased soluble and total P excretion. Equations developed to predict water or HCl soluble fecal P (g/kg) using Ca:P ratio as the independent variable were $y = -0.75 (\pm 0.16) \times \text{Ca:P (g)} + 4.32 (\pm 0.40)$ and $y = -0.51 (\pm 0.40) \times \text{Ca:P (g)} + 7.56 (\pm 1.07)$, respectively. Dietary or animal factors in several of the studies evaluated affected total and soluble P excretion. In one study on maturity of corn silage, cow diets that contained 37% corn silage (DM basis) resulted in an average P balance of -32 g and had greater total P and HCl-soluble P excretion than other studies at similar dietary P concentrations. A better understanding of dietary factors that contribute to greater soluble P excretion in feces will aid in formulating diets to help lower the excretion of soluble P in feces.

Key Words: Phosphorus, Calcium, Feces

607 Separated drinking water from liquid manure for swine. J. Morris*, R. Fleming, and M. MacAlpine, *Ridgetown College, University of Guelph, Guelph, ON, Canada.*

The efficacy of separated clean water from liquid swine manure as a source of drinking water for starter pigs was completed. The objectives of the study were to evaluate the impact of separated clean water as a source of drinking water on the quality of water, the growth performance and the health status of starter pigs. Water was recovered from liquid manure using the Vibratory Shearing Enhanced Processing (VSEP) unit which was fitted with an reverse osmosis (RO) filter pack. The quality of the recovered water (permeate) was assessed and provided for drinking water to young pigs. Three water treatments (A-regular barn water,

B-half barn water and VSEP permeate, and C-VSEP permeate) were prepared and given to the pigs. A total of 54 pigs were allocated to 9 pens of 6 pigs each (3 barrows and 3 gilts). All pigs were fed ad libitum a pelleted corn-soybean meal based pig starter ration. The pigs were subjected to the water treatments for 28 days (12 - 26 Kg liveweight). Performance data was subjected to statistical analysis using the GLM procedure of SAS. Results showed that the VSEP unit produced permeate (separated water) from liquid manure at a quality level acceptable to pigs. No significant treatment effects were found for ADFI - 1.20, 1.18, and 1.23kg/d; se = 0.04; p=0.755, ADG - 0.50, 0.52 and 0.51kg/d; se=0.009; p=0.579, Feed-to-Gain conversion - 2.38, 2.20, and 2.40; se=0.095 and daily water intake - 5.2, 4.3, and 6.1 l/d; se=0.492; p=0.099, for water treatments A, B and C respectively. There were no negative health effects resulting from the treatments during the study. It appeared that the recovered water from liquid manure under the conditions of this study was satisfactory as a source of drinking water for starter pigs.

Key Words: Swine, Water, Liquid Manure

608 Environmental impact of integrating crop and sylvan systems with swine. C. W. Talbott*¹, G. B. Reddy¹, C. Raczkowski¹, T. Barrios¹, M. Matlapudi¹, A. Coffee², and J. Andrews², ¹North Carolina A&T State University, Greensboro, ²USDA/CSREES Forestry, NC Division of Forest Resources, Raleigh, NC.

Many species of swine evolved in sylvan environments where natural canopies provide cooler temperatures and thereby aid in thermoregulation during the warm seasons. During cooler seasons, farmers may be able to develop organic soils by utilizing the rooting behavior of the hogs to incorporate manure and mulch into compost. Forty-eight gestating sows were randomly assigned to one of six 25m x 90m wooded plots or one of four 40m x 30m dirt-lots for warm season application (April through September). Five, 10 m radius areas were surveyed (inches diameter breast high, basal area, % canopy) for species variation and prevalence after two, six-month seasons with swine; timber growth response was adjusted for animal stocking rate. During the cool season (October through March), animals were rotated to eight, 20m x 20m lots with or without leaf mulch. Soil samples were collected in years 2000 and 2001 at planting and at harvest at depth increments of 0-15 cm, 15-30 cm and 30-60 cm. Samples were analyzed for soil NO₃-N, inorganic N, PO₄, total P, organic matter, total C, total N, C:N, and CEC. Integrated plots with pigs had significant increases in NO₃-N, inorganic N and PO₄ concentrations. Results suggest that sylvo-pastoral systems with swine may improve hardwood stands by reducing softwood competition.

Ruminant Nutrition: Dairy - Additives, Vitamins & Models

609 Effects of *Aspergillus oryzae* (Amaferm®) on production and metabolic parameters in Holstein cattle during the transition period. L. H. Baumgard*¹, M. E. Dwyer¹, C. Davis¹, C. E. Moore¹, H. C. Haffiger III¹, O. B. Mendivil¹, H. Jensen², B. Christie², and M. J. VanBaale¹, ¹The University of Arizona, Tucson, ²BioZyme Inc., St. Joseph, MO.

Holstein cattle (n=33; 22 multiparous and 11 primiparous) were assigned to a TMR with or without an *Aspergillus oryzae* (AO) extract (Amaferm®; BioZyme Inc., St. Joseph, MO) from -21 to 60 d relative to calving. Alfalfa hay was the main forage source and steam-flaked corn the primary concentrate. AO (15 g/cow/d) was top-dressed daily at 0600 h. Cows were balanced by previous 305 ME and heifers randomly assigned to treatment, all animals were blocked by calving date and milked at 0600 and 1800 h, yield was recorded daily, and milk and blood samples were obtained 1, 7, 14, 21, 28 and 35 DIM. Body weights (BW) were recorded weekly until 60 DIM. There was no overall effect of treatment or treatment by week interaction on DMI prepartum (18.3 kg/d) or postpartum (39.7 kg/d), and this was independent of parity. BW loss did not differ between treatments (51.9 kg), but AO tended (P<0.1) to reduce week of BW nadir (5.0 vs. 6.2 wk). There were no interactions between parity and treatment on BW change, but overall, heifers lost less BW (31.8 vs. 71.8 kg) and tended (P<0.1) to reach BW nadir earlier than cows (4.9 vs. 6.2 wk). Feeding AO through the transition increased (P<0.05) milk yield (35.0 vs. 37.7 kg/d). The overall

treatment effect was attributed to the enhanced milk yield of cows (40.8 vs. 44.7 kg/d) as heifers had similar milk yields between treatments. Peak yield was achieved earlier (wk 3) in AO compared to control fed cows (wk 5-6) and this resulted in a milk differential of 4.5 kg during wks 3 and 4 of lactation. AO tended (P<0.15) to increase milk fat content (6%) and decrease milk lactose percentage (3%). Plasma glucose concentrations were not altered by treatment. Despite increased milk yield without a corresponding increase in feed intake, plasma NEFA levels tended (P<0.12) to be reduced (14%) by AO. Feeding an AO extract through the transition appeared to increase dietary energy availability and improve production.

610 The effects of feeding yeast culture during the transition from cool to hot weather to Holstein cows on animal performance. J. D. Ward*¹, T. R. Smith², L. Zeringue¹, R. J. Williams², J. Crouch², R. Walz¹, T. Nuefech², and H. M. Wilson², ¹LSU AgCenter, Southeast Research Station, Franklinton, LA, ²Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State.

Forty-two mid to late lactation Holstein cows at two locations were used to determine the effects of feeding yeast culture during the transition from cool to hot weather on dry matter intake (DMI), milk production (MP), blood glucose, body condition score (BCS) and body weight

(BW). Cows were housed at the Mississippi State University dairy (MS; n=23) and the LSU AgCenter Southeast Research Station dairy (LA; n=19). Both groups of cows were housed in free stall barns and individually fed using Calan gates (American Calan, Northwood, NH). The cows at MS were fed a totally mixed ration while those at LA were component fed with forage and grain offered separately. Cows received yeast culture as a top dress on their feed (113 g/d). Milk production and DMI were recorded daily. Blood samples were taken weekly for plasma glucose analysis. Body weight and BCS were recorded at the beginning and end of the eight week study. Milk production and DMI data were averaged within week before statistical analysis. There was a treatment by parity interaction for MP with yeast supplementation decreasing MP in primiparous cows ($P < 0.08$; 31.1 vs 26.4 kg/d) but increasing MP in second and later lactation cows ($P < 0.08$; 29.7 vs 25.1 kg/d). There was also a treatment by parity interaction for DMI with yeast supplementation decreasing DMI in primiparous cows ($P < 0.08$; 20.5 vs 22.1 kg/d) but increasing DMI in third lactation cows ($P < 0.10$; 23.4 vs 20.0 kg/d). Dietary treatment had no effect on plasma glucose, BW, BCS, nor changes in BW and BCS. The results of this research indicate that feeding yeast culture during the transition from cool to hot weather can improve animal performance in second and later lactation cows but may be detrimental to primiparous cows. Further research is needed to determine why primiparous cows respond differently than older cows to yeast supplementation.

Key Words: Yeast Culture, Heat Stress, Milk Production

611 Effects of feeding yeast culture on milk yield during heat stress conditions. F. Y. Bernal*, J. S. Britt, J. W. Tako, and N. C. Speer, *Western Kentucky University, Bowling Green.*

Effects of feeding yeast culture on milk yield during heat stress conditions. F.Y. Bernal, J.S. Britt*, J.W.Tako, N.C. Speer, Western Kentucky University

The objective of this study was to evaluate the effect on milk yield of dietary yeast 2x-2-2-5 fed to lactating dairy cows during heat stress conditions. Sixteen cows per group paired by breed (Jersey and Holstein), lactation number and days in milk were assigned to CONTROL (no yeast) or YEAST 2X-2-2-5 PLUS (2oz - 2-2-5 western yeast) group. Both groups were fed a total mixed ration consisting of corn silage, alfalfa haylage, alfalfa hay, grain mix including whole cottonseed and also had controlled access to alfalfa pasture. The trial ran between August 6 and September 16. Dry matter content of the TMR fed and the refusal was measured to calculate dry matter consumption. Cows were weighed 3 times during the trial. Body temperatures were taken at each weighing. Milk weights were captured at each milking using electronic weigh meters, which download into a computer. Data was analyzed using Microsoft Excel and 7-day average milk weights were used in the analysis. Both groups were subject to the same heat stress conditions. Individual animal milk fat and protein percent was determined by laboratory analysis three times during the trial. During the trial 1 cow from each group had to be removed for health reasons. The matching paired cow from the other group was removed so the final results were based on 14 cows per group. Milk yield, butterfat %, butterfat yield, protein yield, fat corrected and energy corrected milk were not statistically but were biologically higher, FCM 4.78 lbs/day and ECM 4.15 lbs/day, in the YEAST 2X-2-2-5 PLUS group than the CONTROL group. At 13/CWT there was a 0.54 economical advantage daily to the YEAST 2X-2-2-5 PLUS group. The YEAST 2X-2-2-5 PLUS group did have an advantage over the CONTROL group in faster recovery from a drop in milk production following an increase in ambient temperature.

Key Words: Yeast, Milk Yield, Heat Stress

612 Improving the fermentation and aerobic stability of bermudagrass with molasses or a combination of bacteria and enzymes. A. T. Adesogan*, N. A. Krueger, D. B. Dean, M. B. Salawu, and C. R. Staples, *University of Florida, Gainesville.*

This study determined the effectiveness for improving the fermentation and aerobic stability of bermudagrass, of an inoculant (BB), molasses, or a mixture of either BB and molasses (BBM) or BB and fibrolytic enzymes (BBE). A five-week regrowth of Tifton 85 bermudagrass was conserved in quadruplicate in mini-silos alone, or after treatment application. The inoculant contained a mixture of *Pediococcus pentosaceus* 12455, 1×10^5 cfu/g of fresh forage and *Lactobacillus buchneri* 40788, 4×10^5 of fresh forage and beta-glucanase, alpha-amylase

and xylanase. BBE contained similar enzymes as BB, but greater enzyme activities. Chemical composition was quantified after 2, 4, 7, 30 and 60 d of ensiling and microbial composition and aerobic stability were measured after 60 days of ensiling. After 60 d of ensiling, the pH of additive-treated silages was consistently lower ($P < 0.05$) and DM recovery was higher ($P < 0.01$) than in untreated silages. BB, BBM and molasses-treated silages had less ($P < 0.01$) ammonia N than untreated silages. BB, BBM, and BBE-treated silages had less ($P < 0.01$) residual WSC than untreated silages. All silages had high acetic acid (47.5 g/kg DM) and low lactic acid (1.7 g/kg DM) concentrations. However, untreated and BBE-treated silages had more ($P < 0.05$) butyric acid and ammonia N, suggesting that a clostridial fermentation had occurred. These butyric forages were more ($P < 0.05$) aerobically stable (27 d), but less desirable for feeding than those ensiled with BB or molasses, which were stable for 6.9 d. In conclusion, BB and molasses treatments improved the digestibility and fermentation of bermudagrass and produced higher quality silages that were stable for 6.9 days. Mixing BB with molasses or the enzyme tested was not more beneficial than BB or molasses alone.

Key Words: *Lactobacillus buchneri*, Silage, Inoculant

613 Use of exogenous proteolytic enzymes to improve lactational performance of dairy cows. J.-S. Eun* and K. Beauchemin, *Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

The effects of exogenous proteolytic enzymes (EPE) on digestibility and lactational performance were determined using 8 lactating Holstein cows in a double 4x4 Latin square experiment with a 2x2 factorial arrangement of treatments. Diets based on barley silage and alfalfa hay as the primary forage sources were formulated to obtain two forage to concentrate ratios (60:40 vs. 34:66, DM basis) using steam-rolled barley concentrate. Four dietary treatments were tested: HF-EPE = high forage without EPE, HF+EPE = high forage with EPE, LF-EPE = low forage without EPE, and LF+EPE = low forage with EPE. The EPE contained protease activity, but no measurable xylanase or endoglucanase activity. The EPE was added to the concentrate portion of the diets after pelleting at a rate of 1.25 mL/kg DMI. Data were analyzed using the PROC MIXED function of SAS. Increasing the forage proportion or adding EPE decreased intakes of DM and nutrients ($P < 0.01$). However, total tract digestibilities of DM and fiber were increased by decreasing the forage proportion or adding EPE ($P < 0.01$). Increases in digestibilities due to enzymes were highest with the LF+EPE diet. Digestibilities of DM, NDF, and ADF increased by 6.3%, 14.8%, and 23.6%, respectively. Feeding a LF diet increased digestible DMI ($P < 0.01$), but EPE did not influence digestible DMI because of the drop in DMI. Milk yield increased with feeding a LF diet (46.8 vs. 42.1 kg/d, $P < 0.01$), but decreased with adding EPE (43.4 vs. 45.5 kg/d, $P < 0.01$). Adding EPE to the LF diet increased milk fat percentage ($P < 0.01$), but not as much as increasing the forage proportion. Milk protein concentration was decreased when EPE was added to the LF diet ($P < 0.01$). Dairy efficiency calculated as milk/DMI was highest for the LF+EPE diet. Addition of EPE decreased nitrogen utilization for milk production for both the HF and LF diets ($P < 0.01$). Addition of EPE resulted in considerable improvement in the digestibility of nutrients, but the negative effects on intake offset these benefits.

Key Words: Exogenous Proteolytic Enzyme, Digestibility, Milk Yield

614 Effects of mixture enzymes on hydrolysis and rate of fermentation of alfalfa in vitro. A. A. Naserian* and S. Ghasemi, *Animal Science Department of Ferdowsi University, Mashhad, Iran.*

The use of enzymes as additives in ruminant diets has received considerable research interest and recently following positive responses observed in feeding trials, the objective of present study was to determine the effects of mixture enzymes on rate of fermentation of alfalfa in vitro. The gas production system consisted of 64 gas serum bottle (100mL) and one incubation chamber ($39 \pm 1^\circ\text{C}$) were used to hold the 64 serum bottle and bottle were continuously shaken with an orbital shaker. 0.2g of ground alfalfa (four replicate for one time) were weighted in to each bottle. The enzyme mixture (Natuzyyme, Bioproton PTY. LTD., AU) was applied at 4 levels (0, 2, 4, 8 g/kg alfalfa, air dry basis), then 20mL of rumen fluid and 10mL of buffer were added to each bottle and initial volume of each bottle was 30mL, gas production was measured for 96

hours (0, 2, 4, 6, 8, 12, 24, 48, 72, 96), the values corrected for the gas released from blank(rumen fluid+ buffer) and initial volume. Data were analyzed Using General Linear models procedures of SAS V6.12 for ANOVA to evaluate differences among experimental groups, means were compared with Duncan test. Enzyme had significant effect on gas production ($P \leq 0.05$), (Table 1). values for each treatment were averaged across replicates and equation $y = a + b(1 - e^{-ct})$ was employed to fit data, gas production rate and cumulative gas production were affected by enzyme supplementation ($P \leq 0.05$), (Table 1). In conclusion, adding of a fibrolytic enzyme mixture increased the rate of gas production.

Table 1.

Treatment	Control	1x	2x	4x	SEM
Gas production (mL)	29.3 ^c	29.96 ^b	30.27 ^a	29.75 ^b	0.051
a+b (mL)	47.8 ^c	48.5 ^b	48.9 ^a	47.7 ^d	0.001
C (h ⁻¹)	0.102 ^d	0.1039 ^b	0.1035 ^c	0.1055 ^a	0.0001

615 Effect of fibrolytic enzymes on the fermentation characteristics, aerobic stability and digestibility of bermudagrass silage. D. B. Dean*, A. T. Adesogan, N. Krueger, and R. C. Littell, *University of Florida, Gainesville.*

This study determined the effectiveness for improving the nutritive value and aerobic stability (AE) of bermudagrass (*Cynodon dactylon*) silage, of applying four proprietary cellulase/hemicellulase enzymes. A five-week regrowth of Tifton 85 bermudagrass was conserved alone, or after treatment with Promote (Pr), Biocellulase X-20 (X20), Cattle-Ase (CA) or Biocellulase A-20 (A20). The enzymes were applied at 0, 0.5, 1x and 2x the rates recommended by the manufacturers. Six replicates of 1 kg of chopped (5 cm) forage were ensiled for 145 days in 2.8 l mini silos. Three silos per treatment were used for chemical analysis and three to measure aerobic stability (4 x 3 factorial design). The silage juice was analyzed for organic acids, pH, water soluble carbohydrates (WSC), ammonia-N and soluble N. Freeze-dried samples were analyzed for crude protein (CP), NDF and ADF. In vitro digestibility of DM (IVDMD), NDF (IVNDFD) and ADF (IVADFD) were calculated after digesting the silages in buffered rumen fluid for 6 or 48 h in two ANKOMII Daisy Incubators. The following results are based on comparing treated to untreated samples. DM losses and pH were significantly reduced by Pr ($P < 0.01$). Ammonia-N was increased linearly ($P < 0.05$) by X20, but decreased linearly and quadratically by CA ($P < 0.05$) and A20 ($P < 0.05$) respectively. Residual WSC concentration was increased by Pr ($P < 0.01$) and CA ($P < 0.05$). NDF and ADF concentration were reduced ($P < 0.05$) by X20, CA and A20. Additive-treated silages had less ($P < 0.05$) acetic acid than untreated silages, but aerobic stability was unaffected by treatment. The 6 h, IVDMD was increased ($P < 0.01$) by Pr and A20, however only Pr increased ($P < 0.01$) 48 h IVDMD and 48 h IVNDFD. Pr ($P < 0.05$), CA ($P < 0.05$) and A20 ($P < 0.05$) also increased ($P < 0.05$) 48 h IVADFD. These results show that fibrolytic enzymes can improve the nutritive value of bermudagrass silage, and Promote was the most promising enzyme in this respect.

Key Words: Enzymes, Silage, Nutritive Value

616 Development and use of an assay to test enzymatic activity of rumen microflora in calves. B. J. Suarez*, S. Fiardo, A. H. M. Cornelissen, P. Van Wikselaar, and W. J. J. Gerrits, *Wageningen University Unit Research, Wageningen, The Netherlands.*

The objective of this study was to develop an assay to quantify cellulase activity in rumen contents of calves fed different diets. Eighteen male calves (45 ± 0.2 kg) were individually housed and fed diets differing in carbohydrate composition: a Pectin rich diet (> 90% Sugar beet pulp), a NDF rich diet (> 90% soy hulls + maize bran), a Starch rich diet (> 90% barley + maize). Diets were offered to a maximum of 750 g/d on top of a milk replacer. Calves were slaughtered at 12 weeks of age and rumen samples were stored (-20°C). Intra and extra-cellular enzymes and enzymes attached to rumen particles were extracted by a combination of methods: freezing/thawing, sonication and osmotic shock. After thawing, samples were sonified in a 50 mM NaAc buffer (pH 5) including 2 M NaCl and 0.01% NaN₃. Subsequently feed particles and lysed bacteria were removed (centrifugation: 22.5 min, 20000g, 4 °C) and the

enzyme cocktail obtained was dialyzed against a 50 mM NaAc buffer (18 h; 4 °C) to remove dissolved sugars and NaCl. Enzyme activity was determined by the release of reducing sugars after incubation of the enzyme cocktail at 39 °C (120 mM NaAc buffer) with each of 3 substrates: Carboxymethylcellulose (CMC), soybean hulls (SBH) and crystalline cellulose (Avicel), and expressed as μmol reducing sugars (RS) released per minute per kg dry matter (DM) in the rumen. Reducing sugar end-groups were measured by Nelson Somogyi method. Avicel was hardly degraded by the enzyme cocktail (1 μmol of RS/h/kg DM), while CMC and SBH were well degraded (48.7 and 51.6 μmol RS/h/kg DM respectively; $P = 0.05$). CMC- and SBH-ase activities of rumen contents decreased from 61, 48.5 to 41 μmol RS/h/kg DM for calves fed the NDF, Pectin and Starch diet, respectively ($P = 0.1$). Results show that differences in enzyme activity between rumen contents can be detected using this assay. By using different substrates, the degrading capacity of others enzyme systems can be evaluated.

Key Words: Calves Rumen Contents, Microbial Enzyme Activity, Cellulase

617 Effects of feeding increasing levels of vitamin E on milk production variables, plasma fatty acid composition, and milk fatty acid profiles in Holstein cows experiencing diet induced milk fat depression. H. C. Hafliker III*, C. E. Moore, S. R. Sanders, and L. H. Baumgard, *The University of Arizona, Tucson.*

Recent research indicates feeding high levels of vitamin E (VitE) may alleviate milk fat depression (MFD) by altering rumen polyunsaturated fatty acid biohydrogenation pathways. Objectives were to evaluate the effects of extremely high VitE doses on production variables, milk, and plasma fatty acid profiles (a proxy for rumen biohydrogenation) on diet induced (4% corn oil, 45% forage) MFD. Multiparous Holstein cows (283 ± 15 DIM; 136 ± 15 d pregnant; n=6) were randomly assigned to an unbalanced 4x4 Latin square design consisting of a control (0 additional IU/d VitE) and VitE top dressed (4000, 8000, and 16000 additional IU/d). Milk and blood samples were obtained on d 1 and at the end of treatment periods (d 14). A 7-d washout period was provided between periods. Orthogonal contrasts were used to characterize linear, cubic and quadratic effects of VitE dose. As a result of the MFD diet, milk fat content was reduced ($P < 0.02$) by 18% (3.5 to 2.8%) and milk total trans C_{18:1} and CLA increased ($P < 0.01$; 29.4 vs. 62.0 mg/g and 5.4 vs. 14.4 mg/g, respectively). VitE had no effect on DMI (24 kg/d), milk yield (32 kg/d), milk protein (1.1 kg/d), milk lactose (1.6 kg/d), SNF (3.0 kg/d), and SCC (269,855) or the content of these components. There was no effect on milk fat yield, however, VitE linearly increased ($P < 0.01$) milk fat content (2.83, 2.93, 3.05, and 3.12% for 0, 4000, 8000, and 16000 IU/d, respectively). Changes in fatty acids associated with MFD including *t*-10 and *t*-11 C_{18:1} as well as *c*-9, *t*-11 and *t*-10, *c*-12 CLA did not differ in milk or plasma as a result of VitE supplementation. Although the milk fat Δ⁹-desaturase index did not differ, VitE decreased ($P < 0.05$) specific Δ⁹-desaturase product to substrate ratios (C_{14:1}/C_{14:0}, C_{18:1}/C_{18:0}, and *c*-9, *t*-11 CLA/*t*-11 C_{18:1} by 18, 13, and 13%, respectively). Although only slightly, VitE linearly increased milk fat content but this effect was not reflected in plasma or milk fatty acid changes. Milk Fat Depression, Vitamin E, CLA

Key Words: Milk Fat Depression, Vitamin E, CLA

618 Effects of dietary forage and non-fiber carbohydrate concentrations on B-vitamin intake and duodenal flow in dairy cows. E. C. Schwab*¹, C. G. Schwab*², C. L. Girard³, R. D. Shaver¹, D. E. Putnam⁴, and N. L. Whitehouse², ¹University of Wisconsin, Madison, ²University of New Hampshire, Durham, ³Dairy and Swine R&D Center, AAC, Lennoxville, QC, Canada, ⁴Balchem Encapsulates, New Hampton, NY.

Eight Holstein cows (four primiparous, four multiparous) were fitted with ruminal and duodenal cannulas to test the effects of dietary forage (F) and NFC concentrations on intake and duodenal flow of B-vitamins in lactating cattle. Cows were used in a replicated 4x4 Latin square design balanced for carryover effects with a 2x2 factorial arrangement of treatments. Each square contained two multiparous and two primiparous cows and periods were 21 d in length. Experimental diets with 35 or 60% (DM basis) forage (corn silage, alfalfa hay, grass hay) were formulated to contain either 30 or 40% NFC (DM basis). The concentrate portion of the diets was composed of varying proportions of

soybean hulls, beet pulp, corn grain, rolled barley, soybean meal, blood meal, Smartamine-M[®], vitamins, and minerals. B-vitamin intakes and flows presented below are expressed as mg/d. There was a significant F effect for all measurements except for folic acid and B₁₂ intake and pyridoxine (PYR) flow. Intakes of DM, thiamin, pyridoxamine (PAM), and pyridoxal (PAL) and flows of B₁₂ and PAM were affected by NFC. A F×NFC interaction was observed for thiamin and PYR flow. Overall, there was a greater influence of dietary F content than NFC concentration on B-vitamin intake and flow.

619 Effect of feeding malic acid on performance of lactating Holstein cows. R. J. Grant^{*1}, C. S. Ballard¹, M. P. Carter¹, K. W. Cotanch¹, P. Mandevu¹, C. J. Sniffen², M. Suekawa⁵, S. A. Martin³, T. K. Miller-Webster⁴, and W. H. Hoover⁴, ¹W.H. Miner Agricultural Research Institute, Chazy, NY, ²Fencrest LLC, Holderness, NH, ³University of Georgia, Athens, ⁴West Virginia University, Morgantown, ⁵Zen-Noh National Federation of Agricultural Co-operative Associations, Tokyo, Japan.

Limitations on feeding ruminant proteins to cattle necessitate using alternative feeds to supply amino acids such as lysine, or stimulating ruminal microbial growth to increase supply of amino acids for the host animal. In continuous culture, DL-malate (50 g/d) improved microbial growth and efficiency, resulting in an increase in metabolizable protein of 426g/d. The objective of this study was to determine the effect of feeding malic acid (MA; Harcros Chemicals Inc., Kansas City, KS) at a rate of 50 g/d on the performance of mid-lactation dairy cows. Forty cows (70-276 days in milk) were blocked and assigned randomly to control or MA diets in a crossover design with two 28-d periods. Total mixed ration included corn silage, alfalfa-grass silage, alfalfa hay, ground corn, whole cottonseed, and a commercial protein supplement. Cows fed the ration containing MA had greater yield of milk (P = 0.012) and true protein (P = 0.035) compared with cows fed the control ration. There was no effect of MA on body weight, body condition score change, or total tract digestion of nutrients (P > 0.05).

620 Further validation of the fat sub-model in CPM-Dairy. P. J. Moate^{*}, R. C. Boston, and W. Chalupa, *School of Veterinary Medicine, University of Pennsylvania, Kennett Square.*

CPM-Dairy contains a fat sub-model (Anim. Feed Sci. Tech. 112:79) that describes dietary intake, ruminal lipolysis, ruminal biohydrogenation, ruminal denovo production and intestinal absorption of 10 major long chain fatty acids (LCFA) and total LCFA (TLCFA) in dairy cows. The previous validation of intestinal digestion (duodenum - feces) mainly involved young (250 kg) non-lactating cattle. We now report on the ability of the model to predict, in lactating dairy cows, the apparent absorption (intake - feces) of TLCFA. Data used were from 43 diverse diets in ten published feeding experiments that reported intakes and fecal output of TLCFA (g/cow/day). Additional data were with 15 diets from three experiments in which different types of LCFA supplements were infused into the abomasum. In the table, the mean and STD of the measured (X) absorbed TLCFA (g/cow/d) is tabulated and the regression (forced through the origin) between the predicted absorbed TLCFA (Y) and X is given by B (slope) *X. For both the feeding and infusion experiments, the slopes and Lins concordance correlation coefficient indicate a high degree of concordance between measured and predicted absorbed TLCFA. We conclude the fat sub-model in CPM-Dairy accurately predicts the apparent absorption of TLCFA in lactating dairy cows.

TLCFA (Y)	X (mean± STD)	B (±Std Error)	Concordance
Feeding expts.	833 ± 266	0.99 ± 0.011	0.974
Infusion expts.	757 ± 120	1.03 ± 0.016	0.923

†Lin's concordance correlation coefficient

621 Sensitivity analysis of the 2001 Dairy NRC and CNCPS protein fractionation systems. C. Lanzas^{*}, L. O. Tedeschi, and D. G. Fox, *Cornell University, Ithaca, NY.*

Feeding diets not properly balanced for protein decreases its utilization efficiency. Sensitivity analyses of the NRC and the CNCPS protein fractionation systems were conducted to assess the influence of the uncertainty in feed inputs on the model predictions. Two lactating dairy-cow diets either with corn (CS) and alfalfa silages (diet 1) or grass hay and CS (diet 2) plus corn meal and supplements (soybean meal (SBM), canola meal (CM), whole cottonseed (WC), wet brewers (WB) and distillers (DG) grains) were used. A feed database provided by Dairy One lab was used to obtain the distributions and correlations of the variables. Monte Carlo technique was conducted in spreadsheet versions of the models. For each diet, 3 simulations were carried out. In simulation 1 (CNCPS1), CP, Soluble protein, NPN, NDICP, and ADICP were varied. In simulation 2 (CNCPS2), the inputs for protein pools (CNCPS1) and the corresponding digestion rates (kd) were varied. In simulation 3 (NRC), CP, in situ A and C fractions and kd for in situ B fraction were varied. The maximal impact on MP, Lys and Met allowable milk (kg/day) is summarized below. Both models behaved similarly

when variation in kd was taken into account. For the NRC model, the ranking of critical inputs was, for diet 1, SBM kd ($r=-0.5$), CS A fraction ($r=-0.34$), and dried corn kd ($r=-0.25$), for diet 2, SBM kd ($r=-0.55$), grass hay CP ($r=0.32$), and dried corn kd ($r=-0.31$). For the CNCPS, the ranking was, for diet 1, SBM kd of B2 pool ($r=-0.5$), dried corn kd ($r=-0.26$), and WB CP ($r=0.26$), for diet 2, SBM kd ($r=-0.52$), grass hay CP ($r=0.36$), and dried corn kd ($r=-0.35$). One SD increase (1.5 %/h) in SBM kd resulted in a 0.5 SD decrease in MP from RUP (Diet 1 SD=153 g, Diet 2 SD=208 g), while for the CNCPS model, 1 SD increase (4 %/h) in kd for SBM B2 kd resulted in a > 0.5 SD decrease (Diet 1 SD=136 g, Diet 2 SD=177 g). Because of the intrinsic variation in kd measurements and the sensitivity of the current models, research is needed to improve the methodology used to obtain kd.

	Diet 1			Diet 2		
	CNCPS1	CNCPS2	NRC	CNCPS1	CNCPS2	NRC
MP milk from RUP	1.9	2.8	3.1	2.2	3.6	4.2
MP milk from Met in RUP	2.2	2.9	1.8	2.3	3.0	4.2

Ruminant Nutrition: Dairy - Fats

622 Effect of rumen protected conjugated linoleic acid on energy metabolism of dairy cows during early to mid-lactation. K. J. Shingfield^{*1}, D. E. Beever¹, C. K. Reynolds¹, S. K. Gulati^{2,3}, D. J. Humphries¹, B. Lupoli¹, G. Hervas¹, and M. J. Grinari⁴, ¹Centre for Dairy Research, University of Reading, Reading, UK, ²University of Sydney, Sydney, Australia, ³Rumentek Pty Limited, Australia, ⁴University of Helsinki, Helsinki, Finland.

Trans-10, cis-12 conjugated linoleic acid (CLA) inhibits milk fat synthesis and reduces milk energy content. Controlled decreases in milk energy secretion could be used to improve energy balance of the dairy cow during early lactation. Twelve multi-parous Holstein-British Friesian cows were used in a randomized block study to evaluate the effects of rumen protected CLA (RCLA) on energy metabolism in early lactation. Supplements were prepared by casein-formaldehyde treatment of CLA methyl esters containing equal amounts of cis-9, trans-11 and trans-10, cis-12. At calving, cows were paired and allocated at random to a control diet (C) or the same diet supplemented with 110 g of RCLA that supplied 14.3 g trans-10, cis-12 CLA/d. Energy balance (MJ/d) was estimated during weeks 3, 7, 11 and 15 of lactation using 6d excreta collection and respiration calorimetry. On average, RCLA reduced milk fat content (34.9 vs. 19.2 g/kg; $P<0.001$) and milk fat yield (1395 vs. 901 g/d; $P<0.001$), increased ($P<0.05$) milk yield (40.3 vs. 47.4 kg/d) and milk protein output (1.25 vs. 1.42 kg/d) and tended to increase DMI (22.2 vs. 24.6 kg/d; $P=0.06$) and BW (614 vs. 661 kg; $P=0.11$). The effects on DMI and production occurred within one week of lactation. RCLA increased ($P=0.08$) energy intake (389 vs. 434, for C vs. RCLA, respectively), but had no effect ($P>0.10$) on estimated heat energy (155 vs. 169), milk energy (112 vs. 103) or energy excreted in methane (25.0 vs. 26.0), urine (11.1 vs. 11.0) or feces (108 vs. 119). However, RCLA improved ($P<0.05$) tissue energy balance (-17.1, 8.5, 6.6 and 24.4 at weeks 3, 7, 11 and 15 of lactation, respectively) compared with C (-53.1, -19.3, -8.2 and -6.5). In conclusion, RCLA decreased milk fat content, increased milk production and improved tissue energy balance of dairy cows during the first 15 weeks of lactation, with evidence of improved tissue N retention (19 vs. 42 g/d; $P = 0.05$). In contrast to the effects in growing mice, heat energy/BW.75 was not affected (1.26 vs. 1.30).

Key Words: Conjugated Linoleic Acid, Energy Metabolism, Dairy Cows

623 Effects of dietary CLA on production parameters and milk fatty acid variables in Holstein and Brown Swiss cows during heat stress. C. E. Moore^{*}, H. C. Haflinger III, O. B. Mendivil, R. J. Collier, and L. H. Baumgard, University of Arizona, Tucson.

Heat stressed dairy cattle are bioenergetically similar to transition cows in that dietary intake may be inadequate to support maximum milk and component synthesis. Objectives were to evaluate whether CLA induced milk fat depression (MFD) during heat stress would allow for increased milk production and component synthesis. In addition, CLA effects on production variables, MFD and milk composition were compared between Holstein and Brown Swiss cows. Multiparous cows ($n = 8$, Holstein; $n = 5$, Brown Swiss) averaging 97 ± 17 DIM were used in a crossover design during the summer (mean THI = 75.7). Treatment period lengths were 21 d with a 7 d acclimation period prior to and between periods. During acclimation periods all cows received EnerGII[®] (a supplement of palm fatty acid distillate; Bioproducts Inc., Fairlawn, OH). Dietary treatment consisted of either 250 g/d of CLA (Bioproducts Inc.) or EnerGII. The CLA supplement contained a variety of CLA

isomers (5.4% trans-8, cis-10; 6.3% cis-9, trans-11; 7.9% trans-10, cis-12; and 8.2% cis-11, trans-13 CLA). Treatment was applied 2x/d with half of the supplement top dressed at 0600 h and the remaining at 1800 h. There was no overall treatment effect on DMI (23.9 kg/d), milk yield (40.0 kg/d), SCC (305,000), protein% (2.86) or lactose% (4.52) or yield of these milk components. CLA supplementation decreased ($P < 0.01$) overall milk fat content and yield by 21 and 24%, irrespective of breed. The reduction of milk fat content and yield was greater on d 21 (28 and 37%, respectively). Energy balance was improved ($P < 0.01$) by 3.1 Mcal/d for the CLA group (-1.1 vs. 2.03 Mcal/d, respectively). Respiration rate (78 breaths/min) and skin temperature (35.4°C) were not affected by treatment. The CLA supplemented group had higher total milk fat CLA concentrations (8.3 vs. 4.8 mg/g). CLA supplementation caused MFD similarly between breeds and improved energy balance during heat stress, but had no effect on production parameters under these conditions.

Key Words: CLA, Milk Fat, Heat Stress

624 Effects of source and level of dietary lipid on in vitro production of conjugated linoleic acid and trans vaccenic acid. X. Qiu^{*1}, K. E. Griswold², G. A. Apgar¹, D. W. Murdach¹, E. D. Frantz¹, D. L. Hastings¹, and B. N. Jacobson¹, ¹Southern Illinois University, Carbondale, ²Penn State University Extension, Lancaster.

Two in vitro experiments were conducted to investigate the effects of source and level of lipid on biohydrogenation (BH) and the production of conjugated linoleic acid (CLA) and trans vaccenic acid (TVA). Exp. 1 examined the effect of partial (50%) or complete replacement of 4% yellow grease with each of the following three plant oils: soybean oil, corn oil, and sunflower oil (SUO), respectively. Based on the results of Exp 1, Exp 2 with a total of six treatments was designed to investigate the effect of four other plant oil sources, olive oil, peanut oil, canola oil, and safflower oil (SAO), as compared to yellow grease and SUO at 4% of dietary DM. Diets were composed of corn silage, alfalfa hay, soybean meal, and contained 18.4% CP and 32.4% NDF on average. The incubation periods were 0, 8, 12, or 16 h for Exp 1 and 0, 12, 18, and 24 h for Exp. 2. Three samples were incubated per treatment per time point. Fatty acid data were analyzed using the MIXED procedure of SAS with repeated measures. Rate of BH was estimated by linear regression. In Exp. 1, source of lipid did not affect the production of TVA but affected ($P < 0.05$) the production of CLA isomers and total CLA, with SUO producing the largest increase in TVA and CLA yields; elevated level of plant oil increased the production of TVA ($P < 0.05$), total CLA ($P < 0.01$) and CLA isomers ($P < 0.01$). In Exp. 2, SUO and SAO were similarly effective ($P < 0.01$) in increasing TVA production compared to other plant oils. However, SAO was more effective ($P < 0.01$) than SUO in increasing CLA production and SUO ($P < 0.01$) was more effective than the other oils. In addition, combined information from both experiments showed that, within the range of 4% of dietary DM, rate of BH was not affected by lipid source but slightly increased as oil level increased; production of CLA peaked between 12 and 18 h, whereas the peak for TVA occurred later, around 24 h.

Key Words: Conjugated Linoleic Acid, Vaccenic Acid, In Vitro

625 Concentration of cis-12 C18:1 in milk is more closely related to milk fat depression (MFD) than trans-10 C18:1 in cows fed fish oil. M. A. S. Gama¹, J. M. Grinari², P. C. Garnsworthy³, P. H. M. Rodrigues⁴, P. R. Leme⁴, L. W. O. Souza⁴, and D. P. D. Lanna^{*1}, ¹Esalq-USP, Piracicaba, Brazil, ²University of Helsinki, Finland, ³University of Nottingham, UK, ⁴Campus Pirassununga-USP, Brazil.

Diets producing MFD alter pathways of rumen biohydrogenation, resulting in formation of intermediates which inhibit milk fat synthesis. Increased trans-10 C18:1 formation is a consistent observation. Furthermore, trans-10 C18:1 is often associated with formation of trans-10, cis-12 CLA, a precursor of trans-10 C18:1. Fish oil (FO)-induced MFD represents a notable deviation since it is associated with increased formation of trans-10 C18:1 without any increase in milk trans-10, cis-12 CLA content. This study evaluated temporal changes in secretion and fatty acid profile of milk fat in response to FO and low dietary fibre. Mid-lactation Holstein cows were used. The study was conducted in three periods: 1) Baseline: all cows (n=12) received high fibre diet (HF) without FO (baseline diet, BD) for 12 d; 2) Supplementation: cows (n=4) received three treatments for 21 d: a) HF+FO, b) Low fibre diet (LF) and c) LF+FO; 3) Post-supplementation: all cows returned to BD on 12 d. NDF contents of HF and LF were 40 and 25%, respectively. Roughage was corn silage and FO was included at 1.6% of DM. Milk fat content was progressively reduced for the first two weeks of FO supplementation, after which it reached a plateau. Co-variate adjusted LS-means for milk fat yield and content were 0.74a, 0.45b and 0.44b kg/d and 3.88a, 2.83b and 2.60b% for LF, HF+FO and LF+FO, respectively (different superscripts, P<0.05). Milk trans-10, cis-12 CLA content was unchanged by dietary treatments. However, trans-10 C18:1 and cis-12 C18:1 contents increased in FO supplemented diets (P<0.05). Temporal change in milk fat content was more closely associated with cis-12 C18:1 than trans-10 C18:1. We conclude that formation of cis-12 C18:1 is characteristic of the altered rumen biohydrogenation and a putative product of linoleic acid associated with FO-induced MFD.

Key Words: Fish Oil, Conjugated Linoleic Acid, Milk Fat Depression

626 Increasing dietary starch fermentability causes milk fat depression in low-producing, but not high-producing cows. B. J. Bradford* and M. S. Allen, Michigan State University, East Lansing.

The effects of dietary starch fermentability on milk production and fatty acid profile were evaluated in a crossover study. Thirty-two multiparous Holstein cows (121 ± 48 DIM, 41 ± 9 kg 3.5% fat-corrected milk; mean ± SD) were randomly assigned to treatment sequence and were fed a diet intermediate to the treatments during an initial 21-d period. Treatments were dry ground corn grain (DG) and high moisture corn (HM) from the same field. Treatment periods were 14 d, with the final 4 d used for data and sample collection. Diets included corn silage and alfalfa haylage at a 1:1 ratio and were ~26% NDF, 16.5% CP, 32% starch, and ~3% crude fat. Treatments had no consistent effect on production of milk, FCM, or milk components. HM decreased the concentration of C18:0 (P < 0.001) and increased concentrations of trans-9 C18:1 (P < 0.001), trans-10 C18:1 (P < 0.01), and cis-9, trans-11 CLA (P < 0.01), but not trans-10, cis-12 CLA (P = 0.18) in milk fat. HM increased trans C18:1 concentrations at an increasing rate as production level decreased (quadratic regression, P < 0.001), and milk fat depression was evident in cows below approximately 40 kg/d FCM production. In contrast, production level had little influence on milk trans C18:1 concentration for DG (slope = -0.023, P = 0.03). Milk trans C18:1 concentration was negatively correlated with milk fat concentration (r = -0.75), as was trans-9 C18:1 (r = -0.60), trans-10 C18:1 (r = -0.61), and cis-9, trans-11 CLA (r = -0.61, all P < 0.001). Concentration of trans-10, cis-12 CLA was not correlated with milk fat concentration (r = -0.11, P = 0.40). Production level may influence biohydrogenation patterns and trans C18:1 production because of differences in rumen environment; rumen pH and dilution rate can alter metabolism and populations of rumen microbes. Diets with highly fermentable starch sources and without supplemental dietary PUFA can induce milk fat depression in lower-producing cows, possibly because of increased production of trans C18 fatty acids.

Key Words: Milk Fat Depression, Trans Fatty acids, Starch Fermentability

627 Effect of timing of initiation of fat supplementation on milk production, plasma hormones and metabolites, and conception rates of Holstein cows in summer. F. M. Cullens*, C. R. Staples, T. R. Bilby, F. Silvestre, J. Bartolome, A. Sozzi, L. Badinga, W. W. Thatcher, and J. D. Arthington, University of Florida, Gainesville.

Primiparous (n=22) and multiparous (n=25) Holstein cows were used in a completely randomized block design to determine the effects of timing of the initiation of fat supplementation (Megalac-R, Church and Dwight Co. Inc., Princeton, N. J.) on cow performance the first 14 wk postpartum (PP). Four treatments were as follows: 1) control (no supplemental fat source) and 2-4) Megalac-R supplementation (2% of dietary DM) beginning at 28 d prior to expected calving date, at day of parturition, or at 28 d PP. Blood samples were collected 3x weekly from calving through wk 10 PP. An Ovsynch protocol was begun between d 5 to 10 of an estrous cycle (d 62 PP) with AI occurring at d 72 PP. Orthogonal contrasts tested for treatments were 1 vs. (2+3+4), 2 vs. (3+4), and 3 vs. 4. Mean milk production was 38.1, 41.5, 36.5, and 37.1 kg/d, tending to be greater (P = 0.06) for cows fed fat starting in the prepartum compared to the PP period. Pattern of plasma progesterone concentrations accumulated from calving to 79 d PP did not differ among treatments. Of cows that ovulated to the Ovsynch protocol, cows fed fat tended (P = 0.09) to have better first service conception rates than controls (27.8 [3/11], 40.0 [4/10], 70 [7/10], and 63.6% [7/11]). Mean plasma concentration of total bilirubin through 4 wk PP was greater (P= 0.05) in cows fed fat starting prepartum compared to those starting PP (0.36 vs. 0.22 mg/dl). Plasma gamma-glutamyl transferase of cows fed fat starting prepartum increased from wk 1 to 4 PP (25.5 to 41.6 U/L) compared to controls (25.2 to 30.2 U/L) and those fed fat starting at calving (30.4 to 25.4 U/L) (treatment by wk interaction, P = 0.01). Cows fed fat had lower mean concentrations of plasma fibrinogen compared to controls (97.7 vs. 123.0 mg/dl) the first 4 wk PP. Plasma concentrations of BHBA, albumin, alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, and ceruloplasmin were not affected by treatments.

628 Kinetic model of rumen biohydrogenation: effects of rumen-protected fatty acid saturation on fractional rate of biohydrogenation and duodenal fatty acid flow in lactating dairy cows. K. J. Harvatine* and M. S. Allen, Michigan State University, East Lansing.

A simple model of rumen fatty acid (FA) metabolism is proposed that allows calculation of first order fractional rate of FA biohydrogenation and FA passage after determination of ruminal FA pool size and duodenal flux. Saturated and unsaturated rumen-protected fatty acid sources were evaluated for effects on fractional rate and extent of rumen biohydrogenation and duodenal FA flow. Eight ruminally and duodenally cannulated multiparous Holstein cows (77 ± 12 DIM, mean ± SD) were used in a replicated 4x4 Latin square design with 21 d periods. Treatments were control and a linear titration of 2.5% added rumen-protected FA varying in saturation: saturated (SAT; prilled hydrogenated free FA, Energy Booster 100[®]), intermediate mix of SAT and unsaturated (UNS; calcium soaps of long-chain FA, Megalac-R[®]), and UNS FA. Experimental diets were 40% forage and contained 27.5% NDF, 30% starch, and 2.5% rumen available vegetable oil (13.5% cottonseed). Rumen-protected FA increased rumen FA turnover rate. Passage rates of C16:0, C18:0 and total C18 were linearly decreased with increasing UNS and trans-C18:1 fractional passage rate was quadratically affected with a maximum for the intermediate treatment. Increasing UNS increased extent of C18:2 and C18:3 biohydrogenation and decreased extent of 18:1 and trans-18:1 biohydrogenation, resulting in increased duodenal flow of trans-C18:1. Calcium salts failed to protect polyunsaturated FA from rumen biohydrogenation despite a mean ruminal pH of 6.0. This model allows a mechanistic description of rumen biohydrogenation and determination of extent of C18:1 biohydrogenation.

Key Words: Biohydrogenation, Kinetic, Fatty Acid

629 Effect of rumen-protected fatty acid saturation on feed intake and feeding and chewing behavior of lactating dairy cows. K. J. Harvatin* and M. S. Allen, *Michigan State University, East Lansing.*

Saturated and unsaturated rumen-protected fat sources were evaluated for effects on feed intake, meal patterns and chewing behavior. Eight ruminally and duodenally cannulated cows (77 ± 12 DIM, mean \pm SD) were used in a replicated 4x4 Latin square design with 21 d periods. Treatments were control and a linear titration of 2.5% added rumen-protected fatty acids (RPF) varying in unsaturation: saturated (SAT; prilled hydrogenated free FA, Energy Booster 100[®]), 50:50 ratio of SAT and unsaturated (UNS; calcium soaps of long-chain FA, Megalac-R[®]), and UNS. Experimental diets were 40% forage and contained 27.5% NDF, 30% starch, and 2.5% rumen available vegetable oil (13.5% cottonseed). Dry matter intake for SAT was not different from control while UNS linearly decreased DMI 3.2 kg. Wet weight of ruminal digesta decreased linearly up to 11.3 kg (13 %) with increasing UNS. Adding RPF did not change meal number, meal length or time between meals compared to control, but increasing UNS decreased meal size 0.22 kg (9 %) within RPF. SAT increased time spent ruminating 56 (10 %) and 42 (7 %) minutes/d compared to CON and UNS respectively. Increasing SAT did not change rumination bout frequency or interval between bouts, but increased rumination bout length 5.6 min compared to UNS. Water intake was not affected by treatment, but increasing SAT linearly decreased the number of drinking bouts per day up to 2.9 (23 %) bouts. Increased unsaturated FA flow to the duodenum decreased feed intake by decreasing meal size, and increased saturated FA flow to the duodenum increased rumination time per day by increasing rumination bout length.

Key Words: Rumination, Feeding Behavior, Fatty Acid

630 Abomasal infusion of L-carnitine alters hepatic fatty acid metabolism and decreases liver lipid in lactating Holstein cows. D. B. Carlson*¹, H. M. Dann¹, N. B. Litherland¹, J. C. Woodworth², and J. K. Drackley¹, ¹*University of Illinois, Urbana,* ²*Lonza, Inc., Fair Lawn, NJ.*

Eight lactating, multiparous Holstein cows with ruminal cannulas were blocked by DIM (block 1, 162 ± 20 DIM; block 2, 101 ± 16 DIM) in a replicated 4 x 4 Latin square design. A 2 x 2 factorial arrangement of treatments was used to determine the effect of abomasal infusion of L-carnitine (20 g/d). During each 14-d period, treatments consisted of: 1) water infusion, ad libitum DMI (WA), 2) water infusion, restricted DMI (WR), 3) carnitine infusion, ad libitum DMI (CA), and 4) carnitine infusion, restricted DMI (CR). All cows received water infusion (1.2 L/d) on d 1-4 and either water or carnitine infusion on d 5-14. Infusions occurred at 0600, 1200, 1800, and 2400 h. Feed restriction (50% of previous 5-d DMI) was implemented on d 10. Cows were fed a TMR (16.6% CP, 1.68 Mcal/kg NE_L), and bST was injected on d 6 of each 14-d period. Liver was biopsied on d 14 of each period. Liver slices were incubated with [1-14C] palmitate (PALM) to determine conversion to CO₂, acid-soluble products (ASP), and esterified products (EP). Abomasal infusion of carnitine tended to increase conversion of PALM to CO₂ ($P = 0.06$) and increased conversion to ASP ($P < 0.01$) regardless of DMI. As a percent of total PALM metabolism, carnitine increased conversion to CO₂ ($P = 0.05$) and ASP ($P < 0.01$), while decreasing EP ($P < 0.01$). Total liver lipid content (% wet tissue) was greater (infusion x DMI; $P = 0.05$) for WR (5.14%) than for WA (4.33%), CA (4.43%), or CR (4.42%). Carnitine infusion reduced ($P = 0.04$) liver triglyceride (TG) concentration (0.30 %) compared with cows infused with water (0.65%). Infusion of carnitine increased ($P < 0.01$) free carnitine as well as long- and short-chain carnitine esters in liver tissue. Supplemental carnitine supplied posttruminally increased oxidation of PALM by liver slices in vitro and decreased hepatic concentration of total lipid and TG in vivo, which may be of particular benefit to periparturient dairy cows.

Key Words: L-carnitine, Liver, Fatty Acid Metabolism

631 Abomasal infusion of L-carnitine affects metabolic and production responses to feed restriction in lactating Holstein cows. D. B. Carlson*¹, H. M. Dann¹, N. B. Litherland¹, J. C. Woodworth², and J. K. Drackley¹, ¹*University of Illinois, Urbana,* ²*Lonza, Inc., Fair Lawn, NJ.*

A 2 x 2 factorial arrangement of treatments was used to determine the effect of abomasal infusion of L-carnitine (20 g/d) during negative energy balance. Eight lactating, multiparous Holstein cows with ruminal cannulas were blocked by DIM (block 1, 162 ± 20 DIM; block 2, 101 ± 16 DIM) in a replicated 4 x 4 Latin square design. During each 14-d period, treatments consisted of: 1) water infusion, ad libitum DMI (WA), 2) water infusion, restricted DMI (WR), 3) carnitine infusion, ad libitum DMI (CA), and 4) carnitine infusion, restricted DMI (CR). All cows received water infusion (1.2 L/d) during d 1-4 and either water or carnitine infusion during d 5-14. Infusions occurred at 0600, 1200, 1800, and 2400 h. Feed restriction (50% of previous 5-d DMI) began on d 10. Cows were fed a TMR (16.6% CP, 1.68 Mcal/kg NE_L), and bST was injected on d 6 of each 14-d period. Milk was sampled on d 7, 8, and 9 and d 12, 13, and 14. Blood was drawn at 0, 3, and 6 h relative to feeding on d 4, 8, and 12. Carnitine did not affect milk yield or milk composition prior to d 10, except for tending to decrease ($P = 0.08$) milk protein content. Restricted DMI decreased milk yield, milk fat yield, and milk protein content and yield compared with ad libitum DMI ($P < 0.01$). During feed restriction, CR (30.0 kg/d) tended to maintain 3.5% FCM (infusion x DMI; $P = 0.07$) relative to WR (27.6 kg/d). Feed restriction increased plasma NEFA (DMI x d; $P < 0.01$), while CR decreased NEFA compared to WR (infusion x DMI x d x h; $P < 0.01$). Serum BHBA was higher for CR than WR, but similar between CR and CA (infusion x DMI x d; $P = 0.01$) on d 12. Serum insulin was lower on d 12 due to DMI restriction (DMI x d; $P = 0.01$). Carnitine infusion increased ($P < 0.01$) the concentration of total carnitine in plasma compared with water infusion. Carnitine supplied posttruminally improved metabolic responses to negative energy and nutrient balances induced by DMI restriction.

Key Words: L-carnitine, Metabolism, Milk Yield

632 Cholesystokinin mediates intake regulation of high fat diets in ruminants by acting on the reticulo-omasal sphincter. D. Kumar¹, M. A. Froetschel*¹, T. D. Pringle¹, and D. H. Keisler², ¹*The University of Georgia, Athens,* ²*University of Missouri, Colubia.*

Four yearling (320 kg) and four mature (650 kg) ruminally-fistulated Holstein steers were used in two, simultaneously run 4X4 Latin square designed trials to investigate the role of CCK and leptin in intake regulation of cattle fed high fat diets. Steers were fed diets containing 0, 3, 6, or 9% supplemental fat. Megalac was substituted for corn in high fat diets. All diets were formulated to contain 16.5% CP and 38.5% RUP. Diets contained concentrate and chopped Bermudagrass hay in the ratio of 2:1 and were fed once daily. Experimental periods were 10 days in length. On d 9, rumens were evacuated before feeding and again 6 h afterwards. Rumen contents were weighed, sampled and immediately replaced to provide estimates of rumen particulate disappearance rates. Reticulorumen motility was measured 1-3 h after feeding. Reticulo-omasal orifice opening time was measured only in yearling steers. Jugular blood samples were collected every 30 min, 1 h before and 3 h after feeding. Blood samples were analyzed for leptin, insulin, and glucose. On d 10, all procedures on d 9 were repeated except devazepide (70ug/kg BW), a CCK-A receptor antagonist, was injected into the jugular vein 1 h after feeding. Dietary fat decreased DMI 10.6 -13.1% (Linear, $P < .05$) in both yearling and mature steers. Yearling steers ate more as a percent of body weight as compared to mature steers (2.94 % VS 2.14%). Devazepide did not influence DMI. Dietary fat had no effect on reticulo-rumen motility, but devazepide increased motility irrespective of dietary treatment. Dietary fat decreased reticulo-omasal orifice opening time by 7.3 to 33.6% (Linear, $P < .05$) in yearling steers and this effect was blocked by devazepide. Dietary fat decreased disappearance of ruminal digesta in yearling steers and this effect was blocked by devazepide. Neither dietary fat, devazepide or steer maturity affected leptin, insulin, or glucose. This data suggests that CCK-A is involved in regulating activity of the reticulo-omasal sphincter, thereby influencing reticulo-ruminal passage and mediating intake of ruminants fed dietary fat.

Key Words: Intake, Fat, Cholecystokinin

633 Effect of feeding Ca salts of palm oil (PO) or a blend of linoleic and monoenoic trans fatty acids (LTFA) on uterine involution and reproductive performance in Holstein cows. S. O. Juchem^{*1}, R. L. A. Cerri¹, R. Bruno¹, K. N. Galvao¹, E. W. Lemos¹, M. Villasenor¹, A. C. Coscioni¹, H. M. Rutigliano¹, W. W. Thatcher², D. Luchini³, and J. E. P. Santos¹, ¹University of California Davis, ²University of Florida, Gainesville, ³Bioproducts, Inc.

Objectives were to evaluate the effects of Ca salts differing in fatty acid profile on uterine involution and reproduction of dairy cows. After blocking according to parity, BCS at dry off and previous lactation milk production, 397 Holstein cows were randomly assigned to one of the two treatments consisting of Ca salts (2% diet DM) of either PO or LTFA from 23 d prepartum to 70 DIM. Body condition of all cows was scored at -43, -23, calving, and at 40, 70, 100 and 140 DIM. Blood was sampled during the first 21d postpartum four times weekly from a subset of 60 cows and plasma was analyzed for PGF metabolite. Ultrasound evaluation was performed weekly from 14 to 42 DIM to determine uterine diameter, thickness of the uterine wall, presence of fluid and interval to first ovulation. Cows were timed inseminated following the Ovsynch protocol at 72 DIM. Continuous and binomial data were analyzed by the MIXED and LOGISTIC procedures of the SAS (2001) program. Source of fatty acids had no effect on BCS either pre- or postpartum ($P < 0.40$). Incidence of retained placenta (6.5 vs 6.7%) and interval from calving to first postpartum CL (27.9 vs 28.3 d) did not differ ($P > 0.15$) between PO and LTFA, respectively. Interval from calving to disappearance of uterine fluid was reduced in cows fed LTFA compared to PO (27.6 vs 25.8 d; $P = 0.04$). Pregnancy rate after first postpartum AI tended to be higher for LTFA than PO at 27 (36.1 vs 28.1%; $P = 0.09$) and 41 (33.5 vs 25.6%; $P = 0.09$) d after AI, but pregnancy losses were similar ($P = 0.74$) and averaged 7.9%. Ca salts differing in fatty acid profile affected reproduction of dairy cows.

634 Responses of milk fat composition to dietary non-fiber carbohydrates in Sarda dairy sheep. A. Nudda^{*}, S. Fancellu, F. Porcu, F. Boe, and A. Cannas, *Dipartimento di Scienze Zootecniche, University of Sassari, Italy.*

Diets with high concentration of non-fiber carbohydrates (NFC) often induce milk fat depression (MFD) and changes in the fatty acid (FA) composition of milk in cows. In sheep MFD is less common, even when high NFC diets are fed at very high levels of intake or when they are supplemented with unsaturated oil. However, there are very few studies on sheep milk fatty acid composition for these diets. For this reason, an experiment was carried out to study the effect of diets with high (43% of DM) and low (28% of DM) NFC concentration on fat content and FA composition in sheep milk. Ten Sarda dairy sheep in midlactation were individually fed ad libitum diets that contained 56% of finely chopped alfalfa hay and 44% concentrate. The concentrate was mainly corn and barley in the high NFC diet (H-NFC), while soybean hulls were used in the low NFC diet (L-NFC). Both diets had similar fat content but the H-NFC diet contained higher concentration of C18:1 (+28%) and C18:2 (+25%) than L-NFC diet. DMI was affected by dietary treatments (H-NFC = 2501 g/d; L-NFC = 2891 g/d; $P < 0.005$). The ewes fed the

H-NFC diet consumed more C18:1 and C18:2 and less C18:3. Milk yield was not affected by the treatments (H-NFC = 1674 g/d; L-NFC = 1765 g/d). Milk fat content (7.1% vs. 7.0%) and milk fat yield (116 vs. 122 g/d) did not differ between H-NFC and L-NFC diets. Sheep fed H-NFC diets had higher milk C6 to C12 FA and lower C18:0 and cis-C18:1 FA. All trans-C18:1 positional isomers were significantly higher for sheep fed H-NFC diet. The t10 C18:1 content was more than doubled in H-NFC ($P < 0.01$). Total trans-C18:1 acids and individual isomers did not affect milk fat content. The c9,t11 CLA isomer was significantly higher for sheep fed H-NFC. The desaturase index, calculated as c9,t11 CLA/(t11-C18:1 + c9,t11 CLA), was lower in H-NFC group ($P < 0.01$). Overall, the higher trans-C18:1 and CLA and lower C18:0 and desaturase index in milk fat of sheep fed H-NFC diets suggest that rumen biohydrogenation of unsaturated FA is slower and thus more unsaturated FA escapes from rumen. The high NFC diet used in this study did not decrease fat synthesis in sheep milk. (Research supported by MiPAF).

635 Nutritional properties and use of rumen protected oilseed /conjugated linoleic acid (CLA) supplements. S. K. Gulati^{*1}, S. W. McGregor², and T. W. Scott², ¹Sydney University, ²Rumentek Pty Ltd.

FDA (2003) has recently approved the use of formaldehyde as a feed additive for dairy and beef dietary supplements derived from oilseeds/meals. The practical significance of this is that the same diet containing rumen undegraded protein (RUP), rumen undegraded fat (RUF) and designer n-3, n-6 fatty acids can be included in the rations of lactating and non-lactating ruminants. The proportions of RUP and RUF in the supplements made by emulsification and formaldehyde treatment of soybean/canola oilseeds are approximately 90% and 80% respectively; the intestinal digestibility of the C18 unsaturated fatty acids and essential amino acids is 90% and 82%. Oilseeds supplements can be designed in terms of fat content and composition for specific production goals eg, improving reproductive performance, enhancing the physical and nutritional properties of milk and meat. In the current experiment our aim was to determine if the CLA induced suppression of milk fat could be reversed by feeding rumen protected (RP) oilseed supplements. Five Holstein cows in mid-lactation, grazing a predominantly kikuyu based pasture, were fed RP-CLA alone (61.5g/d equivalent to 10.3g/d trans10, cis12 and 10.2g/d of cis9, trans11) for 4 days followed by a combination of RP-CLA and RP-soybean/canola oilseed, the latter providing 656g of additional fat per day. RP-CLA alone reduced milk fat by 30% (from 3.4% to 2.4%; $P < 0.001$) and fat yield by 28% (from 826g/d to 594g/d; $P < 0.001$). In combination with RP-soybean/canola oilseed, milk fat increased from 2.4% to 3.4% ($P < 0.001$) and fat secretion was enhanced from 594g/d to 858g/d ($P < 0.001$). This result indicates that the mechanism of CLA induced milk fat depression occurs primarily in the lipogenic pathways within the mammary gland and not on the uptake and transfer of circulating fatty acids. From a dairy industry perspective, it is now practical to design and feed RP fat/protein supplements that produce beneficial effects on performance and product quality.

Sheep Species

636 Effect of GnRH in conjunction with ram introduction on the induction of fertile estrus during the non-breeding season. K.M. Jordan^{*}, A.K. Wurst, E.K. Inskeep, and M. Knights, *Division of Animal and Veterinary Sciences, West Virginia University, Morgantown.*

Introduction of novel rams to anestrus ewes, the ram effect, can be used as a tool for out-of-season breeding but produces a variable response. A single injection of progesterone at ram introduction (RI) and treatment with PG on d 12-16 improved the proportion of pregnant ewes. Maintenance of the ram-induced corpus luteum (CL) up to PG treatment is probably crucial to success of this procedure. Therefore, the effect of a GnRH injection in conjunction with RI was evaluated in anestrus ewes. In addition, the effect of presence of a CL prior to PG injection on fertility of anestrus ewes was tested. In early July, ewes ($n = 28$ -

32/group) were exposed to intact rams for 35d and given an ovulatory dose of GnRH (100 μ g) on d2, d7 or both days following RI. The presence of a CL was determined by transrectal ultrasonography on d7 and d14 at which time an injection of 20 mg PG (Lutalyse) was given. Pregnancy was diagnosed on d52 and d67 relative to RI. Mean estrous response (56%), pregnancy rate to the first (PR1; 29%) and second (PR2; 65%) service periods did not differ among groups. Because of potential for a CL induced by RI or GnRH to be short-lived, the effect of presence of a CL on d7 and/or d14 on fertility variables was examined. Ewes were reclassified as having: no CL on d7 or 14 (CL 0; $n = 14$), a CL on d7 only (CL 7; $n = 10$), a CL on d14 only (CL 14; $n = 16$), or a CL on both days (CL 7,14; $n = 16$). More ewes ($P < 0.01$) in CL 7 (70%), CL 14 (81%) and CL 7,14 (81%) were marked by rams than in CL 0 (14%). PR1 and PR2 were greater in ewes in CL 7,14 (53 and 81%) and CL 14 (38 and 93%) than in CL 0 (7 and 38%). PR1 tended to be higher ($P = 0.06$)

in ewes in CL 7,14 than in CL 7 (30%), which did not differ from CL 0. Percentages of ewes lambing to the first and both services were 7 and 14, 30 and 50, 25 and 81, and 47 and 76 for the four groups respectively. Percentage of ewes lambing to the first service was greater ($P = 0.01$) in CL 7,14 than in CL 0 and more total ewes lambed in groups with CL than in CL 0. Although one or two injections of GnRH after RI did not improve reproductive performance of anestrus ewes, the value of presence of a CL at PG treatment was confirmed.

Key Words: GnRH, Anestrus ewe, Fertility

637 The effect of metabolizable protein and machine milking on the periparturient relaxation of immunity against *Teladorsagia circumcincta* in dairy ewes. E. C. Partington*, J. Donaldson, L. A. Sinclair, and A. M. Mackenzie, Harper Adams University College, Newport, Shropshire, UK.

Increased anthelmintic resistance has led many to investigate alternative methods of parasite control. It is believed that most larval contamination of the pasture is derived mainly from the mature breeding ewe due to the periparturient relaxation of immunity (PPRI). Increasing the metabolizable protein (MP) supply of the ewe in late pregnancy may moderate the PPRI. Previous studies by the author investigating the effect of MP supply to dairy ewes on faecal nematode egg counts (FECs) have not shown significant differences. This study investigated the effects of MP supply and machine milking on the PPRI. Thirty-two pregnant dairy ewes were fed 1 of 2 diets and allocated to 1 of 4 groups: Low MP (0.98 x daily requirement) milked, Low MP, suckled, High MP (1.75 x daily req.) milked or High MP, suckled, in a 2 x 2 factorial design (n=8), from -6 to +7 weeks around parturition. From week -6 ewes were inoculated with 30,000 *Teladorsagia circumcincta* larvae/week. The lambs from the milked ewes were weaned at 72 hours old and the ewes machine milked 3 times/day (yields recorded and samples collected weekly). The remaining ewes suckled twins with milk yield estimated by lamb weight gain. The ewes were slaughtered in week +7 to determine worm burden (WB). FECs and WB were transformed according to $\text{Log}_{10}(n+1)$ prior to statistical analysis using GENSTAT. An increased MP supply lowered ($p < 0.001$) ewe FECs *pre-partum*. During lactation suckling increased ($p = 0.009$) ewe FECs. Ewes that were suckled had higher milk yields ($p = 0.001$) and higher WB ($p = 0.002$) than the milked ewes. An increased MP supply increased ($p < 0.001$) ewe weight gain up to parturition, while during lactation ewes that suckled lost more weight ($p = 0.003$) than the milking ewes. Conclusion increased MP supply reduced the PPRI in the dairy ewes, however it may not be advised to use solely machine milked animals to study the effects of the PPRI. More work on how increased MP supply lowers FECs is needed.

Key Words: Periparturient, Sheep, Nematodes

638 The effect of iodine supplementation to ewes in late pregnancy on lamb serum immunoglobulin level. T. M. Boland*, M. J. Guinan, M. A. Foley, P. J. Quinn, J. J. Callan, and T. F. Crosby, University College Dublin, Dublin, Ireland.

High levels of iodine, fed as part of a mineral premix, negatively impact on lamb serum immunoglobulin G (IgG) levels at 24h post partum. The objective of this study was to examine if this high level of iodine, when offered independently of other minerals, elicits a similar effect. Forty-four ewes of mixed breeds were used to examine the effect of dietary iodine supplementation in late pregnancy on lamb serum IgG values. The ewes were individually penned and offered grass silage ad-libitum, supplemented with 500g of 19% crude protein (CP) concentrate from day 105 of pregnancy. Ewes were allocated to one of four treatments: T1, control (C) no mineral supplement; T2, supplemented with Ca, P, Mg, Na, Mn, Co, I, Zn, Se and Vit. E (M); T3, as T2 but excluding iodine (-I); T4, supplementary iodine only (IO). Colostrum yield was measured following hand milking at 1, 10 and 18h after parturition. A blood sample was taken from the lambs at 24h post partum for IgG determination. IO ewes had higher DM and CP intakes than C or M ewes ($P < 0.05$). Treatment did not affect gestation length, lamb birth weight, colostrum yield at 1, 10 or 18h or total colostrum yield to 18h post partum. While lambs from the M treatment were fed more colostrum than the C lambs ($P = 0.02$) there was no difference when colostrum intake was expressed per kg lamb birth weight ($P > 0.05$). Treatment had a significant effect on lamb serum IgG level at 24h post partum ($P < 0.001$). Lambs from the -I treatment had the highest IgG level (19.2g/l) and this was higher than in the control (15.1g/l; $P = 0.02$), the M (1.5g/l;

$P < 0.001$) and the IO treatments (1.1g/l; $P < 0.001$). Lamb serum IgG values were higher in C than in the M and IO treatments ($P < 0.001$). We conclude that at the supplementation level applied in the current study that iodine offered on its own or as part of a mineral pre-mix, will equally and significantly lower the lamb's ability to absorb IgG from the colostrum.

Key Words: Iodine, Sheep, IgG

639 The effects of mineral block intake by ewes in late pregnancy on dietary intake and IgG absorption by the progeny. T. M. Boland*, D. Joyce, P. J. Quinn, J. J. Callan, and T. F. Crosby, University College Dublin, Dublin, Ireland.

Molassed mineral blocks are a free choice form of mineral supplementation that minimize both labor in the feeding of minerals and the disruption caused at feeding time. However, relatively little information is available on the intake of these blocks. Target intake guidelines in the range 20-30g/hd/day are commonly quoted. In an attempt to quantify the intake of mineral blocks when offered ad libitum in the last month of gestation, 158 ewes (114 single bearing (SB) and 18 twin bearing (TB)) were group housed, in addition to 26 individually housed TB ewes) were assigned to this study. Block intake was recorded daily in all treatments while food and water intake, colostrum yield, composition and the intake of colostrum by each lamb was measured at 1, 10 and 18h after parturition for the individually fed animals. A blood sample was taken from the progeny of the individually fed ewes at 24h post partum for IgG determination. Daily block intakes for the single bearing, twin bearing group fed and twin bearing individually fed ewes were 73g (range 40-95g), 117g (range 77-138g) and 206g (range 175-223g) per hd/day respectively. These intakes represent a 3-10 fold increase on commonly quoted guidelines. There was no effect of treatment on voluntary food intake. The daily water consumption (l/ewe/d) was higher when the ewes had access to mineral blocks (2.24 vs 0.77; $P < 0.05$). Treatment had no effect on colostrum yield, IgG concentration of the colostrum or total colostrum IgG yield. Although the intake of IgG to 18h was similar for lambs in both treatments (30.0 vs 30.5 g/lamb) the percentage of colostrum IgG absorbed was significantly lower when the ewes had access to mineral blocks (26.1 vs 6.5; $P < 0.05$). We conclude that the provision of ad libitum access to this mineral block to ewes in late pregnancy resulted in intakes that were both variable and excessively high, resulting in increased water intake and a reduction in lamb serum IgG values.

Key Words: Mineral, Sheep, IgG

640 Shear force and sensory attributes of lamb from hair sheep composite breeds. S. P. Greiner¹, D. R. Notter¹, and S. K. Duckett^{*2}, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²University of Georgia, Athens.

One hundred fifty seven lambs from two locations (L1, L2) were evaluated over a three yr period to assess the effect of breed type on shear force and sensory panel attributes. Dorper (DP) and Dorset (DO) cross-breeds (out of $\frac{1}{2}$ -DO, -Rambouillet, -Finnsheep ewes) were produced in all three yr at L1, along with straightbred Katahdin (KT) and Barbados Blackbelly x St. Croix (HH) wethers in 2001 and 2002. At L2, DP and Suffolk (SU)-sired lambs (out of SU dams) were produced in 2001 and 2002. Lambs were weaned at 90 d of age, grazed, and then fed a high-concentrate diet prior to harvest at 8 mo of age. Loins from carcasses were aged at 4° C for 10 d and frozen at -20° C for subsequent Warner-Bratzler shear force (WBS) and sensory analysis. Two 2.54 cm chops from each loin were broiled to an internal temperature of 71° C, and rated by a trained sensory panel for overall tenderness (T), juiciness (J), lamb flavor (LF), and off-flavor (OF) using a 8-point scale (1 = extremely tough, dry, and bland; 8 = extremely tender, juicy, and intense). A model that fit year, location and breed type was used to evaluate DP vs non-DP (ND; DO and SU) breed types. No breed by location interactions were observed. WBS values were 0.25 kg lower ($P = 0.01$) for DP than ND (2.30 vs 2.65; SEM = 0.14). Similarly, panelists tended to rate DP more T ($P = 0.06$) than ND (5.62 vs 5.27; SEM = 0.19). Scores for J, LF, and OF were similar ($P > 0.13$) between DP and ND. At L1, a model that fit breed and year was used to assess differences among breed types. WBS values were 2.81, 2.50, 2.45, and 2.44 kg for DO, DP, KT, and HH, respectively ($P = 0.10$; SEM = 0.16). Breed types rated similarly for all sensory traits. Palatability characteristics

exhibited by hair breeds of sheep may contribute positively to genotypes developed for low input, easy care production systems.

Key Words: Lamb, Tenderness, Sensory Evaluation

641 Evaluation of ultrasound measurements to predict carcass ribeye area and fat thickness in lambs. C. J. Hiemke^{*1}, D. L. Thomas¹, T. A. Taylor¹, R. G. Gottfredson¹, and S. Pinnow², ¹*University of Wisconsin, Madison*, ²*Pinn-Oak Ridge Farm, Delavan, WI*.

The objective of this study was to evaluate ultrasound measurements to predict carcass ribeye area (REA) and fat thickness (FT). Lambs were measured once with an Aloka 500 ultrasound machine with a 3.5 MHz linear probe set over the loin between the 12th and 13th ribs. Lambs were in 8 different groups (n=174, 6 to 89/group) spread over a 13 mo period. Digital ultrasound images were saved to a PC and measured with ImageTool (www.ddsdx.uthscsa.edu/dig/itdesc.html). Carcass measurements on 89 lambs were obtained using a REA grid and ruler on the carcass. Measurements on 85 lambs were obtained by tracing the cross section of the loin and the subcutaneous fat layer onto acetate paper. Carcass REA was measured with a compensating planimeter, and carcass FT was measured with a ruler from the trace. All ultrasound measurements were collected by one operator who was a novice

at the start of the study. Pearson (Spearman rank) correlations between ultrasound and carcass measurements of all lambs were .70 (.71) for REA and .77 (.75) for FT ($P < .001$). Within group correlations increased from .40 to .93 for REA and from .59 to .96 for FT from the 1st to the 8th group of lambs. Ultrasound loin width and 3 loin depths were correlated ($P < .05$) with carcass REA (n=79), however, these correlations (.25 to .58) were lower than the correlation between ultrasound REA and carcass REA (.72). Prediction equations generated using stepwise regression (n=174) were: Carcass REA, $\text{cm}^2 = 3.66 + .85(\text{ultrasound REA})$, ($R^2 = .49$) Carcass FT, $\text{cm} = .071 + .88(\text{ultrasound FT})$, ($R^2 = .60$) Carcass FT, $\text{cm} = -.203 + .82(\text{ultrasound FT}) + .01(\text{carcass wt, kg})$, ($R^2 = .62$). Experience of the ultrasound operator is important. Using all data collected during the study while the operator was gaining experience, approx. 50 and 60% of the variation in carcass REA and FT was accounted for by ultrasound REA and FT, respectively. However, in the last two groups, variation in carcass REA and FT accounted for by ultrasound was approx. 80 and 75%, respectively.

W1 Gluconeogenesis and Krebs Cycle metabolism in 2-day-old fed and fasted chicks. N. E. Sunny*, S. W. El-Kadi, M. Oba, S. L. Owens, R. Angel, and B. J. Bequette, *University of Maryland, College Park.*

Neonatal chicks rapidly adapt their metabolism from the nutrient environment in ovo to exogenous feed at hatch. Our aim was to profile evolution of metabolism and gluconeogenesis by 2-d-old chicks (45 g), and to determine the influence of a 48-h starvation on this metabolism. Broiler hatchlings were assigned to Fed (n=5) or Starved (n=7) groups. Fed (1.5 g/d) chicks were given by gavage (3×/d) a solution (1.5 ml) containing 65% dextrose (43% as [U-¹³C]glucose), 24% casein, 3% soy oil and a mineral-vitamin mix. Starved chicks were dosed (1.5 ml, 3×/d) with water containing [U-¹³C]glucose (50 mg/dose). After 48 h, chicks were killed and plasma collected. Gluconeogenesis and Krebs cycle metabolism were determined from ¹³C-mass isotopomer distribution analysis and isotope dilution of plasma glucose, aspartate (oxaloacetate, OAA) and glutamate (α-ketoglutarate, α-KG), and liver free alanine (3-carbon pool). Rates of gluconeogenesis plus glycogenolysis (112 g glucose/kg BW/d) did not differ, but these accounted for less (P<0.0001) of total glucose entry in Fed than in Starved chicks (82 vs. 96%). Irrespective of feeding regime, glucose carbon recycling accounted for 80% of gluconeogenesis. Glucose metabolized by the Krebs cycle was similar for Fed and Fasted chicks with 26% of acetyl CoA and 6% of OAA flux derived from glucose. Thus, >70% of Krebs metabolism via acetyl-CoA and maintenance of anaplerotic reactions at OAA and α-KG required catabolism of amino acids and lipids. A greater (P<0.001) proportion of glutamate synthesis derived from glucose in Fed (41%) than in Starved (23%) chicks. Proline synthesis from glutamate was 16% for Fed and 22% for Starved chicks. For Fed chicks, the balance (84%) must derive from dietary proline. These data suggest that glucose is not the major substrate for energy metabolism in neonatal chicks. Thus, new criteria may be needed to define protein quality for neonatal chicks that considers requirements for protein synthesis and for energy metabolism.

Key Words: Poultry, Amino Acids, Gluconeogenesis

W2 Effect of decreasing levels of protein in the diet on growth performance of Japanese quail fed fattening diets. R. Barajas*, J. J. Lomeli, J. F. Obregon, and J. J. Portillo, *FMVZ - Universidad Autonoma de Sinaloa, Carr. Culiacan - Mazatlan.*

With the objective of determine the effect of decreasing levels of protein in the diet on growth performance of Japanese quail fed fattening diets, a four week feeding experiment was performed. Six hundred Japanese quail one day old were used. They were randomly divided in 12 groups of 50 animals; each group was placed in elevated metal wire cages (0.9 x 0.9 x 0.5 m). In agreement with a complete randomized experiment design, three feeding programs treatments were assigned: 1) Diet with 24 % of CP (2.92 Mcal ME/kg) during the four weeks (Control); 2) Diet with 24 % CP during the first two weeks, and with 21% CP the last two weeks; and 3) Diet with 28 % CP in the first week, 24 % CP in the second, and with 21 % CP the last two weeks. Food and fresh clean drinking water were free access available. Crude protein levels effect were compared by orthogonal contrasts. Ending body weight (198 ± 2.1 g) was not affected (#8805 0.35) by treatments. In week 3 average weekly weight gain was lower (P= 0.03) with 21 % CP than 24 % CP. Body weight gain of experiment (179.5 ± 3.74 g) was not modified (P= 0.24) by treatments. Food intake was not altered (P= 0.08) by feeding programs. Feed efficiency (gain/feed ratio) during first week was better (P=0.03) with 28 % CP diets than 24 % CP diets (0.748 vs. 0.799 g gain/g food). Feed efficiency of experiment (0.395 ± 0.01 g/g) was similar (P= 0.94) for all treatments. Carcass weight was not affected (P=0.56) by treatments (119.3 ± 2.57 g). Carcass dressing was equal (P= 0.10) across treatments (59.7 ± 0.58 %). These results suggest, that is possible feeding Japanese quail during the last two weeks of fattening period with diets containing 21 % of crude protein without demerits of its growth performance response.

Key Words: Growth Performance, Protein Level, Coturnix Coturnix Japonica

W3 2-Hydroxy-4-(methylthio) butanoic acid (HMTBA) and DL-methionine yield equal growth and carcass performance under Thailand tropical conditions. S. Attamangkune*¹ and S. Chamrusspollert*², ¹*Poultry Research and Development Center, Kasetsart University, Thailand*, ²*Novus International Co.,Ltd, Thailand*.

Two trials compared the performance and carcass quality of broilers fed HMTBA (Alimet(r) feed supplement, Novus International, Inc.) or DLM (dry 99%) as methionine (M) sources in corn-SBM diets. Tropical conditions predominated in both studies with average temperature and relative humidity values of 31 °C and 70%, respectively. In Trial 1, d-old, male and female Ross x Ross chicks were assigned to three dietary treatments consisting of 14 replications of 50 birds each. Basal diets reflected Thai commercial conditions and met the requirements of all nutrients except for total sulfur amino acids (TSAA). TSAA levels were 0.72, 0.67, and 0.62% for the starter (1-21d), grower (22-42d), and finisher (43-49d) diets, respectively. Basal diets were supplemented with HMTBA or DLM equimolar meeting TSAA requirements at 0.92, 0.85, and 0.80% for the starter, grower, and finisher periods, respectively. Birds responded to M addition by improving weight gain and FCR at all times ($P < 0.05$), indicating diets were deficient in TSAA. Performance parameters were similar between M sources at all times ($P > 0.10$) however, there was a trend for higher mortality in the DLM treatments during the finisher period (1.26 vs. 0.66 and 0.18% for birds fed DLM, HMTBA and the control diets, respectively). At 49d, the body weight gain and FCR observed were 2393 and 2387g; and 2.02 and 2.02, for birds fed HMTBA and DLM, respectively. Trial 2 comprised 8 replicates of 50 birds each, fed equimolar HMTBA or DLM added at 100 or 105% of TSAA commercial levels. Weight gain and FCR improved by the addition on M sources ($P > 0.05$). No differences in performance and carcass quality were found between M sources ($P > 0.10$). To conclude, performance and carcass quality data confirm that HMTBA and DLM are equivalent as M sources when fed to broilers under tropical Thai commercial conditions.

W4 Dietary glycine needs of broiler chicks. A. Corzo*¹, M. T. Kidd¹, D. J. Burnham², S. L. Branton³, and B. J. Kerr³, ¹*Mississippi State University, Mississippi State*, ²*Ajinomoto-Heartland*, ³*United States Department of Agriculture*.

Research delineating Gly needs for broilers is sparse. Dietary Gly might become a limiting factor in all-vegetable diets fed to broiler chicks when CP is low. A study was conducted to evaluate dietary Gly needs in broiler chicks from 7 to 20 d of age. Ross 508 male chicks were placed in 32 floor pens (15 chicks/pen; 5 pens/trt) of a closed-curtain sided house. Chicks were fed a common pre-starter corn-soybean meal based diet (3100 kcal ME/kg; 23.1% CP; 1.32% Lys) from 1 to 7 d of age, and then fed a titration diet that contained progressive amounts of 0.12% dietary Gly ranging from 0.62% (1.40% Gly+Ser) to 1.22% (2.00% Gly+Ser) from 7 to 20 d of age. Experimental diets were accomplished by supplementing Gly at the expense of a filler. Using regression analysis (95% of minimum or maximum response) it was determined that chicks optimized BW gain and feed conversion at 0.98% (1.76% Gly+Ser) and 1.02% (1.80% Gly+Ser) dietary Gly, respectively. Blood plasma free threonine and serine were unaffected by Gly supplementation, but plasma Gly linearly increased. Dietary Gly may need to be considered as a limiting nutrient in the young chick, especially if CP is low and only vegetable ingredients are used. Present results also suggest that current NRC (1994) recommendations for Gly+Ser of 1.25% may be low.

Key Words: Glycine, Threonine, Plasma amino acids

W5 Effect of chromium methionine supplementation on internal egg quality preservation in Japanese quail. F.G. Rios*, C. Angulo, G. Contreras, and J.J. Portillo, *FMVZ - Universidad Autonoma de Sinaloa (Mexico), Carr. Culiacan-Mazatlan*.

To determinate the effect of chromium methionine supplementation on internal egg quality preservation in Japanese quail, were used 680 eggs from 320 Japanese quail (240 females and 80 males), and allocated in two batteries, each battery containing with five levels, each level with 4 metal wire cages, and each cage with six females and two males. In

agreement of a complete randomised block design experiment, the animals were assigned to receive one of two treatments: 1) Diet with 21 % of CP and 2,900 kcal of ME/kg (control); and 2) Diet control but supplemented with 100 ppb of Cr from Cr-Met. 170 eggs from every treatment were collected and packed in vinyl film and stored to 4 ° C, and other 340 eggs stored to environment at 33 ° C. To 0, 3, 6, 9 and 12 d of storage time were measurement weight, dense albumin height, yolk height, width and yolk color ($L^*a^*b^*$). From this data Haugh Units and Yolk index, were calculated. Haugh Units and Yolk index were affected ($P < 0.01$) by day collection, environment preservation and storage time, but not was affected by treatment ($P > 0.10$). L^* was affected ($P < 0.01$) by environment preservation and storage time, but not was affected ($P > 0.05$) by day collection and treatment; a^* was affected ($P < 0.01$) by collection and environment preservation, but not by storage time and treatment ($P > 0.05$); b^* was affected ($P < 0.01$) by day collection, environment preservation and storage time, but not treatment ($P > 0.05$). It is concluded, than supplementation of 100 ppb of Cr, as source chromium methionine, not delayed damage the internal egg quality in Japanese quail.

W6 Breeder hen and broiler dietary carnitine: Carry-over and dietary effects on progeny growth and carcass traits. M. T. Kidd*¹, C. D. McDaniel¹, E. D. Peebles¹, S. J. Barber¹, A. Corzo¹, S. L. Branton², and J. C. Woodworth³, ¹*Mississippi State University, Mississippi State*, ²*United States Department of Agriculture*, ³*Lonza Inc*.

L-carnitine is involved in energy metabolism and membrane function: specifically that of long-chain fatty acid transfer into mitochondria and subsequent oxidation. Although Lys and Met are its precursors for in vivo synthesis, its content in grains, of which constitute a large portion of poultry diets, is thought to be limited. Ross 308 breeder hens were fed (beginning at 21 wk) test diets (0 or 25 mg L-carnitine/kg of diet), and progeny (via insemination with Ross males) were evaluated at 30, 35, and 37 wk of age representing Experiments (Exp)1, 2, and 3, respectively. Breeder pen was progeny experimental unit. All progeny were feather sexed at hatch. In Exp 1, chicks were placed in batteries (d 1 to 35) and treatments (16 replications with two subplots each) consisted of hen diet and progeny gender. In Exp 2, chicks were placed in floor pens (d 1 to 42) and treatments (16 replications with four subplots each) consisted of hen diet, progeny gender, and progeny diet (0 or 50 mg L-carnitine/kg of diet). In Exp 3, chicks were placed in floor pens equally by gender (d 1 to 42) and treatments (16 replications with two subplots each) consisted of hen diet and progeny diets (high or low nutrient density). Live performance and carcass traits were measured. Females had less ($P < 0.05$) BW gain and breast meat, but more ($P < 0.05$) abdominal fat and breast yield than males in Exp 1 and 2. Hen diet did not affect live performance, but hens supplemented with L-carnitine had progeny with reduced ($P < 0.05$) abdominal fat in Exp 3. Increasing nutrient density increased ($P < 0.05$) BW gain and carcass weights in Exp 3. Dietary L-carnitine (hen and progeny) increased ($P < 0.05$) male mortality. Additional interactive results indicated that L-carnitine in the hen diet decreased ($P = 0.07$) carcass fat and increased ($P = 0.10$) breast meat in the presence of high nutrient density. In conclusion, dietary hen L-carnitine impacted carcass traits of progeny.

Key Words: Broiler Breeder, L-Carnitine, Progeny

W7 Methionine, cystine, phenylalanine, tyrosine, and non-essential AA maintenance requirements for broiler breeders. J. M. Sun¹, M. Debeer*¹, N. K. Sakomura², and C. N. Coon¹, ¹*University of Arkansas, Fayetteville*, ²*Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil*.

Two hundred and fifty 22 week old Cobb-Vantress broiler breeders were used to determine the maintenance requirement and efficiency of utilization of dietary digestible methionine, cystine, phenylalanine, tyrosine and non-essential AA in a 21 day experiment. The breeders were given crystalline amino acid diets containing graded levels of methionine, cystine, phenylalanine, or tyrosine representing 0, 10, 20, 30, 40% of their suggested requirement level (NRC, 1994) with all other amino acids maintained at 40% of their suggested requirement level. Non-essential AA maintenance requirements was determined with graded levels of glutamic acid to provide 12, 19, 26, 33, 40% of suggested CP

requirement (NRC, 1994) with all other amino acids maintained at the previously determined maintenance requirement level (Sakomura et al, 2003). The slope of methionine, cystine, phenylalanine, tyrosine, and CP accretion regression line indicated that 46% methionine, 29% cystine, 56% phenylalanine, 21% tyrosine, and 9% non-essential AA were retained. The digestible methionine, cystine, phenylalanine, tyrosine and non-essential AA requirements for zero protein accretion (maintenance) were calculated to be 101.8 mg/d, 55.3mg/kgBW.75/d or 200.2mg/kgCP/d; 30.5 mg/d, 17.0mg/kgBW.75/d or 75.4mg/kgCP/d; 229.6 mg/d, 111.7mg/kgBW.75/d or 414.4mg/kgCP/d; 65.9 mg/d, 37.2mg/kgBW.75/d or 175.6mg/kgCP/d; and 3715.2 mg/d, 2003.2mg/kgBW.75./d or 9453.0mg/kgCP/d, respectively. The net requirements of digestible methionine, cystine, phenylalanine, tyrosine and non-essential AA for protein accretion were calculated by applying a constant of specific AA in tissue protein content (10.56 mg methionine, 19.2 mg cystine, 14.28 mg phenylalanine, 24.8 mg tyrosine, 452.6 mg CP per gram of protein) and the utilization coefficient of 0.46, 0.29, 0.56, 0.21, and 0.09 resulting in the requirement of 22.96 mg of digestible methionine, 66.2 mg of digestible cystine, 25.5 mg of digestible phenylalanine, 118.1 mg of digestible tyrosine, and 5028.89 mg of digestible non-essential AA per gram of body protein accretion.

W8 Comparison of methionine requirements between an alternative slow-growing genotype and a commercial genotype during the starter period. A. C. Fanatico*, P. B. Pillai, and J. L. Emmert, *University of Arkansas, Fayetteville.*

Slow-growing genotypes may be utilized in organic or natural production systems, and it is important to assess their amino acid requirements to allow more accurate and appropriate dietary formulation. Because these birds are less heavily muscled, it is theorized that their MET requirement is lower, potentially increasing their suitability for outdoor production systems where diets are not generally optimized. Further, supplemental MET is being phased out of the USDAs National Organic Program, increasing the need for understanding MET requirements. The objective of this experiment was to assess the MET requirement of slow-growing broilers, and to examine the efficacy of HMB in this alternative genotype. A MET-deficient corn-peanut meat basal diet was formulated to contain excess cysteine (CYS), and eight graded levels of DL-Met (0, 0.035, 0.070, 0.105, 0.140, 0.175, 0.210, 0.245%) were added to the basal diet and fed to two genotypes: slow-growing (S) and fast-growing (F). Each of the sixteen dietary treatments was fed to five replicate pens (containing five male chicks) from 8-21 days of age. In addition, two levels of MET (0.04, 0.08%) from HMB were fed to the S genotype. There was a linear response ($P < 0.05$) of gain and feed efficiency to incremental additions of MET below requirements. Using broken-line analysis, weight gain data revealed a digestible MET requirement of 0.30% for the S broilers, and 0.32% for the F broilers. Using slope-ratio methodology, in which weight was regressed versus supplemental MET source intake, HMB was found to be 55.2% as efficacious as DL-Met on a weight basis and 62.7% on a molar basis ($P < 0.05$), which is less than values previously observed in fast-growing commercial broilers fed a diet containing excess CYS. These data suggest that this slow-growing genotype has a MET requirement slightly below that of commercial broilers, and may use HMB less efficiently than commercial broilers.

Key Words: Organic, Methionine, Slow-Growing

W9 Effect of tap water taurine supplementation upon mortality rate by PHS; ascites, body weight and haematocrit in broiler chickens in northern Mexico. N. E. Dominguez-Avila*¹, R. Rodriguez-Martinez¹, M. Arenas-Vargas², R. Villegas-Vizcaino¹, J. H. Del Rio-Martinez¹, F. Sanchez y Garcia Figueroa², and R. Bañuelos-Valenzuela³, ¹Universidad Autonoma Agraria Antonio Narro Unidad Laguna Periferico y Carretera a Santa Fe, ²Universidad Autonoma Metropolitana Unidad Xochimilco Mexico, D.F., ³Unidad Academica de Medicina Veterinaria y Zootecnia, UAZ El Cordobel, Enrique Estrada, Zacatecas, Mexico.

Previous studies have suggested the taurine role in response to hypoxemia (low blood oxygen levels) during the pathogenesis of pulmonary hypertension syndrome (PHS; ascites), because has been proposed that cardiac taurine depletion serves to defend the heart against injury caused by regional ischemia in mammals. However, The role of taurine has not

been well documented in broilers, particularly in relation to PHS; ascites. In the present study, 500 male broiler chickens were provided tap water (control group -CON- n=250), and tap water supplemented with taurine (taurine group -TAU- 0.013% n=250) to determine the effect of taurine supplementation on tap water upon the mortality rate by PHS; ascites, body weight and haematocrit in broilers in Northern Mexico (25° NL 103° WL and 1120 masl) reared under natural conditions during the winter season. Chickens from both groups were fed according with NRC requirements and housed in two different places in the same pen. Body weight was recorded in 15, 22, 29, 36 and 41 experimental days and carcass weight and hematocrit were measured in 41 day when chicken was killed, and PHS, ascites mortality was recorded throughout the experimental period. Haematocrit, body weight were evaluated by GLM procedure and LSD test, and mortality rate by PHS ascites was evaluated by X^2 . Neither body weight nor Hematocrit were affected by treatment ($P > 0.05$) (Table 1), but we found a statistical difference ($P < 0.05$) between treatments respect to mortality rate by PHS; ascites (10.1 in CON group vs 7.2 in TAU group). These findings suggest that taurine plays an important role in the PHS; ascites prevention in broiler chickens under winter natural conditions in Northern Mexico, because the low mortality rate by PHS; ascites although we do not differences in haematocrit, one of the most reliable indicators for this syndrome. More trial to identify in a wide way the possibilities to use this amino acid in broiles chicken industry are needed.

Means of mortality rate (MR), haematocrit and body weight (BW) at 15, 22, 29, 36 and 41days in poultry chickens with tap water (CON n=250) and tap water and taruine at 0.13% (TAU n=250)

Treat-ment	MR	Haemato-crit	BW15	BW22	BW29	BW36	BW41
CON	10.1 ^a	42.0 ^a	413 ^a	792 ^a	1210 ^a	1780 ^a	2100 ^a

W10 Broiler performance and carcass parameters of broiler fed diets containing lysine maize. M. L. Taylor*¹, B. George², Y. Hyun¹, M. A. Nemeth¹, K. Karunanandaa¹, T. T. Lohmann³, and G. F. Hartnell¹, ¹Monsanto, Co., LLC, St. Louis, MO, ²Colorado Quality Research, Inc., Wellington, ³Reussen, LLC, Bannockburn, IL.

Modern agricultural biotechnology holds great promise for meeting animal feed needs for crops that are deficient in certain essential nutrients. Two Lysine maize (LM) events called LY038 and LY049 express a lysine feedback insensitive version of dihydrodipicolinate synthase (cDHDPs) predominantly in the germ of corn kernels, resulting in accumulation of free lysine in the grain. Two 42-day broiler feeding studies using Cobb Cobb 500 male broilers were undertaken to compare the feeding value of corn hybrids containing these LM events compared to the feeding value of their respective near isogenic conventional counterparts and several conventional commercial corn hybrids. LM diets and control diets that were supplemented with crystalline lysine were formulated to have all essential nutrients except lysine above their dietary requirements so that birds would be growth responsive to changes in dietary lysine quantity and availability. Unsupplemented lysine diets were formulated to be approximately 0.08% lower in total lysine than the supplemented diets that were targeted to contain 1.06 % and 0.90% total lysine on an "as-fed" basis for the starter (0-21 days) and grower/finisher (day 21 to study end) phases, respectively. A randomized complete block design was used in the study consisting of 14 treatments that were assigned randomly to pens within 10 blocks of 14 pens each (10 males/pen). Gain, FE, and carcass yield observed with broilers fed diets containing LM were not statistically different ($P > 0.05$) from broilers fed crystalline lysine supplemented diets and were superior ($P < 0.05$) to that of broilers fed diets with conventional maize and no supplemental lysine. Therefore, the bioefficacy of the increased levels of lysine in grain from corn hybrids containing both LM events was not different from that of diets composed of conventional corn supplemented with crystalline lysine.

Key Words: Maize, Broilers, Lysine

W11 Effect of protein level and dietary germanium Biotite(Biotite V[®]) on egg production, egg quality and fecal volatile fatty acid in laying hens. W. B. Lee*¹, O. S. Kwon¹, B. J. Min¹, K. S. Son¹, J. W. Hong¹, Y. K. Han², I. H. Kim¹, and Y. K. Jung³, ¹Department of Animal Resource & Science, Dankook University, Cheonan, Korea, ²Livestock Research Institute, National Agricultural Cooperatives Federation Korea, ³Seobong BioBestech Co., Ltd, Seoul, Korea.

This study conducted to investigate the effect of dietary germanium biotite(Biotite V[®]) by protein level in laying hen diets. One hundred forty four, 51 weeks old ISA brown commercial layer, were used in experiment. Dietary treatments were 1) low protein diet(LPD), 2) high protein diet(HPD), 3) LPD-GB(LPD + 1.0% germanium biotite) and 4) HPD-GB(HPD + 1.0% germanium biotite). Hen-day egg production tended to be increased ($P < 0.01$) as the concentration of protein in diets increased. Egg weight tended to decrease by supplementation germanium biotite in the diets($P < 0.01$). Egg shell breaking strength was not influenced by germanium biotite supplementation($P > 0.05$). Large band of egg was decreased as increasing of germanium biotite supplementation in the diets($P < 0.02$). Sharp and middle band of egg were not influenced by germanium biotite supplementation. Egg yolk index tended to decrease as increasing of germanium biotite supplementation in the diets($P < 0.01$). Fecal propionic acid($P < 0.01$) and butyric acid($P < 0.03$) were decreased as the concentration of germanium biotite in the diet was increased. Also, butyric acids increased($P < 0.02$) as the concentration of protein in diets increased. Supplementation germanium biotite in the diet reduced the fecal acetic acid($P < 0.01$). Fecal NH₃-N of hens fed HPD-GB diet was decreased($P < 0.05$) compared to that of LPD-GB diet. In conclusion, germanium biotite supplementation to layer diets can be reduced fecal volatile fatty acid components.

Key Words: Germanium Biotite, Egg Quality, Laying Hens

W12 Interrelationship of threonine and glycine in growing broilers. A. Corzo*¹, M. T. Kidd¹, D. J. Burnham², S. L. Branton³, and B. J. Kerr³, ¹Mississippi State University, Mississippi State, ²Ajinomoto-Heartland, ³United States Department of Agriculture.

Threonine has the capability of partially sparing Gly in chickens. However, there is little information regarding this interconversion and the impact it has on growing broilers. A study was conducted to evaluate possible Thr and Gly interactions in growing broilers. Day-old Ross 508 male chicks were placed into 30 floor pens of a curtain sided house (14 chicks/pen). Chicks were given a common corn-soybean meal starter diet (3100 kcal ME/kg; 23.0% CP) from 0 to 21 d of age. At 21 d of age, floor pens were equalized in bird number (12 broilers/pen). Birds were fed a corn-soybean meal basal diet (3150 kcal ME/kg; 18.2% CP) with two total Gly+Ser levels (1.55 vs 1.65% of diet) and three digestible Thr levels (0.57, 0.61, and 0.65% of diet) from 21 to 42 d of age. Dietary treatments were generated by the addition of crystalline Gly or L-Thr at the expense of a filler. Two-way interactions ($P < 0.05$) were observed for BW gain where broilers fed the 1.55% Gly+Ser diet increased BW gain with Thr supplementation, while those fed 1.65% Gly+Ser were unaffected by dietary Thr. Similarly, whole carcass weight and yield increased ($P < 0.05$) with Thr supplementation when broilers were fed 1.55% Gly+Ser, but not observed when Gly+Ser was incremented to 1.65%. In parallel with previous effects, total breast meat weight responded in a similar fashion ($P < 0.05$), while its yield as well as percentage abdominal fat were unaffected by either Gly+Ser or Thr. Plasma free concentrations of Ser and Gly were increased ($P < 0.01$) as Gly was supplemented, but Thr was unaffected by Gly. As expected, plasma free Thr only increased ($P < 0.01$) with Thr supplementation. There appears to be an interrelationship between Gly+Ser and Thr, but practical implications are elusive at this point. Further research is warranted to clarify such effects.

Key Words: Glycine, Threonine, Plasma Amino Acids

W13 Dietary spray-dried plasma protein improves feed utilization, BW uniformity, and breast-meat yield of broilers raised in a relatively unsanitary environment. K. Bregendahl¹, D. Ahn¹, D. Trampel¹, J. Campbell², and J. Crenshaw*², ¹Iowa State University, Ames, ²APC.

Two identical experiments (each with 480 1-d-old Ross × Ross 308 male broiler chicks) were conducted in series to evaluate effects of spray-dried plasma (SDP) on performance. Each of 40 floor pens (1.7m², 12 chicks/pen) was assigned to a dietary treatment according to a randomized complete block design. Treatments consisted of 0.0, 0.5, 1.0, 1.5 and 2.0% dietary AP920 SDP in the starter phase (wk 1-2). The dietary SDP contents were halved in the grower phase (wk 3-4) and again in the finisher phase (wk 4-6). The corn-soy-based diets were isocaloric, met or exceeded NRC and pelleted. The dirty litter from Exp. 1 was reused in Exp. 2. The pen average daily BW gain (ADG), feed intake (FI) and feed utilization (GF) were evaluated weekly. Individual BW was recorded on d 41 and all broilers were processed on d 42 of age, after which BW uniformity (pen CV), dressing percentage (pct) and pct breast-meat were determined. Data were analyzed by ANOVA and treatment effects assessed by linear, cubic and quadratic contrasts. Mortality was lowest in Exp. 1 (5% vs. 12%), indicating a less sanitary environment in Exp. 2. SDP did not affect ADG, FI, GF or BW uniformity ($P > 0.1$) in Exp. 1, although GF decreased quadratically ($P < 0.05$) in the grower phase. SDP increased dressing pct linearly ($P < 0.05$) by 1.2 points and decreased the pct breast-meat linearly ($P < 0.05$) by 1.3 points. The decrease was attributed to person-to-person variability in the cut-up process, which was changed in Exp 2. In Exp. 2, SDP increased ADG quadratically ($P < 0.05$) in the grower phase and overall, resulting in 3.7% higher end-BW. Overall FI increased quadratically ($P < 0.05$), but GF was improved ($P < 0.05$) in the starter (quadratic effect) and grower (linear effect) phases by 5.0 and 3.4%, respectively. SDP increased BW uniformity quadratically ($P < 0.05$) by 4.2 points and increased the breast-meat pct cubically ($P < 0.05$) by 0.5 points. Thus, SPD improved performance and breast-meat pct.

Key Words: Broilers, Spray-Dried Plasma, Growth

W14 Comparison of biological efficacy of Alimet feed supplement and DL-methionine in broilers. K. M. Chee*¹, J. H. Choi¹, and M. K. Chung², ¹College of Life Sciences and Biotechnology, Korea University, Seoul Korea, ²Novus International Pte Ltd, Singapore.

Two methionine sources, Alimet feed supplement (Novus International, Inc.) and DL-methionine (DL-M), were added equimolar at two levels of supplementation to basal diets in order to estimate their relative bioefficacy in broilers. Added levels of Alimet or DL-M were 0.075 and 0.150% for the starter and 0.04 and 0.08% for the grower diets on dry weight basis, respectively. The higher supplemental levels were set to provide total sulfur-containing amino acids (TSAA) at requirements (NRC, 1994). Basal diets for starter and grower phases were deficient in TSAA and isocaloric (3,100 kcal AMEn/kg), containing 21 and 19% crude protein, and 0.67 and 0.62% TSAA, respectively. Diets were formulated in agreement with local commercial practice for broilers, and to provide other essential amino acids at a level at least 10% higher than recommended (NRC, 1994) when expressed as % of protein. Total 960, day-old, male and female (1:1) Ross broilers were allotted into four treatments with six replications each and 40 birds per pen. Overall bird performance during the starter phase (0-21 days) was not significantly different among dietary groups. However, during the grower phase (21-35 days) birds had higher weight gain ($P < 0.05$) when fed either methionine source at 0.08% compared to those fed at 0.04%. Weight gain and feed/gain ratios were not different ($P > 0.10$) at any time for any level of supplementation between birds fed Alimet or DL-M. Breast muscle and abdominal fat as % of body weight were not different among the treatments ($P > 0.05$). Cumulative performance (0-35 days) followed the same pattern of that observed during the grower stage. In conclusion, based on growth performance and carcass quality data, the bioefficacy of Alimet was not different from that of DL-M for broilers when compared on dry weight basis.

Key Words: Comparative Bioefficacy, Alimet and DL-methionine, Broiler

W15 AA requirements for broiler breeders at peak production. J. M. Sun, M. Debeer*, K. Bramwell, and C. N. Coon, *University of Arkansas, Fayetteville.*

Four hundred and eighty 32 week old Cobb-Vantress broiler breeders with similar body weight (3714 ± 172 g) and all laying were selected to determine the production requirement of dietary digestible methionine, lysine, phenylalanine, isoleucine, arginine, and CP in a 42 day feeding study. The average hen day egg productions for the beginning and for the 6 weeks period were 80% and 70%, respectively. The breeders were given a corn-soy basal diet plus crystalline amino acids with 8 graded levels of methionine, lysine, phenylalanine, isoleucine, and arginine representing 40% 130% of highest suggested requirement between NRC (1994) and Fisher (1998). All other amino acids were maintained at 100% of their suggested requirement level. The basal experimental diets utilized to determine the methionine and phenylalanine requirements contained added cystine and tyrosine, respectively, to supply the non-essential AA component of TSAA and phenylalanine plus tyrosine requirements. Glutamic acid was added to the basal diet containing 100% of essential amino acids to provide 80% 140% of suggested CP requirement (NRC, 1994). The breeders were fed 154 g feed (467 kcal ME) daily. Each treatment contained ten birds. The average egg weight multiplied by average hen day egg production multiplied by average daily wt gain was defined as g egg mass BW gain product. The average feed consumption divided by the product was defined as feed/product ratio. The digestible methionine, lysine, phenylalanine, isoleucine, arginine, and CP requirement for product and feed/product ratio was calculated to be 427.39 mg/d and 476.34mg/d, 888.91 mg/d and 899.02 mg/d, 643.53 mg/d and 667.54mg/d, 844.59 mg/d and 828.16 mg/d, 1059.45 mg/d and 1022.04 mg/d, 19880.72 mg/d and 18927.56 mg/d, respectively. Fertility was measured 4 times and the results showed that different AA levels had significant effects on fertility.

Key Words: AA Requirement, Broiler Breeder, Performance

W16 Dietary protein regulates short-term adaptations in lipogenic gene expression. R. W. Rosebrough*, B. A. Russell, S. M. Poch, and M. P. Richards, *Growth Biology Laboratory, ARS, USDA, Beltsville, MD.*

The purpose of these experiment was to determine possible relationships between certain indices of lipid metabolism and specific gene expression in chickens fed graded levels of dietary crude protein. Male, broiler chickens growing from 7 to 28 days of age were fed diets containing 12 or 30% protein ad libitum. Both groups were then switched to the diets containing the opposite level of protein. In Experiment 1, birds were killed on days 28 (basal values prior to the switch), 29, 30 and 31. Measurements taken included in vitro lipogenesis, malic enzyme activity the expression of the genes for malic enzyme, fatty acid synthase and acetyl coenzyme carboxylase. In Experiment 2, birds were sampled, again prior to the switch and at 3, 6, 9 and 24 hr. following the switch in protein levels. Measurements taken were confined to malic enzyme activity and the expression of the genes for malic enzyme, fatty acid synthase and acetyl coenzyme carboxylase. In vitro lipogenesis and malic enzyme activity were inversely related to dietary protein levels (12 to 30%) and to acute changes from 12 to 30%. In contrast, expression of malic enzyme, fatty acid synthase and acetyl CoA carboxylase genes appear to be constant over a dietary protein range of 12 to 21%, but are decreased by feeding a 30% protein diet (acute or chronic feeding). Results of the present study demonstrate a continued role for protein in the regulation of broiler metabolism. It should be pointed out that metabolic regulation at the gene level only occurs when feeding very high levels of dietary protein.

Key Words: Lipogenesis, Gene, Metabolism

W17 Efficacy of enzyme supplementation in laying hens fed diets based mainly on barley. M. I. Gracia*¹, A. Flores², E. McCartney³, M. Cortés¹, and J. Sánchez¹, ¹*Imasde Agropecuaria, S.L., S.L. Spain*, ²*Nutreco PRC, Spain*, ³*Pen&Tec Consulting, Spain.*

The aim of the present study was to evaluate the efficacy of a feed enzyme additive (Endofeed DC, EC No 25) containing 1,100 U/g of Endo-1,3(4)- β -glucanase (EC 3.2.1.6) and 1,600 U/g of Endo-1,4- β -xylanase (EC 3.2.1.8) in laying hens from 34 to 58 wks of age. A completely randomized design was applied using two experimental treatments: 1) basal

diet (control), and 2) basal diet with 125 mg/kg of enzyme, the recommended dose. Each treatment was replicated 10 times with 20 laying hens (400 Isa Brown in total) constituting the experimental unit. Egg production, average egg weight, and feed efficiency were calculated every 4 wks. Haugh Units, yolk color, and eggshell strength were measured every 8 wks. There were no significant differences between treatments in egg production or feed efficiency, but there were significant improvements in egg quality in hens supplemented with enzyme. For the overall period (34 to 58 wks of age), the addition of enzyme significantly increased mean egg weight (68.51 vs 69.71 g; $P < 0.05$) with no loss of shell quality. Enzyme supplementation increased both albumen height (8.70 vs 7.27 mm; $P < 0.01$) and Haugh Units (101.5 vs 95.0 ; $P < 0.01$) at 42 wks of age. There were significant improvements in yolk color due to enzyme, measured by both Roche Color Fan (RCF) and Minolta Colorimeter (L, a, and b values). Values were similar for both treatments at study start, but by 58 wks of age, hens supplemented with enzyme had significantly higher RCF values (13.34 vs 12.46 ; $P < 0.01$), lower luminosity (L) value (56.46 vs 57.66 ; $P = 0.06$), and significantly higher red color (a) value (6.26 vs 4.79 ; $P < 0.01$) than controls. Moreover, the a/b ratio, indicative of more intense color, was also increased significantly by enzyme supplementation ($P < 0.01$). The data from this study provide convincing evidence that enzyme improves egg weight and yolk color.

Key Words: Glucanase, Xylanase, Laying Hens

W18 Metabolizable energy of meat and bone meal processed differently in broiler diets. M. Moschini*¹, C. Cerioli¹, L. Fiorentini¹, M. Morlacchini², and G. Piva¹, ¹*Universita' Cattolica del Sacro Cuore Via Emilia Parmense, Piacenza-Italy*, ²*CERZOO San Bonico, Piacenza-Italy.*

The meat and bone meal (MBM) processed according to the 96/449/EC directive can still be used in animal diets in Europe. The safety of the processing may be improved when an alkaline step is added to the heat treatment. The apparent metabolizable energy (AME) and the AME corrected to zero nitrogen retention (AMEn) were assessed for differently processed MBM. The physical setting for MBM processing were: MBMA (100°C, 20 minutes, 3.5% CaO), MBMB (125°C, 20 minutes), MBMC (133°C, 20 minutes) (EC treatment) and MBMD (141°C, 20 minutes). 72 male broiler chickens (Ross), 1.8 ± 0.1 kg body weight, were individually housed and randomly assigned to 9 dietary treatments. The bulk of the base diet (Control) was corn (50%), soybean meal (33%), corn oil (3.4%) plus synthetic amino acids, minerals, trace minerals and vitamins. The MBM were used at two levels of substitution (L1=7%, L2=14%) of the protein from soybean of the base diet. Data were analyzed with the Dunnett type I experimentwise error comparison against the control diet. Diets with MBM were analyzed as a factorial experiment. The AME and AMEn of diets were 12.42, 11, 9.76, 12.87, 13.35, 10.46, 11.99, 12.36, 10.72 and 11.83, 10.24, 9.15, 12.19, 12.7, 9.77, 11.31, 11.67, 10.13 MJ/Kg dry matter, respectively for the control diet, MBMA L1, MBMB L1, MBMC L1, MBMD L1, MBMA L2, MBMB L2, MBMC L2 and MBMD L2. When compared to the control diet, no differences were detected. However, when analyzed as a factorial experiment, there were MBM ($P < 0.05$) and MBM by level interaction ($P < 0.05$) effects on the diet AME and AMEn contents. No level effect was observed. Contrast analysis for the AMEn within the L1 indicates 3.3 MJ/Kg dry matter difference ($P < 0.01$) of diets with MBM processed according to the EC treatment or at higher temperature versus the MBMB containing diet. Also, at the same level of substitution there was a -2.2 MJ/kg dry matter difference ($P < 0.05$) when comparing the diet containing the alkaline treated MBM versus diets containing MBM produced according to the EC treatment or at higher temperature. Using MBM processed according to EC treatment or at higher temperature did not negatively affect the AME or AMEn content of diets.

Key Words: Meat and Bone Meal, Metabolizable Energy, Poultry

W19 True metabolizable energy and amino acid digestibility of distillers dried grains with solubles. A. B. Batal* and N. M. Dale, *University of Georgia Poultry Science Dept., Athens.*

In recent years, policies encouraging the production of ethanol have stimulated an enormous increase in the production of distillers dried grains with solubles (DDGS). The ingredient which is becoming increasingly available differs from that of previous decades in that it is derived almost entirely from corn and is dried under less severe conditions.

Twelve DDGS samples were obtained from six different plants in the Midwest from 2002 to 2004. Each sample was analyzed for TME_n and four representative samples were analyzed for total and available amino acid content by using the precision-fed rooster assay with conventional or cecectomized single comb white leghorn roosters, respectively. Metabolizable energy (TME_n) ranged from 2379-3079 kcal/kg, with a mean of 2831 kcal/kg. Marked variation was noted between samples presumably reflecting modest differences in processing procedure. However, a reasonable consistency was observed in samples from the same suppliers. Considerable differences were observed between the true amino acid digestibilities of the DDGS samples. The majority of samples were golden in color and true amino acid digestibility values were relatively consistent among these samples. Total concentration and percent availability, of several critical amino acids for the golden DDGS samples were: lysine, 0.85% (75); methionine, 0.56% (89); cystine, 0.62% (75); threonine, 1.05% (76); and arginine, 1.25% (84). One DDGS sample was very dark in color, appearing to have been severely overheated during the drying process. The level of total amino acids and percent availability was much lower than that observed for the golden colored samples. Total concentration and percent availability, respectively, of several critical amino acids for the dark DDGS sample were: lysine, 0.64% (58); methionine, 0.047% (83); cystine, 0.50% (63); threonine, 0.92% (64); and arginine, 0.95% (75). The variation observed between samples strongly indicates that confirmatory analyses should be conducted prior to utilizing samples from a new supplier.

Key Words: Distiller's Dried Grains with Solubles, TME, Amino Acid Digestibility

W20 Modelling energy utilization in laying-type pullets. N. Sakomura^{*1}, R. Neme¹, F. Fialho², E. Carrilho¹, and K. Resende¹, ¹Faculdade de Ciências Agrárias e Veterinárias-Universidade Estadual Paulista Jaboticabal-SP - Brazil, ²EMBRAPA Bento Gonçalves -RS.

Three trials were conducted to elaborate the ME requirement models for two commercial laying-type pullet strains. In the first trial, 128 pullets with 9 weeks of age, Hy line Brown (HLB) and Hy line W36 (HLW36), were used to determine the efficiencies of energy utilization (kg) by the comparative slaughter method. In the second trial, the effect of temperature (12, 18, 24, 30, and 36°C) and feathering (0, 50, and 100%) were determined on ME maintenance requirements (ME_m) of two strains. The ME_m was determined by ME_m=MEI - RE/kg, MEI=ME intake, RE=retained energy. In the third trial, the ME requirement for weight gain was estimated based on body energy content per gram and kg. The lower critical temperatures (LCT) changed according to feathering levels (19, 22, and 24°C for 100, 50, and 0% of feathering). According to the equation ME_m=W^{0.75} 92.40+6.73(LCT-T), at temperatures below LCT, the ME_m increases 6.73 kcal/W^{0.75} /d for each increase of 1°C. At temperatures above LCT, the ME_m increases 0.88 kcal/W^{0.75} /d for each increase of 1°C (ME_m=W^{0.75} 92.40+0.88(T-LCT)). Considering these results, the following models were elaborated: ME=W^{0.75} 92.40+6.73(LCT-T)+3.22WG (TLCT) and ME=W^{0.75} 92.40+0.88(T-LCT) + 3.22WG (TLCT) for HLW36 and HLB from 1 to 6 wk-old; ME=W^{0.75} 92.40+6.73(LCT-T) + 4.94WG (TLCT) and ME=W^{0.75} 92.40+0.88(T-LCT) + 4.94WG (TLCT) from 7 to 12 wk-old, for HLB and ME=W^{0.75} 92.40+6.73(LCT-T) + 5.19WG (TLCT) and ME=W^{0.75} 92.40+0.88(T-LCT) + 5.19WG (TLCT) for HLW36; ME=W^{0.75} 92.40+6.73(LCT-T) + 6.32WG (TLCT) and ME=W^{0.75} 92.40+0.88(T-LCT) + 6.32WG (TLCT) from 13 to 18 wk-old for HLB and ME=W^{0.75} 92.40+6.73(LCT-T) + 9.49WG (TLCT) and ME=W^{0.75} 92.40+0.88(T-LCT) + 9.49WG (TLCT) for HLW36, ME=ME requirement (kcal/b/d), W=body weight (kg), LCT=24.54-5.65E (E is the feathering score from 0 to 1), T=temperature, WG=body weight gain (g).

Key Words: Energy Requirement Model, Laying Type-Pullets, Temperature

W21 Effect of different feedstuffs on endogenous energy losses of roosters. S. Zhaj^{*1}, G. Qi², and F. Liu¹, ¹College of Animal Science, Northwest Sci-Tech University of Agriculture and Forestry, Yangling Shaanxi, China, ² Feed Research Institute, Chinese Academy of Agriculture Science, Zhongguancun, Beijing, China.

This study was conducted to determine the endogenous energy losses (EEL) in intact roosters tube-fed Normal Corn(NC), Soybean Meal(SB)

and Fish Meal(FM), the levels of CP in NC, SB and FM were 8.7%,43.5% and 64.5%,fed basis. Twenty-four adult roosters(3.0±0.1kg, Body Weight) were allotted to three treatment groups, each of which included four replicates of 2 birds and kept in individual cages under a daily light period of 16h.Following a 48h period without feed, birds were given 50g of one of experimental feedstuffs via a crop intubation and their endogenous excreta were collected for the 48h-96h after intubation. The average EEL and nitrogen losses of per bird fed NC, SM and FM were found to be 83.78KJ and 1.75g, 92.04KJ and 1.9g, 97.80KJ and 2.11g, respectively. EEL and nitrogen losses of SB group and FM group were significantly higher than that of corn grain group (P < 0. 01), EEL of FM group was significantly higher than that of SB group (P < 0. 05). The EEL corrected to zero-nitrogen balance (EEL_n) for the NC, SM and FM group were 20.00KJ, 19.76KJ and 20.06KJ, there were not significantly difference between each group(P > 0. 1). The result showed that EEL would be affected by the protein level of the tube-fed feedstuffs significantly, but the EEL_n was independent of the tube-fed feedstuffs.

Key Words: Roosters, Endogenous Energy Losses, Endogenous Energy Losses Corrected to Zero-Nitrogen Balance

W22 Meeting metabolizable energy needs of broilers with corn-soy enzymes. A. N. Figueiredo¹, R. L. Dari^{*1}, E. E. M. Pierson², M. Hruby³, J. C. Remus², A. M. Penz¹, and T. H. D'Alfonso³, ¹Nutron Animal Nutrition Research Center Campinas, Sao Paulo, Brazil, ²Danisco Animal Nutrition, St. Louis, MO, ³Danisco Animal Nutrition, Marlborough, Wiltshire, UK.

Enzyme use (excluding phytase) in corn-soybean meal diets is relatively low in corn-sorghum-soy diets; this may be due to a lack of understanding of their practical application. A 24-pen, 42 day-D study was conducted to evaluate the effect of a corn-soy enzyme product (Avizyme[®] 1502: alpha-amylase, endo-xylanase and subtilisin protease; 1502) to meet the energy needs of broilers at different stages of growth. Each of four dietary treatments was randomly allocated to 6 replicate pens of Cobb 500 broilers (20 females:20 males/pen; 640 total). A four-phase feeding (pre-starter Brazilian broiler industry nutrient levels) program was used: (type-starter (PS; 00-07D); starter (S; 08-21D); Grower (G; 22-38D), and Finisher (F; 39-42D). There were two dietary treatments (Trts) in the PS and S phases: diets without (WO) and with (W) 0.05% 1502 added over-the-top. In the G and F phases, metabolizable energy (ME) was reduced (down specification; DS) by 3%. Performance of DS and normal ME diets W and WO 0.05% 1502 was compared. Calculated ME (kcal/kg) for the Trts were: PS-2950, S-3080; G-3085 or 3180; F-3153 or 3250. No significant differences between the Trts W and WO 1502 were observed at 7 and 21D. At 38 and 42D, there were significant effects (P < 0.01) of reducing ME on feed intake (FI) and FCR, and the addition of 1502 at each ME increased (P < 0.15) FI by ~ 40g and BW (P < 0.20) by ~ 25g. The average ME (highest ME diet, no 1502) intake (kcal/day) per phase was: PS (62), S (158), G (466), and, F (546). These data suggest that: the broiler to 21D may respond differently to 1502 than it does after this age; there is room for improving the predictability of dietary response to 1502; addition of 1502 OTT through 21D and then to diets with ME reduced 3% is a viable tool to economically meet the energy needs of the broiler.

Key Words: Corn-Soy Enzymes, AME, Over the Top

W23 Validation of dual energy X-ray absorptiometry (DXA) bone mineralization measures in broilers as an alternative to bone ash and breaking measures. R. Angel^{*1}, A. D. Mitchell², and M. Christman¹, ¹Univ. of Maryland, College Park, ²USDA, Agricultural Research Service, Beltsville, MD.

Bone mineralization status of chickens has traditionally been measured using techniques that generate values such as bone ash, bone breaking strength and force, etc. Most traditional techniques are time consuming and require extensive work related to bone removal and further laboratory work. Use of DXA allows for quick measures of bone mineral content (BMC, g) and density (BMD, g/cm²) on the whole carcass, carcass parts or excised bones. The objective of this study was to determine whether DXA measures can be used to predict traditional measures such as bone ash and breaking strength in whole carcasses as well as in excised bones. Traditional measures used included ash (done on toes, shank, tibia and femur), breaking strength and breaking force (done on tibia and femur). Whole carcasses (270) and excised bones from these carcasses were obtained from a study where broilers were fed diets with

different calcium and phosphorus levels. Broilers were sampled at different ages between 18 and 53 d and within each age, were subdivided at random into two subsets (85 and 15% of the data set). Using the 85% subset (n=225), regressions of each adjusted ash and strength variables were run against each adjusted BMC and BMD variable and regression equations and R² values obtained. These equations were used to predict bone ash and strength variables based on measured DXA variables in the remaining 15% of the data set (n=45). The partial R² values were high between DXA whole body BMC and g of femur (0.82) and tibia (0.80) ash. When DXA measures were used to predict bone ash in the 15% subset based on the regression relationships, correlations between predicted and actual values were high. When DXA whole body and femur BMC measures were used to predict femur ash the R² between predicted and actual was 0.86 and 0.89, respectively. DXA generated BMC values can be used to predict bone ash.

Key Words: Bone Mineralization, Dual Energy X-ray Absorptiometry

W24 A novel organic selenium source (zinc-L-selenomethionine, Availa[®]Se) for broilers. B. George¹, S. Davis¹, and T. L. Ward*², ¹Colorado Quality Research, Wellington, ²Zinpro Corporation, Eden Prairie, MN.

There is renewed interest in Se supplementation of livestock due to research showing forms of organic Se are more bioavailable than sodium selenite (NaSe). The objective of this research was to evaluate zinc-L-selenomethionine (ZnSeMet; Availa[®]Se, Zinpro Corp.) in broilers. A randomized complete block design experiment was conducted using day-old RossxRoss 508 male and female chicks. Chicks were fed: 1) corn-SBM diet without Se supplementation (Control), 2) Control + 0.3 ppm Se as NaSe, or 3) Control + 0.3 ppm Se as ZnSeMet. Twelve pens (6 female and 6 male) were used per treatment with 50 females or 45 males per pen. Diets were fed for 49 d in three phases (starter, 0-16 d; grower, 17-35 d; finisher, 36-49 d). Three birds per pen were bled at the end of the study to determine plasma glutathione peroxidase activity (GSH-Px) and Se concentrations, and pectoralis muscle samples were collected to determine Se content. Birds fed NaSe had lower final BW (2.543, 2.408, 2.505 kg for Control, NaSe, ZnSeMet, respectively) and higher feed/gain (1.740, 1.776, 1.733) than birds fed Control or ZnSeMet. Muscle moisture loss was higher numerically in birds fed NaSe compared to birds fed Control or ZnSeMet (1.27, 1.42, 1.25%). Plasma GSH-Px activities were lower (P<0.05) in birds fed Control vs Se-supplemented diets (10.4, 14.0, 15.4 U/mg protein). Birds fed NaSe had lower (P<0.05) plasma GSH-Px than birds fed ZnSeMet. Plasma Se was higher (P<0.01) in birds fed NaSe or ZnSeMet than in birds fed Control (0.113, 0.144, 0.179 ppm). Plasma Se was higher (P<0.05) in birds fed ZnSeMet than birds fed NaSe. Breast muscle Se concentration was higher (P<0.01) in birds fed ZnSeMet compared to birds fed Control or NaSe (0.393, 0.422, 1.20 ppm DM). Higher Se concentration in muscle of broilers fed ZnSeMet is consistent with selenomethionine being incorporated into proteins in place of methionine. Increased muscle stores of Se when feeding ZnSeMet, indicate a more bioavailable Se source relative to NaSe. Zinc-L-selenomethionine is an efficacious source of Se for poultry.

Key Words: Broiler, Selenium, Zinc-L-Selenomethionine

W25 Interactive effects of Zn, Cu, and Mn supplementation in diets for chicks. J. L. Shelton* and L. L. Southern, Louisiana State University Agricultural Center, Baton Rouge.

Previous research in our lab with pigs indicated that removing the dietary trace mineral premix, which contained Zn, Mn, Cu, Se, Fe, and I, resulted in an increase in Mn and a decrease in Zn concentrations in various tissues. Therefore, an experiment was conducted to determine the interactive effects of Zn, Cu, and Mn addition to diets of 0 to 14-d old chicks on growth performance, bone strength, bone ash percentage, and tissue mineral concentrations. Two levels of Zn (0 and 75 ppm, as Zn sulfate), two levels of Mn (0 and 100 ppm, as Mn sulfate), and two levels of Cu (0 and 7 ppm, as Cu sulfate) were supplemented to corn-soybean meal diets in a 2x2x2 factorial arrangement. Each treatment had six replications with five chicks each, and the initial and final BW were 46 and 382 g. Daily gain, daily feed intake, gain:feed, bone strength, bone ash percentage, and bone and pancreatic Zn concentrations were increased (P < 0.07) in chicks fed the diets with supplemental Zn. Daily gain was decreased and bone, liver, and pancreatic Mn levels were increased in chicks fed diets with Mn addition (P < 0.09). Bone

strength was increased when Zn was added to the diets with or without Cu addition but the increase was greater in chicks fed the diets without Cu addition (Zn x Cu, P < 0.05). Bone ash percentage was increased in chicks fed the diets with Zn, Mn, or Cu addition but the increase was not additive (Zn x Mn x Cu, P < 0.03). Liver Cu level was increased (P < 0.01) in chicks fed the diets with Cu addition. Bone and liver Cu levels were decreased (P < 0.07) in chicks fed the diets with Zn addition. Liver and pancreatic Mn levels were increased (P < 0.07) in chicks fed the diets with Zn addition. This study indicated that Zn addition is necessary for normal growth performance and bone strength of chicks, and that Zn addition had a negative effect on tissue Cu levels and a positive effect on tissue Mn levels.

Key Words: Chicks, Growth, Trace Minerals

W26 Phosphorus availability of distiller's dried grains plus solubles for male turkey poults. J. L. Kalbfleisch* and K. D. Roberson, Michigan State University, East Lansing.

Two experiments were conducted to determine the P availability of distiller's dried grains plus solubles (DDGS) using the slope ratio method. In each experiment, 360 male turkey poults were started at one day of age and fed a low P diet (0.5% non-phytate P (nPP)) for 7 or 6 days, respectively. In both experiments, diets were isocaloric, isonitrogenous and calcium was kept constant at 1.2%. DDGS was analyzed to contain 0.69% TP and 0.29% nPP. In Experiment 1, 8 to 9 poults were randomly sorted into 42 brooder cage pens and fed 1 of 7 dietary treatments from 7 to 14 days of age. Treatments were formulated on nPP basis and consisted of the following composition: (1) corn-soybean meal basal (nPP=0.25%), (2) basal + 0.04% nPP from dicalcium P (DP), (3) basal + 0.08% nPP from DP, (4) basal + 0.12% nPP from DP, (5) basal with 15% DDGS (0.29% nPP), (6) basal with 30% DDGS (0.33% nPP), (7) basal with 45% DDGS (0.37% nPP). Body weight (BW), feed intake, ricket scores and bone ash were measured. At the highest level of nPP in Experiment 1, bone ash was significantly greater with DDGS than DP (P<0.0001). Based on nPP intake, P availability was determined to be 76.5% for bone ash (%), 70% for gain and 81% for gain:feed. In Experiment 2, 7 to 8 poults were randomly sorted into 42 brooder cage pens and fed 1 of 7 dietary treatments from 6 to 14 days of age. Treatments were formulated for total P (TP) and consisted of the following composition: (1) corn-soybean meal basal (0.58% TP), (2) basal + 0.05% P from DP, (3) basal + 0.1% P from DP, (4) basal + 0.15% P from DP, (5) basal with 13% DDGS (0.63% TP), (6) basal with 26% DDGS (0.68% TP), (7) basal with 40% DDGS (0.73% TP). At 0.73% TP, ricket score and bone ash (%) were significantly greater with DDGS than DP (P<0.002; P<0.0001). Based on TP intake per gm gain, regression analysis showed P availability from DDGS was repeatedly greater than DP. Based on total P formulation, dicalcium P may not be the appropriate standard to measure P availability of DDGS and suggests P in DDGS is greater than 85% available.

Key Words: DDGS, P Availability, Turkeys

W27 Effect of supplementing selenium yeast in diets of laying hens on egg selenium content. P. Utterback*¹, C. Parsons¹, I. Yoon², and J. Butler², ¹University of Illinois, Urbana, ²Diamond V Mills, Inc, Cedar Rapids, IA.

An eight-week experiment was conducted using 90 Hy-Line W-98 hens (26 wk of age) to evaluate the use of organic selenium (Se) from Se yeast as a Se source for laying hens. At 22 wk of age, the hens were placed on a low Se corn-soybean meal pretest diet for four weeks. At the end of the pretest period, hens were placed on one of three experimental treatments; the low Se diet without supplementation (basal diet), basal diet with 0.3 ppm of Se added from sodium selenite, or basal diet with 0.3 ppm of Se added from Se yeast (SelenoSourceAF#8482, Diamond V Mills, Inc. Cedar Rapids, IA). The diets contained 0.11, 0.38 and 0.34 ppm of Se, respectively. Each of the experimental diets was fed to 10 replicate groups of three hens for eight weeks (26 to 34 weeks of age). Selenium levels in eggs (mg per kg of whole egg) were analyzed at the end of the pretest period (Week 0), Week 4, and Week 8. Initial egg Se contents at Week 0 were similar among treatments (Table 1). Eggs from hens fed the two Se-fortified diets had higher (P < 0.01) Se concentrations than did eggs from hens fed the low Se control diet at both Week 4 and Week 8. The Se yeast diet also yielded egg Se levels that were significantly higher (P < 0.01) than those from the sodium selenite diet at Week 4 and Week 8. The Se yeast resulted in a 4.8-fold increase

in egg Se concentration compared to a 2.8-fold increase for the sodium selenite diet over the unsupplemented diet at Week 8. There were no differences in egg production, egg weight, feed intake, or mortality among treatments. The results of this study indicate that use of Se yeast in laying hens diets is very effective for increasing the Se content of eggs. Effect of sources of Se on egg Se content.

Egg Se content ppm	Diet			SEM
	Basal	Sodium Selenite	SelenoSourceAF™	
Week 0	0.101 ^a	0.104 ^a	0.103 ^a	0.005
Week 4	0.087 ^c	0.180 ^b	0.301 ^a	0.015
Week 8	0.065 ^c	0.182 ^b	0.311 ^a	0.010

^{a-c}Means within a row with different superscripts differ significantly ($P < 0.01$).

W28 Effects of withdrawing vitamin and or trace mineral premixes from grower and finisher diets of broiler. A. Kamyab, A. M. Hosseini*, R. Mohammadzadeh, and K. Taherpour, *University of Tehran, Karaj, Iran.*

Supplementing broiler diets with vitamin and mineral premixes are of concern. This concern is warranted due to the relative quantities needed and due to the adverse effects on the broilers that occur when inadequate dietary levels are fed. The objective of this experiment was to evaluate the effect of withdrawing vitamin and or mineral premixes from the grower and finisher diets of broilers. This experiment was arranged as a 2x4 factorial design. The factors being; a) supplement (ctrl) or non-supplementing one or both premixes in the diets and, b) two withdrawal times, 28 to 49 and 35 to 49d. Birds from each of the eight treatment combinations were assigned to four replicate pens of 30 birds each. Withdrawing of one or both premixes between 28 to 35 days of age had no significant ($P > 0.05$) effects on body weight gain (BWG), feed efficiency (FE), and feed intake (FI). At the second withdrawing period, FI for birds fed diet with no vitamin supplement was statistically lower ($P < 0.05$) than other treatment groups. Likewise, BWG for group without vitamin supplement and those, which lacked both premixes, were lower ($P < 0.05$) than other groups. Birds fed diet lacking mineral supplement had the worst FE, but this difference was only statistically significant ($P < 0.05$) with the group fed lacking both vitamin and mineral supplement. Other criteria such as carcass characteristics, mortality and incidence of leg disorders were not statistically affected by treatments in the entire of this experiment ($P > 0.05$). Our finding indicates that withdrawing premixes between the ages of 28 to 35 has little or no carry over effect on broiler performance.

Key Words: Broiler, Mineral, Vitamin

W29 Use of phytase and an enzyme complex containing α -amylase, xylanase and protease in commercial layers. J. González*, S. Cornejo, E. Contreras, B. Díaz, and L. Vera, *Universidad de Chile, Facultad de Ciencias Veterinarias y Pecuarias, Santa Rosa, La Pintana Santiago Chile.*

A 35-wk study was conducted to evaluate the effects of 3-phytase (5000 FTU/g from *Trichoderma reesei*) and an enzyme complex (EC=Avizyme^R 1502) in layer diets based on corn, soy and wheat bran on performance, egg quality and ileal nutrient digestibility. One hundred forty-four 18-wk-old layers (HyLine W-36) were randomly assigned to 4 treatments with 3 replicates each (4 hens/cage) in a 2 x 2 factorial design. The treatments: 1) no enzyme supplementation, 2) Phytase (300 FTU/kg), 3) EC (α -amylase 300 U/kg, xylanase 225 U/kg and protease 3000 U/kg) and 4) Phytase + EC. All diets provided 86% and 92% of the daily AMEn and CP requirements of layers, respectively. Phytase inclusion provided the equivalent of .11% available P and .1% Ca in treatments 2 and 4. The use of phytase increased ($p < .05$) egg production (EP) and cumulative eggs/h/h (CE) by 1.16% and 2.45 eggs, respectively. The use of the EC decreased ($p < .05$) EP by .66%. Interactions ($p < .05$) were observed for egg weight (EW) and feed intake (FI). In the absence of EC, EW was not affected ($p < .05$) by phytase, however in the presence of EC, phytase decreased EW by .89g. Phytase + EC did not affect FI, however FI decreased when both phytase

and EC were added. Specific gravity was decreased ($p < .05$) while yolk color, yolk weight, yolk/albumen ratios by weight and volume, were increased ($p < .05$) by EC. Phytase decreased ($p < .05$) shell thickness and breaking strength. The EC improved ($p < .05$) AME (10%), P (30%) and protein (6%) digestibilities, but phytase did not influence ($p > .05$) nutrient digestibility. The parameters measured were not further improved ($p > .05$) by the combined use of both phytase and EC. In the present study, phytase improved layer performance but decreased egg shell quality. The EC improved egg quality and nutrient digestibility. The effect of α -amylase, xylanase and protease on P ileal digestibility deserves further research.

Key Words: Laying Hen, Enzymes, Ileal Digestibility

W30 Effect of microbial phytase in low phosphorus and calcium level diet on the performance and nutrient digestibility in laying hens. B. J. Min^{*1}, O. S. Kwon¹, W. B. Lee¹, K. S. Son¹, J. W. Hong¹, T. H. Moon², Y. K. Han³, and I. H. Kim¹, ¹*Department of Animal Resource & Science, Dankook University Cheonan, Korea,* ²*InterMax System, Inc., Korea,* ³*Livestock Research Institute, National Agricultural Cooperatives Federation, Korea.*

This study conducted to investigate the effects of microbial phytase in low phosphorus and calcium level diet on the performance and nutrient digestibility in laying hens. One hundred ninety two, 50-wks old, ISA brown commercial layers were used in a 12 weeks feeding trial after 7-d adjustment period. Four dietary treatments included CON(control; corn-soybean meal basal diet contained available P and Ca to meet the NRC requirement), P1(0.01% PHYTEX, Agranco, Co.), P2(0.06% Natuphos, BASF) and P3(0.06% PHOSMAX, GENOFOCUS). Ca and available P concentrations of P1, P2 and P3 were 90% and 50% of NRC recommendations to accentuate difference in response to phytase availability. In whole period, egg production was not affected by treatments. At 12 weeks, egg weight was significantly increased in adding phytase treatments ($P < 0.05$). Egg shell thickness was increased in P1, P2 and P3 treatments compared with control ($P < 0.05$) at 9 weeks. Ca concentration of serum was tended to decrease in P1 treatment without significant difference ($P > 0.05$). Ca and P concentrations of tibia were higher in layers fed dietary phytase than layers fed control diet without significantly difference ($P > 0.05$). Digestibilities of DM, N and ash were improved in P1 treatment compared with P2 and P3 treatments ($P < 0.05$). Ca and P digestibilities were the highest in P2 treatment ($P < 0.05$), however, there was not significant difference between control and P1 treatments.

Key Words: Microbial Phytase, Performance, Laying Hens

W31 Market tom turkey performance and dietary phytase inclusion. S. L. Noll^{*1}, J. Brannon¹, and J. S. Sands², ¹*University of Minnesota, St. Paul,* ²*Danisco Animal Nutrition, Marlborough, Wiltshire, UK.*

Inclusion of dietary phytase has been identified as a means to reduce dietary phosphorus content and ultimately the environmental impact of poultry manure by reducing its phosphorus content. Appropriate inclusion levels need to be determined in commercial type diets. A novel 6-phytase expressed in yeast (Phyzyme XP, Danisco Animal Nutrition) was assayed for efficacy in market tom turkey diets in a 16-wk trial. Turkey poults (Large White, Nicholas strain) were randomized into floor pens (12 /pen, six replicate pens per treatment) at d of age and were fed one of eight test diets to 16 wks of age. The eight dietary treatments were: 1) positive control (PC) with NRC (1994) levels of calcium and available phosphorus; 2) negative control (NC) with calcium and available phosphorus reduced by .2%. For Treatments 3-6, the NC diet series was supplemented with phytase and contained analyzed phytase levels of 160, 325, 500 and 650 FTU/kg feed, respectively. Adjustments in the nutrient content of the corn-soybean based basal diet were made for each 4-wk feeding period. The turkeys were weighed initially at the start of the trial and at 4, 8, 12, and 16 wks of age with corresponding measurements of feed intake. At 16 wks of age, four birds from each pen were euthanized for toe ash determination. Body weight (BW) at 8, 12, and 16 wks and toe ash was poorer for NC in comparison to PC turkeys as was cumulative feed intake and feed efficiency (FE) through 16 wks of age ($P > .05$). Phytase supplementation improved performance over NC. Performance equivalent to PC was obtained although optimal level of supplementation changed with the age of the bird. Through 8 wks of age, BW and FE for turkeys fed 160 FTU/kg resulted in performance similar to PC while through 16 wks of age, 500 FTU/kg resulted

in performance similar to the positive control. In conclusion, phytase supplementation restored performance in turkeys fed diets deficient in calcium and phosphorus. Optimal performance to 16 wks of age was obtained when the diet was supplemented with 500 FTU/kg of Phyzyme XP.

Key Words: Turkey, Phosphorus, Phytase

W32 Market turkey performance and inclusion level of corn distillers dried grains with solubles. S. L. Noll*¹, J. Brannon¹, and V. Stangland², ¹University of Minnesota, St. Paul, ²Stangland Feed Consulting, Willmar, MN.

Inclusion of corn distillers dried grains with solubles (DDGS) in poultry diets is usually limited to less than 10% of the diet. Depending on price of DDGS and other ingredients, inclusion levels may exceed 10% in ration formulation. A study was conducted with market tom turkeys to determine if higher levels could be fed without negative effects on performance and if dietary protein regime would change the response. A factorial design of inclusion level (0, 10, 15, and 20% DDGs) and protein regime (95 and 100% NRC threonine (thr)) was used to determine if an interaction existed between DDGs inclusion level and dietary protein regime. Male turkeys (Large White) were randomly assigned to pens (10 birds/pen) at 8 wks of age and were fed one of the test diets to 19 wks of age (7 replicate pens per treatment). Diets were formulated to be isocaloric and with similar levels of digestible lysine and TSAA. Diets were adjusted for nutrient content at 3-wk intervals. Turkeys were weighed individually at 8, 11, 14, 17, and 19 wks age. Feed intake was measured for each feeding period. Level by protein regime was significant for body weight (BW) at 11, 14, and 17 wks of age ($P < .05$). At 100% NRC thr, turkeys fed 10 and 15% DDGS tended to have better performance than 100% NRC thr. At 95% NRC thr, 10% and 15% inclusion tended to depress BW at 14 and 17 wks of age. Feed efficiency responses were similar to those of body weight. Based on live performance, up to 20% DDGS can be incorporated into market turkey diets. At the higher protein regimen, inclusion of 10 and 15% DDGS improved weight over that of the control.

W33 Efficacy of Phyzyme[®] XP phytase in broiler diets containing different levels of calcium and non-phytate phosphorus: nitrogen retention and ileal amino acid digestibility. D. R. Ledoux*¹, J. N. Broomhead¹, and J. S. Sands², ¹University of Missouri, Columbia, ²Danisco Animal Nutrition, Marlborough, Wiltshire, UK.

A six-week floor pen study was conducted to determine the efficacy of Phyzyme[®] XP, in diets containing different Ca & P levels, on nitrogen retention, and ileal amino acid digestibility in broiler chickens. A 3 X 4 factorial arrangement of dietary treatments from hatch to week 3 included 3 Ca & non-phytate P (npP) levels (0.80 & 0.25%, 0.85 & 0.30%, and 0.90 & 0.35%) and 4 levels of Phyzyme[®] XP (0, 250, 500, and 750 U/kg diet). From week 3 to 6, dietary phytase levels were kept the same but Ca & npP levels were reduced (0.70 & 0.15%, 0.75 & 0.20%, and 0.80 & 0.25%). The starter basal diet contained 21.74% CP and 2920 kcal ME/kg, and the grower basal diet contained 19.5% CP and 3010 kcal ME/kg. Six pens of 25 chicks each were assigned to each dietary treatment from day 1 to 42. Significant ($P < 0.05$) interactive and main effects were observed for 3 week nitrogen retention, whereas at 6 weeks there was only a significant ($P < 0.05$) phytase effect. Phytase supplementation improved nitrogen digestibility by an average of 4.3% at week 3, and by 4.4% at week 6. With the exception of tryptophan and serine, significant ($P < 0.05$) interactive and main effects were observed for ileal digestibility of both essential and nonessential amino acids. Ileal digestibility of tryptophan and serine, were affected ($P < 0.05$) by phytase level and by the interaction of Ca & npP and phytase level. For the essential amino acids, phytase supplementation improved average ileal digestibility by 2.2%, whereas for the nonessential amino acids improvements in ileal digestibility averaged 3.2%. These results indicate that Phyzyme[®] XP was effective in improving nitrogen and amino acid utilization, and the efficacy was influenced by Ca & npP level.

Key Words: Phytase, Amino Acid Digestibility, Broilers

W34 Effects of phytase on the bioavailability of phosphorus in diets containing conventional or low-phytate corn and soybean meal for chicks. E. G. Xavier, G. L. Cromwell*, and M. D. Lindemann, University of Kentucky, Lexington.

An experiment was conducted to assess the effects of phytase (Natuphos[®], BASF; 750 units/kg) on the bioavailability of P in normal (N) corn and N soybean meal (SBM) or near-isogenic, low-phytate (LP) corn and LP, low-oligosaccharide SBM from near-isogenic soybeans. The corn and SBM were provided by Pioneer Hi-Bred International. The N-corn, LP-corn, N-SBM and LP-SBM contained 0.25, 0.26, 0.70, and 0.77% total P and 0.05, 0.17, 0.22, and 0.55% non-phytate P. Chicks (3-d-old, 85 g initial weight) were fed a low P (0.24% P) phytate-free, casein-dextrose-sucrose-starch basal diet (1.36% lysine, 0.91% methionine) or the basal with 0.08 and 0.16% added P from monosodium phosphate (MSP). Eight additional diets consisted of the basal with 0.08 or 0.16% added P from a 2:1 blend of N-corn and N-SBM or a 2:1 blend of LP-corn and LP-SBM. These eight diets were fed either without or with phytase. All diets contained 1.0% Ca and 3.56 Mcal ME/kg. Diets were fed for 14 d to five replications of six chicks per pen in batteries. Rate and efficiency of gain, and bone strength and ash increased linearly ($P < 0.05$) with increasing level of dietary P. At the end of the study, all chicks were killed and tibias were removed for breaking strength and ash determinations. Because of low feed intake (thus low P intake) along with uncharacteristically low bone strengths and ash in chicks fed the basal and MSP diets, we were unable to use slope-ratio procedures for determining P bioavailability. However, based on relative responses in tibia strength and ash weight, and assuming from previous studies in our laboratory that the bioavailability of P in the 2:1 blend of N-corn + N-SBM diet without phytase was 20% and in the 2:1 blend of LP-corn + LP-SBM without phytase was 55%, the addition of phytase to these two diets increased the estimated bioavailability of P to 43% and 73%, respectively. The results indicate that phytase, at 750 units/kg, converted approximately one-third of the unavailable P in both types of corn-SBM diets to an available form.

Key Words: Chicks, Phosphorus, Phytase

W35 Influence of phytase enzyme supplementation on the growth performance of broiler chicks. A. S. Hussein* and A. M. Yousif, United Arab Emirates University College of Food Systems, Al-Ain, UAE.

The influence of phytase enzyme supplementation on the performance of broiler chicks fed starter diets containing varying levels of a commercial phytase enzyme (phyzyme, Finnfeeds Danisco Cultor) was investigated using low-phosphorus diets. Four replicate groups of eighteen commercial broiler chicks, one day old, were randomly assigned to each of the four dietary treatments. The diets were isonitrogenous (22.25% CP) and isocaloric (3.05 Mcal/kg). Diet 1 (Control) was a corn-soybean starter diet containing 1.0% Ca and 0.45% available P without added phytase enzyme. Diets 2, 3, and 4 were corn-soybean diets containing 1.0% Ca and 0.26% available P with 0, 500 and 1000 added phytase units/kg, respectively. Average body weight and feed intake were measured after 3 weeks and feed conversion ratio was calculated. Blood samples were obtained at the end of the three-week trial in order to measure plasma inorganic P, total Ca, Mg, K, Zn, Fe and Cu. Body weight gain of broiler chicks receiving a diet deficient in phosphorus (Diet 2) with no added phytase enzyme was significantly decreased ($P < 0.05$) compared to the Control and the other treatments. Also, body weight gain of broiler chicks fed the Control (Diet 1) and the low-phosphorus diets with added phytase enzyme (Diets 3 and 4) was similar. Total feed intake and feed conversion ratio were not significantly affected between treatments. However, these parameters were depressed in the phosphorus-deficient treatment (Diet 2). The data showed that graded levels of phytase enzyme added to phosphorus-deficient broiler starter diets significantly increased body weight in a linear fashion.

Key Words: Phytase, Broilers, Growth Performance

W36 The use of near-infrared reflectance spectroscopy to predict the moisture, dry matter, nitrogen, total phosphorus, and phytase phosphorus contents in broiler litter. R. I. Bakalli¹, T. J. Frost², G. M. Pesti*¹, J. P. Driver¹, and H. M. Edwards, Jr.¹, ¹University of Georgia Poultry Science Dept., Athens, ²Gold Kist, Inc, Atlanta, GA.

One hundred thirteen litter samples were obtained from 9 commercial broiler houses in Georgia to develop calibrations for NIRS predictions of moisture, dry matter, total nitrogen, total phosphorus, and phytate phosphorus. The samples were scanned in a Feed & Forage Analyzer Model 5000 with near-infrared reflectance spectroscopy using routine operation and calibration software WIN ISI-IIc.

Table legend: n = Number of samples used in calibration set for regression. Means = Mean is the average of the constituent lab values used in the calibration. RSQ (R²) = Coefficient of determination. SD = Standard deviation among laboratory values. SEC = Standard error of calibration. SECV = Standard error of cross validation. 1-VR = Is 1 minus the variance or a correlation between the laboratory data and the cross validation results.

The sample compositions by chemical assay versus NIRS predictions were (mean±SE, CV%): moisture 6.15±0.18, 30.78 vs 5.99±0.16, 28.46; total dry matter 71.56±0.76, 28.46 vs 72.51±0.74, 10.85; total nitrogen 3.91±0.07, 17.98 vs 3.84±0.06, 15.89; total phosphorus 1.61±0.03, 22.16 vs 1.59±0.03, 22.21; phytate phosphorus 0.70±0.02, 31.00 vs 0.67±0.02, 25.02. NIRS can be a useful tool in the prediction of moisture, total dry matter, total nitrogen, total phosphorus and phytate phosphorus in litter samples from commercial broiler houses.

Results of the near-infrared reflectance spectroscopy calibration set for broiler litter composition

Constituent (%)	n	Mean	RSQ	SD	SEC	SECV	1-VR
Sample Moisture	49	5.83	0.917	1.936	0.559	0.800	0.838
House Dry Matter	49	71.15	0.943	10.049	2.399	4.043	0.845
Total Nitrogen	47	3.85	0.880	0.623	0.216	0.376	0.637

Key Words: Litter, Phosphorus, Nitrogen

W37 Bioefficacy of probiotics in broiler diets. M. I. Gracia*¹, R. M. Engberg², A. E. Espinel³, M. Cortés¹, and F. Baucells¹, ¹Imasde Agropecuaria, S.L., Spain, ²Danish Institute of Agricultural Sciences, Denmark, ³Norel, S.A., Spain.

Two experiments were conducted to evaluate the efficacy of dietary supplementation with probiotics on performance of broiler chickens. In each experiment, 720 Ross 208 d-old broilers distributed at random in 8 replicates of 30 birds per treatment were used. The experimental design was applied to a grower (0 to 21 d) and a finisher diet (21-42 d), both pelleted and based on wheat, barley and corn. In experiment I, there were three treatments, a basal diet (control) and two levels of inclusion of *Enterococcus faecium* CECT 4515 (containing 10⁹ CFU/g product): 100 and 1,000 g/t. At 21 d of age, *E. faecium* supplementation at the higher dose significantly improved ADG (P<0.05) and feed conversion (FC) (P<0.001) (28.2, 28.9, 29.5 g/d, and 1.46, 1.43, 1.40 g feed/g gain; for control, 100g/t, and 1,000 g/t, respectively). However, significant differences disappeared thereafter. In experiment II, the same experimental design as in experiment I was applied with two levels of inclusion of *Bacillus coagulans* CECT 5940 (containing 10⁹ CFU/g product): 100 and 1,000 g/t. At 21 d of age, *B. coagulans* supplementation at the higher dose significantly improved ADG (P<0.05) and FC (P<0.001) (28.2, 28.2, 29.2 g/d, and 1.46, 1.44, 1.42 g feed/g gain; for control, 100g/t, and 1,000 g/t, respectively). However, no differences between treatments were found at 42 d of age. These results indicate that the probiotics tested improve growth and FC until 21 d of age, but these improvements were not maintained thereafter.

Key Words: Probiotics, Performance, Broilers

W38 Effect of a probiotic containing two *Lactobacillus* strains on growth performance and population of bacteria in the ceca and carcass rinse of broiler chickens. A. C. Murry, Jr.*¹, A. Hinton, Jr.², and R. J. Buhr², ¹The University of Georgia, Athens, ²USDA/ARS.

This study was conducted to examine the effect of feeding a botanical probiotic (Feed FreeTM) containing two strains of *Lactobacillus* (*L. salivarius* and *L. plantarum*) on growth performance and bacteria populations in the ceca and carcass rinse of broiler chickens. Four hundred fifty day of hatch high yield strain male broiler chicks were placed into 20 pens with 30 broilers per pen. The dietary treatments were the basal diet (control with coccidiostat and antibiotic), basal diet without coccidiostat and antibiotic and supplemented with 0.10%, or 0.20% probiotic. The results showed that from 1 to 49 d of age body weight gain for broilers fed diets supplemented with 0.10% or 0.20% probiotic was not different (P > 0.05) from birds fed diets with or without coccidiostat and antibiotic. Feed intake and feed to gain ratio from 1 to 42 d of age were higher (P < 0.001) for broilers fed the control diet than for those fed 0.10% or 0.20% probiotic and those without coccidiostat and antibiotic. Feed intake and feed to gain ratio were not different (P > 0.05) between broilers fed 0.10% or 0.20% probiotic and those fed diets with and without coccidiostat and antibiotic. The population of *Campylobacter jejuni* and *Escherichia coli* recovered from carcass rinses at 56 d of age were not different (P > 0.05) due to treatment. Also, *Lactobacilli* and *Escherichia coli* recovered from ceca contents at 56 d of age for were not different (P > 0.05) due to treatment. These results suggest that diets supplemented with the natural probiotic containing *L. plantarum* and *L. salivarius* supports growth for broilers similar to the basal diet supplemented with antibiotic and coccidiostat, and with lower feed to gain ratio.

Key Words: Probiotic, Broiler Chickens, Growth Performance

W39 Comparison of broiler performance when fed diets containing insect-protected (MON 88017 or MON 88017 x MON 810), control, or commercial corn. M. L. Taylor*¹, B. George², Y. Hyun¹, M. A. Nemeth¹, K. Karunanandaa¹, and G. F. Hartnell¹, ¹Monsanto, Co., LLC, St. Louis, MO, ²Colorado Quality Research, Inc, Wellington.

A 42-day study using Ross x Ross 508 broiler chickens was undertaken to compare the nutritional value of diets containing MON 88017 or MON 88107 x MON 810 corn as compared to those containing the genetically similar control corn or commercially available conventional varieties of corn. MON 88017 corn produces a variant of the wild-type Cry3Bb1 protein, that protects against feeding damage caused by corn rootworm larvae (CRW; *Diabrotica sp.*) and also produces the 5-enolpyruvylshikimate-3-phosphate synthase protein from *Agrobacterium sp.* strain CP4 (CP4 EPSPS), that confers tolerance to glyphosate, the active ingredient in the Roundup family of agricultural herbicides. MON 88017 was also conventionally bred with MON 810, which produces Cry1Ab protein from *Bacillus thuringiensis* subsp. *kurstaki* strain HD-1, protecting against feed damage from the European corn borer (*Ostrinia nubilalis*). Broilers were fed approximately 55% w/w corn grain in their diet for the first 20 days and approximately 60% w/w corn grain in their diet from day 21 to day 42. The only sources of dietary protein were corn and soybean meal supplemented with methionine and lysine. Feed and water were offered *ad libitum*. Eight treatments (5 male and 5 female pens/treatment with 10 birds/pen) were assigned using a randomized complete block design. The standard randomized block (ANOVA) statistical model was used to analyze the data. Performance parameters (gain, feed intake, and feed efficiency) and carcass measurements were not different (P > 0.05) across treatments. Likewise there were no differences for percentages of moisture, protein, and fat in breast meat and percentages of moisture and fat in thigh meat. Therefore, the diets containing grain of MON 88017 or MON 88017 x MON 810 were nutritionally equivalent to diets containing the conventional control or commercial corn grain when fed to broilers in this 42 day study.

Key Words: Corn, Broilers, Carcass

W40 Comparison of broiler performance when fed diets containing corn with a combination of insect-protected (MON 863, MON 810) and glyphosate-tolerant (NK603) traits, control, and commercial corn. M. L. Taylor^{*1}, B. George², Y. Hyun¹, M. A. Nemeth¹, K. Karunanandaa¹, and G. F. Hartnell¹, ¹Monsanto Company, LLC, St. Louis, MO, ²Colorado Quality Research, Wellington.

Growth performance and carcass measurements were evaluated in a 42-day study in which broilers (Ross x Ross 508) were fed either diets containing genetically modified corn containing transformation events MON 863, NK603, and MON 810 or MON 863 and NK603 (each combination produced by traditional breeding), a genetically similar conventional control, or five commercially available varieties of corn. MON 810 produces Cry1Ab protein isolated from *B. thuringiensis* that provides protection from feeding damage by the European corn borer (*Ostrinia nubilalis*), and MON 863 produces a variant of the wild-type Cry3Bb1 protein isolated from *B. thuringiensis* that protects against corn rootworm (CRW, *Diabrotica sp.*) root feeding damage. NK603 produces the 5-enolpyruvylshikimate-3-phosphate synthase protein from *Agrobacterium sp.* strain CP4 (CP4 EPSPS), which confers tolerance to glyphosate, the active ingredient in the Roundup family of agricultural herbicides. Broilers were fed approximately 55% w/w corn grain in their diet for the first 20 days and approximately 60% w/w corn grain in their diet from day 21 to day 42. Broilers were assigned to eight treatment groups, each consisting of 10 pens (5 male and five female) containing 10 birds/pen, using a randomized complete block design. No differences ($P < 0.05$) were detected among treatment groups for feed intake, gain, feed conversion, adjusted feed conversion, thigh and breast meat composition and most carcass parameters. Breast weight (kg) and wing weight (% of chill weight) were different ($P < 0.05$), however no differences were observed when breast weight and wing weight were expressed on % chill weight basis and weight basis, respectively. The diets containing MON 863 x MON 810 x NK603 or MON 863 x NK603 were nutritionally equivalent to diets containing the control and commercial corn grain when fed to broilers.

Key Words: Corn, Broilers, Carcass

W41 Influence of cereal, heat processing of the cereal, and inclusion of fiber in the diet on performance of broilers. E. Jimenez-Moreno¹, J. M. González-Alvarado², D. G. Valencia¹, R. Lázaro¹, and G. G. Mateos^{*1}, ¹Universidad Politécnica de Madrid, Spain, ²Universidad Autónoma de Tlaxcala, Mexico.

We studied the effects of cereal, heat processing of the cereal (HP), and inclusion of fiber in the diet on productive performance of broilers from 1 to 21 d of age. The experimental design was completely at random with twelve treatments arranged factorially with two cereals (60% corn and 60% rice), two HP (raw and cooked at 90 C during 50 min and then rolled), and three fiber sources (absence, 3% oat hulls, and 3% soybean hulls). Each treatment was replicated three times (12 chicks caged together). Birds and feed consumption were recorded at 0, 4, 8, 14, and 21 d of age. The two control diets were based on soy protein concentrate, soy oil, and either corn or rice, and had 2.45 % and 1.54 % of crude fiber, respectively. In the fiber diets, hulls replaced the same quantity of an inert material. Broilers fed rice had better feed conversion (FC) throughout the trial than broilers fed corn (1.30 vs 1.35 at 21 d of age; $P < 0.05$) but no significant differences were found for daily gain (ADG) (34.1 vs 33.6 g) or feed intake (44.3 vs 45.2 g). From 0 to 4 d of age HP of the cereal reduced ADG (12.3 vs 12.9 g; $P < 0.01$) and impaired FC (1.25 vs 1.16; $P < 0.01$) but the effects disappeared thereafter. It was observed that broilers fed rice wasted more feed than broilers fed corn. The inclusion of hulls in the diet tended to improve FC (1.19 vs 1.24, $P < 0.10$) but the difference disappeared with age. From 0 to 4 d of age a significant interaction between cereal and HP was observed; HP reduced ADG and impaired FC in the corn diet but had opposite effect in the rice diet ($P < 0.01$). We conclude that rice can be used successfully in diets for broilers and that HP of the cereal does not improve performance in corn-based diets. Also, the inclusion of additional fiber improves productive performance in chicks, specially during the first stages of life. Therefore, a minimum of dietary fiber is required in broiler diets.

Key Words: Rice, Heat Processing, Fiber Source

W42 Effect of varied levels of expander cone pressure and dietary energy level on apparent metabolizable energy, nitrogen retention, and turkey poult performance during the period day 7 to 21. K. J. Wilson^{*}, K. R. Cramer, J. S. Moritz, and R. S. Beyer, Department of Animal Science and Industry, Kansas State University, Manhattan.

Three levels of dietary energy consisting of 2557, 2690, and 2800 kcal ME/kg were combined with three levels of expander cone pressure consisting of 0, 200, and 400 lbs/in² (0, 14, and 28 kg/cm²). A conditioning temperature of 180° F (82° C) was used for all treatments. The pelleted feed was re-ground to a fine mash consistency using a hammermill equipped with a 1/8 in. (3.18mm) screen. The turkey poults were obtained from a commercial hatchery and placed on a low dietary energy ration for a 7-day pretest period. The experimental period consisted of day 7 through day 21 post hatching. There were 5 replicate pens containing 5 poults per pen. The poults were housed in Petersime battery brooders located in an environmentally controlled room. The poults were allowed ad libitum access to food and water. The calorie to protein ratio was not held constant in this experiment. Dietary crude protein levels were approximately 28 percent. There was a significant dietary energy effect on nitrogen corrected apparent metabolizable energy (AMEn), nitrogen retention (NR), and feed conversion (FC). The improvement in nitrogen retention as dietary energy increased was most likely due to a protein sparing effect. Feed conversion was improved by increasing the dietary energy level as has been previously demonstrated. Nitrogen retention was also improved by increasing the expander cone pressure level during feed manufacturing. Dietary AMEn tended to improve in the lower energy treatments as the level of cone pressure was increased during feed manufacturing although this was not statistically significant. Overall the results of this experiment indicate that hydrothermal processing of turkey starter diets may improve nutrient utilization and the potential improvement should be accounted for when formulating the diets to avoid any nutrient imbalances.

Key Words: AMEn, Expander Cone Pressure, Nitrogen Retention

W43 Bioavailability of lysine and methionine in a broiler starter diet subjected to varied levels of expander cone pressure. K. J. Wilson^{*}, K. R. Cramer, J. S. Moritz, and R. S. Beyer, Department of Animal Science and Industry, Kansas State University, Manhattan.

Five expander cone pressure levels were used in this experiment including 0, 100, 200, 300, and 400 pounds per square inch (PSI). The conditioning temperature for all treatments was 180 °F (82 °C). An unprocessed mash control was also included in this experiment. The 0-PSI treatment served as the standard feed conditioning/pelleting control. The pelleted feed was re-ground to a fine mash consistency and blended into semi-purified diets. Diets deficient in lysine and methionine were fed to establish standard curves in order to calculate bioavailability. Experiment 1 was conducted to evaluate the effect of increasing expander cone pressure on lysine bioavailability as measured by a broiler chick growth assay. Broiler performance responded favorably to increasing dietary lysine levels supplied either as synthetic lysine or from the test feed ($P = 0.0001$). The relative bioavailability of lysine as measured by the standard curve methodology was unaffected by level of expander cone pressure or by thermal processing. Experiment 2 was conducted to evaluate the effect of increasing expander cone pressure on methionine bioavailability as measured by a broiler chick growth assay. Broiler performance responded favorably to increasing dietary methionine levels supplied either as synthetic methionine or from the test feed ($P = 0.0001$). There were no significant differences in relative methionine bioavailability as measured by the standard curve method. Based on the results of these experiments the bioavailability of lysine and methionine was not affected by the feed processing levels used in these experiments.

Key Words: Bioavailability, Expander Cone Pressure, Lysine

W44 Influence of expander cone pressure on apparent metabolizable energy, nitrogen retention and broiler performance during the starter phase. K. J. Wilson^{*}, J. S. Moritz, K. R. Cramer, and R. S. Beyer, Department of Animal Science and Industry, Kansas State University, Manhattan.

In previous research, subjecting feed to increasing levels of expander cone pressure has resulted in an improvement in the physical quality

of the feed. In turn the improved feed physical quality has led to improvements in broiler performance. While the effects of annular gap expansion on feed physical quality and broiler performance have been shown, at this time, there is very little information concerning the nutritional effects of broiler feed subjected to annular gap expansion. Five expander cone pressure levels were used in this experiment including 0, 100, 200, 300, and 400 pounds per square inch (PSI). The conditioning temperature for all treatments was 180 °F (82 °C). An unprocessed mash control was also included in this experiment. The 0-PSI treatment served as the standard feed conditioning/pelleting control. The pelleted feed was re-ground to a fine mash consistency and blended in to a semi-purified diet at an inclusion level of 40 percent. The evaluation criteria included testing for treatment differences with respect to nitrogen corrected apparent metabolizable energy (AMEn) and nitrogen retention (NR). Broiler performance measurements were also collected during the experiment. Nitrogen retention was significantly improved by subjecting the feed to thermal processing compared to the mash control. There were no significant differences among treatments for AMEn or broiler performance measurements. Based on the results of this experiment, hydrothermal processing of broiler starter diets may improve nitrogen retention. The improvement in nitrogen retention might have important environmental implications due to the relationship between excess nitrogen excretion and ground water pollution.

Key Words: AMEn, Annular Gap Expansion, Nitrogen Retention

W45 Effect of dietary putrescine (1, 4-diaminobutane) on the small intestine protein and deoxyribonucleic acid concentration and morphometric indices in turkey poults challenged with a mixed coccidial infection. S. R. Girdhar*, J. R. Barta, and T. K. Smith, *University of Guelph, Ontario, Canada.*

High cell turnover rates and recovery following mucosal damage to the intestinal epithelium is dependent on sustained supplies of mammalian polyamines. Supplemental dietary putrescine is known to partially overcome the adverse effects produced by anti-nutritional factors. Two experiments were conducted, therefore, to determine the potential for dietary putrescine to promote gastrointestinal tract development and overcome the effects of artificially induced subclinical coccidiosis using a mixed infection. In the first experiment, 450 day-old male poults were fed starter diets supplemented with 0.0 (control), 0.1, 0.2, 0.3 and 0.4% putrescine (30 birds per pen, 3 pens per diet) for 21 days. At the end of each week twelve poults per diet were sampled and intestinal tissue was excised for protein, DNA and morphometric analysis. In the second experiment 160 day-old male poults starter diet supplemented with 0.0 (control), 0.1, 0.2 and 0.3% putrescine (8 birds per pen, 5 pens per diet) for 24 days. At day 14, half the birds were infected with approximately 42,000 sporulated oocysts. Ten birds per diet from each of the unchallenged and challenged groups were sampled on day 6 and day 10 post-infection and tissues were excised and analyzed as described in the previous experiment. In experiment 1 and for the unchallenged group of experiment 2, the feeding of increasing concentrations of dietary putrescine resulted in no significant change in concentrations of protein or DNA. Significant morphometric changes from the feeding of increasing concentrations of putrescine were seen in various segments of the small intestine. In the challenged group of experiment 2, significant dietary effects were seen in protein and DNA concentrations as well as in the morphometric indices. It was concluded that supplementation of starter diets with up to 0.3% putrescine may minimize the adverse effects of coccidial infection.

Key Words: Putrescine, Coccidia, Turkey

W46 Effect of conjugated linoleic acid on antioxidant enzyme activities and lipid peroxidation in the intestine and liver of growing broiler chickens. I. S. Jang*, Y. H. Ko, H. Y. Yang, and C. Y. Lee, *RAIRC, Jinju National University, Jinju, Korea.*

The present study was designed to investigate whether dietary conjugated linoleic acid (CLA) would affect the intestinal and hepatic antioxidant enzyme activity and lipid peroxidation in growing chickens. A total of twenty-four 3-wk-old male broiler chickens were fed one of three isocaloric grower-finisher diets containing 1.5% corn oil (Con), 0.75% corn oil plus 0.75% CLA, or 1.5% CLA for 2 wk beginning from d 22 of

age. The activities of superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), catalase (CAT) and glutathione S transferase (GST) and the concentrations of malondialdehyde (MDA), a marker of lipid peroxidation, in the intestine and liver of these animals were measured at sacrifice. The activities of SOD, GSH-Px, CAT, and GST in the small intestine were not influenced by the level of dietary CLA supplementation. Nor the concentrations of MDA in the mucosa of the proximal and distal segments of small intestine were affected by the dietary CLA supplementation. Hepatic SOD, GSH-Px, and GST activities and the MDA concentration of the 0.75%- and 1.5%-CLA groups also were not different from those of the Con diet group. However, supplementation of 1.5% CLA resulted in an increase in peroxisomal CAT activity and a marked decrease in concentrations of total lipid and non-esterified fatty acids in the liver compared with those of the Con diet group. This suggests that dietary CLA may influence the hepatic antioxidant defense system as well as lipid metabolism in growing chickens.

Key Words: CLA, Antioxidant, Chicken

W47 Effect of early feed restriction on egg quality characteristics of Japanese quail. G. Contreras*, P. C. De la Rosa, C. B. Castro, J. J. Portillo, and F. G. Rios, *FMVZ-Universidad Autonoma de Sinaloa (Mexico, Carr. Culiacan-Mazatlan).*

One experiment was conducted to determine the effect of early feed restriction on egg quality characteristics of Japanese quail. The breeders were restricted in rearing during three weeks (two to five weeks old) at 0, 10, 20, and 30 %. After the feed restriction, the quails were allocated in two batteries with five levels, and each level with four cages. Each cage allocated six females and two males. Birds were fed a diet containing 21 % CP and 2.9 Mcal ME/kg. This size sample was determined by randomized sample with $B = 0.04$ (estimation error) and $\sigma^2 = 0.002$, resulting 20 eggs measurement for treatment each week. The data were analyzed in a complete randomly design, and comparison means by orthogonal polynomials. Egg weight, dense albumin height and width, was not affected ($P > 0.10$). Feed restriction increased ($P < 0.01$) egg width by 1.07 % (26.58 vs. 26.86 mm), egg yolk height by 2.8 % (9.67 vs. 9.94 mm) and egg albumin height by 5.6 % (4.56 vs. 4.8 mm). Feed restriction increased ($P < 0.01$) Haugh Units by 1.7 % (87.97 vs. 89.45), yolk index by 3.2 % (39.38 vs. 40.66), and shape index by 1 % (77.04 vs. 77.8). Shell weight and yolk width were different ($P < 0.01$) between feed restriction levels, 1.99 vs. 1.92, and 1.9 g (10 vs. 20 and 30 %), and 24.35 vs. 24.69 and 24.78 mm (10 vs. 20 and 30 %), respectively. It is concluded, than early feed restriction at 10, 20 and 30 % levels, modifies the egg quality internal characteristics of Japanese quail.

Key Words: Food Deprivation, Egg Quality, Coturnix coturnix japonica

W48 Effect of early feed restriction on productive performance and carcass characteristics of Japanese quail. C. B. Castro, G. Contreras*, F. G. Rios, and J. J. Portillo, *FMVZ - Universidad Autonoma de Sinaloa (Mexico) Carr. Culiacan-Mazatlan.*

This study was conducted to determine the effect of feed restriction (FR) during rearing period (two at five weeks old) on productive performance and carcass characteristics of Japanese quail. The experiment used sixty hundred Japanese quails (408 females and 192 males), two week old with an initial BW of 79.89 ± 8.2 g. Treatments consisted of: 1) Feeding ad libitum (FA); 2) FR 10%; 3) FR 20 %, and 4) FR 30%, during three weeks, and each treatment with three repetitions. Quails were allocated in metallic wire crates (1 x 1 x 0.6 m) and were fed a diet containing 28 % CP and 2.9 Mcal ME/kg (Codoestartina#8482, Purina Mills, Co.). Feed intake was recorder daily and quails were weighted at starter and weekly (five weeks old). Weight gain was calculated by crate. At end of experiment ten quails from each treatment were slaughtered and carcass traits measured. The data body weight and carcass components were analyzed a completed randomized design experiment. BW was similar ($P > 0.10$) with FA and FR 10 % (214.01 vs. 204.8 g) and diminished ($P < 0.05$) by 18 % with FR 30 % (214.01 vs. 175.16 g). FR 10% and FR 20% shown similar values (204.8 vs. 200.3 g). Carcass weight was similar with FA and FR 10% (128.16 vs. 119.26 g), but decreased ($P < 0.05$) by 10.8 % with FR 20% (128.16 vs. 114.36 g), and 26 % with FR 30% (128.16 vs. 94.87 g). Total lean weight was diminished ($P < 0.05$) by 29 % with FR 30% (77.07 vs. 54.48 g). Total fat weight was decreased ($P < 0.05$) by FR. Total bone weight was no affected ($P > 0.10$) by treatments (33.31 g). Its concluded than early

feed restriction of 10 % maintain the productive response and carcass characteristics of Japanese quail.

Key Words: Food Deprivation, Carcass Composition, Coturnix Coturnix Japonica

W49 Adding thymol to a broiler diet influences in vitro cecal fermentation and in vivo growth performances. A. Piva*, E. Grilli, G. Casadei, and G. Biagi, *DIMORFIPA - University of Bologna, Ozzano Emilia-Italy.*

Thymol and other essential oils have antimicrobial properties and may be considered among the alternatives to antibiotic growth promoters. We evaluated the effect of thymol in broiler in vitro cecal fermentations and broiler growth performances. In the in vitro study, broiler cecal inoculum was incubated for 24h in graduated syringes and vessels containing a standard predigested diet without or with thymol at 75, 150, 300, 600, 900, or 1200 ppm. Compared to control, total gas production was reduced by thymol at every concentration ($P < 0.01$), being almost completely inhibited by thymol at 900 and 1200 ppm. The rate of gas production was reduced only when thymol was used at 900 and 1200 ppm ($P < 0.01$). Ammonia concentration was lower than in control vessels ($P < 0.01$) at 4 h when thymol was used at 1200 ppm (-27%) and at 8 h with thymol at 600 (-20%), 900 (-25%), and 1200 ppm (-21%); at 24 h, thymol at 150 (+29%), 300 (+28%), and 900 ppm (+33%) resulted in higher ammonia than control ($P < 0.01$). In the vivo trial, 2160 female broilers (Ross 508) were divided immediately after birth into 4 groups (9 cages of 60 birds per group) and received a commercial diet with or without (control) the addition of thymol at 300, 600, or 900 ppm. Birds were fed ad libitum until the slaughtering age (39 d). Compared to control, the final live weight was higher when thymol was fed at 600 ppm (+2%) but lower when thymol was added at 300 (-5%) and 900 ppm (-2%; $P < 0.01$). Feed efficiency was lower in birds receiving thymol at 300 (-6%) and 900 ppm (-2%; $P < 0.01$) than in control birds. Daily feed intake and dressing out percentage were not influenced by thymol dose. Thymol influenced in vitro cecal fermentation, reducing total gas production and controlling proteolysis in the first 8 h of fermentation. Thymol at 600 ppm enhanced birds growth. Nevertheless, thymol had a negative effect on broiler growth and feed to gain ratio when used at 300 and 900 ppm.

Key Words: Broiler, Thymol, Essential Oils

W50 Palm fatty acid distillate calcium soap as vegetable fat source for broiler diets. J. Sánchez¹, A. Gutiérrez², J. I. Fernández³, D. Menoyo⁴, and P. Medel*¹, ¹*Imasde Agropecuaria, S.L., Spain*, ²*Nutreco PRRC, Spain*, ³*Norel, S.A., Spain*, ⁴*Universidad Complutense de Madrid, Spain.*

A total of 1,170 Ross broilers (50 % male and 50 % female) were used to determine the effect of inclusion of palm fatty acid distillate (PFAD) calcium soap in the diet on performance and carcass quality. There were three treatments based on fat source: T1) control diet including soya oil (4.8 %), T2) PFAD calcium soap (5.1 %) and T3) PFAD calcium soap + glycerol (5.1 %). Treatments were applied to both starter (2,975 kcal AME/kg and 1.32 % lys, from 0 to 21 d) and grower (3,050 kcal AME/kg and 1.18 % lys, from 22 to 42 d) diets, which were calculated to be isonutritive among treatments. Each treatment was randomly assigned to 10 pens of 39 broilers each. From 0 to 21 d, control chicks grew 3 % more and showed better feed conversion than animals on T2 and T3 (38.5, 36.8 and 37.9 g/d and 1.33, 1.39 and 1.39 g/g for T1 to T3, respectively; $P < 0.05$), but dietary treatment did not affect performance between 22 to 42 d. For the overall period, chicks on T3 ate 2.5 % more than chicks on T1 and T2 (110.2, 110.1 and 112.9 g/d for T1 to T3, respectively; $P < 0.05$), but broilers fed soya oil showed 3 % better feed conversion (1.72, 1.76 and 1.77 g/g for T1 to T3, respectively, $P < 0.05$). Animals fed T2 had lower BW and carcass weight than the others (2,688, 2,763 and 2,740 g and 2,165, 2,227 and 2,212 g for T1 to T3, respectively; $P < 0.05$) but carcass yield did not differ among treatments (80.6, 80.6 and 80.7 %, for T1 to T3, respectively; $P > 0.05$). It is concluded that i) PFAD calcium soap can be used as an alternative to soya oil, and ii) glycerol addition improves the feeding value of the PFAD calcium soap for broilers.

Key Words: PFAD Calcium Soap, Vegetable Fat Sources, Broilers

W51 Use of palm fatty acid distillate calcium soap as a vegetable fat source for broiler diets. M. I. Gracia*¹, A. Flores², J. I. Fernández³, J. Peinado¹, and C. López-Bote⁴, ¹*Imasde Agropecuaria, S.L., Spain*, ²*Nutreco PRRC, Spain*, ³*Norel, S.A., Spain*, ⁴*Universidad Complutense de Madrid, Spain.*

A total of 1,170 Ross broilers (50 % male and 50 % female) were used to determine the effect of inclusion of palm fatty acid distillate (PFAD) calcium soap on performance and carcass quality. From 21 to 42 d of age there were three treatments (T1 to T3) depending on the level of substitution of 4.8 % soya oil by PFAD calcium soap in fat basis: 0, 50 and 100 %, respectively. All the birds were fed with a common starter diet from 0 to 21 d (2,975 kcal AME/kg and 1.32 % lys) and the experimental treatments were applied in the grower period under isoenergetic basis (3,200 kcal AME/kg and 1.18 % lys). Each treatment was randomly assigned to 10 pens of 39 broilers each. At 21 d BW was similar for all groups (851 g; $P > 0.05$). From 22 to 42 d, chicks on T1 (soya oil) ate 4 % less than birds on T2 and T3 (162.4, 168.7 and 168.7 g/d for T1 to T3, respectively; $P < 0.05$) and grew less than T2 animals, showing birds on T3 intermediate results (87.5, 90.2 and 88.8 g/d for T1 to T3, respectively; $P < 0.05$). However, birds on T3 showed the worst feed conversion (1.86, 1.88 and 1.91 g/g for T1 to T3, respectively; $P < 0.05$). Consequently, animals on T2 showed higher BW and carcass weight (2,709, 2,756 and 2,724 g and 2,183, 2,227 and 2,194 g for T1 to T3, respectively; $P < 0.05$). However, carcass yield did not differ among treatments (80.8, 80.6 and 80.5 %, for T1 to T3 respectively; $P > 0.05$). It is concluded that PFAD calcium soap could partially or totally replace the soya oil with limited effects on performance.

Key Words: PFAD Calcium Soap, Vegetable Fat Sources, Broilers

W52 Processed Mucuna (*Mucuna pruriens*) seeds for broiler production. E. A. Iyayi* and M. Rodehutsord, *Institut für Ernährungswissenschaften, Halle, Germany.*

The ability of Mucuna (an unconventional plant protein source) to replace the conventional soy bean meal was the subject of this study since Mucuna seeds have recently been receiving attention as a potential feed for non-ruminants and food for man. Mucuna seeds were processed by dry heating (roasting) and milled. The meal was used to replace soy bean meal in a commercial broiler diet such that the diets had 0, 6, 12 and 18 g/kg of the roasted mucuna seed meal (RMSM). These levels corresponded to 0, 33.3, 66.7 and 100 % replacement of soy bean meal in the diets. Forty (40) one-week old broiler chicks were randomly allocated to each of the diets after their weights were equalized. Each diet had 5 replicates of 8 birds each. Incorporation of 6 g/kg RMSM in place of soy bean meal gave similar feed intake, body weight gain and efficiency of feed utilization in birds as the soy bean meal diet. But above this level (i.e. at 12 and 18 g/kg) these parameters were significantly ($P < 0.05$) depressed. At the 6 g/kg inclusion level, the weights of air sacs, small and large intestines and ceaca were reduced significantly ($P < 0.05$) while those of liver and spleen were significantly ($P < 0.05$) increased. Histological examination of the organs showed that the higher inclusion levels of RMSM caused various degenerative syndromes in the organs possibly as a result of the disruptive properties of the antinutritional factors in Mucuna when fed at higher levels. Results of the study showed that Mucuna when roasted can replace only a third of the amount of soybean meal in broiler diet. Above this level, Mucuna exerts a negative effect on the performance of the birds.

Key Words: Mucuna, Broilers, Performance

W53 Fat quality assessment of feed and pet food-grade poultry by-product meals. W. A. Dozier, III*¹, N. M. Dale², and A. F. Giesen³, ¹*USDA-ARS Poultry Research Unit, Mississippi State, MO*, ²*The University of Georgia, Athens*, ³*Novus International, Inc, St. Louis, MO.*

Poultry-by product meal (PBM) has long been a valuable protein source for poultry feeds. However, in recent years pet-food manufacturers have mandated to renderers that PBM be manufactured without "lower quality" by-product fractions, such as feathers, heads and paws. This has resulted in a higher protein "pet food-grade" product over conventional feed-grade PBM. It is presumed that the current "feed-grade" PBM is of lower quality and more variable, nutrient value, since the highest quality offal components have been diverted to pet food meals. In addition,

information is limited on the variation of fat quality between pet food and feed-grade PBM sources.

Forty-six PBM samples (25 = feed grade and 21 = pet food grade) were collected from commercial feed mills located in DE, GA, NC, SC, and VA during the winter and summer months of 2003. Sub-samples were analyzed for Initial Peroxide (IPV) (meq/kg), 4 and 20-hr active oxygen method peroxides (AOM) and Ethoxyquin (ppm). Average fat quality measurements for the Pet Food and Feed Grade PBM by season are shown below with their respective STD. The seasonal effect of high temperatures was apparent with extent of fat oxidation, regardless of PBM source. In those samples obtained in the winter, which had similar antioxidant content, the feed-grade samples were characterized by poorer fat stability. In the samples received in summer, when higher temperatures would be expected to negatively affect stability, the residual antioxidant present in the pet food meals was less than half that found in the feed-grade samples (64 vs. 164 ppm). All indicators of fat stability showed increased potential for rancidity in these pet food-grade samples, confirming that the highly unsaturated poultry fat in PBM requires adequate concentrations of antioxidant protection, even when meals are derived from prime offal components.

PBM	Season	IPV (meq/kg)	4-hr AOM (meq/kg)	20-hr AOM (meq/kg)	ETH (ppm)
Pet Food					
Grade	Winter	3.3±8.1	2.1±3.7	1.2±1.1	138.8±142.9

W54 Influence of boiling, Biogen or spices mixture to Mangrove leaves on performance of egg type pullets. A. Eldeek* and M. Al-Harhi, *King Abdulaziz University, Faculty of Meteorology Environmental and Arid Land Agriculture, Jeddah, Saudi Arabia.*

450 Lohmman Egg strain female chicks were randomly distributed to 15 dietary treatments each contained 3 replicates of 10 pullets and 3 levels of Mangrove leaves (ML) (0, 5 and 10%), which was included as raw or boiled for 15 minutes. Therefore, there were 5 main isocaloric and isonitrogenous experimental diets. Each diet was fed with or without Biogen or a spice mixture (SM) (1:1:1) of cardamom, cumin, hot and black pepper supplementation. ML had no adverse effect on pullets growth, feed consumption (FC), feed conversion ratio (FCR) and mortality rate during 8-20 wks of age. However, including 10% of ML in pullet diets significantly increased FC of ML and increased water consumption significantly. Boiling treatment increased significantly growth and improved FCR of pullets by 3% and did not significantly affect FC. Boiling treatment significantly increased water consumption by 11.9%. Biogen or SM had no enhancing effect on growth and FC of pullets; however FCR and water consumption tended to improve insignificantly due to addition of Biogen and SM with spices being more effective. ML at 5 and 10% resulted in 16.7 and 31% reduction in laying rate, egg mass and FCR, respectively. The improvements in egg laying rate due to Biogen and SM equaled 11.7, 11.5, 19 and 17.4% for groups fed diet containing 5 and 10% ML, respectively with egg mass and FCR following a similar trend. SM increased egg weight significantly compared to the control and Biogen groups. SM significantly decreased weight and percentage of ovary and only weight of oviduct, while increased the weight and percentage of spleen. ML had no adverse effect on interior quality of eggs stored for 8 weeks in the fridge. In conclusion, ML could be included in the pullet and laying diets at 5% when supplemented with SM without adversely affecting performances.

Key Words: Mangrove Leaves, Feed Additives, Spices

W55 Effects of Hippophae Rhomnoides fruit extract supplementation on egg quality and performance of layers in the wheat-based diet. F. Liu*, J. Fu, and Z. Niu, *North-west sci-tech university of agriculture & forestry, Yangling, China.*

The objective of this experiment was to evaluate the effect of a natural pigment additive (AY) extracted from Hippophae Rhomnoides fruits on egg quality and performance of laying hens in the wheat-based diet. 480 Lohmann commercial layers at 53 weeks of age were divided into five groups, each of three replicates. The diets were based wheat-soybean meal supplemented with 0.0%, 0.5%, 1.0%, 2.0%, 4.0% resp.. The birds were reared in cages for 21 days. The results showed that: (1) The RFC value was significantly improved when AY in diet was more than 1.0% ($p < 0.05$), and achieved 6.6 at AY 4.0%. L-value was decreased with increase in level of AY ($p < 0.01$), but both a-value (red) and b-value (yellow) were significantly increased ($p < 0.01$). (2) The carotenoid content in egg yolk was linearly increased with the level of AY in the diets ($p < 0.01$), but the concentration of cholesterol was significantly reduced ($p < 0.05$). (3) There were no significant influences of addition of AY on laying rate, egg size, egg mass, feed intake, and feed conversion of laying hens in the wheat-based diet ($p > 0.05$).

Key Words: Natural Pigment Additive, Egg Quality, Laying Hen

W56 The effects of inclusion of a fermented fish by product meal in Guinea fowl (*Numida meleagris*) diets on performance and carcass quality. M. Argüelles*, H. L. Santiago, and A. A. Rodríguez, *Department of Animal Science, University of Puerto Rico - Mayaguez Campus, Mayaguez.*

Guinea fowl (*Numida meleagris*) is a poultry species suitable for use in meat production to expand and diversify the local poultry industry due to its consumer acceptance, resistance to common poultry diseases, and tolerance to poor management conditions. However, the poor feed conversion of this species increases feed costs and limits production. To reduce feed costs it is imperative to find feedstuffs of low cost but with adequate nutritional value. The use of a fermented fish by-product meal (FFBPM) as a protein source in guinea diets could satisfy these criteria and reduce feed costs. The objective of this study was to evaluate the effects of the inclusion of a FFBPM in guinea diets on bird performance and carcass quality. Treatments consisted of FFBPM inclusion at 0 (control), 5, and 10% in each of the starter, grower, and finisher rations. Feed and birds were weighed at 0, 35, 63, and 84 d to determine body weight (BW) and feed conversion (FC). At 84 d, 90 birds were processed to evaluate carcass composition and to determine yields of carcass and major cuts. Their fasted live BW, plucked and dressed carcass weights were recorded and yields calculated. No differences in BW were observed among treatments at 0, 63, and 84 d. At 35 d BW was lower ($P < .05$) in birds with a 10% FFBPM inclusion. FC was also higher with 10% FFBPM and lower in control birds, while those receiving 5% FFBPM did not differ from the other treatments. Birds fed 10% FFBPM showed lower ($P < .05$) live, plucked, and dressed weights than control and 5% FFBPM birds. No differences ($P = .05$) among treatments were observed in yields of dressed carcass, major cuts, and the proportion of flesh, skin, and bone. However, the percentage of abdominal fats was lower ($P < .05$) in birds fed a 10% FFBPM when compared to the control and 5% FFBPM level. The results of this study indicate that the inclusion of up to 5% FFBPM in guinea diets has no detrimental effect on bird performance and carcass quality. Thus, FFBPM could be a valuable feed ingredient to supply part of the dietary protein requirements of guinea fowl.

Key Words: Guinea Fowl, Growth, Fermented Fish

W57 Inclusion of coconut meal in broiler initial diets. S. Bastos, M. de F. Fuentes*, and E. Freitas, *Universidade Federal do Ceará Departamento de Zootecnia, Fortaleza, CE, Brazil.*

Coconut meal (CM) is considered an alternative to soybean meal as a protein ingredient for animal feed. The objective of this work was to evaluate the performance of broiler in the initial period (7 to 21 days of age) fed diets containing different levels of CM. 576 broilers males from a commercial line with seven days of age and similar body weight were distributed at random among six treatments with eight replicates of twelve birds each. Treatments consisted of six diets containing 0; 3.5;

7.0; 10.5; 14.0 and 17.5% of CM. Diets were based on corn and soybean meal and were isoproteic (21% CP) and isocaloric (2950 kcalME/kg). Regression analysis excluding diet with 0% of CM showed that feed intake ($y = 1047 - 0.004x$; $R^2 = 24.67$) and weight gain ($y = 684.89 - 7.20x$; $R^2 = 68.57$) decreased linearly as CM increased in diets. However for feed conversion there was a quadratic effect ($y = 1.66 - 0.02x + 0.002x^2$; $R^2 = 53.75$) and 5% was the maximum level of CM inclusion according to this variable. In relation to diet without CM, Dunnett's test (5%) indicated that all levels of CM used reduced weight gain and feed conversion. These results can be attributed in part to the high fiber content of CM, which lowered feed consumption and nutrient absorption by birds. It can be concluded that CM can be included in levels up to 5% in diets for broilers with 7 to 21 days of age.

Key Words: Coconut Meal, Weight Gain, Feed Intake

W58 Pea, Faba beans and Lupin as an alternative protein source in broiler diet. M. Moschini¹, F. Masoero¹, A. Prandini¹, M. Morlacchini², G. Fusconi², and G. Piva¹, ¹Università Cattolica del Sacro Cuore, del Sacro Cuore Via Emilia Parmense, Piacenza, Italy, ²CERZOO, San Bonico, Piacenza, Italy.

The problems of meat and bone meal and transgenic feeds poses a challenge to animal nutritionist in Europe. The challenge is to find home-grown protein-rich feedstuffs, making sure no antinutritional factors are present that could interfere in the animals' performance. The raw Pea (*Pisum sativum*) (RP), raw Faba beans (*Vicia faba*, variety minor) (RFb) and raw Lupin (*Lupinus albus*, variety multitalia) (RL) were evaluated as an alternative protein sources in broiler diets. 630 Ross 1 d-old male Marek vaccinated chicks were randomly assigned to seven dietary treatments (5 pens per treatment/18 birds per pen). Chicks were floor housed, ad libitum fed isocaloric and isonitrogenous diets and had free access to water. Artificial light was provided 10 h/d. The bulk of the base diet (control diet) was corn (48.7%, 56.6% and 57%), solvent-extracted soybean meal (42.8%, 37.3% and 33.4%), corn oil (4.4%, 5.2% and 6.3%), plus synthetic amino acids, minerals, trace minerals and vitamins, respectively for the 1-10 d-old, 11-28 d-old and 29 to 42 d-old growing periods. The RP, RFb and RL entered the diets in substitution of the soybean and corn according to the cost optimization in diet formulation (P100, Fb100 and L100, respectively for RP, RFb and RL) and at the half of the optimized quantity (P50, Fb50 and L50, respectively for RP, RFb and RL). The amount used as fed basis were: P100: 350 g/kg for all diets; Fb100: 480 g/kg (1-10 d-old) and 500 g/kg (11-42 d-old); L100: 360 g/kg (1-10 d-old) and 300 g/kg (11-42 d-old). At the end of the trial (42d) the percentage yields of breast meat and leg quarters were measured in one animal for each experimental unit for all treatments. Bird mortality was recorded daily and dead birds were removed and weight was recorded. The pen average daily intake (ADI) and average daily gain (ADG) were calculated and adjusted feed to gain ration (F:G) was obtained. The ADG, ADI, F:G, breast yield and leg quarter were not statistically affected by the treatment diets. Data suggest partial substitution of soybean with RP, RFb or RL had no effect on animal performance and could represent an alternative valuable protein source in broiler diet formulation.

W59 Influence of a paprika extract supplementaion on egg yolk color and performance of laying hens. Z. Niu*, J. Fu, and F. Liu, College of Animal Science & Technology, Northwest Sci-Tech University of Agriculture & Forestry, Yangling, China.

This experiment was conducted to evaluate the effects of AR(pigment additive extracted from paprika) on egg yolk color, and laying performance of hens in a wheat-based diet. 480 Lohmann commercial layers at 53 weeks of age were divided into 5 groups, each of 6 replicates, to feed for 21 days. The experimental diets were based on wheat-soybean meal supplemented with 0%, 0.1%, 0.2%, 0.4%, 0.8% AR resp.. The results showed that: (1) AR caused an increase in egg yolk pigmentation. RFC

achieved 9.9 when added 0.8% AR in diet. (2) with an increase in adding AR from 0 to 0.8%, a-value (red) increased quickly ($p < 0.01$), L-value decreased largely ($p < 0.05$), and b-value reduced slightly ($p > 0.05$). (3) The total carotenoids deposition in egg yolk showed a proportionally greater increase with increasing AR level in diet. There were no significant influence of AR supplementation on laying rate, egg size, and feed conversion of hens.

Key Words: Paprika Pigment, Egg Yolk Color, Laying Hen

W60 Fermenting sludge from a broiler processing plant: Effect of inoculation with lactic acid-producing bacteria. S. Pagán*, R. Sanabria, A. A. Rodríguez, and M. Pagán*, University of Puerto Rico - Mayaguez Campus, Department of Animal Science, Mayaguez.

The effects of adding a commercial lactic acid-producing bacterial inoculant (LAPBI) on the fermentation characteristics of sludge from a broiler processing plant (SBPP) was determined. The SBPP was mixed with 20% (w/w) cane molasses and assigned to two treatments: no additive (control) and LAPBI applied at 106 cfu/g of fresh material. Mixtures were placed in lab micro-silos (1.2 kg capacity) under anaerobic conditions and maintained at room temperature (28-30°C). Three samples per treatment were collected after 0, 4, 8, 12, 15 and, 21 d and analyzed for pH, chemical composition, microbial succession and fermentation products. Data was analyzed as a completely randomized design with a 2 (with or without LAPBI) x 6 (fermentation periods) factorial arrangement of treatments. The Bonferroni t-test was used for mean separation. Final pH of SBPP fermented with or without LAPBI was similar ($P < .05$, 3.8 vs 3.87) after 21 d of fermentation. For both treatments, coliforms and lactic acid producing bacteria populations were similar ($P < .05$) at the end of the fermentation process, but yeast and molds were higher ($P < .05$) in SBPP with LAPBI. Chemical composition of the final product indicates no differences between treatments. Lactic and acetic acid content were higher ($P < .05$) in non inoculated sludge compared to sludge with LAPBI. However, for both treatments values for lactic acid at the end of fermentation were indicative of good quality silage. In summary, utilization of LAPBI may not be necessary to ferment SBPP with cane molasses to obtain a stable product.

Key Words: Lactic Acid-Producing Bacteria, Sludge, Anaerobic Fermentation

W61 Assessment of essential oils as potential substitutes for dietary antibiotics. W. Si¹, J. Gong¹, R. Cao¹, T. Zhou¹, H. Yu¹, C. Poppe², R. Johnson², and W. Du³, ¹Food Research Program, Agriculture and Agri-Food Canada, Guelph, Ontario, ²Laboratory for Foodborne Zoonoses, Health Canada, Guelph, Ontario, ³Ontario Ministry of Agriculture and Food, Guelph, Canada.

The concerns over the use of antibiotics in-feed and their contribution to the development of antibiotic resistance have stimulated research in developing antibiotic-replacement. Some essential oils have demonstrated strong antimicrobial activity. In this study, *Salmonella typhimurium* DT104, *E. coli* O157:H7 and K88 were used as target pathogens to evaluate the effect of essential oils. Among 66 essential oils and related chemicals, 14 exhibited more than 80% inhibition against both pathogens. Minimum Inhibitory Concentrations were determined for 9 essential oils/compounds. Cinnamon, clove, geraniol, and thymol were most potent against both pathogens. The effect of the essential oils/compounds on the isolates of beneficial bacteria, such as *Lactobacilli*, was also examined. No significant inhibition was observed. The influence of selected essential oils on the normal gut flora and their potency to inhibit the target pathogens in the presence of digesta are under investigation. Our in vitro assessment suggests the potential of essential oils and related chemicals as the substitutes for dietary antibiotics although in vivo studies are required to verify our in vitro observations

Key Words: Essential Oil, *E. Coli*, *S. Typhimurium*

Nonruminant Nutrition: Feedstuffs & Methodology

W62 Comparison of classical and marker method, using three different markers and two analytical techniques, for the measurement of apparent digestibility in swine. L. L. Oetting*¹, A. L. Abdalla¹, J. D. F. Gomes², A. R. A. Nogueira³, and C. E. Utiyama¹, ¹Universidade de São Paulo, Piracicaba-SP, Brazil, ²Universidade de São Paulo, Pirassununga-SP, Brazil, ³Empresa Brasileira de Pesquisa Agropecuária-Centro de Pesquisa de Pecuária do Sudeste, Sao Carlos-SP.

Use of markers for the measurement of digestibility is a less intensive labor method than total fecal collection. Little is known about the use of rare earth as dietary markers in digestibility assays with swine. The aim of this work was (1) to compare the digestibility coefficient obtained by the classical method (CM) with the marker method (MM), using three dietary markers simultaneously: chromium (Cr), lanthanum (La) and ytterbium (Yb), and (2) to compare two analytical techniques (Inductively Coupled Plasma Atomic Emission Spectrometry - ICP-OES, and Energy Dispersive X-Ray Fluorescence - ED-XRF) of marker analysis. Twelve finishing gilts were housed in individual metabolism crates. The experimental diet consisted of a corn-soybean meal diet added with 0.3% of Cr and 60 mg/kg of La and Yb. Comparison between the digestibility coefficients (DC) of gross energy (GE), dry matter (DM) and crude protein (CP) are shown below. There were differences between analytical techniques in determination of Cr and La. Comparison between the MM with the CM showed that Cr+ICP-OES and La+ED-XRF provided similar results ($P>0.01$) for energy and protein digestibility coefficients. The differences between the two methods can be explained by the low percentage of recovery of the markers in feces (80.97, 66.38, 57.43, 58.22, 82.32 and 46.19% for Cr+ICP, La+ICP, Yb+ICP, Cr+ED, La+ED and Yb+ED, respectively). It can be suggested that La+ED-XRF can be an alternative marker for Cr in digestibility studies with swine and it can be used at lower concentrations without affecting accuracy.

(%)	Classical method	Cr+ICP -OES	La+ICP -OES	Yb+ICP -OES	Cr+ED -XRF	La+ED -XRF	Yb+ED -XRF	SE
GE	87.27	87.07	83.77	80.91	81.65	87.01	84.36	1.09
DM	90.55	86.43	82.98	79.97	80.75	86.37	83.58	1.02
CP	85.58	85.36	81.61	78.38	79.24	85.30	82.29	1.27

Key Words: Apparent Digestibility, Swine, Rare Earth

W63 Comparison of the single dose and withdrawal method for measuring the rate of passage of swine basal diets using multiple markers and alternative analytical techniques. L. L. Oetting*¹, A. L. Abdalla², J. D. F. Gomes³, A. R. A. Nogueira⁴, and C. E. Utiyama¹, ¹Escola Superior de Agricultura "Luiz de Queiroz" da Universidade de So Paulo, Piracicaba-SP, Brazil, ²Centro de Energia Nuclear na Agricultura da Universidade de So Paulo, Piracicaba-SP, Brazil, ³Faculdade de Zootecnia e Engenharia de Alimentos da Universidade de So Paulo, Pirassununga-SP, Brazil, ⁴Empresa Brasileira de Pesquisa Agropecuária - Centro de Pesquisa de Pecuária do Sudeste, Sao Carlos-SP, Brazil.

There are few studies on the determination of the rate of passage of diets in swine. Multiple markers can be used simultaneously to determine different rates of passage in the same animal. Rare earth elements offer some advantages in terms of cost, quantitative analyses and total recovery in faeces. Four finishing gilts were used to determine the rate of passage by single dose and withdrawal method of a basal diet (corn-soybean meal) using the combination of the three markers (chromium, lanthanum and ytterbium) and two analytical techniques: Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-OES) and Energy Dispersive X-Ray Fluorescence (ED-XRF). The Cr was added directly to the diet, but the La and Yb were primarily incorporated to the maize. In the withdrawal method, the markers were administered in diet for 5 d and then were withdrawn. The concentration of markers in faeces was transformed to their natural logarithmic values and simple regression analysis was performed to establish the relationship between the natural log of marker concentration with time. The slopes of the regression lines ("b"), which represents the rate of marker disappearance, were compared for both methods and each marker by Tukey's test. There were no statistical differences between the two methods, with exception for the treatment Cr+ICP-OES. The mean of the slopes of the regression lines for Cr+ICP-OES, Cr+ED-XRF, La+ICP-OES,

La+ED-XRF, Yb+ICP-OES and Yb+ED-XRF was 0.087, 0.086, 0.021, 0.049, 0.032 and 0.046 (SE=0.015), respectively. The difference in the rate of passage found for La and Yb, in relation to Cr, was, probably, a result of the lower rate of passage of the maize in relation to the diet.

Key Words: Swine, Rate of Passage, Rare Earth

W64 International Life Sciences Institute crop composition database: documenting natural variability in crop composition. W. P. Ridley*¹, R. D. Shillito², and L. Kurtyka³, ¹Monsanto Company, St. Louis, MO, ²Bayer CropScience, Research Triangle Park, NC, ³International Life Sciences Institute, Washington DC.

An understanding of the natural variability in nutrient composition of maize and soybeans is an important consideration in the development of diets that promote the healthy growth of swine, poultry, beef cattle and other livestock animals. Most existing publicly available crop composition data sources have relied on data that were 20 or more years old. In many cases the methods used for the generation of these data were not known or their performance parameters were not available. In May 2003, the International Life Sciences Institute (ILSI) released Version 1.0 of an online comprehensive crop composition database (www.cropcomposition.org) that provides up-to-date information on the natural variability in the composition of conventional crops. The database is a compilation of over 53,000 data points on 102 nutritionally important analytes for maize and soybean samples obtained from controlled field trials in multiple worldwide locations between 1995 and 2001. All data can be traced back to their source and every data point is identified with its analytical method. The database is searchable, via a web-browser-based interface, on a number of attributes including analyte, matrix, year of harvest and field location. Information about the database has been shared with regulators, scientific/academic institutions, FAO, OECD, other ILSI task forces, and the US National Academy of Sciences. The ILSI Task Force responsible for the database plans to release Version 2.0 in the spring of 2004 that will contain over 70,000 data points and include data for cottonseed plus additional data sets for maize and soybeans.

Key Words: Crop Composition, Nutrients, Crop Composition Database

W65 Comparison of corn grain from biotech and non-biotech counterparts for grow-finish pig performance. H. H. Stein*¹, T. Sauber², D. Rice², M. Hinds², D. Peters¹, G. Dana², and P. Hunst³, ¹South Dakota State University, Brookings, ²Pioneer Hi-Bred International Inc., Johnston, IA, ³Dow AgroSciences LLC, Zionsville, IN.

An experiment with 96 growing pigs (initial BW 23.5 kg) was conducted with the objective of testing the hypothesis that the inclusion of a genetically modified corn in diets for swine does not compromise pig performance or carcass quality. Four corn sources were used in the experiment. Corn 1 was bin-run obtained from the SDSU feed mill. The remaining three corns were obtained from Pioneer Hi-Bred International Inc. Corn 2 was grain produced from hybrid Pioneer[®] brand 33J56, corn 3 was grain produced from hybrid Pioneer[®] brand 33P66, while corn 4 was grain produced from hybrid Pioneer[®] brand 33P66 containing the TC1507 event. TC1507 is an event that contains the Cry1F gene from *Bacillus thuringiensis* var. azawai. This gene encodes the Cry1F protein that has been shown to have insecticidal activity towards several insects including European corn borer and black cutworm. The trade name for this corn is Herculex#8482 I. This trait was developed through collaboration between Pioneer Hi-Bred International, Inc. and Dow Agrosciences LLC. Diets based on each of the four corns were formulated using a single source of soybean meal. Pigs were assigned to four different treatment groups at approximately 23.5 kg based on ancestry, gender, and BW. There were three pigs per pen and eight replicate pens per treatment. A three phase feeding program was used with diets containing 1.0, 0.8, and 0.63% LYS within each phase. At 120 kg BW, pigs were harvested and carcass measurements recorded. During the first phase of the experiment, pigs fed the diet based on corn 3 had greater ($P \#8804 0.05$) ADFI than pigs fed the other corns, however, there were no treatment differences in ADG or G:F. During the second and third phases and overall, no differences in ADG, ADFI, or G:F were observed. Likewise no differences in dressing percentage, 10th rib back fat, loin-eye area, fat

free lean, or lean meat percentage were detected. It is concluded that no negative effects on pig performance, dressing percentage, or carcass quality are associated with the use of corn produced from seed containing the Herculex#8482 I trait.

Key Words: Genetically Modified Corn, Performance, Pigs

W66 Digestive fate of a *gdhA* gene from a genetically modified corn fed to growing pigs. X. Qiu*¹, G. A. Appgar¹, K. E. Griswold², J. M. Beagle¹, M. P. Martin¹, K. L. Jones¹, M. J. Iqbal¹, and D. A. Lightfoot¹, ¹*Southern Illinois University, Carbondale*, ²*Penn State University Extension, Lancaster*.

Eight female PIC pigs (initial BW, 47.5 ± 1.8 kg) with an additional all-time negative control pig were utilized in a two period switchback design to evaluate the digestive fate of a transgenic corn. Pigs were fed diets comprised primarily of a genetically altered corn or a non-altered isogenic corn grown in the same locations. The genetically altered corn (*gdhA*+) contained a glutamate dehydrogenase gene isolated from *Escherichia coli*. Pigs were surgically fitted with steered ileo-cecal valve cannulas for collection of ileal digesta. Pigs were limit fed at 8% of metabolic body weight (BW^{0.75}), in two equal feedings at 0600 and 1800 each day throughout the experiment. The study consisted of two 15-d periods. Each period was comprised of a 7-d acclimation period, a 3-d total collection of feces and urine, and two 12-h ileal collections separated by a 3-d adjustment period to assure adequate hydration. Samples of corn, diets, ileal digesta and feces were frozen immediately upon collection. Total genomic DNA was extracted, underwent PCR, and was visualized using agarose gel electrophoresis. Primers were designed to yield a 456 bp PCR product expanding from a rice-ubiquitin gene to the *gdhA* gene within the transgenic cassette. These primers were selected to eliminate the potential of replicating the *gdhA* gene from resident gastrointestinal tract bacteria. While the PCR product was detected from *gdhA*+ corn, *gdhA*+ diets, and even a mixture of the two corn sources containing only 1% *gdhA*+ corn, it was not detected from *gdhA*- corn or diets, or from ileal digesta or feces of any pigs, no matter if they were fed *gdhA*+ or *gdhA*- diets. In conclusion, the recombinant DNA fragment from *gdhA*+ corn appears to be digested and is not detected by regular PCR analysis.

Key Words: *gdhA* Gene, Genetically Modified Corn, Pigs

W67 Herbicide-tolerant rice versus conventional rice in diets for growing-finishing pigs. G. L. Cromwell*¹, B. J. Henry², and D. W. Fletcher³, ¹*University of Kentucky, Lexington*, ²*Bayer CropScience LP, Research Triangle Park, NC*, ³*Genesis Midwest laboratories, Neillsville, WI*.

Genetically-modified (GM), herbicide-tolerant rice (LibertyLink[®], event LLRICE62), a near-isogenic (NI) conventional medium-grain rice, and a commercial long-grain, brown rice (CM) were assessed in diets for growing-finishing pigs. The GM and NI rice were grown in year 2001 under similar agronomic conditions. The GM rice was from fields treated (GM+) or not treated (GM-) with Liberty[®] herbicide. The GM+, GM-, NI, and CM rice were similar in composition (DM: 86.4, 85.5, 86.1, 86.6%; CP: 9.7, 10.3, 9.0, 9.2%; NDF: 3.5, 3.9, 3.6, 3.6; ADF: 1.4, 1.6, 1.9, 2.0%; Fat: 2.6, 2.7, 2.6, 3.4%; P: 0.33, 0.37, 0.32, 0.37%; lysine: 0.34, 0.36, 0.33, 0.33%; GE: 3.81, 3.82, 3.78, 3.94 Mcal/kg). Pigs (n = 96) were fed fortified rice-soybean meal diets containing the four rice grains from 25 to 106 kg BW. Diets contained 0.99% lysine initially, with lysine reduced to 0.80 and 0.65% when pigs reached 51 and 77 kg. The rice in diets was constant during each of the three phases (72.8, 80.0, 85.8%). There were six pen-replicates (three pens of barrows, three pens of gilts) and four pigs per pen. All pigs were killed at termination for carcass data. ADG, ADFI, and feed:gain were not different (P > 0.05) for pigs fed the GM vs conventional rice diets (0.86, 0.79, 0.81, 0.85 kg/d; 2.41, 2.49, 2.37, 2.45 kg/d; 2.80, 3.17, 2.95, 2.89 for GM+, GM-, NI, and CM rice, respectively). Carcass traits (adjusted for final BW) were not different (P > 0.10) among treatments (hot carcass yield: 73.5, 72.6, 72.6, 73.2%; 10th rib backfat: 23.0, 22.7, 21.3, 23.8 mm; longissimus area: 38.6, 38.0, 38.2, 38.1 cm²; estimated carcass fat-free lean: 50.5, 50.5, 51.2, 50.0%). Gilts grew slower (P < 0.01) and were leaner (P < 0.05) than barrows. Responses to type of rice were similar for the two genders with no evidence of a diet x gender interaction (P > 0.15) for any trait. The results indicate that the genetically-modified,

herbicide-tolerant rice was similar in composition and nutritional value to conventional rice for growing-finishing pigs.

W68 Ultrastructural-chemical makeup of canola seed tissues explored with synchrotron reflection FTIR microspectroscopy: A preliminary study. P. Yu*¹, J. J. McKinnon¹, R. W. Newkirk², C. R. Christensen³, and D. A. Christensen¹, ¹*College of Agriculture, University of Saskatchewan, Saskatoon, Canada*, ²*Canadian International Grains Institute, Winnipeg, Canada*, ³*Canadian Light Source, Saskatoon, Canada*.

The objective of this study was to use synchrotron reflection FTIR microspectroscopy to explore the chemical makeup (functional group and bonding characteristics) of ultra-structural tissues of yellow (*Brassica Rapa* cv. Klondike) and brown-seeded (*Brassica Napus* cv. Bounty) canola. The investigated chemical bonding and functional groups included the NH&OH group with a broad band at 3298, CH groups (CH₃-asymmetric stretch at 2961; CH₂-asymmetric stretch at 2925; CH₃-symmetric stretch at 2871; and CH₂-symmetric stretch at 2853), amide I at 1650, carbonyl C=O ester stretch at 1740, and hemicellulose at 1240 and total carbohydrates (CHO) at ca. 1180-900 cm⁻¹ as well as their ratios. The results showed IR absorbed intensities (absorbance unit) of CH₃-asymmetric stretch of 0.060 and 0.056; CH₂-asymmetric stretch of 0.090 and 0.087; CH₃-symmetric stretch of 0.052 and 0.048; and CH₂-symmetric stretching of 0.045 and 0.043 for the yellow- and brown-seeded canola, respectively. The ratios of total CH₂:CH₃, CH₃-asymmetric:CH₃-symmetric, CH₂-asymmetric:CH₂-symmetric and total CH-asymmetric:CH-symmetric were 1.06 and 1.13, 1.28 and 1.26, 2.90 and 3.08, 1.82 and 1.78, for the yellow- and brown-seeded canola, respectively. The absorbed intensities (absorbance unit) of the peak area of the NH&OH, total CH, carbonyl C=O, amide I, hemicellulose, and total CHO were 101.623 and 87.123; 8.522 and 7.406; 0.387 and 0.414; 39.200 and 31.045; 1.445 and 1.329; 36.450 and 24.199 for the yellow and brown-seeded canola, respectively. The above results indicate the two varieties are potentially different in terms of ultrastructural-chemical makeup. The results also highlight the fact that synchrotron based reflection FTIR microspectroscopy can be used to determine the microstructural chemical bonding and functional group characteristics of canola tissue. Such information can be used for canola breeding programs for selecting superior varieties of canola for both oil and feed purposes and for prediction of canola quality and nutritive value for humans and animals.

Key Words: Synchrotron Infrared Microspectroscopy, Ultrastructural-Chemical Makeup, Canola

W69 Proximate and amino acid composition in different sources of rice bran for pigs. C. Kaufmann¹, W. Sauer¹, M. Cervantes*², M. Rademacher³, and J. He¹, ¹*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada*, ²*Instituto de Ciencias Agrícolas, Universidad Autónoma de Baja California, Mexicali, BC, Mexico*, ³*Degussa-Huls AG, Hanau-Wolfgang*.

A study was conducted to determine the proximate and amino acid (AA) composition of five samples of rice bran (RB), as well as the relationship between their crude protein and AA content. Five different sources of RB were evaluated: RB 1, Canadian source; RB 2, Riceland Foods Inc., Stuttgart, AR; RB 3, Agribands International, Italy; RB 4, North Luzon Region, Philippines; and RB 5, Agribands/Tradico, Greenville Feed Facility, Greenville, MS. The contents of crude fat (CF), NDF, ash, and CP in RB 1, 2, 3, 4, and 5 were (%): 23.4, 4.1, 24.4, 5.4, and 20.7; 26.4, 26.0, 34.3, 2.1, and 25.5; 21.0, 12.7, 11.0, 4.8, and 16.3; 15.6, 21.0, 15.8, 13.6, and 18.1, respectively. There were considerable variations in the contents of CF, NDF, ash, and CP. The indispensable AA composition (%) in RB 1, 2, 3, 4, and 5 were: Arg, 1.32, 1.73, 1.29, 0.99, and 1.45; His, 0.44, 0.61, 0.44, 0.34, and 0.50; Ile, 0.51, 0.68, 0.56, 0.44, and 0.59; Leu, 1.05, 1.38, 1.14, 0.94, and 1.22; Lys, 0.69, 0.88, 0.75, 0.45, and 0.76; Met, 0.30, 0.40, 0.33, 0.31, and 0.34; Phe, 0.65, 0.86, 0.71, 0.60, and 0.76; Thr, 0.56, 0.75, 0.62, 0.46, and 0.65; Val, 0.80, 1.04, 0.87, 0.64, and 0.89; Trp, 0.20, 0.28, 0.20, 0.17, and 0.22, respectively. Arg and Leu were the most abundant indispensable amino acids in RB, whereas His, Met, and Trp were the least abundant. The relationships between the content of CP (Y) and each AA (X) were: Arg, Y = 0.0825 - 0.1958X (R² = 0.96); His, Y = 0.0308 - 0.1088X (R² = 0.98); Ile, Y = 0.0271 +

0.0347X ($R^2 = 0.96$); Leu, $Y = 0.0502 + 0.1611X$ ($R^2 = 0.97$); Lys, $Y = 0.0449 + 0.134X$ ($R^2 = 0.79$); Met, $Y = 0.0114 + 0.1025X$ ($R^2 = 0.85$); Phe, $Y = 0.0298 + 0.1259X$ ($R^2 = 0.97$); Thr, $Y = 0.0324 + 0.0104X$ ($R^2 = 0.93$); Val, $Y = 0.0439 + 0.0085X$ ($R^2 = 0.91$); Trp, $Y = 0.0116 + 0.0093X$ ($R^2 = 0.96$). There was a linear increase in the content of all AA as the content of CP increased ($P < 0.05$). This study shows that there is considerable variation in the proximate and AA composition in the RB. This also indicates that the AA content in RB can be predicted on the basis of its CP content.

Key Words: Pigs, Rice Bran, Amino Acid Digestibility

W70 Maturity zone effects on composition of soybean meals sampled from 55 U.S. processing plants. L. K. Karr-Lilienthal*, C. M. Grieshop, J. K. Spears, and G. C. Fahey, Jr., *University of Illinois, Urbana.*

Variation in soybean meal (SBM) composition can affect nutrient digestibility of SBM by swine. To quantify variation in U.S. SBM, samples were collected from 55 U.S. processing plants three times at two week intervals (sampling times 1, 2, or 3). These samples were analyzed for crude and acid hydrolyzed fat as well as oligosaccharide and amino acid concentrations. Comparisons were made among SBMs according to maturity zone (1-7) where the SBMs were prepared and sampling times (1-3). Acid hydrolyzed fat concentrations were 1.5 to 3.3 times higher than crude fat concentrations, were greatest ($P < 0.05$) at the second sampling time, and increased for processing plants located in the southern U.S. (3.9 to 4.3% for zones 1 and 7, respectively). Oligosaccharide concentrations varied depending on sampling time and maturity zone. Raffinose concentrations decreased ($P < 0.05$) over time from 12.66 to 11.92 mg/g and verbasco concentrations were lowest for collection 3 (1.70 vs. 1.90 mg/g for collections 1 and 2), while stachyose concentrations increased over time from 51.78 to 53.52 mg/g. Concentrations of stachyose were highest for SBM prepared in zones 3 (55.6 mg/g) and 4 (55.2 mg/g), while verbasco concentrations were highest for samples collected in the southern U.S. Total essential amino acid (TEAA) and total amino acid (TAA) concentrations increased over time from 22.0 to 23.5% and 51.1 to 53.1%, respectively. For the processing plants located in the southern U.S., TEAA concentrations increased (22.3% for zone 1 vs. 23.7% for zones 5 and 6). The lowest TAA concentrations were noted for SBMs prepared in zones 1 (50.8%) and 2 (51.0%). Soybean meals produced in southern maturity zones contained higher concentrations of acid hydrolyzed fat and TEAA. There was variation in oligosaccharide and amino acid concentrations over time, probably due to variation in composition of soybeans arriving at the processing plant.

Key Words: Amino Acids, Oligosaccharides, Soybean Meal

W71 Sensory tests reveal that the efficacy on masking capacity of a strawberry flavor changes with different protein sources and their level in feed. I. Pérez-Portabella, C. Puyuelo, C. Ibáñez, J. Solà, and E. Roura*, *Lucta SA, Barcelona, Spain.*

In piglet diets several types of protein sources are included and often subsequently substituted. Flavors are used to mask these and other dietary changes, thus avoiding olfactory cues that could depress feed intake. Sensory-based procedures were developed to assess the effect of some protein sources and their in-feed level on the efficacy of a strawberry flavor. Firstly, the detection threshold on a salt base for fishmeal, animal plasma and soybean meal was measured by a 15-member expert panel (7 women and 8 men) according to the standard practice (ASTM-E679). In a second step, each one of the three protein sources were mixed at 0, 3, 6 and 12% with corn meal, and 400 ppm of a strawberry flavor was added to all samples. Flavor intensity and masking capacity for each sample was evaluated by 8 panelists and results analyzed by the Tukey B test for differences in type of protein source and level of inclusion. The results of the first study show that fishmeal had the lowest detection threshold at only 5 ppm, animal plasma was detected at 162 ppm and soybean meal at 288 ppm. Women were capable of detecting lower levels than men in all three feedstuffs. Regardless of the protein, the higher the level the lower the flavor intensity. Particularly the level of fishmeal inclusion linearly affected both intensity of the strawberry flavor ($y = -2.3x + 76.4$, $R^2 = 0.77$) and its masking capacity ($y = -4.1x + 76.2$, $R^2 = 0.89$), while the effect of plasma levels ($R^2 \leq 0.6$) and soybean meal ($R^2 \leq 0.3$) did not appear to follow linearity.

Differences due to the protein source on both intensity and masking capacity were significant ($P < 0.05$) at 6% and 12% inclusion, with fishmeal affecting more than plasma and plasma more than soybean meal (but not at 3%). It is concluded that the lower the detection threshold of fishmeal, animal plasma and soybean meal the higher the impact on the flavor intensity and its masking capacity. Flavor responses to the protein inclusion rate was linear only for fishmeal.

W72 An improved method for the rapid determination of phytase activity in animal feeds. T.W. Kim* and X.G. Lei, *Cornell University, Ithaca, NY.*

The current direct colorimetric assay for phytase activity in feeds is interfered by high phosphorus background and other factors. The objective of this experiment was to develop a rapid and reliable spin column method to accurately determine phytase activity in feed ingredients or complete diets. After the feed sample was extracted in 0.2 M citrate buffer, pH 5.5, for 30 min at room temperature, the oily layer of the supernatant was removed by passing an acrodisc syringe filter (0.45 μ m HT Tuffryn membrane, Gelman Laboratory, Ann Arbor, MI). The filtrate was then loaded onto a spin column (MW cutoff 30,000, Millipore, Bedford, MA) to remove free inorganic phosphate prior to the phytase activity assay. Compared with the direct assay, this new procedure improved both accuracy and reproducibility. When diets contained phytase at 0-1,000 units/kg, the coefficients of variation for multiple assays of the same samples ($n = 6$; dietary enzyme levels = 5) by the new method ranged from 1.3 to 4.1%, but 10 to 39% by the direct method. There was a linear regression between the added phytase activity and the actual activity measured by the new method ($R^2 = 0.997$; $P < 0.001$). By concentrating the sample during spin column filtration, the new method could be used to accurately detect low levels of phytase in diets (10 units/kg). In conclusion, this spin column method is considered an improved assay for phytase activity in animal feed, and may be used for quality control of phytase supplementation.

Key Words: Phytase, Phosphorus, Feed enzyme

W73 The effect of dietary calcium on indicators of bone turnover in mares. B. D. Cassill*, S. Hayes, J. Ringler, K. Janicki, and L. Lawrence, *University of Kentucky, Lexington.*

Preliminary studies in our laboratory have found that serum ICTP (carboxy-terminal pyridinoline cross-linked telopeptide region of type I collagen), an indicator of bone turnover, is increased shortly after foaling suggesting mares mobilize bone mineral during lactation. This study was conducted to determine whether dietary calcium and phosphorus concentration would affect indicators of bone turnover in mares during late lactation and after weaning. The study used 12 mares (average age 10 ± 4.8 y) split into 2 groups. Groups were balanced for age and parity. The control group was fed to meet all NRC (1989) requirements. Group H was fed to meet all NRC (1989) requirements, plus enough dicalcium phosphate to increase calcium intake to 150% of the recommended level. The study was initiated at 2.5 mo of lactation and lasted for 16 wk which included 56 d of lactation and 56 d after weaning. Body weights were obtained every 14 d and blood samples were collected every 28 d for the duration of the study. Milk samples were collected every 28 d for the first 56 d. Calcium concentrations of milk were determined using atomic absorption spectrophotometry. Serum was analyzed for ICTP using radioimmunoassay. ICTP concentration in serum decreased over time ($P = 0.057$) but was not affected by diet ($P = 0.363$). Calcium concentration in milk decreased over time ($P = 0.005$) but was not affected by diet ($P = 0.236$). Average daily gain of the foals was not different between groups ($P = 0.675$). Increasing dietary calcium and phosphorus intake by mares did not affect milk calcium or serum ICTP concentrations during late lactation or in the first 2 mo after weaning.

Key Words: Horse, Lactation, Calcium

W74 Partitioning of metabolizable energy by rainbow trout and Atlantic salmon using a multivariate approach: species and diet effects. P.A. Azevedo*, S. Leeson, C.Y. Cho, S. Birkett, and D.P. Bureau, *University of Guelph, Ontario, Canada.*

A study was conducted to investigate how the allocation of energy to growth and maintenance differs between rainbow trout and Atlantic salmon and how the diet affects energy allocation. Rainbow trout and Atlantic salmon were handfed to satiation four isoenergetic diets (DE = 20 MJ/kg) with different digestible protein/digestible energy ratios (DP/DE), i.e., 24, 22, 20, and 18 g/MJ, achieved through reduction of DP level (53 to 39%) and increase of lipid level (19 to 26%). Intake of metabolizable energy (ME), protein (PD), and lipid (LD) gain were determined. Data were analyzed by multivariate analysis of PD and LD on ME. Maintenance energy requirements (ME_m) and efficiency of ME utilization for PD (k_p) and LD (k_l) were estimated. The fraction of ME intake above maintenance for PD (X) was defined as linear function of body weight with slope (d) and intercept (c) estimated simultaneously with the above parameters. The ME_m did not differ (P > 0.05) be-

tween rainbow trout and Atlantic salmon (20 kJ/day/kg^{0.8}). On the other hand, K_p, c, and d were significantly different (P < 0.05) between the two species, independently of the diet. The ME intake above ME_m channeled towards PD (c) was higher in salmon than trout (57 vs. 55%; P < 0.05). The change in partitioning of ME toward PD due to the change in body weight was negative for trout (d = -0.18) while it was positive for salmon (d = 0.16). The values of d agreed well with the increase of LD/PD with body weight for trout and the decrease of LD/PD with body weight for salmon which may have been related to the maturation status of this fish and the associated loss of lipid observed with maturing salmon. The K_p was significantly higher for salmon compared to trout (0.52 ± 0.06 vs. 0.43 ± 0.06; P < 0.05) and independent of the diet while K_l was 0.81 ± 0.13 irrespective of species or diet. Lower cost of protein deposition for salmon compared to trout suggests differences in protein metabolism between these two species. Studies on protein turnover rates and metabolic utilization of nutrients for PD are required to gain insight on k_p differences between salmon and trout.

Key Words: Rainbow Trout, Atlantic Salmon, Energy Allocation

Nonruminant Nutrition: Sow & Gilt Nutrition

W75 Ideal protein to improve lactation performance of multiparous sows. F. Ji*¹, Y. G. Kim², and S. W. Kim¹, ¹Texas Tech University, Lubbock, ²CJ Corporation, Seoul, Korea.

The objective of this study was to validate the ideal dietary amino acid pattern in lactation diets to improve the performance of multiparous sows during lactation. Thirty two (20 second and 12 third parity Camborough-22) sows and their litters were used for this study. On d 109 of gestation, sows with a similar body weight were grouped and allotted to one of four dietary treatments representing: low protein (LC), low protein with ideal protein (LI), high protein (HC), and high protein with ideal protein (HI). Low protein diets contained 17.5% CP and high protein diets contained 19.5% CP. Ideal amino acid patterns among lysine, threonine, and valine were 100:63.0:78.1 (lys:thr:val) for the LI diet and 100:62.3:77.5 for the HI diet when it was calculated based on ileal digestible amounts. To match amino acid pattern to ideal ratios, crystalline amino acids were supplemented. Crude protein contents in the diets with ideal protein pattern were matched to the control diets by adjusting SBM content as crystalline amino acids were added. Weight and backfat thickness of sows as well as the weight of each piglet were measured at farrowing and weekly until weaning at d 21 of lactation. All sows had free access to feed and water during lactation. The body weight of sows after farrowing (224.5±4.5 kg) and litter size at farrowing (10.2±0.2 pigs) were the same (P=0.361 and 0.779, respectively) among the treatments. Voluntary feed intake of sows (5.63±0.22 kg/d) did not differ (P=0.911) among the treatments. Sows fed the low protein diets had greater (P<0.05) weight loss than sows fed the high protein diets. Sows fed the diets with ideal protein tended to have smaller (P=0.051) weight loss than sows fed the control diets. For the second parity sows, there were no differences in backfat loss, litter size at weaning and litter weight gain among the treatment. However, weight loss of the HI sows was smaller (P<0.05) than the LC sows. For the third parity sows, there were no differences in lactation performance among the treatments.

Key Words: Lactation, Multiparous sows, Ideal protein

W76 Utilization of seaweed (*Macrocystis pyrifera*) meal in wheat-based diets for lactating sows. J. Baeza¹, M. Cervantes*², J. L. Figueroa¹, E. Chi¹, M. Cuca¹, and N. Torrentera², ¹Ganadería, Colegio de Postgraduados, Montesillos, Mexico, ²ICA, Universidad Autónoma de Baja California, Mexicali, BC, Mexico.

There is interest in alternative ingredients to enhance productive performance of animals without damage to the environment. Therefore, an experiment was conducted to evaluate the addition of seaweed (*Macrocystis pyrifera*) to wheat-based diets for lactating sows on milk production and composition, daily litter gain, and wean to first oestrous interval of sows. Thirty two multiparous sows (Landrace x Duroc x Yorkshire) were fed four diets with eight replicates. Treatments were: T1) wheat-soybean meal, basal diet; T2) T1+1.5% seaweed; T3) T1+3.0% seaweed; and T4) T1+4.5% seaweed. Litters were standardized to eight piglets

and milk production was estimated at 6, 13, 20, and 27 d by the double-weight method; milk protein concentration was determined at 13 and 27 d. Piglet weights at weaning and daily weight gain, sows milk production, and number of weaned piglets for treatments 1 to 4 were: 7.30, 7.22, 7.21, 7.01 kg; 201, 196, 196, 186 g/d; 5.98, 5.35, 5.75, 6.13 kg/d; 7.86, 7.71, 7.38, 7.87, respectively. Seaweed addition did not affect the analyzed variables. A linear effect was observed (P < 0.05) between productive variables (litter daily gain, milk production, sows feed intake) and days on lactation. The peak of milk production was observed between the third and fourth weeks of lactation. The litter weight gain and feed intake were highest in the fourth week. These results suggest that seaweed addition to lactating sow diets does not affect productive and reproductive performance of lactating sows and their litters.

Key Words: Sows, Lactation, Seaweed

W77 The importance of dietary selenium on antioxidant status and hormonal profile in post-pubertal gilts. M.-É. Fortier*¹, H. Quesnel², A. Giguère³, J.-F. Bilodeau¹, J.-P. Laforest¹, and J. J. Matte³, ¹Université Laval, Quebec, Canada, ²Institut de la Recherche Agronomique, St. Gilles, France, ³Agriculture and Agri-Food Canada, Lennoxville, Quebec, Canada.

This project aimed to determine the effect of selenium (Se) as inorganic Na-selenite (MSe) or organic Se-yeast (OSe) on antioxidant status and hormonal profile, after puberty and in early gestation of gilts. Forty-nine gilts were allocated to one of the 3 feeding treatments at first estrus: control (C: basal diet (Se=0.2 ppm) without added Se) (n=16), MSe (C+0.3 ppm Se) (n=16) and OSe (C+0.3 ppm Se) (n=17). Treatments started at the day after the first pubertal estrus and lasted up to 30 d post-AI (AI at the fourth estrus). Blood was collected from all gilts on the day after each estrus and on d 30 post-AI. Blood was also collected daily from d -4 until d +4 of the third onset of estrus (d 0) in 8 C, 9 MSe and 8 OSe canulated gilts. Blood Se was lower (P<0.01) in C than in Se groups and higher in OSe than in MSe (P<0.01) (C:249±6, MSe:273±6 and OSe:316±8 µg/L on d 30 post-AI). Blood Se-GSH-Px tended to be lower (P<0.06) in C than in Se groups starting at third estrus and was higher (P<0.01) in MSe than in OSe starting at AI (C:2078±74, MSe:2594±84 and OSe:2392±105 mU/mg hemoglobin on d 30 post-AI). Plasma T3, a Se-related hormone, was not altered by treatments (P>0.12) prior to AI but, during gestation, T3 decreased markedly (P<0.03), values for MSe being lower (P<0.02) than for OSe on d 30 of gestation (C:90±2, MSe:79±5 and OSe:94±3 ng/100mL). In canulated gilts, plasma FSH was lower (P<0.04) for MSe than for C on d +2 and d +3. On d +4, FSH (C:0.88±0.12, MSe:0.94±0.19 and OSe:1.27±0.20 ng/mL) and T3 (C:88±12, MSe:75±7 and OSe:97±16 ng/100mL) values became higher (FSH, P<0.05) or tended to be higher (T3, P<0.07) for OSe than MSe. There was no treatment effect (P>0.10) on the profile of LH or E2 during the third estrus. In summary, the Se status response to dietary Se was not reflected on Se-GSH-Px which responded to Se supplements but, in a different way, to the type of Se supplements. Taking into account the role of T3 in FSH synthesis, the FSH and T3 effects after estrus merit

further investigation as well as the T3 response to OSe vs MSe during gestation.

Key Words: Selenium, Post-Puberty, Gilts

W78 The effect of mannan oligosaccharides on reproductive performance in sows. P. Medel*¹, C. Piñero², A. Kocher³, F. Baucells¹, and M. I. Gracia¹, ¹Imasde Agropecuaria, S.L., Spain, ²PigChamp Pro Europa, Spain, ³Alltech Inc, Ireland.

This study was conducted to determine the effect of including mannan oligosaccharides (MOS, Bio-Mos[®]) in diets fed to gestating and lactating sows on their productivity. A total of 80 gestating sows (Landrace × Large White), selected two weeks before the expected farrowing, were randomly allotted to one of two treatment groups taking into account their parity number. The two treatments were as follows: 1) basal diet (control), 2) basal diet with a source of MOS at 2 g/kg in gestation and 1 g/kg in lactating diets. Diets were formulated to contain 18.5% CP and 2.4 Mcal NE/kg. During lactation, all sows were allowed ad libitum access to their treatment diets. Feeding the experimental diets began two weeks before farrowing and continued until weaning of piglets. Sow BW was measured at 107 d of gestation and at weaning. Backfat depth was measured using ultra sound 24 h and 14 d after farrowing, and at weaning. ADFI was recorded daily. Pigs were weighed 24 h after birth and at weaning. Number of piglets born alive, pre-wean mortality and ADG were recorded. Sow weight change, backfat depth change, and ADFI did not differ between treatments (P>0.05). Also, the number of pigs born (11.2 vs 11.9) and pre-wean mortality (1.00 vs 0.88) did not differ between control and MOS supplemented sows (P>0.05). However, piglet birth (1.54 vs 1.70 kg) and weaning weights (6.52 vs 7.12 kg) were 0.16 and 0.60 kg heavier, respectively (P<0.05) for MOS supplemented sows when compared to control sows. These data suggest that MOS supplementation of sow diets during the end of gestation and lactation increases both piglet birth and weaning weights.

Key Words: Mannan Oligosaccharides, Birth and Weaning Weight, Lactating Sows

W80 The Effect of Distillers Dried Grains with Solubles as the Protein Source in a Creep Feed. P. Lancaster, J. Williams*, J. Corners, L. Thompson, D. McNamara, and M. Ellersieck, University of Missouri, Columbia.

A study was conducted to evaluate the effect of Corn Distillers dried grains with solubles (D) vs. soybean meal (S) as a protein source in a creep feed over 2 years. In yr 1 and 2, thirty-six steer calves (avg. 159.9 kg + 26.9 in yr 1; 184 kg + 12.7 in yr 2) were used to compare the effects of D and S on the performance of calves to traditionally weaned (C) calves prior to (68 d) and after weaning (112 d). Steers were randomly allotted by age to 6 endophyte-free tall fescue pastures in yr 1 and blocked by age within sire and randomly assigned to 3 of the same pastures in yr 2. The dietary supplements consisted of a cracked corn / soyhull mix with the protein source and were formulated to contain 14.2 % CP and 1.39 Mcal/kg of NEg. In both years, steers were placed in open drylots upon weaning and adjusted to a receiving diet of cracked corn, soyhulls, and fescue hay with D and S treatments continued, while the C treatment received S as the protein source. After 112 d, steers were placed on a common urea based finishing diet. In yr 1 and 2, creep-fed calves had greater (P < .01) ADG than non-creep-fed calves during pasture phase (1.03 vs. 0.72 and 1.03 vs. .88 kg/d for year 1 and 2, respectively). In yr 1, the feed / extra gain was similar among treatments, while cost / kg of extra gain for D was lower (P < .05) than S (0.88vs.1.89, respectively). Weaning weight was greater (P < .05) for creep-fed than non-creep-fed calves (231.0 vs. 206.6 kg, respectively). There was a trend for creep-fed steers to have a greater (P = .09) ADG than non-creep-fed steers during the feedlot phase (1.66 vs. 1.57 kg/d, respectively). Creep-fed steers had greater (P < .05) final and hot carcass weights than non-creep-fed steers (537.2 vs. 496.7 and 329.2 vs. 300.0 kg for final and carcass weights, respectively). In yr 2,

W79 The influence of feed intake during mid-gestation on performance of pregnant sows and progeny growth: a preliminary study. A. Cerisuelo¹, R. Sala¹, J. Coma², D. Carrión*³, J. Gasa¹, and M. Baucells¹, ¹Universitat Autònoma de Barcelona, Spain, ²Agrocesa, S.A., Spain, ³PIC España, S.A., Spain.

The effect of increased feed intake during mid-gestation (secondary fiber hyperplasia period) on sow performance and progeny growth was studied. A total of 101 pregnant sows of different parity were assigned to two dietary treatments: Control, C (n=48) were fed at a level routinely used on commercial farms (3.16 kg d⁻¹) and Experimental, E (n=53) received 1.75 times C from d 50-85 of gestation. Body weight was recorded at d 45 of gestation, at 48 ± 24h post-partum and at weaning. Backfat thickness at P2 was determined on d 45, 84 and 110 of gestation and on d 18 of lactation. Increases in P2 from d 45-80 of gestation were higher (P<0.05) in E sows. Moreover body weight losses in lactation period were lower in E sows (P<0.10), while decreases in P2 were similar between treatments. Average piglet weight when weaned at about d 23 was not affected by treatment (P>0.05). Castrated males (n=460) were used for a post-weaning study. Animals were divided by treatment (C vs E) into five weight groups each and daily gains were recorded for six weeks postweaning. Growth rate of E group was greater than that of the C group being statistical significant from day 30 post-weaning (Table 1). The greatest differences in growth rate were observed in the lightest groups of pigs. Results suggest that increasing sow feed intake during mid-gestation may improve postnatal growth rate of piglets. More studies are needed in order to check the long term influence in sow performance.

Body weight throughout the weaning period.

Days post-weaning	Body weight, kg		Treatment dif., g/pig	P-value
	Control	Exp.		
0	6.5	6.5	0	NS
14	7.8	8.0	-189	0.12
22	9.9	10.2	-253	0.11
30	13.5	14.1	-580	0.015
42	19.9	20.6	-722	0.014

Key Words: Sow Performance, Growth, Maternal Nutrition

Ruminant Nutrition III

DMI, feed / extra gain, and cost / kg of extra gain were similar but total feed costs were lower (P < .01) for D than S during the pasture phase (13.88vs.18.31, respectively). Final performance and carcass data for yr 2 will be presented later. In conclusion, protein source had no effect on ADG, however DDGS reduced feed costs.

W81 Effects of sire marbling EPD and creep feeding on feedlot performance and carcass characteristics of Hereford calves. J. E. Rossi*¹, T. D. Pringle², and J. K. Bertrand², ¹University of Georgia, Tifton, ²University of Georgia, Athens.

Five-month old nursing Hereford calves (forty-six heifers and forty-one steers; initial BW = 166.6 ± 4.4 kg) were used to determine the effects of sire marbling EPD and creep feeding on feedlot performance and carcass characteristics. Treatments were arranged in a 2 × 2 factorial with factors being sire marbling EPD (high +2.8 or low -2.3) and creep or no creep feeding. Cows and calves were allotted to 8 fescue/bermudagrass mixed pastures with 2 pastures per treatment. Heifers and steers were evenly allotted among pastures within each sire marbling group. Calves were creep fed a 50:50 mixture of ground corn and corn gluten feed for 90 days. All calves were then commingled into a single group and pre-conditioned for 45 days prior to finishing on a 90% concentrate diet. Heifers were fed 169 days and steers were fed 183 days. Calves that were creep fed consumed 2.45 kg (DM basis) of creep feed per day. Daily gains during the creep feeding period were greater (P < 0.01) for calves that were creep fed (1.26 kg/d) versus not creep fed (0.95 kg/d). Daily gains during the creep feeding period were not affected (P = 0.37) by sire marbling EPD. Feedlot ADG was not affected (P > 0.38) by creep feeding or sire marbling EPD. Carcass marbling scores were 10% greater (p =

0.06) for calves creep fed compared with calves not creep fed. Marbling score was not affected by sire marbling EPD ($P = 0.70$). Fat thickness was 12% greater ($P < 0.05$) for creep fed versus non creep fed calves and was 12% greater ($P < 0.05$) for calves sired by a low versus high marbling EPD bull. Ribeye area and dressing percentage was not affected ($P > 0.10$) by creep feeding or sire marbling EPD. Yield grade was greater ($P < 0.01$) for creep fed (3.34) versus non creep fed calves (3.04), and greater ($P < 0.01$) for calves sired by low (3.36) versus high (3.01) marbling EPD bulls. Carcass marbling scores were increased by creep feeding but were not affected by sire marbling EPD.

Key Words: Calves, Creep Feeding, Carcass Characteristics

W82 Effects of feeding byproducts on animal performance and carcass characteristics of finishing beef cattle grazing tropical grass during dry season. A. A. Souza^{*3}, C. Boin¹, M. Q. Manella¹, and A. J. Lourenço², ¹ESALQ/USP, Brazil, ²Instituto Zootecnia, Brazil, ³UNESP, Brazil.

This study has evaluated the effects of feeding byproducts on animal performance and carcass characteristics of Nelore cattle grazing tropical pastures during the dry season. The trial was conducted at Instituto de Zootecnia in Nova Odessa, São Paulo state in Brazil. The performance of 128 Nelore steers was evaluated in a random block design, with four treatments and four replications. The treatments were: Control = *Brachiaria brizantha* + mineral supplement; Leucena = *Brachiaria brizantha* + protein bank (*Leucaena leucocephala*) + 1.8 kg citrus pulp + 0.8 kg Wet corn gluten feed + mineral supplement (animal/day); Supl1 = *Brachiaria brizantha* pasture + 1.8 kg citrus pulp + 0.8 kg Wet corn gluten feed + 0.45 kg soybean meal + mineral supplement (animal/day); Supl2 = *Brachiaria brizantha* pasture + 1.8 kg citrus pulp + 0.8 Kg Wet corn gluten feed + 0.9 kg soybean meal + mineral supplement (animal/day). The initial and final live weight was 416-434; 399-475; 395-490 and 395-488 kg for treatments control, leucena, supl1 and supl2, respectively. After 5 months of trial, animals that had at least 3 mm back fat measured by ultrasound were slaughtered at a commercial plant. The average daily gains were 0.114; 0.528; 0.638 and 0.613 kg/animal/day for control, leucena, Supl1 and 2, respectively (table 1). There were greater carcass yields for the supplemented animals of the treatments leucena, Supl1 and 2. The results of backfat have been like the yield carcass results (table 1). The use of byproducts as grazing supplements may finish grazing animals, with greater backfat thickness. Table 1. Average daily gains and backfat after chilled for different treatments.

Treatments	Kg/animal/day	Backfat	CarcassYield (%)
Control	0.114 ^a + 0.051	3.30 ^a + 0.20	53.9 ^a
Leucena	0.528 ^b + 0.042	4.24 ^{ab} + 0.31	55.6 ^b
Supl1	0.638 ^c + 0.035	4.75 ^b + 0.33	55.6 ^b
Supl2	0.613 ^c + 0.031	4.87 ^b + 0.40	56.4 ^b

W83 Effect of supplements of self feed on efficiency of microbial protein synthesis and excretion of N contents - urea in steers grazing *Brachiaria decumbens*, in the rainy season. J. Tilemahos Zervoudakis^{*1}, M. Fonseca Paulino², L. Cabral¹, E. Detmann³, S. de Campos Valadares Filho², E. Henrique Bevtori Kling de Moraes², and A. Lima de Souza¹, ¹Universidade Federal de Mato Grosso, Fernando Correa da Costa, Cuiaba-MT-Brazil, ²Universidade Federal de Viçosa, Viçosa, MG, Brazil, ³Universidade Estadual Norte Fluminense, Campos dos Goytacazes-RJ, Brazil.

The objective this work was evaluate the effect of supplements of self feed on the efficiency of microbial protein synthesis and excretion of N contents - urea in the urine of steers grazing *Brachiaria decumbens*, in the rainy season, in the west-central region of Brazil. Four crossbred steers, fistulated in the rumen, abomasum and esophagus, with average initial weight of 426 kg, were used for evaluating nutritional parameters, by 4x4 latin square. Mineral salt (SALT) and supplements based on:

urea, mineral mix, grounded corn grain and soybean meal (SBM); urea, mineral mix, soybean meal and corn gluten meal (SBMCG); and urea, mineral mix, wheat bran and soybean meal (WBSBM), with average protein content of 53.60% CP, were fed daily, at level of 1.0 kg/animal, at 10:00 hours. The microbial protein production was calculated by purine determination on rumen and abomasum samples, used purine basis as marker adoted a N-purine:N-total of 0.117. The urea excretion on urine was determined by urine spot colleted 4 hours after supplementation. The animals supplemented excreted higher N content - urea in the urine (95.28 g/day)($P < 0.05$) than the control animals (46.90 g/day). No effect of treatments on the efficiency on microbial protein synthesis in the g CP microbial/100 g TDN, was observed, with average values of 11.75 g CP microbial/100g TDN.

Key Words: Microbial Nitrogen, Supplementation, Steers

W84 Effects of CLA on tissue response to homeostatic signals and plasma lipid metabolism variables in growing beef steers. O. B. Mendivil^{*}, C. E. Moore, H. C. Haflliger III, S. R. Sanders, G. C. Duff, and L. H. Baumgard, *The University of Arizona, Tucson.*

The ability of CLA to modify beef body composition and the mechanism by which it alters lipid metabolism are poorly understood. Objectives of this study were to evaluate basal energetic and temporal metabolite patterns in response to epinephrine, insulin, and glucose challenges in cattle fed rumen protected (RP) CLA. Twenty British x Continental beef steers (280 ± 29 kg BW) were fed isoenergetic steam-flaked corn based diets containing equal amounts of FA (5.74 vs 6.25% EnerGII[®], a RP palm oil and RP CLA, respectively) for 45 d. The CLA supplement contained 71.4% FA of which 40.0% were CLA isomers (5.4% *t*-8, *c*-10; 6.3% *c*-9, *t*-11; 7.9% *t*-10, *c*-12; and 8.2% *c*-11, *t*-13 CLA). Controls were pair-fed with CLA steers in order to minimize caloric intake variability. All steers were fitted with indwelling jugular catheters on d 14, 28, and 42. Epinephrine (1.4 µg/kg BW), insulin (3.0 µg/kg BW), and glucose (0.3 g/kg BW) challenges were conducted and blood samples collected on d 15, 30 & 43; 16, 31 & 44; and 17, 32 & 45, respectively. Subcutaneous adipose tissue was collected from the tailhead region in 10 randomly selected steers (n=5/trt) on d 45. Production variables (ADG, G:F, BW, DMI and DMI as %BW) did not differ ($P > 0.15$) between treatment groups. Dietary CLA did not alter basal circulating plasma NEFA or glucose concentrations. In addition, there were no CLA effects on metabolic responses to the aforementioned homeostatic signals. On d 45, adipose tissue of CLA-fed steers had increased ($P < 0.03$) concentrations of *c*-9, *t*-11 CLA (0.78 vs 0.52%), *t*-10, *c*-12 CLA (0.21 vs 0.08%), total CLA (2.85 vs 0.97%), and total *t*-18:1 FA (8.92 vs 5.70%). There were no effects on the Δ^9 -desaturase index (43.3) or the total saturated and unsaturated levels (45.7 and 54.3%, respectively). These data indicate that short term CLA supplementation did not alter basal or stimulated NEFA or glucose parameters, but has the ability to dramatically increase CLA content in bovine adipose tissue.

Key Words: CLA, Beef, Lipid Metabolism

W85 Dietary effect on n-3 fatty acids, CLA and C18:1trans isomers in beef and lamb meat. K. Nuernberg^{*1}, D. Dannenberger¹, G. Nuernberg^{*1}, N. Scollan², W. Zupp³, and K. Ender¹, ¹Research Institute of the Biology of Farm Animals, Dummerstorf, Wilhelm-Stahl-Allee, Germany, ²Institute of Grassland and Environmental Research, Aberystwyth, UK, ³Research Institute of Agriculture and Fishery Mecklenburg-Pomerania, State Institute for Animal Production, Dummerstorf, Wilhelm-Stahl-Allee, Germany.

The objective of the experiments with cattle and lambs was to produce high quality beef and lamb meat under different feeding conditions and to accumulate the concentration of n-3 fatty acids and CLA in muscle. In total 33 German Holstein bulls (initial liveweight= 205 kg) were fed on either an indoor concentrate system or a period of summer pasture feeding on grass following by an indoor finishing. Bulls were slaughtered at 620 kg. Pasture feeding caused significant increased relative contents of linolenic acid (C18:3n-3) and long-chain n-3 fatty acids in muscle. Relative proportion of CLA_{cis-9,trans-11} was significantly ($P \# 88040.05$) higher in grass fed bulls. The absolute content was not affected by the diet. The main CLA_{cis-9,trans-11} of muscle lipids measured by HPLC decreased from 73.5 % in concentrate fed bulls to 65.0 % in grazing bulls. The second most abundant CLA isomer in pasture fed bulls was CLA_{trans-11,cis-13} and the isomer CLA_{trans-7,cis-9} in concentrated fed

bulls. There was a feeding influence on the relative proportion of all C18:1trans isomers. The absolute amount of C18:1trans-11 was only in tendency increased in grazing bulls (66.2 mg/100 g fresh muscle vs 101.7 mg/100 g). In total 13 male lambs (Black Head x Gotland) were divided into two feeding groups at 24 kg live weight. Lambs (n=6) were kept either on pasture (salt grass) or in stable on concentrate (n=7). Lambs fed grass accumulated a higher C18:3n-3 content and the sum of n-3 fatty acids in muscle lipids. The relative content of CLA_{cis-9,trans-11} (1.9 % vs 1.1 % in muscle) was significantly (P#88040.05) higher by grazing on pasture compared to concentrate feeding. The analyses of CLA isomers (Ag+-HPLC analysis) showed no differences between feeding systems for CLA_{cis-9,trans-11}. The percentage of the CLA_{trans-10,trans-12} isomer was five times higher in concentrate fed lambs vs pasture feeding. The main C18:1trans isomers of intramuscular fat in lambs were C18:1trans-11, C18:1trans-14, C18:1trans-15 and C18:1trans-16. Grass feeding increased significantly the percentage of C18:1trans-11.

Key Words: n-3 Fatty Acid, CLA Isomers, Muscle

W86 Effect of CRINA RUMINANTS, a mixture of essential oil components, on continuous culture fermentation and milk production of lactating cows. G. Varga¹, E. Block^{*2}, P. Williams³, T. W. Cassidy¹, and R. Losa⁴, ¹The Pennsylvania State University, University Park, ²Church & Dwight Co., Inc, Princeton, NJ, ³Akzo Nobel, Inc, Davis, CA, ⁴CRINA S.A., Gland, Switzerland.

Objectives of this trial were to test two levels CRINA RUMINANTS (CRINA) fed in a TMR to continuous culture fermenters and to lactating cows. The TMRs used were identical across treatments for fermenters and cows except for the inclusion of CRINA. TMR was formulated for a high producing cow to meet NRC requirements (2001). CRINA inclusion was at 1.2 g/cow/d for the treatment group, which was equivalent to 4mg/d in the fermenters. Inoculum for the fermenters was obtained from cows in the production trial. An additional fermenter treatment containing 12mg/d CRINA was also evaluated. In fermenters, pH tended to be higher with increasing CRINA and was higher for CRINA diets than the control (P<.08). Concentrations and molar proportions of acetate, propionate, valerate, isovalerate and the A:P were either significantly, or tended to be lower for fermenters supplemented with 4 mg/d CRINA. Nutrient digestibility was not affected, however, there was a trend (P>.15) for increased NDF digestibility in CRINA treatments versus the control. There was a trend (P<.09) for CRINA diets to have higher bacterial protein synthesis versus control. A commercial dairy herd was used to test CRINA supplementation on milk yield for a four month period. All cows in the high group pen at the farm were split into two sub pens and fed identical diets except that Pen A contained CRINA at the rate of 1.2 g/cow/d while Pen B contained no CRINA. Daily milk yield and weekly composition were collected for every cow. Milk samples were assayed by DHIA. Results for cows that began and finished the trial during the feeding period showed that those in Pen A (n=82) produced 3.6 lb/day more milk (p<0.05) than Pen B (n=88). For all cows, including those that were in trial pens for only part of the trial period, the milk increase by cows in Pen A was 1.4 lb/day (p<0.07; n= 248 and 257 in CRINA supplemented and control group, resp.). No differences in milk composition were observed. CRINA RUMINANTS can improve milk yield in cows, which can be explained by modification of rumen microbial populations.

Key Words: Essential Oils, Dairy Cows, Continuous Culture Fermentation

W87 Milk production and milk fatty acid profiles of cows fed different carbohydrate sources and soybean oil. E. C. Eifert^{*1,2}, R. P. Lana^{1,2}, J. M. S. Campos¹, D. P. D. Lanna³, P. B. Arcuri⁴, M. I. Leo¹, and R. D. Valadares¹, ¹Universidade Federal de Viosa-DZO, Viosa, MG, Brazil, ²CNPq, Brasília, DF, Brazil, ³LNCA-ESALQ/USP, ⁴CNPGL-EMBRAPA.

This study was carried out to evaluate the effect of different carbohydrate sources and soybean oil supplementation on milk production and fatty acid profiles of lactating dairy cows. Twelve Holstein cows, purebred and crossbred with Zebu, were used in a 3x3 Latin square design with four replicates. The treatments consisted of 55% of corn silage and 45% of concentrate with corn (CN), wheat bran (WB) or citrus pulp (CP) as energy sources, and associated with soybean oil in the concentrate (0 and 2.25%). Dry matter intake (18.4 kg/day) and milk

production (23.5 kg/day) did not differ among CN, WB or CP, but WB diets showed the lowest total NDF and organic matter digestibility (P<.05). Microbial synthesis was not affected by carbohydrate source or soybean oil (239.4 g microbial N/day). Soybean oil-containing diets showed lower DMI (17.8 vs 19.0 kg/day), milk lactose (4.33 vs 4.49%) and milk fat (3.13 vs 3.34%) than did control diets (P<.07). Soybean oil-containing diets increased the milk protein:fat ratio (1.00 vs 0.94) (P<.05). Fatty acid profile was not influenced by carbohydrate source, but concentration of short and medium chain fatty acids decreased by 27.3 and 26.8%, respectively; while concentration of long-chain fatty acids increased by 44.5% in cows fed soybean oil (P<.01). Soybean oil also increased *cis-9 trans-11* CLA by 230% and *trans-C18:1* by 229% (P<.01). *Trans-11 C18:1* was the main *trans-C18:1* isomer and an interaction between oil and carbohydrate source was observed for *trans-10 C18:1* (P<.05). This fatty acid was similar in CN, WB or CP, but in combination with soybean oil, concentration of *trans-10 C18:1* in CN and WB diets was greater than in CP diet, indicating bio-hydrogenation activities through different pathways. The elevated *trans-10 C18:1* content was consistent with reduction in milk fat and CP had higher potential than CN or WB to supply *trans-11 C18:1* for endogenous CLA synthesis by Δ^9 -desaturase.

Key Words: Bio-Hydrogenation, CLA, Fatty Acids

W88 Effects of increasing doses of a specific blend of essential oils on rumen nitrogen metabolism and fermentation profile in continuous culture system. L. Castillejos¹, S. Calsamiglia^{*1}, A. Ferret¹, and R. Losa², ¹Universidad Autonoma de Barcelona, Spain, ²AKZONOBEL/CRINA SA, Gland Switzerland.

Eight dual flow continuous culture fermenters (1320 ml) were used in two periods (6 d of adaptation and 3 d of sampling) to study the effects of increasing doses of a specific blend of essential oils (EOB, CRINA RUMINANTS) on rumen nitrogen metabolism and fermentation profile. Temperature (39C), pH (6.4), and liquid (10%/h) and solid (5%/h) dilution rates were maintained constant. Fermenters were fed 95 g/d of DM of a 60 to 40 forage to concentrate diet (18% CP; 30.2% NDF) in three times per day. Treatments were: Control (no EOB), D1 (5 mg/L of EOB), D10 (50 mg/L of EOB) and D100 (500 mg/L of EOB), and were randomly assigned to fermenters within periods. A sample was taken daily 2 h after the morning feeding for the determination of ammonia N and volatile fatty acids (VFA). During the last 3 days, samples were taken at 0, 2, 4 and 6 h after the morning feeding and analyzed for peptide, aminoacid and ammonia N concentrations. Total VFA (mM) tended (P = 0.06) to be higher for D1 (129.1) compared with Control (120.4). Acetate proportion (mol/100mol) tended (P = 0.06) to be higher for D1 (63.6) compared with Control (58.0). Propionate proportion (mol/100mol) was lower for D1 (16.9) and D10 (17.5) compared with Control (20.6). Valerate proportion (mol/100mol) was lower for D1 (3.25) compared with Control (4.22). Branch-chained VFA concentration (mM) was higher for all EOB treatments (average of 5.19) compared with Control (3.10). The average peptide N concentration (mg/100ml) was lower for D1 (4.88) compared with Control (5.98). The aminoacid and ammonia N concentrations were similar across treatments. The treatment with 5 mg/L of EOB increased by 7% total VFA, increased by 5 percentage units the acetate proportion, and decreased by 4 percentage units the propionate proportion. The decrease in peptide N concentration suggested that the treatment with 5 mg/L of EOB inhibited proteolysis.

Key Words: Essential Oil Blend, Rumen Microbial Fermentation, Nitrogen Metabolism

W89 Effect of essential oils on ruminal fermentation *in vitro*. A. N. Hristov, J. K. Ropp, and A. Melgar*, Department of Animal and Veterinary Science, University of Idaho, Moscow.

The objective of this study was to investigate the effect of essential oils (EO) on ruminal fermentation *in vitro*. Ruminal fluid enriched with particle-associated microorganisms was recovered from two lactating dairy cows fed an alfalfa hay/cereal silage/concentrate diet one hour before feeding. The *in vitro* media contained: ruminal inoculum, reducing agent, (¹⁵NH₄)₂SO₄, and nutrients (glucose, maltose, sucrose, soluble starch, crystalline cellulose, and hydrolyzed and native casein) dissolved in buffer. Three, 4-h incubations were conducted within a 2-wk period. Forty EO were tested at two concentrations, 10 and 100 ppm (final media concentration). Monensin-Na (M), and sodium laurate (SL)

were also incubated at 5 ppm and 0.2%, respectively. Compared to a Blank (no addition of EO), SL increased ($P < 0.001$) media pH (6.66 vs. 6.82, respectively). A number of EO reduced ($P < 0.05$) media pH. Both, SL and M reduced ($P < 0.001$) ammonia concentration compared to the Blank (1.81, and 1.89 vs. 2.30 mmol/L, respectively). Compared to the Blank and across application levels, only one of the tested EO slightly reduced ($P = 0.058$) ammonia concentration to 2.11 mmol/L. Many EO increased ($P < 0.05$) media total VFA concentration by 8 to 13%. SL, but not M, reduced ($P < 0.05$) total VFA concentration (74.9 vs. 83.2 mmol/L, respectively). Acetate and propionate concentrations were reduced ($P < 0.05$) by SL compared to the Blank. Several EO and SL increased ($P < 0.05$) acetate to propionate ratios from 1.93 (Blank) to 2.05-2.07; M had no effect ($P > 0.05$) on this variable. ¹⁵N-enrichment of ammonia N was greater ($P < 0.001$) in SL and M compared to the Blank (by 38 and 28%, respectively), suggesting reduced deamination of amino acids with the former treatments. EO had no effect on this variable. The EO tested in this experiment did not affect ammonia concentration *in vitro*, but some oils increased total VFA concentration and acetate to propionate ratio and reduced media pH.

Key Words: Essential Oil, Rumen Fermentation, Ammonia

W90 The conjugated linoleic acid and ω -3 fatty acids in milk and cheese from cows fed calcium salts of fish oil alone or in combination with soybean products. S. L. Allred*¹, T. R. Dhiman¹, C. P. Brennan¹, R. C. Khanal¹, D. J. McMahon¹, and N. D. Luchini², ¹Utah State University, Logan, ²Bioproducts, Inc., Fairlawn, OH.

Twenty Holstein cows were used in a complete randomized block design to determine the influence of feeding a total mixed ration (CTL), CTL diet supplemented with 2.7% calcium salts of fish oil (FO), FO plus 5% extruded full-fat soybeans (FOESM), or FO plus 0.75% soybean oil (FOSO), on fatty acid composition and flavor characteristics of milk and cheese. Total fatty acid intake was 0.93^b, 1.28^a, 1.42^a, and 1.29^a kg/day for CTL, FO, FOESM, and FOSO diets, respectively. There was no difference in feed DM and NEL intakes, or in milk yield or milk composition among treatments. Milk fat conjugated linoleic acid (CLA) and *trans*-11 C_{18:1} (TVA) contents for cows fed CTL, FO, FOESM, and FOSO diets were 0.61^b, 1.27^a, 1.44^a, and 1.82^a; and 3.29^c, 4.66^{bc}, 6.30^{ab}, and 7.80^a % of fat, respectively. Total ω -3 fatty acid content was 0.62^b, 0.69^a, 0.69^a, and 0.67^{ab} % of fat for CTL, FO, FOESM, and FOSO diets, respectively. The ratio between ω -3 and ω -6 fatty acids was not different among diets. Concentrations of CLA and TVA in cheese were 0.63^d, 1.14^c, 1.41^b, and 1.70^a; and 2.98^d, 4.91^c, 6.00^b, and 7.00^a % of fat for CTL, FO, FOESM, and FOSO diets, respectively. Total ω -3 fatty acid contents in cheese were 0.62^b, 0.73^a, 0.74^a, and 0.71^a % of fat for CTL, FO, FOESM, and FOSO diets, respectively. No difference in flavor scores was detected by a trained sensory panel for milk (n = 7) and cheese (n = 10), except for acid flavor in cheese ($P < 0.05$), which was 4.30^{ab}, 3.87^b, 4.43^a, and 4.39^{ab} for CTL, FO, FOESM, and FOSO diets, respectively. Results from the present study suggest that calcium salts of fish oil alone or in combination with soybean products can be used to enhance the CLA and ω -3 fatty acid content of milk and cheese with minimal negative impact on flavor characteristics.

Key Words: Milk and Cheese, Conjugated Linoleic Acid, ω -3 Fatty Acids

W91 Evaluation of the degree of rumen inertness and bioavailability of *trans*-10, *cis*-12 CLA in a lipid encapsulated supplement. A. L. Lock*¹, J. W. Perfield II¹, D. E. Putnam², and D. E. Bauman¹, ¹Cornell University, Ithaca, NY, ²Balchem Encapsulates, New Hampton, NY.

The efficacy of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) in reducing milk fat synthesis in dairy cows has been well documented. CLA has potential as a management tool for reducing milk fat in a controlled manner, which may be useful during times of inadequate nutrient intake or in areas where a milk fat quota exists. In order to maximize CLA absorption it must be protected from biohydrogenation by bacteria in the rumen. This requires a rumen-protected product that is optimized for protection from metabolism in the rumen as well as subsequent bioavailability in the small intestine. The objective of this study was to evaluate the degree of rumen inertness and bioavailability of CLA in a lipid encapsulated supplement (LE-CLA). Three rumen fistulated lactating Holstein cows (212±31DIM) were randomly assigned in a 3 X 3 Latin

square experiment. Treatments were: 1) no supplement (control), 2) rumen infusion of LE-CLA (80 g/d), and 3) abomasal infusion of LE-CLA (80 g/d). CLA treatments were designed to provide 7.8 g/d of *trans*-10, *cis*-12 CLA which was either infused into the rumen or abomasum four times a day in equal amounts. Treatment periods were 5 d with a 7 d interval between periods. Milk yield, DMI and milk protein yield were unaffected by treatment. Rumen and abomasal infusions of LE-CLA significantly reduced milk fat content by 13% and 29%, and milk fat yield by 11% and 28% ($P < 0.001$), respectively. The reduction in milk fat yield was due to decreases in both de novo fatty acid synthesis and uptake of preformed fatty acids with the pattern of reductions similar for rumen and abomasal infusions. Milk fat content of *trans*-10, *cis*-12 CLA was <0.01, 0.06 and 0.15 g/100 g of fatty acids for the control, rumen and abomasal treatments, respectively ($P < 0.001$). In conclusion, both rumen and abomasal infusions of a LE-CLA supplement caused a reduction in milk fat content and yield while having no effect on DMI, milk yield or other milk components.

Key Words: Conjugated Linoleic Acid, Milk Fat Depression, Rumen Protection

W92 Milk fat conjugated linoleic acid in selected commercial dairies of Utah and Idaho. R. C. Khanal* and T. R. Dhiman, Utah State University, Logan.

A two-year study was conducted to investigate the conjugated linoleic acid (CLA) content of milk on 2 commercial dairies (Farms A and B) in Utah and 2 dairies in Idaho (Farms C and D). Farms A, B, C, and D had 80, 150, 400, and 500 milking cows, respectively. Cows on farms A and B were grazed on pasture and supplemented with 7.0 kg/cow per day of grain in summer and were fed conserved forage and grain during winter. Cows on Farm C were fed a total mixed ration (TMR) containing conserved forage and grain year-round, with 10% of diet DM as fresh cut grass during summer. Cows on Farm D were fed TMR during winter. During the summer one-third of the cows on Farm D grazed on pasture and were supplemented with TMR and the remaining cows received only TMR. Milk samples were collected every month from the bulk tank and twice per year (during summer and winter) from selected individual cows (15% of the milk cows on the farm or a minimum of 20 cows) for fatty acid analysis. Milk CLA contents (C_{18:2} *cis*-9, *trans*-11 isomer) were 0.66^b, 0.75^a, 0.40^d and 0.58^c % for bulk tank samples and 0.73^a, 0.75^b, 0.43^c and 0.55^a % of fat for individual cow samples from Farms A, B, C, and D, respectively. Milk fat CLA content was higher ($P < 0.01$) during summer compared with winter (0.79^a and 0.42^b for bulk tank and 0.78^a and 0.40^b % of fat for individual cows during summer and winter, respectively). Milk fat CLA contents for individual cows varied from 0.16 to 2.22% of fat across farms. Individual cow variation in milk CLA content was larger for Farms A and B than for Farms C and D. Bulk tank CLA content of milk varied from 0.27 to 1.35% of fat across farms. Total daily yields of CLA/cow were higher on Farms A and B even though total milk yield was less than that of cows on Farms C and D. Results from this study suggest that CLA levels of milk from dairies that utilized some grazing practices had 47% higher CLA than dairies with no grazing. In addition, individual cow variation in milk CLA content is higher when cows are grazing on pasture.

Key Words: Conjugated Linoleic Acid, Cow, Pasture

W93 Synthesis of *trans* fatty acids and isomers of conjugated linoleic acid in the rumen of cows fed grass silage based diets supplemented with incremental levels of sunflower oil. K. J. Shingfield*¹, S. Ahvenjärvi¹, V. Toivonen¹, P. Huhtanen¹, and M. J. Grönari², ¹MTT Agrifood Research Finland, Jokioinen, ²University of Helsinki, Finland.

Based on the potential benefits of conjugated linoleic acid (CLA) for human health there is a need to develop effective strategies for enhancing CLA concentrations in milk and meat. *Cis*-9, *trans*-11, the predominant CLA isomer in ruminant tissues, is derived from two sources; ruminal biohydrogenation of C_{18:2} (n-6) and endogenous conversion of *trans*-11 C_{18:1}. Most evidence to date suggests that endogenous synthesis is the most important source of CLA. Four lactating cows fitted with rumen cannula were used in a 4 x 4 Latin square with 14 d experimental periods to examine the effects of dietary C_{18:2} (n-6) supplementation on ruminal *trans* C_{18:1} and CLA synthesis. Cows were offered a basal diet consisting of grass silage and a cereal based-concentrate (60:40 forage:concentrate ratio, DM basis) supplemented with 0, 250, 500 or

750 g/d of sunflower oil (C, S1, S2 and S3, respectively). The flow of fatty acids leaving the rumen was assessed using the omasal sampling technique and a triple indigestible marker method. Lipid supplementation had no effect on DMI, but shifted ($P < 0.001$) rumen fermentation towards propionate at the expense of acetate, and increased linearly ($P < 0.05$) the flow of C18:0 (237, 408, 514 and 672 g/d for C, S1, S2 and S3, respectively), trans C18:1 (30, 67, 118 and 226), C18:2 (n-6) (5.5, 8.7, 8.7 and 12.5) and total CLA (2.5, 5.0, 9.7 and 12.4) entering the omasal canal. While trans-11 was the predominant isomer (15, 30, 55 and 126 g/d for C, S1, S2 and S3, respectively), the flow of all trans C18:1, including trans-10 (1.3, 4.1, 8.6 and 20.6) and trans-13/14 (4.5, 10.5, 16.9 and 22.6) were enhanced ($P < 0.05$). Cis-9, trans-11 was the most abundant CLA isomer (1.6, 3.9, 8.0 and 9.9 g/d), but sunflower oil supplementation also resulted in linear increases ($P < 0.05$) in ruminal trans-10, cis-12 CLA, trans-8, trans-10 CLA, trans-9, trans-11 CLA and trans-10, trans-12 CLA synthesis. It is concluded that ruminal synthesis is a significant source of cis-9, trans-11 CLA that can be enhanced with dietary supplements of C18:2 (n-6).

Key Words: Ruminal Biohydrogenation, Conjugated Linoleic Acid, Trans Fatty Acids

W94 Effect of fish oil and sunflower oil supplements offered alone or in varying combinations on milk fatty acid composition in cows fed maize silage based diets. K. J. Shingfield^{*1}, C. K. Reynolds¹, D. J. Humphries¹, B. Lupoli¹, V. Toivonen², A. S. Grandison³, M. J. Griinari⁴, and D. E. Beever¹, ¹Centre for Dairy Research, University of Reading, UK, ²MTT Agrifood Finland, Jokioinen, ³School of Food Biosciences, University of Reading, UK, ⁴University of Helsinki, Finland.

Based on the potential benefits of conjugated linoleic acid (CLA) for human health there is a need to develop effective strategies for enhancing CLA concentrations in milk. Five dairy cows in mid-lactation were used in a 5 x 5 Latin Square experiment with 3 week periods to examine the effects of feeding fish oil (FO) or sunflower oil (SO) separately, or in combination, on milk fatty acid composition. Cows were offered 18 kg DM/d of a TMR based on maize silage (65:35 forage:concentrate ratio; DM basis) supplemented (g/kg DM) with FO (15), [FO (15) and SO (15) (FLS)], [FO (15) and SO (30) (FMS)], [FO (15) and SO (45) (FHS)] or SO (60). Lipid supplements were fed during the last 14 d of each period. Treatments had no effect ($P > 0.05$) on DMI, milk yield or milk fat or protein content, but milk fat concentrations were low for all diets (26.3, 26.6, 24.5, 22.9 and 23.6 g/kg, for FO, FLS, FMS, FHS and SO, respectively). Levels of total CLA as determined by GLC and Ag+ HPLC were higher ($P < 0.05$) for FO, FLS and FMS than SO (2.63, 3.04, 2.87 and 1.57 g/100g fatty acids), whilst the response to FHS was intermediate (2.18). For all diets, cis-9, trans-11 was the predominant isomer of CLA (proportionately 0.84, 0.82, 0.81, 0.68 and 0.62 for FO, FLS, FMS, FHS and SO, respectively). Increasing the amount of SO in combination with a fixed amount of FO resulted in a progressive increase in milk trans-10 C18:1 content (8.6, 11.1 and 13.5 g/100g fatty acids, for FLS, FMS and FHS), but caused levels of trans-11 C18:1 to decline (5.6, 5.2 and 2.9). Levels of trans-10 and trans-11 C18:1 were 5.0 and 4.2 for FO and 11.0 and 2.1 for SO. It is concluded that sunflower oil enhances the milk CLA response to fish oil in cows fed maize silage based diets, but high levels induce shifts in ruminal biohydrogenation towards trans-10 C18:1 at the expense of trans-11 C18:1.

Key Words: Conjugated Linoleic Acid, Trans Fatty Acids, Fish Oil

W95 Effects of rumen-protected fatty acid saturation on ruminal and total tract nutrient digestion in lactating dairy cows. K. J. Harvatine* and M. S. Allen, Michigan State University, East Lansing.

Saturated and unsaturated rumen-protected fat sources were evaluated for effects on ruminal digestion kinetics, and ruminal and post-ruminal nutrient digestion. Eight early lactation ruminally and duodenally cannulated cows (77 ± 12 DIM, mean \pm SD) were used in a replicated 4x4 Latin square design with 21 d periods. Treatments were control and a linear titration of 2.5% added rumen-protected FA (RPF) varying in saturation: saturated (SAT); prilled hydrogenated free FA, Energy Booster 100[®]), intermediate mix of SAT and unsaturated (UNS; calcium soaps of long-chain FA, Megalac-R[®]), and UNS FA. Experimental diets were 40% forage and contained 27.5% NDF, 30% starch, and 2.5% rumen

available vegetable oil (13.5% cottonseed). SAT linearly decreased ruminal digestibility of DM and OM because of a linear reduction in ruminal neutral detergent fiber (NDF) digestibility. The reduction in ruminal NDF digestibility was because of a linear decrease in digestion rate and a linear increase in passage rate of potentially digestible NDF for SAT. Total-tract digestibility was not different between treatments because of compensatory post-ruminal digestion. Ruminal FA and C18 FA digestibility tended to increase linearly with UNS, and post-ruminal C18 FA digestibility increased with UNS. SAT linearly decreased ruminal OM digestibility and decreased intestinal long-chain FA digestibility, although differences in FA digestibility may be partially explained by FA intake. Addition of rumen-protected FA may not increase energy intake because of decreased DM intake and negative associative effects on ruminal digestion.

Key Words: Ruminal, Digestibility, Fatty Acid

W96 Effect of Ca salts of palm and fish oils on lactation and reproduction of dairy cows under heat stress. R. G. S. Bruno^{*1}, K. N. Galvao¹, S. O. Juchem¹, W. W. Thatcher², E. J. DePeters¹, D. Luchini³, and J. E. P. Santos¹, ¹University of California Davis, Tulare, ²University of Florida, Gainesville, ³Bioproducts, Inc, Fairlawn, OH.

Multiparous Holstein cows, 331, were randomly assigned to one of the two treatments at calving after blocking according to parity and previous lactation milk yield. Treatments consisted of a diet containing either tallow (TA; 1.3% DM) or a Ca salt of palm and fish oils (CaPFO; 1.5% DM), to provide equal amounts (350 g/d) of fatty acids (FA) from 20 to 130 d in milk (DIM). The Ca salt provided 18 g/d of eicosapentaenoic and docosahexaenoic FA combined. The study was conducted from May to December of 2003 and only cows calving during the hot months (May-August) were enrolled. Cows were milked 3 times daily and production of milk and milk components were measured every two weeks. All cows were subjected to the Presynch/Ovsynch protocol and timed AI was performed between 60 and 70 DIM. Pregnancy was diagnosed at 38 d after AI by ultrasound and reconfirmed 4 weeks later by palpation per rectum. Continuous and binomial data were analyzed by the MIXED and LOGISTIC procedures of the SAS (2001) program. Group DM intake averaged 25.7 kg/d. Yields (kg/d) of milk, 3.5% fat-corrected milk and milk fat did not differ ($P > 0.15$) and were (kg/d), respectively, 44.8, 45.5, and 1.58, for cows fed CaPFO, and 45.51, 46.24, and 1.62 for cows fed TA. Percent of true protein and lactose in milk were reduced ($P < 0.05$) in cows fed CaPFO (2.73% and 4.81%) compared with cows fed TA (2.76% and 4.86%), and solids nonfat tended to be reduced for CaPFO compared with TA (8.37 vs 8.45%; $P < 0.06$). Because of the lower true protein content in milk, protein yield was reduced in cows fed CaPFO (1.22 vs 1.26 kg/d; $P = 0.04$). Conception rates for cows fed CaPFO and TA were similar at d 38 (26.9 vs 25.9%; $P = 0.85$) and 60 (24.1 vs 24.5%; $P = 0.95$) after AI. Similarly, pregnancy loss from d 38 to 60 of gestation did not differ between CaPFO and TA (9.7 vs 4%; $P = 0.41$). These results suggest that feeding Ca salts of palm and fish oils did not influence lactation or reproduction of cows under heat stress, but reduced concentrations of protein, lactose and solids nonfat in milk.

Supported by NRI/USDA Grant 2003-02742.

Key Words: Dairy Cows, Fatty Acids, Milk Production

W97 Modulation of bovine hepatic lipid metabolism by fatty acids. J. A. A. Pires^{*1}, R. R. Grummer¹, D. G. Mashek¹, S. J. Bertics¹, D. Pirazzi², and U. Bernabucci², ¹University of Wisconsin, Madison, ²Università della Tuscia, Viterbo, Italy.

The objective was to investigate the metabolism of different fatty acids (FA) by bovine hepatocytes cultured in monolayer. Hepatocytes were isolated from three 7 to 10 d old male Holstein calves and treated for 48h (from 20 to 68 h after seeding) with either no FA added (control) or 1 mM of palmitic (C16:0), stearic (C18:0), oleic (C18:1), linoleic (C18:2), linolenic (C18:3), eicosapentaenoic (C20:5), docosahexaenoic (C22:6) acid, or a physiological FA mix (NEFA; 15% C18:0, 30% C16:0, 45% C18:1, 5% C16:1, and 5% C18:2). Culture media was collected at 24 and 48h and pooled for total β -hydroxybutyric acid (BHBA) analysis. Total triglycerides (TG) was extracted from cells and quantified. Data were analyzed using Mixed Procedure of SAS. The model included fixed effect of treatment, random effect of calf, and residual error term.

Adding C16:0 or 18 carbon FA caused an increase in TG accumulation. Among 18 carbon FA, increasing unsaturation led to lower levels of TG accumulation. Incubation with C20:5 or C22:6 did not result in TG accumulation. However, adding C20:5 or C22:6 increased BHBA production relative to control, which shows that these FA were being absorbed and oxidized. C18:2 caused the lowest BHBA production of all FA treatments but TG accumulation was similar to all other C18 FA and NEFA. These results show that FA are metabolized differently by bovine hepatocytes. Treatment differences may be related to changes in cell membrane properties, differential absorption of FA, suitability of FA as substrates for enzymes or effects on gene expression of key enzymes in lipid metabolism.

	TG*	BHBA**
Control	3.15 ^{cd} ±0.19	1.37 ^d

W98 Milk fatty acid composition and lactation performance of cows fed linseed oil or fish oil in combination with sunflower seeds. K. F. Kalscheur*, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings.*

This study was conducted to determine the effect of feeding linseed oil or fish oil on production of conjugated linoleic acid (CLA) in milk of cows fed sunflower seeds. Eight primiparous and four multiparous Holstein cows averaging 112 DIM were used in a 4 × 4 Latin square with 4-wk periods. Treatments were: 1) control diet (no oilseeds), 2) 2.5% fat from sunflower seeds (S), 3) 2% fat from sunflower seeds plus 0.5% fat from linseed oil (L), and 4) 2% fat from sunflower seeds plus 0.5% fat from fish oil (F). Diets were composed of a 50% (dry basis) concentrate mix, 25% corn silage, 12.5% alfalfa hay and 12.5% haylage. Cracked sunflower seeds replaced corn and soybean meal in the sunflower diets. Diets averaged 16.6% CP, 29.6% NDF, and 20.1% ADF. Ether extract and NE_L increased from 2.7% and 1.57 Mcal/kg for the control diet, to 5.1% and 1.64 Mcal/kg for the fat supplemented diets, respectively. Dry matter intake (26.9, 27.9, 24.6, and 26.0 kg/d for diets 1 through 4) did not differ ($P > 0.05$). Milk production (38.5, 39.4, 40.7, and 43.8 kg/d) was highest for cows fed F ($P < 0.05$). Milk fat percentage (3.28, 3.25, 3.23, and 2.96) was lower for cows fed F ($P < 0.01$). Addition of supplemental fat did not affect milk protein percentage, MUN, or milk component yields. Concentrations of milk *cis*-9, *trans*-11 CLA (0.53, 0.68, 0.71, and 1.35 g/100 g fatty acids for diets 1 through 4) increased with the inclusion of sunflower seeds, and was highest ($P < 0.01$) when fed with fish oil. Similarly, milk vaccenic acid (TVA) increased (0.60, 0.97, 0.91, and 2.12 g/100g fatty acids) with the addition of sunflower seeds, and was highest ($P < 0.05$) for cows fed F. Cows fed sunflower seeds with fish oil increased milk production and milk CLA and TVA more than cows fed the control or non-fish oil diets. Feeding linseed oil with sunflower seeds did not increase lactation performance or increase milk CLA or TVA.

Key Words: Conjugated Linoleic Acid, Vaccenic Acid, Milk Fatty Acids

W99 The effect of dilution rate and pH on the conversion of stable isotopically labeled oleic acid to trans monoenes in continuous cultures. A. A. AbuGhazaleh*, M. B. Riley, and T. C. Jenkins, *Clemson University, SC.*

A previous in vitro study using batch cultures of mixed ruminal microbes showed that oleic acid was converted to trans monoene isomers. This study was conducted to determine if a similar conversion can occur under different rumen environmental conditions. Four dual-flow continuous fermenters were used to determine the effects of pH and liquid dilution rates on microbial biohydrogenation of ¹³C-labeled oleic acid

to trans monoenes. A 4 × 4 Latin square design with a factorial arrangement of treatments was used, with four 11-d consecutive periods. Treatments were 1) pH 6.5 and 0.10 h⁻¹ dilution rate, 2) pH 6.5 and 0.05 h⁻¹ dilution rate, 3) pH 5.5 and 0.10 h⁻¹ dilution rate, and 4) pH 5.5 and 0.05 h⁻¹ dilution rate. Fermenters were fed twice daily (22g/d) a TMR diet consisting of 55% alfalfa, and 45% concentrate mix (DM basis). The ¹³C-labeled oleic acid (250 mg) dissolved in 5 ml of 95% ethanol was added into fermenters after the morning feeding on d-10 of each period. Samples of digesta were taken at 0 h (before adding ¹³C-labeled oleic acid) and at 24 h after adding ¹³C-labeled oleic acid. Both pH and dilution rate affected trans monoene formation from oleic acid. At pH 5.5, ¹³C enrichment was not detected on the trans double bonds between carbons 11 and 16 compared with pH 6.5. Similarly, at 0.05 h⁻¹ dilution rate ¹³C enrichment was not detected on the trans double bonds between carbons 12 and 16 compared with 0.10 h⁻¹ dilution rate. The percentage of trans-9 and 10 produced from oleic acid was not affected by pH ($P > 0.05$). The percentage of trans-6, 9, 10, and 11 produced from oleic acid was higher ($P < 0.05$) at the 0.10 h⁻¹ dilution rate compared with 0.05 h⁻¹ dilution rate. The percentage of stearic acid produced from oleic acid was not affected by dilution rate ($P > 0.05$) and it was higher ($P < 0.05$) at pH 5.5 (72%) compared with pH 6.5 (26%). The results of this study show that conversion of oleic acid to trans monoenes was reduced under low dilution rate and pH conditions.

Key Words: pH, Dilution Rate, Biohydrogenation

W100 Feeding encapsulated ground full-fat soybean or sunflower oil gel containing tocopheryl acetate to increase tocopherol and linoleic acid levels in lamb carcass. J. H. Lee^{*2,1}, S. L. Melton¹, and J. C. Waller¹, ¹University of Tennessee, Knoxville, ²Fort Valley State University, Fort Valley, GA.

This study investigated the effect of encapsulated ground full-fat soybean (EGFS) or sunflower oil gel (SOG) containing tocopheryl acetate (TA) on tocopherols and fatty acids in feeder lambs. The EGFS were prepared by ground full-fat soybean (GFS) with either acetaldehyde (AC) or diacetyl (DA) to form gels. The SOG contained sunflower oil, TA, defatted soy flour, and DA. In trial 1, lambs (n = 18) were divided into 3 groups (6 heads in 2 pens/group). Groups were fed randomly assigned diets for 9 wk: control (BD+GFS), AC (BD+EGFS-AC), and DA (BD+EGFS-DA) diets. The BD contained corn, alfalfa, and oat. Each lamb was fed daily 0.7 kg of BD and 0.5 kg of GFS to supply same amounts of tocopherols (64 IU). In trial 2, lambs (n = 24) were divided into 3 groups (2 pens of 8 lambs), and the 3 groups were fed randomly assigned diets for 12 wk: BD (control), BD (0.7 kg/lamb/d)+TA(250 IU/lamb/d), and 1/3BD+SOG (0.5 kg/lamb/d). The α-tocopherol levels of longissimus muscle (LD) and pelvic fat (PF) from each lamb in trial 1, as well as LD, gluteus medius (GM), psoas major (PM) and brisket fat (BF) from trial 2, were determined. Fatty acid compositions of LD were also analyzed. All data were analyzed as a completely random design. In trial 1, lambs fed the control diet had a lower ($P < 0.05$) level of α-tocopherol in the PF (2.1 μg/g fat) than lambs fed the AC- or DA-diet (3.0 or 3.3 μg/g fat). Compared with lambs fed the control, lambs fed the EGFS had a higher ($P < 0.05$) level of linoleic acid (18:2) in LD (6.6 vs. 4.8%). In trial 2, lambs fed the BD had lower ($P < 0.05$) levels of α-tocopherol in LD, GM, PM, and BF (3.2, 3.2, 2.2, and 3.2 μg/g, respectively) than lambs fed BD+TA (3.2, 6.1, 6.0, and 12.2 μg/g) or BD+SOG (4.2, 7.6, 7.4, and 12.6 μg/g). Compared with lambs fed BD, lambs fed BD+SOG had higher ($P < 0.05$) levels of 18:2 in LD (13.0 vs. 7.2%). The results imply that both EGFS and SOG supplements may enhance the absorption of tocopherols and increase linoleic acid levels in ruminants.

Key Words: Tocopherol, Tocopheryl Acetate, Linoleic Acid

W101 Corn silage hybrid quality effects on milk production in dairy cows. D. J. R. Cherney*, J. H. Cherney*, L. E. Chase, and W. J. Cox, *Cornell University, Ithaca, NY.*

Higher milk production is the promised outcome for selecting corn hybrids with various traits that impact forage quality. Our objective was to select a set of hybrids most likely to exhibit differences in forage quality and evaluate milk production of cows fed a high forage ration. Four hybrids were selected for the feeding trial: a leafy hybrid (Mycogen TMF 100), a brown-midrib (Mycogen BMR F407), and two hybrids with a range in fiber digestibility (Pioneer 36B08 and Pioneer 35P12). Diets were formulated to provide 1.05% of BW as forage NDF (approx.

31% NDF), and were balanced to meet or exceed NRC requirements. Fifty-six cows were fed for 56 days. Dry matter intake of cows fed BMR and leafy hybrid TMR was higher than those fed the other hybrids. Differences in milk production reflected the differences in intake. Cows fed BMR (41.7 kg d⁻¹) and leafy hybrid (42.1 kg d⁻¹) TMRs were not different from each other in milk production, but had higher (P<0.05) milk production than 35P12 (39.2 kg d⁻¹) and 36B08 (39.0 kg d⁻¹). Higher intake by cows fed BMR TMR than 35P12 and 36B08 TMRs is likely the result of higher digestibility. While the leafy hybrid tended to be higher in digestibility than 35P12 and 36B08, it is likely that lower forage:concentrate ratio of the leafy hybrid TMR than the other TMR also contributed to its higher intake. Ruminal concentrations of propionate were higher in cows fed BMR than those fed other hybrids, which could also result in higher milk production. Corn silage hybrids selected for improved forage quality can result in higher milk production by cows fed the improved hybrids in high forage diets.

Key Words: Corn Silage, Digestibility, Milk Production

W102 Variation throughout lactation and between herds in maintenance energy expenditures of dairy cows estimated from energy balance data. J. L. Ellis*, F. Qiao, and J. P. Cant, *The University of Guelph, Ontario, Canada.*

Maintenance energy expenditures and between-herd variation in maintenance energy expenditures for Holstein dairy cows were evaluated from average weekly NE balance estimates in 21 herds throughout lactation. NE balance was calculated from observed intake, growth and milk production data according to NRC as $DMI \cdot NE(l) \text{ feed} - FCM \cdot 0.749 \cdot 0.08 \cdot BW^{0.75}$. For first-lactation cows, a modified version of the NRC growth expenditure equation was added into the energy balance equation: $0.0103 \cdot (BWT \cdot 0.96)^{0.75}$. Bodyweight was predicted as 0.203 times NE balance if the balance was negative and 0.195 times balance if positive. When the NRC maintenance parameter 0.08 Mcal/kg BWT^{0.75} was used in energy balance calculation, bodyweight was over-predicted, with an increasing difference between predicted and observed bodyweight as lactation progressed. The maintenance parameter that resulted in the least residual sum of squares (LSS) for bodyweight prediction throughout lactation for each data set was determined. The average LSS maintenance parameter for the 21 data sets was 0.096 Mcal/kg BWT^{0.75}, with a standard deviation of 0.0182. Average maintenance energy parameters estimated weekly for an NE balance of 0 Mcal/d were determined and plotted against week of lactation. Average maintenance energy expenditure at the onset of lactation was approximately 0.085 Mcal/kg BWT^{0.75}. This value increased until week 15 of lactation where it plateaued at approximately 0.100 Mcal/kg BWT^{0.75}. At #8805 40 weeks of lactation it decreased. Standard deviation between data sets of weekly maintenance parameter estimates throughout lactation was large but consistent at approximately 20% of the mean. In conclusion, maintenance energy expenditures during lactation appear to vary considerably, but are higher than the conventional 0.08 Mcal/kg BWT^{0.75}, and expenditures during lactation appear to change, increasing up to approximately week 15 of lactation, maintaining an elevated level until approximately week 40 of lactation and then declining again.

Key Words: Maintenance Energy Expenditures, Energy Balance, Lactation

W103 Effect of an amino polysaccharide on production and composition of milk of Holstein and Jersey cows in México. G. González-Luna¹, J. Sánchez-Meraz¹, S. S. González*¹, J. Pinos-Rodríguez², R. Bárcena-Gama¹, Ma. E. Ortega-Cerrila¹, and S. Infante-Gil¹, ¹*Colegio de Postgraduados, Mexico*, ²*Universidad Autónoma de San Luis Potosí, Mexico.*

The main objective of this research was to determine the effect of an amino polysaccharide (Aminoglucolite, Química Foliar, México) on milk production and composition of Holstein and Jersey cows in México. Two trials were performed, one using Jersey cows at San Carlos ranch, State of San Luis Potosí, and the second with Holstein cows at Ojo de Agua ranch, State of Guanajuato. Trial 1 lasted 56 d with two groups of 30 cows each; days on milk (used as a covariable) were 89 d for treated and 74 d for control cows; a complete mixed ratio (50:50 forage:concentrate) was used. Trial 2 lasted 60 d with two groups of 25 cows each; a complete mixed ratio (70:30 forage:concentrate) was used. For both trials, treatments were 0 (control) or 40 g Aminoglucolite/d/cow (mixed with the concentrate); experimental design was completely randomized and

data were analyzed using repeated measurement procedure (SAS), and covariance analysis. In trial 1, Aminoglucolite (vs control; P<0.10) increased milk production (31.9 vs 26.3 L/d), protein (4.1 vs 3.9% at 14 d; 4.2 vs 3.9% at 42 d), lactose (5.1 vs 4.6% at 56 d), non-fat solids (9.7 vs 9.4% at 14 d; 9.7 vs 9.5% at 42 d), but it decreased milk fat (5.4 vs 4.7%), and urea-N (8.4 vs 13.8 mg/dL). In trial 2 (vs control), Aminoglucolite increased fat corrected milk (23.4 vs 20.8 L/d; P<0.05) and solid corrected milk (20.7 vs 19.0 L/d; P<0.10) in the sixth week; there were no differences (P>0.10) for concentration of fat (%), protein (%), lactose (%), nonfat solids (%), and urea-N (mg/dL) in milk. Somatic cell count (SCC) was decreased by Aminoglucolite: 944 000 to 555 000/mL in trial 1, and 615 000 to 266 000/mL in trial 2. Results suggest that addition of this amino polysaccharide to dairy cows diets may improve milk production and composition, and decrease SCC.

Key Words: Amino Polysaccharide, Milk Production and Composition, Dairy Cows

W104 Replacing chopped alfalfa hay with alfalfa silage in barley grain and alfalfa based total mixed rations for lactating dairy cows. J. C. Plaizier*, *Department of Animal Science, University of Manitoba, Canada.*

The effects of replacing chopped alfalfa hay with alfalfa silage in a fine barley grain and alfalfa based total mixed ration (TMR) were evaluated using 12 multiparous Holstein cows in a 3 x 3 Latin square design. Diets contained (DM basis) 53.0% commercial energy supplement, 10.3% commercial protein supplement, and 9.7% corn silage. Diets varied in inclusion of chopped alfalfa hay and alfalfa silage, and contained either 20.0% chopped alfalfa hay and 7.0% alfalfa silage (H), 10.0% chopped alfalfa hay and 17.0% alfalfa silage (HS), or 27.0% alfalfa silage (S). Rumen fluid was collected using an oral probe between 4 and 5 hr after feeding. Contents of protein and fibre did not differ among diets. Replacing chopped alfalfa hay with alfalfa silage decreased dietary dry matter (DM), and increased dietary soluble protein (SP). Replacing chopped hay with silage reduced the proportion of TMR passing through the 8 and 19 mm screens of the Penn State Particle Separator (PSPS) from 27.6 to 37.9%, increased the physical effective NDF calculated as the proportion of dietary NDF retained by the two screens of the PSPS (peNDF_{NDF}), from 13.3 to 15.6% DM, and increased the proportion of DM retained by a 1.18 mm screen after dry sieving multiplied by dietary NDF (peNDF_{>1.18}) from 23.4 to 25.6 %DM. Proportions of TMR retained by the PSPS screens were lower than recommended. Replacing chopped alfalfa hay with alfalfa silage did not affect dry matter intake, rumen pH, rumen VFA, blood lactate, milk fat, and milk protein, but decreased blood glucose, tended to increase blood urea and numerically decreased milk yield. A wider range in peNDF_{NDF} and peNDF_{>1.18}, and a higher inclusion of corn silage might have resulted in greater differences in rumen fermentation and milk production among diets. The pH of rumen fluid samples varied from 5.90 to 5.98, and milk fat percentage varied from 2.50 to 2.60% among diets. These values suggest that subacute ruminal acidosis (SARA) was induced by all diets.

W105 Soybean hulls and corn gluten feed for replacing corn silage neutral detergent fiber in total mixed rations of lactating cows. M. Lima^{*1}, L. G. Nussio², and W. Mattos², ¹Universidade Federal de Goiás, Escola de Veterinária, DPA, Goiania, GO, Brazil, ²Escola Superior de Agricultura Luiz de Queiroz, Padua Dias, Praticaba, SP, Brazil.

Four ruminally and duodenally cannulated Holsteins cows were used in a 4 x 4 Latin square design with 14-d periods to evaluate fiber effectiveness of pelleted soybean hulls (PSH) and corn gluten feed (CGF). Four isonitrogenous and isoenergetic diets were formulated, and low (LF) and high forage (HF) diets [14% and 22% of dietary DM from corn silage (CS), respectively] were compared to diets formulated to contain 14% CS NDF plus 8% of DM from PSH NDF or CGF NDF. Dry matter, CP and NDF were 28.2%, 9.2% and 44.5%; 88.8%, 10.3% and 68.2%; 89.1%, 27.2% and 38.8%, respectively for CS, PSH and GGF. The NDF intake was lower ($P < .05$) for cows fed LF (3.52 kg/d) diets than those fed HF, PSH and CGF diets (4.55 kg/d). Dry matter intake (16.9 kg/d), milk yield (19.9 kg/d) and milk crude protein (3.17%) did not differ among diets, but milk fat was higher for cows fed HF (3.80%) and CGF (3.70%) diets ($P < .05$) than those fed LF (3.27%) and PSH (3.17%) diets. Fat correct milk (3.5%) was significantly lower ($P < .05$) for cows fed the PSH (18.3 kg/d) diet than those fed HF and CGF diets (20.8 kg/d). Mean rumen pH was higher ($P < .05$) for cows fed HF (5.95) than those fed the other diets (5.74). Total VFA concentration did not differ among cows fed experimental diets, but propionic acid (mol/100 ml) was higher ($P < .05$), and acetic acid (mol/100 mol) and acetate:propionate ratio were lower ($P < .05$) for those fed PSH and CGF diets than those fed the HF diet. Ruminating (min/d and min/kg of NDF) and chewing (min/d and min/kg of NDF) activities were lower ($P < .05$) for cows fed the PSH and CGF diets than those fed LF and HF diets. Rumen mat consistency (cm/s) was also lower ($P < .05$) for cows fed PSH and CGF diets than those fed HF diet. Under our condition, PSH NDF or CGF NDF were not as effective as CS NDF to keep mean rumen pH and chewing activities, and these responses can increase the risk of acidosis for cows fed PSH and CGF diets.

Key Words: Fiber Effectiveness, Mean Rumen pH, Chewing Activities

W106 Effects of dietary forage and non-fiber carbohydrate concentrations on apparent B-vitamin synthesis in dairy cows. E. C. Schwab^{*1}, C. G. Schwab^{*2}, C. L. Girard³, R. D. Shaver¹, D. E. Putnam⁴, and N. L. Whitehouse², ¹University of Wisconsin, Madison, ²University of New Hampshire, Durham, ³Dairy and Swine R&D Center, AAC, QC, Canada, ⁴Balchem Encapsulates, New Hampton, NY.

Eight Holstein cows (four primiparous, four multiparous) were fitted with ruminal and duodenal cannulas to test the effects of dietary forage (F) and NFC concentrations on B-vitamin apparent synthesis (AS). Cows were used in a replicated 4x4 Latin square design balanced for carryover effects with a 2x2 factorial arrangement of treatments. Each square contained two multiparous and two primiparous cows and periods were 21 d in length. Experimental diets with 35 or 60% (DM basis) forage (corn silage, alfalfa hay, and grass hay) were formulated to contain either 30 or 40% NFC (DM basis). The concentrate portion of the diets was composed of varying proportions of soybean hulls, beet pulp, corn grain, rolled barley, soybean meal, blood meal, Smartamine-M[®], vitamins, and minerals. Apparent B-vitamin synthesis is defined as the difference between duodenal vitamin flow and vitamin intake. This estimate does not consider potential ruminal microbial metabolism (use or destruction) or ruminal absorption of the vitamins. There was a significant F effect on AS for all B-vitamins except pyridoxal (PAL). Apparent synthesis of B-vitamins was largely unaffected by NFC content, however AS of B₁₂ and PAL were both influenced by dietary NFC content. A FxNFC interaction existed only for thiamin AS. Negative AS values for pyridoxine (PYR) suggest that this form of vitamin B₆ was either ruminally destroyed or utilized, absorbed through the rumen wall, or converted to another B₆ form.

Item	Diets					F	Effect (P<) ⁵	
	3530	3540	6030	6040	SEM		NFC	FxNFC
Thiamin AS mg/d	70	55	48	53	6	0.01	NS	0.02

W107 Effects of physically effective NDF on chewing activity and rumen pH of dairy cows fed diets based on corn silage. W. Z. Yang^{*} and K. A. Beauchemin, *Research Center, Agriculture and Agri-Food Canada, Lethbridge, AB.*

A study was conducted to investigate the effects of physically effective (pe) NDF content of dairy cow diets containing corn silage on chewing activity and rumen pH. The study was designed as a double 3 x 3 Latin square using six lactating dairy cows with ruminal cannulas. Three levels of dietary peNDF (high, medium and low) were compared. The three levels of peNDF were obtained using corn silage as originally prepared, corn silage rechopped once, or corn silage rechopped twice. The peNDF content of the diets was determined as the proportion of the TMR (as-fed) retained on the 0.75" and 0.31" screens of the Penn State Particle Separator multiplied by dietary NDF content (DM basis). The peNDF contents were 11.5, 10.3 and 8.9%, for the high, medium and low peNDF diets, respectively. Ruminating time (494, 472 and 441 min/d, for high, medium or low, respectively) was linearly affected by intake of peNDF. Eating time (273, 315 and 258 min/d, for high, medium or low, respectively) and total chewing time (767, 787 and 700 min/d for high, medium or low, respectively) were quadratically increased with increasing peNDF intake. Mean pH, area between the curve and pH 5.8 or 5.5, and time that pH was below 5.8 or 5.5, were not affected by peNDF intake. Intake of peNDF was not correlated to eating time but was correlated to ruminating time ($r = 0.49$, $P < 0.05$). In contrast, mean rumen pH was negatively correlated to intake of peNDF ($r = -0.39$, $P < 0.15$) and ruminating time ($r = -0.45$, $P < 0.15$). These results indicate that increasing the peNDF content of diets increases chewing time. However, increased chewing time does not always improve rumen pH status. Although increasing chewing time is expected to increase salivary secretion, the increase may not fully overcome the effects of feed digestion and the production of fermentation acids that lower rumen pH. Models that predict rumen pH need to include both peNDF and fermentable OM intake.

Key Words: Physically Effective NDF, Chewing, Rumen pH

W108 Effect of physical and heat processing of cottonseed on chewing activity of Holstein dairy cows. A. R. Foroughi^{*}, A. A. Naserian, R. Valizadeh, and M. Danesh mesgaran, *Ferdowsi University of Mashhad, Tehran, Iran.*

Based on chewing response, whole cottonseed (WCS) appears to be the most effective fiber source from byproduct feeds. Eight multiparous Holstein dairy cows averaging 84.50±10.34 days in milk and 36.10±4.46 milk yield (MY) were used in a 4 x 4 Latin Square design. Cows were divided into four dietary treatment groups. Dietary treatments were 1) WCS; 2) ground cottonseed; 3)GCS heated in 140°C and steeped for 2.5 minute (GHCS1); or 4) GCS heated in 140°C and steeped for 20 minute (GHCS2). Total mixed diets were fed individually free choice twice daily. Diets were formulated to contain 20% alfalfa hay, 17% corn silage, 14% different processed cottonseed and 49% concentrate and had the following composition, dry matter 79.5%, NDF 35.2%, CP 18.5% and NEL 1.58 (Mcal/KgDM). Each period consisted of 21 days and the last 7 days were used for dry matter intake(DMI). Chewing activity

were estimated through a visual observation method at 5-minute intervals during 24h at 18d of each period. The mean DMI was significantly ($P < 0.01$) affected by diets and in treatments of 1,2,3 and 4 were 25.97, 27.24, 27.63, and 27.63 (kg/d), respectively. The mean rumination times between treatments (min/kg NDF intake) were significantly different and for treatments 1,2,3 and 4 were 54.02, 45.63, 44.24, and 46.97, respectively. This represented a 15% decrease between 1 and 2. However, chewing activity was similar for four treatments averaging 279 min/24h. Significant differences were not observed in eating activity min/24h and min/kg NDF Intake and ruminating activity (min/24h), Grinding and heat treatment of cottonseed did not affect of chewing activity of dairy cows.

Key Words: Whole Cottonseed, Grinding and Heat Treatment, Chewing Activity

W109 Relationship between TMR, corn silage particle size and manure evaluation in dairy cows. G. Mancin¹, V. Dell'Orto², and G. Savoini*², ¹Dept. of Morphology, Biochemistry, Physiology and Animal Productions University of Messina, Italy, ²Dept. of Veterinary Sciences and Technologies for Food Safety, University of Milan, Italy.

The aim of the trial was to study the correlation between TMR, corn silage particle size and manure evaluation in order to give some useful tools to dairy farmers to improve milk production efficiency. Five dairy farms were involved in the trial that lasted 60 days. TMR and corn silage particle size were evaluated every two weeks by Penn State Particle Separator (PSPS). Ten fresh cows per farm were selected for manure appearance and particle size evaluation. Faecal samples were collected every two weeks and rinsed with water into a strainer with 1.6 mm openings. Faecal undigested fractions were classified by score from 1 (no large fibre particles, no ground grain) to 5 (large fibre particles, abundant ground grain). Data were analyzed by Pearson correlation. TMR average particle size distribution was quite different compared to PSPS guidelines, indeed the percentage of TMR retained on the upper sieve (15.97%) was greater compared to PSPS guidelines, this is probably due to the high quantity of forage used in our rations (average NDF=37,4%_{ss}) and greater length of hay and grass silage particles. Corn silage particle size distribution was in accordance with the PSPS guidelines, for this reason significant positive correlations were observed between corn silage and TMR percentages retained on mid, low and bottom sieves. Positive correlations were observed among ration NDF and TMR particles retained on upper and middle sieves ($r=0.19$; $r=0.29$); moreover significant positive correlation was observed between eNDF and TMR particle size on upper sieve ($r=0.47$). Significant positive correlation was observed among milk production and TMR particles retained on middle sieve ($r=0.56$) and faecal undigested fraction ($r=0.39$). TMR particle size distribution and manure evaluation are useful tools to improve milk production efficiency, indeed the TMR particles retained on middle sieve is positively correlated to milk production and faecal undigested fractions.

Key Words: TMR, Manure Evaluation, Milk Production Efficiency

W110 Intake and milk production of cows fed diets that differed in dietary NDF and NDF digestibility. C. Kendall* and D. K. Combs, University of Wisconsin, Madison.

This study evaluated how intake and milk production were affected by feeding diets that differed in dietary NDF concentration and NDF digestibility. Twelve rumen cannulated, multiparous Holstein cows averaging 39 DIM and producing 39.5 kg/d of milk, were used in a replicated 4 x 4 Latin Square design with 28 d periods. Treatments were arranged in a 2 x 2 factorial with 28% or 32% dietary NDF concentration (DM basis) and two levels of straw NDF digestibility: 1) untreated wheat straw (control, 77 % NDF, 41% NDFD), and 2) anhydrous ammonia-treated straw (76% NDF, 62% NDFD, DM basis). All diets consisted of alfalfa silage, corn silage and a concentrate mix of cracked corn grain, corn gluten meal, 48% soybean meal, vitamins and minerals. Wheat straw comprised 8.5% DM of the 28% NDF diets and 16% DM of the 32% NDF diets. Cows were offered TMR twice daily and fed ad-libitum. Milk and FCM production were higher on the low NDF diets. Milk and FCM also increased when NDF digestibility of the diets was increased. Intake of DM was greater when cows consumed the 28% NDF diets, but intake of total NDF was greater in the 32% NDF diets. Intakes of DM

and total NDF were not affected by NDF digestibility. Milk production and DMI were not affected by the interaction of dietary NDF and NDF digestibility. These results suggest that dietary NDF and NDF digestibility improved milk production additively. Intake was improved by reducing dietary NDF, but DM and total NDF intakes were not affected by NDF digestibility.

W111 Effect of physical forms of concentrate on milk composition and milk production of lactating Holstein cows. J. Teixeira*, B. Madeira, L. Teixeira*, and M. Santos, Universidade Federal de Lavras, Lavras, MG, Brazil.

Twenty seven lactating Holstein cows averaging 20 kg of milk yield (50 days lactation) were used in a 3x3 Latin square design trial, with three treatments and three periods of 15 days each. The three treatments tested were the physical forms of concentrate: (T1) pelleted, (T2) meal and (T3) extruded. The diets showed the same chemical composition. This trial was undertaken in Bela Vista Farm, in Curvelo, MG, Brazil. The objective of this trial was to determine the effect of these three different physical forms of concentrate on milk composition and milk production of lactating cows in a free stall. The cows were selected based in milking production and number of lactation. Each experimental period consisted of 9 days of adaptation and six days of milk collection. All cows were fed with napier grass and tifton grass haylage. Were collected and weighed milk samples of two milking per day in every 6-days. The following milk components were determined: fat, total solids, lactose, crude protein and urea using infrared method. The treatments did not affect ($P < 0.05$) milk composition, however the extruded form ($P < 0.05$) decreased urea levels (mg/dl) (T1) 21.88; (T2) 21.15; (T3) 19.16 and increased the milk production and milk production corrected by 4% fat.. Average milk production (kg) were (T1) 17.32; (T2) 17.35; (T3) 18.31 and (T1) 15.66; (T2) 15.78, (T3) 16.81 respectively.

Key Words: Milk Production, Milk Composition, Physical Forms of Concentrate

W112 Daily and diurnal variations in fecal ratios of n-alkanes concentrations in lactating cows grazing a tropical plant. D. E. de Oliveira*², S. R. de Medeiros³, L. J. M. Aroeira⁴, and D. P. D. Lanna⁵, ¹FAPESP, ²Agroceres Nutrio Animal, ³Embrapa Gado de Corte, ⁴Embrapa Gado de Leite, ⁵USP/ESALQ.

The objective of this study was to measure the daily and/or diurnal variation in the fecal concentration of the n-alkanes C₃₁, C₃₂, C₃₃. The ratios of C₃₁:C₃₂ and C₃₃:C₃₂, used in estimation of forage intake were also evaluated. Twenty lactating Holstein x Gir cows were used, ten were individually fed 150g of CLA-60 and the other ten 150g of Megalac, mixed in the morning concentrate (4.0 kg/day). The animals were dosed orally with a controlled-release capsule containing the n-alkanes C₃₂ and C₃₆ and managed in a rotational grazing system os Stargrass (Cynodon nlemfuensis). After seven days of capsule delivery, samples of feces were collected from rectum, every morning and afternoon of the next five days. The forage samples were collected by the

hand plucking method. The n-alkanes were extracted by direct saponification and analyzed by gas chromatography. The variations in the individually fecal concentrations of the n-alkanes and ratios, between the morning and afternoon and among days of collection were done by the Proc Mixed procedure (SAS, 2001). There were treatment effects (CLA=226.9 mg vs. MEG=211.3 mg, $P=0.01$), of time of day (morning=203.3 mg vs. afternoon=235.1 mg, $P=0.0001$) and a linear effect of day of collection (-9.6 mg/day) on the fecal concentration of C_{31} . For the fecal concentration of the n-alkane C_{32} there were effects of time of day (morning=102.5 mg vs. afternoon=109.4 mg, $P=0.0001$) and a quadratic effect of day of collection ($P=0.0001$). The fecal concentration of C_{33} varied between time of day (morning=304.4 mg vs. afternoon=338.7 mg, $P=0.0001$). The $C_{31}:C_{32}$ fecal concentrations ratio varied between time of day (morning=2.16 mg vs. afternoon=2.33, $P=0.0007$). For $C_{33}:C_{32}$ ratio there were differences for time of day (morning=2.96 mg vs. afternoon=3.19 mg, $P=0.0009$) and a quadratic effect for day of collection ($P=0.0001$). The variations observed for fecal ratios of n-alkanes concentrations would have important influence on forage intake estimates.

Key Words: Alkanes, Grazing Cows, Tropical Plant

W113 Changes in milk fatty acids during transition of dairy cows from diets based on conserved forage and grain to pasture. G. Aguiar, T. R. Dhiman*, A. L. Ure, S. F. Porter, and L. L. Jeffs, *Utah State University, Logan.*

Eleven cows were used in a 50 d experiment to study the influence of turning cows out to and withdrawal from pasture on fatty acid (FA) profile and vitamin E levels in milk. Prior to the start of the experiment cows received a total mixed ration (TMR) containing 50% conserved forage and 50% grain. Milk samples were collected from a.m. and p.m. milkings during the first 2 d of the experiment (Phase 1) while cows were fed TMR. On day 3, cows were turned out to the pasture and remained on pasture until day 36 of the experiment (Phase 2). Cows were acclimatized to pasture gradually (25, 50, and 75% pasture for 2 d each) over a period of 1 wk. On day 37 cows were withdrawn from the pasture and remained on the experiment until day 50 (Phase 3) on a TMR diet similar to phase 1. Milk samples from both a.m. and p.m. milkings were collected on alternate days during phases 2 and 3 for FA analysis. Milk samples from day 28 during phase 2 and day 50 of phase 3 were analyzed for vitamin E (α plus γ tocopherol). Cows produced 31.4 ± 3.7 , 17.5 ± 4.6 , and 19.0 ± 6.8 kg milk/d with 3.64 ± 0.02 , 4.02 ± 0.37 , and $3.65 \pm 0.16\%$ fat in phases 1, 2, and 3, respectively. The conjugated linoleic acid (CLA) and $C_{18:1}$ *trans*-11 (TVA) contents of milk were 0.63 and 4.09% of fat during phase 1 and reached a maximum of 2.28 and 7.30% on day 32 of turning cows out to pasture ($P < 0.05$), respectively. The $C_{18:3}$ maximized at day 14 ($P > 0.05$) on pasture. Total ω -3 FA were 0.38% of milk fat during phase 1 and increased to 1.12% of fat by day 16 ($P < 0.05$) on pasture. The vitamin E level of milk was higher ($P < 0.001$) when cows were grazing on pasture during phase 2 as compared to consuming conserved forage and grain during phase 3 (0.44 vs. 0.24 $\mu\text{g}/\text{ml}$). Cows grazing on pasture exhibit higher CLA, ω -3, and vitamin E levels in milk compared with cows consuming a forage plus grain diet. In addition, cows moving from a conventional diet to grazing on pasture with a 1 wk transition period may require a minimum of 4 wk to maximize/stabilize CLA, TVA and ω fatty acid levels in milk.

Key Words: Cow, Pasture, Fatty Acid

W114 Preparation of fresh forage for *in vitro* and *in sacco* incubations. A. V. Chaves¹, G. C. Waghorn*², and I. M. Brookes¹, ¹*Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand*, ²*Dexel Limited, Hamilton, New Zealand.*

In vitro and *in sacco* procedures are well established and are usually carried out on forage prepared by freeze drying and grinding through a 1 mm screen. This may be appropriate for grains and high dry matter material, but is not necessarily suitable for ruminants grazing fresh pasture. Ideally the sample preparation for *in vitro* and *in sacco* incubations of fresh forages to determine digestion characteristics should mimic the particle distribution resulting from chewing during eating and rumination. The objective of this work was to compare the particle size

distribution of the rumen contents of animals fed forages and ryegrass prepared using a mincer. Frozen ryegrass at different stages of maturity were chopped into approximately 2 cm lengths (scissors) and minced in a Kreft Compact meat mincer R70 fitted with a screen plate with 12 mm holes. The mincer components were placed in a freezer prior to mincing to ensure the grass remained frozen and this enabled the forage to be macerated rather than squeezed and prevented excessive cell wall rupture during mincing. The process was designed to mimic effects of chewing by ruminants as far as possible. Samples of minced forage were retained for measurement of particle size distribution by wet sieving. Mincing enabled 37% of DM able pass a 0.25 mm sieve and 31% was unable to pass a 2 mm sieve. This distribution is similar to that of rumen contents in sheep and cattle fed forages but the soluble (A) fraction from ryegrass accounted for a slightly higher proportion of DM than identified by sieving. The higher value for A fraction supports studies showing chewing ruptured 60% of the fresh forage cells. The technique for measuring particle size and release of cell contents may contribute to these anomalies. The mincing preparation used for *in vitro* and *in sacco* incubations showed a high degree of uniformity and the proportional distribution of DM across particle sizes resemble these for chewed forage and rumen contents. The preparations used here provide sufficient large particles which are important in forage incubations and mimic mastication by ruminants.

Key Words: Preparation, Forage, Incubations

W115 Inducing subacute ruminal acidosis (SARA): Effects on ruminal pH, DMI, and milk production. K. M. Krause* and G. R. Oetzel, *School of Veterinary Medicine, University of Wisconsin, Madison.*

Data from trials in which SARA was induced in lactating dairy cows (DIM 154 ± 118) were evaluated in order to investigate the effectiveness of the induction protocol and its effect on production parameters. For 13 cows in three trials, ruminal pH was measured continuously and recorded each minute; dry matter intake and milk yield was recorded daily. Milk composition data were obtained from 9 cows in two of these trials. The SARA induction protocol included four separate Periods: four days of Baseline (normal TMR fed), one day of 50% Restricted feeding, one or two day of Challenge feeding (addition of 4-5 kg wheat/barley pellet to normal TMR), and two days of Recovery measurements when feeding normal TMR. Data were analyzed including Period, Trial, and their interaction in the model. Mean comparisons were by least significant difference method after a significant ($P < 0.05$) Period effect was found. All reported differences are significant ($P < 0.05$). The SARA induction protocol lowered mean ruminal pH from 6.29 during the Baseline period to 5.86 during the Challenge period; pH remained below Baseline level during the Recovery period (6.15). Mean ruminal pH was highest (6.57) during the day of Restricted feeding. Nadir ruminal pH decreased from Baseline to Challenge period (5.73 vs. 5.17). Hours below pH 5.6 increased from 1.4 to 8.3 per d from Baseline to Challenge period and area below 5.6 (pH x min/d) increased from 18 to 198. Dry matter intake was not affected by SARA induction. Milk yield dropped from 35.2 kg/d during Baseline to 31.7 kg/d during the Challenge period and did not return to Baseline level during the Recovery period (31.3 kg/d). No depression in milk fat percentage was observed when SARA was induced. Yield of fat was highest during the Restricted feeding period (1.47 kg/d) and was lower during the Recovery period than during the Baseline period (1.12 vs. 1.31 kg/d). Protein percentage was unaffected by the protocol. The protocol successfully induced SARA (low ruminal pH) on the Challenge day. Milk yield was substantially reduced and did not recover within two days after the challenge.

Key Words: Subacute Ruminal Acidosis, Dry Matter Intake, Milk Production

W116 The effects of monensin on feed intake pattern during sub-acute ruminal acidosis in dairy cows. D. E. Lunn¹, T. Mutsvangwa¹, N. E. Odongo*¹, T. F. Duffield², R. Bagg³, P. Dick³, G. Vessie³, and B. W. McBride¹, ¹*Department of Animal and Poultry Science, University of Guelph, Ontario, Canada*, ²*Department of Population Medicine, University of Guelph, Ontario, Canada*, ³*Elanco Animal Health Division, Eli Lilly Canada Inc, Guelph, Ontario, Canada.*

The objective of this study was to determine the effects of monensin on feed intake patterns during induced sub-acute ruminal acidosis (SARA)

in Holstein dairy cows fed a total mixed ration (TMR). The experiments were conducted as a two-treatment, two-period crossover design with a 7-d adaptation period before induction of SARA, a 10-d SARA period and a 7-d post SARA recovery period using six multiparous Holstein cows (630.5 ± 35.4 kg BW; 81.2 ± 49.6 DIM; experiment 1 and 667.7 ± 46.2 kg BW; 150.2 ± 53.2 DIM; experiment 2). In experiment 1, monensin was administered as a controlled-release capsule (Rumensin[®] CRC) (32 g of monensin sodium blended into a hexaglycerol distearate matrix core) whereas in experiment 2, monensin was added as Rumensin[®] Premix (22 ppm of dry matter) using soybean hulls as carrier. In both experiments, the control diet was identical to the monensin treatment diet except it did not contain monensin. Feed intake patterns were monitored continuously over 24 hrs using a weigh cell system within the manger and meal size and meal duration recorded by a computer hooked to the system. SARA was induced by restricting TMR intake to 85% of ad libitum intake and replacing the remaining 15% with a grain pellet consisting of 50% wheat and 50% barley. In both experiments, the number of meals consumed during SARA were lower (P<0.05) than during the adaptation and recovery periods suggesting the animals might have been attempting to attenuate SARA by reducing intake. In experiment 1, CRC had no effect (8.7 vs. 8.7, P=0.96) on feed intake patterns although there was a tendency (7.4 vs. 8.0, P=0.19) for number of meals consumed on CRC during SARA to be higher. In experiment 2, the premix significantly increased the overall number of meals consumed (7.3 vs. 8.1, P=0.01); number of meals consumed during SARA (6.0 vs. 7.2, P=0.04) and number of meals consumed during the recovery period (7.5 vs. 9.0, P=0.004). These results suggest monensin may increase meal frequency in lactating dairy cows when under conditions of SARA. However, potential differences in the mode of action between monensin delivered in a Rumensin[®] CRC or in Rumensin[®] Premix merits further research.

Key Words: Dairy Cows, Ruminant Acidosis, Monensin

W117 Diet digestibility and rate of passage in Jersey and Holstein Friesian cows during transition. P. C. Aikman^{*1}, A. Boydell², A. Le Gallais³, D. J. Humphries¹, C. K. Reynolds⁴, and D. E. Beever¹, ¹CEDAR, The University of Reading, UK, ²BOCM PAULS Ltd, Bristol, UK, ³Jersey Milk Marketing Board, St. Saviour, NJ, ⁴The Ohio State University, Wooster.

The effect of breed on diet digestibility and rate of passage (ROP) was measured in six Jersey (J; initial BW 462 ± 18 kg) and six Holstein Friesian (HF; initial BW 678 ± 18 kg) third parity cows at wk 5 before expected calving date (ECD) and wk 6 and 14 postpartum. From drying-off until wk 3 before ECD cows were fed a TMR (660 g grass silage, 220 g grass hay and 120 g concentrates/kg DM; 146 g CP and 523 g NDF/kg DM) according to BW. From calving, cows were fed ad libitum a TMR (311 g corn silage, 311 g grass silage and 378 g concentrates/kg DM; 173 g CP and 386 g NDF/kg DM). Digestibility was assessed by total faeces collection for 5 d. To determine ROP a dose of Cr-mordanted grass silage (1% of DMI) was fed at the start of each period and Cr concentration in faeces measured at regular intervals for 120 h post-dosing. Transit time (TT; h to first appearance of Cr in faeces) and rate constants describing the proportion of feed passing out of the rumen (k₁) and hindgut (k₂) per hour were estimated. HF had higher (P < 0.001) DM, OM, starch, NDF and ADF intakes (18.12, 16.88, 2.91, 6.92 and 4.18 kg/d, respectively) than J (12.26, 11.41, 1.86, 4.82 and 2.94 kg/d, respectively). Breed did not affect digestibility of DM, OM, starch or ADF (respective mean values: 712, 733, 941 and 538 g/kg). NDF digestibility was higher (P < 0.008) in J compared to HF (629 and 602 g/kg respectively). k₁ was higher (P < 0.016) in J than HF (0.031 v 0.027), k₂ tended to be higher in J than HF (0.078 v 0.074, P < 0.106), but TT did not differ (12.19 v 11.46 h, J and HF respectively, P > 0.377). Fiber digestibility and TT declined (P < 0.001) in both breeds as DMI increased postpartum, but the decrease in TT was less in J (P < 0.050). In conclusion, k₁ was greater for J than HF at equal DMI/kg BW. NDF digestibility was higher for J cows despite faster ROP from the rumen, which may reflect differences in mastication and particle size reduction.

Key Words: Jersey Cows, Digestibility, Rate of Passage

W118 The effects of glucogenic supplements prepartum and calcium soap of fatty acids postpartum on production and peripartum metabolites in high producing dairy cows. U. Moallem^{*1}, H. Lehrer¹, M. Katz^{1,2}, and D. Sklan², ¹Department of Dairy Cattle, Institute of Animal Science, ARO, Isreal, ²Animal Science Department, Faculty of Agriculture, Hebrew University, Rehovot, Isreal.

This study examined the effects of feeding supplements containing glucogenic precursors prepartum and calcium salts of fatty acids (CSFA) postpartum until 120 DIM, on production and blood metabolites. Twenty-four dry and 250 d pregnant cows were housed in an open barn with electronic individual feeding system and were divided on the basis of previous milk production and parity to one of two treatments: control: dry cow diet (NRC requirements) 2) treatment fed the control diet + top dressed with 550 g of a commercial glucogenic supplement (ProGlyc 55; PG). After calving each prepartum group was subdivided to groups that were fed either the control lactating diet or the control diet supplemented with 550 g CSFA. After calving cows were milked and weighed three times a day, BCS was determined weekly and blood samples were taken 3 times a week until 70 DIM. Insulin, glucose, beta-hydroxybutyrate (BHB), triglycerides (TG), cholesterol and aspartate amino transferase (AST) were determined in blood until 30 DIM. The PG supplementation decreased DMI by 6% pre and postpartum and postpartum CSFA decreased DMI by 2.3%. Milk production was decreased by 6.4%, fat percentage was not changed and protein was enhanced by 4% in cows fed PG prepartum. BCS was increased earlier after calving in cows fed PG prepartum. Feeding PG prepartum enhanced insulin, glucose and cholesterol plasma concentrations throughout (P<0.004) and decreased BHB and AST pre and postpartum. Postpartum CSFA decreased glucose and increased cholesterol plasma concentrations with no change in BHB, AST and TG. Significant interactions were observed between prepartum PG and postpartum CSFA in reducing BHB (P<0.007). In conclusion, supplementation of glucogenic precursors pre-calving improved body condition and the metabolic status of dairy cows, pre and post partum.

Key Words: Transition Cow, Glucogenic Precursors, Calcium Soap of Fatty Acids

W119 Physiological responses of Holstein cows fed rations with glucogenic supplements during the transition period. T. I. Belloso^{*1}, M. J. Hayen¹, M. Liboni¹, M. S. Gulay¹, F. Valdez², and H. H. Head¹, ¹University of Florida, Gainesville, ²Kemin Americas, Lancaster, OH.

Multiparous Holstein cows (n=124) were used to evaluate effects of supplementing glucogenic compounds in daily TMR fed during the transition period (-3 wk to +4 wk). Treatments (TRT) were 1) control (CON), none, n=29; 2) NutroCal (NUT; Kemin AmericasTM), 0.114 kg/d, n=33; 3) Metaxerol (MET; Pestell AmericaTM), 0.454 kg/d, n=31; and 4) propylene glycol (PPG), 0.300 kg/d, n=31. Supplements were added to ~13kg of close-up TMR (-3 wk to calving) or lactating TMR (calving to +4 wk) fed in a.m. Blood samples were taken 3x a week and analyzed for concentrations of insulin, IGF-I, glucose, NEFA, β-HBA, and calcium in plasma. Total liver fat (wet weight basis) ~21 d, around calving, and +14 and +28 d postpartum was determined on biopsies taken from a subset of 10 cows/TRT. Overall, blood measures followed expected patterns for Holstein cows during this time period. No incidences of fatty liver or treatment effects on percentage liver fat were detected. However, liver of NUT supplemented cows had numerically greater fat percentage (~30%) compared to CON and PPG supplemented cows, and ~58% more than MET supplemented cows. There was a biopsy day effect (P=0.002) on total liver fat; greatest percentages in liver were on d +14 (9.9%). Adding glucogenic compounds to TMRs fed to transition cows did not alter expected changes in plasma insulin, IGF-I, metabolites or liver lipids around calving but differences in changes were detected due to supplement included in TMR during this period.

Blood Measure		Treatment			PPG
		CON	NUT	MET	
IGF-I (ng/mL)	Prepartum	259.1 ^b	256.3 ^b	229.8 ^a	255.3 ^b

W120 Ruminal and plasma responses in dairy cows to drenching or feeding glycerol. P. L. Linke^{*1}, J. M. DeFrain¹, A. R. Hippen¹, and P. W. Jardon², ¹South Dakota State University, Brookings, ²West Central Soy, Ralston, IA.

Four Holstein dairy cows (137 DIM, 60 kg milk/d) were used in a Latin square design with 1-wk periods to evaluate the effect of methods of oral delivery of glycerol on ruminal VFA and plasma glucose and insulin. All cows were fed only grass hay for ad libitum consumption during 12 h before the experiment. At the start of the experiment, all cows were fed 5 kg of cracked corn. Treatments were: 1) control (C), no glycerol; 2) fed glycerol (F), 1 kg of glycerol solution (80% glycerol) added to the corn; 3) drench glycerol (D), 1 kg of glycerol solution in 1 L of water and delivered as oral drench; and 4) tube delivery of glycerol (T), 1 kg of glycerol solution in 9 L of water and delivered via an esophageal tube. Blood samples were collected at -1, -0.5, 0, 0.25, 0.5, 0.75, 1, 1.5, 2, 4, 6, 8, 12, and 24 h after administering glycerol. Ruminal samples were collected at 0, 2, 4, and 6 h. Acetate decreased ($P < 0.05$) in rumens of cows given glycerol, reaching nadir at 4 h (53.3, 44.9, 44.6, and 43.0 mol% for C, F, D, and T). Propionate and butyrate were increased ($P < 0.05$) by glycerol with peak concentrations at 4 h (26.4, 28.7, 30.4, and 30.4 and 14.1, 20.0, 20.3, and 21.5 mol%, respectively). Glucose was increased ($P < 0.05$) in plasma of D and T compared with C, reaching peak concentrations (21.3 and 18.5 mg/dl over baseline) at 1.5 and 3 h for D and T, respectively. Glucose response expressed as area under the curve (AUC) over baseline for 8 h was greater ($P < 0.05$) for D and T compared with C (9.4, 23.6, 54.6, and 58.1 mg/dl for C, F, D, and T). Insulin concentrations in plasma were increased ($P < 0.05$) for D and T reaching peak concentrations (97 and 115 pg/ml over baseline) at 1.4 and 1.1 h for D and T respectively. The 8-h AUC for insulin concentrations were greater ($P < 0.05$) for D and T than for F and C (80, 67, 244, and 270 pg/ml for C, F, D, and T). These data demonstrate that the ability of glycerol to increase plasma concentrations of glucose and insulin is dependent upon rapid delivery.

Key Words: Glycerol, Metabolites, Volatile Fatty Acids

W121 Adipose tissue metabolism, feed intake and milk production in response to dietary calcium propionate and chromium propionate from 21 days prepartum to 35 days postpartum in Holstein dairy cattle. J. P. McNamara^{*1} and F. Valdez², ¹Washington State University, Pullman, ²Kemin Industries, Inc, Des Moines, IA.

The objective was to determine the action of calcium propionate and chromium propionate on rates of lipogenesis and lipolysis in adipose tissue, dry matter intake and milk production when fed to Holstein dairy cattle 21 days prepartum to 35 days postpartum. Twelve animals each were assigned to treatments: Control, CaP (.125 kg/d); CrP (10 mg trivalent Cr/d) and both CaP and CrP. Dry matter intake and milk production was determined daily from 21 to 90 d. Biopsies of adipose tissue were taken at 7, 14, 28 and 56 d from calving. In control cows, rates of lipogenesis dropped to 98 % of 7 d rates and stayed there through d 56. Lipogenesis in cows treated with either CaP or CrP was 25 to 140 % faster (1.25 to 14 times as fast) at 14 and 28 d postpartum and had returned to prepartum rates by 56 d. Rates of lipolysis in vitro doubled

from 7 to 28 d but were not different at 14 and 56 d from 7 d. On CaP, lipolysis was 94, 79, 53 and 243 % of control and on CrP: 84, 97, 81 and 150 % of control at d 7, 14, 28 and 56. Dry matter intake averaged 11.2 (SD 1.85) and 21.8 (SD 3.7) kg/d from 21 to 1 and 1 to 90 days about calving. CaP increased DMI 11 and 13 % pre and postpartum; CrP increased DMI 10 and 16 % ($P < 0.05$); the combination had no effect. Milk yield was 44.6 (SD 8.7) kg/d overall and CrP increased milk yield by 2 kg/d or 4 % during the first 90 DIM. Milk fat yield was 92 to 95 % of control on CaP and CrP, the difference is approximately the same as the reduction in lipolysis. Milk lactose, protein and solids not fat were not different among treatments. The data are consistent with the theory that providing a small amount of gluconeogenic precursors can reduce net lipolysis from adipose tissue and allow increased feed intake, from which some of the nutrients are partitioned to milk. Additional dietary Cr may be acting through the glucose transporters to increase glucose flux into adipocytes and stimulate more lipogenesis and reduce lipolysis.

Key Words: Adipose, Gluconeogenesis, Lipolysis

W122 Effect of rumen protected choline on liver metabolism in periparturient dairy cows. P. Elek^{*1}, F. Husv eth², T. Ga al³, and J. R. Newbold⁴, ¹AGROKOMPLEX C. S. Co., Zichyujfalva, Hungary, ²Veszpr em University, Keszthely, Hungary, ³Szent Istv an University, Budapest, Hungary, ⁴Provimi Research and Technology Centre, Brussels, Belgium.

The aim of this experiment was to study the effect of rumen protected choline (RPC) on metabolism during the periparturient period. Thirty high producing multiparous Holstein cows were paired by parity, body condition score and previous lactation performance and randomly assigned to one of two groups. Cows were fed 0 (control) or 100 g/d RPC (RPC group, equivalent to 25 g/d choline chloride) from an average of 21 d prepartum and 0 or 200 g/d RPC (equivalent to 50 g/d choline chloride) from calving to 60 d postpartum. RPC was a fat encapsulated product therefore hydrogenated palm oil was used to equalize fat intake in the control diet. All cows were offered a TMR of identical ingredient composition (corn silage 300 g/kg DM, alfalfa hay 160 g/kg DM, wet brewers grain 50 g/kg DM, corn, soybean meal based concentrate 490 g/kg DM). Body condition (BCS) was scored and liver biopsies were taken at -21, 7, 35 and 60 d relative to calving and milk samples were collected on d 7, 35 and 60 postpartum for measurement of choline concentration. BCS and BCS change did not differ between treatments. Total lipid content of the liver varied considerably between cows but was significantly ($P < 0.05$) lower in RPC group (control vs. RPC, g/kg wet weight: 145.8 vs 81.7 (day 7 after parturition), 84.9 vs. 49.6 (day 35)). Glycogen concentration differed significantly only on 35 d sampling; it was higher in the RPC group (control 27.9 vs. RPC 35.8 g/kg wet weight). Milk total choline concentration was significantly ($P < 0.01$) higher in RPC group (control vs. RPC, mg/kg milk: 86.2, 109.4; 97.1, 143.0; 115.3, 137.2; for days 7, 35 and 60, respectively), which proves the better choline supply of RPC supplemented cows. Feeding RPC during the periparturient period had a positive effect on liver metabolism as evidenced by lower total lipid and higher glycogen content.

Key Words: Choline, Cow, Liver

W123 Supplemental choline for prevention and alleviation of fatty liver. R. R. Cooke, R. R. Grummer^{*}, S. J. Bertics, D. Z. Caraviello, M. H. Ramos, and N. Silva del Rio, University of Wisconsin-Madison.

Experiments were conducted to determine if supplemental choline could prevent or alleviate fatty liver in dairy cattle. In experiment 1, 24 cows between 45 and 60 d prepartum were blocked according to body condition and randomly assigned to control or 15 g choline/d in a ruminally protected form (RPC; Reashure, Balchem Encapsulates). From d 0 to 6, all cows were fed 1.4 kg of concentrate/d (without RPC), forage was consumed ad libitum, and samples were obtained for covariate analysis. During fatty liver induction (d 7-17), cows were fed 1.4 kg concentrate/d with or without RPC and forage intake was restricted so that cows consumed 30% of maintenance energy requirements. During fatty liver induction, RPC did not affect blood glucose ($P = 0.42$), but did decrease plasma nonesterified fatty acid (NEFA, 703 vs 562 μ Eq/L, SE = 40, $P = 0.003$) and liver triglyceride (TG) (16.7 vs 9.3 μ g/ μ g DNA, SE = 2.0, $P = 0.015$). Experiment 2 was conducted to determine if RPC could alter the rate of TG depletion from liver when cows are fed in excess

of energy requirements following induction of fatty liver. Twenty-eight cows between 45 and 60 d prepartum were blocked according to body condition and assigned to treatment. Fatty liver was induced by feeding 1.4 kg concentrate/d (without RPC) and restricting forage intake so cows consumed 30% of maintenance energy requirements for 10 d. For the next 6 d, cows were fed 1.4 kg concentrate/d with or without RPC and forage was consumed ad libitum. Treatments were not applied during fatty liver induction, however, liver for cows assigned to control and RPC contained 6.8 and 12.7 ug TG/ug DNA following feed restriction. Measurements obtained prior to treatment served as covariates for statistical analysis. During the depletion phase, plasma glucose and NEFA were not affected by treatment. Liver TG, expressed as a percentage of that after induction and prior to treatment, was 60.4 and 52.2 (SE = 6.0) on d 3 and 48.5 and 29.9 (SE = 6.5) on d 6 of the depletion phase for control and RPC (P = 0.12 for treatment, P = 0.07 for treatment x time). RPC can prevent and possibly alleviate fatty liver induced by feed restriction.

Key Words: Choline, Fatty Liver

W124 Feeding soybeans and rumen-protected choline to dairy cows during the periparturient period and early lactation. 1. Effects on production and energy balance. W. A. Oelrichs*, M. C. Lucy, M. S. Kerley, and J. N. Spain, *University of Missouri - Columbia*.

This study was designed to investigate the effects of soybeans (SB) and rumen-protected choline (RPC; Reashure™ Choline; Balchem, Slate Hill, NY) fed during the periparturient period and early lactation on intake and production of dairy cows. Sixty-four Holsteins were blocked by parity and expected calving date and randomly assigned within block to one of six experimental diets. Dietary treatments were fed from 28 days prepartum to 100 days in milk. Cows were assigned to treatments in a 3 x 2 factorial arrangement. Cows received no SB, SB beginning at calving, or SB for the duration of the study. SB were fed as raw, cracked beans at feeding rates of 1.9 and 2.8 kg DM per cow per day during pre- and postpartum periods, respectively. RPC was top-dressed at a rate of 0 or 15 g dietary choline per cow per day. Cows were individually fed diets as total mixed rations using electronic feeding gates. Body weights and body condition scores were measured weekly throughout the study. Cows were milked 2x daily, and milk yields were recorded. Blood samples were collected weekly prepartum, at days -3, 0, and +3 relative to calving, and twice weekly postpartum. Plasma were analyzed for NEFA, glucose and γ -hydroxybutyrate. Cows fed RPC consumed significantly more DM as a percent of BW over the entire study period. Feeding RPC increased milk yield with little or no change in BW or BCS. Plasma NEFA and γ -HBA concentrations were lower in cows fed RPC. Cows may use energy for milk production more efficiently when fed RPC. Cows fed SB during the prepartum period had lower postpartum DMI than cows fed the other diets. Feeding SB beginning at 28 days prepartum resulted in reduced milk production throughout the study. Cows fed SB beginning either 28 days prepartum or at calving had more positive energy balance, reflected in lower plasma NEFA and higher plasma glucose concentrations. Although SB can be used as an alternative energy source, these results suggest that feeding should not be initiated until after calving.

Key Words: Transition Cows, Rumen-Protected Choline, Soybeans

W125 Feeding soybeans and rumen-protected choline to dairy cows during the periparturient period and early lactation. 2. Effects on reproduction. W. A. Oelrichs*, M. C. Lucy, M. S. Kerley, and J. N. Spain, *University of Missouri - Columbia*.

This study was designed to investigate the effects of soybeans (SB) and rumen-protected choline (RPC; Reashure™ Choline; Balchem, Slate Hill, NY) fed during the periparturient period and early lactation on reproductive performance of dairy cows. Sixty-four Holsteins were blocked by parity and expected calving date and randomly assigned within block to one of six experimental diets. Dietary treatments were fed from 28 days prepartum to 100 days in milk. Cows were assigned to treatments in a 3 x 2 factorial arrangement. Cows received no SB, SB beginning at calving, or SB for the duration of the study. SB were fed as raw, cracked beans at feeding rates of 1.9 and 2.8 kg DM per cow per day during pre- and postpartum periods, respectively. TRPC was top-dressed at a rate of 0 or 15 g dietary choline per cow per day. Cows were individually

fed diets as total mixed rations using electronic feeding gates. Blood samples were collected once weekly prepartum, at days 3, 0, and +3 relative to calving, and twice weekly postpartum. Plasma were analyzed for NEFA, glucose, γ -hydroxybutyrate, and progesterone. Cows were estrous synchronized for oxytocin challenge and timed AI. Plasma obtained during oxytocin challenge were analyzed for 13, 14-dihydro 15-keto prostaglandin F₂ α (PGFM). Feeding RPC increased plasma progesterone concentrations during first synchronized estrous cycle, and improved conception and pregnancy rates. Feeding SB beginning either prepartum or on the day of calving had little influence on reproduction. Plasma progesterone concentrations, interval to first estrous cycle, plasma PGFM concentrations during oxytocin challenge, and rates of cyclicity, ovulation, conception and pregnancy were not different due to feeding SB. However, during the first synchronized estrous cycle, cows fed SB beginning at 28 days prepartum or on the day of calving had fewer small (< 5 mm) follicles and tended to have more medium follicles (6 to 9 mm) than cows fed the control diets. Other studies have reported a more dramatic improvement in reproductive performance.

Key Words: Transition Cows, Soybeans, Rumen-Protected Choline

W126 Estimation of VFA and Glucose Kinetics on Transition Dairy Cows provided monensin. X. Markantonatos*¹, Y. Aharoni³, T. Cassidy¹, R. K. McGuffey², L. F. Richardson², and G. A. Varga¹, ¹*The Pennsylvania State University*, ²*ELANCO Animal Health, Greenfield, IN*, ³*ARO, Newe Yaar Research Center, Israel*.

Eight multiparous Holstein dairy cows were used to evaluate the effects of monensin (M) inclusion during the transition period on ruminal VFA and plasma glucose kinetics. Treatments were a TMR top-dressed with 300 mg M/d, or without M. Cows received M from d -30 prepartum (Pre) to d +56 postpartum (Post). Cows received the same diet consisting of 58:42 forage:concentrate (F:C) Pre or of 51:49 (F:C) Post. Isotopic tracers (1-¹³C₃Na, 1-¹³C₂Na, 1-¹³C₄Na) at 12% enrichment were bolused and intraruminally infused. Tracers were infused on d 13 ± d 1.97 prior to calving and on d 19 ± 1.60 after parturition. Three days prior to sampling, cows were fed every 4 h for 2 d followed by 2 h feeding intervals 1 d prior to and the day of sampling. Sampling times were -30, -20, -10, 5, 10, 15, 25, 35, 45, 60, 75, 90, 110, 130, 150, 170, 210, 230, 260, 290, and 320 min relative to tracer infusion time. A dose of 45 mg of U-¹³C-Glucose (Glu) was injected into the jugular vein. Blood was sampled 20 times during 8 h after tracer administration. WinSAAM simulation program, which assumed a 12-compartment model, was used to analyze Glu and VFA ¹³C Enrichment Curves with Time (ECT). Acetate (Ac) conversion to Butyrate (Bu) was higher Post (2.36mmol/min vs 1.33mmol/min; Post vs Pre). Similarly, Pr incorporation to Glu pool was 0.86mmol/min vs 0.24mmol/min (Post vs Pre) and did not differ between treatments. Propionate (Pr) production rate was numerically higher in M cows (P=0.24) Pre, whereas Glu clearance rate was lower in M cows (4.88mmol/min vs 8.78mmol/min; P<.0001). Glu input rates from other sources than Pr was lower in M vs C (1.79mmol/min vs 3.04mmol/min; Pre, 6.90mmol/min vs 13.37mmol/min; Post). ECT shown that each individual VFA acts kinetically as a single pool. This study suggests that inclusion of M may affect VFA and Glu kinetics, and may also spare glucose to reduce metabolic diseases such as ketosis as the cow transitions into lactation.

Key Words: Monensin, VFA, Glucose Kinetics

W127 Effect of level of prepartum alimentation in dairy cows on milk production, mRNA expression for gluconeogenic enzymes, and liver triglyceride concentration. J. R. Townsend* and S. S. Donkin, *Department of Animal Sciences, Purdue University, West Lafayette, IN*.

Dry matter intake depression in prepartum dairy cows has been implicated in impaired performance and health. To determine the impact of prepartum DMI on performance and metabolic parameters thirty multiparous Holstein cows were blocked by calving date and randomly assigned to the following treatments: fitted with rumen cannulae and force fed orts during the final 14 days of gestation (force fed, FF), intake restricted during the final 14 days of gestation to 75% of ad libitum DMI (restricted, R), or fed for ad libitum intake during the final 14 days of gestation (control, C). From 28 through 15 days prior to expected calving cows were given ad libitum access feed (1.61 Mcal NEL/kg) and similarly following parturition (1.67 Mcal NEL/kg). Liver biopsy and

blood samples were obtained on days -28, -14, -7, +1, +7, +14, +28, and +56 relative to calving. DMI from day -14 to day +1 differed ($P < .05$) among treatments and was 13.0, 9.8, 11.4 kg/d for C, R, and FF respectively. Postpartum DMI during the first 28 days of lactation was greater ($P < 0.5$) for C (18.3 ± 0.6 kg/d) compared with either R or FF, (15.0 ± 0.7 , 15.6 ± 0.7 kg/d, respectively). Control cows produced more milk ($P < .05$) from 1 through 28 DIM than either R or FF (39.0, 32.4, 34.3 kg/d for C, R, and FF). Milk production from 29 through 56 DIM tended ($P < .10$) to be higher for control cows (47.6, 41.3, 42.7 kg/d for C, R, and FF). Plasma NEFA, PUN, and BHBA levels followed typical periparturient patterns but did not differ among treatments nor did liver triglyceride (TG), glycogen and TG:glycogen ratio. Liver mRNA for pyruvate carboxylase (PC) peaked at calving and phosphoenolpyruvate carboxykinase (PEPCK) peaked postcalving. PEPCK mRNA was not affected by treatment but PC mRNA was elevated ($P < .05$) for FF compared with C. The data suggest that a depression in feed intake as part of the natural transition to lactation is not detrimental to postpartum performance but that imposed feed restriction reduces performance.

Key Words: Transition Cow, Feed Intake, Liver

W128 Nicotinic acid supplemented at a therapeutic level minimizes prepartum feed intake depression in dairy cows. P. D. French*, *Oregon State University, Corvallis.*

Nicotinic acid has been used successfully to treat hyperlipidemia in humans for several decades. However, nicotinic acid (NA) supplementation has not been effective in decreasing plasma non-esterified fatty acids (NEFA) around the time of parturition in dairy cattle. The objective of the following experiment was to determine the effect of therapeutic NA supplementation on prepartum feed intake and plasma NEFA. Beginning 30 d prior to calving date, 14 multiparous Jersey cows were blocked by expected calving date and assigned at random to one of two treatments: no supplemental NA (control; C) or 48 g NA/d. The level of NA supplementation was based on human dosages adjusted for weight and predicted rumen stability. Cows were group housed and fed individually via Calan(r) doors beginning 30 d prior to calving date. Cows were offered a TMR once daily and NA was topdressed to ensure a daily consumption of 48 g. The TMR contained 34% (DM basis) corn silage, 14% alfalfa hay, 14% oat hay, 19% corn/barley, 9% soybean meal/corn distillers, 3% molasses, and 7% mineral/vitamin premix. Nicotinic acid supplementation and data collection began 24 d prior to expected calving date. Data were analyzed as repeated measures using the MIXED procedure of SAS. Body weight and body condition score were similar for C and NA. Dry matter intake differed for treatment by day ($P < 0.01$) and was greater the day prior to parturition for cows receiving NA compared to C, 10.0 and 6.7 kg, respectively. Dry matter intake decline, calculated as the change in DMI versus 14 to 21 d average, the last week of gestation was greater ($P < 0.05$) for C (20.5%) compared to NA (4.7%). Plasma non-esterified fatty acids were greater ($P < 0.01$) the day of parturition (1244 and 491 $\mu\text{mol/l}$ for C and NA, respectively) and the day after parturition (716 and 328 $\mu\text{mol/l}$ for C and NA, respectively) for C compared to NA. Results show that NA reduces plasma NEFA by 65% at parturition, and a cause and effect relationship between plasma NEFA and feed intake depression has been established.

Key Words: Feed Intake, Nicotinic Acid, Prepartum

W129 The effects of supplemental anionic salt fed during the periparturient period: Implications of milk production and feed intake for high producing dairy cows. J. Spain, R. J. Vogel*, and J. D. Sampson, *University of Missouri - Columbia.*

The objective of this study was to determine the effect of a sulfur-based anionic salt fed during late gestation on intake, health, and production of Holsteins. Twenty-six mature cows were paired by expected calving date, lactation number, milk production potential, and body weight. Cows within pair were then randomly assigned to one of two diets. The dietary treatments were control (C) and supplemental anionic salt (A). Cows were fed the experimental diets as TMR via electronic feeding gates. Control diet was formulated to achieve a Dietary Cation-Anion Difference (DCAD) of +20 mEq/100 g dry matter. Control diet was predicted to provide 70g of calcium per cow per day. The treatment

group was fed 454g per cow per day of a commercially formulated anionic salt supplement which lowered the DCAD level to -10 mEq/100 g dry matter. Treatment diets were formulated to provide a daily intake of 150g of calcium per cow per day. Diets were fed 30 days prior to expected day of calving. At calving, cows were fed standard lactation TMR for the first 6 weeks of lactation. Feed intake was measured daily. Urine pH was monitored twice each week using an electronic pH meter. Blood samples were collected weekly prepartum as well as on day -3 and day of calving. Postpartum blood samples were collected on day 1, 3, 7, 10 and 14 of lactation and then weekly until day 42. Blood samples were analyzed for Ca and NEFA. Daily milk yields and weekly milk component data were also collected. These data were analyzed for significance using SAS Proc Mixed. Cows fed anionic salts had lower urine pH compared to control cows (6.78 vs. 8.29; $P < 0.0001$). Blood calcium was higher for anionic salt fed cows compared to control cows (8.87 vs. 8.63 g/dl; $P = 0.05$). Plasma NEFA were lower for cows fed anionic salt diet (292 vs. 402 $\mu\text{eq/l}$; $P < 0.01$). Milk was greater over time for cows fed anionic salts versus control cows ($P = 0.05$). Supplementation with sulfur based anionic salt improved calcium and energy balance associated with significant increase in milk production.

Key Words: Anionic Salt, DCAD, Transition Cows

W130 Effects of dry period length on performance and health of dairy cows during the subsequent lactation. J. Fernandez*, C. M. Ryan, D. M. Galton, and T. R. Overton, *Cornell University, Ithaca, NY.*

Holstein cows ($n = 67$) on two commercial dairy farms and producing at least 27 kg/d of milk at approximately 60-d prior to expected parturition were used to determine whether dry period length affects milk yield, milk composition, and metabolic indices during the subsequent lactation. At 60-d prior to expected parturition, cows were assigned randomly to receive either 60-d dry (actual 57 ± 5 d), 40-d dry (actual 41 ± 7 d), or 0-d dry. Milk yield and composition data were collected for the first six monthly test days of the subsequent lactation. Interactions of farm by treatment were not significant ($P > 0.05$) for all variables measured. Cows managed for 60 and 40-d dry periods had comparable yields of milk, fat, 3.5% fat-corrected milk (FCM), and true protein during the first 6 months of the subsequent lactation. Cows managed for 0-d dry periods produced approximately 10 kg/d less milk than cows managed for 40 or 60-d dry periods during the first 6 months of the subsequent lactation. Yields of milk fat, true protein, and 3.5% fat-corrected milk by cows managed for 0-d dry periods were decreased compared to those managed for 40 or 60-d dry periods. Concentrations of B-hydroxybutyrate (BHBA) in single plasma samples collected on d 5 to 20 postpartum were not affected ($P > 0.15$) by treatment. Overall, performance and health during the subsequent lactation of cows managed for 60 or 40-d dry periods were comparable in this experiment; cows managed for 0-d dry had substantially decreased milk yield during the subsequent lactation.

Item	60-d dry	40-d dry	0-d dry	SEM

W131 Effects of Tri-Lution™ on immune response in the pre-fresh dairy cow. D. Jones*, D. Spangler, and R. Arendt, *Agri-King, Inc, Fulton, IL.*

Fifty-six cows were utilized in a completely randomized design to evaluate Tri-Lution™ (a patented probiotic manufactured by Agri-King, Inc.) on colostral immunoglobulin titers, calf blood immunoglobulin

titers and 60 d milk production. Pre-Fresh dairy cows (28 per treatment) were randomly assigned to one of two treatments starting three weeks before expected calving date. Treatments were a control ration or the same TMR containing 68 grams per head per day of Tri-Lution™. Following parturition all cows were fed the same milk cow ration (i.e. Tri-Lution™ feeding stopped at parturition). Colostrum was collected at milking and frozen. A 50 ml aliquot was used to measure immunoglobulin (IgG, IgM, and IgA) titers. Blood from new born calves was collected the day following consumption of colostrum and analyzed for IgG titers. Milk production, components, and SCC were monitored for the first 60 days after parturition on a weekly basis. Milk data was analyzed using two different time periods. Period 1 consisted of 0 to 30 DIM and period 2 from 30 to 60 DIM. Feeding Tri-Lution™ resulted in similar IgG and IgM titers in colostrum. However, colostral IgA titers were significantly higher when Pre-Fresh cows were fed Tri-Lution™ (625 vs 892 mg/100 ml for the control and Tri-Lution™ treatments, respectively, $P < 0.05$) compared to cows fed the control TMR. Serum IgG titers in the calves were similar between treatments the day following colostrum consumption. The SCC of milk from control cows increased 6% from period 1 (199,000 cells/ml) to period 2 (211,000 cells/ml), while the SCC from Tri-Lution™ fed cows decreased 47% (262,000 to 138,000 cells/ml) over the same time period, although the differences were not statistically significant ($P < 0.10$). This study demonstrated that Pre-Fresh dairy cows fed Tri-Lution™ before calving have lower SCC during the first 60 DIM compared to cows fed the control TMR. Feeding Tri-Lution™ to Pre-Fresh dairy cows enhanced colostral IgA concentrations

Key Words: Tri-Lution™, Immune, Dairy

W132 Effect of feeding red clover or ryegrass silage to dry dairy cows on nitrogen balance and blood metabolites. J. M. Moorby*¹, P. H. Robinson², and R. T. Evans¹, ¹*Institute of Grassland and Environmental Research, Aberystwyth, UK*, ²*UCCE, Dept. of Animal Science, University of California, Davis.*

To investigate the effect of feeding a high protein forage to dry cows on N partitioning and blood metabolites during the dry period (DP), and on subsequent lactational performance, 48 Holstein-Friesian dairy cows were offered ad libitum access to either red clover silage (RC; 22.4% DM, 18.9% crude protein [CP]) or ryegrass silage (RS; 28.0% DM, 17.2% CP) for the last 4 wk of the DP. After calving, all cows received the same diet of ad libitum ryegrass silage (29.2% DM, 18.1% CP) with a grain based concentrate (24% CP) at 6 kg/d. A subset of 2 cows per treatment were housed in a metabolism unit for 6 to 8 d of N partition and feed digestibility measurements at about 2 wk before calving, and 3 wk after calving. Blood samples were collected from all cows for metabolic profile measurements at wk 1, 3, 5, 7 and 9 of lactation. Before calving, N intake was higher ($P < 0.01$) in RC cows (376 vs. 349 g N/d), but apparent N digestibility was lower (60.7% vs. 66.8%; $P < 0.001$) so that feces N output was higher. There was no difference in urine N output due to DP treatments, nor whole body N balance (mean 58 g N/d). Whole tract DM digestibility was lower ($P < 0.001$) in RC (62.6% vs. 73.2%). After calving, there was no effect of the prior DP treatment on feed N partitioning or N balance. Mean whole tract diet DM digestibility was 62.2%. Plasma albumin concentrations tended to be higher ($P < 0.1$) in cows fed the DP diet based on RS (44.8 vs. 46.8 g/l), but there were no differences in plasma concentrations of urea, glucose, BHBA or NEFA. The N supplied by the DP diet of RC was used less efficiently than that of the RS, and so the digestible N supply to the cows during the DP did not differ between treatments. Lower plasma albumin concentrations in RC cows after calving indicate a smaller body protein pool than that of RS cows, despite similar N balances during the DP, indicating increased fetal N utilization.

Key Words: Digestibility, Nitrogen Partitioning, Plasma Metabolites

W133 Estimations of milk production by the NRC and the Cornell models when ruminal N balance was negative and MP was limiting. H. Kajikawa*¹, T. Koga², S. Ishizaki³, H. Shinohara⁴, K. Akutsu⁵, S. Sato⁶, K. Shimizu⁷, T. Tamura⁸, and M. Seki⁹, ¹*Natl. Inst. Livest. Grassl. Sci., Tsukuba, Ibaraki, Japan*, ²*Nagano Anim. Ind. Exp. St., Japan*, ³*Chiba Pref. Livest. Res. Center, Japan*, ⁴*Gunma Anim. Husbandry Exp. St., Japan*, ⁵*Tochigi Pref. Dairy Exp. Inst., Japan*, ⁶*Aichi-ken Agric. Res. Center, Japan*, ⁷*Yamanashi Pref. Dairy Exp. St., Japan*, ⁸*Tokyo Metropolitan Livest. Exp. St., Japan*, ⁹*Niigata Livest. Res. Center, Japan*.

A mechanistic approach has been adopted by several models (NRC, CNCPS) for more accurate nutritional estimations for high producing cows. Since we found that evaluation by the NRC model (dairy cattle, 2001) sometimes showed a lower value than actual milk production, we tried to analyze the factor of the underestimation by comparing with the CNCPS model (ver. 5, 2003). Four groups of multiparous cows (17 to 20 cows for each group) were assigned to diets with different CP and RDP levels having timothy hay, alfalfa hay, corn grain, cottonseed, beet pulp, soybean meals (or soy PLUS), and several other by-product feeds. Actual DMI, and milk composition (fat, protein) were input into the model, but the tabular values in each model were used for the feed compositions except the forage CP contents. Actual milk yield during 15 weeks after parturition was around 40 kg/d for each group. Body weight slightly increased during the experiment (5 to 20 kg). For the CNCPS evaluation, ME was always limiting for the production, and ME allowable milk correctly predicted the actual yield (0.2 to 1.2 kg/d of difference). For the NRC evaluation, however, MP was limiting for 3 groups (B, C and D), and MP allowable milk was below the actual yield (4.1 to 8.1 kg/d lower). For these groups, estimations of MP from bacteria by the NRC model were lower than those by the CNCPS model, and these lower values could be mainly attributed to the exclusion of the recycled N from the NRC model. Even endogenous MP, a new additional parameter of the NRC model, could not compensate for it. These results suggest that the NRC model would underestimate milk yield when the ruminal N balance is negative and MP is limiting.

Table 1. Estimations of milk production by the NRC and CNCPS models

		Cow group			
		A	B	C	D
NRC					
(dairy cattle, 2001)	ME allowable milk (kg/d)	40.8	41.7	40.8	38.7
	MP allowable milk (kg/d)	47.1	38.2	34.0	31.3
	MP - Bacterial (g/d)	1334	1226	1192	1157
	MP - RUP (g/d)	1452	1149	1059	1060
	MP - Endogenous (g/d)	116	116	117	113
	Ruminal N balance (g/d)	40	-29	-40	-38
CNCPS					
(ver. 5, 2003)	ME allowable milk (kg/d)	39.7	41.5	41.0	39.7
	MP allowable milk (kg/d)	49.9	45.8	41.0	41.2
	MP - Bacterial (g/d)	1583	1604	1572	1518
	(MP from recycled N, g/d)	202	316	345	321
	MP - RUP (g/d)	1496	1253	1142	1182
	Ruminal N balance (g/d)	70	-16	-47	-43
Actual Milk yield (kg/d)		40.9	42.3	40.6	39.5

W134 Prediction of nutrient supply to dairy cows from concentrates: Comparison of the National Research Council-2001 model with the Dutch system (DVE/OEB). P. Yu*, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to compare the DVE/OEB system (DVE = truly absorbed protein in the small intestine; OEB = degraded protein balance) and the NRC-2001 model in the prediction of supply of protein to dairy cows from selected concentrates: malting-type barley (cv. Harrington), feed-type barley (cv. Valier), field tick beans (Vicia faba), white albus lupines (Lupinus albus), whole soybeans and horse beans (Vicia faba cv. Alfred). The two barleys were processed by coarse (Roller miller, 0.533 mm gap) and fine (Hammer mill, 2 mm screen) processing. The field tick beans and white albus lupines were dry roasted at various conditions. The soybeans and horse beans were pressure-toasted at the temperature 100, 118, 136°C for 3, 7, 15 and 30 min at

Wageningen Processing Centre. Comparisons were made in terms of 1) ruminally synthesized microbial protein, 2) truly absorbed protein in the small intestine, and 3) degraded protein balance, based on 46 samples. The results showed that the predicted values from the DVE/OEB system and the NRC-2001 model had significant correlations with. However, using the DVE/OEB system, the overall average microbial protein supply based on available energy was 10% lower and the truly absorbed protein in the small intestine was 8% lower than that predicted by the NRC-2001 model. The difference was also found in the prediction of the degraded protein balances, which was 16% higher than that estimated based on data from the NRC-2001 model. These differences are due to considerably different factors used in calculations in the two models, although both are based on similar principles. This indicates that a further refinement is needed for a modern protein evaluation and prediction system.

Key Words: NRC Dairy Model, DVE/OEB System, Protein Evaluation

Production, Management and the Environment: Nutrition and Environment

W136 Application of manure screening as an on farm a tool to evaluate the animal / diet interface. M. J. Jerred*¹, T. G. Brion¹, S. R. Burghardi¹, K. A. Ruppel², and M. A. Messman¹, ¹Cargill Animal Nutrition, Elk River, MN, ²Cargill Animal Nutrition, Albany, NY.

Animal performance is dependant on digestion of ingredients in the daily ration allotted to the animal. To better understand ration digestion on farm we have constructed a three screen manure separating apparatus for visual appraisal of manure. Manure evaluation along with knowledge of nutrient and particle size of the diet fed can help diagnose lack of conformance to nutrition model predictions. Sizes of the three screens are: 0.57, 0.31, and 0.16cm in diameter. A representative sample of fresh manure from eight to twelve cows in a pen of cattle is collected and washed through the series screens. Fecal samples from 29 commercial dairy farms were evaluated with the manure screener. The top screen averaged 18% (SE 1.6) by volume fecal particles, the middle screen averaged 30% (SE 4.5) by volume fecal particles and the bottom screen averaged 52% (SE 4.6) by volume fecal particles. On the top screen whole cottonseed, fiber particles and kernels of grain were typically observed. The middle and bottom screens typically contained fiber particles and co-product ingredients. To further evaluate the manure screener 4 no forage diets were fed. The top screen averaged 55% (SE 4.1) by volume fecal particles, the middle screen averaged 18% (SE 3.6) by volume fecal particles and the bottom screen averaged 27% (SE 2.6) by volume fecal particles. A T test was used to compare volume of particles retained on screens between normal and no forage diets. Feces from the no forage diet contained more ($P = 0.001$) particles on the top screen, fewer on the middle ($P = 0.052$) and bottom ($P < 0.001$) screens than diets that contained forage. Increased fecal particles in the top screen may have resulted from increased ruminal particle passage because of reduced ruminal mat formation when the no forage diet was fed. A tool to screen manure to evaluate passage of dietary ingredients can be an aid in determining the source of model non-conformance.

Key Words: Manure Evaluation, Digestion, Ration Evaluation

W137 Prediction of urine N excretion from creatinine and milk urea nitrogen in primiparous and multiparous cows. S.A. Flis* and M.A. Wattiaux, *University of Wisconsin-Madison*.

Urinary nitrogen (UN) excretion is an integral part of predicting N usage by an animal and formulating a farm N management plan. The objective of this research was to compare two UN prediction methods to observed values. Foley catheters were used to collect total urine excretion for 3 days from 8 lactating cows (4 multiparous and 4 primiparous) in a split-plot Latin square. Cows were fed one of four diets ranging from 0 to 20% excess N based on NRC 2001. Cows were weighed twice each period. The first prediction method was according to Kauffman

W135 Nutritive value of processed field tick beans predicted by two dairy models (NRC and DVE/OEB). P. Yu*¹, B. J. Leury², and A. R. Egan², ¹Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada, ²School of Agriculture and Food Systems, University of Melbourne, Australia.

The objective of this study was to compare the Dutch DVE/OEB system and the NRC-2001 model in the prediction of supply of protein to dairy cows from processed field tick beans. Comparisons were made in terms of 1) ruminally synthesized microbial CP, 2) truly absorbed protein in the small intestine, and 3) degraded protein balance. The results showed that the predicted values from the DVE/OEB system and the NRC-2001 model had significant correlations with high R (> 0.90) values. However, using the DVE/OEB system, the overall average microbial protein supply based on available energy was 16% higher and the truly absorbed protein in the small intestine was 9% higher than that predicted by the NRC-2001 model. The difference was also found in the prediction of the degraded protein balances (DPB), which was 5% lower than that predicted based on data from the NRC-2001 model. These differences are due to considerably different factors used in calculations in the two models, although both are based on similar principles.

Key Words: NRC-2001 Model, DVE/OEB System, Field Tick Bean

and St-Pierre, UN (g/d) = 0.0259 × BW (kg) × MUN (mg/dL). The second method was based on UN concentration multiplied by the urine volume (l/d) predicted as (2.9 × BW (kg))/(creatinine concentration in the urine). Both an AM and a PM spot sample of urine were used in predicting urine volume in this method. Cow BW ranged from 435 - 724 kg. The UN and volume predicted from both methods were lower in the primiparous cows ($P < 0.001$), but there was no parity by prediction method interaction ($P = 0.6$), indicating that the method of prediction is the same for both parity. Although the observed urine volume averaged 26.5 l/d, the predicted values averaged 34.7 l/d, for the PM samples, but 28.7 l/d for the AM samples. The PM prediction value was different from both the AM and the observed urine volumes ($P = 0.01$). The prediction of UN based on the AM and PM samples was 226 and 278 g/d respectively; with the observed UN at 208 g/d. Again the PM prediction of UN was different ($P = 0.01$) from both the AM and the observed values. In this trial, parity did not affect MUN, and the prediction of UN from MUN was 188 g/d. This prediction differed from the urine sampling methods ($P < 0.001$), but was not different from the observed values. These results suggest that the prediction of UN should be done from MUN values or AM samples of urine, but not PM samples. Diurnal variation, sampling time relative to feeding or other factors may have contributed to the bias in estimating UN from PM urine samples. MUN values are easier to obtain suggesting that the use of MUN to predict UN is the best approach.

Key Words: MUN, Creatinine, Urine Nitrogen

W138 Identifying dairy farms facing challenges in P management. V. A. Ishler* and L. E. Lanyon, *Pennsylvania State University, University Park*.

Reducing dietary P levels with the goal of minimizing P accumulation on dairy farms has been widely emphasized. Although there is opportunity to improve rations, this tactic alone may not solve the nutrient-loading problem for the most challenging situations, nor will it indicate when P accumulation is a problem. Herds required to comply with P-based nutrient management for crop production in the future or those planning expansions should look closely at the amount of P in manure that is or will be in excess of the local crop utilization potential. Herd size, ration composition, and ingredient source information was collected from eleven diverse Pennsylvania herds along with records of milk production. Accumulating P was determined by subtracting milk P (exported from the farm) and the home-grown crop P from total diet P. Dietary P on all eleven farms was very close to animal requirements, averaging 0.40% P (DM basis) with a range from 0.38% to 0.44%. However, purchased P ranged from 37% to 88% of the total P fed. Accumulating P (g/cow/d) was linearly related to percent purchased P, but was not related to diet P concentration. Farms with potential problems could be readily identified by this purchased P relationship. The ration P levels on farms with potential P problems were close to animal P requirements and not

different from the average. In this case, aggressively pursuing drastic ration changes to reduce dietary P concentration would have little impact on the accumulating P. The most appropriate tactic(s) for these farms may be beyond dietary changes and may rely on other whole farm strategies.

No. of farms	Accumulating P g/cow/day	Dietary P % DM basis	Purchased P %

W139 The effect of TASC0 meal, on body temperature, respiration rate, horn flies, hair score and calf immunoglobulin levels in beef cows. R. R. Evans*, J. E. Huston, and T. F. Best, *Mississippi State University, Prairie, MS.*

Previous work with TASC0 seaweed meal (*Ascophyllum nodosum*), fed at the 10% level in a mineral to cows grazing Ky-31 fescue (*Festuca arundinacea*) infected with the endophyte *Neotyphodium coenophialum*, reduced rectal body temperatures (RBT) for cows and calves and cow respiration rate (CRR) and horn flies (HF). This trial was undertaken to determine if increasing the rate from 10% to 20% would further influence the effects measured in the initial trials. In January of 2002 and 2003, 45 days prior to calving, multiparous and primiparous cows were equally allotted by age, breed and weight into groups and fed minerals that included 0, 10 and 20% TASC0. Cows were fed infected fescue hay prior to grass putout and grazed infected fescue/mixed warm season perennial pastures. All values reported hereafter will be for inclusion rates of 0, 10 and 20%, respectively. Mineral consumption monitored weekly was not different ($P < 0.05$), 111.16; 111.72; and 111.44 g/h/d, with a targeted 112 g/h/d consumption. At birth calves were processed, a 5-ml blood sample drawn and serum collected to determine IgG levels utilizing a Single Radial Immunodiffusion Kit (VMRD, Inc). Samples were compared to a standard, 1=low to 4= high reactivity. Pooled IgG levels for 2002 and 2003 were not different ($P < 0.05$) at 3.320; 3.152; and 3.336. RBT recorded in July of 2002 were 40.25; 40.36; and 40.17 and for 2003, 38.99; 39.46; and 39.34 C, but were not different ($P < 0.05$). Mean RBT across groups was one degree less for 2003 than for 2002, reflective of cooler temperatures and higher rainfall in 2003. Calf weaning weights were not different ($P < 0.05$) between treatment groups for 2002 (232.90; 222.90; 229.33 kg) and 2003 (242.47; 259.98; 244.89 kg), respectively. CRR were taken at 0800, 0110 and 1500 h for 10 days in August and September were not different ($P < 0.05$) between treatments in either year. HF were not different ($P < 0.05$) between treatments within year but were reduced in 2003 vs. 2002. Hair scores for cows was improved but were not different ($P < 0.05$) with the addition of TASC0 at 10 and 20% but calf hair scores were not improved.

Key Words: TASC0, Seaweed, Fescue

W140 Efficacy of yeast ferment as urease inhibitor on controlling ammonia emission from manure slurry. S. Park*¹, S. Oh², and S. Kim¹, ¹*Division of Food Science, Korea University*, ²*Department of Animal Science, Chonnam University, Korea.*

Urease (urea aminohydase, EC 3.5.1.3) is a nickel-containing enzyme that hydrolyzes urea to form carbamate and ammonia; carbamate spontaneously degrades to CO₂ and a second molecule of ammonia. Ammonia causes unpleasant odor and is harmful to animal and human health. The purpose of this study was to evaluate the potential of yeast culture isolated from yeast ferments as an urease inhibitor. About 200 yeast strains were isolated from yeast ferments. Yeasts were incubated with anaerobic and aerobic conditions. The urease inhibitory activities of yeast supernatants were measured by pH indicator assay. Ammonia

contents in manure slurry was measured at anaerobic and aerobic incubations using indophenol method (Berthelot reaction). Six yeast isolates were shown to inhibit urease a ratio about 25-45%. Yeasts supernatant were incubated in anaerobic condition at 25C showed the highest urease inhibitory activities. However yeasts supernatant were incubated in aerobic condition with shaking at 200 rpm/min showed lower urease inhibitory activities than other condition. AHA (acetoxyhydroxyamic acid) and NBPT (n-(n-butyl)thiophosphoric triamide) were known to effective urease inhibitors. However AHA is too expensive to utilize as an ammonia reducing material and NBPT is unable to use animal feed additives. These results demonstrated the potential of yeast culture as an urease inhibitor which is capable of reducing ammonia in animal farms.

Key Words: Urease, Inhibitor, Yeast

W141 Benefits of reducing the volume of cleaning wastewater on large dairy farms. J. K. Diehl* and W. J. Harper, *The Ohio State University, Columbus.*

As dairy farms continue to become larger and more regulated, manure management becomes an ever increasing topic of concern for the farmer. In areas where manure and other wastes are stored and applied to the land when conditions allow, farms are challenged by undersized storage structures and the cost associated with hauling waste. One step in reducing the volume of manure stored would be to reduce the volume of milking center wastewater entering the storage structure. In order to come up with water reduction solutions, the amount of cleaning wastewater used must be known. Literature values for cleaning wastewater volumes are highly variable and likely based on small farms. This study evaluated the amount of milking center wastewater generated and the farmers knowledge of wastewater volumes on large dairy farms in Ohio. Forty four replies were received from a mail survey of the 80 known farms milking more than 290 head. Ten of those responding were visited for an assessment of cleaning water usage. The farms surveyed ranged in size from 290 to 2100 milking cows with a mean of 515 cows. Knowledge of water usage varied by farm. 50% of farmers did not know the volume of water required to clean the pipelines, 71% did not know the volume used to clean the bulk tank, and 84% did not know the volume used to clean the parlor. On 86% of the farms, the wastewater produced by cleaning the bulk tank and pipelines was not reused. Most farmers (75%) indicated reducing the volume of water entering their manure storage structure would be a benefit to their operation. The farms visited ranged in size from 320 to 1850 milking cows with a mean of 596 cows. The total volume of milking center wastewater produced per day ranged from 360 to 4,800 gallons with a mean of 1,303 gallons/farm/day. These farms averaged 475,705 gallons of wastewater per year from cleaning the pipelines and bulk tanks alone. The amount of wastewater produced from the milking center was shown to be 2 to 10 times higher than values found in the literature. The actual volumes found justify exploration of practices to reduce or reuse cleaning water, thereby reducing the total volume of water entering manure storage structures.

Key Words: Dairy, Wastewater

W142 Composting organic wastes from a commercial slaughter house in Puerto Rico. R. Sanabria-León*, A. A. Rodríguez, and H. L. Santiago, *University of Puerto Rico Mayagüez Campus, Mayagüez, PR.*

The objective of this study was to evaluate the composting process as an alternative for the disposal of organic wastes from commercial slaughter houses (OWCS), using yard trimmings (YT) as bulking agent. Digestive tracts of small ruminants (OWCS) and YT were obtained from a commercial slaughter house and the Alzamora Laboratory Farm of the University of Puerto Rico at Mayagüez, respectively. Three treatments were evaluated using 2:1 proportions (w/w): YT only (C); YT/OWCS in a single layer (YW), and YT/OWCS in double layers (YWW). Treatments were placed in composting bins of identical dimensions (3 cubic feet) and the moisture level adjusted to 60%. Temperatures were recorded daily to determine the time (d) needed by each treatment to reach the maximum temperature in each heat cycle. Composting characteristics such as: C:N ratio; OM and IM contents; and pH were measured at d 0, first and second heat cycles, and maturation of the composting process. The time needed to complete each cycle was also determined. Data was analyzed using a completely randomized design with a 3 (treatments) x 6 (composting phases) factorial arrangement of treatments. For the

entire composting process, pH was similar ($P < 0.05$) regardless of treatments and phases. The N content increased and C:N ratio decreased ($P < 0.05$) in all treatments during the entire composting process. In both heat cycles, thermophilic temperatures ($> 45^{\circ}\text{C}$) were reached in treatments containing OWSC. The C group was characterized by reaching mesophilic temperatures (25 to 45°C). At the beginning of the maturation phase, all OWCS were degraded; OM and the IM were higher ($P < 0.05$) in YW and YWW, respectively, compared to the C group. These results suggest that composting could be an alternative for the disposal of organic wastes from slaughter houses. Further studies are needed in order to evaluate its use as an organic fertilizer.

Key Words: Composting, Organic Wastes, Slaughter Houses

W143 Effects of pit flushing frequency on farrowing house odor and gas concentrations. J. M. Schlipf*, M. Ellis, J. Ni, Y. Zhang, A. Mutlu, and T. L. Funk, *University of Illinois, Champaign-Urbana*.

This study was carried out over a 15-d period to determine the effect of pit flushing on gaseous emissions from a farrowing facility. A randomized block design was used with six rooms selected from a 14-room farrowing complex with five replicates over time. Two treatments were compared: control and flushed. Pits were flushed before the start of the study only for the control treatment and before the start and on d 8 of the study for flushed treatment. Samples were collected one day after sows were moved into the room, (d 1) and on d 8, 9, and 15. Samples were taken inside the room at the exhaust fan and outside at the pit fan exhaust. For odor analysis, air samples were pumped into 10 L Tedlar sampling bags and subsequently assessed by an 8-member olfactometry panel. Ammonia and hydrogen sulfide concentrations were measured using colorimetric detector tubes. Fan speed (taken at the same time as gas measurements) were not different ($P > 0.05$) between control and treated rooms. For the control rooms, concentrations of odor, NH_3 , and H_2S in the exhaust air from room and pit fans increased from the start (d 1) to the end of the study (d 15); e.g., pit exhaust concentrations increased from 2.65 to 3.19 (SEM 0.071; $P < 0.001$) for odor units, from 1.27 to 2.75 (SEM 0.157; $P < 0.001$) for NH_3 , and from 0.13 to 0.97 (SEM 0.067; $P < 0.001$) for H_2S . On d 8, odor and gas concentrations were numerically lower after flushing the pit than before from the room and pit exhausts, however, only the H_2S levels were different ($P < 0.05$).

Beef Species: Management and Beef Performance

W145 Evaluation of SafeGuard® (fenbendazole) oral drench in addition to Ivomec® (ivermectin) pour-on on performance and carcass merit of finishing heifers. C. D. Reinhardt*, J. P. Hutcheson, and W. T. Nichols, *Intervet, Inc, Millsboro, DE*.

One thousand one hundred six English×Continental crossbred heifers (340 kg) were used in a randomized complete block study. Treatments were: 1) SafeGuard® (5 mg/kg BW) and Ivomec® pour-on (500 mcg/kg BW) day 0 (SGPO), and 2) Ivomec pour-on (500 mcg/kg BW) day 0 (PO). There were 8 pens per treatment with an average of 69 head per pen. Heifers were fed for 135 days. Heifers treated with SGPO had 73% ($P = 0.06$) and 68% ($P = 0.06$) fewer eggs per 3 g fecal sample at d98 post-treatment and at the end of the feeding period than heifers treated with PO. Heifers treated with SGPO had higher dry matter intake, higher average daily gains, heavier final weight, and heavier carcass weights than heifers treated with PO alone ($P < 0.05$). Percentage of carcasses grading Prime+Choice was higher ($P = 0.07$) and marbling score tended to be higher ($P = 0.13$) for heifers treated with SGPO vs. heifers treated with PO alone. These data indicate that feed intake, daily gain, carcass weight, and carcass quality of feedlot heifers can be improved using fenbendazole in conjunction with ivermectin pour-on compared to using ivermectin pour-on alone due to improved parasite reduction of the combined treatment protocol.

Concentrations of H_2S 4 h before and 4 h after flushing were 0.54 and 0.10 ppm, (SEM 0.119) respectively, in the room exhaust, and 0.87 and 0.24 (SEM 0.125) ppm, respectively, in the fan exhaust. However, at the end (d 15) odor and gas levels were similar in the control and flushed rooms. Overall, results suggest that flushing the pits in this farrowing facility had a limited, short-term effect on odor, NH_3 , and H_2S concentrations.

Key Words: Pigs, Odor, Gaseous Emissions

W144 Evaluation of round bale feeding sites on soil fecal bacteria and nutrient concentrations. N. A. Lenehan, J. M. DeRouchey*, T. T. Marston, M. L. Christian, and G. L. Marchin, *Kansas State University, Manhattan*.

An experiment was conducted over seven months (January to July, 2003) to evaluate fecal bacteria and nutrient concentrations in soil surrounding round bale feeders. Six-inch soil samples were taken monthly from 10 feeding sites at distances of 3, 12, 21, and 30 m from the feeder. Soil samples were taken prior (January) to livestock access to the sites, during (February, March, and April) the feeding period, and after (May, June, and July) cattle removal from the sites. Fecal *E. coli* concentrations reached their highest levels in April at distances of 3 and 12 m, and were greater ($P < 0.03$) than all other months except March. At 21 and 30 m from the feeder, fecal *E. coli* concentrations were greater ($P < 0.01$) in April than all other months. At a distance of 3 m from the feeding area, fecal *streptococci* concentrations were greater ($P < 0.01$) in March and April compared to all other months. While fecal *E. coli* concentrations in July had returned to levels similar to that in January, fecal *streptococci* remained at higher levels ($P < 0.05$). For soil nutrients tested, the greatest increase generally occurred at 3 m from the feeders, with little differences thereafter. The highest level of soil phosphorus at 3 m was recorded in April, and concentrations exceeded ($P < 0.02$) those in January, February, and May. Soil dry matter had quadratic decreases ($P < 0.02$) in March, April, and July, and linear decreases ($P < 0.01$) in May and June as the distance from the feeding area decreased. Results indicate that the immediate area surrounding round bale feeding sites should be cleaned of manure, wasted feed, or bedding following cattle removal to reduce environmental impacts.

Key Words: Feeding Sites, Fecal Bacteria, Environment

W146 Examination of reproduction and weaning results in Limousin cattle population in Hungary. F. Szabo*¹, Z. Lengyel¹, S. Balika², I. Erdei¹, D. Marton¹, T. Major¹, and S. Bene¹, ¹University of Veszprem Georgikon Faculty of Agriculture, Hungary, ²Hungarian Limousin Association, Budapest, Hungary.

Weaning performance, gestation length and calving difficulty of 2555 purebred calves (1305 male and 1250 female) born from 713 cows mated with 43 sires were analyzed in two farms. Heritability, repeatability, breeding value, genetic and environmental variance of weaning weight (VS), preweaning daily gain (SGY), 205-day weight (KVS), gestation length (VI), calving difficulty (EL) the genetic, phenotypic and environmental correlation between VS and SGY were calculated. The genotype-environment interaction was analysed with method of rank correlation. Farm, year of birth, season of birth, sex, number of calving as fixed, while sire as a random effect was treated. Data were analyzed with Harveys (1990) Least Square Maximum Likelihood Computer and SPSS 9.0. The overall mean value and standard error of VS, SGY, KVS, VI and EL were 208 ± 5.29 kg, 997 ± 24.50 g/day, 205 ± 5.54 kg, 285 ± 1.54 day and 0.97 ± 0.03 , respectively. The average age of the analysed calves was 211 days. The heritability of traits was between 0.10 and 0.44. The genetic, phenotypic and environmental correlation between VS and SGY was strong and positive. The rank correlation values were low in the case of the investigated traits ($r = 0.05-0.27$), therefore the order of sire rank were different in the two farms.

Key Words: Weaning Wt, Heritability, Correlation

W147 Predictors of the final carcass grades in crossbred steers. K. Uetake^{*1}, T. Ishiwata¹, N. Abe², Y. Eguchi¹, and T. Tanaka¹, ¹*School of Veterinary Medicine, Azabu University, Sagami-hara, Japan*, ²*Faculty of Agriculture, Tamagawa University, Machida, Japan*.

To determine the predicting parameters for the final carcass grades, 35 Japanese Black × Holstein steers aged 6-10 mo were followed up until slaughter. They were allocated to three pens (6.0 m × 9.5 m each) and fed with commercial grain feed. The steers were allowed to access dry hay or oat straw on an ad libitum basis in the early (E) or middle (M) fattening stage. Behavioral observations (15 categories) for 2 h after morning and evening feedings were performed every 2 mo. BW measuring, blood sampling (7 hormones and 5 metabolites), ultrasonic scanning and physical measuring (10 parts) were conducted after the morning observation. Temperament scores during these handling procedures, entry order into a crush, social rank and ADG were assessed. Carcass grades were obtained after the slaughter. A principal factor analysis with the Harris-Kaiser rotation extracted 11 and 10 clusters in the E and M stages. One-way ANOVA determined clusters in which their factor scores were different between the carcass grades: In the E stage, they were a cluster of chest girth (loading 0.90) and depth (0.88), body weight (0.86), withers (0.84) and hip (0.79) height and rump length (0.77) ($P < 0.01$), and a cluster of the number of scratching their head or neck with facilities (0.92) ($P < 0.05$) for the carcass yielding grades; a cluster of social rank (0.73) and triglyceride concentrations (0.62), and a cluster of the numbers of investigating facilities (0.65) and eating hay (-0.86) (both $P < 0.10$) for the carcass quality grades. In the M stage, they were a cluster of cortisol (0.84) and adrenaline (0.60) concentrations, and the number of eating hay (-0.67) ($P < 0.10$) for the carcass yielding grades; a cluster of hip height (0.87), body weight (0.71), cannon circumference (0.69), chest depth (0.62), withers height (0.57) and chest girth (0.55) ($P < 0.10$), and a cluster of the number of eating grain feed (0.91) and stand-chewing the cud (-0.61), and social rank (-0.66) ($P < 0.10$) for the carcass quality grades.

Key Words: Beef Cattle, Carcass Grades, Prediction

W148 Evaluation of implant strategy and days on feed on performance and carcass merit of finishing yearling steers. J. P. Hutcheson^{*1}, W. T. Nichols¹, C. R. Reinhardt¹, S. R. Swingle², and K. J. Karr², ¹*Intervet, Inc., Millsboro, DE*, ²*Cactus Research, Ltd, Amarillo, TX*.

One thousand nine hundred and eighty-eight head of crossbred, yearling steers (383 kg) were used in a randomized complete block experiment with a 2 × 2 arrangement of treatments to evaluate the effect of implant type and days on feed. Implant treatments were 1) Revalor-S (120 mg trenbolone acetate + 24 mg estradiol) implanted on day 0 only (RS); 2) and Revalor-IS (80 mg trenbolone acetate + 16 mg of estradiol) implanted on day 0 only (IS). Steers were fed 123 or 145 days. There were 5 pens per treatment with an average of 98 head per pen. Steers implanted with RS had higher ($P < 0.05$) live and carcass adjusted average daily gain at both days on feed when compared to IS implanted steers. Daily dry matter intake tended ($P = 0.07$) to be greater in RS steers fed 123 days compared to IS implanted steers. Feed conversion was improved ($P < 0.05$) in RS implanted steers fed 145 days compared to IS implanted steers, but was not different in steers fed 123 days. Hot carcass weight was greater ($P < 0.05$) in RS implanted steers at 123 days on feed compared to IS steers. Steers fed 145 days, had lower average daily gain, higher feed to gain and greater final weight compared to steers fed 123 days ($P < 0.05$). There were no differences in quality or yield grade measurements between implant treatments at either slaughter time. However, feeding steers implanted with RS an additional 22 days did increase the percentage of Choice & Prime carcasses from 48 to 56%. Cattle fed 145 days had a higher dressing percent, greater carcass weight, more rib fat, higher average yield grade and more empty body fat (EBF) compared to cattle fed 123 days ($P < 0.05$). There were no differences in quality grade by days on feed. Feeding cattle an additional 22 days increases out weight and carcass weight with a reduction in average daily gain and increased feed to gain without affecting quality grade. Implanting yearling steers one time with RS provides improved performance without compromising quality grade when compared to steers implanted with IS at either slaughter time.

Animal Performance and Carcass Traits

W149 Comparison of weaning and yearling ultrasonic measures of body composition in Angus breeding cattle. T. Perkins^{*} and A. Rimal, *Southwest Missouri State University, Springfield*.

The objectives of this study were to assess the relationship between ultrasound measurements taken at weaning and yearling weigh periods. One hundred seventy-five registered Angus bulls (n=88) and heifers (n=87) were scanned ultrasonically for ribeye area, fat thickness, percent fat (for the equivalent to marbling score) and rumpfat prior to weaning and again at approximately one year of age. The cattle used in this study were from the Falcon Seaboard Ranch located in Fredericksburg, Texas. Ultrasound values at weaning were then compared to measurements taken at approximately one year of age. All ultrasound measurements were taken by an Ultrasound Guidelines Council (UGC) field and laboratory certified technician, at weaning and yearling, using the Beef Image Analysis (BIA) software. Weaning images were processed by the scanning technician whereas yearling images were interpreted by the National CUP Lab in Ames, Iowa. Weanling means for scan weight (WSW), ribeye area (WREAU), fat thickness (WFTU), percent fat (WPFU), and ribeye shape (WREAS) were 291.9 ± 33.42 kg, 53.78 ± 7.45 cm², .42 ± 0.24 cm, 3.90 ± .67 %, and 2.50 ± 0.73, respectively. Yearling means for scan weight (YSW), ribeye area (YREAU), fat thickness (YFTU), percent fat (YPFU), and rump fat (YRFU) were 469.4 ± 61.39 kg, 66.45 ± 10.49 cm², .64 ± 0.20 cm, 4.54 ± 1.27 %, and .78 ± 0.23 cm, respectively. Pearson correlations for WSW and YSW, WPFU and YPFU, WREAU and YREAU were 0.57, 0.52, and 0.55, respectively; whereas, the correlation between WFTU and YFTU were lower and non significant at 0.16. These coefficients indicate that the relationship between weaning and yearling carcass attributes for scan weight, percent fat, and ribeye area were high and statistically significant. However, these results indicate that ultrasound was not a useful tool in assessing external fat levels on weanling calves prior to going into a performance testing program.

W150 Effects of an artificial sweetener (Sucram C-150) on performance and health of newly received beef cattle. J. D. Rivera^{*1}, J. T. Richeson¹, M. L. Galyean¹, W. Rounds², and P. Schlegel³, ¹*Texas Tech University, Lubbock*, ²*Prince Agri Products, Inc., Quincy, IL*, ³*Pancosma, Geneva, Switzerland*.

Two hundred crossbred (British x Continental) beef steers (average BW = 190.1 ± 4.07 kg) were shipped 1,588 km from an order buyer facility in West Point, MS to the Texas Tech University Burnett Center in New Deal, TX and used in a randomized complete block design to evaluate the effects of an artificial sweetener (Sucram C-150; Pancosma, SA) added to the diet on performance and health for a 60-d receiving period. On arrival, cattle were vaccinated for respiratory disease and clostridial antigens, given a unique ear tag, weighed, dewormed, and assigned to one of two treatments: 1) Control: a standard 65% receiving diet; or 2) Sucram: a standard 65% receiving diet with 200 mg/kg (DM basis) of Sucram C-150 artificial sweetener. Following processing, cattle were moved to their assigned pens, and offered the receiving diet free choice. Long-stemmed sorghum sudangrass hay (1.81 kg/animal, DM basis) was fed for the first 5 d only. Cattle were observed daily for symptoms of bovine respiratory disease (BRD), and treated as needed when rectal temperature was > 39.7 °C. Sucram C-150 did not affect ($P > 0.10$) DMI at any time in the 60-d study, nor, did it affect ADG from d 0 to

14; however, feeding Sucram tended ($P < 0.12$) to increase 28-d ADG (1.43 vs. 1.50 kg/d for Control and Sucram, respectively) and increased ($P < 0.10$) ADG for the overall 60-d period (1.24 vs. 1.33 for Control and Sucram, respectively). Gain efficiency did not differ between treatments, except from d 0 to 28 ($P < 0.02$), when Sucram improved G:F. No differences were detected ($P > 0.10$) for morbidity between the two treatments (59.7% and 58.0% for Control and Sucram, respectively); however, feeding Sucram decreased ($P < 0.02$) the proportion of animals requiring two or more antibiotic treatments (52.6% and 41.0% for Control and Sucram, respectively). The addition of 200 mg/kg (DM basis) Sucram C-150 to the diet of newly received cattle increased receiving period ADG and resulted in fewer repeat antibiotic treatments to recover from BRD.

Key Words: Artificial Sweetener, Beef Cattle, Diets

W151 Effect of shade in feedlot pen on growth performance response of finishing beef cattle the cold season in the northwest of Mexico. R. Barajas^{*1}, B. J. Cervantes¹, R. J. Virgilio², and P. Castro², ¹FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan (Mexico), ²Tecnologia de Maxima Produccion S.A. de C.V., Mexico.

To determine the effect of shade in feedlot pen on growth performance response of finishing beef cattle the cold season in the northwest of Mexico, a 63-d feedlot performance experiment was conducted from January to March of 2003. Sixty-six brahman crossed bull calves (Males, BW=370.14±4.28 kg), were used in a complete block randomized experimental design. The animals were blocked by initial weight, and placed in ground pens (6 x 12 m), the treatments consisted in: 1) Pens without shade (Control); or pens fitted with roof that provides 3 m² of shade by animal (Shade treatment). Animal were fed with 14.86 forage:concentrate, cracked corn based diet containing CP 14%, NEm 1.85 Mcal/kg, and NEg 1.22 Mcal/kg. Mean temperature was 22.4°C and total precipitation was 14.2 mm. Shade increased ($P < 0.01$) 4% final weight (432 vs. 482 kg), and 16% average daily gain (1.50 vs. 1.74 kg/day). Dry matter intake was not affected ($P = 0.58$) by treatments (10.41 vs. 10.14 kg/day). Feed conversion was improved ($P < 0.01$) by use of shade (6.94 vs. 5.84). Carcass weight increased ($P < 0.01$) 5.7% by shade inside of pen (294.10 vs. 310.95 kg). Carcass dressing was not affected ($P = 0.29$) by treatments (64.5 vs. 63.9%). NEM obtained from the diet was improved ($P = 0.02$) by shade (1.866 vs. 2.127 Mcal/kg), and NEg was increased ($P = 0.02$) with shade in pen (1.226 vs. 1.455 Mcal/kg). Observed/expected NEM ratio was 14% higher ($P = 0.02$) in shade treatment (1.01 vs. 1.15), and observed/expected NEg was increased ($P = 0.02$) 18% by shade (1.01 vs 1.19). It is concluded, that the use of shade inside of feedlot pen improves growth performance response of finishing beef cattle in the northwest of Mexico.

Key Words: Shade, Growth-Performance, Beef Cattle

W152 Effect of hormonal implant failure on growth performance response of finishing beef cattle re-implanted during raining hot season in the northwest of Mexico. R. Barajas^{*1}, B. J. Cervantes¹, R. J. Virgilio², and P. Castro², ¹FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico, ²Tecnologia de Maxima Produccion S.A. de C. V., Mexico.

The objective was to determine the effect of hormonal implant failure on growth performance response of finishing beef cattle re-implanted during raining hot season in the northwest of Mexico. A 73-d feedlot performance experiment was conducted from September to December of 2003. Ninety four brahman crossed bull calves (Males, BW=335±4.74 kg), were used in a complete block randomized experiment design. Calves from a 91-d growing period were weighed and reimplanted in the left ear with Revalor. Calves were placed in 12 ground pens and fed finishing diets for 73 d. Calves were harvested and left ear was obtained to evaluate implant condition. Implant condition criteria were: 1) Absorbable implant (Normal, Brocket, etc.); or 2) Not absorbed implant (Encapsulated, Absessed, and not found). Implants in 31 calves were considered as not absorbed. Thirty d prior to implantation, the mean temperature at 14:00 hours was 33.5 °C, relative humidity was 60.41%, and precipitation was 252 mm. Ending weight was not affected ($P = 0.22$) by implant condition. Body weight gain was decreased ($P < 0.05$) in 9% by loss or implant activity (98.02 vs. 89.49 kg), and average daily gain was diminished ($P < 0.05$) in 5.5% (1.33 vs 1.26 kg/day). Carcass

weight, dressing, marbling score, KPH fat, and meat color were not affected ($P > 0.10$) by implant condition. Carcass grading was higher ($P < 0.05$) for carcass from animals with implant failure. It is concluded, that under raining hot condition, implant failure can be high and this negatively affects weight gain in finishing beef cattle. #8482#8482

Key Words: Hormonal Implants, Growth Performance, Beef Cattle

W153 Long term comparative trial of ear tags and ceramic boluses for the electronic identification of beef cattle under European rangeland conditions. J. J. Ghiradi^{1,2}, G. Caja¹, C. Conill¹, M. Hernández-Jover^{*1}, and D. Garín^{1,3}, ¹Universitat Autonoma de Barcelona, Spain, ²Universidad Nacional del Litoral, Esperanza, Argentina, ³Universidad de la Repblica, Montevideo, Uruguay.

A herd of Bruna dels Pirineus beef cows (n = 161) grazing under European rangeland conditions in the Pyrenees Mountains was used to compare two type of electronic identification devices for a period of 7 years (1997-2003). All cows wore two officially approved plastic ear tags with two flaps numerically and barcode recorded by laser (weight, 6 g; Azasa-Allflex, Madrid, Spain), according to the European Regulation for cattle identification (CE 1760/2000), and were also identified with two types of ISO half-duplex radio frequency devices: 1) electronic button ear tags (weight, 10 g; o.d., 30 mm; Allflex, Vitré, France) attached to the left ear; and, 2) electronic ceramic ruminal boluses (weight, 75 g; length×o.d., 21×68 mm; specific gravity, 3.36; Gesimpex, Barcelona, Spain). Reading controls of all devices were carried out at the annual brucellosis and tuberculosis testing and parasites drugging. Electronic devices were read using a Gesreader 2S hand-held reader (Gesimpex). A total of 3 cows died and 95 cows were slaughtered during the experiment. After 7 years, the 63 cows remaining in the herd retained 94.4% of the officially approved plastic ear tags (0.8% annual loss rate). Only 28.6% of tags were read by mean of a barcode reader (Intermec M90, Everett, WA) without immobilizing the head of the cows. Electronic ear tags showed a 96.8% readability (1.5% failed and 3.2% lost). Two electronic boluses (1.2%) were lost 2 h after application and were reapplied on the same day. No new losses or failures of boluses occurred during the experiment. In conclusion, electronic identification proved to be more efficient than conventional ear tagging in beef cows. Long term readability was greater for boluses than ear tags, recommending their use for cattle electronic identification under European rangeland conditions.

Key Words: Electronic Identification, Bolus, Ear Tag

W154 Comparison of pre-yearling, yearling, and post-yearling ultrasonic measurements of body composition in Brahman bulls. T. D. Jennings^{*1}, T. Perkins¹, and J. C. Paschal², ¹Southwest Missouri State University, Springfield, ²Texas A&M University, Corpus Christi.

The objective of this study was to compare ultrasonic measures of body composition in Brahman cattle at various stages of development. There were three individual scan sessions taken on the Brahman bulls (N=72). Individual weights and ultrasonic measurements for ribeye area, fat thickness, percent intramuscular fat and rumpfat were taken during three measurement intervals. The serial measurements were taken every two months (beginning mean age of 11 months and mean ending age of 15 months). The animals used in this study were provided by the J. D. Hudgins Ranch in Wharton, Texas. All ultrasound measurements were taken by an Ultrasound Guidelines Council (UGC) field and laboratory certified technician. Beef Image Analysis (BIA) software was used for the data collection. Pre-yearling, yearling, and post-yearling images were collected and interpreted by the same technician. A positive and significant correlation existed between all pre-yearling, yearling, and post-yearling ultrasonic measurements of body composition within each specific trait (e.g. FTU1 and FTU2 = 0.542; FTU1 and FTU 3 = 0.598; FTU2 and FTU3 = 0.635). Significant correlations existed between post-yearling weight (WT3) and post-yearling ultrasound measures of ribeye area (REAU3), fat thickness (FTU3), and rumpfat (RFU3) (0.676, 0.432, and 0.408, respectively). The correlation between post-yearling percent intramuscular fat (%FatU3) and WT3 was low (-0.05) and non-significant as well as the correlation between %FatU3 and REAU3 (0.013). The correlations between REAU3 and FTU3, and REAU3 and RFU3 were 0.314 and 0.281, respectively. A moderately positive correlation existed between FTU3 and %FatU3 (0.262). These data suggest that ultrasound was effective in measuring changes in body composition traits of external fat thickness, ribeye area and rumpfat.

However, the technology was ineffective in measuring differences in intramuscular fat deposition in pre-yearling, yearling, and post-yearling Brahman bulls.

Key Words: Ultrasound, Brahman, Seriel

W155 Cow-calf efficiency of four different dam genotypes. L. Calegare¹, M. M. Alencar², G. M. Cruz², and D. P. D. Lanna*¹, ¹*Animal Growth and Nutrition Lab. ESALQ/USP, Piracicaba, SP, Brazil*, ²*Brazilian Southeast Cattle Research Center, Brazil*.

Brazil has 53 millions beef cows, 85% of which from the Nelore breed. However there are no data comparing biological efficiency of Nelore and its crosses with *B. taurus*. The objective of this study was to determine cow-calf efficiency. Forty cows from four genotypes Nelore (NL), Canchim x Nelore (CN), Angus x Nelore (AN), and Simmental x Nelore (SN) were randomized in blocks by calving date. Cows and respective calves were individually fed from postpartum to weaning (15-180 d) a 50:50 hay:concentrate diet (16% CP and 2.34 Mcal ME on a DM basis), adjusted weekly to maintain body weigh and condition score. Calves received the same diet of their dams *ad libitum*, beginning at 40 d of age. Crossbred cows were bred to Canchim (5/8 Charolais) bulls and NL cows to Nelore bulls. Milk yield was estimated by weighing calves before and after suckling. ME intakes by cow/calf units were different ($P < 0.05$); 4139.1±78.7 for SN, 3898.2±78.7 for AN, 3777.8±78.7 for CN and 3523.5±78.7 Mcal for NL. The energy intake was parallel to adult body weight, milk yield and calves growth rate. At weaning empty body weight for NL calves was lower ($P < 0.05$) than crossbred calves; 149.1±9.3 vs. 201.3±9.3 for 1/4S, 192.8±9.3 for 1/4A and 183.1±9.3 kg EBW for 3/4C. Body composition was estimated by 9-10-11th rib analysis. Energy retention (Mcal) was higher ($P < 0.05$) for 1/4A than 3/4C and NL; 462.6±28.8 vs. 384.0±28.8 and 321.8±28.8 Mcal, respectively. Calves 1/4S had intermediate energy retention; 429.8±28.8 Mcal. Cow-calf efficiency was higher ($P < 0.05$) for AN compared to NL cow-calf pairs; 113.6±7.1 vs. 88.9±7.1 kcal/Mcal. Results for Simmental and Canchim pairs were intermediate; 99.2±7.1 and 98.8±7.1 kcal/Mcal, respectively. The higher ME intakes by AN cow-calf pairs were compensated by the higher energy retention and EBW gain. Reproduction was not evaluated, but under unrestricted nutritional conditions cross-breeding improved cow efficiency as measured by proportional energy retention in their calves.

Key Words: Weaning Weight, Body Composition, Biological Efficiency

W156 Efficacy and persistency of pour-on dewormers differing in active ingredient and carrier on weight gain and fecal egg count in stocker beef cattle. Jonathon L Beckett*¹, Brian P Wetzell¹, Tim Richards², and Bill Clymer³, ¹*Cal Poly State University, San Luis Obispo*, ²*Kahua Ranch, Ltd, Kamuela, HI*, ³*Fort Dodge Animal Health, Overland Park, KS*.

The objective of the studies was to compare, under field use conditions, the efficacy and persistency of moxidectin (M), ivermectin (I) and doramectin (D) pour-on parasiticides at 500 µg/kg with an untreated control in stocker cattle exposed to naturally acquired nematode infection. The study was conducted over two grazing seasons using single-source crossbred steers and heifers commingled in an intensive grazing situation. During the first year, 100, 100, 99, and 99 cattle (initial weight 146.9kg) were treated on day 0 and retreated on day 70 with M, I, D or CON, respectively. To determine persistency, during the second year, 123, 126, 125, and 125 cattle (initial weight 171.8kg) were treated with M, I, D or CON, respectively, but were not retreated. Weight gains and fecal egg counts (EPG) were determined on 25% of each treatment group each 5-6 weeks. Grazing continued for 105 and 126 days for years 1 and 2, respectively. During year 1, weight gains were 95.3^a, 92.0^b, 94.4^a, and 78.9^c kg for M, I, D and CON treatments, respectively. During year 2, weight gains were 113.7^a, 109.3^b, 110.9^b, and 102.4^c kg for M, I, D and CON treatments, respectively. In both trials, fecal egg counts were significantly higher ($P < .05$) in CON cattle compared with dewormed treatments. No differences in fecal egg counts were consistently detectable between dewormed groups. In summary, with 2 treatments, M and D treatment groups appeared to gain equally while exposed to parasites. Response to ivermectin was poorer than to the other two dewormers ($p < .05$). With only one treatment, moxidectin tended to increase weight gains compared with D or I. CON group demonstrated

significantly reduced weight gains in all cases ($p < .05$). This was true regarding total body weight gain and average daily gain, and is supported by the fecal egg count data. Producers must weigh all of the advantages offered by each of the products including but not limited to efficacy and persistency.

Key Words: Stocker, Cattle, Parasite

W157 Ultrasound and carcass measures of different biological types of beef cattle developed under a rotational management-intensive grazing system. M. L. Thomas*¹, T. L. Perkins², A. H. Brown, Jr.¹, R. T. Baublits¹, D. W. Kellogg¹, and Z. B. Johnson¹, ¹*University of Arkansas*, ²*Southwest Missouri State University, Springfield*.

Yearling beef steers (n=33) representing four biological types, typical of commercial cattle in northwest Arkansas, were evaluated for muscle and fat deposition utilizing real-time ultrasound measurements and carcass traits. Biological types included large framed, late maturing (LL, n=6), medium framed, late maturing (ML, n=9), medium framed, intermediate maturing (MI, n=9) and medium framed, early maturing (ME, n=9) steers. Animal diet consisted of only forages utilizing a rotational management-intensive grazing system in which animals were allocated new paddocks on a daily basis. Target weight and body condition score at harvest were 454 kg and 6.0 (on a 1 to 9 scale), respectively. Average days on trial before harvest were 300 with a mean harvest weight of 462.8 kg and a 5.9 body condition score. Overall mean gain was 222 kg at a 0.74 kg average daily gain. Generally, carcass data were correlated with the final ultrasound readings. Mean marbling score was greater ($P < 0.05$) for ME than LL steers (346 ± 25 vs. 239 ± 27). There was no difference ($P > 0.05$) in mean marbling score for MI and ML steers (285 ± 24 and 253 ± 22). There was an interaction ($P < 0.05$) between biological types and days on grass until harvest for ribeye area. Days on grass did not affect ($P > 0.05$) other carcass traits. Based on marbling scores, ME steers best fit the all-forage diet utilizing a rotational management-intensive grazing system.

Key Words: Ultrasound, Biological Types, Management-Intensive Grazing

W158 Effect of feeding corn silage diets on reduction of drinking water intake and growth performance of cattle in feedlot under hot humid weather in the Northwest of Mexico. R. Barajas*¹, B. J. Cervantes¹, A. Camacho¹, R. J. Virgilio², P. Castro², and E. Sanchez³, ¹*FMVZ - Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*, ²*Tecnologia de Maxima Produccion S.A. de C.V., Sector Humaya, Mexico*, ³*UAEGES, Culiacan-Sanlana, Mexico*.

The objective was to determine the effect of feeding corn silage diets on reduction of drinking water intake and growth performance of cattle in feedlot under hot humid weather in the Northwest of Mexico. A 164-d (Jun-Nov/03) feedlot experiment was conducted using 94 Brahman-cross bull calves (BW= 204.8 ± 2.7 kg). Calves were blocked by weight into eight groups for a completely randomized block design. Calves were assigned one or two feeding programs: 1) diets based in ground corn, containing sudan grass hay as roughage during all the feeding period (Control); or 2) diets containing corn silage substituting all sudan grass hay and partially the ground corn. Diets were fed for 126-d and then fed with control diet until the end of experiment (silage). Mean temperature was 28.4° C and precipitation was 651 mm. Silage treatment shown lower ($P = 0.05$) BW during the first 56-d. Ending weight was not affected ($P = 0.36$) by treatments. Average daily gain was lower ($P = 0.01$) for silage in day 28; however from day 57 to 112 ADG was higher ($P = 0.04$) for cattle feed silage diets. ADG throughout the experiment was similar ($P = 0.41$) (1.32 vs. 1.28 kg). DMI was diminished ($P = 0.01$) by silage diets (8.70 vs. 8.31 kg/day). Feed/gain ratio was not affected ($P = 0.67$) by treatments (6.35 vs. 6.23). Silage diets reduced ($P = 0.01$) drinking water intake by 36% during the first 112 days in feedlot (24.3 vs. 16.4 L/day), and 23% ($P = 0.06$) during the entire experiment (23.54 vs. 18.08 L/day). The sum of feed intake (wet basis) plus water intake was similar ($P = 0.66$) in both treatments (34.58 vs. 35.6 kg/day). The amount of drinking water required by kg of gain was diminished ($P = 0.05$) by 25 % in silage diets (16.79 vs. 12.65 L/kg). Carcass weight, dressing, marbling score, KPH fat, color and quality grade were not affected ($P > 0.10$) by treatments. It is concluded that the use of diets containing corn silage, can help to reduce near of 25

% the requirements of drinking water for feedlot cattle, without affect negatively impacting performance or carcass quality.

Key Words: Corn Silage, Drinking Water, Feedlot Cattle

W159 The effect of different types of morphologically abnormal spermatozoa on bovine embryo development after IVF. A. H. Walters*¹, W. E. Eyestone², R. G. Saacke¹, R. E. Pearson¹, and F. C. Gwazdauskas¹, ¹Virginia Polytechnic Institute and State University, Department of Dairy Science, Blacksburg, ²Virginia Polytechnic Institute and State University, Department of Large Animal Clinical Science, Blacksburg.

The study was conducted to evaluate the effect of semen samples collected from bulls subjected to scrotal insulation on embryonic development after in vitro fertilization (IVF). Morphologically abnormal semen samples from four Holstein bulls were cryopreserved following a scrotal insulation period of 48 h (d 0). Three types of semen samples were used for IVF: 1) semen from bulls collected 5 d prior to scrotal insulation (Pre-insult); 2) semen from d 13 (2 wk-PI); and 3) d 20 (3 wk-PI) post-insult. Following an 18 h sperm-oocyte co-incubation, embryos

were cultured for 8 d and evaluated. The post-thawed morphological evaluation of semen revealed a decrease ($P < 0.01$) in the percentages of normal spermatozoa in the post insult samples (3 wk-PI) compared with the Pre-insult samples for Bulls I and Bull III ($74 \pm 2.4\%$ to $22.3 \pm 2.4\%$ and $67.7 \pm 2.4\%$ to $0.5 \pm 2.4\%$, respectively), while the percentage vacuolated spermatozoa increased significantly for Bull II (diadem-0% to $59.6 \pm 2.0\%$; apical vacuoles- $1.06 \pm 3.6\%$ to $47.8 \pm 3.6\%$). There was no change in abnormal sperm population for Bull IV ($<10\%$). The cleavage and blastocyst formation rates and embryo development scores were affected ($P < 0.01$) by the interaction of bull by sample collection time. For Bull I and Bull III (severe responders) there was a decreased rate of cleavage ($77.9 \pm 1.9\%$ to $62.7 \pm 1.7\%$ and $85.5 \pm 1.7\%$ to $66.3 \pm 1.5\%$) and blastocyst formation ($23.4 \pm 1.9\%$ to $10.6 \pm 1.7\%$ and $26.8 \pm 1.7\%$ to $13.5 \pm 1.6\%$) decreased between the Pre-insult and 3 wk-PI samples. In contrast, the cleavage and blastocyst formation rates for Bull II ($71.6 \pm 1.4\%$ and $16.9 \pm 1.5\%$) and Bull IV ($77.8 \pm 1.7\%$ and $21.4 \pm 1.5\%$) were unaffected. In conclusion, a decrease in embryonic development seems to be related to the changes in head shape morphology.

Key Words: Abnormal Spermatozoa,, Scrotal Insult, IVF

Goat Species

W160 Replacement of alfalfa neutral detergent fiber with a combination of nonforage fiber sources on ruminal pH and performance in Alpine goats raised under natural conditions in northern Mexico. P. A. Robles-Trillo*¹, L. Garcia-Palestina¹, E. De Lazaro-Urbina¹, R. Rodriguez-Martinez¹, and R. Bañuelos-Valenzuela², ¹Universidad Autonoma Agraria Antonio Narro Unidad Laguna, Santa-Fe, Torreon, Mexico, ²Unidad Academica de Medicina Veterinaria y Zootecnia, UAZ, Victor Rosales, Mexico.

There has been a limited number of studies carried out on goats about the physiological and productive consequences when NDF is replaced with nonforage fiber sources (NFFS). To evaluate the effect of replacing NDF from alfalfa with NFFS combination (whole linted cottonseed, soy hulls, and wheat bran) on ruminal pH, ADG, dry matter intake (DMI), and feed efficiency (FE), sixteen Alpine goats (body weight of 22.81 ± 1.84 and 7 months old) were used in a 4 x 4 block design. The four diets were basal control diet (LAD) low in forage and fiber (9.27% of alfalfa NDF and 6.72% of corn silage NDF, DM basis), a normal forage diet high in alfalfa (HAD) (LAD diet, plus 14% of alfalfa NDF), and two low forage diets with either 9.4% NDF (LNFD) or 18.18% (HFND) NDF DM basis from the NFFS combination. Ruminal samples were obtained by stomach tube each 3 h by seven times daily to determinate the pH ruminal content by a potentiometer. DMI and FE were calculated by body weight and weight gain daily. The effects of treatments upon pH, ADG, DMI, and FE were evaluated and analyzed by means of ANOVA. Our results showed an effect of treatment ($P < 0.001$) on ruminal pH, which was highest for the HAD treatment and lowest for LAD, without differences between LNFD and HFND. A difference in ADG ($P < 0.05$) was found between LAD and HAD, but values were similar between LNFD and HFND. There were no differences ($P > 0.05$) in DMI. FE was greater ($P < 0.05$) for LAD vs HAD. The replacement of NDF from alfalfa with NFFS did not reduce ruminal pH with respect to the normal forage diet (LAD) and therefore, ruminal function could have remained normal. However, NFFS had a detrimental effect on ADG and FE without affecting DMI, which could be important to economic profitability depending on cost of NFFS products.

Least square means for ruminal pH (pH), average daily gain (ADG), dry matter intake (DMI), and feed efficiency (FE) in goats (N=16) with four different diets (LAD, LNFD, HFND, and HAD) in Northern Mexico (25° NL)

Variables	Treatments				S.E.M.
	LAD	LNFD	HFND	HAD	
pH	6.13 ^a	6.19 ^a	6.26 ^b	6.33 ^c	0.02
ADG	0.089 ^a	0.060 ^{ab}	0.065 ^{ab}	0.043 ^b	0.01
DMI	47.03 ^a	45.21 ^a	46.71 ^a	44.31 ^a	1.62
FE	0.11 ^b	0.08 ^{ab}	0.08 ^{ab}	0.06 ^a	0.01

W161 Influence of diet and gut fill on blood metabolites and fecal shedding of *E. coli* in sheep and goats. V. R. Gutta*, G. Kannan, B. Kouakou, K. M. Gadiyaram, W. R. Getz, G. W. McCommon, and Y. Lan, Fort Valley State University, GA.

Recent reports have shown that fecal shedding of *Escherichia coli* can be reduced by preharvest management practices in small ruminants. The objectives of this experiment were to determine the effects of diet and feed deprivation time prior to harvesting on fecal *E. coli* shedding and blood metabolite concentrations in sheep and goats. In an RCBD split-plot design, sheep (wethers, n = 16) and goats (bucks, n = 16) were assigned to 8 pens (4 sheep or goats/pen) and fed either a concentrate diet or a hay diet for four days. The animals (8 - 12 mo of age) were then taken to the processing facility and subjected to either 12 or 24 h feed deprivation prior to harvesting, with continuous access to water. Sterile sponges were used to sample (5 x 5 cm area) hind legs of each animal for *E. coli* contamination before and after feed deprivation. Blood samples were also collected to determine urea nitrogen (BUN) and glucose levels prior to harvesting. Generic *E. coli* counts in the rumen were higher ($P < 0.01$) in animals subjected to 24 h feed deprivation than those subjected to 12 h feed deprivation. *E. coli* counts in the rectum were higher ($P < 0.01$) in concentrate-fed than in hay-fed animals. *E. coli* contamination of hair/fleece was higher ($P < 0.05$) in sheep than in goats. Behavioral observations during holding revealed that sheep spent more time lying down than goats, indicating that sheep are more prone for fecal contamination from the pen floor during preharvest holding than goats. The pH values of rumen and colon contents were higher ($P < 0.01$) in hay-fed animals than concentrate-fed animals. Glucose and BUN concentrations were not influenced by diet or feed deprivation. Fecal contamination in sheep and goats can be controlled by preharvest dietary management, with no significant changes in glucose and BUN levels. The results indicate that hay feeding and shorter feed deprivation period decrease *E. coli* counts. Sheep may be more prone for fecal contamination during holding.

Key Words: Sheep and Goats, *E. Coli*, Fecal Contamination

W162 Effect of different levels of food and water deprivation on serum levels of catecholamines, glucose, and creatinine in Mexican-native goats. C Meza, RM Rincon, R Bañuelos, F Echavarria, and CF Arechiga*, *Universidad Autonoma de Zacatecas, Mexico*.

Level of stress by food and water deprivation was evaluated on Mexican native goats by determination of serum catecholamines, glucose, and creatinine. Goats ($n=12$ and weight 29.5 ± 2.0 kg) from north-central Mexico ($23^{\circ} 00'$ latitude N and $102^{\circ} 30'$ longitude W at 2,150 m above sea level), were randomly assigned into 4 groups: FWD 0 = Control, without food and water deprivation (fed daily ad libitum); FWD 1 = food and water deprivation of 1 d (fed every day just for 2 h); FWD 2 = food and water deprivation of 2 d (fed every 2 d just for 2 h); and FWD 3 = food and water deprivation of 3 d (fed every 3 d just for 2 h). The experiment was conducted from November through April (autumn-winter). Every month, during the 4th wk, each goat was bled in order to obtain nine blood samples at different 15-min intervals before and after food and water were given (-45, -30, -15, 0, 15, 30, 45 min). Serum samples of glucose and creatinine were analyzed by spectrophotometry while catecholamines were determined by fluorometric techniques. The average serum concentration was 19.21 mg/dL for catecholamines, 57.22 mg/dL for glucose, and 2.74 mg/dL for creatinine. Food and water deprivation affected serum glucose concentration ($P < 0.05$) without affecting creatinine or catecholamines. In contrast, month of gestation affected ($P < 0.05$) all three variables. In fact, while serum catecholamines levels were intermediate at the beginning of the gestation, they decreased towards the intermediate gestation, and were highest at the end of the gestation. A positive correlation was observed between glucose and creatinine suggesting a possible catabolic scenario in muscular tissue followed by an increased level of hepatic gluconeogenesis. Even though nutritional and hydric stress affected glucose serum levels, this metabolic restriction did not compromise embryonic and fetal development as well as kidding percentage, suggesting a high degree of adaptation of Mexican-native goats to face stress by food and water deprivation.

Key Words: Goats, Catecholamines, Food Scarcity

W163 Effect of buck presence on frequency, amplitude, and concentration of luteinizing hormone (LH) in Mexican-native goats exposed to artificial photoperiod. R. M. Rincon*, C. F. Arechiga¹, F. J. Escobar¹, M. A. Lopez¹, and J. Valencia², ¹*Universidad Autonoma de Zacatecas, Mexico*, ²*Universidad Nacional Autonoma de Mexico*.

The purpose of present work was to evaluate the effect of introducing a sexually-active male buck on LH pulse frequency, amplitude, and concentration in Mexican-native goats exposed to a 6-month long artificial photoperiod. Female goats ($n=30$) were either exposed to the presence or absence of a male buck ($n=15$ /group). Within each group, there were Control (CON, $n=5$), Ovariectomized (OVX, $n=5$), and Ovariectomized + Estradiol-implanted goats (OVX + E2X, $n=5$). All female goats were exposed to a 6-month long artificial photoperiod ranging from 10.6 to 13.4 h of light during the day (short and long days). Blood samples were obtained during short and long days for sampling periods of 6 hours every 15 min. Progesterone and LH levels were determined by RIA. Presence of a male buck increased ovarian activity of native goats. LH frequency, amplitude, and concentration were higher ($P < 0.001$) in response to male buck presence (frequency = 3.13 vs 1.34 pulses/6 h; amplitude = 1.50 vs. 0.96 ng/mL; concentration = 4.61 vs 2.70 ng/mL). Progesterone concentrations were also higher in response to male buck presence (4.04 vs 2.20 ng/mL). Presence of a male buck maintained LH pulse frequency and concentration elevated in goats despite being exposed to an inhibitory photoperiod. In conclusion, male-buck presence influence reproductive activity of Mexican-native goats in north-central Mexico.

Key Words: Goats, Luteinizing Hormone, Photoperiod

W164 Mineral content of diets selected by range criollo goats in a poor condition shrubland of north Mexico. M. A. Cerrillo-Soto*, G. Nevarez-Carrasco, R. Montoya-Escalante, and A. S. Juárez-Reyes, *Universidad Juarez del Estado de Durango, Dgo, Mexico*.

The study was conducted to determine the mineral content in diets selected by goats grazing a poor condition shrubland in a semi-arid region of north Mexico. The study area is located at $24^{\circ} 04'$ N, $103^{\circ} 23'$ W, altitude of 1,435 m, annual mean temperature is 17° C and rainfall is about 278 mm. Six nonlactating female goats (30 ± 4.9 kg BW) fitted with esophageal cannulae were used to collect monthly extrusa samples. The sampling was performed in October, December, January, March, April, May, June, July, and September. Animals were sampled two days each month at 1130 and 1530 for 45 min. The samples were composited, dried, and ground (1 mm). Ca, Mg, K, Na, Co, Cu, Mn, Fe, and Zn determinations were performed by atomic absorption spectrophotometry. Phosphorus was determined by colorimetry. Data were statistically analyzed for a completely randomized design. Macro mineral concentrations of the forage selected by goats varied ($P < 0.05$) among months. Calcium content ranged from 8.2 to 28.8 g/kg (mean = 16.0 g/kg). Content of P ranged from 1.1 to 3.5 g/kg (mean = 2.3). Dietary Mg ranged from 1.7 to 3.3 g/kg (mean = 2.2 g/kg). Potassium content ranged from 9.7 to 21.7 g/kg (mean = 16.1 g/kg). Mean concentration of Na was 3.87 g/kg and varied from 3.4 to 4.3 g/kg. Magnesium concentration ranged from 1.5 to 3.3 g/kg (mean = 2.2 g/kg). Trace minerals concentrations also varied ($P < 0.05$). The Co content varied from 13.2 to 19.4 mg/kg (mean = 14.7 mg/kg). Concerning Cu, concentration ranged from 6.7 to 11.6 mg/kg (mean = 8.4 g/kg). Concentration of Mn ranged from 27.1 to 99.1 mg/kg (mean = 54.2 mg/kg). Zinc concentration ranged from 19.6 to 81.0 mg/kg (mean = 30.4 mg/kg). Iron content varied from 96.1 to 708.2 mg/kg (mean = 350.8 mg/kg). Results suggest that P, Na, Cu, and Zn contents do not satisfy goat requirements; thus, a supplementation program should be implemented.

Key Words: Minerals, Grazing, Goats

W165 Mineral content of forage selected by goats grazing an oak shrubland in north Mexico. M. A. Cerrillo-Soto*, G. Nevarez-Carrasco, R. Montoya-Escalante, and A. S. Juárez-Reyes, *Universidad Juárez del Estado de Durango, Dgo, Mexico*.

A study was conducted to estimate the mineral content of the diet selected by goats grazing an oak shrubland in the central region of Durango, Mexico. The study area is located at the $24^{\circ} 32'$ N and $104^{\circ} 28'$ W at 2340 m. The climate is semi-arid with a mean annual rainfall of 376 mm and temperature of 16° C. Six adult female Spanish criollo goats (35 ± 5 kg BW) were used to obtain samples according to the hand-plucked method. The samples were collected monthly for two days, morning and evening, for a period of twelve months. Mineral concentrations of Ca, Mg, K, Na, Cu, Mn, Fe, and Zn in monthly diets were determined using an atomic absorption spectrophotometer. Phosphorus concentrations were determined by colorimetry. Data were analyzed for a completely randomized design. Macro mineral concentrations of the forage selected by goats varied ($P < 0.05$) among months. Sodium content ranged from 0.17 to 0.33 g/kg with a mean of 0.23 g/kg. Dietary Ca ranged from 4.6 to 17.8 g/kg, with an annual mean of 12.7 g/kg. Phosphorus content ranged from 0.73 to 1.80 g/kg, and the mean was 1.1 g/kg. Annual mean concentration of Mg was 3.1 g/kg and the concentration varied from 1.8 to 4.7 g/kg. Potassium concentration in the forage selected by goats ranged from 8.2 to 16.7 g/kg, with a mean of 12.6 g/kg. Forage concentrations of trace minerals also varied ($P < 0.05$) among months except for Zn. Copper concentration ranged from 4.3 to 9.0 mg/kg (mean = 6.5 g/kg). Concentration of Mn ranged from 69.1 to 276.3 mg/kg (mean = 176.1 mg/kg). Concerning Fe, the concentration ranged from 29.9 to 136.2 mg/kg (mean = 65.8 mg/kg). Finally, Zn content did not differ among months ($P > 0.05$; mean = 59.9 g/kg). Data indicated that contents of Ca, K, and Mg in all months are adequate to meet the requirements of adult range goats for maintenance, pregnancy, and lactation. Moreover, Mn, Zn, and Fe contents also meet the requirements. However, Na, P, and Cu concentrations in the diet are below requirements. Thus, a supplementation schedule for these minerals should be implemented throughout the year to maintain productivity of goats.

Key Words: Minerals, Goats, Grazing

W166 Silymarin administration to transition dairy goats: effects on liver tissue and plasma metabolites. D. Tedesco^{*1}, S. Galletti¹, D. Olivero², M. Tameni¹, and S. Rossetti¹, ¹Department of Veterinary Sciences and Technologies for Food Safety, Milan, Italy, ²BiEsseA, Milan, Italy.

The fatty liver syndrome frequently develops in dairy cows in the transition period between late pregnancy and early lactation. Little is known about this condition in dairy goats. Silymarin, a standardized extract from seeds of *Silybum marianum* L. (Gaertn) (milk thistle), is used in human for the treatment of liver diseases of different aetiologies. The aim of the present study was to determine the silymarin effects on liver tissue and haematic parameters of lipid metabolism in transition dairy goats. A total of 24 dairy goats in their second pregnancy were divided into two groups according to body condition score (BCS), health condition, and previous milk production. From 5 d prior to the expected kidding date to 15 d postpartum, the treated goats received 10 mL/d of silymarin as a water suspension, administered as oral drenches. Blood samples were collected from the jugular vein at -5, 0, and 14 d from kidding. Non-esterified fatty acids (NEFA) and β -hydroxybutyrate (BHBA) concentrations in plasma were measured. Liver biopsies were performed 7 d after parturition and liver samples were immediately frozen at -196°C in liquid nitrogen. Samples were sectioned at 3 μ with a cryostat. The sections were then stained with haematoxylin-eosin and osmium tetroxide. This specific method indicates lipid accumulation. Plasma concentrations of NEFA and BHBA were unaffected by treatment. Histological examinations showed fat accumulation in livers of control goats. This accumulation is black stained with the special method used. No fat accumulation was observed in silymarin treated goats. We conclude that treatment with silymarin extract in the peripartum period completely prevented fat accumulation in dairy goats. Silymarin was kindly granted by Indena S.p.A.

Key Words: Silymarin, Dairy Goats, Liver Tissue

W167 Assay of antibiotic residues in goat milk. M. Bsharat* and R. Attaie, *Prairie View A&M University, TX.*

Ten milking goats, 5 Nubians and 5 Alpines, were randomly selected from the milking herd of the International Goat Research Center at Prairie View A&M University. The objective was to determine the residual amounts of tetracycline in the milk of treated goats. It was essential to determine the safe withdrawal period of tetracycline in goat milk using screening tests such as the Charm ROSA Tetracycline and the SNAP Tetracycline tests. The results of these screening tests were compared with a quantitative procedure that was developed for determination of tetracycline residues in milk using a HPLC technique. Milk samples containing antibiotic residues were deproteinized by HCl and acetonitrile and then extracted. The concentrated extracts were filtered before injection into reversed-phase HPLC using an isocratic procedure. For analysis, a Wakosil II C18 column was used with a mobile phase of 0.02 M H₃PO₄ and 0.01 M Na decansulfonate-acetonitrile (65+35) using UV detection at 380 nm. The Charm Rosa test was able to detect the residues up to 96 hours after administration of drug and then gave doubtful results. The SNAP Tetracycline test was able to detect the residues up to 110 hours after injection, showing higher sensitivity. However, the HPLC procedure determined the tetracycline residues in goat milk at levels less than the tolerance limit of 300 ppb after 72 hours of drug administration.

Key Words: Goat Milk, Antibiotic, Residues

W168 Evaluation of Mimosa (*Albizia julibrissin*) and Leucaena (*Leucaena leucocephala*) as feeds for goats. J. Q. Bing* and R. N. Corley III, *Tuskegee University, AL.*

A study was conducted to determine the potential of mimosa (*Albizia julibrissin*) and leucaena (*Leucaena leucocephala*) as feeds for goats. Mimosa and leucaena were harvested in Tuskegee, Alabama in the fall of 2003 and compared with alfalfa hay. Proximate analysis and measurements of NDF, ADF, Ca, K, and Mg were determined. Three non-lactating Nubian female goats fitted with permanent ruminal cannulas were used in a randomized complete block design to determine the kinetics of ruminal digestion. For alfalfa hay, mimosa, and leucaena, respectively, values for dry matter (92.65, 96.88, and 97.42%), crude protein (24.38, 13.31, and 17.81%), NDF (29.00, 53.00, and 36.00%), ADF (24.00, 37.00, and 29.00%), Ca (1.73, 0.62, and 0.80%), K (1.99,

0.85, and 1.20%), and Mg (0.30, 0.26, and 0.35%) were comparable. Ruminal digestion kinetics of alfalfa hay, mimosa, and leucaena, respectively, estimated that 34, 26, and 24% was soluble, 46, 55, and 29% was potentially degradable, 20, 19, and 47% was indigestible, and that the fractional rate of digestion was 0.10, 0.07 and 0.03h⁻¹. Alfalfa hay had a higher (P<0.05) soluble fraction than mimosa or leucaena, which did not differ (P>0.05) from each other. Mimosa had a larger (P<0.05) degradable fraction than alfalfa hay, which was more digestible (P<0.05) than leucaena. Mimosa and alfalfa hay, which did not differ (P>0.05), had lower (P<0.05) indigestible fractions than leucaena. Alfalfa hay had the highest (P<0.05) fractional rate of digestion, followed by mimosa, which was higher (P<0.05) than leucaena. As a whole, chemical composition and digestibility characteristics of mimosa appeared comparable to alfalfa hay, which shows its potential as a feed for goats. Further study is needed to determine the effects of mimosa on ruminal fermentation and animal performance.

Key Words: Leucaena (*Leucaena Leucocephala*), Mimosa (*Albizia Julibrissin*), Goats

W169 Evaluation of *Albizia julibrissin* (mimosa) for internal parasite control in goats. C. Hopkins-Shoemaker*¹, S. Solaiman², B. Blagburn¹, D. Bransby¹, and C. Kerth¹, ¹Auburn University, AL, ²Tuskegee University, AL.

Anecdotal information in the literature suggests that *Albizia julibrissin* (mimosa) may have anthelmintic properties, and parasite control is a major management concern in the southeastern U.S., especially for goats. This experiment was conducted to determine the effect of mimosa fed to goats, with experimentally induced *Haemonchus contortus* larvae, on parasite burden and selected blood parameters. Eighteen Boer cross goat kids (BW \pm 0.07 kg) were housed in individual pens and randomly assigned to two dietary treatments: 1) 90% fresh cut mimosa with 10% alfalfa hay (MA), as fed, and 2) a control treatment of 85% green chop soybeans with 15% of bermudagrass hay (SB), as fed. Dietary treatments were calculated to be isonitrogenous on a DM basis. Feed intake and refusals were monitored daily and feed offered was adjusted weekly for 4 wk. Body weight was recorded weekly after a 4 h withdrawal from water and feed. Fresh feces were collected from each goat weekly and fecal egg counts were conducted using a modified McMaster method. Blood samples were collected weekly, via the jugular vein, and were analyzed for pack cell volume and plasma protein. Dry matter intake was higher (P < 0.01) for animals fed MA (344 and 305 g/d, SE \pm 11, for MA and SB, respectively). Total egg count did not drop based on Kruskal-Wallis and Mann-Whitney tests during the 4 wk experimental period. Initial fecal egg counts were 5,522 \pm 2,317 and 4,555 \pm 1,385, and final egg counts were 8,878 \pm 3,155 and 8,800 \pm 1,234, for treatment groups MA and SB, respectively. Pack cell volume and plasma protein showed no difference (P > 0.10) between dietary treatments or over time. These results indicated that short-term treatment of goats with mimosa was not effective in eliminating or managing *Haemonchus contortus* under controlled feeding conditions. However, long term feeding of mimosa under field conditions may have benefits as a parasite management tool because it allows the animal to browse rather than graze.

Key Words: Mimosa, Parasites, Goat Kids

W170 The use of crawfish meal waste as a protein source for feeding goats. S. Gebrelul*, C. R. Walker, A. Harris, and A. Dantzler, *Southern University and A&M College, Baton Rouge, LA.*

The cost of feed, especially protein sources, represents the single greatest expense (65-80%) of livestock operations. One alternative protein source for goats is crawfish meal as a substitute for soybean meal. In Louisiana, approximately 15 million tons of crawfish are consumed annually. Only 15 percent of the crawfish is edible and the rest is waste. The purpose of this study was to evaluate the growth performance of weaned kids fed crawfish meal. In a completely randomized design, 20 kids were randomly assigned to four treatment groups. The first group served as a control and was fed a concentrate ration that contained 75% corn, 20% soybean meal, and 5% molasses. Fifty, 75, and 100 percent of the protein source (soybean meal) in the control ration was substituted by crawfish meal for the second, third, and fourth groups, respectively. After an adjustment period of two weeks, kids remained in the experiment for six weeks. Initial and final weights, weekly weights, and group

feed consumption were recorded. Data were analyzed by ANOVA where feeding treatment was fitted as main effect. The average weights at the end of the sixth week for the four groups were, respectively, 15.9, 16.2, 16.7, and 13.8 kg ($P > 0.05$). Feed consumption per week averaged 5.6, 3.5, 3.5, and 2.3 kg. Kids in the control and 50% substitution treatment groups grew faster (62.8 and 41.1 g/day, respectively; $P < 0.05$) than kids in the 75 and 100% substitution groups (17.3 and 8.7 g/day, respectively). From these preliminary data, soybean meal in goat rations can be substituted by crawfish meal up to 50 percent. More detailed studies with more animal numbers are needed to determine the effects of crawfish meal as a true protein substitute in goat rations as well as the quality and acceptability of carcasses produced from goats fed crawfish meal.

Key Words: Crawfish Meal, Goats, Soybean Meal

W171 Evaluation of three novel anthelmintics to control internal parasites in female Boer goats. R. Franco*¹, M. Worku¹, J. Miller², D. Libby¹, T. Hanner¹, and P. Matterson¹, ¹North Carolina Agricultural and Technical State University, Greensboro, ²Louisiana State University, Baton Rouge.

The effect of neem (*Azadirachta indica*), wormwood (*Artemisia absinthium*), and tobacco (*Nicotiana tabacum*)+copper sulfate (CuSO_4) or no treatment on packed cell volume (PCV), body weight (BW), fecal egg count (FEC), total white blood cell counts (TWBCC), and white blood cell differential counts (WBCDC) were studied in goats infected with internal parasites. Twenty female Boer goats weighing approximately 40 kg were randomly assigned to four treatments (5 animals each). Goats were drenched with 250 ml of a crude water extract adjusted for protein concentration. Differences were observed between BW of the control group (38.2 kg) and that of the tobacco+ CuSO_4 group (42.9 kg) ($P \leq 0.019$). The control group had a higher PCV (25.5%) compared to neem (21.7%), wormwood (19.4%), and tobacco+ CuSO_4 treatments (20.4%) ($P \leq 0.002$). TWBCC and FEC analysis showed no differences between any of the treatments ($P \leq 0.941$ and $P \leq 0.832$ respectively). Neem treatment significantly reduced the percentage of neutrophils compared to control and wormwood ($P \leq 0.017$). The lymphocyte count was lower for the wormwood treatment (41.2%) compared to the control (52.43%), neem (51.15%), and tobacco+ CuSO_4 treatments (49.35%) ($P \leq 0.012$). BW was positively correlated with monocyte counts ($r = 0.616$, $P \leq 0.0189$) only. PCV had a negative correlation with FEC ($r = -0.744$, $P \leq 0.0023$), TWBC ($r = -0.769$, $P \leq 0.0013$), and eosinophil counts ($r = -0.736$, $P \leq 0.0026$). High FEC, TWBCC, and eosinophil counts were observed when low PCV values were recorded. FEC correlated positively with eosinophil counts ($r = 0.575$, $P \leq 0.031$). TWBCC correlated positively with monocyte counts ($r = 0.581$, $P \leq 0.029$) and eosinophil counts ($r = 0.599$, $P \leq 0.023$). These correlations existed even though none of the variables were significantly different among treatments. Neutrophil and lymphocyte counts were negatively correlated ($r = -0.92$, $P \leq 0.0001$). A progressive decline in the percentage of neutrophils was observed following neem treatment.

Key Words: Anthelmintics, Goats, Neem

W172 Evaluation of diatomaceous earth as a component of goat production practices. C. Bernard*, M. Worku, P. Matterson, D. Libby, T. Hanner, and M. Ahmedna, North Carolina Agricultural and Technical State University, Greensboro.

Diatomaceous Earth (DE) is a natural insecticide that has been promoted as an alternative anthelmintic with potential production advantages. This study evaluated the effectiveness of DE in goat production. Twenty-two naturally infected South African Boer, Spanish, and Spanish/Boer crosses were grouped by weight and parasite burden. Animals were drenched with 150 mL of distilled water containing 3.54 (Group 1), 5.31 (Group 2), 1.77 (Group 3), or 0 g of DE (untreated control). Observations were made over 6 wk. Fecal egg counts (FEC) were conducted using the modified McMasters' technique. Packed cell volume (PCV) and white (WBC) and red blood cell (RBC) counts and weights were recorded. Data were analyzed using SAS. Highly significant differences ($P < 0.0001$) in PCV, FEC, and weekly WBC and RBC counts and weights were observed between treated and control groups. Group 1 had an increase in FEC during the experiment of 2,230 eggs/g (63%); Groups 2, 3, and 4 had increases of 1,852 (32%), 3,199 (64%), and 1,833 eggs/g (70.1%), respectively. Each group demonstrated significant increases in PCV during the experiment except for untreated controls

(Group 1: 25.2 to 28.0%; Group 2: 22.6 to 25.8%; Group 3: 21.4 to 22.5%; control: 27.9 to 24.5%). Group 2 produced the largest increase in PCV compared with the pretreatment level. Week of the experiment had a highly significant ($P < 0.0001$) effect on RBC and WBC counts. Each group exhibited increases in WBC and decreases in RBC counts over the course of the study. Change in BW during the experiment differed among treatments ($P < 0.0001$; -0.44, +0.30, -11.60, and -0.79 kg for Groups 1, 2, 3, and 4, respectively). In summary, an anthelmintic effect of DE was not observed; however, a dose dependent improvement in PCV was noted.

Key Words: Goat, Alternative Therapy, Production

W173 Effect of two levels of energy supplementation on forage intake, growth, and blood parameters in Boer and Kiko-sired crossbred kids. S. Wildeus¹, K. E. Turner*², and J. R. Collins¹, ¹Virginia State University, Petersburg, ²USDA, ARS, AFSRC, Beaver, WV.

Feed intake, growth, live grade, and blood metabolites were measured in 32 Boer (B) and Kiko (K)-sired intact male kids from Spanish (S) and Myotonic (M) dams, offered tall fescue (*Festuca arundinacea* Schreb.) hay (13.5% CP, 56.1% NDF, 37.9% ADF, 45.2% IVOMD) and supplemented with a corn (*Zea mays* L.)-based concentrate (16% CP) at either 2 or 3% BW. Kids were allocated to 6 pens (3 pens/supplement level) stratified by breed type and fed for 98 d. Total DMI by pen was lower for 2 than for 3% supplementation in the beginning of the trial (4.21 vs 3.55% BW), but decreased and was not different between groups in middle and end of the trial (treatment \times time on trial; $P < 0.01$). Forage DMI was greater ($P < 0.001$) for 2 than for 3% supplementation throughout the experiment (1.46 vs. 0.79% BW) and was reduced ($P < 0.001$) in both groups in the middle and end of the trial. ADG and final BW were lower ($P < 0.001$) at 2% (101 g/d; 25.0 kg) than 3% (137 g/d; 28.4 kg) supplementation, but not affected by sire or dam breed. Kids supplemented at 2% BW had higher ($P < 0.01$) blood concentrations (mg/dl) of urea nitrogen (21.3 vs 19.3) and lower ($P < 0.001$) glucose (63.1 vs 72.1) compared to those supplemented at 3% BW; creatinine was similar. Supplement level had no effect on live grade, but B-sired kids scored higher ($P < 0.05$) than K-sired kids, and kids from M scored higher ($P < 0.05$) than kids from S. B-sired kids had higher ($P < 0.001$) blood concentrations of urea nitrogen (21.7 vs 19) and creatinine (0.63 vs 0.57) and lower ($P < 0.01$) glucose (65.9 vs 69.2) compared to K-sired kids. Kids from M dams had higher ($P < 0.05$) blood creatinine levels than kids from S dams. Data suggest that sire breed impacted live grade and blood metabolites. Animals receiving the 3% level of supplementation grew faster, but incomplete consumption towards the end of the trial would suggest that a maximum level of energy supplementation for finishing goats was between 2 and 3% BW.

Key Words: Crossbred Goats, Forage Intake, Growth

W174 Effects of the number of yearling Boer crossbred wethers per automated feeding system on feed intake, feeding behavior, and growth performance. A. L. Goetsch*, T. A. Gipson, G. Detweiler, R. C. Merkel, and T. Sahl, *E (Kika) de la Garza American Institute for Goat Research, Langston University, Langston, OK.*

Thirty-six growing Boer \times Spanish wethers (initial BW = 30 ± 0.7 kg) were used in an 82-d experiment to determine effects of the number of animals per automated feeding system (NPF; 6, 8, 10, and 12), allowing consumption by only one animal at a given time, on intake of a pelleted 50% concentrate diet (60% TDN, DM basis), feeding behavior, and growth performance. During the entire experiment DMI (1436, 1506, 1506, and 1312 g/d), ADG (156, 167, 181, and 136 g/d), and ADG:DMI (108, 111, 120, and 103 g/kg for 6, 8, 10, and 12 NPF, respectively) were affected by NPF quadratically ($P < 0.05$, 0.05, and 0.06, respectively). The number of feeder visits (17.5, 17.2, 18.0, and 18.6) was similar among NPF, although feeder occupancy per day (97.8, 73.0, 83.3, and 70.7 min) and visit (5.69, 4.34, 4.84, and 3.79 min for 6, 8, 10, and 12 NPF, respectively) decreased linearly with increasing NPF ($P < 0.05$). The rate of DM consumption relative to feeder occupancy time tended to increase linearly ($P < 0.08$) with increasing NPF because of a relatively low value for 6 NPF (14.9, 21.2, 18.9, and 21.1 g/min for 6, 8, 10, and 12 NPF, respectively). In summary, 8 and 10 growing Boer crossbred wethers per automated feeder, allowing consumption of a 50% concentrate diet by one wether at a given time, resulted in growth

performance greater than for 12 wethers, apparently due to limited feed intake by 12 wethers. Also, performance with 6 wethers per feeder was slightly less than with 8 or 10, which may have involved factors such as limited feed intake resulting from conditions other than inadequate feeder availability.

Key Words: Goats, Feed Intake, Growth

W175 Influence of progesterone on synchronization and pregnancy rate of Alpine does. M. L. Looper^{*1}, R. C. Merkel², E. R. Loetz², A. L. Goetsch², L. J. Dawson³, J. M. Burke¹, and R. Flores⁴, ¹USDA-ARS, Dale Bumpers Small Farms Research Center, Booneville, AR, ²E (Kika) de la Garza American Institute for Goat Research, Langston University, OK, ³College of Veterinary Medicine, Oklahoma State University, Stillwater, ⁴University of Arkansas, Fayetteville, AR.

Forty-one non-lactating Alpine does were used in December to evaluate the effects of progesterone on synchronization and pregnancy rate. Body weight and condition score (1 to 5; 1 = extremely thin) averaged 49.1 ± 1.2 kg and 2.85 ± 0.05, respectively. Prior to the experiment, visual observation detected 95% of does exhibiting behavioral estrus. Does were blocked by age (mean age = 3.2 ± 0.3 y) and assigned to receive progesterone (P4) via an intravaginal insert (CIDR) for 12 d (n = 24) or no P4 (n = 17). Does with a CIDR were administered prostaglandin F2_α 15 h prior to CIDR removal. All does were fitted with a HeatWatch (HW) transmitter to record estrous activity and exposed to intact or epididymectomized bucks (1 buck/5 does) with marking harnesses. Does were observed twice daily (0700 and 1700; 20 min/observation) to confirm behavioral estrus. Ultrasonography was performed to determine pregnancy (mean = 56.6 ± 1.9 d post-breeding). Visual observation verified that 50% of does exhibited behavioral estrus within 24 h after CIDR removal, and 93% of does within 48 h. HeatWatch detected 50% of estruses identified by visual observation. Pregnancy rate was not different (P = 0.46) in does receiving P4 (41%) or no P4 (53%). A majority (93%) of does exposed to progesterone via a CIDR for 12 d exhibited estrus within 48 h post-CIDR removal. Furthermore, visual observation was more accurate at detecting does in estrus than HW. Pregnancy rates were not influenced by progesterone exposure.

Key Words: Goats, Progesterone, Synchronization

W176 Effect of breed and litter size on yields of milk, milk fat, and milk protein in Boer x Spanish and Spanish does. B. Tamir, R. C. Merkel^{*}, T. A. Gipson, and A. L. Goetsch, E (Kika) de la Garza American Institute for Goat Research, Langston University, OK.

Forty-four pregnant does (22 Boer x Spanish (BS), 3 to 4 yr of age; 22 Spanish (SP), 3 to 5 yr of age) were used to evaluate effects of breed and litter size on total milk yield and yields of fat and protein. All does were housed in one pasture and had unlimited access to prairie hay (1.1% N, 66.5% NDF, 63% IVDMD), water, and trace mineralized salt. Seventeen does (9 BS and 8 SP) had single kid (SK) litters and the remaining 27 does (13 BS and 14 SP) had litters of two or three kids (MK). Prior to milking, does and kids were separated at 1600 and weighed. Milking occurred at 0900 the following morning, after which kids were reunited with does. Does were milked once every 2 wk through wk 12 of lactation in a 10-stanchion, automated milking parlor (WestfaliaSurge Inc., Naperville, IL) with an automatic milk sampler. Oxytocin (0.5 ml) was administered 5 min prior to milking to stimulate milk letdown. Milk samples were placed in vials with a preservative and analyzed for fat and protein using a DairyLab II milk analyzer (Mulitspec Ltd., Wheldrake, York, England). Individual total milk, fat, and protein yields were calculated from test day data using Shook adjustment factors. Data were then analyzed using analysis of variance with genotype, litter size, and the two-way interaction as independent variables. Total milk (50.1 vs 37.9 kg; SE = 4.2) and milk protein yields (1.7 vs 1.2 kg; SE = 0.16) were greater for BS vs SP (P < 0.06). In addition, total milk (49.1 vs 38.9 kg; SE = 3.65) and milk protein yields (1.7 vs 1.2 kg; SE = 0.14) were greater (P < 0.07) for MK than for SK does. No differences were seen in ADG of BS vs SP kids (73 and 65 g/d for B and BS, respectively; SE = 5.8) or between female and male kids. Kids of SK does had ADG greater than of MK (86.0 vs 52.5 g/d SE 4.4). Litter growth was similar between BS and SP does. In conclusion, BS does produced more milk

than did SP does, although this was not accompanied by greater kid ADG.

Key Words: Goats, Milk Yield, Breed

W177 Evaluation of predictions of body weight and feed intake by growing crossbred Boer goats with a goat simulation model. M. Villalquiran^{*1}, L. C. Nuty², T. A. Gipson¹, A. L. Goetsch¹, and H. D. Blackburn³, ¹E (Kika) de la Garza American Institute for Goat Research, Langston University, OK, ²Cooperative Agricultural Research Center, Prairie View A&M University, Prairie View, TX, ³USDA/ARS/NPA/NSSL/NAGP, Fort Collins, CO.

The Texas A&M Goat Simulation Model, with modifications such as of maintenance energy requirements, is being used in a collaborative project involving institutions primarily in the southern US. However, the model was developed before Boer goats and their crossbreds became prevalent in the US. Therefore, this study was conducted to evaluate model predictions of BW and cumulative feed intake (air-dry; FI) of growing crossbred Boer goats. Data for model evaluation were derived from Prairie View A&M University. There were four genotypes of wethers: Boer x Nubian (n = 10, age = 131.8 to 245.8 d, and BW = 32.14 to 48.27 kg), Spanish x Boer (n = 8, age = 111.4 to 231.4 d, and BW = 13.73 to 38.27 kg), Boer x Alpine (n = 10, age = 132.4 to 245.4 kg, and BW = 21.86 to 41.77 kg), and Boer x Nubian x Myotonic (n = 10, age = 115.0 to 235.1 d, and BW = 24.00 to 43.05 kg). Diet composition was 16% CP and 75% TDN (air-dry basis). Body weight and FI were determined at four times within the growing periods. Model evaluation with pooled data was conducted by regressing observed means of BW (BWO) and FI (FIO) against predicted values (BWP and FIP, respectively). The equation for BW was BWO = 3.73 (SE = 3.489) + (0.935 (SE = 0.0970) x BWP) (R² = 0.86), and that for FI was FIO = -6.84 (SE = 8.062) + (1.012 (SE = 0.0665) x FIP) (R² = 0.94). In conclusion, the model explained considerable variation in BW and FI of growing crossbred Boer goats and provided unbiased predictions. Increased prediction accuracy should result from improved inputs, such as mature BW.

Key Words: Goats, Simulation Model

W178 Goats for vegetation management: animal performance and carrying capacity. S. Hart^{*}, J. Joseph, and A. Goetsch, E (Kika) de la Garza American Institute for Goat Research, Langston University, Langston, OK.

The objective of this study was to measure factors that affect carrying capacity and animal performance of goats grazing diverse range sites to develop recommendations for stocking rates and expected animal performance. This study was the first year of a larger study on the use of goats for vegetation management, which was conducted in collaboration with six Native American Nations in Oklahoma with a variety of vegetation and range site capabilities. Yearling goats were taken to each site in May-June and weighed every 1 to 2 months. There were at least two pastures at each site. Animals were removed when forage availability became limiting, usually late summer or fall. Goats were heavily stocked to provide maximum vegetation control. Doeling and wether Alpine, Angora, Spanish, and Boer x Spanish cross goats were used. Average daily gain varied with site (P < 0.001), month of the grazing (P < 0.001), breed (P < 0.001), and sex (P < 0.001). Wethers gained more than does (3.3 vs -4.1 g/d). Alpine and Angora goats gained less weight than meat breeds and crossbreds. Goats gained the most weight the first grazing period and less weight subsequently as forage availability was reduced (12.7 vs -9.3 vs -13.6 g/d). Gain per hectare was not influenced by site or stocking rate (P > 0.10), whereas grazing days/ha were different (P < 0.001) for the different sites (P < 0.001; range 237-1,109 d) due to different forage productivities. Gain/ha had little relationship to stocking rate (P > 0.30), a consequence of grazing to remove all available herbage. Total gain for the season was most affected by site (P < 0.001), sex (P < 0.001), and breed (P < 0.001). When goats are grazed at a high stocking density to control vegetation, forage productivity is the greatest factor in determining carrying capacity and animal production although sex and breed can have effect.

Key Words: Goats, Vegetation Management, Stocking Rate

W179 Effects of feed restriction on heat production by mature meat goats. I. Tovar-Luna*, A. L. Goetsch, R. Puchala, and T. Sahu, *E (Kika) de la Garza American Institute for Goat Research, Langston University, OK.*

Fourteen Boer (75%) x Spanish wether goats (51 ± 1.8 kg BW and 23 mo of age) were used to determine effects of a moderate degree of nutrient restriction on heat production (HP). The experiment consisted of a 26-d period (P1) followed by one of 46 d (P2). Wethers were fasted on the final 4 d of each period, with gas exchange measured on the last 2 d. Fasting was preceded by collection of feces and urine for 7 d, with the final 2 d for gas exchange. All wethers were fed a 60% concentrate diet at a level of intake near maintenance in P1 (P1-100 and P1-80 treatments). In P2, six wethers continued on this level of intake (P2-100 treatment); to mimic procedures in a separate experiment, eight wethers also continued at this level for 15 d but then had ME intake sequentially reduced by 10 and 20% for 10 and 21 d, respectively (P2-80 treatment). Dietary ME concentration in period 2 was greater ($P < 0.05$) for 80 than for 100 treatments (13.2 vs 12.4 MJ/kg DM). Intake of ME was lowest ($P < 0.05$) for P2-80 (529, 535, 552 and 474 kJ/kg BW^{0.75} (fasted) for P1-100, P1-80, P2-100, and P2-80, respectively). Fed HP was lowest ($P < 0.05$) for P2-80 (495, 505, 467, and 406 kJ/kg BW^{0.75}), whereas that while fasting was similar among treatments (287, 279, 273, and 253 kJ/kg BW^{0.75} for P1-100, P1-80, P2-100, and P2-80, respectively). The ME requirement for maintenance (ME_m) was greater ($P < 0.05$) in P1 than P2 (477, 487, 421, and 376 kJ/kg BW^{0.75}), and when analyzed for P2 separately ME_m was lower ($P < 0.10$; 374 vs 425 kJ/kg BW^{0.75}) and the efficiency of ME use for maintenance was greater ($P < 0.08$) for P2-80 than for P2-100 (0.689 vs 0.625). In conclusion, moderate feed intake restriction impacted HP by mature meat goats largely via decreasing that associated with or responsive to nutrient intake or workload rather than physiological processes responsible for fasting HP, with a magnitude of change in ME_m 65% of that in ME intake. Supported by USDA Project No. 00-38814-9500.

Key Words: Goats, Energy, Feed Intake

W180 Effects of length of pasture access on energy use by growing meat goats. T. Berhan, R. Puchala*, R. C. Merkel, T. A. Gipson, G. Animut, A. L. Goetsch, and T. Sahu, *E (Kika) de la Garza American Institute for Goat Research, Langston University, OK.*

Six Boer x Spanish wethers (21 ± 1.0 kg BW) were used in two simultaneous 3 x 3 Latin squares to determine effects of different lengths of access to pasture with high availability of cool-season annual forage on energy expenditure (EE), retained energy (RE), ME intake, and grazing behavior. Wethers grazed a 0.7-ha pasture of wheat and rye in the fall/winter period for 4 (1200 to 1600), 8 (0800 to 1600), or 24 h; 4- and 8-h wethers were barn confined at other times. Periods were at least 18 d in length, with 4 d for total feces collection with bags, 2 d to measure heart rate (HR) and grazing behavior, and 1 d without feed or water for assessing body composition from urea space. EE was based on HR and the predetermined relationship between EE and HR for each wether, and ME intake was the sum of EE and RE. Available forage mass averaged 2,831, 2,176, and 2,443 kg/ha in period 1, 2, and 3, respectively. EE was greatest ($P < 0.05$) for 24 h (4.96, 5.13, and 6.19 MJ/d for 4, 8, and 24 h, respectively), although RE was similar among treatments (0.88, 2.16, and 1.57 MJ/d for 4, 8, and 24 h, respectively; SE = 0.361). Intake of ME was greater for 8 and 24 h vs 4 (5.84, 7.30, and 7.76 MJ/d for 4, 8, and 24 h, respectively). Gain of fat (15.7, 50.3, and 33.7 g/d for 4, 8, and 24 h, respectively; SE = 9.80) was responsible for numerically

greatest RE for 8 h, with similar gain of water, protein, and ash. As length of pasture access increased, number of steps (2,508, 4,569, and 6,412), time spent ruminating (4.42, 6.33, and 7.28 h), and time eating (3.77, 6.35, and 7.24 h for 4, 8, and 24 h, respectively) increased ($P < 0.05$). In summary, even though 4-h pasture access limited ME intake and eating time, EE was similar to that for 8 h. Full-day pasture access resulted in greater EE than for 8 h presumably because of differences in behaviors such as eating time and number of steps, yet ME intake was not different. In conclusion, these results suggest that with high availability of high-quality forage, limited pasture access of a minimal length could yield performance by growing meat goats at least comparable to that with continuous access. Supported by USDA Project No. 00-38814-9500.

Key Words: Goats, Grazing, Energy

W181 Effects of pasture inclusion of mimosa on growth by co-grazing goats and sheep. G. Animut*^{1,2}, A. L. Goetsch¹, G. E. Aiken³, R. Puchala¹, G. Detweiler¹, C. R. Krehbiel², R. C. Merkel¹, T. Sahu¹, L. J. Dawson⁴, and Z. B. Johnson⁵, ¹*E (Kika) de la Garza American Institute for Goat Research, Langston University, OK*, ²*Animal Science Department, Oklahoma State University, Stillwater*, ³*USDA ARS Dale Bumpers Small Farms Research Center, Booneville, AR*, ⁴*College of Veterinary Medicine, Oklahoma State University, Stillwater*, ⁵*Department of Animal Science, University of Arkansas, Fayetteville.*

Effects of mimosa alley-cropped in grass/forb pastures on growth performance of co-grazing sheep and goat wethers were determined. Three sheep (Khatadin) and three goats (#8805 75% Boer), with initial BW of 22 ± 1.3 and 21 ± 0.7 kg, respectively, and age of 4 to 5 mo, grazed 0.4-ha pastures of grasses such as bermudagrass and johnsongrass and forbs (e.g., ragweed) for 16 wk. Three pastures with mimosa (3.1 m between rows and 0.46-m interval) and three without (W and WO, respectively) were divided into four paddocks for 2-wk rotational grazing. The number of mimosa trees per pasture averaged 928 and 904 at the beginning and end of the experiment, respectively. Daily mimosa leaf DM removal averaged 25.5 g per animal, although harvest was complete before the end of 2-wk grazing periods. Mimosa leaf samples averaged 2.81, 37.8, and 85.9% N, NDF, and IVDMD (true), respectively. Available forage (grass and forbs) mass was similar ($P > 0.05$) between treatments before (2,928 and 2,695 kg/ha; SE = 183.4) and after grazing (1,507 and 1,452 kg/ha for WO and W, respectively; SE = 140.4). Percentage of grass in forage determined by transect pre- (57.5 and 69.9%; SE = 8.34) and post-grazing (66.3 and 78.8% for WO and W, respectively; SE = 8.09) was not affected by treatment ($P > 0.05$). Pre-grazed forage concentrations of N (1.25 and 1.24%), NDF (64.5 and 63.8%), and IVDMD (52.9 and 56.2% for WO and W, respectively) were similar ($P > 0.05$) between treatments, as was also true post-grazing (N: 1.05 and 0.96%; NDF: 66.3 and 69.4%; and IVDMD: 49.0 and 48.0% for WO and W, respectively). ADG in the first (125 and 119 g/d; SE = 13.0), second (87 and 108; SE = 26.9), third (16 and 44 g/d; SE = 14.6), and fourth 4-wk period (-23 and 0; SE = 27.6) and in wk 1-16 (51 and 68 g/d for WO and W, respectively; SE = 8.6) was similar ($P > 0.05$) between WO and W. In summary, mimosa increased high-quality herbage available for grazing (mimosa leaf) but did not significantly influence growth performance of co-grazing sheep or goats, perhaps because of decreasing availability as 2-wk grazing periods advanced and/or relatively low intake of mimosa leaf. Supported by USDA Project No. 00-38814-9502.

Animal Behavior & Well Being

W182 A computerized system for monitoring feeding behavior and individual feed intake of dairy cattle in loose-house conditions. A. Bach*^{1,2}, C. Iglesias², and I. Busto³, ¹*ICREA, Barcelona, Spain*, ²*IRTA-Unitat de Remugants, Barcelona, Spain*, ³*Diputació de Girona, Semega, Girona, Spain.*

The objective of this study was to develop and validate a computerized system to monitor feeding behavior and feed intake of loose-housed dairy cattle. The system consisted of 28 scales located in front of each self-locking place of a regular feed bunk. All cows had access to all scales indifferently. Each visit to the feed bunk was monitored by a transponder in the ear of each cow that was detected by a proximity

reader located at the top right corner of each head-lock. The data from the scales and the proximity readers were continuously recorded by a computer with an average scanning time of 3.5 s. The monitoring system was validated using all 28 feeding places and 51 lactating cows in a series of 5-h observations during 5 different days. During the observation periods two observers recorded the cow number and the exact time of the visit to each scale. The observed data were then compared with the computer records. To validate weight monitorization, on separate days the amount of feed consumed by a cow during a visit was also measured manually with an external scale. The average time spent in a given scale by each cow determined by direct observations was similar

(7 s difference; $P=0.60$) to that determined by the computer. This small difference supports the application of the computerized system to study feeding behavior. Furthermore, the system was accurate and showed a specificity of 98.8% and a sensitivity of 99.6% for cow detections. Feed weights determined by the computer system were similar ($P=0.54$) to those measured manually with an external scale (144 g difference). This implies that the system was also accurate in measuring individual intake weights. In conclusion, the system allows for studying the number of visits per animal, length of each visit, amount of feed consumed per visit and animal, the total amount of feed consumed daily by each animal, and the rate at which animals consume feed.

Key Words: Feeding Behavior, Dairy Cow, Monitorization

W183 A comparison of three animal welfare assessment programs on California dairies. C. L. Stull¹, B. A. Reed^{*2}, and S. L. Berry¹, ¹University of California Cooperative Extension, Davis, ²University of California Cooperative Extension, Orland.

Due to increasing awareness of animal welfare issues by consumers, three voluntary programs have been developed to assess animal welfare on commercial dairies in the US. These programs include Humane Farm Animal Care (HFAC) with minimum standards and a third party audit system, the Dairy Quality Assurance Center and the University of California, Davis (UCD) programs with self-assessments. All three of the welfare assessment programs cover similar topics such as nutrition, housing, handling, and health. However some recommendations and standards vary between the programs. The objective of this study was to compare the three animal welfare assessment programs on commercial California dairies by using a questionnaire, combining specific criteria from each program. The survey was administered to 10 commercial dairies located in the central valley of California. The survey combined 316 statements from DQAC checklist, the UCD assessment, and the HFAC standards. The mean percent (\pm s.d) compliance for the DQAC, HFAC, and UCD programs is 83 ± 8 , 94 ± 3 and $85 \pm 6\%$, respectively. A ranking order from 1 to 10 was assigned to each dairy using the compliance score for the individual assessment program. The comparison between programs of rank order by Spearman correlation statistical analysis was not significant in any comparison indicating that different indices were being measured by each program. The results of this survey indicate that selection of the available assessment programs for animal welfare on the dairy is important in determining the outcomes. A compliance score range for each program should be defined that is considered acceptable to retailers and will assure consumer confidence in dairy food products.

Key Words: Animal Welfare, Dairy Cow, Auditing

W184 Effects of feed barrier design on feeding and social behavior of loose housed dairy cows. M. I. Endres^{*1}, M. A. G. von Keyserlingk², T. J. DeVries², and D. M. Weary², ¹University of Minnesota, St Paul, ²The University of British Columbia, Vancouver, Canada.

The objective of this study was to evaluate the effects of two feed barrier systems on feeding and social behavior of dairy cows. Forty-eight lactating Holstein cows were housed in four pens each with 12 sand-bedded stalls in a free stall barn. Cows were randomly assigned to one of two starting conditions: access to the feed alley via a neck rail or via headlocks in a completely randomized block design repeated over time. Cows were kept on one of the two conditions for 8 d, then switched to the alternative treatment for another 8 d. Feeding behavior was assessed using presence at the feed bunk, scored with scan sampling at 10-minute intervals from 24-h video. These scans were also used to estimate the percentage of cows feeding during the 90-min period following the delivery of fresh feed. Aggressive displacements from the feed bunk were scored continuously from video during these same 90-min periods. Average daily feeding time did not differ ($P > 0.2$) when cows had access to feed via headlocks (271.7 ± 3.8 min per day) compared to the post and rail barrier (277.8 ± 3.8 min per day). There tended ($P = 0.06$) to be a greater percentage of cows present at the feed alley during the 90-min morning period when using the post and rail barrier ($57.0 \pm 1.5\%$) compared with the headlocks ($50.8 \pm 1.5\%$), but there was no evidence of a difference ($P > 0.2$) during the afternoon feeding. There was also no difference ($P > 0.1$) in the number of displacements performed during the 90 min after feeding when the cows had access to the feed via headlocks versus post and rail barrier (0.71 ± 0.14 and 1.10 ± 0.14

displacements per cow per day, respectively). Although the post and rail barrier may allow for greater access to feed during high use periods, these results indicate that the type of feed barrier has no effect on daily feeding times and incidence of aggressive behavior at the feed bunk.

Key Words: Feed Barrier, Feeding Behavior, Dairy Cow

W185 The effect of feed intake levels on behaviors of transition dairy cows. K. J. Daniels*, J. R. Townsend, S. S. Donkin, E. A. Pajor, A. G. Fahey, and M. M. Schutz, Purdue University, West Lafayette, IN.

Our objective was to characterize feeding behaviors of transition cows fed for different intake levels. Thirty Holstein cows were blocked by expected calving date and randomly assigned to treatments. Control cows (CC) were provided feed for ad libitum intake; restricted cows (RC) were fed to 75% of estimated intake; and stuffed cows (SC) were forced through rumen cannulas to 100% of estimated intake. Cows were housed in tiestalls from 28d prior to expected calving and treatments imposed from 15d prior to expected calving through the day of calving. All cows were fed for ad libitum intake post-calving. Cows were video-taped 24 h/d, using time-lapse video recording, during treatments and until 14d after calving. On d -15, -6, -2, 2, 8 and 13 relative to actual calving, durations of standing (S), lying (L), feeding (F), ruminating (R), feeding while standing (FS), ruminating while standing (RS) and ruminating while lying (RL) behaviors were measured. Treatment affected FS (3.40 h for CC, 2.64 h for RC, and 2.98 h for SC; $P<.01$) and F (3.48 for CC, 2.83 h for RC, and 3.05 h for SC; $P<.01$). Treatment by d affected RS ($P<.05$). As cows approached calving, RS was maintained for RC, but increased for CC and SC. Time spent RS decreased dramatically for SC, was maintained for RC, and increased for CC immediately after calving. Differences among treatments after d 2 were not significant. Day affected all treatments for S, FS, L, RL, F, and R ($P<.01$). Time spent S, FS and RS increased prior to calving, decreased immediately after calving and returned to baseline at d 13. Time spent L decreased over the entire time period for all treatments. Duration of R dropped through d 2 then steadily increased for all treatments. Restricting intake levels prior to calving reduced feeding duration, but it also slowed increases in time spent RS compared to CC after calving. Force feeding cows encouraged RS, but RS dropped after calving when force feeding was ended. Restricting intake levels leads to reduced time spent feeding and ruminating while standing after calving.

Key Words: Dairy Cattle, Behavior, Transition

W186 Suckling latency in neonatal Holstein calves. H. E. Carpenter*, J. S. Birney, and K. A. Koudele, Andrews University, Berrien Springs, MI.

Neonatal suckling behavior is critical for calf survival. The objective of this study was to determine if the latency of neonatal calf suckling behavior was correlated with the percentage of inbreeding, calf birth weight, calf gender, difficulty of birth (dystocia), or dams Johnes status. Holstein calves ($n=372$) were evaluated for suckling response when first offered a bottle of warm colostrum. The latency score was on a scale of 1-5: 1=started nursing within one minute, 2=started nursing within 5 minutes, 3=offered bottle again at next regular feeding time and started nursing within one minute, 4= started nursing within 5 minutes, 5= needed to be oro-gastric tube fed at next feeding. Dystocia level was scored 1-4: 1=no assistance, 2=minor assistance, 3=mechanical pull, 4=hard mechanical extraction. The dams Johnes status was either negative or positive. There were 286 calves with a latency score of 1 (77%). There were 86 calves with scores of 2-5 (2=8.6%, 3=10.0%, 4=1.9%, 5=2.7%). No significant difference was found among the groups for birth weight, gender, dystocia score, or dams Johnes status. There was a significant difference between the percentage of inbreeding and latency of suckling score for group 1 vs groups 2-5 ($p=.004$). Calves with the score of 1 had an average inbreeding of 4.8%. Those with a score of 2 or greater had an average inbreeding of 5.4%. Inbreeding percentages were calculated from the Holstein Associations Inbreeding Calculator. The Holstein breed average is 4.5%. The slow-to-nurse calves require more time and effort from the calf feeding staff increasing dairy labor costs. The increased suckling latency of neonatal calves may be an unintended consequence of selection for increased milk production over the past 50 years. The percentage of inbreeding is also of concern not only on how it affects suckling in the neonate but also on other aspects of

cow productivity such as disease resistance, reproductive parameters, and longevity.

Key Words: Calf Suckling Behavior, Inbreeding

W187 Subsequent effects of an environmental enrichment in the early fattening stage of beef cattle on their behavior, physiology and productivity. T. Ishiwata*¹, K. Uetake¹, N. Abe², Y. Eguchi¹, and T. Tanaka¹, ¹*School of Veterinary Medicine, Azabu University, Sagami-hara, Japan*, ²*Faculty of Agriculture, Tamagawa University, Machida, Japan*.

We have reported the effects of an environmental enrichment with a drum can in the early fattening stage of beef cattle (*J. Anim. Sci.* 81 (Suppl. 1), 2003). The subsequent effects of the enrichment in the middle and finishing stage were investigated. Seventy-one Japanese Black × Holstein steers were allocated, in two repetitive experiments, to 3 pens (6.0×9.5 m each): Pen C (control, n=11 and 12) that consisted of a feeding alley for grain feed, a trough for dry hay, a water bowl and resting space; Pen D (n=12 and 12) that a drum can (Φ58×H 90 cm) that contained hay was added to the control pen; Pen GD (n=12 and 12) that a drum can that was put around an artificial turf (30×120 cm) for grooming was added. The drum cans were removed after 5 mo. Behavioral observations were made for 2 h at 10 min intervals after morning and evening feedings for 3 d at 0, 1, 3 and 5 mo after their removal. Jugular vein blood samples were collected and body weight recorded at 1, 3 and 5 mo after their removal. ANOVA, a post-hoc test and a correlation analysis were performed. Although the drum cans had encouraged hay eating during their installation, the number of eating became smallest in Pen GD (P<0.05) after their removal. The number of investigating bars became larger in Pen GD than in Pen C, in which more steers had licked bars (P<0.05). The number of stand-resting became largest in Pen GD, in which steers had been more active (P<0.05). Serum total cholesterol concentrations became higher in Pen D and GD than in Pen C after the removal of the drum cans (P<0.05). Beef belly was thicker in Pen D and GD than in Pen C (P<0.01). In Pen GD, the number of eating from the drum can ($r_s=0.79$, P<0.01) and grooming with it ($r_s=0.63$, P<0.05) correlated with beef marbling. Drum cans installed in the early fattening stage sustained positive effects even after their removal and improved the final productivity of beef cattle.

Key Words: Beef Cattle, Environmental Enrichment, Behavior

W188 Effect of increasing sodium bicarbonate proportion in high concentrate diets on performance, intake, water consumption and feeding behavior in finishing beef heifers. L. González*, A. Ferret, S. Calsamiglia, and X. Manteca, *Universitat Autònoma de Barcelona, Spain*.

Four rumen fistulated Holstein heifers (264 ± 12 kg initial BW) were used in a 4 × 4 Latin square design to determine the effect of increasing levels of sodium bicarbonate (0, 1, 2 and 4 %, on DM basis) on performance, intake, water consumption and feeding behavior. Heifers were allowed to consume concentrate and barley straw on an ad libitum basis, which resulted in a mean forage to concentrate ratio of 12 to 88. Behavior was measured by using scan sampling at 5 minute intervals. Linear, quadratic and cubic effects were analyzed with the Type 1 analysis of variance of the PROC MIXED procedure of SAS with animal and period considered random effects. There was a linear decrease in concentrate DMI (P < 0.05) and a linear increase in straw DMI (P < 0.01) with increasing buffer proportion in the diet, resulting in a linear decrease (P < 0.10) in total DM intake. Protein intake had a linear decrease (P < 0.05) with increasing buffer proportion, but there was no effect on NDF intake. Average daily gain decreased linearly (P < 0.05) with increasing buffer proportion in the diet, from 1.46 to 0.52 kg/d. When water intake was expressed as L/d or % BW, no effects were found, but it increased linearly when expressed as L/kg DM intake (P < 0.05). Moreover percentage of total daily water drunk in the morning (from 0830 to 1230) increased linearly (P < 0.05) with increasing buffer in the diet. Buffer concentration did not affect feeding behavior. Animals spent 19.4 ± 1.25, 8.9 ± 0.42, 2.5 ± 0.16 and 55.5 ± 1.85 percent of the time ruminating, eating, drinking and resting, respectively. The lack of effect on time spent ruminating with a linear increase in straw intake could be due to a reduced concentrate intake. Results indicate that overdosing

sodium bicarbonate to finishing heifers fed high concentrate diets may result in a decreased DM intake and animal performance.

W189 Can sheep learn to minimize the length of their foraging path? A. J. Rook* and J. E. Cook, *Institute of Grassland and Environmental Research, North Wyke, Okehampton, Devon, UK*.

Sheep exploit spatially heterogeneous food resources by selective foraging at preferred patches. But can they minimise the distance traveled to exploit a given set of patches? We laid out a 10 × 10 grid of bowls at 4m spacing in a bare earth arena, filling each of 10, 20, 30, 40 or 50 bowls with 25g concentrate feed (patches). We used a different dry ewe and different random patch positions for each of 3 replicates of each treatment. Each ewe foraged in the arena for 20 min on each of 5 successive days. We recorded the distance the ewe travelled before finding 5 patches and compared this with the shortest possible distance and with the expectation from a random walk. The distance to 5 patches on day 5 was 0.37 that on day 1 for the 10 patch treatment but only 0.67 for the 50 patch treatment. For the 10 patch treatment the distance on day 1 was 4.59 times the shortest possible path but only 1.78 times by day 5. Values for the 50 patch treatment were 2.11 and 1.38. Even on day 1 distance travelled was significantly (P<0.001) shorter than for a random walk as when leaving any bowl (full or empty), ewes continued in the same direction as they had approached it on 64% of occasions. In conclusion after 5 days of learning ewes were close to minimising the distance travelled to find 5 patches. Learning was more marked when the resource was more scarcely distributed. The path taken was always shorter than a random walk.

W190 We have ways of getting you to.... behave! J. K. Haskell* and F. D. Provenza, *Department of Forestry, Range and Wildlife, Utah State University, Logan, UT*.

Our goal is to increase the use of knowledge of behavior to better reconcile ecological, economic, and social facets of management by conducting outreach, education, and research activities that will: (1) improve economic viability and ecological integrity of pasture- and range-based enterprises, (2) enhance and maintain biodiversity of rangelands, (3) restore pastures and rangelands dominated by weeds, (4) optimize wildlife benefits to land owners, managers, and users, (5) mitigate livestock abuse of riparian areas, (6) improve our ability to manage complex adaptive systems. Behavioral principles and practices, once mastered, provide an array of solutions to the problems people face in managing and improving the integrity of the land. Unlike the infrastructure of a ranch such as corrals, fences, and water development, behavioral solutions cost very little to implement and they are easily transferred from one situation to the next. We know the environment interacting with the genome creates behavioral responses. An animals experience of this *in utero* and in early in life is especially critical, and continues throughout life. Thus, animals are in the process of adapting to ongoing changes in social and physical environments every day of their lives. Therefore, those willing to understand how environments interact with the genome to influence behavior, have unlimited potential to shape change. The challenge becomes understanding and applying behavior principles. To further that goal, rather than developing and transferring technology packages, we aim to change, fundamentally, the way people understand and use behavior to manage ecosystems. We want people to realize the power of behavior to transform systems ecologically, economically, and culturally. We are involving producers, land managers, extension, and technical assistance personnel in various education and outreach activities, fact sheets, booklets, videos, slide shows, demonstrations, symposia, workshops, and courses. We also have developed a web site (www.behave.net) in concert with the national Agriculture Network Information Center (AgNIC) - to disseminate information about the project.

Key Words: Animal Behavior, Biodiversity, Foraging

W191 Effects of fescue toxicosis on CYP3A4 in rats at thermoneutrality. R. S. Settivari*, V. C. Dhulipala, P. A. Eichen, L. E. Wax, T. J. Evans, G. E. Rottinghaus, and D. E. Spiers, *University of Missouri, Columbia*.

Fescue toxicosis is caused by the consumption of toxins found in endophyte infected tall fescue. Cytochrome P450 (CYP) enzymes play an important role in Phase I metabolism of many xenobiotics with CYP3A4 being the dominant CYP in liver. The present study determined if rats fed a diet containing infected fescue toxins (E+) induced CYP3A4. Rats (n=24) were implanted with temperature transmitters to measure core temperature (Tc) and activity every 10 minutes during the study. Following an eight day recovery, rats were fed ground endophyte-free (E-) feed for five days. During the five day treatment period, rats were fed ad libitum either an E- or E+ diets (91.5µg EV/kg BW/day). At the end of treatment, rats were euthanized and liver, adrenal, kidney, heart and testis were weighed. Feed conversion efficiency was calculated for both groups. Serum prolactin levels were measured using enzyme immuno assay. Histological sections of liver were analyzed by electron microscopy. Protein levels of CYP3A4 in liver were analyzed using Western blots. E+ treatment lowered body weight, relative liver weight, feed intake, Tc, and serum prolactin levels (P< 0.05). E+ treatment increased relative testes weights (P<0.05) but had no significant effect (P>0.05) on adrenal, kidney and heart weights. Histological section of liver showed numerous vacuolations between the hepatocytes. Feed intake, weight gain and feed conversion of E+ rats began to return to normal levels near the end of treatment. Protein expression level of CYP3A4 was greater (P<0.05) in E+ rats compared to E- group. This may be due to increased expression of CYP3A4 protein, and could reduce levels of E+ toxins and some of the symptoms in E+ rats after the fourth day of treatment. Future studies should evaluate the rate and time course of CYP3A4 induction and activity in rats fed endophyte-infected fescue diet under acute and prolonged heat stress conditions.

Key Words: Fescue Toxicosis, Cytochrome p450, Rat

W192 Dose-response relationship between ergovaline and physiological changes associated with fescue toxicosis. P. A. Eichen*, D. E. Spiers, and G. E. Rottinghaus, *University of Missouri, Columbia*.

Rats fed an endophyte-infected fescue (E+) seed diet experience changes in core temperature, feed intake and weight gain similar to those seen in cattle consuming E+. A study was performed to determine dose differences in response to ergovaline (EV), the primary toxin found in E+ seed, and identify sensitivity of the above parameters. Male rats (n=24) were implanted with telemetric transmitters (Mini-Mitter, Inc.) to record core temperature (Tc), and randomly assigned to either endophyte-free diet (E-) or E+ diet delivering low (30.5µg EV/kg BW/d), medium (61.0µg EV/kg BW/d) or high (91.5µg EV/kg BW/d) levels. Feed intake and body weights were recorded daily. Rats were maintained at thermoneutrality (TN; 21°C) during pretreatment and the first seven days of treatment, followed by seven days of heat stress (HS; 31°C). At the end of HS, all rats were euthanized for measurement of organ weights. Feed intake decreased at TN in all E+ groups compared to E- rats (P<.0001), with a greater reduction in the high compared to low E+ rats (P<.05). During HS, all E+ groups had lower feed intake than E- rats (P<.0001). Maximum reductions in feed intake below pretreatment levels at TN were 47, 42 and 20% for high, medium and low E+ groups, respectively, with additional reductions of 19, 18 and 38% during HS. However, there was recovery of feed intake in both TN and HS periods. Body weights were not different for any treatment group at TN, but rats fed high and medium E+ diets had decreased body weights compared to low E+ and E- groups during HS (P<.002). E+ groups were not significantly different from one another for Tc, so were combined for analysis. There was a treatment by day interaction during HS, with E+ rats displaying a slightly higher Tc (P<.0001). Liver weights, relative to body weights, were decreased in all E+ groups compared to E- rats (P<.0006). These results indicate that feed intake and Tc responses associated with fescue toxicosis are separate events, with feed intake being much more sensitive.

Key Words: Fescue Toxicosis, Heat Stress

W193 Housing effect on behavior and physiology during feed-withdrawal molt in laying hens: furnished cages vs. conventional cages. K. Pohle*¹ and H.-W. Cheng^{1,2}, ¹Purdue University, West Lafayette, IN, ²USDA-LBRU-ARS.

Environmental variations affect an animal's response to a stressor. This study was to examine whether an enriched environment can reduce hens' stress responses during feed-withdrawal induced-molting, which has been identified as a managerial stressor to laying hens. At 19 wk of age, White Leghorn hens were randomly assigned into conventional cages at 6 hens per cage (645 cm² floor space/hen), or furnished cages at 10 hens per cage (610 cm² floor space/hen). Furnished cages contained nests, perches, scratch pads, and dust baths (Big Dutchman, Germany). Feed-withdrawal molt was initiated at 72 wk of age. Feed was withdrawn on Day 0, cracked corn was returned on Day 7, diet was changed to pullet feed on Day 14, then to layer ration on Day 21. Physiological data were collected via blood collection on days -13, 0 (prior to feed withdrawal), 1, 5, 7 (prior to feed return), 14, 35, including serotonin, epinephrine, norepinephrine, dopamine, and corticosterone levels, and hematological parameters. Behavioral data were collected on days 0, 2, 4, 6, 8, 9, and 17 using continuous observation from 0900-0930 and 1430-1500. There were no significant differences between furnished and conventional cages in overall hormone levels and heterophil:lymphocyte ratio during the molting period (ANOVA, P>0.05). Behavioral observations during the feed withdrawal period indicated that hens in conventional cages spent more time sitting on the cage floor than hens in furnished cages (ANOVA, P=0.04). Hens in conventional cages also spent more time inactive than hens in furnished cages (ANOVA, P=0.005). Hens in both conventional and furnished cages increased their time spent preening (ANOVA, P=0.004) and exploratory pecking (ANOVA, P<0.001) following feed withdrawal. In furnished cages, compared to their behaviors before molt, hens increased dust bath usage (ANOVA, P=0.01) during the feed withdrawal period. These results indicate that housing conditions do not fully compensate for the physiological stress induced by feed-withdrawal induced-molt.

Key Words: Molt, Furnished Cages, Welfare

W194 Effects of acute stress on physical and hormonal response in three genetic strains of laying hens. L. Jefferson* and H. W. Cheng, *United States Department of Agriculture, Agricultural Research Service, Livestock Behavior Research Unit, West Lafayette, IN*.

Genetic selection for enhanced production may also affect animals' abilities to cope with stress. In this experiment, the effects of acute stress on physical and hormonal responses were examined in three genetic lines of laying hens: a line selected for high group productivity and survival (KGB), a line selected for low group productivity and survival (MBB), and a commercial line (DXL). All genetic lines were reared in separate cages in two environmentally controlled rooms, at 4 hens/cage (144 in²/hen). At 17 weeks of age, hens housed in one room were transported to a laying facility and re-caged (transport and mixing stress). The re-caging procedure ensured that all hens were unfamiliar, with a single genetic line in the cage. Hens housed in the second room were reared without interruption and served as controls. Both control and stressed hens were sacrificed 24 hours after treatment. Tissue samples and physical characteristics, including body weight, right adrenal gland, and blood, were collected and analyzed for physiological parameters associated with the stress response. There were no significant differences in heterophil to lymphocyte ratios, relative adrenal weights and plasma corticosterone levels among the control hens from all three lines (P>0.05). Compared to their respective controls, the MBB hens tended to have a greater ratio of heterophils to lymphocytes (P=0.06) than the KGB and DXL hens. The relative weight of the right adrenal gland was significantly increased in the KGB hens (P<0.001) but not in the MBB and DXL hens when compared with their respective controls (P>0.05). Compared to the respective controls, plasma corticosterone levels were increased in both KGB hens and DXL hens (P<0.05) but not in the MBB hens (P>0.05). This data supports the hypothesis that genetic selection affects physical and physiological characteristics which may be indicative of animals' abilities to cope with stress.

Key Words: Chicken, Acute Stress, Genetic Selection

W195 Can perches and platforms affect the incidence of gait abnormalities in broiler chickens? C. Falcone*^{1,2}, J. A. Mench², and P. Wakenell³, ¹*Departamento de Psicologia, Universidade de São Paulo, CAPES, Brazil*, ²*Department of Animal Science, University of California, Davis*, ³*Department of Health and Reproduction, School of Veterinary Medicine, University of California, Davis*.

Gait abnormalities affect millions of commercial broilers reared each year. Previous studies demonstrated that exercise can improve bone strength and decrease leg problems. We examined the incidence of gait abnormalities in Ross broilers (N=312) raised in either enriched or standard pens. Enriched pens contained two platforms and two perches. Perches and platforms were 8cm above the floor, and platforms were connected to the feeders so birds had to use them in order to reach the food. The following measurements were taken: gait, measured using the latency to lie (LTL) test, number of jumps (JMP) during the LTL test, final body weight (BW), and the incidences of tibial dyscondroplasia (TD) and femoral head necrosis (FHN). T-tests and chi-square tests were used to compare means and proportions. Final BW (controls 3.01 kg, enriched 2.96 kg) did not differ between treatments ($p=0.139$). Mean LTL was significantly greater for enriched than control birds (403 vs. 274 sec respectively, $p \leq 0.009$). Mean number of JMP was also significantly ($p=0.009$) higher for enriched (1.12) than control (0.77) birds. TD was found in 19% of enriched birds and 14% of control birds, although this difference was not significant ($p=0.297$). FHN was present in 9% of both enriched and control birds ($p=0.869$). Enrichment did not have clear effects on the specific leg problems that we measured. However, low LTL scores are a measure of impaired gait, and these results therefore indicate that enriching the environment to increase exercise can improve the walking ability of broilers. This project was funded by USDA Award No.2001-02498.

Key Words: Broilers, Gait Abnormalities, Enrichment

W196 Evolution of nursing behavior in Meishan-derived and white sows subjected to an auditory stimulus to decrease nursing intervals throughout lactation. C. Farmer* and S. Robert, *Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Lennoxville, Canada*.

The impact of playbacks of recorded sow gruntings on the development of nursing behavior in sows from two genotypes was studied. Yorkshire x Landrace (YL; n = 16) and 25% Meishan (MH; n = 16) sows were equally divided in two groups: 1) no playback, and 2) playbacks of recorded sow gruntings at 35-min intervals. Recordings were played from d 110 of gestation until d 27 of lactation. Sow behavior was videotaped for 24 h every four days, from d 6 to 26 of lactation. Playbacks decreased nursing intervals in MH (34.9 vs 38.2 ± 1.1 min) without altering it in YL (37.9 vs 36.5 ± 1.1 min; breed x treatment, $P < 0.05$), yet this effect in MH was likely due to the increased frequency of non-productive nursings seen on d 6, 10 and 14 ($P < 0.05$) in sows subjected to playbacks. In both breeds, the interval between nursings increased ($P < 0.01$) from d 6 (33.7 ± 0.8 min) to 26 (40.8 ± 0.8 min) of lactation, the interval between non-productive nursings remained similar ($P > 0.1$) and sows ended more nursings as lactation advanced ($P < 0.01$). More nursings were terminated by sows in MH than in YL ($P < 0.01$) whereas more nursings were terminated by piglets from YL than MH sows ($P < 0.05$). Playbacks or genotype did not alter the amount of time over a 24 h period that sows spent standing, sitting, lying on the belly or lying with their udder exposed ($P > 0.1$), but sows spent more time sitting, standing and lying on their belly and less time lying with their udder exposed as lactation advanced ($P < 0.01$). Posture changes were more frequent for MH than YL sows ($P < 0.01$) and increased as lactation advanced ($P < 0.01$). In conclusion, the effects of playbacks on nursing behavior varied across genotypes and all recorded sow behaviors changed as lactation advanced. Piglets from MH sows seem to play a greater role than piglets from YL sows in optimizing lactation performances, as suggested by their lower willingness to end nursings.(Thanks to Hypor (formerly Genex Swine Group) for supplying the animals).

Key Words: Nursing Behavior, Meishan, Sows

W197 Trickle versus drop feeding for gilts and sows in gestation crates or pens: reproductive performance and rates of injury. J. McGlone¹, L. Hulbert*¹, J. Dailey², R. McPherson¹, and J. Morrow², ¹*Texas Tech University, Lubbock*, ²*USDA-ARS*.

Sow housing systems and their effects on sow welfare are important to pork producers and consumers. Specifically, we sought to evaluate the effects of trickle feeding (feed delivered over 30 min) vs. drop feeding (feed delivered in a single moment) for PIC-USA Camborough-22 gilts/sows housed in gestation pens (groups of 5) or individual crates. Gilts were randomly assigned to one of the four factorially-arranged treatments. A total of 8 blocks were established. Pregnant gilts all farrowed in standard farrowing crates and then they returned to their same environment for a second complete parity. A total of 188 litters were farrowed from parity 1 and 2 females. Measures included backfat thickness, farrowing rates, numbers of pigs born alive, weaned, stillborn and piglet birth and weaning weights. Sow weights were collected at farrowing and weaning. Sow injuries, wounds and scratches were quantified. No interactions between parity, housing systems or feeding systems were observed. The interaction between housing and feeding systems was significant ($P = 0.01$) for only sow farrowing weights; drop-fed, penned sows were heavier than drop-fed, crated sows while trickle-fed, penned sows were lighter than trickle-fed, crated sows. Penned sows had more ($P < 0.05$) backfat thickness than crated sows. Drop-fed sows weaned pigs were heavier ($P < 0.05$) than trickle-fed sows. All other measures of productivity were not different among treatments. Injuries, wounds and scratches were statistically similar for sows in each treatment group. Drop-fed, penned sows increased backfat thickness compared with crated sows (perhaps being able to huddle, penned sows required less feed), but this effect was eliminated when penned sows were trickle-fed (and energy expenditure may be increased). Farrowing rates were 10% lower among penned than crated sows. We conclude that overall gilt and sow productivity and injury rates were similar for sows in crates and pens, with the exception that farrowing rates may be reduced among sows housed in social groups during gestation.

Key Words: Pigs, Gestation Housing, Welfare

W198 Performance and longevity of gestating sows housed in pens with electronic sow feeder (ESF) and in individual stalls. L. Anil*¹, S. Anil¹, S. K. Baidoo², and J. Deen¹, ¹*Department of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul*, ²*Southern Research and Outreach Center, University of Minnesota, Waseca*.

A study was conducted at the University of Minnesota Southern Research and Outreach Center, Waseca, MN with 206 sows (body weight 171-259 kg, parity 1-4) housed in four pens (2 mixings per pen at 14 days interval after weaning) with fully slatted floors (12.75m long X 6.75m wide) and a single walk through ESF located at the center of each pen and 176 sows (body weight 140-278kg, parity 1 to 5) housed in stalls (length 200cm X width 60 cm X height 97cm, with fully slatted floors) to compare the farrowing performance and longevity of sows. All the sows stayed in gestation stalls for the first 10 days following weaning before moving to allotted treatments. The means of performance in each group were compared using Independent-samples T test. A higher conception rate compared to sows in pens with ESF (74.76%) was observed in stall-housed sows (81.81%). There was no significant difference in performance between sows housed in pens with ESF and in stalls in terms of litter size, born alive /litter, stillborn /litter and foster-on. Stall-housed sows had significantly ($P < 0.05$) less number of mummies/litter (0.67 vs. 0.86) and higher foster-off (0.67 vs. 0.79) than group-housed sows. Piglet death /litter (1.22 vs.1.58) and pre-weaning mortality (13.16 vs. 16.24) were significantly ($P < 0.05$) lower in group-housed sows. Of the 17 sows removed from the pens with ESF, 11 were removed for lameness. Five sows were removed from stalls including one for lameness. Proportion of sows removed from the pens with ESF was significantly higher ($P < 0.05$) than sows in stalls. Results indicated that group pens with ESF need modification to improve farrowing percentage and sow longevity.

Key Words: Pens with ESF, Gestation Stall, Sow Longevity

W199 Novel arena/object test to assess housing related stress in gestating sows housed in stalls and in pens with electronic sow feeders (ESF). L. Anil*¹, S. Anil¹, S. K. Baidoo², and J. Deen¹, ¹*Department of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul*, ²*Southern Research and Outreach Center, University of Minnesota, Waseca*.

Novel object/ arena test was conducted on day 108 of gestation among sows housed in stalls (29 sows) and in pens with ESF (36 sows) to assess the fearfulness of sows when exposed to a novel arena and/or novel object as a measure of the housing-related stress experienced by the sows. A completely enclosed rectangular pen (4.78 m X 2.4 m) was divided into 10 equal segments and numbered one through 10. In the middle, opposite from the side of entrance a semicircle of radius 0.5 m was marked off (area A) for placement of the novel object, a fluorescent orange safety cone. The sows were moved into the pen, one at a time directly from their daily environment. The sow was observed for the first two minutes for the areas it entered within the arena. The sow was considered to be in an area if the snout entered the area. The novel object was placed in area A for the next three minutes and the sow was observed. Data on areas entered, time to approach the object, total time spent in the area A, time to first interaction with the object and number of interactions were recorded. The results of the test were compared using independent sample T-test and Kruskal-wallis ANOVA. More stall-housed sows (16) entered the area with novel object than sows housed in pens with ESF (13). Stall-housed sows took significantly less time (72.5 s) to enter the area with novel object than sows from pens with ESF (112.6 s). There was no significant difference among sows from both systems in terms of number of squares entered, time to have the first interaction and number of interactions with the novel object. The results were inconclusive as there was no possibility to account for the excitement in stall-housed sows when they were permitted to have a short walk and in a larger area during the test and the individual differences among sows.

Key Words: Novel Arena/Object Test, Pens with ESF, Gestation Stall

W200 The effect of cold draft on behavior of newly weaned piglets. A. Bruni* and T. M. Widowski, *University of Guelph, Ontario, Canada*.

Adverse barn environments resulting from poor ventilation or improper temperature control are often blamed for the development of vices in pigs. Behavior problems that can develop at weaning include ear biting, navel sucking and belly nosing. While it is evident that cold, drafty conditions can lead to reduced performance and health problems, any relationship with oral/nasal behavior has never been explored. The objective of this study was to determine the effect of cold draft on oral/nasal behavior in piglets weaned at 18-22 d of age. Sixteen Yorkshire piglets were used in each of 5 trials (n=80) comprising 2 pens per treatment and 4 piglets per pen. Piglets were housed in an environmental chamber in which half of the pens could be exposed to cold draft while the other half maintained at recommended temperature and air velocity. Treatment piglets were kept at 27.9 (+0.58)°C except when subjected to 2-one h periods of time-unpredictable draft each day during which temperature was decreased 3°C and air velocity increased to 0.8 m/s at

pig level. Control pigs were kept at 28.1 (+0.63)°C with minimal air movement of <0.3 m/s. Behaviors were observed on d 3, 5, 7, 9, 12 and 15 using scan sampling every 5 minutes for 6 h per day. Overall, piglets exposed to draft spent significantly less time engaged in belly-nosing behavior (0.59 + 0.18%) and more time at the feeder (12.46 + 0.68%) compared to controls (1.32 + 0.34% and 9.46 + 0.69%, respectively; P<0.05). Yet, overall feed intake and growth rates did not differ for the two groups (P>0.05). During periods of cold draft, treatment piglets were more active (17.7 + 0.02%) and spent more time nosing and chewing their pen-mates' ears and tails (1.6 + 0.01%) compared to controls (14.3 + 0.01% and 1.1 + 0.01%, respectively; P<0.05). These results show that exposure to cold draft stimulates nosing and chewing pen-mates' ears and tails but not belly nosing. Adverse environmental conditions may contribute to some oral/nasal behaviors but not others.

Key Words: Piglet Behavior, Belly Nosing, Cold Draft

W201 Analysis of euthanasia and death in swine breeding herds. S. S. Anil*, L. Anil, and J. Deen, *Department of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul*.

The pattern of sow deaths and euthanasia and the factors influencing the likelihood of sows to be euthanized or to have a natural death among the removed sows in commercial swine breeding herds were analyzed retrospectively, involving 24,017 records of death and euthanasia from 17 herds from 1999 to 2003. Logistic regression models were fitted to analyze the association of euthanasia with production variables, season and remove day. Of all the females died and euthanized, 23.6 % were euthanized and 16.3 % of females were euthanized for painful conditions. Among the sows and gilts those experienced painful conditions, 67.28% and 58.38% respectively were euthanized. The percentage of euthanized sows (5.2) was higher than that of death (3.4) on farrowing day. The euthanasia to death ratio was lower up to 15 days post-farrowing (0.27 on day 15) and then increased with the peak (0.63) during 31 to 35 days post-farrowing. The proportion of deaths was lower during week-ends. As average number of stillborn/litter increased, the likelihood for euthanasia increased among sows (OR 1.067). Sows of parity 1 and 2 were more likely to be euthanized compared to sows of parity >5 (OR 1.121). The odds of euthanasia was less for lactating sows (OR 0.410) than for non-lactating sows. In sows and gilts, the likelihood for those that were never served to be euthanized was higher (OR 2.423 and 1.686 respectively) compared to those served once. The likelihood was lower (OR 0.86) for sows that were served more than once compared to those served once. The likelihood for euthanasia was higher during weekdays (OR 2.824). The farm had a significant influence on the odds for euthanasia. Average number of litters farrowed / year, average number of non-productive days / parity, average number of pigs born alive / litter, average number of mummies / litter and born alive, mummies and stillborn in the removal parity were not significantly (P>0.05) associated with likelihood for euthanasia among sows. The results indicated that sows were at different likelihoods of euthanasia, depending on stage of production. An effort should be made to ensure that care and pain amelioration are available at all stages of production.

Key Words: Euthanasia, Death, Sow

ADSA Growth and Development

W202 Effects of weaning and ionophore on selected blood metabolites and growth in dairy calves. J. L. Klotz* and R. N. Heitmann, *Department of Animal Science, The University of Tennessee, Knoxville*.

Dairy calf weaning is associated with elevated ketone levels in excess of measured rates of utilization in adults and excess concentrations excreted in urine present a potential energy loss. Lasalocid is frequently supplemented as an anticoccidial in calf starters, but in adults is also known to alter molar ratios of ruminal VFA. Jersey bull calves (n = 24) were blocked in groups of two according to birth date and weight and randomly assigned to receive either a commercial pelleted starter (C), or the same diet containing lasalocid (T; 83 mg/kg DM) to examine effects of weaning transition on weight (BW), gain (ADG), and blood glucose, β -hydroxybutyrate (BHBA), non-esterified fatty acids (NEFA), volatile fatty acids (VFA), insulin, and glucagon (GLN) concentrations over 16 wk. From d 3 - 34 all calves were fed milk replacer twice daily, d 35 - 48

received replacer and C or T, and d 49-112 received *ad libitum* C or T. Repeated measures of BW and metabolite concentrations from jugular samples were recorded weekly. Postweaning intake (2.35 vs. 2.34 kg/d; \pm 0.07), ADG (0.78 vs. 0.75 kg/d; \pm 0.03), and feed:gain (3.10 vs. 3.19; \pm 0.11) did not differ between C and T. Glucose and NEFA concentrations did not differ between C and T, but declined with age. Insulin and GLN concentrations did not differ between C and T, but GLN increased with weaning. Total VFA significantly increased following introduction of solid feed at d 35, but there was a 1-wk lag period with T. Acetate and butyrate concentrations were greater in C than T during wk 7 (P < 0.05). Propionate concentrations and acetate : propionate ratios did not differ between C and T. Blood BHBA concentrations were greater in C than T (P < 0.05) during wk 8 and 9 (1.0, 1.1 vs. 0.7, 0.8 mmol/L; \pm 0.1). Consumption of starter with lasalocid delayed peak acetate and

butyrate and lowered peak BHBA concentrations, but did not appear to significantly influence post-weaning growth or efficiency.

Key Words: Weaning, Growth, Ionophore

W203 The effects of feeding chlortetracycline on the performance of breeding age dairy heifers. E. D. Reid* and P. S. Erickson, *University of New Hampshire, Durham.*

Chlortetracycline (CTC) is a broad spectrum antibiotic that is used to increase profitability in a variety of animals by increasing weight gain, feed efficiency, carcass grades, and conception rates. The use of CTC for this purpose, however, remains controversial, in part because little is known about the mode of action of this antibiotic. The current study was designed to test the effects of CTC on rate of gain, wither and hip height, feed efficiency, body condition score, systemic thyroxine (T4) and glucose levels, and conception rates of breeding age Holstein heifers. Forty 12-mo old Holstein heifers (initial BW = 363 kg) were housed in a free stall with ad libitum access to feed and water for 104 d (transition period starting at 14 d prior to age of 12 mo and 90 d treatment period starting at 12 mo of age). The CTC-fed group (n = 20) received 350 mg of top-dressed CTC/head/d. Measurements for weight, wither and hip height, body condition score, and health score were recorded weekly. Dry matter intake was monitored daily. Blood samples were obtained every 4 d to determine systemic T4 and glucose concentrations. There was no effect of CTC on weight gain, feed efficiency, height, body condition score, blood glucose concentrations, general health or conception rate. There was an interaction (P < 0.03) between treatment and time for systemic T4 concentration. In the beginning of the experiment, systemic T4 concentration was lower in animals supplemented with CTC. There was no difference in systemic T4 concentrations between treatments at the end of the experiment.

Key Words: Chlortetracycline, Dairy Heifer, Thyroxine

W204 The effect of feeding three milk replacer regimens preweaning on heifer intake, prepubertal and pubertal growth parameters and reproductive performance. C. S. Ballard*¹, H. M. Wolford¹, C. J. Sniffen², T. Sato³, K. Uchida³, and Y. Yabuuchi³, ¹W.H. Miner Agricultural Research Institute, Chazy, NY, ²Fencrest LLC, Holderness, NH, ³Zen-Noh National Federation of Agricultural Co-operative Associations, Tokyo, Japan.

As previously reported, sixty Holstein heifer calves at two farms were blocked at birth and randomly assigned to one of three treatments formulated on DM basis: 1) 27% CP/20% Fat fed at 1.5% BW for first week, 2.25% BW from 8 days through 5 weeks, and 1.25% BW from 6 weeks to weaning; 2) 27% CP/20% Fat fed at 200g 2x/day for 2 weeks, 250g 2x/day through weaning; or 3) 27% CP/15% Fat fed at 1.5% BW for first week, 2.25% BW from 8 days through 5 weeks, and 1.25% BW from 6 weeks to weaning. The calves fed milk replacer as a % of body weight had a greater rate of growth for all parameters measured. Calves fed milk replacer at a fixed rate were weaned at an earlier age and had fewer days treated for illness. The objective of this study was to continue to measure the performance of these heifers from 10 to 20 weeks of age for intake and 10 weeks to 18 months of age for growth and reproductive performance. Individual dry matter intakes were measured weekly on a subset of 39 total animals from 10 to 20 weeks of age. Heifer growth was measured monthly from 10 weeks to 18 months. The calves fed as a % of body weight during the wet phase of their life had higher growth rates, resulting in larger framed animals from 2 weeks through 7 months of age. No significant differences between treatments for growth were found after 7 months.

W205 Effects of intake, selection for milk yield, and bST administration on hepatic expression of insulin receptors and components of the somatotrophic axis in growing Holstein heifers. S. H. Wu*, W. J. Weber, H. Cheser-Jones, L. B. Hansen, and B. A. Crooker, *University of Minnesota, St. Paul.*

Hepatic gene expression was determined in heifers from an unselected (since 1964) stable milk yield line (control, CL) and a contemporary line (select, SL) to assess effects of intake, selection for milk yield, and bST. During the 37 d study, heifers (CL: n = 6, 120 ± 5 d old, 116 ± 10 kg BW; SL: n = 7, 124 ± 7 d old, 157 ± 12 kg BW) were fed 150% (d 1 to 18), 100% (d 19), 75% (d 20 to 21), 50% (d 22 to 26), 75% (d 27), 100% (d 28) and 150% (d 29 to 37) of their maintenance energy needs. Heifers received 30 µg bST/kg BW (IM) on d 4 to 10. Liver biopsies were collected on d 1, 8, 23, 26, 30, and 33 and mRNA for insulin receptor isoforms A and B (INSRA and INSRB), total and type-1A growth hormone receptor (GHR-t, GHR-1A), total and class-2 insulin-like growth factor-I (IGF-t, IGF-c2), and IGF-I binding proteins (IGFBP-2, -3, and -5) determined by real-time PCR. Expression, relative to hypoxanthine phosphoribosyltransferase (HPRT) was reported as relative units (ru). Results from a repeated measures analysis (PROC MIXED of SAS) differed when P < 0.05. HPRT was similar between lines but was less on d 33 (23.2^a, 23.2^{ab}, 23.3^a, 23.2^a, 23.2^a, 23.0^b ± 0.1 ru). Line had no effect on expression of any gene measured. Relative to d 1, bST decreased GHR-1A (24%), IGFBP-2 (32%), and IGF-c2/IGF-t ratio (19%) and increased INSRA (25%). Relative to d 1, feed restriction decreased GHR-1A (49%), GHR-t (40%), GHR-1A/GHR-t (22%), IGF-c2 (83%), IGF-t (58%), and IGF-c2/IGF-t (62%) and increased IGFBP-2, -3, and -5 (136, 31, 169%). INSRB and INSRB were increased (163, 121% of d1) on d 23 but similar to d 1 on d 26. There were line by day interactions for GHR-1A and for INSRB. Relative to d 1, GHR-1A decreased more in CL (66%) than SL (31%) during feed restriction. Results suggest mechanisms in the growing heifer that regulate adaptation of the somatotrophic axis to feed deprivation may be affected by genetic potential for subsequent milk yield.

Key Words: Selection, Liver, Somatotrophic Axis

W206 Effect of implant program on somatotropin (ST) response to growth hormone releasing factor (GRF) in finishing Holstein steers. B. A. Crooker*¹, W. J. Weber¹, C. Cheatham², L. H. Baumgard², and G. C. Duff², ¹University of Minnesota, St. Paul, ²University of Arizona, Tucson.

Steers (n=19) were randomly assigned to one of four implant schemes of Raigro (R), Synovex-S (S), or Synovex-Plus (P) and used to determine effects of implants on ST response to GRF. On d 1, 84, and 168, steers received no implants (controls, CON; n = 5) or implants in the sequence RSS (n = 5), RSP (n = 5), RPP (n = 4). On d 228, steers received 5 µg/100 kg BW of human GRF (1-29) analog (Hoffman-LaRoche, Ro23-7863) at 0 min (FLUSH) and 4 µg/100 kg BW GRF 150 min later (CHALL). Blood samples were obtained at -30, -20, -10, -5, 0, 10, and 20 min relative to FLUSH and at -30, -20, -10, -5, 0, 2.5, 5, 7.5, 10, 15, 20, 30, 45, and 90 min relative to CHALL. Mean pre- (-30 to 0 min;

PCST) and post-GRF administration (10 and 20 min; MNST) ST concentrations in serum were determined by RIA. Data were transformed to natural logarithms. Area under the ST response curve for CHALL was quantified (0 to 60 min; AUC60) by trapezoidal summation after subtracting PCST. Effects of implant scheme, GRF, and their interactions were assessed using GLM of SAS. Means differed when $P < 0.05$. Steers averaged 189 ± 4.3 kg BW on d 1. Body weight increased throughout the study, did not differ among implant schemes but was greater for implanted than CON steers by d 112 (370 vs 403 kg), and remained greater throughout the study. At 228 d, BW of implanted and CON steers was 546 and 478 kg. Natural logarithm of PCST was greater for CON than implanted steers (1.15a, 0.51b, 0.99ac, 0.67bc \pm 0.16 ng/ml for CON, RSS, RSP and RPP, respectively) and greater for FLUSH than CHALL (1.00, 0.66 \pm 0.11 ng/mL). Natural logarithm of MNST was similar among schemes (5.17 \pm 0.66 ng/mL) and greater for FLUSH than CHALL (5.67, 4.28 \pm 0.47 ng/mL). AUC60 for CHALL did not differ among schemes (244, 462, 609, 116 \pm 226 ng x min/mL). Sixty days after the terminal implantation, ST concentrations were less in implanted steers but ST response to GRF did not differ from non-implanted steers.

Key Words: GRF, Implant, Holstein Steer

W207 Analysis of in vivo body composition of new born calves using dual energy x-ray absorptiometry (DXA). J. Hampe*, S. Nueske, A. M. Scholz, and M. Foerster, *University Munich, GE*.

The basis of this study is a comparison of body composition among new born calves of different genetic origins. A number of 167 calves of purebred German Fleckvieh (FV), German Holstein (GH), F1 hybrids (FV x GH and GH x FV) and "F2 hybrids" (GH x F1 - mother and FV x F1 - mother) have been examined within the first week after birth. The calves were sedated with a Ketamin - Xylazin mixture, weighed on a bar scale and scanned in the whole body mode (adult normal) on a GE Lunar DXA scanner (DPX-IQ). The evaluation showed a significant genotype influence on bone mineral density (BMD) and bone mineral content (BMC). Bone mineral percentage (BMPC) is significantly affected by the mothers breeding line. In contrary, soft tissue composed of lean tissue and fat is significantly influenced by the fathers breeding line. BMD and BMC from purebred GH is significantly lower than from calves with FV father or mother. Purebred GH calves have a significantly lower BMPC than crossbred calves with GH father. Purebred GH calves reach in tendency higher values than the other genotypes with regard to the lean tissue percentage (LeanPC). However, the main difference in LeanPC and fat percentage (FatPC) exists between male and female calves with 91.24% to 91.6% lean and 4.86% to 4.52% fat. FV x GH calves reach a significantly higher FatPC than GH x FV calves showing a clear position effect in the crossbreeding program.

Breeding Line	BMC (g)	BMD (g/cm ²)	BMPC (%)	Lean PC (%)	Fat PC (%)	n
GH x GH	1605.7 \pm 64.7 ^a	.881 \pm .018 ^a	3.64 \pm .08 ^a	91.75 \pm .26	4.61 \pm .23 ^{cd}	29
FV x FV	1791.9 \pm 63.0 ^b	.943 \pm .017 ^b	3.87 \pm .08 ^b	91.49 \pm .25	4.64 \pm .23 ^{cd}	33
GH x FV	1804.3 \pm 63.7 ^{bc}	.961 \pm .017 ^b	4.02 \pm .08 ^b	91.55 \pm .25	4.43 \pm .22 ^{ac}	36
FV x GH	1789.9 \pm 62.8 ^b	.945 \pm .017 ^b	3.84 \pm .08 ^b	91.17 \pm .25	4.99 \pm .22 ^{bd}	35

W208 Updating growth standards for Canadian Holstein and Ayrshires. D. M. Lefebvre*¹ and R. Lacroix^{1, 2} *Dept. of R&D, PATLQ - Quebec DHI, Quebec, ²Dairy Information Systems Group, McGill University, Ste-Anne-de-Bellevue, Quebec, Canada.*

Average postcalving weight of primiparous Canadian Holstein and Ayrshire cows has increased by 10% in the last 10 years. The objective of this work was to update reference growth curves for evaluating growth of dairy heifers. Growth data were collected on 24191 heifers in 851 Quebec herds. There were 69131 weight observations (estimated by heart girth) from Holstein and 4309 from Ayrshire heifers (3.1 weight observations per heifer). Height at the withers was also collected (64192 observations

for Holsteins, 3654 for Ayrshires). Average body weight by age was compared to growth standards currently used and approximated the value for the 90th percentile ranking until 20 months of age, indicating the need to update the references for calculating percentile ranking. The observed mean growth rate declined after 20 mos, consistent with average age after calving being 28 mos. The observed mean could therefore not be used as an optimal growth curve. Median body weight after calving (HO: 580 kg, AY: 500 kg) of heifers calving between January 2001 and October 2003 (167,651 observations) was used as the target post-calving BW for percentile 50. Pre-calving BW was estimated as 110% of post calving BW, such that the median target pre-calving BW was established as 638 kg for Holsteins and 550 kg for Ayrshires. Values for percentile rank 90 were calculated (1.2975 * SD, SD = 11.553+2.295*Age for Holsteins, 8.73884+2.67656*Age for Ayrshires) as 725 kg for Holsteins and 645 kg for Ayrshires. Birth weight was estimated using the regressions equations fitted on the observed body weights (42.9 and 39.6 kg for HO and Ay, respectively). Constant weight gain from birth to pre-calving at 24 mos. of age was assumed for the entire growth period. Resulting average daily gain for percentile ranks 50 and 90 were 0.81 and 0.91 kg*d⁻¹ for Holsteins and 0.70 and 0.81 kg d⁻¹ for Ayrshires. Standard curves for height at the withers were also established, using a second degree polynomial fitted on the average height by age. Height at the withers for percentiles 50 and 90 at 24 months of age are 141 and 147 cm for Holsteins and 130 and 137 for Ayrshires. The proposed standards should be used as reference to benchmark heifer growth.

Key Words: Dairy Heifer Growth, Growth Standards

W209 Identifying ruminal drinking by measurement of respiratory quotient and methane production in preruminant calves. J. J. G. C. van den Borne*, S. J. J. Alferink, and W. J. J. Gerrits, *Animal Sciences Group, Wageningen University and Research Centre, Wageningen, The Netherlands.*

In preruminant calves, milk is bypassing the rumen by closure of the oesophageal groove and flows directly into the abomasum. Leakage from the oesophageal groove or backflow of milk from the abomasum into the rumen, however, leads to fermentation of the milk replacer and results in reduced performance, meat quality and increased mortality. Several studies have elucidated the mechanism and aetiology of groove closure. In this study (originally not designed to study ruminal drinking) the diurnal pattern of the respiratory quotient (RQ) and methane production in a bloating calf was compared with that of normal calves. Individually housed calves were studied during two, 9-day periods using indirect calorimetry. Milk replacer was fed at 1.5 x MEM and no roughage was supplied. A clinical case of ruminal drinking spontaneously developed in one of the six calves. The calf was bloating and faeces were clay-like. Nutrient digestibility and gas exchange measurements were compared between this calf and five normal calves. Apparent digestibility of crude protein (86% vs 91%) and crude fat (82% vs 92%) was depressed in the bloating calf compared with the other calves. Marked differences in RQ and methane production were observed at 1.5 h postprandially. RQ increased from 0.78 to 1.13 in the bloating calf and from 0.80 to 0.88 in the normal calves. This can be ascribed to anaerobic fermentation of the milk replacer in the rumen, which theoretically results in an infinite RQ and a concomitant production of methane. Methane production, at the same time, increased from 73 mL/kg^{0.75}/d before feeding to 428 mL/kg^{0.75}/d at 1.5 h after feeding in the bloating calf, and from 25 mL/kg^{0.75}/d to 65 mL/kg^{0.75}/d in normal calves. Based on these observations, it is hypothesised that measurement of O₂, CO₂ and CH₄ in breath 1-2 h post-feeding may provide a sensitive indicator for identification of ruminal drinking. The sensitivity of this methodology, however, needs further study.

Key Words: Calves, Ruminal Drinking, Bloating

W210 Cloning the genomic sequence and proximal promoter of bovine pyruvate carboxylase. S. M. Rodriguez*, C. A. Bidwell, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Pyruvate carboxylase (PC) catalyzes a pivotal reaction in gluconeogenesis and lipid metabolism in liver. We previously identified six unique alternative splice variants in the 5 untranslated region (UTR) of PC mRNA. These splice variants may have a role in translational regulation of PC protein abundance. The objectives of this experiment were to clone and sequence the bovine PC gene, to determine the intron/exon

organization of the 5'UTR and to identify PC promoter elements. The RPCI-42 Bovine Bacterial Artificial Chromosome (BAC) library was screened with oligonucleotide sequences corresponding to specific elements of the 5'UTR sequence of bovine PC and to a region of the coding sequence. Two BACs that hybridized to all probes were selected for further analysis. A partial restriction map of the BACs was made with oligonucleotides corresponding to the coding region and the 89 and 110 bp elements of bovine PC 5'UTR. The BAC fragments that hybridized to the oligonucleotide probes were isolated and sequenced. The sizes of the cloned genomic PC 5'UTR fragments were verified by PCR, using genomic DNA from four cows. Sequencing data confirms the existence of a 178 bp exon that contains the 68 and 110 bp sequence elements

of the 5'UTR for PC mRNA. The 178 bp exon appears to be the first transcribed exon in PC and the 68 and 110 bp 5'UTR sequences are most likely generated by alternative transcription start sites. Genomic sequence data also confirms that the 3' end of the 89 bp element is a discrete 41 bp exon. Regions within the genomic sequence adjacent to the 178 and 41 bp exons of the PC 5'UTR contain binding sites for TBP, Sp1, Ap1 and/or CEBP transcription factors. These data provide information about the arrangement of exons in the 5'UTR of PC and about putative promoter regions.

Physiology and Endocrinology: Reproductive Technologies and Management

W211 The effect of day six or day seven prostaglandin F_{2α} (PGF_{2α}) injections and using a disinfectant lubricant with Controlled Internal Drug Release (CIDR) inserts for estrus synchronization in dairy heifers. W. M. Graves^{*1}, A. K. McLean¹, R. C. Smith¹, J. B. Rosenberg², and B. C. Beachnau³, ¹University of Georgia, Athens, ²Fort Dodge Animal Health, IA, ³Pfizer Animal Health, Portland, MI.

Our objective was to compare d-6 versus d-7 prostaglandin F_{2α} (PGF_{2α}) injections and the effect of using a disinfectant lubricant with CIDR inserts (Eazi-Breed CIDR, Pfizer Animal Health, New York, NY) placed intravaginally for 7 d. A total of 164 heifers at two locations received PGF_{2α} (Lutalyse, Pfizer Animal Health, New York, NY, 5 mg; i.m.) on either d 6 or d 7 at the time CIDR inserts were removed. Two different types of lubricants, Safe Lube (H&W Products, Inc, Salem, OH) and Nolvalube (Fort Dodge Animal Health, Fort Dodge, IA) with Nolvasan disinfectant (0.1% chlorhexidine acetate) were used to measure effects on discharge at removal and conception. Insertion devices were dipped in Nolvasan solution (29.57mL per 3.785 L), excess fluid was shaken off, then dried with a paper towel prior to using Safe Lube for application. Insertion devices were just wiped and more Nolvalube added between heifers using the disinfectant lubricant. Data were analyzed by Chi-Square. Twenty-nine of 81 (35.80%) heifers treated with Safe Lube showed signs of vaginal discharge versus 18 of 83 (21.69%) treated with Nolvalube (P<.05). Sixty-six (81.48%) of those treated with Safe Lube were in estrus and 29 (43.94%) pregnant versus 76 (91.57%) in estrus and 40 (52.63%) pregnant for the Nolvalube heifers (NS, P=.11). Seventy-one of 82 (86.59%) heifers that were injected on d 6 were in estrus and 33 (46.48%) pregnant versus 71 of 82 (86.59%) injected on d 7 that were in estrus and 43 (47.89%) pregnant (NS). Day-6 heifers came into estrus in tighter synchrony. A total of four (5.63%) of the d-6 heifers were in estrus on d 8, 52 (73.24%) on d 9 and 15 (21.13%) on d 10. A total of four (5.63%) of the d-7 heifers were in heat on d 8, 45 (63.38%) on d 9, 18 (25.35%) on d 10 and four (5.63%) on d 11. Few discharges were seen using the disinfectant lubricant. The number of heifers in estrus and pregnant were similar for the d-6 and d-7 PGF_{2α} injections.

Key Words: CIDR, PGF_{2α} Synchronization, Disinfectant Lubricant

W212 Development of a boar semen mobility assay. A. A. Olivera, D. L. Fernandez*, and E. S. Fonda, *Department of Animal and Veterinary Sciences, California State Polytechnic University, Pomona.*

Eighteen ejaculates from six mature boars were used to develop a porcine sperm mobility assay that could be performed under field conditions. A modified densimeter was used to determine an index representing the changes in light absorbance after spermatozoa penetrated a resistance medium. The control values were subtracted from the experimental values to create the Net Mobility Index (NMI). Variables used in this experiment were incubation time (5, 10, 15 or 20 min), extender (Modena, X-Cell, MR-A or VSP), sperm concentration (1, 2, or 3 x 10⁸) cells/ml and Accudenz Resistance Media concentration (3%, 6% or 9%). Inactivated sperm cells were used as controls. NMI values were lower (P<.01) for inactivated sperm (3.16±0.22 vs 25.044 ± 0.39). NMI values increased (P<.05) with incubation time (5 min, 13.78±0.39; 10 min, 23.806±0.37; 15 min, 29.00±0.38; 20 min, 32.31±0.37). However, sperm penetration tended to stabilize over time. NMI differed (P<.05) among extenders (X-Cell, 31.42±0.37; Modena, 26.70±0.37; MR-A, 23.91±0.39; VSP, 17.53±0.39). Increasing sperm concentration

increased (P<.05) NMI (1 x 10⁸), 19.20±0.33; 2 x 10⁸), 25.28±0.33; 3 x 10⁸), 30.19±0.33), however, neat ejaculate NMI (29.511±0.39) was similar to (P>.05) NMI for 3x10⁸ cells/ml. NMI differed (P<.05) among the three concentrations of resistance media (3%, 28.71±0.33; 6%, 24.23±0.33; 9%, 21.73±0.33). We conclude that the changes in the light absorbance of the resistance media are an expression of the sperm mobility. Moreover, this technique has a potential application, under field conditions, to assess objectively sperm mobility and categorize males based on a Sperm Mobility Index.

Key Words: Sperm, Boar, Mobility

W213 In vitro production of Holstein embryos using Beltsville method sex-sorted sperm. R. D. Wilson*¹, K. A. Weigel¹, P. M. Fricke¹, M. L. Leibfried-Rutledge², D. L. Matthews¹, J. J. Rutledge^{1,2}, and V. R. Schutzkus¹, ¹University of Wisconsin Madison, ²BOMED Inc, Madison, WI.

Our objective was to explore the impact of sperm sorting on the efficiency of in vitro embryo production in Holstein cattle. Cull cows were used as donors, and ovaries were collected via colpotomy or at the time of slaughter. Oocytes were aspirated from the ovaries, and embryos were produced using sex-sorted semen from three Holstein sires. Embryos were transferred into recipient Holstein cows and heifers on the donors farm. Seven Wisconsin herds participated, and 365 embryos were produced from 104 donor cows. Only 272 were transferred, due to limited availability of recipients. On average, 3.5 ± 0.4 transferable embryos were produced per donor, including 1.4 ± 0.2 grade one embryos and 1.5 ± 0.2 grade two embryos. Individual farms averaged from 1.6 to 5.8 transferable embryos per donor. On average 43.7 ± 4 oocytes were collected per donor. The number of usable oocytes averaged 33.9 ± 3.4 and percent embryo cleavage (52.1 ± 1.9) were significant predictors of the number of blastocysts and number of transferable embryos. Preliminary pregnancy results show strong farm and sire effects. Overall conception rate was 36 percent for heifer recipients and 18 percent for milking cow recipients (P<.05). To test the effect of sperm sorting on the percentage of embryos developing to blastocyst stage, oocytes were recovered from anonymous donors at a slaughterhouse and fertilized using non-sorted sperm or sex-sorted sperm from these sires. Oocytes (n=3312) fertilized using non-sorted sperm produced (P<.05) more embryos developing to blastocysts than oocytes (n=1577) fertilized using sex-sorted sperm (20.1 ± 2.9 percent vs. 12.2 ± 2.3 percent, respectively). These results suggest that sexing sperm using the Beltsville method (fluorescence-activated cell sorting) method may have adverse effects on embryo development and conception rates in in vitro production systems.

Key Words: Sexed Semen, In Vitro Production, Dairy Cattle

W214 Induction of bilateral double ovulation to promote twinning in beef cattle. M. Hogue¹, A. Bor², Y. Lavon¹, M. Maman¹, S. Jacoby², and D. Wolfenson*¹, ¹The Hebrew University, Rehovot, Israel, ²Agricultural Research Organization, Bet Dagan, Israel.

Beef cattle producers gain substantial economic benefits from cows that produce twins. Calf survival and birth weight are greater and incidences of abortion and dystocia are less in bilateral than unilateral twin pregnancies. A major objection to using gonadotropins to induce twins is the wide variation of ovarian response. The present study examined induction of bilateral-double or triple ovulation by stimulating follicle

growth with FSH, use of ultrasound-guided selective follicular aspiration to remove extra-large follicles, followed by supportive FSH to maintain co-dominance. In Exp. 1, Holstein cows were given short (three doses, n=6) or long (five doses, n=6) FSH treatment (50 mg Folltropin) every 12 h, from day (d) 3 of the cycle. On d 5, selective aspiration was performed, on d 6, PGF_{2α} was given, on d 7, two supportive 30 mg doses of FSH were given 12 h apart to maintain co-dominance, on d 8, GnRH was given and post-ovulation CL growth was determined. Short and long FSH treatments induced double or triple ovulation in 42% of the cows. In Exp. 2, a short FSH treatment was given only to cows (n=10) with 7 to 8 mm medium follicles on d 3, and supportive FSH (30 mg) was given on d 5 and 6. Two non-responding cows were excluded, and 6 out of 8 cows (75%) exhibited double or triple ovulation. Control cows (n=6) that did not receive FSH ovulated a single follicle, as expected. In Exp. 3, on Holstein heifers, 4 heifers with no supportive FSH doses ovulated a single follicle, and 50% of those that received 10 mg on d 5, 6 and 7 (n=5) or 30 mg on d 5 and 6 (n=5) exhibited double or triple ovulations. Overall for Exps 1-3: 3.0 medium and 1.8 large follicles were counted on d 4, 2.5 follicles were aspirated on d 5, and 70% of the cows exhibited bilateral ovulations. The results suggest that FSH combined with selective follicular aspiration can be used to induce bilateral twinning in beef cattle.

W215 Effects of holding time prior to freezing on the motility, viability and membrane binding ability of ram sperm. P. H. Purdy*, *USDA-ARS-National Animal Germplasm Program, Fort Collins, CO.*

The United States sheep industry lacks infrastructure to effectively collect and store genetic resources in the national repository. Therefore, we investigated a methodology that could be used to ship diluted ram semen samples that were cooled and held at 5°C for up to 48 hours prior to cryopreservation. Semen samples from 6 rams were collected and the concentration and motility were determined using spectrophotometry and computerized automated semen analysis (CASA), respectively. Samples were diluted to 400 x 10⁶ cells per mL with a one-step Tris-egg yolk-glycerol media and cooled to 5°C over 2 hours using a styrofoam shipping box and commercial cold packs. The samples were maintained at 5°C in the shipping box, and aliquots were loaded into 0.5 mL French straws at 0, 24 or 48 hours after cooling, frozen in vapor 4.5 cm above liquid nitrogen for 12 to 13 minutes and plunged for storage. No differences between freeze times (0, 24, 48 h) were detected using ANOVA in post thaw motility (29, 31, 36%; P > 0.05), plasma membrane integrity (28, 35, 29%; P > 0.05) or live acrosomal integrity (99, 99, 99%; P > 0.05). Motility was assessed using CASA, and plasma membrane integrity and acrosomal integrity were simultaneously determined using the fluorescent stains propidium iodide and FITC-PNA, respectively, with flow cytometry. In addition, no differences were observed in the mean number of cells binding to a chicken oocyte membrane (461, 532, 319; P > 0.05) at time 0, 24 and 48 h, respectively. These results indicate that ram sperm may be held at 5°C for up to 48 hours prior to freezing with no deleterious effects on post thaw motility, plasma membrane integrity and acrosomal integrity. In addition, the chicken oocyte membrane binding assay demonstrates a simple in vitro method to assess post-thaw ram sperm capacitation, acrosome reaction and binding ability. The combination of the shipping protocol and viability testing has the potential to ease the constraint on collecting and freezing ram semen.

Key Words: Ram Spermatozoa, Cryopreservation, Capacitation and Acrosome Reaction

W216 Effects of PGF presynchronization and CIDR on pregnancy rates in suckled beef cattle subjected to fixed-time insemination following estradiol and progesterone treatment to synchronize follicular growth, and PGF and estradiol cypionate treatment to synchronize ovulation. J. A. Small*¹, M. G. Colazo², J. P. Kastelic³, and R. J. Mapletoft². ¹*Agriculture and Agri-Food Canada, Brandon, Manitoba*, ²*WCVM-University of Saskatchewan, Saskatoon, Canada*, ³*Agriculture and Agri-Food Canada, Lethbridge, Alberta.*

The objective was to determine effects of presynchronization and controlled-release progesterone on pregnancy rate in beef cattle subjected to a synchronization program based on estradiol, progesterone

(P4) and PGF treatment for AI without estrus detection (TAI). Cross-bred suckled beef cattle (n = 288) at 47 ± 14.8 d (mean ± standard deviation) post-partum were allocated to three treatment groups on the basis of parity (n=78, 66, 41, and 79 for Lactations 1, 2, 3 to 4 and 5 to 10, respectively), body weight (range 416 to 842 kg), and body condition score (range 3.5 to 6.0). All cattle were treated with 2.5 mg estradiol-17β and 100 mg progesterone (P4; both from Sigma Chemical Co, St. Louis, MO) im on Day 0 and 500 ug cloprostenol sodium (PGF; Estrumate, Schering-Plough, Pointe Claire, QC) and 0.5 mg estradiol cypionate (ECP; Professional Veterinary Laboratories, Winnipeg, MB) im on Day 7, with AI 56 h later (TAI Day 9.3). Experimental treatments were CIDR (1.9 g P4; Bioniche Animal Health, Belleville, ON) for 7 d on Day 0 (Groups 1 and 3), and PGF on Day -7 (Groups 2 and 3). All AI utilized frozen-thawed semen with proven fertility. From Days 11 to 54, the cattle were exposed to fertile bulls and frequently observed for estrus and breeding. Pregnancy was diagnosed by ultrasonography (Day 54) and transrectal palpation (Day 129). There was no interaction of parity and treatment (P>0.05). Pregnancy rate to TAI was lowest (P<0.05) for Group 2 (46.9, 31.2, and 45.3% for Groups 1, 2 and 3, respectively). Pregnancy rate to natural service was greatest (P<0.05) for Group 2 (46.9, 64.6 and 45.3%); most breedings occurred from 17 to 24 d after TAI (85.2, 59.1, and 72.4%; P>0.05). Cumulative pregnancy rates were similar (P>0.05) among groups (93.8, 95.8 and 90.6%). Pregnancy rate to TAI was significantly increased with a CIDR, but was not significantly affected by PGF presynchronization.

Key Words: Estrus Synchronization, Fixed-Time AI, Beef Cattle

W217 Effect of presynchronization with GnRH on fertility of holstein dairy heifers receiving synchronization of ovulation and timed artificial insemination (TAI). H. Rivera* and P. M. Fricke, *University of Wisconsin, Madison.*

To evaluate the effect of presynchronization with GnRH on the response of heifers receiving a hormonal protocol for synchronization of ovulation and TAI, Holstein dairy heifers (n=166) 14.9 ± 0.2 mo of age were randomly assigned to each of two treatments. Heifers (n=82) in the first treatment (GPG) received a hormonal protocol for synchronization of ovulation and TAI (100 µg GnRH, d 0; 25 mg PGF_{2α}, d 6; 100 µg GnRH+TAI, d 8), whereas heifers (n=84) in the second treatment (GGPG) received the same treatment as GPG heifers but with the addition of 100 µg GnRH 7 d before the first GnRH injection of the protocol (d -7). Artificial insemination before scheduled TAI on d 8 was conducted for heifers in both treatments based on once daily assessment of removed tail chalk beginning on d 0. Although presynchronization increased (P<0.05) the proportion of heifers with ≥ 2 CL on d 0 (30% 25/84 vs. 5% 4/81), the proportion of heifers ovulating after the first GnRH injection on d 0 (39%, 31/80 vs. 40%, 32/80), the proportion of heifers undergoing luteal regression after PGF_{2α} on d 6 (89%, 58/65 vs. 94%, 64/68), the proportion of heifers ovulating after the second GnRH injection on d 8 (87%, 66/76 vs. 85%, 66/78), the proportion of heifers receiving AI before TAI (9.5%, 8/84 vs. 4.9%, 4/82), and conception rate 30 d after AI (51%, 43/84 vs. 45%, 37/82) did not differ between GGPG vs. GPG heifers, respectively. Serum progesterone (P4) concentration on d 0 was greater (P<0.05) for heifers with > 1 CL (3.9 ng/ml) compared to heifers with one CL (2.8 ng/ml); however, serum P4 did not differ at the PGF_{2α} injection on d 6 based on CL number (3.8 vs 3.6 ng/ml). In conclusion, presynchronization with GnRH 7 d before initiation of synchronization of ovulation using GnRH and PGF_{2α} failed to decrease the proportion of heifers expressing estrus during the protocol and did not improve synchronization response or fertility to the protocol. *Supported by Hatch project WIS04431 to PMF*

Key Words: Dairy Heifers, Synchronization of Ovulation, Timed Artificial Insemination

W218 Effect of termination of pregnancy on serum concentrations of pregnancy associated glycoproteins in beef cows. D. C. Busch*, J. A. Atkins, D. J. Schafer, J. F. Bader, D. J. Patterson, T. E. Parks, J. A. Green, and M. F. Smith, *University of Missouri, Animal Science Research Center, Columbia.*

Pregnancy associated glycoproteins (PAGs) are produced by binucleate cells in the ruminant placenta and have been used to diagnose pregnancy in cattle from d 27 post insemination to term. Previous studies indicate that PAGs have a half-life of approximately 8 d following calving; however, we hypothesized that the half-life would be shorter during early

gestation. The objective was to determine the half-life of bovine PAGs following prostaglandin $F_{2\alpha}$ (PGF)-induced abortion on d 32 to 36 post insemination. Twenty-five crossbred cows were artificially inseminated and allotted to a control (n = 10) or PGF (n = 15) group by age, breed, and days post AI. Blood samples were collected, via venipuncture, from cows every other day from approximately d 20 (d 0 = estrus) to d 28 post AI, daily from d 29 to PGF injection, and every 8 h from PGF injection until serum concentrations of PAGs decreased below the pregnancy-detection threshold of the assay. The uteri of all cows were examined by transrectal ultrasonography at d 30 and at the time of each blood sample following PGF injection to determine the time the fetal heartbeat stopped and when the embryo was expelled from the uterus. Serum concentrations of PAGs were determined by ELISA and were first detected between d 24 and 28 post AI. Serum concentrations of PAGs increased similarly in the control and PGF groups from d 28 to the time of PGF injection. Following PGF treatment (0 h), serum concentrations of PAGs decreased ($P < 0.05$) by 32 h and remained low through 144 h. The half-life of PAGs (mean \pm SD) following PGF treatment was 59.7 \pm 36.4 h (range 32 to 180 h). Interval (mean \pm SD) from PGF injection to loss of fetal heartbeat, loss of embryo, and estrus was 50.5 \pm 9.3 h, 60.7 \pm 10.1 h, and 97.1 \pm 12.1 h, respectively. In summary, the half-life of PAGs (d 32 to 40) was determined to be 2.5 d and may provide an alternative method to transrectal ultrasonography for monitoring late embryonic/fetal mortality.

Key Words: Pregnancy, Prostaglandin, Beef Cattle

W219 Use of supplemental GnRH following timed-insemination on pregnancy rates in dairy cattle exposed to mild heat stress or cool season environments. T. Dickerson*, K. Graves, J. White, S. Bowers, A. Denson, S. Schmidt, and S. Willard, *Mississippi State University, Mississippi State.*

Reproductive efficiency in dairy cattle decreases when animals are exposed to heat-stress conditions. Studies were conducted in the summer and fall seasons of 2003 to evaluate the efficacy of supplemental GnRH injections post-breeding on pregnancy rates in lactating dairy cattle. Lactating dairy cows in Summer (n=44) and Fall (n=74) were synchronized using the Ovsynch protocol, bred (TAI), and assigned to one of three GnRH treatment groups: Control (CON; no GnRH post-TAI), GnRH on d 5 & 11 post-TAI (GnRH-5/11), or GnRH on d 5 post-TAI (GnRH-5). Blood samples were collected on specified days throughout each trial for evaluation of serum concentrations of progesterone (P4). Ultrasonography was performed on d 5, 11, and 17 post-TAI on a subset of cows (n=8/treatment) for both studies for determination of CL area and number. Ambient temperature and relative humidity were collected daily at 10 min intervals for calculation of temperature-humidity index (THI). Overall Summer THI (24-h) was 77 (mild heat stress). No differences ($P > 0.10$) were observed for serum concentrations of P4, CL area, and CL number with respect to treatment. Pregnancy rates for CON, GnRH-5/11, and GnRH-5 were 7.0%, 20% and 29% respectively with no differences ($P > 0.10$) relative to treatment. Retrospective analysis of P4, and removal of cows (n=11) failing to respond to Ovsynch, resulted in an adjusted pregnancy rate of 13%, 23% and 33 %, respectively. Fall THI (24-h) was 52 (no heat stress). On D14 post-TAI, GnRH-5/11 cows had higher ($P < 0.05$) serum P4 than CON, but did not differ ($P > 0.10$) from GnRH-5 cows. On D17 post-TAI, GnRH-5/11 cows had higher ($P < 0.05$) CL numbers than either CON or GnRH-5 cows. CL area was greater ($P < 0.05$) for GnRH-5/11 than CON cows, but did not differ ($P > 0.10$) from GnRH-5 cows on D17 post-TAI. Pregnancy rates for CON, GnRH-5/11, and GnRH-5 were 33%, 19% and 33% respectively, with no treatment differences ($P > 0.10$). In summary, supplemental GnRH influenced reproductive function (P4, CL number and area) in Fall cows (GnRH 5/11 group). However, overall pregnancy rates were not significantly improved by GnRH treatment in Summer or Fall.

Key Words: GnRH, Progesterone, Pregnancy

W220 Effect of prolonged in vivo incubation of sperm from high and low fertility bulls on pregnancy survival in lactating dairy cows. M. W. Macfarlane*, B. J. Macfarlane*, and J. R. Pursley, *Michigan State University, East Lansing.*

Fertility of lactating dairy cows is altered by timing of AI in relation to ovulation. However, it is not clear how bull fertility affects this relationship. This study was designed to determine the effect of prolonged in

vivo incubation of sperm from high and low fertility bulls on pregnancy rates and pregnancy survival in lactating dairy cows. All cows (n = 907) received Ovsynch to precisely control ovulation. Cows were inseminated at either 8 h prior to (treated), or 16 h after (control), the final injection of GnRH of Ovsynch. Therefore, treated and control cows received AI approximately 36 and 12 h prior to ovulation, respectively. Based on ultrasound examinations, only cows with synchronized ovulations were used in the study. Cows were assigned to treatments based on parity and days in milk (DIM). Bulls (n=5) were selected based on estimated relative conception rate (ERCR: + 4 or -4) and were assigned equally to cows in each treatment by parity and DIM. Ultrasonography was used to diagnose pregnancy at 28 and 56 d after AI. Outcomes were pregnancy rate / AI (PR/AI; %) at, and pregnancy survival (%) between, 28 and 56 d post-AI. Semen (n = 5 straws per bull) was randomly chosen and evaluated post-thaw for numbers of live sperm and percent motility. There was an effect of bull on PR/AI at ($P < 0.01$), and pregnancy survival between ($P < 0.01$), 28 and 56 d post-AI. PR/AI (%) and pregnancy survival (%) was decreased in the bull with the lowest overall fertility in treated vs. controls (10 vs. 25 and 58 vs. 86, respectively), but was not affected in the bull with the highest overall fertility (45 vs. 44 and 91 vs 98, respectively). Numbers of live sperm per straw, percent motility, and total live motile sperm were different between bulls ($P < 0.01$). There were strong correlations between PR/AI and pregnancy survival ($R = 0.68$) and % motility and PR/AI ($R=0.71$). In summary, prolonged in vivo incubation of sperm prior to ovulation appears to have a negative impact in low but not high fertility bulls. It appears that pregnancy losses may be predetermined at the time of fertilization.

Key Words: Dairy, Fertility, Timing of AI

W221 Synchronization of beef heifers using CIDR with estradiol cypionate. D. M. Kniffen*¹, B. M. Neely¹, P. R. Tozer², and M. L. O'Connor¹, ¹*Penn State University, University Park*, ²*Western Australian Department of Agriculture, Geraldton, WA.*

Improving the success rate of estrous synchronization programs may increase the use of artificial insemination (AI) in the beef industry. The time and effort required to detect estrus in beef females continues to be a roadblock to increased use of AI. Introduction of an intravaginal progesterone insert (CIDR) has provided an effective method of estrous synchronization. Improving the synchrony of estrus following CIDR removal without sacrificing fertility will further reduce the time commitment for an effective AI program. The objective of this study was to determine if synchrony of estrus following a CIDR protocol could be enhanced by administration of 2 mg estradiol cypionate (ECP) at CIDR insertion. Seventy Angus and Angus-based crossbred beef heifers of breeding age and weight received a CIDR device on d 0. On d 7, the CIDR was removed and PGF₂ α (25 mg) was administered. The treatment group (n=35) received ECP. Heifers were observed for estrus for 30 min at 2 h intervals for 72 h following CIDR removal. All heifers were inseminated by a professional technician soon after observed in estrus, generally within 12 h. The percentage of heifers observed in estrus within 72 h did not differ ($P > 0.10$) between treatment (74%) and control (71%) groups. First service conception rates (49%) did not differ ($P > 0.10$). However, the average interval to onset of estrus following CIDR removal differed ($P < 0.05$; 45 h for treated vs 51 h for controls). ECP induced an earlier expression of estrus without affecting conception rate.

Key Words: Synchronization, Heifers, CIDR

W222 Synchronization of estrus in suckled beef cows using GnRH, prostaglandin $F_{2\alpha}$ (PG), and progesterone (CIDR): a multi location study. J. E. Larson*¹, G. C. Lamb¹, J. S. Stevenson², S. K. Johnson², M. L. Day³, T. W. Geary⁴, D. J. Kesler⁵, J. M. DeJarnette⁶, F. N. Schrick⁷, and J. D. Arseneau⁸, ¹*University of Minnesota, St. Paul*, ²*Kansas State University, Manhattan*, ³*The Ohio State University, Columbus*, ⁴*USDA-ARS*, ⁵*University of Illinois, Urbana*, ⁶*Select Sires, Inc.*, ⁷*University of Tennessee, Knoxville*, ⁸*Purdue University, West Lafayette, IN.*

We determined whether a fixed-time AI (TAI) protocol could yield similar pregnancy rates to a protocol requiring detection of estrus and if adding a CIDR to GnRH + PG-based protocols would enhance fertility. Estrus in 2,630 suckled beef cows from 14 locations was synchronized and artificial insemination occurred after five treatments: 1) a CIDR for 7 d with 25 mg of PG at CIDR removal, followed by detection of estrus and AI for 84 h with any cow not detected in estrus by 84 h receiving

100 µg of GnRH and TAI at 84 h (Control; n = 511); 2) GnRH, followed in 7 d with PG, followed in 60 h by a second injection of GnRH and TAI (CO-Synch; n = 551); 3) CO-Synch plus a CIDR during the 7 d between the first injection of GnRH and PG (CO-Synch+CIDR; n = 547); 4) GnRH, followed in 7 d with PG, followed by detection of estrus and AI for 84 h, with any cow not detected in estrus by 84 h receiving GnRH and TAI at 84 h (Hybrid Synch; n = 513); and, 5) Hybrid Synch plus a CIDR during the 7 d between the first injection of GnRH and PG (Hybrid Synch+CIDR; n = 508). Pregnancy was diagnosed by transrectal ultrasonography and blood samples were collected (d -17 and -7, relative to PG) to determine cycling status. The percentage of cows cycling at the initiation of estrus synchronization was 67%. Pregnancy rates among locations ranged from 39% to 67%. Pregnancy rates were greatest for the Hybrid Synch+CIDR (57.9%) treatment, although not different from the CO-Synch+CIDR (53.6%) and Hybrid Synch (53.0%) treatments, but greater ($P < 0.05$) than the Control (52.3%) and CO-Synch (43.4%) treatments. Controls did not differ from CO-Synch+CIDR or Hybrid Synch. Overall, the Hybrid Synch+CIDR protocol consistently achieved the greatest pregnancy rates; however, CO-Synch+CIDR was a reliable TAI protocol that gives producers the option to eliminate detection of estrus when inseminating beef cows.

Key Words: Estrus Synchronization, Artificial Insemination, Beef Cows

W223 Synchronization of estrus in replacement beef heifers using GnRH, prostaglandin F_{2α} (PG), and progesterone (CIDR): a multi-location study. J. E. Larson^{*1}, G. C. Lamb¹, T. W. Geary², J. S. Stevenson³, S. K. Johnson³, M. L. Day⁴, D. J. Kesler⁵, J. M. DeJarnette⁶, and D. G. Landblom⁷, ¹University of Minnesota, St. Paul, ²USDA-ARS, ³Kansas State University, Manhattan, ⁴The Ohio State University, Columbus, ⁵University of Illinois, Urbana, ⁶Select Sires, Inc., ⁷North Dakota State University, Fargo.

Our objectives were to determine whether a fixed-time insemination (TAI) protocol could yield similar pregnancy rates to a protocol requiring detection of estrus (EAI) and whether an injection of GnRH at CIDR insertion enhanced fertility. Estrus in 2,077 replacement beef heifers from 12 locations was synchronized and AI occurred after four treatments: 1) a CIDR for 7 d with 25 mg of PG on the day of CIDR removal, followed by detection of estrus and AI during 84 h. Heifers not detected in estrus by 84 h received 100 µg of GnRH and were inseminated (EAI; n = 517); 2) heifers were treated and inseminated as EAI heifers but also received GnRH at the time of CIDR insertion (GnRH+EAI; n = 504); 3) heifers received a CIDR for 7 d with PG on the day of CIDR removal, followed in 60 h by a second injection of GnRH and TAI (TAI; n = 531); and 4) heifers were treated and inseminated as TAI heifers but also received GnRH at CIDR insertion (GnRH+TAI; n = 525). Pregnancy was diagnosed by transrectal ultrasonography on d 30 to 35 and blood samples were collected (d 17 and 7, relative to PG) to determine cycling status. Percentage of heifers cycling at initiation of estrus synchronization was 91%, but the percentage of heifers cycling among locations ranged from 78 to 100%. Overall pregnancy rates among locations ranged from 38 to 74%. Pregnancy rates were 57.3, 54.5, 53.1, and 49.1% for GnRH+EAI, EAI, GnRH+TAI, and TAI, respectively. Although no differences in pregnancy rates among treatments were observed, the GnRH+EAI treatment most consistently achieved the greatest pregnancy rates. In addition, the GnRH+TAI protocol provides an alternative to estrus synchronize heifers with TAI as an option without detection of estrus.

Key Words: Estrus Synchronization, Artificial Insemination, Beef Heifers

W224 Ovulatory and reproductive characteristics of sows treated with an intravaginal GnRH agonist gel. K. Roski^{*1}, W. Flowers¹, G. B. Rampack², D. L. Gregor³, M. Swanson³, and H. D. Hafs³, ¹North Carolina State University, Raleigh, ²University of Georgia, Athens, ³EIEICO, Inc, Radnor, PA.

This study was designed to test the ovulatory and reproductive characteristics of sows treated with Ovugel (EIEICO, Radnor, PA), a gel containing a GnRH agonist administered intravaginally. The treatment groups received 100µg of GnRH agonist in varying viscosities of the gel, 0.6% (n=12), 0.9% (n=12), 1.2% (n=12), and 1.5% (n=12) respectively. A positive control group (n=11) received the 100µg of agonist in saline while the control sows received a vehicle of the 1.2% gel at 96h post weaning. Jugular cannulas were placed 48h before administration of the treatment. Blood samples were taken every 6h before treatment,

then every 2h for the first 12h after treatment, then every 6h for the next 18h. Estrus detection occurred every 6h through the entire study as well as real time ultrasonography every 4h to determine the time of ovulation. Control sows were bred based on the onset of estrus (n=9) and treatment sows were bred at +8 and +32h after the gel was administered. There were no differences in treatments in ovulation time (p=0.28), estrus length (p=0.60), farrowing rate (p=0.80), litter size (p=0.35), or LH surge (p=0.49). However, variation associated with ovulation time was significantly reduced (p=0.01) for saline, 1.2%, and 1.5% treatments compared with controls. The intravaginal absorption of GnRH in Ovugel or saline along with a timed insemination program is an effective method to reduce the interval over which ovulation occurs without overtly decreasing fertility.

Treatment	Saline + GnRH	Control	0.6% + GnRH	0.9% + GnRH	1.2% + GnRH	1.5% + GnRH
Ovulation Time (h)	46.5 ±1.2	43.8 ±5.4	43.8 ±2.0	41.2 ±3.3	43.5 ±1.8	44.5 ±1.5
Estrus Length (h)	45.8 ±3.4	45.6 ±3.8	49.0 ±3.8	47 ±3.9	46.9 ±3.9	55.1 ±3.9
LH Surge (0-30h post treatment)	7/10	5/8	7/10	9/11	8/10	8/9
Farrowing Rate	8/8	9/9	11/12	10/12	11/12	10/11
Litter Size	12.9 ±0.7	9 ±1.2	11 ±1.3	11.6 ±1.0	11 ±0.5	10.6 ±1.4

W225 The effects of estradiol cypionate on expression of estrus in a follicular synchronization program. B. Dixon^{*}, D. L. Ray, T. B. Hatler, and W. J. Silvia, Department of Animal Science, University of Kentucky, Lexington.

The objective of this experiment was to determine the effect of estradiol cypionate (ECP) on expression of estrus when used in conjunction with a presynchronization and estrus synchronization program. Ninety lactating Holstein (n=66) and Jersey (n=24) cows in varying stages of lactation were given two injections of PGF_{2α} fourteen days apart to presynchronize luteolysis. Twelve days following the last PGF_{2α} injection, a follicular synchronization program was initiated with an injection of GnRH (100µg, Factrel, Fort Dodge Animal Health), followed seven days later by PGF_{2α} (25mg, Lutalyse, Pfizer). Half of the cows were then assigned to receive an injection of ECP (1mg, Pfizer) 24 hours after the last PGF_{2α} injection. The other half received no ECP. Venous blood samples were collected three times per week for three weeks during the final phase of the synchronization for determination of progesterone levels. These samples were used to monitor luteolysis and formation of a new corpus luteum. Presynchronization failed to adequately synchronize the cycle of 31 out of 90 cows. ECP had a significant effect on expression of estrus among cows that were successfully presynchronized and ovulated. Of those cows that were properly synchronized for breeding, 100% (28/28) of cows treated with ECP expressed estrus, while only 81.8% (18/22) of untreated animals did so (P=.0318). For animals that fully regressed their corpus luteum and ovulated, expression of estrus was more tightly synchronized among cows receiving ECP (90.3% (28/31) expressing heat between 29 and 53 hours post ECP) than those that did not (53.9% (14/26)) (P=.0025). Of the 46 cows that appeared endocrinologically normal, expressed estrus and were bred, 15 conceived (32.6%). ECP had no effect on conception rate. The postovulatory rise in progesterone appears to be slower in nonpregnant animals than pregnant animals, with pregnant cows reaching progesterone levels 1.0 ng/mL higher 12 days after the final PGF_{2α} than animals that failed to conceive (P=.01). In conclusion, the addition of ECP to a synchronization program improves expression of estrus among cows that were successfully synchronized for breeding.

Key Words: Synchronization, ECP, Estrus Expression

W226 Influence of milk production on conception following artificial insemination or embryo transfer in lactating Holstein cows. D. G. B. Demetrio^{*1}, J. L. M. Vasconcelos¹, C. A. Rodrigues², and J. R. Chiari², ¹FMVZ-UNESP, ²Samvet Clínica e Embrios, Brazil.

The aim of this trial was to evaluate conception following artificial insemination (AI) or embryo transfer (ET) in lactating Holstein cows. The trial was conducted at a dairy farm located in Descalvado, Sao Paulo, Brazil from October to December of 2003. Cycling cows (n=251) producing 33.5±7.2 kg milk/d with 174.4±116.2 DIM received PGF2α (Lutalyse[®], 25 mg, i.m.) and were assigned to two groups. Cows detected in estrus between 48 and 96h after PGF2α injection (n=106) were divided into: G1 (n=57); AI 12h after heat detection, or G2 (n=49); ET 6 to 8 d after detection of estrus. All cows from G2 received fresh embryos (grade 1 or 2) that were transferred by one trained technician. Milk production was measured daily, and the average of 7 d of production was used for analysis (starting on the day of the estrous detection). Pregnancy was detected 25 to 32 d after estrous detection by ultrasonography (Aloka SSD-500). Data were analyzed by a general linear models (GLM) procedure. Variables included in the model were milk production, previous number of AI, DIM, body temperature at d 7 and interactions. Conception was affected by treatment (P=0.07) and the adjusted results were 31.6±10.1% in G1 (IA) and 54.4±9.6% in G2 (TE). An interaction between milk production and treatment was detected (P<0.05). Cows with milk production under the average (33.5 kg milk/d) had similar conception rates: 49.1±14.1% (n=26) in G1 (IA) and 40.1±13.6% (n= 24) in G2 (TE). Cows over the average had different conception rates: 14.0±14.1% (n= 31) in G1 (IA) and 68.7±16.7% (n= 25) in G2 (TE). Variables included in the model: previous number of AI, DIM and body temperature at d 7 did not affect conception, but milk production had adverse influence on AI conception rate, but not on ET. This study suggests that embryo transfer can be used as a tool to increase conception rate in high milk production cows, rather than only on repeat breeder cows. This data also shows that milk production effects on conception could occur during the 7 d after ovulation.

Key Words: Embryo Transfer, Artificial Insemination, Milk Production

W227 Follicular diameter in postpartum Nellore cows treated with CRESTAR protocol. G. C. Perez^{*}, R. M. Santos, J. L. M. Vasconcelos, E. T. N. Pereira, and D. B. Araujo, DPEA-FMVZ-UNESP, Botucatu, SP, Brazil.

The CRESTAR[®] protocol consists of a 9-d ear implant (3mg of norgestomet) combined with injection of estradiol valerate (5mg) and norgestomet (3mg) at the time of implant insertion. The objective of this study was to evaluate if body condition score (BCS), parity and cyclicity affects follicular diameter at the time of implant removal. Nellore cows (n = 415) averaging 119 ± 39.7 d postpartum, and with a BCS between 2.25 to 3.50 (1 to 5 scale), were maintained on pasture (*Brachiaria decumbens*) with mineral provided ad libitum. Ovarian structures were evaluated by transrectal ultrasonography using a B-mode scanner with a 7.5 MHz linear array transducer (Aloka SSD-500, Wallingford, CT). Cyclicity was determined before the beginning of the protocol by two ultrasound examinations 10 d apart. Cows showing luteal tissue at one of the exams were considered to be cycling. Follicular diameter and BCS were evaluated at the time of implant removal. Data were analyzed by a general linear models (GLM) procedure, and the variables included in the model were BCS, cyclicity, and parity. BCS influenced (P<0.05) follicular diameter at the time of the implant removal: 2.5 (8.9 ± 0.28mm; n = 78); 2.75 (9.5 ± 0.22mm; n = 137); 3.0 (9.5 ± 0.25mm; n = 109); 3.25 (10.2 ± 0.34mm; n = 55); 3.5 (9.7 ± 0.42mm; n = 36). Follicular diameter was not affected by parity [9.4 ± 0.27 mm in primiparous cows (n=87) vs 9.7 ± 0.14 mm in multiparous cows (n=328)] nor by cyclicity [9.7 ± 0.20mm in anestrus cows (n=201) vs 9.4 ± 0.20mm in cycling cows (n=214)]. Cows with lower BCS had smaller follicular diameter at the time of implant removal. Mechanisms controlling this phenomenon may be related to the injection of estradiol valerate which could delay the emergence of a new follicular wave by suppressing FSH or LH secretion and cause turnover of the dominant follicle in thin cows. Data suggest that cows with a low BCS may require a longer ear implant period and/or a smaller dose of estradiol valerate at the beginning of the CRESTAR[®] protocol.

Key Words: CRESTAR, Follicular Diameter, Nellore Cows

W228 Serum progesterone concentrations in Nellore x Angus heifers treated with 1.38-g or 1.9-g CIDR devices. R. M. Santos^{*1}, J. L. M. Vasconcelos², G. C. Perez², A. B. B. Maciel², and O. G. Sa Filho², ¹FCAV-UNESP, Jaboticabal, SP, Brazil, ²FMVZ-UNESP, Botucatu, Brazil.

The aim of this study was to determine serum concentrations of progesterone (P4) during treatment with intravaginal devices containing either 1.38 g or 1.9 g of P4 for 25 d. Estrous cycles of Nellore x Angus heifers (n=26) were presynchronized using a modified Ovsynch protocol (GnRH - 50µg - 6d - PGF2α - 25mg - 48h GnRH - 50µg). Seven days after the second injection of GnRH, synchronized heifers (n=18) received PGF2α and 24 h later were assigned to either G1 (n=9; CIDR[®] 1.38 g) or G2 (n=9 CIDR[®] 1.9 g). Only heifers that had a regressed CL (determined by P4 concentrations on d 6, 7, 7.5 and 8) were used (5 heifers in G1 and 7 in G2). Serum P4 concentrations were quantified by RIA. Peak concentrations of P4 were evaluated at 0, 1, 4, 8 and 12 h after CIDR insertion, and every other day for 25 d. The decline in concentrations of P4 d was evaluated at 0, 1, 4 and 8 h after CIDR removal. Data were analyzed by a general linear models (GLM) procedure. Two cows from G2 lost the CIDR (at d 8 and 25, respectively) and were excluded from the analysis. Serum concentrations of P4 peaked within 1 h after device insertion, with peak concentrations higher (P<0.05) for G1 (10.2±1.21ng/mL) than for G2 (6.8±1.02ng/mL). Within 4 h concentrations of P4 were similar for G1 (6.3±0.64ng/mL) and for G2 (6.0±0.54ng/mL) and thereafter through d 25. Concentrations of P4 ranged from 2-3 ng/mL between d 1 and 8 for G1 and until day 11 for G2, and then from 1-2 ng/mL until the day of insert removal. On d 25, mean concentrations were 1.02±0.12ng/mL and 1.12±0.12ng/mL for G1 and G2, respectively. The decrease in P4 concentrations after insert removal was similar between groups. One hour after insert removal, P4 concentrations were 0.3±0.04ng/mL and 0.2±0.04ng/mL in G1 and G2, respectively. Although the 1.38-g CIDR produced a lower overall serum P4 concentration, the peak in P4 concentrations 1 h after CIDR insertion was higher than for the 1.9-G CIDR. This might be important in synchronization protocols, as rapid changes in circulating concentrations of P4 could affect LH pulsatility and turnover of the dominant follicle.

Key Words: CIDR, Progesterone, Beef Heifers

W229 Prolonged in vivo incubation of sperm affects fertility of lactating dairy cows and gender ratio of resulting offspring. M. W. Macfarlane^{*}, B. J. Macfarlane^{*}, and J. R. Pursley, Michigan State University, East Lansing.

The chance of a female calf being born is less than that of a male calf (female: male ratio of calves born is 46:54); and only 85% of female calves that are born successfully begin their first lactation. Therefore, increasing numbers of females available for herd replacement and marketing may increase sustainability and profitability of dairy enterprises. This study was designed to determine if prolonged in vivo incubation of sperm increases the percentage of female calves born. Lactating dairy cows (n=1606) from 3 farms received Ovsynch to precisely control ovulation. Cows were inseminated either in the uterine body or uterine horn ipsilateral to the ovary with the predicted pre-ovulatory follicle at either 8 h prior to (-8 group), or 16 h after (+16 group), the final injection of GnRH of Ovsynch (2 x 2 design). Therefore, cows in the -8 and +16 h groups received AI approximately 36 and 12 h prior to ovulation, respectively. Based on ultrasound examinations, only cows with synchronized ovulations were used in the study. Cows were assigned to treatments based on parity and days in milk (DIM). Ultrasonography was used to diagnose pregnancy at 28 and 56 d after AI. Outcomes were pregnancy rate/AI (PR/AI; %) at, and pregnancy survival (%) between, 28 and 56 d post-AI, and gender of resulting offspring. There was no effect of site of AI on PR/AI, so uterine body and uterine horn groups were combined within -8 and +16 groups. Overall, a greater % of female calves were born in the -8 h vs. +16 groups (55 vs. 45; P < 0.05). Farms 1 and 2, collectively, had greater (P < 0.05) % females born compared to farm 3 in both the -8 and +16 h groups (68 and 56 vs. 49 and 40, respectively). The +16 h group had a greater (P < 0.01) PR/AI (39 % vs. 29 %) than the -8 h group. Pregnancy survival (%) between 28 and 56 d post-AI was similar between 8 and +16 (80 vs. 83, respectively) but was greater in cows receiving uterine body vs. uterine horn AI (85 vs. 79, respectively). In summary, prolonged in vivo incubation of sperm

prior to ovulation appears to improve female:male ratio of calves born, but reduces fertility.

Key Words: Gender Ratio, Timing of AI, Pregnancy Rate

W230 Effect of eCG and/or calf removal after CRESTAR protocol in Nellore cows. G. C. Perez*, J. L. M. Vasconcelos, R. M. Santos, E. T. N. Pereira, and O. G. Sa Filho, DPEA-FMVZ-UNESP, Botucatu, SP, Brazil.

The CRESTAR[®] protocol consists of an ear implant (3mg norgestomet) for 9 days associated with an injection of estradiol valerate (5mg) and norgestomet (3mg) at implant insertion. The aim was to evaluate the effects of eCG injection at implant withdraw and/or calf removal (CR) between implant withdraw and TAI. Nellore cows (n=415) with 119±39.7 days postpartum (DPP), body condition score (BCS) between 2.25 to 3.5 (1-5) were assigned to 4 groups in 2x2 factorial (eCGxCR): G1(n=105) CRESTAR; G2(n=102) CRESTAR + CR (58h); G3(n=104) CRESTAR + eCG (Folligon[®], 400UI) at implant removal and G4(n=104) CRESTAR + eCG at implant removal + CR (58h). TAI was performed in the 4 groups 50-58 h after implant removal. Ovarian structures and pregnancy were evaluated by ultrasound (Aloka SSD-500). Cyclicity was determined before the beginning of the protocol by 2 ultrasound examinations 10 days apart. Follicular development was determined by the difference between the follicle diameter on day of AI and on implant removal. Data were analyzed by general linear models, and parameters included in the model were DPP, CR, eCG, BCS, cyclicity, parity, calf gender and interactions. Cows that received eCG had better follicular development (1.8±0.2 vs. 1.2±0.1mm; P<0.01), higher estrus detection before TAI (42.1 vs. 26.4%; P<0.01), and higher synchronization rate (75.3 vs. 64.5%; P<0.05) than cows that did not received eCG. Calf removal did not affect these parameters. Conception at TAI was not affected by eCG (53.6% in treated cows vs. 50.3% in not treated) and by CR (51.2 with CR vs. 52.7% without). Independent of the treatment, BCS did not affect synchronization rate but influenced (P<0.05) conception at TAI (2.25 59.4%; 36.2%; 2.5 68.2%; 44.1%; 2.75 71.8%; 45.9%; 3.0 77.7; 58.8%; 3.25 74.1%; 57.2%; 3.5 68.1; 69.3%) respectively. The data suggest that eCG treatment improves synchronization rate by keeping the follicular development between implant removal and TAI, but not conception at TAI probably due to the negative effects of BCS in conception are higher than positive effects of eCG treatment.

Key Words: CRESTAR, Synchronization, Nellore

W231 Assessment of pregnancy in the mare using digital infrared thermography. S. Bowers*, S. Gandy, B. Anderson, P. Ryan, and S. Willard, Mississippi State University, Mississippi State.

Digital infrared thermal imaging (DITI) is a non-invasive diagnostic technique that is used to detect symmetry and asymmetry in surface temperature gradients. The objective of this study was to investigate the use of DITI to determine whether temperature differences exist between pregnant and nonpregnant mares. On the day measurements were obtained, each pregnant mare (n=10; beginning at 292.4 ± 1.4 d of gestation) was paired with a nonpregnant mare (n=17). Mares were normalized to environmental conditions prior to imaging. Ambient (AMB) temperature, DITI measurements (left and right flank and wither temperatures and background temperature), and rectal temperatures (RT) were obtained every 7 d for 5 weeks before parturition. Measurements were obtained beginning in March and continued through May with AMB temperatures ranging from 4.2 °C to 28.9 °C. There were no differences (P>0.10) in temperature of the left and right side within group (pregnant vs. nonpregnant) therefore data were pooled within group for analysis. Background temperature was positively correlated with flank and wither temperature (R=0.48, R=0.58, respectively; P<0.01) and was positively correlated with AMB temperature (R=0.92; P<0.01). RT tended to be positively correlated with AMB temperatures (R=0.32; P<0.10) but were not correlated to flank or wither temperatures. Pregnant mares had a higher (P<0.01) flank temperature than the nonpregnant mares (36.0 ± 0.2°C vs. 34.2 ± 0.2°C, respectively). Moreover, the difference (2.4°C) in flank temperatures between the pregnant and nonpregnant mares was greater when the AMB temperature dropped below 19°C. Flank temperature and wither temperature were positively correlated with one another (R=0.72; P<0.01) and were positively correlated with AMB temperature (R=0.48, R=0.64, respectively; P<0.01). However, wither temperatures did not differ (P>0.10) between the pregnant

(33.9 ± 0.6°C) and nonpregnant mares (33.8 ± 0.3°C). In conclusion, pregnant mares had higher flank temperatures than nonpregnant mares regardless of environmental conditions. This suggests that DITI measurements may have value in detecting or confirming pregnancy (late gestation) in some species.

Key Words: Thermography, Equine, Pregnancy

W232 Optimizing sperm concentration to maximize monospermy and minimize polyspermy with bovine *in vitro* fertilization. M. Barcelo-Fimbres* and G. E. Seidel, Jr., Colorado State University, Ft Collins.

We evaluated sperm concentrations and times of fertilization for bovine IVF. Slaughterhouse oocytes were matured in a chemically defined medium (CDM) similar to SOF (J. Anim. Sci. 78:152) plus 0.5% fatty acid-free BSA and hormones (M-CDM) for 23 h, at 38.5°C in 5% CO₂ in air. Then oocytes and frozen-thawed sperm, centrifuged through a Percoll gradient, were co-cultured for 4 or 18h in F-CDM (CDM + heparin). Presumptive zygotes were cultured in CDM-1 (CDM + nonessential amino acids (NEAA), 0.5 mM glucose and 10 μM EDTA) at 38.5°C in 5%CO₂ /5%O₂ /90%N₂. After 5 h, half of the presumptive zygotes were fixed and stained with aceto-orcein to evaluate fertilization (FR) and polyspermy (PS). After 48h the rest were cultured 120h in CDM-2 (CDM + NEAA and essential amino acids and 2 mM glucose). Oocytes (N=960) were randomly allocated to a 2 x 3 x 4 factorial design: time of fertilization (4 and 18 h), sperm dose (1, 0.33, and 0.11 x 10⁶ sperm/mL), and sperm source (4 bulls). Percentages were arcsin transformed and analyzed by ANOVA. Respective main effect means for 1, 0.33, and 0.11 x 10⁶ sperm/mL were: FR (72%, 62% vs. 42%); cleavage (CR) (89%, 81% vs. 58%); PS (24%, 2% vs. 0%); and blastocysts/oocyte (BR) (17%, 21% vs. 9%) (all P<0.01). There was a difference (P<0.01) between 18 and 4 h in FR (69% vs. 48%), PS (13% vs. 4%), and CR (62% vs. 54%), respectively. The bull effect was not significant (P >0.05) for FR (53%, 57%, 62%, 62%), or PS (8%, 9%, 8%, 10%), but CR were higher (P <0.01) for 3 of the bulls (83%, 80%, 76% vs. 58%), and the BR was higher (P<0.05) for two bulls (20%, 20%, vs. 10%, 10%). FR and CR were correlated, r² =0.62. Parthenogenetic, control cleavage (4.1%) stopped at the 8-cell stage. The optimal sperm concentration was 0.33 x 10⁶ /mL. The higher dose caused considerable PS; although the lower concentration decreased PS, it also decreases FR. The longer fertilization time resulted in a higher FR, but more PS.

Key Words: Bovine, IVF, Polyspermy

W233 Fixed-time insemination utilizing an Eazi-BreedTM CIDR[®] in combination with gonadotropin-releasing hormone or estradiol cypionate. K. J. Stutts*¹, D. W. Forrest¹, and C. R. Looney², ¹Texas A&M University, College Station, ²OvaGenix, Navasota, TX.

The objective of this study was to evaluate the efficacy of four estrus synchronization protocols utilizing an intravaginal progesterone-releasing device (CIDR) in combination with estradiol cypionate (ECP) or gonadotropin-releasing hormone (GnRH) on conception rate to a fixed-time insemination in beef heifers. Angus-cross heifers (n=1906) that averaged 13 mo of age and 320 kg BW were randomly assigned to one of four treatments. Treatment (TRT) 1 heifers received a CIDR insert and ECP (1 mg i.m.) on d 0. PGF_{2α} (25 mg) was injected (i.m.) and CIDRs were removed on d 9. A second injection of ECP (0.5 mg) was administered on d 10 and heifers were fixed-time inseminated on d 11. TRT 2 heifers received the same hormonal regimen as TRT 1 except that CIDRs were removed and PGF_{2α} was injected on d 7 followed by the second injection of ECP on d 8 and insemination on d 9. TRT 3 heifers received a CIDR insert and GnRH (50 μg i.m.) on d 0. PGF_{2α} (25 mg) was injected and CIDRs were removed on d 7. A second injection of GnRH (50 μg) was administered and the heifers were inseminated on d 9. TRT 4 heifers received the same hormonal regimen as TRT 3 except that PGF_{2α} was injected on d 6. Beginning 14 d after insemination, heifers were exposed to fertile bulls for 60 d. Conception to the timed insemination was determined by transrectal ultrasonography 30 d after bull removal. Conception rates to fixed-time insemination were different (P<.02) across all treatments. Conception rates to fixed-time insemination for TRT 1, 2, 3, and 4 were 32.4%, 19.6%, 43.2%, and 50.4%, respectively. Overall pregnancy rates for TRT 1 (84.6%), 3 (89.0%), and 4 (87.7%) were higher (P<.0001) than TRT 2 (69.8%). These data indicate that conception rates to timed AI were higher for the CIDR

protocols with GnRH than with ECP, and that injecting PGF_{2α} on d 6 rather than d 7 when using the GnRH/CIDR protocol resulted in a higher conception rate to fixed-time insemination. *Supported by Pfizer Animal Health.*

Key Words: Estrus, Synchronization, Heifers

W234 Deep uterine horn AI improves fertility of lactating dairy cows. J. R. Pursley*, *Michigan State University, East Lansing.*

Currently, fertility levels of lactating cows are approximately 50 % of heifers. This study was designed to determine if fertility of lactating dairy cows could be increased if semen was deposited in the uterine horns compared to the uterine body. Lactating Holstein cows (n=833) from 3 farms were randomly assigned to receive AI in either the uterine body or in the uterine horn by splitting the straw between both horns and depositing the semen near the greater curvature of each horn. Cows were assigned to the two treatments by DIM and parity. Cows received AI following a detected estrus or following Ovsynch (GnRH, 7 d PGF, 48 h GnRH, 16 h AI). Technicians from each farm received training in uterine horn AI prior to the start of the trial. Pregnancy was determined by the farm veterinarian between 35 and 65 d post-AI. Pregnancy rate/AI was greater (P < 0.01) in the uterine horn group compared to uterine body (50 vs. 35 %). There was no effect (P > 0.05) of parity or DIM on pregnancy rate/AI. Pregnancy rate/AI was similar (P > 0.05), and there was no effect (P > 0.05) of treatment, between AI following Ovsynch vs. AI following detected estrus. There was an effect (P < 0.05) of farm on pregnancy rates/AI, but there was no treatment by farm interaction (P = 0.89). All farms had increases in pregnancy rates/AI in cows inseminated in the uterine horns and ranged from 26 to 43 %. In summary, uterine horn AI appears to increase pregnancy rates/AI in lactating dairy cows.

Key Words: Uterine Horn AI, Fertility, Dairy Cows

W235 Addition of ECP or calf removal to a modified MGA + CO-Synch protocol for synchronization of ovulation in beef cows. S. K. Johnson, K. R. Harmoney, and J. S. Stevenson*, *Kansas State University, Manhattan.*

A study was conducted in 735 suckled beef cows to determine if synchronization of ovulation could be improved with estradiol cypionate (ECP) or 48 h calf removal in a modified MGA + CO-Synch protocol. All cows were fed MGA (0.5 mg·hd⁻¹) daily for 14 d (d -32 to -19) and received GnRH (100 µg) on d -7, PGF (25 mg) on d 0, and one fixed time AI at 72 h after PGF. Treatments were applied in a 2 x 2 factorial arrangement of four treatments. Calves either remained with cows (S) or were removed for a 48 h period (CR), beginning 24 h after PGF until after the fixed time AI. Cows either received ECP (E; 1 mg) at 24 h after PGF or GnRH (G; 100 µg) concurrent with fixed time AI. Concentrations of progesterone (P4) were determined in serum samples collected on d -17, -7, 0, and 3. If P4 was ≥ 1 ng·ml⁻¹ on d -17 and/or d -7, cows were classified as cycling. Three locations were studied in year 1 and 2 locations were repeated in year 2. Pregnancy rate to AI (PR) was determined by transrectal ultrasonography on d 33 to 35. The interaction of location nested within year by treatment was significant. The combination of E and S was the least variable of the 4 treatments, with PR ranging from 40 to 58% whereas the other treatments ranged from 29 to 66% from lowest to highest response per location/year. Pregnancy rate was similar for E and G-treated cows (48% and 45%, respectively). Cycling status influenced the response to calf removal. Noncycling CR-treated cows had greater (P<0.05) PR rate than S cows (37% vs. 27%, respectively). Noncycling E-treated cows had greater (P<0.05) PR for CR than S. Cycling E-treated cows had greater (P<0.05) PR for S than CR. Within cycling classification, G-treated cows had a similar response to CR or S. Use of CR in synchronization protocols is most appropriate in herds that anticipate a higher proportion of noncycling cows. Use of ECP to synchronize ovulation did not improve overall PR and required an additional animal handling.

Key Words: Fixed Time AI, Estrogen, Calf Removal

W236 Effect of an addition of a CIDR insert to the Heatsynch protocol on ovulation rate, pregnancy rate and pregnancy loss in lactating dairy cows. K.N. Gavao*, S.O. Juchem, R.L.A. Cerri, A.C. Coscioni, M. Villasenor, and J.E.P. Santos, *University of California Davis, Tulare.*

Objectives were to determine the effects of incorporating a CIDR insert in a pre-synchronized (27 and 41 days in milk (DIM), PGF_{2α} Heatsynch protocol (55 DIM, GnRH; 62 DIM, PGF_{2α}; 63 DIM, estradiol cypionate; 65 DIM, timed AI) on ovulation rate (OR), display of estrus, pregnancy rate (PR), and pregnancy loss (PL) in lactating cows. Holstein cows, 675, from two herds were randomly assigned to treatments. Blood was sampled at 41 and 55 DIM for analysis of progesterone to determine cyclicity. The CIDR was inserted at the time of injection of GnRH, and removed at the the time of injection of PGF_{2α} of Heatsynch. Ovaries were scanned at the time of PGF_{2α} injection and 2 and 7 d later. Pregnancy was diagnosed at 27 and 41 d after AI. Data were analyzed by the LOGISTIC and GLM procedures of SAS (2001). Addition of a CIDR to the Heatsynch protocol eliminated cows displaying estrus prior to the last PGF_{2α} injection (0 vs 2.01%) and decreased proportion of cows bearing a CL at the last PGF_{2α} injection (86.3 vs 93.9%; P<0.001). CIDR did not affect the proportion of cows displaying estrus after the last PGF_{2α} injection (77.2 vs 73.8%; P=0.11) or OR (85.6 vs 86.6%; P=0.30). PR were similar for CIDR and controls on d 27 (35.8 vs 38.8%; P=0.68) and 41 (29.3 vs 32.3%; P=0.33) regardless of cycling status prior to Heatsynch (P>0.15). Pregnancy loss was similar for CIDR and controls (18.3 vs 16.8%; P=0.77). Cyclic cows had higher PR than anovulatory cows at 41 d after AI (33.8 vs 20.4%; P = 0.03) because of lower PL (16.0 vs 30.3; P=0.06). When cows were stratified based on estrus prior to timed AI, at timed AI or no estrus, PR on d 27 (36.9 vs 45.4 vs 17.0%; P<0.001) and 41 (34.2 vs 37.2 vs 12.0%; P<0.001) differed, which might be related to the higher OR (90.0 vs 94.3 vs 63.1%; P<0.001) in cows displaying estrus. PL tended to be lower for cows displaying estrus either prior to or at timed AI than those not in estrus (7.3 vs 18.0 vs 29.6%; P=0.10). Incorporation of a CIDR insert into the Presynch/Heatsynch protocol did not improve PR in lactating dairy cows. Improvements in PR in the Heatsynch protocol are expected when more cows display estrus, thereby increasing synchronization and OR.

Key Words: CIDR Insert, Synchronization, Dairy Cows

W237 Use of milk progesterone following artificial insemination in a resynchronization program for early re-breeding in dairy cows. A. Denson*, T. Dickerson, S. Bowers, S. Schmidt, K. Graves, K. Moulton, and S. Willard, *Mississippi State University, Mississippi State.*

Studies have revealed that the implementation of OvSynch protocols improves synchronization of ovulation and reduces days to first service and days open in dairy cows. Resynchronization of non-pregnant animals in a shortened time-frame post-AI may be beneficial in decreasing days open. The objective of this study was to use milk progesterone (P4) at d 21 following OvSynch and timed-AI to identify pregnant cows and resynchronize non-pregnant cows to accelerate rebreeding. Holstein (n=30) and Jersey (n=10) cows were synchronized using OvSynch and bred AI 16 h post-GnRH. All cows were administered GnRH at d 14 post-AI for resynchronization as part of a subsequent OvSynch protocol. Milk samples were collected on d 21 post-AI to diagnose cows as pregnant or non-pregnant based on qualitative high or low milk P4 (Accufirm). Cows having low P4 were administered PGF_{2α} followed 48 h later with a second administration of GnRH and AI 16 h later. Cows with high P4 were presumed pregnant and not administered PGF_{2α} or GnRH. Blood samples were obtained from all cows on d -9, -2, 0 (AI), 7, 14, 21 through 25 and 28. Blood serum was collected for P4 analysis by RIA. Pregnancy status of cows was confirmed at d 42 post-AI by ultrasonography (US). According to the milk P4 results, 47.5 % of cows were not pregnant to OvSynch/AI based on low milk P4 levels. Serum P4 on d 21 post-AI was low (<1 ng/ml) in 68.4 % of these presumably non-pregnant cows by RIA. Of the 52.5 % of cows with high milk P4 on d 21 post-AI, 85.7 % of the cows exhibited high (>1 ng/ml) serum P4 by RIA. Serum (RIA) and milk P4 on d 21 did not differ (McNemar's test, P>0.10) in pregnant vs. nonpregnant determinations. US at d 42 following the first insemination revealed an overall pregnancy rate of 22.5 %, which represented a 42.9 % pregnancy rate for cows previously identified as pregnant by milk P4 (i.e., US vs. milk P4 disagreed in accuracy of pregnancy rate; McNemar's test, P<0.01). In summary, use

of milk P4 at d 21 post-AI as a selection criteria to identify pregnant cows as part of resynchronization programs may not be accurate enough to justify its use.

Key Words: OvSynch, Milk Progesterone, Synchronization

W238 Use of CIDR with a timed insemination protocol in lactating dairy cows during summer in Mexico. F. Moreira*, R. Flores, and J. Boucher, *Pfizer Animal Health*.

The objective was to evaluate whether addition of EAZI-BREED CIDR Cattle Inserts (CIDR) to the Ovsynch program increases first service pregnancy rate (PR) in lactating dairy cows. The study was conducted in 5 dairies in Central Mexico. Cows were inseminated from June through September, 2001. Within trial site and within parity, cows were assigned to either an Ovsynch (n=255) or an Ovsynch-CIDR group (n=255) for their first service. Ovsynch was initiated at 50±3 d postpartum with an injection of 100 µg of GnRH (2 mL, i.m.; CYSTORELIN), an injection of 25 mg of PGF_{2α} (5 mL, i.m.; LUTALYSE Sterile Solution) 7 d later, a second 100 µg injection of GnRH 48 h later, and timed insemination 8 to 20 hours after the second GnRH injection. Ovsynch-CIDR cows received the same treatments but also received a CIDR Insert (1.38 g of progesterone) which was administered with the first GnRH injection and removed 7 d later at the PGF_{2α} injection. Cows were palpated for pregnancy 40 to 45 d after timed insemination. An interaction between treatments and parity was detected (P=0.023). The interaction indicated that PR was increased for Ovsynch-CIDR compared to Ovsynch in primiparous cows (38.2% and 20%, respectively; P=0.024) but no differences were detected in multiparous cows (22.3% and 27.5%, respectively; P=0.375). A subset of cows (n=466) was classified as anestrous or cyclic based on progesterone concentrations of two blood samples collected 7 d prior to and at the first GnRH injection. For anestrous cows, PR was 18.8% for Ovsynch (6/32) and 18.4% for Ovsynch-CIDR (7/38). For cyclic cows, PR was 23.5% for Ovsynch (47/200) and 29.1% for Ovsynch-CIDR (57/196). Such effects were further subdivided according to parity but none were significant. Addition of CIDR increased first service pregnancy rates of primiparous but not multiparous lactating dairy cows submitted to an Ovsynch program. Because cows were inseminated during summer,

heat stress might have affected embryonic survival but the study was not designed to specifically address such an effect.

Key Words: CIDR, Ovsynch

W239 Efficacy of an injection of Dinoprost Tromethamine when given subcutaneously in two different sites on luteal regression in lactating Holstein cows. R. C. Chebel¹, J. P. Reynolds¹, R. L. A. Cerri¹, J. Versteeg², H. M. Rutigliano¹, and J. E. P. Santos¹, ¹University of California Davis, Tulare, ²Pfizer Animal Health.

The objective of this study was to compare the efficacy of administration of 25 mg of dinoprost tromethamine sterile solution (Lutalyse, Pfizer Animal Health) through different routes and in different sites on luteal regression. Lactating Holstein cows, 109, were synchronized with one injection of PGF_{2α} 14 d prior to enrollment (study d 0). On study d 0, cows were examined by ultrasonography to determine presence of a CL in one of the ovaries. Cows with CL were blocked by parity and d in milk and, within each block, randomly assigned to receive PGF_{2α} as an i.m. injection in the semimembranous/semitendinous muscle (CON); subcutaneous injection in the cervical area (SC); and subcutaneous injection in the ischiorectal fossa (SCI). Blood was sampled at 0, 12, 24, and 48 h after treatments for measurement of plasma progesterone concentrations using a validated EIA. Luteal regression was considered when progesterone decreased to less than 1.0 ng/ml. Relative changes in progesterone (0h=100%) were evaluated after PGF_{2α} injection. Continuous and binomial data were analyzed by the MIXED AND LOGISTIC procedures of SAS (2001), respectively. CL regression for CON, SC, and SCI at 24 (65.7 vs 64.1 vs 68.6%; P=0.92) and 48 h (94.3 vs 86.8 vs 88.6; P=0.55) after treatment did not differ. Relative changes in progesterone (0 = 100%) at 12, 24, and 48h after treatment were 50.4, 34.5, and 27.7% for CON, 53.0, 33.1, and 28.4% for SC, and 52.4, 32.5, and 30.6% for SCI, and no effects of treatment (P=0.98) or treatment by time interaction (P=0.87) were observed. Injection of 25 mg of dinoprost tromethamine subcutaneously in the cervical area or ischiorectal fossa resulted similar changes in progesterone and luteal regression when compared with an i.m. injection in the semimembranous/semitendinous muscle.

Production, Management and the Environment: Reproduction and Health Management

W240 A herd health management program resulted in decreased days open in first lactating cows in northern Thailand. K. Kreausukon¹, V. Punyapornwitthaya¹, P. Kattapan², and W. Suriyathaporn³, ¹Clinic of Ruminant, Faculty of Veterinary Medicine, Chiang Mai University, Chiang Mai Province, Thailand, ²Lumphoon Office of Department of Livestock Development, Thailand.

The herd health management program (HH) is used to improve production performance in dairy farms, especially in Europe and North America. In northern Thailand, the HH program was introduced a few years ago by the faculty of Veterinary Medicine, Chiang Mai University. Therefore, the goal of this study was to evaluate the HH program on reproductive performance in the primiparous crossbred holstein cows. Data from 27 farms in Lamphun province during 1999 to 2003 were used to compare reproductive efficiencies before and after participating in the HH program that started in October 2001. Data on calving date, insemination date, and pregnancy check date were recorded. Calving and breeding season were divided into 3 seasons based on Thai Meteorological Department data, summer (mid Feb.–mid May), rainy (mid May–mid Oct.), and winter (mid Oct.–mid Feb.). The HH program factor was divided into two groups: before and after participating in the program. Factors associated with pregnant cows within 120 days postpartum were evaluated by Cox model. Results from 177 cows showed that median of days open of cows before and after the program were 155 and 129 days, respectively. Results from the Cox's model showed that conception rate after participating in the HH program was increased significantly (HR = 1.96). In addition, conception rate of cows inseminated during the rainy season was lower than in summer (P = 0.07, HR = 1.82) and winter (P < 0.05, HR = 2.28). In conclusion, the HH manage-

ment program improved reproductive performance of primiparous cows in northern Thailand.

Key Words: First Lactating Cows, Days Open, Cox Model

W241 Pregnancy rates and serum cortisol concentrations of relocated recipient cows in an embryo transfer program. J. L. Lopez*, E. Gonzalez, and D. L. Fernandez, *California State Polytechnic University, Pomona*.

Embryo transfer pregnancy rates are lower than pregnancy rates reported for AI or natural service, resulting in a significant economic loss to producers. Recipient cows in embryo transfer programs are routinely relocated. Relocation includes transportation, social regrouping of the animals, climate changes and dietary changes, among others, the stresses of which constitute relocation stress. Because stress affects reproduction, we hypothesized that relocation stress may play an integral role in the success rates of embryo transfer pregnancies. Recipient cows from Montana and Oregon (n=17) were relocated to California State Polytechnic University, Pomona (CPP) and cows from CPP (n=57) were used as non-relocated controls. All cows were treated identically in regards to diet, management and climate after arriving at CPP. Cows were synchronized for estrus and were implanted with Day 7 embryos 7 d after behavioral estrus. Blood samples were collected, centrifuged and the serum stored at -20°C until assayed for cortisol by RIA. The cows were palpated *per rectum* for evidence of pregnancy 60 days after implantation (Day 67) and another blood sample was collected. There was no difference ($\chi^2 = 2.42$, p > 0.10) in pregnancy rates between the control (61%) and the relocated (41%) cattle. Cortisol levels were not different (1.66 ± 0.40 vs. 1.67 ± 0.20 ngml⁻¹, respectively, p > 0.10) between

pregnant and non-pregnant cattle. Cortisol levels were higher 60 days after embryo transfer than day of embryo transfer (2.05 ± 0.24 vs. 1.28 ± 0.33 ngml⁻¹, respectively, $p = 0.059$). We reject our hypothesis that relocation stress reduces pregnancy rates in embryo transfer recipient cows, and hypothesize that relocation stress affects the hypothalamic-pituitary-gonadal axis to reduce fertility, not the cows ability to carry an embryo transfer pregnancy to term.

Key Words: Stress, Cortisol, Embryo Transfer

W242 Evaluation of temperature and temperature-humidity index and their effects on reproduction in beef cattle. J. L. Amundson*, T. L. Mader, R. J. Rasby, and Q. S. Hu, *University of Nebraska-Lincoln.*

Elevated ambient temperatures and humidity during the breeding season can decrease female fertility, reduce the duration of estrus, and results in a lengthened postpartum interval in cattle. The objective of this study was to quantify the effect of temperature-humidity index (THI) on pregnancy rate (PR) of beef cattle. Ten years of calving records were examined from a 150 head herd of commercial, *Bos taurus*, crossbred cows. Cows were managed at the University of Nebraska Dalbey-Hallack Research Farm, located in southeast Nebraska. All cows were bred by natural service, beginning in late May, with a breeding season of 65d. Breeding date was determined by subtracting 283d from the calving date. Relationships were determined between the proportion of cows bred in the first 30d, 60d and the entire breeding season to corresponding average temperature and THI. Weather data were compiled from a Great Plains Climate Center Weather Archives weather station located approximately 20 km from the research site. Average daily temperature and relative humidity were used to calculate daily THI. Average temperature ($R^2=0.38$; $P=0.06$) and THI ($R^2=0.44$; $P=0.04$) for the first 30d of the breeding season decreased PR 1.95 and 1.38% per unit increase in temperature and THI, respectively. Average THI greater than 65 for the first 30d decreased ($P=0.08$) pregnancy rate 1.60%/THI unit ($R^2=0.58$), but had no effect later in the breeding season. In years where the 60d average THI was greater than 70, PR in 60d decreased 3.15%/THI unit ($R^2=0.84$, $P=0.08$) but had no effect on PR for the remainder of the season. Among all years, season THI had no effect ($P>0.1$) on pregnancy rate ($R^2=0.01$). However, the correlation was greater for years where the average THI exceeded 70 ($R^2=0.43$; $P>0.1$). Temperature and THI can reduce 30 and 60d pregnancy rates in beef cows that are pasture bred during years of above average temperature and THI in Southeast Nebraska. However, females acclimatize to temperature and resulting THI because PR did not differ among years.

Key Words: Beef Cattle, Heat Stress, Temperature-Humidity Index

W243 Synchronization of beef cows using GnRH, prostaglandin F_{2α}, and estradiol. W.A. Greene and M.L. Berger*, *The Ohio State University, Wooster.*

The main objectives of this study were to investigate the effect of the addition of estrogen to a common synchronization program on estrus detection rates (EDR) and pregnancy rates (PR). Eighty-four beef cows were allotted to two similar groups (CTRL and ECP) based upon breed, age, postpartum interval, and postpartum cyclicity (as determined by ultrasonography). Each anestrus cow ($n=25$) received an intravaginal releasing device (CIDR), containing 1.38 g progesterone, from d 0 to d 7. All cows received 50 μg GnRH i.m. on d 0 and 25 mg PGF_{2α} i.m. on d 7. The estrogen (ECP) group cows received 0.5 mg estradiol cypionate i.m. 24 h after PGF_{2α}. Cows were observed for estrus 0730 and 1930 and were artificially inseminated (AI) 8-16 h after estrus was observed. If estrus was not observed, CTRL cows were timed AI (TAI) 66 h after PGF_{2α} and received 50 μg GnRH i.m. 0-4 h after AI while ECP cows were TAI 48 h after ECP injection. Following the synchronization period, repeat breedings were done until d 49. Cows were pregnancy diagnosed by ultrasonography on d 80. CTRL and ECP groups had similar ($P>.05$) EDR to synchronization (22.5 and 24.4%), PR to synchronization (30.0 and 36.6%), and overall PR (92.5 and 80.5%). Statistically, the only difference noted was that PR to synchronization was higher

($P=.03$) for anestrus than cycling cows (52.0 vs. 25.0%), perhaps due to the insertion of a CIDR in all anestrus cows.

Key Words: Beef, Synchronization, Pregnancy Rates

W244 Monitoring of estrus characteristics in pubertal and pregnant heifers using radiotelemetry. M. Paczkowski*, T. Craig, D. Magee, J. Thompson, and D. Forrest, *Texas A&M University, College Station.*

Prepubertal (age= 9.5 mo old) Angus-sired heifers ($n=21$) were fitted with HeatWatch® (HW) transponders and continuously monitored for mounting activity. Estrus was defined by a minimum of 3 mounts within a 4-hr interval. Heifers were artificially inseminated (AI) at the second observed estrus. Pregnancy was confirmed 30 d after AI via ultrasound and all pregnant heifers were monitored with HW for at least 35 d up to a maximum of 220 d gestation. The GLM and Mixed Procedures of SAS were used to compare number of mounts, total mount duration, and estrus duration between the pubertal and second estrus. Mean duration of estrus was longer ($P<0.01$) for the second (17.54 ± 3.42 hr) than for the pubertal (12.42 ± 3.42 hr) estrus. Total mount duration and number of mounts did not differ ($P>0.60$) between the pubertal and second estrus. Logistic regression was used to determine if the characteristics of the second estrus were associated with pregnancy (yes/no). Number of mounts at second estrus were greater ($P<0.05$) for pregnant than for non-pregnant heifers after AI. Mean duration of estrus and total mount duration at second estrus were not significantly associated with pregnancy outcome. Estrus events as defined by HW ($n=73$) that occurred during gestation were recorded in 9 heifers. The interestrus intervals during gestation were distributed as follows: <10 d= 48%, 10-16 d= 27%, 17-24 d= 10%, and >24 d= 15%. The Mixed Procedures of SAS were used to determine whether characteristics of the second estrus were predictive of characteristics of estrus during gestation (number of mounts, total mount duration, and interestrus interval). Number of mounts ($P<0.04$) and total duration of mounts ($P<0.02$) at second estrus were predictive of number of mounts during gestation. We conclude that estrus duration is longer for the second estrus compared to the pubertal estrus and the number of mounts received during the second estrus was greater in heifers that were pregnant after AI compared to non-pregnant heifers. Supported by Merial LLC.

Key Words: HeatWatch, Estrus, Pregnancy

W245 The effect of body weight change on conception. C. D. Dechow*, J. E. Vallimont, and M. L. O'Connor, *The Pennsylvania State University, University Park.*

The objective of this study was to estimate the effect of body weight change two weeks prior to insemination (WC14) on the success of insemination. The Afimilk computerized milking and management system records daily body weights for each Penn State dairy cow upon exiting the milking parlor. Body weights and insemination results from the first 200 DIM were retained. Lactation records with fewer than four usable daily body weights over any two week lactation period were eliminated. The final dataset included 77 lactation records from 65 cows with 154 inseminations from 2002 through 2003. Daily body weight variation due to gut fill and measurement error was accounted for by nesting fixed 5th order polynomials of DIM in each lactation record using the PROC MIXED procedure of SAS. A random effect of date was included in the model and regression results were used to reconstruct body weight curves for a cows lactation. The reconstructed body weight curves were then used to derive WC14. Positive values for WC14 indicate cows were losing weight prior to an insemination; a negative value for WC14 indicates cows were gaining weight prior to an insemination. Quartiles of WC14 were constructed (Q1=<-7.7 kg, Q2= -7.7 kg to -2.9 kg, Q3= -2.8 kg to 3.8 kg and Q4=>3.8 kg). Conception outcome (1 = pregnant, 0=open) was treated as a binary response variable in the PROC NLMIXED procedure of SAS. Significant effects included fixed year-season of insemination and WC14 quartiles. Conception outcome was significantly different ($p<.05$) between Q1 and Q4 (odds ratio = 4.2). Conception outcome was also significantly different if WC14 quartiles were expressed as a percentage of body weight lost prior to insemination (Q1:Q4 odds ratio = 3.7). Cows losing more than 3.8 kg of body weight were significantly less likely to conceive than those cows gaining

more than 7.7 kg. Automated daily body weight measurements can be used as a reproductive management tool to optimize the likelihood of conception.

Key Words: Body Weight, Conception, Fertility

W246 Productive and reproductive performance of bathed Holstein cows during the summer. M. Tarazon*, J. Valenzuela, S. Araiza, and F. Denogean, *Universidad de Sonora, Hemosillo, Mexico.*

The objective of the current study was to evaluate the effects of daily baths during the summer months on productive and reproductive performance of multiparous Holstein cows. Eighteen cows were assigned to one of the two groups in a completely randomized design. The treatment group consisted of nine cows, which received a daily bath 30 days before and 30 days after the expected calving date; while the nine cows from the control group did not receive the bath. Cows on treatment were bathed at 15:00 hours using a hose to completely wet the body of the animal. Twenty-five liters of water, at 26 to 29° C were used to wet the animal. Temperature and relative humidity were taken and recorded once every other day at 16:00 hours. Rectal temperatures were measured on all cows during the experimental period. Milk productions from all cows were measured three times a week and daily milk productions were estimated. Days open and services per conception were obtained from the dairy farm records. Also, data from the previous lactating period were used as a covariance. Data were analyzed by the statistical model from Costat) Cohort software, 1986-95).

One of the cows from the group that received the baths, died due to mastitis. The highest temperature and relative humidity were recorded during July (44° C y 68%, respectively) and the lowest ones were during June (35° C y 40%, respectively). Milk yields were not altered by the treatment. Open days for treated cows were numerically lower than the non treated cows, but the difference was not significant. In the same way, services per conception were numerically higher in non treated than in treated cows, but the difference was not significant. Rectal temperatures were significantly ($P < 0.05$) reduced in treated cows before and after calving.

Key Words: Milk Production, Bathed Cows, Temperatures

W247 Financial losses and management practices associated with BTSCC. A. C. O. Rodrigues*, D. Z. Caraviello, and P. L. Ruegg, *University of Wisconsin-Madison.*

The objective of this study was to determine the relationships among bulk tank somatic cell count (BTSCC) and financial and management characteristics of Wisconsin dairy farms enrolled in a state-wide team-based milk quality program. Management and financial data was obtained from a sample of enrolled dairy farms ($n = 149$). The logarithm of BTSCC (LogBTSCC) was regressed on meeting year, season, number of lactating cows, average milk production per cow per day, and financial and management attributes. Linear effects, nonlinear effects and interactions were estimated for financial and management characteristics. The median LogBTSCC was 5.52 (range of 5.08 - 6.07) and the number of lactating cows was 129 (22 - 1838) having a mean RHA of 10034.5 kg. The logarithm of standard plate count had a significant positive correlation with LogBTSCC ($\rho = 0.001$). As LogBTSCC increased the monthly clinical mastitis rate (0.07) and mastitis cull rate (0.02) increased in a significant positive linear association. The duration of milk discard for clinical cases of mastitis was 6.1 days and accounted for 58.8% of total costs. Both the average linear score of first lactation cows (2.97) and second or greater lactation cows (3.7) were higher on farms with higher LogBTSCC resulting in a significant greater monthly production loss per cow due to subclinical mastitis ($\rho = 0.004$). At enrollment in the program, herds received \$0.001 per kg of milk in quality premiums in contrast to available premiums of \$0.011 per kg of milk for achieving their goal SCC values (mean of 188,320 cells/ml). The monthly premium opportunity was positively associated with LogBTSCC. Forestripping and predipping were adopted by 83.7% and 89.1% of farms, respectively. Farms that did not always use gloves during milking cow preparation had higher LogBTSCC as compared to

farms that did use. The use of CMT paddle was associated with lower LogBTSCC ($\rho = .012$).

Key Words: Milk Quality, Management, Finance

W248 Consistency Index as a Dynamic Field Measure of BTSCC Variation. J. Lukas*¹, M. L. Kinsel², and J. K. Reneau¹, ¹University of Minnesota, St. Paul, ²Agricultural Information Management, Inc., Ellensburg, WA.

The objective of this study was to investigate differences in variation in BTSCC depending on the mean BTSCC and develop a field friendly measure of process performance by deriving a consistency index (CI) chart that calculates the maximum allowable sigma to meet each of the following SCC standards: 750000, 600000, 500000, 400000. Bulk tank SCC data was collected daily or every other day for 6 months (January until June 2003) from 1764 Upper Midwest dairy farms. The mean of daily values and variation (sigma) in BTSCC was calculated for each individual herd. The herds were divided into seven categories depending on the mean BTSCC for the 6-month period (mean BTSCC in thousands <150, 150-200, 200-300, 300-400, 400-500, 500-600, 600-750). Average sigma was calculated for each of the seven categories and the relationship between the mean and sigma was investigated. A consistency index (CI) was developed that calculates the maximum allowable sigma to meet the SCC standard at a given mean BTSCC following the formula: $CI = (\text{standard} - \text{mean})/3$ where mean is the average BTSCC and the standard represents one of four different BTSCC standards. CI400 was developed for the 400000 SCC standard imposed in the EU. CI500 relates to the 500000 SCC standard adapted in Canada. CI600 uses the 600000 SCC limit implemented in California while CI750 is based on the 750000 SCC limit obligatory in other states. Analysis of the relationship between the mean and variation of BTSCC indicated that in herds which on average have a low BTSCC, the variation in BTSCC is low. The variation increases as the mean BTSCC increases. Using the consistency index (CI) chart, dairy managers and milk plant field staff can indicate what level of variation (consistency) will have to be achieved to meet a milk quality standard with statistical certainty. The same kind of chart could also be used to assess the prospect of meeting quality premium goals and to encourage improvement in process consistency as a means of further BTSCC improvement.

Key Words: BTSCC, Consistency Index, Statistical Process Control

W249 Factors affecting raw milk quality at milk collecting center-level in Northern Thailand. S. Boonyayatra¹, S. Rojanasthien¹, K. Kreausukon*¹, P. Tharavichitkul², and K. Ajariyakhajorn³, ¹Faculty of Veterinary Medicine, Chiangmai, Thailand, ²Faculty of Medicine, Chianmai, Thailand, ³Faculty of Veterinary Science, Bangkok, Thailand.

To study the herd-level factors affecting the microbiological quality of raw milk at the milk collecting center (MCC), Standard plate count (SPC) was conducted to evaluate the bacterial counts in raw milk samples every week for 2 consecutive months from 4 MCC in Northern Thailand. These selected MCC were divided by the median of average SPC from all MCC in this area into 2 groups; group1: MCC which had low bacterial count ($SPC < 1.6 \times 10^6$ cfu/ml) and group2: MCC which had high bacterial count ($SPC > 1.6 \times 10^6$ cfu/ml). Then, the questionnaires were administered by interviewing about the farm management and observing for the milking technique in 104 dairy farms: 50 and 54 farms for group1 and 2, respectively. The logistic regression modeling technique was used to evaluate the significance of association of each factor while simultaneously controlling for the presence of other factors. The results showed that long duration of dairy farming (OR = 1.137, 95%CI 1.022 - 1.265), high number of milking cows (OR = 1.220, 95%CI 1.033 - 1.440), udder not dry before attachment (OR = 5.817, 95%CI 1.867-18.129) and poor cleanliness of teat cup liner (OR = 6.444, 95%CI 1.835-22.627) were the risk factors to have high level of bacterial contamination in raw milk at the MCC-level. In conclusion, the farmer should pay more attention on milking hygiene and cleanliness of milking equipment to improve the microbiological quality of raw milk at the milk collecting center.

Key Words: Raw Milk Quality, Milk Collecting Center, Northern Thailand

W250 Effect of season on high bulk milk somatic cell count in northern Thailand. S. Rojstian*, V. Punyaporn-wittaya, W. Tiwanuntakorn, S. Boonyayatra, J. Younggad, C. Apairoj, and W. Suriyasathaporn, *Department of Clinic of Ruminant, Faculty of Veterinary Medicine, Chiangmai University, Chiangmai, Thailand.*

The objective of this study was to evaluate the effect of season on bulk milk somatic cell count (BMSCC) in Northern Thailand. Data of BMSCC from 123 dairy farms within 4 milk-collecting centers in Chiang Mai and Lumpun provinces, Thailand, were collected once a month between October 2000 to August 2001. By the definition from Thai Meteorological Department, seasons in Thailand are comprised of winter (Nov.-Feb.), summer (Mar.-May), and rainy season (Jun.-Oct.). High BMSCC was defined when farms had BMSCC higher than 500,000 cells/ml. The percentage of farms with high BMSCC from each milk-collection center and each month was a dependent variable. Seasons and milk-collecting center factors were fixed effects. Data was analyzed using mixed model analysis (Proc Mixed, SAS v.8). Results showed that both season and milk-collecting center were related to the proportion of high BMSCC farms ($P < 0.05$). The percentages of high BMSCC of all centers were ranged between 5.4 and 37.9. The percentage of high BMSCC in rainy season (30.7 %) was significantly higher than summer (20.7 %) and winter (22.4 %). We concluded that a problem of sub-clinical mastitis for dairy farms in northern Thailand is highest during the rainy season.

Key Words: Bulk Milk Somatic Cell Count, Season, Cows

W251 Growth and parasite burdens of St. Croix White and Dorper X St. Croix White lambs grazing native pasture during the wet season in the US Virgin Islands. R. E. Dodson*, A. J. Weis, and R. W. Godfrey, *University of the Virgin Islands, Agricultural Experiment Station, Kingshill, VI.*

St. Croix White (STX; $n = 16$) and Dorper X STX (DRP; $n = 14$) ewe and wether lambs were used to evaluate the growth of lambs grazing during the wet season under tropical conditions. Two wk after weaning, at 63 d of age, lambs were placed in guinea grass (*Panicum maximum*) pastures (0.5 ha) in a rotational grazing system for 147 d. Daily rainfall amounts were recorded during the grazing period. Lambs were moved between pastures every 20 ± 3 d. Forage quantity was determined at the start and end of grazing within each pasture. Each week for the first month and every two weeks thereafter lamb weight, fecal egg count (FEC) and packed cell volume (PCV) were determined for each lamb. The pastures received 978.7 mm of rain with 64.5% of the rain falling by d 45 of the grazing period. Forage quantity was 1264.2 ± 413.9 and 627.5 ± 126.2 Mg/ha at the time of entry into and exit from pastures, respectively. Forage contained 13.3 ± 0.7 % crude protein and 60.8 ± 0.6 % TDN. Average daily gain was higher ($P < 0.05$) for DRP than for STX lambs (76.8 ± 3.8 vs 64.8 ± 4.3 g/d, respectively) and wethers

had higher ADG ($P < 0.009$) than ewes (79.2 ± 4.1 vs 62.5 ± 4.1 g/d, respectively). Wether lambs were heavier than ewe lambs within breed ($P < 0.001$) during the grazing period but there was no difference ($P > 0.10$) between breeds. There was no breed x gender interaction for ADG or BW. There was no difference ($P > 0.10$) between DRP and STX lambs in FEC or PCV during the grazing period. Packed cell volume was negatively correlated ($P < 0.0001$) with FEC in DRP and STX lambs ($r = -0.71$ and -0.67 , respectively). Weight was positively correlated ($P < 0.009$) with PCV in DRP and STX lambs ($r = 0.15$ and 0.16 , respectively). In 3 lambs that died FEC was 2350 egg/g and PCV was 10% the week immediately prior to their death. These results indicate that DRP lambs grow faster and have similar parasite burdens when compared to STX lambs grazing native pasture during the wet season under tropical conditions.

W252 Phylogenetic relationship and distribution of bacteria in the mucosa of chicken guts: from the crops to ceca. J. Gong¹, W. Si^{*1}, R. Huang², F. Deng¹, Y. Yin¹, H. Yu¹, and Y. Han³, ¹Food Research Program, Agriculture and Agri-Food Canada, Guelph, Ontario, ²Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha China, ³Maple Leaf Foods Agresearch, Guelph, Ontario.

Bacterial populations in the mucosa of adult chicken guts at different regions, including the crop, gizzard, duodenum, jejunum, ileum, and cecum, were studied by molecular analysis of 16S rRNA genes. Bacteria in the mucosa of tested gut regions were mainly Gram-positive. Ceca had the most diverse bacterial population in the guts. Eleven out of 100 cloned 16S rDNA sequences from the cecum had less than 95% homology to database sequences. There were 56 phylogenetic types of bacteria (from 100 16S rDNA clones) detected in the cecum, as compared to 8 phylogenetic types (from 51 clones) in the crop, 3 phylogenetic types (from 51 clones) in the gizzard, 15 phylogenetic types (from 52 clones) in the duodenum, 11 phylogenetic types (from 50 clones) in the jejunum, and 7 phylogenetic types (from 50 clones) in the ileum. *Bifidobacterium* and *E. coli* comprised the largest groups among the clones from the cecum, representing 12 and 11%, respectively. *Lactobacilli* were predominant (181 out of 254 clones) in the upper gastrointestinal tract (from crops to ilea) with the highest diversity being found in the crop. *L. aviarius* was the predominant species of *Lactobacilli* detected in the gizzard and duodenum. It also comprised the largest group of bacteria in the jejunum and ileum. This report is the first comprehensive study of mucosa-associated microbiota from different gut regions in broiler chickens.

Breeding and Genetics II

W253 A computerized approach to minimize inbreeding of breeding plans. John R. Garbe* and Yang Da, *Department of Animal Science, University of Minnesota, St Paul.*

Inbreeding is an important issue in animal breeding. Since inbreeding is often associated with detrimental effects, minimizing inbreeding is often desired. Theoretical prediction of inbreeding levels for breeding plans is difficult in real animal populations due to the complex pedigree structures formed over many generations. As computing power rapidly improves, predicting inbreeding levels based on exhaustive calculation of inbreeding coefficients resulting from all potential matings becomes feasible. We developed a computer program named MiniInbred to identify a breeding scheme that minimizes inbreeding. This program predicts inbreeding level in the next generation by identifying matings that yield the lowest inbreeding level in the offspring. The inbreeding coefficient resulting from all potential matings of the current breeding animals (generation 1) are calculated, and the potential matings among the current breeding animals that yield the lowest inbreeding level are identified. The program also has the option to predict the lowest inbreeding available in the third generation. In this case, the hypothetical offspring (generation 2) of the current breeding animals are treated as parents, and the inbreeding coefficient resulting from all potential matings between the hypothetical parents are calculated, and the potential matings among the hypothetical parents that minimize inbreeding are

identified. This computerized approach is illustrated and evaluated using two large animal pedigrees.

Key Words: Inbreeding, Breeding, Animal

W254 Full pedigree analysis of QTL affecting growth, carcass, and meat quality in pigs. N. Vukasinovic*¹, F.-X. Du¹, L. A. Messer¹, J. C. Byatt¹, M. M. Lohuis¹, A. C. Clutter¹, J. Bennewitz², N. Reinsch², G. Otto², K. Sanders², N. Borchers², and E. Kalm², ¹Animal AG, ²Institute of Animal Breeding and Husbandry, Kiel, Germany.

Quantitative trait loci (QTL) detection methods in swine are often based on full- or half-sib families and ignore additional relationships among animals. In this study, a full-pedigree analysis based on a variance component (VC) approach was applied to a three-generational pedigree from a line-cross experiment involving Pietrain and Large White x Landrace hybrid. The pedigree included 17 F0, 118 F1, and 1014 F2 animals originating from repeated matings of four F1 sires to 33 full-sib F1 dams. All animals were genotyped for 27 microsatellite markers on SSC2, SSC6, and SSC7. Phenotypes on 31 growth, carcass, and meat quality traits were available on F2 animals. The analyses were performed using an animal model with random polygenic and QTL effects. The (co)variance

matrix of the polygenic effect was an additive genetic relationship matrix. The (co)variance matrix of the QTL effect contained probabilities that alleles shared by two individuals were identical-by-descent (IBD). The IBD probabilities were calculated for each pair of gametes independently, using a deterministic method that combines a recursive algorithm for general pedigree structure with the method to estimate IBD between sibs, and then combined to obtain IBD probabilities at the individual's level. The VC analysis was performed and LOD scores were obtained at every 1cM. Significant evidence of QTL (LOD>2) affecting daily gains, most fatness traits, meat reflectance and conductivity was found on SSC2. For some traits, more than one significant peak was found, indicating possible presence of two or more linked QTL. There was suggestive evidence (LOD>1.5) of several QTL affecting fatness traits on SSC6. On SSC7, we found a very significant (LOD=14.5) QTL for carcass length. Full pedigree analysis provides stronger evidence of existing QTL and more precise estimates of their positions than traditional methods.

Key Words: Swine, QTL Mapping, General Pedigree

W255 Efficiency of selection on multiple QTL in a crossbred population. N. Piyasatian*, R. Fernando, and J. Dekkers, *Iowa State University, Ames.*

The efficiency of marker-assisted selection on multiple known QTL for a trait with heritability of 0.1 in a line-crossing program was evaluated on the basis of frequencies of favorable QTL alleles and genetic gain over ten generations. Three biallelic unlinked additive QTL were simulated with known QTL positions. Polygenic effects were simulated based on the sum of 100 additive and unlinked loci. Different analyses and criteria for selection were evaluated by considering the effects of factors included in the models and three alternative levels of effects at the QTL (each QTL explaining 10.8, 3.57, and 0.9% of the genetic variance). In each generation 5% males and 25% females were selected out of 500 progeny. Two alternative analyses were considered:

Model A: $\mathbf{Y} = \mathbf{X}_n \beta_n + \mathbf{X}_g \beta_g + \mathbf{Zu} + \mathbf{e}$, and Model B: $\mathbf{Y} = \mathbf{X}_n \beta_n + \mathbf{Zu} + \mathbf{e}$

where \mathbf{Y} is the observed phenotypes; β_n and β_g are non-genetic and genetic fixed effects (= number of favorable QTL alleles); \mathbf{X}_n and \mathbf{X}_g are incidence matrices; \mathbf{u} are additive polygenic effects; and \mathbf{e} are the environmental effects. Selection was based on the sum of BLUE of β_g and BLUP of \mathbf{u} . A total of 50 replicates were run.

For the large QTL, QTL frequencies approached fixation (>0.9) in generations 6 and 10 for Models A and B. For the smaller QTL, it required more generations to approach fixation, in particular for Model B. In generation 2 (F2), genetic gain from Model A was 70% greater than gain from Model B for the large QTL, 20% greater for the medium QTL, and 10% poorer for the small QTL. The latter likely results from the large standard errors of QTL effect estimates for the small QTL. For the large and medium size QTL, extra gains of Models A over B declined over generations. Results show that QTL detected in breed crosses can be used to increase genetic gain in populations that are developed from those crosses. Additional analyses will evaluate the impact of having markers at various distances from the QTL.

Key Words: QTL, Marker-Assisted Selection, BLUP

W256 Comparison of normalization and models for the analysis of gene expression data. S. L. Rodriguez-Zas*¹, M. R. Band², R. E. Everts¹, B. R. Southey¹, Z. L. Liu¹, and H. A. Lewin^{1,2}, ¹University of Illinois at Urbana-Champaign, ²W. M. Keck Center for Comparative and Functional Genomics, University of Illinois at Urbana-Champaign.

The influence of different normalization and parametric models on the analysis of gene expression from three cattle tissues (rumen, large intestine and small intestine) was evaluated. Fluorescence intensities were recorded in cDNA microarrays that included over 6000 double-spotted cattle genes. A total of six microarrays were used in a reference design with reverse labeling. Prior to normalization, individual spots were filtered if the fluorescence intensity was weak or extreme relative to the sample mean for each gene. The fluorescence intensity normalization methods used were log2 transformation, loess transformation, and linlog at 30% intensity transformation and the combination of loess and linlog transformations. Normalized data were then analyzed using three

response variable-model combinations, tissue intensity divided by reference intensity (RATIO), reference intensity treated as a response variable together with the tissue intensities (ABSOLUTE) and reference intensity included in the model as a covariate dependent variable (COVARIATE). A linear mixed effects model including the effects of dye and tissue was fitted and model adequacy was determined by the mean square error criterion. Across all normalization methods, the ABSOLUTE model provided the worst fit and the RATIO and COVARIATE models provided similar fit. However the ABSOLUTE model provided the most significant genes and the COVARIATE model the fewest significant genes. The average difference across normalization methods in the number of genes differentially ($P < 1 \times 10^{-8}$) expressed among tissues was 201 between the ABSOLUTE and COVARIATE models. The log2 transformation provided the worst fit and the combined transformation provided the best fit across all models. The combination transformation provided the most significant results and the linlog provided the fewest. The average difference across models in the number of genes of differentially ($P < 1 \times 10^{-8}$) expressed was 76 between the combined and linlog normalization methods. The variation in results indicates that every cDNA microarray experiment must be studied using different normalizations and models.

Key Words: Gene Expression, Normalization, Mixed Effects Model

W257 Graphical visualization of two large complex populations using Pedigree 2.0. J. R. Garbe* and Y. Da, *Department of Animal Science, University of Minnesota, St. Paul.*

This poster presents pedigree drawings for two large and complex pedigrees to evaluate the capabilities of Pedigree 2.0 developed by the authors. Pedigree 1 is a sub population of the entire US registered Jersey population with 1.3 million daughters from 579 sires in 8 generations. The pedigree drawing used the summarization option that displays the sires and their parents, as well as the counts of daughters of each sire according to the performance of pregnancy rate. The program took 43 minutes to draw the full pedigree on a 2 GHz PC computer. To print out the entire drawing with readable entries would require a piece of paper 17 feet wide and 4 feet tall. Pedigree 2 is the European royal genealogy data (unofficial data available from the internet) with 48,605 individuals spread out over 106 generations, with entries as early as 827 BC and as recent as 1997. The program took 43 minutes to draw the full pedigree on a 2 GHz PC computer. Color lines connecting parents and offspring were used to enhance the visibility of parent-offspring relationship. Using zoom in would allow a clear view of any part of the pedigree. However, to print out the main body of the entire drawing with readable entries would require a piece of paper 80 feet wide and 200 feet tall. Using Pedigree's option of extracting partial pedigrees, we produced the pedigree drawing of Victoria Hanover, Queen of Britain. This partial pedigree contains 5,124 individuals, 3,975 ancestors and 1,148 descendants, and is viewable without the need of an excessively large print. The results show that pedigree graphing for large complex populations is possible. The main limitation is the size of the pedigree printout, which could be too large to be practical.

Key Words: Pedigree, Genealogy, Visualization

W258 Spanish buck β -B inhibin/activin (INHBB) microsatellite polymorphisms. R. Realivasquez*¹, S. A. Ericsson¹, S. F. Spiller¹, W. T. Campbell¹, K. L. Sternes¹, P. H. Purdy², H. D. Blackburn², and J. M. Dzakuma³, ¹Sul Ross State University, Alpine, TX, ²USDA-ARS-National Animal Germplasm Program, Fort Collins, CO, ³Prairie View A&M University, TX.

DNA markers could be useful in selecting for potential spermatozoal fertility. The purpose of this study was to determine if β -B inhibin/activin microsatellite polymorphisms were present in Spanish buck DNA. An α (INHA) subunit and a β -B (INHBB) subunit can dimerize to form inhibin. The β -B subunit can hetero-dimerize with a β -A (INHBA) or with another β -B subunit to create activin. Inhibins impede and activins stimulate spermatogenesis through FSH regulation. Two primer sets designed for human INHBB microsatellite polymorphisms, polymerase chain reaction and electrophoresis were utilized to examine purified DNA from 23 Spanish bucks. The first primer set (forward AACAGCAA-GACCTGACTC, reverse TTAGCGTGCCATCCTCAT) showed distinctive bands located at 284 base pairs (bp) (1 hd), 282 bp (2 hd), 280 bp (14 hd), 278 bp (1 hd), or no detectable bands (5 hd). The second

primer set (forward AACTCCATCCCGGTGC, reverse ATGTGTGC-CTGTGGGTTTAG) also showed distinctive bands that were located at 248 bp (6 hd) and 246 bp (7 hd) or no detectable bands (10 hd). Significant deviation from the Hardy-Weinberg equilibrium were observed for both primer sets due to excess homozygosity. These potential polymorphic bands may imply genetic diversity, and could be used for selection strategies. Additional studies will be needed to identify specific QTL.

Key Words: Inhibin, Activin, INHBB

W259 Mapping QTL in complex pedigrees. G. Freyer*¹ and N. Vukasinovic², ¹Research Institute for the Biology of Farm Animals, Dummerdorf, Germany, ²Animal AG, Monsanto Company.

Traditional methods for detection and mapping of quantitative trait loci (QTL) in dairy populations are based on daughter design (DD) or granddaughter design (GDD). Although these designs are well established and usually successful in detecting QTL, they consider sire families independently from each other, thereby ignoring relationships among other animals in the population and consequently, reducing the power of QTL detection. In this study, we compare a traditional DD with a full pedigree design (FPD) and assess the precision and power of both methods for detecting and locating QTL in a simulated complex pedigree. The pedigree included seven large sire families with overlapping generations and inbreeding. QTL search was considered within a 54cM long chromosomal segment, covered with 11 moderately polymorphic and randomly distributed markers. Marker genotypes were available for all animals. Pedigree information was available for daughters, sires, and two generations of their male ancestors, but not for dams. Phenotypic records were available for daughters and some of the dams. One QTL was placed close to the end of the segment. QTL analyses were performed under the variance component model containing a random QTL and a random polygenic effect. The covariance matrix of the polygenic effect was a standard additive relationship matrix. The (co)variance matrix of the random QTL effect contained probabilities that QTL alleles shared by two individuals are identical-by-descent (IBD). In the DD analysis, IBD probabilities were calculated using sires and daughters marker genotypes. In the FPD analysis, IBD probabilities were obtained using a deterministic approach. Estimation of QTL position and variance components was conducted using REML algorithm. Although both methods were able to find the exact position of the QTL, the FPD method showed better precision of QTL position estimates (narrower, better defined peak) and significantly higher power (3-4 x higher test statistics) than the DD method.

Key Words: QTL Mapping, Daughter Design, Pedigree

W260 INHA microsatellite polymorphisms in Angora bucks. S. F. Spiller*¹, S. A. Ericsson¹, R. Realivasquez¹, W. T. Campbell¹, K. L. Sternes¹, P. H. Purdy², H. D. Blackburn², and J. M. Dzakuma³, ¹Sul Ross State University, Alpine TX, ²USDA-ARS-National Animal Germplasm Program, Ft. Collins CO, ³Prairie View A&M University, TX.

Genetic mediation and variability of sperm production has been hypothesized, however previous heritability estimates have always been low, therefore making selection for semen characteristics difficult. The objective of this study was to determine if α -inhibin (INHA) microsatellite polymorphisms, a dimeric subunit playing a pivotal inhibitory role in the regulation of spermatogenesis, were present in the DNA of Angora bucks. Inhibins are dimeric molecules composed of an α and one of two β subunits (βA or βB) that exert a negative feedback system on the pituitary release of FSH. Using a primer set originally developed to amplify ovine INHA microsatellite polymorphisms, purified DNA from 24 mature Angora bucks was amplified and examined using polymerase chain reaction and electrophoresis. The INHA primer set (forward primer AGCGTGTGAAGCTGGAGAT and reverse primer ACGTGATCAC-TACCACAGTACGGA) produced multiple homozygous and heterozygous banding patterns with varying numbers of base pairs (bp). Homozygous bands were detected at 195 bp (1 hd) and 200 bp (3 hd). The following heterozygous banding patterns (bp) were identified: 185, 215 (2 hd); 195, 200 (1 hd); 195, 225 (1 hd); 195, 240 (1 hd); 200, 225 (4 hd); 200, 230 (1 hd); 205, 220 (1 hd); and 205, 225 (1 hd). No banding was observed in 8 goats. This data demonstrated significant deviations of genotype counts from Hardy-Weinberg equilibrium. The presence of these INHA polymorphisms suggests a range of genetic variation that

could be utilized in selection strategies, with further work required to identify specific associations between potential markers and semen characteristics.

Key Words: Angora, Inhibin, Activin

W261 Effects of the Compact mutant myostatin allele *Mstn*^{Compact-d11Abc} introgressed into a high growth mouse line on skeletal muscle cellularity. C. Rehfeldt*¹, G. Ott², D.E. Gerrard³, L. Varga⁴, W. Schlote⁵, J.L. Williams⁶, and L. Bunger⁷, ¹Research Institute for the Biology of Farm Animals, Dummerdorf, Germany, ²University of Applied Sciences, Lemgo, Germany, ³Purdue University, West Lafayette, IN, ⁴Agricultural Biotechnology Center, Godollo, Hungary, ⁵Humboldt University, Berlin, Germany, ⁶Roslin Institute (Edinburgh), Roslin Midlothian, UK, ⁷ICAPB University of Edinburgh, UK.

The murine *myostatin* mutation *Mstn*^{Compact-d11Abc} (*Compact*; *C*) was introduced into an inbred mouse line with extreme growth (DUHi) by marker-assisted introgression. To study the allelic effects on muscle fiber hyperplasia and hypertrophy, myonuclear proliferation, protein accretion, and muscle fiber metabolism, samples from *Rectus femoris* and *Longissimus dorsi* muscles of animals wild-type (+/+), heterozygous (*C*/+), and homozygous (*C*/*C*) for the *Mstn*^{Compact-d11Abc} allele were examined by histological and biochemical analyses. *C*/*C* mice exhibited lower body (-12%) but higher muscle weights (+38%) than +/+ mice. Total muscle fiber number was increased (+24%), whereas fiber size was not affected. Protein and DNA concentrations and DNA/protein ratios as well as creatine kinase activity remained unchanged implying increases in the total contents of DNA and muscle protein. Fiber type distribution was markedly shifted to the white glycolytic (+17% units) at the expense of red oxidative fibers. Capillary density was substantially lower in *C*/*C* than in +/+ mice as seen by lower number of capillaries per fiber (-35%) and larger fiber area per capillary (+77%). However, the *C* allele was partially recessive in heterozygous mice for both fiber type frequencies and capillary density. The results show that hypermuscularity caused by mutations in the *myostatin* gene results from muscle fiber hyperplasia rather than hypertrophy, and from balanced increases in myonuclear proliferation and protein accretion. However, capillary supply is adversely affected and muscle metabolism shifted towards glycolysis, which could have negative consequences for physical fitness.

Key Words: DUHi, Muscle Fiber, Capillary

W262 Detection and characterization of microsatellite loci based on PCR. H. Y. Chung*, J. M. Ha, S. J. Oh, and S. W. Lee, National Livestock Research Institute, Omokchon.

Tri repeat microsatellite loci have been isolated based on PCR detection procedures in Korean cattle. The pooled genomic DNA samples, which were digested with Sau3A restriction enzyme, were separated onto agarose gels. DNA fragments were recovered for 3 sections (200 to 500 bp, 500 to 1000, 1000 to 1,500). A total of 6 genomic libraries were constructed by a PCR-enrichment procedure with biotined oligo probes, which were used microsatellite selection process. A total of 3,800 clones were analyzed for (ATG)_n, (TAA)_n, (GGC)_n, (CAT)_n, (GCA)_n, and (CTG)_n repeat sequences. Most clones (89%) were contained repeat regions and more than 70% clones contained single nucleotide polymorphisms. Effective clones, which contained repeat sequences that used in this study, were 45%. On the Blast search, 65% of clones were hit, 20% of clones were identified as known microsatellite loci, and 15% of clones were identified as unknown genes.

Key Words: Microsatellite, PCR, Cattle

W263 Using plasma IGF-I concentration for genetic improvement of feed efficiency in beef cattle. R. M. Herd¹, D. J. Johnston², K. Moore², H-U. Graser², and P. F. Arthur*³, ¹NSW Agriculture - Armidale, Australia, ²Animal Genetics and Breeding Unit, Armidale, Australia, ³NSW Agriculture - Camden, Australia.

Providing feed for animals is the single most expensive cost of beef production. Individual animal feed intake is difficult and expensive to measure, and this drawback highlights the need for alternative cost effective measures for genetic improvement of feed efficiency. Recent research in Australia has shown that plasma IGF-I concentration is moderately heritable (0.32 to 0.43) in beef cattle, and is genetically correlated (0.39 to

0.63) with residual feed intake (RFI), a measure of feed efficiency that accounts for differences in size and growth rate. Plasma IGF-I concentration is also genetically correlated with subcutaneous fat depth (0.35 to 0.62) and with intramuscular fat (0.26 to 0.47). The application of IGF-I for genetic improvement of livestock is now a patented technology licensed to Primegro Limited, an Australian company. For 2004, the Australian genetic improvement system (BREEDPLAN) utilised these genetic parameters to incorporate IGF-I information in the generation of estimated breeding values (EBVs) for RFI. The accuracy of EBVs for RFI generated using an animal's actual feed intake information alone is approximately 63%. While the IGF-I measure is relatively inexpensive and convenient, the EBVs for RFI generated from IGF-I information alone have low accuracies (approximately 40%). To improve accuracy, strategies that combine measurement of IGF-I in all breeding animals, and actual feed intake measurement in strategically selected individuals in the herd in a two-stage selection process will be required.

Key Words: Cattle, Feed Efficiency, IGF-I

W264 Growth hormone gene polymorphisms differentially predict ADG and carcass traits in performance tested Angus and Brangus bulls. M. G. Thomas¹, R. M. Enns², G. A. Silver^{*1}, M. D. Garcia¹, K. L. Shirley¹, V. R. Beauchemin¹, and D. M. Hallford¹, ¹New Mexico State University, Las Cruces, ²Colorado State University, Ft. Collins.

Growth hormone is necessary for growth and fat metabolism. Relationships of GH gene polymorphisms to ADG and yearling ultrasound carcass measures were evaluated in performance tested Angus and Brangus bulls ($n = 361$ from 36 sires). Bi-allelic polymorphisms were an intron 4 Msp-I RFLP (+/+, +/-, -/-) and an exon V L-leucine to V-valine single nucleotide polymorphism (SNP). Bulls were spring-born and fall-weaned and then gain tested for 112-d as they approached 1 yr of age with a ration formulated to yield 1.58 kg gain/d. Birth weight, adjusted 205- and 365-d weights, and longissimus muscle area per 100 kg of BW were similar among breed groups. Means for these traits were 37.2 ± 1.2 , 268.8 ± 11.9 , and 463.8 ± 10.2 kg and 6.2 ± 0.2 cm²/100 kg of BW, respectively. Angus bulls had greater ($P < 0.05$) ADG and ribfat thickness than Brangus bulls ($1.59 > 1.53 \pm 0.05$ kg/d and $0.66 > 0.48 \pm 0.05$ cm). Angus bulls had high frequencies (> 0.68) of the homozygous +/+ and LL genotypes, whereas genotypic frequencies were evenly distributed in Brangus bulls. Mixed model analyses revealed that the Msp-I and LV genotypes within breed were significant ($P < 0.05$) sources of variation in prediction of ADG and ribfat. The interaction between Msp-I and LV genotypes was a significant ($P < 0.05$) predictor of intramuscular fat and ribfat. In Brangus bulls, the heterozygous Msp-I genotype had the highest rate ($P < 0.05$) of ADG and the heterozygous LV genotype had the highest ($P < 0.05$) level of intramuscular fat relative to the homozygous genotypes. Concomitantly, homozygous -/- and VV genotypes had greater ($P < 0.05$) amounts of ribfat and ADG relative to the other genotypes in Angus bulls, but these genotypes were observed at very low frequencies (i.e., 0.06 and 0.03). Results suggest that GH gene polymorphisms are informative predictors of ADG and carcass measures in growing Angus and Brangus bulls. However, it appears genotypes of the two polymorphisms differentially predict these traits within the breed groups of Angus and Brangus.

Key Words: Bull, GH, SNP

W265 An improved approximation of the gametic covariance matrix for marker assisted genetic evaluation by BLUP. F. Pita^{*1}, R. Fernando², and L. Totir², ¹Newsham Genetics, LC, ²Iowa State University, Ames.

Marker Assisted Best Linear Unbiased Prediction (MABLUP) with large livestock pedigrees depends critically on efficient algorithms to invert the gametic covariance matrix for the marked QTL. These algorithms are based on tracing the QTL alleles of an individual to its grandmother or grandfather. When marker information is complete, there are simple rules to compute the probabilities (PDQs) of these events. When marker information is incomplete, even if the PDQs are computed exactly, the efficient algorithms would be approximate. Further, computing the exact PDQs becomes difficult when marker information is incomplete. In this study, we examined the effect of estimating the PDQs by MCMC on response to MABLUP. The MCMC method applied is based on the concept of segregation indicators. A pedigree with 96 individuals and four generations was simulated. Two or four bi-allelic markers were

simulated flanking a QTL which accounts for 2.85% of the genetic variation. The candidate individuals for selection did not have phenotypic information. In a previous study, use of an analytical approximation of PDQs was shown to result in a loss of about 50% of the response to MABLUP. The results of this study show that by estimating the PDQs by MCMC the loss in response was of 19.2% and 2.4% when information from 2 or 4 markers was used, respectively. Because the PDQs in this study were estimated accurately by MCMC using all available marker information, the approximation in the inverse is almost due to use of the efficient algorithm. The small loss in response that we observed here indicates that the approximation introduced through the recursive equation is small.

Key Words: Gametic Matrix, MABLUP, MCMC

W266 Identification of quantitative trait loci for carcass and growth traits in swine using principal components analysis. T. M. Stearns^{*}, S. L. Rodriguez-Zas, J. E. Beever, M. Ellis, F. McKeith, B. R. Southey, J. Hartschuh, and R. J. Feltes, *University of Illinois at Urbana-Champaign, Department of Animal Sciences.*

A three generation resource population including 832 F2 pigs was developed by a parental cross between three Berkshire grand sires and 18 Duroc grand dams. The population was genotyped for ten markers spanning 161.5 cM on chromosome 6 (SSC6), and nine markers spanning 125.5 cM on chromosome 13 (SSC13) based on a sex-averaged CRI-MAP map estimates. Animals were weighed from birth to harvest approximately every 21 d, and carcass and meat quality traits were recorded at harvest (approximately 113 kg). There were significant correlations between the 41 traits recorded and a principal component analysis was used to summarize this high dimensional data into few principal components or orthogonal linear combinations of the traits. A linear mixed effects model was used to detect QTL influencing the principal components and thus the traits of interest. The model included the fixed effects sex, birth year and month, QTL additive, dominance and imprinting coefficients, weight at slaughter and the random effect family. Genetic effects were calculated every 1 cM using a least-squares interval mapping method. The analysis identified QTL influencing groups of traits including tenth rib, last rib, and last lumbar backfat on SSC6 (group SUBFAT6); birth, 21 d, 42 d, and 63 d weight on SSC6 (group WEIGHT6) and fat %, moisture % and marbling on SSC13 (group INTFAT13). The first principal component explained 80.85%, 73.48%, and 77.85% of the variation in SUBFAT6, WEIGHT6 and INTFAT13, respectively. A QTL influencing the first principal component was detected at approximately 70 cM ($P < 0.0036$), 111 cM ($P < 0.0078$) and 87 cM ($P < 0.0009$) in SUBFAT6, WEIGHT6 and INTFAT13, respectively. The location and genetic effect estimates were consistent with univariate analysis. These results indicate that QTL mapping of many correlated traits can be enhanced by principal component analysis.

Key Words: Backfat, Weight, Marbling

W267 Chromosomal assignment of 24 candidate genes for swine efficient growth. M. Grosz^{*1}, J. Byatt¹, C. Dyer¹, K. Hinds¹, K. Eyer², and C. Beattie², ¹Monsanto Company, West Chesterfield, MO, ²University of Nevada-Reno, Department of Animal Biotechnology.

Candidate genes believed likely to be involved with growth and feed intake were used to screen a BAC library in an effort aimed at identifying chromosomal regions, and ultimately genes and mutations, responsible for phenotypic variation in efficient growth and related traits. Identified BACs were subcloned, sequenced, and primers designed for locus specific re-sequencing and SNP discovery. A subset of SNPs (filtered for sequence context, spacing, disequilibrium, and platform compatibility) were used to genotype several large, two-generation pedigrees. Linkage analysis (CRI-MAP v2.4) identified 27 linkage groups that were "anchored" to porcine chromosomes through linkage to previously assigned loci (<http://iowa.thearkdb.org/>) or assignment of loci to a porcine radiation hybrid map. The location of the putative human homolog of each gene was identified in silico and used to confirm assignments. This annotation process provided confirmatory evidence for the chromosomal assignment of 24 previously unassigned candidate genes for efficient growth. Subsequent research will now focus on aligning these genes with

QTL detected in various resource populations and comparative sequence analysis to identify functional polymorphisms.

Key Words: Swine, Growth, QTL

W268 Mapping and genetic variation within porcine 70 kiloDalton heat shock protein 2 (HSPA2). M. Grosz*¹ and G. Rohrer², ¹Monsanto Company, West Chesterfield, MO, ²USDA-ARS US Meat Animal Research Center, Clay Center, NC.

70 kiloDalton heat shock protein 2 (HSPA2) is expressed in the testis during the meiotic phase of spermatogenesis in humans and mice. Mutations in HSPA2 have been shown to cause sterility in male mice, while not affecting female reproductive capacity. Based on these comparative observations, HSPA2 is a candidate gene for influencing porcine male reproductive phenotypes. To initiate research assessing this possible relationship, the human HSPA2 sequence was used to identify a putative

porcine HSPA2 sequence from public EST databases. This EST was used to isolate a Bacterial Artificial Chromosome (BAC) clone containing the porcine homolog of HSPA2. BAC DNA was subcloned, and the porcine HSPA2 locus was defined by sequence assembly and analysis. Extant genetic variation was identified by amplification and re-sequencing of HSPA2 (and flanking regions) with a series of overlapping primer pairs. In total, 11 Single Nucleotide Polymorphisms (SNPs) and 1 single base insertion/deletion were identified in the region spanning from 1062 bases upstream of the start codon to 672 bases downstream of the stop codon. None of the identified SNPs alter the amino acid sequence of the peptide. Two SNPs were converted into PCR-RFLP assays and used to genetically map the HSPA2 locus to chromosome 7, 87 cM, consistent with the syntenic relationship between Hsa14 and Ssc7. Future research can now be directed toward detecting associations between genetic variation and swine reproductive performance and other phenotypes.

Key Words: Swine, HSPA2, SNP

W269 Correlation of genomic changes with morphological dimorphism of *Campylobacter jejuni*. H. Wang*¹ and M. Slavik¹, ¹POSC University of Arkansas, Fayetteville.

Campylobacter jejuni is one of the leading causes of human bacterial gastroenteritis. Previous research has shown that variation in pathogenicity of *C. jejuni* may be associated with its polymorphism. The spiral form of *C. jejuni* has been shown to be more highly pathogenic than the coccoid cells of the same strain. The objective of this research was to investigate the possibility of genomic changes associated with the polymorphism in *C. jejuni* using pulsed-field gel electrophoresis (PFGE) and DNA sequencing analysis. *Campylobacter jejuni* isolated from pre-chill, post-chill, and retail chicken carcasses and human stool samples of enteritis patients were cultured on *Campylobacter* enrichment agar for 18 hours (spiral form) and 72 hours (coccoid form) under microaerobic conditions at 42 °C. All isolates were confirmed as *C. jejuni* positive by using polymerase chain reaction (PCR). The isolates then were embedded in agarose plugs and the DNA was analyzed by PFGE (CHEF-DR III system) after digestion using either *Sma* I and *Sac* II restriction endonucleases. After an ethidium bromide staining, the DNA patterns were analyzed using the molecular analyst fingerprinting software (BIO-RAD). The molecular fingerprint of each isolate in the spiral form was compared to the fingerprint of the same isolate in the coccoid form. No genomic variation in the overall restriction patterns associated with polymorphism was observed in the strains tested. Both forms of *C. jejuni* PFGE profiles showed 100% genetic similarity following *Sma* I or *Sac* II digestion. At same time, PCR products of *flaA* gene from the isolated *C. jejuni* were purified by using Wizard PCR Preps DNA Purification System (Promega Corporation, Madison, WI). The purified DNA samples were tested for DNA sequencing analysis and the DNA sequences of each isolate in both forms were computer analyzed by using SeqMan (DNASTar inc., Madison, WI). For two forms of same isolate, the nucleic acid sequences of *flaA* gene showed 90-100% similarity. It is concluded that the morphological dimorphism of *C. jejuni* is not associated with genetic modification.

W270 Risk assessment for antibiotic resistance in foodborne pathogens isolated from poultry products. N. Kotrola and R. Roy*, Auburn University, AL.

Our initial goal of this study was to determine the prevalence of antibiotic resistant foodborne pathogens in poultry product samples at the retail level. 160 samples of chilled raw poultry meat (thighs, drumsticks, and breasts) and fully cooked turkey hot dogs were sampled from selected stores. One strain from each pathogen-positive sample was selected for susceptibility testing with the E-test method (AB Biodisk North America, Inc.). The E-test was performed for ciprofloxacin, tetracycline, and erythromycin according to the manufacturer's instructions. Inocula were prepared by incubating the campylobacter strains for 24 h at 42°C under microaerobic conditions in brucella broth or incubating for 24 h at 37°C in BHI broth for *Listeria monocytogenes*, *Salmonella* and *E.coli* strains. After application of the E-test strips, campylobacter plates were incubated in microaerobic conditions at 42°C for 24

h or 37 C for all other strains. The minimal inhibition concentration (MIC) was read directly from the test strip at the point where the elliptical zone of inhibition intersected the MIC scale on the strip. Our preliminary results indicated that the overall prevalence of tetracycline, ciprofloxacin, and erythromycin resistance in *Campylobacter* strains was 65.52%, 7.69%, and 7.41% respectively. The overall prevalence of tetracycline, ciprofloxacin, and erythromycin resistance in *Listeria monocytogenes* strains was 100%, 0%, and 50% respectively. The overall prevalence of tetracycline, ciprofloxacin, and erythromycin resistance in *Salmonella* strains was 100%, 0%, and 100% respectively. And finally, the overall prevalence of tetracycline, ciprofloxacin, and erythromycin resistance in *E. coli* strains was 56.25%, 0%, and 100% respectively. These initial results confirm the notion of multiresistant strains in *Campylobacter*, *Listeria monocytogenes*, *Salmonella* and *E. coli*.

W271 Risk Assessment of stress factors and *Listeria monocytogenes* Biofilm formation. B. Dean*, P. Mohyla, R. Roy, and N. Kotrola, Auburn University, AL.

Differential adherence capabilities and reaction to sanitizers for biofilm removal among tetracycline resistant, quaternary ammonium compound (quat), and sodium hypochlorite (bleach) stressed, acid and alkali adapted, and non-stressed *Listeria monocytogenes* (LM) were tested by the microtiter bio-screening assay. Cell turbidity and biofilm formation were assessed using a microtiter plate reader at the wavelength of 630 nm. The quantitative analysis of biofilm production was performed by adding 200 ul of 95% ethanol to destain the wells. One hundred microliters from each well was transferred to a new microtiter plate and optical densities (OD) of the crystal violet present in the destaining solution was evaluated. Viable counts were also assessed to determine the efficacy of several sanitizers for the removal of LM biofilm. Results showed significant differences in both biofilm formation and cell turbidity at 630 nm between stressed and non-stressed LM isolates ($p < 0.001$). At 630nm, bleach stressed and tetracycline resistant LM formed stronger biofilm compared to the unstressed LM with OD of -2.75×10^{-3} , -5.70×10^{-3} and 3.31×10^{-3} , respectively. There were significant difference in cell turbidity at a 630 nm, between the stressed cells compared to the positive control ($p < 0.05$), but there were no difference among the cells subjected to the various stressors. Results of the viable cell counts of the stressed LM in biofilm were significantly higher ($p < 0.05$); than the positive controls (average means of $1.8 \times 10^7 \pm 1.6$ and $4.5 \times 10^4 \pm 1.16$, respectively) when treated with sanitizers. In conclusion, stressed LM cells in biofilm appear to exhibit higher tolerance to sanitizer treatment when compared to unstressed LM cells and this tolerance may influence the efficacy of the sanitizer for biofilm removal.

Key Words: Biofilm, L. Monocytogenes, Stressed Cells

W272 Fumonisin B1 absorption study in Ussing Chamber model reveals a possible active transport. G. Casadei¹, F. Galvano², N. Chiulli¹, G. Biagi¹, and A. Piva^{*1}, ¹University of Bologna, Italy, ²University of Reggio Calabria, Italy.

Fumonisin B1 is mainly produced by *Fusarium verticillioides*, *F. moniliforme* and *F. proliferatum* that grow on cereals. As their pathogenic activity depends on bio-availability, fumonisin B1 (FB1) absorption was studied *in vitro* with Ussing chamber technique. Male rats (n=9), *Rattus norvegicus* Wistar strain, weighing 170-230g underwent laparotomy under ether anesthesia. Jejunum, starting 10cm from the ligament of Treitz was removed, cut into 2.5cm segments, and immediately immersed in a modified Krebs-Ringer buffer, oxygenated with 95% O₂ and 5% CO₂ at room temperature. Each piece was cut along the mesenteric border and mounted in Ussing chambers. The experiments started (t=0), within 30 min after the induction of anesthesia, when the buffer in the mucosal reservoirs was exchanged with 5ml buffer containing FB1 at 30ppm. At 0, 20, 40, 60, 80, 100 and 120 minutes, a 1ml sample was withdrawn from serosal reservoir for FB1 analysis, and replaced with fresh media. Of the 150mg FB1 dissolved in the 5ml mucosal solution, serosal recovery at sampling times was: 7.6%, 12.1%, 18.1%, 25.2%, 30.2%, 36.0% respectively. The apparent permeability coefficient Papp [cm/sec*10⁻⁶]=dc/dt*V/(A*Co), where dc/dt is the change in FB1 concentration on the mucosal side per unit time, V is the volume of the chamber (5cm³), A the area of exposed intestine (1.78cm²), and Co is the initial FB1 concentration in the mucosal reservoir (30ppm), was estimated to be as high as 134.3±3.7cm/sec*10⁻⁶. Regression of FB1 concentration over time revealed a linear correlation represented by the equation: y=0.412x+0.816; r²=0.9807, where y=FB1 total absorbed μg and x=minutes. According to this model, FB1 absorption in rat small intestine averages 0.232±0.007μg/min per cm² of exposed mucosa. The linearity of FB1 absorption rate seems to obey an apparent zero-order kinetic involving a carrier-mediated transport. Other studies are required to better describe intestinal FB1 uptake, so far considered to be very low.

Key Words: Ussing Chambers, Fumonisin B1, Rat

W273 Effects of fumonisin B1 on pathological and immunological parameters in pigs consuming diets with or without the addition of activated charcoal. A. Piva^{*1}, D. E. Diaz⁴, G. Casadei¹, E. Cabassi², and G. Piva^{*3}, ¹University of Bologna, Italy, ²University of Parma, Italy, ³Catholic University of the Sacred Heart, Italy, ⁴Fondazione Parco Tecnologico Padano, Italy.

Fumonisin B1 is a mycotoxin found primarily in cereals and that are produced primarily by *Fusarium verticillioides*, *Fusarium moniliforme* and *F. proliferatum*. The effects of fumonisin B1 (FB1) on weaned piglets were evaluated. Fifty-six male weaning pigs (mean initial weight of 6.9kg) were randomly assigned to pens and one of four treatments diets according to their initial weight. The treatment diets were: 1) Corn-soybean basal diet with < 2ppm FB1 (Control) 2) BD + Activated Carbon at 1% of the diet DM (AC), 3) Control+FB1 (FU) (30ppm FB1), and 4) Control+AC+FU (AC+FU). A total of 4 replicates of 3 pigs/pen for treatments 3, and 4 and 4 piglets/pen for treatments 1, and 2 were utilized. Tissue and blood samples were collected at the end of the 42-days experimental period. Pigs fed FB1 contaminated diets showed distinct lesions in lungs, heart, pancreas, spleen, small intestine and liver and had marked pulmonary edema. Animals fed the AC+FU diet had the most severe lesions in these organs and the lowest CD14 (2.61 vs 14.09; P<0.01), CD8 (4.48 vs 27.68; P<0.01) CD4 (2.29 vs 16.22; P<0.01) values compared to control. Animals fed only FB1 at 30ppm showed a reduced functionality only relative to CD14 compared (6.32 vs 14.09; P<0.01). CD4 to CD8 ratio was never influenced by the addition of FB1 (30ppm) with or without activated carbon. The consumption of diets contaminated with 30ppm fumonisin B1, from cultured material, significantly affected organ pathology and macrophage functions in post-weaned piglets. The addition of an activated carbon added at 1% of the diet was not effective in protecting, against the detrimental effects of fumonisin consumption.

Key Words: Fumonisin B1, Swine, Activated Carbon

W274 Comparison of rectoanal mucosal swabs (RAMS) and fecal culture for determining prevalence of *Escherichia coli* O157 in feedlot cattle. M. A. Greenquist^{*1}, J. S. Drouillard¹, T. G. Nagaraja², J. M. Sargeant², B. E. Deppenbusch¹, X. Shi², and K. F. Lechtenberg³, ¹Department of Animal Sciences and Industry, Kansas State University, Manhattan, ²Department of Diagnostic Medicine and Pathobiology, Kansas State University, Manhattan, ³Midwest Veterinary Services, Inc, Oakland, NE.

The lymphoid tissue in the rectoanal junction (RAJ) of the gastrointestinal tract has been suggested as the principal site of colonization of *E. coli* O157 in cattle. Samples collected by swabbing the rectoanal mucosa have been shown to be superior to fecal grab samples for detection of *E. coli* O157 in a study involving experimentally inoculated cattle and in a small number of dairy heifers. Our objective was to compare the utility of the two sampling techniques for determining prevalence of *E. coli* O157 in feedlot cattle (n = 747) fed high-grain diets. Isolation procedures included enrichment of RAMS or fecal samples in Gram negative broth with cefixime, cefsulodin, and vancomycin, followed by immunomagnetic bead separation and plating on sorbitol MacConkey agar with cefixime and potassium tellurite. Sorbitol-negative colonies were identified as *E. coli* O157 based on indole production, positive latex agglutination for O157 antigen and API 20E test strip results. Of the 82 animals that tested positive for *E. coli* O157, 87% were detected by the RAMS method, but only 45% by the fecal culture method. Genomic fingerprints of isolates were analyzed by pulse-field electrophoresis (PFGE) to compare clonal identity between RAMS and fecal isolates from the same animal. Of the 24 pairs of isolates evaluated, 20 had 100% similarity and 4 had >95% similarity in PFGE banding patterns, suggesting that strains colonizing the RAJ are the same as those isolated from feces. RAMS culture appears to be more sensitive than the traditional fecal culture method for determining prevalence of *E. coli* O157 in feedlot cattle.

Key Words: Rectoanal Mucosal Swabs, *E. coli* O157, Feedlot Cattle

W275 Effects of nitrate adaptation and chlorate supplementation on fecal *Escherichia coli* concentrations in Holstein steers. J. T. Fox^{*1}, R. C. Anderson², G. E. Carstens¹, R. K. Miller¹, and D. J. Nisbet², ¹Texas A&M University, College Station, ²USDA-ARS, FFSRU, College Station, TX.

In studies with broilers and pigs, bactericidal activity of an experimental chlorate product (ECP) against enteropathogens was enhanced by nitrate adaptation. Objectives of this study were to examine effects of nitrate adaptation on bactericidal activity of ECP against *E. coli* in cattle. Holstein steers (BW = 210 ± 5.1 kg) were trained to use Calan feeders and assigned to one of six treatments (n = 8) in a 2 x 3 factorial arrangement that included three ECP doses (0, 1.2 or 2.3 g chlorate ion equivalence/kg diet), with or without nitrate adaptation (0.95 g NO₃ ion equivalence/kg diet). The nitrate product (with 0 or 11% NO₃ ion equivalence) was added to the experimental diet (66, 15 and 19% corn, alfalfa hay and supplement) for 3 d immediately preceding administration of ECP (with 0, 12.5 or 25% chlorate ion equivalence), which was added one d prior to termination of the study. Fecal samples were collected prior to nitrate administration and one d following ECP administration, and cultured quantitatively for generic *E. coli*. Supplementation with nitrate and/or ECP did not affect ADG, DMI or feed:gain during the 28-d study, which averaged 1.3 ± 0.1 kg/d, 6.4 ± 0.3 kg/d and 5.2 ± 0.3, respectively. ECP did not affect DMI during the last d of the study. Initial fecal *E. coli* concentrations were not different among treatments and averaged 5.4 ± 0.2 log₁₀ CFU/g. Final fecal *E. coli* concentrations were not affected by nitrate adaptation (P = .26) or nitrate x chlorate interaction (P = .20). ECP supplementation reduced (P < .001) final fecal *E. coli* concentrations (5.2, 2.7 and 2.6 ± 0.3 log₁₀ CFU/g for 0, 1.2 and 2.3 g chlorate ion equivalence/kg, respectively), but not in a dose-dependent manner. ECP supplementation effectively reduced fecal *E. coli* by 48%, but in contrast to previous results with

broilers and pigs, nitrate adaptation did not further enhance the bactericidal effects of ECP. Rapid reduction of ruminal nitrate may account for specie differences. Discovery of nitro-compounds that are more resistant to ruminal degradation may enhance the efficacy of ECP against enteropathogens in cattle.

Key Words: *E. coli*, Chlorate, Cattle

W276 Effect of caffeine on inactivation of *Escherichia coli* O157:H7 in laboratory media. S. A. Ibrahim*, North Carolina A&T State University, Raleigh.

Escherichia coli O157:H7, a leading cause of bacterial food borne disease outbreaks, is responsible for approximately 73,500 cases of food-borne illness per year. Recent research has shown that caffeine has the ability to inhibit DNA repair in bacteria and therefore could be mutagenic compound. The objective of this research was to determine the effectiveness of caffeine on inactivation of (*E. coli* O157:H7 in Brain Heart Infusion (BHI) broth. Overnight samples of six *E. coli* O157:H7 strains (E 1730, E 4546, E 0019, Cider, 380 and 944) were used in this study. These strains were inoculated individually at an initial inoculum level of 2 log CFU/ml into BHI broth containing caffeine with different concentrations of 0.0, 0.25, 0.5, 0.75, 1.00, 1.25, 1.50, 1.75, and 2.00%. Samples were then incubated at 37 C for 24hrs. Samples were withdrawn at different time intervals to determine turbidity using spectrophotometer at 575nm. Results revealed that the addition of caffeine inhibited the growth of *E. coli*. Significant growth inhibition was observed with concentration levels 0.50% and higher. These results indicate that caffeine has potential as an antimicrobial agent and should be investigated further as a food additive to increase the biosafety of consumable food products.

Key Words: Caffeine, *Escherichia coli* O157:H7

W277 Using origanox in combination with sodium lactate and sodium acetate to inhibit the growth of *Escherichia coli* O157:H7. S. A. Ibrahim* and S. R. K. Dharmavaram, North Carolina A&T State University, Raleigh.

Escherichia coli O157:H7, a leading cause of bacterial food borne disease outbreaks, is responsible for approximately 73,500 cases of food-borne illness per year. Origanox, a commercial spice, has been shown to have antimicrobial properties. It is believed that the effectiveness of origanox can be enhanced by the use of organic acids. The objective of this research was to determine the effectiveness of origanox alone

and in combination with chemical preservatives; sodium acetate and sodium lactate on inactivation of *E. coli* O157:H7 in Brain Heart Infusion (BHI) broth. Overnight samples of five *E. coli* O157:H7 strains (E 1730, E 4546, E 0019, Cider and 944) and a mixture of the five strains were added to BHI broth at an initial inoculum level of 2 log CFU/ml. Several combinations of sodium lactate (0,1, and 2 % w/v), sodium acetate (0 and 1 % w/v), and origanox (0, 0.05 and 0.1 % w/v) were used as treatments. The samples were stored at 37 °C for 12 hrs and population changes of *E. coli* O157:H7 were followed using optical density (O.D. 610 nm) measurements and CFU techniques every two hours. Our results indicated that origanox was effective in controlling the growth of *E. coli* O157:H7 at concentration of 0.1 % in BHI broth. Sodium lactate alone was found to be effective at 3% concentration. Sodium lactate at 1-2% in combination with 0.05% origanox or sodium acetate at 1% in combination with 0.05% origanox was found to be the most effective in controlling the growth of *E. coli* O157:H7, > 4 log reduction. Treatments containing a combination of 1% sodium lactate, 1% sodium acetate and 0.05% origanox showed significant reduction of *E. coli* O157:H7, > 5 log reductions. Use of origanox at 0.05% could reduce the usage of chemical preservatives such as sodium lactate and sodium acetate to inhibit the growth of *E. coli* O157:H7.

Key Words: Origanox

W278 Selection of anti-bacterial peptides against *E. coli* O157:H7 and UTI from f88-4/15 library. C. J. Fu*, F. J. Schmidt, S. A. Mounter, and M. S. Kerley, University of Missouri-Columbia.

Phage display technology was used to select anti-bacterial peptides against pathogenic *E. coli* O157:H7 (isolates PA 1 and PA 2 from human clinical case and ground beef, respectively) and UTI (isolate PA 3 from a urinary tract infection case). After 4 rounds of affinity selection, 40 phage clones (PC 1 to 120) bearing colonies selected against each pathogen were examined. The purified phage clones were used to test their function of inhibition/killing the pathogenic *E. coli*. DNA sequencing indicated that only 2 phage sequences were repeated in 16 colonies from the PA 1 and PA 2 selection. A single clone dominated the PA 3 selection (12/16). No similar peptide sequences were found from published databases by BLAST search. Several PC (PC 5, 16, 41, 42, 46, 84, 94, and 95) inhibited or killed the pathogens (40 to 85% within 2 hours). Phage clones selected against either PA 1 or PA 2 inhibited both strains but not PA 3. However PCs selected against PA 3 inhibited PA 1 and PA 2.

Key Words: Pathogenic *E. coli*, Peptide, Phage Display

Dairy Foods: Microbiology

W279 Lactic acid fermentation by *Lactobacillus reuteri* in laboratory medium supplemented with various nutrients. S. Phetsomphou* and S. A. Ibrahim, North Carolina A&T State University, Raleigh.

Lactic acid is a product that has numerous applications in the chemical, pharmaceutical, and food industries. Lactic acid bacteria have been used widely for the production of lactic acid. However, certain nutrients are needed for the maximum production of lactic acid. Therefore, objective of this research was to investigate the effect of nutrient supplements and carbohydrate substrates on lactic acid production using free and calcium alginate immobilized *Lactobacillus reuteri*. *L. reuteri* MM 2-3 in a free cell form and calcium alginate beads (immobilized) was used to determine lactic acid production in laboratory medium supplemented with different nutrients: yeast extract, beef extract, tryptone peptone, and proteose peptone at 0, 10 and 20% concentrations or carbohydrate substrates: maltose, lactose, glucose, sorbitol and sucrose at 10% concentration. Fermentation experiments were conducted in 500 ml flasks with 300 ml final volume at 37 °C for 24 hrs. At different time intervals (2 hrs), samples were withdrawn, and analyzed for pH values and lactic acid concentrations. Fermentations of immobilized *L. reuteri* in samples containing yeast extract, phytone and proteose peptone at 20% produced the highest concentrations of lactic acid after 24 hrs with pH measurements (3.20, 3.41, and 3.61, respectively) as compared to the control (4.70). Lactic acid concentration ranged between 9.00 and

12.50. Regarding carbohydrate substrate (sugar) fermentation, maltose produced the lowest pH (3.32) followed by glucose, lactose and sorbitol (3.47, 4.00, and 6.11 respectively). Results indicated that immobilized cells of *L. reuteri* MM2-3 produced higher lactic acid and in a shorter time when compared to free cells. The results show that immobilized *L. reuteri* could be used for the production of high lactic acid concentrations in a laboratory media supplemented with both yeast extract and maltose.

Key Words: *L. reuteri*, Lactic Acid

W280 Influence of an *Arthrospira (Spirulina) platensis* biomass on acid production of lactococci. N. Molnár, L. Varga*, J. Szigeti, and B. Gyenis, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonyaróvár, Hungary.

Arthrospira (Spirulina) platensis is a planktonic cyanobacterium belonging to prokaryotic algae. Its dried biomass typically contains 3% to 7% moisture, 55% to 60% protein, 6% to 8% lipids, 12% to 20% carbohydrate, 7% to 10% ash, 8% to 10% fiber, 1% to 1.5% chlorophyll *a*, and a wide range of vitamins. *A. platensis* has recently been marketed and consumed as a safe human food and has been approved for human nutrition by many governments, health agencies, and associations of some 80 countries, including the United States. The effect of

a spray-dried *A. platensis* biomass, on the rate of acid development by various strains of major lactic acid producers in mesophilic dairy starter cultures such as *Lactococcus lactis* subsp. *lactis* and *Lactococcus lactis* subsp. *cremoris* was evaluated in cows milk. Acid production of the starter culture strains screened was mostly stimulated significantly ($P < 0.05$), although to varying degrees. The components of the cyanobacterial biomass responsible for the stimulation observed were found to be nitrogenous compounds (peptone, adenine, and hypoxanthine). The *A. platensis* biomass rich in trace elements, vitamins, and other bioactive substrates also had a highly beneficial effect on the nutritional value of milk, thus providing a new opportunity for the manufacture of functional fermented milks, i.e., *Arthrospira*-enriched cultured cream and buttermilk.

Acknowledgments: This work was funded by a grant (FKFP - 0197/2001) from the Ministry of Education, Hungary. László Varga is grateful to the Hungarian Academy of Sciences for the award of a János Bolyai Research Scholarship.

Key Words: *Arthrospira (Spirulina) platensis*, *Lactococcus lactis* subsp. *lactis*, *Lactococcus lactis* subsp. *cremoris*

W281 Occurrence of Glutathione sulphhydryl(GSH) and Antioxidant Activities of Probiotic Lactobacillus spp. Y. H. Yoon* and J. R. Byun, *Department of Animal Science and Technology, Chung-Ang University.*

The antioxidative ability on the basis of reduced glutathione sulphhydryl level, the inhibition activities of linoleic acid peroxidation of cell free extract of *Lactobacillus* spp and the effects of types of media and growth phase of the cells on the cellular GSH level have been determined. Correlation between reduced glutathione sulphhydryl level and antioxidative ability of *Lactobacillus* spp. was analyzed: *Lactobacillus casei* HY 2782 contained the highest level of GSH among the probiotic strains with 25.15 μ mole/g, the cellular GSH level of *L. casei* HY 2782 reached maximum after 24h of cultivation and tended to decrease on further cultivation up to 72h, it revealed significantly higher level of cellular GSH when grown in de Man Rogosa and Sharpe (MRS) broth than in tryptone phytone yeast extract (TPY) broth or bromocresol purple destroxe (BCP) broth ($p < 0.05$). The antioxidant activity of cell free extract of *Lactobacillus* spp have been shown to be significantly differed among the strains in the inhibition of linoleic acid peroxidation by thiobarbituric acid (TBA) test ($P > 0.01$). *L. casei* HY 2782 and *L. acidophilus* ATCC 4356 revealed a high degree of antioxidative effect in linoleic acid oxidation system. Spearman's rank correlation quotient between inhibitory activity on linoleic acid peroxidation and cellular GSH levels of *Lactobacillus* spp was 0.65 which means a significant positive correlation (Key words; GSH level, antioxidant effect)

Key Words: GSH Level, Antioxidant Effect

W282 Functionality and survivability of probiotics in carbonated yogurt beverage. F. Lee and M. Guo*, *University of Vermont, Burlington.*

A prototype carbonated yogurt beverage was developed using a probiotic yogurt as a base and carbonated with 0, 1, 2 or 3 volumes of food-grade carbon dioxide. Inulin (natural prebiotic ingredient) and probiotic bacteria were integrated into the product to create a symbiotic dairy beverage that could benefit the health of consumers. Mean chemical composition of the beverage from all 3 trials consisted of 16.3% total solids, 14.6% carbohydrates, 2.2% protein, 1.7% fat and 0.2% ash. Mean content of Ca, P, K, Mg, Na, Cu and Zn in the beverage were 745, 380, 671, 50, 222, 0.2 and 13 mg/kg, respectively. Mean pH values of the beverage carbonated with 0, 1, 2 and 3 vol of CO₂ during the 10-wk study were 3.58, 3.70, 3.59 and 3.56, respectively. Averaged viscosity values of the beverage for the same treatment and period were 26.3, 24.0, 25.3 and 21.1 mPa.s, respectively. Visual inspection and negative results from 3M yeast / mold and coliform films indicated the beverage remained stable up to ten weeks in refrigerated storage. Survivability of probiotic bacteria in the beverage during a 10-wk study was evaluated according to enumeration methods of Chr Hansen, Inc. Initial estimated levels of *L. acidophilus* in the beverage carbonated with 0, 1, 2 and 3 vol of CO₂ were 7.4, 6.8, 6.9, and 7.3 log CFU/ml, respectively. Correspondingly, initial levels for *Bifidobacteria* were 7.2, 7.3, 7.3 and 9.0 log CFU/ml; and 7.7, 7.9, 8.0 and 8.1 log CFU/ml for *L. casei*. Levels of *L. acidophilus* in the beverage decreased below 6.0 log cfu/mL shortly after week 4, regardless of carbonation levels. Population of *Bifidobacteria*

gradually decreased and remained above 6.0 CFU/ml through week 10 in beverages carbonated with 2 and 3 vol CO₂. Levels *L. casei* of also decreased steadily but remained above 6.0 CFU/ml only through week 8 in all carbonated beverages. In summary, carbonated symbiotic yogurt beverage can be developed to deliver probiotic bacteria. Carbon dioxide may have positive impact on the survival of certain probiotics, i.e., *Bifidobacteria*.

Key Words: Yogurt, Beverage, Probiotic

W283 Influence of bile salts on growth, antimicrobial activity and β -galactosidase activity of *Lactobacillus reuteri*. S. A. Ibrahim* and S. A. Ahmed, *North Carolina A&T State University, Raleigh.*

It is well known that the presence of lactobacilli is important for the maintenance of the intestinal microbial ecosystem. They have been shown to possess inhibitory activity toward the growth of pathogenic bacteria such as *Escherichia coli* O157:H7 and *Salmonellaspp*. This inhibition could be due to the production of inhibitory compounds such as organic acids, hydrogen peroxide, bacteriocins, or reuterin or to competitive adhesion to the epithelium. In order to survive in and colonize the gastrointestinal tract, lactobacilli should express high tolerance to acid and bile. They should have the ability to adhere to intestinal surfaces and produce large quantity of β -galactosidase. The purpose of this work was to investigate the influence of bile salts on growth, antimicrobial activity and β -galactosidase activity of *Lactobacillus reuteri*. Six strains of *Lactobacillus reuteri* (CF 2F, DSM 20016, MF 14C, MM 7, MM 2-3, and SD 2112) were used in this study. These strains were grown in modified Trypticase-protease peptone-yeast extract (TPY) broth containing 0.0 or 0.4% bile salt at 37 C for 48 hrs. The extent of bacterial growth was monitored by measuring the optical density of the samples at 610nm after various time intervals. The effect of bile salt on the production of antimicrobial compounds was tested using the diffusion assay. The β -galactosidase activity was determined during the growth in the presence of bile salt. Results showed that growth and antimicrobial activity decreased in the presence of 0.4% bile salt ($P < 0.05$). The β -galactosidase activity was varied among the tested strains. MM 2-3 showed higher β -galactosidase in the presence of bile salt. Activity ranged between 800 and 1400 Miller units. Bile salt does not affect β -galactosidase activity of MF 14C strain. Our results demonstrate that bile salt has an influence on the biochemical properties of *Lactobacillus reuteri*. Bile salt should be considered when probiotic strains are selected for useful industrial applications.

W284 Incidence of *Escherichia coli* O157:H7 in raw milk and survival of a five strain cocktail of *E. coli* O157:H7 during the 60 days aging period of hard cheese made from unpasteurized milk. J. Schlessner*¹ and R. Gerdes², ¹*Food and Drug Administration, NCFST, Summit-Argo, IL,* ²*Illinois Institute of Technology, Summit-Argo, IL.*

The incidence and concentrations of *E. coli* O157:H7 present in raw milk as delivered to Midwest milk processors were determined. For incidence, raw milk were inoculated in pre-enrichment and enrichment broths and incubated before plating. One ml samples of raw milk was pipetted onto 2 BCM plates and incubated for determination of concentration of the pathogen. All 237 samples tested were less than the lower limits of detection for incidence and concentration. Hard cheese was made from unpasteurized milk inoculated with 10¹ cells/ml of a five-strain cocktail of acid-tolerant *E. coli* O157:H7. Samples of unpasteurized milk, curd and whey were collected during the cheese manufacturing process. After pressing, the blocks of hard cheese were packaged into plastic bags, and sealed with a vacuum-packaging machine, and aged at 7 ° C. After 1 week, the cheese blocks were cut into smaller uniform-sized pieces, and vacuum sealed in clear plastic pouches for ease of sampling at the various aging intervals. Samples were plated and enumerated for *E. coli* O157:H7 using BCM for *E. coli* O157:H7 (+) Plating Medium. Populations increased to 10² in the drained curd and to 10³ at milling and pressing. Population of *E. coli* O157:H7 in cheese aged for 60 and 120 days at 7 ° C, decreased less than 1 log and 2 logs, respectively. After 150 to 180 days, levels declined to <1/ml. Cheese samples in storage were inoculated in pre-enrichment and enrichment broths and incubated before plating. After approximately 240 days, no growth of

E. coli O157:H7 was seen on the plates after either pre-enrichment or enrichment.

Key Words: Raw Milk Cheese, *Escherichia coli* O157:H7, *E. coli* O157:H7 in Raw Milk

W285 Incorporation and survival of probiotic bacteria in yogurt for use as a functional food. S. Hekmat^{*1}, S. Royal^{2,3}, and G. Reid^{2,3}, ¹Brescia University College at The University of Western Ontario, London, Canada, ²The University of Western Ontario, London, Canada, ³Lawson Health Research Institute, London, Ontario, Canada.

Both *Lactobacillus fermentum* RC-14 and *Lactobacillus rhamnosus* GR-1 have been shown to be probiotic agents with intestinal and urogenital therapeutic properties, and both colonize the intestine when ingested in skim milk. Low-fat (1%) probiotic yogurt was made by fermenting standard yogurt starter cultures, *L. delbrueckii var bulgaricus* and *S. thermophilus*, mixes with *L. fermentum* RC-14 and *L. rhamnosus* GR-1. Survival of *L. fermentum* RC-14 and *L. rhamnosus* GR-1 was monitored using selective MRS agar containing 50 µg/mL tetracycline or 15 µg/mL fusidic acid, respectively, after 1, 7, 14, 21, and 28 days of storage at 4°C. In all treatments, *L. rhamnosus* GR-1 survived better than *L. fermentum* RC-14. After one day of storage, mean colony counts of *L. fermentum* RC-14 and *L. rhamnosus* GR-1 were 7×10^5 and 4×10^7 CFU/mL respectively. After one month of refrigerated storage, these counts had decreased to 4×10^3 for RC-14 but remained stable at 2×10^7 CFU/mL for strain GR-1. This study provides a method to derive a new probiotic yogurt as a vehicle to deliver beneficial bacteria to consumers. Such a yogurt, with high counts of probiotic bacteria, would be the first of its type in Canada.

Key Words: Functional Foods, Probiotic Yogurt

W286 Development of probiotic concentrated yogurt using direct reconstitution method. S. Hekmat*, V. W. Y. Ng, and A. J. Holman, Brescia University College at The University of Western Ontario, London.

Concentrated yogurt is traditionally made by draining the yogurt in a double layer cheese cloth bag. This process is time consuming and may introduce unwanted microorganisms into the yogurt through contamination. The objective of this study was to produce probiotic concentrated yogurt by direct reconstitution method. Full-fat milk powder and non-fat milk powder were reconstituted with either water or milk to 12, 16, 18, 20, 23, and 26% total solids (TS). Some of the samples contained 0.3% or 0.6% gelatin. The mixtures were heat treated at 85°C for 30 min., cooled to 41°C, and then inoculated with 4% of the starter yogurt cultures containing *Lactobacillus acidophilus* and *Bifidobacterium bifidum*. The mixtures were stirred well and fermented for approximately 5 h at 42°C until the desired pH was reached. The samples that were reconstituted with milk did not ferment at all. The samples with 20 and 23% TS containing full-fat milk powder and 0.3% gelatin resulted in the best quality in terms of appearance, flavour, texture, and overall quality.

Key Words: Concentrated Yogurt, Probiotic Yogurt

W287 Suitability of *Kluyveromyces* spp. for use in single-cell protein production from sweet cheese whey. B. Ásványi, J. Szigeti, and L. Varga*, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.

Only 51.2% of liquid whey produced in the United States is further processed into food or feed ingredients. An alternative to the traditional uses of whey is the production of single-cell protein (SCP). In this study, the suitability of the strains of two *Kluyveromyces* species (i.e., *K. marxianus* var. *marxianus* LAF4 and *K. lactis* KE 231) for use in SCP production was examined. The major parameter measured was the dry weight of the yeast biomass. The *Kluyveromyces* strains tested were grown in unfractionated, heat-treated sweet cheese whey. Fermentations were run batchwise for 48 h in an automated BIOFLO III[®] batch/continuous fermenter under identical conditions with respect to pH, aeration, and agitation rate. The parameters set were computer-controlled using Advanced Fermentation Software[®] version 3.42. Samples were taken every 4 h with an MX3 Biosampler[®]. After proper

centrifugation and drying, the dry weight of yeast biomass was determined. The lactose, glucose, galactose, and ethanol contents of samples were also measured. *K. marxianus* var. *marxianus* LAF4 was shown to be superior in terms of suitability for production of SCP from sweet cheese whey to *K. lactis* KE 231 under commercial conditions.

Key Words: Single-Cell Protein, *Kluyveromyces* spp., Whey

W288 Ethanol metabolism by probiotic lactic acid bacteria *in vivo*. W. Y. Yang^{*1}, Y. T. Ahn², K. S. Lim², C. S. Huh², Y. J. Baek², and H. S. Kim¹, ¹Culture Systems, Inc., Mishawaka, IN, ²Korea Yakult Co., Ltd, Kyunggi do, South Korea.

Recent studies have shown that probiotic lactic acid bacteria have alcohol dehydrogenase (ADH) and acetaldehyde dehydrogenase (ALDH) activities. However, little is known about the metabolism of ethanol and acetaldehyde *in vivo*. The aim of this study is to test the possibility that probiotic lactobacillus strains are able to metabolize ethanol and acetaldehyde *in vivo*. Four *Lactobacillus* spp. and one *Bifidobacterium* spp. were used for this experiment. Male Swiss Webster mice weighing between 19-21 g were used for *in vivo* experiments. The lactic acid bacteria of 10^9 cfu/ml were delivered orally once a day to the mice for 30 days. Ethanol, diluted in water (25:75; v/v), was administered once a day by gastric intubations for 30 consecutive days. The average daily consumption of ethanol was 12 g/kg body weight. Concentrations of ethanol and acetate *in vivo* were measured with HPLC. The acetaldehyde concentration was analysed by head-space gas chromatography. All lactic acid bacteria were able to metabolize ethanol *in vitro*, with *Lactobacillus fermentum* CS332 exhibiting the highest degradation of ethanol. There was an increase of ethanol breakdown in the jejunum and colon of the mice treated with *L. fermentum* CS332. Ethanol content was 18.2% less in the jejunum and 32.9% less in the colon. Its ability of acetaldehyde conversion into acetate was also significantly higher than the control (P<0.05). The breakdown of ethanol and the conversion of acetaldehyde into acetate were observed in mice intestines by lactic acid bacteria after ethanol intake. Based on these data, we suggest that lactic acid bacteria have a beneficial impact on degradation of ethanol and acetaldehyde following heavy drinking.

Key Words: Lactic Acid Bacteria, Ethanol Metabolism

W289 Effects of proteolytic starter cultures on melt characteristics of low moisture part skim (LMPS) Mozzarella cheese. S. Das* and R. I. Dave, South Dakota State University, Dairy Science Department, Brookings.

The study assessed the feasibility of using selected starter cultures and different types and levels of coagulating enzyme for making LMPS Mozzarella cheese with desired functionality. LMPS Mozzarella cheeses were made from cows milk standardized to 1.8% fat made with four different types of starter cultures comprising *Streptococcus thermophilus* (ST), *Lactobacillus helveticus* (strain SH-Z or L-11), and *Lactobacillus delbrueckii* ssp. *bulgaricus* (LB-12). Cheeses were made with ST and combination of ST and SH-Z, ST and L-11 or ST and LB-12. Rennet and *Cryphonectria parasitica* (CP) were used at two different levels (1X or 6X) as coagulating enzymes. Cheeses were analyzed for fat, protein, moisture, total solids, calcium, salt, and ash on day 1. Changes in melt characteristics and proteolysis during storage (4°C) were monitored on 1, 7, 15, and 30 days (d). Meltability of cheese as measured by modified Schreiber test showed differences for cheeses made with different types of starter cultures, and also for different types and level of coagulating enzymes. Cheeses made with ST + SH-Z with coagulant CP at 6X level of enzyme resulted in highest melt area. Softening time and temperature, and melting time and temperature as measured by melt profile analysis were also significantly effected by the type of starter cultures and storage period. Extent of flow and flow rate were higher for ST + SH-Z cheeses and increased further upon 4°C storage of 30 d. Soluble protein as measured by 12% TCA also increased during storage and was highest for cheeses made with ST + SH-Z with coagulant CP at 6X level of enzyme. As the aging progressed, faster breakdown of intact caseins by CP and proteolytic lactobacilli SH-Z took place resulting in a faster weakening of the protein matrix of the cheese, which in turn translated into favorable changes in functional characteristics, especially meltability. LMPS Mozzarella cheese made with proteolytic

culture along with CP has a clear advantage to cheese manufacturers and end users to achieve the desired melt properties in cheese.

Key Words: Mozzarella Cheese, Melt Characteristics, Starter Cultures

W290 Exo-polysaccharides production in whey mineral concentrate. N. Pandya*¹, R. Dave¹, A. Hassan¹, and L. Metzger², ¹Dairy Science Department, South Dakota State University, ²Food Science and Nutrition Department, University of Minnesota, St. Paul.

The use of whey mineral supplements in neutral pH beverages such as tea and coffee has been limited due to its poor solubility and gritty mouthfeel. Neutral and phosphorylated exopolysaccharides (EPS) produced by Lactic acid bacteria (LAB) have the potential to improve the solubility and reduce the gritty mouthfeel of whey mineral concentrate since they can function as a nucleation site for the formation of calcium phosphate micro-granules. The growth of two EPS-producing bacterial cultures (*Lactobacillus helveticus* or *Lactococcus lactis* subsp. *cremoris*) in whey mineral concentrate (WMC) with 5, 7.5 and 10% total solids was studied during a 24 h incubation period. Both cultures propagated in 11% reconstituted skim milk were inoculated in to WMC at 2% (v/v) rate and incubated at 37°C for *Lactobacillus helveticus* and at 25°C for *Lactococcus lactis* subsp. *cremoris*. The samples were analyzed for titratable acidity, pH and microbial counts at 4 h interval for 24 h. Viscosity of the fermented WMC at 20°C was measured after 24 h of incubation and overnight cooling (7°C). Both cultures produced EPS at all the 3 solids level, which was evident from fluorescence microscopy observations, the ropiness produced and increase in apparent viscosity of WMC. The viscosity increase was approximately 3 fold with *Lactobacillus helveticus* and approximately 2.4 fold with *Lactococcus lactis* subsp. *cremoris*. The growth pattern, rate of drop in pH and rate of increase in acidity were almost similar at all total solids level. Also, for both cultures, there was no significant (P<0.05) difference in the viscosities of WMC at all solids level studied. It was concluded that WMC could support the growth of both EPS-producing cultures and their EPS production was higher in WMC at low solids level. *Lactobacillus helveticus* is recommended due to its ability to produce higher viscosity.

Key Words: Exopolysaccharides, Whey Mineral Concentrate, Lactic Acid Bacteria

W291 Modification of sweet whey for the growth of *Bifidobacterium bifidum*. H. Hernandez-Sanchez*, M. L. Mier-Espinosa, and M. T. Cruz y Victoria, *Escuela Nacional de Ciencias Biológicas - Instituto Politécnico Nacional*.

Sweet whey has been used on a large scale for different biotechnological processes including the manufacture of food and beverages. The purpose of this work was to study the modification of this cheese byproduct for the growth of the probiotic microorganism *Bifidobacterium bifidum*. The modification was done in two stages: first, hydrolysis with two plant proteases and second, thermal treatment at pH 11. For the whey protein hydrolysis, the raw extracts of two proteases from Mexican plants were assayed using the sweet whey (pH 6) as substrate: mexicanin from the cuaguayote fruit (*Pileus mexicanus*) latex and hemisphericin from the timbirichi fruit (*Bromelia hemisphaerica*) juice. The thermal treatment was done with whey whose pH had been adjusted to 11. Temperatures of 60, 70 and 80°C for 15 and 20 min were used in this experiment and the resultant wheys analyzed to detect the formation of lactulose, which is known to stimulate the growth of bifidobacteria. The effect of the modification treatments was followed by inoculating the wheys with *Bifidobacterium bifidum* and registering the growth after 18 h of incubation under anaerobic conditions at 37°C. The activity of hemisphericin was higher on the whey proteins than that of mexicanin. When 1% protein sweet whey was used as substrate, 82 530 activity units were obtained with hemisphericin at 35°C after a 4 h incubation period. The highest lactose to lactulose conversion was obtained after 15 min at 80°C with a final concentration of 1.6 g/L of lactulose in the whey. These two conditions were used for the whey modification. After the fermentation processes, the following final counts were obtained: 1 X 10¹⁴, 1.7 X 10¹⁴ and 6.4 X 10¹⁴ CFU/ml for the untreated whey, hydrolyzed whey and hydrolyzed and heated whey respectively. The results show that when

both modifications (enzymatic and thermal) were applied to the sweet whey, the counts of the bifidobacteria were up to 6.4 times higher than those of the unmodified whey. This indicates that these modifications could be useful in the production of probiotics or functional beverages.

Key Words: Whey, Probiotic, Bifidobacteria

W292 Optimization of fermentation conditions for development of environmentally friendly deicer. L. Zhang, S. Gokavi*, J. Li, and M. Guo, *University of Vermont, Burlington*.

Sodium chloride is the commonly used deicer for road management and safety during winter in Vermont and other Northern states. Studies showed that environment is adversely affected by the salt. Whey containing lactose accounting for 90% of its total solids is a byproduct of cheese making and its disposal poses a negative impact on the environment. The objective of this study was to optimize the fermentation conditions to develop an environmentally friendly deicer from whey. Lactic acid bacteria (LAB) from our culture collection were studied for production of lactate from lactose. Among them *Lactococcus lactis* produced lactate at pH 7.0-7.6. *Clostridium formicaceticum* (27076) was used to produce acetate from lactate at pH 7.3-8.0. Combinations of different LAB and acetogen were studied for production of acetate from lactose in whey permeate (WP). Combination of *Lactococcus lactis* and *Clostridium formicaceticum* produced lactate and acetate and the concentration of acetic acid (AA) after 60-72h was 1.6-2.1% which was increased to 1.8-2.5% by supplementing selected nutrients. The cultures were made lactate and acetate tolerant by growing the cultures in WP having high salt concentration (4%) and isolating and subculturing them. The substrate was optimized by adding 5% tomato juice, 0.1% malt extract, 0.2% ammonium phosphate, 0.2% yeast extract, 0.2% peptone and 0.35% vitamin solution to 5% WP powder as it did not support growth in its pure form. The optimum conditions to ferment this substrate by inoculating 10% of culture were temperature 37°C-39°C, pH 7.3-7.6 maintained using 4M potassium hydroxide, anaerobic condition maintained using nitrogen gas supplied at 1-2 psi, agitation speed 100 rpm and time 84-96h using continuous flow cell-recycle fermentation in a bioreactor. The AA and potassium acetate production was 3.5-4.2% and 5.7-6.9%, respectively and the culture population reached OD 1.6-1.8 at 660 nm. In conclusion, continuous flow cell-recycle fermentation with optimum conditions could be used to increase the yield of AA and/or potassium acetate.

Key Words: Deicer, Potassium Acetate, Whey

W293 Extraction of acetic acid from fermented whey permeate broth. L. Zhang, S. Gokavi, J. Li*, and M. Guo, *University of Vermont, Burlington*.

A combined anaerobic fermentation process was developed to produce potassium acetate (PA) from cheese whey. PA can be used as an organic and environmentally friendly deicer. A coculture consisting of homolactic and heterolactic bacteria was used to convert whey lactose to lactic acid and then to acetic acid (AA) in a bioreactor. The AA is extracted using liquid-liquid reactive extraction to produce potassium acetate. A series of extraction tests was carried out to determine the best solvent and conditions for AA extraction from fermented broth. The broth was adjusted to have pH 3.5, 4.7, 5.9, 7.1 and 8.3 and treated with an equal volume of best extraction solvent Alamine 336 and 2-octanol (1:1). The amount of AA extracted at pH 3.5, 4.7, 5.9, 7.1 and 8.3 was 63.5%, 59.7%, 60.9%, 53.0% and 12.0% respectively. The extraction efficiency (EE) was higher when broth contained K⁺ (66.0%) and Na⁺ (61.0%). NH₄⁺ lowered the EE (7.8%). There was no significant difference between EE in presence of anions SO₄²⁻ or Cl⁻. So it is recommended to use sodium hydroxide or potassium hydroxide to neutralize the pH and hydrochloric acid to decrease pH. EE was 62.8% when the ratio of extractant to broth was 1:1, 46.44% when 2:1 and 42.18% when 1:2. EE was 62.8% when the ratio of extractant to diluent was 50:50, 50.2% when 70:30 and 47.6% when 30:70. The results showed that extraction of acetic acid from whey permeate fermented broth was highest when ratio of Alamine 336 to 2-Octanol was 1:1 and pH 3.5.

Key Words: Acetic Acid, Liquid-Liquid Dxttraction, Potassium Acetate

W294 Evaluation of modified M17 broth for growth of *Lactobacillus reuteri* and *Bifidobacterium* sp. S. A. Ahmed* and S. A. Ibrahim, North Carolina A&T State University, Raleigh.

International dairy federation (IDF) recommends M17 broth for starter lactococci and streptococci and MRS broth (DeMan Rogosa sharpe) for starter Lactobacilli growth. M17 broth medium with specific modifications could be utilized for growth of selected *Lactobacillus reuteri* and *Bifidobacterium* sp. as a convenient medium that can be used easily by the industry in a routine fashion. The objective of this study was to evaluate the ability of modified M17 to promote the growth of *Lactobacillus reuteri* and Bifidobacteria. Six strains of *Lactobacillus reuteri* (DSM20016, MM2-3, MM7, SD2112, CF2-7F, and MF14-C) and four strains of *Bifidobacterium* sp. [*B. infantis*(ATCC 15697, ATCC 15702, ATCC 25962), and *B. longum* 79] were used in this study. The modified M17 broth was prepared by adding M 17 37.25 g/L, Beef extract 5.0g/L, yeast extract 2.5 g/L, and peptone from casein 5.0g/L. Glucose solution (20.0 g/100 ml) was autoclaved separately and added to the autoclaved modified M17 broth. Overnight cultures were centrifuged and washed twice with peptone water. Strains were inoculated into fresh M17 and modified M17 broth, then mixed well and incubated at 37 °C for 24 hrs during incubated period the bacterial growth was monitored using spectrophotometer at 610 nm. At (0.0, 12, and 24hrs). After 24 hrs all tested strains were plated on MRS agar to obtain microbial population. Results showed that higher microbial growth was observed in all tested strains using the modified M 17. The optical density in the modified M 17 reached over 1.30 while it reached only 0.70 in the original M 17. The bacterial population increases by at least 1 logcfu/ml. Modified M17 could be a good growth medium in quality control laboratories for general purpose of bacterial growth of lactic acid bacteria and probiotics.

Key Words: M17 Broth, *Lactobacillus reuteri*, *Bifidobacterium*

W295 Effect of dietary whey protein and *Lactobacillus Casei* ATCC 393 on the change of lymphocytic cell population in rats. H. J. Lim*, J. G. Kim, H. Y. Oh, S. H. Kim, and K. Y. Whang, Korea University, Seoul Korea.

Seventy-five male Sprague Dawley rats (195.26 ± 3.45 g) raised according to the guideline of NRC (1996) were divided into five groups. A commercial murine diet (NIH-31M) was used as a basal diet. Experimental diets used in this experiment were: 1) basal diet (Cont), 2) basal + 1% whey protein concentrates (WPC), 3) basal + 1% live *L. casei* 393 (LLAB), 4) basal + 1% dead *L. casei* 393 (DLAB), 5) basal + 0.5% whey protein concentrates and 0.5% dead *L. casei* 393 (W+D). Both live and dead *L. casei* 393 cultures contained 10¹² cfu/g. After feeding each experimental diet for two weeks, rats of each group were subjected to inoculating with 0.2 mL of influenza hemagglutinin peptide (HIN1, 60 µg/mL) via intramuscular injection. Blood samples were collected prior-inoculation (day 0) or at days 10 and 15 of post-inoculation. Red blood cells of samples were lysed and each sample was incubated with specific antibodies against surface antigens of lymphocyte (CD3, CD4, CD8 and CD45R). Three different types of lymphocyte (CD3+/CD4+ Th-cell, CD3+/CD8+ Tc-cell and CD3-/CD45R+ B-cell) were sorted by FACS analysis. After inoculation, T-cell population was found to significantly increase in all groups, with highest level in WPC and lowest level in LLAB at day 10 (P < .05). The B-cell populations of WPC, DLAB and W+D groups were shown to increase at day 15 compared with days 0 and 10. In contrast, the B-cell population of LLAB group showed highest at day 10, and then decreased at day 15. In conclusion, it is plausible that supplementation of whey protein and *L. casei* 393 increases humoral immunity and dietary live *L. casei* 393 stimulates immune response more rapidly than others.

W296 Viability of *Bifidobacterium longum* and *Lactobacillus reuteri* in sour cream. S. A. Ibrahim and E. D. Wilson*, North Carolina A&T State University, Raleigh.

Over the past two decades the consumption of probiotic products has risen considerably. This is mainly due to the large amount of scientific evidence from human studies, which demonstrate that regular probiotic consumption helps in maintaining a healthy digestive tract. In order for probiotics to be included in dairy food products, they should be in viable quantities for the duration of the shelf life. Therefore, the objective in this research was to determine the viability of probiotic, *Bifidobacterium longum* and *Lactobacillus reuteri* in commercially-available sour cream. Fresh sour cream samples were obtained from a local market and inoculated with one of the following probiotic strains: *B. longum* (ATCC 5708 and NCFB 2254) *L. reuteri* (MM 2-3 and MM 7) and to obtain a final inoculum level of 10⁷cfu/ml. The sour cream samples were then mixed thoroughly and refrigerated at 4 °C for 2 weeks. The samples were analyzed for viable bacterial count using modified BIM 25 agar to enumerate bifidobacteria and MRS agar supplemented with 50 µg/ml vancomycin to enumerate lactobacillus. Our results show that although bacterial counts decreased, the products contained an average 5.0 x 10⁵ cfu/ml of viable probiotics after 15 days of storage. Results also show significant differences (P<0.05) among the tested strains during the storage period. Both *B. longum* strains had two log reduction while *L. reuteri* MM 7 had one log reduction over the storage period. *L. reuteri* MM 2-3 shows a slight decline although it was not significant over the storage period. Our results show that the concept of using sour cream as a probiotic carrier is a feasible application for use in the food industry.

W297 Yogurt development from camel milk. I. B. Hashim* and A. H. Khalil, United Arab Emirates University, Al-Muhandeseen - Giza.

The camel (*Camelus dromedarius*) has the ability to produce more milk for longer period in arid zones and dry lands. Although camel milk has been used to produce acceptable feta-type cheese, hard cheese and ice-cream, it exhibits antibacterial properties causing problems in fermentation. The rheological and microscopic characteristics of the dromedary milk have shown that its coagulum to be a fragile, heterogeneous curd structure which fails to gel with lactic acid cultures. The objectives of this study were to develop yogurt from camel milk and to determine its sensory characteristics. Yogurt was prepared from cow and camel milk using standard procedure following a commercial yogurt formula [2.5% milk solid nonfat (MSNF), 0.6% commercial stabilizer (CS) and commercial yogurt culture (CYC)]. Yogurt made from camel milk using up to double the amount of the ingredients used for yogurt making (MSNF, CS and CYC) produced viscous yogurt with fragile texture. Addition of carboxy methyl cellulose had no significant effect on yogurt texture while addition of gelatin, sodium alginate (ALG) and calcium chloride (Ca) improved yogurt texture. Sensory profile of yogurts conducted by five trained experienced panelists showed that yogurt containing 1% gelatin or 0.75% ALG + 0.075 % Ca had the best texture. Hedonic ratings by 33 consumers indicated that yogurt made from camel milk using 0.75% ALG + 0.075 % Ca had similar sensory ratings and acceptability (6.0-7.6) as yogurt made from cow milk (6.4-7.9). Fruit yogurt prepared by adding 15% fruit concentrates of various mixtures to camel milk containing (0.75% ALG and 0.075 % Ca) had similar hedonic ratings and acceptability. Production of yogurt from camel milk will enable

many arid regions populations to make use of surplus camel milk with potentials for marketing such products.

Key Words: Camel Milk, Yogurt, Consumer Acceptance

W298 Physico-chemical and sensory properties of liquid-type yogurt with *Lactobacillus casei* 00692. B. J. Jeon*, J. S. Seok, and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study was carried out to find the physico-chemical and sensory attributes of liquid-type yogurt with *Lactobacillus casei* 00692 during 72 hr fermentation at 37°. The pH decreased upto 32 hr and plateaued thereafter, and the titratable acidity increased upto 40 hr. The growth

of lactic acid bacteria sharply increased with 9.0×10^9 cfu/ml upto 36 hr of fermentation and slowly increased thereafter. The free amino acids produced during the fermentation reached the maximum value at 40 hr and gradually decreased thereafter. In the result of electrophoresis, the band was the thickest at 44 hr and mostly disappeared at 72 hr fermentation. In a sensory analysis, yogurt flavor was gradually developed during 30 hr, while bitterness score did not significantly changed throughout fermentation periods. The present data showed that the range of optimum fermentation time for liquid-type yogurt using *Lactobacillus casei* 00692 was from 40 to 44 hr.

Key Words: Fermentation Time, Liquid-Type Yogurt, *Lactobacillus casei*

International Animal Agriculture

W299 Utilization of *Leucaena leucocephala* as supplement for goats in the semi arid areas of Venezuela. T. Clavero* and R. Razz, *La Universidad del Zulia, Venezuela.*

A field experiment was conducted in the dry land farming area of north-west Venezuela in order to evaluate three diets in grazing goats (grazing pasture only (buffel grass); grazing pasture + 0.3 kg of commercial concentrate/animal/d; grazing pasture + restricted browsing for two hours daily *Leucaena leucocephala*) on milk production and milk composition. The experiment was laid out randomized block design. The data showed significant difference ($P \leq 0.05$) between treatments. Daily milk yield increased in 35 and 52.7% when goats had access to commercial concentrate or browsing *Leucaena* as well as grass pasture compared with the control treatment. Daily milk yield in goats with access to *Leucaena* was insignificantly different than goats on concentrate. Treatments did not affect milk composition. The results suggest that *Leucaena* can supply an adequate amount of nutrients with similar value to commercial concentrate for milk production without adverse effects on tropical grazing goats.

Key Words: *Leucaena leucocephala*, Goat, Milk Production

W300 Estimation of genetic and phenotypic parameters of total milk production in Suran Holstein dairy farm. S. Zakizadeh, A. Horufi*, and M. Qolipur, *High Education center of Jihad & Agriculture.*

Most traits of economic importance in animal breeding are quantitative in nature. The phenotypes observed are thus the combined results of the action of many genes or quantitative trait loci and environmental effects. As the selection of dairy cattle is focused on the improvement of yield and composition of milk, the object of this research was to estimate genetic parameters and breeding values of total milk production in a Holstein dairy farm in the northeast of Iran. The data used from Animal Breeding Center of Iran and consisted of total milk records from 2247 cows, between 1990 and 2003. Base population was imported from Canada and the Netherlands in 1990. To investigate environmental effects, following model was analyzed in JMP 3.1.2 Software. The model included random effects of sire and dam, lactation and calving year as fixed effects, calving interval, peak of yield, and days in milk as covariates. All factors were significant ($p < 0.05$). It was concluded that the highest milk production would be achieved in the 4th lactation. Animal model procedure was used to estimate genetic parameters and breeding values by DF-REML software. Heritability and repeatability coefficients were 0.2 and 0.36 respectively.

Key Words: Total Milk Production, Genetic and Phenotypic Parameter Estimation, Milk Production Heritability

W301 Assessment of microbial colonization and kinetics degradation of *Distichlis* grass irrigated with fresh or brackish water in dromedary camels. G. Alhadrami*¹, A. El Awad¹, and M. Pessaraki², ¹*Department of Aridland Agriculture, College of Food Systems, United Arab Emirates University, Al-Muhandeseen - Giza,* ²*Department of Plant Sciences, University of Arizona, Tucson.*

An in situ study was conducted to investigate the extent and kinetics degradation of DM, NDF, ADF and microbial colonization of *Distichlis spicata* grass (halophytic grass) irrigated with fresh water (DFW)

or with brackish water (DBW) in the rumen environment of dromedary camels. Three camels fitted with rumen cannulas were used in this experiment. Camels were fed concentrate and Rhodes grass hay individually to maintain body weight constant and had free access to fresh water. *Distichlis* plants were labeled with ¹⁵N as an internal marker. Amount of ¹⁵N in excess of 0.366 atom% were considered as enrichment. Dilution of enrichment estimated percentage of microbial nitrogen. Labeled DFW and DBW grasses were weighed and placed in nylon bags and incubated in the rumen of the camels for up to 48 h. Differences in DM, NDF and ADF degradation were not significant between DFW and DBW, except at 48 hours the DM ($P \leq 0.04$) and NDF ($P \leq 0.027$) of DBW were significantly higher. Contamination expressed as percentage of microbial-N to total residual-N increased with incubation time and was less in DBW compared to DFW, differences were significant after 24 h ($P \leq 0.011$) and 48 h ($P \leq 0.001$) of incubation. Microbial colonization (expressed as percentage of microbial crude protein) and microbial cell mass followed the same trend. After 48 h of rumen incubation, microbial nitrogen was 30.3% in DBW and 42.6% in DFW. Microbial crude protein was 4.7% in DBW and 6.2% in DFW. In both DFW and DBW, microbial colonization and microbial contamination increased with incubation time. Microbial contamination affected estimates of in situ ruminal protein degradation of *Distichlis* grass irrigated with fresh water more than the *Distichlis* grass irrigated with brackish water.

Key Words: *Distichlis* Grass, Microbial Contamination, Dromedary Camels

W302 Effect of molasses on nutritional quality of *Pithecellobium dulce* silage. T. Clavero* and R. Razz, *La Universidad del Zulia, Venezuela.*

This study determined the influence of varying levels of molasses and ensiling time on the content of the nitrogenous fractions, chemical composition and fermentation quality during ensiling of *Pithecellobium dulce* in the farming systems of Venezuela. Chopped fresh plant materials of about 1 cm length were ensiled into laboratory silos stored at 25°C. Treatments were applied according to a 3x3 factorial arrangements in a completely randomized design. Factors studied were three rates of legumes:molasses, 1:8, 1:10, 1:12 (w/v) and three storage periods 1, 2 and 3 months. After opening the silos, dry matter (DM), pH, total nitrogen content (NT), rumen soluble nitrogen (SN), protein nitrogen (NP), nitrogen in acid detergent fiber (NADF), nitrogen fixed to the cell wall of the total nitrogen (NNDF/NT), in vitro DM digestibility (IVDMD), neutral detergent fiber (NDF) and acid detergent fiber (ADF) were determined. DM of *Pithecellobium dulce* was not changed during ensiling and the molasses additive had not significant effect on the silage DM. The mean pH values decreased significantly ($P \leq 0.05$) with increased level of molasses and storage period, respectively. The lowest pH value (4.06) was obtained with the relation 1:12. No significant differences in NT, NP, NADF, NNDF/NT, pH, ADF and NDF were found between molasses treatments. Content of NS and digestibility increased significantly ($P \leq 0.05$) with increased level of molasses. Except for NP and NS, the ensiling time significantly affected ($P \leq 0.01$) the loss in digestibility, NT, NADF, NNDF/NT, pH, ADF and NDF. The greatest losses occurred within 1-2 months of ensiling. The results showed that *Pithecellobium dulce* fodder can be preserved successfully by ensiling with molasses additive.

Key Words: *Pithecellobium dulce*, Silage Quality, Molasses

W303 Cow preference between conventional sand bedded free stalls and free stalls with sand savers. R. J. Norell*¹, P. C. Deaton¹, J. H. Packham², and S. C. Parkinson³,

¹University of Idaho, Idaho Falls, ²University of Idaho, Paris, ³University of Idaho, Preston.

Sand is considered the gold standard bedding for free stalls but it can be expensive due to high sand utilization rates. Commercial sand saving devices have been developed to reduce sand utilization in free stalls. The objective of this study was to compare cow preference between conventional sand based free stalls and free stalls with sand savers on a commercial dairy operation with Holstein cows. The free stall facility had three rows of stalls. Each row had ten conventional sand stalls, ten with Agri-web (Presto Products, Appleton, WI) and ten with Sand Traps (Albers Inc., Jerome, ID). Free-stalls were 2.29m long and 1.22m wide. The neck rail was mounted on top of large loop cantilever stall dividers (1.13m above stall base) and located 1.73m from the back of the curb. Sand savers were positioned on top of tamped gravel and were installed 5cm below the top of the curb. Stalls were then filled with sand. The stocking rate was one cow per stall. Cows were milked 3x daily and had access to an outdoor dirt lot for 3h daily. Cow behavior was monitored for six-24 h periods with a digital camera system that saved images every 20 minutes. Data were analyzed as a randomized

complete block design with replication. Sand saver stalls had more h of stall occupancy/day ($p < 0.005$), more h of cow resting time ($p < 0.003$), and a higher stall turnover rate ($p < 0.01$) than control stalls. Occupancy, resting time, and stall turnover rate were numerically higher for Sand traps over Agri-web based stalls but differences were not significant ($p > 0.10$). Standing in stall behavior did not differ between the three stall bed surfaces ($p > 0.32$). Comfort index (h lying in stall divided by h occupy stall) averaged 90% and did not differ ($p > 0.69$) between stall treatments. Bedding was a fine grain sand that tended to compact in the control stalls but not in the sand saver stalls. Sand utilization did not differ between treatments but sand saver stall were used more hours per day and had a higher turnover rate. Cows appear to prefer stalls with sand saver devices over conventional sand stalls.

Stall usage	Control	Sand Trap	Agri-web	SE
Occupancy	8.1	11.4	10.5	0.3
Resting	7.3	10.3	9.5	0.3
Comfort index %	89.5	90.4	90.3	0.7
Turnover rates (times/d)	6.2	8.2	7.6	0.3

Key Words: Free Stall, Preference, Sand Bedding

* Author Presenting Paper

Contemporary and Emerging Issues: Current and Future Prospects for Animal Nutrition Management for Environmental Impact Reduction

642 Natural Resources Conservation Service (NRCS) involvement in animal nutrition management. T. Christensen*, *USDA NRCS*.

The Natural Resources Conservation Service (NRCS) is the lead federal agency for assisting landowners and landusers with conservation on private lands. It is an agency of the U.S. Department of Agriculture (USDA) and falls within the Natural Resources and Environment Mission Area, along with the Forest Service. The Animal Husbandry and Clean Water Programs Division (AH&CWPD) serves to develop National policies and provide leadership and direction for agency activities related to water quality and quantity, animal husbandry, nutrient management, and air quality programs and issues. The Division collaborates and coordinates with other NRCS divisions on all assigned activities and also acts as the primary interface between NRCS and the Environmental Protection Agency (EPA).

One of the primary responsibilities of the AH&CWPD has been the development of policy and guidance leading to voluntary Comprehensive Nutrient Management Plan (CNMP) implementation on animal feeding operations (AFOs). Feed management is one of the six core elements of the CNMP, and is defined as the managing of the diet or nutrition of the animal in such a way that manure nutrients are decreased, without negatively affecting the performance of the animal or profitability of the operation. Reduction of manure nutrients has been identified as a key action that can mitigate the potential effects of the animal industries on the environment.

Over the last few years, NRCS has developed an action plan to advance feed management, hosted two visiting animal scientists on six-month sabbaticals to help develop and guide policy in this area, conducted a National Dialogue on Feed Management and the Environment, and assessed interest in feed management through a series of sessions with industry animal nutritionists. The 2003 development and adoption by the agency of a National conservation practice standard on feed management allows an NRCS State Conservationist to adopt this practice

as eligible for cost-share under the Environmental Quality Incentives Program.

Key Words: Feed Management, Cost Share, Environmental Policy

643 Industry assessment of feed management practice implementation through animal nutritionist focus groups. G. Carpenter*, *USDA-NRCS*.

The animal industries in the United States produce approximately 250 million dry tons of manure each year from confined operations. Interest exists in ways to decrease the impact of animal production on the environment. A great deal of science and technology exists that supports the practice of reducing manure nutrients by improved feed management. Beginning in 2001, the USDA, NRCS Animal Husbandry and Clean Water Programs Division (AHCWPD) began to coordinate activities in the area of feed management with other divisions within the agency and other agencies within the USDA. An agency Feed Management Action Plan was implemented in the late summer of 2001 to pursue feed management opportunities.

A National Dialogue on Feed Management and Manure Nutrient Reduction was held in June, 2002 in Washington, DC. One of the findings from the Dialogue pointed to the small number of animal nutritionists controlling the diets of animals within the industry. A series of focus group sessions was held for animal nutritionists from the four major animal industries to learn about the needs of the animal industries for adopting feed management as a practice.

All four animal industries indicated that they are currently using a number of feed management practices. Most animal nutritionists felt that adoption of new practices is influenced by economics rather than implicit concern for the environment. Information on new practices and technologies comes from many sources, but speed of adoption depends on economics, risk, and funding. Research needs change by animal sector. Nutritionists felt that a strategy for NRCS to encourage the implementation of feed management practices should include networking with industry, the identification of vehicles for providing information on feed

management to industry, becoming more involved with applied research, demonstration and technology transfer on feed management, and looking for ways to provide incentives, both monetary and non-monetary, for the adoption of feed management practices.

Key Words: Feed Management, Environment, Industry Nutritionists

644 Development of rapid methods for assessing nutrient bioavailability. S. C. Ricke*, V. I. Chalova, and W. K. Kim, *Texas A&M University*.

Accurate assessment of nutrient bioavailability is critical for achieving an optimal balance between sufficient and excess for major feed components such as protein sources. Optimizing feed protein sources for farm animal amino acid (AA) requirements is difficult to achieve given the variations in protein quality. Feeding excess protein to meet AA requirements contributes to excess nitrogen (N) environmental pollution. To avoid productivity losses from an improper AA balance, feeds can be supplemented with pure AA to reduce animal N excretion. This requires AA bioavailability assessment by animal bioassays prior to supplementation. However in addition to the time commitment and costs,

activism interests are beginning to restrict routine animal tests. Ideally the animal feed industry needs alternative rapid methods for quantifying AA availability during feed processing. Rapid assays would allow animal nutritionists to adjust AA addition after assessing basal diet AA bioavailability. *In vitro* microbial bioassays for AA and other nutrients have been examined as a rapid alternative for a number of years. Such assays have the advantages of biological similarity to animal responses while retaining the flexibility and reproducibility capabilities of a conventional chemical test. Although several microorganisms have been examined, *Escherichia coli* has become the assay organism of choice because it is well studied, has simple growth requirements, and genetic modification is relatively easy. Given the molecular techniques currently available *E. coli* can easily be genetically engineered to provide an array of rapid whole cell AA biosensors. General application of this technology opens the door for more precise formulation at the feed mill and avoidance of unnecessary supplementation that result in animal production generated environmental problems.

Key Words: Nutrient Availability, Environmental Excess, Whole Cell Biosensors

Bioethics

645 Culture, values and ethics of animal scientists. John Hodges*, *European Association of Animal Production*.

Culture is defined as the shared worldview of a sub-set of humanity: race, nation, or professional group. In practice Culture means The way we do things around here. Values are the objectives that matter most to a person or to a cultural group to which priority of interest is consistently given in decisions allocating time, energy, resources, wealth and education. Ethics defines the moral component of each decision reflecting self-interest and/or concern about the well-being of other individuals or groups in society. Thus, in any sub-set of humanity, including professional animal scientists, Culture, Values and Ethics are closely linked. The normative cultural assumptions and commonly-held values of animal scientists guide group and individual decisions on the research and application of scientific knowledge. Strong links between animal scientists and business interests mean that the culture and values of commerce also inform and steer decisions by animal scientists. The food chain is increasingly watched by society as a whole, by governments and by special interest groups to determine the extent to which our behaviour is ethical or serving only our special interest group. The changing culture and values of societies in Europe and North America and Developing Countries are examined and compared with those of animal scientists. It is proposed that more radical changes in the culture and values of animal scientists are needed to match the assumptions of all societies for their food supply.

Key Words: Culture, Values, Ethics

646 An Argument that Animal Quality of Life Must be Central to Any Moral Justification of Animal Agriculture. W. R. Stricklin*, *University of Maryland*.

Personal experience has led to my belief that the majority of professional animal scientists have not seriously considered how they would

construct a full moral justification for animal agriculture. And current graduate programs in animal science commonly do not specifically challenge students regarding the moral basis of animal agriculture - or the implications of the student's research to this question. It is common for animal scientists to generally defend animal agriculture from a basis inclusive of premises such as 1) there is hunger in the world today, 2) the world population is expected to double in the next 30-50 years meaning more food must be produced, 3) animals utilize food stuffs not suited to human consumption, etc. However, rarely do animal scientists contend that food animals do - or can - benefit from their existence as sentient beings, i.e., having lived and experienced a reasonable quality of life. Singer originally argued in *Animal Liberation* that it is acceptable to produce food from animals provided they experience a quality of life comparable to that of a wild counterpart, but he subsequently argued that this is not possible with today's modern production systems. There is considerable agreement among the survey data on public attitudes indicating no trend toward vegetarianism or desire to move in that direction. However, there is very strong evidence in these same data sets indicating that the public seeks assurance that animals experience a reasonable quality of life. A utilitarian, or costs and benefits, moral argument for animal agriculture is strongest, possibly only defensible, when the quality of animal life can be predominantly placed into the benefits category - not included as a cost as many persons contend today. Incorporating consideration of the quality of the life experienced by animals into animal science teaching and research activities is in the best long-term interests of animal agriculture. It is also the right thing to do which further promotes the interests of all parties involved.

Breeding and Genetics

647 Evaluation of Dorset, Finnsheep, Romanov, Texel, and Montadale breeds of sheep: Reproduction of F₁ ewes in spring mating seasons. K. A. Leymaster*, E. Casas, and B. A. Freking, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE*.

Objectives were to estimate effects of sire breed (Dorset, Finnsheep, Romanov, Texel, and Montadale), dam breed (Composite III and north-western whiteface), mating season (March and May), ewe age (4, 5, and 6 yr) and their interactions on reproductive traits of F₁ ewes. A total of 1,099 F₁ ewes produced 1,754 litters from 2,330 exposures to Suffolk rams during 42-d mating seasons. Litter size and weight at birth were recorded and litter size and weight at weaning and 20 wk of age were analyzed separately for dam- and nursery-reared lambs. Total produc-

tivity from 4 to 6 yr of age for each ewe entering the breeding flock was calculated as the sum of 20-wk weights for dam-reared lambs. Interactions of sire breed x mating season, ewe age x mating season, and ewe age x dam breed were often significant. Interaction of sire breed x dam breed on conception rate ($P < 0.01$) was due to change in rank as well as magnitude. Averaged over mating seasons, Romanov x Composite III ewes had the greatest conception rate (93%) and Montadale x Composite III the lowest (64%). Interactive effects of sire breed and mating season on conception rate ($P < 0.001$) were due to differences in magnitude, with Romanov-sired ewes being most consistent between seasons (92% in March and 89% in May). Sire breed affected litter size at all ages ($P < 0.001$), ranging from 1.40 lambs at birth for Texel to 2.09 for Romanov. Differences between dam breeds in total productivity of dam-reared lambs were not detected, whereas ewes exposed in March (78

kg) were more productive ($P < 0.01$) than May (68 kg). Means of sire breeds for total productivity were 47, 65, 70, 70, and 111 kg for Texel, Montadale, Dorset, Finnsheep, and Romanov, respectively ($P < 0.001$). Superior reproduction of Romanov-sired ewes was due to greater conception rate and prolificacy at each mating season and ewe age. Use of Romanov crossbred ewes would increase fertility during spring mating, an important constraint of the sheep industry.

Key Words: Breeds, Reproduction, Sheep

648 Linear versus threshold model analysis of trainability in a colony of German Shepherd dog guides. J. Cole*¹ and E. Leighton², ¹*Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD,* ²*The Seeing Eye, Inc., Morristown, NJ.*

The objective of this study was to compare linear and threshold models for genetic evaluation of trainability in a colony of dog guides. Data consisted of trainability and pedigree information on 3305 German Shepherd dogs produced for use as potential guides by The Seeing Eye, Inc (TSE). Trainability is used to assess the ability of a dog to work as a guide, and is scored on a 9-point ordinal scale. Scores range from 1 (worst) to 9 (best) and are assigned by TSEs training staff. A linear model (LM) is currently used by TSE to produce estimated breeding values (EBVs) for use in a selection index. However, theory suggests that a threshold model is the more appropriate tool for this type of analysis. A threshold model (TM) was used to estimate variance components and EBVs which were compared to the LM results. MTDFREML was used to fit the LM and CBLUP90REML was used to fit the TM. The model used for both analyses included fixed contemporary group and random additive animal and residual error terms. Heritability of trainability was 0.14 ± 0.03 and 0.19 for LM and TM, respectively. The algorithm used in CBLUP90REML prevented estimation of SEs in the TM. The higher heritability under the TM is consistent with theory. Pearson's product-moment and Spearman's rank correlations of LM and TM EBVs were 99.2 and 99.3, respectively, indicating that the LM does a good job of predicting and ranking the TM EBVs correctly. Genetic trend was positive for both analyses, 0.24 and 0.20 units/generation for LM and TM, respectively. Of the 3305 animals in the dataset, 2130 spent at least one day in training and 1175 did not. The distribution of trainability scores differed between dogs that spent at least one day in training and those that did not ($P < 0.001$). Trainability EBVs were higher for trained versus untrained animals under both the LM ($P < 0.01$) and TM ($P < 0.01$). While a TM is preferred from a theoretical viewpoint, the current LM does a good job of predicting genetic merit. The TM is preferred for the estimation of variance components, and suggests that the LM has been underpredicting the true heritability of trainability.

Key Words: Genetic evaluation, Dog guides, Threshold model

649 Developing breeding objectives for Targhee sheep. R. C. Borg*¹, D. R. Notter¹, R. W. Kott², and L. A. Kuehn¹, ¹*Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg,* ²*Department of Animal and Range Sciences, Montana State University, Bozeman.*

Breeding objectives were developed for Targhee sheep at different levels of prolificacy and triplet survival. Economic weights (EW) were derived for estimated breeding values (BV) from National Sheep Improvement Program genetic evaluations for 120 d weaning weight (WW), maternal milk (MM), yearling weight (YW), fleece weight (FW), fiber diameter (FD), staple length (SL), and prolificacy (LC; lambs born/100 ewes lambing). A commercial flock was simulated, accounting for nonlinear relationships between performance and profit. Ewes were assumed mated to sires of specified BV and profit was derived from lifetime performance of lambs and replacement females from that lamb crop. Economic weights were determined as change in profit from use of sires with BV that were one additive standard deviation above the mean for each trait [1.98 kg for WW, 1.62 kg for MM, 2.90 kg for YW, 0.36 kg for FW, 0.98 microns for FD, 0.74 cm for SL, and 17.58 lambs/100 ewes for LC], while holding all other BV at breed average. Separate breeding objectives were derived for different costs of meeting increased nutrient needs (P = purchase hay, R = rent pasture, and S = scaling back flock size). Based on replicated simulations, relative EW did not vary with prolificacy or survival ($P > 0.15$) but were affected by feed costs ($P < 0.01$). Selection indexes were derived within and across simulated scenarios, and correlation (r) among indexes of > 0.90 indicated that an

index could be used across multiple scenarios. Indexes derived within feed cost scenarios (P , R , and S) were strongly intercorrelated ($r > 0.97$). Correlations among average indexes (0.97 for R and P ; 0.70 for R and S ; 0.85 for P and S) indicated that two indexes could be used depending on whether flock size was scaled back (S) or not (NS) ($r=0.78$). Indexes were $1.0 WW + 0.23 MM + 0.61 YW + 0.95 FW + 0.26 FD + 0.08 SL + 0.18 LC$ for S and $1.0 WW + 0.33 MM + 0.26 YW + 1.25 FW + 0.29 FD + 0.09 SL + 0.24 LC$ for NS . For a standardized selection differential of one, the expected change in mean index values was 12.55 and 7.40 per ewe per generation for S and NS , respectively.

Key Words: Sheep, Selection Index, Breeding Objective

650 Genetic and environmental factors affecting camel reproduction. S. Hermas*, *Faculty of Agriculture, Department of Animal Production, University of Al-fatah, Tripoli, Libya.*

This study was conducted to evaluate the effect of various factors on female reproductive performance measured by days from parturition to first breeding (DMFB), service period (SP), days open (DO), number of services per conception (NS), conception rate (CR), calving interval (CI), age at first service (AFS), age at successful service (AS), service period (HSP), conception rate (HCR), age at first calving (AFC), and gestation length (HGL). The data used were 380 reproduction records from daughters of 11 sires. Two models were used to analyze the data. Model 1 included as fixed effects month of calving, season, sex of calf, color, age, and service sire. Model 2 included month and year of first service, the rest of factors in model 1 excluding month of calving, and sire as a random effect. The results of analysis of variance indicated a significant effect ($P < 0.05$) of month of calving on DMFB, NS, and CR. Season had highly a significant effect ($P < 0.01$) on DMFB, CI, and significantly affected CR and GL. Age had a highly significant effect on NS and CR. Service sire had a significant effect only on GL. In camel heifers, month of first service had a significant effect on AFS, AS, AFC, HNS, and HGL ($P < 0.05$). Sire and service sire had a significant effect on AS, AFC, HNS, HCR, CI, and HGL. Heritability, genetic and phenotypic correlations were calculated by paternal half sib method. Heritability estimates were 0.38 ± 0.16 , 1.1 ± 0.18 , 0.40 ± 0.17 , 0.02 ± 0.14 , 0.44 ± 0.16 and 0.39 ± 0.17 for DMFB, SP, DO, NS, CR, and AFC respectively. The repeatability estimates were 0.01 ± 0.09 , 0.11 ± 0.08 , 0.15 ± 0.08 , 0.18 ± 0.09 , 0.17 ± 0.08 , and 0.017 ± 0.09 for DMFB, SP, DO, NS, CR, CI, respectively. The additive genetic variation was fairly high indicating possible improvement through selection. Repeatability estimates were low, indicating large temporary environmental effects. The genetic and phenotypic correlations were estimated between all traits. These estimates ranged from medium to very high positive and negative indicating pleiotropic action of genes and common environment between traits of camel reproduction.

Key Words: Genetics, Camel, Reproduction

651 Development of web-based cow-calf decision support software. B. W. Bringham*, D. J. Garrick, and R. M. Enns, *Colorado State University, Fort Collins.*

Sire selection is an important decision directly affecting ranch profitability. The need for decision-support software is increasing with the growing number of EPD available. The objective of this project was to develop web-based tools to evaluate production and economic outcomes from the use of alternative sires. A model simulates the age structure of a herd to predict performance, revenues and costs while accounting for non-genetic effects such as age of the dam. Users provide a minimum number of production inputs comprising herd size, pregnancy rate, replacement rate, mature cow size, calf survival, birth and weaning weights. These define an equilibrium age structure and provide realistic production outcomes for the base herd. Genetic variables that simultaneously influence model behavior are limited to those economically relevant traits that are closely aligned to available EPD. These include heifer pregnancy, calving ease, mature cow size, cow maintenance requirements, stayability, birth and weaning weights. These EPD are used to derive a new equilibrium age structure and corresponding performance levels following perturbation of the base situation. The total number of cows is then modified, accounting for any change in feed requirements, to provide annual feed consumption identical to the base herd. Outputs from the model allow a producer to compare current herd production and economic performances to those predicted if alternative sires had been used and the system allowed to re-equilibrate. Primary

differences in revenue come from changes to the number and weight of sale calves. Other contributions to variation in revenue are from values of cull cows, replacement costs and dystocia costs. Discounting procedures are not included. In contrast to other models, the software provides for sire selection by simulation rather than simply generat-

ing economic values for subsequent use. Accordingly, the model needs to directly incorporate heterosis effects from multibreed evaluation and corresponding EPD from sire summaries.

Key Words: Decision Support, Cow-Calf, Sire Selection

652 Protein profile of goat milk in relation with udder health status and somatic cell counts. G. Pisoni¹, L. Basiricò², P. Moroni¹, U. Bernabucci^{*2}, and G. Savoini³, ¹Dipartimento di Patologia Animale, Igiene e Sanità Pubblica Veterinaria, Milano, Italy, ²Dipartimento di Produzioni Animali, Viterbo, Italy, ³Dipartimento di Scienze e Tecnologie Veterinarie per la Sicurezza Alimentare, Milano, Italy.

The prerequisite to produce hygienic milk and cheese is udder health and, therefore, intramammary infections are the most persistent and widely spread group of diseases of importance to milk hygiene in dairy goats. The effect of udder health on yield and quality of milk and, consequently, on cheese yield and quality has been established. Milk from mastitic udders exhibits greatly increased proteolytic activity. The activity of plasmin (PL), plasminogen (PG), and plasminogen activator (PA) and their correlation with goat milk quality parameters (casein, somatic cell counts (SCC), and udder health status) were investigated. Forty goats from two flocks were monitored and used to provide milk samples. Does were machine milked twice daily without teat post-dipping. 50 mL of milk was collected aseptically from each goat and kept at 4°C until bacteriological procedures. The SCC were determined for each milk sample by an automated fluorescent microscopic somatic cell counter. Activities of PL, PG, and PA in milk were determined with a colorimetric assay. 5 mL of each milk sample was centrifuged and skimmed milk was analyzed to determine protein profile by SDS-PAGE. Quantification of the electrophoretically separated proteins was done by densitometry. Milk samples were categorized on the basis of the presence or absence of pathogens (healthy or infected udder) and as low SCC (< 1,000 × 10⁶/mL), medium SCC (between 1,000 and 2,000 × 10⁶/mL), or high SCC (> 2,000 × 10⁶/mL). The health status of the udder modified only SCC and PA activity; both parameters were higher (P < 0.01) in infected udders. The increase in SCC was followed by increases (P < 0.001) in PL and PA activities and γ -1, γ -2 and proteose-peptone contents, and by decreases in PG activity and α -casein and β -casein contents. Results of the present study demonstrate that udder health is not the main factor responsible for the increase of proteolytic activity and alteration of protein profile of goat milk.

Key Words: Goat, Milk, Protein Fractions

653 Silymarin administration to periparturient dairy goats: effects on milk production and quality. D. Tedesco^{*1}, S. Galletti¹, S. Rossetti¹, J. Turini¹, and G. Varisco², ¹Department of Veterinary Sciences and Technologies for Food Safety, Milan, Italy, ²Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Brescia, Italy.

Silymarin, a standardized extract from seeds of *Silybum marianum* L. (Gaertn) (milk thistle), is used for the treatment of liver diseases. Silymarin administration to periparturient dairy cows resulted in a lower postpartum body condition score (BCS) loss and a higher and earlier milk peak. The aim of the present study was to determine the effects of silymarin treatment in the periparturient period on lactation performance of dairy goats. A total of 24 dairy goats in their second pregnancy were divided into two groups according to BCS, health condition, and previous milk production. From 5 days prior to the expected kidding date to 15 d postpartum, the treated goats received 10 mL/d of silymarin as a water suspension, administered as an oral drench. Individual milk production was recorded on 7, 14, 21, and 28 DIM. Milk samples were collected on the same days and analyzed for protein, fat, lactose, urea, and somatic cell count. The BCS was evaluated on d -7, 0, 14, 21, and 28 from kidding. Silymarin treatment significantly increased milk production. In all days considered, milk yield of treated animals was higher with respect to control animals (P < 0.05). These differences were on average from 0.61 to 0.92 kg/d for each animal. Milk quality parameters were not different between treated and untreated goats. BCS was not different between groups. We conclude that silymarin administration to periparturient dairy goats had a positive effect

on milk production without affecting milk quality, confirming our results obtained with dairy cows. Silymarin was kindly granted by Indena S.p.A.

Key Words: Silymarin, Dairy Goat, Peripartum

654 Effects of goat breed and stage of lactation on yield, sensory quality, and fatty acid concentration of soft cheese. S. S. Zeng^{*}, K. A. Soryal, B. A. Fekadu, K. Tesfai, and B. Bah, Langston University E (Kika) de la Garza American Institute for Goat Research, Langston University, Langston, OK.

In the United States, Nubian and Alpine goats are two major dairy breeds and most dairy goat herds have a seasonal lactation. In this study, the effects of goat milk obtained from two dairy farms with different breeds of goats at various stages of lactation on yield, composition, sensory scores, and fatty acids of soft cheese (Chevré) were evaluated. Results obtained from this study indicated that dairy goat breeds did not affect cheese composition, sensory scores, or fatty acid concentrations (P > 0.05) except oleic acid. However, milk from Nubian goats resulted in a much higher cheese yield (2.71 vs 1.69 kg/10 kg of milk), a lower oleic acid concentration, and a lower unsaturated fatty acid concentration than that from Alpine goats (P < 0.05). Soft cheese made from late lactation milk had higher fat, protein, and total solids concentrations and yields than mid-lactation milk (P < 0.05). While the sensory scores of Alpine goat milk cheese varied throughout lactation, those of Nubian goat milk cheese were virtually the same regardless of stage of lactation. In conclusion, if a dairy goat herd is raised to supply milk for cheesemaking, Nubian goats or a mixed herd with at least some Nubian goats will be advantageous to cheese makers for a higher premium for their higher cheese-yield milk. In addition, a year-round breeding program could help minimize variations in cheese composition, yield, and fatty acid concentration, resulting in a more consistent quality of cheese throughout lactation.

Key Words: Goat Milk, Cheese, Fatty Acids

655 Growth and carcass characteristics of castrated or intact male Boer X Spanish goats grazing Marshall annual ryegrass. C. Hopkins-Shoemaker^{*1}, S. Solaiman², C. Kerth¹, W. Jones¹, and D. Bransby¹, ¹Auburn University, Auburn, AL, ²Tuskegee University, Tuskegee, AL.

Castration of food animals is a common management practice that imposes unnecessary pain and stress, is an extra cost, and may reduce performance. This study was conducted to determine the effect of castration on growth and carcass characteristics of Boer x Spanish goat kids. Seven intact males and seven wether goats (BW 38.03 and 34.79 ± 0.35 kg, respectively) were continuously grazed on Marshall annual ryegrass (*Lolium multiflorum* Lam.) for 56 d. Body weights were recorded after 4 h withdrawals from feed and water, for two consecutive days, every 2 wk. After d 56 animals were harvested and hot carcass weight (HCW), cold carcass weight (CCW), dressing percent (DP), kidney and pelvic fat (KPF), longissimus muscle area (LMA), backfat (BF), and other carcass parameters were measured. Average daily gain over 56 d was greater (P < 0.05) for intact males than for wethers (139 and 66 g/d, respectively). Carcass selection grades were similar between treatment groups: no differences (P > 0.10) were observed in HCW, CCW, or DP between treatment groups. Wethers had higher (P < 0.05) KPF than intact males (0.51 and 0.23 kg, respectively); however, BF and LMA did not differ (P > 0.10) between treatment groups. These results indicate that castration of young market goats reduced growth and did not provide any distinct advantage in carcass characteristics.

Key Words: Goat, Castration, Carcass Characteristics

656 Influence of maternal breed on meat goat carcass characteristics. R. Browning, Jr.*¹, C. Chisley², O. Phelps², S. H. Kebe¹, B. Donnelly¹, M. Byars¹, and T. Payton¹, ¹Tennessee State University, Nashville, ²USDA-Agricultural Marketing Service, Baton Rouge, LA.

Spanish x Boer (n = 16) and Spanish x Kiko (n = 18) wethers (7 mo) and bucklings (5 mo) were harvested under USDA inspection to evaluate the effect of dam breed on carcass traits of crossbred kids. Boer and Kiko dams, respectively, originated from five and seven seedstock farms. Each dam was purebred or fullblood (93.75 to 100%). Traits of interest included live weight and conformation score, carcass grade, carcass weight, dressing percentage, wholesale cut weights, and edible meat yield. Live weight tended to differ (P = 0.08) between Boer (22.96 ± 0.94 kg) and Kiko kids (25.6 ± 1 kg). Hot carcass weight, cold carcass weight, and dressing percentage tended to be greater (P ≤ 0.1) for Kiko than for Boer F1 kids. Kids out of Boer dams had similar (P = 0.29) live conformation scores as their contemporaries out of Kiko dams. Carcass grade scores for Kiko F1 tended to be better (P = 0.08) than those for Boer F1 kids. Paired shoulder and hind leg primal cuts were heavier (P < 0.05) for Kiko (1.66 ± 0.08 kg; 3.05 ± 0.14 kg) compared to Boer (1.41 ± 0.08 kg; 2.59 ± 0.13 kg). Paired foreleg and loin weights for Kiko (2.11 ± 0.1 kg; 1.5 ± 0.09 kg) tended to be heavier (P ≤ 0.10) than for Boer (1.85 ± 0.1 kg; 1.28 ± 0.09 kg). Rib weights were not different (P > 0.2) between breeds of dam. However, when wholesale cut weights were adjusted for carcass weight, only the hind leg tended to be heavier (P = 0.06) for Kiko-cross kids than for Boer-cross kids. Proportional edible meat yields and meat to bone ratios from shoulder, loin, and hind leg were not affected (P > 0.15) by breed of dam. Preliminary results suggest that breed of dam may affect carcass traits from commonly sired crossbred kids.

Key Words: Meat Goat, Breeds, Carcass Traits

657 Size, color, and texture of major muscles from kid goat carcasses. K. W. McMillin* and A. P. Brock, *Department of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, LA.*

Production of value-added products for ethnic and non-traditional goat meat consumers requires information about the constituent raw materials. Linear dimensions and color of major raw muscles from Boer-Spanish kid goat carcasses and texture after moist and dry cookery were determined in two successive years (n=18 and n=10). After weaning and pasture rearing with 0.11 kg/d of corn, kid goats of average 9 mo age and 25 kg were humanely sacrificed. Carcasses were chilled for 24 h at 4°C before evaluation of carcass conformation (selection 2.6), flank color (A⁷⁰), external fat score (1.0), and kidney, heart, and pelvic fat (1.8%). Dressing percentage averaged 41% and cold carcass weight 10 kg. Individual muscles were manually separated by knife from fat and bone within a 3 d period. Weight, length, and width (ruler), diameter (caliper), and color (reflectance spectroscopy) were recorded for *L. dorsi* (LD), *Semimembranosus* (SM), *Q. femoris* (QF), *B. femoris* (BF), *Triceps* (T), *G. medius* (GM), *Infraspinatus* (I), *Supraspinatus* (S), *Psoas major* (PM), *Semitendinosus* (ST), and *B. brachii* (BB) at the time of separation. Muscles from each carcass side were randomly assigned to moist (water bath at 100°C) or dry (167°C oven) heating to 77°C internal temperature. Muscle weights were LD=SM>QF>BF=T#8805GM>I=S=PM=ST>BB. The differences (P<0.05) in length and diameter between muscles were more variable than the differences in L*, a*, and b* color values between different muscles. Cooking losses were less (P<0.05) for larger than smaller muscles, with shear force greatest (P<0.05) for S and least (P<0.05) for ST, BB, PM, GM, QF, T, LD, and I. Cooking losses (24 to 36%) and shear forces (3.0 to 4.7 kg) for each muscle type did not differ (P>0.05) with type of heating. Time to reach internal temperature was longer with dry than moist heating. Year did not influence linear, color, or shear measurements in muscles of the same type. Characterization of different muscles will assist in identification of muscles suitable for retail goat cuts and for processing into value-added products.

Key Words: Goat, Muscle Profile, Color

ADSA - Growth and Development

658 Effects of intramammary endotoxin treatment on porcine milk composition, yield, and resultant piglet growth performance. A. C. W. Kauf*, D. C. Pighetti, A. L. Magliaro, D. A. Pape, L. C. Griel, Jr., and R. S. Kensing, *Penn State University, University Park.*

Mastitis is a contributing factor to preweaning mortality in pork production. We performed an experiment utilizing an intramammary endotoxin (ET) challenge model (Kensing et al., 1999), to determine the effects of mastitis on milk composition, yield, and resultant piglet growth performance. Following cross-fostering to equalize litter size on approximately d 3 of lactation, 11 parity-one Yorkshire sows were challenged (1.5 µg/gland/kg BW) on days 13 and 20. ET (from *E. coli* O55:B5) was infused into two functional, previously non-infused mammary glands on each experimental day. Milk was collected by manual expression from both control and ET-infused glands before and after ET-challenge up to 60 h post infusion, and analyzed for protein content and composition. Milk yield was estimated by weigh-suckle-weigh procedure, and daily piglet weights were recorded. ET-infusion increased rectal temperatures, which peaked at 1.7 °C above baseline at 5 h (P < 0.01), returning to normal by 24 h. ET-infusion increased milk log TNF-α 87 %, chloride 221 %, total protein 20 %, and albumin 44 %; and decreased β-casein 47 % relative to control samples (P < 0.01). Apparent proteolytic degradation of α_s-caseins in post-infusion milk samples was dramatic. ET-infusion decreased hourly milk yields 31 % on experimental days (P < 0.01). ET-infusion decreased 24 h weight gains 75 % for piglets nursing ET-infused glands relative to their control littermates during the first 24 h; the difference in 24 h weight gain between groups remained significant through 5 days (P < 0.01). Our data demonstrate significant increases in milk TNF-α, chloride, total protein, and albumin; significant decreases in milk β-casein and yield; and prolonged decreased daily weight gains of suckling piglets. The changes in milk composition are consistent with opening of tight junctions, and the ET-

challenge model is valuable for studying the effects of mastitis in the sow.

Key Words: Porcine Mastitis, Milk Yield, Piglet Growth

659 Effects of diet and bST on gene expression profile of heifer mammary parenchyma. B. J. Lew*^{1,2}, S. S. Sipkovsky¹, G. J. M. Rosa¹, J. S. Liesman¹, R. P. Radcliff¹, H. A. Tucker¹, M. D. S. Oliveira², and M. J. VandeHaar¹, ¹Michigan State University, East Lansing, ²UNESP Jaboticabal, São Paulo, Brazil.

Increasing growth rates in prepubertal heifers decreases age at puberty and subsequent milk production. Administration of bST before puberty increases parenchymal tissue and decreases adipose tissue within the udder. Our objective was to examine the effects of a high energy, high protein diet combined with injection of bST on gene expression profile within mammary tissue and identify key genes that mediate mammary development. The mammary tissue used was collected in a previous experiment conducted in 1994 (Radcliff et al., 1997). In the experiment 38, Holstein heifers were randomly assigned to one of four treatments: low or high diet, each with or without bST. RNA from parenchymal tissue of 32 heifers (8/treatment) was extracted, and RNA quality was checked using the Agilent Bioanalyzer. RNA was pooled (2 samples/pool), and the 16-pooled samples were examined using a bovine-specific cDNA microarray (National Bovine Functional Genomics Consortium Library, NBFGC) containing 18,263 uniquely expressed sequence tags (EST). A Loop design was used with cDNA from the 16-pooled samples labeled with Cy3 or Cy5 dyes prior to microarray hybridization. Gene expression data were normalized for dye intensity biases using a robust local regression technique (SAS PROC LOESS). Significance levels of differential gene expression among treatments were assessed using a mixed model approach. Compared with no bST, bST altered expression of 671 genes (368 down and 303 up-regulated) in the high diet (P<0.05) and 365 genes (210 down and 155 up-regulated) in low diet (p<0.05).

When compared with low diet, high diet without bST¹ affected expression of 445 genes (168 down and 277 up-regulated) ($p < 0.05$). Genes altered included several hormones, growth factors, receptors and signaling pathway genes involved in mammatogenesis. Ongoing studies focus on verifying changes with Real Time PCR to measure gene expression profile within mammary gland. In conclusion, dietary energy and bST administration alter expression of genes involved in mammatogenesis *First author sponsored by CAPES (Coordination for the Improvement of Higher Education Personnel, Brazil) from may, 2003-april, 2004

660 Growth and developmental characteristics of Holstein and Gir (*Bos indicus*) x Holstein bulls and heifers.. S. Schmidt*¹, S. Bowers¹, T. Dickerson¹, K. Graves¹, R. Vann², and S. Willard¹, ¹Mississippi State University, Mississippi State, ²Brown Loam Experiment Station-Mississippi State University, Raymond.

The crossbreeding of Holstein cows with Gir sires has not been evaluated extensively in the southern United States. Gir cattle have a higher milk production potential than many other *Bos indicus* breeds, yet little information exists regarding the growth, development and production performance of Gir x Holstein crossbred dairy cattle. In this study, Holstein cows were bred by artificial insemination (AI) to either Holstein or Gir-sires, which produced Holstein x Holstein (H x H) or Gir x Holstein (G x H) calves. The objective of this study was to compare the growth and morphological differences of H x H and G x H crossbred dairy calves during their first year of life. Body weight, heart girth, hip width, hip height and wither height measurements were obtained from birth to 378 days of age at 28-day intervals. Calves were housed in hutches from birth until 55 to 60 days of age, and thereafter grazed on improved pastures. All growth and development traits were positively correlated with one another ($R=0.72$ to 0.99 ; $P < 0.0001$). A breed x sex interaction ($P < 0.05$) was noted in BW change and average daily gain (ADG). Specifically, G x H bulls ($n=8$; 0.78 kg/d) exhibited a greater ($P < 0.05$) ADG than H x H bulls ($n=12$; 0.73 kg/d), whereas H x H heifers ($n=18$; 0.80 kg/d) exhibited greater a ($P < 0.05$) ADG than G x H heifers ($n=22$; 0.74 kg/d). Wither height (124.9 ± 0.73 cm), hip height (128.9 ± 0.68 cm) and hip width (42.1 ± 0.32 cm) did not differ ($P > 0.10$) relative to sex of calf or breed. Heart girth was greater ($P < 0.05$) in bulls (164.0 ± 1.1 cm) than heifers (157.7 ± 1.2 cm), but was not influenced by breed ($P > 0.10$). In summary, while expected differences were observed between bulls and heifers in some growth characteristics, contrasting differences between G x H and H x H calves were noted only in ADG. Nevertheless, these data indicate that the growth and morphological development of G x H and H x H calves during their first year of life are relatively similar.

Key Words: Gir, Growth, Development

661 Growth of crossbred and purebred calves from birth to an age of 50 days studied by dual energy x-ray absorptiometry (DXA). J. Hampe, S. Nueske, A. M. Scholz*, and M. Foerster, *Experimental Farm, University Munich, Germany.*

Lean tissue (LTGR), fat tissue (FTGR) and bone mineral growth (BMGR) of female ($n=44$) and male ($n=40$) calves was compared among six different breeding types including German Holsteins (GH, $n=14$), German Fleckvieh (FV, $n=17$), GH sire x FV cow, ($n=16$), FV x GH, ($n=20$), GH x GHxFV crossbred (CR, $n=10$), and FV x CR ($n=7$) from day 4 until day 50 of life. Calves underwent three DXA scans under light sedation using a GE LUNAR DPX-IQ scanner with a three week interval. Up to day 15, all calves were fed individually cow milk (47 l) and housed outside in single calf boxes on straw. From day 16, calves were housed in groups on straw in a cold stall. They received age-dependent milk replacer over an automatic feeder (intake: $5.5 - 7.5$ l/d).

In addition, they received ad libitum hay, corn, and on-farm produced concentrate (average intake < 130 g/d). Generally, growth differences among calves originating from GH or FV sires and GH, FV or crossbred cows were small. During the age period 526 days, calves did not gain fat tissue. Alone calves of FV mothers showed in tendency a positive fat deposition, while calves of GH sires starting with a significantly lower body weight (BW) gained significantly more lean tissue than calves with FV sire. No significant differences in tissue growth could be observed during the second period (27-48 days). However, calves of FV sires gained in tendency more lean and fat than calves of GH sires resulting in still heavier calves at day 48. The breed of the sire seems to have a larger effect on early growth of calves than does the mothers breeding line.

	Start BW (kg)	FTGR ¹ (g/d)	LTGR ¹ (g/d)	BMGR ¹ (g/d)	FTGR ² (g/d)	LTGR ² (g/d)	BMGR ² (g/d)	Final BW (kg)

662 Portal nutrient flux during pre- and post-weaning growth in dairy calves. J. L. Klotz* and R. N. Heitmann, *Department of Animal Science, The University of Tennessee, Knoxville.*

Dairy calf weaning is associated with increases in ketone levels that exceed measured rates of utilization in adults and present a potential energy loss that may be mitigated by ionophore. To assess effects of weaning and ionophore on net portal-drained viscera (PDV) flux in dairy calves, glucose, acetoacetate (ACAC), BHBA, NEFA, VFA, insulin (INS), and glucagon (GLN) concentrations and PDV fluxes were determined on d 35, 56, 84, and 112 in Jersey bull calves weaned at d 49. From d 3-34 all calves ($n=14$) were fed 454 g/d milk replacer. After sampling on d 35, calves were randomly assigned to a commercial pelleted starter without (C) or with lasalocid (T; 83 mg/kg DM) *ad libitum* plus replacer until d 48. From d 49-112 calves received only C or T *ad libitum*. Calves were equipped with catheters in artery (A), portal (P), and mesenteric veins (V) at wk 3-4. Calf number varied by treatment and sample day due to catheter patency (calves = 3-5). Blood flow was measured by continual infusion of para-aminohippurate into V ($1.5\% @ 0.764$ mL/min) and 6 serial samples taken at 30-min intervals simultaneously from A and P. Portal blood flow increased ($P < 0.05$) with age, but did not differ between C and T. Glucose was released pre-weaning and extracted post-weaning by PDV, but not affected by ionophore. Pre-weaning uptake of NEFA changed to post-weaning release, but this change was delayed to d 84 in T. Flux of ACAC and BHBA in C and T went from pre-weaning uptake to post-weaning PDV release that peaked at d 84, but peak release of ACAC was lower and BHBA tended to be lower in T ($P=0.07, 0.15$). Portal release of VFA increased with age, but was similar to ketones with both butyrate and propionate release lower at d 84 in T ($P < 0.1$). Glucagon was greater in C than T at d 84 ($P < 0.05$). Significant changes in metabolic profile and net PDV flux of transition calves were demonstrated and ionophore appears to moderate alimentary output at a post-weaning period (d 84) where ketone concentrations have potential to exceed whole animal capacity for utilization.

Key Words: Weaning, Ionophore, Portal-Drained Viscera Flux

663 Impact assessment of feeding high-oil corn to poultry in Brazil. E. Kebreab*¹, J. France¹, R. Phipps², and S. Leeson¹, ¹Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, ²School of AP&D, The University of Reading, Reading, UK.

Agriculture, especially intensive animal production, contributes significantly to environmental pollution. In poultry, only 30 - 40% of nitrogen

intake and 18 - 35% of phosphorus intake are converted to edible products. In major poultry exporting countries such as Brazil, reducing nutrient loss to the environment is paramount. The economic and environmental impacts of replacing traditional corn, the main ingredient in poultry rations, with a high-oil corn (HOC) variety were evaluated using specialist least cost ration formulation software based on linear programming principles. Parametric analysis showed that HOC based

rations cost up to \$14/tonne less than traditional corn based ones mainly because less ingredient is used to meet the birds requirements. This is equivalent to an annual savings of up to \$266 million to the Brazilian broiler and broiler-breeder producers. Diets formulated with HOC had a lower crude protein content than with traditional corn, and potentially could reduce annual nitrogen excreted to the environment by 5.3 Mtonnes. HOC provided a better nutrient profile than traditional corn, especially in essential amino acids such as methionine and lysine, which led to meeting amino acid requirements without having to increase the total crude protein content of the diet. The analysis also showed a potential to reduce phosphorus excretion by 842 tonnes/yr if HOC was to replace traditional corn, since the need to supplement rations with inorganic phosphorus sources such as dicalcium phosphate would be much lower. We estimate that 36.6 Mtonnes dicalcium phosphate can be saved annually using HOC in poultry rations in Brazil. The literature suggests replacing traditional corn with HOC does not affect bird metabolism and positive impacts on growth rate have been recorded. Substituting traditional corn with HOC has both economic and environmental benefits for the Brazilian poultry production without compromising efficiency of output.

664 Electrostatic space charge system for dust reduction and air quality improvement in commercial broiler facilities. C. Ritz*¹, B. Mitchell², B. Fairchild¹, M. Czarick¹, and J. Worley¹, ¹University of Georgia, ²Southeast Poultry Research Laboratory USDA-ARS.

Reducing airborne dust in enclosed animal housing has been shown to result in corresponding reductions in airborne bacteria, ammonia and odor. Technologies that have been shown to be effective for reducing airborne dust in animal areas include misting with an oil spray, water mists, extra ventilation, and electrostatic space charge systems. Increasing pressure from environmental groups to reduce PM-10 and ammonia emissions from animal housing has led to considerable interest by the poultry and swine industries for practical systems to reduce these air pollutants. An electrostatic space charge system (ESCS) was designed to reduce airborne dust and ammonia emissions from a commercial broiler production house. The ESCS for this application was based on patented technology that was developed to reduce airborne dust and pathogens and has proven effective in poultry hatcheries and broiler breeder pen trials. In the present study, dust and ammonia were measured at 10-minute intervals over a three-flock period in both a treatment and control house with built-up litter. Results of the study during the months of November through April indicate the ESCS reduced airborne dust by an average of 55%. Dust levels in the treatment house were consistently lower than in the control house. Ammonia levels in the treatment house averaged 8% lower than in the control house with most of the reduction occurring during the evening hours when ammonia levels were highest. No differences in bird activity were observed between treatment and control houses. Successful application of this technology in broiler houses has the potential for improving bird performance and reducing house emissions and caretaker health hazards.

Key Words: Electrostatic, Dust, Broiler

665 In-house composting of litter and poultry carcasses infected with avian influenza. G. W. Malone*¹, S. S. Cloud¹, R. L. Alphin¹, L. E. Carr², and N. L. Tablante², ¹University of Delaware, Newark, ²University of Maryland, College Park.

In February 2004 two Delaware farms were found to be positive for H7N2 avian influenza. The litter and carcasses were composted inside

the houses to minimize potential spread of the virus and to address environmental concerns. Farm A had two 12 by 122 m houses with 12,000 dual-purpose birds ranging from 3 to 26 weeks of age while Farm B had three similar size houses with 74,000 five week old commercial broilers. In each house the carcasses and litter were mixed to form a single windrow 97 m long. These windrows had a 10 cm litter base, 4 m wide, 1.5 m high, and capped with 8 cm of litter or sawdust to cover all carcasses. Windrows were turned inside the house, consolidated and capped with additional sawdust at 14 to 19 days. Although the litter moisture was not ideal for composting, temperatures in these windrows were sustained at 55 C for 10 consecutive days. All houses were heated to 38 C for three consecutive days after forming the windrows and again after turning the piles as an additional measure to inactivate this heat-sensitive virus. Virus isolation samples from the compost and house environment were taken prior to turning and again before compost removal from the house. The compost was removed from the house after one month, stockpiled on the farm, covered and allowed to age for another month. Educational materials were developed and used to train poultry company personnel on in-house composting procedures.

Key Words: Composting, Carcass Disposal, Avian Influenza

666 Spatial Variability of Nutrient Species Within a Poultry House. P. R. Owens*, D. M. Miles, and D. E. Rowe, *Waste Management and Forage Research Unit, USDA-ARS, Mississippi State, MS.*

Large broiler operations must annually collect and analyze litter for nutrient content under the U. S. Environmental Protection Agency's Concentrated Animal Feeding Operation Final Rule. The objective of this study was to determine the variability of nutrient species within a poultry house using geostatistical contour plots. This research was conducted in the summer on a tunnel ventilated poultry house that was 146 m by 12.8 m. Prior to sampling, the litter had twenty-eight flocks of chickens grown on it with decaking between each flock. The house was sampled on a grid at 5 m across the house and 12 m down the house for a total of 36 sampling points. The litter was sampled at day 1 and day 21 to examine litter properties. The pH was determined using 1:5 litter water ratio. The total N was determined by total Kjeldahl nitrogen method (TKN). The ammonium, nitrate and phosphate were extracted with DI water and analyzed using flow injection analysis. The litter samples were also dry ashed and total metals were determined using an ICP. For both sampling dates, the samples weren't random and the data did not follow a normal distribution, however, the data indicated a higher average concentration of TKN and ammonium in the cooling cell end of the house and decreased toward the fan exhaust end of the house. The average nitrate data also yielded higher concentrations at the cool cell end of the house and decreased toward the exhaust end of the house. The data from the geostatistical contour plots illustrated higher TKN and ammonium in the brood end of the house, which corresponded with the lower pH (8.6 vs. 7.5) also in the brood end of the house. The contour plots of the nitrate data illustrated highest concentration near the sidewall of the brood end of the house, which corresponded to the areas with the highest litter moisture. These trends held true with both day 1 and day 21. The water extractable P data did not indicate definite trends within the house during the day 1 and day 21 sampling times. These geostatistical estimates of the nutrient concentrations indicated an anisotropic distribution of the nutrients along the house and illustrated spatial variability of nutrient species within the poultry house.

667 Egg antibody to phospholipase A₂ increases carcass yield in male broilers. K. D. Roberson*¹, J. L. Kalbfleisch¹, W. Pan¹, R. A. Charbeneau¹, M. E. Cook², and M. Yang², ¹Michigan State University, East Lansing, ²University of Wisconsin-Madison.

Cockerel chicks (Ross X Ross) were procured from a commercial hatchery and placed at day of age into brooding pens which had fresh litter top-dressed on used litter from a previous trial. Dried chicken egg (whole contents) antibody to phospholipase A₂ was added at 0, 0.1, 0.2

or 0.4% of a corn-soybean meal basal diet fed in three phases. Chicks were brooded for 2 wk with 223 chicks/pen and 4 pens/treatment. After brooding, the birds were separated out into 7 pens/treatment with 125 birds/pen and grown to 43 d of age. Body weight and feed consumption were measured for each pen at 14, 28 and 42 d of age. At 43 d of age, 25 birds/treatment (5 pens of 5/pen) were randomly selected for slaughter and weighed live (averaged 3 kg). Hot carcass weight without giblets was determined and small intestinal samples were collected, washed and weighed individually. There were no significant effects on body weight

or feed conversion. Carcass yield was increased ($p < 0.0001$) linearly as level of antibody increased (70.8 to 73.0%). Intestinal weight was increased ($p < 0.0063$) linearly as antibody level increased. The results show that feeding an antibody to phospholipase A₂, an enzyme that affects arachidonic acid metabolism, to male broilers can increase hot carcass yield by 3% (2.2 percentage units) when supplemented at 0.4% of the diet from whole egg contents.

Key Words: Broiler, Carcass Yield, Phospholipase A₂

668 Effect of growth promoters (antibiotics + Roxarsone + copper sulfate) on broiler performance during stress: Possible mechanisms of growth promotion. A. Mireles Jr.*¹, D. Sutton¹, E. Koutsos², R. Spiller², and S. Kim¹, ¹Foster Poultry Farms, ²California Polytechnic State University, San Luis Obispo.

The objective of this study was to examine the effects and interactions of growth promoters and litter quality on broiler performance during stress. A 2 (NoGrowth vs. +GrowthP) x 2 (Clean vs. Dirty Litter) factorial design study was conducted in commercial-like pens for 43 d. Birds raised on dirty litter had heavier ($P < 0.05$) weight at 20 d (649 vs 672) and 33 d (1648 vs 1684). +GrowthP birds had heavier ($P < 0.05$) weight at 20 d (672 vs 649). Feed/gain was poorer ($P < 0.05$) for birds on growth promoters at 11 d (1.13 vs 1.09). Mortality was similar for all groups (2.21, 2.78, 1.60, 3.19%, respectively). At 11, 17, 34, and 41 d, 12 birds per treatment were injected subcutaneously with 1 mg *E. coli* LPS/Kg BW, and their body temperature measured at 0 and 150 m post-LPS. Birds fed growth promoters developed a similar fever 150 m post-lps throughout all 4 periods (+0.41, +0.39, +0.45, +0.32 C respectively). NoGrowth birds had higher ($P < 0.05$) fever at 11 d and lower at 41 d (+0.64, 0.55, 0.46, 0.22 C, respectively). Gain 2 days post-LPS challenge was higher ($P < 0.05$) for GrowthP birds at 13 d (63 vs 55 gm) and lower ($P < 0.05$) at 19 d (636 vs 687 gm). Intestinal coliform counts at 13 d were lower ($P < 0.05$) in birds on dirty than clean litter (171,425 vs 6809). Bursal disease and *I. bronchitis* titers were increased ($P < 0.05$) by dirty litter. Growth promoters likely improve performance by modulation of the inflammatory response.

Key Words: Growth Promoters, Litter Quality, Acute Phase Response

669 Growth performance of male broiler chicks fed diets supplemented with two levels of Versazyme® to 26 days of Age. N. H. Odetallah*¹, M. H. Fosnaught¹, and J. C. H. Shih², ¹Bioresource International, Raleigh, NC, ²North Carolina State University, Raleigh.

Two inclusion levels of Versazyme (VZ), a feed additive enzyme, were supplemented in broiler diets to determine the optimal level for broiler growth performance from 0-26 d. Birds were fed a control basal diet without (C) or with VZ (0.05% or 0.10% wt/wt). Diets were formulated to NRC (1994) with the exception of CP (19%) and Amino Acids (110%) as research indicates VZ has protease activity and is optimized at lower CP levels. VZ was added in the dry form post mixing of original mash feed. A total of 168 Ross x Ross male broiler chicks were allocated to 24 pens of a battery brooder in a Completely Randomized Design with 12 replicate pens/control and 6 replicate pens/treatment (0.05 or 0.10%); the experimental unit was a pen of 7 birds. Body weight (BW), Gain, and Feed intake were determined at 14, 21, and 26 d, and mortality used to calculate adjusted feed conversion ratio (adjFCR). Level of VZ had no effect on mortality. Feeding VZ increased ($p < .01$) BW at 21 d (852b and 915^a vs. 807^c g for 0.05 and 0.10% vs. C, respectively) and 26 d (1143^b and 1213^a g vs. 1092^c g for 0.05 and 0.10% vs. C, respectively) and Gain at d 21 (412^b and 441^a g vs. 385^c g for 0.05%, and 0.10% vs. C, respectively). Feeding VZ increased ($p < .01$) overall Gain (1102^b, and 1173^a vs. 1052^c g/bird for 0.05% and 0.10% vs. C, respectively) and improved ($p < .01$) overall adjFCR (1.47^a and 1.44^a vs. 1.55^b for 0.05% and 0.10% vs. C, respectively). There was no effect of VZ level on Feed Intake except at d 14 when it was increased ($p = .02$) by the 0.10% inclusion level (520^b, 517^b, and 556^a g/bird for control, 0.05%, and 0.10%, respectively). Both levels of VZ improved growth performance of broilers up to d 26 although the 0.10% level demonstrated a higher response ($p < .01$) in BW and Gain over the 0.05% level. Results of the current research suggest that supplementing diets with VZ at either the 0.05% or 0.10% level will improve broiler growth performance up to 26 days of age but optimal performance will be realized at the 0.10% level.

Key Words: Versazyme®, Growth Performance, Broiler Chick

670 Effects of purified β -Mannanase and commercial product, Hemicell® on performance and uniformity in commercial broilers compared with dietary nutrient adjustment. M. E. Jackson*¹, H.-Y. Hsiao¹, D. M. Anderson¹, R. L. James¹, and G. F. Mathis², ¹ChemGen Corp., Gaithersburg, MD ²Southern Poultry Research, Inc., Athens, GA.

β -Mannans are antinutritional components of soybean meal and other plant protein sources. An enzyme product containing primarily β -mannanase with lower levels of other enzymes including α -galactosidase, xylanase, amylase, and β -glucanase (Hemicell®) has been demonstrated to break down soybean β -galactomannan and improve performance in broiler chickens. An experiment was conducted to determine 1. The extent to which the efficacy of the commercial product (Hemicell®) is due to the presence of β -mannanase, and 2. if the growth performance loss due to adjusting energy downwards by 120 Kcal/Kg ME and amino acids downwards according to matrix recommendations can be recovered by the use of the enzymes. Four dietary treatments consisting of 1. a positive control, 2. a negative control with nutrient reductions, 3. as (2) with the commercial product, and 4. as (2) with purified β -mannanase were provided to 8 replicate pens with 30 male CobbxCobb broilers per pen. All diets were corn-soybean meal based. Individual body weights of all birds were determined on days 17 and 42. Addition of the commercial product to the low nutrient dense diets resulted in live performance improvements comparable to that of increasing the nutrient density (5.6% in gain and 7.7 points in feed conversion, $P < 0.05$). Addition of the purified enzyme also yielded significant improvements in live performance over its negative control. There was no statistically significant difference in performance between commercial product and purified enzyme. Body weight uniformity was significantly improved with the commercial product with a 38% reduction in 42-day %CV ($P < 0.05$). The data shows that the active ingredient of the commercial enzyme product (Hemicell®) is primarily the β -mannanase component, and that β -mannanase is capable of improving performance comparable to an increase in nutrient density on the order of 120 kcal/kg ME plus an additional amino acid benefit.

Key Words: Broilers, β -Mannanase, Uniformity

671 Efficacy of purified β -mannanase isolated from Hemicell® in broiler chickens with Coccidiosis and Necrotic enteritis. H.-Y. Hsiao*¹, D. M. Anderson¹, M. E. Jackson¹, F. L. Jin¹, and G. F. Mathis², ¹ChemGen Corp., ²Southern Poultry Research, Inc.

Hemicell®, a β -mannanase based feed enzyme, has been shown to significantly improve growth performance, and reduce mortality and lesion scores in broiler chicks simultaneously challenged with *Eimeria* sp. and *Clostridium perfringens*. Since β -mannanase used in these trials is a commercial product with some side activities such as amylase, xylanase, β -glucanase and α -galactosidase, etc. an experiment was designed to determine if the benefits observed are due solely to β -mannanase. β -Mannanase was purified through ion exchange (DEAE-Sephacel) and hydrophobic interaction (Phenyl-Sepharose) chromatography to remove all other enzyme activities. The purified mannanase produced a single band on SDS acrylamide gel electrophoresis demonstrating a high level of purity. A 21-day male broiler chick (CobbxCobb) trial was conducted in battery cages with 10 birds per cage, 4 diets, and 8 replications per treatment. Birds were fed diets with four different treatments: Control without medication, Hemicell® added, pure β -Mannanase added and Medication (BMD and salinomycin) added. All birds were challenged with 50,000 *E. acervulina* and 5,000 *E. maxima* on day 7 and with 108 cfu *C. perfringens* on days 12, 13, and 14, all by oral gavage. Results indicated that pure β -mannanase significantly improved weight gain by 9.4% (700g vs. 640g; $P < 0.05$) and feed conversion by 5.4% (1.440 vs. 1.519; $P < 0.05$) over its Control. Hemicell® gave a similar performance improvement over the non-medicated control indicating that the β -mannanase is the primary active ingredient in Hemicell®. This result also provides a foundation for a better understanding of the mechanism of action for Hemicell®.

Key Words: Broilers, β -Mannanase, Necrotic Enteritis

672 Effect of Growth Promoters (Antibiotics + Roxarsone + Copper Sulfate) on Broiler Composition during Stress: Possible Mechanisms of Growth Promotion. A. Mireles Jr.*¹, D. Sutton¹, E. Koutsos², R. Spiller², and S. Kim¹, ¹Foster Poultry Farms, ²California Polytechnic State University, San Luis Obispo.

The objective of this study was to examine the effects and interactions of growth promoters and litter quality on body composition during stress. A 2 (Clean vs. Dirty Litter) X 2 (NoGrowth vs. +GrowthP) factorial design study was conducted in commercial-like pens for 43 d. At 11, 17, 34, and 41 d, 12 birds per treatment were injected subcutaneously with 1 mg E. coli LPS/Kg BW. Two days post-LPS, birds were euthanized. Litter x Growthp x Stress interactions were found ($P < 0.05$) for total serum Ca, liver, spleen, tibia, breast relative weight, and tibia Ca and total P. LPS stress increased ($P < 0.05$) total serum Ca at 19, 36, and 43 days (+11, +4, +4 PPM), liver weight at 13, 19, 36, and 43 d (+0.21, +0.62, +0.36, +0.25%), spleen weight (+0.03, +0.03, +0.01, +0.02%), decreased ($P < 0.05$) breast weight at 19 d (-0.37%) but increased breast moisture at 36 d (+0.77%), and decreased tibia strength at 13 and 43 d (-458, -2868 gm) while increasing ($P < 0.05$) tibia Ca (18.67 vs. 19.87%) and P (8.61 vs 9.13%). At 19, 36, and 43 d, +GrowthP birds had constant serum Ca levels 2 d post-LPS challenge. NoGrowth chicks had higher serum Ca 2 days post-LPS at 19, 36, and 43 d. Spleen weight of NoGrowth chicks was heavier 2 d post-LPS at 36 and 43 d (+0.01, +0.01%). Tibia Ca and P, breast weight and moisture of NoGrowth were higher ($P < 0.05$) than in +GrowthP chicks. Growth promoters likely affect body composition by modulation of the acute phase response.

Key Words: Growth Promoters, Litter Quality, Acute Phase Response

673 Effect of mannan oligosaccharides supplementation to laying hen diets. M. I. Gracia*¹, P. Cachaldora², L. Tucker³, F. Baucells¹, and P. Medel¹, ¹Imasde Agropecuaria, S.L., Spain, ²Coren, S.C.L., Spain, ³Alltech Inc., Ireland.

A study was conducted to determine the effect of feeding laying hens a diet supplemented or not with a source of mannan oligosaccharides (MOS, Bio-Mos[®]) on performance and egg quality. A total of 1,200 Isa Brown laying hens (38-66 wks of age) were allocated randomly to the experimental treatments. A completely randomized block design was applied using two barns (block) and two experimental treatments: 1) basal diet (control), 2) basal diet with 1 g/kg of MOS. Each treatment was replicated 40 times (20 per barn) with 15 laying hens constituting the experimental unit. Egg production, average egg weight, feed efficiency, Haugh units, yolk color measured by Roche Color Fan (RCF), and shell thickness were calculated every 4 wks. For the whole study period (38 to 66 wks of age), MOS supplementation significantly improved laying index (85.1 vs 86.9%; $P < 0.01$), feed consumption (114.3 vs 115.7 g/d; $P < 0.01$), and feed conversion (2.09 vs 2.06 g feed/g egg; $P < 0.05$). Moreover, average egg weight significantly increased from 54 to 58 wks (65.2 vs 66.1 g; $P < 0.05$) and tended to increase from 58 to 62 wks of age (65.8 vs 66.5; $P = 0.09$) with supplementation of laying hen diets with MOS, but the positive effect was lost thereafter. Addition of MOS had no effect on the ratio between normal, dirty and broken eggs. Regarding egg quality parameters, the addition of MOS to the diet of laying hens resulted in a deeper yolk color as measured by the RCF (12.5 vs 12.8; $P < 0.001$), however control hens had higher Haugh units than MOS supplemented hens ($P < 0.05$). It was concluded from this experiment that the addition of MOS to laying hen diets results in improved laying performance and deeper yolk color.

Key Words: Mannan Oligosaccharides, Laying Index, Laying Hens

674 CRINA[®] poultry essential oils and BMD in the diet of broilers exposed to Clostridium perfringens. M. Sims*¹, P. Williams², M. Frehner³, and R. Losa³, ¹Virginia Diversified Research, Harrisonburg, VA, ²Akzo Nobel Surface Chemistry LLC, Davis, CA, ³CRINA SA, Akzo Nobel Group, Switzerland.

Two 7 week floor pen trials were designed to determine if the performance of broiler chickens fed CRINA[®] Poultry Essential Oils was similar to that of broiler chickens fed the growth promotant Bacitracin MD in the presence of a *C. perfringens* (Cp) challenge. In Trial 1 there were 8 groups replicated 8 times: Non-supplemented Uninfected Controls (NUC), Non-supplemented Infected Controls (NIC), Uninfected CRINA 100 ppm (UCR100), Infected CRINA 100 ppm (ICR100), Uninfected

BMD 55 ppm (UBMD), Infected BMD 55 ppm (IBMD), Uninfected CRINA 200 ppm (UCR200) and Infected CRINA 200 ppm (ICR200) for a total of 64 pens (64 birds/pen; density = 0.073 m² /chick). In Trial 2 there were 3 groups replicated 10 times: NIC, ICR100 and IBMD for a total of 30 pens (60 birds/pen; density = 0.078 m² /chick). Broilers of both trials were weighed at 7 weeks of age, challenged with Cp during Week 3 and Cp lesions scored at 7 and 28 days post-challenge in Trial 1 and 7 and 14 days post-challenge in Trial 2. In Trial 1, there were no differences ($p \# 88050.05$) between the Week 7 average live weights of the NIC, ICR100, ICR200 and IBMD fed broilers while in Trial 2 the ICR100 broilers had heavier Week 7 live weights ($p \# 88040.05$) than both the IBMD and NIC groups (2.39 vs. 2.27 and 2.21 kg, respectively). Both IBMD groups had heavier ($p \# 88040.05$) live weights than their NIC counterparts. Week 7 feed conversions and mortality rates of the ICR100 and IBMD groups in both trials were not different ($p \# 88050.05$). There were no differences ($p \# 88050.05$) between the Week 4 Cp lesion scores of the ICR100 and IBMD groups in each trial and both were significantly better ($p \# 88040.05$) than their respective NIC groups. ICR200 broilers performed slightly better than ICR100 broilers (Trial 1). This study suggests that challenged and non-challenged broilers fed diets supplemented with CRINA at 100 ppm had live weights, feed conversion and mortality rates that were similar or better than identically managed broilers fed BMD 55 ppm with both groups better than the Cp infected untreated controls.

Key Words: Essential Oils, Broiler, *Clostridium perfringens*

675 Comparison of direct-fed microbial products Avi-Lution or Avi-Lution Custom to bacitracin methylene disalicylate or no additive in diets of broiler chickens exposed to Clostridium perfringens. D. Spangler¹, J. Corley², G. F. Mathis³, M. D. Sims⁴, and D. M. Hooze*⁵, ¹Agri-King, Inc., Fulton, IL, ²Prince Agri Products, Inc., Quincy, IL, ³Southern Poultry Research, Inc., Athens, GA, ⁴Virginia Scientific Research, Inc., Harrisonburg, ⁵Hooze Consulting Service, Inc., Eagle Mountain, UT.

The objective was to evaluate direct-fed microbials versus an antibiotic or no supplement. In 49-d Exp. 1, Ross x Hubbard HiY mixed-sex chicks (2,700), 54/pen (1.22 x 3.05 m; 10 pens/treatment), were on fresh litter then on built-up litter (d 14). Four birds were removed at 21 d (2) and 35 d (2) for necrotic enteritis lesion scoring. The 5 treatment groups had different dietary supplements and *Clostridium perfringens* (Cp) challenge statuses: no-Cp negative control (nCON), Cp inoculated nCON (nCON+Cp), bacitracin-md 55 ppm (BMD+Cp), Avi-Lution 0.05% (AVN+Cp), and Avi-Lution Custom 0.1% (AVC+Cp) treatments. Birds were individually dosed with fresh culture of Cp types A, C, and D (ATTC, Ames, IA) on d 14, 15, 16, and 17. Intestinal lesions were scored 0 best to 4 worst at 21 and 35 d. Body weight (BW), FCR, lesion scores, and mortality (MORT) were improved ($P < 0.05$) by AVN+Cp, AVC+Cp, and BMD+Cp compared to nCON+Cp. In 49-d Exp. 2, Cobb x Cobb male chicks (1,400) were placed 40/pen with 5 pens/treatment. Coccidial challenge at 14 d was followed by fresh culture of southeastern field isolate of Cp mixed with feed on d 18, 19, and 20. At 22 and 28 d, 5 birds/pen were lesion scored. The 7 dietary treatments were: nCON, nCON+Cp, AVN(0.05%)+Cp, AVN(0.1%)+Cp, and BMD(55 ppm)+Cp. At 49 d, BW and FCR for the nCON, AVC+Cp treatments, and BMD+Cp were statistically similar ($P < 0.05$). The MORT was variable (3.5 to 11.5%) and nonsignificant. The AVC+Cp increased BW 3.7% and decreased FCR 4.5% compared to original AVN+Cp. The 49-d pen drag swab Salmonella concentrations were decreased by AVN+Cp or AVC+Cp compared to nCON+Cp or BMD+Cp. The AVN and to a greater extent AVC resulted in lower Salmonella counts and BW, FCR, and Cp lesion scores similar to BMD for broilers.

Key Words: Avi-Lution, Broiler, *Clostridium perfringens*

676 Growth performance of male broiler chicks fed diets supplemented with Versazyme[®] in dry and liquid form to 26 days of age. N. H. Odetallah¹, M. H. Fosnaught*¹, and J. C. H. Shih², ¹BioResource International, Raleigh, NC, ²North Carolina State University, Raleigh.

Two application forms of Versazyme[®] (VZ), a feed additive enzyme, were evaluated in broiler diets to compare the effect of the dry (D) vs. liquid (L) form on broiler growth performance from 0-26 d. Broilers were fed a basal diet without (Control) or with VZ (D or L). Diets were

formulated to NRC (1994) with the exception of CP (19%) and Amino Acids (110%) as research indicates VZ has protease activity and is optimized at lower CP levels. Diets were fed in the mash form from 0-26 d, and VZ was either added post mixing of original feed (D) or sprayed on top of the feed (L). A total of 168 Ross x Ross male broiler chicks were allocated to 24 pens of a battery brooder in a Completely Randomized Design with 12 replicate pens/control and 6 replicate pens/treatment (D or L); the experimental unit was a pen of 7 birds. Body weight (BW), gain, and feed intake were determined at 14, 21, and 26 d, and mortality used to calculate adjusted feed conversion ratio (adjFCR). Feeding VZ (whether in D or L form) compared to the control diet did increase ($p < .01$) overall Gain (1012^b, 1108^a, and 1087^a g/bird for control, D, and L, respectively) and improve ($p < .01$) overall adjFCR (1.52^b, 1.47^a, and

1.42^a for control, D, and L, respectively). Supplementing VZ in the D form did increase overall ($p = .04$) feed intake (1543^b, 1630^a, and 1545^b for control, D, and L, respectively). FCR at d 14 only was most improved ($p < .01$) by the L form (1.24^a) followed by D form (1.29^b) when compared to control (1.34^c). No difference between the two applications (D vs. L) was observed on mortality, BW, and gain at any age. Supplementing diets with VZ improved all broiler growth parameters measured in this study. These results suggest that VZ supplementation in broiler feed may improve growth performance irrespective of application form (D or L).

PSA-Nutrition: Layer and Miscellaneous Nutrition

677 The influence of restricted intake of energy and fat on egg solids in laying hens. J. A. Arthur^{*1}, K. S. Kreager¹, N. P. O'Sullivan¹, and H. J. Kuhl, Jr.², ¹Hy-Line International, Dallas Center, IA, ²Nest Egg Nutrition, Gardnerville, NV.

Restriction of feed or energy intake has been noted to have an association with a reduced proportion of solids in liquid egg. Hy-Line variety W-98 and W-36 hens were fed rations designed to restrict energy and fat intake by 10% (Low group) for each variety, compared to hens fed a measured amount of feed in accordance with expected intake level for that variety (High group). The amount of feed provided to the W-98 High, W-98 Low, W-36 High and W-36 Low groups was 104.3, 95.2, 95.2 and 86.2 g/bird/day. The energy intake was 297, 265, 276 and 243 kcal/bird/day. The intake of crude fat was 3.45, 3.15, 4.36 and 3.93 g/bird/day. All other critical nutrients were fed at approximately the same level to both High and Low groups within variety. After nine weeks (period one), the feed given to each group was reduced by a further 10% for eight weeks (period two). Eggs were sampled five times during a pre-trial period, 5 times during period one and 8 times during period two, at intervals of one week or more. Egg weight (EW), % yolk (PY), white solids, yolk solids (YS) and total liquid solids (TS) were determined. Body weight (BW) was measured biweekly. Feed consumption (FC) and % production (PD) were measured daily. Results during the experimental period were corrected for differences between groups within variety during the pre-trial period. During period one, not all the feed was consumed and the % restriction was somewhat less than planned. The effect of energy and fat restriction on solids was not significant in period one, but was in period two. In period two there was a significant reduction of 0.32% in TS in the Low group (P#88040.001). TS were reduced because of reduced YS and PY (P#88040.01 and 0.0004, respectively). PD was reduced by 13% (P#88040.0001). Comparison of varieties over both experimental periods showed significant differences for W-36 in contrast with W-98 of 0.81% higher TS, 0.75% lower YS, 2.93% higher PY, 3.89 grams lower EW, and 0.14 Kg. lower BW (P#88040.0001 for each trait).

Key Words: Egg Solids, Energy Restriction, Fat Restriction

678 Evaluation of prediction equations and modeling metabolizable energy intake for commercial strains of laying hens. M. A. Jalal^{*}, S. E. Scheideler¹, and D. Marx², ¹Department of Animal Science, ²Department of Statistics, University of Nebraska, Lincoln.

A study was conducted to assess and contrast the accuracy of 4 existing metabolizable energy intake (MEI) prediction equations (Combs, 1968; Emmans, 1974; NRC, 1981, and NRC, 1994) and our Jalal model using our production data to derive equations for individual strains. Three strains of White Leghorn hens (Hy-Line W-36, Hy-Line W98, and Bovans) were fed 2 levels of dietary ME in a 2 x 3 factorial arrangement in an augmented block design. A total of 60 hens were used for this trial with 10 replicate cages (hen/cage) per dietary treatment. Modified models were derived by reparametrizing parameter estimates of explanatory variables in originak models using nonlinear regression. Results of model assessment showed that Combs model had significantly (P#88040.05) greater bias and mean square error (MSE) values for all strains, and was least accurate predictor of MEI among models evaluated. Therefore, Combs was excluded from further evaluation. NRC models were the best predictors and had the least bias and MSE, with Emmans and Jalal in close second and third. Pooled data results showed modified models predicted MEI more accurately in contrast to original models

for Hy-W36, while only modified Emmans and Jalal were more accurate for Hy-W98 and Bovans. An F-test showed significant differences among strain-derived equations for all models. These equations were tested using 2 sets of field data per strain acquired from a commercial layer facility. Testing of strain-derived models using field data showed no significant differences in bias or MSE estimates for Emmans, NRC or Jalal models for accuracy of predicting MEI. The results indicated that the models fit the field data well for all strains. The NRC models were the best predictors of MEI for the present data set for all strains. Testing of the strain-derived equations using field data showed that Emmans, NRC and Jalal were accurate predictors of MEI as demonstrated by non-significant comparisons of bias and MSE.

Key Words: Prediction Equations, ME Intake, Strain

679 Effect of enzyme supplementation in laying hens on egg weight and commercial egg classification. M. I. Gracia^{*1}, G. L. Campbell², E. McCartney³, J. Peinado¹, and P. Medel¹, ¹Imasde Agropecuaria, S.L., Spain, ²GNC Bioferm, Canada, ³Pen&Tec Consulting, Spain.

Four experiments involving a total of 1,820 laying hens distributed in 108 replicates evaluated the efficacy of an enzyme complex (Endofeed DC, EC No 25) containing 1,100 U/g of Endo-1,3(4)- β -glucanase (EC 3.2.1.6) and 1,600 U/g of Endo-1,4- β -xylanase (EC 3.2.1.8). A completely randomized design was applied in each study using two experimental treatments: 1) basal diet (control), and 2) basal diet with 125 mg/kg of enzyme, the recommended commercial dose. Selected data on egg weight (at 34, 46, and 54 wks of age) were combined in a meta-analysis. The original data used for the statistical analysis were the mean egg weight per replicate, and enzyme supplementation and experiment were considered as main effects. At 46 wks of age enzyme supplementation significantly increased mean egg weight (68.30 vs 66.07 g; $P < 0.001$). At 34 and 54 wks of age, no statistically significant differences were detected between treatments, but hens supplemented with enzyme laid eggs that were numerically heavier than controls (65.90 vs 64.97 g; $P = 0.19$, and 67.76 vs 66.63 g; $P = 0.20$; for 34 and 54 wks of age, respectively). To assess the commercial significance of these improvements, a second meta-analysis was carried out using individual egg weight data at 42 wks of age, obtained from two of the experiments. Each egg was classed according to commercial categories: S (<52.5 g), M (52.5-62.5 g), L (62.5-72.5 g), and XL (>72.5 g). Enzyme supplementation significantly increased the percentage of XL eggs (15.2 vs 5.3 %) at the expense of other commercial categories ($P < 0.01$). In conclusion, the data from these studies suggest that enzyme supplementation improves mean egg weight, allowing classification into larger egg classes.

Key Words: Enzyme Meta-Analysis, Egg Commercial Categories, Laying Hens

680 Enzyme supplementation of laying hens fed diets containing barley and wheat. P. Medel^{*1}, L. Pastrana², J. Méndez³, E. McCartney⁴, and M. I. Gracia¹, ¹Imasde Agropecuaria, S.L., Spain, ²Universidad de Vigo, Spain, ³Coren, S.C.L., Spain, ⁴Pen&Tec Consulting, Spain.

A study was conducted to evaluate the efficacy of a feed enzyme additive (Endofeed DC, EC No 25) containing 1,100 U/g of Endo-1,3(4)- β -glucanase (EC 3.2.1.6) and 1,600 U/g of Endo-1,4- β -xylanase (EC 3.2.1.8) in laying hens. A total of 1,170 Isa Brown laying hens (30-54

wks of age) were allocated randomly to the experimental treatments. A completely randomized block design was applied using two barns (block) and three experimental treatments: 1) basal diet (control), 2) basal diet with 100 mg/kg of enzyme, and 3) basal diet with 125 mg/kg of enzyme. Each treatment was replicated 26 times (13 per barn) with 15 laying hens constituting the experimental unit. From 30 to 38 wks of age, no significant differences were observed. From 38 to 46 wks of age enzyme addition tended to increase egg weight ($P=0.10$) yielding significant differences when comparing control vs 100 mg/kg ($P<0.05$). Also, enzyme supplementation improved feed conversion both per g ($P<0.01$) and per dozen eggs ($P<0.05$). Yolk color was significantly increased in this period ($P<0.01$) and these differences were dose-dependent and linear ($P<0.01$). From 46 to 54 wks of age, enzyme supplementation improved egg weight significantly in a linear, dose-dependent fashion ($P<0.05$), and tended to improve feed conversion per g of egg ($P=0.07$). Enzyme supplementation also increased yolk color ($P<0.01$), improved shell thickness ($P<0.01$) but decreased Haugh Units ($P<0.05$) within this period. For the whole study period, enzyme supplementation improved egg weight by 1.5% (66.60 vs 67.65 g; $P=0.01$), feed conversion by 2.7% (2.05 vs 2.00 g feed/g egg; $P=0.01$), and yolk color in a dose-dependent fashion ($P<0.01$), but control hens tended to have higher Haugh Units than T2 or T3 hens ($P=0.06$). It was concluded that enzyme improves egg weight, feed conversion and yolk color.

Key Words: Glucanase, Xylanase, Laying Hens

681 Evaluation of low-energy diets for a non-feed withdrawal laying hen molt program. P. L. Utterback*, P. E. Biggs, K. A. Rafacz, C. M. Amezcua, K. W. Koelkebeck, and C. M. Parsons, *University of Illinois*.

An experiment was conducted using 504 Hy-Line W-36 hens (69 wk of age) to evaluate several low-energy non-feed withdrawal molting methods. Six treatments provided *ad libitum* access for 28 d to diets consisting of: 1) 47% Low Trypsin Inhibitor soyhulls and 47% corn (LTI-C), 2) 47% Medium Trypsin Inhibitor (MTI) soyhulls and 47% corn (MTI-C), 3) 47% High Trypsin Inhibitor soyhulls and 47% corn (HTI-C), 4) 32% MTI soyhulls, 30% wheat middlings and 32% corn (SH-WM-C), 5) 47% rice hulls and 47% corn (RH50-C), and 6) 25% rice hulls and 68% corn (RH25-C). The seventh treatment consisted of feed withdrawal for 10 d followed by feeding a 16% CP corn-soybean meal diet for 18 d. At 28 d, all hens were fed a 16% corn-soybean meal layer diet and production performance was measured for the next 20 weeks. Hens on the feed withdrawal treatment ceased egg production by Day 8. All other treatments did not reach 0% egg production or ceased production sporadically for one or two days. Body weight loss for hens on the feed withdrawal treatment was 25.8% on Day 10 of the molt period. Hens fed the LTI-C, MTI-C, and HTI-C diets had body weight losses of 17, 18, and 20%, respectively, on Day 28. Hens fed the SH-WM-C, RH50-C, and RH25-C diets had respective body weight losses of 11, 18, and 14% on Day 28. Hen-day egg production was not different ($P > 0.05$) among treatments for Weeks 1 to 24. No consistent differences were observed among treatments for mortality, egg weight, egg specific gravity, feed efficiency, and feed consumption during the 20-wk post-molt production period. When compared to the 10-d feed withdrawal, this research indicates that diets containing soyhulls, wheat middlings, or corn and diets containing combinations of these ingredients are effective non-feed withdrawal methods for molting laying hens.

Key Words: Molt, Laying Hen, Trypsin Inhibitor

682 The effect of supplemental phytase sources on the sparing effect of phosphorus in Pekin ducks. J. K. Rush*, K. M. Banks, K. L. Thompson, and T. J. Applegate, *Department of Animal Sciences, Purdue University*.

Phytate phosphorus (PP) is relatively unavailable to the duck and therefore the majority of the PP that is fed to ducks is excreted. Therefore, an experiment was conducted to determine the effect of supplemental phytase on the sparing effect of phosphorus (P) in Pekin ducks. Drakes were fed 0, 250, 500, 750, or 1000 U/kg phytase (6-15 d) from Eco-Phos. Two reference diets were included that contained 500 U/kg from one of two commercial phytases (A and B) derived from *Aspergillus* and *Peniophora*. Four additional reference diets were also fed (6-15 d) with no supplemental phytase and increasing concentrations of non-phytate phosphorus (nPP) (0.22, 0.29, 0.36, or 0.43 %) to determine P equivalency values of phytase supplementation from improvements in bone

mineralization (6 replicate cages per diet, 4 birds per cage). The nine phytase diets were formulated with 0.22 % nPP and 1.0 % calcium (Ca) (8 replicate cages per diet, 4 birds per cage). Supplementation with 500 U/kg of Eco-Phos improved the P equivalency value based on body weight (BW) gain by 0.147 %. Supplementation with 500 U/kg of phytase B and Eco-Phos improved the P equivalency value based on tibia ash (%) by 0.072, and 0.121 %, respectively. Supplementation with 500 U/kg of phytase B and Eco-Phos improved the P equivalency value based on tibia ash weight by 0.06, and 0.068 %, respectively. When apparent P retention was determined from excreta collected from 13 to 15 d of age, 500 U/kg of phytase B and Eco-Phos improved P retention by 0.048 and 0.092 percentage units, respectively.

Key Words: Phytase, Phosphorus, Duck

683 The availability of energy in meat and bone meal and poultry by-product meal in poultry rations. D. H. Robbins* and J. D. Firman, *University of Missouri-Columbia*.

Meat and bone meal and poultry by-product meal are common by-products used in poultry rations. Unfortunately, the quality of meals varies greatly, making it difficult to precisely measure the nutrient availability. The variability of the above mentioned by-product meals has made it difficult to determine their available energy for utilization by poultry. Several trials were conducted to determine the metabolizable energy (ME) of several meat and bone and poultry by-product meals for both chickens and turkeys. An effort was also made to find an equation that could accurately predict the ME of a by-product meal given its proximate composition. If a simple and consistent method for determining the ME of the feedstuffs could be found, use of meat and bone meal and poultry by-product meal could substantially increase. Briefly, there were few differences found among assay procedures. Species and collection techniques had little impact on the ME values of the feedstuffs. The largest source of variation was the feedstuffs themselves. As mentioned previously, this variability is indicative of animal by-product meals. This made the development of a prediction equation to determine the ME value of meat and bone meals or poultry by-product meals impractical without measurement of gross energy. However, any assay procedure, battery trials or tube feeding, should provide similar results.

Key Words: Meat and Bone Meal, Poultry By-Product Meal, Metabolizable Energy

684 Broiler study nutritional evaluation of b.t.cry1f maize corn from *Bacillus thuringiensis* subsp. *aizawai* and phosphinothricin-n-acetyltransferase. J. L. McNaughton*¹ and L. Zeph², ¹*Solution BioSciences, Inc., Salisbury, MD*, ²*Pioneer Hi-Bred International, Inc. Johnston, IA*.

Two maize (corn) lines have been modified to express both the Cry1F protein from *Bacillus thuringiensis* subsp. *aizawai* and the phosphinothricin-N-acetyltransferase (PAT) protein, referred to as B.t. Cry1F maize lines 1507 or 1360 (Cry1F event TC1507 and event TC1360). Expression of Cry1F and PAT proteins provides control of European corn borer (ECB) and certain other lepidopteran pests, as well as conferring tolerance to glufosinate-ammonium herbicides. A study was conducted to determine the effect of diets containing maize from transgenic Cry1F hybrid maize lines on the performance of commercial broiler chickens (Cobb x Cobb strain) from 0-42 days of age when reared in wire floor cages. Seven reps, containing 5 male broiler chicks per rep, were fed diets containing either Cry1F event TC 1507 and/or event TC1360 and these maize sources were compared to four sources of U.S. corn commercial sources from various feed mill sources in the Eastern U.S. and a positive Control maize hybrid source 7250 (a non-transgenic control maize line). Maize (54.2% in starter and 57.0% in grower rations, across all treatments)- soybean type rations were employed throughout the study and fed *ad libitum* from 0-42 days of age. Prior to adding to rations, hybrid maize kernels from B.t. Cry1F event TC1507 or event TC1360, and control substances were analyzed for expression of the Cry1F protein using a specific ELISA. Cry1F proteins were confirmed to be present in the Cry1F event tC1507 and event TC1360 and absent in the control substances. Based on the results of this study, mortality, mean body weight, and feed conversion were statistically similar ($P<0.05$) among treatment groups. Therefore, maize grain from Cry1F event TC1507 and TC1360 are considered nutritionally equivalent to

maize grain from commercial hybrids when fed to commercial broiler chickens.

Key Words: Maize, Corn, *Bacillus thuringiensis* subsp. *Aizawai*

685 Nutrient composition of peanut meal. N. M. Dale* and A. B. Batal, *Poultry Science, University of Georgia, Athens.*

Solvent extracted peanut meal is becoming increasingly popular as a feed ingredient for poultry. Due to limited availability, levels of inclusion in broiler diets are generally in the range of 3-4%. The ingredient is an especially good source of arginine, while having a low level of lysine. As the origin of nutrient values for peanut meal reported in the standard tables of nutrient composition is unclear, a study was undertaken to document the nutrient composition of peanut meal samples currently available to the poultry industry. Seventeen samples of peanut meal were obtained during 2003 from commercial sources in the southeastern United States. Each was analyzed for proximate composition, true metabolizable energy, and mineral composition. Seven representative samples were analyzed for total and available amino acid content. All values have been adjusted to a 90% dry matter basis, this being representative of the meals evaluated in this study. While considerable variation was noted between samples, a reasonable consistency was observed in samples from each of the five suppliers, reflecting modest differences in processing procedure. Metabolizable energy (TME_n) ranged from 2314-2821 kcal/kg, with a mean of 2663 kcal/kg. Protein ranged from 40.1 to 50.9%, with a mean of 45.0%. Mean values for fat, fiber, and ash were 2.5, 8.7, and 5.2%, respectively. Total concentration and percent availability, respectively, of several critical amino acids were: lysine, 1.58% (85); methionine, 0.53% (88); cystine, 0.66% (80); threonine, 0.58% (81); and arginine, 5.08% (91). Average levels of calcium, phosphorus,

sodium, and potassium were 0.08, 0.56, 0.01, and 1.19%, respectively. The variation observed between samples strongly indicates that confirmatory analyses should be conducted prior to utilizing samples from a new supplier.

Key Words: Peanut Meal, Metabolizable Energy, Protein and Amino Acids

686 Sweet potato as a feed resource for layer production in Nigeria. O. A. Ladokun* and O. O. Tewe, ¹*University of Ibadan, Ibadan, Nigeria.*

A study was carried out on the utilization of sweet potato roots (SPR) as a replacement for maize and sweet potato tops (SPT) as a replacement for wheat bran in layer's diet. 150 point of lay Yaffa birds were fed for 84 days. The SPR was incorporated at levels of 21 and 42% to partially and completely replace maize respectively. The SPT was incorporated at levels of 10 and 20% to partially and completely replace wheat bran. The age at first egg was significantly ($P < 0.05$) different. The birds on the control, laid the first egg at 154 days while those on the complete replacement of maize and wheat bran laid the first egg at 189 days. There was a significant ($P < 0.05$) difference, across the treatments, in the feed intake of the birds, which ranged from 108.77g/bird/day to 127.97g/bird/day. Birds on the control diet had the best hen-day production of 61.83%. The yolk weight did not follow any particular trend but there was a significant ($P < 0.05$) difference across the treatments. Results of the study show that: SPR and SPT can be included in layer diet at not more than 50% of maize and wheat bran respectively. The replacement could be achieved concurrently.

Key Words: Sweet Potato, Replacement, Hen-Day Production

Ruminant Nutrition: Beef and Dairy Calves

687 Calf adipose tissue fatty acid profile, immune function and performance while nursing beef cows consuming high-linoleate or high oleate safflower seed supplements. S. L. Lake*, E. J. Scholljegerdes, E. L. Belden, R. L. Atkinson, D. C. Rule, and B. W. Hess, *University of Wyoming, Laramie.*

Thirty-six Angus \times Gelbvieh calves were used to determine the effect of maternal lipid supplementation on calf adipose tissue fatty acid composition, immune response, and performance. Beginning 3 d postpartum, cows were randomly assigned to be fed hay and a low fat control supplement (CON) or supplements consisting of either high-linoleate cracked safflower seeds (LIN) or high-oleate cracked safflower seeds (OLE) until d 60 of lactation. Cow rations were formulated to be isonitrogenous and isocaloric. Safflower seed supplements were formulated to provide 5% DMI as fat. Calf adipose tissue biopsies were collected near the tail-head region on d 60 of lactation. Calves were injected s.c. with antigen (hen egg albumin) at 21 d of age and again at 48 d of age. Antibody responses were determined in serum; cell mediated immunity was assessed by intradermal antigen injection at 60 d of age. Maternal lipid supplementation did not affect calf adipose tissue content (mg FA/g of adipose tissue) of 14:0 ($P = 0.10$), 15:0 ($P = 0.46$), or 16:0 ($P = 0.12$). Calves nursing LIN and OLE cows had greater content of 18:1 *cis*-9 ($P = 0.05$) than CON calves. Calves nursing LIN cows had greater 18:0 ($P < .0001$), 18:1 *trans*-11 ($P < .0001$), 18:2 ($P = 0.06$), and CLA ($P < .0001$), while OLE calves had greater 18:1 *trans*-9 ($P < .0001$). A trend was noted ($P = 0.10$) for CON calves to have a greater antigen response compared to LIN and OLE calves; however, there was no difference in cell-mediated immune response ($P = 0.86$). Maternal dietary lipid supplementation also did not affect ($P = 0.44$) calf ADG. Adipose tissue content of metabolically important fatty acid was increased in calves nursing lipid-supplemented cows and, although there was a tendency for decreased immune response by these calves, calf ADG was not affected by providing the dam with high-linoleate or high-oleate supplements.

Key Words: Beef calf, Lipid supplementation, Immune response

688 Effect of feeding extruded soybeans to nursing beef cows on conjugated linoleic acid concentrations in adipose tissue of suckling calves. C. Paradis*¹, R. Bertiaume², C. Lafrenière², and P. Y. Chouinard¹, ¹*Universite Laval, Quebec, QC, Canada,* ²*Agriculture and Agri-Food Canada, Lennoxville, QC, Canada.*

The concentration of conjugated linoleic acids (CLA) in meat and milk fat can be increased in ruminants by feeding pasture or extruded soybeans. Nursing calves on pasture have both access to fresh grass and dam milk; the latest being protected against ruminal biohydrogenation by the closure of the oesophageal groove. The objective of this study was to determine the effect of supplementing pasture-fed nursing beef cows with extruded soybeans on the concentrations of CLA in milk fat of cows, and subcutaneous adipose tissue of suckling calves. Thirty-two spring-calving cows and calves were separated in two groups. Cows were distributed in order to have 8 calves of each sex in both groups. Cows and calves were turned out to pasture on June 19 (95 ± 8 days post calving) under a rotational grazing management. Dams received 2 kg/d of full fat soybeans; raw ground (RGSB) for the first group, as a control, and extruded (EXSB) for the second group. Calves were weaned on October 8. The last week before weaning, milk yield of cows was estimated by the weigh-suckle-weigh technique. Milk was sampled for fatty acid (FA) analysis prior to calf nursing. Subcutaneous adipose tissue biopsies were obtained between the 11th and 12th ribs over the longissimus dorsi of the calves. Dietary treatments had no effect on final weight and weight change of cows during the pasture season. Cows fed RGSB tended to produce more milk (5.8 kg/d) than cows fed EXSB (4.1 kg/d) ($P = 0.07$). Weaning weight of calves was not affected by treatments, although the average daily gain tended to be higher for males as compared with females ($P = 0.07$). Milk fat content of CLA increased from 11.2 mg/g of FA in cows fed RGSB to 29.2 mg/g of FA in cows fed EXSB ($P < 0.01$). The CLA concentrations in adipose tissue increased from 17.7 mg/g of FA for calves nursing cows on RGSB to 25.7 mg/g of FA for calves nursing cows on EXSB ($P < 0.01$). Gender had no effect on the CLA concentrations in adipose tissue. Feeding EXSB to cows on pasture increased the concentrations of CLA in subcutaneous adipose tissue of suckling calves by 45%.

Key Words: Conjugated Linoleic Acid, Cow-Calf, Milk Fatty Acids

689 Responses of neonatal calves to milk replacer formulation and pasteurized whole milk. M. Hill*, J. Aldrich, and R. Schlotterbeck, Akey, Lewisburg, OH.

The objective was to compare feeding pasteurized whole milk to feeding milk replacers (MR) formulated using dairy NRC (2001) and Akey guidelines. The whole milk (M) was pasteurized at 72 °C for 15 seconds, quickly cooled and fed immediately. The MR formulated to NRC guidelines (N) was 22% CP from whey and whey protein concentrate (WPC) and 20% fat from edible lard. The MR formulated to Akey guidelines (A) was 20% CP formulated with whey and WPC plus synthetic lysine and methionine, and 20% fat formulated with edible lard plus a vegetable oil blend. Both MR were formulated to contain the same mineral and vitamin contents. Each liquid diet was fed at two levels (1X being equal to a MR powder fed at 454 g as-fed daily=436 g DM daily; 1.2X being equal to 3.8 L of milk, 14.1% DM, 3.2% CP, 3.6% fat=523 g DM daily). The trial used 48 calves (initially 36 kg BW at approximately 3 days of age) that were weaned at 42 days. Data were analyzed as a completely randomized block design with factors of liquid (M, N, A), level of liquid (1X, 1.2X), and the interaction of liquid and level of liquid. Average daily gains from 0-42 days were greatest for A (530 g) and least for N (440 g), with M (483 g) being intermediate ($P < .05$). Average daily gains from 0-56 days were greatest for A (637 g) and least for N (563 g), with M (584 g) being intermediate ($P < .05$). Gains from 0-56 days were greater ($P < .05$) for 1.2X (630 g) vs. 1X (559 g) liquid. Starter (18% CP, 62% corn, .0025% decoquinat) intake from 0-42 and 0-56 days for calves fed M was greater ($P < .05$) than for calves fed N but did not differ ($P > .1$) for level of liquid fed. Feed efficiency was best ($P < .05$) for calves fed A vs. calves fed M and N and for calves fed 1.2X vs. 1X liquid. Abnormal fecal score days were greater ($P < .05$) for calves fed N vs. A and M and for calves fed 1X vs. 1.2X liquid. In summary, calves fed A gained the fastest and were most efficient. Calves fed N gained the slowest and scoured the most. Calves fed 1.2X gained faster and more efficiently than calves fed 1X.

Key Words: Calves, Pasteurized Milk, Milk Replacer

690 Effect of level of starch and Apex botanicals in neonatal calf starter feeds. M. Hill*, J. Aldrich, and R. Schlotterbeck, Akey, Lewisburg, OH.

Previous research in our nursery has shown improvements in calf gains when Apex was fed in all milk protein or soy and milk protein milk replacers (MR). We have observed that gains were improved when Apex was fed via the starter. Additionally, we have observed that high starch (60% corn) starters were used more efficiently by calves than low starch (approximately half of the corn replaced with various of fibrous feeds) starters. Our objective in this trial was to evaluate the addition of .05% Apex 3030 (BFI Innovations) to a high starch (61% corn, 21% soybean meal, 5% distillers grains) and low starch (62% soy hulls, 14% soybean meal, 7% corn, 5% distillers gains) starter (18% CP, .0025% decoquinat, as-fed) when the calves were fed 454 g daily of a 20% all milk protein, 20% fat, .005% decoquinat MR. The trial used 48 calves (initially 41 kg BW at approximately 3 days of age) that were weaned at 42 days. Data were analyzed as a completely randomized block design with factors of starch level, Apex inclusion, and the interaction of starch X Apex. Calves fed the high starch diets grew 11% faster ($P < .09$) and were more ($P < .06$) efficient between 43-56 days than calves fed low starch diets. Calves fed the high starch diets grew 6% faster ($P < .09$) and were 3.6% more efficient ($P < .06$) between 0-56 days than calves fed low starch diets. Calves fed starters with Apex grew 14% faster ($P < .08$) between 43-56 days and 12% faster ($P < .07$) from 0-56 days than calves not fed Apex. Calves fed starters with Apex tended ($P < .14$) to consume more starter from 0-42 days, consumed 10% more ($P < .08$) starter from 43-56 days, and consumed 17% more ($P < .09$) starter from 0-56 days than calves not fed Apex. In summary, calves fed the high starch starter gained 1.2 kg more and were 3.6% more efficient from 0-56 days than calves fed the low starch starter. Calves fed Apex gained 2.4 kg more and consumed 5.3 kg more starter from 0-56 days than calves not receiving Apex.

Key Words: Calves, Starch, Botanicals

691 Effect of feeding neonatal calves selenium yeast or sodium selenite and supplementing specific fatty acids. M. Hill*, J. Aldrich, and R. Schlotterbeck, Akey, Lewisburg, OH.

The objectives were to compare feeding selenium (Se; .3 ppm Se in diets) from either 100% sodium selenite or 100% Se yeast (Lallemand) in the milk replacer (MR) and starter. Additionally we evaluated supplementing a blend of medium chain, 18:2, and 18:3 fatty acids to the MR (FA). The treatments were 1) selenite and no FA, 2) Se yeast and no FA, 3) selenite plus FA, and 4) Se yeast plus FA. Calves were fed 454 g of a 20% all milk CP, 20% all animal fat, .005% decoquinat MR and free-choice 18% CP, 62% corn, 21% soybean meal, 5% distillers, .0025% decoquinat starter. Data were analyzed as a completely randomized design in a 2 by 2 factorial arrangement (Se source and FA) with their interaction. The trial used 48 calves (initially 37 kg at approximately 3 days of age) that were weaned at 42 days. There were no significant ($P > .1$) effects for Se source. Calves supplemented with FA gained 9% faster ($P < .07$) from 0-42 and 0-56 days than non-supplemented calves. Calves supplemented with FA had greater ($P < .01$) starter intakes from 0-42 (28%) and 0-56 (17%) days than non-supplemented calves. Calves supplemented with FA had greater ($P < .07$) hip width changes from 0-42 (8%) and 0-56 (7%) days than non-supplemented calves. Other measurements were not ($P > .1$) significant. Source of Se had no effect on gain, starter intake, or other gross measures in calves up to 56 days. Blood or tissue analysis for Se would have been useful to determine if there were differences in Se status because of Se source. Improvements in gain and starter intake from supplementing specific amounts of medium, 18:2, and 18:3 FA are consistent with five previous trials where the average improvement ($P < .05$) in daily gain from 0-42 days has been 13%.

Key Words: Calves, Selenium Yeast, Fatty Acids

692 Performance and plasma amino acid concentrations of calves on an enhanced-growth feeding program. M. Terré¹, A. Bach^{1,2}, and M. Devant¹, ¹IRTA-Unitat de Remugants, Barcelona, Spain, ²ICREA, Barcelona, Spain.

Thirty-six Holstein and eight crossbred female calves were used in a 2x2 factorial arrangement of treatments to study the effects of level of milk replacer (MR), and addition of a rheological sepiolite for liquid feeding (RSLF) on performance, scour scores, and plasma amino acid (AA) concentrations. The treatments were high MR (HM) or low MR (LM), each of them supplemented with (WS) or without (NS) RSLF. The LM calves were fed 4 l/d of MR at 12.5% DM throughout the suckling period. The HM calves were offered MR at 18% DM: 4 l/d from 1-6 d, 6 l/d from 7-13 d, 8 l/d from 14-33 d, and 4 l/d from 34 d to weaning day at 45 d of study. Calf starter and water were offered ad libitum until the end of the study (94 d). Calves fed HM were heavier ($P < .05$) than LM calves at weaning (69.5 vs 59.0 kg, respectively) and at the end of the study (111.6 vs 102.7 kg, respectively). Starter intake was greater ($P < .001$) for LM than for HM calves until 1 wk after weaning (476 vs 221 g/d, respectively) and similar afterwards. Before day 34 ADG was greater ($P < .001$) for HM calves than for LM (881 and 427 g/d, respectively), but it was lower ($P < .001$) from 34 to 52 d of study (315 vs 707 g/d, respectively). Scour scores were greater ($P < .05$) in HM calves, but HMWS improved ($P < .01$) fecal scores during the highest MR consumption (8 l/d). The positive slope of the regression line that described ADG vs plasma AA concentrations indicated that plasma AA were not limiting growth in HM calves during high MR consumption weeks. However, when MR was reduced to 4 l/d in HM calves, starter intake was insufficient to maintain former ADG. Plasma Lys concentration of LM calves decreased linearly ($R^2 = 0.16$; $P < .05$) as ADG increased during the suckling period, suggesting that Lys could have limited growth. In conclusion, LM calves growth could be limited by Lys supply, whereas the HM treatment seemed to supply sufficient AA to sustain growth while high amounts of MR were fed; but it may limit calves performance due to low starter intake around weaning.

Key Words: Amino Acid, Milk Replacer, Sepiolite

693 A practicum-based course in equine parturition for undergraduate students. P. L. Ryan*, D. L. Christiansen, R. M. Hopper, S. T. Willard, S. D. Bowers, T. W. Dickerson, and G. L. Olsen, *Mississippi State University, Mississippi State.*

The objective of this exercise was to develop a practicum-based pilot course to instruct undergraduate students interested in equine reproduction with specific emphasis on the pregnant mare, parturition and post-natal foal. The course was offered as a Special Topics in Animal Science, but open to students from across campus with an interest in the equine species. Forty three students enrolled (4 freshman, 10 sophomore, 8 junior and 21 senior) representing six majors. The course offered a weekly lecture and six nights of foal-watch duty for a total of two credit hours. Students worked in pairs, assisted with the birth process and performed the post-partum treatments of the foal. Students were required to maintain detailed records in the foal-watch log book of activities related to mare behavior, udder development, time of delivery, time from delivery to foal standing and suckling, and whether there were complications (i.e., dystocia). For credit, students had to complete six nights of duty, attend the weekly lecture and write a report on their experiences while on foal-watch duty. At the conclusion of the course, a course evaluation was conducted to assess student perceptions of the course as a whole. Evaluations were conducted on the basis of a 1 to 5 scale (1 = strongly disagree and 5 = strongly agree) and were analyzed to ascertain the value of lectures and the hands-on experience during foal-watch. Thirty six of the forty three students enrolled responded (83.7%). The course evaluation revealed that the students felt that the course was relevant to equine sciences (4.83 ± 0.07), that lectures complimented the practicum exercises (foal-watch; 4.50 ± 0.12), that they learned a lot from the course (4.17 ± 0.17), and that what they learned would have useful application later in life (4.64 ± 0.11). The students agreed that having more than one instructor team-teaching the course was good (4.28 ± 0.14) and students disagreed that the different teaching styles were distracting (2.11 ± 0.17). There was agreement (4.80 ± 0.12) that the pilot course should be recommended to the university curriculum committee for development as a practicum-based course in the equine sciences.

695 Dairy management symposium training: Instructive partnership between academia and industry. A. Ahmadzadeh* and M. A. McGuire, *University of Idaho, Moscow.*

The traditional educational mechanism cannot provide adequate interaction with industry professionals for up-to-the-minute knowledge about dynamic changes within the dairy industry. The goal of the described educational activity was to provide complementary instruction in a senior level dairy management course to 1) enhance student knowledge and professional competencies for the progressive and challenging dairy industry and 2) to share knowledge and experience of institutional partners, producers, and allied industry experts. Through the semester, the team-taught course provided a foundation in dairy management. To achieve the goals, a mini-symposium occurred at the end of the semester.

Contemporary and Emerging Issues: Current and Future Prospects for Animal Nutrition Management for Environmental Impact Reduction

697 Use of mass balance techniques for nutrient excretion modeling. T. J. Applegate*¹ and R. Angel², ¹*Department of Animal Sciences, Purdue University,* ²*Department of Animal and Avian Sciences, University of Maryland, College Park.*

In the absence of comprehensive biological data on total excreted nutrients, development of models is needed to predict these values for livestock species. Models are usually constructed based on relationships that have been determined biologically and allow for estimation of undetermined values. Estimation of nutrient excretion has become necessary due to the recent emphasis on environmental management and regulation of animal feeding operations. Because of the impact that new environmental regulations will have on animal production it is important to determine if model estimates are accurately predicting biological nu-

trient excretion rates. The majority of current models for estimation of nutrient excretion have largely been derived from a process-based modeling approach, an approach that utilizes known analyses of components (feed analyses, tissue deposition and/or growth, product nutrient composition, average apparent retention, etc.). This mass-balance modeling approach has inherent errors, including: extrapolation of data to other ages, lack of input data for different feeding programs, and unknown referenced inputs for up-to-date industry feeding practices and productivity. Nevertheless, the mass balance approach has been critical in identifying gaps in the existing literature. Models utilizing multivariate least-squares regression may be developed in the future, but knowledge

696 Development of a distance education based food safety microbiology course in poultry science. R. S Hardin*, E. M Hirschler, M. M Kundinger, A. R Sams, and S. C Ricke, *Texas A&M University, College Station.*

With the increasing demand for food safety the responsibilities of food industry personnel has increased. More responsibility requires advanced training, which may not be readily available onsite. Distance education courses have become popular due to the increased number of commuter students as well as people already in the workforce who need more background on foodborne disease. In many cases the ability to physically attend a class at a university that offers such courses and academic expertise can be limited. Therefore a graduate level web based course entitled Special Topics-Poultry Food Safety Microbiology was developed from an existing senior undergraduate advanced food microbiology course in the Poultry Science Department at Texas A&M. Even though the use of the Internet as a teaching tool is becoming more prevalent, converting this course into a distance education course provides some unique challenges, to maintain comparable course content in an asynchronous manner. The overall objective for this course was to examine all aspects of foodborne bacterial activities including ecology in food, animals, raw and processed meat, eggs, and human pathogenesis. To create a graduate level learning experience for the students a research paper assignment was developed in order to provide a more in-depth learning opportunity of microbial pathogens. The writing process was completed through electronic submission of an outline, rough draft, and finally completing a fifteen-page scientific paper related to a food microbiology topic of interest. This instructional approach imparts an effective means for distance education students to extend an understanding of food microbiology.

698 Interactions between indigenous gut microbiota and animal waste production. J. A. Patterson* and A. L. Sutton, *Purdue University, West Lafayette, IN.*

The importance of the ruminal microbiota in altering the form of feed nutrients during ruminal digestion is well known, however, there has been increased interest in the interactions between the hindgut microbiota and diet in altering animal waste emissions. The primary waste emissions include methane, ammonia, phosphorous and odors. The fundamental microbial processes are similar between the rumen and hindgut, yet the microbial populations and their activities are dictated by differences between the two ecosystems. Examples of the influence of diet on animal waste emissions include reduction of methane emissions in ruminants by feeding monensin or high grain diets and reduction of urea/ammonia excretion in nonruminant animals by lowering dietary crude protein and supplementing with synthetic amino acids. Nutrient digestion has been increased by inclusion of enzymes and phosphorus excretion has specifically been reduced by inclusion of various sources of phytase. Composition and emission of odorous compounds are also affected by diet and microbial activities. Alteration of the intestinal microbiota and their activities will be an important method of reducing animal waste emissions in the future. One may also be able to manipulate the intestinal microbiota to enhance useful products derived from animal waste.

Key Words: Intestinal, Microbiota, Animal Waste

699 Historical and current perspectives of nutritional formulation in swine and poultry to reduce environmental impact. G. Allee*, *University of Missouri, Columbia.*

In past years diets for pigs and poultry were formulated on the basis of crude protein, total phosphorus, with a margin of safety added to ensure a nutrient was not limiting. Little, if any, attention was given to excretion of nutrients. In todays formulations, diets are formulated on an available amino acids, available phosphorus basis at the requirement level for the various nutrients with tremendous emphasis being placed on the excretion of nutrients into the environment. Historically pigs were fed a starter, grower, and finisher diet sequence. Today it is a normal practice to change diets frequently (3 or 4 starter diets, two grower diets and three finisher diets) in order to minimize the feeding of excess nutrients. It is well established that dietary manipulation is a very effective method to reduce the environmental impact of poultry and swine production. By using crystalline amino acids and the concept of ideal protein reduced crude protein corn-soybean diets greatly reduces nitrogen excretion. By using these concepts in formulation nitrogen excretion can often be reduced 20 to 30% without influencing growth performance, carcass value or cost of production. In typical corn-soybean meal diets, two-thirds of the phosphorus is bound as phytic acid, making it unavailable to pigs and poultry and consequently excreted. By using a phytase enzyme or low-phytate corn and formulating diets on an available phosphorus basis phosphorus excretion can be reduced 20 to 30%. The use of both low-phytate cereals and phytate enzyme can reduce phosphorus excretion 40 to 50%. Other examples will be given to demonstrate that dietary manipulation is a very effective method to reduce the environmental impact of pig and poultry production.

700 Reducing environmental impact of cattle through precision feeding. D. G. Fox*¹, T. P. Tylutki¹, L. O. Tedeschi¹, and P. E. Cerasolett², ¹*Cornell University, Ithaca, NY*, ²*Cornell Cooperative Extension, Hamden, NY.*

Excess dietary N is volatilized or leached into ground and surface water and excess dietary P is lost through runoff or accumulated in the soil over time where it is subject to loss in watercourses. The risk of air and water pollution increases when nutrient imports greatly exceed nutrients exported as meat or milk (positive mass balance). Our studies on dairy and beef farms indicated over two thirds of the N and P imported as feed were not exported as feed or products (meat and milk). Precision feeding

involves using mathematical models to implement research-based knowledge to formulate diets and feed management programs that optimize production while minimizing nutrients in manure. Precision feeding also requires using management practices that ensure the diets consumed are as close as possible to those formulated. In our case studies on dairy farms, precision feeding with the Cornell Net Carbohydrate and Protein System (CNCPS) reduced N and P excretion by an average of 33% while reducing annual feed costs by 50 to 130/lactating cow. Precision feeding reduced N and P mass balance on a case study farm by 17 and 28%, respectively. In another study in the basin of a P restricted reservoir, reducing P excretion by 33% with precision feeding reduced dairy farm mass P balance by 50%. The CNCPS model was used to evaluate the impact of advances in research-based knowledge on precision feeding. The bias in predicting feed energy values, which are used to predict diet allowable milk and growth and dietary N and P requirements, was reduced from -11.4 to 0.4 % and the variation accounted for was increased from 61 to 80% by using the CNCPS mechanistic rumen model rather than tabular values. The use of bST was predicted to produce the same amount of milk with fewer cows and 8% less N and 12% less P in the manure. We estimated that ionophores have reduced N excretion by 9.8 Gg/yr in feedlot cattle and would reduce N excretion by 67 Gg/yr if fed to lactating dairy cattle in the US.

701 Environmentally friendly feeds: manipulations of diets and feeding to reduce environmental impact from intensive aquaculture. G. Fornshell*, *University of Idaho, Moscow.*

The potential negative environmental impact of aquaculture effluents has received considerable attention from regulatory agencies and non-governmental organizations over the past decade. Aquaculture production systems such as net-pens and raceways where the culture water is readily exchanged with or continuously discharged into the surrounding environment have received the most attention. Feed is effectively the only major source of aquaculture-derived nutrients, such as nitrogen and phosphorus, and solids from these systems that can lead to eutrophication and sedimentation. To reduce the environmental impact of aquaculture effluents several dietary manipulations have been developed to minimize metabolic waste production, maintain product quality and maximize growth efficiency of the fish. This talk reviews the approaches taken including diet formulations, ingredient processing, genetic selection of fish and plants, manufacturing processes, and feeding strategies that have lead to considerable reductions in metabolic wastes and solids. Feed represents the largest single variable cost of production. As such, the efficient use of high-quality feeds is essential for productivity, economic efficiency, and protection of the environment.

Key Words: Environment, Feeds, Aquaculture

702 The history and current perspectives of dietary formulation in the horse. L. Lawrence*, *University of Kentucky, Lexington.*

When the most recent NRC recommendations for nutrient intakes of horses were published in 1989, the values represented minimum nutrient amounts for normal activity and health. In many cases, the nutrient amounts recommended by the 1989 NRC are much lower than amounts fed to horses in practical environments. The natural characteristics of some common feeds can result in nutrient excesses. Grass and legume hays are staples in most horse diets but because of their high potassium content, they result in potassium intakes far above the needs of most horses. The advantages of high forage diets (behavior and gastrointestinal health) outweigh any physiological disadvantages of feeding excess potassium. In addition, because it is difficult to measure optimal performance in horses, diets for horses are often formulated to provide nutrient intakes above the NRC (1989) recommendations. Most of the concentrates fed to horses in the U.S. are formulated for use with hay or pasture. Because forages can vary, commercial concentrates may be formulated to provide adequate nutrition even when low quality forages are used. Excess nutrient intakes can occur when these feeds are used with high quality forages. One approach to reducing nutrient excretion by horses would be to use feed ingredients with high nutrient availability or to include feed additives that enhance nutrient availability. Unfortunately, there have been few studies in this area and more research will be necessary to evaluate feeds and feed additives. Another approach to

minimizing nutrient excretion by horses is the use of commercially manufactured feeds that complement specific forages. For example, when alfalfa hay is used, the amounts of protein and calcium included in the concentrate can be significantly reduced. However, horse owners often have difficulty distinguishing among forages, making the successful application of this approach difficult. The approach with the most potential to reduce nutrient excretion by horses would be enhanced education of horse owners to improve their understanding of how to effectively match feed characteristics with the nutrient requirements of horses.

Key Words: Equine, Waste Management, Nutrient

703 Development of on-farm treatment of animal waste. J. B. Carey*, *Texas A&M University, College Station.*

Development of new and alternative on-farm systems to manage waste must address several obstacles or issues in order to have significant potential for adoption by producers. A primary obstacle is time. The new or alternative method must involve a reduction in the amount of time needed for waste management or at least no increase in time required to address waste management duties. Another issue to address is cost. Obviously, any method that actually reduces costs would be considered favorably. However, it is essential that all costs be considered including any potential costs of marketing final products. Additionally, new or alternative methods must prove effective and reliable under field conditions. If extensive training, monitoring, or non-traditional skills are needed for success then the applicability to commercial settings will diminish. Reliability also includes the assurance of consistent performance and accomplishment of the waste management tasks under all field conditions utilizing the skill sets available among producers and farm workers. It is also important that the new or alternative method produce an advantage or benefit, economic or otherwise to the producer. This can range from reduced pressure on existing methods to financial returns. If producers are expected to adopt new technology or change practices, they must perceive a benefit. While this list of issues and obstacles is not exhaustive, it provides a basis for consideration of new and

alternative waste management technologies. Methods such as on-farm composting and marketing of manure or litter require full consideration of these issues. Mortality management alternatives such as acid or alkaline preservation, in-vessel composting and similar technologies require broad cooperation among a wide range of scientific and professional disciplines in order to adopt a research concept to a workable on-farm solution to waste management issues.

704 Alternative uses and value added processing of animal waste products. C. M. Williams*, *North Carolina State University, Raleigh.*

Traditional animal waste treatment generally involves on-farm land application of manure as a source of plant nutrients. Although cost effective, such practices may not be sustainable in some regions that produce large quantities of meat, eggs and milk. Technologies that provide economically feasible alternative strategies for processing large quantities of manure and generating marketable value-added products are needed. Some processes identified as potentially effective include centralized processing of manure to generate bio-based energy (methane), diesel fuel, and ash for a granular fertilizer product. Examples of work in progress to accomplish these objectives include high solids anaerobic digestion (HSAD), bio-methanol production, and fluidized bed combustion. The HSAD produced approximately 12 decatherms of methane per ton of feedstock and post-processed material met Class A biosolids requirements for fecal coliform bacteria. The bio-methanol plant capacity is approximately 7,500 gallons of methanol daily from a manure feedstock from 12 farms containing 12,000 finishing pigs each. The methanol is railed to a refinery for biodiesel fuel blending. A combustion study processing approximately 90 tons of combined swine biosolids and turkey litter showed that the fluidized bed technology at combustion temperatures above 1,600° F resulted in efficient combustion and low emissions of carbon monoxide, and minimal emissions of criteria pollutants. Collectively, these technologies demonstrate potential new and off-farm alternatives for processing animal waste products.

Food Safety: Alternatives to Antibiotic Use

705 Control of *Salmonella* in poultry production, the European experience - can it be adapted to the US? J. S. Bailey*¹ and T. Roberts², ¹*Agricultural Research Service, USDA, Athens, GA*, ²*Economic Research Service, USDA, Washington, DC.*

Sweden and Denmark have instituted programs which have significantly controlled *Salmonella* in broiler chicken production. Sweden's program was initiated about 15 years ago and Denmark's program was started about 10 years ago. In both programs, extensive testing programs are in place, no *Salmonella* positive feed is allowed, and all breeder birds that test positive for *Salmonella* are eradicated. In Sweden the program is continued for final grow-out and no *Salmonella* positive birds are allowed to be sold to the consumer and any *Salmonella* positive flocks are killed and disposed of. In Denmark, *Salmonella* positive grow-out broilers are processed separately, but can be sold to the consumer. Initially the costs of implementing the programs in both Sweden and Denmark were paid for by the government. Sweden has moved to a program that is self insured through industry check-offs. Denmark is attempting to implement a similar insurance program. Final economic analysis for a similar program in the U.S. is ongoing, but it will likely not be economically feasible to implement this same program in the U.S. However, alternative methods of achieving similar results may be possible. The use of live and killed cell vaccines in breeders, competitive exclusion treatments in breeders and broilers, and extensive biosecurity in breeder and broiler operations should yield similar results without the extensive costs of eradication programs. Intuition would suggest and the European experience has confirmed that the best way to control pathogens like *Salmonella* in food systems is to control the pathogens on the farm and to prevent them from ever entering the processing plant.

Key Words: Broiler, *Salmonella*, Control

706 Use of competitive exclusion to control enterotoxigenic strains of *E. coli*. R. B. Harvey*, R. C. Anderson, K. J. Genovese, T. R. Callaway, and D. J. Nisbet, *Food and Feed Safety Research Unit, ARS-USDA, College Station, TX.*

Foodborne diseases, morbidity, and mortality in food-producing animals, associated with pathogenic strains of *Escherichia coli*, are of public health and economic significance. Increasingly, *E. coli* have become resistant to most antibiotics and alternative control measures are sought. Our laboratory developed a defined culture of commensal bacteria of porcine GI tract origin, maintained it in continuous-flow culture, and designated it as RPCF. When administered to neonatal gnotobiotic pigs, immunoglobulin levels were increased 20- to 100-fold. *In vitro* laboratory studies have shown that RPCF prevented colonization of O157:H7 and F-18 strains of *E. coli*. Other laboratory studies demonstrated that RPCF-treated pigs had decreased mortality and bacterial shedding compared to controls when challenged with enterotoxigenic strains of *E. coli*. In field trials involving five geographically separated nursery farms with a history of high mortality from F-18 strain of *E. coli*, piglets were orally administered 10⁸ CFU of RPCF within 24 h of birth, were monitored throughout the nursery period, and the performance of RPCF-treated pigs were compared to a similar number of untreated pigs on the same farms. A total of 34,676 pigs were included in these trials. We observed decreased medication costs and a 3.53% decrease in nursery barn mortality in RPCF-treated pigs compared to controls. There was an annual cost benefit of \$22,196 per farm due to improved livability and reduced medication. Results from the present studies indicate that under laboratory and field conditions, RPCF was effective in controlling disease induced by enterotoxigenic *E. coli* and may be a viable alternative to the use of antibiotics.

This work was funded in part by a grant from the National Pork Board (NPB #02-196), Des Moines, IA USA

Key Words: Pathogenic *E. Coli*, Alternative to Antibiotics, Mortality

707 Strategies to reduce *Campylobacter*. Norman J. Stern^{*1}, E. A. Svetoch², B. V. Eruslanov², Y. N. Kovalev², L. I. Volodina², V. V. Perelygin², E. V. Mitsevich², I. P. Mitsevich², V. D. Pokhilenko², V. N. Borzenkov², V. P. Levchuk², O. E. Svetoch², and T. Y. Kudriavtseva², ¹USDA-ARS-Russell Research Center, Athens, GA, ²State Research Center for Applied Microbiology, Obolensk, Russia.

We evaluated anti-*Campylobacter* activity among 11,790 isolates of lactic acid bacteria from poultry production environments. We measured zones of *C. jejuni* inhibition surrounding the candidate strains and observed 279 isolates exhibiting antagonism. A *Lactobacillus salivarius* strain PVD32, was identified and deposited under provisions of the Budapest Treaty (NRRL B-30514). The cell-free, ammonium sulfate precipitate from the culture was termed the crude antimicrobial preparation (CAP). A zone of *C. jejuni* growth inhibition surrounding 10 ul of the CAP was observed. *C. jejuni* growth resumed when the CAP was pre-incubated with protease enzymes, thus demonstrating the peptide characteristic consistent with bacteriocin definition. The bacteriocin was further purified using a combination of ammonium sulfate precipitation, CM-Sepharose, Superose, and ion exchange chromatography. SDS-PAGE electrophoresis provided an estimated molecular weight of 6 KDa. MALDI-TOF analysis refined the molecular weight as 5,123 Da. The isoelectric point of the active fraction was determined at a pH of 9.0. The amino acid sequence of the bacteriocin was determined. The bacteriocin activity was stable following exposure to 90°C for 15 minutes. The moiety was purified and encapsulated in polyvinylpyrrolidone (PVP), and added to feed at levels of 250 mg/Kg feed. Day of hatch chicks were colonized with *C. jejuni*; log 10 cfu/gm feces mean levels in untreated, 7-day old control chicks was 6.21, while birds provided bacteriocin in feed 3 days prior to sampling was 1.98; untreated, 10-day old control chicks were colonized at a means of 8.99 and treated birds were colonized at 0.61. Among an additional 14 trials, comprised of 290 chickens, of varying ages, with varying amounts of bacteriocin administered, and challenge strains of *C. jejuni*, we consistently observed at least a one-million fold reduction in cecal levels among treated birds. The bacteriocin from this *L. salivarius* appears useful to control *C. jejuni* in poultry.

Key Words: *Campylobacter*, Poultry, Bacteriocin Therapy

708 Strategies to reduce *Clostridium perfringens*. G. R. Siragusa^{*}, Agricultural Research Service, USDA Russell Research Center, Athens, GA.

In the context of poultry production, *Clostridium perfringens* (*Cp*) represents both a potential food borne pathogen as well as a significant poultry disease. As a human food borne disease agent, this spore forming pathogen has accounted annually for over 248,000 total cases of food borne disease in the United States alone. As illnesses caused by this pathogen are not part of an active surveillance program in the U.S., the aforementioned figure is estimated to be a tenfold under reporting. Within the context of production, *C. perfringens* necrotic enteritis (NE) is a peracute disease associated with predisposing factors including coccidial infections, feed types and environmental stresses. Complete withdrawal of antibiotic growth promoters from feed is one factor strongly associated with NE. This presentation will present newly initiated research to both develop alternatives to antibiotics to control *Cp* in the live bird but also research into our current understanding of gut microbial ecology preceding this disorder. Our lab has been successful in isolating a number of bacteriophage lytic for *Cp*. These virions display a highly narrow spectrum of activity against different *Cp* strains however; it is noteworthy that they show a high level of variation in plaque morphology. Work is ongoing to isolate, purify and clone the phage lytic enzyme responsible for the lysis activity and for potential use as either a therapeutic or prophylactic agent in live production. Work is also underway to identify and characterize bacteriocins for the purposes of *Cp* control. This effort has so far resulted in strains of *Cp* which produce bacteriocins against other non-producing strains. The quantitative profiling of the gut flora during growout is a goal so far achievable only on a small sample basis. Work is underway to develop sets of tools based on non-cultural methodology that can be applied to large numbers of samples thereby enhancing the diagnostic and accuracy of a general gut microbial profile. Results from other antibiotic alternative strategies to control *Cp*, e.g. sodium chlorate, as well as a review of the potential role of quorum sensing in gut modulation of specific pathogens will be presented.

Key Words: *Clostridium perfringens*, Lytic Bacteriophage, Bacteriocins

Women and Minority Issues in Animal Agriculture Symposium

709 Gender and animal agriculture. C. Sachs^{*}, *Rural Sociology and Women's Studies, Penn State University, University Park.*

Women have become increasingly involved in agriculture in the U.S. in recent years. More women are farming on their own, while others are more involved in decision-making with their spouses or other agricultural partners. Women farmers are more likely to be involved in animal agriculture than in crop production. Also, women on farms extensively participate in farm tasks and decision-making related to livestock. This paper will use data from a national survey of 2,661 farm women collected in 2001 to understand the extent of women's involvement in farm tasks, farm decision-making, and off-farm work. This study will report differences in women's involvement in tasks and decision making in livestock production by type of farm, type of livestock, sociodemographic characteristics of farm women, and region.

710 A respect for the land. A. J. King^{*}, *University of California - Davis.*

Historically, Japanese, Chinese and Mexican Americans have made valuable contributions to farming in the West. Today, many Hmong families

have leased lots of a few acres in Washington and California to raise specialty crops that are sold at local farmers markets. There are also populations of East Indians growing several different types of row and fruit crops in Northern California. The number of African American farmers is significant when focusing on the West and the Midwest. Minority groups (African Americans, American Indians, Chinese, East Indians, Hispanics, Hmong, Japanese, Laotians and women) who choose farming as careers continue to face obstacles while contributing in several ways to the ample and diverse food supply produced in the Western United States. What are these obstacles, their similarities and differences? What unique contributions have been made to farming processes and distribution related specifically to animal agriculture? How are minority farmers redefining the profile of animal agriculture and engagement by grassroots organizations?

Key Words: Minority Farmers, Animal Agriculture, Obstacles and Contributions

Animal Health - Growth and Immunity

711 Preliminary evaluation of the efficacy of halofuginone lactate (Halocur[®]) as an aid in the prevention of cryptosporidiosis in Ontario dairy calves. B. D. Jarvie, K. E. Leslie^{*}, A. S. Peregrine, T. F. Duffield, and J. Scott Weese, *University of Guelph, Guelph, ON, Canada.*

Cryptosporidium parvum is a common cause of diarrhea in neonatal calves. The incidence of shedding of *C. parvum* and clinical disease is

high on many dairy farms. There are currently no approved products in North America for the prevention of cryptosporidiosis. In Europe, halofuginone lactate (Halocur[®]) is marketed for the prevention of cryptosporidiosis. The objective of this study is to evaluate the efficacy of halofuginone lactate as an aid in the prevention of cryptosporidiosis in dairy calves. Commercial dairy farms participated in this study from February to July 2003. A total of 509 replacement heifer calves from 24 farms were enrolled and randomly assigned to one of two groups.

The treatment group received 5 mg of halofuginone lactate orally once daily for the first seven days of life. The control group received an equal volume of 10 ml of a placebo solution, administered in an identical manner. Fecal samples were collected from 305 calves on a weekly basis for the first three weeks of life at 3 to 9 days, 10 to 16 days, and 17 to 23 days of age. Fecal samples were collected from another 202 calves once between 14 and 21 days of age. Feces were analyzed for the presence or absence of *C. parvum* oocysts using sucrose flotation and microscopy. The prevalence of isolation was significantly ($p < 0.05$) reduced in halofuginone lactate-treated calves (39%) as compared to placebo-treated calves (50%). In the subset of calves sampled for three consecutive weeks, there were significant ($p < 0.05$) differences between treatment groups in the incidence of *C. parvum* detection during the three weeks of the study. In the overall study population, halofuginone lactate treatment resulted in a significant decrease in mortality up to three weeks of age ($p < 0.05$). In summary, halofuginone lactate has considerable promise as an aid in the prevention of *C. parvum* isolation in Ontario dairy calves.

Key Words: *Cryptosporidium parvum*, Halofuginone Lactate (Halocur[®]), calf Diarrhea

712 A yeast cell-wall derivative and ascorbic acid fed to neonatal dairy calves is protective against enteric challenge with *Salmonella dublin*. D. C. Cary^{*1}, S. D. Eicher², J. A. Patterson¹, and T. A. Johnson¹, ¹Purdue University, West Lafayette, IN, ²USDA-ARS, West Lafayette, IN.

Salmonella dublin frequently causes morbidity and mortality in dairy calves during the first weeks of life. The objective of this study was to examine the efficacy of beta-glucan and ascorbic acid for protection against a *S. dublin* challenge. Thirty-eight bull calves, 3 to 10 days of age, were transported for 4 h, then placed into one of three treatment groups: Immuno-gain, a product containing 2% beta-glucan and ascorbic acid (IG); a purified beta-glucan plus ascorbic acid (BG); and a control (CTL). On day 21, all calves received an oral challenge of 4.28×10^8 CFU *S. dublin*. BW were recorded post-d 0 transport, pre-challenge (d 21), and pre-d 42 transport. Weekly wither heights, feed intake, temperature, average fecal scores, and fecal shedding of *Salmonella* were recorded. Temperatures were taken twice daily, for one week after the challenge. All calves began the study positive for *Salmonella* (non-*S. dublin*). By day 14, shedding of *Salmonella* by BG calves had decreased compared to IG ($P < .05$) and CTL ($P = .15$). Shedding was negligible at the time of *S. dublin* challenge. All groups increased shedding after challenge, with no difference among groups. All calves were negative for fecal *Salmonella* by d 42. BG temperatures peaked at 96 h through 120 h, IG temperatures peaked at 72 h, and CTL temperatures showed a bimodal peak, at 48 and 96 h. At 48 h, the CTL with temperatures higher than 40C (normal=39C) tended to be more than IG ($P = .12$). Mortality tended to be lower ($P < .10$) in IG than BG prior to challenge (8%, 36%), and lower ($P < .10$) than BG and CTL after challenge (8%, 36%, 17%, respectively). There were no significant differences in growth measures of weight or height. Feed efficiency (weight gain/feed intake) was significantly higher in IG than BG ($P < .01$) and CTL ($P < .01$) prior to *S. dublin* challenge on d 21. There was no difference in final feed efficiency. Results indicate that ascorbic acid plus yeast cell wall derivatives containing beta-glucan may provide protection during enteric challenge.

Key Words: *Salmonella dublin*, Beta-Glucan, Ascorbic Acid

713 Dietary protein and energy and the adaptive immune response of milk replacer-fed dairy calves. M. R. Foote^{*1}, B. J. Nonnecke², W. R. Waters², M. V. Palmer², M. A. Fowler³, B. L. Miller⁴, and D. C. Beitz¹, ¹Iowa State University, Ames, IA, ²National Animal Disease Center, ARS, USDA, Ames, IA, ³Land O'Lakes, Inc., St. Paul, MN, ⁴Land O'Lakes, Inc., Webster City, IA.

We have shown previously that increased protein and energy affect specific aspects of immune function. Effects of enhanced nutrient availability on adaptive immune responses, however, have not been studied. Using a *Mycobacterium bovis*, Bacille Calmette-Guerin (BCG) sensitization/purified protein derivative (PPD) challenge model, we have shown that neonatal calves, relative to adult cattle, have robust cell-mediated immune responses and weak antibody responses to antigen. The present study examined the effects of increased protein and energy provided by a commercial, intensified milk replacer on the adaptive (i.e. antigen-specific) immune response of the calf. Holstein bull calves were fed a

standard (ST, 0.57 kg/d of a 22% CP, 20% F milk replacer, n=11) or intensified (IN, 1.14 kg/d of a 28% CP, 20% F milk replacer, n=11) diet from 1 to 7 wk of age. Calves were vaccinated with BCG at the initiation of the study (i.e. approximately 1 wk of age). Average daily gain was greater ($P < 0.0001$) for IN (0.62 kg) than ST (0.29 kg) calves. Liver, thymus, and subcervical lymph nodes from IN calves were heavier ($P < 0.05$) than ST calves. Total leukocyte numbers, serum IgG, IgM, and IgA levels and cutaneous reactions to antigen were affected by age but not by nutrition. Mitogen-stimulated blood mononuclear cells (PBMC) from IN calves produced less ($P < 0.05$) IFN- γ and more ($P < 0.05$) NO than PBMC from ST calves 5 wk after vaccination, as reported previously. Antigen-induced IFN- γ and NO production by PBMC, however, were unaffected ($P > 0.05$) by nutritional plane. TNF- α production of non-stimulated and PPD-stimulated PBMC from IN calves was decreased ($P < 0.05$) relative to responses of cells from ST calves 5 wk after vaccination. These results suggest that antigen-specific responses of vaccinated calves are affected minimally by feeding an intensified milk replacer that is available commercially.

Key Words: Calf, Nutrition, Immune Function

714 Pro- and anti-inflammatory cytokine responses in endotoxin challenged bovine macrophages. J. A. Mills^{*†}, J. E. Campanicki, and R. M. Dyer, Department of Animal and Food Sciences, University of Delaware, Newark.

Endotoxin (LPS) induced inflammatory responses are a complex process mediated by a number of cytokines. A balance of pro-inflammatory and anti-inflammatory cytokines during endotoxin exposure avoids over production of pro-inflammatory cytokines and the resultant widespread tissue damage and dysfunction of the microcirculation. Accordingly, we proposed bovine macrophages respond to LPS by expressing both pro- and anti-inflammatory cytokines. Bovine alveolar macrophages (n=3) were challenged with LPS (1mg/ml) (*E. coli*: O111:B4) and mRNA expression for IL-1 α , IL-1 β , TNF α , IL-10, IL-12, IL-18, TGF β and iNOS was determined by real time QPCR at 1.5, 12, 24 and 36h. Expression of all cytokines and iNOS increased post LPS challenge ($P < 0.05$). IL-1 α , IL-1 β , TNF α and iNOS expression peaked in LPS exposed cells at levels 11.3, 19.7, 6.5 and 11.3 fold higher ($P < 0.05$) than unexposed cells after 24h. By 36h, levels of TNF α and iNOS expression in LPS exposed cells decreased 6.5 and 3.5 fold below ($P < 0.05$) unexposed cells while IL-1 α and IL-1 β remained elevated 2.5 and 9.8 fold above unexposed cells ($P < 0.07$). IL-10 and IL-12 expression peaked to levels 6.1 and 24.3 fold higher ($P < 0.05$) in LPS exposed cells compared to levels in unchallenged cells after 1.5h. By 36h, IL-10 expression significantly decreased to a level 2.8 fold lower ($P < 0.05$) than unexposed cells. TGF β expression peaked ($P < 0.05$) at levels 2.6 fold above those in unexposed cells after 12h; however, decreased 2.1 fold below levels in unexposed cells by 36h. The data indicated LPS activated expression of a mixed pro- and anti-inflammatory cytokine response in bovine macrophages. The early mixed response entailed expression of the pro-inflammatory cytokines IL-1 α , IL-1 β and IL-12 and the anti-inflammatory cytokine IL-10. Later, the mixed responses lead to expression of the pro-inflammatory cytokines IL-1 α , IL-1 β and TNF α and the anti-inflammatory cytokine, TGF β . Expression of IL-1 α and IL-1 β was sustained throughout the LPS challenge while expression of all other cytokines and iNOS was depressed below levels in unexposed cells by 36h.

Key Words: Cytokines, Endotoxin, Alveolar Macrophages

715 Are polymorphisms within the interleukin-8 receptor (CXCR2) gene linked to altered neutrophil function? G. M. Pighetti^{*†}, M. Rambeaud, S. M. Youngerman, and A. M. Saxton, The University of Tennessee, Knoxville.

Recent work within our lab has identified three single nucleotide polymorphisms (SNP 1, 3, and 5) within the CXCR2 gene that are associated with subclinical mastitis. However, mechanisms contributing to this change in susceptibility are unknown. As neutrophils express high levels of CXCR2 and are necessary for resolving infections, the objective of this study was to determine the association between neutrophil functional activity and CXCR2 polymorphisms. Neutrophils from 20 lactating Jersey cows were evaluated for adhesion molecule expression and chemotaxis. Baseline expression of CD11 and CD18 tended to be lower for cows with the less common SNP3 (GC) genotype when compared to the more common GG genotype. This same trend was evident

following activation with interleukin (IL)-8. Whereas stimulation with zymosan-activated sera (ZAS) resulted in significantly elevated CD11 and CD18 expression by neutrophils with GC genotypes when compared to GG genotypes ($P < 0.05$). In contrast to CD11 and CD18, baseline expression of CD62 was significantly greater in neutrophils with the GC genotype when compared to the GG genotype ($P < 0.02$). This difference was still apparent after downregulation of CD62 induced by IL-8, but not ZAS. Not only were differences observed with respect to adhesion molecule expression, neutrophil migration also was significantly reduced with the GC genotype at SNP3 when compared to the GG genotype following stimulation with ZAS ($P < 0.04$). A similar trend was observed following stimulation with IL-8 ($P = 0.17$). Neutrophils from cows with AG genotype at SNP5 performed similarly to those with genotype GC at SNP3 in all measured parameters. However, only CD62 expression was comparable between neutrophils from cows with the AG genotype at SNP1 relative to those with the GC genotype at SNP3. This work provides preliminary evidence of an association between neutrophil function and CXCR2 polymorphisms and suggests a potential mechanism for increased rates of mastitis observed in cows with specific genotypes.

Key Words: Neutrophil, Polymorphism, Mastitis

716 Restoration of normal innate immune function in immunosuppressed sheep with OmniGen-AF: a nutritional product. Y. Wang, S. B. Puntney, and N. E. Forsberg*, Department of Animal Sciences, Oregon State University, Corvallis, OR.

The goal of this research was to investigate effects of a nutritional product (OmniGen-AF) on innate immune function in immunosuppressed sheep. Sixty growing sheep were allotted to five treatments consisting of 1: Control, 2: immunosuppressed via daily injection of Dexamethasone ([Azium] 0.1 mg/kg BW/head, twice/day), 3: immunosuppressed plus OmniGen-AF (0.5% of dry matter intake), 4: immunosuppressed plus a challenge of feed-borne mold (*Aspergillus fumigatus*) and 5: immunosuppressed plus addition of moldy feed and OmniGen-AF. Sheep were provided a "dairy diet" consisting of alfalfa, corn and soybean meal for 28 days. On Day 28, blood samples were taken from six sheep on each treatment and neutrophils were purified using a Ficoll gradient. Neutrophil proteins were processed on SDS-PAGE after which concentrations of L-selectin (a neutrophil adhesion molecule which serves as a marker for innate immune function) and interleukin-1beta (IL-1B: a pro-inflammatory cytokine) were assessed using Western blot analysis. L-selectin and IL-1B concentrations were markedly reduced ($P < 0.05$) in dexamethasone-treated sheep. These observations indicate that dexamethasone effectively repressed immune function and that we had an adequate model of immunosuppression to study effects of the nutritional product. Addition of the nutritional product to Treatment 3 increased L-selectin concentration but had no effect on IL-1B. Addition of *A. fumigatus* to Treatment 4 had no effect on either L-selectin or IL-1B. However, the presence of the nutritional product (OmniGen-AF) in Treatment 5 restored ($P < 0.05$) normal concentrations of both L-selectin and IL-1B. These observations demonstrate efficacy of dexamethasone in immunosuppression and of OmniGen-AF in restoring immune function in immunosuppressed/stressed animals. The presence of a pathogen potentiated the actions of OmniGen-AF on immune function.

Key Words: Immunity, L-Selectin, Interleukin-Lbeta

717 Dietary supplementation of lipoic acid and its effect on circulating metabolic hormones and acute phase proteins of virus-challenged beef steers. T. B. Schmidt*, E. P. Berg¹, E. M. Cochran², J. J. Garcia², S. B. Kleiboeker¹, R. Larson¹, C. W. Morgan², C. D. Grager², J. A. Carroll³, D. H. Keisler¹, K. C. Olson¹, G. Rentfrow¹, and M. S. Brown², ¹University of Missouri-Columbia, ²West Texas A&M University, Canyon, TX, ³Animal Physiology Research Unit, Agricultural Research Service.

Thirty-two, virus-challenged crossbred steers were used to determine if dietary supplementation of lipoic acid (LA) modulates circulating metabolic hormones and acute phase proteins. Steers (BW=308+27kg) were randomly assigned to control (CON), 16mg of LA/kg of BW (LA16), 32 mg of LA/kg of BW (LA32), and negative control (NEG) treatments. Steers were adapted to treatment and environment for 21 d. On d 22, blood samples, nasal swabs, BW, DMI, and rectal temperature were recorded. Control, LA16, and LA32 steers received an intranasal dose of 2 mL/nostril of infectious bovine respiratory virus (Cooper stain, 1 X 10⁶-7 PFU); NEG received 2mL of saline/nostril. Blood samples,

nasal swabs, BW, DMI, and rectal temperatures were collected on 23, 25, 27, 29, 36, and 43 d. Serum samples were analyzed for haptoglobin, amyloid-A, leptin, insulin, and serum-neutralization titer levels. Prior to challenge, DMI (% of BW) was similar among treatments. Seven and 14 d post-challenge, DMI was higher ($P < 0.05$) for LA32 than CON and LA16 (1.35%-7 d; 1.88%-14 d vs. 0.95%-7 d; 1.77%-14 d, and 0.95%-7 d; 1.67%-14 d, respectively), but all treatment groups experienced BW loss during this time. However, LA32 began gaining BW by d 29 (+5.15 kg from previous BW; $P < 0.001$), while NEG, CON, and LA16 to decline (-3.45, -1.59, and -1.42 kg from previous BW, respectively). Haptoglobin concentrations were similar before the challenge (0.147, 0.133, 0.121, and 0.128 ng/mL for CON, LA16, LA32, and NEG, respectively). On d 27, LA32 had lower ($P < 0.04$) serum haptoglobin than CON (0.311 vs. 0.592 ng/mL), and lower than both CON and LA16 on d 29. Haptoglobin concentrations were at or below pre-challenge concentrations by d 36. Serum-neutralization titers for 30/32 steers were negative on d 22. However, all animals were positive for IBRV antibodies by d 43. The geometric mean titer for CON, LA16, LA32, and NEG were similar ($2^{4.29}$, $2^{5.13}$, $2^{5.13}$, and $2^{4.50}$, respectively). Supplementation of LA at 32 mg/kg of BW provides additional protection to steers facing a viral challenge associated with respiratory disease.

Key Words: Immune Response, Antioxidants, Lipoic Acid

718 Colicins E1 and N are effective against *Escherichia coli* strains responsible for post-weaning diarrhea and edema disease in swine. C. H. Stahl*, T. R. Callaway², L. M. Lincoln¹, S. M. Lonergan¹, and K. J. Genovese², ¹Department of Animal Sciences, Iowa State University, Ames, ²USDA-ARS Food and Feed Safety Research Unit, College Station, TX.

Escherichia coli infections causing post-weaning diarrhea and edema disease are one of the most prevalent disease problems in swine in the U.S. More than 43% of the large swine facilities in the U.S. reported *E. coli* infections among weaned pigs in 2000 and in an attempt to prevent the spread of these infections more than 78% of these facilities reported using prophylactic antibiotic treatments. The strains considered primarily responsible for these infections, F4 (K88) and F18, are not well controlled by traditional prophylactic antibiotic treatments, and with worldwide concern over the use of prophylactic antibiotics in animal agriculture, the development of alternatives to conventional antibiotics is urgently needed to protect swine from these *E. coli* infections. Colicins have been shown effective against other pathogenic *E. coli* strains, but their efficacy against the *E. coli* strains responsible for post-weaning diarrhea and edema disease has not been examined. The efficacy of two pore-forming colicins, E1 and N, against *E. coli* F4 (K88) and F18 were determined quantitatively in vitro. Colicin E1 and N were expressed by native producers and purified by ion exchange chromatography. The purified colicins were quantified and used in growth inhibition dose-response studies against *E. coli* F4 (K88) and F18. Both colicins were effective against both strains of *E. coli*, however their efficacy varied greatly. Colicin E1 was more effective against F18 than F4 (K88) ($P < .01$), requiring approximately 1 $\mu\text{g/mL}$ of culture to completely inhibit the growth of F18 and an approximately 50 $\mu\text{g/mL}$ to inhibit the growth of F4 (K88). Colicin N was less effective than Colicin E1 against *E. coli* F18 ($P < .01$), requiring fifty fold higher concentrations in order to achieve the same level of growth inhibition, but more effective against the F4 (K88) strain ($P < .01$), requiring only half the concentration of Colicin E1 to obtain the same growth inhibition. These antimicrobial peptides may provide an effective and environmentally sound method to prevent post-weaning diarrhea and edema disease in swine.

Key Words: Colicin, Antibiotic Alternatives, Post-Weaning Diarrhea

719 Infectious dose of young pigs experimentally inoculated with PRRS virus by oral and intranasal routes. J. R. Hermann*, M. Kaiser¹, M. Roof², K. Burkhardt², and J. J. Zimmerman¹, ¹Iowa State University, Ames, IA, ²Boehringer Ingelheim, Ames, IA.

Prevention and control of PRRS virus requires an understanding of transmission in the field. Current reports in the literature suggest that swine are susceptible to PRRS virus by several exposure routes, including intranasal, intramuscular, and oral. The infectious dose by either intranasal or intramuscular routes is known to be very low. Infection of swine via oral exposure has been reported, but the minimum infectious dose has not been estimated. Thus, data on the specific exposure dose

necessary for infection is needed to assess the likelihood of transmission by oral exposure in the field. This study was designed to estimate the probability that a specific oral dose of PRRS virus would result in infection. The experiment was conducted as a randomized block design in which individually housed 19 - 24 day old pigs were orally exposed to a specific dose (titer) of PRRS virus (2 to 7 logs TCID₅₀). Each replicate consisted of 10 animals: 4 treatment levels of PRRS virus (run in duplicate), plus positive and negative control animals. To test a volume effect, treatment doses were administered in either 10 ml or 100 ml volumes. Animals were bled on days -7, 0, 7, 14, 21 and serum samples tested for evidence of PRRS virus infection by virological and serological assays to determine whether exposure resulted in infection. The pig was considered the experimental unit. The primary outcome for this study is binary, i.e., pigs become infected or not. The resulting probabilities at each dose were used to construct and infectious dose curve using a single hit model based formula. The estimated infectious dose₅₀ (ID₅₀) of young healthy pigs is 10⁵ TCID₅₀. However an oral treatment dose of 10³ TCID₅₀ were sufficient to cause infection in young swine. No differences existed between antibody levels by route or dose of exposure.

Key Words: PRRS Virus, Swine, Oral

Beef Species: Enhancing Energetic Efficiency

721 Growing program effects on efficiency of energy use by feedlot cattle. C. R. Krehbiel*, M. P. McCurdy, and G. W. Horn, *Oklahoma State University, Stillwater.*

Maintenance energy requirements can account for more than half of the ME intake by beef cattle. It is generally accepted that ADG and efficiency during finishing are directly related to plane of nutrition and energy density of the diet during the growing phase. Steers that are fed for high ADG during the growing phase accrete a greater percentage of their BW gain as fat than restricted steers, and contain more fat upon feedlot entry. Restricted steers have greater protein content as a percentage of BW, and are generally considered to have a lower NE_g requirement. Cattle that have had greater rates of BW gain during the growing phase are generally assumed to be less efficient and have decreased gains during the finishing phase. This concept is consistent with the 1996 Beef Cattle NRC Level 1 Model, which shows a negative correlation between predicted ME allowable ADG and initial body fat content. In contrast, recent literature has reported that cattle subjected to greater ADG during the growing phase might not always experience lower ADG or gain efficiency during the finishing phase. Reasons for discrepancies are not fully understood. Changes in visceral organ mass might change the amount of nutrients available for growth. Several authors have observed that when ME intake was restricted, mass of the gastrointestinal tract (GIT) was similar or decreased compared with animals fed above maintenance or ad libitum. In contrast, ruminants restricted by energy density of the diet have greater GIT mass as a percentage of BW. The GIT appears to respond to physical form of the diet and fiber content, which could increase NE_m requirements during finishing. Investigation into gain and efficiency of feedlot cattle must provide a complete picture of nutritional management through all production segments due to the number of potential factors that may determine performance in the feedlot. A comprehensive understanding of animal biology will allow us to enhance efficiency of beef production systems, and improve end-product quality.

Key Words: Cattle, Energetic Efficiency, Gastrointestinal Tract

720 A deterministic risk assessment of macrolide use in swine. A. G Mathew*¹, H. S. Hurd², S. Doores³, D. Hayes⁴, J. Maurer⁵, P. Silley⁶, R. N. Jones⁷, and R. Singer⁸, ¹University of Tennessee, Knoxville, ²Hurd-Health Consulting, Roland, IA, ³Pennsylvania State University, University Park, ⁴Iowa State University, Ames, ⁵University of Georgia, Athens, ⁶MB Consult Limited, Bingley, West Yorkshire, UK, ⁷The JONES Group/JMI Laboratories, North Liberty, IA, ⁸University of Minnesota, St. Paul.

To quantify risks stemming from antibiotic-resistant bacteria as a possible consequence of macrolide antibiotic use in swine, a farm-to-patient deterministic risk assessment was formulated using extensive scientific and government numerical data. The model was developed based on the US FDA Center for Veterinary Medicine Guidance Document 152, which advises veterinary drug sponsors of one potential process for conducting a qualitative risk assessment of drug use in food animals. The scope of modeling included all label claim uses of both antibiotics in U.S. swine production, including therapeutic, disease prevention, disease control, and growth promotion, as indicated by CVM-approved label claims for swine. The defined hazard was illness caused by a food-borne bacterium with a resistance genetic element(s), attributed to pork, and treated with a human-use macrolide drug. Risk was defined as the probability of this hazard combined with the consequence of treatment failure due to resistant *Campylobacter spp.* or *Enterococcus faecium*. A binomial fault tree model was applied to estimate this annual risk for the general US population. This risk assessment demonstrated that use of tylosin and tilmicosin in swine present a very low risk, with an approximate annual probability of less than 1 in 53 million *Campylobacter spp.*-derived and less than 1 in 27 billion *Enterococcus faecium*-derived risks.

Key Words: Macrolide, Antibiotic Resistance, Risk Assessment

722 Nutrition *in utero* and pre-weaning has long-term consequences for growth and size of Piedmontese- and Wagyu-sired steers. P. L. Greenwood*^{1,2}, H. Hearnshaw^{1,3}, L. M. Cafe^{1,3}, D. W. Hennessy^{1,3}, and G. S. Harper^{1,4}, ¹CRC for Cattle and Beef Quality, Armidale, NSW, Australia, ²NSW Agriculture, Armidale, NSW, Australia, ³NSW Agriculture, Grafton, NSW, Australia, ⁴CSIRO Livestock Industries, St. Lucia, QLD, Australia.

Piedmontese (PxH) and Wagyu (WxH) x Hereford steers were selected for divergence in birth weight (PxH, Low mean±SEM 31.4±0.8 and High 42.1±0.9 kg; WxH, Low 27.4±0.7 and High 36.7±0.6 kg) and pre-weaning growth following high (irrigated improved temperate pastures) or low (sub-tropical native pastures) nutrition during pregnancy and either high or low nutrition from birth to weaning. Steers were weaned at 7 months of age and grown on improved temperate pastures, with supplementation as required to maintain growth, to 26 months of age when they entered a feedlot for 105 days prior to slaughter. Steers from dams nutritionally restricted during gestation and/or steers nutritionally restricted from birth to weaning had lower live and carcass weights compared to their high birth weight plus high pre-weaning nutrition (HH) counterparts at 30 months of age, this being most evident in the low birth weight plus low pre-weaning nutrition (LL) steers. These results support the notion that nutritional restriction early in life limits capacity to compensate when adequate nutriment is restored. However, retail yield on a carcass weight-specific basis was greater in the LL steers compared to their HH counterparts. This finding, and the lack of nutritional effects on indices of carcass fatness beyond those attributable to differences in body weight of these animals, does not support the notion that increased fatness later in life is a consequence of nutritional restriction early in life. We conclude that nutrition early in life has long-term consequences for growth and size of steers at any given age to 30 months.

Table. Performance of Piedmontese (PxH) and Wagyu (WxH) x Hereford steers with divergent birth weight and pre-weaning growth as a result of high or low nutrition *in utero* and pre-weaning (HH, LH, HL, LL).

	PxH	WxH	LSD	HH	HL	LH	LL	LSD	Effects
Number of animals	40	39	-	20	19	20	20	-	-

723 Effects of limit feeding on net nutrient flux and oxygen consumption by the portal-drained viscera. M. P. McCurdy*, M. J. Hersom, C. R. Krehbiel, and G. W. Horn, *Oklahoma State University, Stillwater.*

Ten steers (average initial BW = 430 ± 42 kg) were used in a randomized complete block design over two observation periods. Steers were blocked by previous treatment (high or low BW gain while grazing winter wheat pasture) and allotted to two treatment groups in a switch-back design. The purpose of the experiment was to determine the effects of ad libitum feeding versus limit feeding on diet digestibility, visceral organ mass, blood flow, blood gas measurements, oxygen consumption, and net flux of metabolites across the portal-drained viscera (PDV) of finishing beef steers fed a high-concentrate diet. Treatments were ad libitum feeding of the diet (CON) or feeding at 90% of ad libitum (LF). Limit-fed steers consumed 86.5% and 87.8% of the actual DMI of CON steers during period 1 and 2, respectively. Limit-feeding increased DM ($P < 0.05$) and OM ($P < 0.05$) digestibility of the diet by 3.9% and 3.8%, respectively compared with CON steers, whereas N digestibility did not differ ($P = 0.21$) among treatments. The increase in digestibility resulted in similar (5.53 vs 5.22 ± 0.48 kg/d; $P = 0.46$) digestible OM intake among treatments. Net flux of α -amino N and urea N were not different among treatments. Concentrations of glucose in arterial and portal blood tended ($P = 0.06$) to be greater for CON steers; however, net portal removal of glucose tended ($P = 0.07$) to be greater in CON steers suggesting greater glucose utilization by the PDV. No significant differences were observed in blood gas measurements, and oxygen consumption by the PDV did not differ among treatments (-475 vs -437 mmol/h for CON and LF, respectively). After 34 d of limit-feeding, visceral organ mass did not differ among treatment groups. The increase in OM digestibility by LF steers suggests nutrient availability was similar among treatments. Combined with lower utilization of glucose and similar oxygen consumption by the PDV, our data suggests more efficient utilization of nutrients by limit-fed steers.

724 Effect of time of feeding a limit-fed high grain diet during winter months on growing feedlot steers. S. M. Holt*, R. H. Pritchard, and J. A. Clapper, *South Dakota State University, Brookings.*

The effect of feeding time on physiological status and performance of steers in the winter was investigated during a 56-d feedlot growing study. Steers were limit-fed a high moisture ear corn diet (2.04 Mcal/kg NE_m, 1.39 Mcal/kg NE_g) at 0900h (AM) or 1500h (PM) to allow for gain of 1.40 kg/d. Calculations of NE_g intake were derived using NRC equations and tabular values for dietary ingredients. Climatic data were collected

hourly throughout the study via an automated weather station located at the feedlot. Tympanic temperatures (TT) were collected every 15 minutes (3 steers/treatment) for 6d (d45 to 50) during the final 14 d period. Serum free T₃ and T₄ concentrations were determined from blood samples (18 steers/treatment) collected on d44 and d51. Ambient temperature (T_a) during the 56 d growing study ranged from -21.4 to 13.2° C with a mean of -5.7° C. During the 6 d TT collection period, mean T_a was -2.0° C and ranged from -19.2 to 0.4° C. Initial BW was 298 ± 5 kg. Body weight after 56d growing period (393 kg vs 401 kg), ADG (1.70 vs 1.84 kg) and gain efficiency (231 vs 250 g/kg) differed ($P < 0.05$) between AM and PM groups, respectively. Serum free T₃ and T₄ levels were similar for both treatment groups. Mean TT were similar (39.4 vs 38.9° C; $P > 0.10$) between AM and PM groups, respectively. No changes in diurnal TT patterns were observed. Minimum TT during the 6d collection period tended to be higher for the AM compared to the PM group (38.9 vs 38.4° C; $P = 0.09$), respectively. Maximum TT were higher for AM than PM (40.0 vs 39.4° C; $P < 0.05$). Based upon performance, maintenance energy expenditure was increased 25.1% for the AM group ($P < 0.05$). T₃ and T₄ levels were unable to explain this difference. It is possible that when offering feed in the morning compared to the afternoon, basal metabolic rate has to be increased to maintain body temperature. The TT data suggest animals may overestimate energy requirement and increase body temperature above normal levels, resulting in reduced performance.

Key Words: Tympanic Temperature, Steers, Feedlot

725 Residual feed intake: an alternative measure of feed efficiency for beef cattle. Gordon E. Carstens*¹ and M. S. Kerley², ¹Texas A&M University, College Station, ²University of Missouri, Columbia.

Feed inputs represent more than 60% of the cost of producing beef, and manure outputs are the primary contributor to the industry's adverse effect on the environment. Thus, feed efficiency is an important trait to consider developing selection programs to identify cattle that are more economically and environmentally sustainable to produce. Considerable genetic variation is known to exist in feed efficiency, but the expense of measuring feed intake has precluded the implementation of selection programs that target this trait. Moreover, the traditional measure of feed efficiency (feed:gain ratio; F:G) is known to be inversely related to growth and mature size, such that selection for improved F:G leads to increases in cow size. Recent developments provide opportunities to improve the genetic merit of cattle for feed efficiency: (1) emerging commercialization of new technologies to more cost effectively measure feed intake in cattle and (2) discovery of an alternative measure of feed efficiency (residual feed intake; RFI) that will facilitate selection of more efficient cattle with minimal effects on growth traits or cow mature size. RFI is calculated as the difference between an animal's actual feed intake and the feed an animal is expected to consume based on its weight and growth rate—cattle that eat less than expected for their weight and growth will have a negative RFI or improved net feed efficiency. RFI has been shown to be moderately heritable and genetically independent of growth and mature size in cattle. Multidisciplinary research is needed to determine the biological basis for variation in RFI, and to examine the effects of selection for RFI on reproductive efficiency, carcass composition and meat quality. Discovery of management practices, genetic markers, and physiological (e.g., IGF-1) or physical (e.g., exit velocity, feeding behavior) traits that are predictive of RFI would be useful to more accurately and cost-effectively identify animals with superior genetics for RFI. Increasing genetic merit for RFI has potential to reduce production costs, mitigate environmental effects of producing beef and increase the competitive position of the beef industry.

Key Words: Residual Feed Intake, Efficiency, Beef Cattle

726 Correlations among ultrasound carcass estimates, growth performance measures, and residual feed intake in Angus steers. J. I. Szasz*, C. W. Hunt, S. D. Baker, T. Klein, P. S. Kuber, B. Glaze, D. Falk, R. Richard, J. Miller, R. A. Battaglia, and R. A. Hill, *University of Idaho, Moscow.*

Residual feed intake (RFI) has received increasing attention as an alternative measure of gain efficiency (GEF; gain per DMI) in beef cattle. The objectives of the current study were to evaluate RFI in purebred Angus steers using novel linear regression equations and to define correlation coefficients between attributes of growth, ultrasound measures

and RFI. Steers (n = 54; mean BW 341 kg) were individually fed (electronic feeding gates) a forage-based growing diet for 70 d. Daily DMI, biweekly BW, initial (d 0) and final (d 70) ultrasound estimates of 12th rib fat thickness (BF), longissimus muscle area (REA), and intramuscular fat percent (IM) were determined. In addition to RFI computations reported in previous literature ($DMI = \beta_1 \cdot ADG + \beta_2 \cdot \text{metabolic BW}$), DMI was regressed against ADG, metabolic BW (MBW), and ultrasound measurements using stepwise regression techniques. Ultrasound measurements were included as well as their MBW-adjusted counterparts. The adjusted model included effects due to ADG, MBW, and final BF ($R^2 = 0.71$; $RMSE = 0.51$) resulting in a minor improvement over the original equation ($R^2 = 0.68$; $RMSE = 0.53$). Measures of BW, ADG, final REA, and IM were not ($P > 0.90$) correlated with RFI, whereas, RFI was correlated ($P < 0.05$) with DMI ($r = 0.56$), GEF ($r = -0.44$), and final BF ($r = 0.28$). In addition, GEF was correlated ($P < 0.01$) with initial BW ($r = -0.46$), ADG ($r = 0.65$), DMI ($r = -0.40$), and initial REA ($r = -0.64$). Range in RFI was -1.12 to +1.52 kg DMI, and both models indicated that low RFI steers (RFI < 0.5 SD below the mean) had lesser ($P < 0.02$) DMI than high RFI steers (RFI > 0.5 SD above the mean) and that high RFI steers had lesser ($P < 0.01$) GEF than low RFI steers. When the conventional model was used, final BF was lowest ($P < 0.001$) for low RFI steers. These data are consistent with previous studies where low RFI steers appear to be slightly leaner.

Key Words: Beef Cattle, Gain Efficiency

727 Relationship of feeding behavior to feed efficiency in crossbred Angus steers. J. W. Golden* and M. S. Kerley, *University of Missouri-Columbia*.

A study was conducted to determine the relationship between feed efficiency and feeding behavior of feedlot steers. The hypothesis was that high and low efficiency steers would not differ in feeding behavior. Crossbred Angus steers (n = 80) were fed ad libitum and individual feed intakes were recorded by the GrowSafe® feed intake system. Recorded intakes were used to calculate residual feed intake (RFI), a measure of efficiency. RFI values were calculated three consecutive months, and animals were identified as efficient (n = 6) or inefficient (n = 6). Average RFI values for the efficient (-1.564) and inefficient (1.657) groups differed ($P < 0.01$). Data from these 12 animals were analyzed. Starting and ending weights did not differ ($P > 0.10$) between groups. Average daily intake (7.94 kg vs. 11.70 kg) and average eating bouts per day (10.99 vs. 18.15 visits) differed ($P < 0.01$), with efficient animals consuming less feed and eating fewer times per day. Grams eaten/minute (97.9 vs. 94.7) did not differ ($P > 0.10$) between high and low efficiency groups. Average daily gain for the efficient and inefficient animals (1.40 vs. 1.50 kg/day) did not differ ($P > 0.10$). The feed to gain ratio differed ($P < 0.01$) between groups. Time of day eating bouts occurred was divided into eight periods (1,2,3,4,5,6,7 and 8). Each period was 3 hours in length with period 1 occurring from 12-3a.m., and each remaining period following consecutively in 3 hour time blocks. The amount of feed consumed differed ($P < 0.05$) in periods 3,4,5,6 and 7 when comparing groups. Periods 4,5 and 6 represented the periods when most feed consumption occurred. In the high efficiency group the amount consumed between periods 4,5 and 6 did not differ ($P > 0.10$). However, in the low efficiency group the amount of feed consumed in periods 4,5 and 6 differed ($P < 0.05$). The differences in consumption between periods in the low efficiency group and the lack of difference in the high efficiency groups cannot be fully explained. Further study is warranted to determine if a link exists between eating patterns and efficiency status of an animal.

Key Words: RFI, Eating Behavior

728 The effect of mitochondrial uncoupling proteins 2 and 3 on feed efficiency in crossbred angus steers. W. H. Kolath*, M. S. Kerley, and J. W. Golden, *University of Missouri-Columbia*.

The objective of this study was to determine if a relationship exists between uncoupling proteins 2 and 3 (UCP 2&3) and feed efficiency. Inefficient animals would hypothetically be expected to have greater expression of UCPs than efficient animals. Crossbred Angus steers (n=80), fed ad libitum, had their individual feed intake recorded via the GrowSafe® feed intake system over a three-month period. Intakes were used to calculate residual feed intake (RFI), a measure of efficiency. Tissue samples were taken from the *longissimus lumborum* muscle from

both the most (RFI -1.564; n = 6) and least (RFI 1.657; n = 6) efficient animals. Tissue samples were immediately frozen in liquid nitrogen and stored at -80°C until further analysis. Total RNA was extracted and reverse transcribed to cDNA. Uncoupling protein 2&3 cDNA was measured by quantitative real-time polymerase chain reaction. Protein was also extracted from the tissue samples and fractionated on 10% SDS-Page gels, blotted to PVDF membranes and probed with antibodies against UCP 2&3. No difference in either cDNA expression or protein expression was observed. Mitochondrial uncoupling proteins 2 and 3 are therefore believed to be unrelated to feed efficiency.

Key Words: Mitochondria, Uncoupling Protein, Feed Efficiency

729 Variation in energy expenditures between growing steers with divergent residual feed intakes. Monte B White*, Gordon E Carstens, Casey M Theis, Michael W Kurz, Ching-Yi Chen, Lisa J Slay, and Tom H Welsh Jr., *Texas A&M University, College Station*.

Residual feed intake (RFI) is a measure of feed efficiency that quantifies variation in feed intake beyond that needed for maintenance and growth requirements. For this study, steers with the lowest (low; n = 9) and highest (high; n = 9) RFI were selected from 169 Braunvieh-sired crossbred steers that were individually fed a pelleted roughage-based diet (calculated metabolizable energy; ME = 2.2 Mcal/kg DM) for 77 d using Calan feeders. RFI was calculated as the difference in actual DMI and DMI predicted from the regression of DMI on mid-test BW^{.75} and ADG. Objectives of this study were to determine if variation in energy expenditures contributed to differences in feed efficiency between low and high RFI steers. Following the 77-d RFI period, steers were fed the same diet while being halter broken and adapted to respiration chambers. Steers were fed at 1.1X maintenance for 4 d and heat production (MHP) measured for two consecutive 22-h periods using indirect calorimetry. HP was measured on d 3 and 4 of fasting (FHP) and metabolizable energy for maintenance (ME_m) calculated using linear regression of ME intake on retained energy. Heart rate (HR) and motion activity were measured concurrently with HP. During the 77-d RFI period, low RFI steers had lower ($P < .001$) RFI (-1.7 vs 1.6 ± .17 kg/d), DMI (7.7 vs 10.2 ± .42 kg/d) and feed:gain ratio (F:G; 7.2 vs 10.6 ± .60), but similar final BW (331.5 ± 10.2 kg) and ADG (1.1 ± .07 kg/d). However, during the 112-d calorimetry phase, there were less differences in DMI (8.4 vs 9.7 ± .38 kg/d; $P = .02$) and F:G (9.7 vs 10.8 ± .40; $P = .07$) between low and high RFI steers. No differences were found in FHP (98.5 vs 102.1 ± 3.1 kcal/kg^{.75}/d) or ME_m (148.4 vs 151.0 ± 4.1 kcal/kg^{.75}/d) between low and high RFI steers. Likewise, no differences were found in HR, respiratory quotients or motion activities during FHP and MHP measurements. The lack of differences in FHP and ME_m between divergent RFI steers may have been the result of alterations in feeding behavior or activity imposed by adapting steers to calorimetry chambers.

Key Words: Residual feed intake, energy expenditure, cattle

730 Effects of Revalor®-200 vs. Finaplix®-H in single and reimplant strategies for yearling heifers. C. D. Reinhardt¹, W. T. Nichols*¹, J. P. Hutcheson¹, S. Swingle², and K. Karr², ¹*Intervet, Inc., Millsboro, DE*, ²*Cactus Research, Ltd, Amarillo, TX*.

One thousand eight hundred eighty-five English×continental yearling heifers (309 kg) were used in a randomized complete block study to evaluate the effects of Finaplix-H and Revalor-200 in single or reimplant strategies. Heifers were blocked by arrival date and assigned to one of four treatments: 1)Finaplix-H (200 mg trenbolone acetate (TBA)) on d0 (FH); 2)Revalor-200 (20 mg estradiol 17β (E₂) + 200 mg TBA) on d0 (R200); 3)Revalor-IH (8 mg E₂ + 80 mg TBA) on d0 and Finaplix-H on d60 (IHFH); 4)Revalor-IH on d0 and Revalor-200 on d60 (IH200). There were 5 pens per treatment with an average of 94 head per pen. Heifers were harvested after 137 days on feed. The R200 heifers had higher ADG ($P = 0.08$) and tended to have improved feed:gain ($P = 0.11$) on a carcass-adjusted basis than the FH heifers. The FH heifers had higher marbling score and higher percent Prime+Choice than any other treatment ($P < 0.01$), but they also had higher yield grade, calculated empty body fat (EBF), and lighter predicted live weight at 28% EBF than either the R200 or IH200 heifers ($P < 0.05$), indicating that they finished sooner and lighter than the R200 and IH200 heifers. The IH200 heifers had lower DMI than any other treatment ($P < 0.05$), characterized by a

marked and sustained reduction in DMI following the reimplant event. Due to the lower DMI, the IH200 heifers had lighter final weight and lower ADG on a live basis ($P < .01$) than the IHFH heifers, but these differences were reduced on a carcass-adjusted basis. The IH200 heifers had significantly improved feed conversion compared to FH and R200 ($P = 0.01$) and tended to have better feed conversion than IHFH ($P = 0.14$) on a carcass-adjusted basis. The IH200 heifers had significantly higher dressing percent, less rib fat, larger ribeye area, lower average yield grade, greater percentage yield grade 1 & 2, lower EBF, and heavier predicted weight at 28% EBF than any other treatment ($P < 0.01$). These data indicate that Revalor-200 may improve performance and EBF-adjusted final weight compared to Finaplix-H in either single or reimplant strategies utilized in yearling heifers.

Breeding and Genetics: Dairy Genetic Evaluation

731 International genetic evaluation of longevity traits. J. H. Jakobsen* and U. Emanuelson, *Interbull Centre, Uppsala, Sweden.*

The first test run for international genetic evaluation of longevity traits took place in March 2004 and was performed for the Holstein breed. The test run is an outcome of preliminary research studies, which showed feasibility of international genetic evaluation for longevity traits. The 14 countries participating in the research studies defined longevity either as risk of involuntary culling, length of productive life, or survived as a 0-1 trait. Traits were analyzed nationally with linear mixed models and survival analysis. International genetic evaluations were performed using Multitrait Across Country Evaluation (MACE), and correlations between countries ranged in the research study from zero to 0.92, and were on average 0.59. Two different traits have been defined within the longevity trait group. These are longevity as a direct trait and longevity as a trait combined with indicator traits. Combined longevity is a complex trait in the sense that the choice of indicator traits is very variable across countries. Also, procedures to calculate weighting factors for the deregressed national combined proofs, as input to MACE, is unresolved. The first official test run was therefore performed for direct longevity only, but research is currently going on to investigate such unresolved issues for combined longevity. Research is also ongoing to investigate feasibility of international evaluation for longevity for other breeds than Holsteins. The presentation will focus on correlations between countries and selection differentials from the March test run for direct longevity.

Key Words: MACE, longevity

732 Correlated traits used for indirect prediction of productive life in Holsteins. S. Tsuruta*¹, I. Misztal¹, and T. J. Lawlor², ¹University of Georgia, Athens, ²Holstein Association USA Inc., Brattleboro, VT.

The purpose of this study was to update formulas used for indirect prediction of productive life from correlated traits. Productive life was defined as days in milk at age 84 mo within the limit of 305 DIM for each lactation. Genetic parameters for 25 traits (productive life, milk, fat, protein, somatic cell score, days open, 18 linear type, and final score) were estimated with a multiple-trait sire model via Gibbs sampling. The data contained 392,800 records for Holstein cows born from 1995 to 1997. The model included registration status, herd-year, age group, month of calving and stage of lactation as fixed effects, and random sire genetic effects and residual effects. Heritability for productive life was estimated as 0.09. Genetic correlations of productive life with milk, fat, protein, somatic cell score, days open and final score were 0.11, 0.11, 0.12, 0.32, 0.62 and 0.13, respectively. Stronger correlations with linear type traits were 0.37 for udder depth, 0.29 for body depth, 0.27 for fore attachment, and 0.25 for dairy form. Using all of the 24 traits, productive life can be predicted with the maximum reliability of 0.69. Using five traits (in order of declining importance: days open, udder depth, milk, stature and somatic cell score), the maximum reliability was 0.61. Compared to currently used correlations for indirect prediction, many correlations changed sign, indicating changes in definition of productive life and that many conformation traits have intermediate optima. Days open became the most correlated trait with productive life.

Key Words: Genetic correlation, Productive life, Holstein

733 Analysis of the relationship between type traits and functional survival in Canadian Jersey cows. A. Sewalem*^{1,2}, G. Kistemaker², and B. Van Doormaal², ¹Agriculture and Agri-Food Canada, ²Canadian Dairy Network.

The aim of this study was to explore the impact of type traits on the functional survival of Canadian Jersey cows using a Weibull proportional hazard model using the Survival Kit. The data set consisted of 49,791 cows from 900 herds calving from 1985 to 2003. Functional survival was defined as the number of days from the first calving to culling or death or censoring. Type information consisted of phenotypic type scores of 8 composite traits and 20 linear descriptive traits. The statistical model included the effects of stage of lactation, season of production, the annual change in herd size, type of milk recording supervision, age at first calving, effects of milk, fat and protein yields calculated within herd-year-parity deviations, herd-year-season of calving, one type trait and the sire. Analysis was done one at a time for each of 30 type traits. The relative culling rate was calculated for animals in each class after accounting for the above-mentioned effects. Among the composite type traits with the greatest contribution to the likelihood function were final score, mammary system, fore udder, rear udder and dairy character, all having a strong relationship with functional survival. Cows with low scores (i.e., classified as Poor) for these traits had higher risk of culling ranging 2 to 5 times compared to higher scores (i.e., classified as Excellent). Linear type traits with the greatest contribution to the likelihood function were style, fore attachment, udder texture and udder depth. Rump angle and set of rear legs had no strong relationship with functional survival compared to other linear type traits.

Key Words: Functional Survival, Jersey, Type Trait

734 Potential of three-stage selection strategies for enhancing the efficiency of progeny testing programs in US dairy cattle. K. Weigel* and N. Zwald, *Department of Dairy Science, University of Wisconsin, Madison.*

The focus of dairy cattle improvement programs has evolved from single-trait selection for milk yield to multiple-trait selection for production, type, and various measures of health, fertility, longevity, and calving performance. In the US, national genetic evaluations for productive life (PL), somatic cell score (SCS), daughter calving ease (DCE), and daughter pregnancy rate (DPR) have all been implemented in the past decade. However, the reliabilities (REL) of predicted transmitting abilities (PTA) for these "functional" traits are low for many important bulls, because heritability parameters for these traits are =10% and because progeny groups for first-crop artificial insemination (AI) sires in the US typically contain only 60-80 daughters. This can lead to errors in selection of sires of sons. For example, 18 of the top 50 Holstein bulls for Lifetime Net Merit (LNM) in February 2002 ranked below the 80th percentile for LNM in February 2004, long before their sons had completed progeny testing. Our objective was to evaluate the potential for a "third stage" of selection among elite AI sires at 84-90 mo of age (in addition to pedigree selection at 0-6 mo of age and first-crop progeny selection at 48-54 mo of age) resulting from the distribution of additional semen for the top 50% of "sires in waiting" (based on updated parent averages) at 30-36 mo of age. Because service sire calving ease data are typically available

by 30 mo of age, this semen could be used safely on both milking cows and virgin heifers. Based on our analysis, it appears that additional semen collected from sires in waiting could replace sales of semen from the bottom 50% of actively marketed proven sires with no adverse effects on genetic progress. More importantly, distribution of additional semen from potential future sires of sons at 30-33 mo of age would provide REL = 80% for traits such as PL, SCS, DCE, and DPR and REL = 90% by the time AI stud managers make final semen collection decisions on their yearling sons.

Key Words: Progeny Testing, Functional Traits

735 Genetic base and trait definition update. P. M. VanRaden*, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Base changes provide an opportunity to revise trait definitions and to review genetic progress. Genetic bases were updated previously in the United States in 1965, 1974, 1984, 1989, 1995, and 2000, and the next is scheduled for February 2005. Interbull survey forms indicate that 18 of 25 countries plan to update their genetic bases for yield traits on this recommended 5-yr schedule; the other 7 countries update every year or at each evaluation. Countries may each define their own scales of expression and bases, but international marketing would be simpler with some uniformity and harmonization. For Interbull evaluations of udder health (UH), 9 of 19 countries currently reverse their scales so that lower somatic cell scores (SCS) result in higher evaluations. Six countries in northern Europe report relative breeding values with a mean of 100 but different multipliers (4, 5, 7, 10, or 12) of genetic standard deviation (SD). The four countries that report clinical mastitis evaluations all reverse their scales. The United States could report predicted transmitting abilities (PTA) for UH using the formula $PTA_{UH} = -5(PTA_{SCS} - \text{breed mean})$. This formula converts to the reversed, standardized PTA scale used by France and Spain with mean of 0 (instead of breed mean) and SD of 1. One unit of PTA UH would decrease somatic cell count by 13%. The range for PTA UH is similar to those for conformation, productive life, and daughter pregnancy rate PTA. If many traits are evaluated, sub-indexes may provide the public with fewer numbers that are easier to use. For most traits, genetic progress during the last 5 yr was similar to progress during the previous 5 yr. The genetic variance base was last updated in 1995. The SD of PTA for yield traits will increase by about 10% as a result. At the last base change, net merit units were revised from a per-lactation to lifetime-profit basis. Breed-association, USDA, and foreign selection indexes and genetic evaluations might be easier to use if further revised to obtain similar units, directions, and bases.

Key Words: Genetic Base, Udder Health, Scales

736 International evaluation of Milking Shorthorn-type dairy cattle for production traits. R. A. Barrett*¹, F. Miglior², J. Jamrozik¹, and G. Jansen¹, ¹*CGIL, Department of Animal & Poultry Science, University of Guelph, ON, Canada*, ²*Agriculture & Agri-Food Canada, Guelph, ON, Canada.*

Pedigree information and test-day records for the first three parities from Canada, Australia, New Zealand, the United Kingdom, and the United States were received and edited. Number of milk yield test-day records used for each country was 607,655 for Australia, 17,802 for Canada, 155,134 for the United Kingdom, 61,439 for New Zealand, and 176,498 for the United States. Single-country, single trait parameter estimation was done for each data set using a random regression test-day model using Gibbs sampling and Legendre polynomials of order four. Fixed effects in the model included herd-test day class and age at calving-parity-season of calving class. Average daily heritabilities in first lactation ranged between 0.332 and 0.474 for milk and between 0.370 and 0.445 for protein across the five countries. Correlations between lactations were higher for the United States and Canada for both milk and protein, with the more grazing-dependant countries having lower between lactation correlations. Common sires and daughters of common sires were identified, and these daughters were used to select a subset of herds for multiple-country, single trait parameter estimation. Variance component estimation of the multiple country data is underway using a random regression test day animal model using Gibbs sampling and Legendre polynomials of order 4.

Key Words: Dairy cattle, International evaluation, Milking Shorthorn

737 Accounting for differences in rate of maturity in yield evaluations. G. R. Wiggins* and P. M. VanRaden, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Genetic evaluations that include repeated records usually assume genetic merit is the same across all lactations. Repeatability models are simpler to set up and solve than models with separate genetic effects for each lactation, but may be less precise if animals differ in rate of maturity. Several countries now model the first three lactations as separate traits in published evaluations for yield traits. An alternative is to include a regression on maturity in traditional repeatability models. This allows data from five or even all lactations to be modeled by two genetic effects using single-trait rather than multi-trait programming. Maturity effects were scaled to measure the difference between first and second lactation yield, with smaller differences among later parities. The model was tested on US Jersey data of over 3 million lactation records. Maturity regression coefficients for lactations 1 to 5 were set to [-0.7 0.3 0.4 0.4 0.4] based on preliminary analysis. Parent averages calculated from calvings before 1999 were compared to February 2004 breeding values (BV) calculated from all records or from only first parity records. For bulls born since 1990 with reliabilities above 60% for the current evaluation, within birth year correlations were 0.01 to 0.02 higher for predicting first parity BV from a model with 8% of variance assigned to maturity effects than from a model without this effect. For most birth years after 1989, correlations were not higher for predicting the all parity BV from models with maturity effects as compared to the current repeatability model. A range of maturity variances from 2 to 16% was tested. If 8% of phenotypic variance was assigned to maturity effects, genetic correlations of first with second through fifth parity were assumed to be 0.89, 0.87, 0.87, and 0.87. Correlations among third through fifth were 1 and second with later were >0.99. This random regression approach accounts for genetic differences in rate of maturity with little computational expense, but most genetic parameters tested did not result in improved evaluations

Key Words: Parity, Random Regression, Maturity

738 Prediction of service sire fertility. M. T. Kuhn*¹, J. L. Hutchison¹, and J. S. Clay², ¹*Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD*, ²*Dairy Records Management Systems, Raleigh, NC.*

Estimated relative conception rates (ERCRs) are phenotypic predictions of service sire (SSR) fertility computed by Dairy Records Management Systems. ERCRs are based on first service 70-d non-return rate using a linear model that includes the fixed effects of herd-year-month of service, parity, days in milk at breeding, birth year of SSR, and energy-corrected milk yield and the random effects of animal (cow), permanent environment (PE) of the cow and SSR by herd interaction. The ERCR, then, is simply the SSR solution. This research investigated an alternative linear model using all services. The model included the fixed effects of herd-year-season of service, state-month of breeding, parity, and stud; the linear and quadratic effects of milk yield, days-in-milk at breeding, age of cow at breeding, age of SSR at breeding and the linear effects of expected future inbreeding of the daughters (EFI) and inbreeding coefficient of the SSR and also the random effects of animal (SSR), cow and PE of the SSR. A sire's predicted conception rate (CR) was calculated as the sum of his animal, PE, and stud solutions plus the regression on his age, his EFI, and his own inbreeding coefficient. Data for prediction was the result of breeding (0,1) for 530,380 Holstein cows calving between 1995 and 1997. For unconfirmed records, the last service was considered successful unless the cow was coded as sold for reproductive reasons. To assess accuracy of the predictor, mean CR in 1998 was calculated for each SSR and correlated with predicted CR. For bulls with at least 100, 500, and 1000 matings in the predictor, the correlation between predicted and actual CR in a future year was 0.16, 0.26, and 0.36, respectively. For bulls with breedings to at least 1000 cows, in contrast to just 1000 services, the correlation between predicted and future CR was 0.52. Further research will focus on other alternative models, appropriate data edits, and methods to handle the last service where pregnancy status is not known with certainty.

Key Words: Male Fertility

739 Estimation of the economic impact of a unit change in PTA for daughter pregnancy rate. E. Yook*¹, R. E. Pearson¹, and P. M. VanRaden², ¹Virginia Tech, Blacksburg, ²Animal Improvement Programs Laboratory, Animal Research Service, USDA, Beltsville, MD.

The economic impact of a unit change in PTA of daughter pregnancy rate (DPR) on lifetime profit estimates of a bulls daughters was estimated from DHI records for 71,094 cows to determine an economic weight for the PTAdpr in economic indexes. A cows relative net income (RNI) was calculated using all production initiated prior to her tenth birthday with milk-fat-protein pricing. The basic RNI function consisted of [total milk, fat, and protein income feed cost for production] (YI) + [net value of calves + net salvage value] (NYI) rearing cost (RC) [(daily cost for labor, maintenance feed, supplies, and fixed expenses)×days in herd] (DC). The basic RNI was augmented (ARNI) by adding the products of sire PTA for various traits and the net income for those traits proposed in the Net Merit calculation but not included in the basic RNI function; specifically, SCS(M), type composites (T), and DPR and daughter calving ease (PRCE). Regression analyses including herd and birth year in the model were used to estimate the simple and partial regressions of ARNI or partitioned ARNI on PTAdpr. Partial regression included all PTAs in Net Merit, except sire calving ease. Each 1% change in PTAdpr increased ARNI 23.64throughincreasingYIby90.44, NYI by 9.15, Mby5.26, T by 2.34, PRCEby4.51, and DC by 89.04anddecreasingRC0.98. Thus, ignoring other PTA left a substantial positive impact of PTAdpr. Correspondingly, changing PTAdpr by 1% barely broke even when other PTA were held constant because the loss in YI was greater than the savings in daily cost.

Regression coefficients (β) for y on PTAdpr

	Response (y)							
	ARNI	YI	NYI	RC	DC	M	T	PRCE
Simple	23.64	90.44	9.15	0.98	-89.04	5.26	2.34	4.51
Partial	1.81	-51.11	2.00	1.59	46.46	0.00	0.00	2.88

740 Genetic parameters for days open and pregnancy rate in US Holsteins. S. Oseni, I. Misztal*, S. Tsuruta, and R. Rekaya, *The University of Georgia, Athens.*

The influence of different editing of days open (DO) records on genetic parameters of DO and pregnancy rates (PR) in US Holsteins was investigated. Data included first parity 305-d milk yields and DO records in eight states: GA, FL, NC, TX, AZ, CA, NY, and WI. Pregnancy rates was computed as $1/[(DOX)/HI+1]$, where X was the approximate voluntary waiting period, and HI was the heat interval set to 21 d. Upper limit for PR was set to 1.0. A bivariate animal model with DO (or PR) and 305-d milk yield as dependent variables was fit separately for each state. The model included fixed effects of herd-year, month of calving and age of cow, and random animal and residual effects. In separate analyses, large DO records were limited to 150, 250 and 365 d. Additionally, analyses for PR used values of 50, 80 and 120 d for X. PR assigns more weight to small DO records, and larger heritability for PR indicates larger contributions of such records. Large changes in heritability when an interval was limited indicated genetic variability within that interval. Genetic and residual variances for DO were strongly dependent on the upper limit, with residual variances changing up to 10 times. Estimates of heritability for DO varied between 3 and 6%. Increase of heritability with the upper limit changing from 150 to 250 d was over 30% for FL and NC, and smaller to flat for the other states. The increase from 250 to 365 caused small changes. The genetic correlation between milk and DO was the highest for FL (0.6) and the smallest for GA (0.1 - 0.2). For PR with X=50, the heritability was higher than for DO for GA, equal for AZ, and smaller for the remaining

states. For most states, highest heritabilities for PR were obtained at X = 80 (NY, TX, WI) or X=120 (CA, FL, NC). Records of DO > 250 d carry little genetic information whereas records < 120 d carry more or less information depending on management. Days open and PR are strongly influenced by differences in management between states.

Key Words: Days Open, Pregnancy Rate, Genetic Parameters

741 Genetic relationships of milk yield for different parities between bulls and their sons. H. D. Norman*, R. L. Powell, J. R. Wright, and P. M. VanRaden, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

This research examined how bulls differ in rate of maturity of their daughters. The 305-d milk records for Holsteins with first parity calving dates between 1960 and 1998 were used to calculate three predicted transmitting abilities (PTA) for each bull. The first genetic evaluations included only first lactations on daughters and contemporaries (PTA₁). The second and third sets included the first two and three lactations available, PTA₁₋₂ and PTA₁₋₃, respectively. The contribution from individual parities, two (PTA₂) and three (PTA₃), were approximated using a weighted average of the (single trait) evaluations, PTA₁, PTA₁₋₂, and PTA₁₋₃. Weights were based on number of daughters with a second (or third) lactation. Bulls (2864) with ≥500 daughters ranged from +295 to -290 kg in difference between PTA₁₋₃ and PTA₁, with a SD of 85 kg. In contrast, when the same bulls were ranked on the differences between their contribution to separate parities, they ranged from +555 to -610 kg, for PTA₃ - PTA₁ with a SD of 179 kg. To determine if these difference were transmitted, comparisons were made across a generation. For 16,643 sons with ≥40 daughters, expected regressions of son PTA on sire PTA calculated within sire and son birth years (YOB) was 0.44. Actual regressions for PTA₁, PTA₁₋₂, PTA₁₋₃, PTA₁₋₂ - PTA₁, PTA₁₋₃ - PTA₁, and PTA₁₋₃ - PTA₁₋₂ were 0.44, 0.43, 0.43, 0.43, 0.43, and 0.42, most with standard errors (SE) = 0.01. Regressions were also derived on the bulls' specific contribution to second and third parities. Actual regression calculated within YOB for PTA₂, PTA₃, PTA₂ - PTA₁, PTA₃ - PTA₁, and PTA₃ - PTA₂ were 0.42, 0.44, 0.44, 0.45, and 0.43, most with SE = 0.01. These results suggest that differences observed in high reliability bulls as their daughters mature is transmitted to their sons daughters. Modeling separate PTAs for each parity should increase accuracy of, and reduce unnecessary oscillation in, genetic evaluations when number of records per daughter changes.

742 Effects of udder traits on milk flow and their associations with temperament of first lactation dairy cows during milking time. B. rekik*, A. Ben gara, R. Bouraoui, and K. kouki, *ESA Mateur, Tunisia.*

The effects of the main udder traits of 120 first lactating Holstein-Friesian cows on milk flow were studied around the lactation peak using linear regression. Associations of these traits with temperament of cows during milking time were detected using logistic regression. Most of cows had an overall satisfactory mammary system. The main conformation traits of the udder were interrelated. Pearson correlation coefficients ranged from -0.59 (udder cleft with teat placement) to 0.30 (height with width of rear attachment). Mean milk flow was 22.50gr/s with a minimum of 9.14gr/s and a maximum of 36.81gr/s. This rate of yield production was found to vary with udder balance (P<0.05), rear udder width (P<0.01), side teat distance (P<0.05), and udder cleft (P<0.05). Milk was better extracted when udder traits tended towards optimal scores. The odds of an easy milking were four and five times greater than those of a difficult milking when teats are neither too long nor too short (P<0.05) and udder is balanced (P<0.01), respectively. Cows are more likely to get anxious at milking when their udders are not balanced and their teats are shorter or longer than an optimal length.

744 Detection of quantitative trait loci affecting conformation traits in Holstein cattle. M. S. Ashwell^{1,3}, D. W. Heyen², T. S. Sonstegard³, C. P. Van Tassell³, and H. A. Lewin², ¹North Carolina State University, Raleigh ²University of Illinois, Urbana ³USDA-ARS, Beltsville.

Putative quantitative trait loci (QTL) affecting conformation traits in Holsteins have been detected using genotypic data generated by two research groups. Each research group conducted an independent genome scan in a select group of Holstein grandsire families. Six families were used by both groups and genotyped for 367 microsatellite markers in order to identify QTL affecting milk production and health traits. The same merged dataset has now been reanalyzed to identify putative QTL affecting conformation traits. Seventeen linear traits and four composite index traits were included in the analysis. The phenotypes were obtained from the Holstein Association USA (<http://www.holsteinusa.com>) and included standardized transmitting abilities for body type, feet and legs, and udder traits. Data were analyzed using QTL Express (<http://qtl.cap.ed.ac.uk>), a web-based regression interval mapping method. Preliminary analysis had identified 34 putative QTL affecting the conformation traits within the grandsire families. These QTL were significant at the chromosome-wise level (F -statistic > 15) and were located on 15 bovine autosomes. Additional analysis is underway to determine which of these QTL, if any, are significant at the genome-wise level.

745 Statistical power for detecting epistasis QTL effects under the F2 design. Y. Mao* and Y. Da, *Department of Animal Science, University of Minnesota, St. Paul.*

Epistasis refers to gene interaction effect involving two or more genes. Statistical methods for mapping quantitative trait loci (QTL) with epistasis effects have become available recently. However, little is known about the statistical power and sample size requirements for mapping epistatic QTL using genetic markers. In this study, we developed analytical formulae to calculate the statistical power and sample requirement for detecting each epistasis effect. The genetic modeling of QTL genotypic values and variance used the linear partition of Kempthorne (1954), and Bulmers presentation of this linear partition (1980) was used for efficient derivation of variances and covariances. To achieve succinct mathematical expressions and intuitive interpretations, epistasis heritability is defined to denote the ratio of the epistasis variance to the phenotypic variance. Assuming two interactive QTL without linkage and all epistasis effects have the same absolute value, the heritability of additive x additive (a x a) effect is about twice as large as that of additive x dominance (a x d) or dominance x additive (d x a) effect, and is about four times as large as that of dominance x dominance (d x d) effect. Consequently, among the four types of epistasis effects involving two loci, a x a effect is the easiest to detect whereas d x d effect is the most difficult to detect. The statistical power for detecting a x a effect is similar to that for detecting dominance effect of a single QTL. The power is poor for detecting a x d or d x a effect and is extremely poor for detecting d x d effect. The sample size requirements for detecting a x d, d x a and d x d are highly sensitive to increased distances between the markers and the interacting QTLs. Therefore, using dense marker coverage is critical to detecting those effects.

746 Including genetic groups for QTL effects in marker assisted selection. K. J. Hanford¹, R. M. Thallman², S. D. Kachman³, and L. D. Van Vleck¹, ¹USDA-ARS, Roman L. Hruska U.S. Meat Animal Research Center, University of Nebraska, Lincoln, ²USDA-ARS, Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, NE, ³Department of Statistics, University of Nebraska, Lincoln.

Genetic group effects provide a means of accounting for the effect of selection that cannot be accounted for by records of relatives. In a polygenic animal model, genetic group effects are incorporated into the

mixed model equations (MME) by adding one equation for each genetic group corresponding to foundation (phantom) animals. With minor modifications the rules for the inverse of the relationship matrix without genetic groups can be used to obtain the inverse of the coefficient matrix after absorption of the equations for the phantom animals needed for solving the MME. With identification of quantitative trait loci (QTL), information from closely linked genetic markers can be included in prediction of breeding values with mixed model equations to implement marker assisted selection (MAS), where effects of QTL alleles are considered random. As with the polygenic animal model, the distribution of the QTL alleles can be different within different subpopulations. Genetic group effects for the QTL may also arise from QTL effects that depend on the genetic background of the different subpopulations. Current methods for MAS with solutions from mixed model equations do not allow for incorporating genetic group effects for QTL. An extension has been developed which allows genetic group effects to be incorporated in the MME to obtain genetic evaluations for MAS by augmenting the MME by the number of genetic groups used in models without marker information. Rules for constructing the inverse of the QTL coefficient matrix after absorption of the equations for the phantom animals and augmenting the MME with this matrix have been derived and will be presented.

747 Computational analysis of putative imprinting signatures of bovine IGF-II and IGF-II receptor genes. I. G. Imumorin¹, J.J. Kim², O. O. Mgbere³, and D. O. Umehiobi⁴, ¹Valdosta State University, Valdosta, GA, ²Iowa State University, Ames, ³Rivers State University of Science & Technology, Port Harcourt, Nigeria, ⁴University of Natal, Pietermaritzburg, South Africa.

The IGF-II gene and its receptor (IGF-IIR) are members of the insulin family of polypeptide growth factors and also represent two of the earliest imprinted genes identified in mice and later in humans. The IGF-II gene has been shown to be paternally expressed in sheep and pig, but yet to be tested experimentally for genomic imprinting in cattle, whereas maternal expression of IGF-IIR has been reported in a single uncorroborated study in cattle. We conducted preliminary computational analysis of five concatenated cDNA sequences of bovine IGF-II and a full length cDNA sequence of bovine IGF-IIR downloaded from GenBank to gain some insight into putative imprinting signatures of both genes. A total of 2,451 nucleotides of the IGF-II gene and 9,061 nucleotides of IGF-IIR were analyzed. These cDNA sequences were searched for motifs that may be common with genomic sequences of human and mouse IGF-II and IGF-IIR genes using MEME analysis and the motif weight matrix outputs from MEME analyses were subjected to analysis by the MAST program. The MAST analysis identified highest scoring motif sequences of 200 bases for IGF-II and 166 bases for IGF-IIR, which were analyzed by EMBOSS-CpG Plot program respectively. IGF-II contained a 61-base CpG island, with a GC content of 67% and an observed/expected CpG ratio of 0.78. No CpG island in the IGF-IIR motif sequence was identified. This might indicate a differentially methylated region (DMR) in the bovine IGF-II promoter, which is a common signature of imprinted genes. However, a more accurate and robust analysis of these genes awaits the full bovine genomic sequences for comparison with conserved non-coding but regulatory sequences of the mouse and human orthologs of IGF-II and IGF-IIR genes, which in turn require experimental validation of imprinting status.

748 Evaluation of microsatellite markers on bovine chromosomes 1 and 5 for potential allelic associations with meat characteristics and growth traits in beef cattle. K. S. Kim¹, S. Costello², G. J. M. Rosa¹, A. M. Mullen², N. E. Raney¹, and C. W. Ernst¹, ¹Michigan State University, East Lansing, ²National Food Centre, Dublin, Ireland.

Association between molecular marker and phenotypic data is an important tool to expedite genetic improvement of livestock species. Several bovine chromosomal regions (QTL) have been reported to have significant associations with growth and performance traits in cattle. In this study, potential effects of previously identified QTL regions on growth

and beef quality traits were investigated in commercial beef cattle populations. Eight microsatellite markers spanning QTL regions on bovine chromosomes (BTA) 1 and 5 were genotyped in beef cattle populations from Michigan and the Republic of Ireland. Haplotypes of these markers were constructed using the PHAGE program (www.gmap.net). Analyses of allelic associations with phenotypes were performed with chi-square tests to compare allelic frequencies between groups with high and low phenotypic values. Initial analyses have been performed with the Michigan (n=85) and Irish (n=75) data sets. In the Michigan data, the BTA1 markers exhibiting significant allelic frequency differences were BM1312 for slaughter weight ($P < 0.06$), BMS6506 for birth weight ($P < 0.06$), and BMS4048 for hot carcass weight ($P < 0.05$). Significant associations of these markers with meat quality traits from the Irish cattle were also found with BM1312 for firmness ($P < 0.003$), BMS4001 for flavor ($P < 0.005$) and texture ($P < 0.05$), and BMS4048 for pH ($P < 0.05$). A haplotype of BM1312-BMS4001 markers also revealed a significant allelic difference for firmness ($P < 0.01$) and texture ($P < 0.05$) traits. Significant differences in allelic frequency from BTA5 markers were found with BL4 for flavor ($P < 0.05$), and ETH10 for intramuscular fat % ($P < 0.05$). Our results suggest that QTL reported on BTA 1 and 5 may be segregating in commercial beef cattle populations and their effects may extend to economically important meat quality traits. Thus, further study is warranted to define beneficial haplotypes for potential use in marker assisted selection to improve these traits in beef cattle.

749 A combined line-cross and half-sib model to detect and characterize QTL in an F2 outbred cross population. J.-J. Kim* and J. C. M. Dekkers, *Iowa State University, Ames.*

Data from an F2 outbred cross is typically analyzed by a least squares line-cross (LC) model to detect QTL that differ between breeds. Alternatively, data can be analyzed by a half-sib (HS) model for F1 sires to allow for QTL segregating within breeds. The LC and HS models can also be combined (CB model). Objectives of this study were to evaluate the power to detect QTL and to characterize QTL into LC, HS, or CB QTL, i.e. QTL that are fixed, segregating at similar or different frequencies in the parental breeds, using model lack-of-fit tests. Phenotypic and marker data for a 100 cM chromosome with 11 equidistant markers were simulated on 512 F2 progeny for two mating designs: I (II): 2 (20) F0 sires, 10 (80) F0 dams, 8 (19) F1 sires. A biallelic QTL was simulated at 75 cM with additive values of 0.8, 0.5 or 0.32 phenotypic SD. A total of 6000 replicates were generated with the actual difference in QTL allele frequencies (FD) between the alternate F0 parents ranging from 0 to 1. Significance thresholds were from 3000 simulations without QTL. The LC model was most powerful for any size fixed QTL (FD=1) in both designs, followed by the CB model. For FD =0.5, the CB model was more powerful than the HS and LC models (99, 97 and 97% for the large QTL for CB, HS, LC; 84, 76 and 68% for the medium QTL; 44, 40 and 35% for the small QTL, in design I). For FD=0, the HS model had more power than the CB and LC models (74, 70 and 10% for the medium QTL for HS, CB, LC; 30, 22 and 7% for the small QTL in design I). For FD=1, most detected QTL were defined as LC QTL in both designs. This proportion decreased with FD. The opposite was observed for HS QTL. The proportion CB QTL among detected QTL was greatest for FD=0.5 and decreased as FD moved away from 0.5. The latter was more pronounced for the large than the small QTL, for which the proportion of CB QTL was nearly constant across FD. Our results show that the CB model can increase power to detect QTL and enables characterization of QTL detected in F2 crosses that segregate within breeds.

750 Identification of an ovulation rate QTL in cattle on BTA14 using selective DNA pooling and interval mapping. M. G. Gonda*¹, J. A. Arias², G. E. Shook¹, and B. W. Kirkpatrick², ¹*Dairy Science Department, University of Wisconsin-Madison*, ²*Animal Sciences Department, University of Wisconsin-Madison.*

Increased twinning incidence in beef cattle has the potential to improve production efficiency. However, phenotypic selection for twinning rate is difficult because of the traits low heritability and the long time interval necessary to collect phenotypic records. Therefore this trait and

the correlated trait of ovulation rate are ideal candidates for marker-assisted selection. The objective of this study was to identify ovulation rate quantitative trait loci (QTL) in two related sire families. The families (paternal half-sib sires 839802 and 839803) were from a population of cattle selected for ovulation rate at the USDA Meat Animal Research Center, Clay Center, Nebraska. Putative ovulation rate quantitative trait loci have previously been identified in the 839802 family on chromosomes 7 and 19; however, marker coverage in the original scan was not complete. This study fills the gaps in marker coverage of the earlier study by adding approximately 60 informative microsatellites to each sire family. Each family was genotyped using selective DNA pooling. Sons and daughters were included in either the high or low pool based on their estimated breeding value deviations from the midparent average (EBVMD) for ovulation rate. Approximately 40% (839802) and 26% (839803) of available progeny comprised the high and low pools combined. Pooled typing revealed possible associations (nominal $P < 0.05$) between ovulation rate and marker genotype for eleven and fifteen microsatellites in the 839802 and 839803 families, respectively. Subsequent interval mapping provided additional support for the presence of an ovulation rate quantitative trait locus on BTA 14 (chromosome-wise $P < 0.02$).

Key Words: Ovulation Rate, Quantitative Trait Locus, Selective DNA Pooling

751 Power and sample size calculations for two color microarray experiments with biological and technical replication. J. P. Steibel*¹, R. J. Tempelman¹, and G. J. M. Rosa^{1,2}, ¹*Department of Animal Science, Michigan State University, East Lansing*, ²*Department of Fisheries and Wildlife, Michigan State University, East Lansing.*

Very recent work on sample size and power calculations for microarray experiments have simply considered arrays or spots as the experimental units. Nevertheless, biological replicates should be considered to be the fundamental experimental units when broad inferences are of interest. In other words, dye-swap arrays on the same two samples and or multiple spots per gene on a slide should be treated as subsamples. We address sample size calculation and analysis of microarray experiments using linear mixed effects models, with special attention directed towards the distinction between biological replication and technical replication within a broad inference context. Three experimental designs were considered: 1) the Loop design, 2) the Dye swap design, 3) and the Reference design. Power was determined for three levels of differential expression (1.25, 1.5 and 2.0 fold-change), and for several different levels of biological replication ($n = 2, 10$) and technical replication ($r = 1, 4$) based on five different sets of variance components. Results for the loop and the dye swap experiments were virtually identical with slight differences depending on, whether or not Satterthwaites approximation to degrees of freedom was used. The reference design, however, provided the lowest power of test in almost all situations, particularly when the residual variance was large. Increasing technical replication yielded very marginal improvements in power except in situation with high residual variance. Our power analysis indicates that in situations of relatively high biological variability, as many as 40 individuals per treatment are necessary to have at least an 80% probability of concluding differential expression on a gene with 1.25 fold change. This result is particularly relevant for experiments involving livestock species, in which the biological variance (animal-to-animal variability) is generally considerably larger than the technical variance (variability among arrays and among spots). In this situation, the only meaningful way to improve experimental power is by increasing the number of animals in the trial.

Key Words: Microarray, Power Analysis, Biological Replication

752 A new method to fine map a quantitative trait locus using linkage disequilibrium. H. Gilbert*^{1,2}, M. Z. Firat², L. R. Totir², J. C. M. Dekkers², and R. L. Fernando², ¹*Institut National de la Recherche Agronomique, Cedex, France*, ²*Animal Science, Iowa State University, Ames.*

A new approach was developed to fine map a biallelic QTL using linkage disequilibrium (LD). It uses the probability that a maternal (paternal) QTL allele of each individual is the mutant QTL allele, conditional on the pedigree and marker information. These probabilities were derived recursively from the haplotype-specific mutant QTL allele frequencies in the founders. As the haplotypes of founders are not known, their

probabilities were estimated by MCMC methods. This model has fewer parameters than the usual model, because it relates the means and covariances of the QTL gametic values to the QTL allele effect and their frequencies. Consequently, this approach is expected to be more accurate. To overcome the computing difficulties in exact calculation of IBD probabilities, an MCMC method was used to derive approximate conditional probabilities of inheriting maternal and paternal QTL alleles. A residual maximum likelihood method (REML) was implemented to map the QTL, using a Newton-Raphson algorithm. The QTL position, QTL effect, haplotype-specific mutant QTL allele frequencies and polygenic and residual variance components were jointly estimated for each interval. The derivatives of the residual likelihood were obtained by automated differentiation. A simulated population was analyzed to compare the ability of this technique to fine map a QTL with two others methods. In the first method, identity by descent QTL covariances are used to model LD and cosegregation of the alleles at linked loci. In the second, identity by descent QTL covariances are used only to model the cosegregation of the alleles, and LD is modeled by including the marker haplotypes as fixed effects in the model. LD was simulated by introducing a mutation at the QTL followed by 100 generations of random mating. Different genetic designs were simulated, under linkage and linkage disequilibrium and with various QTL effects, to obtain power and accuracy of the parameter estimates.

Key Words: QTL, Linkage Disequilibrium, Simulation

753 Assessment of respiratory chain complex activities and electron transport chain protein expression in muscle mitochondria in Angus steers with low and high feed efficiency. B. A. Sandelin^{*1}, A. H. Brown Jr¹, C. Ojano-Dirain¹, M. Iqbal¹, M. A. Brown², W. O. Herring³, M. Akin⁴, Z. B. Johnson¹, and R. T. Baublits¹, ¹University of Arkansas, Fayetteville, ²USDA-ARS Grazinglands Research Laboratory, El Reno, OK, ³Smithfield Premium Genetics Group, Roanoke Rapids, NC, ⁴Circle A Angus Ranch, Iberia, MO.

The objectives of this study were to determine the relationships between feed efficiency (FE, gain/feed) and respiratory chain complex activity and mitochondrial protein expression in cattle. Feed efficiency was determined on 92 head of contemporary Angus steers fed over a 130 d period. Individual animal intake was measured by a Calan Broad-bent Feeding system. Animals were fed five finishing rations (stepwise) throughout the feeding period. Animals were harvested at a commercial packing plant and muscle (Sternohyoideus) samples were obtained from steers with Low (0.154 ± 0.02 , $n=7$, L) and High (0.252 ± 0.02 , $n=7$, H) FE. Muscle homogenate and mitochondria were isolated using differential centrifugation. Activities of respiratory chain complexes were measured using spectrophotometric methods. The protein bands were separated in 10% SDS-PAGE, stained with Coomassie blue and intensities were quantified using Scion software. Mitochondrial protein expressions were assessed with Western blot analysis with a chemiluminescence detection system. Activities of respiratory chain Complexes (I and II) were higher ($P < 0.02$) in L compared to H steers. While the expression of four immunoreactive mitochondrial proteins, NAD4 (Complex I), core I (Complex II), Cox II (Complex IV), ANT1 (ADP/ATP channels), were higher ($P < 0.05$) in N compared to L steers, there were no differences in the expression of several other proteins. SDS-PAGE revealed that the intensities of seven protein bands were higher in H compared to L steers. It appears that differences in complex activities and protein expressions may be involved in the phenotypic expression of feed efficiency in cattle.

Key Words: Feed Efficiency, Angus, Muscle Mitochondria

754 Samples classification using microarray data: Dealing with potential diagnostics misclassification. R. Rekaya^{*}, Department of Animal and Dairy Science, University of Georgia, Athens.

While microarray was successfully applied in gene expression profiling of tissues/cells, and methods for selecting a subset of discriminative genes

for samples classification have been proposed, the robustness of those procedures to potential misclassification was never investigated. For complex and heterogeneous responses such as disease traits, several subclasses with varying phenotypes exist. Using typical diagnostics tools, different types of a specific disease/trait can be difficult to tell apart. As a result, such similarity can lead to misdiagnosis. It is recognized that an accurate diagnostic is crucial for a successful use of gene profiling as a classification tool. Unfortunately, the accurate assignment of a subject to a specific disease/trait type is a difficult and expensive process. Although, the results obtained using microarray seem to indicate a more accurate prediction, the problem of misclassification is not yet resolved. This type of ambiguity is not rare, and it is either too difficult to detect, or economically unfeasible. In gene expression experiments involving animals, and even human, the present cost of the technology precludes extensive testing. In this study, a method for dealing with this problem or at least to attenuate its effects using a statistical model capable of accounting for potential misclassification was implemented. A simulation was conducted where 30 arrays with 10,000 genes each were generated. In the first case, a binary response was assumed. In the second case, a multinomial response with 5 classes was assumed. In both cases, the status for every sample was assigned as a function of the gene expression intensities in each array. Artificially, some samples status was changed randomly to introduce a misclassification rate of 5% and 10%. When the miscoded data was analyzed without consideration of misclassification, a change of 20-35% of discriminative genes was observed depending on the type of trait and the percentages of miscoding. When the miscoded data was analyzed with a model that contemplated misclassification, the change in the set of discriminative genes ranged from 2-8% depending primarily on the miscoding rate.

Key Words: Microarray, Misclassification, Gene Expression

755 Statistical methods to detect imprinted QTL with gender-specific recombination frequencies. Nicole R. London^{*} and Yang Da, Department of Animal Science, University of Minnesota, St. Paul.

Imprinting is characterized by differential expression of alleles due a parent-of-origin effect. In this study, we developed statistical methods to detect and map imprinted quantitative trait loci (QTL) accounting for gender-specific recombination frequencies under the F2 and reciprocal backcross (RBC) designs. Multi-allelic markers were assumed for both designs. Under the F2 design with gender-specific recombination frequencies, additive and imprinting effects are confounded using currently available contrasts for testing additive and imprinting effects. Alternative contrasts were developed to independently estimate these effects. These contrasts are functions of gender-specific recombination frequencies, and reduce to the currently available contrasts when the two genders have equal recombination frequency. The RBC design requires a reciprocal mating system in terms of parental gender to detect imprinting effect. Contrasts for use with the RBC design were developed to independently test for additive and imprinting effects. These models were used to analyze a simulated population of animals. Monte Carlo simulation studies were conducted to evaluate the theoretical results on statistical power for detecting additive, dominance, and imprinting effects under the F2 and RBC designs. Marker and QTL genotypes were generated such that the true recombination frequency and each QTL effect used to generate these genotypes could be obtained reversely from the data. The analysis of the data showed the methods are accurate and computationally feasible to use with large data sets. Statistical powers observed from the simulated data agreed well with predicted powers. The power depends on the effect size, heritability of the trait, and the marker QTL recombination frequency. An F2 design has higher power than a RBC design to detect imprinting effects. The sample size necessary to detect imprinting effects is similar to the requirements to detect additive effects.

Key Words: Imprinting, QTL, Recombination frequency

756 Comparison of viscosity and stability of bovine fluid and evaporated milks with those of caprine milk counterparts stored under refrigeration. C. O. Maduko*¹, R. Shewfelt¹, R. Toledo¹, J. Frank¹, Y.-W. Huang¹, and Y. W. Park², ¹Department of Food Science and Technology, University of Georgia, Athens, ²Agricultural Research Station, Fort Valley State University, Fort Valley, GA.

Heat coagulation of milk results from a complex series of physico-chemical reactions that eventually lead to precipitation or gelation. Viscosity of milk tends to increase upon heating as it approaches the point of coagulation of the proteins, which is the basis for producing high viscosity in super-heated condensed milk. Although viscous property may have been studied extensively in cow fluid milk, relatively little information is available on viscosities of concentrated milks and comparison of those of different species milks. Commercial cow and goat fluid milks and their evaporated products were purchased from retail outlets to study characteristics of viscosity and physico-chemical stability of bovine milks compared to caprine counterparts stored at 4 and 13°C refrigeration for 4 weeks. The respective initial viscosity values for bovine fluid (BF), evaporated (BE), and caprine fluid (CF), evaporated (CE) milks were: 1.54, 1.55, and 1.72, 2.03 centipoises, indicating that goat milk products had higher viscosity values than cow counterparts. The viscosity of BF was gradually increased until day 12 at 4°C, and the increase continued to day 28 during which gelation occurred. The BE was stable till day 28 at 4°C storage and did not undergo gelation during this period. The viscosity of CF increased slightly under refrigeration until day 7, then decreased gradually to the lowest at day 11. A sharp increase in viscosity occurred from day 12, and continued to day 28 of storage, during which gelation of the CF milk occurred. However, CE did not show a noticeable decrease on day 9 and remained physically stable until day 28 of storage without any gelation. The refrigeration temperatures had minimal effect on the viscosities of the tested milks. The evaporated milks had greater physical stability under refrigerated storage relative to fluid milks. This may be attributable to the fact that heat treated milk products are actually electrodialysed before evaporation, whereby the partial removal of soluble salts by dialyzing milk against water increases the heat stability when the milk is subsequently concentrated.

Key Words: Viscosity, Bovine and Caprine Milk, Refrigerated Storage

757 Immunostimulatory activities of a novel AT oligonucleotide from “Immunobiotic” *Lactobacillus gasseri* on swine Peyer’s patch cells. H. Kitazawa*, T. Shimosato, S. Katoh, M. Tohno, Y. Kawai, and T. Saito, *Graduate School of Agricultural Science, Tohoku University, Sendai, Japan.*

Many works in the biological functions of dairy lactic acid bacteria (LAB) have contributed to the application of LAB as functional foods and supplements in the worldwide market. More recently, the new term “immunobiotics”, identifying probiotic bacteria that promote health through activation of the intestinal immunity compared to those with strictly local immunity, has been proposed and expected for an appropriate evolutionary development. We have studied specific effector molecules and their receptor targets. Recently, we have found that immunostimulatory AT oligonucleotide (ODN), but not CpG ODN, from *Lactobacillus gasseri* JCM1131^T triggered B cell mitogenic responses in mice. This finding suggests the possibility that the AT ODN could activate the immune responses in peyer’s patches, which belong to a gut associated lymphoid tissue. The present study was conducted to elucidate the immunostimulatory ability of AT ODN in swine peyer’s patches as a human model. The AT ODN significantly augmented the mitogenic activity of swine peyer’s patch cells, when they were stimulated at 10 μ M of ODN, as well as D25, which is known to be an optimal active CpG ODN for swine. The AT ODN strongly induced IL-6, 12p40 and IFN γ gene expressions in swine peyer’s patch cells. Preferential expression of Toll like receptor 9 (TLR9), which is a receptor for unmethylated CpG ODN, was detected in peyer’s patches by the real-time quantitative PCR and immunohistochemical analysis. These findings suggest a possibility that the AT ODN could regulate Th1/Th2 responses in the gut via TLR9 signaling as well as CpG ODN, which is expected play an important role in the prevention of infectious and allergic diseases. This study demonstrated that *Lactobacillus gasseri* JCM1131^T was a good

candidate for the production of new functional foods, “Immunobiotic Foods”.

Key Words: Immunobiotics, DNA, *L. gasseri*

758 AT oligonucleotide from “Immunobiotic” *Lactobacillus gasseri* augments immune responses via Toll-like receptor 9 signaling. T. Shimosato*, H. Kitazawa, M. Tohno, S. Katoh, Y. Kawai, and T. Saito, *Graduate School of Agricultural Science, Sendai, Japan.*

Toll-like receptor (TLR) 9 has been identified as a particular receptor for bacterial DNA that contains a specific sequence pattern, unmethylated CpG dinucleotide. From the discovery of TLR9, possible molecular mechanisms in immune responses through bacterial DNA have been rapidly revealed in mice. Recently, we have found the possibility that AT oligonucleotide (ODN), which was a non-CpG ODN from *Lactobacillus gasseri*, induced immunoactivation in peyers patches (Pps) via TLR9. In the present study, to elucidate the role of TLR9 with AT ODN in the intestinal immunity, we performed the following studies. First, we isolated a cDNA encoding a TLR9 from swine Pps, which are considered to be useful for human models. The total RNA was isolated from the Pps of adult swine intestine. The complete open reading frame of sTLR9 contains 3090bp coding and deduced 1029 amino acid residues with a calculated molecular mass of 115.7kDa. Next, we constructed a transfectant of swine TLR9 with mammalian cells for the development of an immunoassay against ODN. We demonstrated that the transfectant recognizing not only CpG but also non-CpG AT ODN from Lactic acid bacteria (LAB) resulted in the induction of NF- κ B activation by gene reporter assay. Furthermore, TLR9 was strongly detected in the follicle-associated epithelium including M cells as well as antigen presenting cells such as dendritic cells in Pps. These findings indicate that the TLR9 positive cells in Pps provide the host defense with the ability to respond to a variety of ODN from the Immunobiotic LAB. This study firstly shows that TLR9 is a receptor for not only CpG but also for non-CpG AT ODN and may help in understanding the intestinal immunoregulation mediated by Immunobiotic LAB DNA through TLR9 for a development of Immunobiotic Foods.

Key Words: TLR9, Swine, Oligonucleotide

759 Extending shelf life of skim milk with micro-filtration. M. W. Elwell* and D. M. Barbano, *Northeast Dairy Foods Research Center, Department of Food Science, Cornell University, Ithaca, NY.*

The objective of the research was to determine the efficacy of a micro-filtration and pasteurization process in extending the shelf life of skim milk. Raw skim milk (ca. 273 kg) from the Cornell University dairy plant was microfiltered at 50°C using a Tetra Alcross M7 Pilot Plant equipped with a ceramic Membralox membrane (pore diameter: 1.4 μ) and collected directly into a sterile container. Approximately 95 percent of the milk was collected as permeate. The collection container was connected directly to a shell and tube pasteurization system. The 50°C permeate was pasteurized at 72°C for 15 s, and collected directly into another sterile container. The experiment was replicated 3 times. Bacteria counts of raw skim were done by standard plate count. Bacteria counts of microfiltered and pasteurized microfiltered milk were determined using a most probable number (MPN) method. For the MPN method, five containers each with 1, 10, 100 and 500 mL of milk were incubated at 32°C for 6 days. Growth or no growth in each container was determined using a Foss BactoScanTM FC. The MPN bacteria count was calculated using a spreadsheet developed by FDA/CFSAN. Bacteria count of the raw milk was reduced from 2400, 3600, and 1475 cfu/mL to 0.2398, 0.9178, and 0.2398 cfu/mL, respectively, by microfiltration. Bacterial counts in the pasteurized microfiltered skim milk for the three trials were 0.0046, 0.0078, and 0.0045 cfu/mL respectively, demonstrating an average 5.6 log reduction from the raw count due to the combination of microfiltration plus pasteurization. The pasteurized microfiltered skim milk was pumped directly from the sterile collection container into 1L sterile sample containers for shelf life tests. Two sample containers were

incubated at each of four temperatures (0, 2, 4, and 6°C) and the total bacteria count was determined weekly until the count reached 10⁶ cfu/mL.

Key Words: Microfiltration, Shelf Life, Pasteurization

760 Descriptive analysis of processed cheese manufactured by extrusion technology. A. C. Cole*¹, K. A. Adhikari², I. U. Gruen¹, and H. Heymann³, ¹University of Missouri, Columbia, ²California State Polytechnic University, Pomona, ³University of California, Davis.

The use of extrusion technology to manufacture processed cheese has rarely been utilized in the US dairy industry. Extrusion technology ought to be explored for the continuous manufacture of processed cheeses, which might result in greater uniformity of the product as well as use in unique applications that are not feasible with current technology. The objective of this study was to determine and compare the physical and sensory characteristics of extruded processed cheese to those of a conventional processed cheese. Processed cheese was manufactured by blending one month, three month, and six month old Cheddar cheeses in the ratio 1:2:1, respectively. A twin screw co-rotating extruder was used to manufacture the experimental cheeses at two temperatures (80 and 90°C), two moisture levels (44 and 48%) and two melting salt levels (1 and 1.5%). Velveeta was used as the control. In total, nine processed cheese samples were tested. Descriptive sensory analysis was performed to identify the sensory characteristics of the processed cheeses by a panel of nine trained judges. Texture profile analysis (TPA) was performed to determine the physical characteristics of the cheese samples. Canonical variate analysis (CVA) was done to find differences among the processed cheeses using SAS, and partial least square (PLS2) regression was done to correlate the sensory data to the physical data. The CVA biplot showed that the high moisture and the low moisture cheeses were separated into two distinct clusters. The control was an outlier. The cheeses with high moisture levels were judged to have a cooked flavor, a sour aftertaste, and to be bitter, moist, and chewy. The cheeses with low moisture levels were found to be buttery, hard, and springy. The control was judged to be sweeter than the experimental cheeses. PLS2 indicated that the physical characteristics of hardness, springiness, and chewiness were highly correlated with the same sensory characteristics, while the physical and sensory characteristics of adhesiveness, gumminess, and cohesiveness were not correlated with physical texture measures.

Key Words: Descriptive Analysis, Processed Cheese, Extrusion Technology

761 Developments in the small scale manufacture of process cheese using RVA. R. Kapoor*, A. Pollard, P. Upreti, and L. E. Metzger, MN-SD Dairy Foods Research Center, University of Minnesota, Saint Paul.

Recently, methodology utilizing a Rapid Visco Analyzer (RVA) was developed that could be used to manufacture and analyze process cheese on a small scale (25 g). Although this methodology was successfully used to manufacture process cheese, a significant difference in the functionality of the process cheese was observed when compared to process cheese produced on a pilot scale. In the present study, adjustments in the RVA methodology involving the RVA processing conditions, preblend preparation and Texture Profile Analysis (TPA) techniques for the final process cheese were investigated. Three replicates of process cheese food (PCF) were manufactured from eight different pre-blends. Each pre-blend was prepared using eight different natural cheeses and was balanced for moisture (43.5%), fat (25%) and salt (2%). These pre-blends were split into three portions and each portion was subjected to three different manufacturing treatments. Treatment 1 (T1) was manufactured in the Blentech twin screw (BTS) cooker, whereas treatment 2 (T2) and treatment 3 (T3) were manufactured in the RVA using different processing profiles. T2 and T3 were produced in triplicate. The resulting process cheeses were analyzed for their chemical and functional properties. PCF produced in the BTS was analyzed for moisture, fat and salt whereas the PCF produced in the RVA was analyzed for moisture. There were no significant differences ($p \#8805 .05$) in the moisture content of PCF among the 3 treatments with each of the eight batches (produced from the eight different pre-blends). TPA and RVA melt analyses were performed on all the PCF. The batch of natural cheese

used had a significant effect ($p < .05$) on both the TPA-hardness and hot apparent viscosity of the PCF manufactured using the three treatments. Additionally, all three treatments indicated a similar ranking for the eight batches. The adjustments in the RVA methodology produced process cheese with functionality similar to the process cheese produced in the BTS and the RVA methodology was able to identify differences in functional properties of PCF caused by the use of different natural cheeses.

Key Words: Process Cheese, Rapid Visco Analyzer

762 Evaluation of process cheese spread meltability using a Rapid Visco Analyzer. L. A. Prow* and L. E. Metzger, University of Minnesota, St. Paul.

The melt characteristics of process cheese spread are an important functional attribute. Currently, there remains a need for a fast, accurate and low cost test to evaluate cheese meltability. The objective of this study was to develop a melt test for process cheese spread using a Rapid Visco Analyzer (RVA). The melt properties of 32 commercial process cheese spread and process cheese product samples from four different manufacturers were analyzed with the RVA, tube melt test and dynamic stress rheometry (DSR). Three replicates using the RVA, five replicates using the tube melt test and two replicates using DSR were performed on each sample. In the RVA melt test a 15 g cylinder of cheese was packed into the RVA canister and then subjected to a heating, holding, and cooling profile during continuous mixing. During the test an apparent viscosity vs. time graph was obtained. The melt time, hot viscosity, and time at 5000 cP were determined from each apparent viscosity vs. time curve. The tube melt test determines cheese flow in mm, whereas the DSR data was used to calculate cheese melt temperature (temperature at $\tan \delta = 1$). There was a high correlation (.91) between the DSR cheese melt temperature and the tube melt test. There was also a high correlation between the RVA melt time and the other melt tests (.84 and .74 for the DSR and tube melt test respectively). The RVA melt test also measures the apparent viscosity of melted cheese at a constant temperature (hot viscosity). The data obtained for hot viscosity had a low correlation (< .44) with the data from other melt test, which indicates that an additional cheese melting property may be measured. The results of this study indicate that RVA melt analysis of process cheese spread or process cheese product is correlated with the results from other melt test, but it may also provide additional information on cheese meltability which is not quantified in other melt tests.

Key Words: Process Cheese, Melt Analysis

763 A microfiltration (MF) process to maximize the removal of serum proteins from skim milk prior to cheese making. B. K. Nelson* and D. M. Barbano, Northeast Dairy Foods Research Center, Cornell University, Ithaca, NY.

MF of milk before cheese making using a 0.1- μ m pore size (ceramic) partially removes serum proteins (SP). The SP (mostly β -lactoglobulin and α -lactalbumin) do not contain residual starter, color, coagulant, and lactic acid from cheese making. Diafiltration (DF) has been used to remove lactose from whey protein retentates during ultrafiltration (UF) using water as the diafiltrant. Water as a diafiltrant has been used to remove SP from skim milk during MF, but this produces a retentate with lower lactose and unbound mineral content than milk and may have a negative impact on conventional cheese making. We hypothesize that high recovery of the SP from skim milk prior to cheese manufacture could be achieved by using permeate from the UF of MF permeate as the diafiltrant instead of water to maintain the lactose and unbound mineral balance of the retentate for cheese making. Pasteurized skim milk was single pass processed to a 3X concentration factor using MF. Permeate from MF was collected and ultrafiltered to produce UF permeate that was used as a diafiltrant. The polysulfone UF membranes had a 10-kDa molecular weight cut-off. The retentate collected during the MF step was diluted back to the original weight of the skim milk with UF permeate. The diluted skim retentate was then processed using MF and this constituted the first DF. After the first DF to 3X, the retentate from MF was again diluted with UF permeate and processed (3X) using MF. The UF permeate used for DF contained a low concentration (ca. 0.07%) of SP. Thus, the total SP in the process was that in the skim plus the SP added with the UF permeate. MF plus the two subsequent DF steps removed about 94% of the total SP. The observed SP removal

was close to the expected theoretical value of 96% serum protein for the process.

Key Words: Microfiltration, Diafiltration, Milk

764 Isolation and identification of *Micrococcus* spp from Egyptian soft cheese. A. S. Zahran*, *Minia University*.

Micrococci are the predominant bacteria of milk drawn aseptically from the udder. They were also isolated from different cheese varieties. These bacteria constitute a major portion of the secondary cheese microflora and contribute to its flavour through their proteolytic, lipolytic and esterolytic enzymes activities. Fifty strains of *Micrococcus* spp were isolated from Egyptian soft cheese (Domiat). They were identified into four different species as follows *M. varians*, *M. roseus*, *M. sedentarius* and *M. luteus*. The species most often isolated was *M. varians* as it represents 55% of the total isolates, strain *M. varians* DC6 was very active producer of extracellular proteinase and lipase. Immobilized cell culture is a widely used technique for achieving high volumetric efficiency and sustained productivity from microorganisms. The entrapment of bacterial cells in 2% agar substantially improved their enzyme activity. Immobilized cells produced from 40-50% more enzymes than free cells. The agar entrapment method appeared to have no adverse effects on the activity of the cells. The agar beads were structurally stable over five usage cycles. Synthesis of the extracellular enzymes by *M. varians* DC6 appeared to be inducible as no enzymes were detected in the absence of organic nitrogen.

765 Use of exopolysaccharides producing lactic acid bacteria for the production of buffalo milk dahi (yogurt). N. Pandya*¹, S. Kanawjia¹, and R. Dave², ¹*Dairy Technology Department, National Dairy Research Institute, Karnal, India*, ²*Dairy Science Department, South Dakota State University, Brookings*.

Exopolysaccharides (EPS) produced by lactic acid bacteria (LAB) have generated increasing attention among researchers and considered novel and safe food additives. In this experiment, two EPS⁺ cultures (*Lactococcus lactis* subsp. *lactis* NCDC 191 & mixed thermophilic strains NCDC 260) in combination with standard dahi culture (mixed mesophilic strains NCDC 167, EPS⁻) were studied for their effects on incubation pattern, rheology and sensory properties of the dahi made from buffalo milk standardized at 4.5% fat and 9.5% SNF. Both cultures were inoculated at 2% (v/v) rate in three different ratios (1:1, 2:1 and 3:1 of EPS⁻ and EPS⁺ cultures respectively) and incubated at 27 and 32°C for NCDC 191 and NCDC 260, respectively. It was observed that the rate of drop in pH and rate of increase in titratable acidity declined with increasing proportion of EPS⁺ cultures. Rheology and overall sensory properties were improved with increasing ratio of EPS⁺ culture. However, the improvement was significant ($P < 0.05$) only with NCDC 260, but not with NCDC 191. With the increasing proportion of NCDC 260, the viscosity increased from 0.384 to 0.596 Pa.s., the curd tension increased from 35.52 to 46.60 g, and the syneresis reduced from 1.48 to 0.33 ml per 10 g of dahi. The flavor scores decreased significantly ($P < 0.05$) with increasing ratio of NCDC 191 culture whereas, effect of NCDC 260 culture on flavor scores was not significant ($P < 0.05$). The body and texture scores improved up to 2:1 ratio (NCDC 167: NCDC 260) but at a higher ratio of EPS⁺ culture the dahi developedropy consistency and resulted into decline in sensory scores. The appearance scores were improved for both EPS⁺ cultures. A combination of NCDC 167 and NCDC 260 with (2:1) ratio was suggested for commercial production of dahi.

Key Words: Exopolysaccharides, Buffalo Milk, Dahi

ASAS - Growth and Development II

766 Influence of dietary protein and lactose levels on protein synthesis and translation initiation factor activation in neonatal pigs. J. W. Frank*¹, J. Escobar¹, A. Suryawan¹, H. V. Nguyen¹, C. W. Liu¹, S. R. Kimball², L. S. Jefferson², and T. A. Davis¹, ¹*USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX*, ²*College of Medicine, The Pennsylvania State University, Hershey*.

Parenteral infusion of insulin (INS) and amino acids increases protein synthesis (PS) and eukaryotic translation initiation factor (eIF) activation in skeletal muscle and liver. Pigs (N = 25; BW = 1.6 kg) were enterally fed isocaloric milk diets with three levels of protein (5, 10, and 15 g/kg/d) and two levels of lactose (11 and 23 g/kg/d) from 1 to 7 d of age. On d 7, pigs were gavage fed after a 4 h fast and blood samples were collected every 30 min for 1.5 h. Pigs were then euthanized and tissues harvested. Daily gain and PS in the longissimus dorsi and gastrocnemius muscles and liver were not influenced by lactose level, but increased with dietary protein and plateaued at the 10 g/kg/d level ($P < 0.01$). Plasma INS was greater in the high lactose fed pigs ($P < 0.01$) and lower in pigs fed the lowest protein diet ($P < 0.001$). Plasma branched-chain amino acids were influenced by dietary protein level ($P < 0.001$). Liver and muscle protein kinase B phosphorylation was greater in the high lactose fed pigs ($P < 0.05$). Liver and muscle ribosomal protein S6 kinase and liver 4E-BP1 phosphorylation increased with dietary protein and plateaued at the 10 g/kg/d level ($P < 0.01$), while muscle 4E-BP1 phosphorylation continued to increase to the highest protein level ($P < 0.001$). The association of eIF4G to eIF4E increased with dietary protein level ($P < 0.05$) and was not influenced by lactose level. The results suggest that growth and PS in neonatal pigs are influenced by dietary protein intake. These changes involve modulation of the availability of eIF4E for eIF4F complex assembly and may be mediated by plasma insulin and amino acid levels. (NIAMS AR 44474, USDA 58-6250-6-001)

Key Words: Pigs, Protein Synthesis, Translation Initiation

767 Infusion of a physiological dose of leucine stimulates muscle protein synthesis in neonatal pigs by enhancing the activity of translation initiation factors. J. Escobar*¹, J. W. Frank¹, S. R. Kimball², A. Suryawan¹, H. V. Nguyen¹, C. W. Liu¹, L. S. Jefferson², and T. A. Davis¹, ¹*USDA/ARS, Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX*, ²*Cellular and Molecular Physiology, College of Medicine, Pennsylvania State University, Hershey*.

In adult rats, skeletal muscle protein synthesis increases in response to pharmacological doses of leucine (Leu) administered orally. The effect of a physiological rise in plasma Leu on skeletal muscle protein synthesis has not been investigated in neonatal pigs, which are highly sensitive to amino acid and insulin stimulation. Thus, 24 crossbred pigs were food-deprived for 12 h and intra-arterially infused with Leu (0 or 400 mmolkg⁻¹h⁻¹). Protein synthesis was measured after 60 or 120 min in liver, and longissimus dorsi and gastrocnemius muscles. Infusion of Leu increased ($P < 0.01$) plasma Leu 2.5- to 3.4-fold while plasma insulin and glucose were unchanged. Infusing Leu for 120 min, but not for 60 min, reduced ($P < 0.05$) plasma essential amino acids levels. Infusing Leu for 60 and 120 min increased ($P < 0.05$) phosphorylation of eukaryotic initiation factor (eIF) 4E binding protein-1 (4E-BP1), ribosomal protein (rp) S6 kinase (S6K1), and rpS6, and decreased the amount of eIF4E associated with its repressor, 4E-BP1, in longissimus dorsi muscle. In liver, phosphorylation of 4E-BP1, S6K1 and rpS6, as well as eIF4E associated with 4E-BP1 were not affected by Leu infusion. Leucine infusion for 60 min increased protein synthesis in longissimus dorsi (38%, $P = 0.04$) and gastrocnemius (67%, $P = 0.005$) muscles, but not in liver ($P = 0.11$). Leucine infusion for 120 min did not increase protein synthesis in skeletal muscle and reduced protein synthesis in liver (25%, $P < 0.01$). Thus, a physiological increase in plasma Leu stimulates protein synthesis in skeletal muscle of neonatal pigs by increasing eIF4E availability for eIF4F assembly. Moreover, this response appears to be insulin-independent, substrate-dependent, and tissue-specific (NIAMS AR 44474, USDA58-6250-6-001).

Key Words: Leucine, Translation Initiation Factors, Protein Synthesis

768 Body protein deposition response following sudden changes in ideal protein intake differs between pig types. H. R. Martínez* and C. F. M. de Lange, *Department of Animal and Poultry Science, University of Guelph, ON, Canada.*

The objective of this study was to evaluate the extent and dynamics of compensatory growth following a period of lysine intake restriction in two pig types. In Exp. 1, 40 Yorkshire barrows (14.4 ± 1.6 BW) were assigned to one of two diets (control, - 50% lysine) and fed restricted at 75% of voluntary daily DE intake according to NRC (1998; % of NRC) from 15 to 35 kg BW. Thereafter, pigs were fed restricted (75% of NRC) or ad libitum diets that were not limiting in ideal protein. In Exp 2, 57 Yorkshire entire male pigs (15.8 ± 0.9 BW) were assigned to one of three diets (control, -30% or - 45% lysine) and fed restricted (90% of NRC) from 15 to 38 kg BW; thereafter they were fed at 90% of NRC diets not limiting in ideal protein. BW gain and body composition (serial slaughter) was monitored for at least 30 days after lysine intake restriction was removed. Lysine intake restrictions reduced growth rate ($P < 0.01$; 533 vs 410 g/d in Exp. 1; 794 vs 672 and 648 g/d in Exp. 2). Based on BW gain, no compensatory growth (CG) occurred in barrows ($P = 0.95$) due to previous lysine intake restriction; there were no interactive effects of feeding regime and previous diet lysine level on BW gain ($P = 0.74$). In entire males at 38 kg BW, lysine intake restriction tended to increase body lipid to protein ratios (L/Pr; 0.83, 0.95, 1.06; SE 0.08, $n = 2$). Entire males showed full CG. The BW gain was inversely related to previous diet lysine levels between 38 and 53 kg (1104, 1152, 1210 g/d; $P < 0.03$) and between 38 and 110 kg BW (1100, 1166, 1180 g/d; $P < 0.01$). Body composition (L/Pr; 1.07, 1.12, 1.12; SE 0.05) and carcass characteristics (backfat 20.0, 20.4, 20.7 mm, SE 1.79; loin area, 4596, 4579, 4557 mm², SE 136; colour; carcass protein/body protein mass, 1.16, 1.19, 1.19, SE 0.06) in entire males at 110 kg BW were not influenced ($P > 0.10$) by diet lysine level between 15 and 38 kg BW. CG is more likely to occur in growing pigs with higher lean tissue growth potentials.

Key Words: Compensatory Growth, Body Composition, Pig Type

769 Human somatotropin is more efficacious than porcine somatotropin in growing pigs. F. R. Dunshie*, *Department of Primary Industries, Werribee, Victoria, Australia.*

While the improvements in productive efficiency in response to daily porcine somatotropin (pST) injection are well documented, there is some evidence that human ST (hST) may be even more efficacious than pST. If the relative differences in efficacy between the two ST's is great enough, then variants of human somatotropin may be worth pursuing as a daily injectable for pigs. Forty two individually-penned crossbred gilts (60.4 kg) were stratified on live weight into 14 blocks and then one pig from each block was then randomly assigned to a treatment group consisting of either 7 doses of pST (0, 1.0, 2.0, 3.0, 4.0, 5.0 and 6.0 mg/day) and 7 doses of hST (0, .2, .4, .6, .8, 1.0 and 1.2 mg/day) for 7 days. The regression equation relating feed conversion ratio (FCR) to dose of pST and hST was described by the following equation (with standard errors in brackets): $FCR = 2.4976 (.0817) - .1279 (.259) \times pST \text{ dose} - .409 (.130) \times hST \text{ dose}$. Thus, the FCR for control animals was 2.50, and decreased by .128 and .409 for every mg/d increase in dose of pST and hST, respectively. Therefore, hST was approximately 3.2x more effective in decreasing FCR than pST. While the effects of ST on plasma urea nitrogen (PUN) could not be as easily explained by regression techniques, both pST and hST significantly ($P < .001$) reduced PUN. Application of pST at 5x the dose of hST was more effective in reducing PUN, indicating that the relative difference in potency was less than 5x. Therefore, it appears that hST is approximately 3x more effective in pigs than pST, at least in the short term.

770 Concentrations of insulin-like growth factors I and II in embryonic fluids of chickens, ducks, and turkeys. D. M. Karcher*¹, J. P. McMurtry², and T. J. Applegate¹, ¹*Animal Sciences, Purdue University, West Lafayette, IN,* ²*USDA/ARS/GBL, Beltsville, MD.*

Insulin-like growth factors (IGF-I, IGF-II) are present in the amniotic fluid of developing mammals and ingestion of the amniotic fluid has been

shown to potentially impact the proper development of the gastrointestinal tract. To investigate IGF-I and II changes in avian embryo fluids, 250 duck eggs, 200 turkey eggs, and 222 chicken eggs were incubated, and the embryos were staged according to Hamburger and Hamiltons classification (1951). Amniotic and allantoic fluid IGF-I and -II concentrations were determined by a chicken radioimmunoassay which has 100% reactivity between all species. When the beak was prominent on the embryo, stage 29, the mean IGF-I concentration (conc.) of the chicken amniotic fluid was 97.9% greater than the mean turkey conc. and 81.5% greater than the mean duck conc. ($P \leq 0.05$). At stage 40, when the external features are complete, the chicken amniotic fluid IGF-I conc. was 34.6% greater in the duck amniotic fluid and 17.5% greater than in turkey amniotic fluid ($P \leq 0.05$). However, at stage 37 and 38 (eye-lids narrow and leg scales appear) the IGF-I conc. in turkey amniotic fluid was 70-80% higher compared to the chicken or duck conc. ($P \leq 0.05$). Within species, amniotic IGF-I conc. were low at stage 29 with maximum conc. occurring at the time of imbibing (stage 42 duck and turkey; stage 44 for chicken). The amniotic IGF-I conc. in the chicken had a cubic relationship ($r^2 = 0.41$; $P = 0.0003$) with a 95% difference ($P \leq 0.05$) between the lowest and highest conc. Duck amniotic IGF-I had a linear relationship ($r^2 = 0.73$; $P < 0.0001$) with a 94% ($P \leq 0.05$) difference observed between highest and lowest conc. The IGF-I conc. in the turkey amniotic fluid followed a similar trend with a quadratic relationship ($r^2 = 0.43$; $P = 0.0006$) and an observed difference in minimum and maximum conc. of 98% ($P \leq 0.05$). Amniotic fluid IGF-II was not significantly ($P > 0.05$) different across species. Overall, the conc. of IGF-I and II varies across and within species.

771 Selection for growth does not alter jejunal glucose absorption and energy metabolism in mice. Y. K. Fan¹, W. J. Croom, Jr.*², I. L. Taylor³, L. R. Daniel², A. R. Bird⁴, B. W. McBride⁵, V. L. Christensen², and E. J. Eisen², ¹*National Chung Hsing University,* ²*North Carolina State University, Raleigh,* ³*Tulane University, New Orleans, LA,* ⁴*CSIRO Health Sciences and Nutrition, Australia,* ⁵*University of Guelph, ON, Canada.*

The present study was designed to investigate the effects of genotype and sodium monensin (NaM) on whole body energetics and jejunal function (JF) using 4 different genetic lines of mice. The lines were M16 (selected for rapid growth), randomly bred controls (ICR) and their reciprocal crosses (M16xICR and ICRxM16). Eight-week-old mice from each line were administered either NaM (20 μ M) or excipient via the drinking water for 14d ($n=6$ mice per cell). Whole-body O₂ consumption was measured on day 11. On day 14, mice were euthanized and the jejunum dissected for measurement of jejunal protein and DNA, total, serosal and mucosal O₂ consumption, jejunal uptake rate and whole jejunal glucose uptake. The apparent energetic efficiency (APEE) of glucose uptake was calculated. M16 mice were larger, had greater feed and water intake and greater body fat %. Selection for growth had no effect on intestinal weight adjusted for fasted body weight, increased SI density (mg/cm) and decreased adjusted SI length ($P < .01$). M16 mice had greater intestinal villus width, crypt depth and enterocyte height ($P < .05$) but decreased villus height/crypt depth ($P < .05$). No changes were noted in serosal or mucosal O₂ consumption. M16 mice had lower jejunal glucose uptake rates, total jejunal glucose absorption adjusted for BW ($P < .01$). APEE of glucose uptake decreased 51% in M16 compared to ICR ($P < .05$). Reciprocal crosses (ICRxM16 vs. M16xICR) had few effects on physiological parameters measured as compared to ICR. NaM decreased feed efficiency (mg gain/g feed) and daily water intake across all lines ($P < .01$) but had no effect on adjusted whole-body O₂ consumption. Jejunal protein/DNA decreased as well as jejunal villus width ($P < .05$) with NaM. Selection for growth resulted in less glucose absorption and efficiency of glucose transport. This supports the existing hypothesis that selection for growth does not inevitably result in a concomitant increase in jejunal function or APEE of nutrient absorption.

Key Words: Genotype, Jejunal Absorption, Monensin

772 Effect of microbial colonisation on activated caspase-3 protein and gene expression in the gnotobiotic pig small intestine. B. P. Willing*, R. H. Siggers, T. W. Shirkey, B. G. Goldade, J. K. Marshall, B. Laarveld, and A. G. Van Kessel, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

Previous gnotobiotic pig experiments have shown dramatic differences in ileal morphology in germ-free (GF) and mono-associated as compared to conventionalized pigs, most prominently characterized by as much as a 2-fold increase in villus length. In three experiments sixteen piglets were derived by caesarian-section, allocated to one of four treatment groups including GF, mono-associated with non-pathogenic *Escherichia coli* (EC) or *Lactobacillus fermentum* (LF) or conventionalized with sow feces (CV) and reared to 13 (exp. 1) or 14 (exp. 2&3) d of age. In experiment 3 the LF group was contaminated with *Klebsiella pneumoniae* making it di-associated (LFKP). In experiment 1, whole intestinal tissue was collected at 75% of the small intestine (SI) length. In experiments 2 and 3, villus tip epithelial cells were harvested from 80 cm lengths of SI with 1.5mM EDTA using the distended sac method. To characterize the morphological differences in relation to apoptosis, activated caspase-3 protein and caspase-3 gene expression were measured by Western blot and quantitative PCR (qPCR). Activated caspase-3 protein was detectable in whole intestinal tissue in CV animals only. In the same tissue, caspase-3 mRNA abundance was similar among CV, LF and EC but reduced 1.8 fold in GF ($P < 0.05$). In villus tip cells there was a slight trend for reduced caspase-3 expression in GF, EC, LF and LFKP treatment groups relative to CV. Results indicate that analysis of both transcript and activated protein abundance can yield complementary information regarding apoptotic activity. Apoptotic activity appeared lower in GF and mono-associated pigs however, relative differences in gene expression in whole tissues versus villus tip epithelial cells suggest that markedly increased cellular infiltration of *lamina propria* and/or development of peyers patches in CV pigs may contribute significantly to apoptotic activity observed when whole intestinal tissue is analyzed.

Key Words: Gnotobiotic, Pig, Caspase-3

773 The effect of microbial colonisation on disaccharidase activity in the gnotobiotic pig. L. M. Williams, B. P. Willing*, R. H. Siggers, T. W. Shirkey, B. G. Goldade, J. K. Marshall, and A. G. Van Kessel, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

In previous gnotobiotic pig research we have found that germ free and mono-associated pigs had up to 2-fold longer villi than conventional pigs, chiefly in the distal small intestine (SI). Enterocytes along the distal villi of mono-associated and germ free pigs contained large and apparently empty vacuoles. To characterize the effect of specific bacteria on digestive function in relation to intestinal morphology, brush border disaccharidase activity was determined in SI segments collected from pigs in two separate experiments. Each experiment included 16 pigs derived by caesarian-section and assigned to, germ free (GF), mono-associated with non-pathogenic *Escherichia coli* (EC), mono-associated with *Lactobacillus fermentum* (LF) or conventionalised with sow feces (CV), treatment groups. In experiment 2 the germ free group was contaminated with a *Staphylococcus* sp. (ST). Pigs were fed a 2:1, Similac[®].water, (v/v) mixture *ad libitum* and killed at 13 days of age. Lactase, sucrase and maltase activities were determined per unit protein, DNA and wet tissue weight, for segments collected at 25 and 75% of SI length. The effect of treatment and SI location on specific disaccharidase activities were similar whether reported per unit protein, DNA or wet tissue weight, were always higher in the proximal SI, were similar among GF and monoassociated pigs and were always lowest in CV pigs. Lactase activity was highest in all treatment groups at both locations, however, this was most notable (2-fold higher versus maltase and sucrase) in distal SI of mono-associated and GF pigs. In conclusion the vacuolated enterocytes, associated with markedly elongated villi observed in the distal small intestine, of GF and monoassociated pigs demonstrated significant disaccharidase activity, however the pattern of activity was consistent with the very early postnatal period and slow enterocyte turnover.

Key Words: Gnotobiotic, Disaccharidase, Pig

774 Characterization of specific gene expression following differentiation of bovine stromal-vascular cells into adipocytes. M. J. Herson*¹, J. W. Ross², D. Stein², L. McBeth², R. D. Geisert², U. Desilva², C. R. Krebbiel², and J. R. Malayer², ¹University of Florida, Gainesville, ²Oklahoma State University, Stillwater.

The objectives of the present experiment were to 1) determine if gene expression differs during adipocyte differentiation of bovine stromal-vascular (SV) cells from different adipose depots and 2) determine similarity of differentiation of cultured bovine SV to the mouse 3T3-L1 cell line. Bovine SV cells were isolated from s.c., i.m., and kidney-pelvic-heart (KPH) adipose depots, cultured to confluence, then stimulated to differentiate for 0, 12, 24, 48, and 72 h. Expression of bovine specific peroxisome proliferators-activated receptor- γ (PPAR γ), stearoyl CoA desaturase 1 (SCD-1), lipoprotein lipase (LPL), fatty acid synthase (FAS), and acyl-CoA synthetase (ACS) mRNA was determined using quantitative RT-PCR. 18S ribosomal RNA was utilized to standardize RNA loading. Relative quantitative mRNA expression was evaluated using the comparative CT method. PPAR γ gene expression of s.c. adipocytes exhibited a 7.5-fold increase from 12 to 48 h compared to 3-fold and 3.8-fold increase in i.m. and KPH from 6 to 12 or 24 h (D x T, $P < 0.001$). SCD-1 gene expression in s.c. increased 7-fold from 0 to 72 h compared to 1.8 and 2.7-fold increases for i.m. or KPH (D x T, $P = 0.04$). Gene expression of LPL in s.c. increased 8-fold by 48 h compared to 2- and 3-fold increases in KPH and i.m. (D x T, $P < 0.001$). FAS (D x T, $P < 0.001$) and ACS (D x T, $P = 0.002$) gene expression decreased 4.9 and 4.6-fold in i.m. and 3.4 and 3.6-fold in KPH, s.c. gene expressions decreased 1.7 and 1.2-fold, respectively. 3T3-L1 PPAR γ gene expression was minimal at 6 h and was 16 and 223-fold greater ($P < 0.001$) at 24 and 48 h. Differences in gene expression exist among bovine adipose depots. A similarity in response time but not magnitude of PPAR γ in bovine s.c. and 3T3-L1 cells indicates that bovine SV cells are an acceptable model for adipocyte differentiation. Differences between mouse and bovine cells and among depots indicate the physiological importance of adipocyte specificity.

Key Words: Adipose, Bovine, Gene Expression

775 Dexamethasone downregulates glucocorticoid receptor expression in cultured bovine preadipocytes. G. Ortiz-Colón*, A. C. Grant, J. L. Burton, M. E. Doumit, and D. D. Buskirk, *Department of Animal Science, Michigan State University, East Lansing.*

Bovine adipose tissue from different depots have been shown to have distinct physiological responses to glucocorticoids. The objectives of this study were to determine if the glucocorticoid receptor (GR) was expressed in cultured preadipocytes isolated from bovine adipose tissues, and to evaluate the effect of dexamethasone treatment upon the GR abundance. Preadipocytes were isolated from intramuscular (i.m.), perirenal (p.r.) and subcutaneous (s.c.) adipose tissues of an Angus steer (556 Kg, 13.5 mo. old), propagated in culture, and seeded in 35 mm-diameter dishes at a density of 2,600 cells/cm². Preadipocytes were fed every other day with growth media: Dulbeccos modified Eagles medium (DMEM) containing 10% fetal bovine serum. After 8 days, cells were exposed to control growth media, or growth media containing .25 μ M dexamethasone for 48 h. The cells were then solubilized by the addition of hot (95°C) electrophoresis sample buffer. Proteins were electrophoretically separated using 10% polyacrylamide gels and transferred onto polyvinylidene fluoride microporous membranes. The membranes were incubated with an antibody against GR and subsequently exposed to a secondary antibody conjugated to alkaline phosphatase. Immuno-reactive bands were visualized upon addition of substrate. The GR was detected as a specific 97 kDa band in the cultured preadipocytes from the three adipose tissues. An antibody against β -actin was used as an internal control. Bands were quantified using Quantity One software (Bio-Rad) and data were analyzed by the GLM procedure of SAS. Glucocorticoid receptor abundance was reduced by dexamethasone exposure in i.m. (7.0%), s.c. (52.7%), and p.r. (35.6%) preadipocytes ($P < .03$). It can be concluded that GR was expressed in these cultured preadipocytes isolated from bovine s.c., p.r., and i.m. adipose tissue and that the synthetic glucocorticoid dexamethasone decreased GR abundance.

Key Words: Bovine, Preadipocytes, Glucocorticoid Receptor

776 Dietary coconut oil and conjugated linoleic acid reduce body fat in mice. K. M. Hargrave* and J. L. Miner, *University of Nebraska, Lincoln*.

Mice raised on a coconut oil (CO)-containing diet for 6 wk prior to the addition of conjugated linoleic acid (CLA) are more sensitive to CLA-induced body fat loss than mice raised on a soy oil (SO)-containing diet. Coconut oil is deficient in essential fatty acids. However the addition of linoleic acid to a CO-containing diet did not alter the enhanced sensitivity to CLA. The objective of this study was to determine if CO enhances sensitivity of mice to CLA-induced body fat loss independent of an essential fatty acid deficiency. Eighty male mice (12 wk old) were fed a purified SO-containing diet for a 1 wk adaptation. Mice were then blocked by body weight and randomly allotted to a treatment diet. Diets were arranged in a 2 x 2 factorial design with SO vs CO and 0 vs 0.5% CLA isomers. Mice were fed for 2 wk and body weight and feed intake were measured weekly. Mice were then killed and body fat and lean mass were determined by dual x-ray densitometry and fat pads and livers were weighed and collected. DNA fragmentation, indicative of apoptosis, was measured in one epididymal fat pad and is expressed as (fragmented DNA/total DNA)*100. CO-fed mice consumed more ($P < 0.05$) feed than SO-fed mice during both weeks of treatment but weighed less ($P < 0.05$) in the second wk. CO+CLA mice consumed less feed than CO mice but SO and SO+CLA mice did not differ in feed intake (CO x CLA interaction, $P < 0.05$). Both CO and CLA reduced ($P < 0.001$) body fat and fat pad weights. There was a trend for a CO x CLA interaction ($P = 0.06$) as CO+CLA mice were leaner than SO+CLA (11.94% vs 15.48% body fat, respectively). There were no differences in lean mass. CLA increased ($P < 0.01$) liver weight. There were no differences in DNA fragmentation but CLA did increase ($P < 0.001$) total DNA content of the fat pad. In summary both CO and CLA reduced body fat with a trend for an interaction. Therefore, feeding CO for a short time appears to increase the sensitivity of mice to CLA-induced body fat loss similar to a longer feeding period. This indicates that CO increases CLA-induced body fat loss in an essential fatty acid deficiency-independent manner.

Key Words: Conjugated Linoleic Acid, Coconut Oil, Body Fat

777 Subcutaneous and abdominal fatty acid composition and CLA profiles in grain finished steers. L. H. Baumgard*¹, S. R. Sanders¹, O. B. Mendivil¹, J. K. Kay¹, J. A. Marchello¹, P. Delmonte², J. M. Griinari³, and M. P. Yurawecz², ¹The University of Arizona, Tucson, ²U.S. Food and Drug Administration, Washington, DC, ³University of Helsinki, Finland.

Subcutaneous (SQ) and abdominal (AB) fat was collected 24 h after harvest from non-implanted Hereford steers (n=3) fed a high concentrate (80%), low forage (20%) finishing diet for 90 d. SQ and AB fatty acid (FA) composition was determined via gas chromatography, and the complete CLA profile (15 isomers) was characterized by triple-column silver-ion high performance liquid chromatography (Ag⁺-HPLC). Levels of total *trans*-18:1 was higher ($P < 0.01$) in AB than SQ (2.37 vs. 1.56%) and the content of *trans*-6,7,8, *trans*-9, *trans*-10, *trans*-11 and *trans*-12 18:1 was 73, 14, 23, 62 and 82% higher ($P < 0.04$), respectively, in AB compared to SQ. Conversely, SQ had a higher ($P < 0.02$) content of unsaturated FA (51 vs. 37%), enhanced CLA levels (0.56 vs. 0.35%) and an increased Δ^9 -desaturase index (47 vs. 30) compared to AB. *cis*-9, *trans*-11 and *trans*-7, *cis*-9 CLA were the first and second most predominant CLA isomers, respectively, in both depots and were higher in SQ compared to AB (69 vs. 59% and 13 vs. 9% of total CLA, respectively). *trans*-10, *cis*-12 CLA was the third and seventh most abundant CLA isomer in SQ and AB depots respectively, but levels did not differ between depots (3.3% of total CLA). *trans*-11, *trans*-13 and *trans*-9, *trans*-11 CLA were the third and fourth most predominant CLA isomers in the AB depot and were higher compared to SQ (5.8 vs 1.5% and 4.9 vs. 2.5% of total CLA, respectively). When adipose depots were combined, the content of total CLA and both the *cis*-9, *trans*-11 and *trans*-7, *cis*-9 CLA isomer (products of Δ^9 -desaturase) were highly correlated with the Δ^9 -desaturase index ($R^2 = 0.97, 0.85$ and 0.81 , respectively). These data indicate marked differences in fatty acid composition including CLA profiles between SQ and AB depots, and suggests the Δ^9 -desaturase system is responsible for *cis*-9, *trans*-11 and *trans*-7, *cis*-9 CLA being the predominant CLA isomers in beef adipose tissue.

Key Words: Beef, CLA, Adipose Depot

778 Exogenous porcine prolactin stimulates mammary development in prepubertal gilts. C. Farmer* and M.-F. Palin, *Dairy and Swine R & D Centre, Agriculture and Agri-Food Canada, Lennoxville, QC, Canada*.

The impact of injecting gilts with porcine prolactin (pPRL) in the prepubertal period on mammogenesis was investigated. Crossbred gilts received sc injections of saline (controls; n = 12), 2 mg of pPRL (4PRL; n = 12) or 4 mg of pPRL (8PRL; n = 12) twice daily for a period of 28 d, starting at 75.1 ± 0.5 kg BW. Injections of saline or pPRL were given at 0730 and 1530. Jugular blood samples were collected from all gilts the morning before the first injection, as well as 14 and 28 d later. These samples were assayed for PRL and insulin-like growth factor-I (IGF-I). Gilts were slaughtered on the 28th day of treatment and mammary glands were collected for dissection of parenchymal and extraparenchymal tissues, and for determination of DNA, dry matter, protein and fat contents. Treatments did not alter ($P > 0.1$) IGF-I concentrations but concentrations of PRL at slaughter were greater ($P < 0.01$) in both 4PRL and 8PRL compared to controls, while at mid-treatment, they were greater ($P < 0.05$) only in 8PRL gilts. Parenchymal tissue weight increased with exogenous pPRL (199.8, 434.4 and 364.1 ± 28.4 g for controls, 4PRL and 8 PRL, respectively; $P < 0.001$) and DNA concentrations were greater in pPRL-treated gilts (2.3, 6.0 and 6.2 ± 0.3 mg/g for controls, 4PRL and 8PRL, respectively; $P < 0.001$). The percentages of protein and dry matter in parenchyma increased ($P < 0.001$) while that of fat ($P < 0.001$) and the protein to DNA ratio ($P < 0.05$) decreased with exogenous pPRL. Treatment differences were always observed between the 4 mg dose and the controls, and no further differences were seen when increasing the dose to 8 mg daily. Extraparenchymal tissue weight and total parenchymal fat were unaltered by treatments ($P > 0.1$). It is apparent that pPRL can stimulate mammogenesis in prepubertal gilts through hyperplasia. It would be of great interest to determine if this favorable effect translates into greater milk yield dur-

ing subsequent lactations. (Sincere thanks to Monsanto for supplying the pPRL).

Key Words: Mammary Gland Development, Prolactin, Gilts

779 Gene expression profiling of bovine mammary epithelial cells in response to prolactin and extracellular matrix. L. Rowley*¹, D. Baird², T. Wilson³, J. Whitley¹, C. Berends¹, M. Wells¹, and M. Goddard¹, ¹Primary Industries Research Victoria, Attwood, Australia, ²AgResearch, Lincoln, New Zealand, ³AgResearch Molecular Biology Unit, University of Otago, Dunedin, New Zealand.

Dairy farming is a financially important agricultural resource to Australia and further economic gains could be realised through improved milk yield or composition. In order to manipulate milk production however, we need to more fully understand the functional regulation of milk protein synthesis and secretion in the bovine mammary gland. In order to identify regulatory mechanisms involved in the differentiation of the mammary gland, primary mammary epithelial cells were cultured in the presence and absence of both prolactin (1 μ g/mL) and extracellular matrix. Culture medium was analysed by Western blotting to evaluate milk protein synthesis and secretion. RNA was isolated from cells in culture to assess gene expression using cDNA microarrays containing 23k bovine expressed sequence tags. Microarray data was statistically analysed by mixed model analysis using REML (restricted maximum likelihood). When cultured in the presence of extracellular matrix, mammary epithelial cells were able to assume three-dimensional spherical structures similar to mammary secretory alveoli in vivo. Western blot analysis showed that the secretion of the milk proteins, β -lactoglobulin, α_{S1} - and β -casein was greatly upregulated in the presence of both prolactin and extracellular matrix. Microarray analysis has identified genes

that are differentially regulated by prolactin and extracellular matrix. Further examination of differentially regulated genes may enable elucidation of the specific regulatory mechanisms and ultimately, control over the production and composition of milk.

Key Words: Microarray, Prolactin, Extracellular Matrix

780 Microarray analysis of prolactin signalling in the bovine mammary gland during lactogenesis. M. Wells^{*1}, C. Prosser², D. Baird³, T. Wilson⁴, M. Auld⁵, J. C. Whitley¹, J. K. Lee¹, J. Argento¹, and M. Goddard¹, ¹Primary Industries Research Victoria, Attwood, Australia, ²AgResearch, Ruakura, New Zealand, ³AgResearch, Lincoln, New Zealand, ⁴AgResearch Molecular Biology Unit, University of Otago, Dunedin, New Zealand, ⁵Primary Industries Research Victoria, Ellinbank, Australia.

The Australia-New Zealand Dairy Genomics Program is a collaborative research project, which aims to improve milk production, alter milk composition and identify novel products. In order to achieve these aims, however, it is necessary to increase our understanding of regulatory mechanisms in the bovine mammary gland. The objective of this trial was to identify genes within the mammary gland that are prolactin responsive, and which therefore regulate lactogenesis and milk yield around calving. Bromocriptine, which blocks the peri-parturient surge in prolactin in dairy cattle, was administered to Friesian cows (5 mg/100kg body weight; n=5) every 2 days, beginning 12 days before expected calving and ending at calving. Controls (n=5) received saline-only injections. At 72 hours post-partum, animals were slaughtered and mammary tissue was collected for RNA isolation. Analysis of gene expression was performed using cDNA microarrays comprising 23,000 bovine expressed sequence tags (ESTs), with a mixed model statistical analysis using restricted maximum likelihood to estimate the variance components. Serum prolactin levels in treated animals decreased by ~90% relative to control cows. In the 3 days following calving, bromocriptine-treated cows demonstrated a 40% reduction in milk yield. Analysis of milk composition showed decreased concentrations of α -lactalbumin, β - and κ -casein, whilst β -lactoglobulin and serum albumin increased. These results are consistent with a delay in the onset of lactogenesis due to the blocking of prolactin secretion by bromocriptine. Microarray analysis has identified 1254 differentially regulated ESTs (827 down-regulated and 427 up-regulated) in the mammary gland of bromocriptine-treated cows relative to control cows. Further investigation of differentially regulated genes will improve our understanding of the role of prolactin in lactogenesis in the dairy cow, and may provide opportunities for the manipulation of milk production.

Key Words: Microarray, Lactogenesis, Bromocriptine

781 Expression of prolactin responsive genes following experimental manipulation of the prolactin axis during early lactation in dairy cows. E. H. Wall^{*1}, H. M. Crawford², G. E. Dahl², and T. B. McFadden¹, ¹University of Vermont, Burlington, ²University of Illinois, Urbana.

Increased milking frequency during early lactation results in a persistent increase in milk yield, however the mechanisms underlying this effect are unknown. Frequent milking elicits additional episodes of milking induced prolactin (PRL) secretion as well as more frequent emptying of the gland. Our objective was to distinguish the relative contributions of each of these factors. We hypothesized that augmented PRL signaling mediates the response to increased milking frequency in early lactation. Hence, we proposed that treating cows milked 2X/d with exogenous prolactin would provoke responses similar to those of cows milked 4X/d. Conversely, blockade of milking-induced PRL release by injection of bromocriptine in cows milked 4X/d would result in similar responses as those of cows milked 2X/d. Twenty multiparous Holstein cows received 1 of 4 treatments from d 2 to 21 postpartum: 2X, 4X, 2X+PRL, or 4X+bromocriptine. Exogenous PRL or bromocriptine was administered coincident with the 3rd and 4th milkings. Mammary biopsies were obtained at 7 DIM (n=5 cows/treatment), and rates of [³H]-thymidine incorporation into DNA in vitro were measured. Expression of mRNA for PRL receptor (long form), α -lactalbumin and suppressor of cytokine signaling-3 (SOCS-3) was measured by real time RT-PCR as indices of PRL signaling. Data were analyzed using the GLM procedure of SAS. Expression of α -lactalbumin mRNA was greater (P<.06) in 2X+PRL cows compared to the other groups, which were similar. Abundance of PRL receptor mRNA was similar among 2X, 4X+bromocriptine, and

4X treated cows, but was reduced in 2X+PRL cows compared to the 4X group (P<.05). 2X cows expressed higher levels of SOCS-3 mRNA than all other treatment groups (P<.06). There was no treatment effect on [³H]-thymidine incorporation into DNA. The differences in expression of PRL-responsive genes suggest interactive effects of PRL and milk removal in regulation of mammary responses.

Key Words: SOCS, Milking Frequency, Prolactin

782 Effects of 21-day short day photoperiod (SDPP) during the dry period on prolactin (PRL) concentrations, lymphocyte PRL receptor (PRL-R) mRNA, and general health of dairy cows. E. D. Reid^{*1}, T. L. Auchtung¹, D. E. Morin¹, T. B. McFadden², and G. E. Dahl¹, ¹University of Illinois, Urbana, ²University of Vermont, Burlington.

Manipulation of photoperiod during the dry period alters subsequent production and cellular immune function in cattle. Specifically, SDPP improves health and milk yield when compared with long day photoperiod (LDPP), likely via increased sensitivity to PRL. Prolactin and PRL-R are responsive to photoperiod and appear to be linked with immune function. However, the minimum duration of SDPP exposure necessary to produce these beneficial effects is unknown. The objective of this study was to determine the effect of 21 d of SDPP at the end of the dry period on PRL concentration, expression of lymphocyte PRL-R mRNA, and general health. Holstein cows (n = 32) were assigned randomly to one of four dry period treatments: LDPP (16 h light: 8 h darkness), SDPP (8 h light: 16 h darkness), AMB (natural lighting schedule during dry period), and SD21 (AMB until 21 d prepartum then SDPP). After parturition, cows were exposed to natural photoperiod. General health was monitored weekly throughout the dry period. Blood was collected at dry off and every 2 wk until 21 d prepartum, at which time sampling occurred weekly until calving. Concentrations of PRL were measured via RIA and expression of PRL-R mRNA in lymphocytes was measured using real-time PCR. There was no difference in PRL concentrations or PRL-R expression among the groups at dry off but by d 28, LDPP had higher (P < 0.05) PRL concentrations than AMB, SDPP or SD21. Prolactin did not differ among the AMB, SDPP, and SD21 groups during the dry period. Expression of PRL-R was higher (P < 0.05) in SDPP cows at d 28 than LDPP, SD21, or AMB, but not different (P > 0.10) between SDPP and SD21 a week prior to calving, after SD21 animals were switched from ambient photoperiod to SDPP. In conclusion, there is an inverse relationship between PRL concentrations and PRL-R mRNA expression in lymphocytes in LDPP and both SDPP and SD21 animals during the short day treatment.

Key Words: Cattle, Photoperiod, Immune Function

783 Exposure to long day photoperiod during the dry period increases mammary gland expression of suppressors of cytokine signaling in dairy cows. E. H. Wall^{*1}, T. L. Auchtung², G. E. Dahl², and T. B. McFadden¹, ¹University of Vermont, Burlington, ²University of Illinois, Urbana.

The mechanism by which short day photoperiod (SDPP; 8h light:16h dark) during the dry period enhances lactational performance in the subsequent lactation is unknown. Cows exposed to SDPP have lower circulating PRL and higher expression of PRL receptor in the mammary gland, whereas long day photoperiod (LDPP; 16h light:8h dark) elicits the reverse. Suppressors of cytokine signaling (SOCS) are induced by cytokines such as PRL and interferon- γ (IFN- γ) and act in a negative feedback manner, inhibiting signaling of such cytokines. We hypothesized that altered expression of SOCS as a result of different daylength modulates mammary sensitivity to circulating PRL during the dry period. Multiparous Holstein cows were dried off 62 days before calving and assigned to LDPP or SDPP during the dry period. After calving, all cows were exposed to ambient photoperiod. Mammary biopsies were obtained at -40, -20, -7 and +7 days relative to calving (n=6 cows/treatment), and mRNA expression for SOCS-2, -3, cytokine inducible SH-2 protein (CIS) and IFN- γ receptor was assessed by real time RT-PCR. Data were analyzed using the mixed procedure of SAS. Expression of SOCS-2 and CIS was low during the dry period, then increased in lactation (P<.05). Higher expression of both CIS (P<.05) and SOCS-2 (P<.09) mRNA was observed in LDPP cows relative to SDPP cows at 20d. CIS expression was also higher at +7d in LDPP cows compared to SDPP cows (P<.01). SOCS-3 and IFN- γ receptor

expression increased from 40d to 7d ($P < .05$) and remained high in lactation for both treatments. These data indicate that cows exposed to LDPP during the dry period experience higher SOCS expression, which may impair PRL induced mammary growth and lead to inferior milk production in the subsequent lactation. The increase in mammary SOCS expression from pregnancy into lactation implies a functional role for SOCS in bovine mammary gland during lactogenesis.

Key Words: SOCS, Photoperiod, Mammary Gland

784 The effects of a 21-day short day photoperiod treatment during the dry period on dry matter intake and subsequent milk production in cows. E. D. Reid*¹, R. L. Wallace¹, T. B. McFadden², and G. E. Dahl¹, ¹University of Illinois, Urbana, ²University of Vermont, Burlington.

The ability to increase milk production by altering day length is a practical management technique in the dairy industry. Long day photoperiod treatment (16 h light:8 h dark, LDPP) during lactation increases milk production in lactating cows. Short day photoperiod treatment (8 h light:16 h dark, SDPP) during the traditional 60 d dry period increases milk production in the subsequent lactation. The purpose of this study was to determine if the effects of SDPP during the dry period could be observed with a 21 d treatment, that could be implemented at the beginning of the transition period and reduce the amount of time animals spend in an enclosed facility. Thirty-one mature Holstein cows were assigned randomly to one of four dry period treatments: LDPP, SDPP, AMB (followed natural lighting schedule during dry period), and SD21 (AMB until 21 d prepartum followed by SDPP). After parturition, animals were exposed to natural lighting treatment during lactation. Milk samples were collected biweekly for 60 d and monthly thereafter. Dry matter intake (DMI) during the dry period was monitored daily. Statistical analysis was performed using a repeated measures model with photoperiodic treatment as the main effect and time as the repeated measure. Multiple comparison tests were conducted to determine significant differences between treatments. Mean SDPP DMI during the dry period was significantly greater than LDPP and AMB ($P < 0.05$), whereas SD21 DMI was intermediate. Mean milk production was higher in SDPP animals ($P < 0.05$), whereas LDPP, AMB, and SD21 were similar over the initial 60 d collection period. Of interest, SDPP, AMB, and SD21 animals display increased persistency when compared with LDPP, suggesting a beneficial effect on milk production through the entire lactation. We conclude that relative to LDPP, SD21 improves DMI during the dry period and increases subsequent lactational persistency.

Key Words: Cattle, Photoperiod, Milk

785 Evidence that prolactin (PRL) mediates effects of milking frequency in early lactation. H. M. Crawford*¹, T. L. Auchtung¹, E. H. Wall², T. B. McFadden², and G. E. Dahl¹, ¹University of Illinois, Urbana, ²University of Vermont, Burlington.

Increasing milking frequency during the first 21 d of lactation results in a persistent increase in milk yield that continues after treatment has ceased. We hypothesized that greater milking frequency increases the number of PRL surges to in turn drive more extensive mammary cell differentiation. To test if PRL surge number was critical to milk yield responses, we assigned 47 mature cows to one of four treatments at calving: 2X (milked twice/d), 4X (milked four times/d), 2X+PRL (2X and PRL injections twice/d), and 4X+Bro (4X and bromocriptine to block two PRL surges/d). Treatments were given from d 2 to 21 postpartum; at d 22 treatments ended and all cows were milked 2X. Blood samples were collected weekly postpartum. Dry matter intake (DMI) was recorded from d 1 to 42 postpartum and milk samples taken weekly. Cows were divided into 2 groups due to season of calving; group 1 consisted of 2X, 4X, and 2X+PRL treatments, and group 2 consisted of 2X, 4X, and 4X+Bro treatments. Basal PRL concentration for d 4 2X+PRL cows was greater than 4X cows ($P < .09$). Basal PRL concentration for d 14 2X cows was higher than 4X+Bro cows ($P < .12$). Energy corrected milk (ECM) was analyzed from week 1 to 6 postpartum. Average daily ECM for the 6 wks for group 1 were 40.5, 45.7, and 46.9 kg/d for 2X, 4X and 2X+PRL. 2X+PRL cows had greater average daily ECM than 2X cows ($P < .11$). Group 2 average ECM for the 6 wks were 51.4, 51.5, and 49.1 kg/d for 2X, 4X and 4X+Bro. For group 1, 4X cows milk yield was greatest for wk 1 ($P < .05$), and greater than 2X for wk 3 ($P < .02$). 2X+PRL cows milk yield was greater than 2X cows for week 3 ($P < .11$) and than 2X and 4X cows for weeks 5 and 6 ($P < .15$). For group 2, 4X

cows milk yield was greater than 2X and 4X+Bro at week 4 ($P < .06$). In group 1 DMI was not different among treatments. In group 2 DMI was greater for 4X+Bro cows than 4X cows ($P < .09$). In summary, increasing PRL pulsatility in early lactation increased ECM similar to the effect of 4X milking.

Key Words: Cattle, Frequent Milking, Prolactin

786 Impact of increased milking frequency in early lactation in multiparous dairy cows. M. J. VanBaale*¹, D. Ledwith², J. M. Thompson³, R. J. Collier¹, and L. H. Baumgard¹, ¹The University of Arizona, Tucson, ²Stotz Dairy, Buckeye, AZ, ³California State Polytechnic University, San Luis Obispo.

Although frequently recommended and occasionally practiced on dairy farms, the effects of increased milking frequency (IMF) on production parameters are poorly understood. Two hundred multiparous cows were randomly assigned to one of five milking frequency treatments at parturition to investigate IMF (6X vs. 3X) effects during early lactation and subsequent milk yield persistency with or without bST. Treatments were 6X milking for 0 (control; milked 3X) or the first 7, 14, 21 DIM (all 4 treatments initiated bST at 63 DIM), or 6X for the first 21 DIM (no bST administration throughout the entire lactation). Cows were housed in a dry lot facility under a thermal neutral environment throughout the study. Individual milk yields were collected daily and milk components were obtained monthly. All cows were body condition scored at parturition and every four wks thereafter. Blood was collected from the coccygeal vein at parturition and weekly for 5 wks thereafter using a subset of cows ($n=15$ /trt from control and the cows assigned to the 21 d 6X treatment with bST). Data reported here in were analyzed through 63 DIM (prior to bST administration). Milk yield tended ($P = 0.07$) to differ between treatments but effects were small (41.2, 39.8, 41.5, 39.1, and 41.0 kg/d, respectively). No overall treatment effects ($P > 0.20$) were observed for milk fat and protein percentages (3.80 and 2.80) nor SCC (220). Treatments did not alter ($P > 0.07$) overall BCS (3.57) or circulating plasma NEFA levels ($P > 0.74$; 467 $\mu\text{eq/l}$). Data suggest that IMF (6X vs. 3X) immediately post partum does not improve milk yield during the first 9 wks of lactation in multiparous cows milked 6X for 7, 14, or 21 d. However, IMF effects (with and without bST) on future milk yield and lactation persistency are currently not known.

Key Words: Increased Milking Frequency, Early Lactation, Dairy Cows

787 Effects of milking frequency during early lactation on performance and health of dairy cows. J. Fernandez*¹, C. M. Ryan, D. M. Galton, and T. R. Overton, Cornell University, Ithaca, NY.

Holstein cows ($n=105$) entering second or greater lactation were used to determine the lactational and health responses to increased milking frequency (IMF) during early lactation. At parturition, cows were assigned to either a control (twice-daily milking during the entire lactation at 12-h intervals; 2X) or IMF (four times per day milking at 5 to 7-h intervals from d 1 through 21 postpartum, then twice daily at 12-h intervals for the rest of lactation; 4X) treatment. Milk yield and composition data were collected for the first 9 monthly test days. Cows milked 4X during the first 21 d of lactation tended to have increased milk yield during the first 9 monthly test days (35.5 vs. 33.9 kg/d; $P < 0.12$) compared to the cows milked 2X. Milking cows 4X during the first 21 d of lactation tended to decrease milk fat percentage (3.37 vs. 3.52%; $P < 0.07$) and decreased milk true protein percentage (2.83 vs. 2.93%; $P < 0.02$) such that yields of milk fat (1.20 vs. 1.20 kg/d), 3.5% fat-corrected milk (35.2 vs. 34.2 kg/d) and true protein (1.01 vs. 1.00 kg/d) during the first 9 monthly test days were not affected ($P > 0.15$) by treatment. Concentrations of NEFA (707 vs. 639 $\mu\text{Eq/l}$) in plasma collected during d 5 to 20 postpartum were not affected ($P > 0.15$) by treatment; however, concentrations of plasma β -hydroxybutyrate tended to be increased in the cows milked 4X (12.1 vs. 10.1 mg/dl; $P < 0.14$). Overall, milk yield responses to IMF during early lactation were modest, and yields of fat and protein in milk were not affected by IMF during early lactation in this experiment.

Key Words: Dairy Cow, Milking Frequency

788 Effects of continuous milking, bST and early-lactation milking frequency on mammogenesis, milk yield and composition in primiparous cows. A. C. Fitzgerald*, E. L. Annen, P. C. Gentry, L. H. Baumgard, and R. J. Collier, *University of Arizona, Tucson*.

Continuous milking (CM) of bST-supplemented primiparous cows results in production losses of 20 to 25%, suggesting mammary growth was inhibited. We hypothesized continuous (throughout late gestation and early lactation) bST supplementation and/or early-lactation increased milking frequency (IMF) would alleviate production losses in CM glands through improved mammary epithelial cell (MEC) functionality and proliferation. Primiparous cows were randomly assigned to either continuous bST (+bST; n = 4) or no bST (-bST; n = 4) treatment throughout the experiment. Within each animal, udder halves were randomly assigned to either CM or a 60-d dry period (CTL) treatment. CTL halves were dried -60 d relative to expected parturition date. CM glands were milked twice daily until parturition or spontaneous dry-off. At parturition all cows were milked four times daily (4X) until 30 d postpartum. Time points for mammary biopsies averaged -19, -7, +2, +7, and +20 d relative to parturition. Average d dry for CTL glands was 59.5 and 49.3 d for 4X+bST and 4X-bST treatments. Due to spontaneous dry-off, CM halves were dry for an average of 1.0 and 13.5 d for 4X+bST and 4X-bST treatments. Prepartum half-udder milk yield was greater (P < 0.01) in +bST cows than -bST cows (11.7 vs. 9.2 kg/d). Postpartum milk yield was reduced (P < 0.01) in CM udder halves regardless of bST treatment (15.0 vs. 25.0 kg/d; CM vs. CTL). Milk composition (fat, protein, SCC linear score) was not affected by CM or bST. MEC proliferation (Ki67 antigen index) was greater (P < 0.01) in CTL glands at d -7 (6.2 vs. 3.4%, CTL vs. CM), but was not affected at d -19, +2, +7, or +20. MEC proliferation was unaffected by bST. Decreased milk yield in CM halves was not overcome by bST in primiparous cows milked 4X. Further, MEC proliferation was reduced in CM halves near parturition (-7 d).

Key Words: Continuous Milking, bST, Mammary Cell Proliferation

789 The anticancer effects of vaccenic acid in milk fat are due to its conversion to conjugated linoleic acid via Δ^9 -desaturase. A. L. Lock*¹, B. A. Corl¹, D. E. Bauman¹, D. M. Barbano¹, and C. Ip², ¹*Cornell University, Ithaca, NY*, ²*Roswell Park Cancer Institute, Buffalo, NY*.

Cis-9, trans-11 conjugated linoleic acid (CLA) has been shown to be anticarcinogenic in a number of animal tumor models. Dairy products are the principal source of CLA in human diets and endogenous synthesis from vaccenic acid (*trans-11* 18:1; VA), the major biohydrogenation intermediate produced in the rumen, is the predominant source of CLA in milk fat. Foods rich in CLA are therefore also rich in VA. We previously reported that dietary VA caused a dose-dependent increase in the accumulation of CLA in the mammary fat pad; this was accompanied by a parallel decreased risk of tumorigenesis in the mammary gland. In an attempt to delineate a direct versus an indirect action of VA, the objective of this study was to determine whether treatment with sterculic oil (SO), a potent inhibitor of Δ^9 -desaturase, would reverse the cancer-protective effect of VA derived from milk fat. Female Sprague-Dawley

rats (9 per diet) were injected with a single dose of carcinogen (methyl-nitrosourea), and fed one of 4 diets: 1) low VA, 2) low VA + SO, 3) high VA, and 4) high VA + SO. After 6 wk, the mammary glands were evaluated histologically for the appearance of premalignant lesions, and tissues analyzed for fatty acids. Total premalignant lesions were 83, 80, 43 and 68 for treatment 1, 2, 3 and 4, respectively (P<0.05). In the same order, the CLA concentrations (g/100g fatty acids) in the mammary fat pad were 2.13, 2.14, 4.75 and 2.98, while the VA concentrations were 0.54, 0.74, 4.89 and 8.20 (P<0.001). Thus the feeding of VA increased mammary tissue level of CLA and reduced the risk of developing premalignant lesions in the mammary gland. Treatment with SO reversed the effects of VA. It is most likely that the anticarcinogenic effect of VA is mediated through its conversion to CLA via Δ^9 -desaturase, and when this conversion is blocked by sterculic oil, the biological response to VA is altered.

Key Words: Vaccenic Acid, Conjugated Linoleic Acid, Mammary Cancer

790 Relationships between somatic cell count and bacterial infection in Italian buffaloes. P. Boettcher*¹, A. Stella², G. Pisoni³, C. Sgoifo Rossi³, R. Fedeli³, M. Rinaldi³, and P. Moroni³, ¹*IBBA-CNR, Seagrata, Italy*, ²*CERSA-FPTP, Seagrata, Italy*, ³*University of Milan, Italy*.

The objective of this study was to examine factors affecting somatic cell count (SCC) and bacterial infection in Italian buffaloes. The data used in the study were 1930 test-day records of SCC and bacterial presence in each of the four udder quarters of 48 buffalo cows in two Italian herds. Nearly 65% of the records showed presence of bacteria. Fourteen different species were observed. *Staphylococcus* species were the most commonly observed bacteria, detected in 47% of the samples. *Streptococcus uberis* was the next most common, observed in approximately 8% of the samples. Various linear mixed models were used to determine the statistical significance of the effects of various factors on SCC. For this analysis, SCC was transformed to somatic cell score (SCS) using the standard log 2 transformation. Fixed effects in the model included herd, parity number (1, 2, 3, 4, 5, and > 6), days in milk, location of the quarter (e.g. left-front, right-rear, etc.), and infection status. Infection status was defined in two different ways. In the first, two classes were established: 1) free from bacteria and 2) infected with any species. The second approach had four groups: 1) uninfected, 2) infected with *Strep uberis*, 3) infected with a *Staphylococcus* species, and 4) infected with any other species. Cow and quarter-nested-within-cow were random effects in the model. No significant difference in SCS was observed across herds. Mean SCS tended to increase with age up until third lactation, and then decreased during later lactations. Consistent with previous studies in other species, SCS tended to increase as lactation progressed. Significant differences in SCS were observed among the different quarters of the udder, as SCS was highest in the front-left quarter (mean = 3.16) and lowest in the right-rear quarter (mean = 2.22). When infection status was defined as "infected" or "healthy", SCS was slightly higher in infected quarters, but the difference was not significant. The analysis based on different bacterial groups indicated that only *Strep uberis* was associated with significantly (P #8804 0.0006) elevated levels of SCS (3.29 vs. 2.37) with respect to uninfected quarters.

Nonruminant Nutrition: Sow Feeding

791 A new sow model to study amino acid arterio-venous differences and uptake by the mammary gland before and after farrowing. Z. Mroz*¹, W. Krasucki², and S. J. Koopmans¹, ¹*Wageningen University and Research Centre, Division Nutrition and Food, Lelystad, The Netherlands*, ²*Agricultural University of Lublin, Poland*.

A new sow model was developed to study the post-absorptive kinetics of amino acids in the mammary gland during pre- and postfarrowing periods. For this purpose, six multiparous sows at late pregnancy were fitted with three blood catheters (*A. epigastrica cranialis superficialis*, *A. iliaca externa*, *V. epigastrica cranialis superficialis*) to measure: 1) arterio-venous differences (AVD), extraction rate (ER) and uptake

of essential amino acids in the mammary gland, and 2) blood acid-base characteristics as affected by two factors - sampling time (pre-prandial versus post-prandial) and phase of the reproductive cycle (pre- and post-farrowing). The AVD, ER and amino acid uptake in the mammary gland of sows as affected by the post-farrowing phase are presented in Table 1. In general, we found that this new sow model can be useful for studying dynamics of essential amino acids uptake for colostrum or milk synthesis. Also, the requirement of the mammary gland in pregnancy and lactation for specific amino acids can be estimated.

Amino acid arterio-venous differences (ADV), extraction rate (ER) and amino acid uptake in the mammary gland of sows as affected by the post-farrowing phase

Lactation day:	ADV ($\mu\text{mol/L}$)			ER (%)			Uptake (g/4 h)

792 Changes in composition in various body tissues in pregnant gilts and its nutritional implication. F. Ji^{*1}, G. Wu², J. R. Blanton Jr.¹, and S. W. Kim¹, ¹Texas Tech University, Lubbock, ²Texas A&M University, College Station.

Thirty-five gilts (158.2±3.8 kg) were randomly assigned to seven slaughter groups: d 0, d 45, d 60, d 75, d 90, d 102, d 112 and were fed 2 kg/d gestation diet (3.1 Mcal/kg ME and 0.56% lysine) until their slaughter. Soft tissue, gastrointestinal tract (GIT), liver, uterus, fetus, mammary gland, and remaining viscera (RV) were separated, weighed, ground, sampled, freeze dried, and chemically analyzed. Dry matter and crude fat contents in soft tissue increased linearly ($P<0.01$), whereas crude protein content in soft tissue increased cubically ($P<0.05$) during gestation. Dry matter, crude protein, and crude fat contents in uterus including placenta increased linearly ($P<0.01$) during gestation. Dry matter, crude protein, and crude fat contents in entire mammary gland increased quadratically ($P<0.01$) during gestation. Dry matter and crude fat contents in RV increased quadratically ($P<0.01$) during gestation. Dry matter, crude protein, and crude fat contents in fetal litter increased cubically ($P<0.01$) during gestation. Dry matter and crude protein contents in GIT decreased cubically ($P<0.01$) during gestation. Crude protein content in liver decreased linearly ($P<0.05$), whereas crude fat content increased quadratically ($P<0.01$) during gestation. Dry matter, crude protein, and crude fat contents in total increased quadratically ($P<0.01$) during gestation. The ADG of conceptus, fetal litter, individual fetus, entire mammary gland, and crude protein in fetal litter were significantly different before and after d 70 of gestation. The protein daily gain from all the maternal and fetal tissues was 40 g/d before d 70 of gestation and 103 g/d after d 70 of gestation suggesting that pregnant gilts may require different amounts of dietary protein during gestation. Considering the needs of maternal and fetal gains as well as maintenance, we suggest that the diet of pregnant gilts should provide 6.8 g/d (or 147 g/d) before d 70 and 15.3 g/d (or 330 g/d) after d 70 of gestation to support the accurate true ileal digestible lysine (or true ileal digestible protein) needs.

Key Words: Gestating Sows, Composition, Lysine Requirement

793 Ideal protein to improve lactation performance of primiparous sows. S. W. Kim^{*1}, F. Ji¹, and Y. G. Kim^{*2}, ¹Texas Tech University, Lubbock, ²CJ Corporation, Seoul, Korea.

The objective was to validate the ideal dietary amino acid pattern in lactation diets to improve the performance of primiparous sows during lactation. Twenty four primiparous sows (Camborough-22, PIC) and their litters were used for this study. On d 109 of gestation, sows were allotted to one of four dietary treatments representing: low protein (LC), low protein with ideal protein (LI), high protein (HC), and high protein with ideal protein (HI). Low protein diets contained 17.5% CP and high protein diets contained 19.5% CP. Ideal amino acid patterns among lysine, threonine, and valine were 100:63.0:78.1 for the LI diet and 100:62.3:77.5 for the HI diet when it was calculated based on ileal digestible amounts. To match amino acid pattern to ideal ratios, crystalline amino acids were supplemented. Crude protein content in the diets with ideal protein pattern were matched to the control diets by adjusting SBM content as crystalline amino acids were added. Weight and backfat thickness of sows as well as the weight of each piglet were measured at farrowing and weekly until weaning at d 21 of lactation. All sows had free access to feed and water during lactation. The body weight of sows after farrowing (207.5±7.6 kg) and litter size at farrowing (10.3±0.3 pigs) were the same ($P=0.361$ and 0.544, respectively)

among the treatments. Voluntary feed intake of sows (4.95±0.22 kg/d) did not differ ($P=0.879$) among the treatments. For the sows fed the low protein diets, there were no differences in weight loss and backfat loss during 21-d lactation between the LI and LC. However, litter weight gain of the LI was greater ($P<0.05$) than the LC. Litter size at weaning was greater ($P<0.05$) for the LI than the LC. For the sows fed the high protein diets, there were no differences in weight loss and backfat loss during 21-d lactation between the HI and HC. Litter size at weaning and litter weight gain were the same between the HI and HC. For all the sows, litter weight gain was improved ($P<0.05$) and litter mortality was reduced ($P<0.05$) whereas body weight loss was not affected ($P=0.841$) by the utilization of ideal protein.

Key Words: Lactation, Ideal Protein, Primiparous Sows

794 Supplementation of sow diets with a mixture of carvacrol, cinnamaldehyde and capsicum; effects on sow performance and piglet gut morphology. S. Illey^{*1}, H. Miller¹, and C. Kamei², ¹University of Leeds, Leeds, UK, ²AXISS France SAS, Bellegarde-sur-Valserine, France.

Many plant extracts contain bioactive compounds that can affect pig performance and health. This study investigated the effects of a combination of 5% carvacrol, 3% cinnamaldehyde and 2% capsicum oleoresin (XTRACT) on sow and piglet performance. Forty-four hybrid sows of mixed parity and fatness were housed in indoor farrowing crates from d107 of gestation to weaning. Sows were allocated, by parity, fatness and history, to one of 2 dietary treatments: Control (C) or XTRACT(XT, 100mg/kg feed). Diets were otherwise identical, with 14 MJ DE/kg and 1% lys. Before farrowing, sows received 2.5kg/d but were thereafter fed ad libitum with feed intake (FI) recorded daily. Piglet liveweight and sow P2 backfat were recorded and milk sampled at birth and d21. On d24 (weaning), 16 piglets per treatment were slaughtered. Data were analysed using the GLM procedure of Minitab 12.2. Sow FI was similar between treatments, however P2 backfat loss was lower in XT sows (0.98 v 2.1mm, $P<0.1$, SEM=0.5). Lactose levels in colostrum and milk were greater for XT sows (d 0: 2.8 v 2.4% $P<0.1$, SEM=0.1; d 21: 5.4 v 4.9% $P<0.01$, SEM=0.1) but fat and protein concentrations did not differ. Milk IgG was lower in XT sows (d0: 94 v 106mg/ml, $P<0.1$, SEM=5.9; d21: 0.65 v 0.72mg/ml, $P<0.1$, SEM=0.02). Piglet pre-weaning gain was not affected by sow treatment. However in the distal small intestine, villus height was greater in pigs suckling XT sows (413 v 312 μm , $P<0.05$, SEM=32) and villus-crypt surface area was higher (165 v 134 $\mu\text{m}^2 \times 10^3$, $P<0.1$, SEM=14). Reduced P2 loss in XT sows and increased milk lactose suggest an effect on nutrient partitioning. Lower milk IgG levels may indicate decreased immune stimulation due to reduced microbial challenge in XT sows. Changes in piglet gut morphology were not reflected in performance but may indicate a carry-over from sow to piglet in the XT group.

795 Comparison of ad-libitum and hand-fed sow lactation feeders. J. Peng^{*}, S. Somes, D. Kirkpatrick, A. Snedegar, and D. Rozeboom, Michigan State University, East Lansing.

A study was conducted to compare the performance of lactating multiparous sows when feed was made available to them using either a hand-fed (HF) or ad libitum (AL) feeder. Both feeders were made of stainless steel and mounted to the head-gates of individual farrowing crates. Sow head space was similar. The bottom of the HF feeder was rounded, whereas the bottom of the AL feeder included a flat surface area, located below a plastic hopper and sow-operated dispensing mechanism, and a shallow bowl area, located below a water nipple. Water for HF sows was provided using a nipple-cup combination independent of the feeder. Sows (n=120) were assigned to feeder treatment based on parity and breed, and moved into farrowing rooms within 7 d prior to parturition. Sows were fed a common lactation diet that met or exceeded NRC (1998) recommendations. Feed was manually added to the hoppers of AL feeders 1 to 2 times daily so that fresh feed was constantly available, while HF sows were fed to appetite (an amount slightly exceeding disappearance in previous meals), twice each day (800 and 1600 hr). A system for collection of wasted feed and water was installed under half of HF and AL farrowing crates which had individual water tanks for measuring water intake. Cross-fostering was used to standardize litter size at a minimum of 10 by d 3 of lactation. Average lactation length was 19.8 ± 0.2 d. Average daily feed disappearance (6.3 ± 0.3 vs. 5.9

± 0.3 kg) and litter wt gain from d 3 until weaning (42.7 ± 2.0 vs. 39.2 ± 2.2 kg) were greater (P < 0.01) with AL feeders than with HF feeders, respectively. Number of pigs weaned did not differ (P > 0.05, 9.7 ± 0.1). The AL sows tended to have greater (P = 0.07) wt gains during lactation (12.2 ± 3.1 vs. 8.2 ± 3.2 kg, AL and HF, respectively). Backfat change during lactation and wean-to-estrus interval did not differ (P > 0.05). Sows with AL feeders wasted less (P < 0.01) water than sows with HF feeders (12.7 ± 14.8 vs. 236.0 ± 20.7 kg, respectively), but water intake and feed waste was similar (P > 0.05). Sows given ad libitum access to feed during lactation responded with productivity.

Key Words: Sow, Lactation, Feeder

796 Interactive effects of milk supplementation, parity and season on preweaning mortality and growth performance of piglets on a commercial farm. B. W. Ratliff¹, A. M. Gaines¹, G. L. Allee¹, M. O'Brien², and J. A. Coalson², ¹University of Missouri, Columbia, ²Merrick's, Inc., Union Center, WI.

A total of 703 (Genetiporc) sows and 7,301 piglets (PIC 337 × Genetiporc) were used on a commercial farm to evaluate the interactive effects of milk supplementation, parity and season on piglet growth performance and pre-weaning mortality. Data were collected over a 12 month period. Sow diets were formulated to meet all minimal NRC requirements. Sows were grouped according to parity as follows: parity 1 =

group 1, parities 2 and 3 = group 2, and all parities greater than 3 = group 3. Litters from sows within the same group were randomly allotted to either milk or no milk treatments. At 48 h post parturition, milk supplementation was initiated and piglets were counted and weighed. All cross-fostering and litter processing occurred prior to 48 h. Mortalities, their weights, and date of occurrence were recorded daily for each litter. At d 14 to 18, each litter was weighed, counted, and weaned. Data indicated that milk supplementation increased (P < 0.05) number of pigs weaned, weaning weight and total litter gain (includes mortality weights), while lowering (P < 0.05) pre-weaning mortality. Parity groups 1 and 2 weaned more (P < 0.05) pigs per sow and had lower (P < 0.05) pre-weaning piglet mortality than parity group 3. Furthermore, parity groups 1 and 3 had lighter (P < 0.05) weaning weights, piglet average daily gains and total litter gains than parity group 2. Warm season decreased (P < 0.03) piglet average daily gain. Treatment by parity group interactions (P < 0.05) were present for number of pigs weaned, litter weaning weight, pre-weaning mortality and total litter gain, with milk supplementation being most beneficial for parity group 2 and 3 sows. Milk supplementation did not affect (P > 0.05) any parameters measured in parity group 1 sows. Collectively, these data indicate that milk supplementation will improve litter growth performance and decrease pre-weaning mortality in parity 2+ sows.

Key Words: Milk Supplement, Piglets, Sows

Production, Management and the Environment: Nutritional Management

797 Blood metabolites during the transition period of Holstein cows receiving a monensin controlled-release capsule. P. Melendez^{*1}, J. Goff³, C. Risco¹, L. Archbald¹, R. Littell², and A. Donovan¹, ¹College of Veterinary Medicine, University of Florida, Gainesville, ²Institute of Food and Agricultural Sciences, University of Florida, Gainesville, ³National Animal Research Center, USDA, Ames, IA.

Monensin increases the rumen molar proportion of propionate. This change might affect energy metabolic dynamics in transition dairy cows. The objective of this study was to determine the effect of a rumen monensin-controlled release capsule inserted at dry-off on energy blood metabolites in Florida transition cows fed diets containing citrus pulp. The study was conducted on a Holstein farm with 3600 milking cows in north central Florida, with a RHA of 10,700 kg. Cows were housed in a dry-lot system and fed the same TMR 3X. In March, 2002, 24 cows dried-off 50 to 70 d before expected parturition (BEP) were randomly assigned either a treatment or a control group. The treated group (n=12) received orally a capsule of monensin (300 mg/d for 95 d, CRC Rumensin[®]). Control cows (no capsule, n=12) were randomly matched by parity. At assignment, on day 21 BEP, at calving, and at 7, 14, and 21 d postpartum (pp) a blood sample was obtained from the coccygeal vein and body condition scoring (BCS) was conducted (scale 1-5). Serum non-esterified fatty acids (NEFA), beta-hydroxy butyrate (BHB) and glucose were measured. Metabolites were analyzed by ANOVA, mixed model for repeated measures. BCS changed over time, and treatment increased BCS significantly in multiparous cows at calving (P ≤ 0.01). BHB was lower in treated primiparous cows at calving (0.52 ± 0.2 vs 0.90 ± 0.1 mmol/L) (P ≤ 0.1) and 14 d pp (0.36 ± 0.2 vs 0.90 ± 0.1 mmol/L) (P ≤ 0.05) and NEFA were lower in treated primiparous cows at 7 d pp (0.78 ± 0.3 vs 1.42 ± 0.2 meq/L) (P ≤ 0.05) and 14 d pp (0.44 ± 0.3 vs 0.91 ± 0.2 meq/L) (P ≤ 0.1). Independent of treatment, NEFA, BHB and glucose increased dramatically at 21 d BEP, indicating that cows around 3 wks prepartum started to change their metabolic status. It was concluded that transition primiparous cows under the influence of monensin and fed a TMR containing citrus pulp had lower levels of BHB, and NEFA at certain times of the transition period. BCS at calving was significantly higher in multiparous treated cows.

Key Words: Monensin, Blood Metabolites, Transition Dairy Cow

798 Rumen and blood metabolites at 10 d postpartum in Holstein cows supplemented with monensin. P. Melendez^{*1}, J. Goff², C. Risco¹, L. Archbald¹, R. Littell³, and A. Donovan¹, ¹College of Veterinary Medicine, University of Florida, Gainesville, ²National Animal Research Center, USDA, Ames, IA, ³Institute of Food and Agricultural Sciences, Gainesville, FL.

The objective was to assess the effect of a monensin controlled-release capsule inserted at dry-off on rumen and energy blood metabolites at 10 d postpartum (pp) in transition cows fed Florida typical diets. The study was conducted on a Holstein dairy with a RHA of 10,700 kg. In March, 2002, 24 cows were randomly assigned at dry-off to 2 groups. Treated cows (n=12) received an oral capsule of monensin (300 mg/d for 95 d, CRC Rumensin). Control cows (n=12) were not treated and matched by parity. At 10 d pp a rumen and blood sample was obtained at 7 A.M. before the first meal. Other samples were taken at 2, 4 and 6 h after feeding (AF). Rumen sample was taken by an orominal tube. Rumen pH was measured immediately after sampling. Serum non-esterified fatty acids (NEFA), beta-hydroxy butyrate (BHB) and glucose were measured by enzymatic colorimetric methods. Rumen samples were analyzed for concentration of VFA, lactic acid and NH3. Variables were analyzed by ANOVA, mixed models for repeated measures. Primiparous controls tended to have lower rumen pH at 4 h AF than treated cows (6.34 vs 6.62) (P ≤ 0.10). Multiparous treated cows tended to have lower NH3 at 4 h AF (4.28 vs 5.01 mmol/L) (P ≤ 0.10) and had significantly lower NH3 at 6 h AF (2.8 vs 4.01 mmol/L) (P ≤ 0.05) than controls. In treated primiparous, BHB tended to be lower at 2 h AF (0.65 vs 1.0 mmol/L) and 6 h AF (0.71 vs 0.99 mmol/L) (P ≤ 0.1) and was lower at 4 h AF (0.57 vs 1.0 mmol/L) (P ≤ 0.05) than controls. NEFA tended to be lower at time 0 (0.82 vs 1.14 meq/L) (P < 0.1) and glucose tended to be higher at 2 h AF (54.4 vs 45.9 mg/dL) (P ≤ 0.1) in treated than controls. In treated multiparous cows, BHB tended to be lower at 4 h AF (0.77 vs 1.05 mmol/L) (P ≤ 0.1) and was lower at 6 h AF (0.82 vs 1.18 mmol/L) (P ≤ 0.05) than controls. NEFA were lower at 2 h AF in treated than controls (0.59 vs 0.92 meq/L) (P ≤ 0.05). Glucose tended to be higher at 2 h AF in treated than controls (51.2 vs 46.3 mg/dL) (P ≤ 0.1) It was concluded that transition cows under monensin had improved energy status within 6 h AF.

Key Words: Monensin, VFA, Transition Dairy Cow

799 Warm-season baleage crops for mid-lactation Holstein cows. M. E. McCormick^{*}, Southeast Research Station, Louisiana State University, Franklinton.

Conserving forage as baleage is becoming widely accepted by Louisiana dairymen. In the present study, production-scale pastures of bermudagrass (*Cynodon dactylon*, L.), signalgrass (*Brachiaria decumbens*, S.)

and forage sorghum (*Sorghum bicolor*, L.) were used to evaluate the effect of forage type on nutrient composition and feeding value of crops conserved as baleage. Annual ryegrass (*Lolium multiflorum*, L.) served as a positive control. Forages were cut, windrow-wilted for 24-48 h, baled, and wrapped with white stretch film. Following a six-month storage period, baleages were fed to forty multiparous, midlactation Holstein cows (30.1 ± 3.2 kg FCM, 181 ± 32 DIM) in a 42-d randomized block design feeding trial. Forages were individually fed (Calan Gate barn) ad libitum and concentrates (6.1 kg DM/feeding) were fed immediately prior to a.m. and p.m. milkings. Milk weights were recorded at each milking, milk samples were collected weekly for compositional analyses, and body weight/condition scores were measured weekly. Signalgrass ADF and NDF concentrations were lower and in vitro digestibility was higher than those recorded for either bermudagrass or sorghum baleages. Protein concentrations were higher for signalgrass and ryegrass than either bermudagrass or sorghum baleages (16.9 and 16.0% vs 13.1 and 13.4%, respectively). Sorghum baleage intake was lower ($P < 0.05$) than that recorded for ryegrass, signalgrass, and bermudagrass (8.3, 9.6, 10.7, and 12.3 kg DM/d, respectively). Actual milk (kg/d), FCM (kg/d), and % milk fat were 27.5, 27.3, 3.58; 28.0, 26.9, 3.31; 28.7, 28.7, 3.52; and 29.9, 29.7, 3.37 for bermudagrass, sorghum, signalgrass, and ryegrass baleages, respectively. Other animal measurements such as body weight (avg. = 664 kg), condition score (avg. = 2.64), and rumen pH (avg. = 6.28) did not differ with forage type. Under management conditions employed in this study, signalgrass nutrient composition and feeding value were similar to annual ryegrass. Sorghum and bermudagrass baleages tended ($P < 0.10$) to have inferior nutrient composition and produce less milk than either signalgrass or ryegrass baleage crops.

Key Words: Baleage, Feeding Trial, Milk Production

800 Evaluating the distribution of fatty acids in the middle and outer layer of market pigs challenged with conjugated linoleic acid. A. Cox*, A. Schinckel, B. Richert, and M. Latour, *Purdue University, West Lafayette, IN.*

A study was conducted to investigate the ability of conjugated linoleic acid (CLA) to alter pig fatty acid distribution within the middle and outer backfat layers during the last 14 and 28 days of the finishing period. Forty-two barrows from a single source were used. Six pigs were slaughtered upon arrival to obtain baseline data. The remaining thirty-six pigs were individually penned and then equally and randomly assigned to control, 0.5% CLA or 1.0% CLA. Eighteen pigs (six per treatment) were sampled on each sampling day. Regardless of layer, there were significant ($P < 0.05$) treatment differences in the percentage of C14:0, C16:0, C16:1, C18:0, C18:1, C18:2, C18:2 9-11, C18:2 10-12, C20:1, C20:4, and C20:5. Both levels of dietary CLA decreased the levels of unsaturated fatty acids compared to control. Conversely, the pigs fed CLA exhibited an overall higher percentages of saturated fatty acids compared to control pigs. Regardless of treatment, significant ($P < 0.05$) differences were observed between the middle and outer backfat layers. The percentage of C16:1, C18:1, and C18:2 were significantly higher ($P < 0.05$) in the outer layer, compared to the middle layer. However, the levels of C18:0 and C20:0 were significantly ($P < 0.05$) higher in the middle layer compared to the outer layer. These data indicate that dietary CLA can alter the fatty acid composition of fat, whereas the differences between layers tends is relatively unaffected by the dietary treatments imposed.

Key Words: Swine, CLA, Fatty Acids

801 Effect of feeding a low nutrient excretion diet on pig growth performance and carcass characteristics in a commercial wean-finish setting. R. B. Hinson*, M. C. Walsh, D. M. Sholly, S. A. Trapp, D. T. Kelly, J. S. Radcliffe, A. L. Sutton, A. P. Schinckel, and B. T. Richert, *Purdue University, West Lafayette, IN.*

Two hundred fifty-six pigs (Initial BW = 25.8 kg) were randomly selected within four 1,000 hd commercial wean-finish swine buildings to determine the effects of feeding a control (CTL) corn-SBM based diet or a low nutrient excretion (LNE) diet, with synthetic amino acids and phytase, on grow-finish (G-F) pig growth, carcass characteristics, and live ultrasound backfat (BF) and loin eye area (LEA). Two barns were fed CTL diets and two fed LNE diets. Six phases of each trt were fed during the G-F period. Thirty-two pigs/sex/barn had individual BW and ultrasound measurements recorded at 3 wk intervals. After 15 wk

on test, 10 pigs/sex/barn were harvested to determine carcass characteristics. Initial BW differed ($P < .01$) between CTL and LNE (24.6 vs. 26.9 kg) and barrows and gilts (24.9 vs. 26.7 kg). ADG for grower (wk 0-9), finisher (wk 9-15), and overall (wk 0-15; 861 vs. 807 g/d) were higher ($P < .01$) for CTL vs. LNE. Barrows had greater overall ADG ($P < .05$; 853 vs. 815 g/d) than gilts. For finisher ADG gilts grew 7 g/d slower than barrows when fed CTL diets, but had 84 g/d lower ADG when fed LNE diets ($P < .05$). Wk 15 LEA and LEA change (31.10 vs. 27.35 cm²) were higher ($P < .001$) for CTL vs. LNE. Final 10th rib (8.8 vs. 6.7 mm) and last rib ultrasound BF change was higher ($P < .05$) for barrows vs. gilts, while LEA change was not different ($P > .50$). Carcass last rib BF (23.7 vs. 21.4 mm), and loin eye color (2.61 vs. 2.44) and firmness (2.94 vs. 2.75) were different ($P < .04$) for CTL and LNE, respectively. Carcass 10th rib (18.6 vs. 14.5 mm), last rib, and last lumbar BF, LEA (42.5 vs. 46.0 cm²), and predicted fat free lean (46.68 vs. 48.42%) were different ($P < .05$) between barrows and gilts, respectively. In a commercial setting with significant disease pressure, feeding a LNE diet did not maintain growth performance compared to a standard corn-SBM diet. However, ribbed carcass characteristics were similar between the LNE and CTL diets.

Key Words: Pigs, Reduced Crude Protein, Growth

802 Finishing steer performance on diets with added vegetable oil. G. M. Hill*¹, S. K. Duckett², J. F. Baker¹, E. Paven², and B. G. Mullinix¹, ¹*University of Georgia, Tifton*, ²*University of Georgia, Athens.*

Effects of adding no vegetable oil (Control), low oil (LO, 4.7 % of DMI), or high oil (HO, 7% of DMI) on steer performance during the last 57 d of a 100-d steer finishing experiment were determined. Steers (n=40; 4 Polled Hereford, 3 Simmental X Angus, 33 Angus; initial BW 435.2 ± 27.8 kg) were randomly assigned to six pens and three treatments and implanted with Synovex-S[®] on d 1. Diets contained corn silage (CS; 41% DM, 8.6% CP) and a concentrate mixture (CM; 89.1% DM, 13.72% CP; 88.1% dry rolled corn, 10.0% soybean meal, 1.9% vitamin/mineral premix; Rumensin[®] at 33 mg/kg CM). A total mixed ration consisted of CM and CS was fed free-choice, with CS fed at 24.4% and 20.6% of dietary DM, respectively, during the preliminary period (B4O; d 1 to d 43), and when oil was fed (WO; d 43 to d 100). Steer rib fat (RF, cm) was measured using ultrasound on d 2 and d 100, and RF (Table) with initial BW as a covariate was not affected by treatments ($P < 0.22$). Steer least square means for ADG B4O with initial BW as a covariate were similar for treatments, but ADG WO and ADG 100 d were lower than Control ($P < 0.08$) using ADG B4O (mean 1.87 kg) as a covariate. The DMI decreased for HO during WO ($P < 0.06$) and for the 100-d experiment ($P < 0.02$), and DM/gain tended to increase for HO during WO ($P < 0.08$) and for the 100-d experiment. Feeding oil tended to reduce steer performance, with the greatest reductions occurring on the HO treatment.

Item	Control	LO	HO	SE	P
ADG, kg B4O	1.71	2.00	1.89	0.13	0.43
DMI, kg B4O	9.32	10.22	9.37	0.16	0.10
DM/gain B4O	5.50	5.12	5.49	0.34	0.61
RF, cm D 2	1.35	1.17	1.37	0.12	0.37
ADG, kg WO	1.95	1.82	1.12	0.19	0.08
DMI, kg WO	10.26	11.88	8.97	0.34	0.06
DM/gain WO	5.38	6.53	8.22	0.40	0.08
ADG, kg 100d	1.92	1.84	1.44	0.11	0.08
DMI, kg 100d	10.28	11.16	9.10	0.12	0.02
DM/gain 100 d	5.66	5.88	6.32	0.17	0.20
RF, cm 100d	3.86	3.22	3.15	0.29	0.23

Key Words: Steer, Gain, Oil

803 Effect of oil supplementation to finishing cattle on carcass quality and subcutaneous fat composition. E. Pavan*¹, S. Duckett¹, and G. Hill², ¹*The University of Georgia, Athens*, ²*The University of Georgia, Tifton.*

Forty steers (4 Polled Hereford, 4 Simmental x Angus, 32 Angus) were used to study the effect of adding no vegetable oil (NO), low oil (LO, 4.7% of DMI), or high oil (HO, 7% of DMI) during the last 57 d of the finishing period on carcass traits and fatty acid (FA) composition.

The basal diet consisted of 20.6% corn silage and 79.4% concentrate mix (88.1% corn, 10% soybean meal). Carcass data was collected at 24 h postmortem and carcass value calculated based on current grid prices. Fatty acid composition was determined from subcutaneous (SC) fat by GLC. Carcass weight was higher for NO and LO than for HO (360, 362 and 334 kg, respectively; SE= 5.3; P=0.05). Neither kidney-pelvic-heart fat (2.7± 0.1% of carcass weight), nor SC fat thickness (1.42± 0.07 cm), intramuscular fat (587± 17 marbling score; 500= small), or ribeye area (79± 1.6 cm²) were affected by oil level. Both yield (3.5± 0.1) and quality grades (5.3± 0.2; 5= choice-) were similar between treatments. The product value per kg (3.61± 0.04), and the total carcass value (2795± 48) were not affected by level of oil. However, SC fatty acid composition (% of total FA) was changed by the level of oil supplied. While total monounsaturated FA decreased by oil supplementation (P<0.01), total trans-octadecanoic acids increased (P<0.01) and PUFA tended to increase (P=0.06) when oil was added. This was mainly due to reductions of oleic acid concentration and increases in the concentration of trans-10 octadecanoic, linoleic acid and total conjugated linoleic acid (CLA; P<0.01). The ratio of n6:n3 was increased by oil supplementation (NO: 4.4 and 5.5 for oil treatments; SE= 0.15; P<0.01). The t10c12 isomer of CLA increased linearly with the addition of oil (HO: 0.01, LO: 0.05 and HO: 0.07%; SE= 0.003; P<0.01); whereas c9t11 was higher in HO (0.59%), but lower in LO (0.39%; SE= 0.02; P<0.01). Supplementing various levels of vegetable oil to high concentrate diets did not alter carcass quality but increased linoleic, trans-10 octadecanoic, and conjugated linoleic acids in subcutaneous adipose tissue.

Key Words: Beef, Carcass Quality, Fatty acids

804 Effects of supplement type on growth and pregnancy rate of yearling, Brahman-crossbred heifers. J. D. Arthington^{*1}, G. C. Lamb², and F. M. Pate¹, ¹Range Cattle Research and Education Center, University of Florida, Ona, ²North Central Experiment Station, University of Minnesota, Grand Rapids.

The effects of winter supplement type on growth and pregnancy rate of fall-born, yearling heifers was investigated over 2 consecutive yr. During both years, heifers were stratified by breed (Braford and Brangus-crossbred) and BW and randomly assigned to one of two treatments consisting of (1) wheat middling-based range cube, or (2) molasses-cottonseed meal slurry (n = 34 and 24 heifers/treatment for yr 1 and 2, respectively). Supplements were fed at rates to achieve a target of 1.47 and 0.34 kg of supplemental TDN and CP daily, respectively. Four limpograss (*Hemarthria altissima*) pastures were utilized each year (n = 2 pastures/treatment; 0.71 and 0.51 ha/heifer for yr 1 and 2, respectively). All heifers were allowed free-choice access to stargrass (*Cynodon nlemfuensis*) hay during periods of limited pasture forage availability. During a 70-d breeding season, heifers were combined by group and exposed to mature Angus bulls. Bulls were rotated among pastures each week. Individual heifer BW and hip height were collected at the start of supplementation and at the start and end of the breeding season. Pregnancy rate was determined by transrectal ultrasonography in late April of each year (minimum of 40 d after the end of breeding). There were no treatment x year, breed x treatment, or breed x year interactions for heifer ADG (P > 0.10). Supplement type did not affect heifer ADG (0.44 and 0.47 kg/d for molasses-slurry and range cubes, respectively). Heifers consuming molasses-slurry had a greater (P < 0.01) overall pregnancy rate compared to heifers consuming range cubes (76.3 vs 49.2% pregnant). Irrespective of treatment, Brangus-crossbred heifers had a greater pregnancy rate (P < 0.01) than Braford heifers (73.2 vs 46.8%). These data indicate that yearling heifers, supplemented with molasses-cottonseed meal slurry, may have increased pregnancy rates compared to heifers supplemented with a wheat middling-based range cube. This response appears to be independent of heifer ADG.

Key Words: Heifer, Molasses, Wheat Middling

805 Effects of supplemental yeast fermentation product on early-weaned calf performance while grazing winter ryegrass summer stargrass pastures in Florida. J. D. Arthington¹, S. Galindo-Gonzalez^{*1}, J. M. B. Vendramini^{1,2}, R. S. Kalmbacher¹, P. Mislevy¹, L. E. Sollenberger², and I. Yoon³, ¹Range Cattle Research and Education Center, University of Florida, Ona, ²Department of Agronomy, University of Florida, Gainesville, ³Diamond V, Cedar Rapids, IA.

The objective of this study was to investigate the effectiveness of a supplemental yeast fermentation product (YFP) on the performance of early weaned calves grazing winter annual ryegrass (*Lolium multiflorum*, 112 d) followed by summer perennial stargrass (*Cynodon* spp., 112 d) in Florida. Ryegrass was seeded at a rate of 16.8 kg/ha in early November, and provided three applications of fertilizer (336 kg/ha; 16-4-16, plus micronutrients). Established stargrass pastures were provided an initial fertilizer application (March; 336 kg/ha, 0-10-20, plus micronutrients) followed by three applications of N (56 kg/ha) during the summer grazing period. Twenty-four calves were early weaned from primiparous cows (66 ± 11 d of age) and randomly allotted to one of eight groups (0.30 and 1.0 ha/calf for ryegrass and stargrass, respectively). All calves received supplemental feed (14 and 75% CP and TDN, respectively) at a rate of 1.0% BW daily. Two treatments were randomly allocated to calf groups (4 groups/treatment) consisting of, 1) commercial yeast fermentation product (YFP, 28 g/d; Diamond V Mills, Cedar Rapids, IA), or 2) a blended corn soybean meal Control. Average available forage did not differ among treatments (P > 0.40), but was greater (P < 0.01) for stargrass compared to ryegrass (0.92 and 6.11 tons DM/ha for ryegrass and stargrass, respectively; SEM = 0.09 and 0.22). Average forage DM digestibility did not differ among treatments (P > 0.26), but was lesser (P < 0.01) for stargrass compared to ryegrass (in vitro organic matter digestibility = 85.1 and 52.9% for ryegrass and stargrass, respectively; SEM = 1.15 and 1.45). Supplementation of YFP did not affect (P = 0.39) calf ADG during ryegrass grazing (0.88 and 0.83 kg/d for Control and YFP, respectively; SEM = 0.04), or during stargrass grazing (P = 0.12) (0.64 and 0.57 kg/d for Control and YFP, respectively; SEM = 0.03). These data suggest that under the grazing management systems used in this study, supplemental yeast fermentation product was ineffective for improving growth performance of grazing early-weaned calves.

Key Words: Calves, Weaning, Ryegrass

806 Response of cow/calf pairs grazing fescue and individually-supplemented with gradient levels of FEB-200TM. D. K. Aaron^{*1}, D. G. Ely¹, J. Wyles¹, and V. Akay², ¹University of Kentucky, Lexington, ²Alltech, Inc..

Angus x Beefmaster cow/calf pairs grazed endophyte-infected (> 90%) KY 31 tall fescue and were supplemented with 0, 10, 20, or 40 g·hd⁻¹·d⁻¹ of FEB-200TM (modified glucomannan, Alltech, Inc., Nicholasville, KY) carried in 0.45 kg ground shelled corn beginning May 6. Cattle were managed in eight pastures (two pastures/supplement level) stocked with 10 to 16 cow/calf pairs until July 15 at which time 20 predesignated cow-calf pairs were allotted to individual 1.6-ha plots of equivalent pasture. Cows continued their respective supplement regimes from this date until calves were weaned October 28. Cow weight changes from May 6 to July 15 were -40, -26, 3, and -23 kg/hd (Quadratic; P < 0.01) and 56, 45, 34, and 67 kg/hd (Quadratic; P < 0.01) from July 15 to October 28 for the 0, 10, 20, and 40 g/d supplement levels. Total cow gains from May 6 to October 28 increased linearly (P < 0.05) as level of supplementation increased. No differences were found for calf gains from May 6 to July 15, but calves gained 87, 96, 107, and 106 kg/hd (Linear; P = 0.12) from July 15 to October 28. A similar linear trend was found for overall calf gains (138, 155, 171, and 172 kg/hd; NS). Tympanic temperatures, monitored at 30-min intervals from July 21 through 24, averaged 38.4, 38.4, 38.3, and 38.5 °C (Quadratic; P = 0.10). Average tympanic temperatures measured from August 22 through 25 were not significantly affected by supplement level. Absence of a greater supplementation effect on deep body temperature may be a result of cool ambient temperatures during the measurement periods (avg. 24 °C). Overall, these results show supplementation with 40 g·hd⁻¹·d⁻¹ of FEB-200TM can increase production of cows and calves grazing endophyte-infected tall fescue.

Key Words: Fescue, Production, Cows

807 Response of cows and calves to gradient levels of a supplemented modified glucomannan when grazing tall fescue. D. G. Ely^{*1}, D. K. Aaron¹, J. Wyles¹, and V. Akay², ¹University of Kentucky, Lexington, ²Alltech, Inc..

Eighty-four Angus x Beefmaster cow/calf pairs were randomly allotted to eight, 10.5-ha, endophyte-infected (>90%) tall fescue pastures on May 6. The objective was to determine production responses to a daily supplement of 0, 10, 20, or 40g FEB-200(tm) (modified glucomannan, Alltech, Inc., Nicholasville, KY) carried in 0.45 kg/hd ground shelled corn (group-fed) until calves were weaned on October 28. Cows averaged 5.4 yr, 500 kg, and 5.6 body condition score (BCS) on May 6. Initially, calves averaged 109 kg at 74 d of age. Interim weights, BCS, and rectal temperatures of cows and weights of calves were taken at 35-d intervals. Cows in 0, 10, 20, and 40 g treatments lost 12, 16, 10, and 4 kg/hd (Linear, $P < 0.10$), respectively, from May 6 to July 15, but gained 44, 36, 49, and 52 kg/hd from July 15 to October 28. Total gain (May 6 to October 28) increased linearly ($P < 0.01$) as level of supplementation increased. Period BCS changes were nonsignificant, but overall BCS (May 6 to October 28) increased linearly ($P = 0.06$) as level of FEB increased. Rectal temperature change from May 6 to October 28 was greatest for 0 and least for 40 g FEBhd⁻¹d⁻¹ (Linear, $P < 0.01$). Calf gains were 63, 56, 57, and 65 (Quadratic, $P < 0.10$) from May 6 to July 15 and 98, 91, 92, and 99 kg/hd (NS) from July 15 to October 28. Overall calf gain response was quadratic ($P = 0.07$). Tympanic temperatures, monitored at 30-min intervals from July 21 through 24 in two pre-designated cows per pasture, were 38.5, 38.2, 38.6, and 38.4 °C (Cubic, $P = 0.08$) for 0, 10, 20, and 40 g FEB. Temperatures of the same cows, measured from August 22 through 25, were 38.7, 38.2, 38.3, and 38.4 °C (Quadratic, $P < 0.05$). These results demonstrate weight gains of cow/calf pairs grazing endophyte-infected fescue can be increased by supplementing with 40 g FEBhd⁻¹d⁻¹ even though body temperatures are not decreased.

808 Birth season, preweaning stocking rates and sex effects on birth-to-harvest growth and carcass composition of Simmental-sired calves. F. M. Rouquette^{*1}, G. Estefan², J. W. Turner², and D. P. Hutcheson³, ¹Texas Agricultural Experiment Station, Overton, ²Texas A&M University, College Station, ³Texas Agricultural Experiment Station, Amarillo.

Growth and carcass data were collected during a 5-year period from 375 fall-born and 160 winter-born $\frac{1}{2}$ Simmental x Hereford x Brahman calves reared at TAMU-Overton to quantify effects of birth season (fall vs. winter), preweaning stocking rates, sex of calf, backgrounding method and feedlot performance on calf performance from birth-to-harvest and carcass characteristics. Calves were grazed at 3 levels of forage mass (stocking rates, SR) preweaning and then sent directly to feedlot or backgrounded on either bermudagrass or rye-ryegrass pasture before entering the feedlot. All calves were fed in Pinpointers at TAMU-Amarillo prior to being harvested at a commercial packing facility. Fall-born calves grazed on low SR weaned heaviest, 305 kg, and winter-born calves grazed on high SR weaned lightest at 216 kg ($P < .05$). Differences in weaning weights between steers and heifers were greater

for fall-born (291 vs. 278 kg) than for winter-born calves (251 vs. 244 kg). Calves grazed at high SR pre-weaning exhibited compensatory gains during the stocker, backgrounding phase ($P < .01$); however feedlot ADG, gain:feed, average daily intake, and final weight of calves were not affected by preweaning SR. At termination of the backgrounding phase, winter-born calves entered the feedlot heavier (424 vs. 334 kg) and older (16 vs. 12 mos) than fall-born calves ($P < .01$). Cattle were harvested at a relatively uniform, visual backfat and thus, no major differences in carcass traits were detected due to pre-or post-weaning management. When finished to a visual backfat of $>.76$ and <1.27 cm, 65% of cattle graded USDA Select with an average USDA Yield Grade of 1.9. This sire-dam combination resulted in good growth rate of calves with high cutability and lean carcasses.

Key Words: Pasture, Stocking Rate, Cow-Calf

809 Performance of early-weaned calves grazing Tifton 85 bermudagrass and receiving three levels of supplemental concentrate. J. M. B. Vendramini^{*1,2}, L. E. Sollenberger¹, J. D. Arthington², J. B. Dubeux, Jr.¹, and S. M. Interrante¹, ¹Department of Agronomy, University of Florida, Gainesville, ²Range Cattle Research and Education Center, University of Florida, Ona.

Early weaning of calves may increase pregnancy rates of primiparous beef cows, however, there is a relatively little information on nutritional management of the early-weaned calf. The objective of this study was to evaluate the performance of early-weaned calves grazing Tifton 85 bermudagrass (*Cynodon* sp.) pastures and receiving three levels of concentrate. Calves were weaned on 6 Jan. 2003 at an average age of 84 d. They grazed annual ryegrass (*Lolium multiflorum*)-rye (*Secale cereale*) mixtures pastures until 14 May 2003, when they were moved to experimental pastures where they remained until 13 Aug. 2003. Three levels of supplementation (1.0, 1.5, and 2.0% BW; 14 and 72% CP and TDN, respectively) were evaluated in a completely randomized design. Experimental units were 0.15-ha pastures, each divided into three paddocks for rotational stocking (7-d grazing and 14-d rest period). Two calves were assigned as testers to each pasture, and additional animals were used to maintain a similar herbage allowance. Every 21 d, calves were weighed and grazing time during daylight was recorded. Herbage mass was measured every 21 d using the disk plate meter methodology. Hand-plucked samples were collected every 21 days and were analyzed for CP and in vitro OM digestibility. Calf ADG (0.54-0.72 kg), stocking rate (10.6-14.2 AU/ha) (AU = 500kg LW), and gain per hectare (1100-1780 kg) increased linearly ($P < 0.10$) as supplementation rate increased. There was no variation ($P > 0.10$) in forage CP and in vitro OM digestibility among treatments but there was a linear decrease ($P < 0.01$) in herbage allowance as supplementation rate increased. Average grazing time decreased linearly ($P < 0.05$) from 274 to 206 min/d as supplementation rate increased from 1.0 to 2.0%. Based on our initial studies, increasing the amount of supplement fed to early-weaned calves increases animal performance and pasture stocking rate, but the economics of its use depend upon supplement cost and calf prices.

PSA-Nutrition: Amino Acids

810 Comparison of methionine sources based on an equimolar trial design with broiler chickens in Brazil. S. Vieira¹, D. Hoehler^{*2}, A. Lemme², A. Kessler¹, S. Pophal¹, A. Ebert¹, and G. Eichner¹, ¹Federal University of Rio Grande del Sul, Brazil, ²Degussa Corporation, Kennesaw, GA.

Methionine is the first limiting amino acid in commercial poultry diets and is commonly supplemented as DL-methionine (DL-Met, 99%) or liquid DL-methionine hydroxy analog-free acid (MHA-FA, containing 88% of active substance). Some controversy still exists about the proper trial design and statistics which should be applied in trials comparing the two sources. In the present trial, 2730 male day-old Ross 308 broilers were fed a commercial starter diet until day 6. From day 7 to 40, chicks

were assigned to 13 dietary treatments housed in floor pens receiving corn/soybean-based diets supplemented with DL-Met (0.030 / 0.06 / 0.10 / 0.14 / 0.19 / 0.24%) or equimolar levels of liquid MHA-FA (0.034 / 0.068 / 0.114 / 0.159 / 0.216 / 0.273%) in the starter (day 7-21) and grower (day 22-40) period. Basal diets were formulated to be deficient in Met but adequate in all other nutrients and energy. Each dietary treatment consisted of 6 replicates with 35 birds per pen. Broilers performed well, maximum responses of weight gain, feed conversion, and breast meat yield (% of carcass) were significantly improved by about 10% to maximum responses of 2417 g, 1.613, and 28.5%, respectively. Responses showed the Met deficiency of the basal diets. Exponential regression revealed a relative effectiveness on equimolar basis of liquid MHA-FA for weight gain, feed conversion, and breast meat yield from

7 to 40 days of age of 59% (significant), 93% (not significant), and 64% (significant), respectively. These figures correspond to relative effectiveness figures of liquid MHA-FA on a weight/weight basis of 52%, 82% and 56%, respectively. The present data agree with numerous recent data as well as with an extensive recent literature survey for broilers, which resulted in a recommended relative bioefficacy figure of 67.8% on a weight/weight basis for liquid MHA-FA for performance criteria in broiler chickens. The data also demonstrate that the trial design - weight/weight or equimolar comparison of the two methionine sources - does not affect the validity of the test.

Key Words: Broilers, Amino Acids, Methionine Sources

811 Very young turkeys utilize 2-hydroxy-4-(methylthio) butanoic acid (HMTBA) effectively as a methionine (M) source. R. Gonzalez-Esquerria, M. Vazquez-Añon, T. Hampton, T. W. York, C. W. Wuelling, and C. D. Knight, *Novus International, Inc., St. Charles, MO.*

The relative efficacy of an 88% aqueous solution of HMTBA (Alimet feed supplement, Novus International, Inc.) vs. d, l-methionine (DLM; dry 99%) as a M source was estimated in very young turkeys using a 2 x 4 factorial with a basal treatment design. A basal sorghum/soy diet deficient in M but adequate in all other nutrients was added HMTBA or DLM at various equimolar levels (0.00, 0.05, 0.10, 0.15 and 0.20 %). Each diet was fed to 8 cages of 12 BUT toms from 1 to 21 days of age. Performance was measured at 7, 14 and 21d of age. A positive response to added M source on body weight gain (BWG) and feed conversion was observed for all ages ($P < 0.01$) proving the basal diet was deficient in M. Changes in BWG closely followed those in feed intake. Performance parameters were not different between M sources at any level ($P > 0.1$). To estimate the relative efficacy of HMTBA vs DLM, BWG per data were plotted versus supplemented M intake or M level using linear regression (LIN) or fitting separate exponential curves for each source of M (EXPI). The goodness of fit of each model was tested using the Schwarz Bayesian (BIC) and the Akaike (AIC) Information Criteria. Better goodness of fit was obtained by using M intake rather than M level at all ages and for both LIN and EXPI models. Relative efficacy obtained by using M intake was 113 ± 24 , 94 ± 17 , and $99 \pm 18\%$ for LIN, and from 113 to 114%, 93 to 94%, and 99 to 100 % for EXPI for toms at 7, 14 and 21d, respectively. An improvement in the goodness of fit was obtained when using LIN rather than EXPI. It is concluded that statistically and biologically the appropriate model for testing bioefficacy should include M intake as the independent variable and not M levels. For the current data, LIN is more appropriate than using EXPI. The confidence intervals for all estimates of relative efficacy included 100% thus HMTBA is equivalent to DLM as a source of M for very young turkeys fed commercial type diets.

Key Words: 2-hydroxy-4-methylthio Butanoic Acid, Methionine, Turkeys

812 The methionine requirements of chicks and hens fed corn and peanut meal or soybean meal based diets. G. M. Pesti*, R. I. Bakalli, and J. P. Driver, *The University of Georgia, Athens.*

Dietary arginine is a known methionine antagonist. Peanut meal (PNM) is higher in arginine than soybean meal (SBM). We hypothesized that chickens fed corn and peanut meal based diets would have higher methionine (MET), or rather methionine plus cystine (TSAA) requirements than those fed corn and SBM based diets. Two identical experiments were conducted with starting broiler chicks in battery brooders to compare the Met requirements when corn and PNM or corn and SBM based diets were fed. The data presented are pooled from both experiments. Chicks fed the corn-SBM based diet performed better than those fed the corn-PNM based diet. Further, chicks fed the most deficient corn-SBM diet (0.72% TSAA) gained 503 g/16 days, compared to 639 g when the highest levels of TSAA were fed while chicks fed the most deficient corn-PNM diet (0.61% TSAA) gained 193 g/16 days, compared to 610 g when the highest levels of TSAA were fed. The results showed that chicks require approximately 0.82% TSAA regardless of the protein source fed. A six-week experiment was conducted with Leghorn hens housed 2 per cage with 4 cages per replicate and 4 replicates per treatment. Feed consumption and egg production were very similar for PNM and SBM fed hens; PNM, (84.0 ± 0.6 HDEP); SBM, (86.2 ± 0.5 HDEP). The best overall performance was by hens fed PNM with 0.15% added Met (89.5 ± 1.0

HDEP). Significant effects of Met supplementation were noted for production, egg weight and % shell. There were no significant TSAA level by protein source interactions, and the requirement was found to be $< 0.63\%$ TSAA for hens consuming 117g feed/day. Significant differences between PNM and SBM were noted for % shell, egg specific gravity and body weight change. The egg specific gravity and % shell results indicate that more study is needed on the Ca and P contents and availabilities of PNM. Reduced body weight gains from the PNM fed hens suggests that we overestimated the energy content of our PNM sample. Our hypothesis was proved incorrect: chickens fed corn-PNM based diets need the same amount of Met as chickens fed corn-SBM based diets, nothing extra.

Key Words: Methionine, Peanut Meal, Broiler

813 The response of broilers to feeds limiting in threonine in the period 7 to 21 days of age. R. M. Gous¹, S. Van Cauwenbergh², C. Relandeau², and D. J. Burnham*³, ¹University of KwaZulu-Natal, Pietermaritzburg, Natal, South Africa, ²Ajinomoto Eurolysine SAS, Paris, France, ³Ajinomoto Heartland LLC, Chicago, IL.

Two trials were conducted to measure the response of starting broilers to digestible threonine (THR). In each, a summit dilution technique was used to measure the response in protein gain and feed intake to a range of feeds limiting in THR. In all studies, three dilution series were used: the first, in each case, was designed to measure the response to digestible THR. In both trials, oil was added to each feed in the second dilution series, to ascertain whether an additional response could be obtained, particularly at the highest protein contents. In the third series in trial 1, synthetic THR was added to each diet in the series, thereby producing a more balanced protein series, where the ratio between THR and protein was higher than in the original series. This was a means of testing whether THR was the first limiting amino acid in the original dilution series. In the second trial, synthetic lysine (LYS) was added to the feeds in the third dilution series in place of THR. The results of this series would provide information on the response to diets differing in their LYS: THR ratio. The responses to THR in all five series in which THR was first limiting was similar, confirming that the addition of oil as an energy source, and L-lysine HCl as a source of lysine, had no influence on the response to dietary THR. By fitting the Reading Model to the data the coefficient of response was 55.08 mg THR/g protein gain when the three series in Trial 2 were combined, and 57.89 when all five series (Trials 1 and 2) were combined. The contents of THR in the body and feathers are about the same, i.e. 44g THR/kg protein, so it is not necessary to separate the body and feather protein when determining the response in protein gain to dietary THR. The coefficient of response obtained suggests that dietary THR was being utilised at an efficiency of $44/55.08 = 79.9\%$ in Trial 2. When the two trials were combined, the efficiency was 76.01%. The coefficient of response obtained by fitting the Reading Model to the data is of value both in estimating the amount of digestible THR required /g protein gain, as well as the efficiency of utilisation of THR during that stage of growth

Key Words: Threonine, Broiler, Amino Acids

814 Impact of L-threonine supplementation in reduced protein diets for broilers. C. Relandeau¹, L. Le Bellego*¹, J. Bartelt², F. Hutterer², R. Khidr³, and R. Leitgeb⁴, ¹Ajinomoto Eurolysine S.A.S., Paris, France, ²LAH, Cuxhaven, Germany, ³Desert Research Centre, Mataria, Egypt, ⁴University of Bodenkultur, Vienna, Austria.

A conventional diet was compared to diets with a lower content of protein and different levels of L-threonine. A total of 293 Ross 308 broiler chicks were allocated to 4 treatments with respective 4 pens each as replicates. Birds were fed a starter diet from day 0 to 21 and a grower diet until day 36. The protein level in the diets of treatment (T) 1 was 210 and 200 g/kg in the starter and grower feed, respectively and 10 g/kg lower in the diets of T2, T3 and T4. Threonine contents in T1 were 7.8 and 7.4 g/kg in the starter and grower diets, respectively. L-threonine supplementation was 0, 0, 0.4 and 0.6 g/kg, in T1, T2, T3 and T4, respectively, so that total lysine:threonine ratio amounted 100:65, 62, 65 and 70, respectively. All other nutrient contents were equal in all diets. Growth performance was recorded per pen and slaughter performance individually on all birds. 7 chickens died. Protein and fat contents in carcasses were analysed on 12 birds per treatment. Live

weight at the end of growth period was 1956, 1870, 1958 and 1970 g in T1, T2, T3 and T4, respectively. Feed conversion ratio during the experimental period was higher in T2 than in T1, T3 and T4 (2.05, 1.90, 1.90 and 1.95, respectively, $P < 0.05$). Carcass weight in T3 was higher than in T2 (1568 and 1488 g, respectively, $P < 0.05$). Breast meat weights in T3 and T1 were also higher than in T2 (361, 362 and 324 g, respectively, $P < 0.05$). The chemical composition of the carcasses was not significantly influenced by the treatments. Supplementation with 0.04% L-threonine to diets with 10 g/kg lower content of crude protein improved growth and slaughter performance of broilers up to the level of T1. A lysine:threonine ratio of 100:65 was found to be optimal for growth parameters and breast meat deposition.

Key Words: Threonine, Reduced Crude Protein, Growth

815 Amino acid requirements of laying hens. G. P. Audren^{*1}, H. L. Classen¹, K. Schwan-Lardner¹, and K. Bolton², ¹Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, ²Saskatchewan Agriculture Food and Rural Revitalization, Regina, SK, Canada.

The objective of this research was to examine the effects of dietary levels of amino acids on hen productivity and manure nutrient content. Treatments 1 through 3 provided 660, 720 and 780 mg of lysine per day, respectively through out the experiment, with diets adjusted in response to changes in feed intake. Treatment 4 delivered 780 and 720 mg of lysine per day in two 12 week phases. Hens in treatments 5, 6 and 7 were fed diets containing 660, 720 and 780 mg of lysine per kg of feed and diet levels were not corrected for changes in daily feed intake. Essential amino acids were kept at a minimum ratio to dietary lysine content in all diets. Two White Leghorn strains were used. Each treatment was replicated four times (15 hens per replication) per strain of birds. Hens were on trial from 18 to 42 wks of age and manure was collected from sample hens at 29 wks of age. Data were analysed as a 7 x 2 factorial analysis with treatment and strain as the main effects. Dietary treatments had no effect on egg production, body weight, mortality or egg shell quality. Hens fed treatments 3, 4, 6 and 7 produced larger eggs than those fed treatments 1 and 5, while hens from treatment 2 laid smaller eggs than those from treatment 3. There was no difference in the feed efficiency (total feed per egg mass) between hens fed treatments 1, 2, 3, 4, 6 and 7. Birds fed treatment 5 had similar feed efficiency to those fed treatment 1, but were significantly more feed efficient than birds fed other diets. Total nitrogen content of the feces was not affected by dietary treatment or hen strain. The results suggest that until 42 wks of age, based on egg size, hens require 780 mg of lysine per day. However, when based on feed efficiency, hens require only 660 mg of lysine per day.

Key Words: Egg, Amino Acid, Manure Nitrogen Content

816 A comprehensive summary of experiments to define factors that may affect the gain response to 2-hydroxy-4 methylthio butanoic acid (HMTBA) and dl-methionine (DLM) in broilers. M. Vazquez-Anon^{*1}, D. D. Kratzer², R. Gonzalez-Esquerria¹, G. F. Yi¹, and C. D. Knight¹, ¹Novus International, Inc., St. Louis, MO, ²E-SCI, Olivet, MI.

A survey of available publications was done by accessing NERAC and Novus databases from 1950 to 2003. The criteria for study selection were that both HMTBA (Alimet feed supplement and MHA feed supplement, Novus International, Inc.) and DLM (dry 99%) were present, weight gain was recorded, methionine (M) addition, age of birds and duration of study were defined, and a control treatment was present. Of 80 references identified, 56 complied with the criteria, which contained 88 experiments with 364 observations (OBS) for HMTBA and 340 for DLM. Between 1980 and 1999, 68% of the OBS were published, 54% were generated in USA and Canada, and 33% in the EU. Males were used predominantly (75%) over mixed sex (19%) and females (4%). The age at start and end of the study averaged 7.7 and 31.10 d, respectively, and 68% OBS used battery cages and 22% fed pelleted diets. Starter and grower diets were fed in 63% of the OBS, and finisher was fed in only 22%. Average nutrient profile of the diets was 0.28 0.04% M, 0.29 0.08 % Cys, 20 2.8% CP, and 3,139 188 Kcal/kg metabolizable energy. Addition of M averaged 0.15 0.18% with a range of 0.03-2 %. The liquid and dry forms of HMTBA, and the Na and free forms of DLM were tested in 67 and 33, and 7 and 93% of the OBS, respectively. Mean gain, feed conversion (FC) and intake (FI) of control treatment were 754 715 g, 2.31 0.9, and 1614 1531g, respectively. The addition of M improved

gain, FC, and FI 20, 19, and 8%, respectively. This database can be used to study the factors affecting the M activity of these products in broilers and to help develop hypotheses for future experimentation. Summary data also indicate a need for more research to be conducted under commercial conditions with pelleted diets.

Key Words: Broilers, 2-hydroxy-4-methyl-thio Butanoic Acid, Methionine

817 Summarized experimental results demonstrate different dose responses of broiler gain to 2-hydroxy-4 methylthio butanoic acid (HMTBA) and dl-methionine (DLM) with multiple putative variables. M. Vazquez-Anon^{*1}, D. D. Kratzer², R. Gonzalez-Esquerria¹, G. F. Yi¹, and C. D. Knight¹, ¹Novus International, Inc., St. Louis, MO, ²E-SCI, Olivet, MI.

The objective was to determine if broiler gain responses to HMTBA (Alimet feed supplement and MHA feed supplement, Novus International, Inc.) and DLM (dry 99%) are different or affected differently by variables that may contribute to the overall methionine (M) response. Data from 88 controlled experiments where HMTBA and DLM were compared in the same study and the levels of addition did not exceed commercial levels of 0.3% were used to create a database. Best predicted gain models were generated for each M source using PROC REG STEPWISE procedure of SAS. R-square and CV of the final prediction models were 0.7, 38% and 0.6, 41% for HMTBA and DLM, respectively. The variables present in both M source models that positively contributed ($P < 0.05$) to the overall M response were level of M, age of bird at end of study, year of study, dietary Lys and energy, pelleted diets, antibiotics, and males. As gain of the basal diet and age at start of study increased, the gain response to M addition decreased ($P < 0.05$). The resulting models for the two M sources were different. Dietary M and CP, coccidiostats, and M source form (liquid vs dry) were only present ($P < 0.05$) in the HMTBA model. Dietary Cys, type of pen, Europe and USA-Canada were only present ($P < 0.1$) in the DLM model. The DLM model described a quadratic response that reached maximum at 0.25% addition, while the HMTBA model described a linear response that resulted in numerically higher predicted gain at 0.25% and greater. These results demonstrate that the M sources have different dose responses ($P < 0.05$). However, gain predictions for the two M source models compared under the average conditions of the database were not significantly different.

Key Words: Broilers, 2-hydroxy-4-methyl-thio Butanoic Acid, Methionine

818 Effect of dietary tryptophan on growth and stress of broiler chicks. A. Corzo^{*1}, M. T. Kidd¹, J. P. Thaxton¹, and B. J. Kerr², ¹Mississippi State University, Mississippi State, ²United States Department of Agriculture.

The need for dietary Trp and its effect on stress of broiler chicks from 0 to 20 d of age was evaluated. Ross x Ross 508 male chicks were used in two studies, a diet-validation and a dose-response study. The first study compared the titration diet (corn-soybean meal-gelatin byproduct based diet) against two corn-soybean meal control diets (marginal and high in dietary lysine). Day-old chicks were randomly distributed across a closed-curtain sided house (24 floor pens; 13 chicks/pen), and fed the experimental diets. Growth and feed intake were determined at 20 d of age. The control diets had higher BW ($P < 0.001$) and feed intake ($P < 0.001$) than the titration diet; however, feed conversion of the chicks was similar among treatments. A second study estimated the Trp needs for growth of chicks from 0 to 20 d of age. The titration diet was fed to chicks (49 floor pens, 13 chicks/pen; 7 replicates/trt) providing 0.13% total Trp to which 0.02% increments of L-Trp were supplemented to 0.25% of diet at the expense of a filler. Using regression analysis (95% of minimum or maximum response), it was determined that chicks optimized BW, feed intake and feed conversion at 0.21, 0.20, and 0.22% dietary Trp, respectively. Blood plasma free Trp displayed a sigmoidal response in agreement with live performance needs. Plasma cholesterol, heterocyte/lymphocyte ratio, high/low density lipoprotein ratio and corticosterone levels were unaffected by dietary Trp, suggesting that no stress effect was imposed with Trp deficiency. Plasma glucose increased in a linear manner with dietary Trp, perhaps as a result of adrenergic driven glycolytic events, rather than gluconeogenic events

associated with physiological stress. Present results are in agreement with current NRC (1994) recommendations of 0.20% total Trp.

Key Words: Tryptophan, Stress, Plasma Corticosterone

819 Standardized ileal amino acid digestibility in broiler nutrition. M. L. Locatelli¹, V. Ravindran², and A. Lemme¹, ¹Degussa Corporation, Kennesaw, GA, ²Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand.

Broiler diets formulated based on digestible amino acids (AA) rather than on total AA allow a more accurate prediction of animal performance. Recent evidence suggests that the determination of ileal AA digestibility is preferable to the traditional excreta digestibility method. The concept of standardized ileal digestibility (SID) as a mean of overcoming the limitations of apparent ileal digestibility (AID) estimates is proposed. The apparent ileal AA digestibility of several major raw materials for growing broilers were determined and standardized by correcting for basal endogenous losses. In the digestibility assays, each assay diet was offered ad libitum to three pens (4 birds/pen) of male broilers from 35 to 42 days of age. On day 42, the digesta was collected from the terminal ileum, pooled within a pen and, analyzed for CP, AA, and the marker (acid insoluble ash). Basal endogenous losses were estimated from five published datasets based on data generated using the enzyme-hydrolysed casein method. SID was calculated using the following formula: $SID = AID + ((\text{endogenous CP or AA losses (g/kg DM intake)}/\text{CP or AA of the raw material (g/kg DM)} \times 100))$. The SID (%) of CP, Met, Met+ Cys, Lys and Thr were: 90, 94, 90, 92, 85 for corn; 90, 91, 86, 90, 85 for soybean meal; and 65, 72, 62, 69, 62 for meat and bone meal, respectively. The strongest effect of standardization on digestibility estimates was observed for cereal grains. The difference between standardized and apparent ileal digestible AA varied 3-17 percentage points for corn and wheat, while it ranged only 1- 3 for soybean meal and meat and bone meal. Among AA, the digestibility of Thr was affected the most by standardization, due to the high concentrations of Thr in endogenous protein. Diets formulated on standardized ileal digestible AA offer better prediction of animal performance, particularly when poor quality ingredients with relatively low AA digestibility are used.

Key Words: Broilers, Amino Acids, Standardized Ileal Digestibility

820 Variations in the digestible lysine requirement of broilers due to sex, performance parameters and rearing environment. A. R. Garcia^{*1}, A. B. Batal¹, and D.H. Baker², ¹University of Georgia, Athens, ²University of Illinois, Urbana.

Three experiments were conducted with broilers to evaluate variations in the digestible lysine requirement (DLR) for body weight gain (BWG) and gain/feed ratio (GF) due to sex and rearing environment from 7 to 21 d. Chicks were sexed immediately after hatch, placed in either starter batteries or floor pens, and fed a corn-soybean meal diet with 23% CP and 3,200 Kcal ME/kg up to d 7 at which time the chicks were sorted and allocated to the experimental diets. Diets were formulated to be isonitrogenous and isocaloric, varying only in the levels of digestible lysine (DL). The DL levels used were 0.70, 0.80, 0.90, 1.0 and 1.1% in experiment 1, 0.80, 0.88, 0.96, 1.04 and 1.12% in experiment 2, and 0.89, 0.97, 1.05, 1.13 and 1.21% in experiment 3. The requirements were estimated by one slope broken-line methodology, fitting the data to a quadratic curve and determining the first point at which the quadratic response curve intersects the plateau of the one slope brokenline. Estimated requirements reported herein are based on results of broken-line analysis. When lysine was deficient the female broiler always out gained the males, but the opposite was true when lysine was adequate. In all three experiments the estimated DLR based on BWG was higher for males (0.97%) than for females (0.93%). However, the estimated DLR based of GF was either not different between males and females or was slightly higher for the females. As it has been reported previously, the estimated DLR based on GF was higher than that based on BWG for both males and females in all three experiments. The differences in the DLR according to the rearing environment were not consistent in the

three experiments, suggesting that rearing conditions have little or no effect on the DLR.

Key Words: Lysine, Sex, Rearing Environment

821 Chick responses to diets differing in essential and nonessential amino acids. C. A. Fritts*, A. Corzo, and M. T. Kidd, *Mississippi State University, Mississippi State.*

Utilization of crystalline amino acids have allowed for the reduction of crude protein in broiler diets. However, there is a point at which supplementation of all amino acids does not support adequate growth. An experiment was conducted to evaluate the effects of low protein diets adjusted for essential and nonessential amino acid content in chicks. Diets were formulated to contain NRC (1994) recommendations for essential amino acid content using corn and soybean meal of known composition. Dietary treatments consisted of a 22% high crude protein (HP) and an 18 % low crude protein diet (LP). The LP diet was then individually supplemented with Gly, Leu, Asp, Glu, Ala, or Pro to equal those values formulated in the HP diet. In addition, another dietary treatment consisted of the LP diet supplemented with all supplemented amino acids to equal those in the HP diet for a total of nine dietary treatments. For the first 5 d all chicks were fed a 23% CP diet and then fed the test diets from 5 to 21 d. Each diet was fed to 10 pens of 6 male chicks from a commercial broiler strain (Ross 308) in electrically heated battery brooders. Pen BW and feed consumption were taken at 5, 13 and 21 d. No significant differences were found between birds fed the LP diet with all amino acids added back and the HP diet for BW gain and feed conversion ratio (FCR) for 5 to 13 and 5 to 21 d. Birds fed the LP or LP diets supplemented with only one amino acid were significantly lower for BW gain and FCR from 5 to 13 d. Feed intake was not affected by dietary treatments. Addition of individual amino acids to LP diets had variable effects on BW gain and FCR for all age periods measured. Results of this study suggest that chicks fed LP diets should meet all essential and nonessential amino acid needs to equal performance of birds fed the HP diets. Although the combined response of all amino acids added back to the LP diet was best, 5 to 21 d live performance responses were improved by the addition of Gly, Leu, and Asp.

Key Words: Crude Protein, Amino Acids, Broiler

822 Effect of dietary lysine and stock density on broiler performance and breast meat quality. C. Berri¹, C. Relandeau², L. Le Bellego^{*2}, and M. Picard¹, ¹INRA Station de Recherches Avicoles, Nouzilly, France, ²Ajinomoto Eurolysine S.A.S., Paris, France.

Responses to increased dietary lysine concentrations were evaluated on 1584 Ross 308 male broilers between 21 and 42 days of age housed according to two bird densities. The experimental design comprised 8 factorial treatments : 2 bird densities (22 or 44 broilers / 2 m²pen) x 4 lysine levels (0.95%, 1.05%, 1.15% and 1.25%). There were 6 repetitions per experimental treatment. Birds were weighed individually at day 21 and 42. Feed consumption was recorded per pen. Body weight gain and feed conversion were calculated over the experimental period. 384 broilers were dissected at 42 days of age (48 per treatment). Final pH and water losses were measured on the pectoral muscle. Density adversely affected feed intake (169 ± 1 and 160 ± 1 g/b/d with 22 and 44 birds per pen, respectively, P<0.05), growth rate (97.4 ± 0.5 and 91.0 ± 0.7 g/b/d, P<0.05) and feed conversion (1.730 ± 0.008 and 1.760 ± 0.006, P<0.05). Except for feed intake, there was no interaction between the effects of bird density and dietary lysine. An increase in dietary lysine from 0.95% to 1.05% resulted in an increased growth rate (91.8 ± 1.6 and 95.5 ± 0.8 g/b/d, P<0.05), reduced feed conversion (1.783 ± 0.008 and 1.742 ± 0.009, P<0.05) and increased breast meat yield on body weight (17.1 ± 0.1 and 17.7 ± 0.1 %, P<0.05). Performance and body composition traits were not significantly improved for concentrations of lysine higher than 1.05%. However, final breast pH was linearly increased from 0.95% (5.91 ± 0.01) up to 1.15% (6.02 ± 0.01) lysine in the diet and water losses tended to be correlatively decreased (1.10 ± 0.06 and 0.85 ± 0.03 %, P<0.05). This result opens new ways of research for the definition of an amino acid requirement and on metabolic pathways involved in variations of breast muscle pH.

Key Words: Lysine, Growth, Meat Quality

823 Efficacy of vitamin D source and level on performance and bone mineralization of broilers fed dietary treatments for six weeks. D. R. Ledoux*¹, J. N. Broomhead¹, D. R. Campbell², J. W. Wilson², and N. E. Ward², ¹University of Missouri, Columbia, ²DSM Nutritional Products, Inc., Parsippany, NJ.

A floor pen study was conducted to determine the efficacy of vitamin D source and level on performance and bone mineralization of broilers fed dietary treatments for six weeks. Dietary treatments included: 1) Basal diet supplemented with NRC recommended levels of vitamin D₃ (200,000 ICU/ton); 2) Basal plus 2.5 million ICU (MICU) D₃ /ton; 3) basal plus 2.5 MICU D₃/ton plus 62.5 mg Hy-D/ton; 4) basal diet plus 5 MICU D₃ /ton diet; and 5) basal plus 62.5 mg Hy-D/ton diet. Diets were fed from day 1 to 42, and nutrient concentrations were adjusted at the end of week 3 according to NRC recommendations. Four replicate pens of 20 chicks were fed each treatment from day 1 to 21. On day 21, 6 chicks from each pen were removed for sampling, leaving 4 replicate pens of 14 chicks from day 21 to 42. Compared with chicks fed diet 1, chicks fed all other treatments consumed more feed and gained more weight ($P < 0.05$) at both weeks 3 and 6. Feed intake and body weight gain were similar ($P > 0.05$) for chicks fed treatments 2 - 4 at both weeks 3 and 6. Feed conversion was not affected ($P > 0.05$) by dietary treatments at either week 3 or 6. Compared with chicks fed diet 1, chicks fed all other treatments had a higher ($P < 0.05$) percent tibia ash at week 3, whereas at week 6, chicks fed diets 1 and 5 had a lower ($P < 0.05$) percent tibia ash compared with other dietary treatments. However, on an absolute bone ash weight basis (mg bone ash), bone ash was not affected ($P > 0.05$) by dietary treatments at either week 3 or 6. Bone breaking strength was also not affected ($P > 0.05$) by dietary treatments at either week 3 or 6. Results indicate that supplemental vitamin D₃ above NRC recommendations was effective in improving chick performance and bone mineralization, and 62.5 mg Hy-D/ton feed was as effective as industry vitamin D₃ levels in improving chick performance.

Key Words: Vitamin D, Bone Ash, Broilers

824 Influence of large doses of vitamin C on performance, plasma and bone calcium and phosphorus, bone characteristics and egg quality of local Dandarawi hens exposed to cold stress. M. M. Metwally*, Department of Animal and Poultry Production, Assiut University, Assiut, Egypt.

An experiment was conducted to investigate the effect of large doses of dietary vitamin C (0 to 2,000 ppm) on performance, plasma calcium and phosphorus, bone characteristics and egg quality of Local Dandarawi Hens exposed to low environmental temperatures in Winter season (December, January and February) of upper Egypt. A total of 192 local Dandarawi hens (32 wks of age) were fed diets containing vitamin C (ranging from 0 to 2,000 ppm) for 4 months. Body weight changes, egg production, weight, egg quality and bone characteristics were determined. Plasma and tibiae were analyzed for total calcium and phosphorus. Results indicated that body weight loss and mortality rate (%) were significantly ($P < 0.05$) lower in groups fed high doses of vitamin C. Egg laying rate (%) was significantly ($P < 0.05$) higher by 20% during the period of cold stress in birds fed the highest level of vit. C than control birds. Egg weight increased up to 6% and egg specific gravity was improved in hens fed 2000 ppm of vitamin C which also had increased calcium and phosphorus in the bone and blood plasma. Egg quality criteria was enhanced by high dose of vitamin C. Improved in both feed consumption and feed conversion with groups fed the highest level of vitamin C. Results recommend that large doses of vitamin C in the diets of laying hens influence calcium metabolism, affecting bone and shell mineralization and improved egg production and quality of laying hens under cold stress.

825 Litter quality and feet dermatitis with broilers in response to corn-soybean vegetarian feeds. G. Eichner, S. L. Vieira*, R. P. Ott, E. S. Viola, and J. G. Almeida, UFRGS, Porto Alegre, RS, Brazil.

Europe and Saudi Arabia require that broiler grown for their market are not fed animal by products. The so called vegetarian feeds are largely formulated with an increased inclusion of soybean meal, which usually

leads to increased excreta viscosity. An experiment was designed with 8 treatments: four ingredient formulation varying in ingredient inclusion and optimizing or not the dietary electrolyte balance (DEB) to 250 meq/kg of feed. Feed treatments were: corn and soybean meal, corn and soybean meal plus a commercial pectinase + beta glucanase, inclusion of poultry by-product, inclusion of corn gluten meal. Feeds did not have any growth promotant. Birds were fed ad libitum to 42 days of age in floor pens having bell drinkers. At the end of the study birds receiving the feed with corn gluten meal had a significantly reduced body weight, but feed conversion was not affected by any treatment. Optimization of DEB did not affect any live performance response. Birds showing feet dermatitis at 21 days were tagged and lesion scores for feet dermatitis were weekly performed afterwards. These lesions were clearly intensified through the end of the study with birds fed diets with corn gluten meal demonstrating a significant reduction. Increasing diet DEB led to higher lesion scores at 21 days of age with no difference between the treatments afterwards. Lesion scores were positively correlated with the moisture of litter.

Key Words: Vegetarian Feeds, Broiler Litter, Feet Dermatites

826 Effects of salmonella typhimurium lipopolysaccharide challenge on the performance and zinc metabolism in laying hens supplemented with zinc from different sources. T. Cheng*, Y. Guo, and J. Yuan, College of Animal Science and Technology, China Agricultural University, Beijing, P.R. China.

The study was conducted to determine the effects of *Salmonella Typhimurium* lipopolysaccharide (LPS) challenge on egg-laying performance, inflammatory response, and zinc metabolism in layers fed diets supplemented with organic or inorganic zinc since 3-week-old. The three dietary treatments were corn-soybean meal basal diet without supplemental zinc or with zinc at 60 mg/kg from ZnSO₄ or zinc amino acid complex (ZnAA). At the age of 58-week-old, twelve hens from each treatment were allotted into two sub-groups. On day 1, 3, 5, 7 of the 58th week of age, six birds of one sub-group were injected intraperitoneally with LPS or sterile saline. Neither effect of zinc source/LPS challenge interaction nor zinc source on egg production performance was observed. LPS-challenge decreased egg production ($p < 0.04$) and increased percentage of cracked eggs ($p < 0.01$). With LPS challenge, the fever response of hens fed ZnAA tended to peak and subside also earlier than fed ZnSO₄ or basal diet, serum IL-1 level at 3-h was higher ($p < 0.01$), but lower at 12 h post-challenge ($p < 0.001$) in hens fed ZnAA than ZnSO₄. In saline-injected groups, serum IL-1 was higher in hens fed ZnAA than the basal diet at 3-h post-injection ($p < 0.01$). LPS-challenged birds had lower serum zinc and higher zinc sequester in liver and spleen ($p < 0.001$). Supplementation of 60mg/kg zinc from either ZnAA or ZnSO₄ significantly ($p < 0.05$) elevated metallothionein (MT) concentrations in liver and spleen. MT concentration in liver of birds fed ZnAA was higher than fed ZnSO₄ ($p < 0.05$). The magnitude of increase of hepatic and splenic MT due to LPS challenge were higher by supplementation of ZnAA than ZnSO₄. The results suggest that zinc amino acid complex enhances MT synthesis and zinc sequester in hepatic and splenic tissues, and increases the sensitivity of immune response due to LPS challenge.

827 Effects of broiler strain on nonphytate phosphorus requirement. M. E. Persia* and W. W. Saylor, University of Delaware, Newark.

With yearly improvements in genetic stock and recent pressure to reduce safety margins of nonphytate phosphorus (nPP) in poultry feed, it is important to revisit strain differences in the nPP requirement of broiler chicks. Experiments were conducted to determine if broiler strain affects the nPP requirements of growing chicks. One-day-old Ross 308 and 708 chicks were obtained from a local commercial hatchery. Chicks utilized in both experiments were from breeder flocks of similar age that received the same level of dietary nPP. Chicks were maintained on a standard starter diet until 8 days of age, when chicks were sorted, wing-banded and randomly assigned to experimental treatments. Chick weight gain and feed intake were measured from 8 to 22 d of age. Chicks were then euthanized by cervical dislocation and the right tibia was harvested to determine fat-free tibia ash. Treatments were arranged utilizing a six by two factorial design. Experimental diets formulated to contain one

of six levels of nPP (0.13, 0.21, 0.29, 0.37, 0.45 or 0.53%) were fed to the two strains of broiler chicks. One hundred forty-four chicks of each strain were randomly assigned to six replicate groups of four chicks for each experimental treatment. Both dietary nPP level and broiler strain significantly affected weight gain and feed intake, but no interaction between the two factors was observed. Broken-line regression analysis resulted in requirement estimates of 0.33 and 0.30% for weight gain and 0.33 and 0.33% for feed intake for Ross 308 and TP7 chicks, respectively. There appears to be little difference in the NPP requirements of the two broiler strains utilized in this experiments.

828 Plasma and tissue selenium and plasma glutathione peroxidase concentrations of broilers fed a selenium-deficient diet following a selenium-loading period. R. L. Payne* and L. L. Southern, *Agricultural Center, Louisiana State University, Baton Rouge.*

An experiment was conducted to compare plasma glutathione peroxidase (pGPX3) and plasma and tissue Se concentrations in broilers fed a Se-deficient diet after having been fed diets supplemented with either sodium selenite (SS) or Se-enriched yeast (SY). Female broilers were assigned to three treatments on d 0, and the trial lasted 22 d. The treatments were: 1) a corn-soybean meal diet without Se supplementation (C-SBM), 2) C-SBM + 0.30 ppm Se from SS, and 3) C-SBM + 0.30 ppm Se from SY. Each treatment was replicated eight times with 15 broilers per replicate, and these treatments were fed from d 0 to 10 posthatching. On d 10, all broilers were fed a Se-deficient diet, which consisted of cornstarch (25%), dextrose (25%), SBM (31%), and torula yeast (10%). Baseline concentrations of plasma and tissue Se and pGPX3 were established using 10 broilers on d 0. On d 10, 13, 16, 19, and 22, three broilers per replicate were randomly selected for plasma and tissue collection. Any significant effects listed are significant at $P < 0.05$. Diet did not affect growth performance during the Se-loading period (d 0 to 10) or overall (d 0 to 22). Broilers fed either SS or SY had similar pGPX3 concentrations on d 10 and 13, but the broilers fed SY had higher pGPX3 activities than those fed SS on d 16, 19, and 22. Both sources of Se resulted in higher pGPX3 and plasma Se concentrations than broilers fed the C-SBM without Se supplementation. Broilers fed SY had higher plasma Se than those fed SS except for d 10 and 22. Liver Se concentration was higher in broilers fed SY on d 10, 13, and 16 compared with those fed SS, but it was similar on d 19 and 22. Similarly, breast Se concentration was higher in broilers fed SY on d 10, 13, 16, and 19 compared with those fed SS, but it was similar on d 22. These results indicate that organic sources of Se are deposited at a greater rate in tissues, and then better utilized for maintaining pGPX3 concentrations over time than inorganic forms of Se.

Key Words: Broiler, Glutathione Peroxidase, Selenium

829 Validation of a selenium-deficient diet for broilers. R. L. Payne* and L. L. Southern, *Agricultural Center, Louisiana State University, Baton Rouge.*

Two experiments (EXP) were conducted to develop a Se-deficient diet that could be used for selenium-dependent plasma glutathione peroxidase (pGPX3) assays in broilers. For each EXP, 288 female broilers were weighed, wingbanded, and allotted to dietary treatment on d 0, and the EXP lasted 21 or 20 d, respectively. All diets were formulated to provide 1.26% total Lys, 1.0% Ca, 0.45% available P, and 3,200 kcal/kg ME. Four basal diets were used in EXP 1 and they were a corn-soybean meal diet (C-SBM), a C-torula yeast diet (C-TY), a cornstarch-dextrose-TY diet (CS-D-TY), and a CS-D-SBM + 20% TY diet (20TY). Each basal diet was supplemented with 0 or 0.30 ppm sodium selenite (SS), and each treatment was replicated six times with six broilers per replicate. The broilers fed C-SBM, regardless of Se level, had higher daily gain (ADG) and gain:feed ($P < 0.05$) than broilers fed any other diet. However, the broilers fed 20TY had similar daily feed intake (ADFI; $P > 0.05$) to those fed the C-SBM. Data from EXP 1 indicated that the best diet of these was the 20TY diet. In EXP 2, two levels of TY were used in the CS-D-SBM + TY diet. Three basal diets were used: 1) C-SBM diet; 2) CS-D-SBM + 10% TY (10TY); and 3) CS-D-SBM + 15% TY diet (15TY). Each basal diet was supplemented with 0 or 0.30 ppm SS, and each treatment was replicated eight times with six broilers per replicate. The broilers fed 10TY, regardless of Se level, had similar ADG ($P > 0.05$) as those fed C-SBM, and those fed 15TY had lower

ADG ($P < 0.05$) compared with those fed C-SBM. All broilers fed diets containing TY had decreased ADFI ($P < 0.05$) and lower gain:feed ($P < 0.05$) compared to those fed C-SBM. However, pGPX3 concentrations in the broilers were lowest in the TY diets without Se supplementation ($P < 0.05$), but they returned to levels comparable to those fed C-SBM when SS was supplemented. Therefore, a semi-purified diet containing 10% TY provides similar ADG while lowering pGPX3 activity in order to properly examine Se activity in the broiler.

Key Words: Broiler, Selenium, Torula Yeast

830 Growth performance and spontaneous bone fracture incidence of toms fed various levels of calcium and non-phytate phosphorus to heavy market weight. K. D. Roberson*, J. L. Kalbfleisch, R. A. Charbeneau, and W. Pan, *Michigan State University, East Lansing.*

This trial evaluated various dietary calcium and non-phytate phosphorus (nPP) levels fed to Nicholas 700 toms from 2 to 19 wk of age. After a two-wk brooding period, 24-25 poult/pen were allocated to 8 pens/treatment. Crumbles were fed from 2 to 5 wk of age and pellets were then fed to 19 wk of age. Treatment diets were fed in three-wk phases except for the finisher II diet which was fed for 2 wk. Diet 1 (LOW) was formulated to provide 0.50% nPP from 2-5 wk of age and matched NRC (1994) recommendations for each phase change ending with 0.25% nPP from 17-19 wk of age. Dietary calcium was kept at a 2:1 ratio with nPP for all diets. Diet 2 (MED) had formulated nPP levels that averaged 0.06 percentage units higher than the LOW diet. Diet 3 (HIGH) averaged 0.10 percentage units higher nPP than the MED diet. Diet 4 (VHIGH) was formulated according to breeder recommendations and was about 0.10 percentage units higher than the HIGH diet for dietary nPP. Body weight was reduced by the LOW diet at 5 wk of age ($p=0.009$). At 8 wk of age, BW was lower when the MED diet was fed compared to the HIGH and VHIGH diets ($p<0.001$). The LOW diet resulted in lower BW compared to the MED diet at 8 wk. Similar responses were observed the rest of the trial. Cumulative feed intake was reduced by the LOW diet at 14 wk ($p=0.001$) compared to the other diets and was lower than the HIGH and VHIGH diets at 17 and 19 wk ($p=0.001, 0.004$). Feed:gain was higher for the LOW diet compared to HIGH and VHIGH diets the whole trial. Within phase, BW gain was not significantly increased by feeding higher calcium and nPP than the MED diet in the 11-14 wk phase and the LOW diet in the 17-19 wk phase. Incidence of leg problems and spontaneous bone fractures (femur and tibia) were increased ($p=0.001$) when the LOW diet was fed compared to other diets. The HIGH and VHIGH diets resulted in the best growth performance and skeletal integrity. The HIGH diet resulted in about 3 g less nPP consumed per tom compared to the VHIGH diet with an average daily gain of 171 g/d for the trial.

Key Words: Phosphorus, Bone Fractures, Tom

831 The impact of dietary copper source and level on hen performance, egg quality and egg yolk cholesterol. P. H. Patterson¹, T. L. Cravener¹, and D. M. Hooge*², ¹*The Pennsylvania State University, University Park,* ²*Hooge Consulting Service, Inc., Eagle Mountain, UT.*

A first-cycle layer feeding trial was conducted for twelve 28d periods (October 2001 to October 2002; 18 to 66wk) using 504 Hy-Line W-36 hens in cages at 387cm²/bd initially. Three dietary treatments were: control (CON), 18.4ppm Cu; copper sulfate (CuSO₄), +125ppm Cu; tribasic copper chloride (TBCC), +125ppm Cu. There were 18 replicates of CON, 12 of each CuSO₄, and TBCC treatments all with 12 hens/replicate. Pullets were grown on corn-soy based CON, CuSO₄, or TBCC diets to 18wk, and as layers fed every pullet/hen diet combination e.g. CON/CON, CON/ CuSO₄, CON/TBCC etc. Laying hen results are reported as main effects. Egg quality measurements were taken in Periods 3, 6, 7, 9, and 12, and eggs were sampled for egg yolk cholesterol in Period 7. Better mixing was observed with the TBCC, which was non-hygroscopic, with small uniform particle size compared to CuSO₄, which had to be ground with mortar and pestle to break up large particles. For CON, CuSO₄, and TBCC fed hens, respectively, results were: final BW 1.692, 1.672, and 1.672 kg ($P = 0.34$); 12-period average hen-day egg production 74.9, 77.5, and 76.0% ($P = 0.19$); feed intake 95.6, 95.1, and 95.6 g/hen/d ($P = 0.88$); kg feed/dozen eggs 1.627, 1.555, and 1.590 ($P = 0.14$); kg feed/kg eggs 2.066, 2.049, and 2.088 ($P = 0.84$); egg weight 58.3, 58.2, and 57.9 g ($P = 0.47$); Haugh units 71.7,

78.2, and 72.2 ($P = 0.87$); and egg yolk cholesterol 1.237, 1.248, and 1.252 g/100g ($P = 0.91$). Shell weight, thickness, % shell, and albumen height means were either equal or very close by treatment. It was concluded that addition of 125ppm Cu from CuSO_4 or TBCC to the diets of first-cycle laying hens containing 18.4ppm Cu did not significantly affect hen performance or egg quality although this does not preclude the possibility that higher levels may be beneficial as shown recently by other researchers.

Key Words: Dietary Copper, Hens Eggs, Cholesterol

832 Use of 2-hydroxy-4(methylthio) butanoic acid (HMTBA) as a ligand for organic trace minerals. J. J. Dibner*, M. Trehy, C. S. Schasteen, and J. A. Hume, *Novus International, Inc., St. Louis, MO.*

Organic trace minerals (OTM) are used in animal feed to provide enhanced mineral availability compared to inorganic salts. Mineral absorption from inorganic salts is limited by their tendency to form complexes with dietary constituents like phytic acid, and by their tendency to interfere with each other when multiple salts are included in the diet. The most common OTM forms are mineral amino acid complexes (such as zinc methionine) or mineral proteinates. The latter consist of hydrolyzed protein; thus, the ligand consists of multiple amino acids, each with its own binding characteristics. HMTBA is an organic acid with a structure identical to methionine except that it bears a hydroxyl group on the alpha carbon instead of an amino group. Its mineral binding is also similar to that of methionine except that the hydroxyl group replaces the amino group in formation of the complex. Mintrex™ Zn mineral supplement is the name of the zinc complex using HMTBA as ligand. It is a 2:1 ligand to mineral complex. In the study reported here, birds were vaccinated with ADVENT® Coccidiosis Control on day of hatch and fed a zinc deficient diet ($\text{Zn} < 30$ ppm) for eight days followed by application of treatment diets consisting of the basal and four supplemented diets: zinc sulfate, Zinpro 100 and Mintrex Zn, all at a final concentration of 70 ppm supplemental zinc. Pre-challenge performance and gut morphometry were affected by vaccination ($P < .01$) and zinc source ($P < .05$). Birds were given a coccidiosis challenge by oral gavage on day 23. Performance and lesion scores following challenge were improved by zinc supplementation ($P < .05$). Post-challenge tibia zinc was affected by vaccination and zinc source with the highest tibia zinc observed in the birds that were fed Mintrex. All zinc supplemented birds had greater tibia zinc than the unsupplemented basal ($P < .01$). ADVENT is a trademark of Novus International, Inc., and is registered in the United States and other countries

Key Words: Mintrex, Zinc, Hydroxy-4(methylthio)butanoic Acid

833 Reduction of ascites mortality in broilers by dietary coenzyme Q₁₀ supplementation. A. Geng*, Y. Guo, and Y. Yang, *College of Animal Science and Technology, China Agricultural University, Beijing, P.R. China.*

One experiment was conducted to study the effects of dietary coenzyme Q₁₀ (CoQ₁₀) supplementation on growth performance and ascites in broilers. One hundred and eighty one-day-old Arbor Acre male broiler chicks were randomly allocated into 3 groups with 6 replicates each. From day 8, the diets were supplemented with CoQ₁₀ at levels of 0, 20, and 40 mg/kg, respectively. During day 15 to day 21, all the chicks were exposed to low ambient temperature (15-18 °C) to induce ascites. Feed intake, weight gain, and feed conversion ratio of the broilers during 0-6 wk were measured, mortality was recorded, and ascites was diagnosed. On day 15, 22, 29, 36, 43 and 47, blood was sampled to measure blood packed cell volume (PCV) and erythrocyte osmotic fragility (EOF) immediately. On day 22, 36, and 43, a method of right cardiac catheter was adopted to determine right ventricular pressure (RVP), pulmonary arterial pressure (PAP) and the maximum change ratio of right intraventricular pressure, and then the right ventricle and total ventricle of heart were weighed to calculate ascites heart index (AHI). The results showed that there were no significant influences observed on broilers growth performance, but the mortality due to ascites was significantly reduced by CoQ₁₀ supplementation ($P < 0.01$). 40 mg/kg CoQ₁₀ decreased EOF significantly compared with the control, but no significant changes were observed in PCV between the CoQ₁₀ supplemented birds and the control. Pulmonary arterial diastolic pressure was significantly lowered at age of 36 days, but no significant changes were observed in RVP, pulmonary arterial systolic pressure, and the maximum change

ratio of right intraventricular pressure. AHI was significantly decreased by dietary 40 mg/kg CoQ₁₀ supplementation ($P < 0.05$). The results of this study suggest that dietary supplementation of CoQ₁₀ has beneficial effect on reducing ascites mortality in broilers.

Key Words: Broilers, Ascites, Coenzyme Q₁₀

834 Comparison of growth potential and carcass components of a new strain of tom turkeys with other commercial strains. K. D. Roberson*¹, J. L. Kalbfleisch¹, and D. Dransfield², ¹Michigan State University, East Lansing, ²British United Turkeys of America.

A 19-wk trial was conducted to evaluate the growth potential and carcass component yield of a newly developed tom strain with two other major strains of commercial toms grown in the U.S. turkey industry. Hybrid Converter (HYB) poulters were smaller ($p=0.005$) at hatch than Nicholas 700 (NIC) or B.U.T.A. T2 (T2) poulters (56.7 vs. 59.8 or 59.0 g). Breeder hen wk of lay was 21 wk (HYB), 19 wk (NIC) or 6 wk (T2). Poulters were brooded at 50 toms/pen for two wk with 4 pens of HYB and NIC toms and 8 pens of T2 toms. After two wk, each pen of poulters was split to provide 32 total pens of 25 toms each. Body weight was measured at 2, 5, 11, 17 and 19 wk of age. T2 toms weighed less than other strains at 2 and 5 wk ($p < 0.001$), but were heavier at 17 and 19 wk ($p < 0.001$). T2 toms were lighter than NIC toms at 11 wk, but heavier than HYB toms ($p < 0.001$). Net cumulative feed conversion was higher for T2 toms than HYB toms at 2 wk ($p < 0.001$) and both HYB and NIC toms at 5 wk of age ($p=0.033$). There were no significant cumulative feed conversion effects in the remainder of the trial. Livability was higher ($p=0.002$) for HYB toms compared to the other strains. Mortality due to cardiovascular problems was higher ($p=0.007$) for NIC toms than the other strains. Three toms per pen were selected based upon similar BW (17.8 kg) at 17 wk and average BW in the pen at 19 wk. There was a significant ($p < 0.001$) difference in BW of toms slaughtered at 19 wk (19.3, 20.5 or 21.2 kg for HYB, NIC, or T2, respectively). Breast yield was higher ($p < 0.001$) for T2 toms than other strains at both market ages. Thigh and drumstick yield were consistently lower ($p < 0.019$) for T2 toms compared to HYB and NIC. HYB toms had lower wing yield ($p < 0.001$) and higher percent breast skin ($p < 0.001$) than other strains. There was no significant effect on lightness of breast meat. The results show that T2 toms will reach heavy (18 kg) market weight sooner with a higher proportion of meat produced as breast tissue than common commercial tom strains from other breeder companies.

Key Words: Carcass Components, Growth Potential, Tom Strain

835 Effects of cereal, heat processing, and fiber on productive coenzyme Q₁₀ and digestive traits of broilers. J. M. González-Alvarado¹, E. J. Moreno², D. G. Valencia², R. Lázaro², and G. G. Mateos*², ¹Universidad Autónoma de Tlaxcala, México, ²Universidad Politécnica de Madrid, Spain.

A battery trial was conducted to study the influence of type of cereal (60% corn or 60% rice), heat processing of the cereal (HP) (raw or cooked at 90 °C for 50 min and then rolled), and sources of fiber (none, 3% oat hulls, and 3% soybean hulls) on productivity and digestive traits of broilers from 1 to 21 d of age. Each of the twelve treatments were replicated 6 times (a cage with 14 birds). The two control diets were based on soybean protein concentrate and fish meal, and had either 2.45% (corn diets) or 1.54% (rice diets) crude fiber. In the high fiber diets, the hull source was included at expenses of an inert material. Birds and feed intake were weighed at 0, 4, 8, 13, and 21 D. Ileal viscosity and digestive organ size were measured at 21 d. From 0 to 21 d broilers fed rice had better feed conversion (FC) (1.34 vs 1.38, $P < 0.001$) than broiler fed corn. Heat processing of the cereal did not affect broiler performance at 21 d of age, but a cereal x HP interaction was detected; HP improved FC in broilers fed rice but not in broilers fed corn. Broilers fed the hull-containing diets had better FC (1.34 vs 1.39, $P < 0.01$), higher ADG (32.5 vs 30.7 g/d, $P < 0.05$), larger gizzards ($P < 0.001$), and heavier gastrointestinal tracts ($P < 0.01$) than chicks fed diets without hulls. Also, a cereal x fiber interaction was observed at 21 d; the inclusion of hulls improved FC in broilers fed rice but not in broilers fed corn. Soybean hulls but not oat hulls increased ileal viscosity at 21 d ($P < 0.05$). Rice can be used successfully in prestarter diets for chicks but no benefits are obtained from HP of corn. The inclusion of additional fiber in the diet improved chick performance, specially when low-fiber

rice diets are used, which indicates the need of a minimum of fiber in broiler diets.

Key Words: Rice, Fiber Source, Early Nutrition

Ruminant Nutrition: Beef - Digestibility & Production

836 Site and extent of digestion in beef cattle consuming restricted amounts of forage and supplemental ruminally undegradable protein. E. J. Scholljegerdes*, T. R. Weston, F. S. D'Angieri, P. A. Ludden, and B. W. Hess, *Department of Animal Science, University of Wyoming, Laramie.*

Twelve Angus-cross cattle (avg. initial BW = 594 kg \pm 44.4 kg) fitted with ruminal and duodenal cannulae were used in a 4 \times 4 Latin square double cross-over designed experiment to determine site and extent of digestion in beef cattle consuming restricted amounts of forage plus a ruminally undegradable protein (RUP) supplement. Heifers were fed chopped (2.54 cm) bromegrass hay (11.4% CP, 57% NDF) at 30, 55, 80, or 105% of maintenance. Cattle fed below maintenance were given increasing amounts of RUP supplement (6.8% blood meal, 24.5% feather meal, and 68.7% menhaden fish meal; DM basis) in an effort to equalize duodenal essential AA flow to that of the 105% of maintenance diet. Experimental periods were 21 d in length with 17 d of adaptation followed by 4 d of intensive sample collection. Total OM intake and duodenal OM flow decreased ($P < 0.001$) proportionally in cattle consuming 105 to 30% of the forage intake required for maintenance. Therefore, OM truly fermented (% of intake) did not differ ($P = 0.43$) as intake declined. True ruminal N digestibility (% of intake) tended to decrease linearly ($P = 0.07$); however true ruminal N digested (g/d) increased as intake decreased from 105 to 30%. Duodenal N flow was equal ($P = 0.33$) across intake level, even though microbial N flow declined ($P < 0.001$) as forage OM intake decreased. Due to the low ruminal degradability of the RUP supplement, non-ammonia non-microbial N flow increased ($P < 0.001$) with RUP supplementation. Post-ruminal N digested tended to increase ($P = 0.06$) with increasing levels of RUP in the diet. The increased ruminal N digested associated with supplemental RUP and restricted forage intake increased ruminal molar proportions of branched chain VFA ($P = 0.02$) and millimolar concentrations of ruminal NH_3 ($P < 0.001$). Therefore, when beef cattle consume restricted amounts of bromegrass hay, supplemental RUP can boost the supply of highly digestible N presented to the small intestine for absorption.

Key Words: Nutrient digestion, Restricted intake, Ruminal undegradable protein

837 Digestion of barley-based high-grain diets supplemented with rumen degradable and undegradable protein in steers. - digestion trial. B. W. Pamp*, M. L. Bauer, G. P. Lardy, and S. A. Soto-Navarro, *Department of Animal and Range Sciences, North Dakota State University, Fargo.*

Fifteen Holstein steers (398.2 \pm 7.3 kg initial BW) were allotted by weight to one of four dietary treatments in a completely randomized design. Objectives of this trial were to determine effects of rumen degradable (RDP) and undegradable protein (RUP) on site and extent of digestion, microbial efficiency, and ruminal fermentation. Dietary treatments were arranged in a 2 \times 2 factorial. Factors were RDP (+/-) and RUP (+/-). RDP source was urea and RUP was a combination of hydrolyzed feather meal and blood meal (80:20 on N basis). The basal diet was formulated to contain (DM basis) 83% barley, 5% alfalfa hay, 5% corn silage, 5% de-sugared molasses, 27.5 mg/kg monensin, and 11.0 mg/kg tylosin. The control diet (without added RDP and RUP) was formulated to contain a minimum of 12.5% CP, 0.7% calcium, and 0.3% phosphorus. Diets were formulated such that +RDP added 1% CP from urea and +RUP added 1% CP from the feather meal/blood meal combination. Steers were adapted to the experimental diets for 29 d before collection. Average DMI during trial period was 11.5 kg/d. Apparent ruminal OM digestibility decreased ($P = 0.05$) with RUP (41.4 vs. 35.1 \pm 2.2%). Digestibility of OM in the small intestine tended ($P = 0.09$) to increase with the inclusion of RUP (2.8 vs. 9.8 \pm 2.3%). Intake and ruminal digestibility of NDF decreased ($P = 0.01$) with the dietary addition of RUP (2.98 vs. 2.64 \pm 1.20 kg/d and 17.1 vs. 0.2 \pm 5.8%, respectively). The inclusion of RDP increased duodenal NDF flow ($P = 0.08$; 2.45 vs. 2.87 \pm 2.06 kg/d) and decreased NDF ruminal digestion

($P = 0.06$; 17.1 vs. 4.5 \pm 5.8%). The addition of RUP alone in the diet increased CP intake over control and RDP diets ($P = 0.02$; 1.62 vs. 1.79 \pm 0.07 kg/d). Total tract OM, CP, ADF, and NDF digestibilities were unaffected by RDP and RUP supplementation. These results suggest protein supplementation decreased ruminal fiber digestion and did not improve digestion of other feed fractions.

Key Words: Barley, Digestion, Ruminal Fermentation

838 Effect of choice-select spread on carcass value and profitability in early-weaned Simmental steers. N. A. Pyatt*¹, L. L. Berger¹, D. B. Faulkner¹, and P. M. Walker², ¹University of Illinois at Urbana-Champaign, Urbana, ²Illinois State University, Normal.

Early-weaned steers (n = 192, ³/₄ Simmental or greater) of known genetics were individually fed in a four-year study to determine the influence of Choice-Select (Ch-Se) spread (\$4, \$8, \$12 or \$16 per 45.4 kg) on performance and carcass factors explaining variation in carcass value and profitability. Steers were weaned at 88.0 \pm 1.1 d and fed a high concentrate diet for 334.2 \pm 0.7 d. Five-year price data were collected for feedstuffs, dressed beef, and grid premiums and discounts. Input costs included annual cow costs, veterinary, labor, feed markup, yardage and interest. Independent variables included growth and carcass EPDs, daily intake (DMI), daily gain (ADG), hot carcass weight (HCW), calculated yield grade (YG) and marbling score (MS). At \$4 Ch-Se spread, HCW (57%), YG (17%) and MS (4%) accounted for nearly 78% of the variation in carcass value among steers. ADG (27%), YG (19%), HCW (16%), MS (7%) and DMI (5%) accounted for nearly 74% of the variation in profit with a \$4 Ch-Se spread. At \$8 Ch-Se spread, HCW (55%), YG (13%) and MS (9%) accounted for over 77% of the variation in carcass value among steers. ADG (22%), MS (19%), YG (16%), HCW (11%) and DMI (4%) accounted for nearly 72% of the variation in profit with an \$8 Ch-Se spread. At \$12 Ch-Se spread, HCW (38%), MS (27%) and YG (11%) accounted for over 76% of the variation in carcass value among steers. Marbling score (26%), ADG (19%), YG (14%), HCW (8%) and DMI (4%) accounted for 71% of the variation in profit with a \$12 Ch-Se spread. At \$16 Ch-Se spread, MS (37%), ADG (16%), YG (12%) and HCW (7%) accounted for over 73% of the variation in carcass value among steers. Marbling score (33%), ADG (15%), YG (12%), HCW (6%) and DMI (4%) accounted for over 70% of the variation in profit with a \$16 Ch-Se spread. When estimating carcass value, the importance of marbling score increased while carcass weight decreased with rising Ch-Se spread. When assessing profitability, the importance of marbling score increased while ADG, carcass weight and YG diminished with increasing Ch-Se spread.

Key Words: Carcass Value, Profitability, Early-Weaning

839 Effect of dressed price on carcass value and profitability in early-weaned Simmental steers. N. A. Pyatt*¹, L. L. Berger¹, D. B. Faulkner¹, and P. M. Walker², ¹University of Illinois at Urbana-Champaign, Urbana, ²Illinois State University, Normal.

Early-weaned steers (n = 192, ³/₄ Simmental or greater) of known genetics were individually fed in a four-year study to determine the influence of base price for dressed beef (\$96, \$108, \$120 or \$132 per 45.4 kg) on performance and carcass factors explaining variation in carcass value and profitability. Steers were weaned at 88.0 \pm 1.1 d and fed a high concentrate diet for 334.2 \pm 0.7 d. Five-year price data were collected for feedstuffs and grid premiums and discounts. Input costs included annual cow costs, veterinary, labor, feed markup, yardage and interest. Independent variables included growth and carcass EPDs, daily intake (DMI), daily gain (ADG), hot carcass weight (HCW), calculated yield grade (YG) and marbling score (MS). At \$96 per 45.4 kg, MS (25%), ADG (19%), YG (18%) and HCW (10%) accounted for nearly 72% of the variation in carcass value among steers. Marbling score (19%), YG

(16%), ADG (14%) and DMI (12%) accounted for over 61% of the variation in profit when base price was \$96 per 45.4 kg. At \$108 per 45.4 kg, ADG (26%), MS (23%), YG (15%) and HCW (11%) accounted for nearly 75% of the variation in carcass value among steers. Daily gain (21%), MS (20%), YG (15%), HCW (10%) and DMI (5%) accounted for over 71% of the variation in profit when base price was \$108 per 45.4 kg. At \$120 per 45.4 kg, HCW (59%), YG (11%) and MS (10%) accounted for over 79% of the variation in carcass value among steers. Daily gain (21%), MS (20%), YG (14%), HCW (13%) and DMI (7%) accounted for over 75% of the variation in profit when base price was \$120 per 45.4 kg. At \$132 per 45.4 kg, HCW (54%), YG (9%) and MS (8%) accounted for nearly 82% of the variation in carcass value among steers. Carcass weight (52%), YG (10%), MS (9%) and DMI (7%) accounted for nearly 78% of the variation in profit when base price was \$132 per 45.4 kg. When estimating carcass value, the importance of carcass weight increased while marbling score decreased with rising base price. When assessing profit, the importance of carcass weight increased with increasing base price for dressed beef.

Key Words: Carcass Value, Profitability, Early-Weaning

840 Effects of carbohydrate source and forage level in the diet on nitrogen balance, digestibility and portal nutrient flux in sheep. A. F. Branco*, G. F. Mouro, F. J. Maia, T. F. Minella, L. P. Rigolon, and S. M. Coneglian, *Universidade Estadual de Maringa*.

The objectives of this experiment was to evaluate the effects of two carbohydrate sources (soybean hulls and corn) and two forage level (40% and 70%) in the diet on nitrogen balance, nutrient digestibility and portal nutrient flux in sheep. Were used four Corriedale wethers with 45 kg of live weight in a 4 x 4 Latin square. The wethers were fitted with catheter in mesenteric and portal veins and mesenteric artery. Digestibility and nitrogen balance were determined using total collection of feces and urine. Portal plasma flow was determined by continuous infusion of *P*-aminohippurate, and net nutrient flux was calculated as the difference between venous and arterial concentration times blood flow. There was no difference among treatments for dry matter intake, and dry matter digestibility was higher ($P < .01$) for corn diets. Intake, digestion and digestibility of neutral fiber detergent (NDF) was higher ($P < .05$) for soybean hulls diets. Corn diets showed higher ($P < .01$) ether extract intake, digestion and digestibility. There was higher ($P < .01$) non fiber carbohydrates intake and digestion in diets with 40% forage and corn diets. Energy concentration expressed as total digestible nutrients (TDN) was higher ($P < .02$) for corn diets. Diets with 40% forage showed higher nitrogen utilization as result of lower ($P < .01$) fecal and urinary losses and higher ($P < .01$) digestibility and nitrogen retention. Carbohydrate source and forage level did not influence portal plasma flow. Portal and arterial glucose concentration were higher ($P < .01$) for corn and 40% forage diets. Carbohydrate source and forage level did not affect variables related to alpha-amino-nitrogen. Portal ammonia and urea concentration, venous-arterial difference and portal ammonia flux were lower ($P < .01$) for 40% forage diets.

Key Words: Portal Nutrient Flux, Metabolism, Carbohydrate

841 Digestion characteristics of corn plus cottonseed meal compared to whole cottonseed plus de-oiled rice bran as supplements for beef cattle and the effects of extrusion. M. S. Gadberry*¹, P. A. Beck², S. A. Gunter², and D. W. Kellogg³, ¹Cooperative Extension Service, University of Arkansas, Little Rock, ²Southwest Research and Extension Center, University of Arkansas, Hope, ³Department of Animal Science, University of Arkansas, Fayetteville.

A 3 x 3 Latin-square design was used to evaluate ruminal digestion characteristics of a conventional versus co-product based supplement for growing beef cattle. Treatments included free choice hay and either 1) corn and cottonseed meal (71:29, wt:wt; CCSM) supplement, 2) de-oiled rice bran and whole cottonseed (62:38, wt:wt; DRCS), or 3) extrusion processed de-oiled rice bran plus whole cottonseed (EXT) offered at 1% BW (DM basis). Contrasts were used to compare supplement type, CCSM vs. DRCS plus EXT, and the effects of processing, DRCS vs. EXT. Neither supplement type nor processing affected marker predicted hay, supplement, or total DM intake ($P > 0.20$). Supplement DM degradation rate did not differ between type ($P = 0.82$) or processing ($P = 0.23$). Rate of passage of the CCSM (5.8%/h) supplement was higher

($P = 0.01$) than the DRCS (4.4%/h) and EXT (4.5%/h) supplements, and EXT tended to be higher than DRCS ($P = 0.08$). Supplement type ($P = 0.09$) and processing ($P = 0.08$) tended to affect supplement rumen degradable DM, 49.0, 50.4, and 52.7%, for CCSM, DRCS, and EXT, respectively. Supplement type or processing did not affect hay DM degradation rate, passage rate, or rumen degradable DM ($P > 0.10$). Supplement type tended to differ ($P = 0.06$) in rumen degradable N to rumen degradable OM (g/kg, RDN:RDOM); however, supplement type or processing did not affect ($P > 0.20$) overall diet RDN:RDOM. The total tract DM digestibility was not affected by supplement type ($P = 0.74$) or processing ($P = 0.67$) and was 68.9, 70.5, and 69.1% for the CCSM, DRCS, and EXT treatments, respectively. Co-product based supplements can effectively be used in place of conventional feedstuffs, and extrusion processing had minor effects on digestion characteristics.

Key Words: Beef Cattle, De-Oiled Rice Bran, Extrusion

842 Using a dynamic mechanistic ruminant model to estimate the effect of large changes in starch fermentation rates and site of digestion on cattle growth. B. N. Nagorcka*¹ and S. Bird², ¹CSIRO Livestock Industries, Canberra, Australia, ²University of New England, NSW, Australia.

We have observed *in vitro* fermentation rates in a range of sorghum grains and processed grains to vary over a 3-fold range. To assess the effect on cattle growth of a 2-fold change in fermentation rate, achieved by steam flaking sorghum (SF), we have used a dynamic, mechanistic model (AusBeef, supported by CSIRO) to predict feed intakes, body growth rates, body protein/fat growth rates and feed conversion ratios (FCR) in an example where a 70:30 sorghum:forage mix is fed to Angus steers at a starting body weight (BW) of 300 kg. The predictions of rumen and whole tract digestibility of starch for dry-rolled sorghum (DR) are 59% and 82%, and for SF the predictions are 78% and 97%, i.e., similar to published observations. Although 18% of the starch is predicted to be lost using DR, the cattle are also predicted (table) to eat more, and have higher BW gains in the early stages of the feeding relative to SF (found to be consistent with recent observations) because there is a shift in the site of digestion to post-rumen causing protein synthesis to be favoured. As a consequence steam flaking produces only a small reduction in the FCR relative to DR. However the FCR for SF is 10% higher (less efficient) than is predicted if all the starch escaping digestion in the rumen using DR is digested post rumen (DR+PR in the table), i.e. maximising the shift in site of digestion. It is concluded that the full commercial potential of sorghum is not achieved in SF.

		Feeding period (d)				
		1-30	31-60	61-90	91-120	1-120
DM intake (Kg/d)	SF	8.35	8.88	9.37	9.66	9.07
	DR	8.78	9.70	10.28	10.64	9.85
	DR+PR	7.91	8.41	8.94	9.39	8.66
BW gain (Kg/d)	SF	1.30	1.39	1.31	1.21	1.30
	DR	1.40	1.51	1.36	1.24	1.38
	DR+PR	1.36	1.48	1.35	1.25	1.36
Feed/gain (FCR)	SF	6.13	6.10	6.83	7.62	6.66
	DR	5.99	6.13	7.22	8.19	6.81
	DR+PR	5.55	5.42	6.32	7.17	6.08

843 Ruminal nutrient degradation of untreated and chemically treated wheat grain. K.-H. Suedekum*¹, M. Klein¹, M. Paschke-Beese¹, and O. Schade², ¹University of Kiel, Germany, ²Raiffeisen HaGe Nord, Rendsburg, Germany.

This study compared ruminal nutrient degradation of untreated wheat grain (dry matter basis: 67.2% starch, 13.4% crude protein [CP]) with a wheat grain that was chemically treated with xylose in aqueous Ca-Mg lignosulphonate solution at elevated temperatures (WeiPass[®]; 55.6% starch, 14.8% CP). A standardized *in situ* procedure was applied using three ruminally cannulated steers. Feed samples were incubated in the rumens for 0, 2, 4, 8, 16, 24, 48, 72, and 336 h to estimate rate and extent (effective degradability at assumed rumen outflow rates of 2, 5 and 8%/h) of ruminal degradation of CP and starch. The proportions of ruminally undegraded CP (RUP) and ruminally undegraded starch (RUS)

were estimated as (100 - effective degradability [%]). Water-soluble fractions of CP (11.1 versus 16.7%) and starch (18.2 versus 18.4%) and lag phases before the commencement of degradation (all values < 0.5 h) were not different ($P > 0.15$) between wheat and WeiPass[®]. The sizes of the insoluble but degradable CP and starch fractions and their rates of degradation were higher ($P < 0.05$) for wheat than for WeiPass[®], and wheat was more extensively degraded ruminally than WeiPass[®], resulting in higher ($P < 0.01$) effective degradability values of CP (72 vs. 42% at 8%/h outflow) and starch (82 vs. 64% at 8%/h outflow) for wheat than for WeiPass[®]. Consequently, WeiPass[®] had RUP values which were 20 to 30 percentage units higher ($P < 0.01$) than those of ground wheat,

depending on the assumed rumen outflow rate. An increase in RUS values for WeiPass[®] compared to wheat was also observed, though not as pronounced numerically as for RUP. The RUS values of WeiPass[®] were between 10 and 20 percentage units higher than the respective values for the wheat. If the increase in RUP and RUS for WeiPass[®] above the wheat values is expressed relative to the wheat values, proportions of RUP and RUS of WeiPass[®] at an assumed rumen outflow rate of 8%/h had doubled compared with the wheat, i.e., it increased from 28 to 58% of CP for RUP and from 18 to 36% of starch for RUS.

Key Words: Rumen, Starch, Protein

Ruminant Nutrition: Dairy - Transition Cows

844 Altered feeding behavior occurs in both primiparous and multiparous Holsteins during the periparturient period. M. A. DeGroot* and P. D. French, *Oregon State University, Corvallis.*

The objective of the following experiment was to describe changes in feeding behavior during the periparturient period. Twenty-four multiparous and 18 primiparous Holstein cows were group housed and fed individually via Calan[®] doors for the three weeks before and after parturition. Behind each door was a feed tub that rested on a digital scale. Scales were connected to a computer that collected date, time, and tub weight during feeding bouts. Data were analyzed using the MIXED procedure of SAS and differences were declared significant at $P < 0.05$. During the prepartum period, total daily mealtime decreased from 227 min/d at 21 d prepartum to 130 min/d 1 d prepartum. In addition, meal duration decreased from 31 to 18 min/d, DMI decreased from 14.0 to 9.0 kg/d, and meal DMI decreased from 1.93 to 1.21 kg/meal. Meals (8.1/d) and feeding rate (81.9 g DM/min) were similar during the prepartum period. Prepartum total daily mealtime (213 and 187 min/d) and meal duration (27.2 and 24.2 min/meal) were greater for primiparous cows. Feeding rate was greater for multiparous compared to primiparous cows, 95.1 and 66.6 g DM/min, respectively. During the postpartum period, total daily mealtime and meal duration increased from 98 to 251 min/d and 15 to 29 min/meal, respectively, the day of parturition compared to 21 d postpartum. In addition, daily DMI and DMI/meal increased from 8.6 to 17.7 kg/d and 1.29 to 2.15 kg/meal, respectively. Except for the day of parturition (6.7 meals/d), meals (8.8/d) was similar during the postpartum period. Postpartum feeding rate decreased from 112.4 g DM/min the day of parturition to 85.5 g DM/min 21 d postpartum. Feeding rate was greater for multiparous compared to primiparous cows, 106.7 and 78.0 g DM/min, respectively. Results show that the depression in DMI that occurs around the time of parturition coincides with a decrease in feeding time. Therefore, strategies that increase feeding time during this critical period may be useful in increasing DMI.

Key Words: Feeding Behavior, Feed Intake, Periparturient

845 Effects of increased exposure to pre-calving diets containing BioChlor: Reproductive performance. P. J. DeGaris¹, I. J. Lean*¹, D. M. McNeill², and A. R. Rabiee¹, ¹*Bovine Research Australasia, NSW, Australia*, ²*University of Sydney, NSW, Australia.*

Holstein and Holstein x Jersey cows (n=993) in three herds, entered a prospective study to examine the effects of increased exposure to pre-calving transition diets on reproductive performance over the first 150 days of lactation. Pre-transition dry cow diets consisted of ad libitum access to ryegrass hays and pastures. Transition diets included, on a DM basis 2.8 kg ryegrass pasture, 4.2 kg ryegrass silage or creal hay, 3 kg grain or grain by-product, 0.1 kg canola or cottonseed meal, 0.6 kg BioChlor, 250 mg sodium monensin and 200 mg virginiamycin or 150 mg tylosin per day, MgSO₄ and trace elements. The transition diets contained on a DM basis (±SE), 16.0 (±1.08)% crude protein, 4.2 (±0.66)% rumen undegradable protein, 6.9 (±0.23) MJ NE_L, 0.4 (±0.06)% calcium and provided a metabolisable protein balance of 286 (±182.2) g/day and a dietary cation anion balance of -15.0 (±5.50) meq/100g. Of 158 cows excluded from analysis: 55 had gestation periods <269 or > 299 days, 58 had data missing or outside analytic limits and 45 died or were culled prior to mating start date. Cox's Proportional Hazards Model was appropriate to describe time to submission for first mating and time to conception. The probability of submission per day increased ($P = 0.021$) by 1.012 (95% Confidence Interval 1.002 to 1.023) and that

of conception per day increased ($P = 0.001$) by 1.019 (95% Confidence Interval 1.008 to 1.030) for each day of exposure to the transition diet. Increasing exposure to transition diets did not significantly increase the proportion of cows that conceived at first mating as assessed by logistic regression ($P = 0.241$). The statistical model used included farm, age, calving order and breed where significant ($P < 0.05$). The results indicate that increasing exposure to a pre-calving transition diet containing BioChlor is positively associated with improved submission of cows for breeding, a shorter time to conception, but not a significantly higher conception rate at first breeding after calving.

Key Words: Transition Diet, Sodium Monensin, BioChlor

846 Effects of increased exposure to pre-calving diets containing BioChlor: Milk production. P. J. DeGaris¹, I. J. Lean*¹, D. M. McNeill², and A. R. Rabiee¹, ¹*Bovine Research Australasia, NSW, Australia*, ²*University of Sydney, NSW, Australia.*

Holstein and Holstein x Jersey cows (n = 993) in three herds, entered a prospective study to examine the effects of increased exposure to pre-calving transition diets on milk production over the first 150 days of lactation. Pre-transition dry cow diets consisted of ad libitum access to ryegrass hays and pastures. Transition diets included, on a DM basis, 2.8 kg ryegrass pasture, 4.2 kg ryegrass silage or cereal hay, 3 kg grain or grain byproduct, 0.1 kg canola or cottonseed meal, 0.6 kg BioChlor, 250 mg sodium monensin and 200 mg virginiamycin or 150 mg tylosin per day, MgSO₄ and trace elements. The transition diets contained on a DM basis (±SE), 16.0(±1.08)% crude protein, 4.2 (±0.66)% rumen undegradable protein, 6.9 (±0.23) MJ NE_L, 0.40 (±0.06)% calcium and provided a metabolisable protein balance of 286 (±182.2) g/day and a dietary cation anion balance of -15.0 (±5.50) meq/100g. Of 182 cows excluded from analysis: 55 had gestation periods <269 or > 299 days; 82 had < six herd recordings and 45 had missing data. Cows were grouped by exposure to the pre-calving transition diet into 0 to 10, 11 to 20 and > 20 days exposure. Statistical models evaluating the association between exposure group and production variable controlled for farm, calving order, breed and age where significant ($P < 0.05$). Mean milk, protein yield, protein and fat percentage (±SE) and P values for exposure groups are tabulated below. Fat yield and individual somatic cell count did not vary significantly with exposure group. The results indicate that increasing exposure to a pre-calving transition diet containing BioChlor is negatively associated with fat and protein percentage but positively associated with milk and milk protein yields.

Exposure (days)	Milk yield (L/day)	Protein yield (kg/day)	Protein %	Fat %
0-10	28.3±0.25	0.96±0.007	3.43±0.014	3.89±0.035
11-20	28.8±0.23	0.97±0.006	3.40±0.013	3.85±0.032
>20	30.4±0.40	1.01±0.011	3.33±0.022	3.67±0.056
P value	0.001	0.003	0.004	0.008

Key Words: Transition Diet, Sodium Monensin, BioChlor

847 Effects of increased exposure to pre-calving diets containing BioChlor: Cow health. P. J. DeGaris¹, I. J. Lean^{*1}, D. M. McNeill², and A. R. Rabiee¹, ¹*Bovine Research Australasia, NSW, Australia*, ²*University of Sydney, NSW, Australia*.

Holstein and Holstein x Jersey cows (n = 993) in three herds, entered a prospective study to examine the effects of increased exposure to pre-calving transition diets on milk production over the first 150 days of lactation. Pre-transition dry cow diets consisted of ad libitum access to ryegrass hays and pastures. Transition diets included, on a DM basis, 2.8 kg ryegrass pasture, 4.2 kg ryegrass silage or cereal hay, 3 kg grain or grain by-product, 0.1 kg canola or cottonseed meal, 0.6 kg BioChlor, 250 mg sodium monensin and 200 mg virginiamycin or 150 mg tylosin per day, MgSO₄ and trace elements. The transition diets contained on a DM basis (±SE), 16.0 (±1.08)% crude protein, 4.2 (±0.66)% rumen undegradable protein, 6.9 (±0.23) MJ NE_L, 0.4 (±0.06)% calcium and provided a metabolisable protein balance of 286 (±182.2) g/day and a dietary cation anion balance of 15.0 (±5.50) meq/100g. Of 103 cows excluded from analysis: 55 had gestation periods < 269 or > 299 days, 58 had data missing or outside analytic limits. Logistic regression modelling was used to describe the risk of retained foetal membranes (RFM), clinical mastitis, lameness, CIDR use and removal from the herds, by 150 days of lactation with farm, calving order and age used as covariates where significant (P < 0.05). Increasing exposure to the pre calving transition diet did not affect the risk of lameness (P = 0.98), clinical mastitis (P = 0.16), CIDR use (P = 0.93) or RFM (P = 0.98) but did reduce the risk of removal from the herd by 150 days of lactation (odds ratio = 0.95, 95% confidence interval = 0.920 to 0.985, P = 0.004). However, time to removal was not significant (P = 0.428). The results indicate that increasing exposure to a pre-calving transition diet containing BioChlor is positively associated with improved cow survival to 150 days of lactation, but did not significantly affect other specific measures of cattle health.

Key Words: Transition Diet, Sodium Monensin, BioChlor

848 Effect of a dry propylene glycol product for postpartum Holstein dairy cows on health and performance. Y.-H. Chung^{*1}, K. S. Heyler¹, T. W. Cassidy¹, S. L. Ward¹, I. D. Girard², and G. A. Varga¹, ¹*Department of Dairy and Animal Science, The Pennsylvania State University, University Park*, ²*Probiotech International Inc., Saint-Hyacinthe, Quebec, Canada*.

Thirty-nine Holstein dairy cattle (primiparous=20 and multiparous=19) were paired by parity and previous 305ME and assigned to one of three treatments: (1) control: no propylene glycol (PG) supplementation, (2) TMR: PG supplemented in the TMR, and (3) top-dressed (TD): PG top-dressed on the TMR. Propylene glycol was supplemented at a level of 250 g/cow/d. Supplementation of PG was started after parturition and continued for three weeks after calving. Cows were fed once and milked twice daily. Dry matter intake and milk yield were recorded daily and milk was sampled weekly. Blood was sampled at 4, 7, 14, and 21 days relative to calving. Body condition score (BCS) and body weight were also recorded before and after the experiment. Supplementation of PG lowered (P<.08) blood concentration of β-hydroxybutyrate (BHBA) compared to the control. Blood concentration of BHBA for the TMR group tended (P=0.07) to be lower than the control (976.12 vs. 1627.88 μmol/L, respectively) and was not different between the TMR and TD. Blood concentrations of glucose, non-esterified fatty acid, insulin, cholesterol, urea, and aspartate amino transferase did not differ across treatments. Dry matter intake (DMI), milk yield, % of milk fat and protein, and yield of milk fat and protein were also not affected by PG treatments. However, there was a treatment by week interaction observed on DMI (P<.01) and milk yield (P<.05) indicating that DMI for the TMR increased at a more rapid rate than the control and TD and increases in milk yield for both PG treatments were greater over time as compared to the control. There was no PG effect observed on BCS and body weight change across treatments. Supplementation of PG significantly reduced blood BHBA when added to the TMR and numerically decreased blood BHBA when TD suggesting a positive benefit of providing dry PG in reducing ketosis after calving.

Key Words: Beta-hydroxybutyrate, Blood Metabolites

849 Effects of method of delivery of glycerol on performance of dairy cows during the transition period. K. L. Ogborn^{*1}, R. Paratte¹, K. L. Smith¹, P. W. Jardon², and T. R. Overton¹, ¹*Cornell University, Ithaca, NY*, ²*West Central Soy, Ralston, IA*.

Holstein cows (n=48) entering second or greater lactation were utilized to determine the effects of method of delivery of glycerol on performance of dairy cows during the transition period. Beginning 21 d before expected parturition, cows were fed either a control diet or a diet containing glycerol (5% of DM). After parturition, cows were assigned to one of four treatments in a 2 (dietary glycerol; 3.3% of DM) X 2 (glycerol drench; 500 ml/d for 5 d) factorial arrangement. From d 22 through 63 of lactation, cows were fed the same diet. Feeding glycerol during the prepartum period increased prepartum DMI (14.8 vs. 13.2 kg/d; P < 0.001). Feeding glycerol during the postpartum period tended to decrease postpartum DMI (20.9 vs. 21.9 kg/d; P < 0.08) and drenching glycerol for the first 5 d of lactation decreased postpartum DMI (20.6 vs. 22.2 kg/d; P < 0.01). Milk yield averaged 42.1 kg/d during the experiment and was not affected (P > 0.15) by feeding glycerol during either the prepartum or postpartum periods or drenching glycerol during the first 5 d of lactation. Percentages and yields of milk fat and true protein were not affected (P > 0.15) by feeding glycerol during either the prepartum or postpartum periods; however, drenching glycerol tended to decrease milk protein content (2.82 vs. 2.94%; P < 0.15) and decreased milk lactose content (4.63 vs. 4.73%; P < 0.05). Overall, feeding glycerol during the prepartum period increased prepartum DMI; however, feeding or drenching glycerol during the postpartum period decreased postpartum DMI. Milk yield during the first 63 d of lactation was not affected by either prepartum or postpartum glycerol administration.

Key Words: Transition Cow, Glycerol

850 Effects of feeding propionate and calcium salts of long-chain fatty acids on transition dairy cow performance. J. M. DeFrain^{*}, A. R. Hippen, K. F. Kalscheur, and R. S. Patton, *South Dakota State University, Brookings*.

Multiparous Holstein cows (n = 40) were used in a randomized complete block design to determine the effects of feeding Ca and Na salts (1:1, wt/wt) of propionate and Ca salts of long-chain fatty acids (LCFA) on transition performance. All cows were fed the same basal diet once daily for ad libitum intake. Treatments (kg/d) were 0.36 corn starch (C), 0.23 propionate + 0.14 corn starch (P), 0.23 propionate + 0.14 LCFA (PF1), and 0.34 propionate + 0.20 LCFA (PF2). Treatments were hand-mixed into the upper 1/3 of the TMR from 2 wk pre- through 3 wk postpartum. Intakes were recorded from 21 d pre- through 21 d postpartum. Energy density and CP were 1.54 and 1.65 Mcal/kg and 14.4 and 18.8% for pre- and postpartum diets, respectively. All cows received a common diet from 22 to 70 DIM. Milk composition was analyzed on d 7, 14, and 21. Blood was sampled at 14, 7, and 2 d prepartum and 2, 7, 14, and 21 DIM. Pre- and postpartum DMI averaged 11.9 and 16.4 kg/d, respectively, and did not differ among treatments. There was a tendency (P = 0.08) for a diet by week interaction for postpartum DMI as cows fed PF2 consumed 2 kg/d less DM during wk 2 relative to other treatments. Milk yields from 22 to 70 DIM were 48.8, 48.5, 47.8, and 51.3 kg/d for C, P, PF1, and PF2, respectively, and were not significantly affected by treatments. Milk true protein (3.32 vs. 3.16%, P = 0.05) was increased and MUN (12.5 vs. 14.4 mg/dl, P = 0.04) was decreased for C relative to other treatments. Milk fat yield from cows fed P tended to be greater than those fed PF1 (1.58 vs. 1.29 kg/d, P = 0.10). Plasma glucose, insulin, and BHBA were not affected by treatments. The PF2 treatment tended to decrease overall NEFA in plasma relative to PF1 (492 and 670 μEq/L, P = 0.08) and postpartum plasma NEFA relative to those fed PF1 (623 and 875 μEq/L, P = 0.03). Relative to PF1, feeding propionate and LCFA at the greater level in this experiment improved postpartum energy balance as evidenced by decreased concentrations of plasma NEFA.

Key Words: Propionate, Fat, Transition Dairy Cow

851 The effect of prepartum monensin supplementation on milk production in dairy cows. A. Arieli* and U. Dicken, *Hebrew University, Rehovot, Israel.*

It is commonly assumed that the effect of monensin on increasing milk yield is higher in dairy cows fed a forage based diet. A trial was conducted using 140 cows (110 multiparous and 30 primiparous) to evaluate the effect of prepartum (-30 d) administration of a monensin controlled release capsule (CRC) on production and composition of milk, and metabolites of high yielding dairy cows fed with a concentrate diet. Cows were evenly assigned, based on former yield, parity, and BCS at drying into two groups: control (CON) and CRC, supplying 300 mg monensin/d for 100 d. Primiparous cows were allocated according to BCS on -60 d. The prepartum and postpartum diets contained 14.5% crude protein and 1.55 Mcal NEL/kg of DM, and 16.5% crude protein (RUP 35% of CP), 29% NDF (forage NDF 58% of NDF), and 1.76 Mcal NEL/kg of DM, respectively. The concentrations of beta hydroxybutyric acid (BHBA) was lower and glucose concentration was higher in the CRC group, during 2 wks to +1 wk. Highest BHBA and lowest glucose concentrations were detected in +1 wk: 10.3 and 8.3 mg/dl for BHBA, and 49 and 53 mg/dl for glucose in CON and CRC, respectively ($P < 0.01$). The proportion of ketotic multiparous cows treated with a drench of propylene glycol was 11 and 34% in CRC and CON ($P < 0.05$). Milk production in multiparous cows during the first three months postpartum was 40.5 and 42.6 kg/d in CON and CRC, respectively ($P < 0.05$). Milk fat and protein concentrations were similar among treatments averaging 3.80 and 3.07% (mo 1), 3.39 and 2.88% (mo 2), 3.17 and 2.82% (mo 3), respectively. Results of the current study are in line with improved energy balance due to CRC supplementation indicating that monensin provided prepartum can be beneficial in terms of health and production when supplied to dairy cows maintained on high concentrate diets.

Key Words: Monensin, Transition Cow, Ketosis

852 Effect of lowered prepartum DCAD on urinary pH: A meta-analysis. E. Charbonneau*¹, D. Pellerin¹, and G.R. Oetzel², ¹ *Université Laval, Quebec, Canada*, ² *University of Wisconsin, Madison.*

Lowered prepartum dietary cation-anion difference (DCAD) reduces milk fever at parturition. Urinary pH has been used to directly monitor dairy cow response to lowered DCAD. A meta-analysis of previously published studies was performed to evaluate the relationship between prepartum DCAD and urinary pH. Twenty-two published studies containing 48 treatment groups met criteria for inclusion in the meta-analysis. The relationship between DCAD and urinary pH was nonlinear and fit well with a symmetric logistic curve. In the nonlinear model, treatment group mean urinary pH decreased from 8.28 to 5.99 as DCAD [(Na+K) (Cl+S)] decreased from about +100 to 150 meq/kg dry matter. Urinary pH did not change if DCAD was increased above +100 or below 150 meq/kg. Five different equations to calculate DCAD were compared to urinary pH using mixed models. The DCAD formula (Na+K) (Cl+S) was the most highly associated with urinary pH. Concentrations of dietary minerals Ca, P, Mg, Na, K, Cl and S (meq/kg basis) were also compared to urinary pH. Among these minerals, only Na, K and Cl were significant in the final model for urinary pH. Both K (0.00376) and Na (0.00339) had similar coefficients, but the coefficient for Cl (-0.00624) was about twice the magnitude. These results validate the DCAD equation (Na+K) (Cl+S) for predicting urinary pH and demonstrate the importance of Cl in lowering urinary pH of prepartum dairy cows.

Key Words: Prepartum Dairy Cows, DCAD, Urinary PH

853 Direct-fed microbial supplementation on ruminal digestion, health And performance of pre- and postpartum dairy cattle. J. E. Nocek*¹ and W. P. Kautz², ¹ *Spruce Haven Farm and Research Center, Auburn, NY* ² *Chr Hansen BioSystems, Milwaukee, WI.*

Effects of direct-fed microbial (DFM) supplementation to dairy cows during the transition period were evaluated. Forty-four Holstein cows were fed close-up and lactating diets either with or without 2 g/cow/d of DFM. The DFM contained approximately 5×10^9 cfu of bacteria (two specific *Enterococcus faecium* strains) and 5×10^9 cfu of yeast and was incorporated into the diets via a cornmeal carrier. Supplemented cows

were fed the DFM 21 days prior to expected calving date and continued through 10 wk postpartum. Cows supplemented with DFM had higher ($P < .01$) 24h ruminal DM digestibility for both corn silage and haylage than nonsupplemented cows. Supplemented cows consumed more DM during the pre- ($P < .10$) and postpartum ($P < .01$) period. In addition, those supplemented with DFM produced 2.3 kg more ($P < .01$) milk/cow/d than nonsupplemented cows. There was no difference in the 3.5 % FCM. Milk fat percentage was lower ($P < .01$), but not depressed (4.50%) for cows receiving DFM. There was no difference in milk fat or protein yield, milk protein percent and postpartum health. Cows consuming DFM had higher ($P < .05$) blood glucose postpartum, as well as lower beta-hydroxy butyric acid levels both pre- and day 1 postpartum. Plasma nonesterified fatty acid concentration was not affected by DFM supplementation. The results of this study indicate that targeted DFM supplementation positively influenced ruminal digestion of forage DM and transition cow performance.

Key Words: Direct-Fed Microbial, Ruminal Digestion, Production

854 Production and blood metabolites in multiparous Holstein and Jersey cows fed rumen-protected choline during the periparturient period. N. A. Janovick*¹, D. B. Carlson¹, J. E. Garrett², and J. K. Drackley¹, ¹ *University of Illinois, Urbana*, ² *Balchem Encapsulates, Slate Hill, NY.*

Choline is proposed to facilitate export of triglyceride from liver as VLDL, however, production responses to supplemental choline have varied. To better understand effects of choline on periparturient metabolism, our study characterized blood metabolite profiles of cows fed rumen-protected choline (RPC) pre- and postpartum. Thirty-two multiparous Holstein and 10 multiparous Jersey cows were randomly assigned to control (CON) or RPC dietary treatments. A close-up diet (1.64 Mcal NE_L/kg; 15.5% CP) was fed from 25 d before until parturition, followed by a lactation diet (1.75 Mcal NE_L/kg; 17.2% CP) from calving through 49 d postpartum. For RPC, diets were topdressed once daily with 60 g rumen-protected choline from 21 d before expected parturition through 21 d postpartum. Blood samples obtained on d -22, -19, -16, -13, -10 through 10, 13, 16, 19, 21, 28, 35, 42, and 49 relative to parturition were analyzed for urea N, total protein, BHBA, cholesterol (CH), glucose, and triglyceride in serum, and NEFA and phospholipid (PL) in plasma. RPC did not affect weekly DMI either pre- (12.1 kg; $P = .99$) or postpartum (15.3 kg; $P = .41$). Yields of milk, fat, and protein were unaffected by RPC (34.1 kg/d, $P = .39$; 1.42 kg/d, $P = .34$; and 1.07 kg/d, $P = .60$). RPC cows had lower ($P = .02$) plasma PL than CON cows at parturition (65.2 and 78.1 mg/dL). Breed*¹ treatment (b*trt) interactions affected plasma NEFA concentration d 1 to 10 postpartum ($P = .03$), urea N prepartum ($P = .05$), and BHBA postpartum ($P = .05$). A b*trt*d interaction affected CH postpartum ($P < .01$). Other metabolites were unaffected by RPC both pre- and postpartum ($P > .15$). Because milk production was not affected, cows were not over-conditioned to begin the study (BCS = 3.3), and did not lose excessive condition by 3 wk postpartum (BCS loss = 0.5), we hypothesize cows were not at great risk for accumulating fat in the liver; therefore, no effects of RPC were observed.

Key Words: Choline, Transition Period, Lipid Metabolism

855 Feeding soybeans and rumen-protected choline to dairy cows during the periparturient period and early lactation: effects on plasma lipid balance. W.A. Oelrichs*, M.C. Lucy, M.S. Kerley, and J.N. Spain, *University of Missouri - Columbia.*

This study was designed to investigate the effects of soybeans (SB) and rumen-protected choline (RPC; Reashure™ Choline; Balchem, Slate Hill, NY) fed during the periparturient period and early lactation on plasma lipid balance of dairy cows. Sixty-four Holsteins were blocked by parity and expected calving date and randomly assigned within block to one of six experimental diets. Dietary treatments were fed from 28 days prepartum to 100 days in milk. Cows were assigned to treatments in a 3 x 2 factorial arrangement. Cows received no SB, SB beginning at calving, or SB for the duration of the study. The SB were fed as raw, cracked beans at feeding rates of 1.9 and 2.8 kg DM per cow per day during pre- and postpartum periods, respectively. The RPC was top-dressed at a rate of 0 or 15 g dietary choline per cow per day. Cows were individually fed diets as total mixed rations using electronic feeding gates. Blood

samples were collected once weekly prepartum, at days 3, 0, and +3 relative to calving, and twice weekly postpartum. Plasma were analyzed for triglycerides (TG), total cholesterol, lipoprotein cholesterol and fatty acids. Changes in plasma lipid concentrations during the periparturient period were characterized for the first time. Plasma lipid concentrations were not affected by feeding rumen-protected choline. Cows fed SB beginning at 28 days prepartum had higher plasma TG, cholesterol, lipoprotein cholesterol, and fatty acid concentrations than cows fed the control diets during the prepartum period. By 14 days postpartum, cows fed SB beginning at parturition had similar plasma lipid concentrations as cows fed SB prepartum. If increased plasma lipid concentrations have reproductive advantages, feeding SB beginning 28 days prepartum as well as at parturition are equally effective in improving lipid balance during early lactation.

Key Words: Transition Cows, Lipid Profiles, Rumen-Protected Choline

856 Effects of physiological state, prepartum dietary carbohydrate source, and chromium supplementation on dynamics of insulin, glucose, and fatty acid metabolism in dairy cows. K. L. Smith*¹, M. R. Waldron¹, T. R. Overton¹, J. K. Drackley², R. C. Boston³, and M. T. Socha⁴, ¹Cornell University, Ithaca, NY, ²University of Illinois, Urbana, ³University of Pennsylvania, Kennett Square, ⁴Zinpro Corporation, Eden Prairie, MN.

Holstein cows (n=72) entering second or later lactation were used to determine whether glucose tolerance test (GTT) indices were affected by source of carbohydrate in the prepartum diet, chromium-L-methionine (Cr-Met) supplementation throughout the periparturient period, and physiological state. Cows were fed a TMR with concentrates consisting of either starch-based cereals (high NFC; 40.3% NFC) or nonforage fiber sources (low NFC; 33.6% NFC) from 21 d before expected parturition until parturition; cows were fed a common diet postpartum. The Cr-Met was supplemented once daily via gelatin capsule at dosages of 0, 0.03, or 0.06 mg of Cr per kilogram of BW^{0.75}. Thus, treatments were in a 2 (carbohydrate source) x 3 (Cr-Met) factorial arrangement. The GTT were conducted on d 10 prior to expected parturition and d 28 postpartum and on a subset (n = 13) of cows on d 5 postpartum. The GTT indices were derived using the Minimal Model and other indices were calculated using Stata. The SI (insulin sensitivity), SG (glucose effectiveness), and DI (disposition index) were lower (P < 0.001) and AIRg (acute insulin response to glucose) was higher (P < 0.001) during the prepartum period compared to the postpartum period. The lipolysis rate (FFAslope) was lower (P < 0.001) during the prepartum period. Feeding diets containing low or high concentrations of NFC during the prepartum period resulted in no significant effects on any of the kinetic indices derived from the GTT. Administering increasing amounts

of Cr-Met linearly increased (P < 0.001) AIRg. These data support the concept that increased insulin resistance during late pregnancy is mediated through decreased insulin sensitivity, and that effects of prepartum dietary carbohydrate source and Cr-Met on tissue responsiveness to insulin are modest.

Key Words: Periparturient Cow, Chromium, Glucose Tolerance Test

857 Inducing hypocalcemia in rumen fistulated steers to determine effectiveness of anionic salt treatments for transition dairy cattle. M. A. Froetschel*¹, D. Kumar¹, P. G. Smith¹, and S. N. Nichols², ¹The University of Georgia, Athens, ²West Central Soy, Ralston, IA.

Eight rumen-fistulated Holstein steers, 4 yearling (Y: 417 ± 10.4 kg) and 4 mature (M: 632.8 ± 54.6 kg), were fed a control diet (C) or three cation-anion difference (DCAD) products: Soy-Chlor 16-7 (S), Bio-Chlor (B) or Animate (A) in a replicated 4 X 4 Latin Square. Sodium bicarbonate (1%) was added to C to make it positive in DCAD. Total mixed rations, 65% concentrate and 35% chopped Bermudagrass Hay, were fed 1X/d. During experimental periods, steers were fed C for 3 d and experimental diets for 11 days. On d 13 and d 14, Y and M steers, respectively, were fit with 2 indwelling jugular catheters. In one, Na-EDTA was infused (5% wt/wt at 6.5ml/min for 5-7 h) and in the other, blood was sampled (at 30 min intervals, 2 before and 12 during EDTA infusion). Intake and urine pH (UPH) were measured daily and reticulo-ruminal motility (RRM), UPH, urine and blood ionizable-calcium (UCA and BCA) were measured before and during IV Na-EDTA infusion. Intake (DMI) and UPH decreased by feeding DCAD. DMI was 29.0, 23.9, 25.2 and 25.4 ± 1.22 kg/d, and UPH was 8.10, 6.62, 6.61 and 6.98 ± .14 for steers fed C, S, B and A. DMI as a % of BW was 2.55, 2.09, 2.25 and 2.28 ± .1. DCAD effects on BCA during EDTA infusion depended on maturity. BCA was 5.54, 5.94, 6.89 and 6.67 mg/dL ± .22 and was 57.6, 62.6, 66.1 and 65.8 ± 1.0 % of pre-infusion BCA (10.1 ± .15 mg/dL) during EDTA (2 to 5 h), for Y steers fed C, S, B and A. BCA averaged 7.17, 6.87, 5.92 and 6.58 ± mg/dL, during EDTA (2 to 5 h), for M steers and was 70.9 % of pre-infusion BCA (9.24 ± .22 mg/dL). During EDTA infusion, frequency of RRM increased in Y but decreased in M steers fed DCAD. Prior to EDTA infusion, UCA was higher in steers fed DCAD (4.38, 29.0, 29.1 and 9.41 ± 2.4 mg/dL for C, S, B and A). During the first 2 h of EDTA, UCA decreased but was still higher in DCAD steers. After 1 h of EDTA, UCA was .4, 18.8, 13.1 and .4 ± 2.4 mg/dL for steers fed C, S, B and A. After 3 h of EDTA, UCA was not detectable. Inducing hypocalcemia with EDTA, especially in yearling steers, was useful to demonstrate efficacy of DCAD products.

Key Words: Hypocalcemia, DCAD, Calcium

Swine Species

858 Gilt selection for improved lifetime productivity. J. L. Patterson*¹, G. R. Foxcroft¹, M. J. Pettitt², and E. Beltrarena¹, ¹Swine Research & Technology Centre, Edmonton, AB, Canada, ²Prairie Swine Centre Inc., Saskatoon, SK, Canada.

In a study of 509 pre-pubertal C22 and L42 (PIC Canada) gilts given direct daily boar contact from 140.1 ± 5.1 d of age, and classified with respect to age at first estrus as Early (148.0 ± 0.5 d), Intermediate (159.8 ± 0.4 d) or Late (175.7 ± 0.5 d) responders, or as Non-Responsive (NR; not cyclic by 180 d), earlier responding gilts accumulated less non-productive days (NPD) in the gilt pool (J. Anim. Sci. Vol 81, Suppl 1). Data on reproductive performance of these gilts until either culling or farrowing as third parity sows is now available to evaluate longer-term productivity. The main differences detected were between any gilt recorded as initially responding to boar contact (R) compared to NR gilts. Analyzed on the basis of overall performance of gilts originally on inventory, R were more productive than NR gilts (P #8804 0.01), as measured by the percentage of gilts successfully bred (R = 96.2 vs. NR = 75.2 %), farrowing one (R = 85.0 vs. NR = 64.2 %), two (R = 72.2 vs. NR = 49.5 %), or three litters (R = 57.6 vs. NR = 37.0 %), and as the average litters produced per gilt on inventory (R = 2.5 ± 0.1 vs. NR = 1.7 ± 0.1 litters), reflecting a lower retention rate of NR gilts in the breeding herd. When different gilt categories were compared on the basis of productivity of sows that actually produced litters, sow NPD were higher (P #8804 0.05) in NR compared to R females, as measured by average weaning-to-estrus interval (6.4 ± 0.4 vs. 5.6 ± 0.2 d, respec-

tively) and weaning-to-conception interval (11.2 ± 1.3 vs. 7.5 ± 0.6 d, respectively). In contrast, mean total pigs born per litter at first, second and third parity was not different (P #8805 0.05) between R(10.7 ± 0.4, 11.2 ± 0.4 and 12.5 ± 0.5, respectively) and NR (10.9 ± 0.2, 11.3 ± 0.2 and 12.1 ± 0.2, respectively) gilts. Gilt selection based on recorded first estrous during periods of good boar contact (heat-no-serve) is therefore predictive of better lifetime reproductive performance.

Key Words: Gilts, Selection, Lifetime Productivity

859 Efficient sows are good mothers. R. Bergsma*, IPG, Institute for Pig Genetics, AA Beuningen, The Netherlands.

Feed intake of sows during lactation is often too low. Increasing feed intake capacity of sows is one solution, increasing feed efficiency another. The aim of this study was to investigate the sources of variation in feed efficiency during lactation. Specifically, the ratio between output (energy gain of weaned and died piglets during lactation) and input (energy from feed intake and body tissue losses corrected for maintenance) was examined. Data were collected on the experimental farm of IPG in Beilen, The Netherlands. Sows were weighed and backfat was measured ultrasonically when sows entered the farrowing house and again at weaning. Piglets were weighed at birth and at weaning. Cross fostering, mortality of piglets and lactation feed intake of sows was recorded. Lactations of three sow genetic lines (CROSS) of different parities were

investigated, resulting in 250 records. The table shows that the 50% most efficient sows produced 30 % extra output at similar level of input. The relation between output and input was not linear, but of diminishing-returns. Efficient sows were better mothers because the mortality among their piglets was lower and litter weight at weaning increased. The Efficient sows had reduced feed intake and increased body tissue losses. Significance levels were estimated using the model: $Y_{ijklm} = \mu + \text{PARITY}_i + \text{BATCH}_j + \text{CROSS}_k + \text{EFFICIENCY}_l + e_m$. For the traits weight loss, piglet survival and output, a quadratic function of input was added to the model. It was concluded that sow feed intake efficiency is a trait to take into account in studies of fertility. Current work focuses on the potential to select sows with similar feed intake and body condition losses and considerably higher output in terms of survival and piglet weight gain.

	50 % Least efficient sows	50 % Most efficient sows	
Input (MJ/d)	58.4	56.0	n.s.
Output (MJ/d)	23.9	29.9	**
Net weight start lactation (kg)	235	233	n.s.
Piglet survival (%)	79.6	88.7	**
Litter weight at weaning (kg)	73.3	84.2	**

860 Comparison of different measures of carcass composition and lean growth in swine. D. W. Newcom¹, K. J. Stalder^{*1}, and G. F. Jones², ¹*Department of Animal Science, Iowa State University, Ames, IA*, ²*Department of Agriculture, Western Kentucky University, Bowling Green*.

Data from 174 pigs from two years of the Southern Kentucky Market Hog Derby Show were utilized for this study to investigate five measures of carcass composition and their impact on estimated lean growth rate. Pigs were weighed on-test at a centralized location and final off-test weights were obtained at the show. Pigs were transported to a major packing facility (Swift, Inc., Louisville, KY) for harvest. Plant employees measured midline backfat depth at the last rib location 45 m post-mortem. At 6 h post-mortem, the carcasses were ribbed and backfat was measured off-midline at the 10th rib (BF). Last rib backfat (LRBF) was measured on the split carcasses. The 10th rib loin muscle area (LMA) was traced onto acetate paper. The LMA was measured on the carcass and the tracing with a plastic grid, and on the tracing using a compensating polar planimeter. Two people made independent measurements with tolerance of 1.29 cm² permitted. Kilograms (WTL) and percent (%L) lean in the carcass and grams of lean gained per day on test (LG) were calculated from the three loin muscle area measures and the two

measures of LRBF. Data were analyzed using a linear model with treatment (method and location of measurement) and year included as fixed effects in all analyses. Off-test weight and BF were included as covariates in the LMA analysis. Off-test weight was included as a covariate in the WTL, %L, and LRBF analyses. On-test weight was included as a covariate for the LG analyses. The LMA measured directly on the carcass was the smallest of the three methods of measurement and was different ($P < 0.05$) from that measured with the polar planimeter. The grid measurement on the acetate paper was intermediate but not different from the other two measures. When estimating WTL, %L, and LG, the three measures of LMA were not different but were lower ($P < 0.05$) than those estimated from LRBF measures. In conclusion, different techniques for measuring LMA were different but had no impact on WTL, %L, or LG estimates.

Key Words: Swine, Composition, Lean Growth

861 Effects of removing different proportions of slaughter weight pigs from pens on subsequent growth performance. J. M. DeDecker^{*1}, M. Ellis¹, B. F. Wolter², and B. A. Peterson¹, ¹*University of Illinois at Urbana-Champaign, Urbana*, ²*The Maschhoffs, Inc., Carlyle, IL*.

Twenty-one pens of crossbred finishing pigs ($n = 651$) were used in a randomized complete block design to evaluate removing three different proportions (0, 10, and 20%) of the heaviest pigs from pens on subsequent performance over a 14-d period. Pens (31 pigs/pen; mean BW = 124.3 ± 1.09 kg) were randomly allocated to treatment, and the heaviest animals were removed as dictated by treatment. Floor and feeder spaces/pig were 0.69m² and 5.25cm, 0.76m² and 5.81cm, and 0.85m² and 6.50cm for the 0, 10, and 20% removal treatments, respectively. Two statistical analyses were conducted. The first compared performance of the entire groups of pigs after removal (31 vs 28 vs 25 pigs/pen for the 0, 10, and 20% removal treatments, respectively). The second analysis compared performance of the lightest 25 pigs in each treatment. ADG ($P < 0.05$; 872, 988, and 1,048 \pm 46.2g/d for 0, 10, and 20% removal treatments, respectively) and feed intake ($P < 0.001$; 2,848, 3,064, and 3,137 \pm 53.7g/d, respectively) increased linearly as the proportion of pigs removed increased. Feed efficiency was not affected ($P = 0.106$) by removal treatment. Comparing the lightest 25 pigs/pen across treatments, ADG increased linearly ($P < 0.05$; 847, 970, and 1,034 \pm 45.8g/d, respectively). The total live weight of pigs produced was similar ($P > 0.05$) across treatments (4,246, 4,256, and 4,243 \pm 37.3kg, respectively). However, the total feed consumed/pen during the study period decreased ($P < 0.001$) linearly as the proportion of pigs removed increased (1,222, 1,200, and 1,097 \pm 19.5kg, respectively). The within-pen coefficient of variation for the entire pen at d14 post-removal was similar ($P > 0.05$) among treatments (7.38, 6.73, and 6.88 \pm 0.419%, respectively). In summary, these results suggest that growth performance increases linearly as the proportion of pigs removed increases from 0 to 20%.

SYMPOSIA AND ORAL SESSIONS

* Author Presenting Paper

Animal Health: Symposium: Integrative Aspects of Immunity, Nutrient Metabolism, and Production in Livestock

862 What are the costs of immunity? Kirk C. Klasing^{*1}, Brooke D. Humphrey¹, Alfonso J. Mireles², and Elizabeth A. Koutsos³, ¹Department of Animal Science, University of California, Davis, ²Department of Feed Research, Foster Farms, ³Department of Animal Science, California State University, San Luis Obispo.

Studies in animal nutrition often describe changes in the immune response that occur when higher levels of nutrients are added to the diet and ascribe these changes to the high needs of the immune system. Likewise, the decrease in growth and productivity that occur during an infectious challenge are normally blamed on the diversion of nutrients to support the immune response. An accounting of the costs of immunity must be accurately made for these theories and arguments to have a sound quantitative basis. Additionally, an understanding of the priority of leukocytes for nutrients is needed in order to determine susceptible populations. The costs of maintaining the immune system are related to allocating nutrients for the continued production of leukocytes, immunoglobulin, and other plasma proteins to replace those lost during normal turnover of cells and extracellular proteins. The costs of using the immune system to thwart the invasion of potential pathogens come in three primary forms. First, there are nutritional costs of mobilizing the responding cell types and fueling their effector functions. Second, there are losses in tissue function that result from damage incurred when leukocytes engage their effector mechanisms and damage tissue integrity and host cell viability (collateral damage). The primary cost of an authentic pathogen challenge is due to the systemic acute phase response, especially recruitment of the liver to aid the immune system by producing protective proteins. Third, additional costs do not appear to be related to effector functions of the immune system and include a loss of bone mass and strength, dissipation of carotenoids and increased metabolic diseases.

Key Words: Immune Response, Requirements, Maintenance

863 Interactive responses in gut immunity, and systemic and local changes in the IGF system in nursery pigs in response to *Salmonella enterica* serovar Typhimurium. B. J. Johnson^{*}, S. S. Dritz, K. A. Skjolaas-Wilson, T. E. Burkey, and J. E. Minton, Kansas State University, Manhattan.

In recent years, we've sought to understand how disparate endocrine and immune signals converge in response to *Salmonella enterica* serovar Typhimurium (ST) to impact growth and the IGF system in the nursery pig. The enteric pathogen ST interacts with gut epithelium to rapidly upregulate the chemoattractive chemokines interleukin-8 and chemokine ligand-20, and to selectively affect toll-like receptors. Activation of these components of the innate immune system appear to confine the immune response largely to the gut mucosa and mesenteric lymph nodes as evidenced by the lack of systemic elevation of proinflammatory cytokines. Despite the apparent restriction of proinflammatory signals to the gut-associated lymphoid tissue, ST provokes peripheral sequelae consistent with danger signaling, including the febrile response and activation of the adrenal axis. Also, pigs undergoing ST-induced febrile responses experience a consistent period of inappetence that is independent of changes in leptin. Additionally, this period of depressed intake is invariably accompanied by an unmistakable decline in serum IGF-I and, less consistently, with parallel reductions in circulating IGFBP-3. More recently, we have characterized changes in expression of components of the IGF system within skeletal muscle of pigs undergoing ST-associated enteric disease. Despite the characteristic decline in circulating IGF-I, relative abundance of skeletal muscle IGF-I and IGFBP-3 mRNA was unaffected by ST. However, mRNA for IGFBP-5 was reduced in skeletal muscle of ST-challenged pigs, suggesting a possible effect of the enteric disease on IGF availability. Taken together, oral challenge with ST engages elements of the mucosal innate immune system that appear to contain the spread of systemic proinflammatory cytokine signals. Even so, ST challenge is associated with parallel changes in both systemic and local IGF systems that may impact pig growth.

864 Protein tyrosine nitration: a membrane-organized mechanism for altered signal transduction during proinflammatory stress. T. H. Elsasser*¹, S. Kahl¹, J. L. Sartin², and C. Li¹, ¹USDA, Agricultural Research Service, Beltsville, MD, ²Auburn University, Auburn, AL.

Three constitutive isoforms of NO synthase (NOS), i.e., endothelial, neuronal, and mitochondrial (a fourth isoform being the high-output inducible form) impact physiological processes through their respective localized low-output production of NO from arginine. Their activities are regulated through specific phosphorylations and cofactor interactions. A significant feature of NO-based cellular function resides in how NO is processed in association with the prevailing redox conditions within cells. Under minor anoxic conditions where tissue pCO₂ increases, concomitant generation of NO via NOS and superoxide anion via xanthine oxidase, can lead to the condensation of these free radicals to form the highly reactive oxynitrogen anion peroxynitrite (ONOO⁻). A major intracellular target for ONOO⁻ is the phenolic ring of protein tyrosines where the attack results in the formation of nitrotyrosine. Nitrated proteins are identifiable by the immunohistochemical localization of nitrotyrosine in a growing number of acute and chronic diseases. We have shown that nutrition is capable of modulating the development of protein nitration during low-level proinflammatory stress. Nutrition regulates NO production rates as well as provides a sink to alter the interaction of NO with intracellular components and mops-up ONOO⁻ via scavenging capabilities of α - and γ -tocopherols. Most recently, however, we have identified membrane-based caveolae as sites of epitope-specific nitrations that appear to play a functional role in the acute modulation of signal transduction cascades where, e.g., the anabolic processes driven by the GH-IGF-1 axis need to be curtailed to facilitate alternative nutrient use paradigms for immunoresponse. Collectively, nutrient management of host response to immune challenge contributes significantly to how protein nitration reactions are processed and their study offers potential to develop intervention strategies to maintain animal health.

Extension Education: The Use of Electronic Media for Extension and Producer Education

866 Maximize your efficiency through online knowledge Bases. C. H. Wood* and A. S. Griffin, *University of Kentucky, Lexington.*

Internet technology has dramatically changed access to information. Technology does not determine change but encourages us to seek new solutions. Our clientele are seeking new solutions by accessing information in the fastest, most cost-efficient way online. A dynamic knowledge base that learns with each clients inquiry can provide such a solution. A knowledge base is a database of questions and answers. It is more than frequently asked questions (FAQ). FAQs are usually just text-based lists of questions and answers about a topic. A knowledge base is searchable, but has additional search options that search on keywords that don't appear in the question or answer. A self-learning knowledge base learns through seeding, capturing, organizing, and managing information. The knowledge information is published to a knowledge base, allowing users to search and find answers on their own through a Web interface. Users have the ability to search for answers to their questions based on the context of their queries. Users who are unable to find answers to their questions have the ability to submit questions. Based on clients past queries, answers are organized so the from the most most useful information moves to the top of the knowledge base ensuring that users find answers to their questions quicker. In the current Extension environment, specialists are asked to be more efficient. A quick way to become more efficient is to reduce the amount of time spent answering redundant or similar questions. The underlying factor is that these repeated questions are still important because clientele are still asking them. How can specialists better handle these similar questions and free up time to develop more effective programming while embracing new ways of information delivery? To address these issues, the Southern Region Equine Extension Specialists developed HorseQuest.info, a self-learning, client-driven knowledge base. It self-propagates based on user interaction and expert responses. In essence, the client populates the knowledge base with the most useful information to them.

Key Words: Extension, Online, Knowledge Base

865 Parturition-Induced Changes in Neutrophil Gene Expression: Implications for Cell Function. J. L. Burton*, S. A. Madsen, L.-C. Chang, P. S. D. Weber, K. R. Buckham, and P. M. Coussens, *Department of Animal Science, Michigan State University, East Lansing.*

Neutrophils (PMN) are the focus of many mastitis studies because of the critical role they play in immune defense against intramammary infections. However, physiological and molecular factors that induce functional changes in PMN during the mastitis-susceptible parturient period are unknown. In our recent immunogenomics studies we hypothesized that circulating PMN become targets of fluctuating parturient steroids, responding with altered expression of master genes that regulate the cells' innate immune activities. We used RNA from PMN of periparturient cows in cDNA microarray, DDRT-PCR, and other experiments to monitor the cells' gene expression and phenotypic profiles. Correlation analyses and in vitro experiments were performed to test possible contributions of cortisol, estradiol, and (or) progesterone to changes in these profiles. To date, the largest ontological cluster of affected PMN genes encode proteins involved in apoptosis regulation, with smaller clusters of affected genes also involved in cell trafficking, opsonic phagocytosis, oxidative metabolism, and less well studied tissue remodeling functions of the cells. Correlation analyses revealed cortisol as a probable factor in the profile changes observed at parturition, and this was largely confirmed in follow-up in vitro studies in which steroids were applied directly to isolated PMN. The nature of identified changes in gene expression and cell phenotype has led us to develop an untested hypothesis, that the surge in parturient cortisol acts to redirect PMN gene expression for extended longevity with heightened tissue remodeling capacity at the expense of their traditional but short lived bactericidal functions. Such a shift would be consistent with the documented role of PMN in cervical and placental remodeling that enables parturition to occur in humans, and may help account for mastitis susceptibility around calving.

Key Words: Neutrophil, Gene Expression, Apoptosis

867 The power of W³: delivering courses, training, and extension programs over the web. A. S. Griffin* and C. H. Wood, *University of Kentucky, Lexington.*

It's not if you build it they will come but the fact that they are already here. Sixty three percent of the U.S. population over the age of 18 is online. Over three-quarters of youth ages 12 to 17 use the Internet. By the fall of 2002, 63 million Americans (34%) used the Internet to conduct education-related research and seek training online. In addition, three out of four Internet users have searched for information related to a hobby or special interest. As the need for quality, non-biased material increases, so does the role of educators and the expectations of the resources they provide. Online learners benefit from being able to gain knowledge through multiple delivery formats: written material, streaming audio and video, interactive games and quizzes, asynchronous and synchronous dialogue, and simulated animations. These tools, delivered in an anyplace, anywhere, anytime, and any platform format, bring new life into the quality of material available to anyone. Many educators have not been trained to conduct courses or Extension programs at a distance. However, once engaging in providing educational materials online, they realize the freedom of time and reduction in redundancy from that of traditional methods. Teaching face-to-face, through written publications, instructional video, and video conferencing formats are all examples of instruction that can integrate seamlessly into online learning environments. The most traditional forms of online course delivery can be achieved through proprietary courseware offered at most universities. However, materials and modules can be successfully prepared through conventional Web sites. Advances in voice over Internet Protocol (IP) allow synchronous learning through standard 28.8 modem connections. Innovations in the use of wireless technology through wireless devices further expand learning potential. Consider the possibilities: for extension clientele and professionals, continuing education, credit, not-for credit, graduate training, and even collaborative teaching, to name a few.

Key Words: Extension, Web, Training

Goat Species: Export Potential, Market Outlook, and Value-Added Processing

868 Export potential, market outlook, and value-added processing of goat fibers. C. J. Lupton*, *Texas Agricultural Experiment Station, Texas A&M University System, San Angelo.*

Goat fiber production in the USA is examined from the perspectives of world production, export potential, market outlook, and adding value. Fibers harvested from more than 85 million goats in 12 countries make up about 0.04% of the world's annual textile fiber production. Cashmere, the fine (mean fiber diameter (MFD) less than 19 microns) undercoat combed or shorn from numerous breeds of goat, comprised about 15 million kg (mkg) of this total in 2003, whereas mohair, shorn from the Angora goat, constituted about 6.60 mkg. Only a very small amount of the cashmere (about 3,000 kg) and 0.75 mkg of the mohair were produced in the USA. Cashmere is more valuable than mohair. Commercial quotations for cashmere (dehaired Chinese white) currently range from 57to68/kg, whereas greasy mohair sold in the range 4/kg(MFDgreaterthan34microns)to18/kg (MFD 24 to 26 microns) in a recent South African sale. The small quantity of US cashmere prohibits export. In contrast, the majority of US mohair is exported, most with little or no added value. Value adding opportunities exist in post-shearing, processing, and textile manufacturing systems. These include skirting, classing, and objective measurement of the raw material before sale; scouring; dehairing (in the case of cashmere); production of sliver, yarn, and fabric (knitted or woven); end-product manufacture; wholesale; and retail. Participation in these opportunities in the USA ranges from none to all of the above. Examples of the latter are activities of the Cashmere America Cooperative and the Mohair Council of America that include retaining ownership of products all the way through retail. Participation in value adding through intermediate stages (e.g., scouring, dehairing, hand spinning, and hand knitting) is practiced by many individuals and groups throughout the country at the cottage industry level. The market outlook for both cashmere and mohair is good. Inclusion of mohair in the 2002 Farm Bill should provide growers with greater financial security through 2007.

Key Words: Goat Fibers, Cashmere, Mohair

869 Marketing slaughter goats and goat meat products. T. L. Stanton*, *Cornell University, Ithaca, NY.*

The survivability of our US meat goat industry is dependent on improving its accessibility and desirability to our consumer base. Goat meat consumption in the US has grown sharply in the last 10 years. The goat slaughter rate at USDA inspected facilities climbed from 207,893 goats in 1991 to 595,500 goats in 2002. Imports from our largest importer, Australia, increased from approximately 3 million pounds in 1990 to 17 million pounds in 2003. At 40 lbs, the largest carcass popular with most importers, this is equal to 425,000 more goats. Increased consumption is driven by the popularity of goat meat with the diverse ethnic groups that immigrate yearly to the US and also the popularity of heart-friendly, ethnic foods. However, desired goat meat products need to be readily available year round to encourage consumers and processors to continue these dietary preferences. It is counterproductive if goat meat is available only sporadically, specific carcass preferences are ignored, people are made to feel unwelcome when seeking out goat meat through established channels, or if our marketing infrastructure collapses in on itself and offers all of us fewer marketing choices. There are many marketing

strategies that producers can adopt to reap more of the market share of their goats. Almost all of these require extra investment in labor and/or capital. Educational institutions can aid meat goat producers by maintaining web-based marketing services directories to facilitate easy access to potential buyers and slaughterhouses, moderating email list serves that allow producers to group together to meet volume demands of specific markets, creating fact sheets on marketing goats through various channels, and presenting case studies on market pools, etc. Programs that help producers and buyers to find each other and arrange necessary market logistics will help maintain and expand our meat goat industry. The goat meat market is highly diverse in part because its customers and producers reflect a wide range of life styles and needs. Presently, programs that provide producers with a wide range of marketing opportunities may help the industry more than establishing a "one size fits all" marketing model.

Key Words: Goat Meat, Marketing

870 Value-added processing and consumer preference of goat meat. K. W. McMillin*, *Department of Animal Sciences, Agricultural Center, Louisiana State University, Baton Rouge.*

Value-added food products have been changed in form, function, or grouping to increase their economic value and/or appeal. Goat meat value is increased with fewer market channel steps or decreased distribution costs, in specific uniform or consistent groups, after processing into more palatable or usable forms, or when available in a different form or at a different time more highly demanded by the purchaser. The fat in primal and retail cuts from kid goats is increased with feedlot or concentrate diets, which lessens the ethnic consumer and processing market value. Value is increased with year-round availability compared with limited seasonal supplies. Meat from kid and yearling goats was not distinguishable by ethnic consumers unless the meat was from goats with low conformation. The consistent size, conformation, and characteristics of imported frozen goat meat has made it acceptable in some markets and its value is increased when shipped as wholesale or retail portions rather than as carcasses. Institutional Meat Purchase Specifications (IMPS) for goat meat provide descriptions of cuts and size uniformity. Processed meat research has been with products or with processes similar to those of other meat species. The tenderness of domestic goat meat is improved with electrical stimulation and postmortem aging of carcasses and blade tenderization of cuts. Addition of oat trim or oat bran reduced fat and shear value while tocopherol antioxidant addition improved shelf-life of goat meat patties. Smoked and fermented sausages from goat meat are acceptable, but more expensive per unit weight than sausages from other species. The emulsification capacity of goat meat proteins is high, with palatability of frankfurters increased with use of mechanically separated goat mince. Goat meat was distinguishable from other species in plain and seasoned meat loaves, chili, curries, and patties. Specific organic acids are associated with goat meat flavor and oxidized or warmed-over flavors develop more rapidly in cooked goat meat than in meat from other species. More convenient product forms and availability would increase value of goat meat to ethnic and non-traditional consumers.

Key Words: Goat, Meat, Processing

International Animal Agriculture: Animal Agriculture in Global Context

871 Setting research agendas for animal science in a global context. M. Gill* and R. Dyer, *Macaulay Institute, Craigiebuckler, Aberdeen, Scotland.*

The world is changing fast, but not homogeneously! Meat consumption in some countries is increasing rapidly, in others decreasing. World Trade is a political issue, favoured by some, rejected by others. Climate change is recognized as an urgent issue by some less by others. What does all this mean for research in animal science?

I will discuss the importance of being aware of global trends and of translating these into potential policy requirements in terms of setting research agendas. 'Thinking globally while acting locally' will be one theme. A second theme will be inter-disciplinarity. Increasingly it is recognized that policies need to be 'joined-up', water is a good example.

In Europe, the Water Framework Directive builds on a number of other policy directives and is a good example of what future policies might look like.

I will use at least 1 Case Study to illustrate how inter-disciplinary projects can be developed to meet policy needs. The Case Study is from the Philippines, where the original aim was to test the hypothesis that intensive livestock production systems inherently have more negative impacts on the environment than small-scale systems. During its implementation, the project has evolved to interest experts in water quality, economists and medics with an interest in environmental health issues in addition to animal scientists. The project has also been discussed with both people living in the communities and with policy people in government departments. I will describe the process and how

the mix of disciplines involved have added value to what is an animal production problem.

Key Words: Environment, Inter-Disciplinary, Policy

872 Today's poultry industry from a global perspective. P. Aho*, *Poultry Perspective, Storrs, CT.*

In the last 50 years the world consumption of chicken eggs increased from 5 to 10 kilos. Chicken meat consumption rose from 2.5 kilos to 10 kilos. While most people have benefited from the overall increase in poultry consumption, the distribution of these products is far from uniform. Using information from the World Bank and the Food and Agriculture Organization of the United Nations, an estimate was made of average income (purchasing power parity) and consumption of chickens eggs and meat by income quintile. The estimates demonstrate a correlation between income and poultry consumption. The future consumption of poultry products will also be influenced by income distribution. This

kind of analysis can be useful for market studies either globally or within individual countries.

Purchasing power parity income quintile and chicken/egg per capita consumption in kg

Quintile	Yearly Income	Chicken	Egg	Total
1	\$26,000	22	18	40
2	\$7,000	15	14	29
3	\$4,000	9	9	18
4	\$2,000	3	6	9
5	\$1,000	1	3	4
Average	\$8,000	10	10	20

Key Words: Income Quintile, Egg Consumption, Chicken Consumption

Animal Behavior & Well Being III

874 Choice of attractive conditions by beef cattle in a Y-maze just after release from restraint. T. Ishiwata*¹, R. J. Kilgour², K. Uetake¹, Y. Eguchi¹, and T. Tanaka¹, ¹*School of Veterinary Medicine, Azabu University, Sagami-hara, Japan,* ²*Agricultural Research Centre, NSW Agriculture Trangie, NSW, Australia.*

To determine the attractiveness of different conditions to cattle, 189 Angus heifers were individually allowed to enter a choice area after 2 min of restraint in a crush to choose between 2 pens. After the animal had chosen a pen, she could freely access both test pens and the choice area for 5 min. In experiment 1, each heifer was given one of the following choices: pen with 3 familiar animals (Peers) vs. pen with a pile of hay on a metal rack (Food) (n=34); Peers vs. the bare pen (Bare) (n=34); Food vs. Bare (n=35). More heifers chose Peers over Bare ($\chi^2=5.76$; $P<0.05$). More heifers tended to choose Peers over Food ($\chi^2=2.94$; $P<0.10$), whereas Food and Bare did not differ. The latency to choose either pen was shorter ($P<0.01$), and they spent less time staying near the crush ($P<0.05$) if Peers was one of the two choices. After choosing, more heifers entered the Peers pen than the Food ($P<0.05$) and Bare ($P<0.01$) pen. Peers were the most attractive for heifers, and food was as least attractive as the bare condition was. In experiment 2, another 86 heifers were given one of the following choice: pen with a familiar handler standing inside (STI) vs. pen with a novel object (NO) (n=29); pen with the handler standing outside the pen (STO) vs. NO (n=29); pen in which the handler is sitting inside (SI) vs. NO (n=28). Fewer heifers chose the pen with the human ($\chi^2=9.97, 12.45$ and 7.00 for STI, STO and SI, respectively; all $P<0.01$). Except for the choice of STO vs. NO, the number of heifers that had voluntarily chosen either pen was larger than that of heifers that had not chosen 5 min after release (both $P<0.01$). The number of times in which the NO pen was entered was larger than the STI and STO (both $P<0.01$), although the numbers of times in which the SI and NO pens were entered was not different. Heifers avoided human, especially with them standing outside the fence. Heifers seem to recognize the sitting human as a kind of object.

Key Words: Beef Cattle, Behavior, Preference Test

875 Out-wintering pads (owp) for steers- animal wellbeing and production. M. C. Hickey*¹, A. P. Moloney², and P. French², ¹*Teagasc Beef Research Centre Grange, Dunsany, Co. Meath, Ireland,* ²*Teagasc Beef Research Centre, Dunsany, Co. Meath, Ireland.*

Indoor slatted floor accommodation raises fundamental concerns for animal wellbeing. The objectives of these 2 experiments were to evaluate the effect of accommodating steers, on OWP or indoors on slats a) with or without daily exercise, b) with access to an OWP or c) with modified slat surfaces, on animal wellbeing and production. In experiment 1, 54 steers were assigned to one of 3 treatments (i) slats at $3\text{m}^2/\text{hd}$, (ii) as with (i) but walked $4\text{km}/\text{d}$ or (iii) accommodated on an OWP. In experiment 2, 75 steers were assigned to one of 5 accommodation systems (i) slats at $2.5\text{m}^2/\text{hd}$, (ii) OWP at $18\text{m}^2/\text{hd}$, (iii) slats at $2.5\text{m}^2/\text{hd}$ with access to an OWP, (iv) rubber matted slats at $2.5\text{m}^2/\text{hd}$ or (v) straw bedding at $4\text{m}^2/\text{hd}$. Animals were offered grass silage ad-lib and 6kg grain daily in experiment 1 and a silage/grain mixture in experiment 2.

Diurnal lying and eating behavior, hoof health, cleanliness, feed intakes, liveweight and slaughter data was recorded. Both experiments were of 5-month duration after which all animals were slaughtered. There was no effect of treatment on the duration of time spent lying or eating on either study. In experiment 1 animals accommodated on slats were dirtier ($p<0.01$) than animals accommodated on OWP, and had a greater incidence of medial erosion ($p<0.05$) on the hind, and lateral and medial erosion on the front hoof. Animals on the OWP had higher ($p<0.05$) feed intake and carcass gain than animals on slats. The inclusion of daily exercise did not affect animal behavior, intake or carcass gain. In experiment 2, when given access to an OWP, animals chose to lie outside irrespective of weather conditions. Animals accommodated on slats were dirtier ($p<0.05$) and had lower carcass gain ($p<0.05$) and feed intake ($p<0.01$) than animals accommodated on or with access to OWP. The provision of straw bedding or rubber matted slat surfaces did not affect behavior, feed intake or carcass gain, relative to animals housed on slats. In conclusion, the performance and wellbeing of steers was enhanced when accommodated on OWP rather than slats with or without modified surfaces.

Key Words: Beef Production, Outwintering, Slatted Accommodation

876 Effect of feeding *Ascophyllum Nodosum* on thermoregulation, behavior, and dehydration of sheep subjected to 12-h of transport. G. S. Archer*, T. H. Friend, C. Iacono, P. Krawczel, and R. Johnson, *Texas A&M University, College Station, TX.*

In order to determine the effect of feeding the seaweed *A. Nodosum* on thermoregulation, behavior and dehydration, 44 lambs ($26\text{ kg} \pm 4.3$) were fed one of four levels of the seaweed for two wk prior to 12-h transport during hot weather. Sheep received seaweed at either 0, 0.5, 1.0, or 2.0% of dry matter intake per day. Each sheep swallowed four gelatin capsules twice a day filled with *A. Nodosum* or their normal ration, depending on the treatment. Prior to transport, temperature data loggers were secured in the ear of all sheep to measure changes in body temperature during transport. Blood samples were taken immediately before and after transport. When the 0% lambs body temperature peaked, the 2% lambs were significantly lower ($P = 0.03$), with the other treatments being intermediate. Variation in body temperature during the course of transport for the 0% lambs (1.3 C) was wider than the 2% lambs (0.9 C , $P = 0.055$). All sheep immediately went to feed post-transport. There was a trend ($P = 0.21$) for 2% lambs to have the shortest latency to drink (589 s) and for 0% lambs to have the longest (823 s). All sheep laid down at approximately the same time post-transport. The 0% lambs significantly increased in sodium (Na), chloride (Cl), and potassium (K) and the 0.5% lambs significantly increased in K concentrations post-transport compared to pre-transport concentrations. Changes in electrolyte concentrations for the other treatments were not different from pre-transport concentrations. Post-transport concentrations of Na and Cl were less ($P < 0.05$) in 1 and 2% lambs than in 0 and 0.5% lambs. The 0% lambs also had higher ($P < 0.05$) K concentrations post-transport than 1 and 2% lambs. Feeding *A. Nodosum* for two weeks prior to transport allowed the animals to better thermo regulate during

transport under hot conditions. Although animals who received higher amounts of A. Nodosum prior to transport tended to drink sooner after transport, they actually had lower electrolyte concentrations post transport, indicating they were better hydrated.

Key Words: Hydration, Thermoregulation, Transport

877 The effect of a naloxone implant on the oestrus behavior, the LH preovulatory surge and on the ovulation rate of the crossbred Mexican ewe during the breeding season. V. Fuentes* and P. Fuentes*, *Centro Universitario de los Altos, Universidad de Guadalajara, Tapatitlan, Jalisco, Mexico.*

With the objective of studying the effect of a naloxone implant on oestrus behavior in the ewe, two groups of 10 crossbred Mexican ewes were selected at random during the breeding season of 2002. One group was implanted with a pellet containing 10 mg of naloxone and the second group received an implant with no drug. The same day of implant all ewes were treated with intravaginal sponges impregnated with 40 mg Medroxi Progesterone Acetate, after 14 days, sponges were withdrawn and 2 ml blood samples were taken through a jugular catheter, at intervals of 20 minutes since 24 hours after the sponges were withdrawn, sampling continued until the beginning and until the end of oestrus. It was observed that in ewes treated with naloxone the Preovulatory LH surge was advanced in the order of 4 h as compared with controls ($p < 0.001$). Furthermore, the duration of oestrus in naloxone treated ewes was significantly longer from that of control ewes (40 ± 6 h vs 28 ± 3 , $p < 0.001$). Ovulation rate in treated animals was in the order of 2.3 ± 5 vs $1.5 \pm .4$ of control ewes ($p < 0.01$). It was concluded that naloxone treatment altered oestrus behavior and ovulation rate. Giving further support to endogenous opioids as modulators of sexual behavior in the ewe.

Key Words: Naloxone, Oestrus, LH

878 Utilization of an onboard watering system by slaughter horses during transport. C. M. Iacono*, T. H. Friend, R. Johnson, P. Krawczel, and G. Archer, *Texas A&M University, College Station.*

This study determined if slaughter horses would drink onboard a semi-trailer, how long water needed to be available, and if water consumption reduced weight loss. Data were from three shipments of slaughter horses originating from Amarillo, TX (16 h, $n=17$), Hutchinson, KS (23 h, $n=19$) and La Grande, OR (28 h, $n=14$). The 19.2 m long semi-trailer was divided into three compartments and ten video cameras were mounted in the trailer to quantify drinking behavior. Five to 10 horses of different breeds, ages, sexes and body condition were placed into each compartment. Horses in two compartments were given water (two 1-h watering sessions for the TX and KS trips, and three for OR) with the third non watered compartment serving as a control. Horses were weighed before and after transport. The mean temperatures inside the trailer for the trips were 30, 22 and 18° C for the TX, KS, and OR trips. For the TX trip, 88.2% of the horses drank at least once during the first watering session. All of the horses on the KS trip drank at least one time during the two watering sessions. For the OR trip, 85.7% of the horses drank at least once over the three watering sessions. For TX, the majority of horses drank within the first 20 min whereas for KS and OR, it was not until 50-60 min that the majority of horses drank. Horses that had access to water on the TX trip lost less weight ($P = 0.018$) than those that did not have access to water. During the cooler weather trips, a trend was evident for the watered horses in the KS ($P = 0.19$), but not OR ($P = 0.74$) trips, to lose less weight. Water consumption averaged 3.79 L/horse during TX, 1.85 L for KS, and 2.80 L for OR. The results from this study indicate slaughter horses will drink during transport if given the opportunity and are more likely to drink sooner when they are transported during hot weather. Watering during transport in hot weather will result in significantly less shrink.

Key Words: Horse, Transport, Drinking

879 Effect of continuous versus rested transport on blood chemistry, electrolytes and behavior of lambs. P. Krawczel* and T. Friend, *Department of Animal Science, Texas A&M University, College Station.*

A proposed set of European Union Regulations for the transportation of livestock requiring multiple rest periods was evaluated for its efficacy. Rambouillet crossbred lambs averaging 17.6 ± 0.5 kg were randomly assigned to one of three treatments: continuously transported for 22 h ($n = 15$); transported for 8 h, unloaded and rested for 6 h, transported for 8 h, unloaded and rested for 24 h, transported for 6 h ($n = 15$); or control which remained in the home pasture throughout the study ($n = 16$). Food and water were provided during rest, which was in novel pens to simulate actual transport. Jugular blood samples were collected from all sheep prior to transport, at the end of each transport or rest period and 24 h after the conclusion of transport. Feeding behavior during rest stops and after final unloading were also quantified. After 14 h, glucose ($P = 0.0001$) decreased while total serum protein ($P = 0.011$) and bilirubin ($P = 0.011$) increased for continuous relative to rested or control. At the conclusion of transport for continuous, glucose ($P = 0.0001$) and magnesium ($P = 0.005$) decreased while blood urea nitrogen ($P = 0.0001$), total serum protein ($P = 0.036$), bilirubin ($P = 0.0001$) and creatinine ($P = 0.01$) increased relative to rested or control. Electrolytes varied between all three treatments at 14 h and 22 h, but no distinct pattern was evident. Both transported treatments chose feed over water immediately following unloading. The latency between unloading and first bout of drinking for continuous (23.9 ± 1.4) and rested (17.7 ± 4.5) was not different. The food and water provided during rest periods prevented signs of food deprivation in the rested lambs, which occurred in the continuous lambs. Blood chemistry and behavioral data indicated access to food was the main benefit of the rest periods. Dehydration was not evident in the continuous lambs despite temperatures peaking at 41° C.

Key Words: Lamb, Transport, Behavior

880 The effect of long-chain polyunsaturated fatty acid and vitamin E supplementation of ewes on neonatal lamb vigour. J. L. Capper*, R. G. Wilkinson, S. E. Pattinson, A. M. Mackenzie, and L. A. Sinclair, *Harper Adams University College, Newport, Shropshire, United Kingdom.*

The long-chain polyunsaturated fatty acid (PUFA) docosahexaenoic acid (DHA) is vital for development of the foetal brain: studies in humans have shown positive effects of DHA supplementation upon infant cognitive development and visual acuity. As ruminant diets are low in DHA, a behavioural response to supplementation may be observed. Furthermore, supplementing pregnant ewes with high levels of vitamin E produces lambs that are more vigorous immediately after birth. This experiment investigated the effects of dietary long-chain PUFA and vitamin E supplementation of ewes on neonatal lamb vigour. Forty eight Lley and Mule ewes were allocated to one of four treatments at 103 days of gestation in a 2 x 2 factorial, randomised block design. Ewes were individually penned from six weeks *pre-partum* to four weeks *post partum* and fed one of four treatment concentrates, each containing either fish oil plus Incomega (a DHA source fed at a 25:75 ratio with fish oil) or Megalac as the main fat source and a basal (50mg/kg) or supra-nutritional (500mg/kg) concentration of vitamin E. At lambing, lambs were focal sampled and the latencies of standing and successful suckling were recorded. Birthweight data was recorded at +12 hours *post partum*. Gestation length was significantly increased in ewes fed fish/DHA (147.8 days v.s 145.6 days; s.e.d 0.51, $P < 0.001$) and lambs born to these ewes suckled on average, 9.4 minutes sooner than lambs from the Megalac treatment (34.0 minutes vs. 43.4 minutes; s.e.d 3.48, $P < 0.01$). Moreover, supra-nutritional vitamin E supplementation reduced the latency of standing in lambs from ewes fed fish/DHA (14.9 minutes vs. 23.6 minutes; s.e.d. 3.23, $P < 0.05$) when compared to those fed Megalac. Supplementation of pregnant ewes with supra-nutritional levels of vitamin E conferred a 0.31kg increase in lamb birthweight (4.17kg vs. 3.86kg; s.e.d 0.135, $P < 0.05$). Long-chain PUFA supplementation of ewes had beneficial effects on neonatal lamb vigour. Supra-nutritional vitamin E supplementation of ewes significantly increased lamb birthweight, however it did not directly affect lamb behaviour.

Key Words: Behaviour, Neonate, Fatty Acid

Breeding and Genetics: Beef Cattle

881 Estimates of genetic parameters for infectious keratoconjunctivitis in beef calves before weaning. G. D. Snoder*¹, L. D. Van Vleck², L. V. Cundiff¹, and G. L. Bennett¹, ¹USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE, ²USDA-ARS, U.S. Meat Animal Research Center, Lincoln, NE.

Bovine infectious keratoconjunctivitis (BIK, pinkeye) is an economically important illness affecting growth of calves. The primary objective of this study was to estimate genetic parameters for BIK in beef calves prior to weaning. Health records of 47,880 calves born at the Meat Animal Research Center, Clay Center, NE from 1983 through 2001 were evaluated. Cows and calves were monitored daily for health until weaning at approximately 194 d of age. Breed groups consisted of nine purebred breeds (Angus, Braunvieh, Charolais, Gelbvieh, Hereford, Limousin, Pinzgauer, Red Poll, and Simmental), and three composite breeds (MARC I, MARC II, and MARC III). Detection of BIK was by physical examination. If BIK was detected during the preweaning period a score of 100 was assigned and if not the score was 200. Overall average prevalence of BIK was 6.5%. Prevalence was significantly greater in Hereford (22.4%) compared to all other breeds. Pinzgauer and Braunvieh breeds had the lowest incidence rates of 1.3 and 1.8%, respectively. Infections began at approximately 45 d of age and frequency of infections increased until approximately 105 d of age. Variance components for each breed were estimated using REML. Fixed effects included year of birth, age of dam, sex of calf, and birth weight. Calf and dam of the calf (direct and maternal genetic) were random effects. Variance due to maternal permanent environmental effects was not significant. Heritability estimates for the direct effect of the calf ranged from 0.00 to 0.28. Hereford and Angus breeds had the highest heritability estimates, 0.28 and 0.25, respectively. Heritability estimates for the maternal effect were low and ranged from 0.00 to 0.11. Estimates of the direct-maternal genetic correlation were highly variable and ranged from -1.00 to 1.00. Within breed, response to selection to reduce the incidence of BIK in calves would be expected to be slow although breed differences suggest a potential to improve BIK resistance by selection, especially in the Hereford breed.

Key Words: Heritability, Disease, Maternal

882 Investigation of gestation length in *Bos indicus* x *Bos taurus* reciprocal backcross calves produced through embryo transfer. T. S. Amen*, A. D. Herring, C. A. Gill, and J. O. Sanders, Texas A&M University, College Station.

Gestation length (GL) was studied on 511 embryo transfer calves belonging to 28 full-sib families born 1990-1996. Calves were produced by backcross matings involving three distinct sire and dam types: Angus (A), *Bos indicus* (B) (Brahman), and F₁ Angus-*Bos indicus* (Brahman or Nellore). Resulting progeny were 3/4 A-1/4 B, or 3/4 B-1/4 A. Calves were born to recipients that were approximately 1/2 Brahman and 1/2 British. Data were studied through analysis of covariance with independent variables of sex, sire-type x dam-type interaction (ST x DT), family nested within ST x DT, sex x ST x DT, embryo quality (EQ), embryo stage (ES), and the regression on birth date within season-year combination. Family nested within ST x DT was considered a random effect, and was the error term to test for differences due to ST x DT. Calf sex, EQ, regression on birth date, and the ST x DT interaction accounted for variation ($P < .05$) in GL. The three-way interaction involving calf sex, ST and DT was not significant as is typically seen for birth weight in these reciprocal cross calves. Male calves averaged 291.2 d and female calves averaged 288.5 d. For A backcross calves, GL averaged 286.8 d from A x F₁ matings, but averaged 289.3 d from F₁ x A matings. For B backcross calves GL averaged 293.8 d from B x F₁ matings, but averaged 289.5 d from F₁ x B matings. Additionally, type of F₁ parent (AB or BA, sire breed first) was found to account for significant differences in GL. Among calves from A sires and F₁ dams, GL was 5 d longer in calves from BA dams (289.6) as compared to those from AB dams (284.5). Among calves from F₁ sires and A dams, GL was 2 d longer in calves from BA sires (290.8) than in calves from AB sires (288.4). For calves from B sires and F₁ dams, GL was 4 d longer in calves from BA dams (296.1) as compared to those from AB dams (292.4). For calves from F₁ sires and B dams, GL was 3 d longer in calves from BA sires (291.1) than calves from AB sires (288.3). In both

the A and B backcross calves the trend was to have a longer GL when the F₁ parent was BA as opposed to AB.

Key Words: Reciprocal Cross, Embryo Transfer, Gestation Length

883 Genetic correlations between postweaning feed efficiency and cow traits. P. F. Arthur*¹, J. A. Archer², A. Reverter³, D. J. Johnston⁴, and R. M. Herd⁵, ¹NSW Agriculture - Camden, Australia, ²AgResearch, Mosgiel, New Zealand, ³CSIRO, Brisbane, Australia, ⁴Animal Genetics and Breeding Unit, Armidale, Australia, ⁵NSW Agriculture - Armidale, Australia.

Postweaning records on 1781 bulls and heifers tested for feed efficiency at 267 d of age and cow records taken at 4 y of age on 751 of the same females were used to estimate genetic correlations between postweaning feed efficiency and cow traits. The study was conducted at NSW Agriculture Research Centre, Trangie. The postweaning feed efficiency traits used were residual feed intake (RFI) and feed conversion ratio (FCR). RFI was calculated as the difference between actual daily feed intake and that predicted from a model that included metabolic weight and ADG. FCR was calculated as daily feed intake per unit ADG. For both traits efficient animals will have lower values. The cow records were taken on non-pregnant cows after the weaning of their second calf. The cow traits were daily feed intake (COWFI), ultrasound measure of rump fat depth (COWFAT), longissimus muscle area (COWEMA) and weight at 4 y of age (4-yWT). Genetic parameters were estimated by REML using animal models. All analyses included pedigrees back to 3 generations of ancestors. Means for the traits were 0.04 kg, 7.56, 15.7 kg, 13.2 mm, 81.3 cm² and 498.3 kg, for RFI, FCR, COWFI, COWFAT, COWEMA and 4-yWT, respectively. Corresponding heritability estimates were 0.42, 0.28, 0.27, 0.47, 0.12 and 0.62. The genetic correlation between RFI and the cow traits were 0.74 (COWFI), 0.32 (COWFAT), 0.41 (COWEMA) and -0.03 (4-yWT). Corresponding values for FCR were 0.39 (COWFI), 0.32 (COWFAT), 0.12 (COWEMA) and -0.33 (4-yWT). The results indicate that when selection of young cattle for improved feed efficiency is based on FCR a weak correlated response in reduced cow feed intake and increased cow weight is expected. However, when selection of young cattle for improved feed efficiency is based on RFI a strong correlated response in reduced cow feed intake is expected with no response in cow weight.

Key Words: Cattle, Feed Efficiency, Body Composition

884 Investigation of birth weight in *Bos indicus* x *Bos taurus* reciprocal backcross calves produced through embryo transfer. T. S. Amen*, A. D. Herring, C. A. Gill, and J. O. Sanders, Texas A&M University, College Station.

Birth weight (BWT) was studied on 511 embryo transfer calves belonging to 28 full-sib families born 1990-1996. Calves were produced by backcross matings involving three distinct sire and dam types: Angus (A), *Bos indicus* (B) (Brahman), and F₁ Angus-*Bos indicus* (Brahman or Nellore). Resulting progeny were 3/4 A-1/4 B, or 3/4 B-1/4 A. All calves were born to recipient dams that were approximately 1/2 Brahman and 1/2 British. Data were studied through analysis of covariance that included independent variables of sex, sire-type x dam-type interaction (ST x DT), family nested within ST x DT, sex x ST x DT, embryo quality (EQ), embryo stage (ES), and the regression on birth date within season-year combination. Family nested with ST x DT was considered a random effect, and was the error term to test for differences due to ST x DT. Calf sex, the regression on birth date, ES, and the three-way interaction sex x ST x DT accounted for variation in BWT ($P < .05$). Male calves averaged 38.2 kg, and female calves averaged 35.2 kg. Among A backcrosses, A x F₁ calves were 3.5 kg lighter ($P = .04$) than F₁ x A calves (34.9 vs. 38.4). Also, among B backcrosses, F₁ x B calves were 4.7 kg lighter than B x F₁ calves (34.4 vs. 39.1). Among A backcross calves from A sires and F₁ dams, the BWT difference was 1.8 kg between male (35.5) and female (34.3) calves, but when A backcross calves were produced from F₁ sires and A dams the difference in male vs. female BWT was 5.0 kg (40.9 vs. 35.9 kg, respectively). For B backcross calves produced from B sires and F₁ dams, male calves averaged 4.6 kg heavier than females (41.4 vs. 36.8 kg), whereas when B backcross calves were produced from F₁ sires and B dams, BWT of male

calves (35.0 kg) averaged 1.2 kg heavier than female calves (33.8 kg). These *Bos indicus*-*Bos taurus* reciprocal differences have been widely reported in natural service calves, and these results are consistent with earlier reports in ET calves.

Key Words: Reciprocal Cross, Embryo Transfer, Birth Weight

885 Teat scores in first-parity Gelbvieh cows: Relationship with suspensory score and calf growth traits. R. L. Sapp*, R. Rekaya, and J. K. Bertrand, *The University of Georgia, Athens.*

Teat and suspensory scores from 9,418 first-parity Gelbvieh (GV) cows and growth records from 19,119 calves were used to estimate genetic and environmental parameters for teat and suspensory scores and to investigate the relationship of teat and suspensory scores with calf growth traits and maternal genetic growth effects. First-parity cows did not have multiple scores within 280 d, gave birth to one calf, were 4 yr of age or younger at first-calving, and were at least 50% GV. Producers scored cows within 24 h of parturition. Teat score (T), a subjective measure of teat size, ranged from 0 (very large) to 50 (very small) and suspensory score (S), a subjective score of udder support, ranged from 0 (very pendulous) to 50 (very tight). Unadjusted birth (BW), weaning and yearling weight of the calves, born in the first three parities to the first-parity cows, were used to calculate pre- (WG) and postweaning (YG) ADG. A mixed model was employed for the multiple trait analysis of T, S, BW, WG, and YG which included herd-yr, mo of calving, age of cow at calving and sex of calf (included only for BW, WG, and YG) as systematic effects; regression on percentage GV; and additive animal, maternal genetic and permanent environment of dam (included only for BW and WG), and residual as random effects. Heritability estimates were 0.27, 0.22, 0.39 (0.09), 0.27 (0.14) and 0.21 for T, S, direct (maternal) BW, (maternal) WG and YG, respectively. The genetic correlation between T and S was 0.95. The genetic correlations between T (S) with direct BW, WG and YG and with maternal BW ranged from -0.18 to 0.38. The genetic correlation between T (S) with maternal WG was -0.47 (-0.55) suggesting that cows with smaller teats and tighter udders produced less milk. Pearson correlations between EBV of T and S with maternal WG indicate that animals with extremely large or small EBV for T or S may have problems with accessibility of milk or adequate milk production. Therefore, it may be more beneficial for producers to select animals with intermediate EBV for T and S.

Key Words: Growth, Suspensory Score, Teat Score

886 Calving day and age at first calving in Angus heifers. J. Minick* and D. Wilson, *Iowa State University, Ames.*

Reproduction is one of most economically important traits in beef production. Due to difficulties in data collection and analysis, in most breeds there has been no objective way to evaluate fertility in females on a between-herd basis. The objective of this study was to determine if calving date (CD) and age at first calving (AFC) could be used to select for female fertility in beef cattle. Records ($n = 2082$) from a university research herd and a large purebred breeder were used. There were a total 147 sires with heifers represented in the CD data. CD was calculated for each heifer by subtracting the calving date of the first heifer to calve in that contemporary group from the calving date of the heifer. For example, within each contemporary group of heifers, heifers that calved on the first day of the calving season were given a calving day of one. Heifers that calved the next day had calving days of two, and so on. To avoid bias, non-calving heifers were assigned a CD of 30, 60, and 90 days after the last heifer in that contemporary group calved. These assigned CD were also used to give open heifers a predicted AFC. Data were analyzed by MTDFREML using a general linear animal model. Fixed effects included herd-year, service sire of the heifer, and age of dam. Covariates that were tested included adjusted yearling weight and age of the heifer at the start of the breeding season (for CD only). Heritabilities for CD for the 30, 60, and 90 day adjustments were 0.07 ± 0.04 , 0.10 ± 0.05 , and 0.11 ± 0.05 , respectively. Average, minimum, and maximum estimated breeding values for sires of heifers were 0.7, -10.6, and 9.8 days for CD30; -1.1, -17.2, and 16.5 days for CD60; and 1.6, -22.6, and 19.5 days for CD90. The estimates for AFC30, AFC60, and AFC90 were 0.28 ± 0.06 , 0.28 ± 0.06 , and 0.28 ± 0.06 , respectively.

Average, minimum, and maximum estimated breeding values for sires of heifers were 0.6, -46.6, and 45.9 days for AFC30; -1.2, -50.1, and 51.6 days for AFC60; and 1.7, -52.9, and 56.7 days for AFC90. These results indicate that AFC may be more useful than CD in selecting for female fertility in beef cattle.

Key Words: Fertility, Calving Day, Age at First Calving

887 Genetic prediction for estimating mature cow maintenance energy requirements. S. E. Speidel*, D. J. Garrick, and R. M. Enns, *Colorado State University, Fort Collins.*

Cow maintenance energy requirements are defined as the amount of dietary metabolizable energy required for maintenance. According to NRC (1996) nutrient requirements of beef cattle, maintenance requirements account for roughly 70% of the total metabolizable energy requirements of a beef cow. The goal of this project was to develop a selection tool to assist producers in improving beef production efficiency by simultaneously accounting for change in income (sale weight) and cost (cow maintenance). A genetic prediction for mature cow maintenance energy requirements was developed using equations from the 1996 NRC to predict the energy required for maintenance of a beef cow and Woods lactation function. These equations were modified so an animals genetic prediction for metabolic weight and weaning weight maternal could be used to predict its maintenance energy requirements through a non-linear combination of the two traits. Metabolic weight genetic predictions were calculated by random regression using Best Linear Unbiased Prediction (BLUP) procedures where metabolic weight (mature cow weight pre-adjusted to condition score 5 and raised to the power 0.75) was regressed on age to predict metabolic weight at 5 years of age. Weaning weight maternal genetic predictions were estimated by applying BLUP procedures to an animal model with birth weight and weaning weight as the dependent variables. A prediction error variance equation was developed using the algebra of variances and co-variances in concert with the genetic prediction equation. The prediction which is reported as a progeny difference in the units of mega-calories per month has been adopted by the Red Angus Association of America and will be published in their 2004 sire summary.

Key Words: Genetic Prediction, Cow Efficiency, Maintenance

888 Estimates of genetic correlations among carcass traits adjusted to different end points. A. Rios-Utrera*¹, L. V. Cundiff², K. E. Gregory², R. M. Koch¹, M. E. Dikeman³, M. Koohmariaie², and L. D. Van Vleck⁴, ¹University of Nebraska, Lincoln, ²Roman L. Hruska U.S. Meat Animal Research Center, ARS, USDA, Clay Center, NE, ³Department of Animal Sciences and Industry, Kansas State University, Manhattan, ⁴Roman L. Hruska U.S. Meat Animal Research Center, ARS, USDA, Lincoln, NE.

Carcass measurements of 1,664 serially slaughtered steers from 12 breeds (Red Poll, Hereford, Angus, Limousin, Braunvieh, Pinzgauer, Gelbvieh, Simmental, Charolais, MARC I, MARC II, and MARC III) were used to estimate genetic correlations among carcass traits adjusted to slaughter age, carcass weight or backfat thickness end points. Traits were carcass weight (CW), dressing % (DP), fat thickness (FT), longissimus area (LA), kidney pelvic heart fat % (KF), marbling (MS), yield grade (YG), predicted % of retail product (ER), retail product wt (RW), fat wt (FW), bone wt (BW), retail product % (RP), fat % (FP), and bone % (BP). The model included breed group, feed energy level, age of dam, year of birth, significant interactions, number of days on feed, and end point nested within breed (except age) as fixed effects, and genetic effect of animal and total maternal effect of dam as random effects. Genetic correlations, estimated by REML, for CW LA, FT RW, LA-KF, LA YG, LA ER, LA FW, LA-BW, LA RP, LA FP, KF RW, KF BW, ER RW and ER RP at constant age, wt, or fat thickness, respectively, were .32, -, and .51; .26, .77, and ; -.01, -.10, and .25; .71, .89, and .66; .68, .85, and .63; .16, -.51, and .22; .24, -.19, and .30; .47, .57, and .27; .44, -.43, and .18; .02, .48, and .15; .08, .55, and .04; .26, .80, and .01; and .72, .73, and .32. The magnitude and the sign of the genetic correlation changed across end points for many pairs of traits. Correlated responses to selection would differ depending on end point. Regardless of end point, FT was highly correlated with YG (.86, .85; common age and wt) and ER (.85, .82; common age and wt), indicating that selection for reduced

FT would improve YG and ER. Carcass quality, however, would be affected negatively because of the moderate genetic correlations (.34, .35; common age and wt) between MS and FT.

Key Words: Carcass Traits, Genetic Correlations, Slaughter End Points

889 Genetic evaluation of beef cattle for growth using records across a wide range of ages. J. Bohmanova* and I. Misztal, *University of Georgia, Athens.*

A simulation study was conducted to validate agreement between multitrait model (MT) and random regression model (RRM) estimates of growth in beef cattle. Secondary goal was to compare RRM with Legendre polynomials and RRM with splines. Four data sets were generated assuming RRM with cubic regression on Legendre polynomials of age for direct genetic and permanent environmental, maternal genetic and maternal permanent environmental effect. First data set contained records located exactly at 1, 205 and 365 days of age. Second data set consisted of records at 1, 205 ± 45 and 365 ± 45 days. Third data set was created by adding two extra records at 100 and 300 days to the first data set. Fourth data set contained birth weight and records located in an interval of 45 days around 100, 205, 300 and 365 days. Three models were fitted: 1) multitrait model with preadjustment to constant age and traits defined at 1, 205 and 365 days of age; 2) random regression model with Legendre polynomials; and 3) random regression model with linear splines. Variance components in all models were equivalent at 1, 205 and 365 days. Accuracies were calculated as correlation between simulated and predicted breeding values estimated at 1, 205 and 365 days of age. Multitrait and both random regression models showed excellent agreement in the first data set. RRM were 1.4 %, 1.9 %, 2.0 % more accurate than MT at 1, 205 and 365 days of age, respectively, in the second data set. Accuracy of RRM with the third data set was 0.5 %, 2.5 %, and 0.2 % higher at 1, 205 and 365 days of age, respectively, over the first data set. Accuracy of RRM with the fourth data set was 0.5 %, 1.6 %, and 0.0 % higher at 1, 205 and 365 days of age, respectively, over the second data set. The gains in accuracy were small due to high genetic correlations between records. RRM with Legendre polynomials and RRM with linear splines gave almost identical results, however the model with splines converged six times faster. Random regression models were slightly more accurate than multitrait model. RRM with linear splines were simpler than such models with Legendre polynomials.

Key Words: Beef Cattle, Growth, Random Regression Model

890 Examining the genetic diversity of Hereford cattle. M. A. Cleveland*¹, R. M. Enns¹, D. J. Garrick¹, and H. D. Blackburn², ¹Colorado State University, Fort Collins, ²National Animal Germplasm Program, National Center for Genetic Resources Preservation, ARS, USDA, Fort Collins, CO.

This study characterized genetic diversity in the U.S. Hereford population by examining the level and rate of inbreeding and effective population size. The impact of breeding structure on inbreeding was evaluated. Pedigree records for 20,624,418 animals were obtained from the American Hereford Association. Inbreeding coefficients for 1900 to 2001 born animals and the mean annual inbreeding coefficients (Fm) were computed from the pedigree. The rate of inbreeding and effective population size were calculated for a subset of the pedigree using all animals born from 1900 to 2001. Inbreeding increased in a linear fashion reaching a maximum Fm of 0.115 in 1966. The rate of inbreeding was not constant over time and five periods were identified in which inbreeding was changing at different linear rates, including a decrease after 1966. Almost 95% of 2001 born individuals were inbred, and the maximum inbreeding coefficient was 0.759. For animals born between 1990 and 2001 inbreeding was less than 0.10 for 56% of the population and ranged from 0.10 to 0.199 for 34% of the population. The mean rate of inbreeding from 1990 to 2001 was estimated as 0.12%, equating to an effective population size of 85 animals. Influential sires and their contribution to the population were identified to help explain changes in the inbreeding trend. A potential explanation for the decrease in inbreeding levels from 1967 to 1986 may be a shift in the popularity of within breed lines leading to a decrease in coancestry among influential sires and selected dams. The fluctuation of inbreeding suggests that changing breeding objectives impacted sire selection, but further study of selection decisions

contributing to inbreeding in successive generations is needed. Most of the population is inbred suggesting that inbreeding levels should be factored into future mating programs to minimize the effects of inbreeding depression and the loss of genetic diversity.

891 Evaluation of Angus field records: Using new sets of variances to estimate weaning weight EPDs and the effect on genetic trends. A. Hassen* and D. E. Wilson, *Iowa State University, Ames.*

The objective of the current study was to evaluate the effect of using new sets of variance components on genetic trends and animal ranking for weaning weight (WWT) records. National Genetic Evaluation Programs for the Angus breed use heritability of 0.20 and 0.14 for weaning direct (WD) and weaning maternal (WM) effects, respectively. Current programs also assume zero covariances between WD and WM effects. In the present study, random samples of WWT records were used to estimate new sets of variance components. For each of the samples, covariances between WD and WM effects were negative and different from zero ($P < .01$). Means of variance estimates from the different samples were then used to calculate expected progeny differences. Weaning weight measures were analyzed together with postweaning gain (PWG) information using multiple trait animal model that included fixed effect of contemporary group (CG), random effects of direct genetic, maternal genetic, permanent environment, and an error term. Model for PWG included fixed effect of CG, random effects of direct genetic and residual. Mean trend for WD and WM effects based on currently used variances were 0.67 and 0.37 kg/yr, respectively. The corresponding values based on the new variance estimates were 0.72 and 0.28 kg/yr, respectively. Overall rank correlation between each of the new and currently published direct and maternal EPDs were 0.99 and 0.94, respectively. However, rank correlations were associated with the accuracy of EPDs. The relatively weaker rank correlations for groups of animals with low accuracy values may suggest that the use of negative covariances between WD and WM effects in cattle evaluation programs may influence the selection of young sires.

Key Words: Beef Cattle, Weaning Weight, Genetic Trend

892 Genetic evaluation of feedlot performance and efficiency in beef cattle marketed at a constant finish endpoint. C. J. B. Devitt*¹, J. W. Wilton², T. L. Fernandes², and S. P. Miller², ¹Beef Improvement Ontario, Guelph, ON, Canada, ²University of Guelph, Guelph, ON, Canada.

Objectives were to estimate genetic parameters and calculate genetic evaluations in the form of across breed comparisons (ABC, across breed EPD) for post-weaning feedlot performance traits in crossbred beef steers. Feedlot feed intake, feed:gain ratio, and growth data from 941 crossbred steers fed at the University of Guelph's Elora Beef Research Centre from 1996 to 2002 were analyzed. Steers were fed either a high-energy diet from start to finish or a haylage-based diet for the first 112 days and then a high-energy diet to finish. All animals were targeted to a slaughter criterion of 8 mm backfat, as determined by ultrasound measurements taken every 28 days. Seventy sires were represented from 5 different breeds (Angus, Simmental, Charolais, Hereford, Limousin), averaging 13 progeny per sire, ranging from 2 to 38. Three feedlot traits, average daily gain, final live body weight, and days on feed were available on all 941 animals. Two additional traits, daily dry matter feed intake, and feed:gain ratio were available on 452 of the steers. A multiple trait animal model was used to estimate genetic parameters and calculate ABCs for all five traits simultaneously. Model effects included regression on breed proportion, age at feedlot entry as a covariate, fixed effects of contemporary group (herd of origin, year, nutritional treatment), and the random animal effect. Heritability estimates were 0.32, 0.44, 0.15, 0.56, and 0.48 for average daily gain, average daily dry matter feed intake, average feed:gain ratio, final live body weight, and days on feed, respectively. Genetic correlation estimates of days on feed with final live weight and feed:gain ratio were 0.72 and 0.56, respectively. Across breed comparisons were calculated from the individual animal effect and the breed covariate solutions. Results show that selection has potential to improve feedlot efficiency in terms of optimizing performance to reach a desired size at a constant level of fatness. Multiple trait selection for

feedlot traits based on economic considerations of the production system is important to achieving improved feedlot performance to constant finish.

Key Words: Feed Efficiency, Beef Cattle, Heritability

893 Predicting breeding values for feed intake from individual or pen-fed data. K. M. Olson*, D. J. Garrick, and R. M. Enns, *Colorado State University, Fort Collins.*

The objective of this study was to determine the reduction in accuracy of breeding values when pen-fed rather than individual observations on feed intake (FI) were used. The simulated data set consisted of 1,000 animals with true breeding values (BV) and phenotypes for FI (heritability of 0.34) representing 49 sires and 200 maternal grandsires (MGS). Three approaches were compared to predict breeding values for FI (EBV). The first approach was animal model BLUP (IAM) using 1,000 individual FI records. The second approach used 500, 250 or 100 combined FI observations on pens of $i=2, 4$ or 10 animals (PAM_{*i*}). The residual variance was modified to account for the number of animals contributing to each pen FI observation. The third approach (IPM_{*i*}) allocated each animal in the pen the average of the pen FI and incorrectly treated that as a unique FI observation in animal BLUP. Correlations were determined between the BV and EBV for each approach, separately for animals with data, sires and MGS. Correlations were 0.633 for animals, 0.767 for sires and 0.266 for MGS using IAM. These correlations are consistent with expectations based on the heritability and amount of information available. Correlations for animals reduced to 0.532 (PAM₂), 0.470 (PAM₄) and 0.371 (PAM₁₀). Corresponding reductions were 0.774, 0.744, 0.619 for sires and 0.225, 0.107, 0.003 for MGS. When penned animals were treated as if they had individual FI the correlations were 0.531 (IPM₂), 0.465 (IPM₄), 0.365 (IPM₁₀) for the animals, 0.776, 0.742, 0.624 for sires, and 0.218, 0.097, 0.002 for MGS. The reduction in accuracy with penning is consistent with the reduction in available data. The correlations were almost identical whether BLUP was correctly accounting for penning (PAM_{*i*}) or allocating pen averages to each individual (IPM_{*i*}). The apparent accuracy computed from the coefficient matrix was overstated in IPM_{*i*}. Pen data can be effectively used in BLUP analyses when individual FI is not available. Correct account of pen information is recommended for reporting accuracy of EBV.

Breeding and Genetics: Swine

895 Validation of QTL's in a swine population selected for ovulation rate. M. R. Mousel*, G. A. Rohrer, K. A. Leymaster, and R. K. Christenson, *U.S. Meat Animal Research Center, USDA-ARS, Clay Center, NE.*

Variations in allele frequency of a four-breed, white composite population of swine selected for ovulation rate (OR) were evaluated. Animals were selected for 11 generations for increased OR and compared to unselected controls (CO). The selection line had an increase of 3.0 corpora lutea and an increase of 0.3 pigs in total litter size as compared to controls. DNA was collected from 146 CO and 156 OR gilts and boars at generations 10 and 11. A QTL analysis for OR identified loci on chromosomes 3, 8, and 10 in a Meishan-White composite population. Three microsatellite markers were selected for chromosomes 3 (17-42 cM) and 10 (85-96 cM) and six for chromosome 8 (1-13 cM) for utilization with selected and control lines. Allele frequencies of markers contained within QTL peaks were analyzed by logistic regression to ascertain any difference in allele frequency due to selection. All markers on chromosome 3 had significant ($P<0.01$) changes between lines in allele frequency. Odds ratio of the most significant marker ($P<0.0001$), SW2429 contained 7 distinct alleles, the 125 base allele was 530.2 times more likely to be present in homozygous OR animals than CO. Chromosome 8 had 3 of 6 markers with significant ($P<0.02$) changes in allele frequency. The marker SW2651, which contained 3 alleles, was most significant ($P<0.0001$) with an odds ratio of 2.6 for the 100 base allele in homozygous OR animals. Significant ($P<0.01$) changes in allele frequency were found on chromosome 10 with all markers. An odds ratio of 7.3 was calculated for the 107 base allele in homozygous OR animals for the most significant ($P<0.0001$) marker SWR1829 which had 8 alleles. Selection for OR has changed the allele frequency of markers from the three QTL regions studied. The QTL discovered in a Meishan cross

894 The use of ultrasound to evaluate growth and carcass quality in Nelore cattle. F. R. C. Araujo^{1,2}, F. Manicardi³, J. R. Hofig Ramos⁴, C. U. Magnabosco^{5,1}, T. R. Famula¹, and R. D. Sainz^{*1}, ¹*University of California, Davis*, ²*Aval Servicos Tecnológicos S/S, Uberaba, MG, Brasil*, ³*Grupo OMB, Pontes e Lacerda, MT, Brasil*, ⁴*Grupo HoRa, Cornélio Procópio, PR, Brasil*, ⁵*Embrapa Cerrados, Bolsista CNPq Brasília, DF, Brasil.*

This study was carried out to support the development of expected progeny differences (EPD) for carcass traits in Nelore cattle raised under tropical grazing systems. Data from 1,721 bulls and heifers raised in central Brazil (Grupo OMB and Grupo HoRa) were collected at approximately 15, 18, 21 and 24 months of age. The animals were weighed (BW) and scanned for longissimus muscle area (ULMA); backfat thickness between the 12th and 13th ribs (UFAT); and fat thickness over the rump (URFAT), at the P8 site. Mean (and SD) scan data were: Age, 19 (SD = 2.6) months; BW, 321 (SD = 58) kg; ULMA, 47.80 (SD = 8.85) cm²; UFAT, 1.5 (SD = 0.62) mm; URFAT 2.0 (SD = 0.97) mm. Data were analyzed using a mixed model. Fixed effects were age in months (AGE_m), month of scanning (MONTH), contemporary group (including management group; CGxMG). The interaction between AGE_m and MONTHSCAN was used to test the slopes for homogeneity, and the individual animal within contemporary and management group was included to account for repeated measures on the same animal. A large portion of observed variance in response variables was accounted for by GCxMG and AGE_m ($P < 0.001$). Month of scanning (i.e., season) had no effect on BW or ULMA ($P > 0.05$) when the contemporary and management groups were properly accounted for. UFAT was not significantly influenced by MONTH or by AGE_m ($P > 0.05$), nor was there any significant AGE_m x MONTH interaction. By contrast, URFAT was significantly affected by AGE_m ($P < 0.01$), indicating that it is a more sensitive fat deposit. The repeatabilities of measurements were very low for UFAT (0.035) but high for URFAT (0.62) and moderate for ULMA (0.44). Nelore cattle raised on tropical pastures exhibit growth patterns and carcass compositions that are very different from those observed in *Bos taurus* cattle raised on high-concentrate diets, but once the contemporary group and management were accounted for, seasonality had no effect on carcass traits and body weight.

896 Identification of quantitative trait loci affecting reproduction and early growth in pigs. J. Holl^{*1}, J. P. Cassady², D. Pomp¹, and R. K. Johnson¹, ¹*University of Nebraska, Lincoln*, ²*North Carolina State University, Raleigh.*

Quantitative trait loci (QTL) in a 3-generation population of a cross of low-indexing pigs of a randomly selected control line with high-indexing pigs of a line selected 10 generations for increased index of ovulation rate and embryonic survival were investigated. Birth weight (BWT, $n = 428$), weaning weight (WWT, $n = 405$), age at puberty (AP, $n = 295$), ovulation rate (OR, $n = 423$), number of fully formed pigs (FF, $n = 370$), number of pigs born alive (NBA, $n = 370$), number of mummified pigs (MUM, $n = 370$), and number of stillborn pigs (NSB, $n = 370$) were collected in F₂ females. Grandparent, F₁, and F₂ animals were genotyped for 151 microsatellite markers. Previous analyses with single Mendelian QTL models identified 16 putative QTL ($P < 0.10$). Data were reanalyzed with composite interval mapping (CIM) including models incorporating genomic imprinting. More QTL for reproductive traits than in the earlier scan (31 vs 16, $P < 0.10$) and two QTL for birth weight were identified. Mendelian QTL affected **FF** (C11, 52 cM, $P < 0.05$), **NBA** (C11, 71 cM, $P < 0.05$), **NSB** (C13, 100 cM, $P < 0.05$; C5, 131 cM, $P < 0.10$; C12, 37 cM, $P < 0.10$), **NN** (C11, 47 cM, $P < 0.05$; C8, 20 cM, $P < 0.05$; C7, 62 cM, $P < 0.05$), **AP** (C8, 172 cM, $P < 0.05$; C7, 1 cM, $P < 0.05$; C7, 58 cM, $P < 0.10$; C18, 40 cM,

P < 0.10; C8, 101 cM, P < 0.10; C8, 136 cM, P < 0.10; C12, 56 cM, P < 0.10), **MUM** (C12, 98 cM, P < 0.10; C12, 70 cM, P < 0.05; C2, 6 cM, P < 0.10; C6, 64 cM, P < 0.10; C6, 165 cM, P < 0.10), and **BWT** (C12, 17 cM, P < 0.10). Partially imprinted QTL affected **OR** (C9, 1 cM, P < 0.01), **BWT** (C6, 155 cM, P < 0.05), and **MUM** (C6, 81 cM, P < 0.05). Paternally imprinted QTL affected **NN** (C6, 85 cM, P < 0.05; C6, 171 cM, P < 0.10; C15, 64 cM, P < 0.10; C15, 109 cM, P < 0.10), **AP** (C15, 98 cM, P < 0.05), and **MUM** (C6, 191 cM, P < 0.10). Maternally imprinted QTL affected **NSB** (C14, 104 cM, P < 0.10), **NN** (C1, 155 cM, P < 0.10), and **MUM** (C2, 29 cM, P < 0.10). Power to detect QTL with small effects increases with CIM with imprinting compared to single QTL models.

Key Words: Pigs, Imprinting, Quantitative Trait Loci

897 Mapping genes affecting scrotal hernia condition in domestic pigs. F.-X. Du*, N. Mathialagan, C. J. Dyer, M. D. Grosz, L. A. Messer, A. C. Clutter, T. Wang, M. M. Lohuis, and J. C. Byatt, *Animal AG Monsanto Company*.

Scrotal hernia (SH) is a congenital defect that results from protrusion of part of the intestine through the abdominal opening of the inguinal canal and into the scrotum. The SH condition is affected by both genetic and environmental factors; however, the effect of ill-defined environmental factors and plausible involvement of multiple genes with likely incomplete penetrance complicate attempts to identify genetic determinants. To map SH genes, a whole genome scan (using microsatellite markers) was performed using 7 independent SH-affected paternal families from 3 commercial pig lines. An identity-by-descent based nonparametric linkage analysis of this dataset identified 3 chromosomes with suggestive statistical evidence for segregation of SH genes. Twenty-seven additional paternal SH families with 2 SH piglets were genotyped for 33 microsatellite markers on these 3 chromosomes, and the subsequent linkage analysis provided additional suggestive statistical evidence for 2 chromosomes: SSC2 and SSC12. Subsequently, an approximately 50 cM chromosomal region on SSC2 and a number of candidate genes from SSC2 and SSC12 were selected. Sequencing a panel of 24 animals identified multiple polymorphic single nucleotide polymorphisms (SNP) in both candidate genes and anonymous sequences derived from bacterial artificial chromosomes mapping to the targeted SSC2 region. Ultimately, 137 polymorphic SNP assays (107 on SSC2 and 30 on SSC12) were validated. Approximately 2,000 animals (sires, affected or unaffected offspring) of 143 paternal families (with at least 1 affected progeny or at least 80 progeny all absent of SH) from Pietrain sires were genotyped for all 137 SNP markers. Linkage disequilibrium analyses of this dataset provided additional statistical evidence for segregation of genes affecting SH on both SSC2 and SSC12, and helps to refine the map of SH genes and to identify associated candidate genes.

Key Words: Scrotal Hernia, Nonparametric Linkage Analysis, Linkage Disequilibrium Mapping

898 Prospecting for pig SNPs in the human genome: have we struck gold? L. Grapes*¹, S. Rudd², R. Fernando¹, K. Megy³, D. Rocha³, and M. Rothschild¹, ¹*Iowa State University, Ames*, ²*Institute for Bioinformatics, GSF-National Research Center for Environment and Health*, ³*University of Cambridge, Cambridge, UK*.

With increasing interest in performing genome-wide association studies in livestock, rapid identification of genetic markers is becoming a necessity. Single nucleotide polymorphism (SNP) discovery in pigs could be increased using in silico methods. In addition, if closely related species have similar SNP frequencies in their coding regions, SNP discovery in pigs could be increased by screening pig coding regions that are homologous to SNP-dense human coding regions. To test this hypothesis, we identified pig SNPs in silico. All porcine expressed sequence tags (ESTs) were downloaded from EMBL (www1.embl-heidelberg.de) and clustered. Clusters containing 8 or more ESTs were analyzed using the SNIpper algorithm, which assigns a score to a deviation within an EST relative to the consensus sequence. Of the clusters containing 8 or more ESTs, 452 contained at least one putative, high-scoring SNP, totaling 1,394 SNP loci. From these SNPs, 231 were located to the coding regions of 80 porcine genes or hypothetical proteins. Using pig coding SNPs (cSNPs) from 25 of these genes and validated human cSNPs from dbSNP (www.ncbi.nlm.nih.gov/SNP) in homologous genes, the correlation between the gene-specific frequency of human and pig cSNPs was

high (0.77; P < 0.00001) given stringent parameters used to identify pig SNPs in silico. This human-pig correlation represents a lower bound of the true correlation due to false-positive and false-negative results known to occur with in silico SNP detection methods. Using validated mouse and human cSNPs from dbSNP in 50 homologous genes, the correlation between the gene-specific frequency of human and mouse cSNPs was only moderate (0.48; P < 0.0005). These results follow the expectation that closely related species have similar mutation frequencies within their coding regions, which could be attributed to their high level of sequence identity. From 15 porcine in silico SNPs, 9 (60%) have been experimentally validated, indicating that EST-based in silico methods will increase the rate of SNP discovery in pigs. Also, the high human-pig correlation indicates that comparative methods can be used to capitalize on the large supply of human SNP information for rapidly identifying cSNPs in pigs.

899 An evaluation of performance and carcass characteristics between pigs sired by boars from two different time periods. C. R. Schwab*, T. J. Baas, D. W. Newcom, and K. J. Stalder, *Iowa State University, Ames*.

This study was conducted to evaluate differences in performance and carcass traits between pigs sired by boars currently available and pigs sired by boars from the mid 1980's. Two lines were developed by splitting and randomly allocating littermate and $\frac{1}{2}$ sib pairs of females for mating to current (CTP) or old (OTP) time period boars. Matings by CTP boars were made using fresh semen and matings by OTP boars were made using frozen semen. Subsequent boar, barrow, and gilt progeny from two replications were weighed on test at a mean pen weight of 39.8 kg. Off test ultrasonic measurements of 10th rib loin muscle area (LMA), backfat (BF10), and intramuscular fat percentage (IMF) were collected on a total of 789 pigs at a mean pen live weight of 109 kg. Records on pigs sired by CTP boars (n=556) were from 23 sires while pigs sired by OTP boars (n=231) were from 15 sire groups. All available barrows and randomly selected gilts (n=277) were then sent to a commercial abattoir and measurements of tenth-rib backfat (CBF10), last rib backfat (CLRBF), last lumbar backfat (CLLBF), and loin muscle area (CLMA) were collected. Time period differences were assessed by the use of a mixed model that included fixed effects of sire time period, replication, sex, contemporary group, and the interaction of sex by time period. Sire and dam nested within time period were included as random effects. There was no difference in average daily gain or adjusted days to 113.5 kg between the two time periods; however, pigs sired by CTP boars had significantly greater lean gain per day on test. Pigs sired by CTP boars had larger (P<0.05) LMA measurements and less BF10, while pigs sired by OTP boars had significantly more IMF. Carcass evaluation revealed more CLMA, and significantly less CBF10, CLRBF, and CLLBF for pigs sired by CTP boars when compared to pigs sired by OTP boars.

Key Words: Swine, Performance, Carcass

900 Characterization of a line of pigs selected for increased litter size for two RFLPs identified in *follicle-stimulating hormone receptor 1*. C. D. Blowe*, E. J. Eisen, O. W. Robison, and J. P. Cassady, *North Carolina State University, Raleigh*.

The objective of this study was to characterize changes in allelic frequencies for two RFLPs associated with the *follicle-stimulating hormone receptor 1* gene in a line of pigs selected for increased litter size (LS). The LS line was selected for increased number of fully formed pigs, and litters were standardized at birth so replacement gilts were reared in litters of ten or fewer pigs. A contemporary control line (C) was maintained. In generation nine, estimated mean breeding values for litter size differed between lines by 0.63 pigs (P < 0.01). *Follicle-stimulating hormone receptor 1*, a cysteine-rich glycoprotein encoded by a single gene, was investigated. Based on expression patterns and implications from studies involving *follicle-stimulating hormone receptor 1* function, it can be concluded that *follicle-stimulating hormone receptor 1* may play an important role in determining litter size. Intronic regions were amplified using PCR, and two different RFLPs, characterized by *MspI* (*FS1*) and *Fnu4HI* (*FS2*), were identified. Frequencies of the B allele of *FS1* increased in LS, and allele frequencies differed between LS and C by 0.25 and 0.18 in generations 10 and 11, respectively. The change in allele frequency for *FS1* differed from 0 in generations 10 (P < 0.01) and 11 (P < 0.057). Standard errors were adjusted to determine if random drift could be excluded as the cause of

changes in allele frequency, and differences were retested ($P < 0.29$) and ($P < 0.31$), respectively. Results for *FS2* were similar to those of *FS1*. The additive effect of the B allele of *FS1* on estimated breeding value for pigs born live in LS ($n = 207$) was +0.09. Marker-assisted selection has the potential to be highly advantageous in selection for lowly heritable and sex-limited traits, such as litter size. Changes in allele frequency to the exclusion of random drift were not detected; however, sufficient evidence exists to support further investigation of *follicistatin* as a candidate gene for litter size in pigs.

Key Words: Pigs, Reproduction, Selection

901 Detection of quantitative trait loci for growth, carcass, and meat quality traits in a Pietrain x (Large White x Landrace) line cross. N. Vukasinovic¹, F.-X. Du¹, L. A. Messer¹, J. C. Byatt¹, M. M. Lohuis¹, A. C. Clutter¹, J. Bennewitz², N. Reinsch², G. Otto², K. Sanders², N. Borchers², C. Looft², and E. Kalm², ¹*Animal AG Monsanto Company*, ²*Institute of Animal Breeding and Husbandry, Christian-Albrechts University of Kiel, Germany*.

An analysis of quantitative trait loci (QTL) affecting growth, carcass and meat quality traits in swine was conducted on an F₂ population created by crossing Pietrain boars with Large White x Landrace hybrid sows at Christian-Albrechts University of Kiel, Germany. Four F₁ sires were repeatedly mated to 33 full-sib F₁ sows to produce 1014 F₂ offspring. All F₀, F₁, and F₂ animals were genotyped for 27 microsatellite markers on chromosomes 2, 6, and 7. Data on eight growth traits (weights and daily gains at various ages), 16 carcass traits (hot carcass and ham weights and percentages, carcass length, loin eye area, and various fatness measurements), and seven meat quality traits (pH, meat color, and conductivity) were analyzed using line cross (LC) and half-sib family (HS) regression methods. LC analysis revealed very strong evidence ($P < 0.001$) of QTL for daily gain, hot carcass weight, and fatness traits (backfat thickness, abdominal fat, loin fat area, meat:fat ratio, and lean percentage) located near the proximal end of chromosome 2. Chromosome 2 also carried a significant QTL ($P < 0.001$) at 34cM for meat reflectance. The significant QTL in the proximal region of chromosome 2 were imprinted. There was a very significant QTL ($P < 0.001$) affecting carcass length around 90cM on chromosome 7. HS analysis of four large paternal families (each with 250 offspring) was performed to detect QTL segregating within the lines. HS analysis confirmed the QTL found by LC analysis. Additional significant QTL ($P < 0.01$) were found on chromosome 2 for ham weight and ham percentage at 2cM, and for loin pH at 113cM. There was suggestive evidence ($P < 0.05$) of several QTL affecting daily gain and fatness traits on chromosomes 6 and 7. These results indicate that some QTL segregate within, rather than between the lines.

Key Words: QTL Mapping, Line Cross, Half-Sib Analysis

902 An evaluation of meat and eating quality traits between pigs sired by boars from two different time periods. C. R. Schwab^{*}, T. J. Baas, D. W. Newcom, and K. J. Stalder, *Iowa State University, Ames*.

This study was conducted to evaluate differences in meat and eating quality traits between pigs sired by boars currently available and pigs sired by boars from the mid 1980's. Two lines were developed by splitting and randomly allocating littermate and $\frac{1}{2}$ sib pairs of females for matings by current (CTP) or old (OTP) time period boars. Matings by CTP boars were made using fresh semen and matings to OTP boars were made using frozen semen. Subsequent boar, barrow, and gilt progeny from two replications were weighed off test at a mean pen weight of 109 kg. All available barrows and randomly selected gilts were sent to a commercial abattoir and used for meat and eating quality evaluation. Records on pigs sired by CTP boars ($n=178$) were from 23 sires while pigs sired by OTP boars ($n=98$) were from 15 sire groups. Chemical intramuscular fat percentage was determined by lab analysis of a sample from the loin at the 10th rib. Additional meat and eating quality traits measured were: Minolta reflectance and Hunter L color (24 and 48 h); pH (24 h and 7 d); water holding capacity and subjective visual scores for color, marbling, and firmness (48 h); Instron tenderness, cooking loss, and trained sensory panel evaluations (7 d). Time period differences were assessed by the use of a mixed model that included fixed effects of sire time period, replication, sex, contemporary group, and the interaction of sex by time period. Sire and dam nested within time period were included as random effects. Pigs sired by OTP boars had a greater

($P < 0.05$) intramuscular fat percentage and higher subjective marbling and color scores than pigs sired by CTP boars. There were no differences between time periods for the evaluations of Minolta reflectance, Hunter L (24 and 48 h), water holding capacity, Instron tenderness, pH (24 h and 7 d), or subjective firmness scores. Trained sensory evaluations revealed higher ($P < 0.05$) flavor scores and lower off-flavor scores for OTP sired pigs; however, no differences in tenderness score, juiciness score, chewiness score, or cooking loss were found between the two lines.

Key Words: Swine, Meat Quality, Eating Quality

903 Growth and carcass composition in pig lines divergently selected for testosterone production and their crossbred progeny. J. M. Bender^{*} and J. P. Cassady, *North Carolina State University, Raleigh*.

The objective of this study was to characterize growth and carcass composition in two Duroc lines of pigs divergently selected 10 generations for testosterone production and then maintained by random within line selection. In generation 21 endogenous testosterone production in the high (HTL) and low (LTL) testosterone lines averaged 49.0 ng/ml and 27.8 ng/ml ($P < 0.01$), respectively. Eight LTL and 10 HTL boars were used to create 29 LTL and 33 HTL litters. These same boars were mated to a common line of white composite (WC) females to generate 11 WC by LTL litters (WLT) and 23 WC by HTL litters (WHT). Barrows and gilts were then selected LTL ($n=55$), HTL ($n=61$), WLT ($n=102$), and WHT ($n=101$) for testing. Pigs were weighed and scanned using real-time ultrasound 48 h prior to one of two slaughter dates. Data were analyzed with a mixed model including fixed effects of genetic group, slaughter date, sex, and random effect of sire nested within line. All possible interactions among fixed effects were tested. Traits analyzed included days to 114 kg (D114), average daily gain (ADG), back fat adjusted to 114 kg (BF114), loin eye area adjusted to 114 kg (LEA), predicted percent lean (%LEAN) and marbling 24 h post-mortem. Lines did not differ for LEA. The HTL had fewer D114 ($P < 0.011$), greater ADG ($P < 0.004$), greater BF114 ($P < 0.001$), and lower %lean ($P < 0.001$) than LTL. For crossbred progeny WHT had greater ADG ($P < 0.010$) and greater BF114 ($P < 0.025$) than WLT and tended to have fewer D114 ($P < 0.068$) and lower %lean ($P < 0.08$) than WLT. Least square means for marbling score for HTL, LTL, WHT, and WLT were 3.63, 3.61, 3.03, and 3.03, respectively. Pure line progeny were more highly marbled than crossbred progeny ($P < 0.01$). Pigs selected for increased testosterone production grew faster and produced fatter carcasses than pigs selected for decreased testosterone. Because of their high marbling scores these lines may be useful in developing premium products.

Key Words: Growth, Carcass Composition, Pigs

904 Detection of quantitative trait loci segregation within pure breeds in a Berkshire x Yorkshire F₂ population. H. Zhao^{*}, J.-J. Kim¹, M. Perez-Enciso², and J. C. M. Dekkers¹, ¹*Iowa State University, Ames*, ²*Universitat Autònoma de Barcelona, Spain*.

Segregation of quantitative trait loci (QTL) within commercial breeds is of great interest because most marker-assisted selection is implemented within breeds. The objective here was to implement a variance component analysis method to detect and characterize QTL in an F₂ cross between two Berkshire grand sires and nine Yorkshire grand dams with data on 525 F₂ progeny. A model that combines fixed between-breed and random within-breed QTL effects and random polygenic effects was used to analyze back fat traits on chromosomes 7 and 12. These chromosomes were partitioned into segments based on previous results from QTL mapping using least squares regression: 0-35, 35-65, 65-95, 95-125 and 125-138 cM for chromosome 7, and 0-45, 45-80 and 80-96 cM for chromosome 12. For each segment, identity by descent probabilities were obtained by a Monte Carlo Markov Chain algorithm. Each segment was first tested separately for presence of a QTL effect, by comparing the full model with a model with only the polygenic effect, and for segregation of the QTL within the parental breeds, by dropping the variance of the segment. All significant segments were then fitted in a full model and tested vs. a reduced model where the effects of one segment were dropped. For chromosome 7, segments 35-65 cM and 95-125 cM had significant ($p < 0.05$) effects on average backfat, tenth rib backfat and lumbar backfat. The variance of segment 35-65 cM was significant for average backfat and lumbar backfat. Both fixed and random effects were significant for segment 65-95 cM for last rib backfat. For chromosome

12, segment 0-45 cM was significant for average backfat and last rib backfat without significant variance. In conclusion, multiple and segregating QTL were detected for backfat traits on chromosome 7 and QTL was detected on one segment on chromosome 12. The variance component approach is a useful method to detect QTL in crosses between outbred breeds and to identify those that segregate within breeds.

Key Words: QTL, Segregation, Variance Component Analysis

905 PACE: An integrated pig genome database. J. W. M. Merks^{*1}, T. J. A. van Kampen², R. van Wijk¹, B. Harlizius¹, A. Rattink³, G. Albers³, and M. A. M. Groenen², ¹IPG, Institute for Pig Genetics BV, Beuningen, The Netherlands, ²Department of Animal Sciences - Animal Breeding and Genetics Group, Wageningen University and Research Centre, Wageningen, The Netherlands, ³Nutreco Breeding Research Centre, Boxmeer, The Netherlands.

Knowledge of farm animal genomes has increased enormously over the last decade. A large part of this information is publicly available for a variety of species and through specific databases such as for pigs; PiG-BASE for mapping data, Pig EST Database, TIGR SsGI for genes and data on their expression patterns and the INRA Comparative and Cyto-genetic mapping home pages. Potentially these databases provide comprehensive public repositories for genome research. However, these data are difficult to combine from the different sources or with private data, but also with genome data of model organisms. This strongly hinders comparative mapping and positional fine-mapping. A new pig genome database - PACE was set up in the Netherlands to enable integration of data from the different sources. For this, the widespread database system of AceDB has been adapted and links with existing farm animal databases but also databases like LocusLink, Genbank, MGI, GeneCards are included to facilitate an efficient comparative mapping with human and mouse. In addition published information on porcine QTL has been included. This database with more than 5000 genetic markers and loci and about 500 QTL's will be available publicly from July 2004.

Key Words: Pigs, Genome Map, Database

906 Estimation of genetic parameters for farrowing mortality, litter size and test performance of first parity Large White sows. J. Arango^{*1}, I. Misztal¹, S. Tsuruta¹, M. Culbertson², and W. Herring², ¹University of Georgia, Athens, ²Smithfield Premium Genetics, Roanoke Rapids, NC.

Selection to increase prolificacy and performance traits may be affecting piglet survivability at different production stages. To investigate this complex of traits, genetic correlations were estimated among total born (TB), number born alive (BA) and number of pigs born dead (PD) from 47,454 first-parity Large White sow records. Data were from 22 pure-line farms. Additional performance data (n=30,832) were available for ultrasound backfat (BF) at end of the test, and days to reach 113.3 kg (AD). Univariate, all pair-wise bivariate, and four sets of trivariate (TB-PD-AD, TB-PD-BF, BA-PD-AD and BA-PD- BF) analyses were carried out using AI-REML. Models included the fixed effects of contemporary group (farm-farrowing year-farrowing month for litter traits

and batch-sex-farm-barn for test traits). Analysis of BF included measurement weight as linear and quadratic covariates. Random effects of animal additive genetic and residual error were also included. Estimates of heritability averaged over analyses were 0.09, 0.08, 0.06, 0.37 and 0.31 for TB, BA, PD, AD and BF, respectively, and were similar across individual analyses. Estimates of genetic correlations averaged over analyses were 0.94, 0.39, 0.03, -0.02 for TB-BA, TB-PD, TB-AD and TB-BF; 0.02, 0.08 and 0.06 for BA-PD, BA-AD and BA-BF; -0.13 and -0.21 for PD-AD and PD-BF, and -0.23 for BF-AD, respectively. The genetic relationship of PD with TB was moderate and positive while negative with AD and BF. Response to selection for increasing litter size may increase piglet mortality at birth. Intense selection for faster growth and increased leanness may increase piglet mortality from first parity sows in this population.

Key Words: Swine, Farrowing Mortality, Litter Size

907 Comparison of deposition rates for loin muscle area, backfat, and intramuscular fat percentage among breeds in the 2003 National Barrow Show Sire Progeny Test. B. D. Martin^{*}, T. J. Baas, C. Schwab, D. W. Newcom, J. F. Lampe, and K. J. Stalder, Iowa State University, Ames.

Weights and serial ultrasonic measurements of 10th rib loin muscle area (LMA), 10th rib backfat (BF), and intramuscular fat percentage (IMF) were used to assess deposition rates and growth patterns of purebred pigs entered in the National Barrow Show Sire Progeny Test. Yorkshire (30), Duroc (71), Chester White (49), and Berkshire (154) barrows and gilts were weighed and scanned for LMA, BF, and IMF every two weeks beginning at a live weight of approximately 68 kg. Off test ultrasonic measurements were taken at approximately 109 kg. Five scans were taken on each animal. At each scan period, BF, LMA, and IMF were analyzed with a mixed model that included fixed effects of breed, sex, contemporary group, and the interaction of breed by sex. Sire and dam within breed were included as random effects. Weight at each scan period was included as a linear covariate. Deposition rates were calculated for LMA, BF, and IMF using intra-pig linear and quadratic regressions for the independent variable live weight. Intra-pig linear and quadratic regression coefficients and y-intercepts were analyzed as dependent variables in a mixed model that included fixed effects of breed, sex, contemporary group, and the interaction of breed by sex. Across all scans, Yorkshires and Durocs were significantly leaner than Berkshires, and gilts were leaner than barrows. At scans 3, 4, and 5, Durocs were significantly leaner and had more (P<0.05) LMA than Chester Whites. Durocs had more (P < 0.05) LMA than Yorkshires and Berkshires at all five scan periods. Chester White pigs had the largest linear regression coefficient for LMA and the smallest y-intercept. Mean deposition rates for IMF were not significantly different between breeds. Gilts had more (P < 0.05) LMA than barrows at periods 3, 4, and 5. Barrows had more (P < 0.05) IMF than gilts at scan intervals 2, 3, 4, and 5. Quadratic regression coefficients for BF were significantly different between barrows (-0.00002) and gilts (-0.00001).

Key Words: Swine, Ultrasound, Regression

Nonruminant Nutrition: Feed Ingredients & Management

908 Effect of whey and lactose source on nursery pig performance. A. M. Gaines^{*}, B. W. Ratliff, P. Srichana, and G. L. Allee, University of Missouri, Columbia.

A 25 d growth assay experiment was conducted to determine the effects of whey and lactose source on nursery pig performance. At weaning, a total of 276 pigs (TR-4 × C22; 5.8 ± 0.03 kg) reared in a commercial research facility were fed one of two diets containing spray-dried whey and crystalline lactose or granular whey and Dairy Lac 80[®]. Pigs were housed 23 pigs per pen and fed in three dietary phases. Each diet contained the same inclusion of whey and other specialty ingredients. Diets were formulated to be lactose equivalent with additional lactose being added from crystalline lactose in the spray dried whey diets or Dairy Lac 80[®] in the granular whey diets. For the phase 1 period (0-7 d), phase 2 period (7-14 d), and phase 3 period (14-25 d) the level of inclusion of whey in the diets was 20.0%, 10.0%, and 0.0%, respectively. A whey source was not included in phase 3; however, both the spray-

dried and granular whey treatments did contain 7% lactose derived from crystalline lactose or Dairy Lac 80[®], respectively. During the Phase 1 period there was no effect of whey and lactose source on ADG (P = 0.91), ADFI (P = 0.29), or G/F (P = 0.54). Similarly, there was no effect of whey and lactose source on ADG (P = 0.57), ADFI (P = 0.37), or G/F (P = 0.63) during the Phase 2 period. However, during the Phase 3 period pigs fed Dairy Lac 80[®] had improved ADG (P = 0.07) as compared to pigs fed crystalline lactose. Improvements in ADG were due to improvements in ADFI (P = 0.08). There were no differences in G/F (P = 0.76) among the lactose sources. For the overall period (d 0-25) pigs fed granular whey and Dairy Lac 80[®] had improved ADG (P = 0.05) and ADFI (P = 0.04) as compared to pigs fed spray-dried whey and crystalline lactose. There were no differences in G/F (P = 0.44). Based on the results, whey and lactose source did not influence growth performance during the early nursery period. However, growth perfor-

mance in the Phase 3 period was improved when the diets contained Dairy Lac 80[®].

Key Words: Pigs, Whey, Lactose

909 Effect of specialty protein supplements on nitrogen balance and digestibility in weanling pigs. J. Zhao*, A. F. Harper, K. E. Webb, Jr., and M. E. Estienne, *Virginia Polytechnic Institute and State University, Blacksburg.*

Inclusion of spray-dried plasma protein (SDPP) in diets for early-weaned pigs improves post-weaning growth. The objective of this experiment was to determine the effects of supplemental SDPP and a marine-based hydrolyzed protein source (Peptiva, VITECH BIOCHEM, San Fernando, CA) in weanling pig diets on N balance and digestibility. At weaning, pigs (n = 48, 5.4 kg BW, and 17 d of age) were placed in metabolism cages with two pigs per cage. There were three dietary treatments (8 cages/treatment): a corn-soy-whey control diet or similar diets containing 6% SDPP or 6% Peptiva. Diets were formulated to be equivalent in energy and essential amino acids. A 7-d adjustment period was followed by two 5-d collection periods, during which total feces, urine, and orsts were collected. Pigs were fed their respective diets in two equal portions at 12-h intervals to give daily intake of approximately 3% of BW. Dry matter content of feed and fecal samples was determined by oven drying. Nitrogen concentration of feces, feed and urine was determined by the Kjeldahl method. Analytical data were used to calculate DM and protein digestibility and N balance. Supplementation of 6% SDPP or 6% Peptiva had no impact on protein digestibility, retention, or biological value of the diet. Percent absorbed N ranged from 88.51 to 89.34%, and was not different among treatments (P = 0.55). Similarly, percent N retention ranged from 69.08 to 72.01, and was not different among treatments (P = 0.39). The calculated percent biological value and DM digestibility were: 80.92 and 91.51, 77.62 and 92.01, and 78.03 and 91.28 for the control, SDPP and Peptiva treatments, respectively, with no difference among treatments (P = 0.22 to 0.39). In summary, inclusion of SDPP or Peptiva in the diet of weanling piglets did not alter digestibility, N balance or biological value of protein. Situations in which supplementation of these products improves performance appear unrelated to effects on N digestibility or N balance.

Key Words: Digestibility, Nitrogen Balance, Pigs

910 Use of rice in substitution of corn in diets for young pigs. B. Vicente¹, D. G. Valencia¹, R. Lázaro*¹, M. A. Latorre², and G. G. Mateos¹, ¹*Universidad Politécnica de Madrid, Spain*, ²*Universidad Cardenal H. Oria CEU, Spain*.

We studied the influence of the cereal portion of the diet on performance and total tract nutrient digestibility (TTFD) of young pigs. Control pigs received a practical feeding program based on a complex diet without antibiotics that included 50% of cooked corn (99 C during 50 min and then rolled) from 25 to 39 d of age and a corn-soybean meal diet from 39 to 53 d of age. The experimental groups received the same complex diet as the control group but corn was substituted by rice either raw, cooked, or cooked and rolled from 25 to 53 d of age. The percentage of starch gelatinization was 56% for cooked and rolled corn, 14% for raw rice, 25% for cooked rice, and 48% for cooked and rolled rice. Each treatment was replicated eight times (five piglets penned together). Digestibility of nutrients was determined at 27, 39, and 53 d using 0.6% celite as an indigestible marker. From 25 to 39 d piglets fed rice ate more feed (481 vs 391 g/d; P<0.001), grew faster (357 vs 277 g/d; P<0.001), and tended to have better feed conversion (1.34 vs 1.42 g/g; P<0.10) than piglets fed corn. Similar results were observed at the end of the trial. No significant differences in performance were observed among piglets fed the three rice diets but piglets fed cooked rice grew 6.3% faster and had 6.1% better feed conversion than piglets fed raw rice. At 27 d of age TTFD of DM, OM, and GE was lower for corn (P<0.001) than for rice diets, but nitrogen retention was the same. Piglets fed heat processed rice tended to have better TTFD of nutrients than piglets fed raw rice but the differences disappeared with age. It is concluded that rice improves piglet performance from 25 to 53 d and nutrient digestibility at 27 d. No differences were observed between cooked and cooked and rolled rice in spite of differences in percentage of starch gelatinization, indicating that the beneficial effects of heat processing of rice on

piglet performance and nutrient digestibility were independent of starch gelatinization.

Key Words: Rice, Piglet Performance, Heat Processing

911 Growth and carcass characteristics of pigs fed biotechnologically derived and non-biotechnologically derived corn and harvested at different weights. M.G. Custodio*¹, W.J. Powers¹, E. Huff-Lonergan¹, M.A. Faust², and J. Stein³, ¹*Iowa State University, Ames*, ²*ABS Global, Inc., DeForest, WI*, ³*Syngenta Biotechnology, Inc., Research Triangle Park, NC*.

To compare growth performance and carcass characteristics, 64 pigs (average initial BW = 62 kg) were fed diets containing biotechnologically derived corn (Bt: Syngenta Bt 11 event) or control corn (C: pooled non-biotechnologically derived inbred lines). Pigs were blocked by sex and weight and allocated to 16 pens. Iso-caloric, isonitrogenous diets contained an indigestible marker. Feed and water were provided ad libitum. Feed disappearance and weight gain data, and fecal samples were collected weekly. At slaughter, pigs were divided into two groups based on market weight: 1 (85 kg) and 2 (110 kg). No difference in ADG was observed between pigs fed C and Bt diets for harvest weight groups. Feed efficiency was greater for pigs fed the C diet (P = 0.002) and was not different between groups 1 and 2 pigs. An interaction between corn and harvest weight was observed. No corn effects were observed for hot carcass weight, loin eye area (LEA), and 1st, 10th, last rib, and last lumbar vertebrae fat. Harvest weight differences were observed; lighter weight pigs had smaller LEA (12.4 vs. 15.7 cm²; P < 0.001) and less backfat. Across both market weight groups, gilts had larger LEA (P < 0.05) and were leaner than barrows. No harvest weight and corn source effects were observed for meat tenderness and drip loss. Hunter color *L*/*b* values were greater for pigs fed C diets (11.71 vs. 11.31; P = 0.02) and group 2 pigs (11.77 vs. 11.26; P = 0.005). There were no significant differences in DM, ether extract or CP content of meat samples. No corn effects were observed for N or P content of fecal samples. There were no differences in apparent digestibility of N between pigs fed Bt and C diets. Pigs fed C diets had greater apparent P digestibility (57.8% vs. 40.2%; P < 0.001). Interactions were observed between treatment and sex; barrows fed Bt corn and gilts fed C corn had lowest apparent P digestibilities. Findings suggest no detrimental effects on growth performance or carcass and excretion characteristics for growing-finishing pigs fed Bt corn. Traits desired by consumers were not different between pigs harvested at light and heavy market weights.

Key Words: Pigs, Biotechnologically Derived Corn, Carcass Characteristics

912 Nutritional value of a corn containing a glutamate dehydrogenase gene for growing pigs. G. A. Apgar*¹, T. A. Guthrie¹, K. E. Griswold², M. P. Martin¹, J. S. Radcliffe³, and M. D. Lindemann⁴, ¹*Southern Illinois University, Carbondale*, ²*Penn State University Extension, Lancaster*, ³*Purdue University, West Lafayette, IN*, ⁴*University of Kentucky, Lexington*.

Eight female PIC pigs (initial body wt. 47.5 ± 1.8 kg) were utilized in a two period switchback design (n = 4 per treatment per period) to evaluate the nutritional difference between a genetically modified corn and a similar non-transgenic corn. The genetically altered corn (*gdhA+*) contained a glutamate dehydrogenase gene isolated from *Escherichia coli*. The non-transgenic corn was the same variety lacking the transgenic cassette, grown at the same locations. Pigs were surgically fitted with steered ileo-cecal valve cannulas for collection of ileal digesta. Diets were comprised primarily of one of the two corn sources. Dietary AA profiles were adjusted using crystalline AA to match Illinois Ideal Protein Ratios. Pigs were limit fed at 8% of metabolic body weight (BW^{0.75}), in two equal feedings at 0600 and 1800 each day throughout the experiment. The study consisted of two 15-d periods. Each period was comprised of a 7-d acclimation period, a 3-d total collection of feces and urine, two 12-h ileal collections, and a 3-d adjustment period between ileal collections to assure adequate hydration. Crude protein, leucine, methionine, alanine, aspartic acid, glutamic acid and tyrosine concentrations were greater (P < 0.05) in the *gdhA+* corn when compared with the non-transgenic variety. The presence of the gene did not alter (P > 0.17) body weight gain, nor (P > 0.32) dry matter digestibility, fecal N excretion (g/d), apparent total tract N digestibility, N balance, net protein utilization, or N retained as % of absorbed. Apparent ileal AA digestibility values did not differ (P > 0.31) between

the two dietary treatments. This study showed corn that contains the *E. coli* gene for glutamate dehydrogenase was nutritionally equivalent to the non-altered variety.

Key Words: Maize, Transgenics, Pigs

913 The digestive fate of the *gdhA* transgene in corn diets fed to weanling swine. J. M. Beagle*¹, G. A. Appgar¹, K. L. Jones¹, K. E. Griswold², X. Qui¹, and M. P. Martin¹, ¹*Southern Illinois University, Carbondale*, ²*Penn State Extension, Lancaster*.

A transgenic corn containing *E. coli* glutamate dehydrogenase (*gdhA*) was used in diets fed to weanling swine and the digestive fate of the *gdhA* transgene was traced. Eight groups of 8 pigs were fed a commercially available (non-*gdhA*) starter feed for 2 wk. One pig was randomly selected from each pen, sacrificed, and negative control samples were collected. The remaining 56 pigs were fed a diet containing 57.97% *gdhA* corn for 2 wk. All pigs were then sacrificed and treatment samples were collected. Samples from both control and treatment pigs included digesta from the stomach, distal ileum, and distal colon, liver, 10th rib muscle, and white blood cells and plasma from the hepatic portal vein. Total genomic DNA was extracted and concentration determined via spectrophotometry. Polymerase chain reaction (PCR) was performed with primers designed to amplify a 456 bp region of the *gdhA* gene, and PCR products were analyzed using gel electrophoresis. DNA extracted from the *gdhA* positive corn acted as a positive control for the PCR and gel electrophoresis while DNA extracted from a commercially available non-*gdhA* corn and an equivalent volume of distilled water acted as negative controls. DNA extracted from the *gdhA* positive diet ensured the transgene was detectable in the diet. The level of detection allowed as little as 0.3 ng transgenic corn DNA per each 20 ul reaction to be detected even when confounded with 6.4 ug of SBM or 1.5 ug non-*gdhA* corn. The 456 bp region of the *gdhA* transgene was detected in 71% of the stomach digesta samples from treatment animals, but was not detected in the small and large intestine, WBC, plasma, liver, or muscle samples. No transgenic DNA was detected in any sample from control animals. These data suggest that degradation of this transgene began in the stomach and that the transgene was degraded beyond detection by the time the digesta reached the distal ileum.

Key Words: Glutamate Dehydrogenase, Transgenic, Corn

914 Effects of increasing pantothenic acid on growth performance and carcass characteristics of finishing pigs reared in a commercial environment. C. N. Groesbeck*, R. D. Goodband, M. D. Tokach, S. S. Dritz, J. L. Nelssen, and J. M. DeRouchey, *Kansas State University, Manhattan*.

An experiment using 1,080 pigs (PIC, initially 40.3 kg) was conducted to evaluate added pantothenic acid (PA) on growth performance and carcass characteristics. Pigs were blocked by weight and gender, and were randomly allotted to one of four dietary treatments. There were 10 pens per treatment with a mean of 27 pigs per pen. Pigs were fed the experimental corn-soybean meal, 5% added fat diets in four phases. Pigs were fed the control diet (no added PA) or the control diet with 22.5, 45 or 90 ppm of added PA from d-calcium pantothenate. Pigs were fed the assigned dietary treatments from 40.3 to 123.6 kg (d 0 to 98), and transported to a commercial packing facility to collect carcass measurements. Pigs were weighed and feed intake was determined every 14 d. There were no PA gender interactions ($P > 0.05$) observed. Increasing dietary PA had no effect ($P > 0.05$) on ADG, ADFI, or feed efficiency (G/F) from d 0 to 98. Barrows had greater ($P < 0.01$) ADG and ADFI than gilts. Increasing pantothenic acid has no effect ($P > 0.05$) on hot carcass weight, dressing percent, fat free lean index (FFLI), average backfat, and loin depth. Gilts had less ($P < 0.001$) backfat and a greater ($P < 0.001$) FFLI than barrows. There were no ($P > 0.05$) gender differences in dressing percent or loin depth. Increasing dietary pantothenic acid during the grow-finish phase does not appear to provide any advantage in growth performance or carcass composition of commercially reared finishing pigs.

915 Effects of reduced crude protein and fiber supplementation on nitrogen and phosphorus digestibility and manure generation. D. M. Sholly*, S. L. Hankins, M. C. Walsh, A. L. Sutton, and B. T. Richert, *Purdue University, West Lafayette, IN*.

Sixteen crossbred barrows (avg initial BW = 32.6 kg) were allotted by weight to 4 experimental diets (4 pigs/diet) in a 2 x 2 factorial design comparing two crude protein (CP) levels and 0 or 10% wheat bran (WB). Dietary trts were: 1) Control (CTL), 17.7% CP; 2) CTL + 10% WB; 3) Low Nutrient Excretion diet (LNE), 13.9% CP, HAP corn, phytase, and synthetic amino acids; and 4) LNE + 10% WB. A 28 d experiment included a 5 d adjustment period to metabolism pens, a 20 d collection of total feces and urine (3 times/wk) for storage in 16 individual PVC columns (122 x 38 cm), and a 3 d total collection to determine nutrient digestibility. There were no differences in initial and final BW among dietary trts. Inclusion of WB decreased ADFI (4.00 vs. 3.66 kg/d; $P < .007$) by 8.5%. Manure generation (as-is basis) was not different among dietary trts. LNE diets reduced manure DM (kg/d) ($P < .004$) by 18.2%, however, WB inclusion increased manure DM (kg/d) by 12.5% ($P < .02$). Manure pH (avg 6.91) was not affected by dietary CP or WB. LNE diets tended to decrease total N (TN) concentration (as-is basis) in the stored manure by 20% ($P < .09$). Manure TN concentration (DMB) was decreased ($P < .0001$) by 14.6% and 21% for the LNE diets and 10% WB inclusion, respectively. Manure ammonium N (AmmN; DMB) concentration was decreased by 22.4% with WB ($P < .003$). The LNE diets decreased ($P < .003$) stored manure total P (TP) concentration (as-is basis) by 38% and TP excreted by 48.2% (4.25 vs. 2.2 g/d; $P < .0001$) when compared to CTL diets. Dietary trts did not affect N and P digestibility. LNE diets reduced total AmmN excreted by 35.5% (3.03 vs. 1.96 g/d; $P < .002$), fecal TP (5.61 vs. 3.67 g/d; $P < .002$) by 34.6%, and total WSP (3.76 vs. 1.74 g/d; $P < .0005$) by 54%. The use of reduced dietary CP and P diets can significantly reduce the amount of N and P excreted by growing pigs. The inclusion of 10% WB did decrease N and AmmN excretion, but also decreased pig ADFI which may hinder growth performance.

Key Words: Pigs, Crude Protein, Fiber

916 Comparison of models fitted to electronically recorded swine growth data over a limited test period. G. Vander Voort* and C. F. M de Lange, *University of Guelph, Guelph, ON, Canada*.

The evaluation of alternative management, marketing and breeding strategies in pork production systems requires knowledge of variation in pig growth patterns. The objective of this research was to evaluate alternative mathematical functions and statistical procedures to represent growth patterns (BW vs time) of individual pigs between about 25 to 120 kg BW. Electronically recorded daily BW data from an 84 d period for 40 group-housed pigs was analyzed. Data was filtered to identify and edit outliers. Three functions (modified Bridges, Gompertz, and exponential second order polynomial) were fit for each individual pig using the non-linear procedure of SAS. A second order polynomial was also fit for each individual pig using a random regression procedure. Least square means of residuals (RESls) for daily BW were calculated for each function and 21 d interval of the test period. Across intervals, the smallest RESls were observed for the random regression derived second order polynomial (-0.16 to -0.01 kg; SE 0.11), these values did not differ from zero and across 21 d interval ($P > 0.10$). For the other functions, RESls differed from zero ($P < 0.05$) for at least one 21 day interval. For the Gompertz function and d 63 to 84 of the test period, the absolute RESls was largest (-1.04 kg; SE 0.12), indicating a systematic bias in the prediction of BW during the last 21 d of the

test period when using this function. Based on analysis of residual patterns, the Bridges, Gompertz, and exponential second order polynomial functions were more sensitive to violation of the assumption of constant residual variance across time. The least amount of bias in the representation of the growth patterns of pigs was observed when using a random regression procedure and a second order polynomial function.

917 Processing of western Canadian feed ingredients improves their digestibility in Nile tilapia (*Oreochromis niloticus*). T. L. Borgeson*, D. L. Thiessen, V. J. Racz, and M. D. Drew, *University of Saskatchewan, Saskatoon, SK, Canada.*

The apparent digestibility coefficients (ADC) of unprocessed and processed pea, canola and flax products were determined on diets, in which 30% of a reference diet was replaced by each test ingredient. Celite was used as an indigestible marker for measuring apparent digestibility coefficients indirectly. The trial was conducted in a semi-closed recirculating system using 5 tanks per diet with 40 fish per tank, and feces were collected using a settling column. The processed ingredients included dehulled flax produced by abrasive dehulling, canola protein concentrate and pea protein concentrate, which were produced by aqueous extraction of peas and canola meal, respectively. Coextrudates of canola and peas (C:P) or flax and peas (F:P) were also tested. Processing had no significant effect on the ADC of crude protein except for flax. Whole flax

had negative ADC for crude protein, energy and dry matter probably due to the high viscosity of this diet. Processing significantly improved the ADC of energy and dry matter for pea, canola meal and flax ($P < 0.05$). The ADC for crude protein for C:P was not significantly different than pea or canola meal while the ADC for crude protein for F:P was intermediate between flax and pea. The coextruded products had ADC for energy and dry matter that were significantly higher than those of the component ingredients ($P < 0.05$). The results suggest that these processing methods can significantly improve energy and dry matter ADC of pea, canola and flax by tilapia but have less effect on protein digestibility.

Ingredient	Crude protein	Energy	Dry Matter
Pea	0.86 ^a	0.58 ^{cd}	0.59 ^{cde}
Pea protein concentrate	0.95 ^a	0.95 ^a	0.93 ^a
Canola meal	0.82 ^a	0.68 ^{bc}	0.54 ^{de}
Canola protein concentrate	0.86 ^a	0.84 ^{ab}	0.78 ^{abc}
Extruded canola:pea	0.76 ^{ab}	0.84 ^a	0.69 ^{bcd}
Whole flax	-0.38 ^d	-0.27 ^e	-0.45 ^f

Physiology and Endocrinology: Stress and Inflammation: Effects on Animal Performance

918 Performance of gilts housed individually in stalls or in groups in pens during the first 30 d post-mating. M. J. Estienne*, A. F. Harper, and J. W. Knight, *Virginia Polytechnic Institute and State University, Blacksburg.*

In the U.S. most sows are individually housed throughout gestation in stalls that allow only standing, sitting and lying. Use of gestation stalls is a contentious welfare issue that may lead to legislation limiting the housing of sows in stalls to a defined interval that is less than the total gestation period. The objective was to assess performance of gilts housed individually in stalls or in groups in pens for the first 30 d after mating. Gilts ($n = 56$; 159.5 ± 1.5 kg BW; 15.0 ± 0.5 mm backfat) were mated via AI twice during estrus. After the second AI, gilts were placed in stalls (0.6×2.0 m) ($n = 14$) or pens (1.7×3.1 m) containing three gilts each ($n = 14$), and were fed at a rate of 2 kg/gilt/d. Gilts housed in pens gained more BW than gilts housed in stalls (11.0 vs. 6.7 kg; SE = 0.8; $P < 0.01$), but change in backfat was similar between treatments (-0.3 vs. -0.4 mm; SE = 0.5; $P = 0.80$). The proportion of gilts exhibiting stereotypies on d 28 was not affected by treatment (81 for groups vs. 93% for stalls; SE = 7.2; $P = 0.26$). Wound scores (0 to 5; 5 = severe) were greater for group-housed gilts and were greatest during the first 7 d post-mating. For example, wound scores for the head, face and ears (2.5 vs. 1.3; SE = 0.2) and neck and shoulders (2.6 vs. 0.3; SE = 0.2) on d 3 were greater ($P < 0.01$) for group- vs. stall-housed gilts. Lameness scores (0 to 5; 5 = severe) on d 30 were greater in group- compared to stall-housed gilts (0.6 vs. 0.2; SE = 0.1; $P = 0.06$). Pregnancy rate at d 30 was lower ($P < 0.01$) for group- compared to stall-housed gilts (85.7 vs. 100%; SE = 3.2). Following slaughter at d 30 of gestation, the number of embryos (13.8 vs. 15.5; SE = 1.8; $P = 0.51$), embryo weight (1.59 vs. 1.58 g; SE = 0.07; $P = 0.89$) and crown-rump length (27.2 vs. 27.1 mm; SE = 0.46; $P = 0.92$) were similar for group- and stall-housed gilts, respectively. Indicators of welfare were differentially affected by type of gestation housing and pregnancy rate was maximized in gilts housed individually in stalls.

Key Words: Gestation, Housing, Gilt

919 Effects of stress and genotype on immune and cortisol measures in pigs. M. A. Sutherland*, S. R. Niekamp, S. L. Rodriguez-Zas, and J. L. Salak-Johnson, *University of Illinois, Urbana.*

Pigs are exposed to many stressors during common management and production practices. Genotypic differences in immune measures and cortisol concentration in pigs have been reported but the influence of genotype on stress responsiveness is limited. The objective of this experiment was to determine the effect of "breed" and commercial genotypes

on immune and cortisol responses in pigs subjected to multiple stressors over 14 d. Piglets from Landrace Cross ($n=36$), Meishan ($n=30$), Yorkshire ($n=32$) and two commercial lines (LineA and LineB; $n=36$) were weaned at 17 to 21 d and kept in a common nursery environment. At 6 wk of age pigs were assigned either no stress (control) or stress (heat, crowding, mixing) treatment. Blood samples were obtained via veni-puncture at d 0 (baseline), 1, 7 and 14 post-stress to determine white blood cell counts, differentials, cortisol (CORT), IgG, lymphocyte proliferation (LPA), natural killer cytotoxicity (NK), phagocytosis and antibody response to sheep red blood cells. There were significant genotype and genotype x day interaction effects for CORT and numerous immune measures. CORT levels were lower ($P < 0.0001$) in stressed pigs compared to controls. At d 7, CORT levels were lower ($P < 0.05$) in stressed Meishans and Yorkshires compared to controls and remained suppressed in Meishans until d 14 ($P < 0.01$). LPA response was higher ($P < 0.05$) in stressed Meishans at d 1, and remained elevated until d 14, compared to control pigs ($P < 0.05$). NK, at E:T ratio of 25:1, was higher ($P < 0.05$) in Landraces and Yorkshires at d 14 compared to control pigs. In commercial lines, CORT levels were lower ($P < 0.05$) in stressed pigs compared to their controls at d 7. LPA response was higher ($P < 0.01$) in stressed LineA pigs at d 1 compared to control pigs. These results indicate a genotype effect on immune and cortisol concentrations in response to stress and that these effects change over time.

Key Words: Immune, Pigs, Genotype

920 The use of a Hens' Odorant Analogue to control stress consequences in Broilers. I. Madec^{*1}, J. F. Gabarrou², A. Bruneau¹, L. Bougrat¹, D. Saffray¹, B. Silliant³, and P. Pageat¹, ¹*Pherosynthese, Saint Saturnin Apt, France*, ²*Esa Purpan, Toulouse, France*, ³*Env Nantes, Nantes, France.*

In poultry, stress has consequences such as pecking behavior, increased feed to gain ratio, high mortality or bad carcass quality. Indicators of stress include: high H/L (Heterophil/Lymphocyte) ratio and elevated corticosterone secretion. We have identified in the uropygial glands in laying hens a secretion (named HOA: Hens Odorant Analogue, under patent). To test the hypothesis that HOA has stress-preventive actions and improves general performance, a trial was conducted (HOA vs control) using two similar buildings, each housing 24,000 chickens. Chickens were maintained on the ground floor under similar conditions. Males were separated from females. The HOA was administered by passive diffusion in the building atmosphere (one diffuser for 1000 chickens). After treatment, HOA-treated animals were heavier than controls: 2.22

vs 2.06 ($p < 0.0001$) for males and 1.13 vs 1.09 ($p < 0.0001$) for females. Percentage of scratched animals was lower in the HOA treated group than in controls: 8% vs 22% ($p < 0.001$) for males, 10% vs 19% ($p < 0.001$) for females. Results concerning suffocated chickens were more ambiguous. Indeed there were more suffocated females in the control group: 6.36% vs 3.25% ($p < 0.001$), whereas there were more suffocated males in the HOA treated group: 1.36% vs 1.11% ($p < 0.05$). Treated animals had a lower H/L ratio: 0.81 vs 1.11 ($p < 0.01$) for males, 0.77 vs 0.85 ($p < 0.001$) for females. Corticosterone level was higher in the control group for males (3.40 vs 2.64, $p < 0.05$) but not for females ($p > 0.05$). The observed differences between the two groups suggest that chickens treated with HOA are subject to less stress than control chickens. Conversely, the number of suffocated animals is generally related to physiological distress, which tends to show that HOA has no real influence on this phenomenon. Economic data indicated that the gross margin was higher for the treated building by 4.8%. Further studies are required to more clearly define the physiologic and economic impact of treating chickens with HOA.

Key Words: Stress, Broilers, Apeasing

921 Involvement of anterior pituitary arginine vasopressin receptor V3 in the stress response of cattle. M. Knights^{*1}, N. K. Ames², and G. W. Smith², ¹*Division of Animal and Veterinary Sciences, West Virginia University, Morgantown,* ²*Departments of Large Animal Clinical Sciences, Michigan State University, East Lansing,* ³*Departments of Animal and Physiology, Michigan State University, East Lansing.*

The stress-induced increase in ACTH and cortisol is stimulated by corticotropin releasing factor (CRF) and arginine vasopressin (AVP). Effects of CRF and AVP are mediated via their anterior pituitary (AP) receptors, CRFR1 and V3 respectively. In the present studies, we evaluated effect of the V3 receptor antagonist deamino-AVP (dAVP) on LPS-induced ACTH and cortisol secretion and AP abundance of CRFR1 and V3 mRNAs in cattle. In Study 1, Holstein steers received i.v. saline or dAVP (10 μ g/kg), followed 1 h later by i.v. LPS (200 ng/kg) or saline ($n = 4$ per treatment). Previous studies demonstrated that dose of dAVP utilized effectively blocks AVP-induced ACTH and cortisol secretion in cattle. Blood samples were collected at time of LPS injection and 2 h later for determination of plasma ACTH and cortisol. ACTH and cortisol secretion were not affected by dAVP treatment alone. LPS increased ACTH secretion by 400% ($P < 0.001$) and the stimulatory effect of LPS was enhanced 200% by dAVP treatment ($P < 0.001$). A similar effect on cortisol secretion was observed, but the magnitude of increase was less. In Study 2, we determined effect of dAVP on LPS-induced changes in AP CRFR1 and V3 mRNA abundance. Intracerebroventricular (ICV) cannulated Holstein steers received either saline or ICV dAVP (750 μ g) followed 1 h later by i.v. saline or LPS. At 4 h post LPS, steers were sacrificed and AP collected for RNA isolation. Relative concentrations of AP CRFR1 and V3 mRNAs (normalized relative to RPL-19 mRNA) were determined using quantitative real-time PCR procedures. LPS decreased ($P < 0.05$) abundance of CRFR1 and V3 mRNAs compared to saline (control), but effects of LPS were blocked by ICV dAVP administration. Results lead to the suggestion that AP V3 receptor signaling pathways inhibit LPS-induced ACTH and cortisol secretion and LPS-induced down regulation of AP CRFR1 and V3 mRNAs in cattle. Supported by USDA 2001-35204-10801 (GWS) and the MI Agricultural Experiment Station.

Key Words: V3 Receptor, Stress, Cattle

922 Plasma progesterone response to ACTH administration in the ewe during diestrus and following ovariectomy. R. W. Godfrey^{*1}, A. J. Weis¹, R. E. Dodson¹, M. Loewer¹, and S. T. Willard², ¹*University of the Virgin Islands,* ²*Mississippi State University, Mississippi State.*

The role of the adrenal gland in reproduction has not been elucidated completely, yet has been suggested to be a significant source of progesterone (P4) in some species. The objective of this study was to evaluate the P4 response following ACTH administration in ewes synchronized to diestrus and in ewes following ovariectomy. Sixteen ewe lambs (27.0 \pm 0.82 kg; 8.1 \pm 0.04 mon of age) were synchronized using CIDRs, which were removed 12 d post-insertion. On d 11 post-CIDR withdrawal (diestrus), ewes received one of three treatments (i.v.): 1.0 IU ACTH ($n = 6$); 0.1 IU ACTH ($n = 5$); saline (control, no ACTH; $n = 5$).

Blood samples (plasma) were collected at Time -15, 0 (infusion), 15, 30, 45, 60, 120, 240 and 480 min in relation to ACTH treatment. Ewes were then ovariectomized (OVEX) 11 weeks later and ACTH challenges repeated. Plasma P4 and cortisol (CT) were determined by RIA. Plasma CT for diestrus ewes peaked at 30 min post-ACTH treatment for the 1.0 and 0.1 IU ACTH groups, increasing 5.5 \pm 0.8- and 2.6 \pm 0.7-fold over pre-treatment values. Plasma CT for OVEX ewes peaked at 60 min post-ACTH treatment for the 1.0 IU ACTH group and at 30 min for the 0.1 IU ACTH group; increasing 15.1 \pm 5.0- and 8.1 \pm 2.8-fold over pre-treatment values respectively. Area under the ACTH response curves (AUC; 0 to 120 min) for plasma CT differed ($P < 0.05$) among treatment groups in a dose-dependent fashion for diestrus and OVEX ewes. In diestrus ewes plasma P4 increased over time ($P < 0.05$) for all groups, and AUC for P4 differed ($P < 0.05$) between the 1.0 IU versus 0.1 IU and control treatment groups. In OVEX ewes, P4 AUC differed ($P < 0.05$) in a dose-dependent fashion, peaking at 60 and 30 min post-ACTH for the 1.0 and 0.1 IU ACTH groups respectively. In summary, ACTH administration in diestrus and OVEX ewes resulted in a dose-dependent increase in CT, as expected. In diestrus ewes only a transient increase in P4 was noted (1.0 IU ACTH group), while in OVEX ewes a dose-dependent effect of ACTH on adrenal P4 production was observed. These data indicate variable responses in adrenal P4 secretion post-ACTH administration in diestrus versus OVEX ewes.

Key Words: ACTH, Progesterone, Adrenal

923 Plasma progesterone response to ACTH administration in the pregnant ewe during early and late stages of gestation. S. T. Willard^{*1}, A. J. Weis², R. E. Dodson², M. Loewer², and R. W. Godfrey², ¹*Mississippi State University,* ²*University of the Virgin Islands.*

The adrenal gland has been suggested to contribute to the maintenance of pregnancy during times of acute stress through stimulation of adrenal progesterone (P4) production. However this has not been firmly established, nor has the secretion of P4 been characterized relative to stage of gestation in response to acute stimulation of adrenal function. The objective of this study was to evaluate the P4 response, above that of luteal/placental origin, following ACTH administration in ewes during early and late stages of gestation. Twenty pregnant St. Croix White ewes (49.7 \pm 2.0 kg; 4.0 \pm 0.4 yrs) were treated (i.v.) with one of the following: 1.0 IU ACTH ($n = 8$); 0.1 IU ACTH ($n = 6$); saline (control, no ACTH; $n = 6$) at 60 and 120 d of gestation. Blood samples (plasma) were collected at Time -15, 0 (infusion), 15, 30, 45, 60, 120, 240 and 480 min in relation to ACTH treatment. Plasma P4 and cortisol (CT) were determined by RIA. At 60 d of gestation, plasma CT peaked at 60 min post-ACTH treatment for the 1.0 IU ACTH group and at 30 min for the 0.1 IU ACTH group; increasing 13.0 \pm 6.1- and 6.3 \pm 1.3-fold over pre-treatment values. At 120 d of gestation, plasma CT peaked at 120 min post-ACTH treatment for the 1.0 IU ACTH group, and at 45-min for the 0.1 IU ACTH group; increasing 6.3 \pm 1.5 and 9.7 \pm 3.0-fold over pre-treatment values. Area under the ACTH response curves (AUC; 0 to 120 min) for plasma CT at 60 and 120 d of gestation differed ($P < 0.01$) among treatment groups in a dose-dependent fashion, while AUC for P4 did not differ ($P > 0.10$) among treatment groups. Plasma P4 increased over time ($P < 0.05$) throughout the day of challenge for all groups at 60 and 120 d of gestation, but did not differ ($P > 0.10$) relative to ACTH treatment. In summary for ewes during early and late gestation, ACTH administration resulted in a dose-dependent increase in CT, as expected. However, ACTH administration did not increase plasma P4 above that of pre-treatment baseline (luteal/placental) concentrations. These data indicate that ACTH administration does not result in a supplemental rise in adrenal P4 during early and late gestation in the pregnant ewe.

Key Words: ACTH, Progesterone, Gestation

924 Effects of temperament on stress indicators in Brahman heifers. K. O. Curley, Jr.^{*1,2}, D. A. Neuendorff², A. W. Lewis², J. J. Cleere², T. H. Welsh, Jr.¹, and R. D. Randel², ¹*Texas Agricultural Experiment Station, College Station,* ²*Texas Agricultural Experiment Station, Overton.*

The objective of this study was to compare adrenal responsiveness to pituitary stimulation with exogenous CRH in calm (C) and temperamental (T) heifers. The C and T groups (selected using exit velocity (EV) from a squeeze chute) consisted of the 6 slowest (EV=1.05 \pm .05 m/sec) and 6 fastest (EV=3.14 \pm 0.22 m/sec) 2-year old Brahman heifers in the herd.

Blood samples were collected via indwelling jugular cannulas (fitted ~18h prior) for a period of 6h pre- and 6h post- administration of CRH (0.1 µg/kg BW). Sampling intervals were 15min throughout the 12h except for the initial 30min and final 180min of the post-challenge period; where the sampling intervals were 5 and 30min, respectively. Serum cortisol (CS) concentrations were determined via RIA. Pearson correlation coefficients and ANOVA were used for statistical comparisons. Basal CS, determined as the mean concentration (ng/mL) within the 1h period prior to CRH challenge, was highly correlated to EV ($r=.90$; $P<.001$) and differed ($P<.001$) between temperament groups ($C=10.07\pm 2.3$ and $T=38.66\pm 3.7$). Following CRH challenge, both peak CS and time to reach peak CS did not differ between temperament groups. However, temperament did influence ($P=.01$) the increase, induced by the CRH challenge, from basal CS ($C=753\pm 220$ and $T=124\pm 47\%$). A negative correlation was found between EV and % increase in CS ($r=-.63$; $P<.03$). Time to return to basal CS was also influenced ($P<.04$) by temperament group as C took longer than T heifers ($C=267\pm 14$ and $T=152\pm 44$ min). The area under the curve following the return to basal CS was also influenced ($P<.01$) by temperament ($C=9222\pm 616$ and $T=14973\pm 1568$ ng*min/mL), indicating that the CS concentrations in the T heifers remained higher than C heifers. As poor temperament relates to increased basal adrenal activity and muted responsiveness to pituitary stimulus, temperament does affect stress mechanisms. Exit velocity can be used as an indicator of temperament and an indicator of pituitary-adrenal function.

Key Words: Temperament, CRH Challenge, Exit Velocity

925 Administration of exogenous prolactin (PRL) to steers on short day photoperiod: effects on PRL, PRL-receptor (PRL-R) expression, and immune function. T. L. Auchtung* and G. E. Dahl, *University of Illinois, Urbana.*

Photoperiod management significantly affects physiology of dairy cattle. For example, long day photoperiod (LDPP) during lactation increases milk yield, whereas short day photoperiod (SDPP) during the dry period increases milk production in the subsequent lactation. We have also observed an improvement in cellular immune function in animals on SDPP relative to their LDPP counterparts. In addition, PRL sensitivity is altered by photoperiod management. Our hypothesis is that the inverse relationship observed between PRL and PRL-R mRNA expression during photoperiod treatment alters the sensitivity of the animal to PRL, thereby affecting the changes in their cellular immune function. The objectives of this study were to supply exogenous PRL in vivo and in vitro models to determine the effects of PRL on photoperiod mediated immune responses. Eight Holstein steers received each of four treatments: LDPP (16 h light:8 h dark), SDPP (8 h light:16 h dark), SDom (SDPP plus PRL via osmotic minipump for 10 d), and SDinj (SDPP plus PRL via 3x daily injections for 10 d). Solutions of PRL were formulated so that animals received 4.0 mg/d PRL with 0.9% saline. Steers on SDPP had decreased PRL concentrations ($P < 0.05$) relative to the other three treatments. Expression of long form PRL-R mRNA on lymphocytes was increased in SDPP treated animals relative to LDPP, SDom, and SDinj. Prior to PRL treatment, SDPP animals had greater lymphocyte proliferation and neutrophil chemotaxis ($P < 0.01$) relative to LDPP animals. However, following PRL treatment, lymphocyte proliferation and neutrophil chemotaxis of SDom and SDinj animals were reduced to the level of LDPP animals. Addition of PRL to the in vitro lymphocyte proliferation increased proliferation of lymphocytes from SDPP animals but did not alter response of LDPP animals. These results support the concept that an animal's altered PRL sensitivity mediates the changes in cellular immune function observed with photoperiod manipulation.

926 Characterization of changes in hepatic expression of inflammation-associated genes during the periparturient period in multiparous Holstein cows using quantitative real time-PCR (RT-PCR). N. A. Janovick*, J. J. Loor, H. M. Dann, H. A. Lewin, and J. K. Drackley, *University of Illinois, Urbana.*

Dietary strategies in the dry period and early lactation might impact hepatic expression of genes associated with inflammatory responses, which in turn could impact metabolic adaptations to lactation. The objective of this study was to characterize changes in hepatic expression

of tumor necrosis factor- α (TNF- α), peroxisome proliferator activated receptor- γ (PPAR- γ), PPAR- α , and interleukin-6 (IL-6) during the dry period through 49 DIM in cows fed according to current NRC recommendations. Five multiparous Holstein cows had ad libitum access to a far-off dry period diet (1.29 Mcal NE₁/kg; 15.8% CP) from d -65 through -25 relative to parturition, followed by ad libitum access to a close-up diet (1.61 Mcal NE₁/kg; 15.7% CP) from d -24 until parturition. Cows were fed a common lactation diet (1.77 Mcal NE₁/kg; 18.1% CP) from 1 through 49 DIM. Liver biopsies were collected on d -65, -30, -14, +1, +14, +28, and +49 relative to calving and RNA was extracted with Trizol reagent. Complementary DNA was made from 2 µg of total RNA and primers for RT-PCR were designed to yield amplicons #8804100 bp. Relative copy number in PCR amplifications was measured using SYBRGreen I Dye fluorescence. Bovine 18S rRNA was used as an internal standard for data normalization. Day -65 relative to parturition was used as a baseline to compare relative changes in expression. Relative to d -65, preliminary analysis of data using all cows showed that relative copy number of TNF- α was 1.85-fold greater ($P = .05$) on d +1 relative to calving. Fold changes on d -14 and +14 were 1.11 and 1.57 compared to d -65 ($P > .17$). Relative to d -65, fold changes in relative copy number of PPAR- γ were 1.36, 1.94, or 1.83 on d -14, +1, and +14, respectively ($P > .36$). Results showing increases in relative copy number for these two genes suggest that inflammatory or general stress responses occurred in the liver after parturition.

Key Words: Real Time-PCR, Hepatic Genes, Periparturient Period

927 Effect of estrus and pregnancy status on growth hormone receptor and IGF-I gene expression in the uterus and liver of postpartum dairy cows. M. L. Rhoads*, J. P. Meyer, W. R. Lamberson, D. H. Keisler, and M. C. Lucy, *University of Missouri, Columbia.*

Growth hormone (GH), the GH receptor (GHR) and IGF-I are thought to play critical roles during early pregnancy in dairy cattle. The objective of this study was to measure total GHR (tGHR) and IGF-I mRNA in liver and uterine (endometrial) tissue around the time of artificial insemination at four stages of lactation (1=46 ± 4 d, n=5; 2=80 ± 3 d, n=11; 3=122 ± 3 d, n=10; 4=160 ± 3 d, n=8). Estrus was synchronized with PGF_{2α} and cows were inseminated 12 h after estrus. Uterine biopsies were collected at the PGF_{2α} injection (before estrus, BE), at the initiation of estrus (E) and 4 d after estrus (AE). Liver was biopsied AE. The amount of tGHR and IGF-I mRNA in liver and uterus was analyzed by real-time quantitative PCR. tGHR mRNA and IGF-I mRNA were correlated in liver ($r=0.64$, $P<0.01$) and uterus ($r=0.85$, $P<0.01$) but neither mRNA were affected by stage of lactation. The amount of liver IGF-I mRNA ($r=0.67$, $P<0.01$) but not uterine IGF-I mRNA ($P>0.10$) was positively correlated with plasma IGF-I concentrations. The conception rates for stages 1, 2, 3 and 4 were 80, 55, 50 and 25%, respectively. There was an effect of pregnancy status on liver tGHR mRNA because cows that became pregnant had more tGHR mRNA than non-pregnant cows (41.8 ± 3.2 and 27.4 ± 3.8 AU, respectively; $P<0.01$). There was no effect of pregnancy status or stage on uterine tGHR or IGF-I mRNA. There was an effect of day of the estrous cycle because uterine tGHR mRNA (eight-fold increase over BE; $P<0.05$), uterine IGF-I mRNA (five-fold increase over BE; $P<0.01$) and plasma IGF-I were highest at estrus. In summary, uterine IGF-I gene expression was correlated with tGHR mRNA. Both tGHR and IGF-I mRNA increased in uterine tissue at estrus, a time when blood IGF-I concentrations were also greatest. Cows that became pregnant had similar uterine mRNA but higher liver tGHR mRNA. These data fail to implicate uterine mRNA in the establishment of pregnancy but instead suggest that liver tGHR is greater in early pregnancy.

Key Words: Growth Hormone Receptor, IGF-I, Uterus

928 Assessments of udder temperature gradients pre- and post-milking relative to milk production in Holstein cows as determined by digital infrared thermography. S. Schmidt*, S. Bowers, T. Dickerson, K. Graves, and S. Willard, *Mississippi State University, Mississippi State.*

Digital infrared thermal imaging (DITI) is a non-invasive diagnostic technique that can be used to measure symmetry and/or asymmetry of surface temperature gradients associated with physiological phenomenon. In the present study, thermal images were acquired from lactating Holstein cows ($n = 16$) to assess temperature gradients of the

mammary gland in high (n = 8; 18.5 ± 1.5 kg milk, 182.9 ± 6.75 DIM) and low (n = 8; 14.9 ± 1.3 kg milk, 182.8 ± 6.7 DIM) milk producers (MP). Three thermal images (left-fore, right-fore and rear udder) were acquired for each cow pre- and post-milking at bimonthly intervals over a period of 3 months (6 measurement periods). Rectangular transects were drawn on thermal images to quantify temperature gradients of the udder, and temperatures (°C) were expressed as MAX, AVG, MIN and standard deviation (SD) within transect areas. Udder volume (UV) measurements were collected at the time of imaging pre- and post-milking. No differences (P > 0.10) were observed in UV for high versus low MP throughout the study. Overall, MAX and AVG udder and teat temperatures were greater (P < 0.001) pre-milking than post-milking, as were MIN teat temperatures (P < 0.01). Udder temperatures also differed (P < 0.01) by udder quarter pre- and post-milking, while teat temperatures by quarter did not differ (P > 0.10) pre- or post-milking. High MP had greater (P < 0.01) udder temperatures than low MP (MAX, AVG, MIN) pre- and post-milking (AVG: High Pre, 34.8 ± 0.07 °C; High Post 34.6 ± 0.08 °C; Low Pre: 34.07 ± 0.09 °C, Low Post 33.7 ± 0.09 °C), while teat temperatures did not differ (P > 0.10) relative to level of milk production. Temperature SD within transect areas did not differ (P > 0.10) pre- or post-milking for udder quarter or teat, indicating uniformity of temperature measurements within transects. In summary, high MP had greater udder temperatures pre- and post-milking than low MP. These data suggest that DITI may have value as a diagnostic tool for assessing udder function in relation to temperature gradient changes and level of milk production.

Key Words: Udder, Thermography, Milk Production

929 Heat dissipation in winter-acclimated lactating cows and non-lactating heifers subjected to increased ambient temperature and solar radiation in Arizona. B. C. Pollard*, E. A. Annen, L. H. Baumgard, R. C. Cheatham, M. D. Es-theimer, M. E. Dwyer, A. C. Fitzgerald, H. C. Halfliger, C. E. Moore, J. K. Kay, O. B. Mendivil, P. C. Gentry, D. A. Henderson, C. M. Steining, and R. J. Collier, *The University of Arizona, Tucson.*

Heat dissipation responses of dairy cattle to heat stress are poorly understood. The objective of this study was to compare total evaporative water loss (TEWL) in winter-acclimated lactating cows vs. non-lactating heifers, under three environmental conditions. Six lactating cows (DIM 60-110) and six pregnant, non-lactating heifers (150 d pregnant) were assigned randomly to bST (Posilac®, Monsanto Co., St. Louis, MO) or no bST. Beginning January 21, 2004, animals were housed in two environmental rooms (n=6/room) with temperature, solar radiation, humidity and day length (18 h light:6 h dark) control. The study was divided into two phases of 14 d each. In phase 1, room 1 was held at thermoneutral (TN; temp. range=8.4-17.0°C) while room 2 was programmed to provide heat stress (HS; temp. range=27.8-38.9°C). In phase 2, cows in room 1 were treated to HS plus 4 h of solar radiation (HS+S; 600 Wh/m²) while room 2 remained at TN conditions. After 1 wk, heat dissipation was determined by TEWL from the loin and rump of both left and right sides (Vapometer®, Delfin Technologies, Finland). Overall, TEWL was greater (P < 0.05) in cows vs. heifers in all environmental conditions. Average TEWL was increased in HS and HS+S over TN (P < 0.001), and TEWL was higher in lactating cows compared heifers in HS and HS+S (P < 0.001). These results demonstrate that cows increase their insensible heat dissipation in order to cope with the increased heat load from both milk production and increased environmental heat stress.

Key Words: Heat Stress, Dairy Cattle, Solar Radiation

930 Hepatic gene expression profiling in lactating dairy cows during an initial period of hyperthermia. R. P. Rhoads*¹, J. D. Sampson¹, R. J. Tempelman², S. S. Sipkovsky², P. M. Coussens², M. C. Lucy¹, J. N. Spain¹, and D. E. Spiers¹, ¹University of Missouri, Columbia, ²Michigan State University, East Lansing.

Environmentally-induced hyperthermia in lactating dairy cows depresses milk production as a consequence of whole body adaptations involving

shifts in metabolism and a reduction in feed intake. In this context, the liver is uniquely positioned to direct exogenously and endogenously-derived nutrients for use by other metabolically active tissues such as the mammary gland. Despite the prominent role of the liver in whole-body metabolism, changes in the molecular mechanisms leading to hepatic adaptation during heat challenge are unclear in the dairy cow. Therefore, the objective of this study was to characterize the gene expression profile of hepatic tissue in dairy cows undergoing a transition from thermoneutral (TN) to heat stress (HS) conditions. Six Holstein dairy cows (61 ± 8 d postpartum) were acclimated to TN conditions (19° C) for 1 wk prior to exposure to HS conditions (29° C). Rectal temperature (Tre) and respiration rate (RR) were measured at 4 h intervals during both periods. Total RNA from liver biopsies obtained on d 4 of the TN period (n=6) and then at 24 (n=2), 48 (n=2) and 96 (n=2) h of the HS challenge was reverse transcribed to cDNA. TN and HS paired samples were sequentially labeled with Cy3 or Cy5 prior to hybridization to a bovine-specific NBFGC microarray containing 18,263 unique ESTs. Reversal of the dye direction between paired samples was used to account for possible dye bias. Gene expression data were normalized and analyzed using a two-stage mixed effects model in SAS. The transition from TN to HS increased Tre (39.0° vs 40.3° C, P<0.01) and RR (62 vs 86 breaths per minute, P<0.01). Preliminary analysis indicates that hyperthermia induced the differential expression of at least 20 genes (P<0.001) with a similar number of up and down-regulated genes. In conclusion, the imposed heat stress was sufficient to alter liver gene expression that may be important in the hepatic adaptation to heat challenge.

Key Words: Liver, Microarray, Hyperthermia

931 Exposure to endotoxin during estrus or corpus luteum formation impaired reproductive functions in cows. Y. Lavon¹, G. Leitner², T. Goshen¹, M. Hogeg¹, R. Braw-Tal³, M. Maman¹, S. Jacoby³, and D. Wolfenson*¹, ¹The Hebrew University, Rehovot, Israel, ²The Veterinary Institute, Bet Dagan, Israel, ³Agricultural Research Organization, Bet Dagan, Israel.

Effects of endotoxin (LPS) during estrus (E) or CL formation were studied in lactating Holstein cows. In Exp. 1, synchronized cows were watched continuously for estrous behavior. LPS was given iv (500 ng/kg) or intra-mammary (imm, 10 ug/cow), 16 h prior to expected onset of E (iv, n=4; imm, n=4), and at onset of standing E (iv, n=13; imm, n=8). Time of ovulation (OV) was determined by ultrasound during 4 days (d). LPS typically induced hyperthermia and increased plasma cortisol (ANOVA, P<0.05). Five cows receiving LPS prior to E (iv and imm) responded abnormally: two neither showed E nor ovulated during 4 d; three that showed E 36 h later than normal, then ovulated after a normal interval (within 30 h). Four cows (31%) receiving LPS iv at E onset responded abnormally: one did not ovulate during 4 d, three shortened their E behavior, showed additional E 60 h later, then ovulated within 30 h. 3 cows (38%) receiving LPS imm at E onset responded abnormally: one did not ovulate during 4 d, two showed normal E but a delayed OV. A delayed OV was associated with a delayed progesterone concentration rise (P<0.05). Collectively, 34% of cows responded abnormally after LPS at E (iv or imm, P<0.05). Control cows (n=12) showed normal E and a normal interval to OV. In Exp. 2, cows were given a single imm LPS dose on d 3 (n=5) or d 5 (n=5) of the cycle. The general pattern of follicular dynamics and progesterone concentrations were not affected by LPS treatment. However, the cycle was extended in 5 of 10 cows (50%) treated with LPS on d3 or d5: three did not show E and did not ovulate by 30 d after the previous E; two had extended cycle (27 d). Of the control cows (n=4), only one had an extended cycle (28 d), three had normal length cycles (22.6 d). Results show that exposure to endotoxin around E delays E and/or time to OV in about one-third of cows; a similar proportion of cows exposed to LPS at time of CL formation exhibited an extended cycle length.

932 Estimation of energy value of feed and its use in ration formulation. H. F. Tyrrell*, *Cooperative State Research, Education & Extension Service, USDA, Washington, DC.*

Estimation of the energy value of a ration is fundamental for the determination of the quantity required to meet the energy requirement of the animal. Net Energy is the best estimate of the energy value of a feed/ration, but is difficult, time consuming and costly to determine. In addition, it is virtually impossible to measure the energy value of a single feedstuff fed to a representative animal because few, if any, feedstuffs contain the appropriate balance of nutrients required by the target animal. In practice, estimated net energy value of individual feedstuffs used in ration formulation have been derived from equations relating net energy to some more easily determined characteristic of a feedstuff, typically some measure of digestibility such as Total Digestible Nutrients (TDN). This method is reasonably accurate as long as the TDN value used is appropriate for the target animal. For example, it is well established that the TDN value of a ration fed to a lactating dairy cow at a daily intake required to support lactation is significantly lower than the TDN value of the same ration fed to the same cow at a maintenance level of intake when the cow is not lactating. Level of intake is only one of several factors which can depress the TDN value of a ration fed at production levels of intake. Protein quantity/quality which is adequate to support maximal digestibility in an animal at maintenance may significantly depress TDN value when protein is limiting for lactation. TDN measured using sheep may be appropriate for the estimation of the energy value of feedstuffs for cattle where appropriate equations are available. Variation in digestibility of feed is the main source of variation in energy value of feed.

Key Words: Net Energy, Digestibility, TDN

933 Feed efficiency is driven by dry matter digestibility. D. P. Casper*, L. Whitlock, D. Schauff, D. Jones, D. Spangler, and G. Ayangbile, *Agri-King, Inc., Fulton, IL.*

The improvement in Feed Efficiency (FE; Milk/Dry Matter Intake) by dairy cows can have a dramatic impact on the profitability of the dairy operation. This study was conducted to evaluate the range in FE across several farms and to determine what factors may affect FE. Total mixed rations (TMR) and fecal samples were collected from six dairy farms that were feeding a total mixed ration, along with measurements of milk production, milk composition, and dry matter intake (DMI). The forages fed on these farms consisted of haylage, corn silage, balage, and dry hay. Total mixed rations and fecal samples collected at the same time were analyzed for standard nutrients. Acid insoluble acid was used as an internal marker to calculate nutrient digestibility coefficients. Twenty-three observations were collected over a period of several months. Milk production averaged 30.8 kg/d and ranged from 21.4 to 36.6 kg/d across the study. Milk fat percentage averaged 3.78% and ranged from 3.43 to 4.10%. 3.5% fat-corrected milk averaged 32.0 and ranged from 27.8 to 35.3 kg/d. Dry matter intake averaged 21.2 kg/d and ranged from 16.3 to 25.9 kg/d. Feed efficiency (Milk/DMI) averaged 1.47 and ranged from 1.23 to 1.85. Dry matter digestibility averaged 70.5% and ranged from 57.7 to 84.6%. Regression analysis demonstrated that the dry matter digestibility of the ration fed to lactating dairy cows was the most significant predictor of FE ($FE = 0.032 + 0.02 * DMD$; $R^2 = 0.59$, $P < 0.01$). This study also demonstrated that as FE increased the DMI by the cows decreased ($FE = 2.76 - 0.062 * DMI$, kg/d; $R^2 = 0.72$, $P < 0.01$). The dry matter digestibility of the ration is the major factor affecting the FE by lactating dairy cows. The biggest factor affecting ration dry matter digestibility is forage quality and the digestibility of that forage.

Key Words: Feed Efficiency, Digestibility, Forage Quality

934 Predicting feed passage rate in dairy cattle. S. Seo*, L. Tedeschi¹, C. Schwab², and D. G. Fox¹, ¹*Cornell University, Ithaca, NY*, ²*University of New Hampshire, Durham.*

The database used to develop the passage rate (kp) equations of the 2001 Dairy NRC was used to perform a sensitivity analysis on the variables used to derive the equations and to investigate the sensitivity of MP supply and allowable milk production using a Monte Carlo technique. Three equations were developed by the 2001 Dairy NRC to predict kp

for dry forage, wet forage, and concentrate using a meta-analysis technique (trial as a random effect). The database was comprised of studies that used rare earth markers. Outliers were identified by acceptance criteria defined a priori or the difference in fit statistic (DFFITS) value. We found the sign of the regression coefficient of ConcpDM in the equation for kp dry forage in 2001 Dairy NRC was inverted; it should be positive: $kp \text{ dry forage} = 3.362 + 0.479 \text{ DMIPBW} - 0.017 \text{ NDF} + 0.007 \text{ ConcpDM}$ ($n=319$), where kp is passage rate, %/h; DMIPBW is DMI as % of BW; NDF is NDF content of the forage, %DM; and ConcpDM = Concentrate content as % of dietary DM. The sensitivity analysis indicated that kp predictions were more sensitive to the variation in DMI than to any other variable. Additionally, based on the 90% confidence interval, a variation in a change in MP supply and MP allowable milk of 188 g and 4 kg, respectively. The kp for concentrate had the highest standardized regression coefficient (0.906) compared to kp for dry forage (0.092) and wet forage (0.019) in the prediction of MP allowable milk from supply of MP. The variation in RDP, RUP, and MP supply were mainly caused by the variations in kd, CP, and kp values of concentrates in the simulation. Accuracy was improved when new kp equations were developed using the entire database (1,271 treatment means). The new equations were: $kp \text{ dry forage} = 2.819 + 0.684 \text{ DMIPBW} - 0.015 \text{ NDF} + 0.003 \text{ ConcpDM}$ ($n=399$); $kp \text{ wet forage} = 2.384 + 0.854 \text{ DMIPBW} - 0.012 \text{ ConcpDM}$ ($n=74$); and $kp \text{ concentrate} = 3.374 + 1.123 \text{ DMIPBW} - 0.016 \text{ ConcpDM}$ ($n=264$). We conclude these empirical equations are suitable for predicting passage rate. However, the development of a more mechanistic model that accounts for more of the biologically important variables affecting passage rate is needed.

Key Words: Passage Rate, Sensitivity Analysis, Dairy Cattle

935 Effect of peNDF and starch source on digestibility and ruminal pH and turnover in dairy cows. P. Berzaghi*¹ and D. R. Mertens², ¹*University of Padova, Italy*, ²*ARS-US Dairy Forage Research Center, Madison, WI.*

The effects of ration physically effective NDF (peNDF) and starch source on ruminal characteristics and digestibility were investigated. A negative control (NC) diet was formulated to induce milk fat depression, which contained 19% peNDF using finely chopped (TLC = 6.4 mm) corn silage as the main fiber source. Three diets were formulated to increase peNDF to 22% by adding about 9.5% finely chopped corn silage (CS), 12.2% chopped alfalfa hay (AH), or 6.7% chopped grass hay (GH) to NC. Diets for the four fiber sources were formulated with dry ground corn (DGC) or finely ground high moisture corn (HMC) to obtain eight diets that varied in starch source and peNDF source and concentration. Twenty-four cows were blocked for milk production and half were assigned to either DGC or HMC diets in replicated 4x4 Latin squares with 21d periods. One Latin square for starch source contained ruminally fistulated cows. In the cannulated cows ruminal pH was measured for one day every three hours and rumen contents were manually evacuated before and after feeding and separated into solids and liquids. Fecal samples were obtained during the last week of each period. Indigestible NDF of feeds, ruminal contents and feces was determined by 240-h in situ incubation in all cows in the period following their collections. Mixed-model ANOVA indicated that NC and CS had lower ($P < 0.05$) ruminal pH at 3-h post feeding, but similar average (24 h) ruminal pH across diets. Rumen pool of DM and indigestible NDF (INDF) was not affected ($P > 0.05$) by diet and starch source. However, turnover rate of INDF was increased ($P < 0.05$) by the addition of AH and GH to the NC diet. Apparent DM digestibility (DMD) was not affected by starch source, but was highest for NC diet and lowest ($P < 0.01$) in AH and GH. A positive relationship ($r^2 = 0.54$; $P < 0.01$) between retention time and DMD partially explained the differences in digestibility. In conclusion, dietary peNDF altered ruminal pH and affected DMD possibly by changes in retention time and associative effects

Key Words: Physically Effective Fiber, Digestibility, Ruminal pH

936 In situ estimation of dry matter digestibility and degradable intake protein to evaluate the effects of corn processing method and length of ensiling. J. R. Benton*, T. J. Klopfenstein, and G. E. Erickson, *University of Nebraska, Lincoln.*

Three ruminally cannulated steers were used to evaluate the effects of corn processing method and length of ensiling on dry matter digestibility (ISDMD) and degradable intake protein (DIP). Corn processing consisted of dry-rolled (DRC), high-moisture at 24% (24HMC) or 30% (30HMC) moisture, and reconstituted corn at 28% (28RECON) or 35% (35RECON) moisture, all of the same hybrid. All corn (except DRC) was ensiled for at least 298 d, and sampled every 28 d. Corn samples were incubated in situ for 0, 22, 30, and 72 h and ISDMD (%) and DIP (% of CP) were calculated. Values (22 h) were regressed over ensiling days. The intercept represents changes in ISDMD or DIP during the first 28 d of ensiling where the greatest changes occurred, with the greatest increase for 35RECON followed by 30HMC and then 28RECON. The slope represents changes in ISDMD or DIP over time of ensiling after 28 d. The slopes of reconstituted corn (RECON) were greater than high-moisture corn (HMC) because RECON had a greater increase in total ISDMD and DIP compared to HMC. The slope of 24HMC was not different from 30HMC for ISDMD, while the slope of 24HMC was greater than 30HMC for DIP. The slope of 28RECON was greater than 35RECON for ISDMD and DIP. When moisture was increased for HMC (from 24 to 30%) and RECON (from 28 to 35%), total ISDMD and DIP increased, and both HMC and RECON had increased total ISDMD and DIP compared to DRC. Results suggest that as moisture and length of fermentation increase, ISDMD and DIP are increased.

Corn	ISDMD		Slope ^{ab}	DIP		Slope ^{ab}
	day 0	(%) Intercept ^a		day 0	(% of CP) Intercept ^a

937 Effects of nonfiber carbohydrate source and protein degradability on ruminal protein fractions and NDF disappearance. M. B. Hall* and C. C. Larson, *Department of Animal Sciences, University of Florida, Gainesville.*

Effects of nonfiber carbohydrate source (NFC) and protein degradability (RUP) on concentrations (mM) of ammonia (NH₃), amino acid (AA), and branch chain VFA (BCVFA) in ruminal fluid, and on in situ disappearance of NDF from sorghum silage were evaluated using 6 ruminally cannulated Holstein cows in a three period (21 d) partially balanced incomplete latin square design with a 3x2 factorial arrangement of treatments. Dietary treatments included three NFC sources (ground corn=starch=ST; molasses+sucrose=sugar=SU; and citrus pulp=soluble fiber+sugar=SF) and two concentrations of ruminally degradable protein (+or-RUP) achieved by addition or omission of expeller soybean meal. Total mixed rations were formulated to be isonitrogenous and offered ad libitum. Sorghum silage (2 mm Wiley mill grind) was incubated in situ in polyester bags (53 ± 10 μm pore size) inserted via the rumen cannula on days 16, 17, and 18 at intervals to allow incubation times of 0, 6, 12, 18, 24, 30, and 48 h; residual NDF was measured. Ruminal fluid samples were collected on day 20 just prior to feeding and hourly for 12 h. Protocols were applied in each period. Significance was declared at P#88040.05; values presented are least squares means. NH₃ differed only for RUP x hr in hours 1 through 3 post-feeding, with -RUP greater than +RUP. AA differed by NFC in hr 1 through 3, with ST less than SU + SF, and for interactions of NFC x hr and RUP x hr for all hours. BCVFA differed by NFC source with ST greater than SU+SF, and SF tended to be greater than SU (P=0.07). BCVFA tended to differ by RUP x hr (P=0.10). In situ disappearance of NDF differed for NFC and NFC x RUP in hours 6, 18, 24, and 30, and tended to differ for NFC x RUP at 48 h (P=0.054). Differences did not appear to be solely due to ruminal pH. Differences in ruminal AA and BCVFA suggest that ruminal protein digestion or use differs by

NFC source. Differences in in situ disappearance of NDF suggest that in situ results are not likely to be uniform across diets and may be best suited for relative evaluation of NDF digestibility.

Item	ST-RUP	ST+RUP	SF-RUP	SF+RUP	SU-RUP	SU+RUP
NH ₃	12.3	10.8	12.1	9.6	11.8	10.1
AA	1.64	1.46	1.86	1.73	1.94	1.76
BCVFA	3.79	3.48	3.31	2.87	2.45	2.26
pH	5.99	5.98	6.11	6.03	5.83	6.07

938 Effect of starch source on supply of glycogenic nutrients in dairy cows. A. M. van Vuuren*, V. A. Hindle, and J. W. Cone, *Animal Sciences Group, Wageningen UR, The Netherlands.*

In ruminants, propionic acid and glucose are the main glycogenic precursors. Thus, the supply of glycogenic precursors from starch is related to its site of digestion. In this study the site of digestion of starch from wheat, corn, and potato was estimated in dairy cows. A Latin square design experiment was performed involving four lactating dairy cows each fitted with a rumen cannula and T-piece cannula in the distal duodenum and terminal ileum. Each cow received either a starch-free diet, containing 43 %DM grass silage, 11 %DM ensiled sugar beet pulp and 46 %DM of a starch free concentrate mixture with 70 % dried sugar beet pulp (DSBP) or diets in which DSBP had been replaced by either wheat (WS), corn (CS) or potato (PS) starch. Diets were fed during periods of four weeks, faecal and digesta collections were performed in the third and fourth week of each period, respectively. The glycogenic nutrient supply for each diet was estimated on the basis of the amounts of OM digested in rumen and large intestine, patterns of VFA concentrations in the rumen and the amount of starch digested in the small intestine. Significance was declared at P<0.05. Starch intake was 0.31^c, 3.47^b, 3.90^a, and 3.69^{ab} kg/day for control diet, and diets with WS, CS and PS, respectively. The rumen was the main site of digestion for starches from all origins and was estimated at 90^a, 75^b, and 84^a % of intake of WS, CS and PS, respectively. In the small intestine, 70% of rumen escaped WS was digested compared to 65% for CS, but this difference was not significant. We observed no disappearance of PS in the small intestine. Almost all starch entering the large intestine was digested, resulting in a faecal starch output of less than 0.10 kg/d. Concentrations of ruminal VFA were similar amongst treatments. The proportion of propionate in rumen fluid differed significantly between the WS diet (21 mol%) and the PS diet (18 mol%). The highest supply of glycogenic nutrients was calculated for the CS diet (0.8 moles per kg ingested OM). According to our calculations, the PS diet yielded the lowest supply of glycogenic nutrients (0.6 mol per kg ingested OM).

939 Microbial profiling of ruminal and omasal samples from cows fed different sources of methionine. S. K. R. Karnati*, J. T. Sylvester, Z. Yu, S. M. Noftsker, N. R. St-Pierre, M. Morrison, and J. L. Firkins, *The Ohio State University, Columbus.*

Supplemental methionine improves milk protein yield with diets low in CP either through stimulation of microbial CP synthesis or through escape of methionine. Previous work suggested that HMB (2-hydroxy-4-methylthiobutanoic acid) might promote changes in ruminal bacterial or protozoal populations. DGGE (denaturing gradient gel electrophoresis) and RIS-LP (ribosomal intergenic spacer length polymorphism) were used to monitor treatment-induced changes in microbial populations in the rumen and omasum of cattle fed control, HMB, dl-methionine, or HMBi (isopropyl ester HMB; estimated 50% rumen protection) in a 4 x 4 Latin square design. For DGGE, a hypervariable region of the 18S rRNA gene was amplified from the extracted DNA using PCR with a ciliate-specific primer set. Amplicons were separated on an 8% acrylamide gel with a 28-36% denaturing gradient. The banding patterns

were similar for both ruminal and omasal samples and were not different among treatments. Protozoal counts were not different among treatments ($P > 0.05$) in ruminal or omasal samples. Generic protozoal counts were not different ($P > 0.05$) among treatments, corresponding with similar banding profiles from DGGE. Multivariate statistics showed no difference ($P > 0.05$) in generic distribution of protozoa in ruminal vs. omasal samples, supporting absence of selective retention of Isotrichs in the rumen. Extracted DNA from omasal contents was amplified in PCR using S926f and L189r primers for RIS-LP analysis. Amplicons containing the complete RIS and parts of the flanking rRNA genes were separated on a 4% polyacrylamide gel. The RIS-LP gel image was exported into image analysis software. Cluster analysis of banding profiles grouped the treatments together, suggesting that bacterial populations differed among treatments. Source of methionine appeared to change ruminal bacterial but not protozoal populations. Future research will characterize bacterial populations altered by HMB supplementation.

Key Words: DGGE of Ruminal Protozoa, RIS Analysis, HMB

940 Effects of different components of garlic oil on rumen microbial fermentation in a continuous culture system. Marta Busquet¹, Sergio Calsamiglia^{*1}, Alfred Ferret¹, and Christopher Kamel², ¹Universitat Autònoma de Barcelona, Spain, ²University of Leeds, UK.

Preliminary in vitro batch culture trials using garlic oil (G) and 4 of its constituents (diallyl sulphide = Ds; diallyl disulphide = Dd; allyl mercaptan = Am; and allicin = A) indicated that only the doses of 30 and 300 mg/L of G, Dd, and Am modified rumen microbial fermentation profile. Eight 1.3-L dual flow continuous culture fermenters were used in three periods (8 d) to study the effects of these extracts on rumen microbial fermentation profile in a long-term in vitro study. Fermenters were fed 95 g/d of the 50 to 50 forage to concentrate diet. Treatments were: no extract or negative control (C), G (300 mg/L = G10) Dd (30mg/L = Dd, 300mg/L = Dd10) and Am (30mg/L = Am; 300mg/L = Am10). Fermenters were maintained at constant temperature (39°C), pH (6.4) and solid (5%/h) and liquid (10%/h) dilution rates. Each day, a sample was taken 2 h after the morning feeding for the determination of ammonia (NH₃ N) and volatile fatty acids (VFA). During the last 3 days, samples were taken at 0, 2, 4 and 6 h after the morning feeding, and analyzed for peptide (Pep), aminoacid (AA) and NH₃ N concentrations. Total VFA were similar across treatments (122.2 mM). Acetate proportion (mol/100mol) was lower in G10 (48.0), Dd (53.5), Dd10 (49.2), and Am10 (51.0) compared with C (60.7). Propionate proportion (mol/100mol) was higher in G10 (30.5) compared with C (21.8). Butyrate proportion (mol/100mol) was higher in Dd10 (20.3) compared with C (12.4). Average Pep-N concentration (mg/100ml) was similar in all treatments. Average AA-N concentration (mg/100ml) tended to increase ($P = 0.07$) in Dd10 (4.6) compared with C (2.9), and the average NH₃ N concentration (mg/100ml) tended to increase ($P = 0.08$) in Am10 (15.4) compared with C (10.5), suggesting that Am10 stimulated deamination. All garlic oil components resulted in similar effects to those observed in G10. However, G10 had stronger effects (and similar to ionophore antibiotics) which could be explained by a synergistic activity between its constituents.

941 Effects of *Lactobacillus acidophilus* and *Propionibacterium freudenreichii* on performance and rumen characteristics of Holstein dairy cows in mid-lactation. M. L. Raeth-Knight* and J. G. Linn, University of Minnesota, St. Paul.

A lactation study (Study 1) was conducted from February 12, 2003 to May 6, 2003. Thirty-nine multiparous and eighteen primiparous Holstein cows were blocked by parity and randomly assigned to one of three

dietary treatments; remaining on treatment for 84 days. Treatments included: 1 x 10⁹ cfu/day live *Lactobacillus acidophilus* strain LA747 and 2 x 10⁹ cfu/day live *Propionibacterium freudenreichii* strain PF24 (Diet A), 1 x 10⁹ cfu/day live *Lactobacillus acidophilus* strain LA747, 2 x 10⁹ cfu/day live *Propionibacterium freudenreichii* strain PF24, and 5 x 10⁸ cfu/day *Lactobacillus acidophilus* strain LA45 (Diet B) and lactose (Control- Diet C). Treatments were administered by mixing 45 grams of finely ground corn with 5 grams of live microbial product or lactose and top dressing on the TMR once daily. All cows received the same TMR: 12.7% hay, 46.2% corn silage and 41.1% concentrate (DM basis). A Latin square study (Study 2) was conducted concurrently with the lactation study. Three rumen cannulated, multiparous Holstein cows were randomly assigned to dietary treatments A, B, and C in a 3 x 3 Latin square design with 28 day periods; 21 days of adaptation and 7 days of data collection. In Study 1, there was no difference ($P > .1$) in average DM intake (23.90, 23.60 and 24.19 kg/d) or 4% FCM (36.68, 35.18 and 36.12 kg/d) for treatments A, B, and C, respectively. There was no difference ($P > .1$) in fat, protein or lactose yield, milk urea nitrogen or somatic cell count. Feed efficiency was 1.53, 1.49 and 1.49 kg FCM per kg of DM intake for treatment A, B, and C, respectively. For study 2, there was no difference ($P > .1$) in rumen pH, concentration of ammonia or total volatile fatty acids (VFA) measured at 0, 1, 3 and 6 hours post feeding. For treatments A, B, and C, average rumen pH was 6.20, 6.15 and 6.15 while the average low, 3 hours post feeding, was 6.01, 5.98 and 5.96. Across treatments, average ammonia concentration was 8.76, 19.69, 12.53, and 8.37 mg/dl of rumen fluid at 0, 1, 3 and 6 hours post-feeding.

942 Effect of calcium source on ruminal soluble calcium and microbial fermentation. E. J. Baird^{*1}, V. Fellner¹, S. J. McLeod¹, J. W. Spears¹, and F. R. Valdez², ¹Department of Animal Science, North Carolina State University, Raleigh, ²Kemin Americas, Des Moines, IA.

A study was conducted to determine the effect of Ca level and source on ruminal soluble Ca concentration and microbial fermentation in continuous culture fermentors. Treatments consisted of control diet (0.18% Ca) or the control supplemented with 0.60% Ca from either: 1) CaCO₃, 2) Ca propionate-prilled (CaP, NutroCAL#8482) or 3) CaP-powder. Fermentors were fed 14 g DM/d of a diet (DM basis) consisting of 35% corn silage, 18% soybean meal, 15% corn, 22% cottonseed hulls, and 10% whole cottonseed. Following a 2-d stabilization period, fermentors were sampled over a 4-d collection period. Each treatment was replicated five times. Calcium supplementation of the control diet increased ($P < 0.01$) ruminal soluble Ca concentrations. Ruminal soluble Ca concentrations were higher ($P < 0.01$) in cultures receiving CaP treatments compared to CaCO₃. Ruminal pH was higher in Ca-supplemented diets compared to control ($P < 0.01$), and CaCO₃ was higher ($P < 0.05$) than CaP treatments. Digestibility of NDF was higher in CaP-prilled compared to control ($P < 0.06$), CaCO₃ ($P < 0.09$), and CaP-powder ($P < 0.05$) treatments. Total VFA production in ruminal cultures was increased ($P < 0.05$) by supplemental Ca. In response to Ca source, total VFA production was higher for CaP-prilled than CaCO₃ ($P < 0.01$) and CaP-powder ($P < 0.08$) treatments. Propionate production and molar proportion were higher ($P < 0.01$) in CaP than control or CaCO₃ treatments. Butyrate production was higher ($P < 0.01$) for CaP-prilled and CaCO₃ treatments compared to control and CaP-powder treatments. Molar proportion of butyrate was higher ($P < 0.01$) for CaCO₃ than the other treatments. Production and molar proportion of isovalerate was lower ($P < 0.01$) for CaP-powder compared to other treatments. These results indicate that both dietary Ca level and source affect soluble Ca concentrations and fermentation in continuous cultures of ruminal microorganisms.

943 Impact of feeding high free fatty acid whole cottonseed on milk yield and composition. J. K. Bernard^{*1}, J. Siciliano-Jones², and T. C. Wedegaertner³, ¹The University of Georgia, Athens, ²FARME Institute, ³Cotton Incorporated.

Whole cottonseed (WCS) is used as a source of energy, protein, and fiber by many dairy producers. The concentration of free fatty acids in the oil

(FFA) may be elevated after tropical storms delay harvest resulting in concentrations exceeding 12% of the oil. These seed are considered to be off quality. Limited data are available on the feeding value of off-quality WCS. Approximately 300 lactating Holstein cows were used in a 3 x 3 Latin square trial to determine the impact of feeding whole cottonseed

with different concentrations of free fatty acids in the oil. Cows were assigned to each pen by parity, DIM, and milk yield. Treatments included WCS with low (10.7% FFA, L), high (35.5% FFA, H) or a 50:50 blend of H and L (23.1 % FFA, M). During each 3-wk experimental period, pen intake was recorded daily, milk weights were recorded at each milking (3X) and milk samples were collected from each milking once weekly for analysis of milk fat, protein, and milk urea nitrogen (MUN). Dry matter intake and milk yield was similar for all treatments: 27.5 and 40.1; 27.4 and 40.2; and 27.7 kg/d and 39.9 kg/d for L, M, and H respectively. Milk fat concentration ($P < 0.001$) and yield ($P < 0.002$) were lower for cows fed H compared with L and M: 3.02 and 1.21; 3.13 and 1.26; and 2.87 % and 1.14 kg/d for L, M, and H, respectively. No differences were observed in concentration or yield of milk protein among treatments (average of 2.97% and 1.18 kg/d). Yield of energy corrected milk (ECM) was lowest ($P < 0.003$) for H reflecting the lower yield of milk fat (37.0, 37.6, and 36.0 kg/d for L, M, and H, respectively). Concentrations of MUN were lowest for L and highest for H ($P < 0.003$): 12.97, 13.12, and 13.42 mg/dl for L, M, and H respectively. The reduced milk fat and increased MUN suggest changes in ruminal fermentation, but the changes were not great enough to alter intake, milk yield, or milk protein synthesis.

Key Words: Whole Cottonseed, Milk Yield, Milk Composition

944 Utilisation of whole-crop pea silage in dairy cow rations as a potential protein source to replace soya bean meal. K. J. Hart*, R. G. Wilkinson, L. A. Sinclair, and J. A. Huntington, *Harper Adams University College, Newport, Shropshire, UK.*

The use of protein concentrates in ruminant diets is both essential and costly. With the consumer demand in the UK for high quality, low cost products, there is a need for a cheap and efficient protein source for inclusion into ruminant rations. Whole-crop pea (WCP) silage has the potential to fulfil this role, being a cheap and easy to grow crop, which can also be used in organic systems. In addition, the presence of condensed tannin in coloured flowered varieties of peas may confer protection of protein in the rumen. The aim of this experiment was to evaluate WCP silage as a replacement for soya bean meal. WCP silage was produced from a spring-sown crop (cv.Racer) which was cut after 13 weeks, wilted and ensiled with a bacterial inoculant. The three diets were ad lib grass silage (GS) and fermented whole-crop wheat (WCW, 50:50) with 8kg of soya based concentrate (GWS), or ad lib GS; WCW and WCP (25:25:50) with either 8kg/day soya based concentrate (PS) or 8kg wheat based concentrate (soya replaced with wheat, PW). Diets were offered to 9 pregnant Holstein-Friesian in late lactation in a latin rectangle design, with each period lasting 28 days. Intakes and performance traits were recorded over the last 7 days of each period. Silage dry matter intakes increased in cows fed diets containing WCP silage (12.0 vs 13.4 vs 13.0, s.e.d. 0.53 $P < 0.05$, GWS, PS and PW respectively) whilst concentrate dry matter intakes were similar across all treatments ($P > 0.05$). Milk yield did not vary significantly across the treatments (23.1 vs 23.8 vs 22.0, s.e.d. 0.86, $P > 0.05$, GWS, PS and PW respectively), although there was a significant increase of 0.08 kg/day in milk protein yield in cows fed PS (0.77 vs 0.85 vs 0.77, s.e.d. 0.032, $P < 0.05$, GWS, PS and PW respectively). Cows fed the control diet of GWS had higher nitrogen efficiency for milk production when compared to the diets containing WCP silage (27% vs 24% vs 24%, s.e.d. 0.01, $P = 0.01$). Results from this experiment suggest that 1kg DM of WCP silage can replace a daily portion of 1kg DM of soya bean meal. With WCP silage costing around 63/T DM, a considerable saving could be achieved

Key Words: Pea Silage, Dairy Nutrition

945 Replacement of blood meal with a supplement containing bacterial and fungal fermentation extracts in diets fed to mid-lactation dairy cows. C. S. Ballard*¹, P. Mandebvu¹, M. P. Carter¹, K. W. Cotanch¹, R. J. Grant¹, C. J. Sniffen², W. Rodee³, and L. Robinson³, ¹*W.H. Miner Agricultural Research Institute, Chazy, NY*, ²*Fencrest LLC Holderness, NH*, ³*Agriformulations, Inc., Waddington, NY*.

Lactational response to a commercial feed supplement containing bacteria and fungal fermentation extracts (Protein Edge[®]) in place of animal protein was measured using 40 primi- and multiparous midlactation (78 to 231 days in milk) Holstein cows in a crossover design study with two 28-d periods. Cows were blocked by parity and milk production and

assigned randomly to a control total mixed ration (TMR) containing blood meal (210 g/cow/day) and corn distillers grain (48 g/cow/day), or a TMR containing Protein Edge[®] (PE; 28 g/cow/day), soybean hulls (45 g/cow/day) and corn gluten meal (81 g/cow/day). In addition, the control TMR contained more Soy Pass compared with the PE TMR (810 vs. 163 g/cow/day). Diets were formulated such that the amounts of lysine and methionine in metabolizable protein in both TMR were close to the recommended levels of 7.2 and 2.2%, respectively, while maintaining a lysine to methionine ratio of approximately 3 to 1 (expressed as % of MP). The TMR contained 49% forages and 51% concentrates with 19% CP and 28% NDF. Milk production and composition from all cows was recorded during the fourth week of each period. Cows fed the control TMR containing blood meal and cows fed the TMR containing PE, respectively, produced 34.2 and 34.2 kg/d milk with 4.00 and 4.01% fat, 3.24 and 3.28% true protein, 4.72 and 4.69% lactose, 12.6 and 12.6 mg/dl milk urea N, and 281,000 and 223,000 somatic cell counts/ml, and 0.10 and 0.10 change in BCS per period ($P > 0.07$). In conclusion, when blood meal was replaced with PE and rations were reformulated to meet lysine and methionine, there were no differences in milk yield and milk composition by Holstein cows, showing that the PE product performed as well as blood meal when fed to supply similar concentrations of methionine and lysine posturally.

Key Words: Methionine and Lysine, Blood Meal, Dairy Cow

946 Replacement of alfalfa haylage with ensiled wet distillers grains and beet pulp in lactating dairy cows diets. A. D. Garcia*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings.*

Wet corn distillers grains (WDG) and wet beet pulp (WBP) are excellent feeds for ruminants. Energy in WDG is supplied by its high lipid and fermentable fiber content, whereas in WBP it results from highly fermentable carbohydrates. The objective of this research was to evaluate the effect on milk production of substituting alfalfa haylage with either one of two WDG/WBP blends. Nine cows (six Holstein and three Brown Swiss) with 92 ± 4 DIM were used in a 3×3 Latin square with 3-wk feeding periods. Experimental diets were: 1) control diet (C) which contained 17.2% DM alfalfa haylage; 2) treatment 1 (T1), where 21.7% DM of a 33% WDG and 66% WBP blend substituted for alfalfa haylage; and 3) treatment 2 (T2), where 24.5% DM of a 66% WDG and 33% WBP blend substituted for alfalfa haylage. All other feeds were maintained constant across treatments with the exception of dry DG, which was added at 10.2, 5.7, and 0% of the diet DM in C, T1, and T2, respectively, to balance for dietary CP. Diets were balanced for 16% CP, 20% ADF, 30% NDF, and 1.60 Mcal NEL/kg. Dry matter intake did not differ between treatments ($P > 0.10$). Feed efficiency tended to increase ($P < 0.07$) in cows fed T1 when compared to C. Cows fed T1 and T2 produced more milk (38.0 and 39.2 vs 35.7 kg/d; $P < 0.06$) when compared to C. Although cows fed C tended to have higher milk protein percentage ($P < 0.07$), milk protein yields were higher (1.2 and 1.3 vs. 1.1 kg/d; $P < 0.05$) for cows fed T1 and T2. Milk fat percentage decreased for cows fed T1 and T2 compared to C (3.1 vs. 3.6%; $P < 0.01$), however milk fat yield did not differ across treatments ($P > 0.10$). Results from this experiment suggest that blends of WDG and WBP can substitute for alfalfa haylage in dairy cow diets while improving total milk production and milk protein yield.

Key Words: Wet Beet Pulp, Wet Distillers Grains, Dairy Cows

947 Increasing wet distillers grains in the diets of dairy cows on milk production and nutrient utilization. K. F. Kalscheur*, A. L. Justin, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings.*

The objective of this experiment was to determine lactation performance and nutrient utilization in dairy cows fed increasing concentrations of wet corn distillers grains (WDG). Four ruminally cannulated multiparous Holstein cows averaging 117 DIM were used in a 4×4 Latin square design with 4-wk periods. Wet distillers grains were included at 10, 20, 30, or 40% of the diet DM. The forage portion of the diets was constant and consisted of 30% corn silage and 15% bromegrass hay (DM basis). Soybean meal, soybean hulls, and animal fat were replaced by WDG as inclusion rates increased. Diets (DM basis) averaged 17.8% CP, 41.7% NDF, 22% ADF, 6.5% EE, and 1.65 Mcal/kg. Diet DM decreased (49.5, 45.8, 41.9, and 40.4% for 10, 20, 30, and 40% WDG, respectively) as diet WDG increased. Dry matter intakes decreased (P

< 0.02) as diet WDG increased in the diets (25.7, 24.6, 22.0, and 18.4 kg/d). Milk production decreased (40.1, 36.7, 34.9, and 34.8 kg/d; $P < 0.01$) as WDG increased from 10 to 40% of the diet. Milk fat percentage (2.64, 2.96, 2.93, and 2.64%; $P < 0.03$) and milk protein percentage (3.21, 3.24, 3.15, and 3.34%; $P < 0.06$) responded quadratically as WDG increased. Milk component yield and MUN did not differ across diets. Total tract digestibilities of DM, OM, ADF, and NDF did not differ ($P > 0.10$) with increasing levels of WDG. Total tract digestibility of CP increased (59.5, 64.7, 67.7, and 67.3%; $P < 0.03$) with increased WDG in the diet. Nitrogen intake (691, 708, 645, 534 g/d) tended to decrease ($P < 0.09$) due to the decrease in DMI. As a result, the response of N efficiency to the addition of WDG in the diets tended to be quadratic (28.0, 25.0, 26.9, 34.2%; $P = 0.10$). As WDG increased in the diets, calculated fecal N decreased ($P < 0.01$), but urinary N was not different. Nutrient digestibilities of the diets with the exception of CP were unchanged across diets. Milk production decreased when WDG was added to the diet above 10% of the dry matter.

Key Words: Wet Distillers Grains, Nutrient Digestibility, Nitrogen Utilization

948 Dietary factors influencing milk protein content of cows fed grass silage-based diets. P. Huhtanen^{*1} and J. Nousiainen², ¹MTT Agrifood Research Finland, ²Valio Ltd, Valio, Finland.

Protein is the most valuable component of milk, and therefore there is an economical incentive to enhance milk protein content (MPC). A mixed model regression analysis was conducted to investigate the relationship between diet parameters and MPC(g/kg). Data consisted of 335 treatment means from 46 studies. Diets were based primarily on grass silage and concentrate supplements containing cereal grains and oilseed meals. Because part of CP is NPN, MPC values were corrected for urea (MPCc). Dietary parameters (g/kg DM) were CP, ether extract (EE), starch, non-structural CHO, lactic acid (LA), NDF, metabolizable protein (MP), protein balance in the rumen (PBV) and ME (MJ/kg DM). Single parameters poorly described the variation in MPC. MP was the best single predictor of MPC ($R^2=0.40$), and EE of MPCc ($R^2=0.23$). Increases in EE and LA had a negative effect on MPC and MPCc. The best equations based only nutrient concentrations were: $MPC=23.9-0.045EE-0.007LA+0.117MP-0.005PBV$ ($R^2=0.63$; $SE=0.44$) and $MPCc=24.2-0.042EE-0.007LA+0.105MP-0.017PBV$ ($R^2=0.61$; $SE=0.45$). Single intake parameters (total DMI, ME and MP intake) explained 62-69 and 56-68% of the variation in MPC and MPCc, respectively. Bivariate models including CP or PBV, in addition to one intake parameter, suggested that a large proportion of increased MPC in response to higher dietary CP concentration was due to increased milk urea. Carbohydrate composition of the diet had few significant effects on MPC, when variation in ME of MP intake was excluded. The best predictive models included: $MPC=24.0+0.018MEI-0.051EE-0.007LA+0.075MP$ ($R^2=0.76$; $SE=0.39$), and $MPCc=26.0+0.022MEI-0.058EE-0.008LA+0.039MP$ ($R^2=0.74$; $SE=0.40$), respectively. Lower MPC with increased EE resulted primarily from dilution. The effect of LA is related to the lower energy supply of silage fermentation acids than carbohydrates for rumen microbes. It is concluded that milk protein content was largely related to energy and MP intake. At a constant ME intake, MPC can be increased by avoiding excessive amounts of fat, restricting in-silo fermentation and increasing MP content.

Key Words: Grass Silage, Milk Protein

949 Effects of NDF from alfalfa hay, grass hay, straw, and whole cottonseed on performance of lactating cows. P. B. Bucci^{*}, M. L. Eastridge, and C. V. D. M. Ribeiro, *The Ohio State University, Columbus.*

Straw is used in some rations in the field for lactating dairy cows as a source of effective fiber; however, limited data are available on using straw versus legume or grass hay on an equivalent forage NDF basis. Four ruminally cannulated multiparous Holstein cows (276 DIM) were used in a 4 x 4 Latin square design, with the following diets fed ad libitum: 1) 17% forage NDF (FNDF) from corn silage (CS) and alfalfa hay (11.7% of DM), 2) 17% FNDF from CS and grass hay (7.0% of DM),

3) 17% FNDF from CS and wheat straw (5.2% of DM), and 4) 12.8% FNDF from CS with 10% whole, linted cottonseed (WCS) in the diet. Corn silage was held constant at 35.7% of the diet. Periods were 21 d, with the last 10 d used for animal performance data. Cows were milked twice daily, and four consecutive milkings per week were sampled for analyses of milk components. Rumen samples for VFA and pH were taken at 6 h post-feeding on d 19 and 20 of each period. The DM intake was similar among treatments (24.7 kg/d), but milk yield was lower for straw than grass and WCS (22.7, 23.5, 21.6, and 24.0 kg/d for alfalfa hay, grass hay, straw, and WCS, respectively). Yields of fat and protein and concentrations of fat (4.28%), protein (3.54%), and urea nitrogen (14.46 mg/dl) in milk did not differ among treatments. Rumen pH was similar among treatments at 6.25. Ruminal proportion of acetate was lower and propionate higher for WCS. The three sources of forage NDF appeared to result in similar ruminal conditions. Data are not available yet to explain the lower milk yield with the straw. Although WCS lowered the acetate:propionate ratio, ruminal pH remained adequate and milk fat percentage was not depressed.

Key Words: Forage NDF, Whole Cottonseed, Straw

950 Rumen fill and intake regulation of grazing dairy cows under continuous stocking. H. Z. H. Taweel^{*}, B. M. Tas, J. Dijkstra, and S. Tamminga, *Department of Animal Sciences, Animal Nutrition Group, Wageningen University, Wageningen, The Netherlands.*

This experiment aimed at studying the possible role of rumen fill in signalling the termination of the three main grazing bouts of dairy cows. For this purpose the day was divided into three main periods (6:00-12:00 h, 12:00-18:00 h and 18:00-24:00 h) where the three main grazing bouts (dawn, afternoon and dusk) of dairy cows usually occur. Four rumen-cannulated dairy cows were used in a repeated measures design, with time of day as the within subjects factor. The cows had access to a 1-ha grass sward under a continuous stocking system. To estimate rumen pool sizes, dry matter intake (DMI), eating time (ET), bite rate (BR), bite mass (BM) and intake rate at the three bouts, cows were rumen-evacuated at 6:00, 12:00, 18:00 and 24:00 h and jaw recorders were fitted to the cows between these time points. To estimate clearance rate (Kcl) cows were deprived of food from 24:00 till 8:00 h next morning, when rumen evacuations were performed again. Rumen pool sizes were larger ($P < 0.01$) at 24:00 h compared to other times of the day (9.5 vs 13.5 kg DM). Because rumen evacuations in the present study were performed at fixed time points during the day and not immediately when grazing ceased, it was important to estimate the fluctuation in rumen fill between the measured points if we want to draw valid conclusions concerning its role in regulating the cessation of grazing. To estimate rumen fill fluctuation during the day, a dynamic model was constructed based on the measured ET, BR, BM, and Kcl. The model consisted of one state variable, which was the rumen NDF pool (QNDF). QNDF receives input from feed intake and its output is disappearance from the rumen through Kcl. Despite the fact that cows grazed 132 min and 175 min during the morning and afternoon grazing bouts, respectively, QNDF did not reach the value it reached at 24:00 h. This indicates that dairy cows interrupted these two grazing bouts long before reaching their maximal rumen fill capacity. However, rumen pool sizes were always maximal at the time when the dusk grazing bout ceased indicating that rumen fill is more likely to play a major role in signaling the termination of the dusk grazing bout.

Key Words: Rumen Fill, Intake, Grazing

951 Corn grain endosperm type and brown midrib 3 corn silage: site of nutrient digestion and ruminal digestion kinetics in lactating dairy cows. C. C. Taylor^{*} and M. S. Allen, *Michigan State University, East Lansing.*

Effects of corn grain endosperm type and the brown midrib 3 mutation in corn silage on site of nutrient digestion and ruminal digestion kinetics in cows were evaluated. Eight ruminally and duodenally cannulated Holstein cows (72 ± 8 DIM; mean \pm SD) were used in a duplicated 4x4 Latin square design with a 2x2 factorial arrangement of treatments. Grain treatments were dry corn grain from hybrids with floury

or vitreous endosperm; silage treatments were corn silage from a hybrid with the *bm3* mutation or its isogenic control hybrid without the *bm3* mutation. Diets contained 26% neutral detergent fiber and 17% crude protein. Treatment corn grain and silage supplied 23% and 38% of the diet DM, respectively. Interactions of main treatment effects did not occur for any measures of nutrient digestibility. Floury endosperm grain increased total tract OM digestibility versus vitreous grain (75.2 vs. 71.9%; $P < 0.01$) primarily by increasing starch digestibility. Floury grain increased apparent ruminal starch digestibility (57.0 vs. 35.0%; $P < 0.01$) compared to vitreous grain because of a 70% increase in starch digestion rate (21.9 vs. 12.9%/h; $P < 0.01$) and a tendency for decreased ruminal starch passage rate (16.2 vs. 21.2%/h; $P < 0.10$). Post-ruminal starch digestibility (% of intake) was 39.3 and 56.8% ($P < 0.03$) for floury and vitreous grain, respectively, but as a % of duodenal flow, floury grain was more digestible than vitreous grain (90.8 vs. 83.6%; $P < 0.01$). Although substantial compensatory post-ruminal starch digestion occurred for vitreous diets, replacing vitreous grain with floury grain increased total tract starch digestibility from 91.7 to 96.3% ($P < 0.001$). Brown midrib corn silage increased total tract NDF digestibility compared to control silage (51.1 vs. 45.8%; $P < 0.02$) by numerically increasing ruminal and post-ruminal NDF digestibility, but digestion and passage rates of potentially digestible NDF did not differ across treatments. Endosperm type of corn grain can affect site and extent of starch digestion.

Key Words: Endosperm, Brown Midrib, Digestion

952 Effects of physically effective NDF on chewing activity and rumen pH of dairy cows fed diets based on barley silage. K. A. Beauchemin* and W. Z. Yang, *Research Center, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

A study was conducted to investigate the effects of physically effective (pe) NDF content of dairy cow diets on chewing activity and rumen pH. The study was designed as a double 3 x 3 Latin square using six lactating dairy cows with ruminal cannulas. Three levels of dietary peNDF (high, medium and low) were compared. The diets contained whole crop barley silages prepared with two theoretical lengths of cut (TLC): coarse (3/8") and fine (3/16"). The high, medium and low peNDF diets were formulated using coarse silage, equal proportions of coarse and fine silages, or fine barley silage, respectively. The peNDF content of the diets was determined as the proportion of the TMR (as-fed) retained on the 0.75" and 0.31" screens of the Penn State Particle Separator multiplied by dietary NDF content (DM basis). The peNDF contents were 13.8, 11.8 and 10.5% (DM basis) for the high, medium and low diet, respectively. Increasing peNDF content of diet had no effect on eating time (280, 247 and 267 min/d for high, medium and low, respectively) but quadratically increased ($P < 0.05$) ruminating time (440, 465 and 363 min/d for high, medium and low, respectively) and total chewing time (720, 712 and 630 min/d for high, medium and low, respectively). Mean pH, area under the pH curve, and duration of pH < 5.8 or < 5.5 were not affected by the peNDF content of diets. Unexpectedly, the peNDF content of the diet and ruminating time were negatively correlated to mean rumen pH ($r = -0.42$; $P < 0.15$) but positively correlated to the time during which pH was below 5.5 ($r = 0.40$, $P < 0.15$), an indicator of rumen acidosis. The results suggest that increasing the peNDF content of the diet can increase chewing activity which reduces the risk of acidosis. Dairy cows fed barley silage as the predominant forage source require a minimum dietary peNDF of 12% of DM.

Key Words: Physically Effective NDF, Chewing, Rumen pH

953 Effect of barley and its amylopectin content on ruminal fermentation and nitrogen utilization in lactating dairy cows. A. E. Foley*¹, A. N. Hristov¹, A. Melgar¹, J. K. Ropp¹, R. P. Etter¹, C. W. Hunt¹, and K. Huber², ¹*Department of Animal and Veterinary Science, University of Idaho, Moscow,* ²*Department of Food Science and Toxicology, University of Idaho, Moscow.*

The objective of this study was to evaluate the effect of partial substitution of corn grain by either normal or high-amylopectin (waxy) barley on ruminal fermentation, digestibility of nutrients, nitrogen (N) losses, and ammonia utilization in lactating dairy cows. Six late-lactation ruminally and duodenally cannulated Holstein cows were allocated to dietary

treatments in a replicated 3 x 3 Latin square design. Diets contained (DM basis): 40% corn grain (C), 30% normal barley and 10% corn (B), and 30% waxy barley and 10% corn (WB). All grains were steam-rolled. Barley grain had a greater rate of in situ ruminal DM degradability than either waxy barley ($P < 0.05$) or corn grain (trend at $P = 0.105$). Ruminal pH and VFA concentrations were not different ($P > 0.05$) between treatments, but ammonia and acetate concentrations were less ($P < 0.05$) in C compared to B and WB. Microbial protein synthesis (MPS) and efficiency were not affected ($P > 0.05$) by treatment. Ruminal and total tract N digestibility were reduced ($P < 0.05$) in C compared to B. Diet B resulted in the greatest ($P < 0.05$) N intake, and total N loss was greater ($P < 0.05$) in WB than in B. Plasma urea N concentration was not different ($P > 0.05$) among diets, but milk urea N (MUN) was greater ($P < 0.05$) in B and WB compared to C. Ruminal ammonia (labeled with ¹⁵N) utilization for MPS or milk protein was not affected ($P > 0.05$) by treatment. Tracer excretion in milk protein was greater ($P < 0.05$) in C compared to WB. Milk yield and composition were not affected ($P > 0.05$) by treatment. Ruminal ammonia and MUN concentrations suggested less efficient utilization of dietary N in B than in C, but overall, N losses were not affected by grain type. Inclusion of WB in the diet resulted in increased N losses compared to B and reduced efficiency of utilization of ruminal ammonia for milk protein synthesis compared to C.

Key Words: Barley, Corn, Dairy Cow

954 A nutritional evaluation of assiniboia oat, baler oat, and rosier barley silage for dairy cattle. T. L. Heck*, D. A. Christensen, J. J. McKinnon, and P. Yu, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

Three studies were conducted to evaluate the nutritional value of oat silage (*Avena sativa*) for use in dairy cattle rations. A total tract digestibility study using 18 lambs in a complete random design was conducted to determine the digestibility of dry matter (DM), organic matter (OM), crude protein (CP), crude fat (EE), neutral detergent fibre (NDF), acid detergent fibre (ADF), and acid detergent lignin (ADL) of Assiniboia (ASS) and Baler (BAL) oat silage compared to Rosier (ROS) barley silage. An *in situ* study was conducted using a non-lactating fistulated cow to determine rumen kinetic parameters of carbohydrate fractions. A dairy production trial was carried out using 9 lactating Holsteins at 90±20 DIM averaging 43 kg/d milk yield in a triple 3x3 Latin square design to determine the effect on milk yield and composition when fed 48% of ASS, BAL, and ROS silage (DM) in a total mixed ration (TMR). Lamb voluntary intake was higher ($P < 0.05$) for ROS compared to the two oat varieties, however BAL was higher than ($P < 0.05$) ASS. Digestibility of DM and OM were significantly different across treatments (DM 71.8, 65.2, 60.9, OM 73.9, 66.9, 63.3 for ROS, ASS, and BAL, respectively). CP digestibility was greater ($P < 0.05$) for ROS compared to the oat varieties. The digestibility of NDF, ADF, and ADL, and EE were similar between ROS and ASS treatments and both were higher ($P < 0.05$) than BAL. Dairy DM intake was similar across all dietary treatments. Milk yield was similar for ASS and BAL (41.6 kg/d), and 6% lower ($P < 0.05$) than ROS. Milk fat percentage was greater ($P < 0.05$) for ASS and BAL compared to ROS, which resulted in similar milk fat yields and 3.5% fat corrected milk among treatments. Milk protein yield and percentage were higher ($P < 0.05$) for ROS compared to ASS and BAL. It was concluded that oat silage could be substituted for barley silage as a forage source for dairy cattle rations.

Key Words: Silage, Dairy, Digestibility

955 Lactation performance and milk fatty acid profile of dairy goats fed four different forage species. A. Doyon*¹, G. F. Tremblay², and P. Y. Chouinard¹, ¹*Universite Laval, Quebec, QC, Canada,* ²*Agriculture and Agri-Food Canada, Quebec, QC, Canada.*

Forages provide substantial lipids in ruminant diets, and more than 50% of total fatty acids in certain forage species are C18:3. Our objective was to evaluate the effect of feeding four different forages on milk production and composition in dairy goats. Two grass [timothy (*Phleum pratense*), Italian ryegrass (*Lolium multiflorum*)] and 2 legume [alfalfa (*Medicago sativa*), white clover (*Trifolium repens*)] forages were harvested as silage. The C18:3 concentration in those forages was 8.8, 18.6,

7.8, and 9.8 mg/g DM, respectively. Twelve dairy goats of 3 different breeds (4 Alpine, 4 Saanen, and 4 Toggenbourg) that averaged 216 days in milk were used in a replicated 4 x 4 Latin square arrangement with 21-d periods. Goats were offered ad libitum access to a basal diet consisting of timothy, ryegrass, alfalfa, or white clover silage, supplemented with 180 g/d of a blend of rolled barley (65%), Topsoy® (22%), molasses (2%), and vitamin and mineral mix (11%). Milk yield and milk protein content were decreased, and fat content was increased with timothy as compared with ryegrass, alfalfa, and white clover ($P < 0.01$). Milk fat yield was not affected by forage type. Feeding grass forages decreased ($P < 0.01$) the proportion (% by weight) of C10:0, C12:0, C14:0, and C16:0, and increased the proportion of C18:0 and *cis*-9 C18:1 in milk fat as compared with legume forages. The C18:3 concentration was higher for alfalfa (1.68%), intermediate for ryegrass (1.59%) and white clover (1.60%), and lower for timothy (0.91%) ($P < 0.01$). Concentration of *cis*-9, *trans*-11 C18:2 was higher for ryegrass and alfalfa (0.47 and 0.45%, respectively), and lower for timothy and white clover (0.36 and 0.33%, respectively) ($P < 0.01$). The concentration of *trans*-11 C18:1 was higher for ryegrass (0.88%), intermediate for timothy (0.71%) and alfalfa (0.73%), and lower for white clover (0.53%) ($P < 0.01$). The concentration of *cis*-9, *trans*-11, *cis*-15 C18:3 was higher with ryegrass (0.048%) as compared with timothy, alfalfa, and white clover (0.009, 0.012, and 0.013%, respectively) ($P < 0.01$). The fatty acid profile of milk fat can be modified by feeding different forage species to dairy goats.

Key Words: Conjugated Linolenic Acid, Omega-3 Fatty Acid

956 Effects of feeding flaxseed on fatty acid composition in milk and cheese in dairy ewes. R. Zhang*, A. F. Mustafa, and X. Zhao, *McGill University, Ste-Anne-De-Bellevue, QC, Canada.*

A study was conducted to determine the effects of feeding various levels of flaxseed to lactating ewes on milk fatty acid composition, cheese yield and cheese fatty acid composition. One hundred and twenty lactating ewes (Suffolk East Friesian) were divided into 4 groups and were randomly assigned to one of 4 different isonitrogenous concentrates. The concentrates contained 0% (C1), 8% (C2), 12% (C3) and 16% (C4) flaxseed. The EE content (DM basis) of the concentrates was 3.2, 5.4, 7.4 and 9.4%, respectively. All animals were fed 1 kg of concentrate each plus ad-libitum intake of alfalfa hay. Animals were fed in pens. Results showed flaxseed supplementation had no effect on milk protein, lactose and casein percentages. However, milk fat percentage was higher ($P < 0.05$) for ewes fed C3 and C4 than for those fed C1 and C2. Cheese yield was 12% higher for ewes fed C3 than for those fed C1. However, flaxseed supplementation had no effect on cheese fat or protein percentage. Flaxseed supplementation linearly decreased ($P < 0.05$) the concentrations of medium chain and saturated fatty acids and increased ($P < 0.05$) those of long chain, mono- and poly-unsaturated fatty acids. Conjugated linoleic acid (CLA) and omega-3 fatty acid in milk and cheese were linearly increased ($P < 0.01$) as a results of flaxseed supplementation. Feeding C4 increased CLA and omega-3 fatty acids of milk by 66 and 75%, respectively. The corresponding increases in cheese were 67 and 74%, respectively. It was concluded that feeding flaxseed to dairy ewes can increase health-promoting fatty acids without major changes in milk fat or protein percentages

957 The luteolytic potential of reduced doses of prostaglandin. J. Brinkerhoff*, R. Silcox, J. Donley, and C. Kubo, Brigham Young University, Provo, UT.

Prostaglandin (PGF) and its analogs have greatly contributed to managing the reproductive performance of dairy herds. The most effective route of administration as well as the minimal dose requirement for induction of luteolysis has been investigated previously. This study was designed to compare the luteolytic response of lactating cows treated with a reduced dose of Prostamate administered in the ischioanal fossa versus the recommended dose given intramuscularly. Non-pregnant lactating Holstein cows with a functional corpus luteum (CL > 20 mm as determined by transrectal ultrasonography) were sorted by lactation into three groups; 1st (n=40), 2nd (n=40), 3rd and greater (3+) lactation (n=40). Cows within lactation group were paired. One cow of each pair was randomly assigned to be treated with 25 mg Prostamate intramuscularly (IM group) or with 15 mg Prostamate given in the ischioanal fossa (IRF group). Ovaries of cows were examined by ultrasound 72 hours post-injection to determine luteal regression. The functionality and regression of the CL were confirmed through analysis of serum progesterone concentrations in blood samples collected by tail venipuncture at the time of PGF administration, then 24 and 72 hr later. Tail heads of all cows were chalked at the time of PGF treatment. Estrus was detected daily for seven days post-PGF by assessing chalk removal. Luteal regression was induced in 103/120 cows. Luteolytic response was not affected by lactation number ($P > .05$). Route of administration and dose of prostaglandin did not affect response rate ($P > .05$; IRF:50/60, 83%; IM:53/60, 86%). Overall estrus detection rate for all cows given PGF was 43% (IM:29/60, 48%; IRF:23/60, 38%; $P > .05$). Estrus detection rate among cows that responded to PGF did not differ due to treatment (IM:29/53, 55%; IRF:23/50, 46%; $P > .05$). The IRF is a viable alternate route of administering a reduced (60% of normal) dose of PGF to lactating dairy cows since both luteolysis and estrus are induced at rates comparable to that attained with a normal dose administered IM.

958 Evidence for differential degradation of α_s - and β -casein in milk from mastitic quarters. K. M. Matson*, A. C. W. Kauf, A. L. Magliaro, and R. S. Kensinger, The Pennsylvania State University, University Park.

Mastitis decreases the yield of cheese from milk through the proteolytic degradation of milk casein. Our objective was to compare the changes in the pattern of proteins seen in mastitic milk samples caused by different pathogens. Milk samples were aseptically collected from inflamed and control quarters of seven mid-lactation Holstein cows upon diagnosis of clinical mastitis. Bacterial pathogens isolated included *E. coli*, *Strep. non-ag. spp.*, *Staph. spp.*, and gram-positive spp. Milk yield data was collected before and after diagnosis. Milk protein was determined by Lowry assay, and samples were analyzed by SDS-PAGE in 4 M Urea. Mean milk yields for the -5, 0, and +5 milkings relative to diagnosis of clinical mastitis were 20.2, 13.7, and 18.5 kg/milking (± 2.2 SEM), respectively. There was a consistent trend for increased total protein in mastitic compared to control milk samples. Degradation of caseins was significant in all of the mastitic milk samples. Densitometric analysis of bands in gels from infected versus control milk samples indicated that there was a reduction of 37.9 ± 21.4 % in α_s -casein, with somewhat less degradation of β -casein. Degradation of α_s -casein was more extensive than that of β -casein, and this trend was common across pathogens. As further evidence of proteolytic activity, smaller molecular weight fragments appeared in the mastitic milk samples. In addition, an increase in immunoglobulins and albumin in mastitic milk was apparent. Results show that the degradation of α_s - and β -caseins are consistently observed among the mammary pathogens detected.

959 Cottage cheese manufactured using transglutaminase enzyme for increase in yield. K. Nielsen* and D.R. Henning, South Dakota State University, Brookings.

The purpose of this study was to confirm and quantitate the recovery of whey proteins from skim milk into cottage cheese curd when using

a food grade enzyme, transglutaminase. Other food processing methods have used this enzyme to crosslink proteins in the presence of calcium. The enzyme has been used to produce a curd. In our study, three replicate trials with unfortified skim milk and direct set cottage cheese manufacturing were completed. Experimental vats were manufactured using 10 units of transglutaminase enzyme per gram of total protein in the skim added immediately after the glucono delta lactone acidogen. Three washes of the cooked curd were completed. Samples of the skim milk, whey, wash waters, and curd were collected for a mass balance. All trials resulted in more protein recovery in the experimental cheese compared with the control cheese. The magnitude of the increased recovery was not significant. All experimental vats contained less protein in the whey than the corresponding control; however the magnitude of decreased protein was not significant.

Key Words: Cottage Cheese, Yield, Transglutaminase

960 Analysis of financial measures comparing 3 management styles. W. T. Wencil* and G. Hadley, *University of Wisconsin, River Falls.*

The objective of this research was to determine if management style influenced profitability. The management options compared included: Management Intensive Rotational Grazing (MIRG), a stored feed group, and a mixed feeding group. Survey results were used to define management style. MIRG was defined as a producer who used pasture as the major forage source of feed. The stored feed group was defined as farms that had no pasture access for animals. Finally the mixed feeding group was defined as farms that provide minimal grass for grazing, but pastures are not managed intensively. The number of farms whose survey results indicated the different management styles were: MIRG-30 farms, stored feed-226 farms, and mixed feeding-26 farms. There were nineteen different financial ratios used in this research; they dealt with issues of: liquidity, solvency, profitability, repayment capacity, and financial efficiency. Dupont analysis was performed on the financial ratio measures calculated from the Agricultural Financial Advisor (AgFA) database. This database contains the financial information of 600 Wisconsin dairy farms. The results were analyzed using a statistics program to test for statistical significance between results. Based on the results, MIRG is at least a competitive option for dairy producers.

Dairy Production Undergraduate Paper Presentations

962 Leptin: What is its role in the dairy cow? D. C. Barbour* and E. H. Jaster, *California Polytechnic State University, San Luis Obispo.*

Dairy cows in early lactation experience a negative energy balance that often pre-disposes them to metabolic disorders. Ketosis, periparturient paresis, and displaced abomasum are examples of these disorders that arise from insufficient energy levels at parturition and freshening. Negative energy balance occurs in the dairy cow because the amount of energy expended for body maintenance and production exceeds the amount of energy available from dietary sources. Leptin is a peptide hormone produced by white adipose tissue that acts on the hypothalamus as its primary target organ. Leptin has been demonstrated to be closely associated with metabolic traits that maintain homeostasis despite negative energy balances in early lactation. Leptin is also thought to regulate processes that are highly dependent on positive energy supply. Some of these are developmental processes which include the onset of puberty, ovarian function, and formation of mammary secretory tissue, as well as other processes including responses to stress and general reproductive and immune functions. Research has determined that leptin serves as a mediator of nutrition, and an indicator of nutritional status and body conditioning in dairy cattle. Recent discoveries in nutritional biochemistry and DNA technology indicate that leptin has been shown to contribute to fat deposition, nutritional status, reproductive function, and immune response in dairy cattle.

961 Wastewater treatment to reduce phosphorus losses from dairy farms. L. D. Hughes*, K. F. Knowlton, N. G. Love, A. M. Gamboni, and C. M. Parsons, *Virginia Polytechnic Institute and State University, Blacksburg.*

Dairy farms are a major source of phosphorus (P) contamination of surface water. One approach to reduce P runoff from farms is to apply biological wastewater treatment techniques to reduce the nutrient content of land-applied waste. Enhanced biological P removal (EBPR) is a system used to reduce the P content of municipal waste. EBPR involves treating waste in a reactor with alternating anaerobic and aerobic conditions. P-accumulating microorganisms in the waste sequester P, yielding a P-depleted liquid and a P-enriched biomass for export. Our objectives were to evaluate the compositional suitability of dairy manure for EBPR, and to evaluate the effects of diet and manure separation on parameters important to reactor design. Waste samples were collected from 9 cows fed a high P diet (0.47%P), a low P diet (0.32%P), or low P with exogenous phytase (0.32%P), in a Latin square design. Total collection of urine and feces was conducted, a mixed slurry was created, and slurry was separated mechanically to generate liquid effluent. Slurry and effluent samples were analyzed for P and chemical oxygen demand (COD). COD:P, reflecting energy available to drive P removal, was calculated. Phytase had no effect on waste composition, but the P content of slurry and effluent from cows fed low P (with and without phytase) was lower than from cows fed high P (224 and 242 vs. 375 mg/l), and the COD content tended to be higher (47,078 and 51,081 vs. 45,282 mg O₂/l; P < 0.09). The COD:P ratio of all wastes was sufficient to support EBPR, but waste from cows fed low P had a higher COD:P ratio than cows fed high P (310:1 and 289:1 vs. 149:1). Effluent had less COD and P than slurry, but the COD:P ratio was similar in the two wastes. These results indicate that dairy manure slurry and effluent will support EBPR, and that diet affects waste composition in a way that will affect reactor design. More work is needed to assess reactor performance and the economic feasibility of applying EBPR to dairy waste.

Key Words: Enhanced Biological Phosphorus Removal, Wastewater Treatment, Manure Composition

963 Managing an ovulation synchronization program with PCDART. J. C. Roberts*, *Louisiana State University, Baton Rouge.*

Ovulation synchronization is the use of exogenous hormones to induce the onset of ovulation in dairy cattle. Ovulation synchronization is a common practice on many US dairy farms. It can increase profitability on a dairy farm by reducing the average days to first breeding and consequently the average days open per cow on the farm. It can also improve the labor efficiency on the farm by reducing the need for heat detection. Ovulation synchronization requires that specific hormonal events be given to individual animals at specific time intervals. One disadvantage of using ovulation synchronization is the difficulty in coordinating several events associated with the protocol on a large number of animals in a dairy herd when different animals require different events on a particular day. Another disadvantage of using ovulation synchronization is the need to keep accurate records on which events were given to which animals during a given time frame. There would be no way of knowing which event an animal should receive at what time without this information. This would quickly render the program ineffective. PCDART is a computerized record keeping system for use in dairy herds. PCDART is used to manage all of the information recorded on individual animals such as milk production, breeding, calving, etc. PCDART can also be used to manage ovulation synchronization programs in a dairy herd. Dairy farmers can use default ovulation synchronization protocols that are built into the program or they can design their own protocols. After setting up an ovulation synchronization protocol the farmer wants to use, they then tell PCDART which cows are going to be synchronized. PCDART will then create daily or weekly reports telling the farmer which cows receive which hormonal treatments on a given day. This process greatly reduces the amount of time the farmer has to spend de-

termining when to give each animal a particular treatment. This allows farmers to utilize their time resources more efficiently and greatly improves the overall potential for success using ovulation synchronization.

Key Words: Ovulation Synchronization, PCDART, Dairy Management

964 Factors affecting fertility rates in embryo transfers. J. Hockney*, *North Carolina State University, Raleigh.*

Such reproductive technologies as artificial insemination and embryo transfer are becoming increasingly popular in the Dairy industry, greatly increasing the number of offspring from elite bloodlines and therefore improving the overall genetics of the industry. In this presentation, the procedure for embryo transfers will be discussed, including a variety of techniques, and the corresponding fertility rates associated with different protocols. These techniques vary from the use of fresh or frozen embryos, environmental factors, the use of bST, freezing and thawing methods, and surgical transfer. Through this data, one hopes to gain a greater understanding of the embryo transfer protocol, thus increasing success rates and therefore making a more economical procedure.

Key Words: Embryo Transfer

965 Effects of pasteurization on colostrum quality. M. L. Moody*, *Pennsylvania State University, University Park.*

Colostrum intake is essential for the development of passive immunity in the neonatal bovine because placental structure does not allow in utero transfer of antibodies from dam to fetus. For this reason calves must ingest an adequate amount of colostrum containing high levels of antibodies within hours after birth. Poor colostrum management may cause calves to consume pathogenic organisms such as *Mycoplasma* or *Mycobacterium paratuberculosis*. A large percentage of dairy producers pool colostrum from fresh cows, increasing this risk of disease spread by creating a mix of uncertain antibody contents and pathogenic bacteria. Pasteurization may present an alternative to calf raisers who pool colostrum when attempting to reduce disease transmission from dam to calf by killing pathogenic bacteria through heating colostrum to high temperatures. While pasteurization may rid colostrum of disease causing organisms, it may also reduce the concentration of Immunoglobulin G, the main antibody whose absorption leads to passive immunity in calves. Godden (2003) reported IgG concentrations were reduced by 58.5% in 95 L batches and 23.6% in 57 L batches of pasteurized colostrum.

Key Words: Pasteurization, Colostrum

966 Got Milk Insurance? L. B. Core*, *University of Kentucky, Lexington.*

Dairy producers nationwide continually struggle with the volatility of the milk market. From the record high prices of 1998 and 1999, to the devastating low prices of 2000, and the rebound of 2001, producers constantly have to strike a balance between enjoying the highs and budgeting for the lows in milk prices. However, another option is available to producers. Insuring milk prices with forward, futures, and options contracts rather than accepting the cash market is a viable option for many dairy producers. These three alternatives do not guarantee maximum profit, but instead allow producers to budget more effectively as they are better able to manage returns. Furthermore, securing long-term contracts for feed ingredients, hay, fuel, and other inputs to manage input cost will ensure the producer isn't challenged by unexpected price fluctuations. Each marketing alternative can be equally effective when ensuring prices; however, when choosing which alternative to employ, it is important to consider the individual needs of the producer. Dairy operators nationwide have enjoyed positive economic returns from the use of contracts. A Wisconsin family who milk approximately 400 Jerseys increased their profit margin by \$34,000 by using the contract method over their regular cash market method. Moreover, producers who had 200,000 lbs. of Class III milk with 3.5% butterfat contracted at \$12.00 for 2001 and 2002 made \$19,600 over the cash market value in the two year period. As impressive as these numbers are, everyone knows that nothing in life is a sure thing, including forward, futures and options contracting. However, these three alternatives do help to insure a long-term future for many dairy producers.

Key Words: Milk Prices, Futures, Profitability

967 The battle against high somatic cell counts: worth fighting – worth winning. A. R. Hazel* and J. K. Reineau, *University of Minnesota, St. Paul.*

In a world market where the BTSCC of most herds is required to be below 400,000, most major dairy production countries outside the U.S. average below 250,000. With a national average of 350,000 in 2002, the U.S. has increased its risk of losing share in this growing global market. Low somatic cell scores are important in every link of dairy product production, and has the potential to save the U.S. industry over 1 billion dollars every year. Low SCC is beneficial to the cow because it creates better overall health. For dairy producers, reducing mastitis levels will indirectly increase their milk price through quality premiums and create a higher level of productivity. Dairy product processors profit through higher product quality and increased yields during production. The marketing industry wins by being able to sell a product proven to have a longer shelf life. And the consumer wins with a high quality product that they can always trust to be wholesome, nutritious, and good tasting. Lowering SCC just makes sense for everyone! So how should producers go about lowering the SCC of their herd? The process is not as daunting as it first appears. First, producers need to understand the problem by culturing cows and developing a plan of attack against high SCC. Then, managers need to evaluate sanitation, especially protocols for milking procedures as well as stall and bedding management. Cow care is also important because animals need a healthy and stress-free environment to be highly productive. Last, but definitely not least, a producer must change his mindset about milking cows in order to lower SCC. This involves setting goals for SCC, developing effective protocols for management, and training everyone who milks to follow the process without fail. The U.S. dairy industry has a clear need to lower its SCC in order to compete on a world marketplace and remain a viable industry in the domestic sector. The time to do something about it is now.

968 The effects of presynchronization, in conjunction with Ovsynch, on pregnancy rate in dairy cattle. R. A. Stery* and S. C. Kelm, *University of Wisconsin, River Falls.*

The U.S. dairy industry has become increasingly competitive and many producers have responded by expanding herd sizes and striving for greater production per cow. While these adjustments have led to improved efficiency, herd reproductive performance has suffered. One of the factors associated with declining reproductive performance is reduced efficiency and accuracy in estrus detection. A proactive approach to solving this problem is the use of timed A.I. protocols. An example of a widely accepted hormonal intervention protocol is Ovsynch (50µg GnRH day 0, 25mg PGF_{2α} day 7, and 50µg GnRH day 10, followed by timed A.I. 10-24 hrs later). However, one of the drawbacks of Ovsynch is that all cows enter the protocol on the same day, regardless of their estrous cycle stage. Cows in later stages of the estrous cycle face a greater risk to fail to ovulate to the first GnRH injection and ovulate before the second GnRH injection, leading to a lower pregnancy rate to subsequent A.I. To overcome this obstacle and improve uterine health two doses of PGF_{2α} (25 mg) can be administered before initiation of Ovsynch. Presynch effectively groups cows in the early luteal phase of the estrous cycle, which has been demonstrated to be the optimal stage to start Ovsynch. Moreover, Presynch may improve uterine health by increasing the ovulation rate, luteal activity, and decreases the occurrence of pyometria. Overall presynchronization has the potential to increase the number of pregnancies per first service by 11.6 ± 3.8% 32 days after A.I. and 21.2 ± 4.3% at day 74 post A.I.

Key Words: Presynchronization, Ovsynch

969 Ionophores: Friend or foe? M. C. Scott*, *Virginia Polytechnic Institute and State University, Blacksburg.*

Ionophores are carboxylic antibiotics introduced in the late 1970s to aid in control of coccidiosis. It was also discovered that ionophores, when added to feed in small amounts, increased feed efficiency and decreased methane production in ruminants. To accomplish this ionophores alter the acetate: propionate ratio in the rumen in favor of propionate. The increased level of propionate, the main precursor for glucose, results in faster growth rates. Ionophores also have potential to increase milk production and lower occurrence of postpartum metabolic diseases in lactating cows, such as ketosis. Feeding sub-therapeutic levels of carboxylic antibiotics such as ionophores, which are not used in humans,

can prevent diseases and infections, such as coccidiosis, that would normally be treated with stronger antibiotics commonly used in human treatment. Therefore, ionophores may reduce the threat of antibiotic resistance. Ionophores are approved for use in young stock, and are currently under review for approved use in lactating cattle.

Key Words: Ionophores

970 Centralized pregnancy detection: A new option for fertility evaluation. A. Barten* and L. Fox, *Washington State University, Pullman.*

Pregnancy Specific Protein B (PSPB) can be used as a centralized pregnancy detection aid. During the third week after conception, binucleate giant cells, in the ruminant placenta produce a glycoprotein called Pregnancy Specific Protein B. This protein can be detected with an enzyme-linked immunosorbent assay (ELISA) at day 30 of gestation in multiparous cows and at day 28 of gestation in primiparous heifers. The test is 92.5% accurate for identifying pregnant cows and over 99% accurate for identifying nonpregnant cows. A blood sample is collected from

each cow and delivered to a centralized laboratory, (usually at a veterinary clinic), where the test is completed. The laboratory then prepares a report for the herd manager or veterinarian. Results are available electronically to the herd manager and/or veterinarian within 27 hours after the sample was taken. The centralized pregnancy evaluation concept provides the following advantages over traditional on-site palpation for pregnancy: 1) A high degree of quality control for assay accuracy as opposed to potentially low quality control for on-farm testing; 2) Data from multiple herds can be easily summarized; 3) Increased ability of the veterinarian and management team to compare herds with regard to application of successful programs; 4) More quality time available for the veterinarian and management team to evaluate and make improvements; 5) Reduced probability of embryonic death due to palpation and erroneous hormone use and 6) Elimination of error prone steps with data recording and transfer. PSPB can be used as a tool to improve reproductive efficiency by minimizing days open, reducing the calving interval and maintaining adequate days in milk. This approach is currently in use in the states of Washington and Idaho and will provide new options for evaluating pregnancy status in dairy cattle.

Key Words: Pregnancy Specific Protein B, Testing

Dairy Foods Undergraduate Paper Presentations

971 An industry approach to increasing the consumption of dairy products. B. Lyons*, *Louisiana State University, Baton Rouge.*

According to USDA, consumption of soft drinks has steadily increased over the past 40 years while milk consumption has decreased. The incidence of bone fractures has increased by 42%, especially among children and young adults, over the past 30 years. Researchers are concerned that many children and teenagers are not getting proper amounts of calcium in their diets. In time, the trend of less milk and more soda could lead to increased occurrences of osteoporosis. These data show that consumption of dairy foods is important to our nutritional well-being. The Food Guide Pyramid recommends consumption of 2-3 servings of dairy products/d. Milk and dairy products offer a range of well-known health benefits, the best known being calcium for proper bone health. In 1984, the Dairy Check-Off Program was implemented to provide funding for marketing, research, and educational programs. Through this program, the industry is working to increase dairy product demand and strengthen dairies image. Since the program began, dairy consumption per capita has increased 11%. Researchers across the country are finding new ways to make dairy products more appealing to young consumers through checkoff funds. Education is important to keep the importance of nutrition at the top of everyone's priorities and with the help of the Dairy checkoff, the dairy industry is able to offer nutritional information to consumers of all ages. The checkoff funds 3-A-Day of Dairy, a nutrition-based marketing and education campaign to promote healthy diets and increase demand for dairy products. The Got Milk? ads are still a big hit with consumers, and checkoff funds are continually used to feature new celebrities for promotion. Fast food restaurants are beginning to offer milk with children's meals, and this is receiving positive responses from parents. With the consumption of dairy products continuing to decline, the dairy industry must persist in efforts to promote their products. The research, marketing, and educational programs funded by the checkoff are steps in the right direction for increasing consumer awareness of the importance of dairy products for health and well-being.

Key Words: Dairy Products, Consumption, Industry Programs

972 Probiotics in dairy products- Beyond nutrition. S. Phetsomphou*, *North Carolina A&T State University, Raleigh.*

Microbial cultures have been used for thousands of years in food and food fermentations. Since the past century, there is strong evidence that the microbial cultures have the ability to prevent and cure a variety of human diseases. Probiotics are one group of these microbial cultures that are becoming increasingly popular in the United States and Europe. Although there are many different types of probiotics, the most common are *Lactobacillus bulgaricus*, *L. acidophilus*, *L. reuteri* and bifidobacteria. Dairy products such as fluid milk and yogurt are the popular food products that contain probiotic cultures. Probiotics are defined as viable microbial cultures that have positive impact on human health. A number of studies have found probiotic consumption to be useful in

the treatment of many types of diarrhea, including antibiotic-associated diarrhea in adults and young children. Several studies have shown that certain strains of probiotics, such as *L. bulgaricus* and bifidobacteria, can alleviate symptoms of lactose intolerance by providing bacterial lactase to the intestine and stomach. Probiotic consumption may also be a means for primary prevention of allergy in susceptible individuals. Studies have shown that regular consumption of probiotic could have a positive impact on cancer prevention. Animal and in vitro studies indicated that probiotic bacteria may reduce colon cancer risk by reducing the incidence and number of tumors. Functional foods including dairy food products have been known as a mean for disease prevention and the quest for optimal health at all ages. Therefore, probiotics cultures could play a big role in the human diet beyond nutritional aspects.

Key Words: Probiotics, Bifidobacteria, Dairy Products

973 On-farm milk processing. A. R Nelkie*, *North Carolina State University, Raleigh.*

On-farm milk processing plants are becoming increasingly popular as an enterprise option for dairy producers as they try to add value to their commodity of raw fluid milk. Lemajru Dairy Farm, a 100% registered, 100 cow milking herd located near West Branch, MI is being used as the experimental farm in this research model to determine if an on-farm milk processing plant is profitable. The cost of the equipment, the construction of the plant, the increased labor in the form of new employees, and the cost of operating it will be calculated. Figurative prices fabricated from local grocery stores and current on-farm processing plant are used to calculate the profit. Last year's gross income for the farm sale of raw fluid milk was around \$300,000. To build an on-farm processing plant, the income will have to cover the \$300,000 plus enough to pay for employees, loans and the cost of extra utilities needed to operate the machinery. The farm is capable of producing approximately 5000 gallons of milk each week. An estimated cost for the building and purchasing of equipment is around \$700,000 upwards to \$800,000. The endeavor has the ability to produce \$750,000 per year, making this an equitable project if family help can be obtained to work the plant thus keeping start up costs down.

974 Farmstead cheese production. K. E. Harwick*, *Pennsylvania State University, University Park.*

The farmer's share of the consumer food dollar has dropped from 46% in 1913 to 20% in 2000. A natural result has been to increase farm size, but not all producers can or want to expand. Alternatively some dairy producers have opted to produce and market value-added products such as cheese. These products produce a higher return, can open new markets, and provide brand recognition while adding variety to a farms normal operation. Consumers are willing to pay more for a value-added product, allowing for a higher quality of farm life. When deciding

whether farmstead cheese production is a good alternative to marketing wholesale milk, there are several key areas to address. Produce a high quality product, and test-market the product with family and friends before continuing. Develop a business and market research plan, be sure funding is adequate, and research food safety laws and other relevant regulations. Farmstead cheese production can be the solution to the financial constraints many small dairy producers are facing. By producing a value-added item that consumers are willing to buy at a premium, a smaller dairy can remain profitable.

Key Words: Cheese, Value-Added

975 Eliminating the calcium crisis. J. D. Woodcock*, *University of Kentucky, Lexington.*

Only 13.5 percent of girls and 36.3 percent of boys age 12 to 19 in the United States get the recommended daily amount of calcium, placing them at serious risk for osteoporosis and other bone diseases, according to statistics from the U.S. Department of Agriculture. Because nearly 90 percent of adult bone mass is established by the end of this age range, the nation's youth stand in the midst of a calcium crisis. Not only will increasing dairy intake reduce the risk for osteoporosis, but it will combat against other serious diseases and illnesses as well. One way the dairy industry is taking preventative measures is by developing new products and flavors. Flavors like chocolate, vanilla, strawberry, as well as new flavors like mocha cappuccino, orange vanilla, peaches and cream, and caramel shake have been developed and are found to be more palatable to today's youth. Researchers have also learned that by splitting the lactose enzyme, the resulting glucose and galactose can

be used to sweeten dairy products. Applying the lactase enzyme to the product will eliminate any lactose intolerance issues. Between the years of 1985 and 1997, school districts nationwide, decreased the amount of milk they bought by nearly 30 percent. It is time the school districts were held accountable for this decrease and put dairy vending machines in the hallways of the nation's schools and eliminate the national calcium crisis.

Key Words: Calcium, Crisis, Increasing Intake

976 Low-fat dairy products: Meeting the needs of a health conscious generation. L. Daubert*, *Virginia Polytechnic Institute and State University, Blacksburg.*

Consumption of low-fat dairy products has shown significant health benefits to consumers. When consumed in moderation and in conjunction with a regular exercise program, low-fat dairy products have been shown to reduce the occurrence of cancer, increase metabolism, build and maintain muscle, maintain a normal blood pressure, and decrease body fat. Conjugated Linoleic Acid, a component of milk, has been shown to both increase metabolism and to be anticarcinogenic. Other milk components including protein, calcium, phosphorus, riboflavin, and Vitamins A and D are essential for maintaining good health. Low-fat dairy products are a new trend in the health industry; as additional research becomes available about the benefits to a healthy diet, the market is predicted to increase for these specialty products.

Key Words: Low-Fat Dairy Products

SUBJECT INDEX

- A**
- A. Fumigatus*, 480
 AA Requirement, 15
 Abnormal Distribution, 29
 Abnormal Meat Color, 50
 Abnormal Spermatozoa, 159
 Abortion, 96
 Absorption, 138, 446
 Accuracy, 893
 Acetate, 152, 237, 595
 Acetic Acid, 293
 Acetone, 205
 β -N-Acetylglucosaminidase, 325
 Acid Buf, 186
 α_1 -Acid Glycoprotein, 64
 Acidification, 244, 245
 Acidified Sodium Chlorite, 285
 Acidosis, 63, 153, 158, 198, 481
 ACTH, 922, 923
 ACTH Challenge, 433
 Activated Carbon, 273
 Active Yeast, 104
 Activin, 258, 260, 307
 Acute Phase Proteins, 66, 238, 505
 Acute Phase Response, 284, 668, 672
 Acute Stress, 194
 Adaptability, 25
 Adaptation, 333
 Additional Heat, 58, 59
 Adhesion, 199
 Adipocyte, 117, 151
 Adipose, 121, 150, 774
 Adipose Depot, 777
 Adipose Tissue, 155
 Adipose Tissue Explants, 131
 Adrenal, 922
 Aerobic Stability, 188, 212
 Aflatoxin, 203
 Aflatoxin B1, 88
 Aftertaste, 279
 Age, 58, 160, 436
 Age at First Calving, 2, 214, 886
 Age at Puberty, 258
 Age-Related Macular Degeneration, 270
 Aging, 71, 144, 287, 371, 374, 488
 AGP Alternatives, 112
 Agricultural Change, 11
 Agricultural Education, 557
 Agro-terrorism, 178
 Agroindustrial Residue, 205
 AI, 417, 418
 AI-REML, 16
 Air Emissions, 190, 194
 Air Interface, 81
 Air Quality, 9
 Albumen Quality, 321
 Alcohol-Fermented Feedstuff with Live Yeast, 162
 Alfalfa, 150, 151, 220, 278, 332, 568
 Alfalfa Grazing Dairy Cows, 143, 144
 Alfalfa Hay, 249
 Alimet and DL-methionine, 14
 Alkane, 112, 129, 142
 Alkane Markers, 567
 Allele Frequency, 443, 895
 Allergies, 491
 Allied Industry, 695
 Alpaca, 96, 97
