Breeding and Genetics

M1 The impact of herd opportunity and milk recording periods in estimating lifetime net income. E. Yook*, R. E. Pearson, and B. G. Cassell, *Virginia Tech, Blacksburg.*

The Purpose of this study was to determine how well estimators of lifetime net income based on 305 lactation yields and a ten year opportunity (RNI305.10) and based on complete lactation data but a five year opportunity (RNIc.5) predict the estimate based on complete lactations and a ten year opportunity (RNIc.10). Previous studies have used shorter (five year and seven year) opportunity periods and only production through 305-d to estimate a cow's lifetime net income. Records for 22,854 cows in Virginia herds born in 1988, 1990, and 1992 from the Dairy Records Management Systems (DRMS) in Raleigh, North Carolina were used. The relative net income (RNI) function included total milk, fat, and protein income - feed cost for production + net value of calves + net cull value - rearing cost - ((daily cost for labor, maintenance feed, supplies, and fixed expenses) × days in herd). Each RNI was calculated using milk-fat-protein pricing. A cow's RNIc.10 was calculated using all production initiated prior to her tenth birthday. All lactations initiated prior to her fifth birthday were used to calculate a cow's RNIc.5. We calculated an RNI305.10 using only milk produced during the first 305-d of every lactation initiated prior to tenth birthday. Total milk, fat, and protein based on c.5 were 20845kg, 737kg, and 666kg; those based on c.10 were 28539kg, 1009kg, and 905kg; finally, those based on 305.10 were 25304kg, 883kg, and 792kg. The means of RNIc.5, RNIc.10, and RNI305.10 were \$1445, \$2279, and \$1857, respectively. Regression analyses including herd and birth year in the model were used to estimate the regression of RNIc.10 on RNIc.5, and RNIc.10 on RNI305.10. The resulting regression coefficients were \$1.52 and \$1.14 explaining 68% and 96% of the variation of RNIc.10. Using RNIc.10 as the measure to estimate lifetime profit is strongly recommended over the two alternatives tested.

Key Words: Lifetime Net Income, Relative Net Income, Herdlife Opportunity

M2 Genotype by environment interactions in the association among milk yield, age and body weight at first calving in Holstein cows. R. Ruiz-Sánchez¹, H. Castro-Gómez², F. Sánchez y GF¹, and H. Castillo-Juarez*¹, ¹Universidad Autónoma Metropolitana, Unidad Xochimilco, ²Universidad Nacional Autónoma de México.

This study evaluated the effect of herd environment on the genetic and phenotypic relationships of milk yield (MEM) on age (AFC) and body weight at first calving (BW) in primiparous Holstein cows. Data analyzed were 248,230 first parity records of Holstein cows calving from 1987 to 1994, daughters of 588 sires in 3,042 herds in the US. Herds were classified into low and high environment classes. Genetic parameters were estimated with bivariate linear mixed models using the multiple trait derivative free software (MTDFREML). Heritability for AFC and BW were 0.33 ± 0.01 and 0.07 ± 0.01 in high environment herds and 0.20 ± 0.01 and 0.07 ± 0.01 in low environment herds respectively. Genetic correlations between MEM and AFC were -0.52 ± 0.02 and -0.31 ± 0.03 in high and low environment classes, whereas between MEM and BW in both classes were similar (-0.19 ± 0.06 and -0.21 ± 0.06 , respectively). Correlated responses estimated per 1000 kg of genetic gain in MEM for high and low herd environment classes were -22.1 and -19.3 days for AFC and -0.81 and -0.41 kg BW, respectively. BW information, as provided by AIPL (USDA) is inaccurate. Hence, results related to this trait are not conclusive. Different values of heritability for AFC, as well as changes in the genetic correlation between MEM and AFC across environments, indicated genotypic by environment interaction. Thus selection for MEM correlates with reduced AFC, but expected correlated response changes across environments.

Key Words: Genotype by Environment Interaction, Age at First Calving, Genetic Parameters

M3 Heritability of body weight at 130 days from hatching in the Pacific white shrimp (*Litopenaeus vannamei*) using an animal model. H. Castillo-Juarez*, *Universidad Autónoma Metropolitana, Unidad Xochimilco.*

To estimate the heritability of body weight (BW) in the Pacific white shrimp, *Litopenaeus vannamei*, an experiment was conducted using 101 families in two commercial units of a Mexican hatchery and two prawn

population densities (9.1/m² and 14.8/m²). These 101 families consisted of 17296 prawns, sibs from 51 sires and 101 dams. Prawns were injected with a colored, elastomer tag to identify families, which allowed mixing of families for performance evaluation. Prawns were individually weighted at an average of 130 days from hatching. Small differences in days from hatching were related to management practices. BW family phenotypic mean (s.d) was 18.2 g (2.3), ranging from 15.6 to 22.5 g. Females were 0.5 g heavier than males. Breeding values were calculated for all prawns using mixed model methodology with an animal model and MTDFREML software. The model included fixed effects of days from hatching and sex, plus commercial unit, population density and the animal additive genetic effect as random effects. BW heritability was 0.57. Since genetic selection in shrimp industry is based on family selection, families were ranked using BW phenotypic means, BW least square means and BW breeding value means. The rank correlation between family phenotypic means and family breeding value means was 0.64, and between least square means and breeding value means was 0.87. BW family breeding value means ranked from -1.921 to 3.527 g. Family breeding value means allow to better select families and apply different selection intensities within family to increase genetic gain in an optimal way.

Key Words: Shrimp, Genetic Parameters, Animal Model

M4 Merit of obtaining genetic evaluations of milk yield for each parity on Holstein bulls. H. D. Norman, J. R. Wright*, R. L. Powell, and P. M. VanRaden, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Modeling separate Predicted Transmitting Abilities (PTA) for each parity is becoming more frequent internationally. A concern when using a single trait genetic evaluation model is that changes in PTAs could be larger than expected for bulls whose daughters deviate considerably from the typical response due to aging. The objective of this research was to examine how difference in rate of maturity of bulls daughters impacts changes in bull evaluations across time. The 305-d milk records for Holsteins first calving between 1960 and 1998 were used to calculate 12 tailored PTAs for each bull. Tailored PTAs (controlled by parity combinations and run dates) were calculated for 1996 to 1999 run years using records of cows first calving prior to each January. Four annual evaluations included only first lactations on daughters and contemporaries (PTA₁). Four more included the first two lactations available (PTA₁₋₂), and the last four included the first three lactations (PTA₁₋₃). The three PTAs (different parities) for each year included cows first calving by the same cutoff date. Tailored PTAs had more uniformity across years in mean records/daughter than published PTAs. Stability (absolute differences, standard deviations (SD) of differences, and correlations between bull evaluations) across time was compared. Bulls born after 1984 having ≥500 daughters were examined because of their high precision and recent activity. SD of bull differences in PTA₁, PTA₁₋₂, and PTA₁₋₃ for milk between 1996 and 1997 were 28, 28, and 27 kg compared to 63 kg for the published evaluations. Similarly, SD between 1996 and 1999 were 36, 32, 32, and 79 kg, respectively. PTA₁₋₂ was usually intermediate to PTA₁ and PTA₁₋₃ for any bull having a large difference between PTA₁ and PTA₁₋₃. Results suggest that modification of the current evaluation model should reduce fluctuations in PTAs for individual bulls across time and should also improve the accuracy of evaluations.

Key Words: Milk Yield, Parity, Lactation Number

M5 Joint genetic evaluation of male and female fertility using longitudinal binary responses. R. Rekaya and T. Averill*, *Department of Animal and Dairy Science, University of Georgia, Athens.*

The improvement or at least the maintenance of herd fertility has become a major objective in several genetic improvement programs worldwide. Several types of responses are used in fertility evaluation including binary, count and continuous traits. Consequently, different models and methodologies used to analyze reproductive performances. Independently of the trait or methodology used not all sources of variation are accounted for making a joint evaluation of male and female fertility unfeasible. However, a longitudinal model that accounts for all breeding events makes a better use of available information and allows for joint

evaluation of males and females. Furthermore, as a by product of longitudinal analysis, several new selection criteria could be computed and used rather than the single breeding value. In this study, insemination records from dairy herds in California, generated between 2002 and 2003 and provided by AgriTech Analytics were used. After editing, the data consisted of a total of 369,353 insemination records with an average of 1.76 inseminations per cow. A random regression model at the liability scale was used to model the success (failure) of insemination events. The models included herd-year, technician and month of insemination as fixed effects and service sire, quadratic regression on days of milk, permanent environmental effects and residual terms as random effects. The heritability of success of insemination increased slightly with days in milk and ranged between 0.04 -0.055. The service sires and permanent effects variances were 0.01 and 0.012 respectively. Although small, these estimates are within the range of reported estimates for reproductive traits and indicate the possibility of improvement of male and female fertility through selection. Several new selection criteria such as the probability of conception after first insemination, after 3 insemination or the probability of no conception after a number of days were computed and can be used for selection decisions.

Key Words: Fertility, Male, Female

M6 Evaluation of net energy efficiency for lactation and economic performance as selection criteria in dairy cattle. P. Zamani*¹, S. R. Miraei Ashtiani¹, A. Naserian², A. Nik Khah¹, and M. Moradi Shahrabak¹, ¹*Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran,* ²*Department of Animal Science, Faculty of Agriculture, University of Ferdowsi, Mashhad, Iran.*

Improvement of feed efficiency and related economic performance is of great importance in dairy farming. This study was conducted to evaluate the net energy efficiency and economic performance of lactation as selection criteria for dairy cattle. 2589 monthly records collected from 723 lactating cows in 3 dairy farms were analyzed for the mentioned purpose. Different usages of energy were estimated, using National Research Council (NRC) models. A multivariate animal model including fix effects of herd-year-season, parity number and lactation stage, and random effects of animal genetic and permanent environment was adopted for estimation of genetic and phenotypic parameters, using Derivative Free approach of Restricted Maximum Likelihood (DFREML). Heritability estimates of milk yield, 3.2 percent fat corrected milk, net energy efficiency, gross income and variable profit, were 0.30, 0.31, 0.32, 0.34, 0.24 and 0.29 respectively. The results of this study showed that, the genetic factors considerably contribute to the feed efficiency and economic performance of lactating cows. However if measuring the feed efficiency is not feasible, considering 3.2 percent fat corrected milk in selection index may be an effective way for indirect selection and improvement of feed efficiency and economic performance in dairy cows.

Key Words: Dairy Cattle, Net Energy Efficiency, Fat Corrected Milk

M7 Estimates and relationships of growth curve parameters in NDama cattle. O. Mgbere^{1,2}, I. Imumorin*³, O. Olutogun¹, and A. R. Abdullah¹, ¹*Dept of Animal Science, University of Ibadan, Ibadan, Nigeria,* ²*Dept of Animal Science, Rivers State University of Science & Technology,* ³*Dept of Biology, Valdosta State University.*

Weight-age records of purebred NDama, a West African taurine beef cattle breed, were used to estimate growth curve parameters based on non-linear regression models of Brody, Von Bertalanffy and Richards and phenotypic relationships of the parameter estimates within each model. Records covered from birth to 69 months of age for 549 males and up to 84 months for 670 females accumulated over a 16-yr period at Fashola Cattle ranch in Oyo, Nigeria. Least squares estimates of asymptotic weight (A) from the models ranged from 386 ± 9.8 kg and 254 ± 4.6 kg in Von Bertalanffys function (model II) to 441 ± 33.2 kg and 273 ± 10.6 kg in Richards function (Model III) for NDama bulls and cows with a corresponding average maturing rate (K) of 0.032 and 0.044 kg.kg⁻¹.Mo⁻¹, respectively. Values of A and K for the breed average from the models were essentially intermediate between the two sexes. Estimates of integration constant (B) for the groups ranged from 0.46 ± 0.03 to 0.98 ± 0.02, while estimates of shape parameter (M) provided for only in Richards model were 0.91 ± 0.16, 0.68 ± 0.11 and 1.09 ± 0.38 for

Ndama males, females and breed average, respectively. The phenotypic relationship between A and K in the models were highly negative ($r_p = -0.76$ to -0.98), indicating that genetic selection for early maturity would lead to small mature weights and vice versa in NDama cattle. With minor exceptions involving Richards model, the pattern of relationships followed similar trends indicating that growth curve parameters in the different models measured similar growth characteristics. We show that growth curve parameters, their relationships and biological implications can improve our understanding of the growth and development pattern of NDama cattle under various production environments in the tropics.

Key Words: Non-Linear Models, Growth Curves, Cattle

M8 Analysis of daughter pregnancy rates and estimated relative conception rates for a bimodal distribution. H. N. Schlessner^{*1}, R. D. Shanks¹, S. L. Rodriguez-Zas¹, J. S. Clay², P. M. VanRaden³, P. J. Berger⁴, and M. H. Healey⁴, ¹University of Illinois Urbana-Champaign, ²Dairy Records Management Systems, ³Animal Improvement Programs Laboratory, ⁴Iowa State University, Ames.

The objective of this research was to determine whether daughter pregnancy rates (DPR) and estimated relative conception rates (ERCR) have a bimodal distribution for certain bulls as seen with perinatal survival. Perinatal survival rates were computed for 12,034 sons at Iowa State University. AIPL calculated DPRs for 48,117 sons. One hundred and seventy six bulls with a minimum of 50 sons had DPRs. Dairy Records Management Systems computed ERCRs for 3,276 sons from breedings in 1988 through 1997. Seventeen bulls had at least 50 sons with ERCRs and were included in the analysis. A kernel density procedure estimated density of DPR and ERCR for each bull. Three different bandwidth multipliers were used (1,2,3). Densities that were bimodal at bandwidth multiplier one but fail to remain bimodal at bandwidth multiplier two were considered unimodal. None of the bulls were bimodal for DPR or ERCR. Of the 21 bulls that were bimodal for perinatal survival, all 21 had DPRs but only five had ERCRs. A significant ($P < 0.0001$) correlation of 0.134 between DPR and perinatal survival (8552 sons) was found. This positive correlation indicates that bulls with higher DPR tend to have higher perinatal survival. The correlations between DPR with ERCR for 1996 (1346 sons) and DPR with ERCR for 1997 (1611 sons) were not significant, nor were the correlations between perinatal survival with ERCR for 1996 (463 sons) and perinatal survival with ERCR for 1997 (414 sons). A significant ($P < 0.0001$) correlation of 0.361 between ERCR for 1996 and ERCR for 1997 (541 sons) was found. From this research we conclude that daughter pregnancy rates and estimated relative conception rates do not have a bimodal distribution like the ones seen with perinatal survival.

Key Words: Daughter Pregnancy Rate, Fertility, Dairy Bulls

M9 Genetic variation in residual energy intake and its association with body weight, milk yield, fat corrected milk yield and economic merit in dairy cattle. P. Zamani^{*1}, S. R. Miraei Ashtiani¹, A. Naserian², M. Moradi Shahrbabak¹, and A. Nik-Khah¹, ¹Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Iran, ²Department of Animal Science, Faculty of Agriculture, University of Ferdowsi, Mashhad, Iran.

Residual energy intake is defined as the difference between actual energy intake and that predicted on basis of requirements for maintenance, lactation and body weight change. Residual energy intake is proposed as a measure of feed efficiency, because animal efficiency increases as the proportion of accountable energy intake increases or residual energy intake decreases. Variation in residual energy intake in relation to body weight, milk yield, fat corrected milk yield and economic merit (income over feed cost) was investigated using 2589 monthly records collected from 723 Holstein lactating cows in 3 herds. Energy requirements of each cow were estimated using NRC models. Genetic and phenotypic parameters were estimated using Derivative Free approach of Restricted Maximum Likelihood based on two-trait animal mixed model analyses. The model contained fixed effects of herd-year-season, parity number, stage of lactation (months after parturition) and random effects of animal genetic and permanent environment. Heritability estimation of residual energy intake was 0.17 ± 0.07 . Residual energy intake was negatively correlated to body weight, milk yield, fat corrected milk yield and economic merit, both phenotypically (-0.021 , -0.208 , -0.298 and -0.385 , respectively) and genetically (-0.031 , -0.363 , -0.465 and -0.618 ,

respectively). Fat corrected milk showed the most significant correlations with economic merit both phenotypically (0.635) and genetically (0.928). Because of its high correlations with residual energy intake and economic merit, more selection emphasis could be placed on fat corrected milk, when selecting indirectly for feed efficiency and economic performance.

Key Words: Dairy Cattle, Residual Energy Intake, Fat Corrected Milk

M10 Designer pork studies with small-scale farmers targeting niche markets. T. Barrios^{*1}, C. Talbott¹, T. See², and R. Pfortmiller³, ¹North Carolina Agricultural and Technical State University, Greensboro, ²North Carolina State University, Raleigh, ³National Swine Registry, West Lafayette, IN.

Small-scale producers may be able to secure a place at the pork industry table by producing a different type of pork than the the other white meat. By selecting for pork with higher levels of marbling, darker color and optimum pH levels, hog producers may be able to survive by marketing the other red meat through niche markets. Progeny sired from four different genetic populations of boars (not selected for lean conversion) were used to examine the potential to increase intramuscular fat in pork for niche-market application. Forty gilts were randomly assigned to one of four sire lines and bred artificially or by natural service. Upon detection of pregnancy, gilts were distributed to one of four participating farmers. Two castrates from each litter were identified with sire and sow lines and monitored through harvest. Carcass quality was assessed and IMF levels correlated with the presence or absence of the heart fatty acid binding protein (H-FABP) allele. Potential for conducting genetic studies with small-scale farmers are discussed.

Key Words: Designer Pork, Farmer Participatory Research, Niche Markets

M11 Contribution of inbreeding and recessive defects to early embryo loss. P. M. VanRaden and R. H. Miller^{*}, Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.

Lethal recessive genes that cause early embryo loss are difficult to detect because they may appear to be failed inseminations or missed heats. Nonreturn rate at 70 d after first insemination (NR70) was evaluated as a trait of the embryo from 1,739,055 first services using a nonadditive genetic model. Effects modeled included herd-year-season, parity of cow, sire of cow, service bull, interaction of service bull with sire of cow, and regression on inbreeding of embryo. Simultaneous solutions for all effects were not possible; thus, main effect variances were estimated using REML, and those effects were removed from the data. Interaction variance was estimated from the residuals using the tilde-hat approximation to REML. Service bull effects were assumed to be constant across time and unrelated. An additive relationship matrix was used for sire of cow and a dominance relationship matrix for the interaction term. Data included observations from January 1995 through January 2001 and represented 1,251 Holstein service bulls and sires of cows. For each 1% increase in inbreeding, NR70 declined by an estimated 0.096. A regression of this size could be explained by >20% of animals carrying defects that cause early embryo loss. Of the total variance, service bull contributed 0.36%; sire of cow, 0.24% (heritability of 1.0%); and interaction, 0.18% (dominance variance of 2.8%). Number of records per interaction averaged only 6 but with a maximum of 2,077, and 50 bull pairs had >500 records, which resulted in reliabilities of >50% for their interactions. Predicted interactions that included effects of inbreeding ranged from 3.6 to +2.9 as compared to the mean NR70 of 56%. The poorest interactions were not caused by known recessive defects. Complex vertebral malformation (CVM) generally causes loss of pregnancies later in gestation, and few current bulls carry the gene for deficiency of uridine monophosphate synthase (DUMPS). Further study of the families with poorest interactions could uncover new recessive defects.

Key Words: Fertility, Embryo Loss, Recessive Defects

M12 Relationships among measures of growth performance and plasma urea nitrogen (PUN) in barrows. J. Klindt*, USDA-ARS; U.S. Meat Animal Research Center, Clay Center, NE.

Our previous work [J. Anim. Sci. 81(Suppl. 2):36, 2003] showed that plasma concentrations of PUN are genetically regulated and moderately heritable, 0.35. Objective of the present study was to examine the relationships among measures of growth and PUN in grower/finisher pigs. Barrows, $n=96$, $BW=29.3\pm 0.5$ kg, 3 to 4 per litter, 27 litters, were assigned at 69 ± 0.5 d of age. Pigs were placed in individual pens and fed standard grower/finisher diets until slaughter at 118 kg BW. At slaughter, chilled carcass wt (ClDwt) and wt of trimmed lean cuts (Tlncut) were recorded. At 2-wk intervals during the trial BW, average of ultrasonic backfat at three sites, and feed consumption were recorded. At each weighing a blood sample was collected for determination of plasma urea nitrogen (PUN). Within pig PUN was averaged to obtain mPUN. Two pigs were removed before the end of the trial. Data recorded at the end of the trial was adjusted to average slaughter wt, 117.2 ± 0.3 kg. Daily change in average of three backfat measures (ADCBF), ADG, days to slaughter (Tday), final average backfat thickness (FnBF), ClDwt, Tlncut, and mPUN were affected ($P<0.05$) by litter. Litter affected ($P<0.08$) total feed consumed (Tfeed). Feed/d and efficiency of BW gain (Eff) were not affected by litter ($P=0.14$). For the subsequent examination of the relationship of mPUN with growth measures, pigs were classified as loPUN ($n=31$; mPUN, 26.1 to 36.1, mean= 32.1 mg/dL), medPUN ($n=32$; mPUN, 36.4 to 42.1, mean= 39.2 mg/dL), and hiPUN ($n=31$; mPUN, 42.4 to 91.3, mean= 54.3 mg/dL). PUN group influenced ($P<0.05$) feed/d, ADCBF, FnBF, and Tlncut. hiPun barrows had higher feed/d, ADCBF, and FnBF and reduced Tlncut. Effect of PUN group on feed/d, was nonlinear. Results concur with the reported low phenotypic and genetic correlations among PUN and growth measures [Klindt, et al., J. Anim. Sci. 81(Suppl. 2):36, 2003]. These results suggest that selection against PUN may be accomplished without significant sacrifices in growth performance.

Key Words: Plasma urea concentrations, Growth, Genetic influences

M13 Relationship between performance test traits and subsequent reproductive performance of Yorkshire females. Z. B. Johnson*¹ and R. A. Nugent, III², ¹University of Arkansas, Fayetteville, ²The Pork Group, Tyson Foods, Inc., Springdale, AR.

The objective of this study was to examine relationships between performance test traits and subsequent reproductive performance of Yorkshire females. Performance test records were collected in a commercial swine operation from 1992 to 1999. All females in the breed were grown to 100 d of age (AGE100; $n = 38,979$). At this time pigs were weighed (WT100) and selected for performance testing based on a combination of maternal and performance indexes with more emphasis given to the maternal index. Pigs were weighed at the end of the 77-d performance test (WT177; $n = 32,623$) and ADG calculated. Backfat (BF), loin eye area (LEA), and body length (LEN) were measured. Reproductive traits were number born live (NBA; $n = 3,140$ litters) and weaning weight (WWL; $n = 2,892$ litters) of the first litter. Genetic parameters were estimated using an animal model with litter effects and multiple-trait DFREML procedures. A series of two-trait models was conducted to estimate genetic correlations. Fixed effects for performance traits included contemporary group and either age at 100 d or age at 177 d as a covariate. Contemporary group was the only fixed effect for NBA; while age at weaning was included as a covariate for WWL. Estimates of heritability for NBA, WWL, WT100, WT177, ADG, BF, LEA, and LEN were $0.09 \pm .03$, $0.10 \pm .03$, $0.22 \pm .01$, $0.32 \pm .02$, $0.28 \pm .02$, $0.47 \pm .02$, $0.31 \pm .02$, and $0.23 \pm .02$, respectively. Genetic correlations for NBA with WT100, WT177, ADG, BF, LEA, and LEN were -0.43, -0.20, 0.06, 0.01, -0.17, and -0.11, respectively. Genetic correlations for WWL with WT100, WT177, ADG, BF, LEA, and LEN were 0.55, 0.14, -0.04, -0.05, -0.05, and 0.13, respectively. These correlations indicated that 100-d weight of the mother was more related to NBA and WWL than any performance trait measured. Females that weighed more at 100 d of age had smaller litter sizes, but greater weaning weight of the litter.

Key Words: Swine, Performance Traits, Reproductive Traits

M14 Evaluation of the effects of heterosis on reproductive efficiency and milk yield in South Florida. S. I. Madrid*, T. A. Olson, A. de Vries, C. A. Risco, and P. J. Hansen, University of Florida, Gainesville.

Holstein (H), Brown Swiss (B) and Guernsey (G) cows and their crosses were evaluated in South Florida. Levels of heterosis were determined for 305d ME milk production and days open. The herd was located in Okechobee County, Florida. The cows in this herd were grazed for the majority of the day along with supplemental feeding of concentrates. Records provided by Dairy Record Management Systems (DRMS) were utilized in the analyses. This herd had been utilizing crossbreeding for a period of at least 18 years. During the initial years the herd was composed primarily of Holstein and Guernsey cows. Brown Swiss sires and dams were later added to the herd. Breed composition for the animals in the project were determined by using pedigree records kept in DRMS files. Milk yield was analyzed using a model which included the main effects of year, month of calving, lactation number and breed composition. Heterosis levels for milk yield were 11, -1.4, 2.8, 5, -.05, -.004% for H X G, G X H, B X H, H X B, B X G and G X B respectively. Breed of sire is represented first in the cross. Only the heterosis level observed for the Holstein-sired cows from Guernsey dams was significant ($P < 0.05$). The lowest levels of heterosis for milk yield were found for crosses between the Guernsey and Brown Swiss breeds. Days open were calculated using only the last two calving dates of each cow (DYSOPCD). The data were edited to remove records for days open of less than 70 d, the voluntary waiting period practiced in this herd. The model used in the analyses of days open included effects of year, breed composition and lactation number. The days open for purebred H, B and G cows which were 165, 146, and 164 respectively. Days open for H X G, G X H, B X H, H X B, B X G and G X B were 154, 173, 143, 139, 131, and 179d, respectively. The average days open for all crossbred cows was 20 days shorter than that of the average of the purebred cows. The mean heterosis for days open was 10.5% ($P < 0.05$). Thus, these data indicate that while the effect of heterosis on milk yield was small the advantage for reproductive traits might be substantial.

Key Words: Crossbreeding, Dairy Cattle, Florida

M15 Analysis of sow longevity in commercial herds using competing risks. B. R. Southey*¹, S. L. Rodriguez-Zas¹, R. V. Knox¹, J. F. Connor², J. F. Lowe², and B. J. Roskamp², ¹University of Illinois, Urbana, ²Carthage Veterinary Services Ltd., Carthage, IL.

The length of time a sow remains in a herd or sow longevity is an important component of pork production. Removal of a sow from a herd can be due to many reasons including fertility failure, poor reproduction and litter performance, disease, injury, or death. Competing risks analysis of sow longevity provides a suitable approach to account for the different reasons of removal while accounting for the positive, non-normal and censored sow longevity data. Sow longevity records for 158,940 sows from 32 US commercial herds across five years were analyzed under independent competing risks. The reasons for removal were grouped into common categories including fertility, reproduction, litter performance, disease, injury, old age and death. The Cox proportional hazard model was used to analyze sow longevity including effects of genetic line, herd and year of entry. Genetic line included eight major genetic lines that were present in multiple herds. The relative hazard of removal between the major genetic lines varied depending on removal reason. No difference in hazard of removal was observed for fertility category. For the other removal categories the relative hazard of removal varied among the major genetic lines. For example, the hazard ratio for sow longevity between the Camborough 22 and Camborough 15 lines ranged from 0.43 for old age category to 1.3 for longevity related to poor reproduction. This indicated that Camborough 22 sows had a 60% lower hazard of removal due to old age and a 30% higher hazard of removal due to reproductive reasons than Camborough 15 sows. In contrast, under a single removal cause, the hazard ratio of Camborough 22 relative to Camborough 15 line for sow longevity was 0.87 indicating that Camborough 22 sows had a 13% lower hazard of removal than the Camborough 15 sows. These results illustrate the importance of accounting for removal reason in the analysis of sow longevity. The use of competing risks permits the elucidation of the decision process involved in sow removal and identification of opportunities for management intervention to maximize sow longevity.

Key Words: Longevity, Survival Analysis, Swine

M16 Estimation of correlation between maternal permanent environmental effects of related dams in beef cattle. H. Iwasaki¹, S. Tsuruta^{*2}, I. Misztal², and J. K. Bertrand², ¹Niigata University, Niigata, Japan, ²University of Georgia, Athens.

Correlation (λ) between maternal permanent environmental (MPE) effects of dams and their daughters was estimated using a maternal animal model for beef cattle. Two data sets for weaning weight consisted of 82,138 and 88,639 records of Gelbvieh (GV) and Limousin (LM) breeds, respectively. Numbers of dams and animals in the pedigree file were 39,678 and 121,390 for GV and 52,012 and 155,101 for LM, respectively. The model included fixed effects of contemporary group, sex of calf, age of dam at calving and month of calving; fixed regressions on age of calf; random direct genetic, maternal genetic, MPE and residual effects. The REML procedure was employed with a grid search, in which the likelihood was computed for a series of values for λ . Two models Model 1 without λ and Model 2 including λ were compared by a likelihood ratio test. Model 2 fitted the data significantly better than Model 1. The maximum restricted likelihood was obtained for λ of approximately 0.2 for both breeds. Estimates of residual and direct genetic variances were similar for both models. Compared with those of Model 1, estimates of maternal genetic and MPE variances of Model 2 increased and decreased slightly, respectively, for both breeds. Accordingly, the estimates of maternal heritability and the proportion of MPE variance to total variance for Model 2 were higher and lower, respectively, than those for Model 1. For Model 1, estimates of direct-maternal genetic correlation were 0.26 and 0.59 for GV and LM, respectively, while those for Model 2 were slightly lower (0.20 and 0.54). Pearson and rank correlations for direct and maternal effects were very high (>0.99) for both models. These results indicate that the relationship between MPE effects of two subsequent generations for weaning weight in both breeds is negative but low, and that the consideration of maternal environmental relationships between dams and their daughters in the models does not significantly affect the estimates of (co)variance components and may not be important in genetic evaluations.

Key Words: Maternal Permanent Environmental Correlation, AI-REML, Beef cattle

M17 Effects of climate and photoperiod on feed intake of beef bulls during feedlot performance tests. G. T. Tabler, Jr.^{*}, A. H. Brown, Jr., Z. B. Johnson, E. E. Gbur, Jr., I. L. Berry, D. W. Kellogg, and K. C. Thompson, *University of Arkansas, Fayetteville.*

Climate and photoperiod data were analyzed to identify and quantify impacts on feed intake of beef bulls during 52 post-weaning feedlot performance tests. Feed intake data originated from bulls ($n = 1,874$) in University of Arkansas Cooperative Bull Tests at Fayetteville, Hope and Monticello from 1978 to 1990. Bulls were given a 21-d adjustment period, then individually full-fed a total mixed ration twice daily in the same stall for 140 d. As formulated, the diet contained 1.6 Mcal NE_m, 0.9 Mcal NE_g and 12% CP per kg DM. Initial age and weight were recorded at start of each test with weights taken at 28-d intervals thereafter. Photoperiod and climate data were obtained from the U.S. Naval Observatory (Washington, DC) and National Climatic Data Center (Asheville, NC), respectively. Variables included maximum, minimum, average, and dew point temperatures; relative humidity; barometric pressure; rainfall; day length and wind speed. Data were pooled, divided into five 28-d periods, with each period analyzed separately using all animals over all tests. Initial age and initial weight were included in principal components regression as independent variables to adjust for initial animal differences. Principal component analysis was utilized to reduce the number of independent variables in the regression and overcome collinearity concerns associated with photoperiod and numerous climatic variables. Three principal components within each period accounted for 59% to 66% of the variability in explanatory variables. Nine to 14 components accounted for 97% to 100% of variability. Results provide additional information on effects climate and photoperiod have on cattle feeding and indicate photoperiod and climate conditions have differing effects on feed intake of feedlot cattle as feeding periods progress.

Key Words: Beef Cattle, Climate, Feed Intake

M18 Feed efficiency in the West Virginia Bull Test Evaluation Program. E. E. D. Felton^{*}, J. E. Warren, Jr., W. R. Wagner, and J. W. Yates, *West Virginia University, Morgantown.*

The "GrowSafe 4000E" system was installed and used to measure individual feed intake during the 2003-2004 West Virginia Bull Test Evaluation Program. This system of hardware and software consists of feed troughs mounted on load cells. An antenna grid is incorporated in the trough, and animals are fitted with electronic ear tags that are read by the antenna grid. An animal feeding at a trough is identified at five second intervals and feed available in each trough is weighed every second with an accuracy within 50g. The animal identification and feed consumed data are sent wireless via a communication panel to a computer with software to compile individual feed intake and individual feeding events. Bulls arrived at the test station in mid-October, 2003. Following a 3-week acclimation period, bulls were weighed on d 1 and 2: (averaged for on test BW; **IBW**), 42, 77, and 104 and 105 (averaged for off test BW; **FBW**). During the acclimation period and the 105-day test, bulls were fed *ad-libitum* a total-mixed-ration containing 13.6% crude protein and 73.6 and 45.0 Mcals of NEm and NEg per cwt, respectively. A subset of 98 Angus bulls (372 ± 22 days of age, $IBW = 375 \pm 45$ kg, $FBW = 582 \pm 48$ kg) was subjected to correlation analysis of feed:gain data from the beginning of the test to d 42 to various production and descriptive variables. Additional data will be included upon completion of test summary. Weak r-values existed ($P = 0.02$) with frame score (-0.23) and age of the bull (0.24) while much stronger r values existed ($P < 0.001$) with ADG over the entire test period (-0.62) and DMI expressed as a percentage of BW (0.43). There were no detected relationships with birth weight, age of dam, muscle score or longissimus muscle area, back fat and marbling scores measured by ultrasound at the end of the 105 d test period. Many of these variables are important to beef production and are currently used in the selection of sires and dams. These data indicate that it may be possible to also use feed efficiency as an additional selection tool without influencing other important selection variables.

Key Words: Feed Efficiency, Bulls, Beef

M19 Maternal and reproductive performance of crossbred cows mated to moderate or high weaning weight EPD sires. S. M. DeRouen^{*1} and F. A. Thrift², ¹Louisiana State University Agricultural Center, Homer, ²University of Kentucky, Lexington.

Maternal and reproductive performances were evaluated over 5 yr for Angus-, Brahman-, Brangus-, Gelbvieh-, and Gelbray-sired cows when mated to Simmental sires varying in weaning weight (WWT) EPD. Four moderate (MOD) (mean = 9.91 kg WWT EPD) and three high (HIGH) (mean = 17.98 kg WWT EPD) sires were mated to 307 cows by artificial insemination (AI). Accuracies of WWT EPD were > 0.80 . Cows were exposed to clean-up bulls for 60 d following AI. Statistical analyses were conducted using a generalized linear mixed model. Sire type x calf sex interaction was not significant for any response traits studied. A total of 120 AI-sired calves were evaluated. Least squares means for Julian birth date and birth weight for calves sired by MOD and HIGH growth sires were 47.7 d and 41.7 kg and 49.7 d and 44.4 kg, respectively, and did not differ ($P > 0.07$). Weaning weight and 205 d weight for calves sired by MOD and HIGH growth sires differed ($P < 0.04$) and were 271 kg and 248 kg and 284 kg and 261 kg, respectively. A total of 109 cows were evaluated for pregnancy rate while nursing MOD and HIGH growth calves, BW and BCS at weaning, BW and BCS at subsequent breeding, and subsequent pregnancy rate. Pregnancy rates were similar ($P > 0.90$) among cows nursing MOD and HIGH growth calves and were 96.0% and 96.5%, respectively. Body weight and BCS at weaning were 596 kg and 5.47 and 580 kg and 5.39 for cows nursing MOD and HIGH growth calves, respectively, and did not differ ($P > 0.33$). Subsequent BW and BCS at breeding were 600 kg and 5.52 and 579 kg and 5.35 for cows nursing MOD and HIGH growth calves, respectively, and did not differ ($P > 0.19$). Subsequent pregnancy rates were similar ($P > 0.70$) among cows nursing MOD and HIGH growth calves the previous year and were 91.7% and 93.6%, respectively. In conclusion, calf weaning weight differences were similar to sire weaning weight EPD differences and subsequent reproduction was not adversely affected for cows nursing high growth calves.

Key Words: EPD, Reproduction, Weaning Weight

M20 Selection for meat tenderness in Angus. L Praharani*, T. A. Olson, D. D. Johnson, R. L. West, and J. R. Alday, *University of Florida, Gainesville.*

The objective of this study was to evaluate the response to selection of Angus bulls for tenderness based on Warner-Bratzler Shear (WBS) values. The study began with Angus calves born in 1994. About 30-35 bulls were evaluated annually from those born from 1994 through 2000. After evaluation, three or four of the bulls with the highest and lowest WBS values were selected for use. Beginning in 1996, calves were sired by selected bulls. After the bull calves were expected to have reached puberty, at 13 and 14 months of age, semen was collected and frozen. The bulls were then slaughtered and their tenderness was determined using WBS evaluation. The semen from selected bulls was used to inseminate purebred and grade Angus cows at the Santa Fe Beef Unit Angus herd. Warner-Bratzler shear force data from a total of 262 bulls from 45 sires and 195 dams were collected. Analyses were performed to estimate variance and covariance components using AsREML. Genetic trends were plotted as averages of breeding values, estimated by the solution of animal model equations for year of birth, and overall trend was estimated as a regression of all breeding values on year of birth of calves. The average breeding value of progeny of sires selected for tenderness (-0.29 kg) was lower ($P < 0.05$) than that of sires selected for toughness (0.44 kg) over the years of the study. The estimate of direct heritability ($h^2 = 0.41 \pm 0.19$) was quite high. This estimate indicates that selection for meat tenderness in this manner might be effective. The genetic trends for WBS values tended to decrease over the years -0.0038 and -0.0149 kg per year for the progeny of tough and tender selected-sired, respectively. The breeding values of the progeny of both tender and tough selected sires declined. An explanation for declining breeding values of progeny of sires selected as tough is not clear but might be due to the low selection pressure applied in this study, since there were limited numbers of the bulls evaluated and it was not possible to collect freezable semen from all of the bulls prior to slaughter.

Key Words: Selection, Tenderness, Angus

M21 Genetic parameters estimated with multi-trait and linear spline random regression models using Gelbvieh early growth data. H. Iwaisaki¹, S. Tsuruta^{*2}, I. Misztal², and J. K. Bertrand², ¹Niigata University, Niigata, Japan, ²University of Georgia, Athens.

Estimates of direct and maternal genetic parameters in beef cattle were obtained by a random regression model with a linear spline function (SFM) and compared with those obtained by a multi-trait model (MTM). Most of SFM parameters are on the same scale as in MTM, simplifying validation and implementation. Weight data of 18,900 Gelbvieh calves were used, of which 100, 75 and 17% had birth (BW), weaning (WW) and yearling (YW) weights, respectively. The MTM analysis was conducted with a three-trait maternal animal model. The model included an overall linear partial fixed regression on age at recording for WW and YW, and direct-maternal genetic and maternal permanent environmental effects. The SFM included the same effects as MTM, plus direct permanent environmental effect, and heterogeneous residual variance. Three knots, or breakpoints, were set to 1, 205 and 365 d. (Co)variance components in both models were estimated with a Bayesian implementation via Gibbs sampling using flat priors. For BW with no variability of age at recording, a good agreement was observed between corresponding components of variances estimated from both models. For WW and YW, with the exception of the sum of direct permanent environmental and residual variances, there was a general tendency for SFM estimates of variances to be lower than MTM estimates. Direct and maternal heritabilities estimated with SFM tended to be lower than those estimated with MTM, some of which were particularly high. For example, the direct heritability for YW was 0.59 with MTM and 0.48 with SFM. Estimated negative genetic correlation for direct and maternal effects with SFM were lower than those with MTM. For example, the direct-maternal correlation for WW was -0.43 with MTM and -0.33 with SFM. Estimates by SFM may be superior to MTM due to accounting for constant days and also for random effects. The SFM is simpler to implement than a random regression model with Legendre polynomials.

Key Words: Random Regression, Linear Spline Function, Beef Cattle

M22 Estimated genetic parameters for growth, carcass, and tenderness traits of Brahman steers. D. E. Franke^{*1}, T. Smith¹, J. D. Domingue¹, T. D. Bidner¹, and J. C. Paschal², ¹LSU Agricultural Center, Baton Rouge, LA, ²Texas A&M University, Corpus Christi, ³University of Nebraska, Lincoln.

Purebred Brahman bull calves ($n=430$) were purchased at weaning from private breeders in Louisiana (1996 through 2000) to evaluate genetic (co)variation for growth, carcass, and tenderness traits. Calves were castrated, vaccinated, dehorned, dewormed, and backgrounded and grazed on ryegrass for an average of 120 d over the 5 yr period. Steers were fed in south Texas. Steers were harvested in groups of 20 to 30 head when the group reached 500 to 575 kg BW and 7 to 10 mm fat thickness. Carcasses were electrically stimulated and chilled for 24 hr. A 15-g 24 hr postmortem longissimus muscle sample was taken for calpastatin assay. A primal rib was purchased and 2.54-cm-thick steaks were cut for 14-d aging. Tenderness was determined by averaging the force required to shear six 1.26 cm cores taken parallel to muscle fibers. A full animal model was used to estimate genetic (co)variation in order to compute heritability and genetic correlations. Heritability estimates (\pm SE) were .33 (.14) for feedlot adg, .56 (.15) for hot carcass weight, .51 (.16) for ribeye area, .38 (.17) for fat thickness, .49 (.17) for yield grade, .38 (.16) for marbling score, .21 (.11) for shear force, and .44 (.17) for calpastatin activity. Most genetic correlations were below .25 with similar magnitude of standard errors. Exceptions were -.63 (.25) for yield grade and shear force and -.43 (.17) for marbling score and calpastatin activity. These genetic parameters indicate possible response from selection.

Key Words: Brahman Steers, Carcass Traits, Genetic Parameters

M23 The use of real time ultrasound to estimate variance components for growth and carcass traits in Nelore cattle. C. U. Magnabosco^{*1,2}, F. R. C. Araujo^{1,3}, F. Manicardi⁴, J. R. Hofig Ramos⁵, C. U. Faria², R. B. Lôbo⁶, L. A. F. Bezerra⁶, T. R. Famula¹, and R. D. Sainz¹, ¹University of California, Davis, ²Embrapa Cerrados, Bolsista CNPq, ³Aval Serviços Tecnológicos S/S, ⁴Grupo OMB, ⁵Grupo HoRa, ⁶Universidade de São Paulo.

Real-time ultrasound (RTU) technology was used for collection of data on carcass traits thg Nelore cattle in Brazil, for longissimus muscle area (ULMA), backfat between the 12th and 13th ribs (UFAT), and rump fat at the P8 site (URFAT). The data were collected on ranches in southeastern and midwestern Brazil (Grupo OMB and Grupo HoRa, participants of the Program for Genetic Improvement of the Nelore Breed - PMGRN). The final data set contained 1,721 animals at approximately 15, 18, 21 and 24 months of age, that were produced by 85 different sires. These data were analyzed to estimate genetic parameters and calculate Expected Progeny Differences (EPDs). The pedigree file used for calculation of the inverse numerator relationship matrix contained 25,941 animals, including those augmented so that each animal with data had two ancestral generations. The linear model included fixed effects for contemporary groups (herd-year-season-sex) and age of dam at calving. The model also included random effects for direct genetic effects. Data were analyzed using both a single and bivariate animal model. A Multiple Trait Derivative Free Restricted Maximum Likelihood (MTD-FREML) was used to establish the variance components and genetic parameters. Heritability estimates for ULMA, UFAT and URFAT were 0.29, 0.44, and 0.62, respectively. The EPDs for all traits presented a range that allows the possibility to significantly improve carcass quality in Nelore cattle. Ultrasound scan data produced consistent and heritable results for Nelore cattle and they may be used in genetic evaluation schemes to improve carcass traits.

Key Words: Beef Cattle, Carcass Traits, Genetic Evaluation

M24 Assessment of temperament at weaning in calves produced from diallel matings of Angus, Brahman, and Romosinuano. D. G. Riley^{*1}, C. C. Chase, Jr.¹, S. W. Coleman¹, R. D. Randel², and T. A. Olson³, ¹USDA, ARS, Brooksville, FL, ²TAES, Overton, ³University of Florida, Gainesville.

Objectives were to assess breed differences and estimate genetic effects for measures of temperament in cattle: exit velocity (m/s; higher values may indicate more excitable temperament) of calves when released from a squeeze chute; chute score and pen temperament score, the subjective evaluations of calf behavior when confined in a chute or approached in

an open pen. Scores were rated from 1 to 5; higher scores indicated more nervous or aggressive behavior. Calves (n = 657) were from diallel matings of Angus (A), Brahman (B), and Romosinuano (R; tropically adapted Colombian breed). Fixed effects included breed (n = 9), calf sex, year (n = 2), farm (n = 3), day of record (n = 3; 0, 24, or 72 h post-weaning). Order through the chute and calf age at weaning were covariates. Random effects were calf and sire. BB (sire and dam breed, respectively) calves had the highest values for exit velocity, chute score, and pen score (2.41 ± 0.1 m/s, 2.42 ± 0.06 , 3.31 ± 0.09); all were higher ($P < 0.05$) than all other breed groups for chute and pen score, and had higher ($P < 0.05$) exit velocity than all but BA and AB. RR calves had the lowest exit velocity (1.66 ± 0.07 m/s), lower ($P < 0.05$) than all but AA, RA, and AR. AA calves had the lowest values for chute and pen score, lower ($P < 0.05$) chute score than all but RR, and lower ($P < 0.05$) pen score than all but RR and RA. Estimates of direct breed effects for exit velocity ($P < 0.001$) were 0.68 ± 0.16 m/s for B and 0.49 ± 0.14 m/s for Romosinuano. Estimates of direct effects for chute and pen score were highly significant for B (0.91 ± 0.1 and 1.13 ± 0.15), A (0.5 ± 0.1 , 0.6 ± 0.14), and R (0.41 ± 0.09 , 0.52 ± 0.13). Estimates of heterosis ($P < 0.05$) were 0.21 ± 0.09 m/s (7.4%) for exit velocity for B with A, 0.12 ± 0.05 (3.1%) for chute score for A with R, and 0.18 ± 0.08 (3.2%) for pen score for R with B. Results suggest that R may be included in similar breeding programs without detrimental temperament changes.

Key Words: Brahman, Romosinuano, Temperament

M25 Estimates of adaptability and stayability for postweaning weight gain in crossbred beef cattle raised in five environments in Brazil. J. C. d. C. Balieiro^{*1,2}, J. B. G. Barros², J. B. S. Ferraz¹, J. P. Eler¹, E. d. S. Balieiro^{*3}, L. G. G. Figueiredo¹, and E. C. Mattos¹, ¹University of São Paulo, Duqu de Caxias Norte, 225. Pirassununga/SP-Brazil, ²University Center of Av. Dr. Octavio da Silva Bastos, S/n. S. João da Boa Vista/SP-Brasil, ³Federal Rural University of Rio de Janeiro, Rodovia BR-465, km 47. Serpédica/RJ-Brasil.

This study was conducted to evaluate adaptability and stability parameters of nine genetic compositions of crossbred European-Zebu cattle raised in five different Brazilian environments. Data (n=16,546) from the present study refer to characteristic gain from weaning up to 160 days postweaning. The statistical model included the effects of genetic composition (G), environment (E), GxE interaction and contemporary group within E. Also included was a covariate adjustment for cow's age at calving (linear and quadratic). All sources of variation in the analysis were highly significant ($P < 0.01$). The decomposition of the GxE interaction was accomplished by regression method. Intercepts ($\beta_{0(i)}$) for genotypes 2, 3 and 5 showed the highest weight gains up to 160 days postweaning. On the other hand, the genotypes 7, 9, 8 and 6 showed the smallest postweaning gains. Based on t-tests for the angular coefficients ($\beta_{1(i)}$) adjusted for the environmental index from each environment, it was verified that only genotype 2 had general adaptability. In contrast, genotypes 1, 3, 4 and 5 were classified as having specific adaptability to favorable environments and genotypes 6, 7, 8 and 9 were classified as having specific adaptability for unfavorable environments. The variance components related to the deviations of the regression for the genotypes indicated that all genotypes had low stability. Genotypes 3 and 5 should not be considered completely undesirable since they had high weight gains and coefficients of determination from the regression. The adaptability analysis was efficient in discriminating among genetic types. However, the stability analysis was not effective in discriminating the variance components attributed to deviations from regression. In this case, it was necessary to use another approach (coefficient of determination) to aid in decision making.

M26 Interaction genotype and protein level on feed efficiency of Japanese quail in dry tropic weather. J. J. Portillo^{*1}, R. Barajas¹, M. A. Carmona², F. G. Rios¹, and G. Contreras¹, ¹FMVZ - Universidad Autónoma de Sinaloa (Mexico) Carr. Culiacan-Mazatlan km 3.5, ²FES Cuautitlan UNAM (Mexico) Cuautitlan Izcalli, Estado de México.

This study was conducted to evaluate the interaction genotype and protein level and protein level on egg production of Japanese quail, were used 515 females and 200 males of four strains: 1) HH, quails selected for high mature weight; 2) LL, quails selected for low mature weight; 3) HL, reciprocal crosses from males HH with females LL; and 4) LH, reciprocal crosses from males LL with females HH. At 52 days old, the quails was contained in batteries with five levels and four cage by level. In each cage, was allocated six females and two males. With base at arrangement combinatory, five cages of each strain was designated a 16, 19, 21, 24, and 27 % of crude protein (CP) level. During eight weeks, was registered egg production and egg weight from strain and protein level. Each week was measurement the feed intake (FI) only by three days consecutives. To evaluate the interaction genotype-protein level, was utilized a general lineal model of fixed effects by week, strain, protein, and interaction strain-protein level, the tendency on the response was determinate by orthogonal polynomials, a simple lineal regression was used to estimate protein level with better feed efficiency (FE). ANOVA shown effect ($P < 0.01$) in FE by week production, strain, protein level, than as interaction by week x strain, and strain x protein, the tendency by FE was lineal ($P < 0.01$) to strain HH, and quadratic ($P < 0.03$) to strain HL, LH and LL, with CP levels and FE estimated of 26, 20.5, 16, 16 %, and 0.246, 0.248, 0.219, 0.264, to strain HH, HL, LH and LL, respectively. It is concluded, that exist interaction genotype protein in FE to egg production in Japanese quail, and better FE in low mature

weight strain with 16 % CP, than high mature weight strain require 26 % CP.

Key Words: Protein Level, Feed Efficiency, Coturnix coturnix japonica

M27 Interaction genotype - protein level on egg quality of Japanese quail in dry tropic weather. J. J. Portillo^{*1}, R. Barajas¹, M. A. Carmona², F. G. Rios¹, G. Contreras¹, and I. V. Ferrer¹, ¹FMVZ - Universidad Autónoma de Sinaloa (Mexico) Carr. Culiacán-Masatlan km 3.5, ²FES Cuautitlan - UNAM (Mexico) Cuautitlan Izcalli, Estado de México.

To evaluate the interaction genotype and protein level on egg quality of Japanese quail, were used 639 eggs from four strain: 1) HH, quails selected for high mature weight; 2) LL, quails selected for low mature weight; 3) HL, reciprocal crosses from males HH with females LL; and 4) LH, reciprocal crosses from males LL with females HH. At 52 d old, the quails was contained in batteries with five leves and four cage by level. In each cage was allocated six females and two males. With base at arrangement combinatory, five cages of each strain was designated a 16, 19, 21, 24, and 27 % of crude protein (CP) level. From two weeks start hatching and every 14 d, during egg was collected by strain - CP level combination. The next measurement weight, length, width of eggs, dense albumin height, yolk height, and width. From these data, shape index (SI), yolk index (YI), and Haugh Units (HU) were calculated. To evaluate the interaction genotype-protein level, was utilized a general lineal model of fixed effect by week, strain, protein, and interaction strain-protein level, the tendency of the response determinate by polinomial and the means comparison was used contrasts. ANOVA shown effect ($P < 0.03$) in SI, YI, and HU, by week, strain, protein level, and strain x protein level, except to genotype-protein interaction in HU ($P = 0.20$). Was observed lineal response ($P < 0.01$) and difference between 16-19-21 vs. 24-27 % of CP ($P < 0.01$) in SI to strain HH with

79.12 vs. 77.96; strain LH, the lineal tendency ($P < 0.01$) was by difference between 16-19 vs. 21-24-27 % ($P < 0.01$) with 76.90 vs. 78.35; egg SI of strain HL and LL, was similar between CP level ($P > 0.10$) with 78.16 and 77.36. YI and HU were similar between CP levels ($P > 0.10$) in four strain, with 45.50, 43.37, 44.62, and 43.68 to YI, and 93.16, 92.52, 92.06, and 89.98 to HU in HH, LL, LH, and HL, respectively. It is concluded, than exist interaction genotype-protein level to SI and YI, but not to HU, although CP levels to 16 at 27 % was not affected YI and HU.

Key Words: Protein Level, Egg Quality, Coturnix coturnix japonica

M28 Effect of genotype and protein level on hatchability of Japanese quail in dry tropic weather. J. J. Portillo*¹, R. Barajas¹, M. A. Carmona², F. G. Rios¹, G. Contreras¹, and S. Aza¹, ¹FMVZ - Universidad Autonoma de Sinaloa (Mexico) Carr. Culiacan-Mazatlan km 3.5, ²FES Cuautitlan - UNAM (Mexico) Cuautitlan Izcalli, Estado de Mexico.

To evaluate the interaction genotype and protein level (IGP) on hatchability of Japanese quail in dry tropic weather, were incubated 5176 egg four strains, 1) HH, quails selected for high mature weight; 2) LL, quails selected for low mature weight; 3) HL, reciprocal crosses from males HH with females LL, 4) LH, reciprocal crosses from males LL with females HH. At 52 days old, the quails were contained in batteries with five levels, and four cage by level. In each cage was allocated six females and two males. With a base at arrangement combinatory, five cages of each strain was designated to consume 16, 19, 21 (control), 24 and 27 % PC. After two weeks of adaptation, each 21 days, egg hatch was selected and incubated with four repetitions by treatment. To evaluate the interaction genotype-protein level, was used a general lineal model to fixed effects by period, strain, protein, and interaction genotype-protein level, comparison means by orthogonal polynomials. ANOVA shown effect ($P < 0.01$) of period and protein, but not was strain ($P = 0.60$), and IGP ($P = 0.29$), with 71.35, 68.31, 64.79, 77.13, and 77.81 % for 16, 19, 21, 24 and 27 % respectively, with difference between control vs. others level ($P < 0.01$), the levels of 16-19 vs. 24-27 ($P < 0.01$), without difference between 16 and 19 ($P = 0.40$), and 24 and 27 % PC ($P = 0.86$). It is concluded that not exist interaction genotype-protein level on hatchability of fertile eggs, and 24 % is the better level.

Key Words: Protein level, Hatchability, Coturnix coturnix japonica

M29 Relationship between internal and external egg characteristics of Japanese quail. J. J. Portillo*, G. Contreras, F. G. Rios, and I. V. Ferrer, FMVZ-Universidad Autonoma de Sinaloa, Mexico Carr. Culiacan-Mazatlan km. 3.5.

With the objective of characterize the relationship between measuring internal and external egg of Japanese quail, were measured weight, length, width, height and width of yolk, and dense height of 1644 eggs. From this data were calculated: shape index (SI), yolk index (YI) and Haugh Units (HU). Data was conducted a descriptive analysis and correlation lineal simple (Pearson coefficients). Egg weight (13.89 ± 1.44) was related ($P < 0.01$) mainly with the width (26.93 ± 0.98 mm) with correlation coefficients of 0.82 to 0.90, length (37.01 ± 1.74 mm) 0.70 to 0.78 and width of yolk (25.99 ± 1.66 mm), 0.52 to 0.64. The width of the egg was related ($P < 0.01$) with the length, with coefficients of 0.44 to 0.51, as well as with the weight of yolk, 0.52 to 0.57. Length associates in negative form ($P < 0.01$) with SI (77.93 ± 3.39), -0.70 to -0.72, as well as width of yolk (0.48 to 0.53), and the height of yolk (11.40 ± 1.26 mm) 0.28 to 0.44. YI (44.24 ± 4.46) this determined ($P < 0.01$) for the height of the yolk (0.80 to 0.82) and in minor grade and negative form the width the yolk (0.17 to -0.41), while the measurements of yolk associate with values of 0.20 to 0.40. Haugh Units (91.85 ± 4.72) was determined ($P < 0.01$) for the dense albumin height (5.26 ± 0.90 mm) 0.98 to 0.99, and still when for their calculation the egg weight is employed, it has a null relationship ($P = 0.19$) whit is (0.01 to 0.05). The remainder of the correlations has a minor magnitud to 0.30. It is concluded that the most related positive measurements is weight and the width of the egg, length with the shape index, height of the yolk with the yolk with the yolk index, and the Haugh Units with dense albumin height, with negative relationship of the length of the egg with shape index.

M30 Interaction of Breed-by-Chitosan Supplementation on Growth and Feed Efficiency at Different Supplementing Ages in Broiler Chickens. Yoon O. Suk*¹ and Hyung C. Sung², ¹Sahmyook University, 26-21 Kongneung Dong, Nohwon-Ku, Seoul South Korea, ²EZ Life Science Co., Ltd., 335 Yangjae Dong, Seocho-Ku, Seoul, South Korea.

Three experiments were conducted to investigation the interaction of breed-by-chitosan supplementation on the major economic traits in broiler chickens. In experiment 1, one-day-old broiler chicks were fed ad libitum on a basal diet (CON-group) or basal diet containing chitosan at an inclusion level of 10.5 mg/bird/day (EXP-group). In experiments 2 and 3, the diets of 15-day-old broiler chicks were supplemented by the same amount of chitosan as used in experiment 1. In experiment 1, the mean body weight of the EXP-group chickens were significantly ($P < 0.05$) heavier in comparison with those of CON-group birds on day 21 of the experiment in two of three breeds. Furthermore, the EXP-group birds showed to be significantly ($P < 0.05$) heavier than the CON-group birds in all of the three breeds on day 28 and 35 of the experiment. Especially in the 35-day-old mean body weight, the EXP-group birds of Arbor Acres, Peterson, and Ross were significantly ($P < 0.05$) heavier by 121.8 g, 118.5 g, and 242.8 g than the CON-group birds, respectively. However, the body weights in experiments 2 and 3 did not significantly differ between the CON-group birds and the EXP-group birds fed with chitosan supplementation from day 15 post birth. The mean 15 35 d FCR of the EXP-group birds were generally lower ($P < 0.05$) than that of the CON-group birds in experiment 1 only. By the results of the analysis of variance, the breed-by-diet (chitosan) supplementation interactive effect on 35-day-old mean body weight and 1 35 or 15 35 day-old mean weight gains showed significant ($P < 0.05$) in experiment 1 only; however, these traits in both experiment 2 and 3 were not shown significant interaction of breed-by-diet supplementation. The interactive effects of breed-by-diet supplementation on the mean 15 35 d FCR. Results of these experiments indicate that dietary supplementation with chitosan for the improvement of growth or feed conversion ratio has an efficacy when the supplementation begins from one-day-old broiler chickens.

Key Words: Breed, Chitosan, Broiler

M31 Male and female fertility and hatchability in chickens: A longitudinal mixed model approach. R. L. Sapp*¹, R. Rekaya¹, I. Misztal¹, and T. Wing², ¹The University of Georgia, Athens, ²Cobb-Vantress, Inc., Siloam Sprints, AR.

The objective was to investigate different approaches for handling missing records and to develop and implement a multivariate longitudinal mixed model for the genetic evaluation of male and female fertility and hatchability in chickens. Traits recorded on a weekly basis were eggs set (E), fertility percentage (F), and percentage hatched of fertile eggs (H). Three approaches for handling missing records were investigated: 1) records with zero weekly laid eggs were removed and remaining records with missing F and H were predicted (M1); 2) missing records, including zero weekly laid eggs, were assumed known and equal to zero (M2); and 3) zero weekly laid eggs were assumed as a valid record and missing F and H were predicted (M3). A longitudinal mixed model was employed for the multiple trait analysis of E, F, and H. Fixed effects included week-flock, age of service sire, and age of hen; unrelated service sire, additive hen, permanent environment, and residual were included as random effects. Heritability estimates of E, F, and H ranged from 0.104 to 0.127, 0.055 to 0.074, and 0.059 to 0.074, respectively, using the three methods. Heritability estimate of E using M1 was significantly higher than estimates obtained from M2 or M3 suggesting that removing records of E that were zero was not the best approach. Heritability estimates of F and H using M2 were significantly larger than estimates obtained from M1 or M3 indicating that predicting missing F and H was a better approach than assuming missing F and H were zero. Correlations among the three traits were highest using M2 and lowest using M1. Pearson correlations indicate that virtually no reranking of animals or service sires was expected between M2 and M3 for the three traits. However, greater reranking could occur when using M1. Therefore, M1 should not be used for the analysis of longitudinal fertility and hatchability data in chickens. Furthermore, M3 seems to be the most ideal method for handling missing records.

Key Words: Eggs Set, Fertility, Percentage Hatched of Fertile Eggs

M32 Growth parameters of live body weight, feather and protein weight of four commercial laying-type pullet strains. R. Neme¹, N. Sakomura*¹, F. Fialho², E. Carrilho¹, and F. Santos¹, ¹Faculdade de Ciências Agrárias e Veterinárias-Universidade Estadual Paulista Jaboticabal-SP Brazil, ²EMBRAPA Bento Gonçalves - RS.

A study was conducted to evaluate the growth curves of four commercial laying-type pullet lines, from 1 to 18 weeks. 300 birds of each line, Hy line Brown (HLB), Hy line White 36 (HLW), Hisex Brown (HSB), and Hisex White (HSW) were distributed into 4 groups of 75 birds. Eight birds of each group were slaughtered weekly to determine the chemical composition and to measure feathers weight. The data were used to the Gompertz growth equation in order to estimate the growth parameters $W_t = W_m \exp(-\exp(-b(t-t^*)))$. The weights of body, feather, protein and fat contents at time t (W_t) were described in terms of the mature weight (W_m , g), their rates of maturing (b), and the time to reach the maximum rate of growth of each component (t^* , day). According to the growth parameters for live weight, the HLB, HSB and HSW showed lower b than HLW, consequently, those lines showed higher t and W_m than HLW. The brown pullets presented higher feathers weight at maturity (W_m) and b compare to the white pullets. The HLW took more time (58 days) to reach the maximum rate of feathers growth. In contrast to the results of live BW, this strain exhibited the lowest t, indicating that it was precocious to BW. The W_m and t for body protein weight for Hy line were higher than those of Hisex, however the b for Hy line were inferior to Hisex. The b for protein deposition showed that the pullets are near to the maximum development of lean and visceral tissue. The rates of protein deposition at maturity were higher for HLB than HLW and for HSB than HSW, which could modify the protein requirements, and show that the genetic provides differences in body composition.

Growth curve parameters for the pullet strains studied

Parameters	HLB	HLW	HSB	HSW
Live weight				
W_m	2060	1533	2064	1598
b	0.023	0.026	0.023	0.023
t^*	59	52	59	55
Feather weight				
W_m	165	158	157	142
b	0.032	0.026	0.032	0.028
t^*	55	58	56	55
Protein weight				
W_m	782	678	657	509
b	0.022	0.020	0.026	0.024
t^*	71	71	63	60

M33 A comparison of carcass fat variables in different meat-type breeds of chickens. Z. Niu*, F. Liu, and S. Zhai, College of Animal Science & Technology, Northwest Sci-Tech University of Agriculture & Forestry, Yangling, China.

The genetic characteristics of carcass and the cellularity of the adipose tissue were analyzed and compared when a Chinese local breed (White-feather Lueyang, WL), a modern commercial broiler strain (Arber Acres, AA), and their F1 achieved a common physiological age. The result demonstrated that, compared with AA and F1 broilers at a body weight of 1800 g, WL broilers had lower breast meat yield, higher leg meat yield, and lower abdominal fat weight ($p < 0.05$ or $p < 0.01$), and the slaughtering age of WL was 132 d, which is 3 times more than that of AA (43 d). The number of adipose cells of WL in the abdominal fat pad was significantly greater, but the size of adipose cells was smaller ($p < 0.01$). F1 broilers had a greater positive heterosis in growth rate and abdominal fat deposition. High-protein diet can significantly reduce fat deposition of broilers, and there is a greater interaction between genotypes and diets.

M34 Identification of virulence genes in Salmonella enteritidis required for survival in chicken infection. R. K. Gundelly* and Y. M. Kwon, University of Arkansas, Fayetteville.

Salmonella enteritidis (SE) is one of the most common serotypes of Salmonella causing food borne diseases in industrialized countries, which is frequently associated with chicken shell eggs. Persistent infection of SE in laying hens is an essential step for contamination of forming eggs. We have devised a genetic technique, termed transposon footprinting and demonstrated the utility of the technique in the rapid identification of SE genes that are required for survival during infection of 5-day-old chickens. The transposon-flanking sequences were amplified simultaneously from each pool of 24-30 random SE Tn5 mutants (input pool) and the mutants recovered from the spleen of infected chickens (output pool). Several mutants attenuated during infection were identified by the PCR bands that are present in the input pool but not in the corresponding output pool. We will continue the mutant screening, and the attenuated mutants identified in this screening will be tested for attenuation during infection of adult laying hens. We expect that the results of this study will contribute to the development of effective method to control egg contamination.

Key Words: Salmonella Enteritidis, Transposon Footprinting, Chicken

M35 Specific gene cloning and sequencing in pectoral muscle of Korean native chicken. S. Sun*, N. Kim, S. Kim, and D. Kim, Chonnam National University, 300 Yongbong-dong, Buk-gu, Gwangju, 500-577, Korea.

The objective of this study is to identify specific functional genes that related with growth in Korean native chicken (KNC). The KNC (12 months old, 2.4kg) and Cornish chickens (16 months old, 2.7kg) were obtained from Korean Livestock Research Institute. Pectoralis muscles were dissected and frozen immediately in liquid nitrogen. mRNA was subtracted by suppression hybridization method using PCR-select cDNA Subtraction Kit. Cloned cDNA were inserted in PCR4 Blunt-TOPO vector. The cloned vector was transformed in TOP 10 electro-competent cells. Cloned DNA was sequenced and the homology was compared with GEN-Bank in NCBI. The inserted DNA size was 0.5 - 1.0kb from agarose gel electrophoresis. Seven hundred cDNAs were sequenced and they were identified as triosephosphate isomerase, glyceraldehyde-3-phosphate dehydrogenase, 11-beta-hydroxysteroid dehydrogenase, carbamoyl phosphate synthase, endo-1,4-beta-D-glucanase, and makorin etc. Most genes were not specific in KNC. However, several candidates' genes were identified as a KNC specific DNA. We have been found eight (KNC-NDS-Clone 6, 8, 12, 13, 21, 22, 23, and 24) specific cDNA clones. These sequences were very low (less than 5%) homology in GEN-Bank. Three sequences were registered in GEN-Bank (Chicken, Korean native breast muscle cDNA clone KNC-NDS6, 8, and 21, Bankit 579658, 579768, 584343, respectively). The function was not confirmed yet, but they are related with pectoralis muscle development in chicken.

M36 Chicken and quail microsatellite primers are not efficient markers for guinea fowl. S. N. Nahashon*, N. Adefope, A. Amenyeu, and D. Wright, Institute of Agricultural and Environmental Research, Tennessee State University, Nashville.

Microsatellite markers are tandem repeats of short nucleotides which are abundant, evenly distributed and highly polymorphic in eukaryotic genomes. As such, they are a useful tool in poultry breeding. Microsatellite markers have been identified in genomes of poultry such as chickens and quail. Exchange of marker information between chickens, quail and other avian species such as guinea fowl would be an important step towards the construction of a high-resolution comparative genetic map of these poultry species of agricultural importance. Using the polymerase chain reaction, chicken and quail microsatellite markers were tested to see if they would be suitable as genetic linkage markers in guinea fowl. Eighty three percent (30/36) and 73 percent (19/26) of chicken and quail primers, respectively, amplified individual loci in guinea fowl. Fifty percent (15/30) and 42 percent (8/19) of the amplified loci using chicken and quail primers, respectively, were found to be polymorphic. These very few chicken and quail microsatellite markers that seem to work well in guinea fowl could be used as anchor points for comparative mapping.

However, more effort should be committed to developing guinea fowl-specific markers since those of chickens and quail may not be sufficient for studies in guinea fowl.

Key Words: Guinea Fowl, Microsatellite Markers, Polymorphisms

M38 Dioxin-induced changes in chicken macrophage (HD11) gene expression. N. Puebla-Osorio^{*1}, K. S. Ramos³, D. Abi-Ghanem¹, M. H. Falahatpisheh³, and L. R. Berghman^{1,2}, ¹Department of Poultry Science, Texas A&M University, College Station, ²Department of Veterinary Pathobiology, Texas A&M University, College Station, ³Center for Genetics and Molecular Medicine, University of Louisville Health Sciences Center, Louisville, KY.

In this study, we used specific chicken immune cDNA arrays (constructed at the Fred Hutchinson Cancer Research Center) to identify the transcriptional profile induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in chicken macrophages (HD11). The complete array contained 3,011 chicken lymphocyte cDNA spots representing 2,200 genes. Cultures of the chicken myelomonocytic line HD11, transformed by the myc-encoding MC29 virus, were exposed to two doses of TCDD (1 and 10 nM) for 6 and 12 h. Cells exposed to a similar amount of DMSO were used as the negative controls. Total RNAs were extracted using the Trizol method. The labeled cDNA samples (Cy3 and Cy5) were co-hybridized to an individual array. Scanning and image processing involved a GenePix 4000 scanner. The resulting images were analyzed using GenePix Pro 3.0. The Log₂ values of the median of ratios were used. Upon filtering, a total of 217 genes showed significant up- or down regulation, and were further analyzed using hierarchical clustering (HCL) and tree formation, k-means clustering, and self-organizing maps (SOM). Nine clusters were formed using tree average linkage of genes with similar expression. Seven clusters were selected from the SOMs. K-means clustering produced 6 clusters. At least a 2-fold up-regulation after 6 h of exposure to TCDD (regardless of the dose) and subsequent down-regulation after 12 h of exposure, was observed in the following genes: mitochondrial cytochrome C, M phase inducer phosphatase 2, lysosomal transmembrane protein, alpha enolase, and HSP70

M41 Preparation and characteristics of spent hen meat enzymatic hydrolysate. O. Sangthrapitikul, Y.C. Chen*, and T.C. Chen*, *Mississippi State University, Mississippi State.*

Excessive expansion of egg industry resulted in abundant availability of spent hen. Meat from spent hens is generally tough and poor in functional properties. Due to the inherent qualitative differences between broiler and spent hen meat, the spent hen meat has created a difficulty in its effective disposal.

Spent layer carcasses were obtained from a commercial spent hen processing plant and breast meat was hand-deboned. Bromelain (B), trypsin (T), papain (P), and *Aspergillus oryzae* protease (A) were purchased from Sigma Chemical Co. (St. Louis, MO). Fine ground breast meat, water, and enzyme were mixed and hydrolyzed in a water bath at 50°C for four hours. For optimal hydrolyzing pH selection, the pH of the meat suspension were adjusted by adding either 1N HCl or 1N NaOH. The enzyme activity was terminated by placing the reaction bottles in boiling water for 15 min. Optimal hydrolyzing pH and concentration were determined for each enzyme and enzyme combinations. The sensory characteristics of enzymatic hydrolysates were also investigated.

Data indicated that the optimal pH values for enzyme hydrolysis of spent hen breast meat suspension were: 5.0-7.0 for B, 6.0 for T, 5.0-7.0 for P, and 5.0-7.0 for A. One percent (w/w) of P and A based on raw meat weight showed the highest (P<0.05) hydrolysis efficacy, followed by 0.5% (w/w) and 0.1% (w/w). Considering the enzyme cost factor, the hydrolysates from A, P+A, P+B, and P+A+B were selected for sensory study. Undiluted enzymatic hydrolysates showed higher (P<0.05) scores in chickeny, meaty, mouth feeling, bitterness, and umami sensory

and HSP90. Consistently down-regulated genes included: inflammatory response-related MTMMP2 (matrix metalloproteinase 2), AKT1 (involved in TNF-related activation of NFκB), and oxidative-stress related neuronal NOS, among others. Specific primers will be designed for each of these genes and real-time PCR will be used for validation of the microarray data.

Key Words: Dioxin, Microarray, Macrophages

M39 The expression of genes related to egg production performance in the liver of Taiwanese country chickens. S. T. Ding^{*1}, Y. H. Ko¹, M. C. Huang², Y. P. Lee², and W. T. K. Cheng¹, ¹Dept. of Animal Science, National Taiwan University, Taipei 106, Taiwan, ²Dept. of Animal Science, National Chung Hsiung University, Taichung, Taiwan.

The purpose of this study was to detect expression of genes related to egg production performance in Taiwanese country chickens by suppression subtraction hybridization (SSH). Liver samples from two Taiwanese country chicken breeds (L2 and B lines) with very distinct egg production rates were taken for mRNA extraction. The SSH procedure utilized a kit from Clontech (PCR Select). Two-way subtraction was performed and the differentially expressed gene fragments were cloned into pGEM-T Easy TA cloning vector (Promega). cDNA from the high egg production line (L2) was subtracted by the cDNA from the low egg production chickens (B). The resulted clones were selected for sequence analysis by a genetic analyzer (ABI 3730). We have select 288 clones for forward subtraction and 96 clones for the reverse subtraction. These genes were subjected to further differential screening to confirm the differential expression of genes between the two genetic breeds of chickens. We found that at least eight genes expressed greatly in the liver of L2. Among the genes were chicken apoVLDLII, liver basic fatty acid-binding protein, and two novel genes. We have also found that a glucose-regulated protein and chaperonin T-complex protein 1 were highly related to the poor egg production trait. The chicken apoVLDLII and liver basic fatty acid-binding protein in the liver involved in the egg yolk ingredient deposition. Greater expression of these genes assures more egg forming capacity in order to generate greater egg production rate. Specific functions of the other genes for egg production need to be further investigated.

Key Words: Chicken, SSH, ApoVLDLII

M40 Withdrawn by author. . .

PSA-Processing and Products

attributes compared with the controls but there were no (p<0.05) difference on all sensory attributes among those enzyme hydrolysates. Generally, P+A showed the highest acceptability in sensory attributes among treatments followed by P+A+B, A, and P+B. Considering enzyme efficacy, cost, and sensory attributes, P+A and P+A+B were recommended for spent hen meat hydrolysate preparation.

Key Words: Spent Hen Meat, Enzyme, Hydrolysate

M42 Spent hen meat enzymatic hydrolysate as a flavoring base. O. Sangthrapitikul, Y. C. Chen*, and T. C. Chen*, *Mississippi State University, Mississippi State.*

Due to the inherent qualitative differences between broiler and spent hen meat, the spent hen meat has created a difficulty in its effective disposal. The industry is actively seeking new and alternative uses for spent hens. Proteins are the best sources of flavor because of their amino acids, peptide, and nucleotide components. Protein hydrolysates are the main products derived from protein hydrolysis and have been used specially for flavoring purposes, as savory flavors or taste enhancers. Fine ground spent hen breast meat and water (1:10 or 1:2) were blended and hydrolyzed with either Papain + Protease (P+A, 0.5% (w/w) of raw meat weight for each enzyme) or Papain + Protease + Bromelain (P+A+B, 0.33% (w/w) of raw meat weight for each enzyme) at their optimal hydrolyzing conditions in the water bath at 50°C for four hours. The enzyme activity was terminated by placing the reaction bottles in boiling water for 15 min. After cooling, either whole hydrolysates or

filtrates were used for product preparations. Freeze-drying and evaporation methods were used in preparing hydrolysate powders or paste accordingly. Yields and microbiological analyses of final products were measured.

Yields of white light and fine freeze-dried powders from P+A and P+A+B hydrolysate prepared at 1:10 (meat: water) filtrates were 22.8% (W/W) and 23.0% (W/W), respectively. Yields of freeze-dried whole hydrolysates were 26.0% and 24.8% for P+A and P+A+B, respectively. Meanwhile, freeze-dried powders from P+A and P+A+B hydrolysate prepared at 1:2 filtrates had 26.7% and 26.2% of yield, respectively, while the yields of concentrated paste from whole hydrolysates were 47.8% and 51.0% for P+A and P+A+B, accordingly. Both freeze-dried filtered hydrolysate and the freeze-dried hydrolysate products had a total aerobic plate count ranging from log 2.59 cfu/g to 2.97 cfu/g. Similar range of total aerobes (log 2.74 to 2.84 cfu/g) was obtained in concentrated paste products. No *Salmonella* and *E. coli* /Coliform were detected from the prepared products.

Key Words: Spent Hen Meat, Enzymatic Hydrolysate, Flavoring Base

M43 *Listeria monocytogenes* prevalence and distribution within a poultry further processing plant over 12 months. M. E. Berrang*¹, R. J. Meinersmann¹, J. F. Frank², and D. P. Smith¹, ¹USDA-ARS-Russell Research Center, Athens, GA, ²University of Georgia, Food Science and Technology, University of Georgia, Athens.

In light of recent outbreaks and FSIS directives, it is important for poultry further processors to define the potential for cross contamination or cooked product re-contamination with *Listeria monocytogenes*. The objective of this study was to determine the prevalence of *L. monocytogenes* in a commercial poultry further processing plant. Furthermore, the effect of production shift activities on the spread of the organism was examined. One line producing fully cooked product was sampled 9 times over the course of a year (approximately every 6 weeks). Environmental sites were sampled by sponge or swab between sanitation and start up of production (pre-op) and again after an entire 8 hour shift was completed (post-op). Sample sites on both the raw and cooked side of the line included drain pipes, drain covers and condensate drip tubes from overhead coolers. Further pre-op and post-op sampling was conducted on cooked product contact surfaces. During the course of the production shift, purge from each bin of raw meat used for product formulation was collected and variable additional samples (16 per sample day) were collected in an effort to hunt for the organism. All samples were cultured using the FSIS *L. monocytogenes* protocol of preenrichment in *Listeria* enrichment broth and selective enrichment in Fraser broth. Darkened Fraser broth was plated on modified oxford agar and isolates were confirmed as *L. monocytogenes* using the FSIS cultural confirmation protocol. In 7 of 9 samplings at least one drain on the raw side was positive before production began. Raw side drains were positive at post-op in 8 of 9 trips. *L. monocytogenes* was never detected in cooked side drains or on product contact surfaces at pre-op; however, in 5 of 9 samplings one floor drain was positive at post-op. Despite such drain contamination, *L. monocytogenes* was not detected on any cooked product contact surface. *L. monocytogenes* was detected in raw meat used for product formulation in 8 of 9 samplings suggesting a possible source of plant contamination.

Key Words: *Listeria*, Processing, Environment

M44 Antimicrobial susceptibility patterns of *Salmonella* from fresh whole chicken carcasses. S. R. Ladely*¹, M. E. Berrang¹, P. J. Fedorka-Cray¹, M. Simmons², and D. L. Fletcher³, ¹USDA-ARS-Russell Research Center, Athens, GA, ²University of Georgia, Food Science and Technology, University of Georgia, Athens, ³Poultry Science, University of Georgia, Athens.

Salmonella is frequently reported as a cause of food-borne illness. The emergence of antimicrobial resistant *Salmonella* associated with food animals and their products has heightened concerns regarding antimicrobial use in food animal production. Eighty *Salmonella* isolates recovered from fresh whole chicken carcasses purchased at retail outlets were examined for susceptibility to 18 antimicrobials. Fifteen serotypes were identified; predominant serotypes included; *S. Heidelberg* (25%), *S. Typhimurium* var. *copenhagen* (18.75%), *S. Kentucky* (17.5%), *S. Berta* (11.25%), and *S. Hadar* (8.75%). Across all serotypes, 43.75% of the isolates were resistant to one or more antimicrobial. Fourteen

resistance patterns were observed among the isolates. Among these isolates, 22.5% were resistant to 3 or fewer antimicrobials, 16.25% were resistant to 4-6 antimicrobials, and 5.0% were resistant to 7 or more antimicrobials. Across all serotypes, resistance was most commonly observed to tetracycline (25%), ampicillin (22.5%), streptomycin (21.25%) and cephalosporin derivatives (cephalothin 18.75%, ceftiofur 16.25%, and cefoxitin 15%). Resistance patterns tended to group by serotype, however, 3 resistance patterns were common among different serotypes. The prevalence of antimicrobial resistance varied by serotype, ranging from 20% for *S. Heidelberg* to 100% for *S. Hadar*. All 7 *S. Hadar* isolates were resistant to 1-2 antimicrobials, 4 of 20 *S. Heidelberg* isolates were resistant to 3 or fewer antimicrobials, 10 of 15 *S. Typhimurium* var. *copenhagen* isolates were resistant to 4-5 antimicrobials, 7 of 14 *S. Kentucky* isolates were resistant to 1-7 antimicrobials, and 3 of 9 *S. Berta* isolates expressed resistance to 9-11 antimicrobials. These data indicate that *Salmonella* recovered from retail poultry carcasses may be resistant to multiple antimicrobials, and that resistance among these isolates varies by serotype.

Key Words: *Salmonella*, Antimicrobial Resistance, Chicken

M45 Influence of irradiation and storage on the quality of ready-to-eat turkey breast rolls. M. Zhu*, A. Mendonca, E. J. Lee, and D. Ahn, Iowa State University, Ames.

Influence of irradiation and storage on the quality of ready-to-eat (RTE) turkey breast rolls was investigated. Commercial oven roasted turkey breast rolls purchased from local stores were sliced and vacuum packaged. The sliced samples were randomly divided into three groups and irradiated at 0, 1.0, or 2.0 kGy using a Linear Accelerator. Color, 2-thiobarbituric acid reactive substances (TBARS), sensory characteristics and volatiles were measured at 0, 7 and 14 days of storage. Irradiation increased color a*-value of turkey breast rolls. TBARS values were not influenced by irradiation and storage. The production of acetaldehyde increased with storage time and irradiation dose. Irradiation also increased the production of 3-methyl butanal and 2-methyl butanal, which were suggested to be radiolytic product of leucine and isoleucine, respectively. However, there was no difference in hexanal content. Both 1.0 and 2.0 kGy irradiation greatly increased the amount of dimethyl disulfide. Irradiation also induced other sulfur compounds but at lower amounts. Irradiation of RTE turkey breast, especially at 2.0 kGy, significantly increased the production of benzene. The production of toluene in turkey breast was increased but to a less extent. Since both benzene and toluene have negative effects on health, their formation during irradiation warrants further studies to control the formation of these compounds. Sensory panelists pointed out that both sulfury odor and flavor of turkey breasts irradiated at 2.0 kGy were stronger than those of non-irradiated, but the sulfury odor and flavor of samples treated at 1.0 kGy were not significantly different from those of non-irradiated control. It was concluded that irradiation significantly influenced the odor and flavor of RTE turkey breast rolls under vacuum packaging conditions. Therefore, strategies to prevent negative changes in the quality of irradiated RTE turkey breast roll are needed.

Key Words: Ready-To-Eat Turkey Breast Roll, Irradiation, Volatiles and Sensory Characteristics

M46 Effects of extended storage on egg quality factors. D. R. Jones* and M. T. Musgrove, Russell Research Center, Poultry Processing and Meat Quality Research Unit, USDA-ARS, Athens, GA.

Eggs were collected from a single in-line processing facility once a week for three weeks (replicates). All eggs were stored at 4C and 80% RH for the 10 wk. Analyses began the day after collection and continued each week of storage. Two dozen eggs were examined for egg weight, albumen height, Haugh unit, shell strength, and vitelline membrane strength. Pooled egg yolks were analyzed for color values. Eggs from the second replicate were significantly ($P < 0.0001$) heavier than the other replicates by an average of 3 g. During storage, egg weight decreased ($P < 0.0001$) from approximately 61 g to 57 g after 10 wk of storage. Albumen height was approximately 2 mm higher for the eggs in replicate two compared to the other replicates ($P < 0.01$). On average, albumen height decreased with extended storage ($P < 0.0001$) from 7.05 mm to 4.85 mm. Haugh unit values decreased during cold storage from 82.59 to 67.43 ($P < 0.0001$). There were no differences between replicates for Haugh unit values. No differences were detected for shell strength

between replicates or during extended storage. A significant difference ($P < 0.05$) was found in detectable force required to break the vitelline membrane between treatments. This difference was less than 0.05 g. The elasticity of the vitelline membrane decreased during storage ($P < 0.01$) remaining low after 6 wk. Significant differences were detected for L^* , a^* and b^* values. While numerically these differences existed, they were below the degree detectable by the human eye. Therefore, these differences would have no effect on consumer perceptions. Extended cold storage did lead to decreases in egg weight, albumen height and Haugh units. Average Haugh unit values were still within the range of A grade. Shell strength was not affected by the extended storage. Vitelline membrane elasticity also decreased which could lead to yolks more easily rupturing as consumers cracked the eggs.

Key Words: Egg, Storage, Quality

M47 Chemical analyses of commercial shell egg wash water collected from three different operations. J. K. Northcutt*, M. T. Musgrove, and D. R. Jones, *USDA, Agricultural Research Service, Russell Research Center, Athens, GA.*

A study was conducted to evaluate egg wash water from in-line shell egg processing facilities (Plants X, Y and Z). Water samples were collected from the tap, washer 1 (W1) and washer 2 (W2) in each facility. Samples were evaluated for chemical oxygen demand (COD), total Kjeldahl nitrogen (TKN), total suspended solids (TSS), total dissolved solids (TDS), pH, temperature, chlorine and soluble iron. Values for COD, TKN, pH, temperature and chlorine varied significantly among the facilities ($P < 0.05$). Sample (tap, W1 or W2) had a significant effect on COD, TKN, TSS, TDS, pH, temperature, chlorine and soluble iron ($P < 0.05$). COD values for both W1 and W2 followed the order of: Plant Z > Plant X > Plant Y. Wash water had COD values that ranged from 7300 mg/L to 1765 mg/L. TKN values for the wash water ranged from 302 mg/L to 81 mg/L. Highest values for TSS and TDS occurred in W1 (601 mg/L and 5287 mg/L, respectively) as compared to W2 (401 mg/L and 3087 mg/L, respectively). Wash water pH varied from pH 11.4 (W1, Plant Z) to pH 10.0 (W2, Plant X). No difference was found in the pH of tap water which averaged from pH 6.1 to 6.7. Wash water temperature ranged from $44.1 \pm 0.1^\circ\text{C}$ to $39.7 \pm 0.3^\circ\text{C}$, and was generally highest in W2 samples from all three plants. Chlorine levels in the wash water for Plant Y (0.89 mg/L, W1; 0.91 mg/L, W2) were significantly lower ($P < 0.05$) than the levels for Plant X (2.72 mg/L, W1; 2.62 mg/L, W2) or Plant Z (4.5 mg/L, W1; 2.35 mg/L, W2). Chlorine levels in the tap water were similar among the facilities and ranged from 0 to 0.15 mg/L ($P < 0.05$). Average values of soluble iron (ferrous) in the egg wash water were 0.29 ± 0.02 mg/L to 1.60 ± 0.29 mg/L; however, iron levels were found to be above the 2.0 mg/L guideline in W1 for Plant X during one of the sample collections. Data provided by the present study may be useful for identifying process deficiencies and minimizing organic and inorganic discharge loads in the waste stream.

M48 Evaluation of carcasses obtained from broilers fed with ostrich oil and/or soybean oil as energy source. W. Martinez, E. Posadas, E. Avila, and M. P. Castañeda*, *Universidad Nacional Autónoma de México, Salvador Díaz Mirón s/n, Col Zapotitlan, México D.F.*

Ostrich oil is a waste product from the production of leather and meat on Mexican ranches. The objective of this study was to evaluate carcass yield, breast, leg and thigh yields, pigmentation, and fatty acid profiles in meat obtained from broilers fed with ostrich oil and/or soybean oil.

Four hundred twenty broiler chickens (Ross x Ross) were randomly distributed in four treatments with five trials of 21 chickens each. The treatments were as follows: T1 (5% soybean oil in both feeding phases), T2 (5% ostrich oil in both feeding phases), T3 (5% soybean oil in starter feed and 5% ostrich oil in finisher feed) and T4 (5% ostrich oil in starter feed and 5% soybean oil in finisher feed). At 49 days, the birds were processed under commercial conditions and pigmentation, carcass yield, breast, leg and thigh yield, and fatty acid profile (Folch's method) were determined. There were no statistical differences among treatments ($P < 0.05$) for the weight of the carcass, weight of carcass with viscera, carcass yield and breast, leg and thigh yield, and yellowness value. The redness value was not significantly different after picking; however, after chilling T1 (7.79) was only significantly higher than T2 (4.962). The lightness value following chilling indicated T4 (71.79) was significantly higher than T1 (69.16). The results from the fatty acids profile indicated T3 and T4 had the highest content of lipids and saturated fatty acids in breast, leg and thigh. T4 had the highest content of monounsaturated fatty acids in breast and the T3 the highest in leg and thigh compared to the remaining treatments. The content of omega-3, omega-6 indicated that T4 had the highest concentrations in the breast and leg-thigh meat samples compared to the remaining treatments. T4 was significantly higher in omega-9 in the breast meat and T3 was significantly higher in omega-9 in the leg-thigh meat samples compared to the remaining treatments. The results obtained in the present study suggest that ostrich oil and soybean oil increased the polyunsaturated fatty acids levels without affect the yield and pigmentation levels. The ostrich oil is a viable option in the broiler feed as energy source.

Key Words: Ostrich Oil, Soybean Oil, Carcass

M49 Effects of post-defeathering electrical stimulation on moisture retention characteristics of broiler carcasses and phosphate-marinated breast fillets. L. L. Young*¹, D. P. Smith¹, J. A. Cason¹, R. J. Buhr¹, and J. M. Walker², ¹USDA, Athens, GA, ²Stork-Gamco, Inc., Gainesville, GA.

Processing technologies sometimes interact in a way that alters their individual functionalities. The objective of this study was to evaluate effects of simultaneous application of two such technologies, electrical stimulation (ES) of broiler carcasses immediately post-defeathering to improve texture of early harvested breast fillets and marination of breast fillets in sodium tripolyphosphate (STPP) solution to enhance moisture absorption and retention. Mixed-sex broiler chickens were conventionally slaughtered. Half were stimulated by pulsed electrical current (220 VAC, 2 s on, 1 s off) for 90 s immediately after defeathering and prior to evisceration and half remained unstimulated. After chilling, breast fillets were excised. Half the fillets from each stimulation treatment were marinated in STPP and half without STPP. Chiller water absorption by intact carcasses and pH and moisture absorption and retention by marinated fillets were observed. ES slightly depressed chiller water absorption by the carcasses (4.0% v. 4.6%), but its effect on breast fillets was much greater. ES improved marinade absorption by fillets (11.1% v. 9.6%) but did not affect cooking loss. Although the STPP increased fillet pH somewhat (6.28 v. 6.22), it had little effect on marinade absorption (10.1% v. 10.6%); however, fillets marinated without STPP lost more moisture in cooking than those marinated without STPP (17.6% v. 12.4%). No significant statistical interactions between ES- and STPP-treatments were observed in this study. These results suggest that ES affects chiller water absorption by broiler carcasses only slightly and has little effect on the efficacy of STPP in enhancing moisture absorption and retention by marinated breast fillets.

M50 DFD-like (dark, firm, dry) meat in a broiler commercial plant. J. Schneider^{2,3}, S. H. I. Oda¹, A. L. Soares¹, E. I. Ida*¹, P. D. Guarnieri², R. Olivo³, and M. Shimokomaki^{1,2}, ¹Department of Food and Drug Technology, Londrina State University, Londrina, PR, Brazil, ²Food Science Graduate Program, Faculty of Pharmaceutical Sciences, São Paulo University, São Paulo, Brazil, ³Globalfood Advanced Food Technology, Alberto Sampaio, São Paulo, S, Brazil.

It has been established there is occurrence of PSE (Pale, Soft, Exudative) chicken meat in commercial plants in Brazil. Attempts to control

its development are currently applied and one of them consists on the use of water shower spray to lower the chicken body temperature. This manoeuvre has been shown to be successful but it seems to be one cause of the appearance of DFD-like meat. The objective of this work was to evaluate the occurrence of DFD-like poultry meat and its functional properties in a commercial plant. Commercial Ross chickens were divided into two groups: Untreated Group (UG) (n=811) and Treated Group (TG) (n=425), without and with water shower treatments, respectively. Carcasses were refrigerated through water chiller and af-

ter deboning, fillet (*Pectoralis major*) samples were stored for 24h at 4°C and pH, L*, drip loss, cook loss, emulsion capacity were evaluated. Samples were classified as DFD-like, PSE and Normal meat based on the previous established parameters such as L*#880444.0 as DFD-like, L*#880553.0 as PSE and 44.0#8804L*#880453.0 as Normal. The results obtained for UG were 0.37, 21.95 and 77.68% for DFD-like, PSE and Normal meat samples, respectively while for TG the incidence was 0.94, 5.41 and 93.64% for DFD-like, PSE and Normal meat samples, respectively. Birds preslaughter treatment with water shower decreased PSE incidence and increased DFD-like occurrence reflecting the glyco-gen depletion. DFD-like meat showed pH values of 6.15 (± 0.23) similar to the Normal samples 5.93(± 0.26). In addition, DFD-like samples presented the values of L* 43.2 (± 0.53), drip loss 1.11% (± 1.01), cook loss 22.88% (± 2.65), emulsion capacity 0.70% (± 0.12) significantly different (p#88040.05) from the Normal samples of L*49.6 (p#88041.90), drip loss 2.55% (± 2.16), cook loss 25.38% (± 3.96) and emulsion capacity 0.78% (± 0.20). Finally, it is recommended DFD-like meat to be used as raw material to produce emulsified meat products with technological and cost benefits to the industries.

Key Words: Functional Properties, GLycogen Depletion, Abnormal Meat Color

M51 Biochemical and ultrastructural evaluation of PSE (pale, soft, exudative) broiler breast meat in a commercial plant. M. Shimokomaki^{1,2}, A. L. Soares¹, P. D. Guarnieri², R. Olivo³, E. I. Ida¹, R. M. G. Macedo¹, and J. Schneider^{2,3}, ¹Department of Food and Drug Technology, Londrina State University Londrina, PR Brazil, ²Food Science Graduate Program, Faculty of Pharmaceutical Sciences, São Paulo University, São Paulo, SP, Brazil, ³Globalfood Advanced Food Technology, Alberto Sampaio, São Paulo, SP, Brazil, ⁴Maringa State University, Maringa, PR, Brazil.

PSE meat is becoming a problem for the poultry meat industry and it has been demonstrated that it is the consequence of myofibril protein denaturation caused by pre-slaughter handling, particularly physical stress which promotes a rapid muscle pH decline at a relatively high body temperature. It is becoming a routine practice in Brazilian poultry industries to have water spray and air ventilation treatments just before broiler slaughter. The objective of this work was to investigate the influence of these practices on the quality of breast meat (*Pectoralis major*). The characteristics studied were the physicochemical and ultrastructural changes promoted by the biochemical/physiological events during the onset of rigor mortis. Commercial Ross chickens were divided into two groups: Untreated Group (UG) (n=608) and Treated Group (TG) (n=611), without and with water shower treatment, respectively. Drip loss was 3.74% for UG and 2.24% for TG and cook loss was 32.01% for UG and 28.04% for TG (p#88040.01). pH values were 5.85 (± 0.08) and 6.06 (± 0.10) for UG and TG, respectively while colour values were L*53.11 (± 1.50) and 48.78 (± 1.72) for UG and TG respectively, measured after 24h post-mortem both significantly different (p#88040.01). Histological studies of the PSE samples from UG birds 72h post-mortem revealed under light microscopy a shrinking of muscle cell diameter by approximately 10% in relation to TG samples (p#88040.01) and an extra cellular enlargement of endomysium and perimysium sheaths. By electron microscopy of PSE meat, Z-lines appeared fragmented, A-bands including the M-line disappeared and a super-contraction of sarcomeres was observed, indicating that proteins were adversely affected by heat stress. These results showed that water shower spray just before slaughter prevented chicken PSE meat development as determined bio-chemically and ultrastructurally.

Key Words: Breast Meat, Microscopic Evaluation, Myofibril Proteins

M52 Effect of feeding program and sex on productive performance and carcass quality of Iberian crossbred pigs. M. P. Serrano¹, D. G. Valencia¹, R. Lázaro^{*1}, M. Nieto², and G. G. Mateos¹, ¹Universidad Politécnica de Madrid, Ciudad Universitaria sn, ²Copese S.A. Conde de Sepúlveda 24.

A total of 192 crossbred (Duroc sire x Iberian dam) pigs were used to study the influence of the feeding program (energy level in isonutritive diets per kcal of NE during the growing period and source of added fat during the finishing period) on performance and carcass quality of Iberian-cross pigs. From 29 to 110 kg BW there were 6 treatments with 3 levels of energy (2.07, 2.21, and 2.35 Mcal NE/kg) and 2 sexes (castrated males and castrated females). From 110 to 145 kg half of the

pigs received a diet with 6% animal fat and the other half the same diet but with 6% olive soapstocks instead of animal fat. Each treatment was replicated eight times from 29 to 110 kg and four times from 110 to 145 kg and the experimental unit was a pen with 4 pigs. At the end of the trial males tended to grow more than females (846 vs 817 g/d; P#88040.10). Also, an increase in NE concentration of the diet tended to improve feed efficiency (3.99, 3.93, and 3.83 g/d, for low, medium, and high NE diets, respectively; P#88040.10). From 110 to 145 kg BW average daily gain was higher for males than for females (926 vs 875 g/d; P#88040.05) but source of fat did not affect any trait. Males had longer carcasses (86.7 vs 85.1 cm; P#8804 0.001), more proportion of shoulder (14.05% vs 13.82%; P#88040.05), and heavier loins (4.78 kg vs 4.46 kg; P#88040.01) than females; but carcass and ham yield were similar. Backfat and tarsus bone diameter were greater for males than for females (64.4 vs 62.0 cm and 17.5 vs 17.2 cm, respectively; P#88040.05). Experimental treatment did not affect drip losses or pH or temperature of *m. semimembranosus* at 45 min or 24 h *post mortem*. We conclude that an increase in NE of the diet in the growing period improved feed efficiency less than expected and that the type of fat did not influence fattening performance. Both sexes could be used to produce Iberian-cross carcasses with little differences in productivity and carcass quality when slaughtered at same BW.

Key Words: Iberian pigs, Net energy, Carcass quality

M53 Effect of sex and slaughter weight on productive performance and carcass quality of Iberian crossbred pigs. M. P. Serrano¹, D. G. Valencia², R. Lázaro^{*3}, J. Viguera⁴, M. Nieto⁵, and G. G. Mateos⁶, ¹Universidad Politécnica de Madrid Ciudad Universitaria sn, ²Copese S.A. Conde de Sepúlveda, 24.

A total of 360 crossbred (Duroc sire x Iberian dam) pigs were used to study the influence of sex (castrated males, CM, castrated females, CF, and entire females, EF) and slaughtered weight (145 and 155 kg BW) on performance and carcass quality. Each of the six treatments were replicated four times and the experimental unit was pen (15 pigs/pen). At the end of the trial pigs slaughtered at 155 kg BW ate more feed (2808 vs 2630 g/d; P#88040.01) and tended to be less efficient (3.65 vs 3.50 g/g; P#88040.10) than pigs slaughtered at 145 kg BW. Also, EF ate less and had better feed efficiency than CF or CM (2598 vs 2733 and 2825 g/d and 3.38 vs 3.67 and 3.68 g/g; P#88040.01, respectively). Pigs slaughtered at 155 kg had more carcass yield and tended to have higher trimmed ham yield than pigs slaughtered at 145 kg. Carcasses of pigs slaughtered at 155 kg BW presented higher pH (P#88040.01) and temperature (P#8804 0.001) at *m. semimembranosus* at 45 min or 24 h *post mortem* than carcasses of pigs slaughtered at 145 kg BW. Entire females had less carcass yield (80.0 vs 80.6 and 80.8%; P#88040.01) and carcass fat (55.6 vs 63.0 and 61.9 mm at P2 and 47.9 vs 55.0 and 54.4 mm at *m. Gluteus medius*; P#88040.001) than CM or CF. Also, EF had more loin yield at 24 h *post mortem* (4.0 vs 3.5 and 3.6% for cm and cf, respectively; P#88040.001) and higher trimmed hams and shoulders yields (18.2 vs 16.8 and 17.2% and 11.6 vs 10.9%; P#88040.001, respectively) than CM and CF. Entire females and CM had higher proportion of shoulders at 6 h *post mortem* than CF (17.1 and 16.9 vs 16.0%; P#88040.05). Castrated males had higher pH of *m. semimembranosus* at 45 min or 24 h *post mortem* (P#88040.001) than EF or CF. We conclude that EF had better productive performance and yield of primal cuts than CF or CM. Nevertheless entire females had less carcass yield than CF or CM. It is recommended to study in detail the possibilities of using EF instead of CF in commercial production of Iberian-cross pigs.

Key Words: Iberian Pigs, Sex, Carcass Quality

M54 Early postmortem pH influences proteolysis of cytoskeletal proteins during aging in porcine longissimus muscle. G. Bee^{*2}, S. M. Lonergan¹, and E. Huff-Lonergan¹, ¹Iowa State University, ²Swiss Federal Research Station for Animal Production and Dairy Products, 1825 Posieux, Switzerland.

The objective of this study was to determine the extent to which early postmortem (PM) pH decline influences proteolysis of the intermediate filament protein desmin and the costameric protein talin in the longissimus muscle (LM) of pigs from two genetic lines (A and B). Based on the 3 h pH (H = pH > 6.0; L = pH < 5.7) PM, 10 pigs per line and pH group were selected from 120 pigs. The average 3 h pH within pH group was 6.19 (H) and 5.41 (L) in line A and 6.27 (H) and 5.47 (L) in line B. LM samples were collected 24, 48, 72 h, and 7 d PM and percent

drip loss was measured after 1, 2, and 7 d PM. These samples were also used to monitor desmin and talin degradation by immunoblotting. The ratio (relative intensity of the 53 kDa band of desmin and 225 kDa band of talin in the samples/intensity of desmin or talin in a reference) was used as a measure of proteolysis. Drip loss at all time points was lower ($P < 0.01$) in the H-pH (d 1: 1.62%; d 2: 1.80%; d 7: 2.99%) than in the L-pH group (d 1: 3.11%; d 2: 3.40%; d 7: 4.72%) regardless of line. Drip loss was lower ($P < 0.01$) in line B (d 2: 2.04%; d 7: 3.14%) than line A (d 2: 3.15%; d 7: 4.56). Independent of the line, proteolysis of desmin was faster ($P < 0.03$) after 1 and 2 d in the LM from the H-compared with those from the L-pH group. At d 7, relative abundance of intact desmin was 45% lower ($P < 0.01$) in the LM from pigs of line B than line A. Compared to the L-pH group, relative abundance of talin determined in the LM 24, 48, 72 h, and 7 d PM decreased ($P < 0.03$) at a faster rate in the H-pH group. Line effects were found at 48 h PM with 46% less intact talin abundance in the LM of pigs from line A compared with those from line B. Disappearance of desmin was positively correlated ($r = 0.51$; $P < 0.01$) with the disappearance of talin. Furthermore, proteolysis of both proteins was positively correlated ($P < 0.01$) with percent drip loss. Degradation of cytoskeletal proteins is related to early postmortem pH and improves water-holding capacity.

Key Words: pH, Proteolysis, Water-holding capacity

M55 Oxidation, ionic strength, and pH affect porcine skeletal muscle calpain and calpastatin activity. K. R. Maddock*, E. Huff-Loneragan, L. J. Rowe, and S. M. Lonergan, *Iowa State University, Ames.*

The objective was to evaluate how oxidation affects activity of μ - and m-calpain and their inhibition by calpastatin at different pH and ionic strengths. Purified porcine skeletal muscle μ - or m-calpain (0.45 units) were incubated in the presence of calpastatin (0, 0.15, or 0.30 units) at pH 7.5, 6.5, or 6.0 with either 165 mM NaCl or 295 mM NaCl. The reactions were initiated with addition of CaCl_2 (100 μM for μ -calpain; 1 mM for m-calpain). Calpain was incubated with the fluorogenic peptide Suc-Leu-Leu-Val-Tyr-AMC (170 μM). Either 0 or 0.160 μM H_2O_2 was added to each assay. Activity was measured at 60 min. In a second experiment, calpain was incubated with highly purified porcine myofibrils (4 mg/ml) under conditions described. Either 0 or 100 μM H_2O_2 was added immediately prior to the addition of calpain. Degradation of desmin was determined with immunoblotting at 2, 15, 60, 120 min. Fluorescence activity was greatest ($P < 0.01$) at pH 6.5 for μ -calpain and 7.5 for m-calpain. No activity of m-calpain was observed at pH 6.0 at either ionic strength or at pH 6.5 at 295 mM NaCl and 0.160 μM H_2O_2 . In general μ - and m-calpain were less active at 295 mM NaCl than at 165 mM NaCl ($P < 0.01$). Oxidation decreased activity of both μ - and m-calpain ($P < 0.01$) at all pH and ionic strength conditions and decreased inhibition of μ - and m-calpain by calpastatin ($P < 0.01$). At pH 6.0, degradation of intact desmin was delayed compared to pH 7.5 or 6.5 and at 295 mM NaCl compared to 165 mM NaCl. Oxidation decreased proteolytic activity of μ -calpain against desmin at pH 6.0 and m-calpain at all pH conditions. Inhibition of μ -calpain by calpastatin was decreased by oxidation at pH 7.5 and 6.5. This is consistent with the observation that oxidation in the presence of calpastatin results in more proteolysis of desmin. Taken together, these results suggest that calpastatin may limit the possibility of oxidation-induced inactivation of μ -calpain.

Key Words: Calpain, Calpastatin, Oxidation

M56 The use of creatine as a means of improving the belly/bacon quality of market barrows fed 4.5 g/ton Paylean®. C. A. Stahl*, M. S. Carlson, T. B. Schmidt, G. Rentfrow, E. K. Burger, and E. P. Berg, *University of Missouri-Columbia, Columbia.*

The objective of this study was to determine if dietary supplementation of creatine monohydrate (in conjunction with high glycemic carbohydrate) influences the belly/bacon quality of market hogs fed 4.5 g/ton Paylean®. Barrows ($n = 128$; 85 kg) were blocked by weight and allotted to one of 16 pens (8 pigs/pen; 4 reps/treatment) using a completely randomized design. A pelleted corn-soybean diet containing 4.5 g/ton Paylean® (PAY) was tested against a positive control (PCON; pelleted corn-soybean diet formulated to meet or exceed the nutrient requirements of the growing pig), and pelleted corn-soybean diets containing

0.92% creatine and 2.75% dextrose (COMBO) and a combination of 4.5 g/ton Paylean®, 0.92% creatine, and 2.75% dextrose (PAYPLUS). Barrows were humanely harvested following 27 d on test. Fresh pork bellies ($n = 64$, 4/replicate pen) were obtained from the fabrication line and weighed. Bellies thickness was recorded as the average depth of eight separate quadrants. Uncooked bellies were then pumped using a commercial brine solution, weighed, hung by a bacon comb, placed on smokehouse trucks, and heat processed according to plant protocol. The following morning, individual bacon slabs were removed from the cooler, weighed, pressed and sliced. Following the removal of comb marks and incomplete slices, individual bacon slabs were weighed to determine slicing yield and divided into five separate sections. Bacon slices (1/section, 5/belly) were weighed and evaluated for subjective fracture analysis (shatter) and cooking loss. Treatment did not influence belly weight, average belly thickness, smokehouse yield, slicing yield, or shatter ($P > 0.05$). However, bacon slice cooking loss was lowest for PAY bellies (PAY: 56.84, PCON: 60.96, COMBO: 60.92, PAYPLUS: 59.75 +/- 0.97%, $P < 0.05$). These findings suggest that feeding creatine in conjunction with a high glycemic carbohydrate has no measurable influence on the belly/bacon quality of market barrows fed 4.5 g/ton Paylean® 27 d pre-harvest.

Key Words: Creatine, Paylean®, Bacon

M57 Physical parameters of lamb meat as affected by aging time. J. Zapata*, *Universidade Federal do Ceara.*

Fresh meat quality is generally associated with the physical aspect of the cuts at the retail market level. Functional properties of the meat, on the other hand, are important parameters to be considered by the further processing industry. The purpose of this study was to determine the effect of aging selected cuts (leg and loin) from tropical lambs on physical characteristics (pH, color and shear force) and functional properties (cooking losses, water holding capacity and emulsifying capacity) of the meat. Meats from the loin (*longissimus dorsi* muscle) and the leg (*semimembranosus* and *biceps femoris* muscles) of tropical lambs with average weight of 35kg were aged for 1, 7, 14 and 21 days at 1C. Meat pH values increased from 5.48 in day one to 5.56 on day 21 and showed a significant ($P < 0.05$) correlation with aging time. The color of the meat was not significantly affected by aging time. Shear force decreased from 8.86kg in day 1 to 6.77kg in day 21 of aging and showed a close correlation with aging time. A significant ($P < 0.05$) correlation of cooking losses with aging time was found in the meat with values increasing from 26.96 to 34.92% throughout the aging period. Meat water holding capacity varied ($P > 0.05$) from 33.85% on day 7 of aging to 29.82% on day 21. Emulsifying capacity of lamb meat decreased ($P > 0.05$) slightly during the aging period from 92.39 to 91.80%. It can be concluded that aging tropical lamb meat for 21 days at 1C does not affect color, water holding capacity or emulsifying capacity. The increase in meat pH, and cooking losses as well as the decrease in shear force are dependent on aging time and regression curves can be drawn for these attributes.

Key Words: Cooking Losses, Water Holding Capacity, Emulsifying Capacity

M58 Extracellular matrix (ECM) properties of lamb skeletal muscle as related to age and muscle. F. Filetti, G. Maiorano*, A. Ciarlariello, M. Gambacorta, and A. Manchisi, *University of Molise Campobasso, Italy.*

Decorin (D), being expected to facilitate the alignment of intramuscular collagen (IMC) fibers, could be followed by a rapid synthesis of hydroxylysylpyridinoline (HLP) crosslinks, which are regarded as main factors contributing to meat tenderness. To study relationships among D, IMC and HLP in skeletal muscle ECM, 24 Italian Merino male lambs were slaughtered in groups of equal number, at 5, 30, 50 and 70 d of age. *Longissimus dorsi* (LD), *semimembranosus* (SM) and *gluteobiceps* (GB) samples were lyophilized and hydrolyzed in 6N HCl for analysis of hydroxyproline (Hyp) and HLP. IMC was calculated assuming that it weighed 7.25 times the measured Hyp weight. HLP was quantified by RP-HPLC. Raw muscles were analyzed for D by immunoblotting with a polyclonal antibody to human D (1:5,000) and an alkaline phosphatase conjugated goat anti-rabbit IgG (1:30,000). D was quantified by densitometry. ANOVA was performed and relationships among variables were analyzed with simple linear regression. Muscle affected IMC ($P < 0.05$) and HLP ($P < 0.001$) amounts, and HLP/IMC ratio ($P < 0.05$). LD compared to SM and GB had lower amounts of IMC (22.0a, 29.1b,

31.9b $\mu\text{g}/\text{mg}$, respectively) and HLP (2.7a, 4.7b, 4.0c $\mu\text{g}/\text{mg}$, respectively). IMC was less mature in LD and GB than in SM, as showed by the HLP/IMC ratio (0.09a, 0.09a, 0.12b mol/mol, respectively). Muscle also affected ($P < 0.001$) D expression, which was higher in LD than in SM and GB (20.1a, 13.0b, 13.6b RDU/mg, respectively). Age clearly ($P < 0.001$) influenced ECM. In the first month of age, a marked reduction was found on IMC (66.0a, 28.5b, 25.4b, 26.1b $\mu\text{g}/\text{mg}$ at d 5, 30, 50, and 70, respectively) and HLP (7.2a, 3.1b, 3.4b, 4.2c $\mu\text{g}/\text{mg}$) amounts. In the same period a sudden rise was detected on D (11.6a, 19.4b, 14.9a, 14.6a RDU/mg), temporally followed by an increase in IMC maturation (0.08a, 0.08a, 0.09a, 0.11b moles HLP per mol IMC). D correlated with HLP muscle amount ($r = -0.61$; $P < 0.001$) and ratio to IMC ($r = -0.37$; $P < 0.01$) confirming that a decorin/crosslink relationship may exist.

Key Words: Lamb, Age, Skeletal Muscle Extracellular Matrix

M59 Carcass and meat quality in three varieties of rainbow trout (*Oncorhynchus mykiss*). A. L. Rentería Monterrubio^{*1}, J. A. García Macías¹, and M. Espinosa^{2, 1} *Universidad Autónoma de Chihuahua, Periferico Francisco R. Almada. Km 1, Chihuahua, Chihuahua, 2Asociación de Productores de Trucha, Región de Madera, A. C..*

240 rainbow trouts of 3 varieties, Danish (80), Mexican (80) and American (80) were evaluated, in four weight groups: 175 - 224 g (1), 225 - 274 g (2), 275 - 324 g (3) and 325 - 375 g (4). The trouts came from farms of the Asociación de Productores de Trucha, Región de Madera, A.C. Measurements of weight and dissections of trouts were made to obtain the carcass quality characteristics. The effect of weight and trout variety were analyzed with a random design in a factorial arrangement of 3 x 4 with PROC GLM procedure of SAS. The greatest carcass yield occurred in the Mexican at 3 (88.35) and 4 group (87.34) and the Danish in group 1 (87.05) and 2 (86.34) ($P < 0.05$). The greatest fillet yield was registered in the Danish group 1 (53.17), in the American group 2 (53) and 4 (54.67) and in the Mexican group 3 with 54.36% ($P \# 88040.05$). Meat quality was evaluated, in luminosity (L^*), the Danish group 2 showed the lowest L^* (43.02) and the American group 3 the highest (47.53) ($P < 0.06$). The Mexican group 1 pH was the highest at 7.25 ($P \# 88040.05$), with the American group 2 at 7.14, 3 at 6.98 and 4 at 6.79 ($P < 0.05$). The four Danish weight groups water holding capacity were the best (51.19, 54.65, 52.16 and 51.42, respectively) ($P \# 88040.05$). The highest electrical conductivity was obtained from the Danish group 3 (13.32) and the lowest with the American group 4 (9.42) ($P \# 88040.05$). The greatest percentages of crude protein were seen with Danish group 1 (20.12), 2 (20.82) 4 (21.58), and the Mexican group 3 (21.50) ($P \# 88040.05$). The Danish weight group 1, 2, 3 and 4 presented the lowest content of fat ($P \# 88040.05$) (2.64, 2.48, 2.66 and 2.98, respectively). It is concluded that the Danish group 1 and the Mexican groups 2, 3 and 4 are the most acceptable rainbow trout carcasses. Fillet commercialization is better in the American group 2 and 4 and the Mexicans weight group 3.

Key Words: Rainbow Trout, Carcass Quality, *Oncorhynchus mykiss*

M60 Effects of sedated-harvest on channel catfish fillet color, pH, and drip-loss. B. G. Bosworth* and D. J. Gregory, *Catfish Genetics Research Unit, USDA-ARS, Stoneville, MS.*

Stress and activity associated with harvest and transport of meat animals elicit physiological responses that negatively impact meat quality. Previous research with channel catfish demonstrated that sedation of fish during harvest with the anesthetic iso Eugenol (Aqui-S#8482) minimized detrimental physiological responses (lower muscle lactate and serum cortisol, higher muscle pH and ATP) compared to control fish. Our objectives were to determine the best method (N_2 gas, CO_2 gas, or electrical stun) for killing sedated fish prior to slaughter and to determine effects of sedated-harvest on fillet quality (color, pH, and drip-loss) during iced-storage. CO_2 was selected as the best method to kill sedated fish based on physiological responses of fish (higher muscle pH and lower blood lactate compared to N_2) and worker safety issues associated with use of electrical stunning during harvest. Two treatments were compared for fillet quality: sedated-harvest (fish sedated with 15 ppm iso Eugenol, then placed in ice slush with CO_2) and control (simulated industry conditions - fish harvested, placed in live-haul tanks at 0.8 kg L^{-1} for 2 h, then electrically stunned). Fish were processed, and fillets were placed in polyethylene bags, immediately chilled in ice slush, and stored on ice for 7 d. Fillets ($n = 10$ treatment/time/replicate) were measured for CIE color (L^* , a^* , b^*), pH, and percent drip-loss

(100*weight loss/initial weight). Two replicate trials were conducted and data were analyzed by ANOVA. Sedated-harvest fillets had lower L^* values than controls at 1 d (49.4 vs. 54.3, $p < 0.001$), 4 d (52.5 vs. 54.1, $p = 0.04$), and 7 d (53.9 vs. 54.9, $p = 0.03$); and lower a^* values at 4 d (0.1 vs. 1.2, $p = 0.02$) and 7 d (-1.0 vs. -0.3, $p < 0.001$). Sedated-harvest fillets had higher pH than controls at processing (7.52 vs. 6.47, $p < 0.001$) and 1 d (6.64 vs. 6.40, $p = 0.002$). Fillet drip-loss was lower in sedated-harvested fish than control fish at 1 d (0.32 vs. 1.36 %, $p < 0.001$), 4 d (0.80 vs. 2.85 %, $p < 0.001$), and 7 d (1.60 vs. 4.14 %, $p < 0.001$). Sedated-harvesting has the potential to improve fillet quality in farm-raised catfish.

Key Words: Catfish, Fillet, Quality

M61 Effect of sexual condition and slaughter weight on carcass traits from buffaloes finished in feedlot. A. M. Jorge^{*1}, C. Andrighetto², D. D. Millen³, and M. G. Calixto², ¹UNESP-FMVZ-DPEA-Botucatu, ²UNESP-FMVZ-PGZOO-Botucatu, ³UNESP-FMVZ-DPEA-Botucatu.

The objective of this work was to evaluate the carcass traits from intact and castrated buffaloes, of the Brazilian type, finished in feedlot and slaughtered at 450 and 500 kg of live weight. There was no significant difference between cold carcass yield of intact animals and castrated (52.4 vs 51.3%). A significant increase was verified in hindquarter and whole shoulder yield from intact males. Castrated animals had a higher forequarter and pistol style cut yield (due to the higher round yield and not a higher yield of spare ribs). There was no difference in the carcass length, longissimus dorsi area and back fat thickness among intact and castrated animals. Carcass back fat thickness from intact males (5.9 mm) was lower than castrates (7.1 mm). The backfat level of intact males was very close of the ideal limits considered by retailers and may contribute to reducing the resistance to slaughtering intact animals. No difference was observed for cold carcass yield (50.5 vs 52.2%), primal cut yield, carcass length, longissimus dorsi area (54.9 vs 58.3 cm²) and back fat thickness (5.3 vs 5.9 mm) from buffaloes slaughtered at 450 kg vs 500 kg of live weight, although heavier animals tended to present the higher values of longissimus dorsi area and back fat thickness.

Key Words: Backfat Thickness, Longissimus dorsi Area, Water Buffalo

M62 Quantitative carcass traits from buffaloes of three genetic groups finished in feedlot and slaughtered at different stages of maturity. A. M. Jorge^{*1}, C. Andrighetto², D. D. Millen³, and M. G. Calixto², ¹UNESP-FMVZ-DPEA-Botucatu, ²UNESP-FMVZ-PGZOO-Botucatu, ³UNESP-FMVZ-DPEA-Botucatu.

This work was conducted to study the quantitative carcass traits from 36 buffaloes, average live weight 330 kg and age 18 months, representing 12 Murrah (MUR), 12 Jafarabadi (JAF) and 12 Mediterranean (MED) finished in a feedlot setting. Four animals inside of each genetic group, were randomly assigned to initial slaughter. The 12 animals of each genetic group, were randomly assigned in three sub-groups of four animals and submitted to the following treatments, respectively: Maturity 1 (Slaughter Weight-1) - 400 kg LW; Maturity 2 (Slaughter Weight -2) - 450 kg LW; Maturity 3 (Slaughter Weight -3) - 500 kg LW. An ad libitum ration was used for all the animals, in that 50% of DMS were supplied by roughage. The empty body weight was determined after each pre-fixed slaughter of the animals through the sum of the total parts of the body. There were no differences ($P > 0.05$) among genetic groups and maturities regarding yield of hind and forequarters, whole shoulder and whole rump. Animals slaughtered at 400 kg LW had higher yield of pistola style cuts than 500 kg LW animals ($P < 0.05$), while 450 kg LW animals did not differ from others. It was observed that whole shoulder yield differed from one side of the carcass to the other. These differences may have been the result of a section of spares ribs left on one side. This may have involuntarily increased ribs proportionally larger in heavier animals.

Key Words: Mediterranean, Murrah, Water Buffalo

M63 Physical carcass composition and tissue relations from buffaloes of three genetic groups finished in feedlot and slaughtered at different stages of maturity. A. M. Jorge^{*1}, C. Andrighetto², D. D. Millen³, and M. G. Calixto², ¹UNESP-FMVZ-DPEA-Botucatu, ²UNESP-FMVZ-PGZOO-Botucatu, ³UNESP-FMVZ-DPEA-Botucatu.

This work was conducted to study the physical carcass composition from 36 buffaloes with 18 months of average age and average initial live weight (LW) of 330 kg, being 12 Murrah (MUR), 12 Jafarabadi (JAF) and 12 Mediterranean (MED) finished in feedlot. Four animals, inside of each genetic group, were randomly assigned to initial slaughter, as reference in the study of the empty body (EBW) and of the initial carcass. The 12 animals of each genetic group, were randomly distributed in three sub-groups of four animals and submitted to the following treatments, respectively: Maturity 1 (Slaughter Weight-1) - 400 kg LW; Maturity 2 (Slaughter Weight -2) - 450 kg LW; Maturity 3 (Slaughter Weight -3) - 500 kg LW. A "ad libitum" ration was used for all the animals, in that 50% of DM were supplied by roughage. The EBW was determined after each pre-fixed slaughter of the animals through the sum of the total parts of the body. There was no difference among genetic groups, regarding to values of carcass length, back fat thickness and loin eye area, expressed in absolute values and in % EBW. There was no difference among genetic groups (MUR, JAF and MED) regarding to the proportions of muscles and adipose tissue (AT). On the other hand, JAF presented larger ($P < .05$) proportion of bones (B) than MUR and MED. MED animals presented larger ($P < .05$) relationship soft tissue/bone (ST/B) and muscle/bone (M/B), while JAF presented smaller ($P < .05$) ST/B and M/B. There was not difference among the maturities regarding the proportion of muscles and of fat tissues. Animals slaughtered at 500 kg LW presented larger ($P < .05$) relationship ST/B, M/B and AT/B than animals slaughtered at 405 kg LW.

Key Words: Fat, Muscle, Water Buffalo

M64 Chemical composition, meat quality and consumer acceptability in Mexican retail beef. E. J. Delgado¹, M. S. Rubio^{*1}, F. A. Iturbe², R. D. Mendez¹, L. Cassis³, and R. Rosiles¹, ¹Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autonoma de Mexico Circuito Exterior, Cuidad Universitaria, Mexico, ²Facultad de Quimica, Universidad Nacional Autonoma de Mexico Circuito Exterior, Mexico, ³Departamento Tecnologia alimentos, Universidad La Salle Benjamin Franklin 47, Col. Condesa, Del. Cuauhtemoc.

Mexican beef cattle producers claim the largest part of imported beef is of poor quality and represents a hindrance for the development of the Mexican beef industry, which has exhibited a poor growth for the last years. Under these circumstances, it is vital for the Mexican beef industry to establish a benchmark for the composition and quality of retail beef. The purpose of this investigation was to study the quality characteristics of Mexican and imported retail beef samples. Mexican and imported (USDA-Choice and commodity US) strip loin beef steaks (NAMP 180) were randomly selected from 80 supermarkets in Monterrey, Mexico City, and Villahermosa. Meat samples were analyzed for chemical composition, Warner Bratzler shear force (WBSF), instrumental color (L^* -, a^* -, and b^* - values), and consumer acceptability. All sources of Mexican beef and commodity US beef had similar composition ($P > 0.05$), averaging $73.0 \pm 0.2\%$ moisture, $3.0 \pm 0.2\%$ fat, $22.1 \pm 0.1\%$ protein, 11.7 ± 0.4 mg/g total collagen, and $16.2 \pm 0.4\%$ soluble collagen. In comparison, USDA-Choice beef had significantly higher ($P < 0.05$) fat content ($6.3 \pm 0.2\%$), lower ($P < 0.05$) moisture ($69.9 \pm 0.2\%$) and total collagen content (9.7 ± 0.4 mg/g). Mexican beef from Monterrey and USDA-Choice beef were tender and paler (WBSF 3.6 ± 0.1 and 3.1 ± 0.1 kg, respectively; a^* -values 14.3 ± 0.3 and 14.1 ± 0.3 , respectively) than Mexican beef from Mexico City, Villahermosa and commodity US beef (WBSF 4.6 ± 0.1 , 4.7 ± 0.1 , and 4.6 ± 0.1 kg, respectively; a^* - values 17.1 ± 0.3 , 17.1 ± 0.3 , and 16.6 ± 0.2 , respectively). Consumer acceptability for Mexican beef from Monterrey was similar to that of USDA-Choice. Commodity US beef had the lowest overall desirability score. Results indicate Mexican beef has some advantages to compete with imports in the current open market. Even so, there is still considerable scope for improvement in its quality characteristics and uniformity.

Key Words: Beef Quality, Chemical Composition, Consumer Acceptability

M65 Effects of sodium lasalocid and electrolytes on carcass characteristics of young bulls from north-central Mexico, finished with a brewery grain-based ration. F. Winston-Bennett, J. J. J. Chavez*, R. Bañuelos, S. Mendez, C. F. Arechiga, and F. Echavarría, Universidad Autonoma de Zacatecas, Zacatecas, Mexico.

The objective was to determine the effect of feeding brewery grain, sodium lasalocid and electrolytes on carcass characterization (post mortem) of young bulls (Angus, Brahman, Charolais crosses with an average weight of 380 kg) from north-central Mexico ($22^\circ 52'$ northern latitude and 102° western longitude, and 2,153 m above the sea level). Young bulls were exposed to a feeding-adaptation period of 15 d, followed by a 60 d finishing period. Young bulls ($n=20$), were randomly allotted into two treatments groups: 1) RBG, a ration based on Brewery Grain as a control. 2) RBG+LE, a ration based on Brewery Grain containing Lasalocid and Electrolytes. Measurements include: live weight (LW), hot carcass-weight (HCW), cold carcass-weight (CCW), carcass rudiment (CR), empty body-weight (EBW), water-holding capacity (WHC), pH at 45 min, and 24 h post mortem (pH45m & pH24h), electrical conductivity at 45m and 24 h (EC45m and EC24h), cooking losses (CL). Statistical analysis were performed by a complete-randomized design, contrasting means by Tukey test, besides analyses of principal components. Addition of Lasalocid and Electrolytes increased live weight and carcass weight of the bulls (21.2 and 24.3 kg/bull, respectively), as well as mean carcass-rudiment. Whereas, tended to decrease overall pH, EC and CL. In conclusion, Lasalocid and Electrolytes fed in brewery grain-based ration for young bulls improved live weight, carcass weight, carcass rudiments as well as other meat characteristics of quality such as pH, electrical conductivity, water holding capacity and cooking losses.

	CR	pH45m	pH24h	EC45m	EC24h	WHC	CL
RBG	62.17	6.78	5.59	13.4	77.6	35.28	33.27
RBG+LE	64.55	6.76	5.46	0.4	6.6	33.15	30.47

Key Words: Lasalocid, Feedlot Bulls, Brewery Grain

M66 Hanging the beef carcass by the forequarter to improve tenderness of the *Longissimus dorsi*. A. Luchiar-Filho^{*1}, R. P. Macedo², A. S. C. Pereira¹, S. da L. e Silva¹, P. R. Leme¹, and G. F. Feitosa¹, ¹Faculdade de Zootecnia e Engenharia de Alimentos - USP, Pirassununga, SP, Brazil, ²Marfrig Brazilian Beef Via Dr. Shuhei Uetsuka, km 02, Promissão, SP, Brazil.

During four subsequent days 40 Nellore steer carcasses (10/day) were chosen at random in a federally inspected slaughter plant and hanged alternate left and right sides either in the traditional way by the hindquarter (HQ) or by the forequarter (FQ) hung by the carpi radialis muscle. Carcasses had an avg hot carcass wt of 244.1 kg and up to 30 months old. The 24 h pH was not statistically different, 5.69 for HQ and 5.7 for FQ. Carcasses were chilled for 48 h, when samples from the LD at the 12th rib level and the $\langle I \rangle$ Biceps femoris $\langle /I \rangle$ (BF) at the P3 site level were removed, kept under refrigeration ($0-2^\circ\text{C}$) for 5 d and then frozen for future analysis. The temperature of the $\langle I \rangle$ Longissimus dorsi $\langle /I \rangle$ (LD) after 48 h, taken adjacent the 12th rib was not statistically different 1.0°C for HQ and 0.9°C for FQ. Fat thickness measured at the 12th rib level was different ($P < 0.05$), 3.8 mm for HQ and 4.3 mm for FQ. All samples were thawed for 48 h to refrigeration temperature to evaluate tenderness. Warner Bratzler Shear force from the LD was lower ($P < 0.001$) for the FQ (3.53 kg) than for HQ (4.78 kg) and the BF was not statistically different, 3.61 kg HQ and 3.52 kg FQ. Total cooking losses were not statistically different, 19.7% HQ and 18.9% FQ. Hanging the beef carcass by the forequarter caused a significant improvement in tenderness of the LD without any detrimental effect on the BF (sirloin level). Although not evaluated in this work, it was noticed an increase in diameter and a decrease in length in the LD muscle, that could partially explain the thicker fat layer for the FQ treatment. Further work has been done to evaluate the effects of hanging by the forequarter in forequarter muscles as well as other major hindquarter muscles.

Key Words: Beef, Meat Quality, Tenderness

M67 Estimation of percentage of lean meat on rib loin by computer image analysis for carcass cross section of Wagyu cattle. M. Hasegawa*¹, K. Kuchida¹, S. Hidaka¹, H. Houkiyama², T. Sakai², Y. Yamamoto², and Y. Sato², ¹Obihiro University of Agriculture and Veterinary Medicine obihiro-shi Hokkaido 080-8555 Japan, ²Hokkaido Animal Research Center Shintoku-cho Hokkaido 081-0038 Japan.

For the improvement of meat quantity, it is desirable to utilize more detailed data than merely the carcass weight and cutability, which have been measured and recorded at carcass grading. In this study, each muscle area and the ratio of muscle area to total area (MAR) were calculated from the 6-7th cross-section of Wagyu cattle, and the relationship between their image analysis traits and the percentage of lean meat was investigated. Images of 41 cross-sections of Wagyu steers (19-21 mo.) were used for the analysis. Areas calculated by image analysis included 13 muscle areas, such as M.longissimus thoracis (LONG), M.trapezius (TRAP), M.latissimus dorsi (LATIS) etc., total muscle area, subcutaneous and intermuscular fat area, cross-section area and MAR. Weights of lean meat, fat, bone and sinew of the 9-11th rib loin were measured by physical dissection. The relationships among muscle areas, as well as those among the percentage of lean meat, each muscle area and MAR were investigated. The percentage of lean meat was predicted using a multiple regression analysis with 21 covariates associated with 17 image analysis traits and grading records. The ranges for carcass weight, percentage of lean meat and MAR were from 129 to 228 kg (mean; 180.8 kg) from 52.1 to 61.2% (56.3%) and from 49.6 to 67.0% (56.7%), respectively. The correlation coefficient between muscle areas in LONG and TRAP was 0.64 ($p < 0.01$) and 0.73 ($p < 0.01$) in LONG and LATIS. The correlation coefficient between the percentage of lean meat and MAR was 0.53, which was the highest value among the image analysis traits. Selected variables for the prediction equation for estimating the percentage of lean meat were M.ilicostalis area, M.semispinalis capitis area, M.serratus ventralis area, total muscle area and cross-section area. The coefficient of determination (R^2) of the multiple regression equation was 0.69 ($p < 0.01$).

Key Words: Image Analysis, Wagyu, Muscle Area

M68 Development of new photography equipment for carcass cross section of Wagyu beef and its potential use in meat quality evaluation using digital images. K. Kuchida*¹, T. Hori², T. Honma², M. Nami², K. Takahashi¹, M. Hasegawa¹, H. Hokiayama³, T. Sakai³, and Y. Yamamoto³, ¹Obihiro University of Agriculture and Veterinary Medicine Obihiro-shi Hokkaido 080-8555 Japan, ²Hokkaido Industrial Research Institute Sapporo-shi Hokkaido 060-0819 Japan, ³Hokkaido Animal Research Center Shintoku-sho Hokkaido 081-0038 Japan.

In Japan, meat quality grade and yield grade of Wagyu cattle are evaluated by macroscopically observing the cross section of the 6th and 7th rib. Computer image analysis of high resolution for the cross section image may lead to the objective meat quality evaluation. The aims of this study were to develop new photographic equipment for carcass cross section using a digital camera with resolution of 13.5 million pixels, and to investigate the feasibility of this new evaluation method for beef marbling using clear digital images obtained by the equipment. KODAK DSC 14n with a 35mm CMOS device was used as the digital camera with a wide angle lens (Nikkor AF ED 14mm F2.8D). The circumference of light division was shielded so that it would not receive external light. The stainless frame installed on the bottom face of the lighting division was in contact with the carcass surface at photography, so that constant distance and vertical direction could be obtained in the digital image. The height of this equipment was 330 mm, and the photographed image had a range of 300×400mm and included the middle point of *M. latissimus dorsi*. Carcass cross sections of nine Japanese Black steers were photographed. The accuracy of binarization was sufficient for the analysis of meat quality because the source of light was illuminated uniformly on the rib eye area, even when binarization with a single threshold value with the discrimination analysis method was executed. Moreover, a slight fine marbling area of about 0.005cm² (30 pixels) could be clearly and accurately binarized. Means for rib eye area (44.1±6.9 cm²) and marbling percentage (29.5±6.6%) in rib eye obtained from this new equipment were close to those (45.4±7.0 cm², 29.5±5.9%) obtained from the former equipment developed in 1999. No

significant differences were recognized between measurement values from both equipments ($P > 0.05$).

Key Words: Image Analysis, Wagyu, Marbling

M69 Correlations among carcass traits taken by ultrasound and after slaughter in Mediterranean (Bubalus bubalis) bulls fed in feedlot. A. M. Jorge*¹, C. Andrighetto², D. D. Millen³, and M. G. Calixto², ¹UNESP-FMVZ-DPEA-Botucatu, ²UNESP-FMVZ-PGZOO-Botucatu, ³UNESP-FMVZ-DPEA-Botucatu.

The objective of this work was to estimate the correlations among measurements taken in vivo with ultrasound equipment with some carcass traits measured after slaughter. Twenty eight Mediterranean bulls, with average shrunk body weight of 300 kg and 15 months of age, were fed a high concentrate diet for by 120 days. The shrunk body weight, the ribeye area (REAU) and the fat thickness (FTU) over the Longissimus dorsi muscle between 12 and 13th ribs, were measured at 28 days intervals. Real-time ultrasound equipment Piomedical Scanner 200 VET, with 18 cm linear array transducer was utilized. After the slaughter, the hot carcass weight (HCW) and the kidney, pelvic and inguinal fat (KPIF) were weighted and the dressing percentage (DP) calculated. After 24 hours of cooling the ribeye area (REAC) and the fat thickness (FTC) were measured. Both the REAC and the FTC were underestimated by ultrasound measurements. The Pearson correlation coefficients for ribeye area and backfat thickness, measured in the carcass and with ultrasound, were 0.78 and 0.89, respectively. The coefficient between DP and REAU was 0.28; 0.45 between DP and REAC, - 0.28 between DP and FTU and -0.30 between DP and FTC. The KPIF presented a 0.52 correlation coefficient with FTC and FTU. The Spearman correlation was estimated between REAU and REAC and FTU and FTC, and the values were 0.90 and 0.79, respectively.

Key Words: Backfat Thickness, Ultrasound, Water Buffalo

M70 Effect of dietary vitamin E supplementation and storage time on physical characteristics of ten muscles from beef cattle. F. G. Rios*, R. Cortina, G. Contreras, and J. J. Portillo, FMVZ-Universidad Autonoma de Sinaloa, Mexico Carr. Culiacan-Mazatlan km. 3.5.

The objective was to determinate the effect of dietary vitamin E supplementation and storage time on the physical characteristics of ten vacuum packaged beef muscles. A complete randomized block design experiment used eighty Brahman-cross bull calves (28 months of age), assigned to receive one of two treatments during experimental period of 30 d prior to slaughter: 1) Regular finishing diet supplemented with 2000 IU of vitamin E for kg/DM and 2) Regular finishing diet. The animals were slaughtered and carcasses refrigerated for 24 h. Ten, 100g samples were obtained from the following muscles: *longissimus thoracis* (LT); *obliquus abdominis externus* (OAE); *longissimus spinalis* (LE); *pectoralis profundis* (PP); *supraespinatus* (SE); *longissimus lumborum* (LL); *biceps femoris* (BF); *semiteminosus* (ST); *semimembranosus* (SM); and *gluteus medius* (GM). Samples were packed with a Ultravac#8482 machine and refrigerated at 4 C. Muscle sample drip loss (DL), pH and colour ($L^*a^*b^*$) were determined on day 0, 7, 14, 21, and 28. Muscles LT and OAE, showed no effect ($P > 0.05$) by treatments for DL. Muscles LE, GM, and BP, DL was 15.35 % less ($P < 0.01$) at d 14, but showed no difference in others periods of storage. Muscle pH diminished ($P = 0.03$) at 7 to 21 storage time for LT, LE, OAE, SM, SE, GM, and PP, with a mean of 5.71 in the muscles from the vitamin E treatment. Brightness (L^*) was modified by vitamin E supplementation in LT (44.35 vs. 40.64) at 21 d, ST (39.19 vs. 37.64) at 7 d, and GM (39.18 vs. 37.60) at 14 d. Redness (a^*) was modified by vitamin E supplementation in SE (20 vs 10.74), PP (15 vs. 11.69), GM (20.9 vs. 10.74) at 28 d storage, and BP (20.9 vs. 10.28) at 7 d storage. It is concluded that 2000 IU/ kg DM vitamin E supplementation improve the physical characteristics of fresh, vacuum packaged bovine meat.

Key Words: Vitamin E, Bovine Meat, Vacuum Packed

M71 Tenderness improvement in fresh and frozen/thawed beef strip loins treated with hydrodynamic pressure processing. M. B. Solomon*, M. Liu, J. Patel, E. Paroczay, and J. Eastridge, *USDA, ARS, FTSL*.

The effect of hydrodynamic pressure processing (HDP) using two different shaped charges (rectangular [REC] vs cylindrical [CYL]) and meat state at 48 h postmortem of beef strip loins (N=16) on meat tenderness was evaluated. HDP was performed by detonating 100 g of explosive placed above vacuum packaged meat samples immersed in water in plastic containers. Meat state was fresh, never frozen compared to frozen at 48 h postmortem followed by thawing at 6-d postmortem. Meat samples were evaluated for tenderness by shear force measurements at both d-1 and d-6 after being treated with HDP. Both shapes of explosives improved ($P < 0.01$) shear force on d-1 (CYL 4.6 vs 5.4 kg; REC 4.4 vs 5.4 kg) compared to controls. The effect of HDP was sustained ($P < 0.01$) throughout d-6 of aging, with the CYL reaching 3.9 kg and the REC reaching 3.6 kg compared to controls (4.5 kg). Freeze/thaw samples were 1 kg lower at d-1 compared to fresh samples (4.3 vs 5.3 kg) and 0.9 kg lower at d-6 (3.6 vs 4.4 kg). There were no significant interactions for meat state and HDP treatments. The percentage of samples with HDP improvements $> 10\%$ was higher for the REC shaped explosive (81%) compared to the CYL shape (56%). Furthermore, the percentage of samples with HDP improvements $> 10\%$ was higher for fresh meat samples (71%) compared to frozen/thawed samples (66%). The percentage of samples that improved greater than the aged control was 100% for REC, 87% for CYL, 94% for fresh samples, and 81% for frozen/thawed samples. These results suggest that both HDP and early postmortem freezing followed by thawing are successful treatments for improving meat tenderness and are better than extended aging for non-treated controls.

Key Words: Tenderness, Pressure Processing, Aging

M72 Recombinant hepatocyte growth factor (rHGF) over-expressed by C2C12 myoblasts is biologically active. C. Zeng*¹, D. E. Gerrard¹, K. H. Hannon², and A. L. Grant¹, ¹*Department of Animal Sciences, Purdue University, West Lafayette, IN*, ²*Department of Basic Medical Sciences, Purdue University, West Lafayette, IN*.

Hepatocyte growth factor (HGF) is a growth factor that activates quiescent satellite cells and alters their growth in culture and in skeletal muscle. In an attempt to increase the amount of local HGF in skeletal muscle, we generated an expression construct to produce an epitope-tagged HGF (rHGF) protein. Reverse transcription-polymerase chain reaction (RT-PCR) was used to clone a cDNA encoding full-length HGF from mouse liver total RNA (forward primer: ATGATGTGGGGGACCAAACCT, reverse primer: TTACAACCTGTATGTCAAAA). The cDNA was subcloned into the pcDNA3.1/V5-His-TOPO expression vector and used to transfect C2C12 myoblasts. Immunoblots containing the concentrated conditioned media from myoblasts stably expressing rHGF showed that the expressed rHGF could be detected using antibodies against HGF or the V5 epitope. Monoclonal anti-HGF antibody detected the N-terminal 70 kDa α -chain of rHGF, whereas the anti-V5 antibody detected the C-terminal 40 kDa β -chain in which the V5 epitope was located. Moreover, subjecting conditioned media to a His-column removed the majority of immunoreactive protein, further suggesting that the product was recombinant HGF-V5-His protein. Furthermore, the conditioned media stimulated C2C12 myoblast replication similar to a commercially available HGF. In experiments in which one-half of DMEM was replaced with FBS-free conditioned medium from stably transfected C2C12 myoblasts, the proliferative effect on normal C2C12 myoblasts was the same ($P > .05$) as that observed when normal C2C12 myoblasts were cultured in DMEM containing a commercial HGF at 5 ng/ml. Finally, immunoneutralization of conditioned media using an anti-HGF antibody at the concentration of 1 $\mu\text{g/ml}$ eliminated ($P < .05$) this proliferative effect in culture, suggesting that rHGF is the major component in conditioned medium to exert the proliferative action. We conclude that our recombinant epitope-tagged HGF is biologically active when expressed in C2C12 myoblasts. This construct provides a valuable reagent for investigating the role of HGF in controlling satellite cell-mediated muscle growth.

Key Words: Hepatocyte Growth Factor (HGF), Muscle, Satellite Cell

M73 Correlations and prediction equations for fatty acids and sensory characteristics of beef longissimus rib steaks from three forage rations and commercial USDA Choice and Select rib steaks. R. T. Baublits*¹, F. W. Pohlman¹, A. H. Brown, Jr.¹, Z. B. Johnson¹, D. C. Rule², C. M. Murrieta², D. O. Onks³, B. A. Sandelin¹, H. D. Loveday³, C. J. Richards³, and R. B. Pugh³, ¹*University of Arkansas, Fayetteville*, ²*University of Wyoming, Laramie*, ³*University of Tennessee, Knoxville*.

Rib steaks (n = 52) from cattle grazing fescue, fescue with soyhull supplementation, orchardgrass with soyhull supplementation, and USDA Choice and Select rib steaks obtained from area purveyors were utilized to determine fatty acid profiles and sensory characteristics. Correlations between fatty acids and sensory characteristics were performed. Also, utilizing fatty acid values, prediction models for sensory characteristics were developed. The beef/brothy and beef fat sensory characteristics were positively correlated ($P < 0.05$) with 16:0, 16:1cis-9, and 18:1, and negatively correlated ($P < 0.05$) with 15:0, α -18:3, 20:4, 20:5, 22:5, and 22:6. The grassy sensory characteristic was positively correlated ($P < 0.05$) with 15:0, 16:1trans-9, 18:0, 18:2cis-9,trans-11 (CLA), α -18:3, 20:5, 22:5, and 22:6. Regression utilizing stepwise selection to develop prediction equations for sensory characteristics was performed, and the beef/brothy sensory characteristic was best predicted ($P < 0.05$) by the single fatty acid 20:5, with this fatty acid explaining 40 % of the variation in beef/brothy flavor. Conjugated linoleic acid (CLA) and α -18:3 were utilized in the model that best predicted ($P < 0.05$) milky/oily flavor, with these two fatty acids explaining 31 % of the variation. These results indicate that CLA and the 20- and 22-carbon polyunsaturates have large roles in influencing flavor, causing increases in grassy and milky/oily flavor or decreasing beef/brothy flavor.

Key Words: Fatty Acid, Sensory, Correlation

M74 Characterization of Romosinuano breeding on palatability traits and retail shelf life of beef steaks. W. J. Horne*¹, J. C. Brooks¹, S. W. Coleman², W. A. Phillips³, D. G. Riley², C. C. Chase Jr.², and M. F. Miller¹, ¹*Department of Animal and Food Sciences, Texas Tech University, Lubbock*, ²*USDA, ARS, SubTropical Agricultural Research Station, Brooksville, FL*, ³*USDA, ARS, Grazinglands Research Laboratory, El Reno, OK*.

This study was conducted to evaluate if Romosinuano (R) cattle, a *Bos taurus* breed native to Columbia, would differ from Brahman (B) and Angus (A) cattle in palatability and retail shelf life properties of beef steaks. Steers (n=142) representing a three-breed diallel crossbreeding program (AA, BB, RR and crossbreds: AB, AR, BA, BR, RA, RB; first letter indicates breed of sire and second letter indicates breed of dam) were fed in El Reno, OK. Carcass data was collected at 48 h post harvest. Loins were recovered, aged for 7 d and fabricated into 2.54 cm-thick steaks for use in Warner-Bratzler shear (WBS), slice shear, and sensory analysis. WBS results indicate that BB cattle exhibited the highest ($P < 0.05$) values (3.98 kg \pm 0.16) while AA and RA had the lowest (3.16 kg \pm 0.20). RA cattle had WBS values similar to the RB cattle, while AR had lower ($P < 0.05$) WBS values than BR. Slice shear results indicate that BB cattle had the highest ($P < 0.05$) values (15.58 kg \pm 0.87) while AB had the lowest (11.93 kg \pm 0.82). RA and AR cattle had similar slice shear values to RB and BR cattle. When R was used on the maternal side of the cross, steers exhibited higher Warner-Bratzler shear values and less desirable sensory panel tenderness scores ($P < 0.05$) than steers sired by R bulls. Breed did not have a significant effect on retail display properties. Results indicate that palatability and shear force values were improved when R was represented on the paternal, rather than maternal, side of the cross. Finally, RA and AR cattle produced panel tenderness scores, shear force values, and retail display properties similar to the BA and AB cattle.

Key Words: Romosinuano, Shelf Life, Palatability

M75 Comparison of beef tallow versus poultry fat in the finishing diets of steers on muscle and subcutaneous fatty acid profiles. S. Hutchison^{*1}, E. B. Kegley¹, J. K. Apple¹, T. J. Wistuba², and D. C. Rule³, ¹University of Arkansas, Fayetteville, ²Morehead State University, Morehead, KY, ³University of Wyoming, Laramie.

Poultry fat has become a more economical source of energy than by-products currently used. Therefore, this study was conducted to determine the effects of dietary fat source (poultry fat or beef tallow) in finishing diets for cattle on the fatty acid composition of beef. Sixty Angus crossbred steers (410.8 kg initial BW) were stratified by source, blocked by weight, and assigned within block to 15 pens (4 steers/pen). Pens were then assigned randomly within blocks to one of three dietary treatments consisting of: 1) a corn-soybean meal control diet devoid of supplemental fat (Ctrl); 2) the control diet formulated with 4% tallow (TAL); or 3) the control diet formulated with 4% poultry fat (PF). Cattle were fed for 112-d and harvested at a commercial beef packing plant. Wholesale ribs were collected during carcass fabrication (357.7, 357.3, and 369.5 kg for carcasses of Ctrl, TAL, and PF-fed cattle, respectively), and samples of subcutaneous fat and LM were analyzed for fatty acid composition (reported as mg/g wet tissue). In the LM, total saturated fats (14:0, 15:0, 16:0, and 18:0) were similar ($P > 0.10$) among diets. Furthermore, total monounsaturated fatty acids (MUFA) were not ($P > 0.10$) affected by finishing diets. The LM from the steers fed PF had increased ($P < 0.05$) 18:2 and total PUFA than the LM of the steers fed Ctrl or TAL-diets. Conversely, the LM of TAL-steers had lower ($P < 0.05$) concentrations of 20:3 than Ctrl or PF-fed steers. The only changes detected in subcutaneous fat were steers that consumed the Ctrl-diet had the highest ($P < 0.05$), and PF-fed steers had the lowest ($P < 0.05$), 17:0 concentrations. Furthermore, subcutaneous fat from TAL-fed steers had lower ($P < 0.05$) conjugated linoleic acid concentrations than fat from controls and PF steers; however, diet did not ($P > 0.10$) affect total saturated, MUFA, PUFA, omega-6, or trans fatty acids. Feeding finishing steers diets formulated with poultry fat did not negatively impact the fatty acid composition of subcutaneous fat or the LM, and may serve as an alternative to beef tallow as a source of energy for cattle finishing diets.

Key Words: Beef Tallow, Poultry Fat, Fatty Acids

M76 Comparison of beef tallow versus poultry fat in the finishing diets of steers on beef quality during retail display. S. Hutchison^{*1}, J. K. Apple¹, E. B. Kegley¹, and T. J. Wistuba², ¹University of Arkansas, Fayetteville, ²Morehead State University, Morehead, KY.

The current study was conducted to determine the effects of dietary fat source (poultry fat or beef tallow) in finishing diets of cattle on beef quality traits during 7 d of simulated retail display. Sixty Angus crossbred steers (410.8 kg initial BW) were stratified by fat source, blocked by weight, and assigned to 15 pens (4 steers/pen). Pens were then assigned randomly within blocks to one of three dietary treatments consisting of: 1) a corn-soybean meal control diet devoid of supplemental fat (Ctrl); 2) the control diet formulated with 4% tallow (TAL); or 3) the control diet formulated with 4% poultry fat (PF). Cattle were fed for 112-d and harvested at a commercial beef packing plant. Wholesale, bone-in ribs were collected during carcass fabrication, and 2.54-cm thick, boneless LM steaks were cut, weighed, placed on foam trays with an absorbent pad, and overwrapped with PVC film for display (deluxe warm white

Nonruminant Nutrition: Weanling Pig - Vitamin & Mineral

M78 Is vitamin B6 a modulator of the effect of supplementary tryptophan on tryptophan metabolism and growth responses in weanling pigs? J. J. Matte^{*1}, N. LeFloc'h², C. Relandeu³, L. Le Bellego³, A. Giguère¹, and M. Lessard¹, ¹Agriculture and Agri-Food Canada, Lennoxville, Qc, Canada, ²Institut National de la Recherche Agronomique, St-Gilles, France, ³Ajinomoto Eurolysine S.A.S., Paris, France.

The present experiment aimed to determine if tryptophan (Trp) metabolism and the eventual growth response to dietary supplement of Trp is modulated by the dietary supply of pyridoxine (B6). Early-weaned piglets ($n = 544$) (BW: 5.96 ± 0.14 kg) were grouped in 32 pens ($n = 32$) of 17 animals and distributed by initial weight ranges in four

light; 1600 lx) in chest-type display cases (3°C). On d 0, 1, 3, 5, and 7 of display, a three-person panel scored steak discoloration (1 = total discoloration to 7 = no discoloration), and instrumental color (L^* , a^* , and b^* values) was measured and used to calculate hue angle, chroma, and delta E (measure of total color change from d-0) values. Thiobarbituric acid reactive substances (TBARS) of steaks were measured on d 0 and 7 of display. Beef became lighter (higher L^* value; $P < 0.01$), and less red (lower a^* value; $P < 0.001$) and yellow (lower b^* value; $P < 0.001$) during the 7 d of retail display. The LM from Ctrl-steers tended to be lighter (higher L^* value; $P < 0.10$); however, there were no ($P > 0.10$) diet effects on a^* , b^* , hue angle, chroma, delta E, or discoloration scores. Even though TBARS concentrations were numerically higher in the LM of steers consuming diets formulated with fat (0.54, 0.53, and 0.34 mg/kg for PF, TAL, and Ctrl, respectively), diet had no ($P > 0.10$) appreciable effect on the development of oxidative rancidity. Results indicated that replacing beef tallow with a more economical energy source, poultry fat, in cattle finishing diets had no detrimental effects on beef quality during retail display.

Key Words: Dietary Fat, Beef Quality, Retail Display

M77 Glycolytic intermediates in muscle and adipose tissue of cattle fed different sources and amount of energy. R. D. Rhoades^{*}, J. T. Vasconcelos, D. K. Lunt, J. E. Sawyer, K. Y. Chung, and S. B. Smith, Department of Animal Science, Texas A&M University, College Station.

Seven Angus and eight Wagyu steers (BW = 208 and 172 kg) were used to evaluate energy source effects on glycolytic intermediates within muscle and adipose tissue. Steers were blocked by breed and fed a corn-based diet for 244 d (total energy: 3207 Mcal/kg) or a hay diet for 362 d (total energy: 6293 Mcal/kg). Corn-based diet was fed for 1.3 kg/d gain. Hay-fed steers were fed to the same carcass endpoint. Carcass adjusted fat thickness (AFT), marbling score, postmortem plasma, muscle, subcutaneous, and intramuscular adipose tissues were collected. Data were analyzed as a complete block design. Plasma glucose ($\mu\text{mol/ml}$) was numerically greater ($P=0.06$) in corn-fed (3.77 ± 0.06) vs. hay-fed (2.88 ± 0.05) steers. Glucose ($\mu\text{mol/g}$) in muscle was greater ($P=0.04$) in hay-fed steers (4.68 ± 0.07 vs. 3.07 ± 0.08). Muscle glucose-6-phosphate (G6P), and fructose-6-phosphate (F6P; $\mu\text{mol/g}$) were similar ($P=0.10$) among treatments. Glucose ($P=0.13$), G6P ($P=0.34$), and F6P ($P=0.22$) concentrations in subcutaneous adipose were also similar. Glucose and F6P concentrations in intramuscular adipose were 2-fold and 10-fold higher, respectively, than observed in subcutaneous depots, but were similar ($P>0.6$) for corn-fed and hay-fed steers. G6P was numerically greater in hay-fed (0.186 ± 0.008) vs. corn-fed steers (0.084 ± 0.009 ; $P=0.08$). Steers were fed to a common AFT (0.47 cm). Mean marbling score in corn-fed steers (710 ± 78) was numerically greater than in hay-fed steers (564 ± 72) although statistical separation was not achieved ($P=0.4$). Plasma glucose indicates greater glucose pool size in corn-fed steers; greater concentrations of glucose and intermediaries in muscle of hay-fed steers may reflect decreased pathway flux. Correlations between marbling score and intramuscular adipose glucose concentration were -0.6 ($P=0.18$) for corn-fed steers and 0.7 ($P=0.04$) for hay-fed steers, supporting the concept that corn-based diets promoted provision and utilization of glucose for accretion of intramuscular fat relative to hay-based diets. Manipulation of glucose disposal rate in finishing steers may improve carcass quality grade.

Key Words: Glucose, Marbling, Energy

factorial treatments ($n = 8$ pens in each): two dietary additions of B6 [0 (B6-) vs. 5 ppm (B6+)] and two dietary additions of synthetic Trp [0 (Trp-) vs. 0.05 % (Trp+) for a Trp/Lys ratio of 0.174 vs. 0.204, respectively]. Growth performance was recorded every week from 2 to 9 wk of age. Blood samples were taken from 64 piglets, two from each pen, before initiation of treatments and at 4, 6 and 8 wk of age. No treatment effect ($P > 0.19$) was observed on overall ADFI (679 ± 7 g), ADG (454 ± 4 g), or feed conversion (1.50 ± 0.01), although the B6+Trp+ piglets had the highest ADG and feed conversion during the last week of experiment (B6 x Trp x Age linear, $P < 0.02$). Pyridoxal in red blood cells was 19% lower in B6- ($2.8 \pm 0.1 \mu\text{M}$) than in B6+ piglets ($3.3 \pm 0.1 \mu\text{M}$; B6 x Age quadratic, $P < 0.01$). Initial values

($33.1 \pm 1.5 \mu\text{M}$) of plasma Trp declined ($P < 0.01$) with age but the effect tended to be more pronounced (B6 x Age linear, $P < 0.08$) in B6 than in B6+ piglets; values at 8 wk of age were 22.6 ± 1.7 vs $26.7 \pm 1.4 \mu\text{M}$, respectively. Initial values ($1.48 \pm 0.09 \mu\text{M}$) of plasma kynurenin, an intermediate metabolite of Trp oxidation, decreased with age but were higher, at 4 and 6 wk of age, in Trp+ than in Trp- piglets (Trp x Age quadratic, $P < 0.01$); this effect faded ($1.21 \pm 0.07 \mu\text{M}$) at 8 wk of age. It seems that, although stimulated by dietary Trp at 4 and 6 wk of age, Trp oxidation would not be altered at 8 wk of age in spite of the B6 x Trp effect. This apparent sparing effect of B6 on Trp status could originate from the small intestine microflora since bacterial synthesis of Trp is B6-dependent. Those late (8 wk of age) metabolic and growth performance effects merit further investigation especially for their eventual carry over impact shortly after the nursery period.

Key Words: Tryptophan, Pyridoxine, Piglets

M79 Vitamin C and β -carotene in weanling pig diets. D. M. Fernandez^{*1} and J. A. Cuaron², ¹Universidad Nacional Autonoma de Mexico Mexico City, ²Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias Queretaro, MX.

Two experiments were conducted to evaluate productive performance of lightweight pigs at weaning in response to vitamin C and β -carotene supplementation at 150 and 350 mg/kg of diet, respectively, on both a commercial farm (Trial 1) and an experimental farm (Trial 2). Supplementary energy source used in each experiment was oxidized canola oil in Trial 1 and oxidized tallow in Trial 2. In Trial 1, piglets were weaned at 22.08 ± 1.66 days of age and 5.47 ± 1.18 kg. In Trial 2 animals were weaned at 21.5 ± 0.85 days of age, weighing 5.79 ± 1.12 kg. Vitamins were added from a corrected standard commercial premix. Both trials were conducted as a randomized complete block design in a factorial arrangement (2 vitamin C 2 β -carotene levels) and the treatments were: 1) Vitamin C, 0 and β -carotene, 0 mg/kg of diet (T1); 2) Vitamin C, 150 and β -carotene, 0 mg/kg (T2); 3) Vitamin C, 0 and β -carotene, 350 mg/kg of diet (T3); 4) Vitamin C, 150 and β -carotene 350 mg/kg (T4). In Trial 1, there were no differences ($P > .13$) in ADFI, ADG and feed efficiency (FE). In Trial 2, after 20-d, a Vitamin C by β -carotene interaction in ADFI was observed ($P < .03$). ADFI was greater for T1 and T4 compared to T2 and T3 (.292 and .287 vs .251 and .259). The ADG and FE were not affected. It is concluded that antioxidant capacity of the diet provided by standard levels of Vitamin E, Se and chemical antioxidants (BHT) is sufficient to overcome oxidative stress imposed on lightweight pigs at weaning.

Key Words: Weanling Pigs, Vitamin C, Beta-Carotene

M80 Ontogeny of mitochondrial carnitine palmitoyltransferase I in porcine liver and skeletal muscle. P. Lyvers Pepper^{*1}, X. Lin¹, L. Averette Gatlin¹, J. Woodworth², and J. Odle¹, ¹North Carolina State University, Raleigh, ²Lonza, Inc., Fairlawn, NJ.

Molecular evaluation of carnitine status can be made by comparing tissue carnitine concentrations with the carnitine- K_M of carnitine palmitoyltransferase I (CPT I). Therefore, a study was conducted to assess hepatic and muscle mitochondrial CPT I kinetics in pigs during different stages of development. Mitochondria were isolated from liver and semitendinosus muscle from suckling, 24-h-old and fed 5-wk-old (2 wk post-weaning) pigs. Activity of CPT I was determined via radioenzymatic analysis, and the V_{max} and apparent K_M for carnitine were estimated. Activity (V_{max}) in skeletal muscle increased between 24 h and 5 wk of age, signifying developmental induction, but no change in V_{max} was detected in hepatic tissue. Despite increased CPT I activity of skeletal muscle, differences in the K_M for carnitine were not detected for either tissue examined. The ontogenic induction of skeletal muscle CPT I may be necessitated by contracting muscle preferentially oxidizing fatty acids as their primary fuel.

Carnitine palmitoyltransferase I kinetic constants (V_{max} and apparent K_M) measured in mitochondria from hepatic and muscle tissue of pigs¹

	AGE	
	24 h (n = 5)	5 wk (n = 4)
V_{max} , $\mu\text{mol}/(\text{hg mitochondrial protein})$		
Liver	25.1 ± 4.4	30.3 ± 4.9
Skeletal Muscle ^a	25.8 ± 4.0	44.9 ± 4.5

M81 Determination of true digestible calcium and phosphorus requirements in weaned pigs. M. Fan^{*1}, Y. Shen¹, T. Archbold¹, A. Holt¹, and Y. Yin², ¹University of Guelph, Guelph, Ontario, Canada, ²The Chinese Academy of Sciences, China.

This study was conducted to determine true digestible calcium (Ca) and phosphorus (P) requirements in weaned pigs. Thirty-six Yorkshire pigs (18 barrows and 18 gilts), initial and final BW of 10 and 18 kg, were fed six experimental diets for six periods according to a completely randomized block design. The six diets were corn and soybean meal-based, and formulated to contain six levels of total Ca at 0.49, 0.58, 0.67, 0.74, 0.83, and 0.92%, and total P at 0.42, 0.50, 0.58, 0.64, 0.72, and 0.80%, respectively, through supplementing limestone and dicalcium phosphate. Diet 1 was the control diet and contained 0.49% total Ca and 0.42% total P corresponding to 0.40% true digestible Ca and 0.21% true digestible P without supplemental P but with limestone supplementation. Each experimental period lasted 25 d with 20-d adaptation and 4-d collection of total urine excretion and fecal samples. BW gain and feed intake were recorded. Graded levels of Ca and P did not affect ($P > 0.05$) feed intake, weight gain, and feed conversion. Supplementation of P did not improve ($P > 0.05$) P retention, whereas Ca supplementation increased ($P < 0.05$) Ca retention. Diet 1, with total Ca and P contents below the NRC (1998) recommendations, was associated with the minimal levels of total manure Ca and P excretion. In conclusion, the current NRC (1998) recommendations of Ca and P requirements for weaned pigs are likely overestimated, therefore resulting in excessive manure Ca and P excretion.

Key Words: Calcium and Phosphorus, Requirements, Weaned Pigs

M82 Diet buffer capacity and mineral sources alter growth and Salmonella prevalence in nursery pigs. P. Bahson, M. E. Glenn, and T. D. Crenshaw^{*}, University of Wisconsin, Madison.

Diet buffer capacity and organic acids are potential substitutes for sub-therapeutic antibiotics in nursery pigs. Coliforms and clostridia, but not lactobacillus, were reduced in ingesta from nursery pigs fed diets with low buffering capacity (LB) vs. high buffering capacity (HB), organic acids, or antibiotics. The LB diets involved shifts in sources and levels of minerals, but LB and HB diets were based on plant protein (Pln) ingredients. Whether shifts in microflora were related to minerals or Pln ingredients was not distinguished. This trial involved pigs fed complex diets (Cmx) which included whey, lactose, porcine plasma protein and blood cells, or Pln diets used earlier. Diets included: 1) Cmx + carbadox, 2) Cmx + citric acid, 3) Cmx + HB, 4) Cmx + LB, 5) Pln + HB, 6) Pln + LB. No antibiotics were added to diets 2-6. In LB diets sources (tricalcium phosphate and calcium sulfate) and levels (0.80 % Ca and 0.80 % P, diets 1, 3, and 5; 0.55 % Ca and 0.65 % P, diets 2, 4, and 6) were altered. Ninety-six pigs (PIC Cambrough X Line 19) were weaned (3 wk) and randomly allotted to diets for 31 d (P1, 14 d; P2, 17 d). In P1, pigs fed Cmx + carbadox and Cmx + LB gained faster ($P < 0.01$) than those fed other diets over both P1 and P2. Pigs fed Pln diets gained less ($P < 0.01$) than pigs fed Cmx diets during P1, but not P2, or the entire 31 d. On d 0, 41% of pigs were Salmonella positive. Pigs fed the Cmx + LB diet had the highest prevalence on d 7, but prevalence was also higher on d 0 ($P < 0.01$). Salmonella prevalence apparently did not compromise growth. Feeding LB diets improved growth to levels equal to pigs fed carbadox.

Trait	Period	Cmx		Pln				SEM
		+ Carbadox	+ Citric acid	+ HB	+ LB	+ HB	+ LB	
Gain, kg/d								
	0-14 ^{abc}	0.098	0.073	0.062	0.117	0.048	0.016	0.011

^cCmx + HB, + LB differs from Pln + HB, + LB ($P < 0.05$).

Key Words: Antibiotics, Minerals, Salmonella

M83 Effect of supplementing zinc oxide and biotin with or without carbadox on nursery pig growth performance. H.D. Wilt* and M.S. Carlson, *University of Missouri, Columbia*.

A 28-d nursery experiment was conducted to evaluate the effects of supplementing zinc oxide (ZnO) and biotin with or without a feed-grade antibiotic (carbadox) on nursery pig performance, as well as plasma and fecal Zn concentrations. One hundred ninety-two crossbred pigs (5.94 ± 0.03 kg; 20 d of age) were weaned and allotted to one of eight treatments based on weight, sex, and ancestry in a randomized complete block design (3 pigs/pen and 8 reps). Phase 1 (d 1 to 14) and Phase 2 (d 15 to 28) nursery diets were fed in meal form. Fecal samples were collected weekly and pigs were bled on d 1, 14, and 28 to measure Zn concentrations. Phase 1 and Phase 2 diets utilized 8 dietary treatments in a 2 × 2 × 2 factorial design: (1) Basal diet contained 135 ppm Zn as ZnSO₄ and no supplemental d-biotin, (2) Basal + 25 g/T carbadox, (3) Basal + 3,000 ppm Zn as ZnO, (4) Basal + 3,000 ppm Zn as ZnO + 25 g/T carbadox, (5) Basal + 440 ppb biotin, (6) Basal + 440 ppb biotin + 25 g/T carbadox, (7) Basal + 3,000 ppm Zn as ZnO + 440 ppb biotin, and (8) Basal + 3,000 ppm Zn as ZnO + 440 ppb biotin + 25 g/T carbadox. Dietary treatments had no effect ($P > 0.05$) on growth performance during wk 1 or Phase 2. During wk 2, Phase 1 and overall, pigs fed either 3,000 ppm Zn as ZnO or 440 ppb biotin independently or in combination with or without carbadox had greater ADG ($P < 0.05$) than the pigs fed the basal diet. However, the greatest overall ADG ($P < 0.05$) was observed in pigs fed 440 ppb biotin with or without ZnO and carbadox. During wk 3 and Phase 2, pigs fed 440 ppb biotin with or without ZnO and carbadox had greater ADFI ($P < 0.05$) than the pigs fed the basal diet. Overall, Gain/Feed improved ($P < 0.05$) when pigs fed either the 3,000 ppm Zn as ZnO or 440 ppb biotin independently or in combination with carbadox. Plasma and fecal Zn concentrations were higher ($P < 0.05$) for pigs fed the 3,000 ppm Zn as ZnO compared to pigs fed the other dietary treatments. These results indicate that feeding nursery pigs either 440 ppb biotin or 3,000 ppm Zn as ZnO improve growth performance with or without carbadox.

Key Words: Biotin, Nursery pigs, Zinc

M84 Impact of feeding herbal extracts and additional copper plus zinc on growth performance and immune function of newly weaned piglets. H. Namkung* and C. F. M. de Lange, *Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada*.

The effect of feeding herbal extracts or additional copper plus zinc to newly weaned piglets on growth performance, gut morphology, and immune system stimulation were investigated. One hundred eighty piglets

(16-19 days of age) were randomly assigned to one of five treatments: non-medicated control (CO), medicated (44 ppm Lincomycin; CO+), herbal extract product (essential oils and spice extracts; Phodé, Albi, France) at diet levels of 0.3 and 0.15% (HEh) or 0.2 and 0.1% (HEl) for phase I and II, respectively, and 160 and 150 ppm of additional copper plus zinc (from copper sulfate and zinc oxide; Cu/Zn). Phase I diets (20.5% CP) were fed for the first three weeks post-weaning and Phase II diets (19.6% CP) thereafter. During phase II, weight gain was highest ($P < 0.01$) for pigs on Cu/Zn, lowest ($P < 0.01$) for CO and intermediate for the other treatments. Over the 7-wk period, there were no differences ($P > 0.01$) in weight gain among pigs on HEh, HEl and CO+ (442, 418 and 431 g/d, respectively), while it was highest for Cu/Zn (481 g/d) and lowest for CO (351 g/d; SEM, 18). Gain:feed and fecal consistency scores were not different among treatments ($P > 0.05$). There were no differences ($P > 0.05$) in morphology of intestine of pigs among treatment, although full and empty weights of total gut, small intestine, and cecum were numerically lower in the pigs on HEh and Cu/Zn and the numbers of goblet cells tended to be increased in villi and decreased in crypt in intestines of pigs fed HEh and HEl. Counts of white blood cells and neutrophils were higher ($P < 0.01$) in pigs on d 14 than on d 7 post-weaning. Lymphocyte count was lower ($P < 0.05$) in pigs on HEl compared to other treatments. Plasma concentrations of IgG on d 14 tended to be lower ($P < 0.10$) in pigs on HEl, HEh, Cu/Zn, CO+ than on CO. These results suggest that the herbal extract product could be used as an alternative to in-feed antibiotics.

Key Words: Piglets, Herbal Extract, Growth Promotion

M85 The role of high dietary zinc oxide in cholecystokinin and insulin-like growth factor I secretion and growth in weaned pigs. D. Li* and J. Yin, *Ministry of Agriculture Feed Industry Center, China Agricultural University, Yuanminyuan, Beijing*.

In this study, the mechanism through which high levels of dietary zinc oxide (ZnO) stimulate pig growth was investigated. Thirty-six, 28-d old weaned male pigs (initial BW, 7.5 ± 0.5 kg) were randomly assigned to one of two treatments, with 6 pens per treatment and 3 pigs per pen for the 4-wk experiment. The pigs were fed a corn-soybean meal basal diet (20% CP) either supplemented or unsupplemented with 2,000 mg/kg zinc as ZnO. Blood samples (n = 10/treatment) were collected from anterior vena cava, and RNA samples (n = 6) were extracted from the duodenum and the liver. Real time fluorescence quantitative PCR was used to evaluate hormone gene expression of cholecystokinin (CCK), growth hormone receptor (GHR) mRNA, and insulin-like growth factor I (IGF-1) at the transcription level. The results indicated that ADG was improved by zinc supplementation from 0-2 wk ($P < 0.02$) and 0-4 wk ($P < 0.03$) with an improvement in feed conversion from 0-2 wk ($P < 0.01$). Dietary supplementation of ZnO increased the levels of plasma CCK (5.11 vs 3.07 pmol/L, $P < 0.01$) and serum IGF-1 (386.11 vs 227.42 ng/ml; $P < 0.03$). No changes were detected in other gut-brain peptide concentrations including insulin, gastrin, somatostatin (SS) or growth hormone (GH). In the duodenum, the abundance of CCK mRNA and pregastrin mRNA were 2.54 times ($P < 0.01$) and 1.97 times ($P < 0.01$) greater in pigs receiving the diet containing ZnO. In the liver, levels of IGF-1 mRNA and GHR mRNA were increased [4.74 vs 0.23 ($P < 0.001$) and 16.02 vs 6.28 ($P < 0.02$), respectively] by ZnO supplementation. No differences in the level of duodenum IGF-1 mRNA were detected ($P > 0.10$). In conclusion, results indicate that supplementation of pharmacological level of zinc oxide used in this study may enhance plasma CCK content at the level of mRNA transcription, and further upregulate the liver GHR mRNA and IGF-1 mRNA abundance and raise plasma IGF-1 levels. This may help explain the mechanism through which piglet growth is stimulated by zinc oxide.

Key Words: Pig, Zinc Oxide, Gene Expression

Nonruminant Nutrition: Weanling Pig - Energy & Protein

M86 The interaction between cereal source and lactose level on piglet growth performance post weaning. J. M. O'Connell*, J. J. Callan, and J. V. O' Doherty, *Department of Animal Science and Production, University College, Dublin, Ireland.*

Both barley and wheat contain anti-nutritive factors such as β -glucans and xylans, respectively. However, β -glucans have been shown to promote lactic acid bacteria in the large intestine and this would be very beneficial in the absence of in-feed antimicrobial growth promoter. A 2 x 2 factorial was used to investigate the interaction between cereal type (wheat vs. barley) and lactose inclusion (108 vs. 216 g/kg) on piglet performance post weaning. Two hundred weaned piglets (24 d of age; 6.0 kg weight) were blocked on the basis of weight and were assigned to one of four treatments. The treatments were as follows: (1) 150 g/kg lactofeed 70 (LF70); 840 g whey permeate and 160 g soybean meal/kg; Volac Feeds Ltd, U.K.) and barley, (2) 150 g/kg LF70 and wheat, (3) 300 g/kg LF70 and barley, and (4) 300 g/kg LF70 and wheat. The diets were formulated to have identical digestible energy (3.82 Mcal/kg) and total lysine (16 g/kg). The pigs were offered the diets *ad libitum* for 33 d post weaning. Pigs offered 300 g/kg LF70 had a higher ADFI than the pigs offered 150 g/kg LF70 in the diet (0.489 vs. 0.424 kg/d; SEM, 0.014; $P < 0.01$). The inclusion of 300 g/kg LF70 resulted in a deterioration in food conversion ratio (FCR; 1.29 vs. 1.15 kg/kg; SEM, 0.05; $P < 0.05$) compared to the 150 g/kg LF70 inclusions. Cereal source had no effect on ADFI or FCR. There was a significant interaction ($P < 0.05$) between cereal source and lactose levels in ADG and final live weight. In wheat-based diets, the inclusion of 300 g/kg LF70 increased ADG and final live weight compared to 150 g/kg inclusions. However, in barley-based diets, the inclusion of 300 g/kg LF70 had no effect on ADG or final live weight. In conclusion, the inclusion of 300 g/kg LF70 increased ADFI compared to 150 g/kg LF70. However, higher lactose inclusion is more beneficial in wheat-based diets than in barley-based diets.

Key Words: Pigs, Lactose, Cereal

M87 Performance and nutrient digestibility of low tannin sorghum fed to pigs from 10 to 30 kg. E. T. Fialho*, P. B. Rodrigues, J. A. F. Lima, H. O. Silva, and V. Oliveira, *University Federal of Lavras - UFLA- BRAZIL.*

Two experiments were conducted to determine the effect of corn substitution by low tannin (LT) sorghum on pig performance from 10 to 30 kg BW. In a metabolism assay, nitrogen retention, digestibility of CP (DCCP), DE and ME of diets with sorghum substitution at 0, 33, 66 and 100% for corn. The metabolism assay was carried out in two periods by using 24 pigs (Landrace x Large White; 12.5 \pm 0.7 kg BW). A 7 d period for adaptation and 5 d period for total collection of feces and urine with ferric oxide (2%) as the indigestible marker was used. In the performance assay, 96 pigs (Landrace x Large White; 9.4 \pm 0.86 kg BW) weaned at 35 days were assigned to six replicates of the same four treatments as described for the metabolism assay. The experimental period was 30 days. The data revealed no effects ($P > 0.10$) over all treatments tested for nitrogen retention (21.20% for the diet with 100% corn as the cereal vs 19.07% for diet with 100% sorghum as the cereal), DCCP (85.00% for diet with 100% corn vs 85.80% for diet with 100% sorghum), DE (3821 Kcal/kg DM for diet with 100% corn vs 3793 Kcal/kg DM for diet with 100% sorghum) and ME (3619 Kcal/kg DM for diet with 100% corn vs 3670 Kcal/kg DM for diet with 100% sorghum). The data of feed intake (1.21 kg/d for 100% corn vs 1.25 kg/d for 100% sorghum), ADG (0.648 kg for 100% corn vs 0.620 for 100% sorghum) and feed:gain (1.86 for 100% corn vs 2.02 for 100% sorghum) also revealed no differences ($P > 0.10$) among all diets tested. Corn can be replaced by LT-sorghum up to level of 100% in pig diets from 10 to 30 kg BW with no influence on nutrient digestibility or pig performance.

Key Words: Pigs, Sorghum, Performance

M88 Effect of different sources and levels of lipids on the performance of pigs postweaning. M. E. Pimenta², J. A. Lima^{*1}, E. T. Fialho¹, P. Logato¹, and L. D. Murgas¹, ¹University Federal of Lavras - UFLA-Brazil, ²Universidade de Alfenas- UNIFENAS-Brazil.

A total of 144 crossbred piglets (72 barrows and 72 gilts; initial BW 6.90 \pm 1.32 kg) were utilized at 28 days of age to determine the effect of the addition of two sources of lipids (soybean oil and coconut oil) at different levels (2, 4, 6 and 8%) on postweaning performance. A 2 x 4 factorial arrangement of treatments (sources and levels of oils) plus an additional treatment (control diet without lipids addition). The experimental diets were isocaloric, isoprotein and isolysine, formulated based on corn, soybean meal, skimmed milk powder and fish meal supplemented with minerals, vitamins and lysine. There were no interactions between sources and levels of oil tested ($P > 0.05$) for any of the performance parameters. Also, no differences were shown ($P > 0.05$) in the ADG or feed/gain of pigs fed diets supplemented with soybean oil (ranging from 0.450 - 0.470 and 1.42 - 1.65) or coconut oil (ranging from 0.400 - 0.486 and 1.57 to 1.64) at the different levels tested. Comparing the performance of pigs fed diets with 2, 4, 6, 8% soybean oil and coconut oil with the control diet (without lipid addition), it was observed higher ($P < 0.01$) daily feed intake and poorer ($P < 0.01$) feed:gain when lipid was not added to the diet. The addition of lipids in the postweaning diets is a viable option due to better pig performance.

Key Words: Pigs, Coconut Oil, Soybean Oil

M89 Piglets at weaning or three weeks post-weaning prefer rice to sorghum. D. Solà-Oriol¹, E. Roura^{*2}, and D. Torrallardona¹, ¹IRTA, Centre de Mas Bové Apartat 415, Reus, Spain, ²Lucta SA Montornés del Vallés, Barcelona, Spain.

Palatability of feed ingredients may affect voluntary feed intake particularly when sudden dietary changes such as occur after weaning. The aim of the trial was to design an experimental model to establish feed ingredient preferences. A double choice test was performed between broken rice and sorghum at different inclusion levels in the diet (25, 50 and 100%) at two different piglet ages, 28 and 48 days (12 pens each). For each age group the pigs were distributed into four blocks of initial body weight. The diets were offered *ad libitum*, in mash form and feed intake measured over an 8d period for the 25 and 50% inclusion levels and over a 6d period for the 100% inclusion level. The preference of sorghum relative to rice was calculated as the percentage contribution of the sorghum diet to total feed intake. Preference values were analysed as a complete block design with four blocks and six treatments (2 ages by 3 levels of inclusion). Treatment effect comprised the components age, inclusion level and their interaction. ANOVA was performed using the GLM procedure of the statistical package SAS. The average preference for each of the treatments was compared to a neutral value of 50% using a Student's t test. With the newly weaned pigs, the preferences for sorghum (relative to rice) at 25, 50 and 100% inclusions were 45.8, 22.7 and 27.3 % respectively. The adverse preference observed for the 50% inclusion level was significantly different to the neutral value ($P < 0.01$). In the post-weaned pigs, the preferences for sorghum (relative to rice) at 25, 50 and 100% inclusions were 12.4, 19.7 and 29.9 % respectively. The preference values were significantly different to 50 ($P < 0.01$) for the 25 and 50% inclusion levels. No statistically significant effects were observed for animal age, inclusion level of the ingredients or their interaction. In conclusion, pigs prefer rice to sorghum and this preference is not dependent on animal age or the inclusion level in the diet.

Key Words: Palatability, Rice, Sorghum

M90 Enzyme supplementation of piglets fed diets containing barley, wheat, and corn. J. Sánchez¹, A. Fuentetaja², J. C. González¹, J. Peinado¹, and M. I. Gracia^{*1}, ¹Imasde Agropecuaria, S.L. Spain, ²Copese, S.A. Spain.

A study evaluated the efficacy of a feed additive enzyme (Amylofeed, EC No 34) containing 275 U/g of endo-1,3(4)- β -glucanase (EC 3.2.1.6), 400 U/g of endo-1-4- β -xylanase (EC 3.2.1.8), and 3,100 U/g of α -amylase (EC 3.2.1.1) on performance of piglets from weaning at 28 d to 60 d of age. Five hundred and twenty eight crossbred piglets (Duroc x Large

White*Landrace, half of each sex), weighing 7.36 ± 1.29 kg, were allocated randomly to 16 replicates of 33 piglets each. A completely randomized design was applied using two experimental treatments: 1) basal diet (control), 2) basal diet with 500 mg enzyme/kg feed, the recommended dose. The experimental design was applied in both the prestarter (28 to 44 d of age) and the starter (44 to 60 d of age) periods. Diets were based on barley, wheat and corn, and had 2.4 Mcal NE/kg and 14.8 g/kg lysine for prestarter, and 2.4 Mcal NE/kg and 13.3 g/kg lysine for starter. Data were analyzed as a completely randomized design with dietary treatment and sex as main effects and weaning weight as a covariate. General performance in the post weaning period was good. There were no significant differences between treatments with regard to feed consumption, growth, mortality or piglet cleanliness. But, for the overall period (28 to 60 d of age), piglets supplemented with the enzyme had better feed conversion ratio than control animals (1.18 vs 1.32 g feed/g gain; $P=0.01$). It was concluded that the addition of the enzyme to piglet diets improved feed efficiency from weaning until 60 d of age.

Key Words: Glucanase, Xylanase, Amylase, Enzyme, Piglets

M91 Technical feasibility of processed corn and soybeans in diets of piglets from 21 to 56 days of age. P. A. Castelo Branco, J. A. Lima, E. T. Fialho*, P. V. R. Logato, and R. T. Freitas, *University Federal of Lavras - UFLA-Brazil*.

Two experiments were carried out to evaluate the use of two corn types (common corn - C1 and pre-jellied flour of corn [higher temperature starch extrusion] - C2) and two soybean types (soybean meal - S1 and micronized soybean - S2) and their combinations in diets of post-weaning pigs from 21-56 days. The performance, relative weight of the digestive organs, and duodenum and jejunum villi height and crypt depth were evaluated. A total of 112 pigs (56 barrows and 56 gilts; mean initial BW of 7.2 ± 0.8 kg) weaned at 21 days were utilized in a 2×2 factorial design with seven replicates and four pigs per replicate pen. There was no interaction among types of corn or soybean on the performance (ADG, ADFI and feed conversion). The relative weight of the liver and large intestine of piglets at 33 days of age was influenced ($P<0.05$) for the two soybean types, being the highest for those fed soybean meal and the smallest when the micronized soybean was utilized. The relative weight of the stomach was influenced by the two corn and soybean types ($P<0.05$), being the highest weight observed for the C1+S1 combination (0.912 g) and the lowest for the C2+S2 combination (0.744 g). The treatment mixtures of C1+S2 (414.6) or C2+S2 (428.7) shown higher villi height and lower (122.2 and 152.6) crypt depths ($P<0.05$) respectively. According to the results it is technically feasible to utilize the pre-jellied flour of corn and the micronized soybean in diets since they provide gut health improvements in piglets from 21 to 56 days old. The economic viability should be considered at the current market feed prices.

Key Words: Feeds, Performance, Soybean

M92 Efficacy of a vegetable-based peptide product as a replacement for plasma protein in nursery pig diets. E. C. Halbrook*¹, C. V. Maxwell¹, M. E. Davis¹, Z. B. Johnson¹, D. C. Brown¹, R. Dvorak², and R. Musser³, ¹University of Arkansas, Fayetteville, ²Alltech Inc., Nicholasville, KY, ³Hubbard Feeds, Mankato, MN.

A total of 216 pigs were fed one of three dietary treatments to evaluate the efficacy of feeding a vegetable-based peptide product (NuPro#8482) as an alternative to plasma protein in nursery pig diets. Pigs were sorted by weight, and divided into three weight blocks. Pigs within each block were allotted into equal subgroups (six pigs/pen) with equal distribution of sex and litter. Four treatments were randomly assigned to pens within each weight block (9 pens/treatment). Three dietary treatments were fed from d 0 to 7 after weaning (Phase 1) and d 7 to 21 after weaning (Phase 2) and were comprised of: 1) a basal diet consisting of a complex nursery diet containing spray dried plasma protein devoid of NuPro, 2) the basal diet with 50% of the plasma protein replaced by NuPro, and 3) the basal diet with 100% of the plasma protein replaced by NuPro. During Phase 3 (d 21 to 42 after weaning), a common diet was fed to groups previously receiving treatments 1 and 2. One half of the pigs previously fed treatment 3 (100% replacement level of NuPro) were fed the common diet received by the treatment groups 1 and 2; while the other half were fed a diet containing 1.3% NuPro during the first week of Phase 3 (d 21 to 28), followed by the common diet for the

remainder of the phase (d 28 to 42). During Phases 1 and 2, no significant differences were observed among the four dietary treatments with regard to ADG, ADFI, or G:F, regardless of level of NuPro replacement for plasma protein. During the first week of Phase 3, pigs previously fed the basal diet containing plasma protein and fed NuPro at the 50% replacement level tended to have lower ($P = 0.07$) ADFI than pigs previously fed NuPro at the 100% replacement level and pigs fed NuPro at 1.3% of the diet during the first week of Phase 3. This study indicates that NuPro maybe used as an alternative to spray-dried plasma protein in nursery pig diets without detrimental effects on growth performance.

Key Words: Growth, Protein, Swine

M93 Effect of reduced protein in weaning pig diets. M. G. Zangeronimo, E. T. Fialho*, J. A. F. Lima, P. B. Rodrigues, and L. D. S. Murgas, *University Federal of Lavras-UFLA-BRAZIL*.

In order to evaluate the effect of a reduction of the CP content in diets of weaning piglets formulated on an ideal protein concept, a metabolism assay (1), an organs characteristics weight (2) and a performance assay (3) were conducted. In Assay 1, eight barrows (LD x LW; 12 ± 2.4 kg initial BW) were utilized to evaluate four treatments with pig as the experimental unit. In Assay 2, 60 weaning pigs (8.6 ± 0.8 kg initial BW) were utilized with a factorial scheme of the 4 dietary treatments and 3 slaughter periods resulting in five replications (each pig served as an experimental unit). In Assay 3, a total of 60 weaning pigs (8.0 ± 0.7 kg initial BW) were utilized to evaluate four dietary treatments; a total of five replicate pens of three pigs each with pen as the experimental unit resulted. For all assays the dietary treatments were formulated to contain different levels of CP, being one control (21% CP, 3400 Kcal DE/kg) diet and the others with reduced levels of CP (19.5; 18.0 and 16.5%) with all diets corrected by crystalline AA (lysine, methionine and threonine) according to NRC (1998). The digestibility of dry matter (DDM); N retention (NR); liver, spleen and pancreas weight; the duodenum villi height and crypt depth; pH of the stomach and cecum contents; and pig performance were analyzed. It was found that the treatments did not influence ($P>0.05$) any of the parameters studied, except for the crypt depth in first week postweaning ($P<0.05$) for those pigs fed diet with 18.0% CP. The ADG (kg) and feed conversion were 0.378 and 1.90 for control (21% CP); 0.393 and 1.97 for the 19.5% CP; 0.452 and 1.88 for 18.0% CP and 0.420 and 1.83 for 16.5% CP, respectively. In conclusion it is technically feasible to reduce the CP in the diets for weaning pigs if the essential AA are kept at similar levels. The environmental impact should be reduced by using lower levels of CP in the diets.

Key Words: Performance, Environmental, Lysine

M94 Effects of feeding rice protein concentrate on growth performance and ileal digestibility in early weaned pigs. C. Byung-Jo*, Y. Jung-Ho, Y. Ji-Soon, C. Jae-Yong, K. Jae-Young, and L. Jayant, *Kangwon National University, Chunchon, South Korea*.

These experiments were conducted to evaluate the feeding value of rice protein concentrate (RPC) in weaning pigs. In Exp. 1, a 5-week feeding trial was conducted with a total of 126 pigs (LYD; 21 d-old; 5.32 ± 0.34 kg). Treatments were spray-dried plasma protein (SDPP; control), soy protein concentrate (SPC) and RPC (Phase 1), and dried porcine soluble (DPS; control), SPC and RPC (Phase 2). An ileal digestibility trial was also conducted to compare digestibility of amino acids in the tested protein sources. In Exp. 2, a total of 160 weaning pigs (LYD; 21 d-old; 5.65 ± 0.35 kg) were used in a 5-week feeding trial to determine the optimal inclusion level of SPC in the diet. Treatments were control (9% SPC), and three levels of RPC instead of SPC in the diet (3, 6 and 9%). During Phase 1, pigs fed SDPP had better ($P<0.05$) ADG and FCR (308 g, 1.29, respectively) compared to those fed SPC (263 g, 1.49) or RPC (266 g, 1.51), while there was no difference in ADFI among treatments. During Phase 2, however, pigs fed DPS had lower ($P<0.05$) ADG (350 g) than those fed SPC (436 g) or RPC (434 g). The apparent ileal digestibilities of His, Lys, Phe, Thr, and Met were not different among the tested protein sources. In Exp. 2, there were no significant differences in ADG and FCR when SPC was substituted with RPC up to 9% during the total period. In conclusion, based on our

experimental results, RPC can replace SPC in the complex prestarter diet.

Key Words: Rice Protein Concentrate, Soy Protein Concentrate, Growth

M95 Effect of RPC (rice protein concentration) as a substitute for protein sources in weaning pigs. O. S. Kwon^{*1}, B. J. Min¹, K. S. Son¹, J. H. Cho¹, J. D. Kim², I. H. Kim¹, S. H. Ahn³, and H. S. Ahn³, ¹Dankook University, Cheonan, Korea, ²CJ Feed Co. Ltd., Korea, ³EUNJIN International Co. Ltd., Korea.

A total of 120 pigs (LYD, 7.79 kg average initial BW) were used in a 28-d growth assay to determine the effect of RPC (Rice Protein Concentration) as a substitute for protein sources on growth performance and nutrient and amino acid digestibility in weaning pigs. Dietary treatments (Trt) included: 1) A (basal diet; Control), 2) B (replaced protein source with 3% RPC), 3) C (replaced protein source with 4.5% RPC) and 4) D (replaced protein source with 6% RPC). Through entire experimental period, pigs fed diet containing 3% RPC tended to have increased ADG compared to pigs fed diet containing 4.5% RPC ($P < 0.05$). However, there were no differences in ADFI and G/F among the treatments ($P > 0.05$). Although there was no difference in blood urea nitrogen (BUN) among all treatments ($P < 0.05$), pigs fed the basal diet were numerically higher than other treatments. Nitrogen digestibility in Trt D tended to be higher than Trts A and C ($P < 0.05$). The apparent digestibility of asparagic acid tended to be higher for Trt D compared to other treatments ($P < 0.05$). However, there were no differences in other amino acids among the treatments ($P > 0.05$). In conclusion, the results obtained from this feeding trial suggest that dietary RPC for weaning pigs can be utilized as a substitute for protein sources.

Key Words: Rice Protein Concentration, Digestibility, Pigs

M96 Influence of a soy protein hydrolysate on the productive performance of early weaned pigs under an enterotoxigenic E. coli (ETEC) colibacillosis or under a healthy status. G. Ferrini¹, E. Borda², D. Martinez-Puig^{*2}, E. Garcia-Manzanilla¹, S. Martin-Orue¹, and J. Perez¹, ¹Universitat Autònoma de Barcelona Spain, ²BIOIBERICA Spain.

There are numerous reports that suggest an association between some protein sources (as soya) and the incidence of diarrhea in early weaning piglets. The mechanisms proposed are a likely hypersensitivity reaction, and/or a disbiosis promoted by the fermentation of undigested carbohydrates or proteins. We studied the effect of three prestarter diets (CP 193 g/kg, Lys 13.7g/kg) on the productive results of 192 early weaned (21d) piglets: 96 under an ETEC colibacillosis (Experiment 1) and 96 under a healthy status (Experiment 2). Diets contained soybean ingredients: SBM (extruded soybean meal 28.9 g/kg, and soybean meal, 107.8 g/kg), SPC (a soy protein concentrate, 92.3 g/kg), or SPH (a soy protein hydrolysate, 100 g/kg). Chromium oxide was used as internal marker for digestibility measurements. Animals were placed in 32 replicates (4 animals/replicate). During Experiment 1, an ETEC colibacillosis was clinically diagnosed on d 6 after weaning. Although scours were evident in all groups on d 7, most of the piglets fed SPH and SPC recovered after antibiotic therapy on d 9, whereas those fed SBM continued having severe diarrhea. Mortality was higher with SBM (18.7%), than SPC (9.37%) and SPH (3.1%). In Experiment 2, a higher digestibility of OM was found for the SPH (87.8%) than SPC (86.6%) and SBM (84.8%; $P < 0.05$). Nitrogen digestibility was also higher for SPH (83.4%) than SPC (81.2%) and SBM (79.1%; $P = 0.11$). During the second week after weaning, the ADG of the pigs fed SPH (247 g/d) and SBM (244 g/d) were higher ($P < 0.05$) than that of the pigs fed SPC (228 g/d). The overall results suggest that the hydrolysis of soy protein improves the health and productive performance of early-weaned piglets under healthy and unhealthy environment conditions. In conclusion, SPH appears to be an excellent protein source for the early-weaned pigs.

Key Words: Soybean, Protein, Piglets

M97 Liquid diets containing vegetable proteins accelerate piglet growth above milk-protein-based diets. A. Ebert¹, A. S. Berman¹, R. H. Harrell², S. G. Cornelius¹, and J. Odle^{*1}, ¹North Carolina State University, Raleigh, ²Milk Specialties Co, Dundee, IL.

Technologies to rear suckling piglets apart from the sow recently have been implemented on large commercial farms, and success has been measured in both accelerated growth and in reduced pre-weaning mortality. However, diets formulated with cow-milk proteins can be cost-prohibitive. This experiment compared the replacement of whey protein (WHEY) with isolated soy protein (ISP), a hydrolyzed vegetable-protein mixture (HYDROL) or the latter in 50% combination with whey protein (WHEY/HYDROL) in liquid diets fed to neonatal pigs from two to 19 d of age. Pigs were housed individually in an environmentally controlled room and were offered the liquid diets ad libitum via a gravity-flow feeding device. On d 19, pigs fed the vegetable-protein diets weighed 20% more ($8,179 \pm 211$ g; $P < 0.05$) than pigs fed the WHEY diet ($6,805 \pm 244$ g). The ADG was 35% higher for pigs fed the HYDROL diet than for pigs fed the WHEY diet, and ADFI was greater for WHEY/HYDROL and HYDROL diets compared to the WHEY diet ($P < 0.05$). Overall, pigs fed the HYDROL diet had a 16% higher G/F than pigs fed the WHEY diet. Although the apparent ileal digestibilities of most amino acids were 7-10% greater for the WHEY diet, digestible amino acid intakes were about 20% greater for HYDROL and ISP diets. Carcasses of pigs fed the WHEY diet contained a higher percentage of fat and ash and a lower percentage and accretion of protein. These results are likely related to a poorer balance of amino acids (especially arginine) in the WHEY diet. Leucine aminopeptidase activity in the distal small intestine was up to 58% greater in pigs fed the WHEY/HYDROL diet than in those fed the ISP diet. Similarly, villus height ($P < 0.02$) and area ($P < 0.006$) along the small intestine were greater in pigs fed the WHEY/HYDROL diet than in those fed ISP. Collectively, these data support the conclusion that both the hydrolyzed vegetable protein and isolated soy protein are good alternatives to whey protein in liquid diets formulated for neonatal pigs and that an appropriate balance of amino acids is more important than the source of protein per se.

Key Words: Protein, Liquid Feeding, Amino Acid Digestibility

M98 Interaction between threonine and avilamycin on piglet growth performance post weaning. J. M. O'Connell^{*}, J. J. Callan, and J. V. O' Doherty, Department of Animal Science and Production, University College, Dublin, Ireland.

The amino acid Threonine (Thr) is involved in the synthesis of intestinal mucin, which plays a key role in the innate immune defence of the mucosa. Synthesis and secretion of mucin is greatest when gut inflammation is high such as at weaning. The requirement for dietary threonine may be increased in the absence of in-feed antimicrobial growth promoters (AGP). A 3 x 2 factorial was used to investigate the interaction between Thr level [55, 65 and 75% of lysine (lys)] and AGP (0 or 60 ppm avilamycin) on piglet performance post weaning. Three hundred and sixty weaned piglets (24 d of age; 5.9 kg live weight) were blocked on the basis of weight and were assigned to one of six treatments. The treatments were as follows: (1) Thr:Lys ratio of 55% and avilamycin (300 ppm Maxus, Elanco Animal Health Ltd., USA), (2) Thr:Lys ratio of 55% and no avilamycin, (3) Thr:Lys ratio of 65% and avilamycin, (4) Thr:Lys ratio of 65% and no avilamycin, (5) Thr:Lys ratio of 75% and avilamycin, and (6) Thr:Lys ratio of 65% and no avilamycin. The diets were formulated to have identical digestible energy (3.82 Mcal/kg) and total lysine (16 g/kg). The pigs were offered the diets ad libitum for 28 days post weaning. There was no interaction between Thr and avilamycin ($P > 0.05$) in any variable measured. The inclusion of avilamycin in the diet had no effect on feed intake (FI; 0.546 vs. 0.552 kg/d; SEM, 0.009), ADG (0.402 vs. 0.405 kg/d; SEM, 0.007), food conversion ratio (FCR; 1.36 vs. 1.37 kg/kg; SEM, 0.02) or final liveweight (17.2 vs. 17.3 kg; SEM, 0.2). Thr:Lys ratio had no effect on FI (0.545 vs. 0.550 vs. 0.552 kg/d; SEM, 0.010), ADG (0.399 vs. 0.411 vs. 402 kg/d; SEM, 0.008), FCR (1.37 vs. 1.34 vs. 1.38 kg/kg; SEM, 0.02) or final liveweight (17.1 vs. 17.5 vs. 17.2 kg; SEM, 0.3). In conclusion, optimum piglet performance was obtained at a Thr:Lys ratio of 55% and there was no advantage to avilamycin inclusion in the diet under current conditions.

Key Words: Pigs, Threonine, Avilamycin

M99 Developmental regulation of fructose and amino acid transporter gene expression in the small intestine of pigs. X. Xiao*, E. A. Wong, and K. E. Webb, Jr., *Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg.*

To evaluate the developmental regulation of nutrient transporter gene expression in the small intestine, piglets from each of seven sows were killed at birth (d 0), during lactation (d 1, 3, 7, 14, and 21) and post-weaning (d 22, 24, 28, and 35; weaned at d 21). Intestinal segments (duodenum, jejunum, and ileum) were collected for RNA isolation. The abundance of mRNA was determined by Northern blotting using probes specific for transporters of fructose (GLUT5), neutral amino acids (LAT2) and cationic amino acids [$b^{0,+}$ AT, ATB(0)]. During lactation, there was an interaction ($P < 0.01$) between time and segments for abundance of GLUT5 mRNA. Abundance of GLUT5 mRNA generally increased from d 1 to 7 and subsequently declined to d 14 in the jejunum and ileum. In duodenal tissue, abundance decreased from d 0 to

3 and then increased to d 21. Abundance of LAT2 mRNA declined ($P < 0.001$) linearly from d 0 to 21. The LAT2 mRNA was predominantly distributed in the ileum ($P < 0.05$). Abundance of $b^{0,+}$ AT mRNA changed quadratically ($P < 0.001$) from d 0 to 21. Abundance of $b^{0,+}$ AT mRNA was greater ($P < 0.05$) in the ileum and jejunum than the duodenum. There was an interaction ($P < 0.001$) between time and segments in abundance of ATB(0) mRNA. Abundance generally increased from d 0 to 21 in the duodenum and ileum with the change in the ileum being greater. In the jejunum, abundance increased from d 0 to 7 and then decreased to d 21. During post-weaning, mRNA abundance of all transporters dramatically increased from d 21 to 22 or 24 and then rapidly decreased to d 24 or 28. Subsequent changes varied with transporter and intestinal segment. In conclusion, gene expression of these four nutrient transporters is not only differentially regulated by age but also differentially distributed among intestinal segments.

Key Words: Pig, Intestine, Amino Acid Transporter

Nonruminant Nutrition: Weanling Pigs - Additives

M100 Evaluation of organic acid blends and antibiotics for promoting growth of young pigs. D. W. Giesting*¹, M. J. Pettitt², and E. Beltranena^{2,3}, ¹*Cargill Animal Nutrition, Minnetonka, MN*, ²*Prairie Swine Centre, Inc., Saskatoon, SK, Canada*, ³*Provincial Department of Agriculture-Alberta, Edmonton, AB, Canada*.

Two, 5-wk, post-weaning growth experiments were conducted to evaluate the effects of blended organic acids (OA) alone or in combination with antibiotics on young pig performance. In the initial study, two acidifier blends were each included at 0.4% to starter diets alone, or in combination with LS20 antibiotic (22 mg/kg each lincomycin+spectinomycin). In the first 2-wk phase, each additive treatment improved gain (ADG) and feed conversion (F/G) v. negative controls ($P < .05$). ADG was 141, 178, 185, 187, 183 and 175 g/d for pigs fed the negative control (NEG), OA Blend A, Blend B, LS20, Blend A+LS20 and Blend B+LS20, respectively. F/G was improved ($P < .05$) for each of the OA, LS20 or OA+LS20 treatments. F/G was 1.80, 1.49, 1.45, 1.50, 1.37 and 1.42, for the treatments, ordered as above. Differences were not significant in the subsequent 3-wk period ($P > .10$). In experiment 1, OA blends improved performance similarly to LS20. In the second experiment, pigs were fed OAs (Blend C or Blend D), at 0.3% inclusion rate, ASP250 (110 mg/kg each of chlortetracycline and sulfamethazine, 55 mg/kg penicillin) or ASP250+Blend C. Pigs fed Blend C had 10% higher ADG (164 g/d) v. negative controls (148) ($P > .10$); pigs fed Blend D gained 17% faster (175) v. controls ($P < .10$). ASP250 improved ADG 33% (199) ($P < .05$). ASP250+Blend C improved ADG 61% (238) ($P < .05$). F/G was 1.38, 1.29, 1.33, 1.27 and 1.16 for negative control, ASP250, Blend C, Blend D and Blend C+ASP250, respectively. Only the combination of the OA blend and antibiotic improved ($P < .05$) F/G significantly. In period 2, gain was increased 6% by either blend ($P < .10$), 17% by ASP250 ($P < .05$) and 20% by ASP250+Blend C ($P < .05$). In this study, the antibiotic produced a stronger response than the OA blends, but an additive benefit was noted when the additives were used together. In these two experiments, OA blends improved ADG and F/G and enhanced the effects of antibiotics in promoting improved performance.

Key Words: Growth, Organic Acids, Antibiotics

M101 Interaction between lactose, avilamycin and inulin on piglet growth performance and nutrient digestibility post-weaning. K. M. Pierce*¹, J. J. Callan¹, P. McCarthy², and J. V. O'Doherty¹, ¹*University College Dublin, Ireland*, ²*Volac International Ltd, UK*.

One hundred and eighty piglets (24 d, 6.0 kg BW) were used to investigate interactions between lactose, avilamycin and inulin on growth performance and nutrient digestibility in post weaned piglets. The piglets were blocked on the basis of live weight and within each block assigned to one of six dietary treatments (6 pens/trt with 5 pigs/pen). The piglets were offered diets containing either a low (175 g/kg) lactofeed (LF70; 860 g/kg whey permeate, 140 g/kg soy bean meal; Volac International, UK) (LLF) or high (350 g/kg) LF70 (HLF) level with one of the following feed additives (FA) 1) 0 supplementation 2) 60 ppm avilamycin (Maxus, Elanco Animal Health, USA) (M) or 3) 15 g/kg inulin (I) in a

3 x 2 factorial arrangement. The starter diets were fed for 21 days and all diets contained chromic oxide at 150 ppm. There was an interaction ($P < 0.05$) between LF70 and FA in daily gain (ADG) between d 0-21. The pigs receiving HLF had a higher overall ADG compared to pigs receiving LLF at 0 supplementation (368 vs 281 g/d). However, there was no difference between the LLF and the HLF when the diets were supplemented with either M or I. Inulin improved feed efficiency ($P < 0.05$) between d 0-7 compared to Maxus or 0 supplementation (1.69 vs 2.50 vs 2.35 SEM 0.250). There was an interaction between LF70 and FA in fecal organic matter (OMD) and nitrogen (ND) digestibility ($P < 0.05$). The HLF and the HLF+M treatments improved OMD (89.02 and 89.32 %) compared to the LLF and LLF+M (87.44 and 87.61 %). However, there was no difference between LLF and HLF when the diet was supplemented with I (89.31 vs 88.49 % SEM 0.49). The HLF+I resulted in a reduced ($P < 0.05$) ND compared with the LLF+I. However, there was no difference between the LLF and the HLF when the diets received 0 or M supplementation. In conclusion, HLF improved ADG compared to LLF. Inulin inclusion improved FCR in the first week postweaning. The inclusion of inulin improved the OMD of diets low in LF70.

Key Words: Pigs, Lactose, Inulin, Avilamycin

M102 Effects of probiotic supplementation on gut histometry and fecal microflora in weaned pigs. V. Bontempo*¹, A. Di Giancamillo¹, C. Domeneghini¹, M. Fava¹, C. Bersani¹, R. Paratte¹, E. Chevauux², V. Dell'Orto¹, and G. Savoini¹, ¹*Department of Veterinary Sciences and Technologies for Food Safety, University of Milan, Italy*, ²*Allemand Animal Nutrition, Blagnac, France*.

Two hundred weanling piglets averaging 25 d of age and 5.0 ± 0.5 kg initial BW were assigned to two dietary treatments to determine the effects of supplementation with *Pediococcus acidilactici* on growth, gut histometry and fecal microbiota. Piglets were fed one of two liquid dietary treatments for 42 d after weaning: 1) Control (C), and 2) Control diet + *P. acidilactici* (1×10^{10} cfu/g) (P). Piglets were weighed and fecal samples from 16 homogeneous piglets (8 per group) were collected at 0, 14 and 42 d. These piglets were sacrificed for histology and histometry at the end of the experiment. No significant difference in growth was observed within the groups. Diet affected gut histometry of the P animals: histometrical analysis revealed an increase in villi height (C: 300 μ m; P: 327 μ m; SE: 7.52; $P < .01$) and crypt depth (C: 247 μ m; P: 287 μ m; SE: 10.31; $P < .01$) of the ileum, as well as in an increase of the cecum crypt depth (C: 387 μ m; P: 423 μ m; SE: 13.07; $P < .05$). A thicker mucous gel layer in the ileum of C piglets was also observed (C: 2.95 μ m; P: 2.35 μ m; SE: 0.07; $P < .01$). Fecal *Lactobacillus* populations were increased by *P. acidilactici* addition when compared to C diet (C: 10×10^8 cfu/g; P: 27×10^8 cfu/g; SE: 9.41×10^6 ; $P < .05$), while no difference was observed in the *E. coli* populations. In conclusion, the addition of *P. acidilactici* to piglet diet resulted in positive effects on gut structure and in a greater concentration of possibly beneficial bacteria.

Key Words: Piglets, *Pediococcus Acidilactici*, Gut Histometry

M103 Antimicrobials, probiotics, prebiotics and herbal extracts as growth promoters on performance of weanling pigs. C. E. Utiyama*, L. L. Oetting, P. A. Giani, U. S. Ruiz, and V. S. Miyada, *Escola Superior de Agricultura "Luiz de Queiroz" da Universidade de São Paulo, Piracicaba-SP, Brazil.*

One hundred and twenty 21-d-weaned pigs were used to compare five treatments with 12 replications (pens of two pigs each) per treatment in a 35-d randomized complete block design experiment. Treatments consisted of: control - basal diet of corn, soybean meal, dried whey, lactose and dried plasma; antimicrobial - basal diet plus antimicrobials (Zn bacitracin and olaquinox, 50 ppm of each); probiotic - basal diet plus 1300 ppm probiotic (*Bacillus subtilis* and *Bacillus licheniformis*); prebiotic - basal diet plus 3000 ppm mannanoligosaccharide; herbal extract - basal diet plus 500 ppm herbal extracts (garlic, clove, cinnamon, pepper and thyme). Antimicrobial agents improved ($P < .05$) ADG during d 1-35 (+21.4%) and d 15-35 (+22%) post-weaning compared to pigs fed the control diet. Although not significant ($P > .10$), ADG of pigs fed mannanoligosaccharide was 25.7% higher than those fed control diet during 1-14 days post-weaning period. Performance of pigs fed mannanoligosaccharide was intermediary between that of pigs fed the control and antimicrobial diets during d 15-35 and d 1-35 post-weaning. The herbal extracts did not improve pig performance ($P > .10$) in any period. Probiotic did not improve the growth performance ($P > .10$) of pigs. Mannanoligosaccharide seemed to be an alternative to antimicrobial agents as growth promoter of weanling pigs. However, dietary levels, how to incorporate in the diet, palatability, environmental conditions and mechanisms of action of all these alternative growth promoters should be better studied.

Key Words: Weanling Pig, Antimicrobial Agents, Alternatives

M104 The effect of bacillus and active yeast complex supplementation on the performance, fecal bacillus counts and ammonia nitrogen concentrations in weaned pigs. B. J. Min^{*1}, O. S. Kwon¹, K. S. Son¹, J. H. Cho¹, W. B. Lee¹, J. H. Kim², B. C. Park³, and I. H. Kim¹, ¹*Dankook University, Korea*, ²*Agribands Purina Korea, Inc., Seoul, Korea*, ³*CTC Bio. Inc., Korea.*

This experiment was conducted to investigate the effect of bacillus and active yeast complex supplementation on the performance, fecal bacillus counts and ammonia nitrogen concentration in weaned pigs. One hundred twenty LandraceYorkshireDuroc pigs (8.87±0.11 kg BW) were used in a 35 d growth assay. Dietary treatments included: 1) CON (control; basal diet), 2) AY (CON diet + 0.075% active yeast; BioSaf[®]), 3) BS (CON diet + 0.04% *bacillus subtilis* and *bacillus licheniformis* complex; BioPlus 2B#8482) and 4) YB (CON diet + 0.04% active yeast, 0.02% bacillus strains). During experimental days 0-14, ADG and ADFI were numerically higher in pigs fed active yeast diet than pigs fed other diets ($P > .05$). For days 15-35, pigs fed dietary bacillus and active yeast complex diet were numerically higher in ADG and ADFI compared with others ($P > .05$). For the entire period, ADG was greater for pigs fed active yeast, bacillus or complex diets than for pigs fed basal diet but without significant differences ($P > .05$). ADFI and Gain/Feed were not affected by treatments ($P > .05$). After 14 and 35 days of experiment, digestibility of dry matter was improved by 1.2-4.4% in pigs fed AY, BS and YB diets compared with pigs fed CON diet; also, digestibility of nitrogen was increased by 2.1-5.6% in AY, BS and TB treatments ($P < .05$). Pigs fed bacillus and complex diet were higher in fecal bacillus counts than pigs fed basal diet ($P < .05$). However, there is not a difference in fecal NH₃-N concentration ($P > .05$).

Key Words: Bacillus, Active Yeast, Pigs

M105 Efficacy of addition of *B. licheniformis* and *B. subtilis* in pig diets from weaning to slaughter. M. I. Gracia^{*1}, S. Hansen², J. Sánchez¹, and P. Medel¹, ¹*Imasde Agropecuaria, S.L. Spain*, ²*Chr Hansen A/S Denmark.*

A study was performed to evaluate the efficacy of a feed additive (EC No E1700) containing 1.6·10⁹ CFU/g of *Bacillus licheniformis* DSM 5749 and 1.6·10⁹ CFU/g of *Bacillus subtilis* DSM 5750 on performance of piglets from weaning at 28 d to slaughter at 95 kg. A total of 420 Large White x Landrace*Large White pigs, 50 % males and females, was used. There were two treatments: 1) basal diet (control), and 2) basal diet with 400 mg probiotic/kg feed. The experimental design was

applied in the prestarter (28 to 41 d of age, 1.48 % lys), starter (41 to 64 d of age, 1.33 % lys), and grower (64 to 116 d of age, 1.07 % lys) periods. From d 116 to slaughter at 167 d of age all pigs received a common diet (0.92 % lys). Each treatment was replicated 15 times with 14 pigs housed together constituting the experimental unit. Pigs supplemented with the probiotic were heavier than controls at the end of the prestarter period (10.2 vs 9.8 kg; $P < .05$) and at the end of the trial (94.7 vs 92.4 kg; $P < .05$). During the prestarter period, piglets fed the probiotic grew faster (204 vs 174 g/d; $P < .05$) and ate more feed (270 vs 247 g/d; $P < .05$) than controls. No significant differences were observed during the starter or the grower periods, but considering the overall period, probiotic supplementation of pig diets improved ADG (627 vs 611 g/d; $P < .05$) and ADFI (1,536 vs 1,491 g/d; $P < .05$). No differences were observed for feed conversion between dietary treatments for any of the periods studied. These results suggest that the probiotic tested improves growth of pigs from weaning until slaughter.

Key Words: Probiotic, Performance, Wean to Finish Pigs

M106 Isolation of *Bacillus* strains to inhibit pathogenic *E. coli* and enhance weanling pig performance. D. S. Parrott* and T. G. Rehberger, *Agtech Products, Inc., Manhattan, KS.*

E. coli causes edema disease and post-weaning diarrhea in swine. Previous research in our laboratory determined that these *E. coli* were a genetically diverse group. The objective of this research was to isolate *Bacillus* strains capable of inhibiting pathogenic *E. coli* and determine their effect on performance. Over 30,000 *Bacillus* isolates from environmental samples were screened using a replica plating technique against forty-eight *E. coli* strains isolated from six states. Twenty-five *Bacillus* strains were found to inhibit all of the *E. coli* strains. Two of the *Bacillus* strains were selected for feeding studies due to their higher level of inhibitory activity. Six replicate field trials involving a total of 1012 nursery pigs were conducted at a commercial farm. Each trial consisted of six pens with pigs blocked by weight into three blocks (heavy, medium, and light). For each trial, one pen of each block was assigned to either the standard nursery diet or standard nursery diet supplemented with the two *Bacillus* strains. Pigs were weighed by pen on days 0, 7, and 28. Feed consumed was recorded for each pen for the whole nursery time period. Mortality was also recorded. Data were analyzed using the PROC MIXED procedure of SAS and the effects of block and treatment, with day included, to take into account repeated measures and interactions, was evaluated. Pig weight was influenced by treatment ($P < .01$), block ($P < .0001$), treatment x block ($P < .01$) and block x day ($P < .01$). Heavy and light pigs fed the *Bacillus* strains had higher body weights than pigs fed the control diet at day 28 ($P < .005$ and $P < .01$). Feed intake in pigs in the light weight block was higher ($P < .01$) whereas intake of pigs in the other blocks was similar (treatment x block, $P < .05$). Feeding the *Bacillus* strains reduced mortality in the high ($P < .01$) and the medium ($P < .01$) weight blocks at day 28 (treatment x block x day, $P < .09$). This study indicates feeding the *Bacillus* strains can decrease mortality and enhance weanling pig performance.

Key Words: Swine, *E. coli*, *Bacillus*

M107 Effects of dietary herbal extracts (Animon Plus) on growth performance and blood composition in nursery and growing pigs. K. S. Son^{*1}, O. S. Kwon¹, B. J. Min¹, W. B. Lee¹, J. H. Kim², J. W. Hong¹, I. H. Kim¹, and H. S. Kim³, ¹*Dankook University, Cheonan, Korea*, ²*Agribands Purina Korea, Inc., Seoul, Korea*, ³*Kumbo Trading Co., Korea.*

Two experiments were conducted to investigate the effect of herbal extracts (including *Solanum xanthocarpum*, *Hedychium spicatum*, *Curcuma longa*, *Piper longum* and *Ocimum sanctum*) on the growth performance and blood composition in pigs. A total of 96 nursery pigs were randomly allocated into four treatments with six replications for four weeks (initial average BW 27.6 ± 2.63 kg). Dietary treatments included: 1) Con (Control), 2) AB (Control + 0.1% Antibiotics), 3) AM (Control + 0.1% Animon) and 4) ABAM (Control + 0.1% Antibiotics + 0.1% Animon). For the overall period, ABAM (562 g) treatment increased ADG compared to CON (500 g) and AB (506 g) treatments ($P < .05$). The difference of IgG concentration was increased in pigs fed AM and ABAM diets compared to pigs fed AB diet ($P < .05$). Pigs fed ABAM (3.5 g/dL) diet had higher albumin concentration than pigs fed

CON (2.9 g/dL) and AB (3.0 g/dL) diets ($P < 0.05$). Lymphocyte concentration difference of AB and ABAM diets had increased by 9.51% compared to CON and AM diets ($P < 0.05$). The digestibility of dry matter in ABAM treatment was increased by 5.3% compared to that of AB and AM treatments ($P < 0.05$). However, no differences were found for total protein of serum and N digestibility of feces ($P > 0.05$). In Exp. 2, a total of 75 growing pigs were randomly allocated to three treatments with five replications for 29 days (initial average BW 40.22 ± 2.82 kg). Dietary treatments included 1) CON (Control), 2) AM1 (Control + 0.1% Animon) and 3) AM2 (Control + 0.2% Animon). For the total experiment, the pigs fed AM1 (887 g) and AM2 (894 g) diets had greater ADG than pigs fed CON (831 g) diet. The AM1 diet increased ADFI compared to the CON diet. In serum characteristics, difference of IgG concentration of AM1 and AM2 treatments were greater than those of CON treatment ($P < 0.05$). Lymphocyte was greatest for AM1 and lowest for CON, with AM2 intermediate ($P < 0.05$). In conclusion, herbal extracts were effective in growth performance, IgG, albumin, total protein and lymphocyte responses in pigs.

Key Words: Herbal Extracts, Growth Performance, Pigs

M108 Efficacy of antimicrobials and herbal extracts as growth promoters of weanling pigs. L. L. Oetting*, C. E. Utiyama, P. A. Giani, U. S. Ruiz, and V. S. Miyada, *Escola Superior de Agricultura, Piracicaba-SP, Brazil.*

Two experiments involving a total of 80 weanling pigs (from 21 to 56 d of age) were conducted to compare antimicrobials and herbal extracts (HE) as growth promoters. Pigs were allotted to eight replications (pens of two pigs each) of five treatments in a randomized complete block design. Treatments consisted of: C - control, basal diet of corn, soybean meal, dried whey, lactose and dried plasma; A - basal plus antimicrobials (olaquinox, colistin, and Zn bacitracin, 50 ppm of each); HEa - basal plus 700 ppm HE; HEb - basal plus 1200 ppm HE; HEc - basal plus 2100 ppm HE. The HE consisted of a mixture of equal amounts of essential oils of thyme, clove (plus eugenol) and oregano (plus carvacrol). During d 1-14 post-weaning, DFI was higher ($P < .05$) for A than for HEa and HEb (.326, .256 and .265 kg/d, respectively). ADG and BW were improved ($P < .05$) when fed A compared to C and HEa (.229, .170 and .157 kg/d; and 8.63, 7.79 and 7.65 kg, respectively). For the overall 35d period, HEb resulted in lower DFI ($P < .05$), ADG and BW ($P < .10$) than A. ADG values were .350, .411, .335, .321 and .365 kg/d and BW values were 17.68, 19.83, 17.19, 16.68 and 18.19 kg for C, A, HEa, HEb and HEc, respectively. F:G was not affected ($P > .05$) by dietary treatments and the values were 1.60, 1.46, 1.59, 1.53 and 1.52 for C, A, HEa, HEb and HEc, respectively. Pigs fed high dietary level of HE (2100 ppm) showed intermediary results between A and C diets for all pig performance variables. The results of this study showed that, probably, higher levels of HE should be used to improve weanling pig performance.

Key Words: Herbal Extract, Weanling Pig, Performance

M109 Effect of dietary melatonin on serum melatonin level and growth performance of weaned pigs. G. H. Lee, J. G. Kim*, and K. Y. Whang, *Korea University, Seoul, Korea.*

A 21-d experiment was conducted to determine the effect of dietary melatonin on the serum melatonin level and growth performance of weaned pigs. Sixty-four pigs (8.2 ± 0.28 kg) were randomly allotted to one of four treatments: control (CON), 0.5 ppm melatonin (M1), 1 ppm melatonin (M2), and 2 ppm melatonin (M3). Diets were formulated to contain 3,525 ME kcal/kg, 1.49 % lysine, 0.26 % tryptophan and the other nutrients met or exceeded the NRC (1998) requirements. Pigs were allowed free access to the diet and water. Pigs were sampled weekly by jugular venipuncture between 1300 and 1600 h to determine the serum melatonin (SMT) level. Samples were analyzed by a direct radioimmunoassay. The SMT levels of the M1, M2, and M3 were linearly increased by dietary melatonin level at day 7, 14, and 21 ($P < 0.001$). Interestingly, the SMT level of M1, M2, and M3 reached the highest level at day 7, and decreased at day 14 and further decreased at day 21. The weight gain was shown to decrease as the dietary melatonin level increased. The ADG of M2 and M3 were lower ($P < .01$) than that of CON. However, ADFI tended to decrease as the dietary melatonin level increased (but not significantly). In conclusion, although the dietary melatonin increased the SMT, there was no positive effect on the growth in weaned pigs.

Item	CON	M1	M2	M3	SEM	P-value

M110 Botanical additives masked by a flavor do not affect feed intake, growth, or fecal consistency in weanling pigs. E. Roura*¹, R. Fontanillas¹, and P. Bikker², ¹*Lucta SA Barcelona, Spain,* ²*Schothorst Feed Research, Lelystad, The Netherlands.*

Previous reports show that addition of botanicals to nursery diets may significantly reduce feed intake interfering with the assessment of potential benefits in piglets. A four-week trial was carried out at the Schothorst Feed Research, to study the effect on pig performance and fecal consistency after weaning of three botanicals (internal reference number [Ref] 44 with 3% capsicum, Ref 45 3% capsicum & 50% chicory extract, and Ref 46 50% chicory extract) dosed at 0.1, 0.2 & 0.4% for Ref 44 and 45, and 0.1 & 0.2% for Ref 46. Except for the negative control (T1) diet, a cherry-honey flavor was applied to all diets aimed at masking the botanicals (T3 through T10) or flavoring the control (T2). In total 300 piglets (26 d of age) were blocked by weaning weight (avg. 8 kg) and offspring and randomly allocated to treatments. Piglets received Phase 1 (0-14 d) and Phase 2 (15-28 d) growth promoters & acidifier-free diets. Compared to control T1 application of flavor alone (T2) numerically ($P > 0.05$) increased feed intake (5%) and daily gain (6%) in the four-week period. The flavor seemed to prevent depression of feed intake normally associated with botanical additives except for the highest inclusion of Ref 45 (T8) particularly when compared to the positive control T2 (12% decrease; $P < 0.05$). Inclusion of botanicals Ref 44 and 46 did not have significant effects compared to control T1 and tended to perform worse than piglets on the flavored control T2. Feed conversion ratio and fecal consistency were not affected by treatments. It is concluded that, overall, compared to a negative control, the three botanical additives tested did not improve gut health or performance of weanling pigs. The reduction on feed intake observed in previous works was largely avoided presumably due to a compensatory effect of the addition of the flavor. Treatment with a flavor alone tended to improve feed intake and daily gain.

Key Words: Piglets, Botanicals, Flavor

M111 Effect of bedding with mycotoxin contaminated straw and low levels of dietary mycotoxin on piglet performance. B. E. Strickler and P. Spring*, *Swiss College of Agriculture, Zollikofen, Switzerland.*

The aim of this study was to evaluate the effect of using mycotoxin-contaminated straw as bedding for weaning piglets fed diets with and without mycotoxin adsorbent on animal performance. The trial was set up as a complete randomized block design with 18 groups of 5 weaning piglets each (BW: 8.5 kg). Piglets received a starter diet (14.0 MJ/kg DE, 16.5% CP and 1.20% lysine) and water ad libitum. Treatments were as follows: Control: bedding with 200 g of wood shavings/hd/d; Straw: bedding with 200 g of contaminated straw/hd/d; Straw+Adsorbent: bedding with 200 g of contaminated straw/hd/d plus diet with 2000 ppm of mycotoxin adsorbent (Mycosorb#8482, Alltech Inc.). Straw was contaminated with 821 ppb deoxynivalenol (DON), 528 ppb zearalenone (ZEA) and < 50 ppb T-2 toxin. The piglets were also exposed to a natural infection with HPS (*Haemophilus parasuis*). Feed intake, ADG FCR, medical treatments and fecal scores were recorded. Data were analyzed by ANOVA and means were compared using the test of Tukey-Kramer. The mycotoxin-contaminated straw had no effect on piglet performance. However, the mycotoxin adsorbent led to improved performance during the first trial period. The feed was designed to contain low levels of

mycotoxin, however analyses revealed 220 ppb on DON, < 10 ppb ZEA and < 50 ppb T-2. The data suggest that in piglets exposed to weaning stress and a natural infection with HPS, DON levels as low as 220 ppb can decrease performance. From day 15-20, all piglets were treated with Vital TSS (Trimethoprim, Sulfathiazolum and Sulfadimidinum). This treatment effectively controlled the HPS infection. During this trial phase no differences in performance were recorded between treatments, indicating that a reduction in stress level did allow the piglets to cope with 220 ppm of dietary DON. Mycotoxin-contaminated straw did not affect piglet performance or health. However, low levels of dietary DON led to a reduction in performance in piglets exposed to weaning and microbial stress. Mycotoxin adsorbent can help in alleviating the negative effects on performance.

Table 1: Effect of contaminated straw and mycotoxin adsorbent on piglet performance

M113 Nutritive quality of *Poa pratensis* in model grassland communities exposed to ground-level ozone. D. Dodson¹, J. Bender², J. Lin¹, and R. Muntifering¹, ¹Auburn University, Auburn, AL, ²Federal Agricultural Research Center, Braunschweig, Germany.

Tropospheric (i.e., ground-level) ozone (O₃) is the most significant phytotoxic air pollutant in the US and Europe, and its concentration globally is expected to increase by 0.3 to 1.0%/yr for the next 50 yr. Because interspecific plant competition is theorized to amplify O₃ stress, especially early in the growing season, a phytometer-based approach was utilized to investigate effects of exposure to elevated O₃ on nutritive quality of *Poa pratensis* (phytometer) and four competitor species (*Anthoxanthum odoratum*, *Achillea millefolium*, *Rumex acetosa* and *Veronica chamaedrys*) representative of an extensively managed, species-rich grassland community of Central Europe. Model plant communities (mesocosms), in which *P. pratensis* was grown in monoculture and in mixed cultures with each of the competitor species, were placed into open-top chambers and exposed continuously during April and May to carbon-filtered air + 25 ppb O₃ (control) or non-filtered air + 50 ppb O₃ (elevated O₃). *Poa pratensis* was harvested from mesocosms at the end of the exposure period and assessed for relative food value (RFV), which was predicted from concentrations of NDF and ADF. Across all mono- and mixed cultures, concentrations of NDF, ADF and lignin were greater ($P < 0.001$), and RFV was lower ($P < 0.001$) for *P. pratensis* grown under elevated O₃. Increased concentrations of lignin were considerably greater than could be explained on the basis of increased concentrations of NDF and ADF, consistent with the general mechanism of plant response to environmental stress. Concentrations of cell wall constituents and N were not affected by competition, and N concentration was not affected by exposure to elevated O₃. While effects of early-season O₃ stress on RFV of *P. pratensis* were not amplified by interspecific competition, exposure to elevated O₃ decreased RFV of *P. pratensis* by an

M112 Influence of diet on microbial community structure and activity in the intestinal tract of weaning pigs. A. Piva^{*1}, L. Magnani¹, G. Casadei¹, P. P. Gatta¹, K. M. Selig², and J. A. Patterson², ¹University of Bologna, Italy Via Tolara di Sopra, 50, Ozzano Emilia (BO), ²Department of Animal Sciences, Purdue University, West Lafayette, IN.

Weaning is the hardest step in the lifespan of a pig, and is often characterized by microbial imbalance, changes in intestinal structure and function, scours, low performance, or even death. Different nutritional strategies were studied relative to their ability to modulate intestinal microflora and performance. Three diets were fed over 5 weeks as follows: 1) standard U.S. diet with plasma protein, carboxox, zinc oxide and copper sulfate (US), 2) standard plant-protein-based European diet (EU) 3) EU diet + TRILAC (US Patent # 6,217,915) as a source of tributyrin and lactitol (TL). Performance was recorded at 7, 21, and 35 days, along with NH₃, VFA and Lactic Acid Bacteria (LAB) count in cecum, colon and jejunum. Despite any effects recorded during the first week, after 21 days US diet fed piglets reported significantly ($P < 0.05$) greater LW (11.36 kg, SE=0.42, n=30) and Feed Efficiency (0.53, SE=0.03, n=5), compared to EU (LW=9.38 kg; FE=0.39), or TL (LW=9.83 kg, FE=0.40) fed piglets. No differences were noticed between EU and TL treatments. A similar pattern was recorded at the end of the study (35 d) when US fed animals showed the highest ($P < 0.05$) LW (18.87 kg, SE=0.62, n=25) whereas Feed Efficiency did not differ among groups. NH₃ was not affected by any treatment throughout the study, whilst colonic VFA concentration after 21 days was higher in EU and TL groups compared to US piglets (+27% and +77%, respectively, $P < 0.03$). Moreover TL diet increased ($P < 0.01$) LAB count in the cecum (9.02 ± 0.36 log 10 cfu/g feces) and colon (9.15 ± 0.28 log 10 cfu/g feces) of piglets than did US diet (7.50 ± 0.44 and 8.03 ± 0.45 log 10 cfu/g feces, respectively). In conclusion a standard US diet added with plasma protein, carboxox, zinc oxide and copper sulfate out-performed a plant-protein-antibiotic-free European diet. Nevertheless the addition of tributyrin and lactitol together beneficially affected microbial balance and fermentation products leading to a LW numerically between those of US and EU formulations.

M114 Effect of increased cutting height of corn silage on nutritive value, milk yield and milk composition. D. Dominguez-Diaz^{*2} and L. D. Satter^{1,2}, ¹Dairy Forage Research Center, USDA-ARS, Madison, WI, ²Dairy Science Department, University of Wisconsin-Madison, Madison.

The objective of this study was to evaluate the effect of increasing cutting height of a conventional corn hybrid (Golden Harvest H8250) from 20 cm (Normal cut corn silage, **NC**) to 61 cm (High cut corn silage, **HC**) on the nutritive value of corn silage, milk yield and milk composition. Thirty six multiparous and six primiparous Holstein cows averaging 70 days in milk (SD±16) and 45.2 kg milk/d (SD±6.4) were randomly assigned to the NC or HC diets following a 1-wk pretrial period. The experiment was a single reversal design with two 6-wk periods. The silages were chopped at 0.95 cm theoretical length of cut and stored in plastic bag silos. The NC and HC diets contained 65% forage, of which 70% was corn silage and 30% alfalfa silage. Increasing cutting height reduced DM yield by 8.3%, and increased grain content by 11.6% and decreased stalk by 38.5%. The concentration of DM, CP and starch were increased 9.1, 4.8 and 22.3% with the HC silage, and NDF, ADF and ADL concentrations were reduced by 9.9, 14.9 and 23.5%. Corn silage pH was slightly increased with the HC treatment. DMI was similar between the NC and HC diets (24.4 and 24.6 kg/d). The HC treatment increased yield of milk ($P \leq 0.03$) and 3.5% FCM ($P \leq 0.19$) compared to the NC diet (40.4 vs. 39.3 and 41.6 vs. 40.8 kg/d). Feed efficiency was increased ($P \leq 0.06$) with the HC treatment (1.66 vs. 1.62). Milk composition, body weight and body weight change were unaffected by treatment.

Key Words: Cutting Height, Corn Silage

M115 Site and extent of digestion of diets containing brown midrib-3, low-cut, or high-cut corn silage. D. Dominguez-Diaz*² and L. D. Satter^{1,2}, ¹Dairy Forage Research Center, USDA-ARS, Madison, WI, ²Dairy Science Department, University of Wisconsin-Madison, Madison.

The objective was to evaluate the effect of feeding brown midrib-3 corn silage (bm3) and conventional corn silage (Golden Harvest H8250) cut at 20 cm (Normal cut corn silage, NC) or 66 cm (High cut corn silage, HC) on ruminal fermentation, digestion kinetics, and site and extent of digestion. Nine multiparous Holstein cows averaging 172 DIM (SD±70) and 40.1 kg milk/d (SD±1.5) were randomly assigned to NC, HC and bm3 diets in a 3 × 3 Latin square design with 21-d periods. Dry matter digesta flow to the omasum was estimated using Ytterbium, CoEDTA and indigestible NDF markers. Omasal digesta samples were obtained by inserting a sampling device through the ruminal cannula. Fecal grab samples were used to estimate total tract digestibility. DMI was similar among NC, HC and bm3 diets (22.8, 22.9 and 23.7 kg/d). Milk yield and 3.5% FCM were similar among treatments (33.4, 31.8, 34.0 and 34.9, 32.8 and 35.9 kg/d). The daily mean of ruminal pH, acetate, propionate and total VFA concentrations were similar among treatments. The A/P ratio and ruminal ammonia concentrations were decreased ($P \leq 0.05$) with bm3 compared to the NC and HC diets (3.56 vs. 3.67 and 3.68, and 6.64 vs. 7.70 and 7.62 mM). Ruminal pool sizes of DM, OM, CP, NDF, ADF and starch were unaffected by treatment. Ruminal turnover rates of NDF and ADF were increased ($P \leq 0.003$) with feeding of bm3 compared to the NC and HC diets (5.34 vs. 4.52 and 4.56, and 5.0 vs. 4.17 and 4.24%/h). Apparent ruminal, post-ruminal and total digestibility of DM, OM and NDF were unaffected by treatment. Ruminal digestion of starch was reduced with the bm3 treatment, but resulted in 0.32 kg/d more starch digested in the small intestine. Ruminal and post-ruminal digestion of ADF were unaffected by treatment, but total tract digestion of ADF was increased ($P \leq 0.03$) with the bm3 compared to the NC and HC diets (46.5 vs. 42.6 and 43.6%).

Key Words: bm3, Cutting Height, Corn Silage

M116 Nutritive quality of early-season *Trifolium* forage as influenced by nitrogen and ground-level ozone. K. E. Kittendorf*¹, B. Sanchez-Gimeno², J. Sanz², J. Lin¹, and R. B. Muntifering¹, ¹Auburn University, Auburn, AL, ²Centro de Investigaciones Energeticas, Medioambientales y Tecnologicas, Madrid, Spain.

Tropospheric (i.e., ground level) ozone (O_3) is the most significant phytotoxic air pollutant in the US and Europe, and its concentration globally is expected to increase by 0.3 to 1%/yr over the next 50 yr. Because N enrichment is theorized to increase susceptibility of vegetation to O_3 injury by altering leaf-cell apoplast pH, combined effects of O_3 and N on forage quality were investigated in an experiment in which seedlings of three *Trifolium* species representative of a Mediterranean dehesa community (*T. subterranean*, *T. cherleri* and *T. striatum*) were grown in open-top chambers (OTC) in which added air had been carbon-filtered (CF), representing approximately half-ambient O_3 concentration; non-filtered (NF), characteristic of ambient air; or enriched to twice-ambient O_3 concentration (2X). Within each air treatment, N fertilizer was applied to simulate a range of N enrichment levels (10, 30 and 60 kg N/ha) suggested from soil-test values and estimates of wet deposition in the vicinity of Madrid, Spain. Plants were exposed to air treatments for 30 d, removed from OTC, and maintained in ambient air until they were harvested 1 mo later. Exposure to elevated O_3 decreased ($P < 0.01$) biomass yield (2X < NF < CF), whereas N enrichment increased ($P < 0.01$) biomass yield (60 > 30 > 10 kg N/ha) in all three species. Exposure to elevated O_3 decreased ($P < 0.01$) relative food value (RFV) of *T. subterranean* (2X < NF < CF) and *T. cherleri* (2X < NF, CF), but not of *T. striatum* as predicted from increased ($P < 0.01$) concentrations of NDF, ADF and lignin. Nutritive quality of *Trifolium* forage was not affected by N enrichment and, contrary to the original hypothesis, N enrichment did not amplify negative effects of O_3 on biomass yield or RFV. Across all treatments, early-season exposure to 2X O_3 decreased RFV of *T. subterranean* and *T. cherleri* by an average of 13% compared with CF and NF exposures, which is sufficient to have nutritional implications to its utilization by herbivores.

Key Words: Tropospheric Ozone, Forage Quality, *Trifolium*

M117 Forage production and quality of triticale cultivars in the Tennessee Valley. M. Lema*¹ and E. Cebert², ¹Tennessee State University, Nashville, ²Alabama A & M University, Normal.

Because of its cold tolerance and double-cropping potential, triticale (*XTriticosecale Wittmack*) can play an important role in bridging the feed shortage gap in late fall and winter in the Tennessee Valley when other cool season grasses become dormant. Field trials were conducted in 2001 and 2002 at Winfred Thomas Agricultural Research Station (WTARS) and Sand Mountain Agricultural Substation (SMAS) in the Tennessee Valley to evaluate the forage yield and quality of six triticale cultivars (TCL105, TCL111, TX98D955, TX96VT5019, Tritical 498 and Tritical 2700). The cultivars were planted in four replicated 6-row plots 6.1 m long with rows 1.22 m apart in a randomized complete block design. At both locations, TX98D955, TX96VT5019 and Tritical 2700 produced higher ($P < 0.05$) forage DM than the other cultivars (2-yr average of 4,134; 3,851 and 4,063 kg/ha for TX98D955, TX96VT5019 and Tritical 2700, respectively versus 2,744; 3,070 and 3,077 kg/ha for TCL105, TCL111 and Tritical 498, respectively at WTARS and 6,326; 5,974 and 5,938 kg/ha for TX98D955, TX96VT5019 and Tritical 2700, respectively versus 4,531; 3,784 and 4,060 kg/ha for TCL105, TCL111 and Tritical 498, respectively at SMAS). Crude protein, ether extract and gross energy contents were lower ($P < 0.05$) for TCL111 and TCL105. Acid-detergent fiber content was higher ($P < 0.05$) and IVDMD lower ($P < 0.05$) for TCL 105. The cultivars TX96VT5019 and TX98D955 had higher ($P < 0.05$) P content and the cultivars TCL105, TCL111, TX96VT5019 and TX98D955 higher ($P < 0.05$) Ca content than the rest. The cultivars TCL105 and TCL111 were higher ($P < 0.05$) in Mg and lower ($P < 0.05$) in K than the other cultivars. Sulfur was higher ($P < 0.05$) for Tritical 498 and Zn higher ($P < 0.05$) for TCL498, TX96VT5019 and TX98D955. Iron content was lower ($P < 0.05$) for TX96VT5019 and TX98D955 than for the other cultivars.

Key Words: Triticale cultivars, Forage yield, Forage quality

M118 Effects of a bacterial inoculant on fermentation, quality, degradability and aerobic stability of whole head grain sorghum ensiled at two stages of grain maturity. L. O. Abdelhadi*¹ and J. M. Tricarico², ¹Est. El Encuentro, Research and Extension in Ruminant Nutrition. Cnel. Brandsen, Argentina, ²Allech Biotechnology Inc., Nicholasville, KY.

Pasture based systems around the world are being displaced to marginal areas where sorghum has agronomic advantages with respect to corn. Because high quality forages are needed to feed high producing animals, Argentina's producers need to improve silage quality. A completely randomized design with a 2x2 factorial arrangement of treatments was used to evaluate the effects of a commercial bacterial inoculant (Sil-All, Alltech Inc., Nicholasville, KY) on DM recovery, OM degradability (OMD), fermentation, chemical composition and aerobic stability of whole head grain sorghum ensiled at two stages of maturity. The same hybrid was harvested at both milk (MS) and dough stages (DS) of grain maturity and ensiled for 3 months in triplicate mini silos constructed from PVC pipe with or without bacterial inoculant. Samples were collected before ensiling, after ensiling for 3 months, and after exposing 3 month-old silage to air for 3d. Samples were analyzed for pH, DM, CP, NDF, WSC, NH_3 -N, and OMD after incubation with ruminal fluid for 24, 28 or 72h. Inoculation increased silage DM recovery over the control at MS (92.4 vs 97.9%, $P = .08$) but had no effect at DS of sorghum maturity. Ensiling sorghum at MS resulted in lower ($P < .01$) DM and WSC content, and greater ($P < .01$) CP content than ensiling at DS. Inoculation had no effects on DM, CP and NDF content, pH or NH_3 -N concentrations, but increased ($P = .05$) WSC content regardless of sorghum maturity at harvest. The OMD of sorghum harvested at MS was greater ($P < .01$) than that of sorghum harvested at DS after incubation for 24 or 48h. Inoculation improved aerobic stability of silage regardless of sorghum maturity as indicated by lower ($P < .01$) temperature in inoculated silage after exposure to air for 3d. We conclude that inoculation of whole head grain sorghum silage may be more advantageous when harvesting at an earlier stage of maturity.

Key Words: Silage, Grain Sorghum, Inoculant

M119 Estimating degradable intake protein on producer farms in northern Arkansas. W. K. Coblenz*, J. E. Turner, R. K. Ogden, K. P. Coffey, F. W. Pohlman, A. H. Brown, M. B. Daniels, J. L. Gunsaulis, M. L. Thomas, and J. B. Humphry, *University of Arkansas, Fayetteville.*

Two case studies were conducted on producer farms in northwest Arkansas during 2000-01 to assess concentrations of degradable intake protein (DIP) and undegradable intake protein (UIP) in forages grown throughout the region. In Case Study 1, DIP was greater ($P < 0.05$) by 11.7 and 0.76 percentage units of N and DM, respectively, for samples from cool-season pastures compared to samples collected from pastures dominated by warm-season grasses. For both photosynthetic types, NDF exhibited a strong negative correlation ($r < -0.605$; $P < 0.006$) with DIP; generally, both N and in-vitro organic matter disappearance (IVOMD) were strongly and positively correlated ($r > 0.665$; $P < 0.002$) with DIP, but N was not correlated with DIP ($P > 0.05$) in warm-season pastures when DIP was expressed as a percentage of total plant N. In Case Study 2, N fertilization at two producer sites increased concentrations of N in primarily linear ($P < 0.0001$) patterns for bermudagrass forages, but there was no carryover effect ($P > 0.05$) on a second harvest that received no additional fertilization. In harvests immediately following fertilization, DIP increased with N fertilization rate; the linear term was significant ($P < 0.004$) in each case, but it was coupled with quadratic or cubic effects in some harvests. Pool size for UIP also increased linearly ($P < 0.002$) with N fertilization in three of four harvests that immediately followed applications of N fertilizer, but the magnitude of these responses was small compared to those observed for DIP. As observed in Case Study 1, there were strong negative correlations ($r < -0.451$; $P < 0.0001$) between concentrations of NDF and DIP at both individual harvest sites, and on a combined basis. Conversely, DIP was correlated in a strong positive manner with concentrations of N ($r > 0.778$; $P < 0.0001$) and IVOMD ($r > 0.408$; $P < 0.0001$) at both sites, and in a combined analysis. Despite the diverse conditions of the two studies, DIP was positively correlated with concentrations of N and IVOMD, but negatively correlated with NDF.

Key Words: DIP, UIP, N fertilization

M120 Comparison of mechanically processed barley silage with regular barley silage on lactational performance of Holstein cows. J.-S. Eun¹, S.-H. Hong*², and K. Beauchemin¹, ¹*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*, ²*Sahmyook College Cheongnyangni, Seoul, Korea.*

Mechanical processing of whole crop barley prior to ensiling may be useful for improving nutrient utilization by dairy cattle. The objectives of this study were to assess the effects of feeding mechanically processed barley silage as the main forage source on lactational performance. Sixteen primiparous (187 ± 52 DIM) and 8 multiparous (87 ± 69 DIM) Holstein cows were used in a completely randomized design with a 2-wk covariate period and a 6-wk treatment period. The 2 treatments were: 1) RBS = TMR diet containing regular barley silage, and 2) MPBS = TMR diet containing mechanically processed barley silage. Barley silage and alfalfa hay supplied 41% and 5% of the diet DM. Intake, BW, and milk production were measured during the covariate and the treatment periods. In addition, 2 multiparous cows were used for in situ measurements of the ruminal DM and fiber degradation kinetics of the barley silages and diets. Results were analyzed with repeated measurements using a mixed model that included a covariate adjustment. Feeding MPBS had no significant effects on DMI (21.7 kg/d), milk yield (33.9 kg/d), or milk composition with only FCM (31.7 vs. 29.7 kg/d, $P = 0.51$) and milk fat concentration (3.57 vs. 3.30%, $P = 0.32$) showing a numerical improvement. Dairy efficiencies calculated as milk yield/DMI or FCM/DMI were not different between the diets. Body weight and BCS were not affected by treatments. Effective ruminal degradability of DM was similar for both barley silages, indicating that when the silages were ground to remove the effects of mechanical processing, the potential digestion was similar. In summary, mechanical processing did not improve the nutritional merits of barley silage for lactating dairy diets under the conditions of this experiment.

Key Words: Mechanically Processed Barley Silage, Degradability, Milk Production

M121 Effect of forage diversity on intake and productivity of grazing lactating dairy cows over two grazing seasons. K. J. Soder*¹, M. A. Sanderson¹, J. L. Stack², and L. D. Muller², ¹*USDA-ARS, Pasture Systems and Watershed Management Research Unit*, ²*The Pennsylvania State University, University Park.*

A study was designed to determine the effects of forage diversity on intake and productivity of grazing lactating dairy cows over two grazing seasons. In a randomized block design, twenty lactating Holstein cows (100 DIM, 634 kg BW) were assigned to one of four treatments for four 21-d periods. The four pasture treatments were: Orchardgrass(OG)/white clover (2SP); 2SP + chicory(CH; 3SP); OG + CH + red clover + tall fescue + perennial ryegrass + birdsfoot trefoil (6SP); and 6SP + white clover + alfalfa + KY bluegrass (9SP). Pasture allowance was 25 kg DM/cow/d. Cows were fed a 13% CP corn-based concentrate (1 kg/4 kg milk) in two equal feedings after milking. Pasture DMI was measured using Cr₂O₃ as a fecal marker. Pasture CP was higher while IVDMD was lower in Year 2. Pasture CP and IVDMD was higher for the more complex mixes. Pasture DMI was higher during Year 1, which was a drought year. Milk yield, milk fat and milk protein were not affected by year or treatment. Level of forage diversity did not have a major impact on DMI or productivity of grazing dairy cows. However, forage production and carrying capacity were greater on the complex mixtures than on the 2SP mix, particularly during drought.

M122 Nitrogen characteristics and nitrogen degradation kinetics of crabgrass harvested in northern Arkansas. R. K. Ogden*, W. K. Coblenz, K. P. Coffey, J. E. Turner, D. A. Scarbrough, J. A. Jennings, and M. D. Richardson, *University of Arkansas, Fayetteville.*

Common crabgrass [*Digitaria ciliaris* (Retz.) Koel.] is undesirable in fields of bermudagrass [*Cynodon dactylon* (L.) Pers.], because it dries slowly, and can cause spontaneous heating and molding in hay. However, the visual observation suggests that livestock prefer crabgrass to many other summer forages. Our objectives were to assess N partitioning within leaf, stem, and whole-plant crabgrass; and to determine the in-situ disappearance of N for whole-plant crabgrass forages. Alfalfa (*Medicago sativa* L.), bermudagrass, and orchardgrass (*Dactylis glomerata* L.) also were evaluated for ruminal in-situ disappearance of N as diverse controls. Crabgrass was harvested at weekly intervals between 11 July and 22 August 2001. Concentrations of N and neutral detergent soluble N (NDSN) in whole-plant crabgrass decreased over sampling dates. These decreases exhibited a linear ($P = 0.001$) relationship with time for N, and linear ($P < 0.0001$) and cubic ($P = 0.006$) effects of time for NDSN. When crabgrass was evaluated for in-situ disappearance of N in five (383 ± 22.7 -kg) ruminally cannulated crossbred steers, the mean disappearance rate over seven sampling dates (0.092/h) was more rapid ($P < 0.0001$) than observed for bermudagrass hay (0.046/h), but was slower ($P < 0.0001$) than observed for alfalfa (0.223/h). The effective ruminal degradability of N was greater ($P < 0.0001$) for crabgrass (mean = 85.3%) than alfalfa (83.3%), bermudagrass (72.3%), and orchardgrass (76.0%) hays. Over the seven harvest dates, the effective ruminal degradability of N for crabgrass was 10.8 to 14.8 percentage units greater ($P < 0.0001$) than the bermudagrass hay evaluated simultaneously. These results indicate that crabgrass N exhibits high (\geq

83.1%) effective ruminal disappearance on all harvest dates, but exhibited a much slower disappearance rate than alfalfa.

Key Words: Crabgrass, Nitrogen, Degradation

M123 Chemical composition and in vitro digestibility of three cultivars of Guinea grass (*Panicum maximum* Jacq) at three ages of cut under tropical dry forest conditions. M. A Cuauro, B. Gonzalez, O. Araujo-Febres*, and J. Vergara, *La Universidad del Zulia, Facultad de Agronomía Maracaibo, Venezuela.*

A field experiment was carried out, during the rainy season in order to evaluate crude protein (CP), neutral detergent fiber (NDF), in vitro digestibility of dry matter (IVDDM) and in vitro digestibility neutral detergent fiber (IVDADF) contents in leaves of guinea grass (*Panicum maximum* Jacq) var. common, var. Mombasa and var. Tanzania. Plots (4 x 5 m) were established in randomized complete block design with a split plot arrangement of treatments, with harvest at 21, 42 and 63 days of age after an initial cut. Grass variety served as the main plot and cutting ages as subplot. Data were analyzed by least squares ANOVA using the GLM procedures of SAS. Total CP concentration in var. common is higher ($P < .05$) than var. Tanzania and var. Mombasa (17 vs 12% at 21 d, 12 vs 10% at 42 d and 11 vs 9% at 63 d). The var. common had lower NDF concentration than var. Tanzania and var. Mombasa at 21 d, but not at 42 and 63 d. The IVDDM were similar in all grasses at 21 and 42 d. In contrast, the var. common decreased ($P < .05$) IVDDM at 63 d. No differences ($P > 0.05$) were detected among cultivars.

Key Words: *Panicum maximum*, Crude Protein, In Vitro Dry Matter Digestibility

M124 Effects of a bacterial inoculant on fermentation, quality, degradability and aerobic stability of whole-plant grain sorghum and corn silages. L. O. Abdelhadi*¹ and J. M. Tricarico², ¹Est. El Encuentro, Research and Extension in Ruminant Nutrition. Cnel. Brandsen, Argentina, ²Alltech Biotechnology Inc., Nicholasville, KY.

Ensiling of sorghum and corn in Argentina frequently result in low quality silages that must be fed at low inclusion rates to avoid negative effects on animal performance. A completely randomized design was used in two studies to evaluate the effects of a commercial bacterial inoculant (Sill-All, Alltech Inc. Nicholasville, KY) on DM recovery, OM degradability (OMD), fermentation, chemical composition and aerobic stability of whole-plant grain sorghum (SS) and corn silages (CS). Sorghum and corn were harvested at the milk and dough stages of maturity, respectively, and ensiled for 3 months in triplicate mini silos constructed from PVC pipe with or without bacterial inoculant. Samples were collected before ensiling, after ensiling for 3 months, and after exposing 3 month-old silage to air for 3d. Samples were analyzed for pH, DM, CP, NDF, WSC, NH₃-N, and OMD after incubation in ruminal fluid for 24, 48 or 72h. Inoculation tended to increase DM recovery of SS by 3.0% and increased ($P < .05$) DM recovery of CS by 5.1%. The DM, CP, NDF and WSC contents, pH and NH₃-N concentrations were similar in control and inoculated SS. On average, inoculation increased ($P = .02$) the DM content, reduced pH ($P = .05$) and NDF ($P = .09$) content in CS. Trends towards increased OMD were observed for both SS and CS, being the numerical increases 3.4 and 3.5% for SS and CS, respectively after *in vitro* incubation for 48 and 72h. Inoculation did not affect the temperature of SS but reduced ($P = .01$) the temperature of CS after exposure to air for 3d, thus improving its aerobic stability. Although greater benefits were observed when inoculating CS compared to SS, the numerical increases in DM recovery and OMD obtained for SS may be of economic importance. We conclude that bacterial inoculation may be applied successfully to improve the quality of whole-plant sorghum and corn silages.

Key Words: Grain Sorghum Silage, Corn Silage, Inoculant

M125 Biomass yield and nutritive quality of eastern gamagrass (*Tripsacum dactyloides*) exposed to ground-level ozone. J. Lin*, J. Lewis, R. Muntifering, S. Ditchkoff, and A. Chapelka, *Auburn University, Auburn, AL.*

Tropospheric (i.e., ground-level) ozone (O₃) is the most significant phytotoxic air pollutant in the US, and its concentration globally is expected to increase by 0.3 to 1.0%/yr for the next 50 yr. Because very little is known about effects of ground-level O₃ on yield and nutritive quality of native grass species, we conducted an experiment in which eastern gamagrass (*Tripsacum dactyloides*) was grown in open-top chambers (OTC) to which added air had been carbon-filtered (CF), representative of that found at the cleanest air-quality sites in the US; non-filtered (NF), characteristic of ambient air in Auburn, AL; or enriched with O₃ to twice ambient concentration (2X). Primary-growth and regrowth forages were harvested monthly from each of nine OTC (three OTC/air trt). Mean daytime O₃ concentrations over the entire experiment (June 9 to September 4, 2003) were 14, 29, and 61 ppb, respectively, for CF, NF and 2X treatments. Across all three primary-growth harvests, biomass yield and concentrations of NDF and ADF were greater ($P < 0.05$) for 2X than CF, but not NF forage. A harvest period x treatment interaction ($P < 0.05$) was observed such that biomass yield and concentrations of NDF and ADF in the final primary-growth harvest were greater ($P < 0.05$) for 2X than NF and CF forages (23.2 vs. 16.1 and 13.8 g DM/plant; 73.7 vs. 68.2 and 65.2%; and 37.6 vs. 33.5 and 32.8%, respectively). Relative feed value (RFV) calculated from NDF and ADF concentrations in the final primary-growth harvest was lower ($P < 0.05$) for 2X than NF and CF forages (75.3 vs. 85.7 and 90.5, respectively). Concentrations of CP and lignin in primary-growth forages were not different among treatments, and no differences in biomass yield or chemical composition of regrowth forages were observed among treatments. Nutritive quality (RFV) of primary-growth eastern gamagrass forage was decreased by 14% in the 2X compared with NF and CF treatments, which is sufficient to have nutritional implications to its utilization of by herbivores.

Key Words: Tropospheric Ozone, Forage Quality, Eastern Gamagrass

M126 Effect of type of concentrate on grazing behaviour of dairy cows. R. G. Pulido*, E. Felmer, A. Hinostroza, and F. Wittwer, *F. Cs. Veterinarias, Universidad Austral de Chile, Valdivia, Chile.*

Two experiments were carried out to evaluate the effect of two sources of carbohydrate (fibrous and starchy) and two levels of crude protein in concentrate supplements (17.0% in exp 1 and 11.9% in exp 2) on grazing behaviour and herbage intake (HI) of spring calving dairy cows. In exp 1, 12 multiparous Friesian dairy cows (BW 529 kg), yielding 33 l/d and at 53 days of lactation, were assigned to a 3x3 Latin square design with periods of 21 days. In exp 2, 30 multiparous Friesian dairy cows (BW 512 kg), yielding 29.3 l/d and at 65 days of lactation, were assigned to a continuous randomized design for 45 days. For both experiments the treatments included: grazing alone (TGO), grazing plus 6 kg/d of sugar beet pulp-based concentrate (TFC) and grazing plus 6 kg/d of cereal-based concentrate (TSC). The concentrates were balanced by CP and ME. The cows were supplemented twice a day and managed under a strip grazing system on pasture consisting mainly of perennial rye grass. During the last week of each period in exp 1, and at one time point in exp 2, a record of individual grazing behavior was made every 10 minutes for all the cows during 24 hrs grazing activities. Throughout the trial BW was recorded weekly. HI and total dry matter intake (TDI) was estimated using Cr₂O₃. The results for HI during exp 1 were 15.4, 10.5 and 10.9 kg/d for treatments TGO, TCF and TCS, respectively ($P < 0.05$). TDI was 15.4, 15.8 and 16.2 kg/d, respectively ($P > 0.05$), grazing time (GT) was 562, 510 and 507 min/d, respectively ($P > 0.05$), ruminating time (RT) was 393, 367 and 418 min/d, respectively ($P = 0.06$) and body weight change was 0.18; 0.50 and 0.69, respectively ($P < 0.05$). The results for HI during exp 2 were 16.8, 11.2 and 12.1 kg/d for treatments TGO, TCF and TCS, respectively ($P < 0.05$). TDI was 16.8, 16.5 and 17.4 kg/d, respectively ($P > 0.05$), GT was 510, 456 and 466 min/day, respectively ($P > 0.05$), RT was 451, 491 and 442 min/day, respectively ($P = 0.06$) and body weight change was 0.72; 0.99 and 0.88, respectively ($P > 0.05$). The results suggest that carbohydrate source did not affect the grazing behaviour of dairy cows on this experiment. Key words: Cows grazing, intake, carbohydrates

Key Words: Grazing Cows, Intake, Carbohydrates

M127 The effects of xylanase addition on the fermentation of distillers wet grains in laboratory silos. V. Akay*, *Alltech, Inc., Nicholasville, KY.*

The objective of this study was to investigate the effects of the addition of xylanase on the fermentation of distillers wet grain (DWG). Distillers wet grains (36.36% DM) were obtained from New Energy Corporation (South Bend, IN). Treatments were: 1) control (CONT; water); 2) XYL1 (xylanase; 1.0 million XU/tonne); 3) XYL2 (xylanase; 2.0 million XU/tonne); 4) XYL3 (xylanase; 3.0 million XU/tonne). Three different levels of enzyme were prepared from a concentrate (200,000 XU/g) by dissolving 0.5, 1.0 and 1.5 g in 100 ml distilled water for XYL1, XYL2 and XYL3, respectively. Seven kilograms of DWG was placed into a mixer and 7 g of distilled water or enzyme solution was sprayed to obtain proper levels of enzyme concentrations for each treatment. Equal portion of treated DWG was packed into three 1 L Weck jars and sealed for each treatment (total 12 jars). Treated samples were incubated at room temperature. Jars were opened after 14 days of incubation and analyzed for pH, DM, ADF, NDF, N and soluble sugars. Data were analyzed as completely randomized design using the GLM procedure of SAS. Significant was declared at $P \leq 0.05$. Crude protein, arabinose and maltotriose did not differ among treatments. The pH content of ensiled samples was lower for XYL2 compared to CONT, XYL1 and XYL3. Neutral detergent fiber was lower in enzyme treated samples compared to CONT, and enzyme supplementation had both a linear and quadratic effect on NDF. Enzyme supplementation decreased lactic acid and had both a linear and quadratic effect on lactic acid. Dextrin was higher in enzyme treated samples compared to CONT, and enzyme supplementation had both a linear and quadratic effect on dextrin. Dextrin content was higher for XYL2 and XYL3 compared to XYL1. Glucose was higher in enzyme treated samples compared to CONT. Enzyme supplementation increased xylose compared to CONT. These changes in the composition of enzyme treated DWG may have some effect on animal performance.

Key Words: Distillers Wet Grains, Xylanase, Silo

M128 Herbage and animal performance responses to management intensity of continuously stocked bahiagrass pastures. R. L. Stewart, Jr.*, L. E. Sollenberger, J. C. B. Dubeux, Jr., and J. M. B. Vendramini, *University of Florida, Gainesville.*

Bahiagrass (*Paspalum notatum*) pasture covers approximately one million hectares in Florida, 90% of which is utilized by beef cattle. Increasing urbanization may force beef producers to achieve economic livelihood on reduced land area. One option is to increase intensity of management of the remaining pasture resource. The objectives of this research were to evaluate the effects of management intensity (MI), defined as a combination of N fertilization and stocking rates (SR), on yearling beef heifer and bahiagrass pasture performance. Treatments included LOW (40 kg N ha⁻¹ yr⁻¹, 1.2 animal units [AU, one AU=500 kg live weight] ha⁻¹ SR), MODERATE (120 kg N ha⁻¹ yr⁻¹, 2.4 AU ha⁻¹ SR), and HIGH MI (360 kg N ha⁻¹ yr⁻¹, 3.6 AU ha⁻¹), and each was replicated across two pastures. Herbage mass (3.0 MG ha⁻¹) and herbage allowance (4.0 kg forage kg⁻¹ animal weight) were greater for LOW and decreased ($P < 0.05$) as MI increased to HIGH (2.6 Mg ha⁻¹ and 1.1 kg forage kg⁻¹ animal weight). This occurred despite herbage accumulation rate being greater ($P < 0.02$) for HIGH (33 kg ha⁻¹ d⁻¹) than LOW (19 kg ha⁻¹ d⁻¹). Nutritive value increased with increasing MI, in part due to greater N rate and also because the higher stocking rates likely increased the frequency at which cattle revisited grazing locations. Average daily gain decreased ($P < 0.02$) from LOW to HIGH (0.46 to 0.36 kg d⁻¹) because of the lower herbage allowance for HIGH. Gain per hectare increased ($P < 0.02$) with increasing MI due to greater forage utilization. Bahiagrass cover increased ($P < 0.03$) with the HIGH MI (7.1%) and decreased with LOW (-6.4%) and MODERATE (-4.7%) due to invasion of bunchgrass weeds. In conclusion, the increase in liveweight gain per hectare did not compensate for the additional cost associated with increased management. Therefore, if the need for increased production per unit land area becomes acute, the use of another more management-responsive grass species likely will be required.

Key Words: *Paspalum notatum*, Nitrogen Fertilization, Stocking Rate

M129 Responses by steers compared under continuous and frontal grazing. H. Lippke, T. D. A. Forbes*, E. Rivera, P. G. Soderstrom, and B. G. Warrington, *Texas Agricultural Experiment Station, Uvalde, TX.*

Forage intake, digestible DM (DDM), and ADG by steers grazing ryegrass (*Lolium multiflorum* L.) under a frontal grazing system (FGS) were compared with responses under continuous stocking (CGS) at three stocking densities. All pastures were irrigated by a center pivot system. In the FGS, a break wire attached to the towers of the center pivot was advanced at a rate that would leave 30% of the leaf with the ungrazed residue (e.g., 10 cm min⁻¹ for 6 h daily). Each pasture was stocked with five Angus steers (testers), balanced for weight and sire effects. Additional steers (grazers) were placed in the FGS and high-density CGS pastures. Initial stocking densities were 1375, 1258, 895, and 717 kg BW ha⁻¹ for the FGS and the three CGS pastures, respectively. Dry matter intake (DMI) and DDM were estimated in January (Jan), February (Feb), and April (Apr), using alkane marker techniques. In Jan, mean DDM ranged from 773 to 779 g kg⁻¹, except for the medium CGS pasture with 740 g kg⁻¹ ($P < 0.05$). In Feb, DDM ranged from 747 to 773 g kg⁻¹, except for the high CGS pasture (650 g kg⁻¹, $P < 0.05$). In Apr, the medium CGS had greater DDM (710 g kg⁻¹, $P < 0.05$) than the FGS and low CGS pastures (680 g kg⁻¹); mean DDM of the high CGS pasture was 692 g kg⁻¹. In Jan, mean estimates of DMI ranged from 21.8 to 24.6 g kg⁻¹ BW among pastures and were not different ($P = 0.19$). In Feb, DMI for medium CGS (25.2 g kg⁻¹ BW) and low CGS (23.0 g kg⁻¹ BW) were greater ($P < 0.05$) than for high CGS (19.3 g kg⁻¹ BW); mean DMI for FGS (20.4 g kg⁻¹ BW) was different ($P < 0.05$) from medium CGS. In Apr, means for DMI ranged from 17.3 to 19.4 g kg⁻¹ BW and were not different ($P > 0.2$). Mean ADG for the medium CGS pasture (1.09 kg) was greater ($P < 0.05$) than for high CGS (0.89 kg), with low CGS (1.01 kg) and FGS (0.92 kg) intermediate. These data are consistent with the observed rank growth and earlier maturity of the low-density CGS pasture and the persistently lower herbage mass of the high-density CGS pasture. The FGS provided no performance benefit over CGS.

Key Words: Intake, Digestibility, Alkane

M130 Kura clover spreading ability with grass competition. B. Kim*¹ and K. Albrecht², ¹College of Animal Resources science, Kangwon National University, ²Department of Agronomy, University of Wisconsin-Madison.

Kura clover (*Trifolium ambiguum* M. Bieb.) is known to develop an extensive rhizome system when grown in monoculture. However, there is no information about the effects that competition from companion grasses could have on its rhizome development. This study was conducted to determine the difference in rhizome development of Kura clover planted in three different grass treatments of smooth bromegrass (*Bromus inermis* Leyss) and Kentucky bluegrass (*Poa pratensis* L.) swards and to evaluate the effect of defoliation height on Kura clover rhizome development. The experimental design was a randomized complete block with split, split-plot arrangement using three replications. The three grass treatments (killed-grass, grass and grass+N fertilizer) were randomly assigned to whole plots with two cutting height treatments (4-cm or 10-cm stubble height) assigned to sub plots. Two plants of each of the ten different entries of Kura clover (populations started from seeds or clones started from rhizomes) were randomly assigned to sub-sub plots. Rhizome development was measured in mid-September two years after transplanting in both swards at the University of Wisconsin Arlington Agricultural Research Station. Individual plants spread up to 1 m in diameter over a 2-year period after transplanting with no grass competition. The mean spread of kura clover by rhizome growth was greatest in killed-grass plots (85-cm diameter), least in the grass+N plot (29-cm diameter), and intermediate (57-cm diameter) in the grass only plots for both swards. The defoliation height of the swards did not significantly affect the spread of Kura clover regardless of grass status (killed or + or N) in either smooth bromegrass or Kentucky bluegrass. Kura clover generally spread more in smooth bromegrass sward compared to Kentucky bluegrass swards. Reducing the competition from grasses is a management tool that can be used to maximize the colonizing ability of Kura clover.

Key Words: Kura Clover, Rhizome

M131 The effects of addition of pectinase on the levels of soluble sugars during ensiling of whole sugar beets in laboratory silos. V. Akay* and P. Karnezos, *Alltech, Inc.*

The objective of this study was to examine the effects of pectinase on the levels of soluble sugars during ensiling of whole sugar beets in sealed Weck jars. Whole sugar beets were obtained from Best Agri Marketing, CA. Treatments were: 1) CONT (control, water); 2) PECT25 (pectinase; 2.5 million AJDU (apple juice depectinizing unit)/tonne); 3) PECT50 (pectinase; 5.0 million AJDU/tonne); and 4) PECT75 (pectinase; 7.5 million AJDU/tonne). Sugar beets were washed with tap water and shredded with a pruning shredder. Three different levels of enzyme were prepared from a concentrate (1 million AJDU/g) by dissolving 0.250, 0.500 and 0.750 g in 100 ml distilled water for PECT25, PECT50 and PECT75, respectively. Seven kilograms of shredded sugar beets was placed into a mixer and 7 g of distilled water or enzyme solution was sprayed to obtain proper levels of enzyme concentrations for each treatment. Equal portions of treated sugar beets were packed into six 1 L Weck jars and sealed for each treatment. Treated samples were incubated at room temperature. Jars were opened after 14 days of incubation and analyzed for pH, dry matter, soluble sugars and liquid content. Data were analyzed as a completely randomized design using the GLM procedure of SAS. Significance was declared at $P \leq 0.05$. Addition of pectinase to sugar beets decreased the pH, arabinose and acetic acid contents, and increased the lactic acid, fructose and galactose contents compared to control. Addition of pectinase to sugar beets also increased the liquid content of ensiled sugar beets compared to control.

M132 Comparison of forage drying methods. T.W. White*, A.J. Phelps, H.G. Bateman, and C.C. Williams, *Louisiana State University Agricultural Center.*

Effects of drying method on forage analysis were compared using fresh-cut samples of immature and mature alfalfa, red clover, crimson clover, white clover, Coastal bermudagrass, Grazer bermudagrass, bahiagrass and ryegrass. Eight samples of each forage were cut at two stages of maturity. Four samples were oven-dried at 50 °C and four samples were freeze-dried. After the initial drying, the forages were ground to pass a 2-mm screen and DM determined at 100 °C. Ash, CP, NDF and ADF were determined on the oven-dried (50 °C) and freeze-dried samples and reported on DM (100 °C) basis. A 2x2x8 factorial arrangement of treatments was analyzed as a completely randomized block design. Immature forage contained more ash ($P < 0.01$) and less ($P < 0.01$) NDF and ADF than mature forage. Legumes were lower ($P < 0.01$) in NDF, generally lower in ADF and higher ($P < 0.01$) in CP than grasses. Ash and NDF were higher ($P < 0.02$) and CP was lower ($P < 0.01$) in oven-dried forages than in freeze-dried forages. These results suggest that drying method may affect apparent forage composition.

Key Words: Forage, Drying methods, Analysis

M133 Effect of winter stocker growth rate and finishing diet on beef longissimus fatty acid composition. C. Realini¹, S. Duckett*¹, J. Neel², J. Fontenot³, and W. Clapham², ¹University of Georgia, ²USDA-ARS, ³Virginia Tech University.

Seventy-two Angus-cross steers were stockered during the winter months at three growth rates (LOW [0.36 kg/d], MED [0.55 kg/d] or HIGH [0.82

kg/d] prior to finishing on pasture (PAST) or corn silage-concentrate diet (CONC) to determine the effects on longissimus muscle fatty acid composition and cholesterol content. Fatty acid profile and cholesterol content of ribeye steaks (12th rib) were determined by GLC. Data were analyzed as a 3 x 2 factorial design with stocker growth rate (LOW, MED, HIGH), finishing diet (PAST or CONC) and two-way interaction in the model. Total lipid content was two-fold greater ($P < 0.01$) for CONC than PAST, and similar between stocker growth rates. Longissimus muscle from CONC had greater ($P < 0.01$) proportions of myristoleic, palmitic, palmitoleic, oleic, and total monounsaturated fatty acids than PAST. Saturated fatty acid concentration was greater ($P < 0.05$) for PAST-LOW than PAST-MED or CONC-HIGH. Trans-11 octadecenoic acid and the cis-9 trans-11 isomer of CLA were 234% and 90% greater ($P < 0.01$), respectively, for PAST than CONC. Omega-3 fatty acid concentration was 136% greater ($P < 0.05$) for PAST than CONC due to increases in EPA (C20:5), DPA (C22:5), and DHA (C22:6). For omega-6 fatty acids, PAST-MED had greater ($P < 0.05$) levels of omega-6 and linoleic acid than PAST-LOW or CONC-HIGH with CONC-LOW and PAST-HIGH being intermediate. The ratio of omega-6 to omega-3 fatty acids was lower ($P < 0.05$), more desirable from a human health standpoint, for PAST than CONC. Cholesterol content tended ($P = 0.06$) to be greater for PAST than CONC with no differences among stocker growth rates. Increasing growth rate during winter stockering prior to finishing had only minor influences on longissimus fatty acid composition. Finishing cattle on pasture reduced the total fat content of the longissimus and increased the concentrations of omega-3 fatty acids, CLA and trans-11 octadecenoic acid.

M134 Effect of winter stocker growth rate and finishing diet on beef rib composition, quality and palatability. C. Realini¹, S. Duckett*¹, J. Neel², J. Fontenot³, and W. Clapham², ¹University of Georgia, ²USDA-ARS, ³Virginia Tech University.

Angus-cross steers (68 steers in 2002; 62 steers in 2003) were stockered at three growth rates (LOW, MED or HIGH) during the winter months prior to finishing on pasture (PAST) or corn silage-concentrate diet (CONC) to determine the effects on 9-10-11th rib composition, color, and palatability. Steers were harvested at a commercial meat plant and rib (IMPS107) removed from each carcass. The percentage of lean, fat and bone was determined by physical dissection of the 9-10-11th rib section. Data were analyzed as a 3 x 2 x 2 factorial design with stocker growth rate, finishing treatment, year and all interactions in the model. Percentages of bone and lean in the 9-10-11th rib section were greater ($P < 0.05$) for PAST than CONC finished. Rib sections from steers finished on PAST had a 46% reduction ($P < 0.05$) in fat trim (subcutaneous and intermuscular) compared to CONC finished. Reduced growth rate (LOW) during winter stockering reduced ($P < 0.05$) percentage of bone and tended ($P = 0.08$) to increase the percentage of fat in the rib section. Rib section weight increased ($P < 0.05$) with higher winter growth rates for CONC but did not differ among stocker growth rates for PAST. Overall, rib section weight was 28% heavier for CONC than PAST. Longissimus muscle from PAST was darker ($P < 0.01$), less ($P < 0.01$) red, and less ($P < 0.01$) yellow compared to CONC. Subcutaneous fat color was darker ($P < 0.01$) and more yellow ($P < 0.01$) for PAST than CONC. The interaction between finishing treatment and year was significant ($P = 0.01$) for Warner-Bratzler shear force (WBSF). In 2002, WBSF at 14-d of postmortem aging did not differ between PAST and CONC; however in 2003, WBSF was greater ($P < 0.05$) for PAST than CONC. Increasing growth rate during winter stockering had only minor effects on rib weight and composition. Finishing diet altered rib weight and composition, lean and subcutaneous fat color, and tenderness.

Key Words: Beef, Forages, Tenderness

M135 Effect of winter period rate of gain on finishing growth rate, final weight and carcass parameters from pasture or feedlot finished cattle. J. P. S. Neel*¹, J. P. Fontenot², W. M. Clapham¹, and S. K. Duckett³, ¹USDA-ARS, AFSRC, ²Virginia Tech, ³The University of Georgia.

English-type crossbred steer calves (71 head in 2002; 62 head in 2003) were used to compare growth rate, final weight and carcass parameters from cattle finished on pasture (PAST) or corn silage-concentrate (CON) in feedlot, after being wintered at projected low (LOW, ADG =

0.36 kg), medium (MED, ADG = 0.55) or high (HIGH, ADG = 0.82) growth rates. Steers were harvested on the same dates, across treatments, at a commercial meat plant. Data were analyzed as a 3 x 2 x 2 factorial design with winter treatment, finishing treatment, year and all interactions in the model. Winter treatment influenced ($P < 0.05$) finishing ADG (ADG), final weight (FW), carcass weight (CW), dressing percentage (DP) and quality grade QG. Steer ADG during finishing was greater ($P < 0.05$) for LOW than MED and MED than HIGH wintering treatments. Animal FW and QG was greater ($P < 0.01$) for HIGH than LOW winter treatment. Carcass weight and DP was greater ($P < 0.05$) for HIGH. Finishing treatment influenced ($P < 0.001$) yield grade (YG), rib fat (RF), ribeye area (REA), kidney, pelvic and heart fat (KPH) and QG with values being higher for the CON treatment. The interaction between finishing treatment and year was significant ($P < 0.05$) for ADG, FW, CW and DP. Pasture finished cattle had lower ($P < 0.001$) ADG, FW, CW and DP in year two than one, while no differences were seen between years for the CON treatment. Year influenced ($P < 0.05$) RF, KPH and QG. Cattle had higher ($P < 0.05$) RF and QG, and lower KPH in year 1. Lower winter period gain resulted in greater finish period gain. Finishing cattle on CON resulted in greater ADG, FW, CW, DP, YG, QG, RF, REA and KPH. Carcass quality grades were lower in year 2 than year 1.

Key Words: Finishing, Pasture, Winter

M136 Effects of γ -terpinene, terpinolene, α -copaene, and α -terpinene on consumption of alfalfa pellets by sheep. R. E. Estell¹*, E. L. Fredrickson¹, D. M. Anderson¹, K. M. Havstad¹, and M. D. Remmenga², ¹USDA/ARS Jornada Experimental Range, ²New Mexico State University, Las Cruces.

Secondary chemistry influences shrub consumption by free-ranging ruminants. However, effects of many specific terpenes on herbivory have not been examined. Four experiments were conducted to examine effects of individual terpenes on alfalfa pellet intake by lambs. Forty-five lambs (9 lambs/treatment) were individually fed alfalfa pellets sprayed with either γ -terpinene, terpinolene, α -copaene, or α -terpinene at one of five concentrations in an ethanol carrier. Treatments (0, .5, 1, 2, and 10X) were multiples of the concentration (X) of a specific terpene on the leaf surface of *Flourensia cernua*. Terpenes were applied to alfalfa pellets (0.64 kg-lamb⁻¹·d⁻¹, DM basis), and consumption was measured during a 20-min interval for 5 d. Lambs were adapted to handling and individual pen feeding for 10 d and were maintained and fed alfalfa pellets in one group (except during 20-min tests) at a mean total daily intake of 3.9% of BW (DM basis). A day effect ($P < 0.02$) was detected for intake with γ -terpinene ($P < 0.0001$ for both linear and quadratic contrasts). A treatment effect ($P < 0.02$) was observed for α -copaene, with intake on the 2X treatment lower than other treatments. No effect of terpinolene or α -terpinene on intake was observed during the 20-min interval. None of the chemicals tested were strongly related to intake of alfalfa pellets by lambs under the conditions of this study.

Key Words: Intake, Sheep, Terpenes

M137 Forage quality differences between grass hay stored as dry large round bales or wet wrapped round bales. E. B. Rayburn, W. L. Shockey*, and R. M. Wallbrown, West Virginia University, Morgantown.

High humidity associated with the Appalachian region of the US, requires hay producers to wait 2 to 3 days between mowing and baling. Most hay is stored at 80 to 85% dry matter (DM) as large round bales (DRB). Hay harvested as wrapped, large round bales (WRB) usually range from 40 to 60 % DM. The ability to store WRB at high moisture reduces field drying time to 1 to 2 days. Reduced drying time and increased forage moisture increases leaf retention and decreases field losses. In an on-farm research study 7 forage producers representing 7 WV counties harvested hay as either DRB or WRB that was cut from the same field on the same day. Samples (n = 16) were analyzed for DM, crude protein (CP), available protein (AP), degradable protein (DP), soluble protein (SP), acid detergent fiber, neutral detergent fiber (NDF), crude fat (CF), total digestible nutrients (TDN), net energy lactation (NEL), net energy maintenance (NEM), net energy gain (NEG), calcium, phosphorus, magnesium, potassium, sulfur, relative feed value, ash, lignin, NDF insoluble CP (NDICP), starch, nonfiber carbohydrate, and sugar. WRB hay contained higher levels of CP (12.1 vs 10.7% DM; $P < .05$), CF (3.6 vs 2.2% DM; $P < .01$), NEM (.51 vs .42Mcal/lb;

$P < .05$), SP (6.0 vs 2.2% DM; $P < .001$), and SP (50.6 vs 21.4% CP; $P < .001$) and lower levels of NDICP (2.7 vs 4.5% DM; $P < .01$) compared to DRB. WRB hay tended to contain higher levels of AP (11.1 vs 9.7% DM; $P = .07$), TDN (56.8 vs 52.2% DM; $P = .07$), NEL (.53 vs .43 Mcal/lb; $P = .43$), NEG (.26 vs .17Mcal/lb; $P = .05$), DP (68.8 vs 55.4% CP; $P = .05$) and lower levels of lignin (8.5 vs 7.2% DM; $P = .1$) compared to DRB. The economic impact of the improved quality only covered the cost of the plastic. To maximize the value of wrapping hay it is necessary to harvest at earlier stages of growth so that forage quality improvements will pay for the additional machinery, labor and material cost. For WV cattle producers, WRB could be a cost effective way to improve nutrition of hay-fed animals if the productive state of those animals require additional nutrients.

Key Words: Forage, Hay, Large Round Bales

M138 Assumption testing of the optimal sampling schedule of diet components. B. Cobanov* and N. R. St-Pierre, The Ohio State University, Columbus.

The accounting of forage inventory can be conceptualized as a quality control issue that can be monitored using a Shewhart X-bar chart. This procedure requires three inputs: number of samples n , sampling frequency h , and control limits L . All three affect the performance of the chart and, thus, the total quality cost (TCQ). A TCQ function consists of cost/cycle while the process is in-control (IC) A , cost/cycle while the process is out of control (OC) B , cost/cycle for sampling and analyses F , and expected duration of a cycle D . $A = C_0/J$, where C_0 is quality cost/d while producing is IC, and $J=1/\text{mean time process is IC}$. $B = C_1(E-\tau A_2 h + T_1 + T_2) + sY/A_1 + W$, where C_1 is quality cost/d while producing is OC, E =time to sample and analyze one item, $\tau = [1 - (1+Jh)e^{-Jh}]/[J-Je^{-Jh}]$ is the expected time for assignable cause to occur given that it occurs between the i^{th} and the $(i+1)^{\text{th}}$ sample, $A_2 = 1/(1-\beta)$ is the average run length while OC, T_1 is the expected time to discover the assignable cause, T_2 is the expected time to fix the diet, β is the probability(IC_signalprocess_is_OC), $s = (e^{-Jh})/(1-e^{-Jh})$ is the expected number of samples taken while IC, $A_1 = 1/\alpha$ is the average run length while IC, α is the probability(OC_signal-process_is_IC), and W =cost to fix the diet. $D = 1/J - \tau + E + A_2 h + T_1 + T_2$. $F = (a+bn)/hD$ where a is the fixed cost per sample, and b is the cost/(unit sampled). The daily TCQ = $(A+B+F)/D$. The model assumes the normal distribution, but the true distribution remains unknown. We have performed extensive simulation varying J parameter from 5 to 90 d using: Standard Normal (SN); SN with +/- 3.5 SD outliers inserted with a frequency of 1, 5 and 10%; LogNormal with σ taking values 0.3, 0.6, 1.0, 2.0, 4.0, SN with graduate change of mean from 0 to 1.5 SD over 7, 14 and 28 d. The simulation showed that the optimal solution is not sensitive to outliers (the average TCQ cost change was less than 1%) or to long tails (LogNormal test showed the average TCQ cost change in range 6.12 to +1.74%). Finally, the gradual mean change test yielded the most significant cost increase (27.8 to 42.9%).

Key Words: Sampling & Simulation, Quality Control, Assumption Testing

M139 Effects of source and level of two legumes or cotton seed meal on intake and digestibility of Coastal Bermudagrass (*Cynodon dactylon*) hay diets by goats. J. L. Foster*¹, W. C. Ellis², J. P. Muir¹, and J. Sawyer², ¹Texas Agricultural Experiment Station, Stephenville, TX, ²Texas A&M University, College Station.

The objective of this study was to determine effects of two levels of *Strophostyles helvula* (Hel; 1.57% N, 47.57% NDF), *Strophostyles leiosperma* (Leo; 1.88% N, 49.0% NDF), or cotton seed meal (CSM; 8.10% N, 35.26% NDF) upon intake of coastal bermudagrass (CBG; 2.03% N, 68.12% NDF) hay and apparent digestibility of dietary OM (OMD), NDF (NDFD), and N (ND). Six Boer-Spanish goats (average weight 46.22 ± 3.99 Kg) were fed CBG plus fixed levels of Hel, Leo, or CSM at 0.34 or 0.68% of BW / d in a 6 by 6 Latin square design with 3 by 2 factorial arrangements of treatments. The CBG was fed ad libitum, and legumes / CSM fed in two equal daily feedings during a 7 d adjustment period and 7 d collection period in metabolism crates. Feces were collected every 24 h, weighed, sub-sampled, and frozen until dried at 100°C. Diet, legumes / CSM, and fecal samples were ground to pass a 1 mm screen in a Wiley mill and analyzed for OM, NDF and N. Nutrient intake and digestibilities were calculated and data analyzed

by GLM procedures of SAS. Interactions between source and amount were insignificant ($P = 0.16$). Intake of N was greater ($P < 0.01$) by goats fed CSM (111.3 ± 6.0 mg/kg BW) than by those fed Hel or Leo (each 74 ± 6.0 mg/kg BW). Otherwise N intake did not differ. Lack of differences due to inclusion of legumes was probably due to similarity in N content of legume and CBG ($P = 0.29$). Other than a trend for CSM to increase N intake, source and level of legume or CSM had no effect on intake of hay or digestibility of dietary NDF ($P > 0.05$). There was a tendency for improved digestibility of OM with the 0.68% supplementation level of all sources ($P = 0.06$; 56.5 vs. 63.3 ± 2.4 , 0.34 and 0.68% levels respectively). There was no benefit from feeding these legumes or CSM with CGB for these goats. Feeding these sources and levels of the two legumes or CSM did not impair intake or digestibility of CBG in this trial. Similarities in nutrient intake among treatments indicate that legumes and CSM replaced dietary CBG instead of increasing total intake.

Key Words: Goat, Legume, Supplement

M140 Effect of corn silage chop length on lactation performance of dairy cows on a commercial farm – a case study. T. D. Nennich^{*1}, J. H. Harrison¹, D. L. Davidson¹, J. Werkhoven², and A. Werkhoven², ¹Washington State University, Puyallup, ²Werkhoven Dairy, Monroe, WA.

The theoretical length of cut (TLC) of corn silage can affect the lactation performance of dairy cows. An on-farm case study was conducted to compare the differences in the lactation performance between cows fed corn silage that was chopped at 1.6 cm (SHORT) or 2.5 cm (LONG) TLC. Two pens of mid-lactation Holstein dairy cows (115 cows per pen) were assigned to one of two treatments in a 2 x 2 Latin square design. Diets were fed for two periods of 24 days each. The corn silages were stored in a bunker (SHORT TLC) or AgBag (LONG TLC) silo. Diets were formulated to contain 22.7% corn silage (DM basis) and were similar except for the corn silage. Cows were milked an equal number of times and averaged 3.2 milkings per day. Pen milk weights were recorded at each milking. Milk was sampled for composition analysis four times each period using the California DHIA in-line sampling kit. As expected, LONG diets resulted in a greater percentage of material on the top screen of the particle separator than SHORT diets. Milk production was numerically greater (0.4 kg/milking or 1.2 kg/d on a 3x milking schedule) for cows consuming SHORT diets. Dry matter intake and milk composition were similar for the two diets. Feeding SHORT corn silage diets resulted in numerically greater milk production (0.4 kg/milking) when corn silage was fed at a rate of approximately 23% of the dietary DM on this commercial dairy.

Treatment	Milk, kg/milking	DMI, kg/d	Milk fat, %	Milk protein, %
LONG	12.9	26.6	3.47	3.11
SHORT	13.3	26.5	3.50	3.09
SD	1.6	1.5	0.24	0.09

Key Words: Corn Silage, Dairy, Chop Length

M141 Peanut stover and bermudagrass hay for wethers on summer hardwood range in north central Texas. C. E. Packard^{*1,2}, J. P. Muir¹, R. Wittie², and R. Harp², ¹Texas Agriculture Experiment Station, Stephenville, TX, ²Tarleton State University, Central Texas.

Goats in the south-central United States raised on range often face a mid-summer forage quantity and quality deficit that may be mitigated by feeding inexpensive hay or stover. Peanut stover (10 % CP, 40% ADF) and Bermudagrass hay (12% CP, 33% ADF) were tested in north-central Texas as a 0.5% and 2.0% BW supplement/substitution on 20 kg Spanish X Boer goat wethers that browsed native hardwoods (8 head ha-1) and in a traditional feedlot, using a complete feed ration as a control. For 10 weeks from July to September in 2002 (216 mm rainfall) and in 2003 (354 mm rainfall) average daily gains (ADG) were measured and ADF and CP concentration of the primary browse species were determined. Goats receiving 0.5% BW bermudagrass in 2002 had greater ADG than those in the control and 0.5% BW peanut paddocks ($P < 0.1$). There were no differences ($P > 0.1$) in ADG among goats fed 2.0% BW of bermudagrass, and peanut stover or control animals in

2002. There were no differences ($P > 0.1$) among treatments in 2003. Goats fed concentrates in the drylot had greater ($P < 0.1$) ADG than goats eating either hay or stover ad libitum both years. There were no differences ($P > 0.1$) in carcass percent among animals in the range treatments. Control goats in the drylot had greater ($P < 0.05$) carcass percentages than animals fed either stover or hay (45, 37 and 31%, respectively). Supplementing goats on hardwood range with bermudagrass hay at 0.5% BW improved ADG only when low rainfall resulted in diminished browse (450-750 kg ha-1 at an average 11% CP and 29% ADF). Goats on woodland range at excessive stocking rates or on degraded range may also benefit from bermudagrass supplementation even during high rainfall years.

Key Words: Goat, Stover, Hay

M142 Forage intake, digestibility and gain by five beef breedtypes grazing rye-ryegrass-bermudagrass pasture and subsequent feedlot performance. T. D. A. Forbes^{*1}, F. M. Rouquette², R. D. Randel², and J. J. Cleere³, ¹Texas Agricultural Experiment Station, Uvalde, TS, ²Texas Agricultural Experiment Station, Overton, TX, ³Texas Cooperative Extension, Overton, TX.

An experiment was conducted using Angus (ANG), Bonsmara (BON), Brahman (BRM), Bonsmara x Angus (BA) and Braunvieh (BRV) steers grazing bermudagrass pastures overseeded with rye and ryegrass to determine forage intake and digestibility (DMD) using alkane markers, and to relate performance on pasture to subsequent feedlot performance. Ten animals of each breed were allotted to 5 pastures on Dec. 12. Animals were weighed at the start of the trial and at 28-d intervals for 121-d. On April 19, 5 animals of each breed were dosed with a controlled-release alkane capsule for the determination of intake and digestibility. From April 29, fecal samples were collected from each dosed animal on 5 consecutive days. Forage samples were collected daily for alkane determination, and forage mass was measured at the start and end of the intake trial. Forage and fecal samples were frozen and lyophilized prior to extraction of alkanes and determination by GC. Initial BW (kg) was 255 ± 7.3 , 183 ± 6.9 , 197 ± 6.9 , 256 ± 7.7 , and 213 ± 6.9 , respectively for ANG, BON, BRM, BA and BRV. The BON and BRM steers were 4 mo younger than the other breeds. Consequently, ADG and intakes are reported on a BW basis. Average daily gain on forage was highest ($P = 0.006$) in the BON steers (3.47 ± 0.275 g.kg LW⁻¹.d⁻¹) followed by BRV, ANG, BRM and BA (3.6 ± 0.26 , 3.5 ± 0.27 , 3.3 ± 0.26 and 2.8 ± 0.29 , respectively). Breed did not differ ($P = 0.50$) in DMI (5.2 ± 0.19 kg DM/d). Diet DMD tended ($P = 0.07$) to be higher in BRM and BRV and lowest in BA (0.69, 0.69, 0.68, 0.67, and 0.65 ± 1.07 for BRM, BRV, ANG, BON, and BA respectively). Feedlot ADG tended to be higher ($P = 0.09$) in the BON steers followed by ANG, BA, BVH, and BRM (5.5 ± 0.25 , 5.1 ± 0.26 , 5.1 ± 0.26 , 4.9 ± 0.23 and 4.5 ± 0.23 g.kg LW⁻¹.d⁻¹ respectively). Steers had higher ADG in the feedlot than on forage, but there was no correlation ($r = 0.117$, $P = 0.445$) between ADG on forage and ADG in the feedlot. These data suggest that BON steers, though smaller at the onset of the study, were able to grow efficiently, and that steers that perform well on forage can also perform satisfactorily in the feedlot.

Key Words: Alkanes, Steers, Grazing

M143 Soybean by-products for feeding grazing dairy cows. 1. Milk production and composition. R. F. Gregoret^{*1}, M. C. Gaggiotti¹, M. R. Gallardo¹, S. E. Valtorta², G. A. Conti¹, and C. Arakaki³, ¹Experimental Station Rafaela INTA, Ruta 34 km 227 Rafaela 2300 Santa Fe Argentina, ²National Research Council (CONICET) CC 22 Rafaela 2300 Santa Fe Argentina, ³CICV INTA CC 77 Castelar 1712 Buenos Aires Argentina.

The objective of this trial was to evaluate the effects of three soybean by-products on milk production and composition. Nine Holstein lactating cows, rumen fistulated (133 DIM) were used in a 3x3 Latin squares design replicated 3 times (28 days periods). The treatments were: SH = Soybean hulls, SM = Soybean meal (Solv-extd, 44) and SSR = Soybean seeds raw. The diets were iso-energy (1.6 Mcal NEL/kg DM), iso-protein (CP = 16%) and iso-fiber (NDF = 42%), and were formulated on a DM basis with alfalfa grazing (28%), a silage based partial mixed ration (PMR = 71%) and a mineral mix (1%). In SH soybean hulls represented 26% of total offered DM; in SM the soybean meal was 16%, while soybean seed represented 17% in SSR. Corn silage, on the

other hand, represented 13, 40 and 42 % in SH, SM and SSr, respectively. The PMR was fed to each cow in individual pens between the am and the pm milking. The rest of the day cows were sent to an alfalfa pasture, on daily strips. No differences were detected in DM intake. However, NDF consumption was higher in SH. There were no significant treatment effects on milk production and composition. The milk fat content was lower in SH ($P = 0.06$). Soybean hulls may be included in a high proportion (26 %) to feed grazing dairy cows in winter, to partially replace corn silage.

M144 Soybean by-products for feeding grazing dairy cows. 2. Rumen fermentation. M. C. Gaggiotti^{1*}, C. Arakaki², M. R. Gallardo¹, R. F. Gregoret¹, S. E. Valtorta³, G. A. Conti¹, and O. Quaino¹, ¹Experimental Station Rafaela INTA Ruta 34 km 227 Rafaela 2300 Santa Fe Argentina, ²CICV INTA CC 77 Castelar 1712 Buenos Aires Argentina, ³National Research Council (CONICET) CC 22 Rafaela 2300 Santa Fe Argentina.

Nine ruminal fistulated Holstein cows in mid lactation, were used to evaluate soybean by-products on rumen fermentation, in a 3x3 Latin squares design replicated 3 times (28 days periods). The treatments were: SH= Soybean hulls, SM= Soybean meal (Solv-extd, 44%) and SSr= Soybean seeds raw. The diets were isoenergy, isoprotein and isofiber, and were formulated with alfalfa grazing, a silage based partial mixed ration (PMR) and a mineral mix. Soybean by-products represented 26, 16 and 17% of the DM diet, in SH, SM and SSr. Corn silage was 13, 40 and 42 %, respectively. The PMR was fed individually between am and pm milking, after which all cows were sent to an alfalfa pasture, on daily strips. Ruminal fluid samples were taken on days 23 and 25 during each period, at 0, 3, 6, 9, 12, 15, 18, 21 and 24 hours post-am PRM feeding to analyze pH, NH₃, total VFA, acetate (Ac), propionate (Pr) and butyrate concentrations. There were significant treatment effects on pH, total VFA and Ac:Pr ratio. In SH, pH and Ac:Pr ratio were lower, while total VFA were higher. Values for pH were never below 6.0 and the lowest Ac:Pr (1.75) was recorded 9 hours after the PRM feeding. There was a trend in all treatments for Ac:Pr to grow higher 6 hours after the beginning of grazing. Except for treatment by sampling time in Ac and Pr, no other significant interactions were detected. Soybean hulls can partially replace some winter diet ingredients, such as corn silage, with no evident negative effects.

M145 Evaluating the use of indigestible neutral detergent fiber to predict dry matter intake of cattle fed high forage diets. R. Driskill*, J. R. Russell, K. Bormann, and W. J. Powers, Iowa State University, Ames.

The efficacy of NDF and indigestible NDF (iNDF) to predict voluntary feed consumption of steers fed a grass hay diet was determined in a digestion trial. Six Angus-Hereford growing steers (mean BW, 304 kg) were used in two 3 x 3 Latin square trials with a 7 d adjustment and 3 d collection periods. Three maturities of smooth bromegrass hay (pre-bloom, mid-bloom, mature) were fed at ad libitum levels individually in metabolism crates. Neutral detergent fiber was determined in an Ankom Fiber Analyzer (Ankom Technology Corp., Fairport, NY) with sodium sulfite and a heat-stable alpha-amylase on forage and fecal samples and the remaining residues after a 96 h fermentation of forage and fecal samples in ruminal fluid and a phosphate buffer in a Daisy¹¹ Incubator (Ankom Technology Corp., Fairport, NY). Concentrations of NDF and iNDF for the pre-bloom, mid-bloom, and mature hays were 56.1, 18.4; 67.6, 27.5; 70.1, 29.1% DM. Intakes and excretions of NDF and iNDF were 2.07±0.33, 0.92±0.21; 0.80±0.16, and 0.80±0.19 %BW and did not differ between steers. Regressions predicting NDF and iNDF excretion (%BW) from NDF and iNDF intakes (%BW) were $NDF_{fecal} = -0.11 + 0.50 NDF_{intake}$, $r^2 = 0.61$; $iNDF_{fecal} = -0.02 + 1.03 iNDF_{intake}$, $r^2 = 0.74$. Regressions predicting NDF and iNDF intake (%BW) from DMI (%BW) were $NDF_{intake} = 0.48 + 1.08 DMI$, $r^2 = 0.70$; and $iNDF_{intake} = 0.38 + 0.23 DMI$, $r^2 = 0.19$. Although iNDF excreted as %BW did not differ from iNDF consumed, large variations in iNDF intake as %BW suggests that iNDF is less accurate than NDF in predicting DMI of steers fed a single forage species.

Key Words: Indigestible Neutral Detergent Fiber, Forage Intake, Beef Cattle

M146 Visual assessment versus compressed sward heights as predictors of forage biomass in cool-season pastures. R. E. Vibart^{1*}, S. L. White-Bennett², J. T. Green², and S. P. Washburn¹, ¹Department of Animal Science, North Carolina State University, Raleigh, ²Department of Crop Science, North Carolina State University, Raleigh.

Two methods to predict pasture biomass for fescue-ladino clover and orchardgrass-ladino clover swards were studied. Visual assessment by an experienced observer was compared to compressed heights using a 0.2-m² acrylic plate meter that exerted 6.0 kg/m² pressure on the sward. Regression analyses were conducted for each method using clipped and dried plant material to ground level from 0.25-m² quadrats used as the referral method. Sampling included 150 observations for fescue on 38 d and 119 observations for orchardgrass on 30 d from 1995 to 1998. Estimates of biomass were sequential from least to most invasive: visual assessment; compressed sward height; and clipped biomass. Higher coefficients of determination (R^2) and lower errors of prediction (S_{xy}) for regressions indicated improved prediction of forage biomass. Regressed across sampling days and all observations, visual assessments ($R^2 = 0.69$ and 0.65, $S_{xy} = 685$ and 624 kg DM/ha for fescue, and orchardgrass, respectively) were more accurate in predicting forage biomass than were compressed sward heights ($R^2 = 0.37$ and 0.47, $S_{xy} = 998$ and 775 kg DM/ha for tall fescue and orchardgrass, respectively). Regression equations within sampling days were also more precise for visual assessment than for compressed sward heights for fescue ($R^2 = 0.94$ vs. 0.83 ± 0.03 ; $P < 0.01$; $S_{xy} = 297$ vs. 442 ± 48 ; $P < 0.05$; $n = 38$) and tended to differ for orchardgrass ($R^2 = 0.94$ vs. 0.89 ± 0.02 ; $P = 0.07$; $S_{xy} = 247$ vs. 321 ± 42 ; $P = 0.16$; $n = 30$). Compared to compressed sward heights, visual assessment had a higher percentage of predictions with $R^2 \geq 0.8$ (92 vs. 68% of 38, $P < 0.05$) for fescue and a numerically higher percentage (93 vs. 83% of 30) for orchardgrass. Reasons for lower accuracy using compressed sward heights were not clear. Indentations in soil surface, differences in composition, maturity, or ground cover could contribute to less precision using the plate meter. Visual assessment proved to be a simple and accurate method of predicting forage biomass in cool season pastures.

Key Words: Pasture Biomass

M147 Effect of swine manure application on winter wheat tissue growth and nitrogen, phosphorus, and potassium content. D. M. Sholly*, M. C. Walsh, B. C. Joern, A. L. Sutton, and B. T. Richert, *Purdue University, West Lafayette.*

Two studies were conducted to determine the effect of swine manure application on winter wheat growth and nutrient uptake. Manure was added to soil on an N basis at 224 and 325 kg plant available nitrogen (PAN)/hectare for Exp. 1 and 2, respectively. Soil was mixed with manure from pigs fed diets 1-4: 1) Standard (STD), 17.7% CP; 2) STD + 10% wheat bran (WB); 3) Low Nutrient Excretion diet (LNE) containing 13.9% CP, HAP corn, synthetic amino acids, and phytase; 4) LNE + 10% WB; 5) Negative Control (NC), 0 added PAN; and 6) Positive Control (PC), 325 kg PAN from $(\text{NH}_4)_2\text{SO}_4$ (Exp. 2 only). In Exp. 1 and 2, 20 and 30 winter wheat (CV. Patterson) seeds were sown/pot, respectively; 4 pots/trt. Exp. 1 wheat was defoliated at d 35, 63, and 91 for harvest 1 (H1), 2 (H2), and 3 (H3), respectively, and in Exp. 2 at d 28 and 56 for H1 and H2, respectively. Exp. 1, all manure trts increased H1, H3, root, total vegetative tissue (TVT), and total plant tissue (TPT) wt and N, P, and K tissue content compared to the NC ($P < .05$). STD manures increased H1 tissue wt by 12% (1.78 vs. 1.56 g; $P < .03$) and N and P content ($P < .001$), but decreased H2 tissue wt by 49% (0.31 vs. 0.61 g; $P < .0002$) and N, P, and K content ($P < .001$) compared to LNE manures. WB manures had no effect on plant growth or nutrient content ($P > .10$). Exp. 2, the PC increased H1, root, TVT, and TPT tissue wt ($P < .05$) and N content of H1, H2, TVT, and TPT and root K content ($P < .04$) compared to the NC. STD manures increased ($P < .03$) H2 tissue wt and N content by 19% and TVT tissue wt and N content by 10% compared to LNE manures. Manure trts increased H1 and TVT tissue wt ($P < .10$) and N ($P < .05$) content over the PC. Total P content of H1, H2, TVT, and TPT was increased ($P < .01$) by all manure trts over PC and STD manures were higher than LNE manures ($P < .01$). WB manures increased H1 P content by 11.5% compared to manures without WB (4.14 vs. 4.68 mg; $P < .01$). Manure trts yielded greater wheat growth than the NC and PC while also increasing plant tissue N and P content. Manure from pigs fed WB had minimal effects on wheat growth.

Key Words: Swine Manure, Wheat, Growth

M148 Effect of grass nonstructural carbohydrates on milk yield and composition and dry matter intake of dairy cattle. A. Buyserie*, P. French, and T. Downing, *Oregon State University, Corvallis.*

Previous research indicates increasing NSC content of grass forages increases utilization of degradable protein, microbial protein synthesis, and milk production. Dry matter intake also increases and N excretion decreases. Objectives were to identify differences in milk yield and composition, dry matter intake, and rumen fermentation between a high NSC and a lower NSC grass ingested as greenchop. Cool-season, perennial ryegrasses, one with a relatively high NSC content (HNSC) and one commonly grown in Oregon (CNSC) were selected. Grasses were planted fall, 2002 and fed spring, 2003. Twelve Holsteins and 2 Jerseys were blocked by milk yield and assigned at random to treatment. Individual intake and milk yield were collected twice daily for 21 days. Milk samples were collected for four consecutive milkings days 0, 7, and 21. Days 9 and 21, rumen samples were collected at 0, 1, 2, 3, 4, 6, 8, 10, and 12 hours relative to TMR feeding and analyzed for pH and ammonia. Grasses were cut, sampled, and offered *ad-lib* twice daily. TMR was offered for one hour twice daily. Data were analyzed with the MIXED procedure of SAS. For grass DMI, treatment by day interaction was significant ($P < .01$), with grass DMI being greater for HNSC during week 2. TMR DMI was greater for HNSC treatment ($P < .05$). Milk yield and yield of milk fat and milk protein were greater for HNSC treatment ($P < .05$). MUN and rumen ammonia did not differ between treatments ($P > .05$). Grass nutrient composition was different than expected. Grass NDF and ADF were similar ($P > .05$), HNSC was higher in CP ($P < .01$) and lower in NSC ($P < .05$). In this study, milk and component yields for HNSC were greater than CNSC treatment, however effects appear to be caused by factor(s) other than grass NSC.

Key Words: Grass Forages, Nonstructural Carbohydrates, Protein Utilization

M149 Number of experimental units required to detect differences in grazing time. D. H. Seman*¹, J. A. Stuedemann¹, and L. W. Douglass², ¹USDA-ARS, *Watkinsville, GA*, ²University of Maryland, *College Park.*

The objective of this study was to determine the number of cattle necessary to detect differences in time spent grazing by steers on E+ tall fescue. In each of two years, 12 yearling Angus steers grazed tall fescue pastures, three pastures were highly infested (64%) (*Neotyphodium coenophialum*) KY-31 fescue, while three had low infestation rates (32%). One steer on each pasture received an experimental drug to overcome effects of endophyte infection and one received a placebo on Monday, Wednesday, and Friday during the three-week (1988) and four-week (1989) study. All 12 steers were fitted with vibracorders to record continuous grazing behavior during the studies. Statistical analyses of time spent grazing/h was conducted by the Mixed Procedure of SAS with day as a repeated measure and pasture considered a random effect. The Mixed Procedure calculated eight standard errors, one for each endophyte, drug and year combination and resulted in a range of values when estimating the number of experimental units. It would take from 14 to 115 steers/treatment to detect a 5% difference in minutes spent grazing/h $\alpha = .05$. Up to 30 steers/treatment would be needed to detect a 10% difference, 7 to 15 to detect a 15% difference, 4 to 9 to detect a 20% difference, 4 to 6 for a 25% difference, and 2 to 5 to detect a 30% difference. These analyses point out the importance of calculating an accurate standard error with which to estimate experimental units. Box-Jenkins ARIMA time series analysis showed that minutes spent grazing/h differed ($P < .05$) between days when steers were gathered and given drug and days when steers were left alone in 1988 and during week 1 in 1989. Grazing behavior at any given time of the day was correlated with the previous one or two hours. A significant 24-h seasonal component showed that grazing behavior repeated ($P < .01$) at the same time on subsequent days. Results suggest that it may not be necessary to monitor grazing behavior continuously day after day to obtain a representative sample. Data on days when normal grazing behavior is disrupted, e.g., by gathering steers, may not be representative of time spent grazing throughout a given collection period.

Key Words: Cattle, Grazing Behavior

M150 Relationship of rate of appearance of vaccenic acid and pH during in vitro biohydrogenation of linolenic acid from alfalfa hay. C. V. D. M. Ribeiro* and M. L. Eastridge, *The Ohio State University, Columbus.*

Using an in vitro system, approximately 0.5 g of DM from alfalfa hay (92%) and sucrose (8%) was incubated with rumen fluid using two different buffers: one at average pH at 6.3 (HpH buffer, 100:0 $\text{NaHCO}_3/\text{NaCl}$, wt/wt) and the other at 5.8 (LpH buffer, 50:50 $\text{NaHCO}_3/\text{NaCl}$, wt/wt). Samples were incubated for 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12 h. At each time point, the pH was measured and the tubes were immediately put in ice and stored at -20°C until freeze-drying. Fatty acids (FA) were methylated with sodium methoxide (10 min at 50°C) followed by HCl in methanol (10 min at 80°C). Rates (mg/ml/h) for individual FA were determined using PROC NLIN of SAS (2002). The pattern of linolenic acid disappearance was similar for both pH. The amount of linolenic acid remaining was high for the LpH buffer until 7 h. After 7 h, the amounts were the same for both buffers. A similar pattern for the amounts of vaccenic acid (VA) was observed from 0 to 6 hours. The amount of VA formed from 0 to 6 h was the same, peaked at 2 h and decreased until 6 h for both buffers. After 6 h, the rates of VA appearance were 0.00502 and -0.000783 for the HpH and LpH buffers, respectively. The amount of VA from 6 to 12 h of incubation changed very little for the LpH buffer. The amount of stearic acid was always higher for the HpH buffer. The rates of stearic acid appearance from 0 to 6 h were 0.00214 and 0.00103 for HpH and LpH buffers, respectively. Disappearance of linolenic acid from alfalfa hay was slightly affected by a low pH, with no difference after 7 h. Based on linolenic acid disappearance, the final reduction step of biohydrogenation appears to be more susceptible to the low pH than the steps prior to the formation of VA.

Key Words: Vaccenic Acid, Alfalfa, Biohydrogenation

M151 Comparison of biohydrogenation of fatty acids in lyophilized forage and air dried forage with sucrose additions. C. V. D. M. Ribeiro* and M. L. Eastridge, *The Ohio State University, Columbus.*

Grazing animals produce a higher percentage of conjugated linoleic acid (CLA) in milk fat compared to animals fed TMR, and most of the CLA is synthesized in the animal from vaccenic acid (VA). It has been proposed that this higher amount of CLA in milk fat is due to higher concentrations of soluble sugars in fresh plants. To observe the effect of sucrose on biohydrogenation (BH) and formation of trans-18:1 fatty acids (FA), four continuous culture fermenters were used in a 4 X 4 Latin square. Each period consisted of 7 d of adaptation and 3 d of sample collection. Fresh alfalfa samples (prebloom to early bloom) were obtained from a greenhouse at the Ohio Agricultural Research and Development Center (Wooster, OH). Samples were harvested randomly and immersed immediately in liquid nitrogen using a metal grid. Samples were freeze-dried, ground at 1mm, and stored at -20 °C. Alfalfa hay was purchased and contained 38% NDF and 21% CP. The treatments were: 1) fresh alfalfa, 2) alfalfa hay, 3) 96% alfalfa hay and 4% sucrose, and 4) 92% alfalfa hay and 8 % sucrose. The FA analyses were performed on the effluent samples. The FA were methylated with sodium methoxide (10 min at 50 °C) followed by HCl in methanol (10 min at 80 °C). Data were analyzed by the PROC MIXED procedure of SAS (2002). Total BH and BH of linolenic acid were higher ($P < 0.05$) for fresh alfalfa compared to alfalfa hay with no sucrose. The BH of linoleic and linolenic acid decreased linearly with higher sucrose supplementation. Total BH decreased linearly ($P < 0.05$) for alfalfa hay with higher sucrose supplementation. It seems that sucrose impaired total BH. Fresh alfalfa had a more complete BH with lower levels of trans-18:1 FA in the effluent. Although not different statistically, percentage of VA in the effluent was numerically lower ($P = 0.13$) for fresh alfalfa. Percentage of trans-10 18:1 also tended to be lower ($P < 0.10$) for fresh alfalfa. We concluded that sucrose itself may not be responsible for the higher VA observed in milk of grazing cows. We speculate that other factors, such as pH and soluble proteins, may also be involved.

Key Words: Biohydrogenation, Alfalfa, Continuous Culture

M152 Effects of level of protein supplementation on performance of crossbred calves grazing Tifton 85 bermudagrass. S. A. Woods*¹, F. M. Rouquette, Jr.², G. E. Carstens¹, T. D. A. Forbes³, and W. C. Ellis¹, ¹Texas Agricultural Experiment Station, College Station, TX, ²Texas Agricultural Experiment Station, Overton, TX, ³Texas Agricultural Experiment Station, Uvalde, TX.

The high protein requirement of growing crossbred calves fuels the search for grazing management programs that effectively meet their nutritional needs. The objective of this study was to determine the effects of level of protein supplementation (PS) on performance of crossbred calves grazing Tifton 85 bermudagrass (TIF85). Weaned Simmental-sired, 25% Angus, 25% Brahman steers and heifers ($n = 59$; mean BW = 345.4 ± 4.1 kg) were blocked by BW within sex, and randomly assigned to one of four treatment groups (three pasture replicates/trt): (1) pasture (PAS), (2) PAS + 0.2% BW of a 2:1 SBM:corn PS containing salt, dicalcium phosphate, magnesium oxide, and Rumensin 80, fed daily (.2BW), (3) PAS + 0.4% BW PS (.4BW), or (4) PAS + 0.8% BW PS (.8BW). The PAS calves were provided free choice access to a mineral premix without Rumensin 80. TIF85 pasture plots (0.68 ha) were stocked at 8.6 hd/ha and grazed for 90 d during the summer of 2003. Calves were weighed at the start of the study and 28 d thereafter. ADG during the first 56 d of the study increased ($P < 0.001$) in a linear manner as the level of PS increased (0.93, 1.03, 1.16 and 1.27 ± 0.05 kg/hd/d for PAS, .2BW, .4BW and .8BW, respectively). Overall ADG during the 90 d study also increased ($P < 0.001$) in a linear manner (0.70, 0.81, 0.92 and 1.11 ± 0.04 kg/hd/d for PAS, .2BW, .4BW and .8BW, respectively). Overall, calves receiving .8BW treatment gained 37 kg more than those grazing PAS. Using pasture plot as experimental unit, BW gain per ha increased ($P < 0.001$) in a linear manner as level of PS increased (546, 634, 716 and 864 ± 32.5 kg/ha for PAS, .2BW, .4BW and .8BW, respectively). Additional calf gain was 0.11, 0.21 and 0.40 kg/d for .2BW, .4BW and .8BW, respectively. Efficiency of supplementation, expressed as PS:extra gain ratio, was 6.83, 6.85 and 7.24 for .2BW, .4BW and .8BW treatments, respectively. In this study, level of

PS up to 0.8% of BW was effectively used to increase the performance of calves grazing Tifton 85 bermudagrass.

Key Words: Tifton 85 bermudagrass, Protein Supplementation, Stocker

M153 Forage quality of perennial grass as influenced by stubble height. J. H. Cherney* and D. J. R. Cherney*, *Cornell University, Ithaca, NY.*

Timing of spring grass harvest is critical to obtaining optimum forage quality, and the harvest window is narrow. We studied the feasibility of harvesting grass at a higher stubble height to improve forage quality. Rival reed canarygrass, Okay orchardgrass, and Select tall fescue were fertilized with 0, 112 and 224 kg N fertilizer/ha at spring greenup and sampled in late May or early June in 2001, 2002 and 2003. Four replicates at each of two sites were sampled, a fertile site in Ithaca, NY and a more marginal high elevation site in Dryden, NY. Samples were cut at a 10-cm stubble height and sectioned into 5-cm increments using a paper cutter. Samples were dried, ground and analyzed for forage quality parameters. The study was analyzed as a randomized complete block with a split plot arrangement of treatments. Main plots were grass species; subplots were nitrogen fertilizer treatments. Dry matter yield per cm of stubble height above a 10-cm cut was highly positively correlated with total stand yield ($r^2 = 0.88$; $P < 0.01$), ranging from 36 to 108 kg DM per cm of vertical growth. Percent of total yield per cm of lower canopy varied with the height of the stand. For grass fertilized with 112 kg of N, CP increased by 0.25 percentage units ($r^2 = 0.74$; $P < 0.01$) and NDF decreased by 0.30 percentage units ($r^2 = -0.85$; $P < 0.01$) per cm of vertical height above a 10-cm stubble. In vitro digestibility increased by 0.29 percentage units ($r^2 = 0.74$; $P < 0.01$) and fiber digestibility increased by 0.30 percentage units ($r^2 = 0.59$; $P < 0.01$) per cm of vertical height above a 10-cm stubble. Forage quality of the total stand increased in CP by 0.15 percentage units and decreased in NDF by 0.13 percentage units per cm of additional stubble left in the field, which is inconsequential.

Key Words: Forage Quality, Stubble Height, Grass

M154 Evaluation of tall fescue, soybean hulls and ionophores in vitro. L. A. Briggs*, J. C. Waller, H. M. Blalock, and C. J. Richards, *The University of Tennessee, Knoxville.*

Combinations of endophyte (*Neotyphodium ceonophialum*) infected (E+) Kentucky-31 tall fescue (*Festuca arundinacea* Schreb.) and soybean hull (SH) were incubated *in vitro* with ionophores to determine VFA and gas production, DM disappearance, and NH₃-N release. Substrates consisted of tall fescue:SH ratios of 100:0, 85:15, 70:30, 55:45, and 0:100. Substrates were incubated with no ionophore, Rumensin[®], or Bovatec[®] in a 5 x 3 factorial design with three replicate runs. Both ionophores were mixed at a rate to provide 33 mg of active ingredient per kg of substrate. Substrates (0.5 g; DM) were sealed in F57 bags (Ankom, Inc., Macedon, NY) and incubated in 100 mL of McDougalls buffer:rumen fluid inoculum (4:1). Gas pressure sensors were used to continuously monitor changes in pressure over a 72 h period. At the end of the incubation, the F57 bags were removed, washed with hot water, and dried for determination of DM disappearance. A sample of the remaining inoculum was retained for VFA and NH₃-N analysis. Ionophore addition did not affect DM disappearance, gas production, or VFA and NH₃-N concentrations. DM disappearance increased linearly ($P < 0.05$) with SH concentrations from 0 to 45%. There was a tendency ($P < 0.08$) for the rate of gas production to respond in a quadratic manner as SH increased from 0 to 45%. Gas production per unit of substrate disappearance did not differ ($P > 0.48$). Acetate and total VFA concentrations increased linearly ($P < 0.05$) while propionate concentrations tended ($P < 0.08$) to increase with SH concentrations from 0 to 45%. Incubation of 100% SH resulted in the greatest valerate and isovalerate concentrations. Concentrations of NH₃-N decreased as SH concentrations increased from 0 to 45%. Substitution of up to 45% soybean hulls in fescue-based diets resulted in greater substrate digestion with increased energy release and decreased NH₃-N release.

Key Words: Fescue, In Vitro, Digestion

M155 Effects of stocking method and rate on seasonal cow-calf performance and forage quality. W. E. Wyatt^{*1}, B. C. Venuto², J. M. Gillespie³, and D. C. Blouin³, ¹Louisiana State University Agricultural Center, Jenerette, ²Grazing Lands Research Laboratory, USDA, ARS, El Reno, OK, ³Louisiana State University Agricultural Center, Baton Rouge.

Effects of stocking method and rate on cow-calf performance and forage quality were evaluated by the following treatments: continuous-stocked pastures at a low (1.2; CL), medium (2.0; CM), and high rate (2.7 cows per ha; CH) and rotational-stocked pasture (8 paddocks) at a high rate (2.7 cows per ha; RH). Brangus cows and calves were stocked on replicated treatment pastures on a year-around basis for three years. Cows were weighed prior to calving (January), prior to breeding (April), at weaning (October), and again the following January. Spring-born calves were weighed at birth, in April, and at weaning. Seasons corresponding to weigh periods were February-April (ES), May-June (LS), and July-October (S). The LS period represented a transition from annual ryegrass (principal forage in ES) to common bermudagrass-dallisgrass (principal forages in S) forage bases. Statistical analyses were conducted using a generalized linear mixed-model procedure. Cow weight gains and calf ADG were similar ($P > .2$) among treatments in ES. In LS, CL cows lost less weight than CM ($P < .01$; -33 vs -48 kg), and CH cows lost less weight than RH ($P < .01$; -39 vs -54 kg). Calf ADG in LS was greater for CL than for CM ($P < .01$; .93 vs .8 kg) and was greater for CM than for CH (.72 kg; $P < .01$), but similar ($P = .54$) between CH and RH calves. In LS, forage CP (12.7 vs 11.1 %) and IVTD (60.9 vs 57.3 %) were greater for CH than for RH ($P < .05$). In S, CM cows gained more weight than CL cows ($P < .05$; 34 vs 28 kg) and than CH cows ($P < .01$; 34 vs 18 kg) and CH cows gained more weight than RH cows ($P < .01$; 18 vs 11 kg). In S, CL and CM calves had similar ADG ($P = .76$; .98 and .96 kg), but CM was greater than CH (.78 kg; $P < .01$) and CH was greater than RH (.7 kg; $P < .05$). In S, forage CP was greater for CH than for RH ($P < .01$; 13.3 vs 11.7 %). Selected forage IVTD tended ($P < .1$) to be higher for CM than for CH. Stocking rate and method affected cow-calf performance and forage quality in late-spring and summer (warm-season, perennial grasses), but had less impact during the early-spring (cool-season, perennial grasses).

Key Words: Stocking Rate, Stocking Method, Cow-Calf

M156 Evaluation of ensiled sorghums with and without condensed tannins as feeds for ruminants. H. Carneiro^{*1}, P. B. Arcuri¹, J. A. Rodrigues², F. S. Sobrinho¹, S. S. Brum¹, and M. Villalquira³, ¹Embrapa Gado de Leite Juiz de Fora, MG, Brazil, ²Embrapa Milho e Sorgo Sete Lagoas, MG, Brazil, ³E (Kika) de la Garza American Institute for Goat Research, Langston University, Langston, OK.

Historically, there is a believe that condensed tannins (CT) are responsible for low digestibility of plant material and are recognized as anti-nutritional factors in diets of monogastric animals. High CT concentrations can reduce the absorption of protein from the small intestine of monogastric. However, in ruminant diets low concentrations (1-3% DM) can be beneficial by reducing ruminal degradation of forage protein, which outweigh any detrimental effects of reduced protein availability in the small intestine. A total of 10 Sorghum cultivars (lines CMSXS114 Tannin (T) and CMSXS165 Without Tannin (WT), Hybrids 9953101(T), 9953130(T), BR601 (WT), BR701 (T), BR700 (T), and AG2005 (WT), and Varieties BR 501(WT), and BR506 (WT)) with 8 replications were ensiled in PVC silos of 3 kg per silo for 60 d and then analyzed for CT, (colorimetric analysis by the butanol-HCl method) CP, NDF, ADF, and in situ and in vitro (4, 24, and 48 h) digestibilities. Condensed tannins from quebracho were purified using affinity chromatography with sephadex LH-20 and used as a standard. Low concentration of CT have been defined as 10 g/kg DM or less and medium as 10 to 50 g/kg DM or more. Hybrid BR701 had the highest concentration of CT among the sorghums ($P < 0.05$) with 7 g/kg DM. Differences among sorghums were not detected for NDF ($P = 0.10$), ADF ($P = 0.10$), or in vitro digestibility ($P = 0.09$). The highest CP content was noted for line CMSXS165 (9.74 g/kg; $P < 0.05$). Concentrations of CP in CMSXS114 (8.32 g/kg), BR 700 (7.44 g/kg), and BR701 (8.05 g/kg) were above the overall mean (7.4 g/kg). The Hybrid BR700 showed the fastest rate of ruminal degradation of these 3 in the 4 h ($P < 0.05$), followed by CMSXS114 and CMSXS165. The two latter were sorghums isogenic lines that differ only in CT concentration. It was concluded that digestibility was not affected by CT level; however, relative CT concentrations were low. Therefore, we would do not anticipate significant effects of CT content on DM intake, digestibilities, or performance in cattle fed these sorghum silages.

Ruminant Nutrition I

M157 Effect of increasing sodium bicarbonate proportion in high concentrate diets on ruminal fermentation in finishing beef heifers. L. González^{*}, A. Ferret, S. Calsamiglia, and X. Manteca, *Universitat Autònoma de Barcelona Edifici V, Campus UAB, Bellaterra, Barcelona, Spain.*

Four rumen fistulated Holstein heifers (264 ± 12 kg initial BW) were used in a 4 x 4 Latin square design to determine the effect of increasing levels of sodium bicarbonate (0, 1, 2 and 4 %, on DM basis) on ruminal fermentation. The main ingredients of the concentrate were: 33% barley grain, 32% corn grain, 16% tapioca and 10% soybean meal. Heifers were allowed to consume concentrate and barley straw on an ad libitum basis, which resulted in a mean of 12 to 88 forage to concentrate ratio. Linear, quadratic and cubic effects were analyzed with the Type 1 analysis of variance of the PROC MIXED procedure of SAS with animal and period considered random effects. Mean ruminal pH and total area under the pH curve tended to increase linearly ($P < 0.15$) with increasing buffer proportion. The lowest pH (5.65 ± 0.09) was similar across treatments. Hours in which pH was below 5.8 tended ($P = 0.10$) to a quadratic effect, the values being 12.6, 3.6, 3.2 and 4.7 h, for 0, 1, 2 and 4 % of sodium bicarbonate, respectively. Average ammonia nitrogen concentration was not affected by treatment (2.44 ± 0.87 mgN/100mL). Total VFA concentration was not affected by treatment (143 ± 12 mM). Molar proportion of propionate decreased linearly ($P < 0.05$) and acetate tended to increase linearly ($P < 0.10$) with increasing buffer proportion in the diet. Acetate to propionate ratio, molar percentage of butyrate and branch-chained VFA increased linearly ($P < 0.05$) as sodium bicarbonate proportion increased in the diet. Valerate was not affected by treatment. Data suggests that increasing sodium bicarbonate beyond 1% does not bring any further benefits to overall pH and ruminal fermentation conditions. Factors other than sodium

bicarbonate proportion used as a buffer must play a role in the control of the effects of high concentrate diets on ruminal fermentation.

Key Words: Beef Heifers, Rumen Fermentation, Sodium Bicarbonate

M158 Effects of sodium bicarbonate on ruminal pH and feed intake in feedlot cattle. L. Paton^{*1}, M.A.G. von Keyserlingk¹, K. A. Beauchemin², and D. M. Veira³, ¹University of British Columbia Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada, ²Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, ³Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

The objective of this study was to determine whether sodium bicarbonate (NaHCO₃) could reduce the risk of acidosis in cattle receiving high concentrate diets. Ruminally cannulated Jersey steers (n=3) and Holstein cows (n=3), previously adapted to a high concentrate diet, were used in a repeated 3x3 Latin square to study the effects of NaHCO₃ on daily feed intake and ruminal pH. Cattle were provided ad libitum access to a control diet of steam-rolled barley, barley silage, and a protein-mineral supplement at 80, 12 and 8% (DM basis), respectively. Treatments were control, control plus free choice NaHCO₃ mixture and control supplemented with 0.7% NaHCO₃ (% DM basis). The free choice NaHCO₃ mixture was offered as 30% dried molasses and 70% NaHCO₃ based on a previous palatability trial. Periods consisted of 11 d adaptation and 3 d of continuous ruminal pH measurements using indwelling electrodes. Daily DMI (mean ± SE) did not differ between the control (7.95 ± 1.34 kg/d) and free choice NaHCO₃ (8.27 ± 0.86 kg/d) ($P = 0.67$) or the NaHCO₃ supplemented diet (7.94 ± 0.48 kg/d) ($P = 0.99$). Mean lowest feed intake for the control diet, free choice NaHCO₃ diet and 0.7% NaHCO₃ supplemented diet were 2.98 kg/d, 5.51 kg/d and 6.89 kg/d, respectively. Considerable variation in daily free choice

NaHCO₃ intake (104.6 ± 45.6 g/d) was also observed. Control mean ruminal pH (5.81 ± 0.09) did not differ from the free choice NaHCO₃ diet (5.88 ± 0.08) ($P = 0.43$) or the NaHCO₃ supplemented diet (5.92 ± 0.10) ($P = 0.39$). Variation in control ruminal pH did not differ from the free choice NaHCO₃ ($P = 0.43$) or the NaHCO₃ supplemented diet ($P = 0.47$). These results suggest that supplementing a feedlot diet with either 0.7% NaHCO₃ as a component of the diet or free choice has no effect on total daily DMI or daily mean ruminal pH when compared to the control diet.

Key Words: Acidosis, Feedlot Cattle, Rumen pH

M159 Effects of monensin and different dose levels of essential oils on feed intake, growth performance and feed efficiency of beef cattle. C. Benchaar^{*1,2}, E. Charmley³, and J. Duynisveld³, ¹Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, Quebec, Canada, ²Nova Scotia Agricultural College, Truro, Nova Scotia, Canada, ³Crop and Livestock Research Centre, Agriculture and Agri-Food Canada, Nappan, Nova Scotia, Canada.

The objective of this study was to investigate the effects of dietary addition of monensin (Rumensin[®]; MO) or different dose levels of a commercial mixture of essential oils (Vertan[®]; EO) on feed intake, growth performance and feed efficiency of beef cattle. The mixture of EO consisted of thymol, eugenol, vanillin and limonene. Twenty steers and twenty heifers (Angus × Herford, initial BW = 369 ± 29 kg) were assigned to ten blocks of four cattle according to BW and fed for *ad libitum* intake a TMR comprising 75% grass/legume silage and 25% of rolled barley (dry matter basis). Within each block, cattle were randomly assigned to one of four experimental treatments; unsupplemented TMR (Control, CO) or TMR supplemented with MO (220 mg/d) or EO (2 and 4 g/d). During the experiment (98 and 82 days duration for the steers and heifers; respectively), feed intake was recorded daily and animals were weighed at the start and end of the trial and at two week intervals during the trial. Data were analyzed as a randomized block design using the PROC MIXED procedure of SAS. Specific prior contrasts were used to test differences between CO and diets supplemented with MO and EO, and to determine the linear or quadratic response to EO dose level. Dry matter intake (DMI) was not affected by the addition of EO (8.6 kg/d; $P > 0.05$). However, DMI was 10 % lower ($P < 0.01$) for cattle fed MO compared to those fed CO. Average daily gain (ADG) was similar between cattle fed CO and those consuming supplemented diets (1.2 kg/d; $P > 0.05$). Feed efficiency (DMI to ADG ratio) was not different between cattle fed CO and those receiving MO and EO treatments (7.0; $P > 0.05$). However, a quadratic effect of EO dose level was observed ($P < 0.05$). Feed efficiency was decreased by the addition of 2 g of EO/d (6.6 vs 7.0), where as it was increased when the diet was supplemented with 4 g of EO/d (7.8 vs. 7.0). Results from this study suggest that further work is required to determine the optimum level of EO supplementation to improve feed efficiency in beef cattle.

Key Words: Monensin, Essential Oils, Beef Performance

M160 Monensin or decoquinat in high concentrate diets fed to Santa Ines lambs. I. Susin^{*1,2}, C. Q. Mendes^{1,2}, A. V. Pires^{1,2}, and I. U. Packer^{1,2}, ¹University of São Paulo, ²ESALQ.

Feedlot lamb meat production has increased in Brazil. However, feedlot lambs are more susceptible to coccidiosis occurrence. Addition of an anticoccidial drug to the diet may improve lamb performance. Two trials were performed to evaluate the effects of using decoquinat or monensin on feedlot lamb performance. In each experiment, animals were assigned to a complete randomized block design according to body weight and age at beginning of the trial. Trial 1: Forty-two Santa Ines ram lambs (initial BW 19.2 ± 0.1 kg and 81 ± 1.4 d old) were fed a 95% concentrate and 5% raw sugarcane bagasse diet for 56 days. To the control diet (CON) was added either decoquinat (DEC, 17 mg/kg DM) or sodium monensin (MON, 25 mg/kg DM). Both DEC and MON were effective in reducing oocysts per gram of feces as compared to the control diet ($P < 0.001$). However, there were no differences on performance among treatments. Average daily gain (ADG), dry matter intake (DMI), feed conversion (FC) and hot carcass yield (HCY) were 270, 287 and 271 g/day; 0.94, 0.97 and 0.95 kg/day; 3.48, 3.43 and 3.51 kg DMI/kg gain and 46.8%, 47% and 47.2% for treatments CON, DEC and MON, respectively. Trial 2: Forty-eight Santa Ines ewe lambs (initial BW 18.4 ± 0.1 kg and 89 ± 2.5 d old) were fed the same diet of Trial 1 for 56 days

(Phase 1). In Phase 2, the same ewe lambs were fed a 70% concentrate and 30% coarcross hay diet during an additional 56 day period. There were no differences among treatments in Phase 1 for ADG, DMI and FC (186, 199 and 183 g/day; 0.77, 0.81 and 0.74 kg/day; 4.2, 4.1 and 4.1 kg DMI/kg gain for treatments CON, DEC and MON, respectively). In Phase 2, however, ewe lambs on MON treatment had a higher ADG and better FC ($P = 0.03$). There was no difference on DMI, ADG, FC and DMI in Phase 2 were 121, 121 and 149 g/day; 8.7, 8.8 and 7.4 kg DMI/kg gain; 1.05, 1.07 and 1.1 kg/d for CON, DEC and MON, respectively. Adding monensin to a 70:30 (concentrate:roughage ratio) diet for ewe lambs improved ADG and FC 19 and 15%, respectively. The addition of monensin or decoquinat in feedlot lamb diets control oocyst discharge; monensin also improves ADG and feed efficiency in older ewe lambs.

Key Words: Hair Sheep, Ionophore, Performance

M161 Effects of yeast culture in barley-based backgrounding and finishing diets for cattle on health, growth performance, and fecal *Escherichia coli* populations. Y. Wang^{*1}, T. A. McAllister¹, S. J. Bach¹, D. J. Gibb¹, and I. Yoon², ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, Canada, ²Diamond V Mills, Inc., Cedar Rapids, IA.

The effects of a naturally fermented *Saccharomyces cerevisiae* feed additive (Diamond V XP#8482 Yeast Culture, YC) on health, growth performance and fecal *Escherichia coli* were assessed using 390 newly weaned British × Charolais crossbred steers (292.5 ± 1.23 kg initial BW) in a completely randomized study that included backgrounding (BKGD) and finishing (FNSH) periods. Barley silage/barley grain-based feedlot diets were fed as is (control) or amended with YC to provide 56.7 g/d to each steer for the first 28 d, followed by 28.3 g/d to the end of BKGD (treatment YC-B) or through to the end of FNSH (treatment YC-BF). Feed intake, ADG, and gain/feed were determined on a per-pen basis ($n = 10$) at 4-wk intervals. Fecal samples collected from each steer ($n = 130$) were analyzed for total *E. coli* counts (at end of BKGD) and presence of *E. coli* O157:H7 (and end of BKGD and end of FNSH). Carcass weight, fat cover, longissimus area, and dressing percentage were recorded at harvest (commercial abattoir). Growth rates averaged 1.26 kg/d during BKGD and 1.32 kg/d during FNSH. Feeding YC did not affect ($P > 0.05$) DMI, ADG or gain efficiency of the steers during BKGD or FNSH, nor were treatment effects on carcass traits observed ($P > 0.05$). Prevalence of *E. coli* O157:H7 was low. At the end of BKGD, this pathogen was detected in only four steers from a single YC-BF pen. At the end of FNSH, *E. coli* O157:H7 was present in fecal samples from two control steers (in 1 pen) and 13 YC-B steers (in 3 pens), but none in the YC-BF group. Total fecal *E. coli* counts at the end of BKGD were similar across treatments. Three deaths due to bloat were recorded in the control group, plus removal of one YC-B steer. There were no fatalities due to bloat in the YC-BF group. In the present study, YC did not affect health, growth performance or fecal shedding of *E. coli* O157:H7 by feedlot cattle.

Key Words: *E. coli* O157:H7, Feedlot Cattle, Yeast Culture

M162 Effects of alcohol-fermented feedstuff with live yeast on growth characteristics, serum metabolites, and meat compositions in Korean native bulls. S. Jong Suh^{*}, P. Byung Ki, and H. Byong Ju, Department of Animal Resources Science, Kangwon National University, Chunchon, Korea.

The effects of alcohol-fermented feedstuff with live yeast (AFF) on average daily gain, serum metabolites, and meat compositions were investigated using forty Korean native bulls (initial wt: 255.9, final wt: 649.2). The AFF (cracked corn:cracked oat:water:molasses:live yeast=48.48%:12.12%:30.30%:6.07%:3.03%) was fermented anaerobically in an incubator at 30° for 48 hours. Experimental diets were commercial feed, AFF, and rice straw. The feeding of rice straw was *ad libitum* feeding in control and treatment. Bulls were individually fed for 14 months. The experiment was composed of two groups: control (100% of commercial feed), treatment (50% of commercial feed and 50% of AFF). Average daily gain (ADG) was higher in treatment than in control ($P < 0.05$; 1.06 vs 0.89). Total gain, total dry matter intake (TDMI), and feed conversion were not different between treatment and control. The blood cholesterol and triglyceride concentration were higher in treatment than in control, but the blood urea nitrogen (BUN) concentration of treatment was lower than that of control during growing (200–400)

period. The blood glucose, cholesterol, and triglyceride concentration were high in treatment, compared to control ($P < 0.05$) during finishing (400–700) period. The ether extract content of longissimus dorsi (LD) muscles of treatment was higher than that of control ($P < 0.05$). The essential and nonessential amino acid content of LD muscles were similar between control and treatment. The saturated fatty acid content of LD muscles was lower in treatment than in control, but the unsaturated fatty acid content of LD muscles was high in treatment, compared to control. The oleic acid content of LD muscles was significantly higher in treatment than in control ($P < 0.05$). Consequently, the increase of ADG and unsaturated fatty acid content was observed in treatment according to feeding the AFF. Therefore, it is expected that the AFF will be effective to improve growth performance and meat quality in Korean native bulls.

Key Words: Alcohol-Fermented Feedstuff with Live Yeast, Korean Native Bulls, Meat Composition

M163 Rate and extent of *in situ* DM disappearance of feedstuffs in cows fed different strains of yeast. J. C. Silva* and L. W. Greene, *Texas Agricultural Experiment Station, Amarillo, TX.*

An *in situ* experiment was conducted to determine rate and extent of DM disappearance (DMD) of corn grain (CG), sorghum grain (SG), alfalfa hay (AH) and brown mid-rib forage sorghum silage (SS) in the presence of different strains of yeast. Four mature rumen cannulated non-lactating cows were fed a control diet (C), or C diet plus 20 g/d P7, 20 g/d SC47 or 40 g/d DV-XP strains of yeast in a 4X4 Latin square design. A 13% high concentrate diet (9.5 kg/d) consisting of 80% of steam flaked corn, 10% soybean hulls and 10% protein/vitamin/mineral supplement was fed to each cow twice a day (60% at 0800 h and 40% at 1600 h). Yeast strains were top dressed on the respective diet at the morning feeding and mixed by hand. Cows were fed their respective diet in each period of the Latin square for 14 d. On d 12 of each period, duplicate *in situ* digestion bags (10 X 20 cm) containing substrate (12.5 mg/cm² of bag surface area) were incubated for 72, 48, 24, 12, 6, 3, 1.5, 0.5 and 0 h. Immediately after submersion of the 0 h bags of substrate into the ruminal fluid, all bags were removed and rinsed with tap water. After an initial rinse, all bags were placed into an automatic clothes washing machine and rinsed using 4 to 6 gentle cycles of agitation until rinse water was clear. Bags were then dried at 60 C for 48 h and weighed to determine DMD. The rate of DMD for CG, SG, AH and SS was 2.7, 2.1, 1.88 and 0.94 %/h, respectively. P7 and SC47 increased ($P = 0.0075$) rate of DMD of CG over that of C and DV-XP (3.28 and 3.43 vs 1.96 and 2.52 %/h, respectively). Yeast strains did not change the rate of DMD of SG, AH or SS ($P > 0.10$). The extent of DMD was similar across all treatments for CG (95.4%), SG (89.3%) and AH (74.54%). The extent of DMD of SS was decreased ($P = 0.04$) when DV-XP was fed compared C, P7 and SC47 (56.0% vs 76.9, 74.0 and 69.5, respectively). These data indicate that various yeast strains affect rate or extent of DMD of CG and SS in this study.

Key Words: Cattle, DM Disappearance, Yeast

M164 Fermentable and nutritional characteristics of fermented feedstuffs added *Aspergillus oryzae* and *Saccharomyces cerevisiae*. P. Byung Ki, R. Chang Six, and S. Jong Suh*, *Department of Animal Resources Science, Kangwon National University, Chunchon, Korea.*

This study was conducted to compare and evaluate fermentable and nutritional characteristics of fermented brewery meal with *Aspergillus oryzae* (AO) and *Saccharomyces cerevisiae* (SC). Experiments were divided into three treatment groups; FFAO (fermented feedstuff with 1% of *Aspergillus oryzae*), FFSC (fermented feedstuff with 1% of *Saccharomyces cerevisiae*), and FFAS (fermented feedstuff with 0.5% of *Aspergillus oryzae* and 0.5% of *Saccharomyces cerevisiae*). For changes of crude protein contents by 48 hours fermentation, there were no significant difference among treatments. Ether extract contents were significantly increased by 48 hours fermentation ($P < 0.05$). Neutral detergent fiber contents of FFAO, FFSC and FFAS were significantly decreased by 48 hours fermentation ($P < 0.05$), but acid detergent fiber and acid detergent lignin contents were not different. The pH of FFAO and FFAS was decreased more rapidly than that of FFSC, reaching a plateau after 24 hours ($P < 0.05$). Alcohol content was increased rapidly until 18 hours in FFAO and was increased rapidly until 12 hours in FFSC and

FFAS, and alcohol content of FFAO, FFSC and FFAS was maintained constantly after 24 hours ($P < 0.05$). The ammonia N content of FFAO, FFSC and FFAS was 0.022, 0.073 and 0.040% at 48 hours, respectively, and then ammonia N was over twice higher in FFSC compared with FFAO and FFAS ($P < 0.05$). Dextrose content was increased until 6 hours in FFAO, but it was rapidly decreased in FFSC and FFAS until 6 hours ($P < 0.05$). Lactate content was higher in FFAO and FFAS compared with FFSC ($P < 0.05$). Consequently, if AO is added for the formulation of fermented feedstuff with brewery meal, which has high moisture content, ether extract, alcohol, and lactate contents were increased, but NDF and ammonia N contents were reduced. Therefore, it is expected that AO will be effective to increase the feed value and the preservation of fermented feedstuff with a high moisture content.

Key Words: *Aspergillus oryzae*, *Saccharomyces cerevisiae*, Fermented Feedstuff

M165 Effects of chlortetracycline (CTC) and steroidal implant on growth and plasma growth hormone (GH) and thyroid hormone release after challenge with thyrotropin-releasing hormone (TRH) and GH-releasing hormone (GHRH) in beef steers. S. E. Kitts*¹, J. C. Matthews¹, G. L. Sipe¹, T. S. Rumsey², T. H. Elsasser², S. Kahl², R. L. Baldwin³, and K. R. McLeod¹, ¹University of Kentucky, Lexington, ²Growth Biology Laboratory, ARS, USDA, Beltsville, MD, ³Bovine Functional Genomics Laboratory, ARS, USDA, Beltsville, MD.

Twenty-four Simmental-Angus steers (365 kg \pm 4) were used to test the hypothesis that CTC, in the absence and presence of steroidal implant, alters composition of tissue accretion by attenuating GH and thyroid-stimulating hormone (TSH) release. Steers were assigned randomly to a 2 x 2 factorial arrangement of treatments of either 0 or 350 mg CTC/d, with and without estrogenic implant (EI). Steers received ad libitum amounts of a 80:20 concentrate-forage diet formulated to provide 105% of the MP requirement for steers gaining 1.6 kg/d. On d 0, 15, 30, 56 and 106, steers received a challenge injection via jugular catheter of 1.0 μ g/kg BW TRH + 0.1 μ g/kg BW GHRH and blood samples were collected from 30 to 360 min post-challenge. Steers were slaughtered after d 112 to determine carcass characteristics. Across the feeding period, DMI was unaffected ($P = 0.17$) by treatment; however, EI increased ($P = 0.01$) rate and efficiency of gain. Treatment did not affect ($P = 0.2$) area under the response curve (AUC) for GH, TSH, or thyroxine; however, AUC for triiodothyronine (T₃) tended to be greater ($P = 0.14$) for EI steers following each GHRH + TRH challenge. Carcass weight was greater ($P = 0.05$) and longissimus fat cover was lower ($P = 0.02$) in steers fed CTC in the absence of EI, but not in the presence of EI (interaction, $P = 0.03$). Marbling score was 13% greater ($P = 0.18$) for steers fed CTC. In conclusion, subtherapeutic feeding of CTC had subtle effects on carcass characteristics, but did not attenuate the release of GH or TSH in response to GHRH + TRH challenge. Conversely, steroidal implant increased tissue accretion and tended to increase circulating T₃ following GHRH + TRH challenge.

Key Words: Chlortetracycline, Carcass Quality, Beef Cattle

M166 Effects of salinomycin and virginiamycin on performance and carcass traits of feedlot steers. S. L. Silva¹, R. Almeida*², D. Schwahofe¹, P. R. Leme¹, and D. P. D. Lanna³, ¹FZEA/USP Pirassuninga, SP, Brazil, ²UFPR and PUCPR & LNCA-ESALQ/USP Piracicaba, SP, Brazil, ³LNCA-ESALQ/USP Piracicaba, SP, Brazil.

Seventy-two Nellore steers, with an initial BW of 416 \pm 26 kg and approximately 36 months of age, were fed for 69 days at the experimental feedlot from University of Sao Paulo. The animals were blocked by initial weight and randomly allocated to 24 pens, with three steers per pen. Steers were fed four dietary salinomycin and virginiamycin supplementation groups: control (CONT), 15 ppm of salinomycin (SAL), 16 ppm of virginiamycin (VIRG) and 10 ppm of salinomycin plus 8 ppm of virginiamycin (SAL+VIRG), mixed on ground dry corn. The commercial products used were Coxistac[®] (Salinomycin) and Phigrow[®] (Virginiamycin). During the trial period, steers were fed once daily, with meals delivered at 0700 h. Diets contained a higher proportion of roughage than normally observed in feedlots using *B. taurus* animals: 77% of DM as concentrate, 40.8% NDF, 13.5% CP and 70.5% TDN. All statistical analyses were conducted using the GLM procedure of SAS. No differences were observed for average daily gain (ADG)

for the CONT treatment compared to SAL or VIRG. But surprisingly the ADG of the SAL+VIRG treatment was 17.9% higher ($P < 0.05$) than CONT. SAL and VIRG treated steers had lower ($P < 0.05$) DMI than SAL+VIRG steers: 10.1 ± 0.4 , 10.2 ± 0.4 , and 11.3 ± 0.4 kg/d, and 2.24 ± 0.08 , 2.25 ± 0.08 , and $2.46 \pm 0.08\%$ of BW, respectively. CONT animals showed intermediate ($P > 0.05$) intakes. Feed efficiencies were not different ($P > 0.05$) among groups. Treatments with higher gains had also greater intakes. Nevertheless, even without statistical differences, there were improvements of 5.6, 8.3, and 8.0% in feed efficiency, respectively for SAL, VIRG and SAL+VIRG, over controls. Few differences were observed on carcass traits between supplemented and control steers. Among them, steers fed SAL had higher backfat thickness than ($P < 0.01$) CONT and than ($P < 0.05$) VIRG and SAL+VIRG steers: 8.7 ± 0.7 vs. 6.3 ± 0.7 , 6.8 ± 0.7 and 6.8 ± 0.7 mm, respectively. The improvements in efficiency are very consistent with previous research and would have important economical and environmental impact.

Key Words: Beef Cattle, Ionophores, Antibiotics

M167 Effects of semduramicin on performance and carcass traits of feedlot steers. R. Almeida^{*1}, S. L. Silva³, R. T. Y. B. Souza³, D. P. D. Lanna², and P. R. Leme³, ¹UFPR and PUCPR & LNCA-ESALQ/USP Piracicaba, SP, Brazil, ²LNCA-ESALQ/USP Piracicaba, SP, Brazil, ³FZEA/USP Pirassununga, SP, Brazil.

Forty-three Nelore steers, approximately 36 months of age, were individually fed in outdoor pens with electronic Calan gate feeders at University of Sao Paulo experimental feedlot. The animals were blocked by initial weight and randomly assigned to four levels of dietary Aviax[®]: 0, 45, 67.5, or 90 mg semduramicin/head/day. After a 27-day adaptation period, steers had an average shrunk weight of 457 ± 18 kg at the beginning and 540 ± 19 kg at the end of the trial. During the 62-day experimental period, steers were fed once daily at 0900 h. Because *B. indicus* steers are more liable to develop acidosis, roughage content was higher than normally observed in feedlots using *B. taurus*: 77% of DM as concentrate, 40.8% NDF, 13.5% CP and 70.5% TDN. Data were analyzed using the REG and the GLM procedures of SAS. Average daily gain was not affected ($P > 0.05$) by semduramicin supplementation, although steers treated with 67.5 mg had increased daily gains of 0.136 kg/day above controls. Steers supplemented with 90 mg had lower dry matter intakes ($P < 0.05$) than steers supplemented with 67.5 mg of semduramicin. During the evaluation period, intakes for steers supplemented with 67.5 and 90 mg were: 11.73 ± 0.30 and 10.73 ± 0.28 kg/day, and 2.35 ± 0.06 and $2.12 \pm 0.05\%$ of BW, respectively. Feed efficiency (BWG/DMI) was not different ($P > 0.05$) between treated and non-treated steers. Improvements in overall feed efficiency were observed to be: 2.8, 7.4, and 7.3% for treatments 45, 67.5, and 90 mg, respectively, over controls ($P > 0.05$). However, there was an improvement in feed conversion efficiency determined as residual feed intake calculated by regression ($P < 0.05$). Carcass characteristics from supplemented steers did not differ ($P > 0.05$) from the controls. The improvements in efficiency are very consistent with previous research with other ionophore molecules and would have important economical and environmental impact.

Key Words: Beef Cattle, Nelore, Ionophores

M168 Chlortetracycline, but not Synovex-S, differentially affects tissue expression of high-affinity glutamate transporters in fattening steers. G. L. Sipe^{*}, S. E. Kitts, K. R. McLeod, and J. C. Matthews, University of Kentucky, Lexington.

Chlortetracycline (CTC) fed sub-therapeutically and estrogenic growth implants (Synovex-S; S) are used to alter the amount and site of skeletal muscle and/or adipose tissue accretion of fattening cattle. However, effect(s) of these nutrient-repartitioning agents on nutrient absorption capacity are unknown. Because the expression of two high-affinity glutamate transporters, GLT-1 and EAAC1, by tissues of fattening steers is sensitive to physiological load (Gissendanner et al., 2003, FASEB J. 17(5):A738), this study was conducted to determine if expression of GLT-1 or EAAC1 was affected by none (control; C), S (d0 and d56 implanted) and/or CTC (350 mg/d) treatment ($n = 6$) of Simmental x Angus steers (BW = 350 ± 10 kg) fed a finishing diet (see companion abstract, Kitts et al., 2004) for 112 d. Immunoblot analysis was used to determine the relative content of EAAC1 and GLT-1 in plasma membrane vesicles isolated from the duodenum (D), jejunum (J), ileum (I), liver (L), skeletal muscle (M, longissimus dorsi), subcutaneous fat (SF), omental fat (OF) and interstitial fat (IF). EAAC1 and GLT-1 content

of D, J, and I ($P > 0.48$), and EAAC1 content of L and M ($P > 0.53$), were not affected by treatments. In contrast, for CTC steers, M GLT-1 content was 128% greater ($P < 0.01$) than C steers, whereas L GLT-1 content was 236% and 160% greater ($P < 0.008$) than C and S, respectively. For adipose tissues, SF EAAC1 content did not differ ($P > 0.94$), but OF EAAC1 content of CTC steers was 74% greater ($P < 0.078$) than C. CTC steers also contained 319% more ($P < 0.053$) IF EAAC1 than S, but not C ($P > 0.26$) animals. OF and IF GLT-1 did not exhibit a treatment effect ($P > 0.33$) in contrast to SF GLT-1 content, which was 524% ($P < 0.08$) and 237% ($P < 0.09$) greater in CTC than for C and S steers, respectively. Although Synovex-S had no effect, CTC appears to increase the capacity for glutamate absorption by up-regulating GLT-1 (L, M, SF) and EAAC1 (OF, IF) expression, in contrast to having no effect on intestinal epithelium.

Key Words: Gene Expression, SLC1A1, SLC1A2

M169 Influence of genotype and diet on steer performance. C. L. Ferrell^{*}, E. D. Berry, H. C. Freetly, and D. N. Miller, USDA-ARS; U.S. Meat Animal Research Center, Clay Center, NE.

Objectives were to evaluate genotype and diet effects on steer performance during the growing period and subsequent responses to a high concentrate diet during the finishing period. Fifty-one [MARC III (M; 14) and Brahman cross (Bx; 37)] steers were allotted to eight pens and individually fed chopped brome grass hay (BG; $N = 26$; $DM = 0.85$, $CP = 9.5\%$, $ME = 2.19$ Mcal/kg) or a corn silage based diet (CS; $N = 25$; $DM = 0.51$, $CP = 11.9\%$, $ME = 2.75$ Mcal/kg) for 119 d (PD1) followed by a high corn diet (HC; $DM = 0.79$, $CP = 11.7$, $ME = 3.08$ Mcal/kg) to a target wt of 560 kg (PD2). Data were analyzed by ANOVA with genotype, diet (BG, CS), and the two-way interaction included. The interaction was not significant. Initial (273 kg) and final wts (559 kg) did not differ due to genotype or diet, but wt of BG (325 kg) steers was less than CS (384 kg) steers at the end of PD1. ADG and intake of DM, CP, and ME were less ($P < 0.05$) for Bx than for M during PD1, PD2 and total, but efficiency of M and Bx was similar ($P > 0.40$). Carcass wt, marbling, quality grade, and REA were similar ($P > 0.12$), but Bx steers had greater backfat (1.26 vs. 0.87 cm) and yield grades ($P = 0.07$) than M steers. During PD1, daily DMI (6.91 vs. 7.11 kg) was similar, but CP (0.66 vs. 0.85 kg) and ME (15.2 vs. 19.5 Mcal) intake of BG was less ($P < 0.001$) than CS. DMI/gain (21.5 vs. 6.9), CP intake/gain (2.06 vs. 0.83), and ME intake/gain (47.1 vs. 19.2 Mcal/kg) were greater in BG. CS manure accumulated more total VFA but less branched-chain VFA and aromatics than BG manure. When fed the HC diet (PD2), feed intake, ADG, and efficiency were improved ($P < 0.02$) in the BG vs. CS steers. Shedding of *E. coli* 0157 was associated with reduced DMI and ADG ($P < 0.10$). Over the total study, ADG was lower (0.97 vs. 1.03 kg), and DMI (8.50 vs. 7.62) and DMI/gain (8.09 vs. 7.17) were greater in BG than in CS fed steers, but neither CP intake/gain (0.86 vs. 0.84) nor ME intake/gain (22.2 vs. 21.1) differed. Carcass weight, backfat, and yield grade were greater ($P < 0.04$) for CS than for BG, but marbling, quality grade, and REA did not differ.

Key Words: Efficiency, Odor, *E. coli*

M170 Zinc increases differentiation of bovine intramuscular adipocytes by suppressing nitric oxide production and increasing PPAR γ 2 gene expression. Y. S. Oh¹, S. B. Smith², and C. B. Choi^{*1}, ¹Department of Animal Science, Yeungnam University, Gyeongsan, Korea, ²Department of Animal Science, Texas A & M University, College Station.

Zinc (Zn) is a micromineral that functions as a cofactor of many enzymes and is known, recently, to be involved in adipocyte metabolism, insulin resistance, and obesity. This study was conducted to determine the effects of Zn on the differentiation of bovine intramuscular adipocytes and on the production of nitric oxide (NO). Preadipocytes were isolated from intramuscular fat depots of 26-mo-old (adult) Korean (Hanwoo) steers and maintained in Dubelcco's Modified Eagles's Media (DMEM) containing 5% FBS. At confluence, the cells were treated with 10 μ g/mL insulin, 0.25 μ M dexamethasone, and 0.5 mM 1-methyl-3-isobutyl-xanthine to induce differentiation (accumulation of lipid droplets) for 48 h. Zinc was supplemented to the differentiation media in the form of either zinc chloride ($ZnCl_2$) or zinc sulfate ($ZnSO_4$) to attain the final concentrations of 0, 5, 25, 50 and 100 μ M. Glycerol-3-phosphate dehydrogenase (GPDH) activity, an index of adipocytes

differentiation, was significantly ($P < 0.05$) increased as the concentration of both forms of Zn in media increased, showing the highest activity (25.74 ng/min/mg protein) at 25 μM ZnSO_4 at 10 d after differentiation induction. On the other hand, supplementation of Zn into the media of bovine intramuscular adipocytes tended ($P > 0.05$) to decrease (from 15 μM to 10.5 μM) the production of NO. Peroxisome proliferator-activated receptor gamma 2 (PPAR γ 2) gene expression in bovine intramuscular adipocytes was increased at 10 d after differentiation induction by treatment with Zn. The current results indicate that Zn strongly promotes lipogenic activity in cultured bovine intramuscular adipocytes via suppression of NO production. These data further indicate that Zn may increase adipocyte differentiation by stimulating PPAR γ 2 gene expression.

Key Words: Zinc, Nitric oxide, PPAR γ 2

M171 Performance and residual feed intake differences between steers housed in individual or group pens. P. V. Paulino^{1,2}, F. C. Castro¹, A. C. Magnabosco^{1,3}, and R. D. Sainz¹, ¹University of California, Davis, ²Universidade Federal de Vicosa, Vicosa, MG Brasil, ³Universidade Catolica de Goias, Goiania, GO, Brasil.

Residual feed intake (RFI) is a useful measure of feed efficiency, but it requires individual records of dry matter intake (DMI) as well as body weight gain (ADG). There is some question as to the behavioral differences in animals fed individually vs. those in a group. Thirty Angus \times Hereford (AX) and 30 (Angus \times Hereford) \times Gelbvieh (GX) steers were fed a corn-based diet on an *ad libitum* basis for 84 days in individual ($n = 24$) or in group pens ($n = 36$, 6/pen). Feed intakes were recorded weekly and steers were weighed every 28 days. Average ADG was estimated by individual or pen as the slope of the regression of body wt and time. Residual feed intake was calculated as the difference between observed dry matter intake (DMI) and that predicted by regression: $E(\text{DMI}) = 0.0491 \text{ BW}^{0.75} + 2.07 \text{ ADG}$, $R^2 = 0.81$. DMI required for maintenance (DMI-M) was estimated as $\text{DMI} - 2.07 \text{ ADG}$, i.e., assuming a constant net efficiency for gain. DMI, ADG, RFI and DMI-M were analyzed using the GLM procedure of Minitab. Model effects were genotype, housing, and their interaction. DMI was higher ($P < 0.05$) for AX (8.17 kg/d) than GX (6.89 kg/d) steers and for animals housed in group (8.18 kg/d) compared to individual pens (6.87 kg/d). Consequently, AX steers gained more ($P < 0.05$) weight (1.37 kg/d) than GX steers (0.97 kg/d), and animals in individual pens gained more ($P < 0.05$) than those housed in groups (1.29 and 1.06 kg/d, respectively). RFI was higher ($P < 0.05$) in AX than GX steers. A significant ($P < 0.05$) genotype \times housing interaction was detected only for RFI, because the difference in RFI between genotypes was larger for the animals housed in group pens than for those housed individually. For both genotypes, animals housed in group pens had higher RFI values than animals housed individually. This could have been due to higher maintenance requirements, since DMI-M was higher in AX than GX steers (+8.5%, $P < 0.05$), and in group-fed than individually-fed steers (+10.1%, $P < 0.05$). Type of housing had significant effects on performance and feed efficiency in the feedlot and this effect was not uniform across genotypes. These results raise questions about the protocols for measuring RFI. Financial Support: CAPES

M172 Effect of supplemental chromium on tissue chromium concentrations in cattle. J. W. Spears^{*1}, K. E. Lloyd¹, M. E. Tiffany¹, and M. T. Socha², ¹North Carolina State University, Raleigh, ²Zinpro Corp, Eden Prairie, MD.

Supplemental chromium (Cr) has increased performance of dairy cows and immunity of stressed beef calves. Experiments were conducted to determine the effects of supplemental Cr on: 1) tissue Cr concentrations in finishing beef steers and dairy cows and 2) placental transfer of Cr in calves. In Exp. 1, liver and kidney samples were obtained at harvest from 36 Angus and Angus-cross steers (initial BW 332 kg) that received either: 1) control (no supplemental Cr), 2) 0.4 mg Cr/kg DM from Cr-nicotinic acid complex (CrNA), 3) 0.8 mg Cr/kg DM from CrNA or 4) 0.8 mg Cr/kg DM from Cr chloride. Experimental diets were fed for 146 d. Chromium concentrations were low in liver ($\bar{X} = 11.4 \mu\text{g/kg DM}$) and kidney ($\bar{X} = 20.6 \mu\text{g/kg DM}$), and were not affected by Cr supplementation. Twenty-four Angus and Angus-cross steers (initial BW 288 kg) were randomly assigned to treatments consisting of 0, 0.2, 0.4

or 0.8 mg supplemental Cr/kg DM from Cr-L-methionine (MiCroPlex[®]; CrMet) in Exp. 2. Steers were fed a growing diet for 125 d prior to harvest. Control steers had higher ($P < 0.05$) muscle Cr concentrations than Cr-supplemented steers. Liver ($\bar{X} = 41.3 \mu\text{g/kg DM}$) Cr concentrations were not affected by treatment. In Exp. 3, 18 Holstein cows, at approximately 35 d prepartum, were assigned to either 0 or 0.06 mg Cr/kg metabolic BW from CrMet daily via gelatin capsule. Calves were harvested at birth prior to nursing to determine placenta transfer of Cr. Cows continued to receive treatments until 30 d postpartum, at which time they were harvested. Calves born to Cr-supplemented dams had higher ($P < 0.01$) Cr concentrations at birth in semitendinosus muscle (98 vs 68 $\mu\text{g/kg}$) than controls. Supplemental Cr did not affect Cr concentrations in liver, heart or kidney of calves. Similarly, Cr concentrations in tissues of cows were not affected by supplemental Cr. These studies indicate that supplementing low concentrations of Cr to ruminant diets had minimum effects on tissue Cr concentrations.

Key Words: Chromium, Cattle

M173 Magnesium sulfate affects water consumption and drinking behavior of beef cattle. A. S. Grout¹, D. M. Veira^{*2}, D. M. Weary¹, M. A. G. von Keyserlingk¹, and D. Fraser¹, ¹Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada, ²Agriculture and Agri-Food Canada, Kelowna, British Columbia, Canada.

Sulfate (SO_4) salts of Na and Mg are common in rangeland water sources and pose problems for animal health, production and welfare. This experiment considered the effect of Na_2SO_4 and MgSO_4 on water consumption, fecal DM and drinking behavior of cattle. Sixteen yearling Hereford and Hereford Angus cattle (initial weight: 421 ± 24 kg) were watered twice daily with tapwater (16 ppm SO_4) or water containing Na_2SO_4 at concentrations of 2000 ppm SO_4 (low Na_2SO_4), MgSO_4 at 2000 ppm SO_4 (low MgSO_4) or MgSO_4 at 4000 ppm SO_4 (high MgSO_4) in 21-d treatment periods separated by 7-d interim periods when all animals were given tapwater. Treatments were applied in an incomplete Latin Square where each animal was exposed to 3 of the 4 treatments yielding 8 animals for each treatment comparison. Paired t-tests were used for analysis of average daily water consumption, fecal DM and refusals to drink. Variability in water consumption patterns was assessed by Wilcoxon paired sample tests. Daily water consumption was highest for tapwater (41.3 ± 6.6 L/d; $P < 0.01$) and lowest for high MgSO_4 -water (24.4 ± 9.0 L/d; $P < 0.01$). Response to high MgSO_4 -water was highly variable, with mean daily consumption ranging from 12.4 to 40.9 L. After 11 d on treatment, fecal DM was not different for any of the treatments, but was higher ($P < 0.03$) after 21 d of high MgSO_4 -water. Of the 42 drinking opportunities per treatment (twice per day \times 21 d), cattle refused to drink 10.1 ± 6.3 times on high MgSO_4 -water compared to 1.5 ± 1.9 times on tapwater ($P < 0.05$). Variation in intake was larger for high MgSO_4 -water (SD of 42 intakes = 11.7) than for tapwater (6.3) and low MgSO_4 -water (8.9) ($P < 0.05$). These findings indicate that high levels of MgSO_4 in water can lead to lower and more variable water consumption sufficient to increase fecal DM. Some cattle also forgo drinking when offered high MgSO_4 -water, further indicating that this water is unacceptable to cattle.

Key Words: Water Quality, Sulfate, Drinking Behavior

M174 Selenium concentration of colostrum and milk from beef cows receiving different forms of selenium supplementation. P. A. Davis^{*}, L. R. McDowell, R. Van Alstyne, E. Y. Matsuda-Fugisaki, and N. S. Wilkinson, Department of Animal Sciences, University of Florida, Gainesville.

Forty-three Angus cows (125-150d gestation) were stratified by age and randomly assigned to five groups receiving either no selenium (Se) supplementation (control), 5 ml sodium selenite via subcutaneous injection (Mu-Se, Burns Biotech Labs, Inc. Oakland, CA) every four mo, 9 ml barium selenate via subcutaneous injection (Deposel, Grampian Pharmaceuticals Ltd, Lancashire, UK), sodium selenite, or selenized yeast (Se-Plex, Alltech, Nicholasville, KY) via free-choice (FC) salt-based mineral mixtures (26 ppm Se) in a one year experiment to evaluate the effects of selenium supplementation methods on milk Se concentration. Animals on each treatment grazed bahiagrass pastures and received bahiagrass hay (< 0.02 ppm Se DM basis) during winter. Colostrum and

subsequent milk was collected at parturition, 30, 90, and 180 d postpartum. Samples were analyzed for selenium concentration using a fluorometric method. Colostrum Se concentration did not differ ($P < 0.05$) among control, Deposel, Mu-Se and FC sodium selenite treatments and were below critical level (0.05 ppm) at 0.038, 0.035, 0.035, and 0.038 ppm, respectively. Sel-Plex was higher ($P < 0.05$) than control and all other treatments at 0.071 ppm. At 30 d postpartum, Sel-Plex was higher ($P < 0.05$) than control and both injectable products. FC sodium selenite was higher ($P < 0.05$) than both Mu-Se and Deposel and tended to be higher than control ($P = 0.07$). At 90 d postpartum, milk Se concentrations did not differ among treatments with Sel-Plex tending ($P = 0.07$) to be higher than Mu-Se. Milk Se concentrations did not differ at 180 d among control, Deposel, Mu-Se, and FC sodium selenite, however, Sel-Plex was higher ($P < 0.05$) than all other treatments at 0.042 ppm. At no time during the study did either injectable Se source produce milk Se concentrations higher than control or above the critical level. FC sodium selenite outperformed both injectable products only at 30 d. Overall, milk Se concentrations from cows receiving Sel-Plex were higher than all other treatments.

Key Words: Beef Cattle, Colostrum, Selenium Supplementation

M175 Effect of high-level copper supplementation on copper status and performance of beef heifers consuming molasses-based supplements. J. D. Arthington* and F. M. Pate, *University of Florida, Range Cattle Research and Education Center, Ona, FL.*

The objective of this study was to examine the effects of high-levels of Cu supplementation on the performance and Cu status of growing steers consuming molasses-based supplements. Twenty-four crossbred heifers were stratified by BW and randomly assigned to individual pens. Four treatments, consisting of a complete mineral supplement fortified with 0, 15, 60, and 120 ppm supplemental Cu (Cu sulfate), were randomly assigned to pens (6 pens/treatment). Treatments were offered 3 times weekly in molasses-cottonseed meal slurry (1.5 kg of TDN and 0.3 kg of CP/hd). All heifers were offered free-choice access to ground star-grass hay. Individual BW, jugular blood, and liver biopsy samples were collected d 0, 42, and 84. Forage DM refusal was determined daily. Diet DM digestibility was estimated over a 21 d period (beginning on d 42) by the use of a sustained release chromic oxide bolus (Captec, New Zealand). Heifers consuming the highest rate of supplemental Cu (120 mg/kg) tended ($P = 0.13$) to have a lesser ADG compared to heifers supplemented with 15 mg/kg of Cu (0.18 vs. 0.05 kg/d; SEM = 0.06). There was no significant sampling day x treatment interaction for liver Cu accumulation, however average liver Cu concentrations among all treatments decreased ($P < 0.05$). Therefore, data were also analyzed combining treatments that provided 60 and 120 mg/kg of supplemental Cu into a single treatment (High Cu). Heifers supplemented with 15 mg/kg Cu had a greater ($P < 0.05$) increase in liver Cu concentration compared to 0 ppm and High-Cu treatments (average change = -200, 5, -109 ppm DM for Control, 15 ppm, and High-Cu treatments, respectively; SEM = 46.8). Forage DMI was lower ($P = 0.07$) for heifers receiving no supplemental Cu compared to all other treatments (6.6 vs. 5.8 kg/d; SEM = 0.37). Apparent forage digestibility was not affected ($P > 0.05$) by Cu treatment. These data suggest that high rates of Cu supplementation (Cu sulfate; > 60 ppm total Cu) results in a decline in liver Cu accumulation into the liver of beef heifers consuming molasses supplements.

Key Words: Cattle, Copper, Molasses

M176 Supplemental phosphorus removal for finishing yearling Holstein steers. A. M. Brokman*¹, J. W. Lehmkuhler¹, and D. J. Undersander¹, ¹*University of Wisconsin-Madison, Madison*, ²*University of Wisconsin, Madison*.

Two experiments were performed to determine responses of removing supplemental phosphorus from the finishing ration offered to yearling Holstein steers. In Experiment 1, 96 Holstein steers (419 kg) were blocked into four weight groups and assigned to eight pens. Steers were fed a diet consisting of approximately 74% corn, 18% corn silage and 8% supplement on a DM basis. Dietary treatments, supplemental phosphorus (DC) or no supplemental phosphorus (NDC), were randomly assigned to pens within each block. The phosphorus (dicalcium phosphate) was pre-incorporated into the protein/mineral pellet at a level to

achieve 0.3% in the complete ration. Steers were implanted with an estrogenic product on d 0. Steers in heavier weight blocks were harvested after 82 d to avoid heavy carcass weight discounts. The remaining steers were harvested on d 125. Carcass data were collected following a 24-hr chill. No differences ($P > 0.05$) were detected in carcass characteristics. NDC tended to be heavier at the end of the trial ($P = 0.07$). During period three NDC resulted in heavier weights ($P < 0.05$) and a trend for better gain efficiency ($P = 0.09$). The overall gain efficiency for NDC was better than DC ($P < 0.05$). Experiment 2 consisted of 78 Holstein steers (491 kg) blocked into two weight groups. Steers were fed a TMR consisting of approximately 81% corn, 8% supplement, 6% corn silage, and 5% alfalfa haylage on a DM basis. Steers were implanted as in Experiment 1. Steers were harvested on d 84 and 112 d on test. Carcass data were collected after a 48-hr chill. NDC carcasses tended to have a higher trim weight ($P = 0.09$) and a lower percent trimmed than DC carcasses ($P = 0.05$). No differences ($P > 0.05$) were detected in overall ADG (DC=1.63 kg vs. NDC=1.63 kg), weights, overall dry matter intake or gain efficiency (DC=0.15 vs. NDC=0.15). A trend existed for DC to have higher DMI ($P = 0.10$) during period three in comparison to NDC. Removing supplemental phosphorus from the feedlot diet did not produce adverse effects on steer performance or carcass characteristics for yearling Holstein steers.

Key Words: Beef, Holstein, Feedlot

M177 Evaluation of machine milking and weigh-suckle-weigh technique for quantification of milk production at six or twelve hour udder-fill intervals. W. J. Sexten*, D. B. Faulkner, and J. M. Dahlquist, *University of Illinois, Urbana.*

A randomized complete block design with a 2 x 2 factorial arrangement was utilized to evaluate the effects of collection method and udder-fill interval on milk production estimates collected during middle (Exp. 1) and peak lactation (Exp. 2). Each cow represented a block to which all four of the possible treatment combinations were applied. Factors tested were milk collection method, using a portable milk machine (MM) or weigh-suckle-weigh (WSW), and udder-fill intervals of 6 h (6) or 12 h (12). Twenty-four Simmental cows were utilized in Exp. 1 ($n = 96$) that were 119.4 ± 2.8 d postpartum. The 24 Simmental cows used in Exp. 2 ($n = 96$) were 64.5 ± 0.05 d postpartum. A collection method by udder-fill interval interaction was observed ($P = 0.01$) in Exp. 1 and 2. Milk machine estimates did not differ ($P = 0.11$) due to udder-fill interval, while WSW estimates were lower ($P < 0.05$) at 6 h than 12 h in both Exp. Estimates taken using a 6 h udder-fill interval were lower ($P < 0.001$) for WSW than MM in Exp. 1 and 2. In Exp. 1, 12 h estimates did not differ ($P = 0.81$) due to collection method however in Exp. 2 estimates taken using MM-12 tended higher ($P < 0.10$) than WSW-12. A positive correlation ($P = 0.001$) was observed between WSW estimates at 6 and 12 h in Exp 1 (0.77) and Exp. 2 (0.62). Milk machine estimates at 6 and 12-h were positively correlated ($P < 0.01$) in Exp. 1 (0.62) and Exp. 2 (0.62). Weigh-suckle-weigh and MM estimates were not correlated ($P > 0.05$) at any udder fill interval. Regression of WSW-12 on WSW-6, MM-12 and MM-6 confirmed correlation results, as WSW-6 in Exp. 1 was the only estimate predicted by WSW-12. The quadratic effect of WSW-12 did not influence ($P > 0.15$) predictions indicating calf capacity for milk consumption did not influence milk production estimates. These experiments suggest milk production estimates taken using different collection methods are not comparable.

Key Words: Milk Production, Machine Milking, Weigh-Suckle-Weigh

M178 Effect of esterase enzyme treatment on the in situ rumen degradability and soluble carbohydrate content of tropical grasses. N. A. Krueger*, A. T. Adesogan, D. B. Dean, and W. K. Krueger*, *University of Florida, Gainesville.*

Previous work showed that application of an esterase enzyme preparation (Depol 740, Biocatalyst, U.K.) increased the digestibility in vitro of tropical grasses. This study examined the effect of the same enzyme preparation on the water soluble carbohydrate (WSC) fraction and the in situ degradability of three tropical grass hays. The enzyme was applied at 0, 0.5, 1, 2, and 3 g/100g DM on hay produced from 12-wk regrowths of common bahiagrass (B), Coastal bermudagrass (C), and Tifton 85 bermudagrass (T) 24 h before ruminal incubation. Duplicate samples of each forage were incubated in each of two cows for 0, 3, 6,

9, 12, 24, 48, 72, 96, and 120 h. The cows diet consisted of bermudagrass hay supplemented with 0.4 kg/d of soybean meal. Treatments were arranged in a 2 x 3 x 5 factorial design. The McDonald model, $P = A + B(1 - \exp^{-c(t-L)})$, was fitted to the in situ data. There was a cubic increase ($P = 0.04$) in the WSC fraction as enzyme application increased. Increasing enzyme application rate also produced quartic increases in the wash fraction ($P = 0.0036$), degradation rate ($P = 0.0047$), effective degradability and total degradability ($P = 0.0053$; 643, 651, 622, 663, 661, and 648 g/kg DM) of the hays. The potentially degradable fraction (B) also tended to increase ($P = 0.071$) with increasing enzyme rate whereas the lag phase decreased cubically ($P = 0.0106$). The highest degradation rate (0.03 per hour) occurred at the 1% enzyme application rate but the shortest lag phase occurred at the 3% rate. In conclusion, application of the esterase enzyme enhanced the release of WSC from the hays and increased the rate and extent of degradation of the hays.

Key Words: Tropical Grass, Esterase, Degradation

M179 Effect of exogenous amylase and corn type on performance and carcass characteristics of finishing beef heifers. S. M. Speight^{*1}, K. C. Hanson¹, J. Tricarico², K. R. McLeod¹, and D. L. Harmon, ¹University of Kentucky, Lexington, ²Alltech Biotechnology, Inc., Nicholasville, KY.

Two experiments were conducted to evaluate the efficacy of feeding a fungal amylase preparation on the performance and metabolism of beef cattle fed high grain diets. Experiment 1 used 12 rumen cannulated steers divided into one of three dietary treatments: 1) control, no enzyme; 2) 5 g/d amylase; or 3) 10 g/d amylase enzyme preparation. The diet consisted of 50% concentrate (corn-based), 50% corn silage. There was no effect of exogenous amylase on daily dry matter intake, VFA proportions, total concentrations, acetate:propionate or ruminal pH. In situ starch disappearance was also unaffected by treatment. In Experiment 2, 96 crossbred heifers were fed finishing diets until slaughter to evaluate the effects of corn type and inclusion of an exogenous amylase preparation on animal performance and carcass characteristics. Animals were assigned randomly to a 2 x 3 factorial arrangement of treatments in a completely randomized design. Factors were corn type (dry vs. high moisture) and amount of exogenous amylase preparation (0, 7.5, or 15 g amylase/(hd·d)). There were no differences in corn type throughout the study. During the first 28 d, average daily gain increased linearly ($P < 0.05$) with amylase supplementation. However, this increase in gain was not observed during the remainder of the trial. The increased average daily gain during the first 28 d was largely the result of increased intake (quadratic $P < 0.05$), as feed efficiency was not affected. The greatest longissimus area ($P < 0.05$) and lowest ($P < 0.05$) yield grades, as well as a tendency ($P < 0.10$) for lower back fat, were observed in heifers receiving amylase at 7.5 g/(hd·d). These studies suggest that the amylase preparation used may be beneficial for starting calves on feed but we saw no effects on fermentation or starch degradation that would suggest long term benefits with addition to finishing diets.

Key Words: Amylase, Supplementation, Cattle

M180 Effect of an exogenous fibrolytic enzyme on intake and ruminal variables in lambs fed Guinea grass (*Panicum maximum* var. Mombasa) hay. J. H. Avellaneda-Cevallos¹, S. S. González^{*2}, J. M. Pinos-Rodríguez³, A. Hernández², R. Bárcena-Gama², M. Cobos², and D. Hernández-Sánchez², ¹Universidad Técnica Estatal de Quevedo UTEQ, Quevedo, Ecuador, ²Colegio de Postgraduados Montecillo, Estado de México, México, ³Universidad Autónoma de San Luis Potosí UASLP, Estado de San Luis Potosí, México.

This study was performed to evaluate the effect of an exogenous fibrolytic enzyme (enzyme; Fibrozyme) on intake, digestion and ruminal variables in lambs fed Guinea grass hay. Four Suffolk lambs fitted with permanent ruminal and duodenal cannulas were fed only Guinea hay cut 35 d (11.4% CP) or 90 d (6.4% CP) after regrowth. Experimental design was a repeated Latin Square (4x4) with a factorial arrangement of treatments (2x2; enzyme, 0 and 3 g; Guinea hay 35 and 90 d). Guinea 90 d increased ($P < 0.05$) DM flow to duodenum and feces. Lambs fed Guinea 35 d showed an increased digestion of DM ($P < 0.05$) and OM ($P < 0.01$) in the rumen and intestine; higher ($P < 0.01$) intake, ruminal and total CP degradation, and retained N; and increased ($P < 0.01$) rate of passage. NDF intake ($P < 0.09$) and flow to duodenum and feces ($P < 0.01$) was higher, but ruminal and total digestion was lower

($P < 0.01$) for lambs fed Guinea 90 d. ADF flow to duodenum and feces was increased ($P < 0.01$) by Guinea 90 d; whereas ruminal, intestinal and total ADF digestion was increased ($P < 0.01$) by Guinea 35 d. ADF flow to duodenum was decreased ($P < 0.01$), but ADF ruminal degradation ($P < 0.01$) and hemicellulose intestinal digestion ($P < 0.08$) were increased, by enzyme addition for both hays. Lambs fed Guinea 35 d showed higher ($P < 0.01$) intake, ruminal and total degradation of hemicellulose, as well as increased ($P < 0.01$) ammonia-N (0, 3, 6, 9 and 12 h). pH (0, 3, 6, 9 and 12 h) was higher ($P < 0.01$) for lambs fed Guinea 35 d. According to these results, there were differences between Guinea hay 35 and 90 d for most of the variables, whereas the exogenous fibrolytic enzyme improved digestion of ADF and hemicellulose.

Key Words: Intake and Digestion, Exogenous Fibrolytic Enzyme, Tropical Grass

M181 Evaluation of modified sodium silicate as a grain conditioner for corn and grain sorghum. C. R. Richardson^{*1}, K. F. Wilson¹, T. C. Bramble¹, J. H. Mikus¹, and I. Cisneros², ¹Texas Tech University, Lubbock, ²Concorde Technologies, Odessa, TX.

Laboratory experiments at Texas Tech Univ. and two trials at a commercial feedyard feedmill were conducted to determine the effects of a modified sodium silicate product (RumiSil) on conditioning corn and grain sorghum. RumiSil has a pH of 11.2, freezing point of 0° C, specific gravity of 1.05, and low corrosive properties. Time required for the uptake of 6% added moisture by corn and grain sorghum was determined in roll jars and recorded with a stopwatch. Treatments were 0, 0.5, 1.0, 1.5, and 2.0 ml of RumiSil diluted with water to make 100 ml of each solution and were added to increase moisture content by 6 percentage points. RumiSil decreased ($P < 0.05$) time to absorb the 6% added moisture at levels of 0.5 and 1.0, with a further reduction ($P < 0.05$) at levels of 1.5 and 2.0 for both grains. In vitro DMD was increased ($P < 0.05$) for corn at the lowest level of RumiSil, while grain sorghum was improved ($P < 0.05$) at the two highest levels. Two trials were conducted to compare the 1.5 level of RumiSil to water alone in flaking corn at four flake weights. In trial one, the average starch availability was higher across flake densities (water 39.5%, SD 8.35 vs. RumiSil 52.0%, SD 8.21). In trial two, starch availability was 42.3 (SD 7.46) and 47.8 (SD 7.18) for water and RumiSil, respectively.

Key Words: Steam Flaking, Grain Processing, Grain Conditioner

M182 Effects of replacing rice straw with wormwood (*Artemisia Montana* Pampan) silage in the diets of Korean Hanwoo steers on performance, carcass characteristics and muscle fatty acid profile. S. C. Kim^{*1}, J. H. Kim^{*2}, J. H. Shin², A. T. Adesogan¹, and Y. D. Ko², ¹Department of Animal Science, University of Florida, Gainesville, ²Division of Applied Life Science, Gyeongsang National University, Jinju, Korea.

This study was conducted to examine the performance, carcass characteristics and muscle fatty acid profile of Hanwoo steers fed diets containing four levels of wormwood silage. Twenty Hanwoo steers (326 ± 23kg) with similar ($P > 0.05$) initial body weights across treatments were fed at 3% of body weight on a DM basis for 12 months. The steers were individually fed a basal diet of rice straw (30%) and supplementary concentrates (70%; corn grain, 36.5%; wheat grain, 15.0%; coconut meal, 11%; wheat flour, 5.0%; corn gluten, 3%; palm meal, 6%). The steers were allotted to one of four dietary treatments, which were designed to progressively substitute rice straw with 0, 5, 10 and 15% of wormwood silage in the basal diet. Feed intake was calculated daily and body weight was measured monthly. At the end of the trial, the steers were slaughtered and graded by trained carcass evaluators, using the Korean meat-grading scheme. The fatty acid profile of meat samples (300g) obtained from the loin and top round muscles was analyzed by gas chromatography. Final body weight, average daily gain and feed conversion efficiency were improved ($P < 0.05$) by substituting 5, 10 and 15% of straw with wormwood silage, but there were no differences in performance between the levels of wormwood silage substitution. Compared to steers in the control group, steers fed diets containing wormwood silage had greater ($P < 0.05$) carcass weight, carcass quality, and loin-eye area and less ($P < 0.05$) backfat thickness. Steers fed wormwood silage also had higher ($P < 0.05$) muscle CLA content and higher ($P < 0.05$) omega 6:omega 3 fatty acid ratios than steers in the control group. It is concluded that substituting rice straw with wormwood silage

improved the performance, carcass characteristics and muscle fatty acid profile of Hanwoo steers.

Key Words: Wormwood Silage, Hanwoo Steer, Conjugated Linoleic Acid

M183 Rumen digestibility of receiving rations for feedlot steers containing wheat midds and soybean hulls. P. M. Walker^{*1}, K. E. Earing¹, L. A. Mathews¹, and J. E. Ringler², ¹Illinois State University, Normal, ²University of Kentucky, Lexington.

Six Simmental-Angus, ruminally fistulated steers were used in a two period crossover design in situ trial to evaluate the rumen digestibility of a wheat mid-*soybean hull* ration (WS) and a shelled corn-commercial protein supplement ration (SC). Steers were randomly assigned to treatment rations at the beginning of the first experiment period (WS containing 74.1 % wheat midds and soybean hulls, and SC containing 75% shelled corn and 25% of 33% CP commercial protein supplement). Steers were allowed ad libitum access to water and grass hay. Treatment rations were fed once daily at 1600 h at .95% BW (wet wt. basis). Each experiment period was 17d with a 14-d adaptation period. On d 15, 3 Dacron bags containing 10g:bag were placed into the rumen of each steer at 0, 12, 24, 36, 48, 60 and 66h. All bags were removed at 72 h. Each time Dacron bags were placed into the rumen, rumen fluid was collected and pH analyzed. Feed samples were analyzed for OM, N, NDF, ADF, AIA and ash. Crude protein and HC were determined by calculation) N% $6.25 = CP$ and $NDF - ADF = HC$). WS contained 85.56% OM, 2.50% N, 15.63% CP, 68.34% NDF, 42.53% HC, 25.81% ADF, 19.99% cellulose, 0.14% AIA and 14.46% ash. The SC contained 95.16% OM, 2.46% N, 15.38% CP, 44.43% NDF, 38.72% HC, 5.81% ADF, 3.27% cellulose, 0.05% AIA and 4.84% ash. Rumen pH was similar between WS and SC ranging from 6.5 to 6.7. Rumen disappearance for OM and CP was not different ($P > 0.05$) between WS and SC at each time interval through 36 h of digestion comparing $59.83 \pm 12.90\%$ and $61.03 \pm 30.55\%$ and $72.18 \pm 21.17\%$ and $72.33 \pm 6.06\%$ at 36 h, respectively. Rumen disappearance for ADF and cellulose was not different ($P > 0.05$) between WS and SC by 72 h of digestion comparing $64.10 \pm 12.32\%$ and $63.86 \pm 22.27\%$ and $65.53 \pm 28.43\%$ and $63.54 \pm 27.17\%$, respectively. Rumen disappearance for OM, CP and NDF was greater ($P < 0.05$) by 72 h of digestion for SC than WS. The rumen digestibility of higher fiber rations containing wheat midds and soybean hulls appears similar to a ration lower in NDF and ADF.

Key Words: Wheat Midds, Soybean Hulls, Rumen Digestibility

M184 Effect of vitamin E and method of administration on performance and meat color of beef cattle. I. García^{*1}, R. Alderete¹, A. Alarcón¹, C. Rodríguez¹, J. Ortega¹, J. Pedraza², and O. Medina², ¹Facultad de Zootecnia, Universidad Autónoma de Chihuahua Periférico Fco. R. Almada km. 1.5 C.P. 31031. Chihuahua, Chih. México, ²Facultad de Química, Universidad Nacional Autónoma de México Cd. Universitaria, Del. Coyoacan, C.P. 04510. Distrito Federal, México.

The objective of the present study was to evaluate the effect of vitamin E (VitE) and the method of administration on performance of beef cattle and meat color. VitE was applied to thirty four crossed Charolais and Brangus heifers either by subcutaneous administration (SUB, 167 IU/a/d applied at 1, 30, 60 and 90 d of trial, n=16) or in finishing diet (DIE, 500 IU/a/d for 110 d, n=18); and a third group received no VitE and was taken as the control (CON, n=16). Animals were fed in pens and pen was the experimental unit. Performance parameters (body weight, BW; average daily gain, ADG; hot carcass weight, HCW; carcass yield, CY; and rib eye area, REA) as well as quality characteristics (color, L*, a*, b*; electrical conductivity, EC; water holding capacity, WHC) of packed meat were evaluated. A subsampling was done within experimental group (SUB n=9; DIE n=11 and CON n=10) to evaluate the effect of vitE on *L. dorsi* color during storage (4 C) for up to 28 d *postmortem* (3, 7, 14, 21 and 28 d). Thirty more *L. dorsi* steaks (one/subsampling animal) were aerobically packed (polyvinyl chloride PVC) and stored (4°C) for daily evaluation during 8 d. Variables evaluated during time (BW, ADG, color and WHC) were analyzed with PROC MIXED, considering the animal effect as random. HCW, CY and REA data was analyzed with PROC GLM of SAS. VitE administration method did not showed advantages ($P > 0.05$) on performance parameters. No difference ($P > 0.05$) in color and WHC of vacuum packaged steaks was observed among treatments. Likewise L* and b* values of PVC packaged steaks did not change ($P > 0.05$) among

treatments. However redness value (a*) of CON showed a linear tendency ($P < 0.05$) during storage, and the tendency for DIE and SUB was quadratic ($P < 0.05$). DIE and SUB had greater value ($P < 0.05$) than CON after day 4 (12.09 ± 0.43 and 11.43 ± 0.47 vs 10.28 ± 0.45) and DIE had greater value ($P < 0.05$) than SUB at days 7 and 8. VitE concentration ($\mu\text{g}/\text{mg}$ muscle) was higher for DIE (3.3 ± 0.4) than SUB (2.2 ± 0.5) and CON (1.3 ± 0.4). It is concluded that VitE applied subcutaneously or in feed improves color stability of aerobic packaged beef steaks.

Key Words: Vitamin E, Beef, Color Meat

M185 Effect of monensin on milk production, composition and body condition score of Murrah buffalo cows in early lactation. A. M. Jorge^{*1} and C. Andrighetto², ¹UNESP-FMVZ-DPEA-Botucatu, ²UNESP-FMVZ-PGZOO-Botucatu.

This experiment was carried out at the Buffaloes Production Area of the Unesp FMVZ Botucatu/SP/Brazil. Twenty four Murrah buffalo cows, were submitted to two treatments T1 (0 mg of monensin/buffalo cow/day) T2 (300mg of monensin/buffalo cow/day) evaluated on 150 first days of lactation. The total ration was composed by sorghum silage, elephant grass, and ration. The effect of monensin on milk production, milk composition and body condition score of buffaloes cows in early lactation. The milk control was done weekly, milk was collected for analysis of protein, fat and total solids were measured, the buffaloes cows was weighed and given body condition score. The design was completely randomised. There no statistical differences ($P > .05$) between treatments for daily milk production, total milk production, corrected for 270 days, milk production on peak of lactation, mozzarella production, percentage of protein, total solids, protein:fat ratio, weight and body condition score. Monensin influenced positively ($P < .05$) daily protein (T1 = 147.10 g, T2 = 162.07 g) and fat production, (T1 = 226.90g, T2 = 259.62g) and fat percentage (T1 = 5.41%, T2 = 5.84%).

Key Words: Ionophor, Lactation, Water Buffalo

M186 The effect of Acid Buf in dairy cow diets on production response and rumen parameters. C. W. Cruywagen^{*1}, J. P. Swieggers², S. J. Taylor³, and E. Coetzee⁴, ¹Department of Animal Sciences, University of Stellenbosch, Stellenbosch, South Africa, ²Bokomo Feeds, Malmesbury, South Africa, ³Celtic Sea Minerals, Carrigaline, Co. Cork, Ireland, ⁴Formufeed, Villiersdorp, South Africa.

A high concentrate TMR, formulated to be potentially acidotic, was used to construct five dietary treatments in which Acid Buf, the skeletal remains of the seaweed *Lithothamnium calcareum*, was included at increasing levels of 0.125, 0.3, 0.6, 0.9 and 1.2% of dietary DM. The response to Acid Buf included at the 0.3, 0.6 and 0.9% levels was measured using three groups of nine Holstein cows fed individually via Calan gates from calving to 70 DIM. Milk production was monitored daily and milk samples were taken weekly and analyzed for protein, fat and lactose. Cows were weighed and condition scored at 0, 28, 56 and 70 DIM. The response to Acid Buf at levels lower (0.125%) and higher (1.2%) than the main treatment levels was similarly measured but using group fed cows. Milk yield was adjusted by covariate analysis against initial performance. Adjusted average milk yield was 44.6, 41.4 and 39.3 liters/cow/day ($P < 0.05$) and efficiency of feed into milk was 1.83, 1.75 and 1.67 kg milk/kg feed for treatments containing 0.3, 0.6 and 0.9% Acid Buf, respectively. Adjusted milk output increased significantly ($P < 0.05$) as the Acid Buf inclusion was increased from 0.125 to 0.3% of DM but there was no significant effect on milk yield by increasing the level of Acid Buf from 0.9 to 1.2%. The five dietary treatments were also fed individually to five ruminally cannulated lactating Holstein cows in a latin square arrangement. Every cow received each diet for a period of 22 days prior to a collection period of 8 days. Rumen pH was monitored continuously every 10 minutes for 4 days using a portable data logging system and in-dwelling electrodes. Samples of rumen liquor were collected on two consecutive days, 2 hours before the morning feeding and again at 2, 6 and 10 hours after this feed allocation. Samples were analyzed for VFA and $\text{NH}_3\text{-N}$. The impact of feeding on rumen pH was clearly visible and increasing the dose of Acid Buf in the diet increased rumen pH throughout the period of measurement. However, the optimum dose of Acid Buf to optimize milk output and the efficiency of feed into milk was 0.3% of dietary DM or 80g/day.

Key Words: Acid Buf, Milk Production, Rumen Parameters

M187 Effect of malate supplementation on rumen fermentation and milk production in postpartum cows. M. Devant¹ and A. Bach^{*1,2}, ¹IRTA-Unitat de Remugants, Barcelona, Spain, ²ICREA, Barcelona, Spain.

A total of 38 Holstein cows were assigned to either Control or MALATE groups between 21 and 28 d prior to calving date to evaluate the effects of pre- and post-partum malate supplementation on rumen fermentation and milk production. Control cows (n=18) received a concentrate of 40% extruded corn, 30% soybean meal, 7.5% carob bean, 6.5% barley, 5% propylenglycol, 5% bypass fat, 3.45% sugar cane, 2.5% yeast, and, 0.05% binder. MALATE cows (n=20) received the same concentrate but yeast, and propylenglycol, and bypass fat were partially replaced by 4% of Rumalato (Norel& Nature, Spain) to provide 84 g/d of malate. Before calving, all cows were fed a TMR ad libitum and 1 kg/d of either MALATE or Control concentrate at a feeding station. After calving, cows were fed a TMR ad libitum and 1 to 3 kg/d of concentrate was gradually increased by 300 g/d. Milk production was recorded daily and milk composition monthly during the first 90 lactation days. Rumenocentesis was conducted 4 times for each cow at 7, 35, 63, and 90 d postpartum 4 hours after TMR delivery to determine rumen pH. A tendency (P = 0.096) in milk yield x week interaction was found. MALATE cows produced more milk at the 4th and 5th weeks postpartum than Control cows (37.1 and 38.4 kg/d vs 33.4 and 35.7 kg/d, respectively). Malate supplementation did not affect milk fat and protein contents (3.87 vs 3.67% and 3.15 vs 3.16%; Control vs MALATE, respectively). Mean rumen pH was not affected by treatment (P > 0.05; 6.19 vs 6.28, Control vs MALATE, respectively). Ruminal pH at 7d postpartum was lower (P = 0.08) than at 36, 63, 91 d postpartum (6.11, 6.19, 6.23, and 6.41, respectively). Mean concentrate intake was greater in MALATE than in Control cows (P < 0.05; 2.23 vs 1.96 kg/d, respectively). Although cows supplemented with malate consumed more concentrate, rumen pH did not decrease, indicating that malate may effectively prevent rumen acidosis. Also, supplementation of malate may result in increased milk production during peak of lactation.

Key Words: Malate, Milk, Rumen

M188 The effect of an inoculant containing *Lactobacillus buchneri* 40788 on fermentation and aerobic stability of corn silage at two packing densities. M. Antoniali¹, O. C. M. Queiroz², R. J. Schmidt^{*3}, and L. Kung, Jr³, ¹Universidade Estadual Paulista Jaboticabal, SP Brazil, ²Universidade de Sao Paulo Piracicaba, SP, Brazil, ³University of Delaware, Newark.

Whole-plant corn was harvested at 1/3 milcline (38% DM) and packed in 20-L laboratory silos to investigate the effects of inoculation and packing density on silage fermentation. Treatments were: 1) untreated forage, tightly packed at 241 kg DM/m³ (15 lb/ft³); 2) forage inoculated with *L. buchneri* 40788 (400,000 cfu/g of forage) and *Pediococcus pentosaceus* (100,000 cfu/g) (Lallemand Animal Nutrition, Milwaukee, WI), tightly packed; 3) untreated forage, loosely packed at 194 kg DM/m³ (12 lb/ft³); and 4) inoculated and loosely packed. The experimental design was a 2 x 2 factorial arrangement of treatments. The effects of packing density, inoculation, and their interactions were tested. The results are detailed in the table below. After 60 d of ensiling, treatments had no effects on silage pH. Silages that were loosely packed had more acetic acid (P < 0.05) and unexplainably more lactic acid bacteria (LAB) (P < 0.05) than did silages that were tightly packed. Inoculation, regardless of packing density, resulted in silages with higher concentrations of acetic acid (P < 0.05) and lower lactic:acetic acid ratios (P < 0.05), lower concentrations of water soluble carbohydrates (WSC) (P < 0.05), and fewer yeasts and molds (P < 0.05). The results of this study show that application of an inoculant containing *L. buchneri* 40788 is effective at improving the aerobic stability of corn silage under a variety of packing densities.

Item	Loose pack		Tight pack		S.E.	Effects ³

M189 Effect of feeding *Aspergillus oryzae* fermentation culture to lactating dairy cows on milk yield, composition, and rumen fermentation. T. Sato*, T. Takano, and K. Murata, ZENNOH National Federation of Agricultural Co-operative Associations 1708-2 Tsukuriya Tsukuba Ibaraki, Japan.

The objective of this study was to evaluate the effect of feeding *Aspergillus oryzae* fermentation culture (AO) on the performance of lactating dairy cows and rumen fermentation. Twelve multiparous Holstein cows between 40-130 days in milk and three ruminally cannulated lactating cows were randomly assigned to one of three treatments: 1) Control, 2) Control + 25g/head/d (AO1), and 3) Control + 50g/head/d (AO2). Cows were housed in a tie-stall barn for the duration of the experiment and individually fed for ad libitum intake twice a day at 0800 and 1700 h. The experiment followed a 33 Latin square design with three 21-day periods. Samples and data were collected during the final 7 days of each period. The TMR (DM basis) were 46:54 forage:concentrate for all treatments. The main dietary ingredients were alfalfa-hay, timothy-hay, ground corn, whole cottonseed, beet pulp, soybean meal and Japanese commercial supplement. The control TMR was balanced using CPM Dairy (version 3.0.4a). The respective levels of AO product were mixed in the TMR and purchased from Nichimo Co., Ltd. (Tokyo, Japan). Feeding AO to lactating dairy cows improved milk production and lactose % in milk. Milk production (kg/d) was higher (P<0.05) in AO1 and AO2 than control (33.4, 34.1 and 32.2). Lactose (%) and % solid not fat (SNF) in AO2 was higher (P<0.05) than control (4.6, 4.55; and 8.86, 8.74; respectively). Ruminal pH and volatile fatty acids of rumen fluid (mM) from 2 to 4 h after feeding were higher for AO1 and AO2 than control (6.3, 6.4, 6.0; and 120.9, 121.4, 105.9). There were no treatment differences in dry matter intake, milk fat % and yield, milk crude protein %, milk urea nitrogen, and somatic cell counts. In conclusion, feeding *Aspergillus oryzae* fermentation culture to dairy cows altered rumen parameters at 2 and 4 h postfeeding which may explain the increase in milk yield realized from feeding AO at both 25g and 50g/head/d.

Key Words: Dairy Cow, *Aspergillus oryzae*, Rumen Fermentation

M190 Effect of live yeast *Saccharomyces cerevisiae* on milk production, quality and health status of Saanen dairy goats. R. Paratte^{*1}, A. Stella¹, G. Cigalino¹, G. Soncini¹, L. Valnegri¹, E. Chevaux², G. Savoini¹, and V. Dell'Orto¹, ¹Dept. of Vet. Sci. Tech. Food Safety, University of Milan via Celoria, 10 Milano-Italy, ²Lallemand SA rue de Brequetiers, 19 Blagnac Cedex-France.

The effect of a live yeast supplement in dairy goats has been examined in a limited number of studies. While the yeast culture does contain some viable cell, the yeast live cell supplement contain higher numbers of 100% active *Saccharomyces cerevisiae* (SC). 57 Saanen dairy goats were utilized to investigate the effects of the supplementation of SC during the first half of lactation. Goats were assigned according to parity and milk production during the first three weeks of lactation in two groups. All goats were fed a total mixed ration (TMR) containing 40% commercial concentrate, 28% triticale silage, 22% hay, 10% dried beet pulp. Treatments lasted for 15 weeks starting from week 3 of lactation and were: control (C)-TMR; (SC)-TMR mixed with 0.2g of SC (4x10⁹ CFU/g, Levucell SC20). DMI, BCS and milk yield were recorded for 126d postpartum with milk samples analysed weekly for fat, protein, lactose, urea and SCC. Blood samples were analysed monthly for urea, glucose, BHBA, NEFA, GOT/AST and GGT. In order to monitor intestinal microflora, faeces were monthly analysed for total bacterial load, enterobacteria,

E. coli, coliforms, lactic bacteria, clostrides, moulds, yeasts. BCS, DMI and milk yield (C: 2.23Kg±0.04; SC: 2.37Kg±0.02) were positive affected by the treatment (P<0.05). Milk fat content was lower and milk urea content was higher in treated goats (P<0.05). Plasma metabolites were similar among treatments. NEFA was not affected by the treatment, although there was a non significant trend toward lower values in the treated animals (P=0.06). SC did not affect liver functionality, AST/GOT and GGT were similar among treatments. *E. coli* faeces content was positively reduced (C: 2.39; SC: 0.72; log10 CFU/g, SE 0.25) by the treatment where lactic bacteria content was significantly higher (P<0.001). Yeast in the faeces was confirmed by the microbiological analyses (P<0.001). SC increased milk yield and reduced *E.coli* in faeces.

Key Words: Live Yeast, Dairy Goat

M191 Dose response of a direct-fed microbial on milk yield, milk components, body weight, and days to first ovulation in primi- and multiparous Holstein cows. D. R. Stein¹, D. T. Allen¹, K. W. Gates¹, T. G. Rehberger², K. J. Mertz², D. A. Jones¹, and L. J. Spicer¹, ¹Oklahoma State University, Stillwater, ²Agtech Products, Inc., Waukesha, WI.

From 14 d before parturition to 175 d postpartum, 38 primi- (pp) and multiparous (mp) Holstein cows were blocked by expected milk production and randomly assigned to treatment groups: Control, n=13, received a total mixed ration (TMR); Low treatment, n=11, received control TMR plus Low dose (1X/head/d) of Propionibacterium strain P169 (P169); High treatment, n=14, received control TMR plus High dose (10X/head/d) of P169. Rumen fluid was collected at -14d, +60d, +120d, and +175 d of lactation. Milk samples were collected twice weekly and analyzed for milk components. Daily milk production (4% fat-corrected milk; FCM) was influenced by treatment (P < 0.01) such that FCM (averaged across pp and mp cows) was greater (P < 0.05) in the High (32 ± 0.5 kg/d) and Low (33 ± 0.5 kg/d) P169 vs Control (30 ± 0.5 kg/d) cows; FCM did not differ between the High and Low P169 groups. Milk lactose was affected by treatment x age (P < 0.03) with High P169 pp and mp cows having a higher percentage lactose (5.04 and 5.10 ± 0.04 %, respectively), than the Low P169 pp and mp cows (4.89 and 4.91 ± 0.04 %, respectively) or the Control pp and mp cows (4.93 and 4.77 ± 0.04 %, respectively). Weekly body weights (BW) from wk 1 to 25 were greater (P < 0.05) in High P169 mp cows (635 ± 18 kg) than Low P169 (604 ± 16 kg) and Control (601 ± 17 kg) mp cows. BW in pp cows (528 ± 13 kg) did not differ (P > 0.10). P169 treatments influenced the fold differences of rumen propionate (P < 0.05) which were greater in High P169 (5.69 ± .70) vs Low P169 (2.91 ± .65) and Control (2.74 ± .62) groups at 60,120, and 175 d. No main effects or interactions were found for days to first ovulation (progesterone conc. greater than or equal to 1.0 ng/ml). We conclude that P169 may hold potential as an effective direct-fed microbial to increase milk production.

Key Words: Propionibacteria, Milk Yield, Direct-Fed Microbial

M192 Effect of forage to concentrate ratio on B-vitamins in different ruminal fractions. D. E. Santschi¹, R. Berthiaume², R. Martineau³, J. J. Matte², A. F. Mustafa¹, and C. L. Girard², ¹McGill University Ste-Anne-de-Bellevue, Qc, Canada, ²Dairy and Swine R&D Centre Lennoxville, Qc, Canada, ³Universite Laval, Qc, Canada.

Six ruminally caulked lactating Holstein cows (78 ± 13 DIM) were used in a cross-over design to evaluate the effects of forage to concentrate ratio on B-vitamin concentrations in ruminal contents. Diets were formulated to have forage to concentrate ratios of 60:40 (high-forage, HF) and 40:60 (low-forage, LF), and contained respectively (DM basis) 43.0 and 23.5% mixed silage, 16.9 and 16.4% corn silage, 28.4 and 40.0% high moisture corn, 4.0 and 8.6% soybean meal, 5.3 and 8.6% protein supplement, and 2.3 and 2.7% mineral and vitamin premix (without B-vitamins). Rations were fed as a TMR in 12 daily meals (at 95% of the ad libitum DMI of the HF diet). Ruminal samples (250 g of solid and 1.23 L of liquid material) were collected at the end of each 4-wk adaptation period and ruminal fractions were separated (1989. Br. J. Nutr. 61:725). B-vitamins were analyzed in the particle-free fluid (PFF) and in the freeze-dried liquid- and solid-associated bacteria (LAB and SAB). B-vitamin concentrations were similar for LAB and SAB, and were 125 to 5000 times higher than in PFF. The concentrations of B-vitamins in SAB were as follows for the HF and LF diet respectively:

riboflavin (40.51 vs 47.79 µg/g; P=0.01), pyridoxamine (7.04 vs 9.05 µg/g; P=0.06), pyridoxine (0.95 vs 0.63 µg/g; P≤0.01) and true B12 (4.00 vs 3.08 µg/g; P≤0.01). The HF diet also yielded higher concentrations of true B12 in the LAB fraction (6.34 vs 4.75 µg/g; P=0.07) and of pyridoxine (98.62 vs 57.15 ng/ml) and biotin (24.32 vs 18.53 ng/ml) in the PFF (P≤0.04). Therefore, B-vitamins were present mainly in the bacterial fractions of the rumen while only limited amounts were found in the surrounding fluid. A change in the forage to concentrate ratio had a greater effect on vitamin synthesis by the bacteria associated to the solid fraction than by those present in the liquid portion of the rumen. In conclusion, it appears that ruminal B-vitamin synthesis is altered by changes in the forage to concentrate ratio, which suggests that the supply of vitamins to dairy cows is influenced by the diet composition.

Key Words: Cow, B-Citamins, Forage:Concentrate Ratio

M193 A statistical evaluation of early- or mid-lactation dairy cow responses to dietary sodium bicarbonate. W. Hu* and M. R. Murphy, University of Illinois, Urbana.

Our objectives were to examine, using mixed model statistical analysis, effects of dietary NaHCO₃ on the performance of early- or mid-lactation dairy cows and to determine if an optimal amount of buffer inclusion exists for these cows. A database was developed from 27 studies published between 1980 and 1999 that included a total of 30 trials, 73 dietary treatments, and 369 cows. Dietary NaHCO₃ was categorized according to amount in the diet as control (0%), moderate (0.70 to 1.0%), or high (1.05 to 1.5%); NaHCO₃ concentrations outside these ranges were not included. Forage type was categorized as corn silage (CS) when it was the sole or main dietary forage or as forage other than CS (NCS) when alfalfa hay, or silages based on alfalfa, barley, sorghum, triticale, or wheat were the sole or main dietary forages. The statistical model included the fixed effects of buffer concentration and forage type, and the random effect of study. Dry matter intake did not differ among buffer treatments for cows fed NCS; however, cows fed CS without NaHCO₃ addition consumed 1.24 kg/d less dry matter (P < 0.02) than cows fed buffer. Intake was not affected in cows fed CS with dietary NaHCO₃. Milk production, milk protein percentage, and protein yield were unaffected by buffer treatments regardless of forage type; however, milk fat percentage of cows fed CS-based diets was 0.27 percentage units higher when NaHCO₃ was included (P < 0.02). The 4% fat-corrected milk was also higher for buffered compared to unbuffered diets, by 1.86 kg/d (P < 0.02). Addition of NaHCO₃ at 0.70 to 1.0% of dietary dry matter, based on contrast analyses, appeared optimal for early- or mid-lactation cows fed CS-based diets. Forage type was confounded with acid detergent fiber content of the diet; therefore, differences in response to buffer treatments related to forage type might be explained by variation in the fiber contents of the forages themselves.

Key Words: Sodium Bicarbonate, Performance, Dairy Cows

M194 Fate of supplemental B-vitamins in the gastrointestinal tract of dairy cows. D. E. Santschi¹, R. Berthiaume², J. J. Matte², A. F. Mustafa¹, and C. L. Girard², ¹McGill University Ste-Anne-de-Bellevue, Qc, Canada, ²Dairy and Swine R&D Centre, Lennoxville, Qc, Canada.

Four lactating Holstein cows equipped with ruminal, duodenal (30cm from pylorus) and ileal (60cm from ileo-cecal valve) canulae were used to evaluate disappearance of supplemental B-vitamins in the rumen and the small intestine. Cows were fed a TMR with chromic oxide in 12 daily meals. Each study consisted of a control (Ctrl; no vitamins) and a vitamin supplementation period (Trt). Daily amounts (mg) for studies 1 and 2 were respectively: B1:300,15; B2:1600,1.6; B6:800,40; B9:2600,130; B12:500,0.5. In study 1, vitamins were added to the feed 5 days prior to and during the 4 collection days. In study 2, vitamins were infused post-ruminally one day prior to and during the 4 collection days. Disappearance prior to the small intestine was calculated as the amount of vitamins appearing at the duodenum relative to the quantity given. Intestinal disappearance was calculated as the amount disappearing between the two intestinal canulae compared with the amount arriving at the duodenum. Important ruminal disappearance was noted in study 1 (68% B1, 99% B2, 41% B6, 97% B9 and 63% B12), but there was almost no disappearance of post-ruminally infused vitamins prior to the duodenum, confirming that extensive destruction occurs in the rumen. The negative intestinal disappearance for B9 during the control periods

suggested extensive recycling of this vitamin (probably through the enterohepatic cycle), leading to underestimation of the true disappearance rate. The proportion of vitamins disappearing from the small intestine was not decreased by supplementation ($P \geq 0.09$). For all vitamins but B2 in study 1, absolute amounts being absorbed were greater during the Trt than the Ctrl periods, suggesting that B-vitamin supply in dairy cows is increased by supplementation, although losses in the rumen are extensive.

Vitamins	Study 1			Study 2		
	% Disappearance	% Disappearance	P	% Disappearance	% Disappearance	P
B1	77 (7)	55 (13)	0.09	73 (6)	67 (5)	0.47

M195 Ruminal degradability of nitrogen, phosphorus, and potassium from dairy feedstuffs. A. N. Hristov^{*1}, A. Melgar¹, A. E. Foley¹, and R. Kincaid², ¹Department of Animal and Veterinary Science, University of Idaho, Moscow, ²Department of Animal Sciences, Washington State University, Pullman.

The objective of this study was to determine ruminal degradability parameters of nitrogen (N), phosphorus (P), and potassium (K) from feedstuffs common in Northwest dairy diets. Alfalfa hay (AA), corn silage (CS), and whole cottonseed (WCS) were oven dried and ground through a 2-mm sieve. Barley grain (BG), corn grain (CG), and whole soybeans (SB) were coarsely ground. All feeds were sieved through a 100-mm screen and particles retained on the sieve were incubated *in sacco* in the rumen of three lactating dairy cows for up to 72 h. Ruminal microorganisms were labeled through a continuous intraruminal infusion of $(^{15}\text{NH}_4)_2\text{SO}_4$; ^{15}N was used to correct the nylon bag residues for microbial (N, P, K) contamination. The soluble/instantly degradable fraction of N was greatest ($P < 0.05$) for CS ($82.9 \pm 1.76\%$) and lowest ($P < 0.05$; except *vs.* BG) for CG ($6.5 \pm 2.05\%$). Alfalfa hay and WCS had the greatest ($P < 0.05$) rates of N degradation (13.4 ± 2.28 and $14.9 \pm 3.07\%$ /h, respectively). Alfalfa hay, CS, and WCS had the greatest ($P < 0.05$) effective degradability (ED) of N (82.3 ± 1.08 , 87.5 ± 1.09 , and 82.2 ± 1.06 , respectively). P was very soluble in AA, CG, CS, and WCS (from 63.0 ± 11.2 , $97.0 \pm 5.48\%$, CS), but not BG and SB. Rates of P degradability did not differ ($P > 0.05$) among feedstuffs. ED of P were: 93.0 ± 4.26 , 58.0 ± 4.65 ($P < 0.05$), 83.8 ± 4.26 , 97.8 ± 4.15 , 76.3 ± 7.14 , and $92.1 \pm 4.24\%$ (AA, BG, CG, CS, SB, and WCS, respectively). Solubility of K in AA, BG, SB, and WCS was 98.5 ± 1.53 , 62.7 ± 1.66 , 60.0 ± 1.59 , and $92.6 \pm 0.99\%$, respectively. ED of K was high for all feedstuffs (from 94.0 ± 0.59 , BG to $99.7 \pm 0.67\%$, AA). Although the K degradation parameters for CG and CS could not be estimated, K solubilities were 94 and 99%, respectively. Ruminal degradability of N varied, but P and K were very soluble and rapidly degradable in most of the feedstuffs studied.

Key Words: Nitrogen, Phosphorus, Potassium

M196 Effects of a fibrolytic enzyme formulation on forages, co-products, and byproducts fermented *in vitro*. K. F. Wilson^{*1}, G. V. Pollard², and C. R. Richardson³, ¹Animal Feed Technologies, Greeley, CO, ²Texas State University, San Marcos, ³Texas Tech University, Lubbock.

The effectiveness of enzymes in animal feeding has been well proven, however, due to the constant influx of new co-products and byproducts the affects of enzyme formulations on these ingredients are unknown. Therefore, an *in vitro* dry-matter digestibility study was designed to determine the effect of Cattle-AseTM C on a broad spectrum of forages, co-products, and byproducts. The feedstuffs evaluated were alfalfa, wheat straw, sorghum sudan grass, almond hulls, corn cobs, cotton moats, peanut hulls, rice hulls, soy hulls, beet pulp, corn/barley middlings, distillers grains, wheat middlings, and sweetbranTM and ranged

broadly in chemical analysis and fiber level. Alfalfa, cellulose, cornstarch, and ground corn were used as indicator ingredients to the evaluated feedstuffs. Dry-matter disappearance was evaluated utilizing the Moore modification of the two-stage Tilley-Terry procedure at incubation times of 24 h and 48 h. A 0.7 g sample of ingredient was combined with 50-mL of buffer and rumen fluid mixture and placed in a 39°C water bath for the predetermined incubation times. Results showed that at 24 h, Cattle-Ase improved ($P < 0.10$) dry-matter digestibility for the higher fiber ingredients such as sorghum sudan grass, almond hulls, corn cobs, cotton moats, soy hulls, and corn/barley middlings. On average for the 24 h period, Cattle-Ase improved digestibility by 31.6%. The only difference ($P < 0.10$) observed at 48 h was for sweetbran. On average for the 48 h period Cattle-Ase only improved digestibility by 7.7%. The likely attributing effect to Cattle-Ase not improving ($P > 0.10$) digestion at 48 h treatment would be a loss of fermentable energy associated to these types of feedstuffs. In previous experiments, Cattle-Ase improved *in vitro* dry-matter digestibility across times and feedstuffs by over 20%. Therefore, these results substantiate the benefit of including enzymes in a feeding regime in which products containing higher fiber levels are used.

Key Words: Fibrolytic Enzymes, Co-Products, Byproducts

M197 Effects of fibrolytic enzymes and fat supplementation on fiber digestibility, nitrogen metabolism and fermentation profile in continuous culture system. A. Bouattour, L. Castillejos, R. Casals, S. Calsamiglia^{*}, and E. Albanell, *Universitat Autònoma de Barcelona*.

Eight dual flow continuous culture fermenters (1320 mL) were used in a 2x2 factorial design in two consecutive periods of 8 days (5 for adaptation and 3 for sampling) to study the effects of an exogenous fibrolytic enzyme (E: 0 vs 2 ml/kg DM) complex (Promote[®], Agribrands International) and sunflower oil (SF: 0 vs 28 g/kg DM) on rumen microbial fermentation and nutrients digestibility. The enzyme was sprayed on the forage and immediately dried at 55°C for 48 h, and the non enzyme treatments were sprayed with water and processed identically. Diets (95 g DM/d of a 60 to 40 forage to concentrate ratio, 17.9% CP, 42.2% NDF) were fed in three equal amounts along the day. Fermentation conditions (temperature = 39°C, pH = 6.4, and liquid = 10%/h and solid = 5%/h dilution rates) were maintained constant. Effluent samples were taken from a composite of the three sampling days, and bacteria were isolated from fermenter flasks on the last day of each period for chemical analysis. There were no effects of E on true digestion of OM (47.5%), NDF (38.5%), and ADF (43.3%). Fat digestibility increased ($P < 0.0001$) from 32.1 to 52.4% in SF treatment and decreased ($P < 0.05$) from 46.3 to 38.2% in E treatment. The SF decreased ($P < 0.01$) the total VFA concentration (mM) from 103.4 to 95.4 and E decreased ($P < 0.025$) it from 102.8 to 95.9. There was an E by SF interaction for butyrate ($P < 0.038$) and isobutyrate ($P = 0.068$) proportions. Ammonia N concentration (9.72 mg N/dL), the flow (g/d) of total N (3.04), ammonia N (0.31), non ammonia N (2.74), bacterial N (1.00), and dietary N (1.74), CP degradation (33.4%), and efficiency of microbial protein synthesis (23.3 g N/kg OM truly digested) were not affected by dietary treatments. The use of fibrolytic enzymes and sunflower oil decreased the concentration of total VFA but did not affect fiber digestion. Acknowledgment: financial support from CICYT-Spain (project AGL-2001-2617).

M198 Effects of fibrolytic enzymes on *in vitro* ruminal degradation and gas production of alfalfa hay. J.-S. Eun^{*1}, S.-H. Hong², K. Beauchemin¹, and M. Bauer³, ¹Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, ²Sahmyook College, Cheongnyangni, Seoul, Korea, ³Syngenta Biotechnology Inc., Research Triangle Park, NC.

A series of recombinant, single activity enzyme products (supplied by Zymetrics, MN), including 13 cellulases (END) and 10 xylanases (XY), were evaluated for their potential to improve ruminal degradation of forages *in vitro*. Enzyme activities were determined at pH 5.3-5.4 and 37°C using 1.0 to 1.4% substrate (arabinoxylan from wheat for endoxylanase and beta-glucan from barley for glucanase; Megazyme, Ireland). Based on these enzyme activities, a dose level (1000 U/kg) was chosen for the addition of enzymes. One gram of alfalfa hay DM was weighed into fermentation bottles (125 mL capacity). Because the enzyme products were freeze-dried, they were resuspended by adding H₂O, and then the

enzyme solution was added to the corresponding bottles in 6 replications. Forty milliliters of anaerobic buffer medium adjusted to pH 6.0 was added to the bottles. The strained ruminal fluid was inoculated into culture bottles and incubated for 18 h. Headspace gas produced by substrate fermentation was measured at 2, 6, 12, and 18 h post inoculation. Apparent OM degradation (OMD) was determined after 18 h of incubation. Data were analyzed using the Proc Mixed procedure of SAS 8.1. Total gas production measured at the end of incubation (18 h) was higher ($P < 0.05$) for most of the END (except for END A and END C) compared with the control (alfalfa without enzyme). Addition of END increased ($P < 0.05$) OMD (except for the same 2 END products). Total gas production and OMD were increased by 5 XY enzymes, but these were not the same XY products in each case. Increases in OMD ranged from 5.4% to 14.1% and from 5.6% to 16.3% for the END and XY enzymes, respectively. Addition of END or XY decreased the partitioning factor of fermentation calculated as mg OM degraded/mL gas produced. In summary, some of the pure END and XY enzymes we tested increased in vitro degradation of alfalfa hay, and they greatly influenced partitioning of fermented substrate.

M199 Ranges of optimal cellulase activity of commercial fibrolytic enzyme preparations used in ruminant diets. E. González*, E. Albanell, G. Caja, and R. Casals, *Grup de Recerca en Remugants, Departament de Cincia Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

An in vitro study was conducted to investigate factors by which cellulase activity of fibrolytic enzyme preparations for ruminants are affected. Two liquid commercial enzyme products, Promote (PRO) and Cellupract AL 100 (CEL), both isolated from aerobic fungus (*Trichoderma longibrachiatum* and *Trichoderma reesei*) and with recognized cellulase activity, were used to examine the effects of pH, temperature, enzyme dose, and its interactions. Cellulase activity was determined in a factorial design (3 × 4 × 3) for three pH (4.0, 5.5 and 6.5), four temperatures (30, 40, 50 and 70 C), and three doses (1, 2 or 3 g/kg DM of substrate). Average and extreme values for experimental treatments were selected according to practical criteria either for current ruminal or industrial conditions. Carboxymethyl cellulose (CMC) was used as substrate, and concentrations of reducing sugars were determined in absence of ruminal liquor by the Nelson-Somogyi copper reduction method with glucose as standard. There were no significant differences for the average enzymatic activities between products (561 and 631 μmol of released sugar $\text{min}^{-1} \text{g}^{-1}$ for CEL and PRO, respectively). Cellulolytic activity was highly affected ($P < 0.001$) by pH, temperature, and enzyme doses, as well as by pH × temperature and pH × temperature × doses interactions. Maximum cellulolytic activities were obtained for pH 4.0, temperature 50C and the greatest dose (3 g/kg DM) on average (854, 2047 and 905 μmol of released sugar $\text{min}^{-1} \text{g}^{-1}$ of the enzyme applied, respectively). Optimal interactive cellulolytic activities were obtained for the sets pH 4.0-50C, and for pH 4.0-50C, with an enzyme dose of 3 g/kg DM (2931 and 4608 μmol of released sugar $\text{min}^{-1} \text{g}^{-1}$ of the enzyme applied, respectively). Optimal conditions for commercial enzyme products evaluated in this experiment, demonstrated to be out of the normal ranges in ruminal environment.

Key Words: Fibrolytic Enzymes, Cellulase Activity

M200 Effects of a supplemental amylase enzyme preparation on lactational performance in commercial dairy herds. 1. Whole herd responses. G. A. Harrison* and J. M. Tricarico, *Alltech Biotechnology, Inc., Nicholasville, KY.*

Field trials with a supplemental amylase preparation (AmaizeTM, Alltech Biotechnology Inc., Nicholasville, KY) were conducted during 2002 and 2003 in 45 commercial dairy herds across the U.S. and Canada (approximately 8150 cows). Number of cows, days in milk, milk production and composition were collected from two consecutive monthly Dairy Herd Improvement (DHI) test records. Fat-corrected (FCM) and energy-corrected milk (ECM) were calculated from milk yield and composition measurements. Herds began receiving supplemental amylase after the first monthly DHI test. The amylase preparation was added to the base herd ration at the rate of 12 grams/head/day. Cows were fed supplemental amylase, on average, for 26 d before the second monthly DHI test. Response to enzyme supplementation was evaluated using a Students t-test on the difference obtained by subtracting the second

from the first monthly test. The null and alternate hypotheses were the difference equals zero or greater than zero, respectively. Data were weighted by herd size. Milk yield was greater during the enzyme treatment test period (32.0 vs 31.7 kg, $P=0.059$) when data from all 45 herds were included in the analysis. The dataset included twelve trials conducted with herds in the Southeastern U.S. in the summer of 2002 during severe heat stress. When data from all herds with an initial DHI test in June or July of 2002 were excluded (leaving 32 herds in the dataset), amylase supplementation increased milk yield (32.8 vs. 31.8 kg, $P=0.001$), FCM yield (34.3 vs. 33.7 kg, $P=0.072$), ECM yield (33.8 vs. 33.1 kg, $P=0.051$), and milk protein yield (1.02 vs. 0.99 kg, $P=0.014$). In addition, milk fat percentage was reduced (3.80 vs. 3.87, $P=0.037$) but milk fat yield was not affected by amylase supplementation in those 32 herds. Amylase supplementation increased milk yield in 56% of the herds when data from all herds were included in the analysis and increased milk yield in 72% of the herds when data from summer 2002 trials were excluded.

Key Words: Amylase, Dairy Cows, Field Study

M201 Effect of a supplemental amylase enzyme preparation on lactational performance in commercial dairy herds. 2. Individual cow responses. G. A. Harrison* and J. M. Tricarico, *Alltech Biotechnology, Inc., Nicholasville, KY.*

Individual cow data from field trials with a supplemental amylase preparation (AmaizeTM, Alltech Biotechnology Inc., Nicholasville, KY) conducted during 2002 and 2003 in 12 commercial dairy herds were included in this summary. Days in milk (DIM), milk production, and composition were collected from downloaded Dairy Herd Improvement (DHI) test records. Fat-corrected (FCM) and energy-corrected milk (ECM) were calculated from milk yield and composition measurements. The dataset included 1079 cows with three consecutive DHI tests and initial DIM>60. Herd was used as the experimental unit and weighted herd means were used in the analysis. Amylase was added to the base herd ration at the rate of 12 grams/head/day. Herds began receiving supplemental amylase after DHI test 1. Diets containing amylase were fed for an average of 24 days prior to DHI test 2. Amylase was removed from the diets after test 2 and the base diets (no amylase) were fed for an average of 22 day prior to DHI test 3. The response to amylase supplementation was evaluated by a contrast between test 2 (amylase) and tests 1 and 3 (no amylase) as described by McGillard and Stallings, 1998 (J. Dairy Sci. 81:1353). Predicted milk yield and composition for test 2 were calculated based on test 1 and 3 measurements adjusted for changes in DIM. For test 2, actual milk was greater than predicted milk yield (33.3 vs. 32.2 kg, $P=0.101$) while actual milk fat percentage was lower than predicted (3.77 vs. 3.90, $P=0.013$). Actual milk protein percentage, FCM, and ECM were not different from predicted, though actual milk protein yield did tend to be higher than predicted (1.03 vs. 1.00 kg, $P=0.153$). Summarizing individual cow records yielded comparable results to the whole herd summary. In cows greater than 60 DIM, actual milk was 1.1 kg greater than predicted milk based on the increase in DIM. Actual milk fat percentage was lower than predicted, but the increase in milk yield resulted in similar fat and numerically greater protein yields.

Key Words: Amylase, Dairy Cows, Field Study

M202 Effect of increased residual water-soluble carbohydrate concentration in ryegrass silage on intake, milk production, and N excretion in dairy cows. J. M. Moorby*, W. J. Fisher, and R. T. Evans, *Institute of Grassland and Environmental Research, Aberystwyth, UK.*

To study the effects of increased residual water-soluble carbohydrates (WSC) in grass silage, 16 multiparous mid-lactation Holstein-Friesian dairy cows were offered one of two ryegrass silages ($n = 8$ per treatment) over 2 consecutive 7 wk periods (wk 8-14 and 15-21 of lactation). During each period silages made from a high WSC variety of ryegrass (HS; var. AberDart) or a control ryegrass (var. Fennema) were compared, offered ad libitum with 5 kg/d concentrates. In period 1 (P1) the two silages were second cuts, while in period 2 (P2) the silages were third cuts. Four cows per treatment underwent whole-body N partitioning and feed digestibility measurements for 6 d in the last week of each period. Silage DM was similar for both varieties during each period (means of 25% for P1 and 23% for P2). WSC was higher ($P<0.05$) in HS silage fed during P1 (2.4% vs 1.7% of DM), but not in P2. Crude

protein was higher ($P < 0.05$) in HS silage in both periods (18.2% vs 17.3% in P1, and 17.7% vs 16.9% in P2). In P1 feed DMI and milk yields were similar for both diets (means of 17.3 kg DMI/d and 27.8 kg milk/d). In P2 DMI was higher ($P < 0.05$) for cows fed the HS diet (16.2 vs 15.0 kg/d), but milk yields were similar (mean 22.5 kg/d). Milk fat concentrations and yields of cows fed HS were higher ($P < 0.05$) in both periods. Milk protein concentrations were also higher on the HS diet in both periods, but protein yields were only higher ($P < 0.05$) in P2. In P1, cows given the HS diet with higher WSC excreted a lower ($P < 0.05$) proportion of their feed N in urine, but in P2 when the HS silage had similar WSC content to control, urine N excretions were similar. In P1, feed whole-tract digestibility was similar for both diets, but in P2 it was higher ($P < 0.05$) for the control diet. Although differences in silage WSC content were small, it is concluded that when cows are fed ryegrass silages containing higher concentrations of WSC they yield milk with improved composition and partition less of the dietary N to urine.

Key Words: Dairy Cows, Grass Silage, Water-Soluble Carbohydrates

M203 An evaluation of FuzZPellet™ whole cottonseed product on milk production in post-peak Holstein cows. P. A. Porter^{*1}, N. L. Scott¹, and R. B. Harding², ¹Land O'Lakes Inc., Gray Summit, MO, ²Buckeye Technology, Memphis, TN.

Thirty-nine (29 multiparous, 10 primiparous) Holstein cows, approximately 110 DIM at trial initiation, were assigned to either WCS (10% of the ration DM as whole cottonseed) or FuzZ (10% of the ration DM as pelleted cottonseed product, FuzZPellet™, Buckeye Technology, Memphis, TN) diets in an 8-wk randomized complete block design. On a DM basis, the ration contained 34% corn silage, 23% alfalfa hay, 13% ground corn and 19% protein-mineral-vitamin blend; TMR nutrient parameters (DM basis) were 17.9% CP, 21% ADF, 30% NDF, 5.7% crude fat, 37% NFC, 18% forage NDF. Milk samples taken at the weeks 0, 4 and 8 were analyzed for percent CLA; blood samples taken at weeks 4 and 8 were analyzed for percent gossypol. Cows received Posilac per label instructions. When covaried for milk production, FuzZ produced more milk than WCS (44.9 vs. 43.0 kg/d, $P = 0.05$); multiparous and primiparous animals had similar numerical response (46.0 vs. 44.0, $P = 0.08$, 41.9 vs. 39.7, $P > 0.20$, respectively). Compared to WCS, FuzZ had higher ($P < 0.10$) milk protein yield (1.32, 1.25 kg/d) and milk lactose yield (2.17, 2.03 kg/d) and tended ($P < 0.20$) to have higher milk protein content (2.96, 2.90%) and lower milk fat content (3.36, 3.62%) and MUN (12.9, 14.0 mg/dl). DMI (25.6, 26.1 kg/d), 3.5% FCM (43.7, 43.9 kg/d), 4.0% SCM (40.5, 40.0 kg/d), milk fat yield (1.50, 1.55 kg/d), milk lactose content (4.84, 4.73%), milk total solids content (12.03, 12.12%), milk solids yield (5.39, 5.20 kg/d) and SCC (345, 230, 1000/ml) were similar ($P > 0.20$) for FuzZ and WCS, respectively. Feed gossypol content was 0.80% (FuzZ) and 0.63% (WCS). Blood gossypol was lower for FuzZ at weeks 4 (1.73, 2.14 ug/ml, $P = 0.02$) and 8 (1.82, 2.40 ug/ml, $P = 0.001$). CLA content in milk fat was similar. FuzZPellet™ pelleted whole cottonseed product provides both production and handling advantages.

Key Words: Whole Cottonseed, Milk Production, Gossypol

M204 Effect of feeding red clover or ryegrass silage to dry dairy cows on milk productivity in the next lactation. J. M. Moorby^{*1}, P. H. Robinson², W. J. Fisher¹, and D. W. R. Davies¹, ¹Institute of Grassland and Environmental Research, Anerstywyth, UK, ²UCCE, Dept. of Animal Science, University of California, Davis.

To investigate effects of feeding a high protein silage to dry cows on their subsequent lactational performance, 48 Holstein-Friesian dairy cows were offered ad libitum access to either red clover silage (RC; 22.4% DM, 18.9% crude protein [CP]) or ryegrass silage (RS; 28.0% DM, 17.2% CP) for the last 4 wk of the dry period (DP). After calving, all animals received the same diet of ad libitum ryegrass silage (29.2% DM, 18.1% CP) with a grain based concentrate (24% CP) at 6 kg/d. BW and BCS were recorded weekly until 2 wk before predicted calving date, after which BW was recorded daily until calving, and BCS and ultrasound scans of the *Longissimus dorsi* were recorded every 3 d until calving. BCS and muscle scans were also recorded weekly during lactation. After calving, milk yields were recorded daily and samples for component assays were collected weekly until wk 10 of lactation. DM intake was similar for the two groups during the DP (13.3 vs. 12.8 kg DM/d for cows offered RC and RS respectively). There was no difference in DM

intake over the first 10 wk of lactation (17.2 vs. 17.0 kg DM/d). Mean BW (659 kg), BCS (2.5; 0 to 5 scale), milk yield (32.3 kg/d) and milk composition over the first 10 wk of lactation were not affected by DP treatment, although milk fat percentage over the first 4 wk of lactation was higher ($P < 0.05$) from cows offered RS during the DP (4.0% vs. 4.3%). Calf birth weights were higher ($P < 0.05$) from cows fed RC during the last 4 wk of gestation (bulls: 43.2 vs. 42.1 kg; heifers: 41.8 vs. 39.5 kg), while mean *L. dorsi* depth tended ($P < 0.1$) to be smaller in RC fed cows vs. those fed the GS diet (39.1 vs. 41.4 mm). Feeding RC during the dry period offered little benefit over RS in terms of subsequent lactational performance, although RC may have induced tissue repartitioning at the end of gestation, leading to higher birth weights in calves and smaller *L. dorsi* depths in the cows.

Key Words: Body Condition Score, Calf Birth Weight, *Longissimus dorsi*

M205 Coffee hulls in diets of dairy cows: Nitrogenous compounds balance. A. Lima de Souza^{*1}, R. Garcia², L. Cabral¹, F. Salgado Bernardino², J. Tilemahos Zervoudakis¹, F. Cipriano Rocha², and R. Ferreira Diniz Valadares², ¹Universidade Federal de Mato Grosso DZER/FAMEV/UFMT, ²Universidade Federal de Viçosa DZO/UFV.

The nitrogenous compounds balance of dairy cows fed with four levels (0.0, 8.75, 17.5 and 26.25% DM) of coffee hulls in substitution of ground corn in their concentrate ration, which corresponding to levels of 0.0, 3.5, 7.0 and 10.5% of the total DM in the diet were evaluated. Twelve Holstein-Zebu dairy cows were used in the experiment and they were assigned to three 4 x 4 Latin square design, squares were design using milk production period. All isoproteic diets, 14% CP, contained 60% of corn silage and 40% of concentrate on dry matter basis. The estimative of the faecal excretion was done by indigestible acid detergent fiber (IADF) use as marker. The daily total nitrogen compounds (TN) and urea excretion on urine was obtained by spot urine samples. The regression analysis not verified effect of the coffee hulls levels on total nitrogen intake (441.3 g/day), N-urine excretion (190.8 g/day) and N-milk (114.7 g/day). However, was verified linear effect ($P < 0.05$) on faecal N excretion and N balance, have been estimated increase of 1.244 and a reduction of 1.793 g/coffee hulls units adicioned, respectively. The high N concentrations present on the fiber fraction of coffee hulls as neutral detergent insoluble nitrogen (NDIN) and acid detergent insoluble nitrogen (ADIN), can has been the major responsible by higher faecal N excretion and for negative N balance on animals feeds with higher levels of coffee hulls.

Key Words: Agroindustrial Residue, Concentrate Ration, Nitrogen Balance

M206 Treated extruded soybean meal as a source of fat and protein for dairy cows. A. L. Ure^{*1}, T. R. Dhiman¹, M. D. Stern², and K. C. Olson¹, ¹Utah State University, Logan, ²University of Minnesota, St. Paul.

Two experiments were conducted to study the influence of lignosulfonate-treated or lignosulfonate plus calcium oxide-treated, extruded, partially expelled soybean meals as undegradable protein and bypass fat sources on lactation performance and ruminal fermentation characteristics of dairy cows. In experiment 1, nine lactating dairy cows were used in a replicated 3 x 3 Latin square design with cows being blocked according to milk yield. Each period was 3 weeks in duration with the first 2 weeks for diet adaptation and the last week for data collection. Cows were fed a total mixed diet containing 440 g/kg forage and 560 g/kg grain with one of three extruded soybean meals fed at 110 g/kg of the dietary dry matter. The three soybean meals were 1) twice-extruded soybean meal (ESM), which was used as the control; 2) lignosulfonate-treated, twice-extruded soybean meal (LSM); and 3) calcium oxide plus lignosulfonate-treated, twice extruded soybean meal (CLSM). In experiment 2, 3 ruminally cannulated cows were used in a 3 x 3 Latin square to study the influence of method of treatment of soybean meal on ruminal fermentation characteristics. Treatments and experimental procedures were the same as described in experiment 1. Feeding treated soybean meal to cows in LSM and CLSM treatments did not improve feed intake, milk yield, fat yield, or milk composition in experiments 1 and 2, except that cows fed the LSM and CLSM treatments produced less milk protein compared with the ESM treatment. The proportion of linoleic acid in milk fat of cows fed ESM, LSM, and

CLSM was 4.66^b, 4.67^b, and 4.89^a % of fat, respectively ($P < 0.01$). Ruminal pH, ammonia concentration, and total volatile fatty acids were not affected by treatment. An increased proportion of linoleic acid in milk fat suggests that there is a potential use of calcium salts of fatty acids in protecting the lipid portion of extruded soybean meal and further research is needed to explore this potential with full-fat extruded soybeans.

Key Words: Treated Soybean Meal, Cow, Milk

M207 Forage quality of legume hays fed to dairy cows in the tropics. T. M. Ruiz* and M. Rosario-López, *University of Puerto Rico, Mayaguez, PR.*

Quality of rhizoma perennial peanut (RPP), alfalfa (AH), and Bermudagrass hay (BGH) was evaluated when fed to lactating cows in the tropics during summer. Nine Holstein cows in mid-lactation were assigned to treatments according to a 3x3 Latin Square Design. The three hays were fed *ad libitum* in individual hay feeders. Concentrate allotment was based on milk production at 1kg/ 2.25 kg of milk produced. Production of milk from cows consuming BGH, AH, and RPP hay was 18.9, 20.5, and 20.0 kg/cow/day, respectively. Differences among treatments were not statistically significant ($P > .05$). Fat and protein content of milk were not different among treatments. Composition of the consumed rations was on average 46% hay DM. Hay consumption tended to be lower when RPP hay was fed, these differences were reflected in a significant difference ($P < .05$) in the DM consumed (16.0, 16.6, and 14.9 kg/cow/DM for BGH, AH, and RPP hays). However, when expressed as a percentage of bodyweight, differences in hay (1.27%) and total DM intake ((2.75%)) were not statistically significant. Cows consuming high levels of concentrate supplementation and having low milk yields, do not increase production when fed hays with high nutritive value and quality potential. Under these conditions the use of legume hays with high quality potential is not recommended.

Key Words: Rhizoma Perennial Peanut, Bermudagrass, Hay

M208 Lactational response of Holstein dairy cows to grinding and heat processing of cottonseed. A. R. Foroughi*, R. Valizadeh, A. A. Naserian, and M. Danesh, *Ferdowsi university of Mashhad.*

The objective of this study was to evaluate the effect of processing (grinding and heating) of whole cottonseed (WCS) on milk composition and production of Holstein lactating cows during early lactation. Multiparous cows ($n=8$) averaging 84.50 ± 10.34 days in milk and 36.10 ± 4.46 milk yield (MY) were used in a 44 Latin square design. Cows were divided into four groups, receiving one of the following treatments: 1) WCS; 2) Ground cottonseed (GCS); 3) GCS heated in 140°C and steeped for 2.5 minute (GHCS1); or 4) GCS heated in 140°C and steeped for 20 minute (GHCS2). Diets were similar CP, NDF and NEL. The percentage of whole or processed was fixed at 14%. Total mixed diets were fed individually free choice twice daily. Each period consisted of 21 days and the last 7 days were used to determine milk composition and production. MY was significantly ($P < 0.01$) affected by the diets and was greatest for HGCS2 (34.13 kg/d) and the lowest for WCS (31.13kg/d). Supplementation with HGCS2 resulted in increased milk fat percentage ($P < 0.05$) (3.68%, 3.33%, 3.59% and 3.98% for 1,2,3 and 4 treatments, respectively) and milk fat yield ($P < 0.01$). Milk fat yield showed the same pattern of response as observed for milk fat percent. Milk protein percent was progressively increased, averaging 3.21%, 3.02%, 3.42% and 3.42% for 1,2,3 and 4 treatments, respectively. This represented a 6.5% increase between WCS and HGCS2. Milk protein yield tended ($P < 0.05$) to be higher for cows fed CHCS1 and GHCS2 than for cows fed WCS and GCS. Results indicate that heat associated with grinding process was sufficient to decrease ruminal degradation of the cottonseed protein.

Key Words: Whole Cottonseed, Grinding and Heat Treatment, Dairy Cow

M209 Factors affecting the concentration of hydrogen sulfide in the rumen gas of dairy cows. R. J. Dewhurst*, L. J. Harris, and R. T. Evans, *Institute of Grassland and Environmental Research, Aberystwyth, UK.*

Our earlier work identified a range of potentially useful diagnostic gases in the rumen head-space. Some of these gases, or their derivatives, are

present in breath and could be monitored using sensors incorporated into feeding or milking equipment. Hydrogen sulfide is present at high concentrations in rumen gas and concentrations change rapidly after a meal. The current study investigated the relationship between the addition of sulfur-containing compounds to the rumen and concentrations of hydrogen sulfide in rumen gas. This work used lactating Holstein-Friesian dairy cows with established rumen cannulae. All cows had *ad libitum* access to ryegrass silage prior to the experiments. Silage was taken away prior to each run and test feeds were given when hydrogen sulfide concentrations had declined close to zero (3.5 h later). The first experiment was a Latin Square with 4 cows, 4 periods and 4 treatments—a control (C; no addition) and three iso-sulfur additions to the rumen: 9.98 g sodium sulfate (SS; in 100 ml water), 8.52 g L-cysteine (cys; in 100 ml water) or 9.32 g L-methionine (met). The second experiment was a two-period cross-over design with 4 cows and 2 feeds: freshly-cut ryegrass or freshly-cut white clover. Cows received 9.5 kg of one of the forages and consumed their allocation within 25 min. Samples of rumen head-space gas were obtained at 30 min intervals for 4 h and hydrogen sulfide concentrations were measured immediately. Hydrogen sulfide concentrations increased rapidly (within 30 min), peaked after 1 h and declined close to zero after 4 h. Hydrogen sulfide concentrations at 1 h after test feeds were given were 9, 133, 466, and 98 ppm for C, SS, cys and met respectively (s.e.d. = 64.9; $P < 0.001$). Contrary to expectations, concentrations of hydrogen sulfide were much lower after cows consumed white clover in comparison with ryegrass (83 vs. 604 ppm at 1 h after feeding; s.e.d. = 102.6; $P < 0.001$). Subsequent investigation suggests that this results from the use of sulfide in detoxifying HCN produced from white clover.

Key Words: Rumen, Hydrogen Sulfide, Clover

M210 Sorting by dairy cows fed a dry diet in a tie-stall or free-stall barn. C. Leonardi* and L. Armentano, *University of Wisconsin, Madison.*

The objectives were to compare sorting in tie- vs. free-stall barns and also to measure its relation with milk composition. Forty multiparous and 20 primiparous lactating Holstein cows were utilized in a Cross-over design, with 21-d periods. At the beginning of the study cows averaged 102 DIM and produced 37.7 kg of milk daily. Cows were divided into two homogeneous groups; one group was housed in a free-stall during period one and tie-stall during period two; and *vice versa* for group two. In the free-stall 10 extra cows were also present. Animals were fed the same diet once daily in the free-stall and twice daily at 1100 and 1500 in the tie-stall to obtain approximately 10% daily refusals. Diet consisted of 10.3% wheat straw, 30.2% alfalfa hay, 20.2% corn silage, and 39.3% grain mix (DM basis). Individual cows sorting was estimated in both barns utilizing naturally occurring alkanes and determined directly in the tie-stall barn. The alkanes technique did not work and free-stall individual sorting values are not available. Therefore, only group average sorting in the free-stall was measured and compared to the group average in the tie-stall. Group average sorting was analyzed including treatment and period in the model. Sequence effect and true error were combined. Group average sorting against the longest particles was 63.3% in the free- vs. 73.2% in the tie-stall ($P = 0.03$). There were no significant differences in sorting between the two facilities of the other particles. There were no significant correlations between individual sorting measured in tie-stall and milk production and milk composition. Individual sorting of the longest particles was negatively correlated ($r = -0.57$, $P < 0.001$), and of finer particles was positively correlated ($r = 0.67$, $P < 0.001$), with the percentage of refusals. Sorting estimates made with individual cows in tie-stall is likely to underestimate average sorting in a free-stall barn. Sorting variability among cows in a free-stall setting is not available, but may also differ from that observed in a tie-stall barn.

Key Words: Sorting, Dairy Cows

M211 Utilization of rejected milk in dairy farms by custodial with rice hulls for animal feeding. M. Crespo*, A. A. Custodio, and A. A. Rodríguez, *University of Puerto Rico, Mayaguez, PR.*

In Puerto Rico, milk that does not meet minimum standards for human consumption is dumped in the waste lagoons of the dairy farms, contributing to pollution and not allowing for its nutrient utilization. Rice hulls, although of very low nutritional value, is abundant and accessible especially in the greater dairy cattle zone of the island. The

purpose of the current study was to examine the maximum amount of milk (M) that can be recycled and fermented with rice hulls (RC) to obtain stable silage for use in animal feeding. The experiment was performed with seven treatments in triplicates: 1) Control (39% water 61% rice hulls w/w), 2) 35M:65RC, 3) 42M:58RC, 4) 45M:55RC, 5) 50M:50RC 6) 60M:40RC and 7) 70M:30RC w/w, ensiled in sealed jars of PVC pipes. For pH and the fermentation products value studies, three samples from each treatment were drawn at 0, 14 and 28d. Data was analyzed as a completely randomized design with a 7 (TRT) × 3 (length of fermentation) factorial arrangement of treatments. Results shows pH level was about 3.8 at 14d and 3.9 at 28d for all treatments with 50M or more. Major fermentation product was lactic acid in all treatment except control, which was butyric acid. Lactic acid concentration was highest ($P < 0.05$) for 50 and 60M treatments reaching a level of about 2% by 14d and remained at that level by 28d. For the 70M it reached a peak of 1.76% at 14d. Butyric, acetic, propionic and isobutyric acids concentrations remained below 0.5% in all treatments. Lactic acid in the control was almost undetectable showing the incapacity of rice hulls to provide enough substrate to promote fermentation. Results indicate that proportions of 50 and 60M ensiled well. Ensiling milk with other more nutritive materials, such as straw or hay, should be even more successful as a method of preserving the nutrients of discarded milk for animal feeding and therefore contributing to reducing soil and water contamination.

Key Words: Rejected Milk, Rice Hulls, Silage

M212 Effect of different whole cottonseed concentrations on some hematologic data in dairy cattle. F. S. Hatipoglu¹, M. S. Gulay¹, F. Karakas Oguz², and N. Oguz², ¹Department of Physiology, Burdur Veterinary Faculty, Akdeniz University, ²Department of Animal Nutrition, Burdur Veterinary Faculty, Akdeniz University.

The effects of different concentrations of whole cottonseed (WCS) in the diet on blood parameters (% hematocrit, hemoglobin, MCHC and osmotic fragility of red blood cells) were examined in lactating cows. Four Holstein cows were assigned to a 4X4 Latin Square design with four stages. All stages had 14 d of adaptation and 7 d of data collection periods. All plasma samples were collected before the morning feeding and milking from vena jugularis. The dietary treatments included 0% (control; C), 12.7 % (W-I), 25 % (W-II) and 37.5 % (W-III) WCS of total diet. Total WCS in the diet was calculated to be 0 (control), 1 (W-I), 2 (W-II), 3 (W-III) kg/d. No significant effects of WCS concentration in diet fed were observed for mean % hematocrit ($C=40.75 \pm 1.55$, $W-I=41.00 \pm 3.19$, $W-II=40.25 \pm 5.03$ and $W-III=43.25 \pm 4.96$), hemoglobin ($C=10.93 \pm 0.72$, $W-I=11.19 \pm 1.01$, $W-II=10.26 \pm 0.56$, and $W-III=10.89 \pm 0.31$ g/L) or MCHC ($C=267 \pm 12$, $W-I=277 \pm 30$, $W-II=270 \pm 40$ and $W-III=263 \pm 35$ g/L). Osmotic fragility of erythrocytes showed no treatment effect. Mean milk yield was increased numerically but not significantly by WCS concentrations in the diet ($C=18.30 \pm 0.77$, $W-I=19.77 \pm 0.73$, $W-II=20.09 \pm 0.81$, and $W-III=20.45 \pm 0.91$ kg/d; $P > 0.1$). Short time feeding of up to 37.5% WCS had no negative effects on the hematology of animals. Further studies may be needed to determine whether high concentrations of WCS can be fed safely for longer time periods.

Key Words: Whole Cotton Seed, Osmotic Fragility, MCHC

M213 Effects of conservation of timothy on nitrogen metabolism in lactating dairy cows. R. Martineau¹, H. Lapiere², D. R. Ouellet², D. Pellerin¹, and R. Berthiaume², ¹Université Laval, Québec, Canada, ²Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, Québec, Canada.

The effects of three methods of conservation of timothy (*Phleum pratense* L.) on N metabolism were investigated in a replicated 3 × 3 Latin square design with 35-day periods. Treatments were: 1) sun-cured hay (H), 2) formic acid-treated silage (F), and 3) bacterial-inoculated silage (I). Percentages of DM were 88.1, 42.3 and 44.5 (SEM=0.96), and percentages of CP (DM basis) were 10.2, 12.0 and 12.2 (SEM=0.27) for H, F and I, respectively. A similar concentrate (14.4% CP; 69.8% ground corn and 13.6% soybean meal) was offered in all treatments at a forage-to-concentrate ratio of 60:40. Six ruminally- and intestinally-cannulated Holstein cows (DIM=162) were randomly assigned to treatments and fed 12 equal meals daily. Cows were allowed to adjust to their diet for a 2-w period, followed by a 6-d total collection period of

urine and feces. The DMI averaged 16.0 kg/d ($P=0.15$). Nitrogen intake was 15% lower with hay (H) than for silages (F+I), yet neither milk production (20.4 vs. 20.2 kg/d; $P=0.63$) nor milk protein content (3.09 vs. 3.12; $P=0.95$) was different. Nitrogen apparent digestibility was 3.8% lower ($P=0.03$) for H than for F+I. At those levels of N intake, cows fed H were 9.8% more efficient ($P=0.06$) to convert digested N into milk N than cows fed F+I, yet they retained 13.2% less nitrogen ($P=0.04$). The proportion of digested N lost in urine was 6.3% lower ($P=0.04$) with restrictively (F) rather than extensively (I) fermented silage, yet N secreted into milk was not increased.

Item	Treatments			SEM	Contrasts ^a		P

Key Words: Nitrogen Balance, Formic Acid-Treatment, Bacterial Inoculation

M214 Fermentation characteristics of ensiling wet corn distillers grains in combination with wet beet pulp. K. F. Kalscheur*, A. D. Garcia, A. R. Hippen, and D. J. Schingoethe, South Dakota State University, Brookings.

The objective of this study was to evaluate the fermentation and preservation characteristics of ensiling WDG with WBP. Combinations of WBP and WDG were ensiled in silo bags as follows: 1) 100% WBP; 2) 66% WBP + 33% WDG; 3) 33% WBP + 66% WDG; and 4) 100% WDG. Samples from each treatment were collected for analyses prior to ensiling. Samples were collected at d 4, 8, 21, and 112 for analysis. The initial pH was the greatest for 100% WBP and decreased ($P < 0.05$) as concentration of WDG increased (4.2, 3.9, 3.6, and 3.3 for 100%, 66%, 33%, and 0% WBP, respectively). Dry matter of the feedstuffs prior to ensiling was 23.1, 26.5, 30.2, and 33.0% for 100%, 66%, 33%, and 0% WBP, respectively. Concentrations of ammonia-nitrogen (0.95, 2.98, 5.83, and 6.75% DM) and crude protein (8.6, 18.4, 25.4, and 30.5% of DM) increased with increasing concentrations of WDG. Lactic acid prior to ensiling was greatest for 100% WDG (6.41% of DM) and decreased as WBP was included in the treatments. Propionic and butyric acids were not present prior to ensiling. Acetic acid prior to ensiling was highest ($P < 0.05$) for 100% WBP (1.06% of DM) and decreased as WDG was included in the treatments. By d 4 the pH of all feeds were below 4.0 and did not change throughout the experiment. Acetic acid increased ($P < 0.05$) over time in all treatments, and was highest for the 100% WBP (5.17% of DM). Ensiling WBP and WDG can be an effective method of preserving both wet co-products. The low initial pH for all treatments and the increased acetic acid over time, suggests preservation is enhanced by combining both feedstuffs. Although both feedstuffs are an excellent energy source for ruminants, they have a different nutrient profile. High concentrations of CP, fat, P, and S present in WDG are matched with low concentrations in WBP. Combining both feedstuffs result in blends that are easier to formulate into dairy cattle rations.

Key Words: Wet Distillers Grains, Wet Beet Pulp, Fermentation

M215 Effect of two forms of lauric acid on ruminal protozoa and fermentation pattern in dairy cows. A. P. Faciola^{1,2}, G. A. Broderick¹, A. N. Hristov³, and M. I. Leão², ¹U. S. Dairy Forage Research Center, Madison, WI, ²Universidade Federal de Viçosa MG, Brazil, ³University of Idaho, Moscow.

Reducing ruminal protozoa may improve N utilization. Medium-chain saturated fatty acids such as lauric acid (C12:0) have been shown to suppress protozoa. Six Holstein cows fitted with ruminal cannulae were

used to test the effectiveness of two different forms of lauric acid (LA) for suppressing protozoal population in the rumen; ruminal parameters and DMI also were measured. Cows were randomly assigned to three treatments: 1) Control, 2) 160g/d of LA, or 3) 160g/d of sodium laurate (NaLA, dissolved in 1,600 ml of water). Both LA and NaLA were given in a single dose into the rumen via cannulae before morning feeding. The TMR contained (DM basis): 15% alfalfa silage, 40% corn silage, 30% rolled high moisture corn, 14% soybean meal, 16.6% CP and 29% NDF. Cows were fed ad libitum, protozoal counts were done daily, pH was measured weekly, and ruminal fluid was collected in the last week and analyzed for metabolites. Data were analyzed using proc mixed in SAS. The results are reported in the table below. Protozoa declined rapidly with dosing of both LA and NaLA, approaching the final populations within 3 days. Ruminal ammonia and total free AA decreased with LA and NaLA in parallel to protozoa, suggesting reduced intraruminal turnover of bacterial protein. The results showed that LA, which is less expensive, was equivalent to NaLA for reducing ruminal protozoa, obviating the need to convert LA to NaLA under practical conditions.

M216 Effects of forage source on the response of milk fatty acid composition to soybean and marine algal oil supplementation in ewes. C. K. Reynolds¹, S. C. Loerch¹, G. D. Lowe¹, D. D. Clevenger¹, P. A. Tirabasso¹, V. L. Cannon¹, and J. R. Abri², ¹The Ohio State University, Wooster, ²Martek Biosciences, Boulder, CO.

Milk conjugated linoleic acid (CLA) is increased by a mixture of fish and sunflower oils to a greater extent than feeding the oils individually. Our objective was to determine in ewes (78.4 kg BW) the effects of diet forage source on the response of milk fatty acid (FA) composition to an oil supplement (3% of ration DM) based (2:1 respectively, wt:wt) on soybean oil and marine oil in dry microalgae (DHA Gold, Martek Biosciences) high in C18:2 (n-6) and C22:6 (n-3), respectively. Hampshire X Dorset ewes (48) were assigned to one of 4 treatments and 12 pens in a 2 X 2 factorial completely randomized design blocked on the basis of lambing date and number of lambs suckled. Control rations (60:40 forage:concentrate, DM basis) based on alfalfa pellets (AL) or corn silage (CS) were each fed to 6 pens from lambing. After 3 wk adaptation 3 pens each fed AL or CS were switched to similar rations with added oil (ALO and CSO). Milk yield over 3 h and composition were measured at 42 d postpartum. DMI was lower ($P < 0.02$) for CS vs. AL and for oil, but milk yield was not affected. Milk fat content was increased by oil ($P < 0.1$) and milk protein content was higher for AL vs. CS ($P < 0.04$). Total CLA was increased ($P < 0.01$) for CS vs. AL and by oil, and the response to oil was greater for CS ($P < 0.04$). Similarly, total *trans*-C18:1 and C22:6 (n-3) were higher for CS vs. AL and for oil, with a greater response to oil for CS ($P < 0.06$ and 0.01, respectively). In conclusion, milk fatty acid responses to feeding vegetable and marine oils were affected by forage source. Despite large increases in *trans*-C18:1 concentration, milk fat content was increased by feeding unsaturated oils to ewes.

M217 Use of liquid whey, urea and molasses as additives to ensiled wheat straw. F. T. Sleiman*, N. J. Rebeiz, M. G. Uwayjan, M. T. Farran, R. A. Zurayk, E. K. Barbour, and S. K. Hamadeh, American University of Beirut.

Changes in fermentation pattern, consumption and apparent digestibility of wheat straw (S) ensiled with liquid whey (W), urea (U) and molasses (M) were studied using 12 Awassi ram lambs averaging 6 months in age and 36.7 kg BW. The study consisted of a 3 wk trial and a 1 wk collection period. The experimental treatments were: I) 100% S, II) 41% S + 58% W + 1% U, III) 41% S + 55% W + 1% U + 3% M, and IV) 41% S + 54% W + 1% U + 4% M. In addition to ad libitum feeding of straw treatments, each lamb received 1 kg concentrate (14% CP on DM basis) per day. Variations in silage temperatures, recorded at 3 days interval for 30 days, were not significantly different ($P > 0.05$) among the silage treatments (II, III and IV) and averaged 15.5, 18.0 and 17.2 °C, respectively. PH of treatment III was significantly lower ($P < 0.05$) than those of II and IV over the 4 wk ensiling period and averaged 4.56 Vs 4.87 and 4.98, respectively. All lambs had positive but non significant ($P > 0.05$) weight gains at the end of the trial with the highest body weight change recorded for treatment III as compared to I, II and IV (338.5 Vs 194.5, 230.5 and 316.9 g/d, respectively). Silage DMI of W treatments (II, III, and IV) were not significantly different ($P > 0.05$); but these intakes were significantly higher ($P < 0.05$) than that of treatment I and averaged 686, 736 and 707 Vs 435 g/d, respectively. Apparent digestibility of DM was not significantly different ($P > 0.05$) among all treatments and averaged 69.3%. CP digestibility of treatment II was significantly higher ($p < 0.05$) than other treatments (79.7 Vs 59.0 and 60.3% for treatments I, III and IV, respectively). Digestibility of the fiber fractions of II, III and IV were significantly higher ($P < 0.05$) than treatment I; CF (60.2, 66.1 and 62.2 Vs 48.6%), ADF (61.2, 65.8 and 63.5 Vs 46.0%) and NDF (66.7, 71.2 and 68.2 Vs 60.7%). However, digestibility of CF, ADF and NDF of the W supplemented treatments were not different ($P > 0.05$). Results of this study indicate that additives as used improved feed acceptability, animal response, fermentation characteristics and digestibility of ensiled wheat straw.

Key Words: Liquid Whey, Wheat Straw, Ram Lambs

M218 Undegradable intake protein content and digestibility of brome, birdsfoot trefoil, and heat-treated alfalfa samples. H. L. Haugen, S. K. Ivan*, and T. J. Klopfenstein, University of Nebraska, Lincoln.

Two experiments were conducted using two ruminally and duodenally fistulated steers (658 kg) to determine the digestibility of undegradable intake protein (UIP) of smooth bromegrass (*Bromus inermis*), birdsfoot trefoil (BFT; *Lotus corniculatus*), and heat-treated alfalfa (*Medicago sativa* L.) using the mobile nylon bag method. Undegradable intake protein was determined using neutral detergent insoluble crude protein at a single in situ incubation time point based on 75% of the mean retention time estimated from in vitro dry matter disappearance plus a 10 h passage lag. In the first experiment, UIP (% DM) of brome in June and July was 1.82 and 1.71, respectively ($P = 0.11$). Undegradable intake protein (% DM) of BFT increased from 1.30 in June to 1.94 in July ($P < 0.01$). Total tract indigestible protein (IDP) of brome and BFT increased in July ($P < 0.05$). Digestible UIP decreased in July for brome ($P < 0.01$) and tended to increase for BFT ($P = 0.07$). The disappearance of UIP of BFT increased 0.19 percentage units (DM) in July ($P < 0.01$). In the second experiment, alfalfa from plots fertilized with low (66 kg N ha⁻¹) and high (200 kg N ha⁻¹) amounts were dried to simulate three preservation methods: dehydrated (100°C, 10 h), sun-cured

(50°C, 15 h), or lyophilized (-50°C, 72 h) alfalfa. Undegradable intake protein (% DM) was estimated as in experiment one and was 3.13, 2.10, and 1.84 for dehydrated, sun-cured, and lyophilized alfalfa, respectively. Total tract IDP was increased ($P < 0.05$) for dehydrated alfalfa (1.66 % DM) above sun-cured (1.54 % DM) or lyophilized alfalfa (1.57 % DM). Digestible UIP was greater ($P < 0.01$) for dehydrated (46.4%) than sun-cured (25.6%) or lyophilized alfalfa (14.7%) as a result of greater UIP flow to the lower tract. Heat-treated alfalfa samples increased net UIP absorbance in the lower tract as 1.47, 0.56, and 0.27 more percentage units of UIP (% DM) of dehydrated, sun-cured, and lyophilized alfalfa, respectively, disappeared. Overall, UIP digestibility of these forages was low.

Key Words: Undegradable Intake Protein, Undegradable Intake Protein Digestibility, Forages

M219 Preliminary report on dry matter degradability of Cassia tora. J. A. Vergara-Lopez* and R. E. Maldonado, *Instituto Nacional de Investigaciones Agrícolas (INIA) municipio Cataumbo, estado Sulia, Venezuela.*

To evaluate dry matter degradability of Cassia tora (CT) in a tropical dry forest of Venezuela, two Criollo Limonero steers fitted with permanent rumen cannulae and 506 ± 3.5 kg LW, were used. Animals were housed in a feedlot during 14-d and fed with a mixture of Aleman-grass Maraquita in a 80:20 ratio. Samples of CT and Aleman-grass (AG) were cutted from paddock, dried at 105°C in a forced air oven to assess dry matter and milled to 3 mm. Dry samples were weighed in nylon bags (50 μ m pore size) and incubated on 0, 6, 12, 24, 48 and 72 h and analysed for dry matter in a forced air oven at 105°C. Ruminal degradability data were fitted by the model $d=a+b(1-e^{-ct})$, which were analyzed by ANOVA and least square differences test for means comparison. Initial solubility (a) was higher ($p < 0.001$) in CT than AG (20.83 ± 0.43 and 22.21 ± 0.36 for AG and CT, respectively); while b was higher ($p < 0.001$) in AG than CT (58.35 ± 0.81 and 38.77 ± 0.62 for AG and CT, respectively). Fractional rate of degradation (c) was lower ($p < 0.001$) in AG than CT (0.050 ± 0.002 and 0.120 ± 0.011 for AG and CT, respectively), and a+b was higher ($p < 0.001$) in AG than CT (79.22 ± 1.08 and 60.95 ± 0.69 for AG and CT, respectively). Cassia tora had a lower dry matter rumen degradability than Aleman-grass.

Key Words: Cassia tora, Echinocloa polystachya, Ruminal Degradability

M220 Roundup ready® alfalfa is compositionally equivalent to conventional alfalfa. M. McCann*¹, G. Rogan¹, and S. Fitzpatrick², ¹Monsanto Company, St. Louis, MO, ²Forage Genetics International, West Salem, WI.

Roundup Ready® alfalfa has been genetically modified to contain the *cp4 epsps* gene that confers resistance to Roundup® agricultural herbicides. As part of the food/feed safety evaluation, compositional equivalence studies were performed on forage collected from different cutting samples in replicated field trials over two years. Data were collected for proximates (protein, fat, ash and moisture), acid detergent fiber (ADF), neutral detergent fiber (NDF), lignin, amino acids, and minerals (calcium, copper, iron, magnesium, manganese, phosphorous, potassium, sodium and zinc), as well as carbohydrates by calculation. Roundup Ready® alfalfa was compared to its null-segregant control line to determine any statistical differences at the 5% level of significance ($P < 0.05$). Additionally, commercial alfalfa varieties were included to provide population intervals. Results from the analyses in these studies showed that for the majority of comparisons made (310 out of 385), there were no statistically significant differences. For those few comparisons that showed differences between the test and control samples, it is unlikely they were biologically meaningful, since the differences were not consistently observed across field sites, test values were within the population intervals, or test values were observed to be similar to literature and historical ranges. These data are consistent with the conclusion that Roundup Ready® alfalfa forage is compositionally equivalent to the forage produced from other commercial alfalfa varieties currently on the market.

Key Words: Composition, Alfalfa, Equivalence

M221 Digestibility of Streptomyces solubles and effects of its inclusion in diets of lactating dairy cows. M. R. Murphy, M. A. Shah, W. Hu*, A. C. Norman, and C. J. Laesch, *University of Illinois, Urbana.*

Our objective was to determine the digestibility of *Streptomyces solubles* (a 14% crude protein, 10% fat, and 48% dry matter product of the pharmaceutical industry) and effects of its inclusion in diets of lactating dairy cows. Sixteen Jersey cows averaging 131 days in milk were randomly assigned to 4 4 Latin squares with 21-d periods after blocking by parity and rBST. Treatment diets were 50% concentrate, 35% corn silage, and 15% alfalfa silage (on a dry matter basis) and included 0, 2, 4, or 8% *Streptomyces solubles*. Apparent digestibilities of basal diet and *Streptomyces solubles* dry matter were estimated to be 70(SE = 1) and 104(22)%, respectively; digestibility of dietary dry matter tended ($P < 0.11$) to increase linearly with inclusion of *Streptomyces solubles*. Milk fat percentage and 4% fat-corrected milk production increased ($P < 0.05$) when *Streptomyces solubles* were included in the diet, from 5.04 to 5.23% and 26.9 to 28.1 kg/d. Milk and 4% fat-corrected milk production changed quadratically ($P < 0.05$) with *Streptomyces solubles* inclusion and dry matter intake tended ($P < 0.08$) to as well (24.0, 24.4, and 23.1; 27.8, 29.2, and 27.4; and 21.5, 22.3, and 21.7 kg/d at 2, 4, and 8% *Streptomyces solubles*). Body weight decreased linearly ($P < 0.01$) with inclusion of *Streptomyces solubles* and milk protein percentage tended ($P < 0.06$) to also (479, 473, and 467 kg; and 3.96, 3.96, and 3.87% at 2, 4, and 8% *Streptomyces solubles*). *Streptomyces solubles* are a digestible and palatable product that improved lactation performance, particularly when included at 4% of dietary dry matter.

Key Words: Digestibility, Dairy cows, *Streptomyces Solubles*

M222 Effect of replacing concentrates with wormwood on nitrogen balance and ruminal fermentation characteristics in sheep. Y. D. Ko*¹, J. H. Kim¹, M. D. Lee¹, A. T. Adesogan², and S. C. Kim², ¹Division of Applied Life Science, Gyeongsang National University, Jinju, Korea, ²Department of Animal Sciences, University of Florida, Gainesville.

This study investigated the effect of replacing concentrates with air-dried wormwood (*Artemisia montana* Pampan) on the performance of sheep. Four Corriedale x Polwarth sheep weighing 41.3 kg (± 1.3 kg) were fed a diet of rice straw (80%) and pelleted supplements (20%) at 2% of body weight, for four, consecutive 15 d periods. The supplements were made by substituting the concentrate with no wormwood (0%; CT), or low (3%; LW), medium (5%; MW) or high (10%; HW) levels of wormwood on a DM basis (4 x 4 Latin square design). The concentrate (15.58 % CP, 72.1% TDN) contained corn, ground wheat, wheat bran and rapeseed. In each period, sheep were individually housed in metabolism cages for 10 days of dietary adaptation and 5 days of total collection of feces and urine. Rumen fluid was collected from a stomach tube at 0, 0.5, 1, 2, 4 and 8 hr after the morning feed, on day 5 of the measurement period, and analyzed for volatile fatty acids, ammonia and pH. CP digestibility was greater ($p < 0.05$) in LW, MW and HW (56.6, 55.4 and 55.4%) than CT (52.1%). Digestibility of crude fat was greater ($p < 0.05$) in LW (77.2%) than other treatments (72.1-74.5%). N intake did not differ among treatments, but N retention was greater ($p < 0.05$) in LW, MW and HW (2.2, 2.6 and 2.8 g/d) than CT (0.8 g/d). Microbial nitrogen yield was also greater ($p < 0.05$) in HW (17.3 g N/d) than CT (13.6 g N/d). Ruminal pH, was unaffected by treatment, but from 0.5 to 2 hr after feeding, ruminal ammonia N was greater ($p < 0.05$) in sheep fed wormwood diets (8.2-9.7 mg/100ml) than in those fed CT (6.9-7.2 mg/100ml). Total-VFA concentration at 1 and 2 hr after feeding was greater ($p < 0.05$) in sheep fed LW (9.5 and 10.4 mmol/100ml) or MW (10.6 and 10.2 mmol/100ml) than CT (9.1 and 8.8 mmol/100ml). In conclusion, this study suggests that replacing concentrate with 3-5 % wormwood improved N balance and the efficiency of N retention in the sheep.

Key Words: Wormwood, Digestibility, Ruminal Fermentation

M223 Effects of nonstructural carbohydrate and protein sources on performance, ruminal fermentation, total tract digestibility and feeding behavior in growing calves. A. Rotger, A. Ferret, S. Calsamiglia*, and X. Manteca, *Universitat Autònoma de Barcelona Edifici V, Campus UAB, Bellaterra 08193, Barcelona, Spain.*

Four rumen fistulated Holstein calves (BW 132.3 ± 1.61 kg) fed high concentrate diets (10 to 90, forage to concentrate ratio) were assigned to a 4 x 4 Latin square design to investigate the effects of nonstructural carbohydrate (barley or corn) and protein (soybean meal or sunflower meal) sources on ruminal fermentation and animal performance. The following 2 x 2 factorial arrangement of treatments (13.7% CP, 2.8 Mcal ME/kg DM) was used: 1) Barley-Soybean meal; 2) Barley-Sunflower meal; 3) Corn-Soybean meal and 4) Corn-Sunflower meal. Data were analyzed using the PROC MIXED procedure of SAS, main factors being nonstructural carbohydrate source, protein source and their inter-

action. Calf and period were considered random effects. Intake of DM was higher in the corn vs. barley based diets ($P < 0.05$), without affecting ADG (1.2 ± 0.12 kg/d). Consequently, feed efficiency was higher for the barley based diets. Average ruminal pH, total VFA and NH_3N concentration were not affected by main factors (6.6 ± 0.14 , 116.4 ± 5.27 mM and 5.9 ± 2.17 mg/dL, respectively). Total VFA per kg of DM intake was lower in the corn vs. barley based diets (20.07 vs. 25.42 mM/kg DMI, $P = 0.02$) and no significant effects were observed for the proportions of individual VFA. Nonstructural carbohydrate and protein sources did not affect total tract digestibility of DM and OM, estimated with chromium oxide (64.5 ± 2.67 and 65.1 ± 2.74 %, respectively). Feeding behavior, measured by scan sampling at 5 minute intervals, did not vary significantly among treatments. Calves spent 9.97, 2.11, 25.13 and 62.79% of the time eating, drinking, ruminating and resting, respectively. In conclusion, while nonstructural carbohydrate source affected intake, feed efficiency and total VFA per kg of DM intake, protein source did not affect these measurements.

Rabbit Species

M224 Effects of dietary mannan oligosaccharide in comparison to oxytetracyclin on cecal fermentation and performance of rabbits. A.P. Fonseca¹, L. Falcão¹, P. Spring*², and A. Kocher³, ¹Universidade Técnica de Lisboa Instituto Superior de Agronomia, Lisboa, Portugal, ²Swiss College of Agriculture, Zollikofen, Switzerland, ³Alltech Biotechnology Center, Dunboyne, Co. Meath, Ireland.

Digestive disorders in rabbits are quite frequent. Feed additives, which can lower the risk of digestive disorders and enhance performance are useful tools to the rabbit nutritionist. The aims of the present trials were to compare the effects of mannan oligosaccharide (MOS) and oxytetracycline (OTC) on rabbit performance and intestinal fermentation. Two trials were set up as complete randomized designs with Hybrid Hyla rabbits (31 to 70 days). Rabbits were housed individually in metabolic cages. Grower feed was offered through day 46 and finisher feed from day 47 to the end of the trial. The diets did either contain 2000ppm of MOS (Bio-Mos[®], Alltech Inc.) or OTC (20%) in the grower and 1000ppm of MOS or OTC in the finisher diet, respectively. Trial 1 was performed with 48 rabbits. Performance as well as purine derivatives excreted in the urine and caecotrophes (soft feces) composition was determined.

Trial 2 involved 24 rabbit. Performance, diet digestibility and cecal pH and VFA concentrations were determined. All data were subjected to ANOVA. Average daily gain and FCR did not differ between treatments. ADG was 41.7g and 44.1g for the MOS treatment vs. 42.7g and 43.9g for the OTC treatment in trial 1 and 2, respectively (RSD 4.2 and 2.9). Average feed conversion was 3.05 in trial 1 and 3.50 in trial 2 and was not affected by treatment. Composition of the soft feces did not differ among treatments. Diets did affect purine derivatives excretion. Allantoin and uric acid excretion did not differ between treatments; however, rabbits fed MOS did excrete significantly less hipoxantin and xantin. Diet digestibility in trial 2 was modestly affected by treatment, with a significant improvement in ADL digestibility for MOS compared to OTC. Average cecal pH was 6.2 for both treatments. Total VFA concentrations averaged 36 mmol/l and did not differ between treatments. Under the present trial conditions performance with MOS was similar to performance with OTC. MOS did show a reduction in mortality. Differences in cecal fermentation patterns and diet digestibility were modest between the two additives.

M225 Minimum dry period length to maximize performance. M. T. Kuhn*, J. L. Hutchison, and H. D. Norman, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

The objective of this research was to find the minimum dry period length while maintaining performance in the subsequent lactation. The number of days dry, month of calving in the subsequent lactation, linear and quadratic effects of the last somatic cell score in the previous lactation, linear and quadratic effects of previous days open, and linear and quadratic effects of age at subsequent lactation were included in the model to look at the effect of dry period length on actual milk yield in the subsequent lactation, adjusted for producing ability. Data included Holstein cows first calving from 1997 to 1999. There were 64,100 records with a second lactation, 28,376 with a third lactation, and 11,997 with a fourth lactation. Peak yield during the following lactation occurred at a dry period length of 45 to 60 days for parities 2, 3, and 4. A difference in milk production of +33, +50, and -16 kg between 56 to 60 and 61 to 70 days dry was not significant for lactations 2, 3, and 4, respectively. A dry period length over 70 days resulted in a 250, 622, and 727 kg decrease in milk production for lactations 2, 3, and 4, respectively. Although peak yield in subsequent lactation occurred between 45 and 60 days, the rate of increase from zero to 45 days was not linear. Cows that were dry from zero to 35 days following first, second, and third lactations showed an average decrease of 1111, 491, and 1802 kg in second, third, and fourth lactations, respectively. In contrast, cows that were dry from 35 to 45 days had an average loss of only 280, 172, and 182 kg in lactations two, three, and four, respectively. Further research

will determine optimum dry period length for lifetime yield, somatic cell score, female fertility, fat and protein percentages, and productive life.

Key Words: Dry Period Length, Milk Production, Performance

M226 Effect of photoperiod on milk production in lactating dairy cows. M. J. VanBaale*¹, D. V. Armstrong¹, R. M. Mattingly², and J. B. Fiscalini², ¹The University of Arizona, Tucson, ²Fiscalini Dairy Farm, Modesto, CA.

Ninety-eight multiparous and 60 primiparous Holstein animals were utilized in an extended lighting trial to investigate photoperiods impact on milk yield. After parturition all animals were housed in one pen until 20 DIM under normal daylight/nightlight conditions. On d 21, animals were randomly assigned into two treatment groups receiving supplemental light (SL) or normal daylight and darkness (NL). There were four groups of multiparous cows; two were assigned to SL and two to NL. There were only two groups of primiparous animals that were assigned to SL or NL. While in freestalls both multiparous and primiparous cows in the SL groups were exposed to 17h of natural light and SL above 15 foot candle (FC) and 7h of light below 5 FC in the freestall area. The light exposure for the NL groups followed the normal sunrise-sunset pattern common for the north 40th parallel of sunrise 0530 to 0730 and sunset 1700 to 1900, an average of 12h of light and darkness. Light intensity was measured every two wks at 2200 to 2300 at two points in the freestall barn (feed manger and outside lane at animal head level) and in the milking parlor holding pen (front, middle, and back). Diets for both treatments were balanced for 52 kg milk/d. There was no difference ($P = 0.48$) observed between primiparous animals assigned to SL (32.9 kg/d) or NL (32.7 kg/d) treatments. Multiparous cows in

SL groups produced more ($P < 0.05$) milk (49.4 kg/d) than the multiparous groups on the NL treatments (46.5 kg/d). Average pen DMI for multiparous (29.3 vs. 28.4 kg/d) and primiparous (23.4 vs. 22.4 kg/d) animals exposed to SL or NL were not measurably different. Exposure to increased lighting enhanced milk production in multiparous cows but had no effect on primiparous animals. Intakes were similar for the multiparous animal groups exposed to increased day length; however, milk yield was improved. Since no physiological measurements were obtained it is not known what contributed to the increase in milk yield, but increased lighting is an effective management practice that can be used to improve milk production on high producing dairy herds in the San Joaquin Valley of California.

Key Words: Photoperiod, Lactating, Dairy Cows

M227 Reasons and timing of cows leaving dairy herds in Florida and Georgia. B. L. Butler* and A. de Vries, *Department of Animal Sciences, University of Florida, Gainesville.*

Our objectives were to determine the reasons and timing of cows leaving dairy herds in Florida and Georgia. DHIA records for individual cows ($n=61,532$) culled on 257 Florida and Georgia dairy herds between 2000 and 2002 were used in the analyses. Producers using DHIA list a major reason for culling. Reasons for culling include voluntary reasons such as cows sold for dairy purposes (DHI code 2) and culled for low milk production (3). Involuntary reasons for culling include feet and legs (1), reproductive problems (4), injury (5), death (6), mastitis (7), disease (8) and udder problems (9). Frequency of the reasons for culling were calculated for the month of culling, herd size (small: 50 to 199 cows, medium: 200 to 699 and large: > 700) and days in last lactation. Values are expressed as average herd cull rates. Total cull rates in months January through December were respectively 3.27%, 3.13%, 3.50%, 2.56%, 3.06%, 2.73%, 3.00%, 3.20%, 3.13%, 3.40%, 3.30% and 3.82% ($p < .0001$). Frequency of death (6) ranged from a high in August (0.42%) to a low in May (0.27%). Most reproductive culls (4) were in January (0.41%), with the fewest in June (0.26%). Annual herd size culling rates for small, medium and large herds were 34.2%, 30.6% and 32.5% ($p < .0001$). Most feet and leg (1) culls were at large farms (4.04%) with the fewest in small herds (1.75%). By herd size, reproductive culls (4) were SM: 5.98%, MD: 4.43% and LG:3.12%. The median days in milk by culling reasons 1 to 9 were respectively 182, 138, 263, 412, 167, 90, 163, 129 and 186 days. Unlike other culling reasons, which occurred more frequently earlier in lactation (< 210 days), culling for reproductive problems (4) occurred more frequently later in lactation (> 240 days). We concluded that the seasonality in the main reasons for culling were substantial.

Key Words: Culling Reasons, Herd Size, Seasonality

M228 Effect of automatic milking systems on milk yield in Italian conditions. M. Speroni, G. Pirlo*, and S. Lolli, *Animal Production Research Institute via Porcellasco, Cremona, Italy.*

Automatic milking systems (AMS) are expected to increase milk yield because of the higher number of daily milkings in comparison with the conventional milking systems. Many factors can influence the number of milking per day per cow. Two of them are parity and environmental conditions which affect animals activity. Most of the studies on AMS have been carried out in Northern Europe and they do not consider the extreme conditions of the Southern Europe, where the summer is very hot and humid. The aim of this experiment was to compare milk yield of cows reared in identical condition and milked by AMS or by milking parlour (MP) in a typical Italian dairy herd located in the Po Valley. From November 2002 to November 2003, 26 primiparous and 10 pluriparous cows were milked with an AMS (DeLaval VMS[®]), at the same time on the other side of the barn 31 primiparous and 10 pluriparous were milked twice a day in a MP (8+8 herring-bone). A selection gate allowed cows to access to the AMS only if interval from last milking was > 5 h. Cows in the MP had milking intervals of 11 h and 13 h between morning and afternoon and between afternoon and morning respectively. Groups were fed the same TMR. Milk yield was recorded one day a week at each milking; temperature and humidity were recorded hourly and used to calculate temperature and humidity index (THI). Summer 2003 was particularly hot and THI constantly exceeded 72 between June and September. In the AMS, milking frequency (MF) was significantly higher ($P < 0.001$) in primiparous than in pluriparous cows. In winter and autumn, MF was 2.67 ± 0.03 and in spring and summer it

was 2.51 ± 0.05 . Effect of season on MF ($P < 0.005$) was higher in primiparous than in pluriparous. Pluriparous cows of AMS yielded 6.68 ± 0.83 kg/d of milk more ($P < 0.001$) than MP pluriparous cows. There was not difference in milk yield between AMS and MP primiparous cows. The negative effect of hot season ($P < 0.001$) was higher for AMS cows than for MP cows. In conclusion AMS increased milk yield but primiparous cows had some difficulties adapting to AMS. Both primiparous and pluriparous milked with AMS were more sensitive to high THI than cows milked with MP

Key Words: Automatic Milking System, Dairy Cows, Milk Yield

M229 Relationship between international body condition scoring systems. J. R. Roche*¹, P. G. Dillon², C. R. Stockdale³, L. Baumgard⁴, K. Macdonald¹, and M. VanBaale⁴, ¹Dexel, Hamilton, New Zealand, ²Teagasc Moorepark, Fermoy, Co. Cork, Ireland, ³Primary Industries Research Victoria, Kyabram, Victoria, Australia, ⁴The University of Arizona, Tucson.

Managing body reserves is critical for farm management, and requires an accurate assessment of the cow's 'condition'. BW alone is not a good indicator of body reserves, as cows of a specific weight may be tall and thin or short and fat. Therefore measuring BCS and changes in BCS of dairy cattle have become essential tools in both farm management and research. The subjective appraisal of body fat stores has been rationalized into numerical BCS systems, but there are many scales in use. In the United States and Europe, 5-point scales are in operation, while an 8-point scale is utilized in Australia and New Zealand uses a 10-point scale. In New Zealand and Ireland, BCS is assessed by palpating individual body parts, while in Australia and the United States the same body parts are visually evaluated. Even though the anatomical regions considered most important are similar in all systems, to date no attempt has been made to relate and compare these systems, making extrapolation and transfer of research findings difficult between systems, and dependent on simple mathematical conversions. The New Zealand 10-point scale was compared to the scoring systems in the U.S., Ireland and Australia by trained assessors. Cows were assessed visually in the U.S. and Australia, and in Ireland by palpating key areas of the cow's body ($n = 105, 112$ and 120 , respectively). Data were analyzed by regression. Positive linear relationships ($P < 0.001$) were found between the New Zealand 10-point and the U.S. 5-point BCS scale (USA = $1.5 + 0.32NZ$; $r^2 = 0.54$; Residual S.D. = 0.34), the European 5-point scale (IRE = $0.81 + 0.40NZ$; $r^2 = 0.72$; Residual S.D. = 0.16) and the Australian 8-point system of scoring (AUS = $2.2 + 0.54NZ$; $r^2 = 0.61$; Residual S.D. = 0.48). The recorded scores converged as the degree of emaciation increased. Results are useful for extrapolating research findings from different countries.

Key Words: Body Condition Score, Dairy Cows

M230 Evaluation of alternative body measurements for growing heifers. D. M. Lefebvre*, B. Gosselin, and R. Lacroix, *PATLQ - Quebec DHI Ste-Anne-de-Bellevue, Quebec, Canada.*

The objective of this study was to validate the use of the Hipometer[®] and other body measurements to evaluate dairy replacement growth. Measurements were made on 969 heifers (898 Holsteins, 71 Ayrshires) from 27 Quebec dairy herds. Body weight (BW) was measured using a portable electronic scale. Body weight predictions from hip width (HW) were made using a Hipometer. Additional measurements included heart girth (HG) taken with a flexible metal tape, height at the withers (HW) and at the hip (HH) using a measuring stick with a crossbar, and body condition score BCS (1-5 scale). BW predictions from HG (HGW) were also calculated using a polynomial equation in use at PATLQ ($559.18 - 22.841 * HG + 0.365 * HG^2 - 2.725 * 10^{-3} * HG^3 + 1.04 * 10^{-5} * HG^4 - 1.526 * 10^{-8} * HG^5$). Age and breed of the heifer were also recorded. Average age of measured heifers was 11.75 ± 7.15 months (Mean \pm SD), ranging from 0 to 30.5 months and BW was 334 ± 176 kg, ranging from 29 to 769. HW was 120 ± 18 cm (range 69-152 cm) and HH was 125 ± 18 cm (range 75-156 cm). HW was closely associated with BW: $HW = 0.9875 BW + 4.9795$; $r^2 = 0.9675$, SD = 31.7 but yielded greater variation than HG-predicted weight: $HGW = 1.0392 BW - 2.3935$; $r^2 = 0.9834$, SD = 23.7. A new second-degree polynomial equation for predicting BW from HG was developed but only yielded marginal improvement in precision ($BW = 58.5 - 2.09 * HG + 0.024 * HG^2$, $r^2 = 0.9843$, SD = 22.03). HW is the commonly used measurement to evaluate skeletal growth but HH is easier to obtain, is less subject to

be influenced by the posture of the heifer being measured and is used by breed associations to evaluate stature for type classification. HH was closely associated with HW, $HH=7.13 + 0.9795 * HW$, $r^2 = 0.984$, $SD=2.3$ cm. These results suggest that the Hipometer[®] is an acceptable method for evaluating BW but is less precise than HG. HH can be used to evaluate skeletal growth, but adjustments are required for comparisons to references.

Key Words: Dairy Heifer Growth

M231 Effect of bedding materials and modified rubber free-stall bases on stall usage by lactating dairy cows. R. Panivivat^{*1}, E. B. Kegley¹, D. W. Kellogg¹, J. A. Pennington², and Z. B. Johnson¹, ¹Department of Animal Science, University of Arkansas, Fayetteville, ²University of Arkansas Cooperative Extension Service, Little Rock, AR.

Two studies were conducted to observe cow preference for using stalls bedded with different materials. In the first experiment, a 2 x 3 factorial arrangement of treatments, commercially available rubber free-stall bases that filled the entire stall were compared to handmade modified rubber bases that filled only the rear half of the stalls, in conjunction with three types of bedding materials (rice hulls, sand, or a base of sand covered with rice hulls [combination]). Thirty-six stalls were equipped with either the full base or the modified base and stalls were filled with the three types of bedding from August 8 to 29, 2001. Cows were observed beginning 3-h post-milking, four times at 30 min intervals on d 7, 14, 21, and 31. Cows used the stalls equipped with the full bases (56% usage) more than the modified bases (44%; frequency procedure [$P < 0.05$]). Cows preferred the combination (61%) to the sand (52%), or the rice hulls (41%; $P < 0.01$). Using the GENMOD procedure, there was a type of base by material interaction ($P < 0.05$); stalls bedded with the combination were used 4.6 times more likely ($P < 0.01$) with the full base than with the modified base. In the second study, 36 stalls were equipped with the full bases and were bedded with the same three types of material from November 19 to December 19. Cows preferred the sand (72%) to the combination (69%), or the rice hulls (60%; $P < 0.001$). Bacterial counts in the bedding were determined on d 30, 31, and 38. There were material by day interactions ($P < 0.05$) for gram-negative, coliform, and *Streptococci* bacteria counts. Bacterial counts were greatest initially in rice hulls and lowest in sand; by d 38 counts were similar for all materials. Cows preferred stalls equipped with the commercially available free-stall bases that filled the entire stall. Cows also preferred stalls bedded with sand or the combination of materials rather than with rice hulls.

Key Words: Cow Preference, Bedding Material, Free-Stall Base

M232 Use of ambient and physiological markers to predict production changes in dairy cows resulting from acute heat challenge. J. D. Sampson^{*}, D. E. Spiers, J. N. Spain, R. P. Rhoads, and M. Ellersieck, University of Missouri, Columbia.

It is well known that cows reduce production during summer months with either acute or chronic exposure to heat stress (HS). An ambient indicator of heat stress (i.e., temperature-humidity index; THI) is traditionally used to predict milk yield (MY) of heat-stressed cows. More recently, a strain index (PSI) has been developed for humans using physiological markers (i.e., rectal temperature, heart rate) to determine HS impact (Moran et al., Am. J. Physiol. 275: R129-134, 1998). The objective of this study was to measure effects of acute HS on lactating dairy cows to identify ambient and physiological parameters that could be used to develop a similar strain index. Multiparous Holsteins (61±8 d postpartum) were acclimated to thermoneutral (TN) conditions (19°C, 55% RH) for 1 week, followed by TN or HS (29°C, 50% RH) exposure for 24 (n=6), 48 (n=4) or 96 (n=2) hrs. Individual daily milk yield (MY; 0400 and 1600 hr) and feed intake (FI) were recorded. Respiration rate (RR), skin temperature (Tsk) and rectal temperature (Tre) were measured every four hrs. Both MY and FI of HS cows decreased ($P < .05$) within 48 hrs from 34.5 to 28.2 kg and 40.2 to 24.5 kg, respectively. Likewise, Tre increased 0.5°C at 24 hrs and 1.7°C at 96 hrs of HS ($P < .05$). Multivariate linear analyses were performed to determine best predictors of production and thermal status. Only correlation coefficients (r) for HS alone were used for comparisons since these values were higher than for a combination TN and HS values. MY was linearly correlated with FI ($r = 0.79$), followed by Tre and change in Tre ($r = -0.73$). Likewise, best physiological predictors of FI included Tre and

change in Tre ($r = -0.75$). There was a close relationship between RR and Tre using either actual values ($r = 0.89$) or change from baseline ($r = 0.91$). Skin temperature was a reliable predictor of RR ($r=0.91$) and Tre ($r=0.88$). These data suggest that thermal status is a reliable predictor of production and should be used in different combinations when developing a PSI for the dairy cow.

Key Words: Heat Stress, Performance, Index

M233 Investigating effects of heat stress on milk production and composition of Iranian Holstein dairy cattle. A. Naserian^{*}, B. Saremi, and F. Karavan, Animal Science Department, Ferdowsi University of Mashhad.

Dairy farms are developing so fast in recent years at north of Iran. This area has a special climate condition (High temperature and humidity during May-October). It's so important to investigate effects of this climate on the performance of cows. The objective of this study was to investigate the effects of temperature and humidity of the weather via an Index (THI), which it is calculated from the following equation: $[Temperature^{\circ}F - (0.55-0.55 \times Humidity\%) \times (Temperature^{\circ}F-58)]$ on milk production and composition of Iranian Holstein dairy cattle in this area. Treatments consider as T1) THI<52 T2) THI between 52-62 T3) THI between 62-72 T4) THI between 72-82 T5) THI>82. Data were obtained from Gorgan dairy farm (700 heads), which is located at line coast of Caspian Sea at north of Iran (Golestan state). Cows were kept in open shed system and milked three times a day and rations were offered as a TMR. Study was conducted between years 2000-2004 and cows were fed according to NRC 1989 and 2001. Measured data were: 1) Mean daily milk for each cow adjusted to Fat 4% (MDM4), 2) Total milk production (TM), 3) Total milk production adjusted to fat 4% (TM4), 4) Fat% (Fat), 5) Maximum daily temperature (MaxT), 6) Daily humidity (Humid). Data were analyzed using General Linear Model procedures of SAS v6.12 to evaluate differences among experimental groups. The design was completely randomized. Means were compared with Duncan test. Data showed that there is a significant difference between MDM4, TM, TM4 and Fat by year and month of recording; at 2003-2004 and between December-May all of milk production and composition were improved ($p \leq 0.01$), which are because of improvement at management of the herd and lack existence of heat stress between mentioned months, respectively. Results showed that all measured factors were reduced significantly by increase in THI ($P \leq 0.05$) (Table1). The results of this study showed that investment for dairy industry in this area is possibly unaccepted.

Table 1: Effect of heat stress on milk production and composition of Holstein dairy cattle

THI	MDM4 Kg	TM Kg	TM4 Kg	Fat%
<52	17.91 ^a	4803 ^b	4451 ^b	3.53 ^a
52-62	18.10 ^a	5046 ^a	4663 ^a	3.52 ^a
62-72	17.17 ^b	4773 ^b	4376 ^b	3.45 ^b
72-82	15.80 ^c	4546 ^c	4090 ^c	3.33 ^c
>82	13.81 ^d	3961 ^d	3529 ^d	3.28 ^d

M234 Effects of different bone preparation methods (fresh, dry, and fat-free dry) on bone parameters and the correlations between bone-breaking strength and the other bone parameters. W.K. Kim^{*1}, L.M. Donalson¹, P. Herrera¹, C.L. Woodward¹, L.F. Kubena², D.J. Nisbet², and S.C. Ricke¹, ¹Texas A & M University, Collete Station, ²USDA-ARS, Southern Plains Agricultural Research Center, College Station, TX.

A study was conducted to evaluate effects of different bone preparation methods on bone parameters and the correlations between bone-breaking strength and the other bone parameters. Bone-breaking strength is dramatically altered depending on bone preparation methods whereas the other bone parameters such as ash content and ash concentration are not significantly influenced by bone preparation methods. Thus, the objective of this study was to evaluate the effects of three bone preparations (fresh, dry, and fat-free dry) on bone parameters. A

total of 60 Single Comb White Leghorn hens were used for this study. At the end of the 2nd laying cycle (approximately 120 wk of age), hens were euthanized using carbon dioxide gas, and the right tibia and femur were collected. The bones were divided into three treatment groups: fresh, dry, and fat-free dry. Fresh weight, bone volume, dried weight, ash weight, ash concentration, and bone-breaking strength were evaluated. There were no significant differences in fresh weight, bone volume, dried weight, ash weight, and ash concentration of tibia and femur among the treatments. However, fresh tibia (24.13 kg) had a greater bone-breaking strength compared to the dried (9.90 kg) and fat-free dried bones (7.41 kg) ($P < 0.05$). The bone-breaking strength (20.97 kg) of fresh femur was also significantly higher than the dried (9.22 kg) and fat-free dried femurs (6.94 kg). The bone-breaking strength of the fresh bone was highly correlated with dried weight, ash weight, and ash concentration whereas that of the fat-free dried bone was poorly correlated with the other bone parameters. The results indicate that fresh bone gives better bone-breaking strength correlated to the other bone parameters than dry or fat-free dry preparation.

M235 Interrelationships of traits measured on male Angora goats during a central performance test. F. A. Pfeiffer*, C. J. Lupton, and D. F. Waldron, *Texas Agricultural Experiment Station, College Station, TX, Texas A&M University System, San Angelo.*

A pooled correlation analysis was conducted to estimate the phenotypic relationships between traits measured, calculated, or scored on yearling Angora male goats ($n = 462$) that had participated in a central performance test (1997-2003). These annual tests were initiated in 1967 to evaluate goats from different herds at a central location for growth, mohair production, and fiber characteristics, and to help breeders identify genetically superior animals. Correlation analyses had been reported earlier (1981 to 1984 data) when selection emphasis was primarily on mohair production. With changes in economic emphasis and the size and structure of the Angora goat industry over the past ten years, it is of interest to re-estimate these correlations. Characteristics measured or scored included initial and final body weights (IW and FW), average daily gain (ADG), scrotal circumference, grease fleece weight (GFW), clean fleece weight (CFW), average fiber diameter (AFD) and variability (SDFD), clean yield (CY), med (M), kemp (K), average staple length, face cover score, neck cover score, and fleece character score. Previously reported significant correlations ($r = 0.3$, $P < 0.01$) between FW and the fleece weights were not present ($r < 0.1$, $P > 0.05$) in this analysis. Conversely, significant but antagonistic correlations ($r = -0.15$, $P < 0.01$) between ADG and the fleece weights and CY and AFD ($r = 0.18$, $P < 0.01$) were present in the current analysis but had not been reported previously ($r < 0.05$). The magnitude of the favorable correlation between FW and ADG ($r = 0.47$) and the antagonistic relationships between GFW and CY ($r = -0.23$), GFW and AFD ($r = 0.50$), and CFW and AFD ($r = 0.57$) were similar in both studies. Three previously unreported correlations are noteworthy: AFD and M ($r = 0.40$), M and K ($r = 0.60$), and ADG and SDFD ($r = 0.16$). The newly calculated correlation coefficients are expected to assist breeders to better understand the consequences of selecting for individual traits.

M236 Factors affecting performance and carcass characteristics of beef cattle: a meta-analysis. M. J. McPhee*, J. W. Oltjen, T. R. Famula, and R. D. Sainz, *Department of Animal Science, University of California, Davis.*

A meta-analysis of the main factors affecting finishing average daily gain (FADG; kg/day), intramuscular fat percentage (IMF), 12/13th rib fat (BF; cm), longissimus muscle area (REA; cm²) and kidney, pelvic and heart fat percentage (KPH) at harvest were assessed. Twenty-six papers from 1990 to 2003 were evaluated where consistent IMF data was a key selection criterion. Twenty experiments from 16 papers were selected and used in the analysis. Over 80 variables were entered into a data base and additional variables were created as the data were coded for analysis. In total 93 variables were available for analysis, e.g. sample sizes (n), pen numbers and s.d. for each carcass characteristic. Three categories were developed to distinguish: (1) end point at harvest (i.e.

age, weight or fat depth); (2) experimental unit (pen or individual animal (ExpUnit); and (3) weight class (WtClass) (e.g. adjusted for carcass weight). The data were analyzed using the mixed model procedure in SAS with n as the weighting variable. The terms in the model were paper, system (feedlot or pasture), implant (Yes or No), breed (8 categories), End Point, ExpUnit, WtClass, Weaning age, Days on feed before harvest (DOF), Final Age and Carcass wt. All terms were fitted as fixed effects except for paper which was fitted as random; weaning age, days on feed, final age and carcass weight were covariates. Non-significant terms were deleted from the model and the three most significant, determined by the F statistic, are reported. Residual variances of papers were 12, 4, 5, 6 and 4 % for FADG, IMF, BF, KPH and REA respectively. The most significant variables in order were: system, DOF and Carcass wt for FADG; System, Carcass wt and End Point for IMF; Carcass wt, Breed and WtClass for BF; Carcass wt, WtClass and End Point for KPH; and Carcass wt, Breed and Weaning age for REA. These analyses will provide valuable inputs to an ongoing program for modeling beef cattle growth and carcass quality.

Key Words: Cattle, Meta-Analysis, Carcass Characteristics

M237 Cow and calf performance in a management system including twinning and early weaning. R. Wasson*¹, J. E. Larson², D. R. Brown¹, A. DiCostanzo², J. D. Arthington³, and G. C. Lamb¹, ¹North Central Research and Outreach Center, University of Minnesota, Grand Rapids, ²Department of Animal Science, University of Minnesota, St. Paul, ³Range Cattle Research and Education Center, University of Florida, Opa.

We evaluated the effects of early weaning calves from cows that had twins on cow and calf performance, compared to a system of early-weaned single calves or normal weaned single calves. During the spring of 2003, cows that gave birth to twins simultaneous to cows calving to a single calf were assigned based on days postpartum and calf sex to one of three management systems: 1) cows with twins were maintained together until both calves were early-weaned from the cow at 81 ± 2.5 d (TWIN; $n = 7$); 2) cows with a single calf were maintained together until the calf was early-weaned at 76 ± 3.4 d (SE; $n = 8$); 3) cows with a single calf were maintained together until the calf was weaned at 202 ± 3.4 d (SL; $n = 8$). At early-weaning calves assigned to the TWIN and SE systems were exposed to a step-up feeding procedure until they consumed an 85% concentrate diet consisting of corn and soybean meal, with access to grass hay. Body weight (BW) and body condition score (BCS) of cows and BW of calves were recorded every 28 d. The MIXED model of SAS was used to analyze all data as repeated measures. At 60 d prior to calving BW and BCS of cows did not differ. At Calving the percentage change in BW and BCS was greater ($P < 0.05$) for SE (0% and 5.2 ± 0.2 for BW change and BCS, respectively) and SL (-3% and $5.6 \pm .2$ for BW change and BCS, respectively) than TWIN (-12% and $4.0 \pm .2$ for BW change and BCS, respectively) cows. At d 44, 72, and 100 BW and BCS was greater ($P < 0.05$) for SE and SL than TWIN cows, whereas at d 128 to 204 BW and BCS for TWIN cows was similar to SE and SL. Average BW of calves at birth was greater ($P < 0.01$) for SE (42.3 ± 8.6 kg) and SL (42.2 ± 8.1 kg) calves than individual TWIN (30.8 ± 6.5 kg) calves. From birth to d 204 ADG was greater ($P < 0.05$) for SE ($0.98 \pm .06$ kg) and SL (1.05 ± 0.06 kg) than individual TWIN (0.83 ± 0.04) calves; however, total weight per cow weaned was greater ($P < 0.05$) for TWIN (406 ± 13 kg) than SL (253 ± 12 kg) and SE (241 ± 12) systems. We conclude that weaning cows by 80 d with twins influenced BW change and BCS in cows. In addition, TWIN cows weaned more total calf-weight per cow than their single counterparts.

Key Words: Beef Cows, Twinning, Early Weaning

M238 Acute phase protein response to weaning and transport in calves produced by matings of Romosinuano, Angus, and Brahman. J. D. Arthington*¹, D. G. Riley², C. C. Chase, Jr.², W. A. Phillips³, and S. W. Coleman², ¹Univ. of Florida, Gainesville, ²USDA, ARS, Brooksville, FL, ³USDA, ARS, El Reno, OK.

Objectives were to assess acute phase protein (APP) response in calves due to weaning and transport, and to evaluate breed influence on any detected response. Straightbred and crossbred calves ($n = 297$) were produced from all possible matings of Romosinuano (R; tropically adapted breed native to Colombia), Angus (A), and Brahman (B) in central Florida. Calves were weaned at approximately 7 mo of age (September, 2002) and provided a commercial preconditioning concentrate and

free-choice grass hay. Approximately 28 d after weaning, steers (n = 143) were transported 2,200 km to central Oklahoma. As an estimate of inflammation, concentrations of ceruloplasmin, fibrinogen, and haptoglobin were measured in blood samples collected at weaning, 24 and 72 h post-weaning, and on the day of shipping, 24 and 72 h after arrival. Fixed effects were breed type (n = 9 levels: straightbreds [RR, AA, BB], and crossbreds [RA, AR, RB, BR, AB, BA] where letters indicate breed of calfs sire then dam, respectively), herd, sex (weaning only), and sampling time. Animal was a random effect. Following weaning, the concentration of each APP increased ($P < 0.01$; 15, 17, and 19% in the interval from weaning to 72 h for ceruloplasmin, fibrinogen, and haptoglobin, respectively). Irrespective of breed of sire, concentration of each APP was lesser ($P < 0.01$) in calves derived from B dams (average APP concentration = 21.7 and 23.2 mg/dL, 102 and 124 mg/dL, and 2.9 and 3.3 mg HbB for ceruloplasmin, fibrinogen, and haptoglobin, respectively). Following transportation, concentrations of ceruloplasmin and fibrinogen decreased ($P < 0.05$; 10 and 17% in the interval from pre-shipment to 72 h after arrival for ceruloplasmin and fibrinogen, respectively). In contrast, average haptoglobin concentration increased 78% for all calves by 24 h following arrival. Increased haptoglobin concentration was most evident as heterotic effects for AR; i.e., crossbred (AR and RA) concentration (2.71 mg HbB) was greater ($P < 0.01$) than straightbred (AA and RR) concentration (1.41 mg HbB). These data suggest that certain breed effects impact the APP response to calf weaning and shipping.

Key Words: Acute Phase Proteins, Romosinuano, Brahman

M239 Effects of fasting and handling stress of market pigs on plasma concentrations of stress-associated enzymes and carcass quality. D. H. Kim*, J. T. Seo, D. M. Ha, and C. Y. Lee, *Regional Animal Industry Research Center, Jinju National University, 150 Chilamdong, Jinju, Korea.*

One hundred and forty-four cross-bred market pigs weighing approximately 110 kg were randomly divided into six groups in a 3 (duration of fasting prior to loading; 0, 12 and 24 h) \times 2 (handling stress; minimal vs stimulated handling stress) factorial arrangement of treatments. The stimulated handling stress group received overall rough handling including electric prod stimulation during loading, transport and lairage at least once at each step. All the animals received 3-h lairage prior to slaughter. Blood and longissimus dorsi muscle (LM) samples were taken at slaughter and after overnight chilling of the carcass, respectively. Mean plasma glucose concentration, as expected, was less in the 12 h- or 24 h-fasting group than in the 0 h-fasting, whereas cortisol concentration was greater ($P < 0.05$) in the 24 h- vs 0 h-fasting group. Plasma concentrations of stress indicators glucose, cortisol, creatine kinase and lactate dehydrogenase were greater in the stimulated vs minimal handling stress group. There were no interactions between the duration of fasting and handling stress in their effects on these blood

variables. The incidence of pale, soft and exudative (PSE) carcass and drip loss of LM were reduced in the 12 h- or 24 h- vs 0 h-fasting group, whereas the 24-h postmortem LM pH and color including the lightness and redness were not affected by the duration of fasting. The incidence of PSE carcass and physico-chemical characteristics of LM, however, were not changed by the stimulated vs minimal handling stress. In conclusion, results suggest that fasting the market pig overnight prior to transport is desirable in terms of reducing the incidence of PSE carcass. Rough handling of market pigs may not affect the carcass quality of the animals when an enough lairage time is provided. However, rough handling inflicts a stimulated stress on the animal, which is manifested by increased blood concentrations of stress indicators, and therefore should be avoided for animal welfare.

Key Words: Pig, Stress, Carcass

M240 Economic evaluation of gestation crates versus loose-housing systems for gestating sows. M. Ellis, M. E. Kocher*, and G. D. Schnitkey, *University of Illinois, Urbana.*

The objective of this study was to model the economics of a change from confinement to loose-housing of gestating sows using an economic engineering approach. Analysis was conducted with the base case of a 2,200 sow breeding to weaning operation with gestating sows housed in two alternative systems (crates or loose-housing/fed from electronic sow feeders). Annual total costs for each system were estimated on the basis of the following assumptions. Building and equipment costs were depreciated over 15 and 10 years, respectively, assuming an interest rate of 7%. Total fixed costs of \$1,184,348 and \$1,236,786 for a crate and loose-housed system, respectively, which consisted of costs of building (\$656,613 and \$623,996, respectively), equipment (\$299,480 and \$375,615, respectively), and ownership (i.e., depreciation, interest, repairs, taxes, and insurance) (\$228,255 and \$237,175, respectively). Operating costs (i.e., labor, genetics, feed, utilities, transportation, and veterinary and medicine) and sow productivity levels were assumed to be the same for both systems. Total cost for the system based on gestation crates was \$1,311/sow/year (at a total floor space allowance of 1.67 m²/sow). The costs of the loose-housed system varied with the floor space allowed per sow. At the same floor space assumed for the conventional crate system (i.e. 1.67 m²/sow), the costs for the two systems were similar (\$1,311 vs. \$1,334/sow/year, respectively.) However, costs per sow increased with increasing floor space in the loose-housed system (e.g. 2.04 m²/sow = \$1,521; 2.42 m²/sow = \$1,701; 2.79 m²/sow = \$1,875). In conclusion, the cost to the industry of a move from gestation crates to loose-housed systems will depend on the floor space necessary for successful operation of the loose-housed system.

Horse Species

M241 Handling method influences equine urinary calcium and nitrogen. C. I. O'Connor*, B. D. Nielsen, and M. Mayack, *Michigan State University, East Lansing.*

Four mature geldings were used to study the effects of urine handling prior to analysis on Ca and N values. Urine was collected into a clean bucket and then poured through three layers of cheesecloth to remove any hair or debris. The urine was stirred to suspend any precipitate and 5 ml of urine was pipetted into 7-ml vials and the vials were tightly capped. An additional 500 ml of urine was poured into a total collection device (TCD) for later sampling. Urine from each of the 4 horses was blocked by horse and evaluated with twenty-one treatments. Seven combinations of holding time and temperature were examined (frozen immediately, 6 h at 30 C, 6 h at 10 C, 12 h at 30 C, 12 h at 10 C, TCD for 6 h, TCD for 12 h). There were 3 acidification methods evaluated for each combination (no acid, acid added just before freezing, or acid added after urine was thawed). Sample processing was completed within 45 min of collection. Acid was added at a rate of 20 μ l of 12 M HCl/ml urine. All samples were frozen at -4 C until analyzed. Differences between treatments were determined by orthogonal contrasts using the mixed model procedure in SAS 8.2. Urinary Ca was higher when acid was added compared to when no acid was added (1.52 mg/ml \pm 0.18 vs. 0.59 \pm 0.18) regardless of holding time, temperature, or location ($P < 0.01$). The addition of acid prior to freezing tended to result in

samples having higher Ca than samples in which acid was added after urine was thawed ($P = 0.07$), though no other variables had an effect. Urine N was unaffected by the addition of acid to the sample (1.04% \pm .26 vs. 1.05 \pm .26; $P = 0.22$). There was a trend for urine placed in the TCD for either 6 or 12 h to have lower N than urine not placed in the TCD ($P = 0.06$) and urinary N was higher when acid was added after thawing compared to before freezing (1.05% \pm 0.01 vs. 1.01 \pm 0.01; $P < 0.01$). There was no difference in N based upon holding time ($P = 0.77$). Vials were tightly capped and N was not able to volatilize, which may explain why other differences were not seen. These data suggest that urinary Ca is more sensitive to the addition of acid than urinary N but that urine handling methods do influence results.

Key Words: Horse, Urine Nitrogen, Calcium

M242 The effects of FEB-200 on serum progesterone and cortisol levels of pregnant mares in early gestation grazing on endophyte-infected tall fescue pastures. V. Akay*¹, R. Stepp², and P. Karnezos¹, ¹Alltech, Inc., Nicholasville, KY, ²Southern States Cooperative, Inc., Richmond, VA.

Fifty pregnant mares in early gestation from a commercial horse farm in Lexington, KY were used to evaluate the effects of modified gluco-

mannan ergot alkaloid adsorbent (FEB-200, Alltech, Inc., Nicholasville, KY) on serum progesterone and cortisol levels. Pregnant mares (36.2 d pregnant) were maintained on endophyte-infected fescue pastures. Fifteen of these 50 mares received 909 g/head/d of pelleted horse feed (EI-FESCUE). The remaining thirty-five pregnant mares received 909 g/head/d of pelleted horse feed, which included 20 g of FEB-200 (FEB-200). Mares began receiving their respective pelleted feed on June 2, 2003. Pasture tiller analysis indicated that endophyte infection level was higher than 80% in all endophyte-infected tall fescue pastures. Blood samples were drawn into evacuated tubes without anticoagulant every 21 d from May 29, 2003 through Aug 21, 2003. Samples were allowed to clot at room temperature, centrifuged at 1800 x g for 20 min, transferred into small vials, and then frozen (-20°C) for later analysis. Serum samples were analyzed for progesterone (P4) and cortisol levels by the University of Kentucky. Data were analyzed as completely randomized design using PROC MIXED procedure of SAS. PDIFF test was used to examine differences between means of treatments. Differences were declared significant at $P \leq 0.10$. Serum progesterone levels were higher for FEB-200 compared to EI-FESCUE (10.739 vs. 9.678 ng/dl, respectively). At the onset of the experiment, serum cortisol levels were 7.229 and 6.049 $\mu\text{g/dl}$ for EI-FESCUE and FEB-200, respectively. Change in serum cortisol levels was similar ($P = 0.10$) between EI-FESCUE and FEB-200. Pregnant mares grazing on endophyte-infected tall fescue pastures and supplemented daily with FEB-200 had higher serum progesterone levels compared to pregnant mares grazing on endophyte-infected tall fescue pastures without FEB-200 supplementation.

Key Words: Fescue, Progesterone, FEB-200

M243 The effect of MOS supplementation on immune response of mares and their foals. K. R. Spearman* and E. A. Ott, *University of Florida, Gainesville.*

Previous research in other species suggests that mannan oligosaccharide (MOS) supplementation to the diet has positive effects on immune function, including increased serum and colostrum immunoglobulin levels. The objective of this trial was to identify the effects of MOS supplementation to the diet on colostrum and serum immunoglobulin concentrations in the pregnant mare and serum immunoglobulin concentration in her foal. Twenty-six pregnant Thoroughbred ($n=21$) and Quarter Horse ($n=5$) mares were paired by expected foaling dates and assigned at random to the treatment or control group. Treatment mares received 10g of MOS mixed in 45g of ground corn in the morning ration. Control mares received 55g of ground corn in the morning ration. All mares were fed a concentrate designed to provide NRC recommended or higher nutrient intake when fed with Coastal bermudagrass hay or bahiagrass pasture *ad libitum* in season. Both treatments began 56 days prior to the expected foaling date (day-56) for each mare and continued through 28 days post-parturition (day 28). IgG, IgM, and IgA values were determined on mare serum at days -56, 0, and 28. IgG, IgM, and IgA values were determined on colostrum collected before the foal had nursed. IgG, IgM and IgA values were determined on foal serum collected at 0 hour (before foals had nursed), 6-10 hours post-parturition, and at days 7, 14, 28, 56, and 112 of age. The mares receiving MOS supplementation had higher colostrum IgA ($p=0.008$), IgG ($p=0.033$), and tended to have higher IgM ($p=0.076$) concentrations when controlled for pre-lactation colostrum loss, age, and breed. Pre-lactation adversely affected colostrum IgG ($p=0.006$) and IgA ($p=0.008$) immunoglobulin concentration, but had no effect on IgM concentration. There were no significant differences between treatments for mare or foal IgG, IgM, and IgA serum levels at any collection period. This trial suggests that MOS supplementation to pregnant mares increases colostrum immunoglobulin content.

M244 Influence of extender and processing method on fertility and motility of cold stored stallion semen. C. L. Dekat*, G. W. Webb, and K. E. Harrison, *Southwest Missouri State University, Springfield.*

Breeding with cold stored stallion semen has become commonplace in the horse industry. Addition of antioxidants to combat the deleterious effects of reactive oxygen species have been shown to improve motility and conception rate in cattle and sheep. Therefore, an experiment was designed to determine if pregnancy rates could be increased by supplementing the diluents used to store stallion spermatozoa with a Tyrode's

media containing pyruvate and lactate. Semen was collected from a mature stallion on an every other day basis. At least one aliquot from each ejaculate was diluted in a commercially available 2.4% skim milk-5% glucose extender (SKMG) (Exodus Breeder's Supply, York, PA) at a ratio of 3:1 (extender: semen). Additional aliquots were centrifuged at 400 x g for 10 min to remove the majority of seminal plasma. The sperm pellet was re-suspended with the same extender used in the other treatment supplemented at a ratio of 2:1 with a Tyrodes (Sigma # T2145) media (TLP) which contained 20mM lactate (Sigma #L1375) and 6mM pyruvate (Sigma # P4562). Following processing aliquots were stored for 48 h in a commercially available cooling device (Equine Express®, Exodus Breeder's Supply, York, PA). After storage aliquots were analyzed for spermatozoal motility (CASA system) and used to inseminate mares. Thirteen mares were assigned to extender treatment on an every other mare basis when a follicle of 30 mm was visualized by trans-rectal ultrasonography. At d 14 post ovulation mares were examined for pregnancy, administered prostaglandin, and assigned to the alternate extender treatment for the resulting estrus. No difference ($P > 0.05$) in pregnancy rates between SKMG, TLP, and fresh were realized even though spermatozoa stored in TLP had higher means for total and progressive motilities ($P < 0.05$). Findings of this study indicate that removal of seminal plasma by centrifugation and the addition of a Tyrode's media supplemented with lactate and pyruvate to long term storage media had a significant effect on motility but not conception rates.

Key Words: Stallion, Semen, Pyruvate

M245 Affect of pyruvate and cholesterol on post thaw motility of frozen stallion spermatozoa. K. E. Harrison*, G. W. Webb, and C. L. Dekat, *Southwest Missouri State University, Springfield.*

Inclusion of Tyrode's salt solution, pyruvate and/or cholesterol as components of semen extender has been shown to be beneficial for some stallions. The purpose of this study was to determine if either cholesterol or pyruvate, or the combination of the two, would be beneficial when stallion spermatozoa were frozen with an extender consisting of skim milk glucose supplemented with Tyrode's salt solution. Four ejaculates were collected from each of two stallions. After centrifugation at 400 x g to remove the majority of seminal plasma the sperm pellet was re-suspended in one of six extender treatments. Two treatments were re-suspended with 2.4% skim milk-5% glucose extender supplemented with a Tyrode's solution (Sigma # T2145) that contained 20mM lactate (Sigma # L1375) with (TLP) and without (TL) 6mM pyruvate (Sigma # P4562). The same diluents were used for two additional treatments with a further supplementation of a cholesterol-cyclodextrin complex (TLPC, TLC). The fifth treatment served as a control and was re-suspended in SKMG without Tyrode's solution. The first five treatments all contained egg yolk (4%) and glycerol (3%). The last treatment consisted of a commercially available Lactose-EDTA extender (E-Z Freezin, ARS, Chino, CA). Semen was packaged in 0.5 mL straws and frozen in liquid nitrogen. Following minimum 24 h storage, thawed samples were analyzed by CASA for total and progressive motility of sperm, VAP, VCL, VSL and elongation after 5, 10 and 15 min of warming. After 5 and 10 min of warming, motility ($P < .001$) and progressive motility ($P < .001$) of both aliquots that contained cholesterol (TLC, TLPC) were higher than all treatments. The inclusion of cholesterol as a component of a modified Tyrode's salt media used to supplement SKMG improved the post thaw motility of stallion spermatozoa.

M246 Influence of season and cooling device during commercial shipment of stallion semen. G. W. Webb*¹, M. J. Arns², M. A. Harris², and C. L. Dekat¹, ¹Southwest Missouri State University, Springfield, ²University of Arizona, Tucson.

Producers have several commercially available cooling devices available for use during the transportation of stallion semen. Some concern has been expressed regarding disposable static cooling devices in regards to their ability to maintain satisfactory cooling rates and/or storage temperatures. In the current study, Smart Button temperature loggers (Empire Instrument, Big Bear Lake, CA) were incorporated within diluted semen packaged according to manufacturers instructions for two commercially available transportation devices. One of the devices was a disposable unit and the other a standard rigid/plastic device designed for multiple shipments. A temperature logger was also attached externally

to measure ambient temperatures. Semen was collected from each of two stallions diluted at a ratio of 3:1 (extender: semen) with a commercially available stallion semen extender (Exodus Breeders Supply, York, PA) and packaged into each of the containers. Three sets of containers per season (winter and summer) were commercially shipped from Tucson, AZ to Springfield, MO with overnight delivery. Spermatozoal motilities were evaluated utilizing CASA following shipment. Containers were exposed to ambient temperatures that range from a high of 41°C during the summer to a low of 5.5°C during flight in the winter. Values for progressive motility of spermatozoa following 24 h of storage and shipment were similar ($P > .05$) for both cooling devices. Final storage temperatures following 24 h were similar ($P > .05$) for both devices. These data suggest that during both the winter and summer months in the southwestern United States, disposable cooling devices can be used to ship or cool stallion spermatozoa for 24 h.

M247 **Massage as a recovery method in exercising horses.** C. A. S. Porr* and K. Bennett-Wimbush, *Ohio State University, Wooster.*

Delayed onset muscular soreness (DOMS) is a painful condition which often occurs after unaccustomed or intense exercise. While no current therapy prevents DOMS, massage is a one that may alleviate pain more quickly, potentially allowing athletes to compete more effectively in subsequent exercise that may occur within a short time period. With regard to horses, the weight and ability of a rider can compromise proper back function, resulting in shortened strides, stiffened posture, and resistance to riders cues. The objective of this research was to evaluate the effects of massage as a recovery aid on subsequent performances of an exercise test in horses. Ten geldings, five Thoroughbreds (TB) and five Quarter Horses (QH), were randomly divided into two groups and subjected to two exercise tests. A test consisted of two exercise bouts with a 30 min recovery between them and a two hr data collection period following the second bout. Recovery between bouts was either control (walking and standing) or 30 min massage. Massage included a combination of Swedish and sports techniques, and was performed by a single certified equine massage practitioner. Horses in Group 1 received a massage recovery during the first test and a control recovery during the second while horses in Group 2 had reversed treatments. All horses received the same recovery after the second bout of exercise, and 10-12 d elapsed between exercise tests. Heart and respiration rates and plasma for lactate were collected before and after each exercise bout and at 5, 10, 20, 30, and 120 min post exercise. Serum for creatine kinase was collected before and after each exercise bout and at 120 min post exercise. Horses showed lower heart rate (46 ± 8 vs 52 ± 7 ; $P < .03$) and respiration rate (57 ± 15 vs 69 ± 13 ; $P < .05$) during the second exercise test, most likely due to lower environmental temperatures (24.9 vs. 20.8). Also, QH had higher serum lactate concentrations than TB ($P < .01$). There were no effects of massage on any parameters measured, though there were expected effects of exercise on each ($P < .0001$).

M249 **Residual feed intake (RFI) and serum concentrations of insulin in developing Brangus heifers from sires with differing EPDs for growth and scrotal circumference.** K. L. Shirley*¹, M. G. Thomas¹, D. H. Keisler², D. M. Hallford¹, D. M. Montrose¹, G. A. Silver¹, and M. D. Garcia¹, ¹New Mexico State University, Las Cruces, ²University of Missouri, Columbia.

Objectives were to evaluate growth, feed intake characteristics, and metabolic hormones related to puberty in Brangus heifers from a desert breeding program. Heifers were from sires with EPDs (accuracy) for yearling weight and scrotal circumference of 28.5 (0.55) and 0.2 (0.44) for a large growth-moderate scrotal circumference sire (LG-MSC), 17.2 (0.61) and 1.0 (0.49) for a moderate growth-large scrotal circumference sire (MG-LSC), and 19.5 (0.54) and 0.5 (0.44) for a sire with balanced EPD values. Eight heifers per sire were weaned at 6 mo of age, trained to a Calan gate system for daily feed intake evaluation, and fed a diet of 11.6% CP and 79.4% TDN until 15 mo of age. Heifers were bled twice weekly to determine concentrations of progesterone and metabolic hormones via RIA and BW was measured every two weeks. In 2003,

M248 **Comparisons of behavioral testing on Morgan horses at different training levels.** K. M. Holt and M. C. Nicodemus*, *Mississippi State University, Mississippi State.*

Horses with an early, successful show career are more profitable and while locomotive studies have been able to predict show performance, limited research has been done on behavioral characteristics that demonstrate show aptitude. The objectives were to quantify behavior in 2 training levels of Morgan horses by performing standardized behavioral tests: 1) 2-year olds in the initial stages of show training (Group 1) and 2) Adult horses (7-13 years old) successfully showing at an advanced level (Group 2). Comparisons of tests results should indicate that if Group 1 has similar results as Group 2 then they are more likely to demonstrate the same success in the future training process as Group 2. 6 registered Morgan horses, 3 for each group, were selected according to the following criteria: 1) consistently managed in the same program (W.H. Miner Agricultural Research Institute); 2) similar training and training levels within each group; and 3) were clinically healthy and sound. The following standardized behavioral tests were randomly performed in a consistent manner on the same day and location: 1) Learning retention- time for the horse to select a previously taught symbol; 2) Problem solving- time to find a reward placed under an obstacle; 3) Touch stimulus- amount of pressure on the skin before the horse reacts; 4) Auditory stimulus- time to re-approach a point where a loud noise was sounded; and 5) Visual stimulus- time to re-approach a point where an unfamiliar object was introduced. If the horse did not immediately and correctly perform test 1 or 2, "failing" was assigned. Both groups were similar in their results except for the learning retention test in which the adult horses were disinterested in the test, both the teaching and testing process, while the young horses were curious. While the similarity between group responses may indicate that the young horses, similar to the adult horses, should be successful in their future training process leading to a more promising show career, unforeseen events may hinder or further future performance. Larger sample populations with different backgrounds may result in more variations.

Table 1. Means (SD) of behavioral testing results for the young minimally trained (Group 1) and adult advanced-trained (Group 2) Morgan horses.

	Group 1	Group 2
Learning Retention	100% Pass	100% Fail
Problem Solving	67% Fail	67% Pass
Touch Stimulus (psi)	2.7(.8)	2.7(1.2)
Sound Stimulus (s)	3.7(4.1)	2.5(.5)
Visual Stimulus (s)	5.6(.8)	5.2(.9)

Key Words: Morgan Horses, Behavioral Testing, Training

results of ANOVA among sires were reported for growth traits, level of feed intake, serum concentrations of leptin, and puberty (J. Anim. Sci. 86(Suppl.1):236). These analyses suggested that heifers from the Balanced EPD sire achieved puberty (i.e., progesterone concentrations > 1 ng/ml) 1 mo earlier than heifers from LG-MSC or MG-LSC sires. Heifers from the Balanced EPD sire also consumed less feed from 11 to 13 mo of age, but no differences in serum concentrations of leptin were observed among sires. Further analyses suggest serum concentrations of insulin were lower ($P < 0.05$) in heifers from a sire with balanced EPDs relative to heifers from LG-MSC ($2.8 < 5.1 \pm 0.7$ ng/mL). Since a strong ($R^2 = 0.96$) regression was observed between BW and time, residual feed intake (RFI) was estimated by predicting daily feed intake with metabolic midweight ($BW^{0.75}$) and ADG. In heifers born to the sires with Balanced and LG-MSC EPDs, RFI was less ($P < 0.05$) than in heifers born to the MG-LSC sire ($-0.59 = -0.38 < 0.70 \pm 0.30$ kg/d). Results suggest Brangus heifers from a sire with balanced EPDs for growth and scrotal circumference appear to have concentrations of

insulin and RFI favorable for earlier onset of puberty than heifers from LG-MSC or MG-LSC sires.

Key Words: Heifer, Puberty, Intake

M250 Inhibition of development of bovine embryos by gossypol timing of inhibitory effects and possible involvement of apoptosis. J. Hernández-Cerón¹, F. D. Jousan^{*2}, P. Soto², and P. J. Hansen², ¹Universidad Nacional Autónoma de México, México, ²University of Florida, Gainesville.

Gossypol, a polyphenolic pigment in cottonseed, inhibits development of bovine preimplantation embryos. The embryonic stage most sensitive to gossypol is not known, however, nor the mechanism by which gossypol blocks development. Objectives were to characterize embryonic stages at which gossypol inhibits development and test involvement of apoptosis in actions of gossypol. For Exp. 1, presumptive one-cell embryos were cultured continuously in medium containing 0, 2.5, 5, and 10 µg/ml gossypol. Cleavage rate was not reduced by gossypol but the percent of one-cell embryos that became blastocysts 8 d post-insemination (pi) was reduced (P<0.05) by 10 µg/ml gossypol (14.4, 14.3, 12.2, and 7.6% for 0, 2.5, 5 and 10 µg/ml; 6 replicates with 180-242 oocytes/group, SEM=1.5%). For Exp. 2 (6 replicates, 237-268 oocytes/group), presumptive one-cell embryos were exposed to 0 or 10 µg/ml gossypol for either 24 h or 8 d. The proportion of embryos developing to the blastocyst stage was not reduced by 24-h exposure to gossypol (18.4 vs 17.7% for 0 or 10 µg/ml) but was reduced when gossypol exposure was for 8 d (13.0 vs 3.1%; gossypol x incubation time, P<0.03, SEM=1.5%). For Exp. 3 and 4, gossypol did not affect development to the blastocyst stage when two-cell embryos were collected at 30-31 hpi and cultured with gossypol until 8 dpi (Exp. 3) or for 24 h (Exp. 4). In Exp. 5, embryos > 16 cells were collected at 5 dpi, cultured with 0 or 10 µg/ml gossypol for 24 h, and analyzed by the TUNEL procedure to determine apoptosis (n=6 replicates/99-100 embryos/group). There was no effect of gossypol on cell number (51.0 ± 2.8 vs 51.9 ± 2.6 for control and gossypol, respectively) or the percentage of cells that were apoptotic (8.2 ± 0.7% vs 9.2 ± 0.6%). Results indicate that embryonic development can be disrupted by long-term exposure to 10 µg/ml gossypol and that exposure at the one-cell stage is required for disruption in development. Inhibition of development does not appear to involve induction of apoptosis. (USDA NRICGP 2002-35203-12664).

Key Words: Gossypol, Embryo, Apoptosis

M251 Distinct steroidal regulation of mRNAs for aromatase and gonadotropin receptors in bovine granulosa cells. W. X. Luo* and M. C. Wiltbank, University of Wisconsin-Madison, Madison.

Many genes are regulated through estrogen and androgen receptors; however, regulation of gene expression by these steroids in follicular cells has not been completely defined. Granulosa cells of 5 mm bovine follicles were cultured in Medium 199 with 1% fetal bovine serum. Real-time PCR was used to determine mRNA concentrations. In expt. 1, cells were treated with eight different doses of 17 beta-estradiol (E₂), testosterone (T), or 5 alpha-dihydrotestosterone (DHT) for 5 days. Aromatase mRNA was induced by all doses of E₂, but only by high doses (300, 100, 30, 10ng/ml) of T and DHT. Concentrations of LH receptor mRNA increased only after treatments with high doses of E₂, T, and DHT. FSH receptor mRNA was increased by high doses of T and DHT, but not by any dose of E₂. In expt. 2, cells were treated with 30 ng/ml of E₂, T, or DHT for 1, 3, or 5 days. Aromatase mRNA was increased by E₂ and T at all days, but only after 5 d of DHT treatment. The mRNA for LH receptor was not increased by any steroidal treatment on day1. E₂ and T stimulated LH receptor expression on days 3 and 5. FSH receptor mRNA was induced by T and DHT on all days, but by E₂ only on day 1. In expt. 3, ICI (specific estradiol receptor antagonist) inhibited E₂-induced aromatase and LH receptor mRNA expression. In expt. 4, cells were treated with different combinations of FSH (F) (0.3 ng/ml), E₂ (30 ng/ml), and DHT (30 ng/ml) to investigate synergistic effects. F + E₂ + DHT dramatically synergized to induce aromatase mRNA expression compared with other treatments (F + E₂ + DHT = 2373%; FSH = 166%; E₂ = 519%; DHT = 92%; F + E₂ = 1022%; F + DHT = 254%; E₂ + DHT = 760% of control). Thus, androgen from the thecal cells specifically induces FSH receptor and synergizes with FSH and estradiol to induce aromatase expression in granulosa cells. These inter- and

intra-cellular regulatory mechanisms may be critical for normal follicle growth and dominant follicle selection.

Key Words: Granulosa Cell, mRNA, Steroid

M252 Expression of genes encoding steroidogenic enzymes and *in vitro* steroidogenesis by dominant bovine follicles during the 1st follicular wave. K. E. Valdez*¹, S. P. Cuneo², P. J. Gordon³, and A. M. Turzillo^{4,5}, ¹Physiological Sciences, University of Arizona, Tucson, ²Department of Veterinary Science and Microbiology, University of Arizona, Tucson, ³Dairy Veterinary Services, Chandler, AZ, ⁴Department of Physiology, University of Arizona, Tucson, ⁵Department of Animal Sciences, University of Arizona, Tucson.

The hallmark of follicle health is the capacity to produce estradiol (E₂), which requires supply of androgen from theca interna. During the 1st follicular wave following ovulation, concentrations of E₂ in follicular fluid (FF) of the dominant follicle peak around Day 4 of the wave and then quickly decline. The purpose of this study was to elucidate mechanisms responsible for this abrupt decline in E₂ production. Follicular dynamics were monitored by ultrasonography and dominant follicles were collected from Holstein heifers on Day 4, 6, or 8 of the 1st follicular wave (n=4/Day). Steady-state levels of mRNA encoding 17α-OH in theca interna and aromatase in granulosa cells were determined by ribonuclease protection assay. Theca interna and granulosa cells were cultured for 3 h. Granulosa cells were cultured in the presence or absence of 10⁻⁷ M testosterone as substrate for aromatase. Decreased ability of granulosa cells to produce estradiol on Day 6 preceded a loss in aromatase mRNA on Day 8. However, this decrease was not accompanied by significantly lower amounts of 17α-OH mRNA or decreased androstenedione (andro) production by theca interna. From these results we conclude that the decline in FF E₂ observed on Day 6 of the follicular wave is not due to lack of androgen substrate for aromatization or down-regulated expression of the aromatase gene, but instead may be the direct result of decreased activity of the aromatase enzyme within the granulosa cells. Supported by USDA 35203-9167.

M253 Effects of dietary supplemental fat on reproductive performance and body composition in pre-puberal beef heifers. A. R. Dos Santos*¹, S. T. Willard², O. J. Sharpe³, and R. C. Vann¹, ¹Brown Loam Experiment Station, Raymond, MS, ²Mississippi State University, Mississippi State, ³Sharpe Farm, Rolling Fork, MS.

Varying results have been reported on use of fat in animal diets to improve growth and influence body composition. Effects of feeding fat on reproduction may occur through stimulation of ovarian function in association with increased dietary energy. Previous data by our laboratory has shown a relationship between body composition (percent intramuscular fat; %IMF) and reproductive cyclicity in beef heifers. The objective of this study was to evaluate supplemental fat sources, tallow vs Extruded-expelled Soybean meal (ESBM), on reproductive performance and body composition traits in pre-puberal beef heifers. Angus-crossbred heifers (n=63; grazing Ryegrass/bermudagrass) were assigned to two diet groups: corn and commercial protein pellet (G1; n=31) with 3.6% fat (tallow; ME=4.70 Mcal/kg), and corn and ESBM (G2; n=32) with 4.2% fat (ESBM; ME=4.75 Mcal/kg). Diets were formulated to be isonitrogenous (CP 15%) and fed daily at 2.3 kg/hd for 70 d. Ultrasound measurements for body composition traits were taken at d 0, 23, 46, and 70 for ribeye area (REA), back fat (BF), rump fat (RF), gluteus medius depth (GMD) and %IMF. Blood was analyzed for serum progesterone

(P4), total (CH) and HDL-cholesterol. After d 70, estrus was synchronized using CIDRTM and heifers were bred AI. As determined by P4 and estrus detection through d 70, a similar proportion ($P>0.10$) of heifers G2 and G1 were cycling (78% vs 71%) prior to synchrony; however G2 had greater ($P<0.05$) luteal phase serum P4 pre-synchrony than G1. CH increased over the feeding period for both G1 and G2 ($P<0.05$). IMF stress score was negatively correlated to %IMF (-0.24 , $P<0.07$), and GMD was negatively correlated to GMD stress score (-0.34 , $P<0.006$). REA, BF, RF and GMD did not differ ($P>0.10$) relative to the two groups at any time. Pregnancy rate was 54.4% for G2 vs 45.7% for G1 ($P>0.10$). In summary, ESBM as a supplemental fat source vs tallow did not influence body composition or overall reproductive performance post-breeding (AI).

M254 Lipid transport in the developing bovine follicle: mRNA expression for selective uptake receptors increases and for endocytosis receptors decreases. N. Argov^{*1}, U. Moallem², and D. Sklan¹, ¹Hebrew University, Rehovot, Israel, ²ARO, Bet Dagan, Israel.

Differences in rates of steroid production and secretion will, eventually, determine the developmental rates of ovarian follicles. The major supply of cholesterol, the precursor for steroid and androgen biosynthesis, to ovarian cells is from circulating lipoproteins via membrane receptors from the low density lipoprotein receptor (LDL) superfamily. This occurs by either endocytosis, which has been described for very low density lipoprotein receptors (VLDLr) and for LDL receptors, (LDLr) and by the selective uptake pathway described for the scavenger receptor class B type 1 receptor and the recently described ovarian receptor, lipoprotein receptor related protein 8 (LRP8). The objective of this study was to determine mRNA expression of these four cholesterol receptors in bovine ovarian cells at four different stages of follicular development by semi-quantitative PCR. A different pattern of expression was found for the two types of receptors. In small antral follicles, mRNA expression of the endocytosis receptors was higher than in large antral follicles. Expression of LRP8 mRNA increased linearly with follicular size ($P<0.01$), together with an increase in LDL, VLDL and cholesterol concentrations in the follicular fluid ($P<0.01$). Expression of SRB1 mRNA tended to increase with follicular diameter ($P<0.1$). Since different mRNA expression patterns were found for the two types of receptor, this may imply different regulation of cholesterol supply at different stages of follicular development. Accumulation of LDL and VLDL particles in the follicular fluid of large antral follicles enhances cholesterol availability for the intense steroidogenic activity which is essential at these stages. These processes are vital for normal estrous cycles, follicular function and conception.

Key Words: Bovine, Follicular Development, Cholesterol

M255 The expression and localisation of angiogenic growth factors in the porcine corpus luteum. R. S. Robinson^{*}, A. J. Hammond, G. E. Mann, and M. G. Hunter, *Division of Animal Physiology, University of Nottingham, Sutton Bonington Campus, Loughborough, Leics, UK.*

The growth and development of the corpus luteum (CL) is dependent on angiogenesis. Studies in ruminants have shown that vascular endothelial growth factor (VEGF) and fibroblast growth factor 2 (FGF-2) are likely to be the most important factors controlling angiogenesis in the CL. However, to date, FGF-2 and VEGF protein have not been measured or localised in the porcine CL. The objective of this study was to determine VEGF and FGF-2 concentrations in the porcine CL throughout the oestrous cycle and localise components of the VEGF system. Ovaries were collected from the slaughterhouse and were divided into early, mid and late luteal phase based on their visual appearance ($n=4$ per group). From each animal, 3 CL were homogenised and VEGF and FGF-2 concentrations were determined by ELISA. VEGF and its 2 receptors, VEGFR-1 and VEGFR-2 were localised by immunocytochemistry. Both VEGF and FGF-2 concentrations varied with stage of the oestrous cycle ($P<0.05$). The highest concentrations of VEGF and FGF-2 were observed in the early luteal phase, at the time of the peak of angiogenesis, supporting the hypothesis that FGF-2 and VEGF are key angiogenic factors in the porcine CL. VEGF was localised to both small and large luteal cells at all stages. The strongest VEGFR-1 immunostaining was observed in the endothelial cells of larger capillaries,

but was also present in the cytoplasm of large and small luteal cells at all stages of the cycle. There was moderate staining of VEGFR-2 in the endothelial cells of both larger capillaries and luteal parenchyma throughout the cycle. Since VEGF was localised to the hormone producing cells and the VEGF receptors to endothelial cells, this suggests that VEGF stimulates angiogenesis in a paracrine manner. VEGFR-2 staining was also seen on the membrane and in the cytoplasm of luteal cells, pre-dominantly in the mid and late luteal phase CL, which suggests that VEGF may also regulate luteal cell function. In conclusion, FGF-2 and VEGF system are present in the porcine CL and are likely to play an active role in porcine CL angiogenesis.

Key Words: Pig, Corpus Luteum, Angiogenesis

M256 Factors associated with multiple ovulation in lactating dairy cows. H. Lopez^{*1}, D. C. Caraviello¹, L.D. Satter^{1,2}, and M. C. Wiltbank¹, ¹Dairy Science Department, University of Wisconsin, ²US Dairy Forage Research Center, USDA-ARS, Madison.

The objective of this study was to evaluate factors that might alter natural multiple ovulation rate in lactating dairy cows. Ovaries of cows ($n=267$; > 50 days in milk; DIM) were evaluated weekly by transectal ultrasonography to determine natural (no hormonal treatment) ovulation rate. Cows were fitted with a transmitter to record standing estrous activity, were housed in a freestall barn, and were milked twice daily with milk production recorded. Serum concentrations of progesterone (P4) were recorded weekly starting at wk 1 postpartum and body condition scores (BCS) were determined for all cows monthly. There were 76 (28.5%) anovular and 191 (71.5%) ovular cows by 70 DIM. Lower BCS ($P<0.001$), but not level of milk production ($P>0.10$), was associated with the incidence of anovulation. Multiple ovulation rate for first ovulations in anovular cows that naturally recovered from the condition was 46.3% [19/41]. For second and subsequent ovulations ($n=463$), the level of milk production for 14 d before the d of estrus was associated with increased ovulatory rate ($P<0.001$). To illustrate, incidence of multiple ovulations was 1.6% [2/128], 16.9% [32/189], and 47.9% [70/146] for ovulations when cows were producing <35 , 35 to <45 , and $\#880545$ kg/d, respectively. Duration of estrus (4.3 ± 0.7 vs. 9.9 ± 0.5 h; $P<0.001$) was shorter for multiple (47.2 ± 0.9 kg/d; 92 ± 5 DIM; $n=48$) than single ovulations (38.1 ± 0.5 kg/d; 95 ± 2 DIM; $n=237$). Serum concentrations of estradiol were lower (5.5 ± 0.3 ; $n=15$ vs. 7.8 ± 0.4 pg/ml; $n=71$; $P=0.005$) for estruses with multiple ovulations in spite of larger preovulatory follicle volume (4136 ± 123 vs. 3085 ± 110 mm³; $P<0.001$). Similarly, 7 d later, serum P4 was lower (2.5 ± 0.3 vs. 3.2 ± 0.1 ng/ml; $P=0.04$) in multiple than in single ovulations in spite of larger luteal tissue volume (8291 ± 516 vs. 6405 ± 158 mm³; $P<0.001$). In summary, first ovulation after an anovular condition, and level of milk production for 14 d before the day of estrus, were associated with increased rates of multiple ovulations. Additionally, multiple ovulations were associated with lower E2 at estrus, shorter duration of estrus, and lower P4 7 d after estrus.

Key Words: Dairy Cow, Multiple Ovulation, Milk Production

M257 What regulates ovine placental steroidogenesis? C. Weems^{*}, Y. Weems^{*}, and C. Yin, *University of Hawaii, Honolulu.*

By d 90, the placenta (PL) secretes half of the progesterone (P4) and 85% of the estradiol-17 β in blood and ovariectomy (OVX) does not abort ewes (Y Weems et al., Prostaglandins (PG) 46:277, 1992; 48:139, 1994). Regulation of luteal P4 secretion at d 90 of pregnancy is by PGE₂, not LH, in ewes (Y Weems et al., PG 53:337, 1997) and PGE concentration in uterine and ovarian venous plasma (6 ng/ml) is similar (Y Weems PG 46:277, 1993). Ovine PL PGE secretion is regulated by LH up to d 50 and by pregnancy specific protein B (PSPB) after d 50 of pregnancy (Y Weems et al., PG 71:55, 2003). Indomethacin (INDO), a PG synthesis inhibitor, lowers P4 and PGE in blood by half at d 90 (Bridges et al., PG 58:113; 58:267, 1999). Ovine PL from d 90 OVX pregnant ewes secrete 2-3 fold more estradiol-17 β , PSPB, PGE, and P4, but not PGF₂ α in vitro than intact ewes (Y Weems et al., PG 58:139, 1999). The objective was to determine what regulates ovine PL P4 and estradiol-17 β secretion at d 90 of pregnancy. In Expt. 1, PL slices from d 90 intact or OVX (d 83) pregnant ewes were incubated in vitro in M-199 with vehicle, LH, FSH, PL lactogen, PGE₁, PGE₂, PGD₂, PGI₂, IGF₁, IGF₂, LTC₄, PAF-16, or PAF-18 (1, 10, or 100 ng/ml) for 4 hr. In Expt.

2, PL slices from d 90 intact and OVX (d 83) ewes were incubated in vitro with vehicle, INDO, meclufenamate (MECLO), PGE₁, PGE₂, INDO+PGE₁, MECLO+PGE₁, or MECLO+PGE₂ for 4 hr. Media were analyzed for P4, estradiol-17β, PGE, or PGF₂α by RIA. Hormone data in media were analyzed in Expt. 1 by a 2x3x13 and in Expt. 2 by a 2x9 factorial ANOVA. In Expt. 1, PL P4, PGE, or estradiol-17β secretion was increased (P<0.05) by OVX (two-fold), P4 was not increased (P>0.05) by any treatment other than OVX, and only FSH increased (P<0.05) estradiol-17β secretion (two-fold) in both OVX and intact ewes. In Expt. 2, INDO or MECLO decreased (P<0.05) PL P4 secretion by 88% but did not decrease (P>0.05) PL estradiolβ secretion from intact or OVX ewes and PGE₁ or PGE₂ increased (P<0.05) P4 secretion by more than two-fold only in ewes also treated with INDO or MECLO. It is concluded that FSH probably regulates d 90 ovine PL estradiol-17β secretion, while PGE₁ or PGE₂ regulates d 90 PL P4 secretion.

Key Words: Placenta, Sheep, Steroidogenesis

M258 Evaluation of an SNP in steroidogenic acute regulatory (STAR) protein for reproductive traits in swine. J. G. Kim*, J. L. Vallet, R. K. Christenson, G. A. Rohrer, and D. J. Nonneman, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

STAR transports cholesterol from the outer to the inner mitochondrial membrane, which is the rate limiting step for steroidogenesis. STAR mRNA is expressed in reproductive organs including the testis, ovary, and placenta of the pig. The porcine STAR gene was previously mapped by PCR-RFLP analysis to a region that is within one (chromosome 15; 95% confidence interval: 53-101 cM) of several QTL associated with ovulation rate in swine. However, sequence variation in the porcine STAR gene and its association with swine reproductive traits has not been studied. The objectives of this study were to 1) confirm the location of the STAR gene, 2) identify sequence variation in the coding region, and 3) determine the association of STAR gene single nucleotide polymorphisms (SNPs) with reproductive traits. Primers were designed to amplify and sequence the STAR gene. Two contiguous SNPs (G/C and G/T) in STAR were identified from genomic DNA of Meishan x White composite pigs. The G/T polymorphism changes amino acid 126 from valine to leucine. An assay was designed to genotype the SNP by mass spectrometry. Genotyping of the founders of the resource population indicated that the T allele was found only in Meishans (frequency = 0.81). F2, F8, and F9 gilts with phenotypic data were genotyped for association analysis. Linkage analysis mapped the STAR gene to chromosome 15 position 58.5 cM. Data were analyzed by the General Linear Models procedure of SAS. There was no significant association between the SNP and ovulation rate or age at puberty. Ovulation rate for TT homozygotes (n = 30), GT heterozygotes (n = 90), and GG homozygotes (n = 79) were 12.8 ± 0.53 (least squares mean ± standard error), 13.4 ± 0.32, and 13.4 ± 0.35, respectively. Age at puberty for TT homozygotes (n = 33), GT heterozygotes (n = 93), and GG homozygotes (n = 97) were 169 ± 6, 166 ± 3, and 170 ± 4 days, respectively. Although STAR is located in a QTL region for ovulation rate in the pig, this polymorphism does not appear to affect ovulation rate or age at puberty significantly.

Key Words: Ovulation Rate, Age At Puberty, Gene Mapping

M259 Ontogeny of uterine gene expression in the prepuberal pig. R. L. Richardson*, G. J. Hausman¹, R. Rekaya², L. Lee-Rutherford¹, R. R. Kraeling¹, and C. R. Barb¹, ¹USDA-ARS, Athens, GA, ²University of Georgia, Athens.

The molecular mechanisms that regulate uterine development in the pig are not understood. To better understand physiological pathways controlling uterine function, a custom microarray was developed to profile differential gene expression. Oligonucleotides (70 mer) were produced from sequenced ESTs from the Meat Animal Research Center, ARS, USDA libraries that had at least 90% homology to known genes in The Institute of Genome Research pig gene index. Total uterine RNA was isolated from gilts at 90, 150, and 210 days (d) of age and dye labeled cDNA probes were hybridized to arrays representing about 600 pig genes involved in growth and reproduction. Quantitative analysis using a mixed linear model statistical program identified (P<0.01) 45 genes differentially expressed from 90 to 210 d of age, which included growth factor/hormone receptors, growth and cell cycle regulators, apoptosis and seven transcription factors. The gene bone morphogenetic protein

4, a structural protein and signaling growth factor, was down regulated at 90 d and up-regulated at 150 d. The gene for zona pellucida glycoprotein 3A (sperm receptor) was up-regulated by 150 d and oviductal glycoprotein 1 was up-regulated by 210 d. Both of these genes play a role in the fertilization process and/or early embryonic development. A number of these differentially regulated genes expressed in the pig have not been reported in the human or the pig, including melanocortin 3 receptor and PPAR gamma coactivator 1. These results demonstrate, for the first time, differentially expressed uterine genes in the prepuberal pig. The temporal expression of these key genes that regulate uterine development and function during the prepuberal period will lead to a better understanding of the molecular mechanisms controlling fertilization and early embryonic development.

Key Words: Pig, Uterus, Gene

M260 Observed frequency of monozygotic twinning in lactating Holstein cows. N. Silva Del Rio*, B. W. Kirkpatrick, and P. M. Fricke, *University of Wisconsin - Madison, Madison.*

Bonniers equation has been used to mathematically estimate the frequency of monozygotic twinning in epidemiologic studies of twinning in dairy cattle. Our objective was to empirically determine the frequency of monozygotic twinning in lactating Holstein cows and compare it with that predicted by Bonniers equation. Ear biopsies were collected from 102 sets of Holstein twins from 6 Wisconsin dairies resulting in a sex ratio (Bull:Heifer) distribution of 39% B:H, 27% B:B, 34% H:H. The frequency of monozygotic twinning estimated using Bonniers equation based on the deviation from the expected sex ratio distribution of 50% B:H, 25% B:B, 25% H:H was 34.6% of same-sex twins and 21.0% of all twins. To empirically determine the frequency of monozygotic twinning, DNA was extracted from ear biopsies from same-sex twins (62/102) and was PCR amplified using primers for seven polymorphic microsatellite markers (BM4305, BM6425, BM9289, BMS360, BMS650, BMS823, UW20). Mixed-sex and same-sex twins differing in at least one microsatellite marker genotype were classified as dizygotic twins. Same-sex twins were classified as monozygotic when genotypes were identical for at least 5 microsatellite markers. Of the 62 same-sex twins, 58 were classified as dizygotic and 4 were classified as monozygotic resulting in a monozygotic twinning frequency of 6.5% of same-sex twins and 3.9% of all twins. Complete twinning data was collected throughout a 12-month period on two of the farms representing a total of 1,291 calvings. Both farm (P<0.0001) and season of calving (P<0.005) affected twinning rate. The overall twinning rate was 12.1% for farm 1 and 3.9% for farm 2. Twinning rate was 8.3% from April to June and 9.8% from July to September, both of which were greater (P<0.0005) than the twinning rate of 5.3% from October to December and 2.3% from January to March. We conclude that Bonniers equation overestimated the frequency of monozygotic twinning in this population of Holstein cows. *Supported by USDA NRICGP grant 2002-02033 to PMF*

Key Words: Twinning, Dairy Cattle, Monozygotic

M261 Ontogeny of ovarian gene expression in the prepuberal pig. R. L. Richardson¹, C. R. Barb¹, R. Rekaya², L. Lee-Rutherford¹, R. R. Kraeling¹, and G. J. Hausman*¹, ¹USDA-ARS, Athens, GA, ²University of Georgia, Athens.

The molecular mechanisms that regulate ovarian development in the pig are complex. To better understand physiological pathways controlling functions of the ovary, a custom microarray was developed to profile differential gene expression. Oligonucleotides (70 mer) were produced from sequenced ESTs from the Meat Animal Research Center, ARS, USDA libraries that had at least 90% homology to known genes in The Institute of Genome Research pig gene index. Total ovarian RNA was isolated from gilts at 90, 150 and 210 days (d) of age and used to prepare dye labeled cDNA probes, which were hybridized to arrays representing about 600 pig genes involved in growth and reproduction. Quantitative analysis using a mixed linear model statistical program identified (P<0.01) 41 genes differentially expressed from 90 to 210 d of age, which included genes involved in lipid/steroid metabolism, cell growth and regulation, and extracellular matrix adhesion. The gene, protein kinase-c theta, involved in apoptosis was up-regulated at 210 d. The transcription factor, PRDM2, was up-regulated at 90 and 150 d, but down regulated at 210 d. One unknown gene was down-regulated at 90d and up-regulated by 210 d. A number of these differentially regulated genes which were

expressed in the pig ovary had not been reported in the human, including transcription factors, ATP binding cassette B member 11 and CAAT/enhancer binding protein alpha. These results demonstrate, for the first time, differentially expressed pig genes in the prepuberal pig. The ontogeny of expression of these key genes that regulate ovarian development and function leading to onset of follicular growth during the prepuberal period will lead to a more detailed understanding of the molecular mechanisms controlling follicular development and ovulation.

Key Words: Pig, Ovary, Gene

M262 Ovarian activity of dairy cows fed two amounts of phosphorus. S. K. Tallam*, A. D. Ealy, L. C. Griel, Jr., K. A. Bryan, and Z. Wu, *Pennsylvania State University, University Park.*

Multiparous Holstein cows were used to determine the effect of dietary P on ovarian activity and reproductive performance. Cows were assigned randomly at calving to either a 0.35% (n = 27) or 0.47% (n = 27) P (DM basis) TMR; the high P diet was obtained by adding monosodium phosphate to the low P diet. Ovarian activity was monitored three times weekly by ultrasonography starting 10 DIM until the end of a 60-d voluntary waiting period, after which cows were synchronized and bred using the Ovsynch protocol. During wk 2 of lactation, the number of small (3-5 mm) or large (> 9 mm) follicles and the diameter of the dominant follicle did not differ between groups, but the number of medium (6-9 mm) follicles was lower for the low P diet than for the high P diet. Days to first ovulation and the diameter of the ovulating follicle were not affected by dietary P. During the first wave of follicular growth following the first ovulation, dietary P did not affect the number of follicles of all size categories or the diameter of the CL. The diameter of the dominant follicle was greater for the low P group during this period. Multiple ovulation rate or the proportion of cows that were anovulatory or developed follicular cysts did not differ between groups. The first service conception rate and pregnancy loss during 30-60 d after AI were not influenced by dietary P treatment. Milk production for the first 170 d of lactation, based on DHIA records, was not different between groups. Increasing dietary P from 0.35 to 0.47% did not improve ovarian activity.

Item	0.35% P	0.47% P	SEM	P
Number of small (3-5 mm) follicles ^a	4.6	4.4	0.6	0.81

M263 Association between plasma urea nitrogen levels and reproductive fluid urea nitrogen and ammonia concentrations in lactating dairy cows. D. S. Hammon*¹, G. R. Holyak², and T. R. Dhiman¹, ¹Utah State University, Logan, ²Oklahoma State University, Stillwater.

Two experiments were conducted to study the relationship between blood plasma urea N (PUN) and ammonia (NH₃), urea N concentrations in fluid of preovulatory follicles and in uterine fluids in lactating dairy cows. In Experiment 1, mean PUN levels were used to distribute cows into two groups: (1) cows with PUN #8805 20 mg/dl (HPUN), and (2) cows with PUN < 20 mg/dl (LPUN). Blood and follicular fluids from preovulatory follicles of 38 early lactation dairy cows were collected on the day of estrus (d 0) 4 hr after feed was offered. Follicular fluid NH₃ was significantly (P < 0.01) higher in HPUN cows (308.05 ± 72.27) compared to LPUN cows (93.88 ± 13.09). Follicular fluid urea N was

significantly (P < 0.001) higher in HPUN cows (22.36 ± 0.44) compared to LPUN cows (17.0 ± 0.34). PUN and follicular fluid urea N were correlated (r = 0.93) within cows. In Exp 2, blood and uterine fluids were collected from 30 cows on d 0 and on d 7. Uterine fluid NH₃ was significantly (P = 0.05) higher in HPUN cows (1562 uM ± 202) than in LPUN cows (1082 uM ± 202) on d 7 d, but not on d 0. Uterine fluid urea N was significantly (P < 0.001) higher in HPUN cows than in LPUN cows on d 0 (26.9 ± 1.3, 20.4 ± 0.7) and d 7 (26.5 ± 1.1, 21.4 ± 1.1). There was a significant (P < 0.01) correlation (r = 0.41) between PUN and uterine fluid urea N within cows. The results of this study indicate that high PUN concentrations were associated with elevated NH₃ and urea N concentrations in the preovulatory follicular fluids on the day of estrus and in the uterine fluid during the luteal phase of the estrous cycle in early lactation dairy cows. Elevated NH₃ or urea N concentrations in the reproductive fluids may contribute to reproductive inefficiency in dairy cows with elevated plasma urea nitrogen.

Key Words: Cattle, Urea, Ammonia

M264 Gonadotropin secretion and ovarian activity in non-pregnant mares treated continuously with GnRH during the anovulatory season. S. Morton*^{1,2}, D. Zieba^{1,2}, and G. L. Williams^{1,2}, ¹Texas A&M University Agricultural Research Station, Beeville, TX, ²Texas A&M University, College Station.

Objectives were to determine if low-dose, continuous infusion of GnRH from Fall to Spring would prevent seasonal anovulation in mares. Twenty Quarter Horse mares, ages 18 mo to 24 yrs, were stratified by age and body condition score and assigned randomly to either a saline Control (n = 9) or GnRH (n = 11) treatment group. Treatments were instituted between September 23 and October 9. Gonadotropin-releasing hormone was delivered in 0.9% physiological saline via Alzet osmotic minipumps (Model 2004) placed s.c. at the base of the neck, with Silastic sham pumps placed in control mares. Pumps were inserted on day 3 following ovulation or during the follicular phase if ovulation did not occur by October 9. Delivery rate of GnRH was 2.5 µg/h (60 µg/d) for the first 60 d, followed by 5.0 µg/h (120 µg/d) thereafter, with all pumps replaced every 30 d. By December 1, all mares had become anovulatory and remained anovulatory until February. Mean serum concentrations of LH were not affected by treatment in anovulatory mares. In contrast, control mares that exhibited ovulatory cycles after study onset had higher (P < 0.05) mean concentrations of LH during all phases of the estrous cycle except diestrus. Mean serum concentrations of FSH were not affected by treatment, but were lower (P < 0.05) from November through January relative to all other months in anovulatory mares. Interovulatory intervals in mares that cycled temporarily did not differ between groups. Ovulatory control mares had slightly larger (P < 0.10) follicles overall than GnRH-treated mares; however, ovulatory follicle diameters for control and GnRH-treated mares did not differ. Ovulatory control mares had higher (P < 0.10) mean concentrations of progesterone during metestrus and late diestrus. In a subgroup of control (n = 5) and GnRH-treated (n = 5) mares, total releasable pools of LH in response to 1 mg GnRH did not differ between groups. Ovulation resumed in 3 control and 3 GnRH-treated mares by March 30. Results indicate that continuous infusion of native GnRH at the doses employed in this study is not sufficient to maintain ovulatory cycles during the anovulatory season.

Key Words: GnRH, Seasonal Anovulation, Equine

M265 Effect of genetic strain, feed allowance, and parity on interval to first ovulation and the first estrous cycle in pasture-managed dairy cows. J. P. Meyer*¹, G. A. Verkerk², P. J. Gore², K. A. Macdonald², C. W. Holmes³, and M. C. Lucy¹, ¹University of Missouri, Columbia, ²Dexel Ltd., Hamilton, New Zealand, ³Massey University, Palmerston North, New Zealand.

Cows with North American (NA) pedigrees in traditional New Zealand (NZ) dairy herds may have poor reproductive performance. The objective was to measure postpartum anovulatory interval (PPAI) and the length of the first postpartum estrous cycle in strains of NA and NZ cows managed in a NZ pasture system. The Overseas90 strain (OS90; n=76) were modern NA cows [high breeding worth (BW) with predominately NA pedigree]; the NZ90 strain (n=86) were modern NZ cows (high BW with predominately NZ pedigree); and the NZ70 strain (n=45) were low BW cows with NZ pedigree. Cows (first, second, or third parity) were

allocated to different pasture-based feeding levels (tons DM per cow annually). Milk was sampled twice weekly and analyzed for progesterone (P4) to determine PPAI (interval to first milk P4 > 2 ng/ml) and the interval between first and second ovulations (cycle one). There was an effect of parity (P<.001), strain (P<.02) and a feed by strain interaction (P<.01) for PPAI. First parity cows had a longer PPAI (40±3 d) compared with second (28±3 d) or third (28±1 d) parity cows. The NZ90 strain had a longer PPAI (35±2 d) compared with either OS90 (27±2 d) or NZ70 (30±3 d). Increasing feed allowance did not decrease PPAI for OS90 or NZ70 cows but led to a shorter PPAI for NZ90 cows (44, 40, 27, and 30±4 d for 5.0, 5.5, 6.0, and 6.5, ton DM/cow, respectively). Cycle one was longer (P<.001) for OS90 (18±1 d) compared with NZ90 (13±1 d) or NZ70 (13±1 d) cows. Both parity and strain affect PPAI in dairy cattle. First parity cows had longer PPAI. Selection for production in NZ (NZ90 vs. NZ70) has led to longer PPAI that can be shortened by increasing feed allowance. OS90 cows have BW similar to NZ90 but shorter PPAI and a longer first cycle. Independent physiological mechanism may control PPAI and the first luteal phase in dairy cattle selected for production in NA and NZ.

Key Words: Postpartum, Dairy, Ovulation

M266 Effect of ovulation rate on development of the ovine corpus luteum. S. E. Echternkamp*, R. A. Cushman, and R. K. Christenson, *USDA, ARS US Meat Animal Research Center, Clay Center, NE.*

Relationships among ovulation rate (OR), corpus luteum (CL) weight (wt), and numbers of small (< 3mm dia.) and medium (3-6 mm) antral follicles were evaluated for Rambouillet (Ram), 1/2 Romanov x 1/2 Dorset (RxD), Romanov (Rom), and Synthetic III (1/2 Columbia x 1/4 Suffolk x 1/4 Hampshire; SIII) ewes. Ovaries were collected at slaughter on d 14 to 17 of pregnancy, and numbers of CL and of visible follicles were recorded. Ovaries and excised CL were weighed individually. None of the variables differed (P > 0.1; NS) between the left and right ovaries and data were combined. Means (± sem) for OR, ovarian wt (less CL), total CL wt, mean CL wt and number of small and medium follicles are reported in Table 1 for the four genetic groups. OR ranged from 2 to 10. Rom ewes had the largest (P < 0.01) OR but the lightest (P < 0.01) individual CL; RxD ewes were intermediate for OR and CL wt relative (P < 0.01) to Rom or to Ram and SIII. Thus, OR and individual CL wt correlated negatively (r = -0.72; P < 0.01). However, total CL wt and number of antral follicles did not differ (P > 0.1) among the genetic groups. SIII ewes had heavier (P < 0.01) ovaries than Rom or RxD. Variables did not differ (P > 0.1) between Ram and SIII. The negative relationship between OR and individual CL weight implies that either 1) the number of follicular cells and/or their luteinization is compromised in prolific ewes or 2) the progesterone threshold level for negative feedback on LH secretion is similar among individual ewes regardless of prolificacy; thus, development of individual CL is limited by lower LH stimulation in ewes with increased OR. Table 1. Genetic effects on OR, ovarian wt, total and individual CL wt, and follicle number

Breed	n	(OR) (No. CL)	Ovarian wt (g)	Total		Small follicles (n)	Medium follicles (n)
				CL wt (g)	Individual CL wt (g)		
Ram	7	2.3±0.4	4.03±0.33	1.83±0.14	0.80±0.05	42.8±6.0	7.0±1.4
RXD	17	3.2±0.3	3.66±0.22	1.59±0.11	0.53±0.03	43.6±3.8	7.2±0.9
Rom	26	4.8±0.3	3.46±0.17	1.60±0.09	0.35±0.02	39.3±3.1	7.5±0.7
SIII	17	2.4±0.3	4.91±0.22	1.73±0.11	0.71±0.03	37.4±3.8	9.2±0.9

Key Words: Ovulation Rate, Corpus Luteum, Sheep

M267 A comparison of the anti-luteolytic activities of recombinant ovine IFN-tau and alpha in sheep. M. P. Green*¹, L. D. Spate¹, J. A. Bixby¹, A. D. Ealy², and R. M. Roberts¹, ¹Dept. of Animal Science, University of Missouri, Columbia, ²Dept. of Dairy & Animal Science, Pennsylvania State University, University Park.

Interferon-tau (IFN-τ) is well established as the maternal recognition signal produced by ruminant conceptuses at the peri-implantation period. The question as to whether IFN-τ is superior as an anti-luteolytic agent to closely related Type I IFNs, such as IFN-α, however, remains unanswered. Previous studies have employed both intramuscular and

intrauterine administration of recombinant IFN-τ or IFN-α and demonstrated that both proteins can extend estrous cycle length in cattle and sheep, but a concurrent comparison of these IFNs has not been undertaken. Thus the aim of this study was to determine whether equivalent antiviral units of ovIFN-τ and ovIFN-α are equipotent in extending estrous cycle length. Recombinant ovine IFNs (ovIFN-τ4 and ovIFN-α1) were expressed in yeast (*Pichia pastoris*) and purified from the culture media. The anti-viral activity of the IFNs was determined on MDBK and ovine uterine epithelial cells by a cytopathic protection assay. Indwelling uterine catheters were fitted into crossbred ewes (n=16) and on d3 post-estrus (d0=estrus). Between d10 to 18 post-estrus, ewes received twice daily infusions of 0.7x10⁷U of either IFN-τ or -α in PBS (n=6 ewes/treatment), adjusted for protein concentration by addition of serum albumin. Control ewes (n=4) received an equivalent amount of serum albumin. Daily blood samples were collected and ewes were monitored twice daily for estrus. Mean estrous cycle lengths were 16.3±0.9, 21.7±4.0 and 33.3±13.9 days for control, IFN-α and IFN-τ treated ewes respectively. Recombinant IFN-τ (p=0.01) and to a lesser extent IFN-α (p=0.04) increased cycle length. Number of CL, d10 temperature and progesterone concentrations throughout the cycle were not significantly (p>0.1) different between the three groups. These data demonstrate ovIFN-α to be an anti-luteolytic agent, but not as potent of one as ovIFN-τ. Supported by NIH Grant HD21896.

Key Words: Interferon, Infusion, Ovine

M268 Effects of monensin supplementation peripartum in metabolic and reproductive parameters in anestrus postpartum Nellore cows. M. C. Matos*¹, D. F. Biluca², J. L. M. Vasconcelos², and F. S. Wechsler², ¹FCAV-UNESP Jaboticabal, SP Brazil, ²FMVZ-UNESP Botucatu, SP, Brazil.

The aim of this study was to evaluate the effects of monensin supplementation peripartum on plasma concentrations of insulin-like growth factor I (IGF-I), nonesterified fatty acids (NEFA), follicular diameter and response to GnRH in anestrus postpartum Nellore cows. Primiparous (n=123) and multiparous (n=179) cows were allocated randomly to 2 groups: G1 = 100g/d of a mineral supplement and G2 = 350g/d of a mineral supplement mixed with citrus pulp and monensin (150mg/d), from 30d prepartum to 90d postpartum. Blood samples, follicular diameter, and body condition score (BCS, scale of 1-5 adapted for 0.25 points) were determined at 54.3±23.08d postpartum, the d of GnRH injection (Cystorelin[®], 50µg, i.m). IGF-I and NEFA were analyzed in a sub-group of animals (n=120) by RIA and enzymatic methods, respectively. Follicular diameter and ovulation to GnRH injection were evaluated by ultrasound. Data were analyzed using a general linear models procedure. Cows supplemented with monensin had greater concentrations of IGF-I (112.0±6.91 vs 65.4±6.89ng/mL, P<0.01) and lower of NEFA (956.8±51.52 vs 1131.2±54.12µmol/L, P<0.05) in relation to the controls. Monensin ingestion increased (P<0.05) the average diameter of the largest follicle in the animals that did (10.0±0.18mm) or did not (9.5±0.17mm) receive monensin. Despite evidence of better metabolic status and larger follicular diameters, monensin did not increase the frequency of ovulation to GnRH (67.5±0.09 vs 63.7±0.09%) nor BCS (3.0±0.02 vs 3.1±0.02). Monensin influenced positively follicular diameter, probably due to effects on energy metabolism, which may have increased LH pulsatility and delayed the turnover of the dominant follicle. These data suggest that monensin ingestion can be a good strategy to improve energy status of peripartum cows and follicular development. This also could improve the responses to synchronization protocols and/or induce cyclicity in anestrus postpartum Nellore cows.

Key Words: Nellore Cows, Anestrus, Monensin

M269 Progesterone intravaginal device and/or calf removal on anestrus Angus/crossbred cows during a 60-day breeding season. J. L. M. Vasconcelos*, G. C. Perez, R. M. Santos, A. T. N. Silva, and A. B. B. Maciel, *FMVZ-UNESP Botucatu, SP, Brazil.*

The aim was to evaluate if treatment with a progesterone device and/or calf removal before the beginning of the 60-day breeding season (BS) could improve reproductive parameters in anestrus Angus/crossbred cows. Anestrus cows (n=286), 53±5 days postpartum (DPP), body condition scores (BCS) between 2.5 to 3.5 (1-5) were assigned to 4 groups: G1 (n=73) Control; G2 (n=70) calf removal (CR) for 48h; G3 (n=73) intravaginal progesterone device (CIDR(r)) for 7 days; G4

(n=70) CIDR for 7 days and CR for 48h. All groups were subject to AI 12h after heat detection. Ovarian structures and pregnancy were evaluated by ultrasound (Aloka SSD-500). BCS and cyclicity (evaluated by two ultrasound examinations 10 days apart) were determined before the beginning of BS. Data were analyzed by GLM, and the parameters included in the model were DPP, treatment, calf gender, BCS, and interactions. Cows bred during the BS were not affected by treatment: G1-53.3%; G2-64.1%; G3-56.5%; G4-64.5%. Number of days and conception to first IA were affected ($P<0.01$) by treatment: G1-28.5d; 45.7%; G2-13.3d; 29.3%; G3-26.9d; 50.9%; G4-9.6d; 76.6%, respectively. Treatment affected the number of days to conception (G1-34.3d; G2-40.5d; G3-36.4d; G4-13.0d; $P<0.01$), but not the percentage of cows pregnant at the end of the BS (G1-43.5%; G2-41.1%; G3-38.8% G4-45.5%). Conception at first AI and percentage of pregnant cows at the end of the BS were affected by BCS (2.5-40.2%; 20.4%; 2.75-42.5%; 37.5%; 3.0-41.6%; 40.7%; 3.25-56.8%; 54.1%; 3.5-72.0%; 58.3%; $P<0.05$), respectively. These data suggest that treatments G2 and G4 decrease the number of days to first AI, comparing with G1 and G3 (13.3d; 9.6d vs. 28.5d; 26.9d) respectively, but G2 had a decrease in conception (29.3%). Thus combining calf removal with CIDR insertion is a good strategy to induce fertile estrous and to enhance early season pregnancy. The responses may be even higher in cows with better body condition score.

Key Words: CIDR, Calf Removal, Short Cycle

M270 Effect of subluteal concentrations of progesterone on an estradiol cypionate induced LH surge in lactating Holstein cows. T. B. Hatler*, D. L. Ray, S. H. Hayes, and W. J. Silvia, *Department of Animal Science, University of Kentucky, Lexington.*

Intermediate circulating concentrations of progesterone (INT P4: 0.1-1.0 ng/ml) are often associated with ovarian follicular cysts in lactating dairy cows. The following experiment was conducted to determine if INT P4 during the follicular phase affected the occurrence of a LH surge induced by estradiol cypionate (ECP). Eazi-Breed CIDRs (1.38 g of progesterone) were preincubated in host cows for either 0, 14 or 28 days (CIDR-0, CIDR-14, CIDR-28, respectively) for subsequent use in this experiment. Ovaries of lactating Holstein cows were examined by transrectal ultrasonography to identify those with a corpus luteum (CL). Luteal function was later verified by RIA for P4 (>3.0 ng/ml). Within 24 hours of CL detection, preincubated CIDRs were inserted into 15 cows (n=5 per preincubation time). The day of CIDR insertion was designated as experimental day -1. Four cows received no CIDRs and served as controls (CONT). CIDRs remained in place for the following 3.5 days. Luteolysis was induced with 2 injections of PGF 2α (Lutalyse, 25 mg, i.m.) given at 6 PM on day -1 and at 6 AM on day 0. Plasma samples were collected from day -1 to 2.5 at 12 hour intervals to measure P4. At 6 AM on day 1, an injection of ECP (3 mg, i.m.) was administered. Blood samples were collected via jugular venous catheter every 2 hours for the next 36 hours to detect the LH surge. The average circulating concentration of progesterone in the four samples collected on

days 1 and 2 was calculated for each cow. The mean P4 concentrations were 1.20, 0.78, 0.45, and 0.11 ng/ml for cows treated with CIDR-0, CIDR-14, CIDR-28 and CONT, respectively ($P<0.01$). Treatment altered the occurrence of the ECP-induced LH surge ($P<0.01$). In all 4 CONT cows, the LH surge was detected an average of 18 hours after ECP injection. LH surges were not detected in any of the 5 CIDR-0 cows. The surge of LH was detected in 2 of 5 CIDR-14 and 4 of 5 CIDR-28 cows, respectively. It was concluded that intermediate progesterone during the follicular phase may contribute to cyst formation by blocking the estradiol-induced LH surge.

Key Words: Progesterone, Ovarian Follicular Cyst, LH Surge

M271 Effect of subluteal concentrations of progesterone on follicular phase events in lactating Holstein cows. T. B. Hatler*, D. L. Ray, S. H. Hayes, and W. J. Silvia, *Department of Animal Sciences, University of Kentucky, Lexington.*

Intermediate circulating concentrations of progesterone (INT P4: 0.1-1.0 ng/ml) are often associated with ovarian follicular cysts in lactating dairy cows. The following experiment was conducted to determine if INT P4 during the follicular phase prevented ovulation. In order to synchronize ovarian events, lactating Holstein cows were administered 2 injections of PGF 2α (Lutalyse, 25 mg, i.m.) 14 d apart. An injection of GnRH (Factrel, 100 μ g, i.m.) was administered 12 d later (designated experimental d 0). Daily transrectal ultrasonography of ovaries and collection of blood samples (for quantification of P4) began on d 0 and continued for the next 22 d. Eazi-Breed CIDRs (1.38 g of progesterone) were preincubated in host cows for either 0, 14 or 28 d (CIDR-0, CIDR-14, CIDR-28, respectively) for subsequent use in this experiment. On d 7(AM), preincubated CIDRs were inserted (CIDR-0 (n=5), CIDR-14 (n=5), CIDR-28 (n=6)) and left in place until the conclusion of the experiment. Cows without CIDRs served as untreated controls (CONT; n=4). Luteolysis was induced with 2 injections of Lutalyse (25 mg, i.m.) given 12 h apart on d 7 and 8. Jugular venous blood samples were collected every 4 h from 8 AM on d 9 to 8 AM on d 14 to detect the LH surge. Treatment with preincubated CIDRs during the follicular phase altered ($P>0.01$) the frequency of ovulation. Ovulation occurred in 0/5 and 1/5 cows treated with CIDR-0 and CIDR-14 while ovulation occurred in 3/6 and 4/4 cows treated with CIDR-28 and CONT, respectively. Preovulatory surges of LH were detected in all cows that ovulated and were not detected in any cows that did not ovulate. On average, LH surges were detected on d 11. Follicular phase concentrations of P4 were determined by calculating the average of P4 concentrations on d 9 thru 11. Circulating concentrations of P4 during the follicular phase were 1.25, 0.71, 0.36 and 0.14 ng/ml for CIDR-0, CIDR-14, CIDR-28 and CONT, respectively. Intermediate progesterone during the follicular phase may contribute to the formation of cysts by blocking the LH surge and thus, ovulation.

Key Words: Progesterone, Ovarian Follicular Cyst, LH Surge

PSA-Environment and Management

M272 Comparative study of body characteristics of broiler chickens from different rearing systems. A. O. Best*, W. L. Willis, and C. Murray, *Department of Animal Sciences, North Carolina A&T State University, Greensboro.*

An experiment was conducted to investigate the relationship between certain body characteristics and growth performance of broiler chickens subjected to different systems of rearing. Two hundred forty female day old broiler chicks were obtained from a local commercial hatchery, and divided into groups of 40. Each group was subjected to one of the following rearing systems: 1) battery cage-no heat; 2) battery cage-heat; 3) floor pens-no heat; 4) floor pens-heat; 5) pasture poultry-no heat and 6) floor pens/pasture. At seven weeks of age, whole carcass, bursa, gizzard, liver, spleen, stomach, and heart weights were taken. Abdominal and leg lengths were measured, and intestines lesion scores were observed. Although all birds were of the same age, their body characteristics were variable for each rearing system. Treatment 4, floor pens-heat, had the highest average body carcass weight (2.53 kg) and the lowest came from treatment 1, battery cage-no heat (1.37 kg). The bursa weights which reflect the health status of broilers in most treatments were above average, ranging from 0.20 (trt. 4) to 0.37 gms (trt.1). The mortality

rate was highest in the pastured poultry system (trt. 5). The results of this study indicate that different rearing systems influence the body characteristics such as organ weights, carcass weights and abdominal length.

Key Words: Body Characteristics, Broilers, Rearing Systems

M273 *Campylobacter Jejuni* Assessment in Organic vs. Conventional Reared Broiler Chickens. L. T. Donaldson*, W. L. Willis, and C. Murray, *Department of Animal Sciences, North Carolina A&T State University.*

An experiment was conducted to investigate the prevalence of *Campylobacter jejuni* in broiler chickens that were produced and marketed as organic or conventional. Trials were performed during the summer and winter utilizing three farms, each of which practice, organic or conventional rearing. Ten broilers from each farm were collected in the processing plant and subjected to carcass rinse (serial dilutions), crop swabbing, ceca swabbing and drug sensitivity prior to evisceration and after chilling. The prevalence of *Campylobacter jejuni* in organically

produced broilers vs conventional was very similar (93 vs 97%) respectively during the summer, but the percentage of positive conventional reared broilers was lower during the winter (77 vs 100% in organically reared broilers). The viable count for *Campylobacter jejuni* in conventional broilers showed a reduction during the winter from 27.3 to 15.3 cfus; whereas, the count in organic broilers increased during the winter from 28.3 to 58.9 cfus. The crop and ceca positive isolates were similar for both rearing systems. The drug sensitivity profile comparison did not differ greatly. Salmonella was found in 91% of the broiler fecal samples collected at the organic farms, while 81% of the samples were positive from the conventional reared broilers. The results from this study showed that organically produced poultry maybe highly contaminated with *Campylobacter jejuni* and care in handling should be encouraged to prevent foodborne illness in humans.

Key Words: *Campylobacter jejuni*, Broilers, Organic

M275 Effect of molting on *in vitro* tissue invasion by *Salmonella enteritidis*. R. W. Moore* and P. S. Holt, *United States Department of Agriculture, Agricultural Research Service, Southeast Poultry Research Laboratory, Athens, GA.*

A tissue culture was utilized to compare tissue cell invasion by *Salmonella enteritidis* from molted and full feed hens. Three identical trials were performed in which 80 wk-old active laying hens were divided into two groups of 6 birds each. The molted hen group was subjected to a 14 day feed withdrawal and full fed hen group was administered a standard layer ration. After feed treatment, crop, ileum, cecum, and ovary (small and large yellow follicles removed) were collected, rinsed in PBS, and placed into 50 mL of RPMI medium. The ends of intestine and crop tissues were tied to allow attachment of *Salmonella* only to the lumen surface. RPMI medium containing 10^7 - 10^8 CFU of novobiocin (NO) and nalidixic acid (NA) resistant phage type 13 *Salmonella enteritidis* was injected into the lumen of the intestine and crop tissues. Additionally, ovaries were incubated in 50 mL of RPMI medium containing 10^6 - 10^7 CFU of the *Salmonella enteritidis*. Tissues were incubated with *Salmonella* at 37°C for 2 hr, after which tissues were placed in 50 mL of fresh RPMI medium containing 500 µg/mL of gentamycin and incubated for 5 hr at 37°C to remove any *Salmonella* which had not penetrated tissues. Tissues were rinsed, stomached in 10 mL of PBS, serially diluted, and plated onto Brilliant Green agar containing 25 µg/mL NO and 20 µg/mL NA for *Salmonella* enumeration. *Salmonella* invasion of ovaries was reduced in tissues from molted hens in trials 1 and 2 as compared to full fed controls (> 1.2 log reduction), but not in trial 3. *Salmonella* invasion of ceca from molted hens was numerically increased in trials 1 and 2 and significantly increased in trial 3 as compared to controls (> 0.8 log increase). No significant differences in *Salmonella* invasion was determined for crops and ileum. These data suggest that molting may effect invasion of tissues by *Salmonella enteritidis*.

Key Words: *Salmonella Enteritidis*, Molt, Invasion

M276 Influence of experimental chlorate product (ECP) in drinking water on environment of the gastrointestinal tract and *Salmonella enteritidis* (SE) in laying hens during an induced molt. L. F. Kubena*¹, J. L. McReynolds¹, J. A. Byrd¹, R. C. Anderson¹, S. C. Ricke², and D. J. Nisbet¹, ¹USDA-ARS, SPARC, Food & Feed Safety Research Unit, College Station, TX, ²Department of Poultry Science, Texas A & M University, College Station.

The use of feed deprivation to induce molting and stimulate multiple egg-laying cycles in laying hens is a common practice in commercial egg production. Unfortunately, an increased risk of *Salmonella enteritidis* (SE) may result; therefore, alternative methods are needed. Hens over 50 wk of age were placed in individual laying cages, with 3 groups of 11 hens per treatment. Two wk prior to dietary changes, hens received an 8-h light and 16 h-dark photoperiod that continued for the 9-day experiment. All hens were challenged orally with 10^6 cfu of SE on day 4 of the study. Treatments were non-fed hens with distilled water (NFD), non-fed hens with the experimental chlorate product (ECP which provided 15mM chlorate ion concentration water; NFECP), alfalfa diets with distilled water (ALD), and alfalfa diets with ECP water (ALECP). When compared with the NFD hens, no significant changes in the pH of the crop or in the lactic acid concentrations of the crop and ceca for the NFECP or ALD hens occurred; however, the lactic acid concentrations were higher in the ALECP hens. Also, there were increases

in the concentrations of propionic acid and total volatile fatty acids of the ceca in the NFECP, ALD, and ALECP hens. When compared with NFD hens, the numbers of SE positive crop and ceca were reduced in the NFECP hens (67%, 35%), ALD hens (9%, 0%), and ALECP hens (84%, 59%). The ECP reduced invasion of the liver, spleen, and ovaries by more than 50%. The intake of alfalfa was low in this study and most likely accounts for the lowered protection against SE. Results suggest that ECP added to the drinking water may be a useful tool to reduce the risk of SE during an induced molt by feed deprivation or the use of alfalfa molting diets. The combination of ECP and the alfalfa molting diet was the most efficacious for several parameters, indicating that an active fermentation during molting is an important factor in maintaining a hostile environment for enteropathogens.

Key Words: Laying Hens, Molting, Experimental Chlorate Product

M277 Impact of the laying hen cycle and molting on the prevalence and populations of *Salmonella*. X. Li*, J. B. Payne, F. B. O. Santos, K. E. Anderson, and B. W. Sheldon, *Department of Poultry Science, North Carolina State University, Raleigh.*

Salmonella species are recognized as major foodborne pathogens that are closely associated with the consumption of contaminated poultry and egg products. The objective of this study was to determine whether the hen's laying cycle and feed withdrawal (molting) influence the prevalence and populations of *Salmonella* in the feces. Composite fecal samples were periodically taken from a commercial layer complex containing multiple houses. Each house contained 90,000 hens housed in 2700 cages arranged across 6 rows. Composite fecal samples across each row were collected from different houses as a function of bird age [18 wks (pullets housed), 25 to 28 wks (1st production cycle), 65 to 74 wks [molting] and 75 to 78 wks (2nd production cycle)]. Populations of *Salmonella* spp. were enumerated using a MPN (most probable number) procedure. House temperatures and ammonia levels were recorded at each sampling time. For 18-week birds, *Salmonella* populations ranged from log 1.81 to 1.97 MPN per g with 55.6% of the samples testing positive (n = 18). For the 25 to 28-week birds, *Salmonella* populations ranged from log 1.34 to 2.73 MPN per g with 41.7% testing positive (n = 24). No *Salmonella* (<1 log) were detected in the feces from 65 to 74-week (n = 12) and 75 to 78-week birds (n = 6). The average ammonia levels were 13.3, 55.0, 20.0 and 20.0 ppm for houses containing the 18, 25 to 28, 65 to 74 and 75 to 78-week old birds, respectively. The 18-week old birds had the highest incidence of *Salmonella*-positive (55.6%) samples but the lowest average ammonia levels whereas the 25 to 28-week old birds had the highest average population of *Salmonella* (log 2.73 MPN per g) and highest ammonia levels. These results indicate that layer age and feed withdrawal (molting) did impact both the incidence and populations of *Salmonella* recovered from layer feces. Moreover, feed withdrawal molting practices did not appear to increase the incidence or shedding of *Salmonella* in the feces.

Key Words: *Salmonella*, Production Cycle, Molting

M278 Late post-molt egg production in laying hens molted with different rations of alfalfa and layer ration. L. M. Donalson*¹, W. K. Kim¹, C. L. Woodward¹, P. Herrera¹, L. F. Kubena², D. J. Nisbet², and S. C. Ricke¹, ¹Department of Poultry Science, Texas A&M University, College Station, ²USDA Agricultural Research Service, College Station, TX.

A total of 116 White Leghorn laying hens were induced to molt after being acclimated and monitored for pre-molt egg production. The hens were then divided into five treatment groups: full fed (FF), feed withdrawal (FW), 100% alfalfa (A100), 90% alfalfa / 10% layer ration (A90), and 70% alfalfa / 30% layer ration (A70). The hens were put on a lighting program and molted for 9 days. At the end of the molt, 56 birds were euthanized and organ weights were taken while the other 60 were returned to a layer ration and evaluated for post-molt performance. Parameters examined included: egg height, egg weight, albumen height, yolk height, yolk diameter, shell breakage, specific gravity and overall egg production. Overall egg production was significantly lower (P<0.05) at week 17 when FF treatment birds were compared to A90, A100 and NF birds. At weeks 21 and 23 FF birds were significantly different than NF birds. At week 26, A100 birds had significantly shorter egg lengths than all other treatments. The yolk diameters from A70 birds were significantly smaller at week 22 than all other treatments. The yolk heights were significantly smaller in NF birds at weeks 24, 35 and 38

when compared to FF birds. FF birds had significantly lower albumen height measurements at weeks 17, 18, 23, 24, 25, 27 and 28 when compared to NF and at weeks 29 and 34 when compared to A70 and A90 respectively. A70 birds showed significantly higher egg weights at weeks 21, 24, 26, 27, 29, 33 and 34 when compared to A100 and at weeks 21, 27, 30, 31 and 33 when compared to FF. When shell breakage strengths were compared, A90 proved to be significantly stronger than A100, FF, and A70 at weeks 22, 24, and 30 respectively. Specific gravity for A90 also proved to be significantly higher than A70 and A100 at weeks 24 and 32.

Key Words: Molting, Egg Quality, Alfalfa

M279 Evaluating bone and eggshell parameters of molted hens at the end of 2nd laying cycle compared to non-molted hens. W. K. Kim*¹, L. M. Donalson¹, P. Herrera¹, C. L. Woodward¹, L. F. Kubena², D. J. Nisbet², and S. C. Ricke¹, ¹Texas A & M University, College Station, ²USDA-ARS, Southern Plains Agricultural Research Center, College Station, TX.

A study was conducted to evaluate bone and eggshell parameters of molted hens at the end of 2nd laying cycle. Osteoporosis in laying hens is important animal welfare issue as well as economic issue for the poultry industry. Osteoporosis in laying hens is defined as a condition that involves the progressive structural bone loss. Osteoporosis is one of the main reasons of subsequent fractures in laying hens. An induced molt using feed withdrawal is a potential factor increasing structural bone loss and the incident of osteoporosis in old laying hens. The objectives of this study were 1) to evaluate bone and eggshell parameters of molted hens at the end of 2nd laying cycle and 2) to evaluate the relationship between eggshell and bone parameters. A total of 60 Single Comb White Leghorn hens were used for this study. There were two controls and four molting treatments: full-fed control 1 (82 wk old) (FF1), full-fed control 2 (122 wk old) (FF2), feed withdrawal (FW), 100% alfalfa (A100), 90% alfalfa/10% layer ration (A90), and 70% alfalfa/30% layer ration (A70). At the end of the 2nd laying cycle (approximately 122 wk of age), eggs were collected, and then hens were euthanized by CO₂ to collect left tibia and femur. The tibia percent ash of the FF1 was significantly higher than the A90. The tibia ash concentration of the FF1 was significantly higher compared to the FW, A100, and A90 (P<0.05). The FF1 had a significantly greater femur percent ash than the A90 (P<0.05). In the eggshell parameters, the FF1 had significantly higher shell weight, percent shell, and shell thickness compared to the A100 (P<0.05). However, the egg weight of the FW was significantly heavier than the FF1 (P<0.05). The correlation analysis showed that overall bone parameters were negatively correlated with eggshell parameters. These results suggest that age of hens and molting practice have an impact on bone status of hens at the end of 2nd laying cycle, and eggshell formation is closely related to bone metabolism in laying hens.

Key Words: Molting, Bone Parameters, Eggshell

M280 Reduction of *Salmonella typhimurium* (ST) yeast agglutination and intestinal colonization in broilers by galactose or mannose liberated from guar gum. J. T. Lee*, S. E. Tichy, C. A. Bailey, A. L. Cartwright, and D. J. Caldwell, Texas A&M University System.

Several laboratories have reported on the ability mannose, administered by feed or drinking water, to interfere with *Salmonella* intestinal colonization in commercial poultry. Guar gum has a mannose backbone with galactose bound to alternating mannose sugars. The mannose:galactose ratio in guar gum is approximately 2:1. Addition of Hemicell[®], a galactomannanase, hydrolyzes the gum to produce mannose monomers and oligosaccharides as verified by the Matrix Assisted Laser Desorption and Ionization (MALDI) procedure. The objective of the present experiments was to investigate the ability of hydrolyzed guar gum to reduce the ST intestinal colonization in broiler chicks. First, an *in vitro* yeast agglutination test was performed to investigate the ability of hydrolyzed guar gum solution (4.5%) to prevent ST agglutination of yeast cells. Mannose and galactose solutions were used as positive and negative controls, respectively. Hydrolyzed guar gum solutions were as effective as mannose at inhibiting the ability of ST to agglutinate yeast cells while galactose had no inhibitory effect on agglutination. Two duplicate *in vivo* experiments were performed to determine the inhibitory ability of hydrolyzed guar gum, mannose, and galactose on ST cecal colonization (Log₁₀ ST cfu/g) in broiler chickens. Experiment 1 indicated galactose

(2.18 cfu/g) significantly (P<0.05) reduced ST cfu recovered from broilers while mannose (3.88 cfu/g) and hydrolyzed guar gum (2.40 cfu/g) did not differ from control (3.37 cfu/g). In experiment 2, mannose (0.82 cfu/g) and galactose (1.24 cfu/g) fed broilers significantly reduced ST recovered from the ceca while no difference was observed between control (2.23 cfu/g) and hydrolyzed guar gum treatments (2.10 cfu/g). These experiments indicate that both mannose and galactose interfere with the ability of ST to agglutinate yeast cells *in vitro* and colonize the ceca of broilers.

Key Words: Galactose, Guar Gum, Mannose

M281 Attachment of *Salmonella* and *Campylobacter* spp., to chicken spermatozoa viewed by scanning electron microscopy. N. A. Cox¹, J. S. Bailey¹, D. E. Cosby*¹, R. J. Buhr¹, L. J. Richardson¹, J. L. Wilson², D. V. Bourassa², W. L. Steffans³, and M. B. Ard³, ¹U. S. Department of Agriculture, Russell Research Center, Athens, GA, ²Department of Poultry Science, University of Georgia, Athens, ³Department of Veterinary Pathology, University of Georgia, Athens.

We previously demonstrated that vertical transmission of *Campylobacter* could occur. The mechanism of this transmission is still unclear. Previously negative broiler breeder flocks have been reported to become positive with the introduction of spike roosters at 45 wk of age. To determine if the rooster semen is a possible source of transmission to hens for colonization, we evaluated the association of both *Campylobacter* and *Salmonella* spp., to segments (head, mid-piece and tail) of individual spermatozoa after artificial inoculation. Three strains of *Salmonella* (Typhimurium, Heidelberg and Montevideo) or one strain of *Campylobacter jejuni* (in 0.85% saline) was added to a freshly collected (by abdominal massage) aliquot of pooled semen from roosters housed in individual cages. The semen-bacteria solutions were incubated 1 hour at room temperature. Samples were fixed in 2% (para)formaldehyde, 2% glutaraldehyde, 0.2% picric acid in 0.1 M Cacodylate-HCl buffer, pH 7.25, for 24 hours prior to centrifuging and rinsing in the 0.1 M Cacodylate-HCl buffer. Individual aliquot samples were placed on coverslips and allowed to settle overnight in a wet chamber. Samples were taken through an ethanol gradient and critical point dried in an Autosamdri-814 Critical Point Dryer. After drying, the coverslips were mounted and sputter coated with 300 angstroms of gold with the SPI-Module Sputter Coater. The samples were then viewed with a JSM-5800 Scanning Electron Microscope. *Salmonella* was found associated to all three segments (head, mid-piece and tail) of the spermatozoa apparently equally distributed. *Campylobacter* was mainly associated with the mid-piece and tail segments, with few located on the head segment. Further work is planned to determine if the adherence is actually attachment.

Key Words: *Salmonella*, *Campylobacter*, Spermatozoa

M282 Efficacy of Sal CURB[®] brand ASF liquid antimicrobial against various *Salmonella* species in a meat and bone meal matrix. M. L. Burke*, J. K. Murphy, and V. J. H. Sewalt, Kemin Americas, Inc., Des Moines, IA.

Sal CURB[®] brand ASF liquid antimicrobial (SC ASF) is a formaldehyde-based product that is used to maintain feeds and feed ingredients *Salmonella*-negative for up to 21 d. Previous work has demonstrated that an application rate of 6.5 lbs/ton of SC ASF is sufficient to eliminate *Salmonella* from corn/soy feed (Welch et al., 2003). Its efficacy against various *Salmonella* species in a high protein matrix, such as meat and bone meal, has not been fully explored. The purpose of this experiment was to evaluate the efficacy of SC ASF against *Salmonella typhimurium* ATCC 14028, *Salmonella senftenberg* ATCC 43845, *Salmonella montevideo* ATCC 8387, and *Salmonella enteritidis* ATCC 13076 in a meat and bone meal matrix. These strains, combined in the form of a lyophilized culture, were used to inoculate sterilized meat and bone meal at 1,500 CFU/g. The meat and bone meal was treated with 6.5, 9, 12 and 15 lb/ton of SC ASF. Samples were done in triplicate. A positive control and negative control were included in the study. The efficacy of SC ASF against *Salmonella* was determined by assaying for *Salmonella* via the FDA BAM methodology on Day 1 post-treatment, post-inoculation. Testing on Day 1 revealed that 12 and 15 lb/ton of SC ASF were sufficient to eliminate *Salmonella* in all replicates, and 9 lb/ton killed the *Salmonella* in two of the three replicates. Further studies are required to confirm if Sal CURB ASF can maintain

meat and bone meal Salmonella-free after re-exposure. Results of this study demonstrate that at least 9 lb/ton of Sal CURB[®] brand ASF liquid antimicrobial is required to effectively eliminate Salmonella in high protein matrices such as meat and bone meal, contrary to corn/soy feed, in which 6.5 lb/ton is sufficient.

Key Words: Sal CURB ASF, Salmonella, Meat and Bone Meal

M283 Effect of storage time on *Campylobacter jejuni* isolation and drug sensitivity in broiler wings. W. L. Willis*, K. Smith, and C. Murray, *Department of Animal Sciences, North Carolina A&T State University, Greensboro.*

An experiment was conducted to determine the effect of storage time on the isolation and drug sensitivity of *Campylobacter jejuni* (C.j.) from broiler wings subjected to a commercial antimicrobial treatment. In trial one, wings (2 each) were collected from 64 whole carcasses in a commercial processing plant produced as organic or conventional during the summer and winter. They were subjected to an antimicrobial treatment after chilling. The wings were pooled, placed into zip-locked storage bags, stored in the refrigerator for 1, 5, 10, and 15 days, then swabbed. Swabbs were plated on BBL blood Agar and incubated at 42° C for 24-48 hr then tested for C.j. presence and drug sensitivity. Disk-diffusion for drug sensitivity utilized five antimicrobials (enrofloxacin, erythromycin, gentamicin, tetracycline, and naladixic acid). In trial two, 8 non-commercial chicken wings from pastured and 8 conventional reared poultry were processed without an antimicrobial treatment. The wings were stored in a Campy-gas mixture and refrigerated for 1, 5, 10, and 15 days. The results from trial one showed no difference in the isolation of C.j. at 1, 5, or 10 days regardless of how they were raised or the storage time. C.j. could not be isolated from any 15 day samples. Trial 2 results were similar with almost 100 percent isolation, except for day 15. The treated wings showed a greater reduction ($P < 0.05$) in positive samples when compared to non-treated. C.j. was more susceptible to tetracycline than other drugs. There was a trend for 10-day C.j. isolates to become more susceptible to erythromycin. The results suggest that extended storage time affects the isolation of C.j. and drug sensitivity. Moreover, it was concluded that the antimicrobial treatment reduced C.j.

M284 Effect of Immustim[®] and Protimax[®] on *Campylobacter jejuni* and *Salmonella typhimurium* Populations in Broilers. J. Spruill*, R. Plunsk, J. Grimes, P. Ferket, and B. Sheldon, *North Carolina State University, Raleigh.*

The objective of study 1 was to estimate the populations of *S. typhimurium* (S) and *C. jejuni* (C) in the GI tracts of broilers fed a diet containing beta-1,3/1,6-glucan (Immustim[®]). Study 2 evaluated the effects of a diet containing a spray-dried egg product from immunized hens (Protimax[®]) on intestinal S and C populations. Both studies consisted of the same experimental design. Chicks (720) were placed 10/pen (12 pens/battery) in 3 rooms (2 batteries/room). C- and S-challenged and non-challenged chicks were housed in separate rooms. Pens were randomly assigned 1 of 3 feed treatments added to a standard starter feed. Dietary Immustim[®] levels were 0, 20 or 40g/ton. Feed treatments for the second study consisted of a negative control (a standard starter feed), a positive control (a spray-dried egg product without immunoglobulins) and Protimax[®] (both at 6kg/ton). In study 1, 3-day old chicks were gavaged with 1mL of 10⁶ cfu/mL of a nalidixic acid-resistant S strain. The C challenge (1mL of 10⁶ cfu/mL) occurred at 14d. Lower GI tract and cecal samples were collected on 7, 14, 17 (C only) and 21d. In study 2, chicks were gavaged with S at 7d and C at 14d. Samples were removed on 14, 21 and 28d. The samples were serially diluted and spiral plated (50µL) onto BHI agar, BHI agar with 800ppm nalidixic acid or Campy Cefex agar. Control plates and those plates estimating S growth were incubated at 37C for 24h, while C plates remained in a 42C incubator for 48h under microaerophilic conditions. Data were analyzed using GLM of SAS with means separated using LS Means ($P \leq 0.05$). Neither feed treatment affected broiler GI tract S or C populations. Improved bird performance was observed for non-challenged birds fed Immustim[®]. S-challenged birds showed improvement in growth and FC at 20g/ton of Immustim[®], while birds challenged with C showed improved growth when fed 40g/ton. The addition of Protimax[®] resulted in reduced growth for C-challenged birds. However, Protimax[®] improved FC for S-challenged birds, but had no effect on non-challenged birds.

M285 Acidified Sodium Chlorite application in the drinking water to control Salmonella colonization in market age broilers. P. Mohyla*¹, S. F. Bilgili¹, D. E. Conner¹, C. C. Warf², and G. K. Kemp², ¹*Auburn University, Auburn,* ²*Alcide Corporation, Redmond, WA.*

Acidified sodium chlorite (ASC; SANOVATM) is approved as a carcass disinfectant in poultry processing. ASC is produced by combining sodium chlorite (SC) and citric acid (CA). Under low pH, SC forms chlorous acid, a bactericidal oxychlorine species. Efficacy of ASC in reducing Salmonella colonization in broilers was determined. ASC was prepared either by adding CA or sodium acid sulfate (SAS). Two hundred and forty broilers (35 days of age) were randomly allocated to four Petersime batteries (5 birds/pen, 12 pens/battery). Study involved 12 treatments: negative control (plain water-no challenge), positive control (plain water-challenged), and five concentrations (0, 150 ppm, 300 ppm, 600 ppm and 1200 ppm) of SC, acidified to pH of 2.6 ± 0.1 either with CA or SAS. All birds, except for the controls, were fasted for two hours and orally gavaged with 104 CFU/ml of *Salmonella typhimurium* one hour before the initiation of treatments. Treatments were freshly mixed and replaced every 4 hours. Live performance (body weight, water consumption and weight gain/loss) was measured during the 24 hour experimental period. All 240 birds were then necropsied, digestive tracts were aseptically removed, split into 3 segments of upper (crop to gizzard), middle (duodenum to cecal junction) and lower (ceca to cloaca) for *Salmonella* enumeration (CFU/g). No significant ($P > 0.05$) changes were found in body weight, weight gain and in the appearance/color of the excreta. There was no significant acidifier (CA vs. SAS) effect on water consumption or *Salmonella* counts. However, a significant ($P < 0.05$) concentration effect for ASC was detected, where levels beyond 600 ppm negatively affected water consumption. ASC reduced *Salmonella* in the upper segment of the digestive tract linearly ($P < 0.05$) with increasing concentrations. Levels of ASC to reduce *Salmonella* in the middle and lower digestive tract segments were >600 and 1200 ppm, respectively. Pre-slaughter inclusion of ASC in the drinking water may be an effective way to reduce foodborne pathogens in poultry.

Key Words: Broilers, Acidified Sodium Chlorite, Salmonella

M286 Changes in intestinal microbiota and ileal susceptibility to pathogen attachment in broilers subjected to 24 hr heat stress. K. B. Selig* and J. A. Patterson, *Purdue University, West Lafayette, IN.*

The intestinal microbiota in chickens can be altered during periods of stress, which may contribute to intestinal susceptibility to pathogen colonization. The objectives of this study were to determine the effect of 24 hr heat stress on the microbial community structure of broilers and the susceptibility of intestinal tissues to colonization by *Salmonella enteritidis*. Male broilers were raised for six weeks in floor pens, fed standard corn-soybean meal diets and were adapted to normal (74 degrees F) temperatures as part of another study. At six weeks of age, randomly selected birds were subjected to 86 degrees F for 24 hr, then control and heat stressed birds (10 per treatment) were killed by carbon dioxide asphyxiation and intestinal contents and tissues were sampled. Changes in microbial community structure were determined using denaturing gradient gel electrophoresis separation of the V3 region of 16S ribosomal DNA extracted from luminal and mucosal wall associated intestinal bacteria. An in vitro ileal loop assay was used to determine the susceptibility of intestinal tissue to colonization by *Salmonella enteritidis*. The similarity index of ileal communities from birds within the heat stressed treatment was significantly lower (55% similarity coefficient) than from birds within the control treatment (65% similarity coefficient). The similarity index between heat-stressed and control treatments (41% similarity coefficient) was lower than the similarity indexes within either treatment ($p < 0.05$). *Salmonella enteritidis* attachment to ileal tissues in the in vitro attachment assay was 1.9 fold higher in tissues from heat stressed birds compared to tissues from control birds (8.77 vs. 8.50 log₁₀ cfu/g, respectively; $p < 0.05$). The data indicate that stress-induced alterations of the intestinal tract create opportunities for pathogen colonization by altering both the protective microbiota populations and by altering the epithelial susceptibility to attachment.

Key Words: Poultry, Intestinal Microbiota, Salmonella Enteritidis

M287 Case Study: The effect of drinking water treated with KEM SAN™ brand liquid acidifier on the livability of breeder candidates. J. K. Murphy*¹, P. A. Welch², and V. J. H. Sewalt¹, ¹Kemin Americas, Inc., Des Moines, IA, ²Nutritional Services Consulting, LLC, Laurel, MS.

KEM SAN™ brand liquid acidifier (KEM SAN) is an EPA-registered water sanitizer for the control of bacteria in poultry drinking water. KEM SAN treated drinking water has been demonstrated to improve livability, reduce plant condemnations, and improve feed efficiency in broilers (Welch et al., 2003; 2004). The purpose of this field study was to determine the effect of KEM SAN treated drinking water on the livability of breeder candidates. This study was conducted at a large commercial broiler integrator complex using a Ross 344 male x Cobb 500 slow feathering female strain cross. A 33% stock solution of KEM SAN was administered to the drinking water resulting in a final concentration of 2.58 ml/L of KEM SAN in the treated drinking water. KEM SAN treated drinking water was administered to two houses of pullets and rooster chicks continuously for the first 21 days after placement in the first study and the first 8 days after placement in the subsequent two studies. Mortalities were recorded daily and maintained in an M-Tec flock database. Fourteen-day mortality was calculated for each test flock and results were compared with settlement records of 88 previous and contemporary flocks that were not treated with KEM SAN. Pullet mortality was reduced ($P < 0.05$) by 1.10% when chicks were administered KEM SAN treated drinking water for at least the first 8 days following placement when compared to pullets provided untreated drinking water in previous and contemporary flocks. A numerical reduction in mortality was observed in rooster chicks receiving KEM SAN treated drinking water. Results of this study demonstrate that KEM SAN™ brand liquid acidifier administered at a rate of 2.58ml/L to the drinking water of pullets continuously for a period of at least 8 days following placement significantly reduced 14-day pullet mortality.

Key Words: KEM SAN Liquid Acidifier, Pullets, Livability

M288 Comparison of antibiotic resistance frequency of *Salmonella* Typhimurium growth in glucose-limited continuous culture at slow and fast dilution rates. N. Karabasi¹, S. Bulajic¹, W. K. Kim*², K. D. Dunkley², T. R. Callaway³, T. L. Poole³, S. C. Ricke², R. C. Anderson³, and D. J. Nisbet³, ¹University of Belgrade, Belgrade, Serbia-Montenegro, ²Texas A & M University, College Station, ³USDA-ARS, FFSRU, College Station, TX.

The objective of the study was to determine the frequency of spontaneous acquisition of resistance to select antibiotics by *Salmonella* Typhimurium when grown in glucose limited continuous flow culture at slow ($D = 0.025 \text{ h}^{-1}$) or fast ($D = 0.27 \text{ h}^{-1}$) dilution rates. The bacterium was grown in LB minimal medium (pH 6.25) containing no antibiotics. Upon achieving steady state, samples were plated to tryptic soy agar (TSA) alone or supplemented (per ml) with 2 and 16 ug oxytetracycline, 4 and 16 ug tetracycline, 2 and 64 ug kanamycin and 0.25 and 2 ug enrofloxacin. After 24 h incubation at 37C, recovery of *Salmonella* from unsupplemented TSA was 2.3 and 1.6×10^9 CFU for slow and fast growing cultures, respectively. Regardless of growth rate, the likelihood of recovering resistant *Salmonella* from the TSA containing the higher antibiotic concentrations was less than 1 in 10^8 for all antibiotics tested. The likelihood of recovering *Salmonella* from TSA containing 2 ug oxytetracycline/ml was also less than 1 in 10^8 /ml or 0.25 ug enrofloxacin/ml. Tests of representative isolates from the antibiotic supplemented TSA for their susceptibility to these respective antibiotics, using the NAHMS panel, revealed little if any difference in susceptibilities. Since *Salmonella* concentrations in the gut rarely exceed 10^6 CFU/g, these results suggest that in recovery of *Salmonella* from TSA supplemented with 4 ug tetracycline/ml was more likely for cells that had been sampled from the faster rather the slower growing culture (1 in 10^6 versus 1 in 10^8 , respectively). Recovery of *Salmonella* was much more likely (< 1 in 10 regardless of dilution rate) from TSA supplemented with 2 ug kanamycin. These results indicate that alterations in phenotypic expression of resistance appear to not be influenced by flow rate or exposure to lethal or sublethal antibiotic concentrations in this cultivation system.

Key Words: Antibiotic Resistance, *Salmonella* Typhimurium, Continuous Culture

M289 The influence of a fructooligosaccharide (FOS) prebiotic with feed substrates on *in vitro* *Salmonella typhimurium* growth of laying hen cecal bacteria. L. M. Donalson*¹, W. K. Kim¹, P. Herrera¹, C. L. Woodward¹, L. F. Kubena², D. J. Nisbet², and S. C. Ricke¹, ¹Department of Poultry Science Texas A&M University, College Station, ²USDA-ARS, College Station, TX.

The objective of this study was to investigate the effect of combining a prebiotic with feed substrates on the growth of *Salmonella typhimurium* in an *in vitro* model. Cecal contents from three laying hens were pooled and diluted to a 1:3000 concentration in an anaerobic dilution solution. The cecal dilution was added to sterile test tubes filled with alfalfa and grain with and without FOS. Two controls, inoculum only and no inoculum were used. The samples were processed in the anaerobic hood and incubated at 37°C. Samples were inoculated with *Salmonella* at 0, 6 and 24 hours after *in vitro* fermentation then plated at 0, 6 and 24 hours after inoculation. Plates were incubated for 24 hours then counted. Samples inoculated at 0 hours after *in vitro* fermentation increased in *Salmonella* 64-fold from 0 to 6 hours after inoculation (beginning count 10^7 and 10^9 respectively), however between 6 and 24 hours after inoculation, no further significant increase was observed. *Salmonella* counts for inoculum and no inoculum controls 24 hours after inoculation were significantly lower than other treatments ($P < 0.05$). For samples inoculated at 6 hours after *in vitro* fermentation (average initial counts 10^7) *Salmonella* generally grew slowly over time (4.5-fold) with significant differences at 24 hours after inoculation for inoculum and no inoculum when compared to all other treatments. Samples inoculated with *Salmonella* 24 hours after fermentation showed a general decrease of *Salmonella*. At 24 hours after inoculation, grain plus FOS and alfalfa plus FOS samples (average initial counts 10^9) had significantly lower *Salmonella* counts (99.95% and 99.96% respectively). These results show 24 hour *in vitro* cecal fermentation reduced *Salmonella* growth especially when FOS was present.

Key Words: Prebiotic, *In Vitro*, *Salmonella Typhimurium*

M290 Comparison of *Aspergillus* meal or inulin prebiotics as substrates for *Salmonella* or *Lactobacilli* *in vitro*. G. M. Nava*¹, V. Davila², L. Newberry¹, G. Tellez¹, A. M. Donoghue³, and B. M. Hargis¹, ¹University of Arkansas, Fayetteville, ²Universidad Nacional Autonoma de Mexico CEIEPA, FMVZ-UNAM. Mexico City 04510, ³PPPSRU/ARS/USDA, Fayetteville, AR.

The establishment of beneficial microflora, such as *Lactobacilli*, is believed to be important for intestinal health, possibly promoting immune system development, mucosal development, mucosal integrity, and other functions. Prebiotics, or non-digestible dietary microbial substrates, should hypothetically promote the amplification of beneficial microflora, such as *Lactobacilli* while not supporting potential pathogens such as *Salmonella*. Presently, we evaluated the specific growth rate (SGR) of *Lactobacillus casei* or *Salmonella enteritidis* (SE) in basal medium supplemented with either 0.2% (w/v) *Aspergillus* meal (AM) or 0.2% (w/v) of inulin. Each medium was inoculated with approximately 1×10^5 cfu/ml of the target bacteria. Two hundred microliters of each inoculated media were transferred to microtiter-plates and incubated for 10 hours at 37 C. Each hour, the SGR of the respective bacterium was evaluated through optical density using a bio-kinetic reader. In experiment 1, AM or inulin supplementation enhanced ($P < 0.001$) the propagation of *Lactobacillus* when compared to controls. In Experiment 2, either supplementation with either prebiotic (AM or inulin) significantly ($P < 0.001$) reduced SE-SGR when compared to the control without prebiotic. These results suggest that some prebiotic products may specifically enhance the growth of some *Lactobacilli* believed to be beneficial gastrointestinal microflora while simultaneously reducing the growth of harmful pathogenic bacteria (SE). These results are consistent with several recently published *in vivo* studies with these candidate prebiotics and may suggest a role for *in vitro* screening of other candidates or combinations of putative prebiotics.

Key Words: Prebiotic, *Lactobacillus*, *Salmonella*

M291 Antibiotic, prebiotic and probiotic programs for *Salmonella* sp. reduction in chicks, pullets, hens and their eggs. A. St. John*¹, B. Love², D. Shaw², and P. Patterson¹, ¹Department of Poultry Science, The Pennsylvania State University, University Park, ²Department of Veterinary Science, The Pennsylvania State University, University Park.

Salmonella sp. can be responsible for food borne illness among people who ingest contaminated poultry meat and eggs. The efficacy of antibiotics, prebiotics and probiotics or products in combination were evaluated by the level of *Salmonella* reduction in commercial chicks and pullets. Experiment 1 demonstrated that treatment products resulted in a zone of inhibition ranging from 0.0 to 2.5mm on Sensititre plates with *Salmonella* enteritidis phage type 8 (SePT8). The antibiotic Baytril had the greatest inhibition followed by CuSO₄, Gentamycin, Calsporin and four Terpene mixtures (P<0.05). Experiment 2 determined the appropriate SePT8 dose for chicks with recovery and titration in liver, spleen, duodenum, ceca and colon. From this study it was determined that a dose of 0.20ml with 2.0 x 10⁹CFUs/mL was sufficient for a systemic infection to reach all organs. Experiment 3 evaluated promising prebiotics, probiotics and antibiotics for chicks challenged with SePT8. In four trials, the products demonstrated a range of SePT8 reduction in tissues from 21.1% to 98.0% compared to positive controls. Feed intake was not significantly impacted by any of the dietary or drinking water additives (P>0.05). The final experiment evaluated the most promising treatments in 17 and 19 wk old pullets as well as 21 wk old hens. Initial results demonstrated that Baytril, Calsporin, and Terpenes-B and -PL effectively reduced SePT8 in all tissues from 10.3% to 99.8%. In both the 17 and 19 wk studies, all products including the positive and negative controls had no culturable SePT8 in ovarian tissue. In the hen study, tribasic copper chloride and Primalac eliminated SePT8 in all tissues samples, while Terpene-B and Immunomilk reduced SePT8 in tissues from 8.8% to 99.9%. Egg pools from hens during the 7d post inoculation phase were all negative for SePT8. This study identified promising prebiotics, probiotics and antibiotics that reduce the level of SePT8 in commercial Leghorn chicks, pullets, hens and their tissues.

Key Words: Prebiotic, Probiotic, *Salmonella* Enteritidis

M292 Evaluation of alternative host bacteria as vehicles for oral administration of bacteriophages. L. R. Bielke*, S. E. Higgins, K. L. Guenther, G. I. Tellez, and B. M. Hargis, University of Arkansas, Fayetteville.

Survival of bacteriophages (phages) through the upper gastrointestinal tract (GIT) is essential for treatment of enteric infections. Few phages survived the upper GIT of chicks when administered without protection (> 6 log reduction). We selected alternative host bacteria (AHB) that would support amplification of our *Salmonella enteritidis* (SE) phages, and infected these AHB prior to administration by either oral gavage alone or with supplemental administration in the drinking water (DW). Phages (9 log pfu) with AHB (100X dilution of turbid culture) were incubated (10 min) prior to administration. Phages from cecal contents were enumerated using SE overlay plates to determine GIT survival. Wild-type phage isolates WHR8 or WHR10 were individually evaluated in Exp 1. Cecal contents were obtained at 6, 26, or 77 h post-gavage. At 6-h, 7.63 and 7.71 log pfu were recovered when phage was administered via oral gavage only or with supplemental administration in DW, respectively. By 77-h, phage recovery was 2.77 and 1.88 log. Recovery of WHR10 at 6-h was 5.75 log when administered via oral gavage only, additional administration in DW did not increase phage recovery. At 77-h, no detectable phages were recovered in the gavage only group, but 1.97 log were detected when phage and AHB were added in DW. In Exp 2, only WHR10 was evaluated. Phages were administered by gavage alone (G1), combined with AHB and administered by oral gavage only (G2), oral gavage + AHB in DW at 6.35 log/mL (G3) or 5.35 log/mL in DW (G4), or phage + AHB by oral gavage every 12-h (G5). In G1, 4.73 log phages were recovered at 6-h and 1.54 log phages were detected at 72-h. In G2, 5.33 log were recovered at 6-h, and by 72-h, no phages were detected. Addition of phages and AHB in DW (G3 and G4) had no effect on phage recovery when compared to G2. After an initial recovery of 2.36 log in G5, the number of recovered phages remained constant for 72-h. Further selection of AHB and acid-resistant phages may increase the efficacy of phage treatments for *Salmonella* infection.

Key Words: Bacteriophage, Chickens, *Salmonella enteritidis*

M293 Effects of nitrocompounds and feedstuffs on *in vitro* methane production in chicken cecal contents. S. Saengkerdsub*¹, W. K. Kim¹, T. R. Callaway², R. C. Anderson², D. J. Nisbet², and S. C. Ricke¹, ¹Texas A & M University, College Station, ²USDA, Agricultural Research Service, Southern Plains Agricultural Research Center, College Station, TX.

The ceca are the primary site for anaerobic microbial fermentation in chicken. One of the end products of this process is methane. The objective of this study was to examine effects of feedstuff and nitrocompounds on methane production in *in vitro* incubation with laying hen cecal contents. Cecal contents from laying hens were diluted to a 1:20 concentration with anaerobic dilution solution. The cecal dilution was added to serum tubes containing alfalfa or layer feed. There were four treatments: control, 12 mM nitroethane, 12 mM nitroethanol, 12 mM 2-nitropropanol. The samples were incubated at 37 C for 24 hours under CO₂ and H₂ (50:50) gas mixture in closed tubes with 120 mM sodium formate. In alfalfa supplementation, methane production was reduced 99.7 ± 0.0, 99.2 ± 1.0, and 46.6 ± 9.9% (P < 0.05) when nitroethane, nitroethanol, and 2-nitropropanol were added, respectively, compared to controls (59.1 ± 5.3 μmol/g cecal content). Similar to providing alfalfa, methane was reduced 99.0 ± 0.1% in treatments incubated with added feed plus nitroethane or nitroethanol when compared to controls (19.1 ± 1.6 μmol/g cecal content). However, methane production increased 6 and 2 times (P < 0.05) due to alfalfa and feed, respectively. The results indicate that nitroethane and nitroethanol inhibit *in vitro* methane production; conversely, alfalfa and feed promote methane generation in cecal contents of chicken.

Key Words: Methane, Nitrocompound, Microbial Ecology

M294 Incidence of *Clostridium perfringens* in yolk follicles of broiler breeder hens. G. R. Siragusa*¹, N. A. Cox¹, J. S. Bailey¹, L. J. Richardson¹, R. J. Buhr¹, K. L. Hiatt¹, D. E. Cosby¹, J. L. Wilson², and D. V. Bourassa², ¹USDA-ARS, Russell Research Center, ²Department of Poultry Science, University of Georgia, Athens.

Subtypes of *Clostridium perfringens* are a major cause of human food borne gastroenteritis as well as the poultry disease necrotic enteritis. The natural presence of *C. perfringens* in individual mature and immature yolk follicles and the homologous ceca from 66 and 60 week old broiler breeder hens were determined from two different commercial facilities. In accordance with humane animal treatment guidelines, hens were transported for overnight holding and processing at the University of Georgia. Using extraordinary measures to reduce external as well as cross contamination, immature/mature yolk follicles and the corresponding ceca were aseptically removed. Samples were placed into individual stomacher bags, and immediately transported to our laboratory for within-the-hour analysis. Analytical determinations were based on non-selective enrichment culture followed by both cultural and PCR based tests. In the first trial, *C. perfringens* was detected and isolated from all ceca (n=8) and from only a single immature follicle (1 of 8) and from none of the mature egg follicles (0 of 8). In the second trial, *C. perfringens* was detected in 11 of 12 ceca, and from none of the immature or mature yolk follicles. At this stage, based on the low follicular-derived isolation rate of *C. perfringens*, observed in this limited sized study, it appears that the ovary section of the reproductive tract is not a particularly major source of *C. perfringens*. However, this evidence does not exclude the potential for the other segments of the hens reproductive tract nor the contribution of rooster semen as a harborage or source of *C. perfringens*. For the extent of the reproductive tract as a reservoir for *C. perfringens* to be more fully understood, trials during overt instances of necrotic enteritis and from drug-free facilities will be performed over different seasons. The genotypic comparison of the cecal-immature follicle paired isolates of *C. perfringens* is ongoing.

Key Words: *Clostridium Perfringens*, Broiler Breeder Hens, Yolk Follicles

M295 Response of broilers to graded levels of sodium chlorite and citric acid in water. P. Mohyla*¹, S. F. Bilgili¹, C. C. Warf², and G. K. Kemp², ¹Auburn University, Auburn, AL, ²Alcide Corporation, Redmond, WA.

Acidified sodium chlorite (ASC; SANOVA) is a highly effective sanitizer, currently approved for product-contact use in poultry processing. ASC is formed by combining sodium chlorite (SC) and citric acid (CA). The

in vivo efficacy of ASC against foodborne pathogens has not been assessed. This study was conducted to evaluate the tolerance of birds to graded levels of SC and CA administered in the drinking water. A total of 320 broilers, at 35 days of age, were randomly allocated to 64 pens (5 birds/pen). Water treatments consisted of 8 concentrations of SC (0, 0.012, 0.03, 0.06, 0.12, 0.3, 0.6 and 1.2%) and 8 concentrations of CA (0, 0.003, 0.01, 0.02, 0.04, 0.08, 0.18 and 0.4%). All solutions were prepared and replaced twice a day. Water intake, feed consumption, weight gain, and mortality were monitored during the seven day experimental period. No significant ($P>0.05$) differences were detected in mortality during the experiment. CA levels of up to 0.4% did not affect live performance. Whereas, SC concentrations above 0.12% significantly lowered weight gain and feed consumption. Linear and quadratic response to daily and 7-day water consumption was observed for graded levels of CA and SC in the water. Overall, concentrations of up to 0.02% of CA stimulated water consumption and may actually have a positive effect on feed efficiency ($P<0.05$). SC concentrations beyond 0.06% negatively affected live performance and water intake ($P<0.05$).

Key Words: Citric Acid, Sodium Chlorite, Performance of Broiler

M296 Effect of high flow rate nipple drinkers on the performance of 21 d old male broiler chicks. W. B. Roush^{*1}, B. D. Lott², and S. L. Branton¹, ¹USDA-ARS Poultry Research Unit, Mississippi State, MS, ²Poultry Science Department, Mississippi State, Mississippi State.

Two trials were conducted to examine three week production effects of providing water to broiler chicks with bell and two nipple drinker treatments with low (week1: 30ml/min; week 2: 40ml/min and week 3: 50ml/min or continuous high (120 ml/min) flow rates. In each trial, 80 male chicks were placed on litter in each of nine environmental chambers. Each treatment was replicated in three environmental chambers. Temperature was 32 degrees C for the first week and reduced by 2.6 degrees C weekly. Starter diets, provided as crumbles, and water were provided for ad libitum consumption. Light was continuous. Water consumption was recorded at 6 hour intervals. Bird weights, feed consumption and litter moisture for each chamber were determined weekly. Litter samples for moisture determination were collected in a 1 foot radius of the drinkers. Statistical significance was considered at $P = 0.05$. There were no significant differences in the weight gain for the first two weeks. At week 3 the weight gains for broilers on the bell drinker were significantly larger (469 g) than the birds on low (455.7g) or high flow (451.0g) drinker treatments. Feed conversion during the first week was significantly improved for birds drinking from high flow drinkers; however, there were no differences in feed conversion for the second or third weeks. There was no difference for water usage between bell (121.1 ml/bird) and high flow (121.5 ml/bird) drinkers with a significantly lower usage (109.4 ml/bird) for low flow drinkers. There were no treatment differences in litter moisture or percent livability.

Key Words: Broiler, Nipple Drinkers, Bell Drinkers

M297 Turkey strain effects on commercial turkey tom and hen performance. J. L. Grimes^{*1}, A. N. Crouch², P. R. Ferket¹, A. G. Gernat¹, J. L. Godwin¹, and R. Neely¹, ¹Dept. of Poultry Science, N. C. State University, College of Agriculture & Life Sciences, Raleigh, Dept of Poultry Science, Raleigh, NC, ²B.U.T.A, Lewisburg, WV.

The effect of strain on turkey performance was examined. Birds of four strains (males and females) from two primary breeders (B3,B2,N88,N85) were reared in a curtain-sided house with 96 pens (6.2 sq m per pen). Fifty tom or 66 hen poults were placed, on day of hatch, in each of 48 pens on one end the house in a randomized complete block design to provide 6 pens per strain and sex for a total of 1200 toms (300 per strain) and 1600 hens (400 per strain). There were 4 rows of pens with 12 pens per row. One row of pens served as a block. Two blocks were used for toms and two for hens. At five weeks of age, each pen of birds was evenly split. One half remained in the original pen while the other half was placed into a pen at the other end of the building. The same experimental design was used on both ends of the building. Feed was provided by a commercial mill. Feed consumption (by pen) and mortality were monitored. Feed conversion ratios (FC) were calculated. Birds were weighed at 5, 10, and 15 wk. Toms were weighed and processed in a commercial processing plant at 144 d while the hens were weighed and processed at 147 d. Carcass yield was determined for P. major, P. minor

& total breast meat for four pens of toms and three pens of hens per strain. The pen was the experimental unit and data were analyzed by regression ($P<0.05$). At market age, B3 toms were heavier than B2 while both were heavier than N88 or N85 (22.1^a, 21.5^b, 20.6^c, and 20.1^c kg, sem=0.20). At 15 wk, B3 hens were significantly heavier than B2, N88 or N85 hens (9.4^a, 9.0^b, 9.0^b, and 8.9^b kg, sem=0.07) At market age, B3 hens were the heaviest followed by B2, N88, and N85 (14.2^a, 13.6^b, 13.2^{bc}, and 13.1^c kg, sem=0.13). Neither Toms (FC=2.60, sem=0.04) nor hens (FC=2.64, sem=0.05) differed in FC at market age. B3 (5.8 kg) and B2 (5.7 kg) toms produced more breast meat than N88 (5.2 kg) or N85 (5.3 kg) toms but had increased relative breast meat yield only when compared to N88 toms. B3 (3.7 kg) and B2 (3.65 kg) hens produced more breast meat than N88 (3.4 kg) or N85 (3.4 kg) hens but only B3 hens had a greater relative breast meat yield. In conclusion, tom and hen turkeys performed differently due to strain under the conditions of this study.

Key Words: Turkey, Performance, Strains

M298 The effect of vitamin C supplementation to breeder hens and light during incubation on embryonic development and hatchability. T. El-Sheikh^{*1}, N. Makled², and A. El-Gammal², ¹Faculty of Agriculture, South Valley University, Sohag, Egypt, ²Faculty of Agriculture, Assuit University, Assuit, Egypt.

A total number of 500 Dandarawi laying hens were divided randomly into two groups of 250 each, the first was fed basal diet supplemented with 200 grams of vitamin C per ton, while the second was kept as a control. A total of 4200 hatched eggs representing vitamin C supplemented and unsupplemented groups. The eggs from each group were classified into seven treatments as follows: 1- The eggs were subjected after setting to 24 L:0D for 18 days and then darkness during the last three days. 2-The eggs were subjected to 24 L:0D for 12 days of incubation period. 3- The eggs were subjected to 24 L:0D for 6 days. 4-The eggs were subjected to 0L:24 D during all incubation period. 5-The eggs were subjected to 12L:12D for 18 days. 6-The eggs were subjected to 12L:12D for 12 days of incubation. 7-The eggs were subjected to 12L:12D for 6 days of incubation. The relative embryo weight to initial egg weight, chemical composition of embryos, hatchability, embryonic viability and incubation period were measured. Embryos from eggs subjected to different systems of illuminations were heavier than those from eggs which were unilluminated. The eggs incubated under 24L:0D had heavier embryos than those incubated in 0L:24D, while those incubated under 12L:12D had intermediate weights. The moisture content decreased by age of the embryo and increased by vitamin C supplementation. Also, it decreased by the increase in photoperiod and by the time of exposure. Protein content decreased by age in all treatments and increased by vitamin C addition. Also, it increased by the increase in photoperiod and time of exposure. Fat content increased as the age of embryo increased. Vitamin C addition led to significantly increase in the fat content at all ages. Continuous light caused an increase in embryonic mortality than those of 12L:12D and 0L:24D lighting program. The overall percentage of dead embryos (based on fertile eggs) was 3.23, 2.9 and 1.9 % for 24L:0D, 12L:12D and 0L:24D, respectively. Total embryonic mortality increased as the time of light exposure increased. Eggs incubated in 24L:0D had lower hatchability than that of their control and 12L:12D.

Key Words: Dandarawi Embryo Development, Incubation Light, Vitamin C

M299 Evaluation of different means of feeding corticosterone to broilers to elicit a stress response. W. S. Virden^{*1}, C. D. Zumwalt¹, J. P. Thaxton¹, S. L. Branton², and M. T. Kidd¹, ¹Mississippi State University, Mississippi State, ²United States Department of Agriculture.

Glucocorticoid hormones such as corticosterone (CS) are necessary to facilitate the catabolism of protein and fat to produce glucose for energy during stress. If excessive levels of blood CS are maintained, detrimental effects on growth can occur due to excessive turnover of body tissue for gluconeogenesis. Two experiments (Exp) were conducted to determine the effects of feeding CS on broiler performance using two methods at different ages. In Exp 1, Ross 308 male chicks were placed in floor pens and received either a control diet, or a diet containing 5 mg/kg of CS suspended in soybean oil (2 treatments, 24 replications) during the prestarter period (d 1 to 7). From d 8 to 21, chicks received common starter diets containing no CS. A factorial array of diet (high or low

nutrient density (ND) fed from d 1 to 42) and CS (0 or 20 mg/kg of diet in ethanol administered from d 18 to 21) was used to evaluate performance of Ross 308 chicks in Exp 2. In Exp 1, chicks receiving CS had decreased ($P < 0.05$) BW gain, feed intake, and livability from d 0 to 21. In Exp 2, CS and ND interacted ($P < 0.05$) to affect feed intake from d 0 to 34, as broilers fed diets containing high ND and CS had higher feed intake than broilers fed low ND and CS. From d 0 to 21 and d 0 to 42 feed intake was decreased ($P < 0.05$) in broilers fed CS. Dietary ND improved ($P < 0.05$) BW gain in all periods, but only overall feed conversion. Dietary CS decreased and increased ($P < 0.05$) BW gain and feed conversion, respectively, from 0 to 21, 0 to 34, and 0 to 42 d. Subsequent experimentation is underway to evaluate blood profiles and chemistry of broilers to correlate findings to the results presented herein.

Key Words: Broiler, Corticosterone, Stress

M300 The impact of egg weight on hatchability, chick weight, chick length, and chick weight to length ratios. J. J. Lawrence*, A. D. Gehring, A. D. Kanderka, G. M. Fasenko, and F. E. Robinson, *Department of AFNS, University of Alberta, Edmonton, Alberta, Canada.*

The objective of this study was to examine the effects of egg weight on hatchability, and hatched chick and two week old broiler growth parameters. Broiler hatching eggs ($n=900$) were obtained from a 43 wk old Cobb 500 FF commercial flock. Eggs ($n=300$) from three weight ranges (Small (S):6063g; Average (A):6065g; Large (L):70-73g) were incubated then candled at 7 and 14 days to remove and break open any eggs with non-viable embryos. Eggs remaining at 18d were weighed and transferred into pedigree hatch baskets. At 21.5d all saleable chicks were neck tagged, weighed, and chick length measured. Eleven groups of 20 chicks for each egg weight range were randomly allocated to one of 33 cages and provided with feed and water ad libitum. At 14 d of age the birds were weighed and body and shank length measured. The data were analyzed using the GLM procedure of SAS[®] and probability assessed at $P \leq 0.05$. Egg, chick, and two week broiler weights were significantly different between the egg weight groups (Segg=61.8±0.1g; Aegg=66.5±0.1g; Legg=71.3±0.1g; Schick=43.0±0.1g; Achick=46.4±0.1g; Lchick=49.9±0.1g; S2week=264±0.7g; A2week=281±0.7g; L2week=296±0.7g). Hatchability of fertile eggs was lowest in the L (81.8±2.0%) compared to the S (92.4±2.0%) and A groups (89.4±2.0%) which did not differ from one another. This was due to a higher incidence of culled chicks from the L (12.2±1.6%) versus the A (5.1±1.6%) or S (2.8±1.6%) groups, which did not differ from each other. Chick and two week broiler lengths (Schick=185±0.3mm; Achick=188±0.3mm; Lchick=191±0.3mm; S2week=311±0.7mm; A2week=316±0.7mm; L2week=326±0.7mm) and weight to length ratios (Schick=0.233±0.001; Achick=0.247±0.001; Lchick=0.261±0.001; S2week=0.848±0.001; A2week=0.888±0.001; L2week=0.907±0.001) were also significantly different between all three egg weight groups. These data support previous research showing that chick weight is dependent upon egg weight at setting, and also provide new data on the relationship between egg weight and chick length.

Key Words: Egg Weight, Hatchability, Chick Weight to Length Ratios

M301 Detection of early changes in fertile eggs during incubation using a hyperspectral imaging system. D. P. Smith*¹, J. M. Mauldin², K. C. Lawrence¹, B. Park¹, and G. W. Heitschmidt³, ¹USDA, ARS, Russell Research Center, Athens, GA, ²Department of Poultry Science, University of Georgia, Athens, ³Biological and Agricultural Engineering, University of Georgia, Athens.

Detection of fertility prior to incubation or the recognition of development during the first 3 days of incubation could benefit hatcheries, as they could remove infertile or non-developing eggs before investing significantly in incubator space and utilities, or risking contamination from "exploding" eggs. This study was conducted to determine the feasibility of using a hyperspectral imaging system (CCD detector, spectrograph, lens assembly, and software) to detect changes in incubated eggs related to fertility and development. For each of two replicate trials, 48 unincubated SCWL eggs were obtained from a commercial hatchery, incubated, and then 12 eggs were removed and imaged on each of days 0, 1, 2, and 3 ($n=96$). Hypercube images were collected on each egg (wavelengths from approximately 400 to 900 nm) using tungsten-halogen backlighting

with a 30 millisecond exposure time. Eggs were then broken out for confirmation. A ratio of transmittance images at two different wavelengths, (found to optimize detection of blood in eggs during a preliminary experiment) was used to detect blood ring formation. On day 3, 23 of 24 eggs were determined fertile by breakout; the hyperspectral imaging system accurately classified the one infertile egg and 22 of the 23 fertile eggs. The blood ring was not detected on days 0 or 1, and not consistently on day 2. Insufficient light transmission for one fertile egg prevented its classification. The hyperspectral imaging system appears capable of detecting fertile egg development based on blood ring formation on day 3 of incubation.

Key Words: Egg Fertility, Embryo Development, Hyperspectral Imaging

M302 Broiler litter sampling procedures. A. S. Tasistro, C. W. Ritz*, and D. E. Kissel, *University of Georgia, Athens.*

Sampling procedures are critical in broiler litter analysis for appropriate nutrient management planning efforts and to minimize the spatial variability of nutrient concentrations influenced by conditions such as litter moisture content and waste feed. There is a need for practical alternatives that help obtain representative samples and that simultaneously allow enough time to receive and apply the analytical results. Litter from a commercial broiler house was sampled in two ways: 1) Thirty samples were taken based on a grid that incorporated sampling points around the feeders, waterers, and center of the house), and 2) Five samples were taken from trenches dug from the center of the house to the sidewall. The number of sub-samples needed to have mean estimates for each elemental litter component within specified limits of statistical accuracy were estimated using conventional statistical procedures and computer intensive random resampling procedures. The mixing of litter material associated with trench sampling reduced the variability in the concentrations of all elements analyzed, and resulted in a reduction in the number of sub-samples needed to attain comparable levels of statistical accuracy. Specific for nitrogen (N), the Coefficient of Variation of N concentrations in samples from the grid and trenches were 17 and 6 %, respectively. The number of sub-samples needed to estimate the mean N concentration within 15% of the experimental mean 95% of the time when sampling by taking individual floor samples and digging trenches were 6 and 2, respectively.

Key Words: Broiler Litter, Sampling, Composition

M303 Effects of organic acid on control of bacteria growth in drinking water for broilers. G. M. Pesti*¹, R. I. Bakalli¹, P. F. Vendrell², and H.-Y. Chen³, ¹Department of Poultry Science, University of Georgia, Athens, ²Agricultural and Environmental Services Laboratories, University of Georgia, Athens, ³Kemira Oyj Helsinki, Finland.

A total of 664 male Cobb birds were used to evaluate the effect of an organic acid product AMMFOR-pH on the control of microbial growth in drinking water. AMMFOR-pH is a formic acid based product, which is partially ammoniated for improving handling characteristics. One-day-old birds with an average body weight of 40 g were randomly assigned to one of four pens. There were two water treatments, control and experimental (with added AMMFOR-pH at 0.01%). Birds in both treatments were fed the same commercial broiler diets. There were 12 bell drinkers in total, three bell drinkers per pen. Water consumption and pH and bird mortality in each pen were recorded daily. Water samples were taken from all drinkers three times a week for five weeks, and were analyzed for pH, *E. coli* and total enterococcus counts. All birds were weighed on days 0 (43 vs. 43 g), 18 (715 vs. 707 g), and 35 (2117 vs. 2146 g for control and AMMFOR-pH treated birds, respectively). Feed consumption was measured on days 18 (928 vs. 932 g) and 35 (3301 vs. 3310g) and feed conversion ratios (FCR) were calculated. From 0 to 18 days and from 0 to 35 days FCR (1.380 vs. 1.405, and 1.592 vs. 1.574 kg feed/kg gain) were very similar. In the AMMFOR-pH treated group, water pH rose from 3.68 to 5.45 after 24 hours, compared to an average of 7.06 in the control group. The changes in water pH resulted from contaminations of feed and litter materials. Water consumption and bird mortality were not significantly different between the control and AMMFOR-pH treated groups. *E. coli* and total enterococcus were reduced by 49% and 56%, respectively, in drinking water treated with AMMFOR-pH, compared with the control. The results of this study suggest that incorporation of AMMFOR-pH in drinking water for broilers improves the hygienic quality of drinking water by inhibiting the

growth of bacteria, and may reduce contamination of bacteria in broiler chickens.

Key Words: AMMFOR-pH, Broiler, Drinking Water

PSA-Extension/Instruction

M304 Development of a quality control laboratory design project for poultry science undergraduate students enrolled in an advanced food microbiology course. R. S. Hardin*, M. M. Kunder, C. L. Woodward, L. M. Donalson, J. L. Golbach, and S. C. Rieke, *Department of Poultry Science, Texas A&M University, College Station.*

With the ever-increasing demand for problem solving skills in today's poultry workforce, more emphasis is needed on integrated training at the undergraduate level. An exercise for designing a quality control laboratory was developed as a laboratory group project in a senior level undergraduate advanced food microbiology course taught in the poultry science department at Texas A&M University. The assignment was based on the students designing their own laboratory and implementing testing methods for different types of bacteria known to cause food-borne illness. They were responsible for determining what equipment was needed for their specific pathogen as well as general supplies and materials required for setting up a fully equipped laboratory. Individual research papers were required of each student midway through the semester to gain a sufficient background on the pathogen; including discussion of the importance, detection methods, and the prevention and control of the pathogen assigned to their group. In each of the laboratory sections students were separated into groups of four students who were then responsible for a group project report. At the end of the semester the group report was required to include a lab diagram indicating where equipment would be placed as well as a comprehensive budget including a list of prices needed to set up the laboratory designed by the group. The group project report was also required to contain justification for specific equipment and materials requested, based on the pathogen and scenario given to the groups discussed where samples would be taken from, how often samples would be taken, as well as what isolation methods would be used. Students were also required to develop waste management procedures to handle all possible biohazard materials. Successful completion of the project provided students with problem solving skills essential for the poultry industry.

Key Words: Food Microbiology, Review Paper, Quality Control Laboratory Design

M305 Student understanding of molecular genetics concepts. B. S. Walters* and T. J. Buttles, *University of Wisconsin, River Falls.*

The purpose of this study was to increase student understanding of molecular genetics concepts. Current students in colleges of agriculture will be entering a world shaped by biotechnology. Applications of biotechnology such as genetically modified crops have been adopted at a rate greater than any other technology in the history of agriculture. Animal applications of biotechnology are also on the rise and raise additional ethical questions. DNA transcription, RNA translation, and protein structure development all play a key role in modern applications of biotechnology. An understanding of these processes lays the foundation for understanding the bigger picture of biotechnology applications in agriculture. The goals of this Scholarship of Teaching and Learning project were to first identify students' background knowledge and then

to evaluate the effectiveness of different instructional approaches in increasing student understanding. The starting point for the project was to determine the level of understanding students brought to the course. Students were given the opportunity to complete a short questionnaire asking for related course information (completed or in-progress: Introductory Biology, Animal/Plant Genetics, Animal/Plant Breeding, Introduction to Biotechnology) and definitions of 5 terms (messenger RNA, transfer RNA, ribosomal RNA, transcription, translation). Nearly all students had completed Introductory Biology and at least one additional course that included molecular biology concepts. Despite this background, few students could correctly define all 5 terms. Based on these findings, classroom activities were developed where students examined the core molecular genetics concepts from a variety of perspectives.

Key Words: Undergraduate Education, Teaching, Biotechnology

M306 What does the poultry industry want when recruiting undergraduates? - an ongoing perspective survey to evaluate the importance of certain employable skills to the poultry industry. K. M. Downs*¹, J. E. Mehlhorn², J. B. Hess³, and J. L. Wilson⁴, ¹Middle Tennessee State University, Murfreesboro, ²The University of Tennessee at Martin, Martin, ³Auburn University, Auburn, AL, ⁴The University of Georgia, Athens.

A survey instrument was developed to assess personality traits and competency levels important to poultry managers for achieving success in the poultry industry. Twenty questions seek to evaluate the importance of personality characteristics and subject matter competencies sought in new employees. Remaining questions evaluate the importance of seven common industry recruitment efforts. A Likert scale (1=unimportant to 5=critically important) is used to quantify responses, and managers in all phases of broiler and table egg production are targeted. Surveys are mailed with an explicative cover letter, self-addressed stamped envelope, and appreciation gift. At present, personnel in TN, AL, and GA have been targeted; however, to strengthen statistical inferences, administration will continue.

Response rate is currently 52.3%. Most managers completing the survey classified themselves as working in the processing (36%), live production (23%), or HR (19%) sector. To date, respondents (n=23) indicate the five most important characteristics for employment success are integrity (4.87), teamwork (4.83), adaptability (4.39), problem-solving (4.39), and oral communication (4.39). Conversely, the five least important parameters were undergraduate major (2.74); knowledge of foreign language (2.83), basic science (2.83), or computer hardware (2.87); and previous work experience (2.91). Respondents evaluated the most effective recruitment tools to be departmental career fairs (3.64) and informal university contacts (3.64). Trade publications (2.48) and on-line job sites (2.40) were considered the least beneficial for recruitment.

Developing aptitude in team building, problem-solving, and oral communication should be priorities in undergraduate education. Furthermore, fostering strong industry ties should be a significant objective of those in academia to more effectively place students in the poultry industry. This collaborative work is ongoing.

Milk Protein and Enzymes: Dairy Foods

M307 Exploring the structure and dynamics of labeled β -lactoglobulin using high field NMR spectroscopy. P. J. B. Edwards¹, G. B. Jameson¹, G. E. Norris², T. S. Loo², K. A. N. S. Ariyaratne¹, D. Uhrin³, P. N. Barlow³, and L. K. Creamer*⁴, ¹Institute of Fundamental Sciences, ²Institute of Molecular Biosciences, ³Edinburgh Protein Interaction Centre, ⁴Fonterra Research Centre.

Bovine β -lactoglobulin (BLG) is the major whey protein and dominates the effects of heat and pressure on the structure and disulfide bonding of this protein. The two common genetic variants, BLG A and BLG

B, behave quite differently in their reactions. For example, BLG A is more readily hydrolyzed and easier to heat denature than BLG B. The X-ray crystal structures do not show any features that could explain this behavior and consequently an extensive project was initiated to resolve this question. A polynucleotide was synthesized and expressed to give fusion proteins, corresponding to both the A and B variants. These were subsequently cleaved to obtain synthetic BLG A and BLG B. Addition of ¹⁵N and/or ¹³C nutrients to the growth media allowed labelled proteins to be made and these have been used to confirm the previously

published assignments for the A variant and to assign residues close to the substitution sites in the B variant. Using this base information the accessibility of each of the amide N atoms was determined as a function of temperature using H/D exchange. Preliminary results of a ^{15}N NMR relaxation study indicate some small differences in the backbone dynamics of BLG A and BLG B. The significance of these results will be discussed in terms of the different stabilities of BLG A and BLG B.

Key Words: Molecular Dynamics, Labeled Lactoglobulin, Temperature Effects

M308 Water distribution in cheese and cheese models: Application of NMR techniques, including the inverse 2D-LaPlace transform. A. Gottwald¹, P. L. Hubbard¹, P. T. Callaghan¹, P. J. Watkinson², and L. K. Creamer^{*2, 1} *School of Chemical and Physical Sciences, Victoria University of Wellington, New Zealand, ²Fonterra Research Centre, Palmerston North, New Zealand.*

Most cheese is a complex dispersion of protein (casein), butterfat, and their degradation products, in water containing some mineral material. Using a 7 T NMR spectrometer (300MHz for ^1H) ^1H signals of water and oil can be resolved by chemical shift differences. The protein signals are usually overwhelmed by these two major signals because of the differences in relaxation time. NMR-relaxation (T_2) and NMR-diffusion (D) were determined for the water and were then transformed to give two-dimensional (2D) plots of D vs T_2 . There were a number of spots on the 2D plot and this indicated that there were several water environments. A similar plot was obtained from the butterfat signal. For a better understanding of the origin of different relaxation rates and/or diffusion coefficients, cheese models with a simpler composition were prepared and studied under similar conditions as the cheese. The simplest model was sodium caseinate dissolved in water at neutral pH. The simplest butterfat model was liquid paraffin oil, in which all protons are bonded to carbon, which was emulsified into the caseinate solution. Further complexity was introduced by replacing some of the sodium ions with calcium. This changed the concentrated caseinate solution with emulsified oil into a semi-solid visco-elastic material. Diffusion coefficient D and relaxation time T_2 of the water protons in the models are similar to the values in real cheese. Both values (D and T_2) decrease if the protein content in the model system is increased. The NMR behavior of the oil, which exists in discrete droplets, is unaffected by protein concentration.

On the other hand, there are some significant differences between natural cheese and these model systems which clarifies our understanding of the natural cheese system.

M309 Effects of genetic modification, pressure, and heat on the binding of various probes to β -lactoglobulin. H. A. Patel^{1,2}, T. Considine^{1,3}, S. G. Anema^{3,2}, H. Singh³, and L. K. Creamer^{*1}, ¹Fonterra Research Centre, Palmerston North, New Zealand, ²Institute of Nutrition, Food and Human Health, Massey University, Palmerston North, New Zealand, ³Riddet Centre, Massey University, Palmerston North, New Zealand.

Native β -lactoglobulin (BLG) has been shown to bind a number of hydrophobic and amphipathic molecules within the central calyx. Examples are: hexane, retinol (vitamin A), cholesterol, 12 bromo-dodecanoic acid, palmitic acid, and cis-parinaric acid (CPA) but not anilino-naphthalene sulfonate (ANS). The binding of retinol and CPA can be followed by induced circular dichroism or increased fluorescence. This has allowed the determination of the displacement of CPA or retinol by dodecyl sulfate (SDS) or palmitate, but not by ANS. Heat treatment denatures the BLG, and the binding of CPA and retinol decreases in proportion with the extent of denaturation while ANS fluorescence increases. Pressure treatment has a similar effect. Addition of these ligands of BLG increases the stability of the protein under increased temperature and pressure. ANS does not have this effect. Polynucleotides were synthesized and expressed to give fusion proteins, corresponding to both the A and B variants of BLG. These were subsequently cleaved to obtain synthetic BLG A and BLG B. Modification of the polynucleotide allowed the preparation of a number of different BLG mutants. Some of these were modifications close to the binding site of retinol and the fatty acids. In particular the change of lysine to glutamic acid at residues 60 and 69 showed dramatic differences in behavior. These two residues are close spatially but the change at residue 60 prevents binding of retinol or CPA while that at residue 69 does not.

Emerging Issues in Homeland Security & Food Safety**

1 Antibiotic use in Animals and the Impact of the Growth Promoter Ban in Europe. R. B. Phillips*, *Animal Health Institute, Washington, DC.*

Antibiotic use in food animals in the United States is trending down as producers become more careful and efficient in their use of antibiotics. Surveillance data and recent quantitative risk assessments suggest the human health risk from resistance food borne pathogens is quite small. Conversely, risk assessments and the European experience suggest the benefits of antibiotics used in food animals have been underappreciated. A non-science driven ban on growth promoter use in Europe resulted in increased bacterial illnesses in animals while producing no human health benefits. Taken together, these bodies of evidence suggest that policy actions not based on science will have negative unintended consequences. The best public health measures will include a combination of increased surveillance, continued improvements in food hygiene and rational, judicious use of antibiotics in food animals.

2 Enzymatic degradation of prions and prevention of transmissible spongiform encephalopathies. J. Shih*, *Department of Poultry Science, North Carolina State University.*

Infectious prion protein (PrPres) is believed to be the causative agent of bovine spongiform encephalopathy (BSE) or mad cow disease, sheep scrapie elk chronic waste disease (CWD) and human Creusfeldt-Jakob disease (CJD). The protein is recalcitrant and resistant to common proteases and heat sterilization. A feather-degrading keratinase, was found to be able to degrade PrPres in the brain tissues of BSE cows and scrapie sheep. After homogenization, pre-heating at 115 oC, and the keratinase digestion, PrPres was completely degraded to an undetectable level by Western blott. Biological tests in transgenic mice are in progress to confirm the dis-infection of the tissue born PrPres by the enzyme. In order to study the degradation mechanism and to improve the effectiveness of the enzyme, a non-pathogenic surrogate protein system was

developed in this laboratory. Sup35NM, a prion-like protein from yeast, was produced and analyzed for its characteristic folding, aggregation, and degradation by proteinase K and keratinase. With the keratinase and the surrogate protein, this laboratory is equipped to develop a new process for enzymatic inactivation of PrPres in the decontamination of equipment and the rendering process for prion-free animal products. This new method and other existing dis-infection methods will be reviewed in the presentation. (Supported by USDA, FDA and National Cattlemen's Beef Association)

3 Mycotoxin detoxification and microorganisms in feeds. G. Schatzmayr*¹, D. Schatzmayr*¹, M. Täubel¹, S. Nitsch¹, A. P. Loibner², and E. M. Binder³, ¹*Biomim IAN GmbH, Industriest. 21, 3130 Herzogenburg, Austria*, ²*IFA-Tulln, Department of Environmental Biotechnology, Konrad Lorenzstrasse, 3430 Tulln, Austria*, ³*Erber AG, Industriestrasse 21, 3130 Herzogenburg, Austria.*

Mycotoxins are secondary metabolites of fungi affecting human and animal health. Mycotoxins of major concern for poultry are especially aflatoxins, trichothecenes and ochratoxins. In poultry aflatoxins cause for instance haemorrhages, nervous syndrome and pale bird syndrome whereas certain trichothecenes lead to feed refusal, haemorrhages and oral as well as dermal lesions. Ochratoxin A is responsible for damages of kidneys and liver. All of the above mentioned mycotoxins suppress the immune system of birds at relatively low concentrations. In spite of all efforts to prevent the formation of mycotoxins in the field and during storage high contaminations still occur. To alleviate negative effects on animals detoxification strategies are needed. Clay minerals have been used in the feed industry to bind aflatoxins, but it turned out that these binders are very specific for aflatoxins but not for the other toxins which show a great variation in their chemical structures. A novel strategy to control the problem of mycotoxicoses in poultry is the application of microorganisms capable of biotransforming mycotoxins into non-toxic

metabolites. A new strain belonging to the genus of Eubacterium isolated out of rumen fluid of cattle is able to deactivate trichothecenes by reduction of the epoxide ring. This mode of action was proven in vitro and also in vivo by applying trichothecenes and the detoxifying strain Eubacterium BBSH 797 to chicken. In a very recent project a novel yeast strain, capable of degrading ochratoxin A and zearalenone was isolated and characterised. Due to its affiliation to the genus of Trichosporon and to its main property to degrade mycotoxins this strain was named Trichosporon mycotoxinivorans. This strain showed detoxification in vitro and in vivo. Together with clay minerals Eubacterium BBSH 797 and Trichosporon mycotoxinivorans can be used in a formulation to prevent poultry from mycotoxicoses caused by aflatoxins, trichothecenes and ochratoxins.

5 Avian Influenza, Vaccines and Control. D. Swayne*, *US Department of Agriculture, Agricultural Research Service, Southeast Poultry Research Laboratory, Athens, GA.*

Avian influenza (AI) is a viral disease of birds caused by type A orthomyxoviruses. Avian influenza viruses are further classified into 15 different hemagglutinin (H1-15) and 9 different neuraminidase (N1-9) subtypes. Biologically, AI viruses can be of low (LP) or high pathogenicity (HP) for chickens and related poultry species. Dealing with AI

has focused on one of three goals: prevention, management (control) or eradication. In most developed countries, LP AI and HPAI are not common in commercial poultry and thus prevention is the primary goal. However, if AI occurs, eradication is the overall goal with epizootics of HPAI being eradicated through a strategy that includes enhanced biosecurity, surveillance or diagnostics to identify infected farms, quarantine of infected premises, depopulation and disposal of infected poultry, and cleaning and disinfection of infected premises. Vaccines have been used to manage economic losses from LP AI or, in some instances, have been used as a tool in LP AI or HPAI eradication strategies. AI vaccines can prevent clinical signs and death in poultry, increase resistance of birds to infection, and decrease the amount of virus shed in the environment. However, vaccines alone will not eradicate AI. High pathogenicity AI impacts international trade as does some forms of LP AI. Experimental studies in chickens have shown that LP AI viruses cause respiratory and gastrointestinal infections without infecting the meat. By contrast, HPAI viruses produce infection of respiratory and gastrointestinal tracts, produce a viremia and virus is present in the meat and internal contents of eggs during the acute stages of the infection. Additional experimental studies have demonstrated that pasteurization of liquid egg products using USDA guidelines will inactivate HPAI virus that have been artificially added to levels in excess of those reported in eggs laid by HPAI virus-infected hens. Although, no virus has been demonstrated in internal contents of eggs laid by LP AI virus infected hens, pasteurization has been shown to inactivate LP AI virus artificially added to egg products.

Combined Animal, Dairy and Poultry Extension Workshop

6 Washington update. R. Reynnells, *National Program Leader, Animal Production Systems, USDA-CSREES.*

The 2004 Annual Extension Special Recognition Award is presented to Dr. Mike Hulet, (PA), who has made many significant leadership contributions in the areas of environmental protection and animal well-being. Muquarrab Qureshi joined us as National Program Leader (NPL) for Animal Genetics. Our NPL position for Veterinary Medicine continues to be available. I want to encourage you to participate in multi-state research committees, which will increase in importance with our ever-reducing number of poultry faculty. WCC-204, Animal Bioethics, is an important committee that complements other activities at Land Grant Universities. The Southern Region Poultry Extension Workshop (Triennial) committee is more national in character and continues discussions of scheduling changes. John Carey (TX) is Chair, and Ken Anderson, Vice Chair of that committee and they request you provide comments and volunteer. The 2004 National Poultry Waste Management Symposium is in Memphis, and is coordinated by Mike Hulet (PA); with Susan Watkins (AR) Coordinator for 2006. The Future Trends in Animal Agriculture held a program in 2002 (Standards), two in 2003 (Science and Ethics; and, Costs of Changes), with another scheduled for 2004 (Local and Global Considerations) to create opportunities for positive dialogue between industry and activists. Proceedings are available. The National Poultry Infobase will be terminated in 2004. A national Regionalization Workshop prioritized mechanisms to implement effective programs. Proceedings are available.

7 Confined Animal Feeding Operation (CAFO) regulations impact and record keeping requirements for livestock operations. G. E. Erickson*, R. Koelsch, C. Shapiro, and C. Wortmann, *University of Nebraska, Lincoln.*

In 2002, USEPA revised regulations for confined animal feeding operations (CAFO) to appropriately update federal requirements in the 1972 Clean Water Act, and specifically the National Pollutant Discharge Elimination System (NPDES). The goal of the revised regulations is to ensure clean surface water in the US. The revisions address runoff control, manure storage, nutrient utilization, and record-keeping and related livestock water quality issues. CAFO is defined by facility, risk of nutrients entering water, and size. Large CAFOs have at least 1000 cattle, 700 dairy, 2500 finishing swine, or 125,000 broilers. Smaller operations can be designated as a CAFO under some circumstances. By December 31, 2006, nutrient management plans (NMP)

and record keeping are required for CAFOs. The USEPA requirements are the minimum requirements to which individual States must respond. State requirements may be more demanding and comprehensive than the minimum established by USEPA. Comprehensive Nutrient Management Plans (CNMP) are defined by USDA to monitor nutrient flow, minimize excretion, appropriately utilize nutrients, and keep records. CNMPs are more comprehensive than NMP and address feed management and alternative uses or technologies for managing manure. NMP records that must be maintained for five years include: the annual NMP, analysis of manure and soils receiving application, crop nutrient requirements, the basis for determining the rate of application, dates and methods of application, amounts of N and P applied, and a cropping season summary. The USEPA regulations require that CAFOs submit an annual report. USEPA is allowing the States to determine the threshold at which manure application rates can no longer be based on crop N need or removal and P-based application are required. This threshold is affected by several that define the potential for runoff P loss from individual fields. Considerable education efforts are underway nationally, regionally, and through land-grant institutions.

8 Waste management alternatives: composting, methane production and other options. L. E. Carr, *University of Maryland, College Park.*

This presentation will address waste management alternatives to include: composting manures and normal mortalities from animal and poultry production systems; methane production from various manures and potential utilization of the end products; processing poultry and turkey litter for organic fertilizer and value added fertility products; and direct combustion. Process feedstocks will be limited to cattle, swine, horse and poultry manures/litter and normal mortalities. The carbon to nitrogen ratio of some manures are in the desirable range while others will have to be adjusted with a carbon source for good composting and methane production. Methane is not a readily compressible gas which creates some storage limitations, therefore, direct contentious use of the gas as it is generated will be discussed. In this process, the nutrient content of the feedstock changes very little which will have to be utilized properly upon discharge from a digester. Litter from broiler and turkey production are ideal for further processing into organic fertilizer and other value added fertility products because they are from dry production systems with a high NPK content. In recent years, there has

been a lot of activity in direct combustion of poultry and turkey litter. A review of on and off farm combustion systems will be presented. Each of the alternatives shown will have their pros and cons and will be discussed.

9 Air quality, PM_{2.5}, and related concerns. F. M. Mitloehner, *University of California, Davis.*

Public concerns related to air quality impacts of intensive livestock and poultry operations have grown drastically over the recent years. Pollutants of concern are particulate matter, ammonia, methane, hydrogen sulfide, volatile organic compounds, and odors. However, there is a general paucity on character, amount, and dispersion of livestock air pollutants. Despite dramatic knowledge gaps, the Environmental Protection Agency (EPA), State and local air quality agencies are mandated to use best available emission factor data for their emission inventories. In serious non-attainment regions like the San Joaquin Valley, pollutants like particulate matter and ozone precursors have to be reduced significantly. New legislation forces livestock producers to reduce emissions using best available control methods that for the most part were never scientifically tested. The US Department of Agriculture (USDA) is mandated to support farmers with scientifically based emission mitigation techniques and technologies but again scientific information is scarce. Both, EPA and USDA appointed the National Research Council (NRC, 2003) to review the scientific basis for current emission estimates and emission mitigation. Major NRC findings were that current emission estimates are largely inappropriate because instead of being based on representative surveys from a class of operations (e.g., dairies) over several seasons, they are predominantly grab-sample measurements conducted on one operation at one time. The committee recommended replacing the current emission factor approach with the use of process-based modeling using nutritional mass-balance approaches. A second major NRC finding was that intensive research is needed into cost effective emission mitigation for livestock and poultry operations.

Key Words: Air Quality, Emission Mitigation, Emission Estimates

10 Water quality concerns—are they real? What needs to be done? T. G. Gunter*, *Oklahoma Department of Agriculture, Food, and Forestry.*

Many states continue to debate the question of whether or not animal agriculture is the cause of water quality pollution concerns. Using Oklahoma as an example, animal agriculture's potential impacts on water quality are often stated as the driving force behind legislative enactments restricting the activities of livestock or poultry operations. While animal agriculture can be a contributor to water quality problems, in many cases the real reason for the changes are related more to social or quality of life issues instead of water quality. Unfortunately, no matter what the state response is and no matter what the real reasons are behind that response, the results are livestock producers feel they are unfairly blamed for the entire problem and are subject to increasing regulation. Producer response to that regulation is ongoing and is likely

to shape the continuing evolution of animal agriculture in the U.S. and the world. This paper will provide the reader with an overview of Oklahoma's experience with the evolving world of livestock production, the state's reactions to real and perceived problems, producer reactions, and the future of animal agriculture and water quality.

11 Urban encroachment and how Extension can assist farmers. K. S. Kremer, *Wartburg College, Waverly, IA.*

Development in the rural fringe of urban areas has eliminated both farm and timberland. While an assumption is often made that urbanization is destiny, this paper suggests communities, groups, and individuals can act to modify trends. This includes a role for university extension in their work with producers and communities.

Key Words: Urban Sprawl, Agricultural Change, Communities

12 Assimilation vs. accumulation of macro- and micro-nutrients in soils: relations to livestock feeding operations. N. A. Cole*, R. C. Schwartz, and R. W. Todd, *USDA-ARS Conservation and Production Research Lab, Bushland, TX.*

Amending soils with animal manures is a common practice to increase soil quality and dispose of potential wastes from concentrated animal feeding operations (CAFO). However, improper application of manure can result in runoff of nutrients or pathogens to surface water, percolation of nutrients to ground water, accumulation of nutrients in the soil, or loss of N and C to the atmosphere. The trend toward larger animal feeding operations has resulted in higher rates of manure and litter application in localized areas; thus, increasing the potential for pollution from land applied manure. With the advent of the new clean water regulations, all CAFO and many smaller AFO must have comprehensive nutrient management plans designed for proper utilization of manure nutrients. However, only 20 to 50% of CAFO have adequate land to meet application standards. The capacity of soils to accumulate nutrients, as well as the nutrient composition and phytoavailability of manures, vary greatly. In some cases, nutrients can accumulate in soils to the point of being toxic to plants. Application of manures to pastures is normally not sustainable because less than 20% of the nutrients applied leave the field in animal products. However, when forage is cut for hay or silage, appreciable quantities of applied nutrients can be exported. Areas adjacent to CAFO can receive large quantities of nitrogen via dry or wet deposition. These can be advantageous to some crops, but may be detrimental to plants sensitive to nutrient inputs such as native range or forests. Speciation data indicate that the relatively nontoxic dietary organic form of As (ROX) can be converted to the more toxic As(V) form in soils. For optimal sustainability, fertilization levels need to be balanced with plant requirements. However, even under the best management systems some accumulation or escape of nutrients is inevitable. Therefore, nutrient management plans must recognize the need to deal with nutrients that accumulate in soils or leave the field or production area.

Growth and Development: ASAS-Emerging Roles of Gut Peptides in the Regulation of Appetite and Metabolism

13 Role of PYY in Appetite Regulation during Obesity. C. W. le Roux*¹, S. Shurey², R. P. Vincent¹, M. A. Ghatge¹, and S. R. Bloom¹, ¹*Department of Metabolic Medicine, Imperial College London Hammersmith Hospital, London, UK,* ²*Experimental Surgery, Imperial College London Northwick Park Hospital, London, UK.*

PYY is present throughout the gastrointestinal tract, with the highest tissue concentrations in distal segments. PYY is released into the circulation following food intake and postprandial concentrations is proportional to meal size, with peak plasma levels appearing in the second hour. PYY reduces gastric emptying and delays gastro intestinal transit. Chronically elevated PYY have been described in several gastrointestinal diseases associated with loss of appetite. More recently, PYY has been demonstrated to have a physiological action inhibiting food in-

take through its action on the NPY Y2 receptor in the arcuate nucleus. Bariatric surgery remains the most effective treatment for obesity. In a rodent model of intestinal bypass PYY was elevated in the bypass compared to the sham bypass group. Humans following Roux-en-Y gastric bypass surgery for the treatment of obesity also have higher postprandial PYY responses and this might contribute to their increased satiety. In contrast, obese subjects treated with gastric banding had equivalent initial weight reduction, but do not demonstrate similar hormonal changes. The weight loss following gastric banding is not as long lasting as that observed after gastric bypass. Obese humans and diet induced obese mice have reduced fasting and an attenuated post-prandial PYY response. A greater meal calorie content is required to achieve similar PYY concentrations in obese compared to lean humans; postprandial satiety was also less in the obese. Infusions of exogenous PYY at increasing doses across the physiological range produced a graded increase

in satiety and reduced food intake in humans. These findings suggest that the lower postprandial PYY levels observed in the obese subjects might account for their reduced satiety response. Obese subjects may have a weaker PYY induced satiety signal for an equivalent meal, which could reinforce obesity. Current findings are consistent with PYY being a factor in appetite regulation.

Key Words: PYY, Obesity, Weight Loss

14 Proglucagon: A gene with diverse metabolic functions. D. Burrin*, *USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX.*

The proglucagon (PG) gene is expressed in the gastrointestinal tract (GI) and brain in several animal species. The PG gene is differentially translated in the GI tract by specific endocrine cells to produce glucagon in the pancreas and glucagon-like peptides 1 and 2 (GLP-1/GLP-2), glicentin, and oxyntomodulin in the intestine. These PG-derived peptides have diverse functions involving insulin secretion, motility, and tissue growth within the GI tract, but also have systemic actions on glucose homeostasis and appetite regulation. There is considerable interest in the therapeutic potential of GLP-1 and GLP-2 in respective treatment of type-2 diabetes and intestinal dysfunction, including short-bowel syndrome and inflammatory bowel disease. GLP-1 and GLP-2 are co-secreted from the gut in response to enteral nutrition, particularly fat and carbohydrate, but are suppressed by total parenteral nutrition. GLP-1 and GLP-2 secretion are also stimulated by short-chain fatty acids that are produced by colonic fermentation of malabsorbed carbohydrate and dietary fiber. GLP-1 is a key incretin hormone that increases insulin secretion, islet neogenesis, β -cell proliferation. GLP-2 is a potent intestinotrophic hormone that increases intestinal mucosal cell proliferation, blood flow and suppresses apoptosis and inflammation. The GLP-1/2 receptors are G-protein-coupled membrane proteins that signal via intracellular cAMP release. The GLP-1/2 receptors are expressed in the brain and GI tract; however, the cellular localization is poorly understood. There is limited information on the biological function of GLP1/2 in the growth and development of domestic animals. However, these hormones may be possible therapeutic targets for modulation of feed intake and intestinal dysfunction in production animals.

Antibiotics in Animal Feeds: Are There Viable Alternatives?

16 Novel preharvest strategies involving the use of inorganic and nitro-based compounds to prevent colonization of food producing animals by foodborne pathogen. R. C. Anderson*, Y. S. Jung, J. A. Byrd, K. J. Genovese, T. R. Callaway, T. S. Edrington, R. B. Harvey, and D. J. Nisbet, *USDA-ARS, Food & Feed Safety Research Unit, College Station.*

Foodborne diseases caused by enterohemorrhagic *Escherichia coli*, *Salmonella* and *Campylobacter* are of public health and economic significance. Shedding of these pathogens during production and slaughter are critical risks for contamination of products for human consumption. Consequently, strategies are sought to prevent or reduce the carriage of these pathogens in food animals before slaughter. Experimental products containing chlorate salts have been proven efficacious in reducing, by several hundred-fold, concentrations of *E. coli* and *Salmonella* in the gut of cattle, sheep, swine and poultry when administered as feed or water additives. Mechanistically, chlorate selectively targets bacteria expressing respiratory nitrate reductase activity, such as most members of the family *Enterobacteriaceae*, as this enzyme catalyzes the reduction of chlorate to lethal chlorite. Most beneficial gut bacteria lack respiratory nitrate reductase activity and thus the technology appears compatible with many bacteria exhibiting competitive exclusion capabilities. Research and development of the chlorate technology continues and a much improved product has been designed to increase passage of the active ion to the lower gut. More recently, select oxidized nitrogen compounds are being investigated as potential feed additives and while these nitrocompounds significantly reduce pathogens on their own, evidence indicates that they may most effectively be used to complement the bactericidal activity of chlorate. A particular attractive aspect of the nitrocompound technology is that as potent inhibitors of ruminal methanogenesis, they may allow producers the opportunity to recoup costs associated with their use. At present, neither chlorate nor the ni-

15 Gut peptides and feed intake regulation in lactating dairy cows. C. K. Reynolds*¹ and J. A. Benson², ¹*The Ohio State University, Wooster,* ²*The University of Reading, Reading, UK.*

For the modern dairy cow to achieve her potential for production with minimal body energy loss, nutritionists seek to maximize feed intake in early lactation. In contrast, a goal of modern human nutritionists is to reduce obesity by limiting appetite and energy intake in excess of requirement. In both cases, a clearer understanding of the factors regulating short- (meal size) and long-term (body fat) appetite and nutrient intake is needed. In future, new findings regarding the role of gut and hypothalamic peptides in rodents will undoubtedly prove relevant to the dairy cow. The portal-drained viscera (gut, pancreas, spleen and associated fat) produce a number of peptides which are demonstrated regulators of appetite, intake and nutrient utilization, and for many their release to peripheral tissues is modulated by liver removal. Insulin regulates acute and chronic intake in part through effects on nutrient use and the hypothalamus. Insulin secretion is modulated by a variety of nutrients, as well as 'incretin' peptides from the gut, such as glucose-dependent insulinotropic polypeptide and glucagon-like peptide 1 (GLP-1). In cattle, over half of immunoreactive glucagon released by the PDV is of gut origin (presumably oxyntomodulin and glicentin). Other products of proglucagon processing released by the PDV include pancreatic glucagon, GLP-1 and GLP-2. The active form of GLP-1 (7-36 amide) is one of an emerging group of gut peptides that inhibit intake through effects on gut function and the hypothalamus, which include cholecystokinin-8 (CCK8) and peptide YY (PYY). Evidence suggests an increase in CCK8 may be responsible for decreased DMI in lactating dairy cows fed fat, but in lactating cows abomasally infused with vegetable oils decreased DMI was associated with increased net PDV release and arterial concentration of GLP-1, while portal vein CCK8 concentration was reduced. Considering effects in other species, it is highly likely that PYY regulates intake and gut function in lactating dairy cows as well, but further research on the roles of gut peptides in ruminants is needed.

Key Words: Glucagon-like peptide-1, Cholecystokinin, Insulin

trocompounds have been approved as feed additives by the U.S. Food and Drug Administration and consequently, they are not yet available for commercial use.

17 Alternative to Antibiotics - Utilization of bacteriophage to prevent foodborne pathogens. W. E. Huff*, G. R. Huff*, N. C. Rath, J. M. Balog, and A. M. Donoghue, *USDA/ARS/PPPSRU Poultry Science Center, University of Arkansas, Fayetteville.*

Bacteriophage are potentially a safe alternative to antibiotic therapy. Bacteriophage lytic to a non-motile, serotype O2 isolate of *Escherichia coli* were isolated from municipal waste water treatment plants and poultry processing plants. This *E. coli* isolate is pathogenic to poultry, causing a severe respiratory and systemic infection. Two bacteriophage isolates were selected to use in studies designed to determine the efficacy of these bacteriophage to prevent and treat severe colibacillosis in poultry. Colibacillosis is induced by injecting 6×10^4 cfu of *E. coli* into the thoracic airsac when the birds are 1 week of age. Initial studies demonstrated that mortality was significantly reduced from 85% to 35% when the challenge culture was mixed with equal titers of bacteriophage, and the birds were completely protected when the challenge culture was mixed with 10^8 pfu of bacteriophage. In subsequent studies, we have shown that an aerosol spray of bacteriophage given to the birds prior to this *E. coli* challenge could significantly reduce mortality even when given 3 days prior to the *E. coli* challenge. Our research on treating colibacillosis in poultry has demonstrated that an intramuscular injection of bacteriophage given 24 or 48 h after the birds were challenged rescued the birds from this severe *E. coli* infection. Our research has

demonstrated that bacteriophage can be used to both prevent and treat colibacillosis in poultry and may provide an effective alternative to antibiotic use in animal production.

18 Antibodies: an alternative for antibiotics? L. R. Berghman*¹ and S. D. Waghela², ¹*Departments of Poultry Science and Veterinary Pathobiology, Texas A&M University, College Station,* ²*Department of Veterinary Pathobiology, Texas A&M University, College Station.*

Infectious diseases of both humans and farm animals are re-emerging as significant problems, because our arsenal of effective anti-infective tools is not expanding proportionally. Thus, there is an urgent need for new approaches to the treatment of infectious disease, especially in cases of drug-resistant microbes, microbes for which therapy is not available, or in cases of host immune impairment. Recently developed technologies have opened up new avenues for the use of immunotherapy with pathogen-specific antibodies. While the idea is far from new (serum therapy in the early 1900s preceded the advent of antibiotics), for the approach to be affordable, an inexpensive, abundant source of specific antibodies is required. Polyclonal antibody sources therefore are limited to chicken egg yolk antibodies (also called IgY) and bovine colostrum antibodies. Numerous successful applications have been reported, ranging from treatment of rotaviral and cryptosporidial diarrhea to prophylaxis against dental caries. Monoclonal antibodies, while offering enhanced specificity, have long been disqualified, even for human treatment, due to lack of economical production systems. The recent introduction of transgenic animals and especially transgenic plants for production of therapeutic proteins has dramatically changed this perspective. Molecular farming of antibodies has made it possible to produce antibodies as complex as secretory IgA (sIgA) at a fraction (estimated at between 2-10%) of the cost of the conventional production systems. The plantibody approach is especially attractive for the production of recombinantly simplified antibodies, the so-called single chain variable fragments (scFvs). With decreasing cost of production, the potential to

tailor antibodies to very precise specifications and our increasing molecular knowledge of host-pathogen interactions, antibodies seem to have a bright future ahead as a redesigned tool for prophylaxis and treatment of infectious disease, both in animals and in humans.

Key Words: Antibodies, Therapy, Prophylaxis

19 Alternatives to Antibiotic Use - Natural food and feed amendments. S. C. Ricke* and M. M. Kunding, *Texas A&M University.*

Successful control of foodborne pathogens requires placement of antimicrobial hurdles during preharvest and postharvest food production. Chemical additives have traditionally included organic acids to control microbial contamination in animal feeds. However, there is some concern that continuous application of chemical antimicrobials can lead to a buildup of microbial resistance. This creates problems if foodborne pathogens evolve survival/resistance to a variety of environmental stressors that organisms encounter in pre- and postharvest animal production. To expand the diversity of potential antimicrobials that would have practical application for food animal production requires exploring the interaction between the food matrix and foodborne pathogens that become associated with it. Of particular interest is the potential for generating natural antimicrobial compounds during processing that originate from the food or feed. Possibilities include natural compounds formed during heating such as Maillard products and other chemically altered complexes and derivatives from foods and feeds which may possess antimicrobial properties for specific foodborne pathogens. Pathogens may also encounter natural antimicrobials in food products such as certain botanical compounds where they have historically been used for flavor enhancement as well as preservatives. Understanding the potential application for these natural compounds in foods and feeds will require examination of foodborne pathogen response under experimental conditions comparable to the environment where the pathogen is most likely to occur.

20 Effects of photoperiod on the immune function of multiparous gestating sows. S. R. Niekamp*, M. A. Sutherland, G. E. Dahl, T. L. Auchtung, and J. L. Salak-Johnson, *Department of Animal Sciences, University of Illinois, Urbana.*

Photoperiod manipulation has provided a non-invasive, easily implemented, effective, method to improve immune status while enhancing productive efficiency in gestational dairy cattle. In this study, our objective was to evaluate the impacts of photoperiod manipulation on endocrine and immune responses of gestating sows. At d83 of gestation, sows were moved to gestation crates and kept on a 12L:12D photoperiod during an adjustment period. At d90, sows were allotted to either long day (LD; 16L:8D) or short day (SD; 8L:16D) photoperiod until farrowing. Blood samples were taken at d 90, 97, 103, and 110 of gestation to evaluate cortisol (CORT), prolactin (Prl), total white blood cell (WBC), lymphocyte (Lymph), and neutrophil (Neut) counts, IgG concentrations, lymphocyte proliferation (LPA), neutrophil chemotaxis (CHTX), and neutrophil phagocytosis (PHAG). At d97, IgG concentrations were higher ($p < 0.05$) in animals experiencing LD than those on SD. Sows on SD photoperiod had higher ($p < 0.05$) conacavalin A and LPS-induced ($p < 0.01$) LPA responses compared to LD sows. CORT concentrations also tended to be higher ($p = 0.18$) in SD than LD animals. At d103, the only treatment effect was on LPA in response to LPS which was higher ($p < 0.05$) in LD sows than SD animals. There were no treatment differences at d110. While there were treatment differences at certain time points, there were no trends of treatment effects over the period of the experiment. It appears that photoperiod is affecting immune status and endocrine responses but may have no long term effects. Further investigation is needed to determine the precise effects of photoperiod on gestational sows and their piglets.

Key Words: Sows, Immune, Photoperiod

21 Effects of photoperiod on immune function in 7 and 21 day old piglets. S. R. Niekamp*, M. A. Sutherland, G. E. Dahl, and J. L. Salak-Johnson, *Department of Animal Sciences, University of Illinois, Urbana.*

Photoperiod manipulation provides a non-invasive, easily implemented, effective, method to improve immune status while enhancing production efficiency. The objective of this study was to evaluate the impact of photoperiod manipulation pre- and post-gestational on piglet immune responses. Piglets' dams were subjected to either long day (LD; 16L:8D) or a short day (SD; 8L:16D) photoperiod at d90 of gestation. During farrowing-lactation some of the sows remained on their original photoperiod (LD:LD or SD:SD) treatment while others were switched to the opposite treatment (LD:SD or SD:LD). Blood samples were taken from piglets at 7 d of age for cortisol (CORT), total white blood cell counts (WBC), and IgG concentrations. At 21 d of age, blood samples were obtained for CORT, WBC, neutrophil counts (Neut), lymphocyte counts (Lymph), lymphocyte proliferation (LPA), neutrophil chemotaxis (CHTX), and neutrophil phagocytosis (PHAG). At 7 d of age, piglets subjected to LD:SD had higher ($p < 0.05$) total WBC compared to all other treatment groups. Plasma CORT was higher ($p < 0.05$) among piglets kept under a LD:SD photoperiod but lower among SD:SD and SD:LD treated piglets. Plasma IgG tended to be lower ($p < 0.07$) for piglets on SD:SD and SD:LD compared to animals on LD:LD and LD:SD photoperiod. At 21 d of age, piglets whose dams were on SD:LD had higher total WBC ($p < 0.05$) compared to all other treatment groups. LPA response to conacavalin A was higher ($p < 0.01$) among piglets on SD:SD than any other treatment group. A similar trend was apparent with LPA in response to LPS ($p < 0.07$). There was also a tendency for piglets subjected to LD:LD to have higher ($p < 0.1$) PHAG compared to animals on LD:SD. These data support the concept that photoperiod manipulation can alter immune function in piglets during gestation and before weaning.

22 Farrowing performance and injury in a group housing system for gestating sows. M. J. Séguin*, T. M. Widowski, and D. Barney, *Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada.*

The University of Guelph research station converted one of two gestation rooms from 108 dry sow stalls to group housing with floor feeding. The new floor plan eliminated all alleyways, but was used to house the same number of sows (3.2m²/sow). Reducing the floor space allotment would make the system more economical. The objective of this study was to determine the performance and injuries of gestating multiparous sows housed in static groups at three floor space allotments and compare their performance records to that of the referent herd housed in stalls. Yorkshire sows were mixed after d 35 post-breeding into pens measuring 2.3, 2.8 or 3.2m² per sow. Group sizes ranged from 11-31. Body condition (5 point range) was scored upon entering and leaving gestation. The number and severity of superficial skin scratches on the shoulders (6 point range) were scored 24 h pre-mixing, 24 h post-mixing and on a weekly basis thereafter for five weeks. Mean, change and variation in body condition scores were not affected by group housing at any of the space allowances ($P > 0.1$), but the herd tends to be over-conditioned (average score: 3.5 ± 0.04). The day after mixing, 42.9 ± 8.3, 28.2 ± 7.7 and 28.0 ± 10.6 % of sows within a group had multiple skin scratches (scores 5-6) when housed at 2.3, 2.8 and 3.2m² per sow ($P > 0.1$), respectively. By two weeks post-mixing, most of the scratches had healed and by the end of the first month and for the remainder of gestation, fewer than 5% had multiple scratches. Shoulder scratches were a short-term consequence of group housing.

23 Application of guar hull by-product as a full-fed molting supplement. C. Zhang*, A. L. Cartwright, J. B. Carey, and C. A. Bailey, *Department of Poultry Science, Texas A&M University, College Station.*

A 5 × 5 Latin square experiment was conducted to explore the feasibility of molting hens by feeding relatively high concentrations (15 or 20%) of guar hull by-product. A total of 125 Bovan laying hens (64-week-old) of similar body weight were assigned to 5 groups of 5 replications with 5 hens in each replication, and were induced to molt by feed withdrawal (FW), or feeding 15 or 20% guar hull with or without β-galactomannase (Hemicell[®] at 250,000 unit/kg) for 14 days. Feed withdrawal birds, hens fed 15 or 20% guar hull without enzyme, and 20% guar hull with enzyme ceased laying at day 6, 10, 8 and 10 of treatment, respectively but hens fed 15% hull with enzyme continued to lay throughout the 14-day molting period. Feed withdrawal hens resumed laying in week 3 of post-molt, and reached 50% hen-day egg production in week 4. Full-fed groups laid eggs in the first week of post-molt, and reached 50% egg production in week 3. No differences ($P > 0.05$) were observed on egg production between FW hens and full-fed groups during the 8-week post-molt period, except that in week 7 fasted birds had lower egg production than the 20% guar hull-fed hens. The 20% guar hull-fed hens also had higher production than hens fed 15% hull with or without enzyme in week 6, 7 and 8. Fasted hens had higher mortality than all full-fed groups. All hens had higher egg weight, improved Haugh unit and shell quality, but decreased yolk color, when compared with the pre-molting period. No difference in egg quality was observed between each group except that FW hens had higher egg weights than full-fed hens. The results showed

that feeding guar hull by-product at 20% of complete diet may be a preferable molting approach to complete feed withdrawal.

Key Words: Guar, Laying Hen, Egg Production

24 A comparison of the behavior of broiler chickens raised on two different bedding types. S. J. Shields*, J. P. Garner, and J. A. Mench, *University of California, Davis.*

Exercise may be important for reducing leg problems in broiler chickens. A previous study (Shields et al., *in press*. Appl. Anim. Behav. Sci.) showed that sand bedding was preferred by broiler chickens for one form of exercise, dustbathing. The aim of this study was to determine the effect of sand bedding on the general behavioral activity of broiler chickens. In Experiment 1, 6 pens were divided down the center and bedded half with sand and half with wood shavings. Male broiler chickens (N=10/pen) were observed to determine day and nighttime behavioral time budgets on each side of the pens; nighttime behavior was videorecorded under red light. Each pen was observed 5 times per wk for 6 wk beginning when the chicks were 1 wk of age. Each observation period lasted for 1 hr during which scan samples of behavior were taken every 5 min. There was a significant behavior x bedding x week interaction ($F_{9,675} = 4.39, p < 0.0001$). During the day, drinking, dustbathing, preening, and sitting all increased on the sand (to 2.0%, 1.9%, 3.1% and 37.7 % of the time budget, respectively) but decreased on the wood shavings (to 0.1%, 0.0%, 1.1%, and 22.1% of the time budget). At night, resting increased on the sand (from 13.9% to 61.2% of the time budget). In Experiment 2, eight pens (N=50 birds/pen) were bedded either in sand or wood shavings. In contrast to the first experiment, bedding type did not affect time budgets (GLM: $F_{12,566} = 0.53, p = 0.8946$) or dustbathing ($F_{1,38} = 0.12, p = 0.73$). Thus, while in the first experiment some active behaviors were performed increasingly more often on the sand side of the pens, the results of the second experiment indicated that broilers will use wood shavings for these behaviors if it is the only substrate available. Therefore, although sand is a preferred substrate, providing sand bedding is unlikely to increase overall activity levels.

Key Words: Broiler Chicken, Behavior, Sand Bedding

25 Incidence of bone breakage in three strains of end-of-lay hens. K. L. Budgell¹ and F. G. Silversides^{2,3}, ¹*Nova Scotia Agricultural College, Truro, Nova Scotia,* ²*Crops and Livestock Research Centre, Charlottetown, Prince Edward Island, Canada,* ³*Pacific Agri-Food Research Centre, Agassiz, British Columbia, Canada.*

Bone fragility in commercial end of lay hens leads to breakage before slaughter which is a significant welfare concern, and after slaughter which is a concern because it reduces the value of the carcass. When 72 weeks old, 180 spent hens of three genetic lines were slaughtered at a provincially inspected plant. The carcasses were subsequently frozen for storage, then thawed and dissected to determine the number of bone fractures. Fractures were separated into those that showed signs of healing, an indication of breakage before shipping, those surrounded by tissue trauma, indicating breakage during depopulation and shipping, and those with no healing or soft tissue damage, indicating that they occurred after the hens were dead. Two lines of commercial layers, ISA-Brown and Babcock B300, had higher incidences of old (11.1% and 11.7%) and shipping breaks (7.9% and 10.0%) than a heritage line of Brown Leghorns (0.0% and 3.5% respectively). Most bones were broken during processing, and all hens had at least some broken bones. The ISA-Brown and Babcock B300 hens had a higher average number of breaks (13.5 and 18.9 respectively per bird) than Brown Leghorn hens (8.7 per bird). The majority of breaks were of the pubis, ischium, sternum, and rib cage, with 97.8, 90.6, 89.4, and 71.7% respectively of the hens experiencing breaks in these bones by the end of evisceration. These results show that spent laying hens suffer broken bones before, during, and after depopulation and slaughter. Differences between the lines in the incidence of broken bones suggest that selection of commercial layers for high egg production may have affected bone strength.

Key Words: Layers, Strains, Bone Breakage

26 Unexpected estimates of variance components with a true model containing genetic competition effects. L. D. Van Vleck*¹ and J. P. Cassady², ¹USDA-ARS, Roman L. Hruska U.S. Meat Animal Research Center, ²North Carolina State University.

Simulation of the model of Muir and Schinckel containing genetic competition effects was initiated to determine how well REML could untangle variances due to direct and competition genetic effects and pen effects. A two-generation data set was generated with 6 unrelated males, each mated to 5 unrelated females to produce 300 progeny from which 30 females (one per mating in previous generation) were mated to 6 unrelated males to produce 300 more progeny. Progeny were randomly assigned 6 per pen to 50 pens per generation. Parameters were V_g , V_c , C_{gc} , V_p and V_e representing direct and competition genetic variance with covariance, and pen and residual variance. Eight statistical models were used to analyze each of 400 replicates of 16 sets of parameters. Both V_g and V_e were fixed at 16. Values of C_{gc} were -2, -1, 0.1, 1 and 2. Values of V_c were 1 and 4 and of V_p were 0.1, 1, and 10. With the full model, average estimates resembled true parameters except that V_p was consistently overestimated when small (0.1 and 1) which, in turn, slightly changed other estimates. The most unexpected result was overestimation of V_p when V_c and C_{gc} were ignored in the analysis. The overestimation depended on V_c and number of competitors in common between records in a pen. The upward bias was greater when C_{gc} was positive than when negative. For example, with $C_{gc} = 2$, $V_c = 4$ and $V_p = 0.1$, mean estimate of V_p was 20.4 when C_{gc} and V_c were dropped from the model and 15.3 when $C_{gc} = -2$. When V_p was ignored, estimates of both C_{gc} and V_c increased proportional to V_p . Also V_g increased more with greater V_p . Another unexpected result was that when pen was considered fixed for the analysis, sampling standard errors of estimates of C_{gc} and V_c were reduced generally by factors of 2 to 30. These results suggest that a high estimate of pen variance may indicate genetic competition effects are important and that ignoring pen effects will bias estimates of other components.

Key Words: Genetic Parameters, Pen Effects, Simulation

27 An animal model with autoregressive covariance structures among residual and genetic effects for genetic evaluation of Holstein cows with test day records. R. M. Sawalha*¹, J. F. Keown², S. D. Kachman², and L. D. Van Vleck³, ¹University of Nebraska, Lincoln, ²Department of Statistics, University of Nebraska, Lincoln, ³USDA, ARS, Roman L. Hruska U.S. Meat Animal Research Center, Lincoln, NE.

This study was to evaluate an animal model with first order autoregressive covariance structures (AR1) among residual and genetic effects of test day (TD) records. This model was compared with a simple TD repeatability model and a 305-day lactation model. Data consisted of 106,472 test day records of 12,071 first lactation Holstein cows. Estimates of components of variance and autocorrelation coefficients were obtained for milk, fat, and protein yields and somatic cell scores (SCS) using ASReml. Likelihood ratio tests indicated that AR1 model was significantly more appropriate for the TD data than the simple repeatability model for all four traits. Estimates of heritability were slightly lower for yield traits (0.09) with AR1 model than with simple TD repeatability model (0.10-0.11). Estimates of heritability with 305-d yield traits were in the range of 0.14 to 0.36. For SCS, both TD models resulted in similar estimates of heritability of 0.06. Estimates of residual variance were probably underestimated with simple repeatability model compared with AR1 model. Average estimates of accuracy of PBV for all traits were always higher with simple repeatability model than with AR1 model for both sires and cows. The least change in rank of the top 100 elite sires and cows was between the two TD models (4-9% for sires). The greatest difference in ranking of elite animals was between simple repeatability model and 305-d model (26-36% for sires). Similar patterns were also observed for values of correlation among PBV of different models. The AR1 model resulted in similar or slightly lower correlations between actual lactation records of cows and the averages of PBV of their parents compared with the simple repeatability model. Average PBV tended to increase with advancement of lactation for yield traits and to decrease for SCS. Averages of PEV of PBV were highest at the beginning and at the end of lactation.

Key Words: Milk Yield, Test Day, Autoregression

28 Detection of different shapes of lactation curve in cattle by standard mathematical models. N. P. P. Macciotta*¹, D. Vicario², C. Di Mauro¹, and A. Cappio Borlino¹, ¹Dipartimento di Scienze Zootecniche Via De Nicola 9, 07100 Sassari, Italia, ²ANAPRI Via Nieveo 19, 33100 Udine, Italia.

Four mathematical models of lactation curve (Wood WD, Wilmik WIL, Ali and Schaeffer AS parametric models and Legendre fifth order polynomials LEG) were fitted to individual milk yield patterns of 27,837 Italian Simmental cows, each having at least 7 records. Aims of the work were: i) to assess goodness of fits; ii) to check sensitivity of models in discriminating different shapes of lactation curve; iii) to analyse relationships among curve shapes and parameter values and (co)variances. About 70% of individual regressions showed an adjusted $R^2 > 0.75$ for all models. Among these best fits, three-parameter models (WD and WIL) detected two main families of curve shape, the typical curve (with a first increasing phase till a peak followed by a declining phase), and the so-called atypical curve, characterised only by the declining phase. AS and LEG models assigned most of lactation patterns to the two main families but, due to their greater flexibility, around 15% of curves were allocated in about 10 other not well defined forms. Each family of curve shape had a specific combination of signs of parameters. Range of absolute values of parameters and correlations among them were similar in the two families highlighted by WD and WIL models, whereas differences among some families were detected by AS and LEG functions. The great heterogeneity of lactation curve shape could explain some problems encountered in the analyses that require comparison between parameter values and estimation of their (co)variances, as the anomalous variance of estimated yields at the first phase of lactation. The drastic solution to discard atypical lactations could not be applied when the occurrence of these patterns is relevant, as in the present study (about 30%). An alternative solution suggested by results of this study could be to perform separate analysis within each of the main family of lactation curve shape.

Key Words: Mathematical Models, Lactation Curve Shape, Parameter Values

29 Impact on calving ease evaluations of excluding herds with abnormal distribution of scores. C. P. Van Tassell, G. R. Wiggins, and L. L. M. Thornton*, Animal Improvement Programs Laboratory, Agricultural Research Service, USDA Beltsville, MD.

Threshold model sire and maternal grandsire (MGS) calving ease evaluations for the United States were calculated after excluding two sets of 10% of the data. Herds were excluded based on χ^2 goodness of fit test. To determine the first set of herds to be excluded, frequencies of observed (O) records were determined by parity (1 vs. 2+) and difficulty score (1-5). Expected (E) numbers of records were calculated as the total number of calvings by parity multiplied by the fraction of difficulty scores across all herds in each parity. Goodness of fit values were calculated as the sum of $(O-E)^2/E$ across parity and difficulty score. The 299 herds failing this test tended to be large. The second set of 8605, mostly small herds, was identified using frequencies in place of counts. Evaluations were calculated using data from all years or only calvings before 1999. Pedigree indexes ($0.5 \times \text{sire} + 0.25 \times \text{MGS}$) were calculated from two earlier data sets (abnormal distribution herds included or excluded). Correlations were calculated between pedigree index and solutions from evaluations for bulls with at least 30 calvings in the complete data. Correlations were higher between solutions from sets with abnormal distribution herds excluded. For the first set of excluded herds, for sire solutions, the increase was from .579 to .599 for 25,067 bulls, and for MGS, from .598 to .617 for 21,221 bulls. For the second set, the increases were .004 greater. Differences between evaluations from early and complete data were also examined. Variances of these differences and mean and maximums of the absolute values of differences tended to be larger when the first set of abnormal distribution herds were excluded. These differences are likely due in part to the reduction in total data represented in the predicted breeding values. The differences tended to be smaller when the second set was excluded. These improvements indicate that the evaluations should better predict

future performance when data from herds with abnormal distributions is excluded.

Key Words: Calving Difficulty, Dystocia, Abnormal Distribution

30 Effects of heteroscedasticity on sires' predicted transmitting ability in grazing and confinement herds. A. G. Fahey*, M. M. Schutz, D. L. Lofgren, A. P. Schinckel, and T. S. Stewart, *Purdue University, Lafayette, IN.*

The number of grazing (G) herds in the USA is increasing. Heteroscedasticity (HV) of data may affect the ability of sires' predicted transmitting ability (PTA) to predict actual performance of daughters. The objective of this study was to investigate the effect of HV on the predictability of PTA for mature equivalent (ME) milk (MEM), ME protein (MEP), and ME fat (MEF) for daughters in G and confinement (C) herds. Data consisted of 366 G herds from 11 states with 72,489 records and 373 C herds from 12 geographically similar states with 117,629 records. Herds were divided into mean quartiles (Q_{M1} - Q_{M4} , from low to high) and variance quartiles (Q_{V1} - Q_{V4}) based on MEM, and a transformation was applied to reduce HV. The method of transformation was to standardize the within herd variance to the average variance of a base year for each parity, and was similar to that used in the USDA-DHIA genetic evaluations. Coefficients of regression (RC) of daughter yield on PTA in G herds indicated that PTA overestimated daughters' production for all traits in Q_{M1} - Q_{M3} ($P < 0.01$) and for MEF in Q_{M4} ($P < 0.05$). In C herds, RC in Q_{M1} and Q_{M4} for MEP and in Q_{M1} , Q_{M2} , and Q_{M4} for MEF were less than unity ($P < 0.05$). After transformation, changes in RC for G herds were negligible. For C herds, only the RC for MEP in Q_{M4} was different from unity ($P < 0.05$). Analysis within variance quartiles also showed that PTA overestimated production of all traits in Q_{V1} - Q_{V3} ($P < 0.01$) and MEM in Q_{V4} ($P < 0.05$) in G herds. For C herds, yields of MEM in Q_{V1} and Q_{V2} ($P < 0.05$), and of MEP ($P < 0.01$) and MEF ($P < 0.01$) in Q_{V1} were overestimated; MEP was underestimated in Q_{V4} ($P < 0.05$). Reducing HV had little effect on G herds; but for C herds, RC was no longer different from unity for MEM and MEP in Q_{V1} and Q_{V2} . Production was more accurately predicted by PTA in C herds than G herds. Accounting for HV had little effect on the predictability of PTA, indicating that observed scaling effects do not arise solely from effects of HV.

Key Words: Heteroscedasticity, Predicted Transmitting Ability, Grazing

31 Effects of heteroscedasticity on the heritability and genetic correlations of production traits in grazing and confinement herds. A. G. Fahey*, M. M. Schutz, D. L. Lofgren, T. S. Stewart, and A. P. Schinckel, *Purdue University, West Lafayette, IN.*

Grazing (G) herds in the USA are increasing in number. Heteroscedasticity (HV) of data may bias estimates of genetic correlation (r_G) for yield traits between environments, an indicator of genotype-by-environment interaction (GxE). The objective of this study was to investigate the effect of HV on estimates of heritability (h^2) and r_G for mature equivalent (ME) milk (MEM), ME protein (MEP), and ME fat (MEF) yield of daughters in G and confinement (C) herds. Data consisted of 366 G herds from 11 states with 72,489 records and 373 C herds from 12 geographically similar states with 117,629 records. Herds were divided into mean quartiles and variance quartiles based on MEM. A transformation was used to reduce HV. The method of transformation was to standardize the within herd variance to the average variance of a base year for each parity, and was similar to that used in the USDA-DHIA genetic evaluations. In G herds, estimates of h^2 were near 0.19, 0.19, and 0.20 for MEM, MEP, and MEF. For C herds, h^2 from lowest to highest quartile. Estimates of r_G between G and C were greater than 0.89 in all mean quartiles, implying little GxE. Reducing HV by transforming yield records had little effect on h^2 or r_G . For variance quartiles, h^2 fluctuated as variance quartiles increased. For MEM, MEP, and MEF, h^2 were approximately 0.17, 0.17, and 0.19, respectively. The r_G for yield traits between C and G environments within each variance quartile suggested a GxE only for the lowest quartile for MEM. Transforming the records had negligible effects on the h^2 and r_G for variance quartiles. For G and C herds, h^2 were similar for all traits. The r_G near unity for the highest variance quartiles suggests that traits in both environments are controlled largely by the same genes. Reducing HV did not affect

estimates of h^2 or r_G , indicating that modest evidence for existence of GxE, especially in the lowest quartile, did not arise solely from HV.

Key Words: Heteroscedasticity, Heritability, Genotype-By-Environment Interaction

32 Segregation analysis of milk flow in Swiss dairy cattle by Bayesian approach. H. Ilahi and H. N. Kadarmideen*, *Statistical Animal Genetics Group, Institute of Animal Science, Swiss Federal Institute of Technology (ETH) Zurich ETH Zentrum (UNS), CH-8092 Zurich, Switzerland.*

Segregation analyses via Gibbs sampling were applied to investigate the mode of inheritance and to estimate the genetic parameters of milk flow of 3 breeds of Swiss dairy cattle. Data consisted of 204,397, 655,989 and 40,242 lactation records of milk flow in Brown Swiss (BS), Simmental (SM) and Holstein (HO), respectively (collected in the last 4 to 22 years). Number of animals in pedigree ranged from 343,969 to over 1 million (1,013,610) animals. Separate segregation analyses of first and multiple lactations were carried out for each breed by an individual animal model, implemented by Gibbs sampling algorithm with blocked sampling of genotypes and a polygenic model for first lactation data sets of all breeds by Restricted Maximum Likelihood Method. Genetic parameters of milk flow were very similar under both mixed inheritance (polygenes and major gene) and polygenic models. Estimated marginal posterior means of additive and dominance effects of the major gene were 0.016, 0.010, 0.023 for first lactation data set of BS, SM and HO, respectively and 0.013 and 0.012 for multiple lactations data set of BS and SM, respectively. Segregation analyses yielded very low major gene variances which favor the polygenic determinism of this trait, in contrast to confirmed mixed inheritance of this trait in dairy goats. Heritabilities and repeatabilities of milk flow in both BS and SM were high (0.44 to 0.48 and 0.54 to 0.59, respectively), however the heritability of this trait (based on scores of milking ease) in HO was intermediate (0.25). Variance components and heritabilities in the first lactation were slightly larger than those estimates for multiple lactations especially for error variances. Our results suggest that milk flow (quantity of milk per minute of milking) is a relevant measurement to characterize cows milking ability which is a good candidate trait to be included in selection program in dairy cattle.

Key Words: Segregation Analysis, Milk Flow, Bayesian Method

33 Prediction of longevity breeding values for U.S. Holstein sires using survival analysis methodology. D. Z. Caravillo*, K. A. Weigel, and D. Gianola, *University of Wisconsin, Madison.*

Breeding values of Holstein sires for daughter longevity in each of nine geographical regions of the US were predicted using a Weibull proportional hazards model. Longevity was defined as days from first calving until culling or censoring after correction for within-herd-year 305-d mature equivalent production. Records from 2,322,389 Holstein cows with first calving from 1990 to 2000 were used. In addition to the sire's additive genetic merit, the failure time model included time-dependent effects of herd-year-season of calving, parity-stage of lactation, and within-herd-year quintiles for mature equivalent fat plus protein yield, as well as the time-independent effect of age at first calving. The relative risk of culling for daughters of each individual sire was expressed relative to that of a daughter of an average sire (within a specific region). Predicted breeding values for functional longevity, expressed as relative risk ratios, ranged from 0.7 to 1.3. Sizable differences in sire rankings were observed between geographical regions, suggesting that a single national ranking may not hold in every region. Substantial differences in estimates of the sire variance and the gamma parameter of the distribution of herd-year-season effects occurred between regions. Two random samples of herds were selected from the full national data set; these samples contained 375,086 records and 256,751 records, respectively. PTA of sires for daughter longevity were compared with predictions from a linear (animal) model, as currently used for routine national (US) genetic evaluation of length of productive life. Logistic regression of daughters' stayability to 36, 48, 60, 72 or 84 months of life, among animals that had opportunity to stay that long, on sires predicted transmitting ability indicated that the proportional hazards model yielded more accurate predictions of daughter longevity than the linear animal model, even though the latter relies on more dense pedigree information.

Breeding and Genetics: Genetics of Dairy Health Traits

34 Potential for inclusion of health data in international genetic programs. P. D. Miller*, *University of Wisconsin, Madison.*

Genetic selection programs for dairy cattle in many countries are reviewed, breeding goals are compared, and the degree of uniformity that exists and is required for international genetic programs for health traits is discussed. The most prevalent health disorders in dairy cattle are mastitis, infertility, lameness, milk fever, ketosis, metritis, and displaced abomasums. The manifestation of these disorders can be partly attributed to management and environmental factors, but there is evidence that each also has a genetic component. Health traits are genetically correlated with traits for which international genetic evaluations are routinely available from Interbull, including milk production, conformation, and udder health traits. Evaluations for longevity (length of herd life) are expected this summer. Genetic evaluations for female fertility traits are available in many countries and international evaluations are imminent. Effective selection using quantitative genetic approaches requires measurement and recording of phenotypes and frequent evaluation of candidates for selection. Producers use many different definitions to record health data and do not use a standardized format in on-farm or DHIA databases. Change will require significant time and effort by many people. Direct genotyping using DNA technologies offers potential for direct selection for genes causing health problems, but this is likely to be a slow and incomplete solution. Potential exists for genetic improvement of health in dairy cattle. Economic, social, and political forces will shape the changes that occur.

Key Words: Health, Genetic, International

35 Genetic basis and risk factors of infectious and noninfectious diseases in US Holsteins. I. Estimation of genetic parameters for single diseases and general health. G. Abdel-Azim¹, A. E. Freeman², M. E. Kehrli³, S. C. Kelm⁴, J. L. Burton⁵, A. L. Kuck¹, and S. Schnell¹, ¹*Cooperative Resources International, Shawano, WI*, ²*Department of Animal Science, Iowa State University, Ames*, ³*National Animal Disease Center-USDA-ARS, Ames, IA*, ⁴*Animal & Food Science Department, University of Wisconsin, River Falls*, ⁵*Michigan State University, East Lansing.*

Health data collected over a period of four years, 1996 to 1999, from 177 herds in Minnesota and Wisconsin were analyzed to establish genetic basis for infectious and noninfectious diseases. Three types of health traits were targeted, first, selected infectious conditions were fit together in a statistical model to identify animals that are superior in their general immunity for infectious diseases. Generalized immunity may be thought of as a combination of immune responses to a variety of immune system challenges. Second, single infectious and noninfectious diseases were analyzed separately. Third, infectious reproductive diseases as one category of related conditions and cystic ovary disease as one category of 3 related noninfectious ovary disorders were studied. Data were analyzed by a threshold model that included herd, year, season of calving, parity, sire, and cow as cross-classified factors. Days at risk and days in milk at the start of the trial were adjusted for by fitting the days as continuous covariates in the model. A heritability value of 0.202 ± 0.083 was estimated for generalized immunity. Heritability values of 0.141 and 0.161 were estimated for uterine infection and mastitis, respectively. Heritability of single noninfectious disorders ranged from 0.087 to 0.349. The amount of additive genetic variance recovered in the underlying scale of noninfectious disorders tended to 0 when combining together multiple conditions. Therefore, although the study is in favor of combining infectious diseases into categories of interest, we do not recommend the same approach for noninfectious disorders because of the different mechanisms controlling them.

Key Words: Disease Resistance, Generalized Immunity, Genetic Evaluation

36 Multivariate genetic parameters for health, reproduction, body condition score, and conformation traits in Swiss Holsteins. H.N. Kadarmideen*, *Statistical Animal Genetics Group, Institute of Animal Science, Swiss Federal Institute of Technology (ETH) Zurich ETH Zentrum (UNS), Ch-8029 Zurich, Switzerland.*

Data on body condition score (BCS), days to first service (DFS), non-return rate (NRR), somatic cell count (SCC), and 305-day yields of milk, fat and protein from 38,930 multiple lactation records of cows, daughters of 243 sires in 1830 herds were used to estimate genetic parameters. Single- and multi-trait repeatability animal models were used to estimate parameters based on restricted maximum likelihood methodology. Fixed effects in the model varied depending on the individual trait. Further, genetic relationships between 27 (linear and descriptive) type traits and functional traits (fertility and SCC) were estimated by regressing daughter type records on their sire estimated breeding values for functional traits, using the same data set. BCS had a moderate heritability (h^2) of 0.26 and fertility traits had low h^2 (0.12 for DFS and 0.06 for NRR). Heritability of SCC and milk production traits was 0.14 and around 0.30, respectively. BCS had favorable genetic correlations with fertility traits (-0.35 with DFS and 0.04 with NRR) suggesting that BCS could be considered in a fertility index. BCS had a favorable genetic correlation (r_g) with SCC, but not strong (-0.08). Selecting for milk production alone would lead to decline in genetic merit for functional traits considered here, as milk production has antagonistic r_g with fertility (range 0.12 to 0.27 with DFS and -0.12 to -0.24 with NRR), with BCS (-0.39 to -0.50), with SCC (0.10 to 0.15). Many type traits (especially udder traits) had a favorable genetic relationship with fertility traits and somatic cell counts whereas dairy character had an unfavorable genetic relationship. Results (genetic correlations) suggest that future selection indexes may include BCS (possibly also dairy character) as an indicator of fertility with appropriate (high) economic weights while including production traits with (less) optimal economic weights.

Key Words: Reproduction, Body condition score, Genetic correlations

37 Estimation of genetic parameters for health traits in large commercial herds using data recorded in on-farm herd management software programs. N. R Zwald* and K. A Weigel, *University of Wisconsin, Madison.*

The objective of this study was to estimate genetic parameters for clinical mastitis, lameness, metritis, ketosis, and displaced abomasum using data recorded on commercial dairy farms. Disease incidence data were recorded in one of three herd management programs: DC305, PCDART, or DHIPLUS. Data were collected directly from 141 herds that participated in the Alta Genetics Advantage progeny test program, and Dairy Records Management Systems provided data from an additional 160,264 cows in 438 herds that routinely recorded health disorders. Incidence rates on were: 14.1%, 10.4%, 5.4%, 4.9%, 2.2%, for mastitis, lameness, ketosis, metritis, and displaced abomasum respectively. In the genetic analysis, herds were required to have a recorded incidence rate of $>1\%$ for ketosis, metritis, and displaced abomasum and $>3\%$ for mastitis and lameness. After removal of herds with incomplete reporting and cows with unknown sires or sires with < 5 daughters, data included: Clinical mastitis: 441 herds, 143,592 cows and 4505 sires Lameness: 228 herds, 79,413 cows, and 1109 sires Displaced abomasum (DA): 326 herds, 106,998 cows, and 2165 sires Metritis/Retained Placenta: 471 herds, 148,885 cows, and 2162 sires Ketosis: 133 herds, 44,335 cows, and 730 sires A threshold sire model was used. The model for early metabolic disorders (metritis, ketosis, and DA) was response = HYS + Lactation + sire. A three-trait model, treating occurrences of disease in each of the first three lactations as separate traits, was used for mastitis and lameness. This model was response = HYS+ stage of lactation + sire. Heritability estimates ranged from 0.06 to 0.11. Cases of ketosis, metritis, and DA were combined in an analysis of early metabolic health. Due to the binary nature of these traits, relationships between traits, and low incidence rates combining traits into an early metabolic health index has great potential for implementation in a selection program.

Key Words: Early Metabolic Disorders, Progeny Test, Genetic Parameters

38 Health parameters in F1 Jersey x Holstein, backcross (Jersey x Holstein) x Holstein, and pure Holstein calves. C. Maltecca* and K. Weigel, *Department of Dairy Science, University of Wisconsin, Madison.*

The present study is part of a larger project that aims to detect quantitative trait loci (QTL) affecting health, fertility, calving ease, and milk composition in a crossbred Holstein x Jersey cattle population. Fecal and respiratory scores and birth weights were recorded for F1 Jersey x Holstein, backcross (Jersey x Holstein) x Holstein, and pure Holstein calves on two farms. Fecal and respiratory scores were measured on a five-point scale of severity. Ninety two pure Holstein calves (41 females and 51 males) and 31 F1 Jersey x Holstein calves (15 females and 16 males) were from a commercial dairy in Wisconsin, while 60 pure Holstein calves (31 females and 29 males) and 35 crossbred calves (15 females and 20 males) were from the University of Wisconsin experimental herd. Mean Fecal scores were 1.36 (\pm 0.37) and 1.49 (\pm 0.38) for Holstein calves in the commercial and experimental herds, respectively. Corresponding means were 1.22 (\pm 0.16) and 1.44 (\pm 0.24) for F1 Jersey x Holstein calves and backcross (Jersey x Holstein) x Holstein calves, respectively. Mean respiratory score were 1.03 (\pm 0.01) and 1.10 (\pm 0.09) for Holstein calves on the commercial and experimental farms, respectively, and 1.04 (\pm 0.02) to 1.18 (\pm 0.12) for F1 and backcross calves, respectively. Mean birth weights for calves from multiparous dams in the experimental herd were 42.7 (\pm 3.3) and 39.2 (\pm 6.7) for Holstein males and females and 40.2 (\pm 7.4) and 41.2 (\pm 3.3) for backcross males and females, respectively. Mean birth weights for the commercial herd were 45.1 (\pm 6.4) and 42.0 (\pm 6.4) for Holstein males and females and 35.7 (\pm 3.4) and 31.4 (\pm 3.9) for backcross males and females, respectively. Differences between pure Holstein, F1 Holstein x Jersey, and backcross (Holstein x Jersey) x Holstein calves for scours and respiratory score were not significant.

39 Application of a finite mixture model to somatic cell scores of Italian goats. P. Boettcher*¹, D. Gianola², G. Pisoni³, C. Vimercati³, M. Rinaldi³, and P. Moroni³, ¹IBBA-CNR, Segrate, Italy, ²University of Wisconsin, Madison, ³University of Milan, Milan, Italy.

Mastitis infection usually results in high concentrations of somatic cells (SCC) in the udder of affected animals. Data on SCC from infected and uninfected mammary glands can be viewed as drawn from many statistical distributions with different means and, possibly, different variances. Information on bacterial infection is often not available to indicate the distributions from which a given data point originates, but an analysis with finite mixture models can account for this uncertainty by assigning each record to a given distribution with a certain probability. The objective was to apply such an analysis to data for SCC in dairy goats. Data were 1378 test-day records of SCC and presence of bacteria in each of the udder halves of 92 primiparous goats in five Italian herds. The approach regarded all observations from a given udder half as arising from the same distribution. The fit of a single component (standard) model with mixtures of two or three distributions was examined. From a biological standpoint, a two-component model would be appropriate if observations from healthy and infected udder halves were from two different distributions and a three-component (or more) model would be appropriate if bacterial species differed in their effect on SCS. The two-component model was able to separate distributions that differed in mean by 0.89 SCC (log 2), or approximately 0.30 standard deviations. The proportions of the "low" and "high" SCS components were approximately 60 and 40%, respectively. The ability of the analysis to assign observations to different distributions according to bacterial presence was tested. A clear association with bacterial infection was observed. For example, observations from udder halves with no bacterial infection were assigned to the component with a low mean SCS with a probability of 65%. In contrast, udder halves with bacterial presence at eleven test days were assigned to the high group with a 70% probability. The three-component model was unable to distinguish separate distributions. Application of a mixture model in genetic evaluations may improve selection programs based on EBV for SCC.

40 Test day model evaluation for production traits and somatic cells score for the Italian Holstein. F. Canavesi*, S. Biffani, and F. Biscarini, *ANAFI Via Bergamo 292,26100, Cremona, Italy.*

In the past three years the Italian Holstein association in cooperation with Canadian Dairy Network (CDN) has been working toward the development of a random regression test day model evaluation for milk, fat, protein and somatic cell score (SCS). The model is a multiple trait, multiple lactation test day animal model with fixed effects of herd-test day-parity. A Legendre polynomial of 4th order is used to fit the fixed effect of age-parity-region-season and the random effects of the animal and of the permanent environmental effect. Heritability for production traits is on average 0.30 the same parameter used for the official evaluation based on lactation records. Heritability of SCS is 0.17 in first, 0.21 in second and 0.25 in third lactation respectively, much higher than the present 0.08 value used for genetic evaluation based on first lactation test day records with a repeatability test day model. The correlation with the official sire production proofs is around 0.97 for yield traits and 0.70 for SCS. For cow proofs the correlation is around 0.92 for production traits and 0.69 for SCS. The first official publication is expected before the end of 2004.

Key Words: Test Day Model, Genetic Evaluation, Random Regression

41 Crossbreds of Normande-Holstein, Montbeliarde-Holstein, and Scandinavian-Holstein compared to pure Holsteins for production and SCS during the first 150 days of first lactation. B. J. Heins, L. B. Hansen*, and A. J. Seykora, *University of Minnesota, St. Paul.*

Normande-Holstein (NxH) crossbreds (n = 171), Montbeliarde-Holstein (MxH) crossbreds (n = 194), and Scandinavian-Holstein (SxH) crossbreds (n = 120) were compared to pure Holsteins (H, n = 294) for milk, fat, and protein production and SCS during the first 150 days of lactation of first lactation. Cows were housed in seven commercial dairies in California and calved from June 2002 to December 2003. Dependent variables for analysis were test-day observations from DHI. All Holstein sires and all Holstein maternal grandsires were required to have an NAAB sire code to assure they were A.I. sires. Normande, Montbeliarde, and Scandinavian crossbreds were all daughters of A.I. sires via imported semen. Independent variables were breed (H, NxH, MxH, SxH), random effect of sire within breed, random effect of cow within sire and breed, stage of lactation (4-30 d, 31-60 d, 61-90 d, 91-120 d, 121-150 d), herd-year-season (3-mo seasons within the seven herds), age at calving (linear, months), milking frequency (2X, 3X), and PTA of Holstein maternal grandsire (linear). Breed was significant for all traits. Least squares means for fat plus protein were 2.03 kg (H), 1.90 kg (NxH), 2.05 kg (MxH), and 2.18 kg (SxH). Relative to production of pure Holsteins on a percentage basis, differences were -6% (NxH), +1% (MxH), and +7% (SxH). Least squares means for SCS were 2.13 (H), 2.40 (NxH), 2.33 (MxH), and 1.88 (SxH).

Key Words: Crossbreeding, Production, SCS

42 Accuracy and stability of national and international somatic cell score evaluations. R. L. Powell*, A. H. Sanders, and H. D. Norman, *Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Most research on accuracy of dairy bull genetic evaluations has been with yield traits. This report focuses on somatic cell score (SCS) evaluations. International evaluations through Interbull (IB) have been available since May 2001. February 2004 U.S. and IB SCS PTA were matched with U.S. and IB PTA from May 2001 (US04, IB04, US01, and IB01, respectively) for 14,821 Holstein bulls. All four evaluations were required for each bull. Over the three years, the means were essentially the same (increased 0.001) in each system (U.S. and IB). Correlations of 0.96 and regressions of later on earlier PTA of 0.99 were nearly as expected. Bulls adding substantially to numbers of U.S. daughters had mean increases in PTA of about 0.01 and regressions of nearly unity but correlations between earlier and later PTA were about 0.04 lower than expected considering reliabilities. The US01 and IB01 PTA were compared as predictors of US04 where IB01 PTA included data from at least one other country. As expected, US01 was the better predictor where it contained essentially the same daughters as US04, but IB01 was better when U.S. daughters increased at least 25%. Mean PTA difference

from US04 was closer to zero, standard deviation of the differences was smaller, and correlations were higher. The advantage in correlation from IB01 increased with the amount of new U.S. data in the 2004 evaluation. Both U.S. and IB evaluations were stable on average, increasing in mean only slightly. Regressions were essentially unity in both systems. Correlations were less than expected by about 0.01 overall and lower by 0.04 for subsets with substantial added data. Inclusion of foreign data in addition to U.S. data improved the prediction of later U.S. SCS evaluations.

Key Words: Genetic Evaluation, Somatic Cell Score, Interbull

43 Genetic component of heat stress. S. Oseni, I. Mistral*, S. Tsuruta, and R. Rekaya, *The University of Georgia, Athens.*

A norm reaction model was used to estimate the genetic parameters of days open (DO) and pregnancy rate (PR) under heat stress. Data included DO records for GA, TN and NC. Pregnancy rate was computed as $PR = \min\{1, 1/[(DO-50)/21-1]\}$. PR, unlike DO, assigns greater weight to smaller DO records. Fixed effects model included herd-year-month of calving, age of the cow, and a regression on 305-d milk yield. The norm-reaction model additionally included the effect of animal with random regression on a heat index, which was normalized solutions to months of calving from the fixed model; residual variance was assumed to be a function of the heat index. The shape of the heat index for DO (PR) was close to sinusoidal (triangular) function with the highest value in April (May) and the lowest value in October (October). For DO and PR, genetic and residual variances and heritabilities were highest for spring calvings and lowest for fall calvings. For DO (PR), the variance associated with the highest level of heat index was 33% (33%) of the genetic variance of the regular effect. Genetic correlation between regular and heat stress effects for DO (PR) was 0.67 (-0.65). As a validation process, DO was computed with the model above, without the heat stress index and the months of calving grouped into four seasons treated as multiple traits. In general, the genetic and residual variances of the multiple trait model followed those of the norm-reaction model for DO.

Dairy Foods: Chemistry

45 Utilization of front face fluorescence spectroscopy for rapid analysis of process cheese functionality. S. K. Garimella Purna*, L. A. Prow, and L. E. Metzger, *University of Minnesota, St. Paul.*

The purpose of this study was to evaluate the feasibility of front face fluorescence spectroscopy (FFFS) to predict the functional properties of process cheese spreads. A total of 27 different commercial samples from three different manufacturers were used in this study. Each sample was analyzed using tube melt test and dynamic stress Rheometry (DSR). The tube melt data is a measure of cheese flow in mm, whereas the DSR data was used to calculate the melt temperature (temperature at $\tan\delta = 1$). Additionally fluorescence spectra of tryptophan (excitation: 290nm; emission: 305-400 nm) were collected on each sample at 20°C using a front face accessory. Six replicates were taken from each sample and six scans were performed on each replicate. After collection the curves were normalized and the mean curve was baseline corrected. Multivariate statistical analysis was used to correlate the fluorescence data with the functionality data. In the initial analysis two samples with large spectral and concentration residuals were eliminated from the calibration set. The calibration models were developed using partial least square regression (PLS). The analysis included preprocessing using mean centering and verification using cross validation. A correlation coefficient of 0.90 and 0.82 between the fluorescence spectra and the functionality data was obtained for the DSR and tube melt respectively. The regions from 309-315 nm and 355-395 nm of the tryptophan spectra had highest correlation to DSR; while the tube melt data had the highest correlation between 334-348 nm. Examination of the tryptophan spectra indicated that an increase in the melt temperature measured by the DSR resulted in a blue shift in the spectra. These spectral shifts have been related to the protein conformational changes due to change in the environment of tryptophan residues present in the protein. These results indicate that the melt properties of process cheese spreads are related to molecular structure that can be measured using FFFS.

Key Words: Fluorescence, Process Cheese, Functionality

Genetic correlations of spring with summer, and fall with winter were 0.97 and 0.98, respectively. Genetic correlations between spring/summer and fall/winter were around 0.8. The norm reaction model for DO allows inexpensive but limited genetic evaluation of fertility under heat stress. Results of such an evaluation may strongly depend on the editing criteria and on the details of the model.

Key Words: Days Open, Pregnancy Rate, Heat Index

44 Use of peeling and reverse peeling to estimate the power to map a recessive disease gene. L. R. Totir*, R. L. Fernando, and J. M. Reecy, *Iowa State University, Ames.*

Animal pedigrees containing individuals that exhibit the phenotype of a recessive disease (e.g. dwarfism) can be used to map the causative recessive disease gene by performing a genome scan. When planning a linkage study, however, it is important to know beforehand the number of animals that must be genotyped and the marker density needed to have sufficient power to locate the disease gene. Conditional on the observed disease phenotypes, reverse peeling can be used to sample genotypes at the disease locus and at two flanking marker loci. Given the sampled genotypes and the observed disease phenotypes, peeling can be used to compute the logarithm of the likelihood ratio (LOD score). By replicating this process, the power to detect the disease locus can be estimated by calculating the frequency of samples where the LOD score is larger than 3. This strategy was applied to an Angus cattle pedigree of 39 animals including six affected individuals. For this pedigree we studied the behavior of the power to map a disease gene as a function of the number of animals genotyped, and the size of the marker interval. It was determined that, for this pedigree, the power to map a disease gene was larger than 90 percent for marker intervals equal to or smaller than 15 cM. This strategy can be used to design genome scans to map disease genes with adequate power.

Key Words: Power, Peeling, Recessive Disease Gene

46 Modified milk vs. producer milk samples for calibrating infrared (IR) milk analyzers: which gives the best validation performance? K. E. Kaylegian*¹ and D. M. Barbano^{1,2}, ¹Dept. of Food Science, Cornell University, Ithaca, NY, ²Northeast Dairy Foods Research Center, Ithaca, NY.

Nine IR milk analyzers were calibrated with modified milk samples and nine different IR analyzers were calibrated with producer milk samples. No single lab had more than two instruments. The population of instruments represented three different manufacturers, several different models, and FTIR and filter based instruments. The validation study was replicated three times with different calibration and validation samples. Labs that calibrated analyzers with producer samples used their normal calibration samples and procedures. Modified milk samples (n = 14) were made from pasteurized gravity separated cream, skim milk UF retentate and permeate, lactose, and water. Validation samples (n = 12) were raw individual producer milks. Both the modified milk calibration set and the producer milk validation set were preserved with dichromate and analyzed by all labs using chemical reference methods (ether extraction, Kjeldahl, and oven drying) to produce all lab mean reference values. Validation of individual instruments was assessed by the mean difference (MD) and standard deviation of the difference (SDD) between the IR predicted values and all lab mean reference chemistry values. Comparison of the two calibration sample types was done using Euclidian distance plots. The range of MD for fat, true protein, and total solids tests on the validation set across labs was reduced by 30% or more for analyzers calibrated with modified milks vs those calibrated with producer milks. In general, the SDD was lower for analyzers calibrated with modified milks vs those calibrated with producer milks.

Key Words: Infrared Milk Analysis, Calibration, Validation

47 Rapid impedance method to detect adulterated milk. D. L. Marshall* and G. M. Duran, *Food Science and Technology Dept, Mississippi State University, Mississippi State.*

Illegal milk adulteration can reduce cheese yield, slow fermentation rates, and reduce milk quality. To detect adulteration, a cryoscope is used to measure milk freezing point. Because changes in solute concentration affect the freezing point, some adulteration practices that add water also include addition of salt, sugar, or dried milk powder to increase solids content to maintain freezing point and fool the cryoscope. At certain solid-to-water adulteration ratios, the cryoscope gives readings that indicate the milk was unadulterated. Impedance technology, which analyzes resistance to flow of electrical currents, is used by the dairy industry to measure product quality and estimate shelflife. The purpose of the present study was to investigate whether impedance can be utilized to detect added salt water in milk. In this study, adulterated milk samples were prepared by adding various amounts of salt solutions to whole milk, resulting in concentrations of 0, 0.01, 0.02, 0.03, 0.04, and 0.05% salt, and 0, 1, 2, 3, 4, and 5% water. Freezing points of the samples were determined using a cryoscope and Impedance I-values were determined using a Bactometer. The Bactometer was unable to detect added water in the absence of salt. With water alone added in increasing amounts, the cryoscope readings showed an R^2 of 0.994, while the Bactometer had an R^2 of 0.2. In contrast, the Bactometer was able to easily detect the addition of salt. R^2 for the Bactometer and cryoscope readings were 0.998 and 0.843, respectively, for varying salt concentrations. The Bactometer was able to rapidly detect (6 minutes) salt-water additions even when the cryoscope could not. The cryoscope was more effective than the Bactometer at testing milk or milk with added water, but the Bactometer was superior at detecting adulteration with salt water. Because many dairy plants use a Bactometer microbiological testing, it could be used as a supplemental test to the cryoscope to determine if milk is adulterated.

Key Words: Impedance, Cryoscope, Milk Adulteration

48 Characterization of flavor and flavor compounds in dried whey protein concentrates and isolates. M. Carunchia Whetstone*, M. Drake, and A. Croissant, *North Carolina State University, Raleigh.*

Dried whey and whey protein are important food ingredients. Functionality of whey products has been studied extensively, but flavor has not been systematically studied. Flavor inconsistency and flavors which may carry through to the finished product can limit whey ingredient applications in dairy and non-dairy foods. The application of analytical sensory and instrumental methods to identify and characterize specific flavors and the chemicals that cause specific flavors enhances our understanding of whey ingredients. The objectives of this research were to identify and characterize sensory flavor and volatile aroma-active compounds that contribute to flavor in whey protein concentrates (WPC) and isolates (WPI). Seven WPC80 and 8 WPI samples, less than three months old, were collected in duplicate from 6 different manufacturers. Samples were rehydrated and evaluated in duplicate by descriptive sensory analysis ($n=7$). Duplicate samples with internal standards were extracted with diethyl ether, followed by isolation of volatile material by high vacuum distillation. Volatile extracts were analyzed using gas chromatography-olfactometry (GCO) with post peak intensity analysis. Compounds were identified by comparison of retention indices, odor properties and GC-MS data against reference standards. Selected compounds were quantified by standard addition. Sensory analysis of model systems was used to confirm the relationship between selected compounds and specific flavors. Whey proteins were variable in flavor and exhibited cardboard/wet paper, animal/wet dog, soapy, brothy, cucumber, and cooked/milky flavors, along with the basic tastes sweet and bitter, and the feeling factor astringency. Key volatile flavor compounds in WPC80 and WPI were guaiacol (burnt/smoky), 2-nonenal (fatty/old books), (E,E)-2,4-nonadienal (fatty/oxidized), (E,Z)-2,6-nonadienal (cucumber), (E,Z)-2,4-decadienal (fatty/oxidized), and dodecanal (waxy/soapy). Baseline data on flavor and flavor sources in whey proteins will aid in the identification of methods to control or minimize flavor variability.

Key Words: Whey Protein Flavor, Gas Chromatography Olfactometry, Sensory Analysis

49 Effect of fat type and fat globule surface coating on the volatile fatty acid profile of yogurt. D. W. Everett*¹, J. Crownshaw¹, A. Ginestet², R. Wierda¹, M. Leus¹, and J.-P. Dufour¹, ¹University of Otago, Dunedin, New Zealand, ²Ecole nationale supérieure de biologie appliquée à la nutrition et l'alimentation, Dijon, France.

Yogurt (20 g) was manufactured containing either soy oil or anhydrous milk fat (AMF) globules coated with one of four materials: two spray-dried buttermilk powders (BMP), casein, or freeze-dried milk fat globule membrane (MFGM) produced by centrifugation at 15°C. Natural fat globules in yogurt was used as a control. Skim milk was standardized to 5% casein by ultrafiltration. Soy or AMF emulsions were prepared at 75 MPa using a Microfluidizer, and added to the concentrated skim to a fat:casein ratio of 4:3. *Mucor miehei* rennet protease was added to duplicate samples. Yogurt was cultured with *Lactobacillus bulgaricus* and *Streptococcus thermophilus* at 31°C until pH 5.5, stored for 122 days at 12°C, then kept at -80°C before analysis by gas chromatography (GC). Samples were heated at 50°C for 60 minutes and volatile components adsorbed onto carboxen/polydimethylsiloxane solid phase microextraction fibers. Fatty acids were identified by GC- mass spectrometry, and peak areas measured using GC with flame ionization detection. Standard plate counts of the four milk powders were less than 10³ cfu/g at 32°C. The rennet protease had no significant effect on GC peak areas. C4 acid concentration was 10-fold higher for AMF compared to soy yogurts. For soy yogurts, MFGM coating gave a 3-fold increase in C4 acid compared to the other coatings, a 2-fold decrease in C5 and C7 acids, and a 2-fold increase in C8 and C10 acids. No trends were evident for C6, C9, or C12 acids. Casein and both BMP coatings gave similar fatty acid profiles. For AMF yogurts, natural fat globules produced a 30 to 100-fold increase in C4 acid compared to the other coatings, a 10-fold increase in C5 acid, and no evident trend for the other fatty acids. Comparing AMF and soy yogurt, AMF produced 5-10 times more C4 acid, 3-6 times less C7 acid, 2-3 times more C8 acid, 2-3 times less C9 acid, and 2 -6 times more C10 acid. The low heat MFGM generated a greater amount of even numbered fatty acids compared to casein or the high heat treatment BMP. The nature of the fat globule coating evidently impacts upon lipolysis in yogurt.

50 The influence of non-fat dry milk characteristics on yogurt functionality. A. Pollard* and L. E. Metzger, *Department of Food Science and Nutrition, University of Minnesota, St. Paul.*

Yogurt functionality, especially non or low fat yogurt is almost entirely dependent on the characteristics of the milk solids used in the formulation. Yogurt formulation utilizes a high proportion of non fat dry milk (NFDM) either as base material, or for fortification purposes to achieve appropriate solids concentration. Variation in milk solids characteristics can cause substantial differences in yogurt viscosity and syneresis. The characteristics of NFDM can vary markedly due to many factors including method of production (spray drying conditions), date of production (seasonal changes), and storage conditions. Currently there is no method of determining the functional characteristics of NFDM samples other than solubility tests. Unfortunately, solubility tests do not provide an accurate prediction of the characteristics of the NFDM samples when used for yogurt manufacture. To address the issue of NFDM functionality, a measurement technique using a Rapid Visco Analyser (RVA) was developed. In this method, a NFDM sample is added to water (50%w/w), and mixed at a high shear rate (950RPM) for 5 minutes at 70°C. Subsequently, the sample is heated from 70°C to 92°C over 18 minutes with continuous mixing at 150RPM. During the entire test, the viscosity profile is recorded using the RVA. In a preliminary study, seven low-heat NFDM samples were analyzed using this method. In this test, viscosity profile varied significantly for different samples even though all samples were low heat NFDM. Non fat yogurts at 15 and 20% total solids were then manufactured using the NFDM samples. A significant correlation between RVA viscosity profile and yogurt viscosity was observed at both solids levels (R^2 of 0.84 for 15% total solids, 0.92 for 20% total solids) and yogurt syneresis at 15% solids only (R^2 of 0.85 for 15% total solids). This indicates that the viscosity of NFDM measured in the RVA can be used to predict functionality of the NFDM when used for yogurt manufacture. This should be of great interest to commercial

manufacturers as it allows a quick, easy and cheap test to determine the functionality of the NFDM samples used for yogurt manufacture.

Key Words: NFDM, Yogurt, RVA

51 Characteristics of κ -casein stabilized emulsions treated with rennet. R. Richter, G. Anita*, G. Perez-Hernandez, and B. Davis, *Texas A&M University, College Station.*

The objective of this research was to determine if gels could be formed from κ -casein stabilized emulsions by treatment with rennet. Emulsions were prepared with κ -casein separated from acid casein (Cayot et al. 1992) and butteroil. The compositions of the emulsions were 0.3% κ -casein and 3, 10 or 20% fat. The pre-emulsion mixtures were heated to 65°C before homogenization at 20 or 100 MPa and cooled to room temperature. CaCl₂ was added to emulsions to obtain a concentration of 20 mM. A 0.1% solution of rennet (200 μ l) was added to 30 ml emulsion samples. Rheological properties were measured before and after the

addition of rennet. The effect of fat concentration and homogenization pressure on the rheological properties of the emulsions was determined. Emulsion behaved as Newtonian fluids before the addition of rennet with mean viscosities of 1.21, 1.45 and 2.12 cP for emulsions containing 3%, 10% and 20% fat respectively. The addition of rennet caused yield stress in all of the emulsions and the viscosity increased to 3.59, 18.18 and 51.17 cP for emulsions that contained 3%, 10% and 20% fat respectively. The mean viscosity of the emulsions increased from 20 cP when emulsions were homogenized at 20 MPa to 26 cP when emulsions were homogenized at 100 MPa. Under the studied conditions, κ -casein gels could not be formed. However, yield stress was observed on the κ -casein emulsions treated with rennet. The changes on the rheological properties depended upon the composition of the emulsions and the pressure applied during homogenization.

Key Words: κ -casein, Rennet, Rheological properties

Forages and Pastures: Management of Tall Fescue Forage

52 Performance of beef heifers grazing stockpiled endophyte-infected, endophyte-free or non-toxic endophyte-infected fescue. E. J. Oliphant*, M. H. Poore, J. T. Green, and M. E. Hockett, *North Carolina State University, Raleigh.*

A 70-d study was conducted from Dec 20 to Feb 28 in order to evaluate heifer performance on Jesup endophyte-infected (E+), endophyte-free (E-) and non-toxic endophyte-infected (EN) tall fescue. Botanical composition and nutrient content of each treatment (tmt) was also evaluated. Forty-eight Angus cross heifers (initial wt 269 kg, initial body condition score 5.1) were placed in groups of 4 and randomly assigned to 12 paddocks (avg 1.25 ha). Paddocks were fertilized with 95 kg of N per ha on Sept 24, and forage was stockpiled until the initiation of the trial. Heifers were given a daily allotment of forage with a target residual height of 5 cm. Mineral containing monensin (1780 mg/kg) was available ad lib. The initial grazable mass was higher ($P < 0.06$) for E+ (1443 kg/ha) than for E- (1100 kg/ha) or EN (1233 kg/ha). Daily gains did not differ by tmt (0.33, 0.42 and 0.45 kg/d for E+, E- and EN, respectively). Forage grab samples were taken at 14-d intervals starting Dec 2, and subsamples were separated into green fescue, brown fescue and species other than fescue (primarily crabgrass). There were no differences in nutrient content among tmt within green or brown fescue tissue: (E+ green: 43.3% NDF, 19.8% ADF, 11.75% CP; brown: 67.1% NDF, 34.3% ADF, 7.75% CP), (E- green: 42.5% NDF, 19.3% ADF, 11.62% CP; brown: 66.8% NDF, 33.9% ADF, 7.76% CP), (EN green: 43.6% NDF, 19.9% ADF, 11.25% CP; brown: 68.1% NDF, 34.6% ADF, 7.35% CP). From Dec to Feb, percent green fescue decreased in all tmt ($P < 0.01$) with no significant difference among tmt. Percent fescue in the sward DM was higher ($P < 0.01$) in E+ (87.8%) and EN (87.5%) than in E- (81.1%). Nutrient content of the sward declined ($P < 0.01$) over the winter, but average nutrient composition was similar across tmt: E+ (52.0 % NDF, 25.5 % ADF, 10.96 % CP), E- (52.2 % NDF, 26.1 % ADF, 11.16 % CP) and EN (52.1 % NDF, 25.4 % ADF, 10.53 % CP). These results indicate that endophyte status of stockpiled fescue may have little influence on animal gain or forage quality during the winter grazing season.

Key Words: Endophyte, Fescue, Beef Heifers

53 Calving rate and production responses of long-term exposure to endophyte-infected tall fescue. J. M. Burke*, D. K. Brauer, and M. L. Looper, *USDA, ARS, Booneville, AR.*

The objective was to examine the effect of continuous exposure to endophyte-infected (EI) tall fescue on pregnancy, calving rates, and calf growth in cow-calf pairs. In April 1999 and 2000, Angus and Angus x Hereford cows were randomly assigned to graze 16 ha endophyte-free (EF; n = 20/yr) or 24 ha EI (n = 30/yr). From spring 2000 until fall 2003 cows were continuously exposed to each forage. Heifers were bred in April and cows were bred in May for a 90 and 60 day breeding period, respectively. Cows were removed or culled from treatments if they did not conceive or lost a pregnancy or calf. Cows grazing EI fescue were supplemented daily with 0.5 kg/cow of corn/SBM for 90 d in winter so that body condition scores were similar between EF and EI cows by

April. At weaning (early October) pregnancy rate, determined by transrectal ultrasound, and calving rate were similar between pasture groups and length of time on pasture. Calving interval tended to be reduced in cows grazing EI fescue the first year ($374.0 \pm 4.8 < 386.2 \pm 4.4$ d; forage \times exposure; $P < 0.06$). Percent of cows culled or that died between forage treatments was similar. Despite supplemental feeding of EI cows over winter, body weight (forage \times exposure \times days postpartum, $P < 0.03$) and condition scores (1 = emaciated, 9 = obese; forage \times exposure \times days postpartum, $P < 0.001$) were greater in cows grazing EF fescue. Body weight and condition were greater in cows exposed for 3 to 5 years in both forage groups compared to those exposed to forage for 1 or 2 years. Birth weights of calves born to cows exposed to 2 years were reduced compared with 1 or 3 to 5 years of EI fescue exposure (forage \times exposure, $P < 0.008$). However, by weaning, the 205 day adjusted weaning weight was similar among exposure groups and greater in EF compared with EI calves ($224.3 \pm 3.8 > 199.7 \pm 2.4$ kg; $P < 0.001$). In summary, number of years of exposure to EI tall fescue did not greatly impact cow-calf performance.

Key Words: Beef, Production, Tall fescue

54 In situ digestibility of tall fescue fertilized with different swine manure treatments and harvested on four dates. J. L. Reynolds¹, R. K. Ogden¹, K. P. Coffey*¹, W. K. Coblenz¹, C. V. Maxwell¹, and K. VanDevender², ¹University of Arkansas, Fayetteville, ²Cooperative Extension Service, Little Rock, AR.

Forage digestibility varies across a growing season due to factors such as fertility and harvest date. Our objective was to evaluate the in situ DM digestibility of tall fescue (*Lolium arundinacea*, Schreb.) fertilized with different swine manure treatments and harvested on different dates. "GA-Jessup" tall fescue infected with a non-ergot alkaloid producing endophyte (Max-Q[®]) was either not fertilized (CONT), or fertilized (126 kg N/ha) with normal swine manure (NORM); swine manure from pigs fed phytase (PHY), or PHY treated with aluminum chloride (PHY+AL). Accumulated forage was harvested by clipping with hand shears (2.5 cm stubble height) on April 3, April 28, May 16, and June 23, 2003. Ruminally cannulated steers (n=5; 548 kg BW) were used to evaluate these forages in situ. Degradation rate of DM was greater ($P < 0.05$) from NORM and PHY than from CONT and decreased ($P < 0.05$) with advancing harvest dates through the May 16 harvest. A fertility treatment by harvest date interaction was detected ($P < 0.05$) for most variables. The slowly degradable (B) fraction, potential extent of degradation, and effective ruminal degradability were higher ($P < 0.05$) on April 3 and 28 than on May 16 and June 23 from all fertility treatments. The soluble (A) fraction, fraction B, potential extent, and effective degradability were greater ($P < 0.05$) from fertilized than CONT fescue harvested April 3, but the improvement was not consistent across harvest dates. By May 16 and June 23 harvests, fraction B and potential extent were greater ($P < 0.05$) from CONT than from fertilized fescue. Effective ruminal degradation was not consistently impacted by fertility treatment after April 3. Therefore, inclusion of phytase in swine diets along with subsequent treatment of the manure with aluminum chloride did not

have consistent impacts on forage degradation compared with normal swine manure. Furthermore, fertilization with swine manure increased effective degradation of fescue initially, but the impact was not consistent at later harvest dates.

Key Words: Swine Waste, Phytase, Tall Fescue

55 Selenium concentration of fescue and bahiagrasses after applying a selenium fertilizer. G. Valle, L. R. McDowell*, D. L. Wright, and N. S. Wilkinson, *University of Florida, Gainesville.*

Two experiments were conducted, one with bahiagrass (August to November) in North Central Florida (Gainesville) and the other with fescue (January to July) in Northwest Florida (Quincy), to evaluate the selenium levels of the grasses after applying a slow release selenium fertilizer (Selcote Ultra). The hypothesis is that selenium fertilizer would elevate forage selenium to acceptable levels for ruminant requirements. In the bahiagrass study, forage samples were collected from 3 x 5 m plots replicated 4 times which had been sprayed with Selcote Ultra at randomized treatment rates of 0, 5, 10, 15 and 20 g ha⁻¹ selenium. Samples were collected every two weeks for a total of six collections. In the fescue study, the procedure was the same except that forage samples were collected at 2, 4, 6, 10, 16 and 22 wk after applying the fertilizer, and the rates were 0, 5, 10, 24 and 120 g ha⁻¹ selenium. For bahiagrass, only the 10, 15 and 20 g ha⁻¹ selenium treatments reached acceptable levels in the forage (>0.1 ppm) for beef cattle. The 10 g ha⁻¹ selenium treatment reached adequate levels (0.25 ppm) only at 4 wk after application. The 15 g ha⁻¹ selenium treatment presented adequate levels of selenium at 2, 4 and 6 wk after application (0.19, 0.17 and 0.17 ppm, respectively). The 20 g ha⁻¹ selenium treatment had adequate forage selenium at 4 and 6 wk after application (0.19 and 0.23 ppm respectively). All treatments were deficient at 8 and 12 wk. In the fescue study, all treatments presented adequate concentrations (0.1 ppm) of selenium in the forage, except for the control. At two weeks after application, the 24 g ha⁻¹ and the 120 g ha⁻¹ selenium treatments had toxic selenium levels in forage. However, these values declined to below toxicity (4-5 ppm) at all other collection dates. In conclusion applying Selcote was more effective for fescue than bahiagrass, with fescue forage selenium still more than adequate 22 wk after application.

Key Words: Selenium, Fertilizer, Forage

56 Rumen parameters of cattle grazing tall fescue pastures differing in endophyte status. A. M. Corrigan*, J. C. Waller, A. M. Saxton, L. C. Miller, and C. J. Richards, *The University of Tennessee, Knoxville.*

Objectives of this experiment were to compare weight and composition of rumen contents and substrate *in situ* degradation in steers grazing tall fescue (*Festuca arundinacea* Schreb.) pastures. Pasture treatments consisted of continuous grazing of Kentucky-31 endophyte (*Neotyphodium coenophialum*) infected (E+), Jesup endophyte-free (E-) or Jesup infected with a non-ergot alkaloid producing endophyte (MaxQ). The d was separated into two 12-h grazing periods. Day grazing (DG) was from 0700 to 1900 and night grazing (NG) was from 1900-0700. Two ruminally cannulated steers were randomly assigned to each pasture in early May 2003. After a 7 d acclimation period, steers were subjected to four rumen evacuations NG at 0700 and four DG at 1900. Contents were weighed and sub-sampled. Evacuated rumens were washed and steers were returned to appropriate pastures for 45 min to obtain masticate samples. Between the four evacuation days, alfalfa hay, corn grain, corn gluten feed, and soybean hulls *in situ* degradation was determined for the NG and DG periods by placing a 5 g sample of each substrate, within a 10 x 20 cm Dacron bag, into each steer consuming the three forage treatments. After a 12-h incubation, Dacron bags were mechanically washed and dried. Rumen content, masticate, *in situ* substrate, and *in situ* incubated residue samples were analyzed for DM, NDF, ADF, and CP. Rumen DM contents for steers grazing E- and MaxQ were greater ($P < 0.05$) than steers grazing E+ and DG contents were heavier ($P < 0.01$) than NG. *In situ* DM, NDF, and CP degradation of corn grain was greater ($P < 0.05$) in steers grazing E- and MaxQ than in steers grazing E+. *In situ* alfalfa hay and corn gluten feed DM, NDF, and ADF degradation appeared greater ($P < 0.15$) in steers grazing E- and MaxQ than in steers grazing E+. Soybean hull degradation was not

affected by pasture. Generally, nutrient degradation of substrates was not affected by incubation time (NG vs DG).

Key Words: Tall Fescue, Degradability, Endophyte

57 Use of novel endophyte-infected tall fescue for cow-calf production in Arkansas. J. M. Burke*, D. K. Brauer, and M. L. Looper, *USDA, ARS, Booneville, AR.*

The objective was to examine pregnancy, calving rates, and calf growth in cow-calf pairs on endophyte-free (EF), novel endophyte-infected (NE), and endophyte-infected (EI) tall fescue. Angus cows grazed EF, NE ($n = 20/16$ ha), or EI ($n = 30/24$ ha) starting November 2001 through July 2003. To prevent overgrazing, NE cattle were removed from July to November 2002 and in May 2003. Hay was provided as needed during winter. Pastures were fertilized at a similar rate among fescue varieties with N, P and K in early March and October both years. Cows were bred beginning in May for 60 d. Cows were removed if not pregnant at weaning or lost a pregnancy or calf after calving and replaced with a comparable pregnant cow or cow-calf pair that had previously grazed bermudagrass (for EF and NE groups) or EI (for EI group) fescue. Forage yields were determined monthly in exclusions ($n = 3$ /pasture) in 2003. Yield of EI was greater than EF or NE from April to June and EF and EI forage yield was greater than NE in August (forage x month, $P < 0.02$). Cows grazing EF fescue gave birth to heavier calves than those grazing EI ($P < 0.04$) and NE calf weights were similar to EF and EI weights (EF, 38.3 ± 0.7 ; NE, 36.7 ± 0.7 ; EI, 36.3 ± 0.6 kg; $P < 0.10$). Between May and July 2002, EF and NE calves were heavier than EI calves (forage x time, $P < 0.001$); however, calf weights were similar in May 2003 among forage groups ($P = 0.15$). At weaning (early October 2002) pregnancy rate, determined by transrectal ultrasound, was greater in NE than EI cows ($P < 0.03$) and similar between EF and EI cows (EF, 70.9 ± 9.7 ; NE, 96.2 ± 9.8 ; EI, $67.8 \pm 8.6\%$; $P < 0.07$). By spring, calving rates were similar among forage groups (EF, 70.0 ± 10.7 ; NE, 80.2 ± 10.9 ; EI, $63.2 \pm 9.5\%$; $P = 0.35$). In summary, calf gains from cows grazing NE fescue were greater than EI calves. However, the use of NE fescue as a summer forage at a similar stocking rate as EI (1 cow/0.8 ha) is limited in Arkansas because of overgrazing potential.

Key Words: Beef, Novel endophyte, Tall fescue

58 Using orchardgrass and endophyte-free fescue versus endophyte-infected fescue overseeded on bermudagrass for cow herds: four-year summary of cattle performance. W. K. Coblenz*, K. P. Coffey, D. A. Scarbrough, T. F. Smith, D. S. Hubbell, III, K. F. Harrison, B. C. McGinley, J. E. Turner, and J. B. Humphry, *University of Arkansas, Fayetteville.*

A four-year trial was initiated in January 2000 with 65 spring-calving cows (549 ± 23.0 kg) to evaluate cow-calf performance on pastures with endophyte-infected tall fescue (IF; *Festuca arundinacea* Schreb.), endophyte-free (FF) tall fescue, or orchardgrass (OG; *Dactylis glomerata* L.) overseeded into dormant common bermudagrass [*Cynodon dactylon* (L.) Pers.]. Two management systems were evaluated to help FF and OG forages persist; these included rotations to new paddocks twice weekly or twice monthly. Pastures with IF were managed with twice monthly rotations. Generally, effects of year and forage management system x year did not affect ($P > 0.05$) calf performance. Actual weaning weight ($P = 0.083$), adjusted 205-d weaning weight ($P = 0.032$), total gain from birth to weaning ($P = 0.081$), and average daily gain from birth to weaning ($P = 0.028$) were greater or tended to be greater for calves raised on non-toxic forages (FF and OG) than for those raised on IF pastures; for actual weaning weights, this represented a 21-kg advantage for non-toxic pastures (OG and FF). Cows grazing OG and FF pastures exhibited higher ($P < 0.035$) bodyweights and body condition scores (BCS) at calving, breeding, and weaning than cows grazing IF pastures; however, BCS for cows grazing IF pastures remained acceptable (range = 6.1 to 6.7). Milk production in May for cows grazing nontoxic forages was greater than observed for cows grazing IF pastures (6.52 vs. 5.42 kg/d; $P = 0.011$), but this differential was not observed in July ($P = 0.587$). Serum prolactin levels also were greater for cows grazing non-toxic forages (181 vs. 90 ng/mL; $P = 0.005$) than for those grazing IF pastures. Conception rates did not differ ($P > 0.456$) among forage treatments (overall mean = 85.8%). Cow-calf performance was improved marginally by including non-toxic, perennial cool season grasses in bermudagrass pastures, but establishment costs

and additional management requirements may limit the acceptability of this approach.

Key Words: Tall Fescue, Orchardgrass, Cow-Calf Performance

59 Using orchardgrass and endophyte-free fescue versus endophyte-infected fescue overseeded on bermudagrass for cow herds: four-year summary of forage characteristics. W. K. Coblenz*, K. P. Coffey, D. A. Scarbrough, T. F. Smith, K. F. Harrison, D. S. Hubbell, III, B. C. McGinley, J. E. Turner, and J. B. Humphry, *University of Arkansas, Fayetteville.*

A four-year trial was initiated in January 2000 to evaluate forage production, basal cover, and persistence of endophyte-infected tall fescue (IF; *Festuca arundinacea* Schreb.), endophyte-free tall fescue (FF), or orchardgrass (OG; *Dactylis glomerata* L.) overseeded into dormant common bermudagrass [*Cynodon dactylon* (L.) Pers.] for spring-calving cows. The FF and OG pastures were managed with either a twice weekly (HM) or twice monthly (LM) rotation schedule, while the IF pastures were managed with a LM rotation schedule only. Forage-related response variables were evaluated with a split-plot design, where forage

system (IF-LM, FF-HM, FF-LM, OG-HM, and OG-LM) was the whole-plot term and sampling/evaluation date was analyzed as a repeated measure. Forage availability (four-year mean = 3809 kg/ha) was not affected ($P = 0.601$) by forage management system, but was affected by sampling date ($P < 0.0001$) and the forage system \times sampling date interaction ($P = 0.010$). Total basal cover varied ($P < 0.0001$) with sampling date, ranging from 36.3 to 51.5%, but was not affected by forage system ($P = 0.679$) or the interaction of main effects ($P = 0.354$). The interaction of forage system and evaluation date affected ($P = 0.038$) the percentage of the desired cool-season species in each pasture. Generally, FF and IF remained relatively stable over the entire study, ranging from 49.2 to 72.5% for FF-HM, 54.0 to 73.5% for FF-LM, and 46.9 to 65.8% for IF. However, the percentage of OG declined markedly ($P < 0.1$) since June 2002 in both the HM and LM grazing systems, ending at 36.2 and 14.7%, respectively, on the final (November 2003) evaluation date. After four years, FF has persisted well, but OG stands have thinned markedly, particularly under the LM rotation schedule. Therefore, FF may be a better choice than OG as an alternative to IF for spring-calving cow herds in the Upper South.

60 Influence of pre-exposure of mycobacterium avium sub sp paratuberculosis to different environments on invasion of bovine epithelial cells in in vitro cell culture system. D. A. Patel*¹, L. Meunier-Goddik¹, and L. Bermudez², ¹*Food Science and Technology, Oregon State University, Corvallis,* ²*Department of Biomedical Sciences, Oregon State University, Corvallis.*

Mycobacterium avium sub sp paratuberculosis (MAP) is a causative agent of Johnes disease (JD) in cattle having significant economic impact. It is known that after crossing the mucosal barrier, MAP can disseminate and infection can spread to various sites including mammary gland. MAP can be exposed to high osmolarity and the intracellular environment of mammary gland epithelial cells. To study the influence of the environment on MAP invasion of bovine epithelial cells; MAP strain ATCC 19698 was used in the study. Immortalized MDBK (Madin Darby Bovine Kidney) cells were used as a model of bovine epithelial mucosa. MAC-T cells (mammary epithelial cells) were used for intracellular passage of MAP. MAP culture was inoculated in to raw milk, water and Middlebrook 7H9 broth (7H9 broth) containing Mycobactin J and OADC (10 % V/V) at 37 °C in the presence of antibiotics. MAP was also used to infect MAC-T cells for 1d and 4d at 37°C. MAC-T were then lysed and bacteria separated from host cell by differential centrifugation at 4 °C. MAP exposed to several environments was then added to polarized MDBK cells for 2hr. The percentage MAP invasion was calculated as percent of MAP inoculum that internalized in to MDBK cells. Statistical significance was determined by students t test and ANOVA. Our results indicated that MAP invasion is not significantly different at 1d among milk, broth and water preexposed samples. However, MAP passage in MAC-T cells significantly increased invasion percent (15 fold at 1d, p-value < 0.001 and 10 fold at 4d, p-value < 0.001) compared to control. Employment of RNA subtraction hybridization will help to define which MAP genes are associated with the invasive phenotype. These results indicate that exposure of intracellular MAP significantly increases its invasion efficiency for bovine epithelial cells. This characteristic may be important in establishing successful infection in susceptible host.

Key Words: Mycobacterium avium sub sp paratuberculosis, Invasion Assay, Mammary Epithelial Cells

61 Elucidation of the role of chymosin-mediated proteolysis in texture development during Cheddar cheese ripening. J. A. O'Mahony*^{1,2}, J. A. Lucey², and P. L. H. McSweeney¹, ¹*Department of Food and Nutritional Sciences, University College, Cork, Ireland,* ²*Department of Food Science, University of Wisconsin, Madison.*

More than 20 years ago, it was hypothesized that proteolysis of α_{s1} -casein by residual chymosin, early in ripening, is responsible for the initial softening observed in Cheddar cheese. To investigate this hypothesis, full-fat, Cheddar cheeses (2 kg) were manufactured with 0.1, 1.0 or 10.0 μmol pepstatin (a potent inhibitor of chymosin) added per litre of

curd/whey mixture at the start of cooking to obtain residual chymosin levels of 89, 55 and 16% of the activity in the control cheese, respectively. Texture profile analysis of cheeses was performed by compression (2 cycles) to 25% of original height. Levels of intact α_{s1} - and β -caseins were measured by densitometric analysis of urea-polyacrylamide gel electrophoretograms of pH 4.6-insoluble fractions from the cheeses. During the first 21 d of ripening, the rate of development of pH 4.6-soluble nitrogen (expressed as % of total nitrogen) was 0.29, 0.14, 0.06 and 0.04 %/d for control cheese and cheeses made with 0.1, 1.0 or 10.0 $\mu\text{mol L}^{-1}$ pepstatin, respectively. Concurrently, the level of intact α_{s1} -casein decreased by 49, 25, 7 and 3% in these cheeses. At 21 d of ripening, there was a significant ($P < 0.001$) reduction in hardness (maximum force on first compression cycle) in each of the 4 cheeses with initial (1 d) hardness values of 189, 204, 207 and 233 N decreasing to 115, 139, 163 and 187 N, in cheeses made with 0.0 (control), 0.1, 1.0 or 10.0 $\mu\text{mol L}^{-1}$ pepstatin, respectively. It was concluded that, irrespective of the extent of α_{s1} -casein hydrolysis, there was a significant softening of Cheddar cheese texture during the first 21 d of ripening and it appears that the hydrolysis of α_{s1} -casein by chymosin is not a prerequisite for Cheddar cheese softening. We believe that some physicochemical change(s), such as a reduction in the amount of calcium associated with the *para*-casein matrix of the curd may be responsible for this textural change.

Key Words: Proteolysis, Texture, Cheddar Cheese

62 Compositional factors associated with calcium lactate crystal formation in naturally smoked Cheddar cheese. P. Rajbhandari* and P. S. Kindstedt, *University of Vermont, Burlington.*

We have observed a high incidence of surface crystals among retail samples of naturally smoked Cheddar cheese. We have also occasionally observed that some samples displayed crystals whereas others originating from the same vat of cheese did not. This study compared the compositions of naturally smoked Cheddar cheese samples that contained surface crystals (Cry+) with those of samples originating from the same vat that were crystal-free (Cry-). Six pairs of retail samples (Cry+ and Cry-) produced at the same cheese plant on different days were obtained from a commercial source. Each pair was 5-6 mo old upon receipt and was stored for up to 18 mo at 4°C to insure that the Cry- sample remained crystal-free. Then, the crystalline material was scraped off the surfaces of Cry+ samples and analyzed for lactic acid, Ca, P, moisture and CP. Cry+ and Cry- samples were then sectioned into 3 concentric subsamples (0-5mm, 6-10mm and > 10mm depth from the surface) and analyzed for pH, TA, TS, NaCl, total and water-soluble Ca and P, and CP. The data were analyzed by ANOVA according to a repeated measures design with 2 within-subjects variables. The crystalline material contained 52.9% lactate, 8.1% Ca, 0.1% P, 28.5% water and 8.9% CP on average. Both Cry+ and Cry- cheese samples contained significant gradients of decreasing moisture from center to surface. Compared to Cry- samples, Cry+ samples possessed significantly higher moisture,

TA, water-soluble Ca and P, and significantly lower salt, pH and total Ca. The data suggest that within-vat variation in salting efficacy may have influenced calcium lactate crystal formation. Lower salt uptake by Cry+ cheese curd during salting may have resulted in higher moisture (and thus lactose) retention, which caused more lactic acid to be produced in the cheese. Higher lactic acid resulted in lower pH, which shifted calcium to the soluble state. Lactate and soluble Ca in Cry+ cheese became further elevated at the cheese surface as a result of dehydration during natural smoking, possibly triggering the formation of calcium lactate crystals.

Key Words: Cheddar, Calcium Lactate, Crystals

63 Influence of calcium, phosphorus, residual lactose, and salt-to-moisture ratio on cheese quality: pH changes during ripening. P. Upreti*, P. S. Lehtola, and L. E. Metzger, *Department of Food Science and Nutrition, MN-SD Dairy Food Research Center, University of Minnesota, St. Paul.*

The pH of cheese is an important attribute that influences its quality. Large changes in cheese pH are often observed during ripening. Changes in cheese pH during early ripening are associated with calcium (Ca), phosphorus (P), residual lactose, and salt-to-moisture ratio (S/M) of the cheese. Ca and P have the ability to act as a buffer that stabilizes cheese pH, whereas lactose is converted to lactic acid that causes a decrease in cheese pH. The S/M can influence bacterial growth that can affect the rate of conversion of lactose to lactic acid. The net balance between the buffering capacity and the formation of lactic acid should, therefore, determine cheese pH. In order to assess this hypothesis, 4 treatments of Cheddar cheese with 2 levels (high and low) of calcium (Ca) and phosphorus (P), and 2 levels (high and low) of residual lactose were manufactured. Each treatment was subsequently split in half and salted at 2 levels (high and low) for a total of 8 treatments. The detailed experimental design and manufacture of these cheeses is a subject of another abstract submitted for this conference. All the cheeses were salted at a pH of 5.4, pressed for 5h, and then ripened at 6-8°C. The pH of the salted curds before pressing, cheese at day 1, and weeks 1, 2, 3, and 4 of ripening was measured. The cheeses with low levels of Ca and P, high lactose, and low S/M showed a considerable drop in pH (mean=0.20 units) from salting to d1 of ripening, whereas, cheeses with high levels of Ca and P, low lactose, and high S/M showed an average drop in pH of 0.07 units. The comparison of pH of cheeses at 4wk indicated that cheeses with higher levels of Ca and P had higher pH ($p<0.05$) as compared to lower Ca and P cheeses. Also, cheeses with higher S/M were

higher in pH ($p<0.05$) as compared to lower S/M cheeses. Residual lactose content of cheeses had a significant effect ($p<0.05$) on cheeses at low salt content. However, at high salt content the effect of residual lactose was not significant. This study determined that changes in cheese pH during early ripening were influenced by Ca and P, lactose, and S/M.

64 Effect of starter inoculation rates and incubation temperatures on physical properties of yogurt. W. J. Lee* and J. A. Lucey, *Department of Food Science, University of Wisconsin, Madison.*

Textural attributes are considered as important criteria for the quality of yogurt. The objectives of this research were to investigate the effect of different starter culture inoculation rates and incubation temperatures on physical properties and microstructure of yogurt gels. A two factor (5×2) experimental design was used for data analysis. Yogurt gels were made with 0.5, 1, 2, 3, or 4% (w/w) inoculation rates and incubated at 40 or 46°C. Dynamic low amplitude oscillatory rheology was performed to monitor rheological properties of yogurt gels. Gel permeability and amount of surface whey were determined. Confocal scanning laser microscopy was used to examine gel structure. Storage modulus values (stiffness) increased with increased inoculation rate and decreased incubation temperature. Gels made at higher inoculation rate and incubation temperature exhibited higher yield stress and had higher loss tangent values (ratio of viscous to elastic moduli) during gelation, respectively. Higher permeability and whey separation values were observed in yogurt gels made at lower inoculation rate and higher incubation temperature, which indicated an increased susceptibility of the network to rearrange. These rearrangements resulted in the formation of large pores in gel network. An increase in inoculation rate resulted in a decrease in the pH where the maximum in loss tangent occurred, presumably reflecting less efficient solubilization of colloidal calcium phosphate (which is a slow process) and the need to attain a lower pH to complete the solubilization. Whey separation was positively correlated with the value for maximum in loss tangent ($r = 0.94$) and permeability ($r = 0.89$), respectively. A negative correlation was observed between whey separation and storage modulus ($r = -0.48$). It was concluded that rearrangements of casein particles in gel network and pH at which the solubilization of colloidal calcium phosphate occurred were important driving forces involved in whey separation and a weak network.

65 Cloning the genomic sequence and proximal promoter of bovine pyruvate carboxylase. S. M. Rodriguez*, C. A. Bidwell, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Pyruvate carboxylase (PC) catalyzes a pivotal reaction in gluconeogenesis and lipid metabolism in liver. We previously identified six unique alternative splice variants in the 5 untranslated region (UTR) of PC mRNA. These splice variants may have a role in translational regulation of PC protein abundance. The objectives of this experiment were to clone and sequence the bovine PC gene, to determine the intron/exon organization of the 5UTR and to identify PC promoter elements. The RPCI-42 Bovine Bacterial Artificial Chromosome (BAC) library was screened with oligonucleotide sequences corresponding to specific elements of the 5 UTR sequence of bovine PC and to a region of the coding sequence. Two BACs that hybridized to all probes were selected for further analysis. A partial restriction map of the BACs was made with oligonucleotides corresponding to the coding region and the 89 and 110 bp elements of bovine PC 5 UTR. The BAC fragments that hybridized to the oligonucleotide probes were isolated and sequenced. The sizes of the cloned genomic PC 5 UTR fragments were verified by PCR, using genomic DNA from four cows. Sequencing data confirms the existence of a 178 bp exon that contains the 68 and 110 bp sequence elements of the 5 UTR for PC mRNA. The 178 bp exon appears to be the first transcribed exon in PC and the 68 and 110 bp 5 UTR sequences are most likely generated by alternative transcription start sites. Genomic sequence data also confirms that the 3 end of the 89 bp element is a discrete 41 bp exon. Regions within the genomic sequence adjacent to the 178 and 41 bp exons of the PC 5 UTR contain binding sites for TBP, Sp1, Ap1 and/or CEBP transcription factors. These data provide

information about the arrangement of exons in the 5 UTR of PC and about putative promoter regions.

66 Relationship between antibiotic susceptibility of mastitis pathogens and treatment outcomes. F. Hoe* and P. Ruegg, *University of Wisconsin, Madison.*

Antimicrobial susceptibility testing is commonly used to guide mastitis treatments. Broth microdilution is used to obtain quantitative results that are recorded as minimum inhibitory concentrations (MIC). The objective of this study was to determine the relationship between MIC values of mastitis pathogens and clinical outcomes. Duplicate quarter milk samples were obtained from cows observed with mild to moderate mastitis in a single quarter. Cows were ineligible if they had secondary clinical signs or had received antibiotics within the previous 30 days. Cows were treated with intramammary pirlimycin and could not receive ancillary treatments. Milk samples were collected before treatment and 14 and 21 days after treatment. Microbiological procedures were as described by the NMC. MIC values were determined using a commercial microdilution method (Sensititre, Westlake, OH). Of eligible milk samples ($n = 217$), 58 samples were no growth, 17 produced different growth on the duplicates and 6 were contaminated. MICs were obtained for: Strep spp. (34.6%); E.coli (25.7%); CNS (19.1%); Klebsiella spp. (9.6%) and other minor pathogens (14.0%). No significant difference was observed for days of treatment (2.8 and 2.9) and days until clinical cure (3.5 and 3.8) for gram positive and gram negative isolates, respectively

($P > 0.09$). No significant difference was observed for days of treatment (2.8 and 2.9) and days until clinical cure (3.4 and 3.8) for isolates that were susceptible or resistant to pirlimycin, respectively ($P > 0.9$). No significant differences in bacteriological cures were observed for gram positive (40.9% and 50.7%) and gram negative (50% and 50.9%) isolates, at day 14 and 21, respectively ($P > 0.8$). No significant differences in bacteriological cures were observed at day 14 (41.2% and 47.8%) or day 21 (50.9% and 50.7%) for susceptible or resistant isolates, respectively ($P > 0.7$). There was no association between farm and mean MIC for any antibiotic included in the mastitis susceptibility panel. This study did not identify an association between results of susceptibility testing and clinical outcomes of mastitis.

Key Words: Mastitis, Treatment, Susceptibility

67 Effect of selection for milk yield on hepatic prolactin receptor (PRLR) mRNA in Holstein cows. M. Carriquiry*, S. H. Wu, W. J. Weber, H. Chester-Jones, L. B. Hansen, and B. A. Crooker, *University of Minnesota, St. Paul.*

Prolactin participates in regulation of liver metabolic function, promotion of hepatocyte proliferation, and induction of growth related gene expression. Cows from control (stable milk yield since 1964; C) and select (S) genetic lines that differed in milk yield by more than 4,500 kg/305 d in milk (DIM) were used to evaluate effects of selection on hepatic mRNA for long (L-PRLR) and short (S-PRLR) isoforms of PRLR. Lines were fed ad libitum and exposed to the same environment. Multiparous (CM, SM) and primiparous (CP, SP) cows ($n = 8$ per line \times parity) blocked by calving date were biopsied at -12, 20, and 68 DIM. Hepatic RNA was isolated and L-PRLR and S-PRLR mRNA determined by real-time PCR. The same forward primer (5'-GCAGTGGCTTTGAAGGGCTATA-3') was used for each isoform. The reverse primer (5'-ACAAGGCGAGAAGGCTGTGATAT-3') for S-PRLR bound within the 39 bp insert specific for the S-PRLR isoform while the L-PRLR reverse primer (5'-GACTTGCCTTCTCCAGCAGAT-3') spanned the point (nucleotide 942) of this insert. Gene expression relative to hypoxanthine phosphoribosyltransferase (HPRT) was reported as relative units (ru). Results from a repeated measures analysis (PROC MIXED of SAS) differed when $P < 0.05$. Milk yields of CP, CM, SP, and SM cows were 18.6, 29.1, 29.6, and 48.6 kg/d. HPRT decreased as DIM increased primarily due to a lower expression in SP and CP at 68 DIM. L-PRLR (8.00b, 15.28a, 14.77a \pm 1.28 ru) and S-PRLR (5.24b, 8.07a, 8.45a \pm 0.72 ru) were less at -12 than at 20 or 68 DIM. There was a line by parity interaction for L-PRLR as mRNA in SM was greater than SP, CM and CP cows (21.00a, 11.57b, 8.82b, 9.35b \pm 1.85 ru). Select cows had more mRNA for L-PRLR (16.28, 9.08 \pm 1.31 ru) and S-PRLR (8.64, 5.87 \pm 0.74 ru) than control cows. The ratio L-PRLR to S-PRLR did not differ by DIM for control (1.88, 1.60, 1.55 \pm 0.16) but increased in select cows postpartum (1.46a, 2.12b, 1.95b \pm 0.16). Data suggest liver expression of L-PRLR is associated with increased milk yield.

68 Exposure to short day photoperiod enhances mammary growth during the dry period of dairy cows. E. H. Wall*¹, T. L. Auchtung², G. E. Dahl², and T. B. McFadden¹, ¹University of Vermont, Burlington, ²University of Illinois, Urbana.

Exposure to short day photoperiod (SDPP; 8h light:16h dark) during the dry period increases milk yield of cows in the subsequent lactation. We hypothesized that this effect is due to increased growth of mammary epithelial cells in response to enhanced prolactin signaling converging on the IGF axis. Multiparous Holstein cows were dried off 62 days before parturition and assigned to long day (LDPP; 16h light:8h dark) or SDPP during the dry period. Mammary biopsies were obtained at -40, -20, -7 and +7 days relative to calving ($n=6$ cows/treatment) and rates of [³H]-thymidine incorporation into DNA *in vitro* were quantified. IGF-1, -2, and IGFBP-5 mRNA expression was assessed by real time RT-PCR. The mixed procedure of SAS was used for statistical analysis. For both treatments, cell proliferation rate increased from 40d to 7d ($P < .01$), then decreased in lactation ($P < .001$). However, timing of the proliferative response differed between treatments ($P < .05$). Proliferation rate increased from 40d to 20d in SDPP cows ($P < .01$) and was higher than LDPP cows at 20d ($P < .01$). The increase in proliferation did not occur until -7d for LDPP cows ($P < .01$). IGF-2 expression increased at -7d for SDPP cows ($P < .05$) and remained high in lactation, but did not increase in LDPP cows until after parturition ($P < .05$). IGFBP-5 mRNA

increased during lactation in both groups ($P < .05$) but was higher overall in LDPP cows vs. SDPP cows ($P < .05$). Expression of IGF-1 did not differ over time or between treatments. We conclude that exposure to SDPP during the dry period elicits earlier mammary cell proliferation relative to LDPP. Despite the lack of treatment difference in IGF-1 expression, lower IGFBP-5 expression in SDPP cows may increase IGF-1 availability to support mammary cell growth and survival. Temporal differences between treatments suggest the existence of a critical window wherein photoperiod affects mammary gland development during the dry period.

Key Words: Photoperiod, Mammary Growth, Prolactin Axis

69 Nutrient status influences the effect of conjugated linoleic acid on milk synthesis. M. J. de Veth*¹, E. Castaneda-Gutierrez¹, D. A. Dwyer¹, A. M. Pfeiffer², D. E. Putnam³, and D. E. Bauman¹, ¹Cornell University, Ithaca, NY, ²BASF-AG, Ofenbach, Germany, ³Balchem Encapsulates, New Hampton, NY.

The *trans*-10, *cis*-12 conjugated linoleic acid (CLA) isomer inhibits milk fat synthesis, whilst milk yield and synthesis of other milk components generally remains unchanged in cows in established lactation. However, in some CLA studies increases in milk yield and/or milk protein yield have been observed in cows limited in energy, either in early lactation or when fed pasture. Our objective was to evaluate the milk response to CLA when cows were provided limited dietary energy in combination with adequate or excess protein. Holstein cows ($n = 48$ mid-lactation) were fed ad-lib a TMR diet that met energy and protein requirements for a 16-d adjustment interval. Based on performance during this interval, the Cornell Net Carbohydrate and Protein System (CNCPS) model was used to design an energy-limiting ration that provided 80% of metabolizable energy requirement, which was fed to the experimental cows throughout the treatment periods. Cows were randomly allocated to four treatments (2 \times 2 factorial), in a 2 period crossover design. Treatments were: 1) protein adequate ration (PAR), 2) PAR + CLA, 3) protein excess ration (PER), and 4) PER + CLA. PAR and PER were set at 88% and 117%, respectively, of the metabolizable protein requirement established during the 16-d adjustment interval as estimated by the CNCPS model. Each experimental period comprised 16-d, with crossover of CLA within each level of protein. The dietary supplement of CLA was a lipid-encapsulated form that provided 12 g/d *trans*-10, *cis*-12 CLA. Milk samples were collected on the last 5d of each period. CLA treatment reduced milk fat yield (20.8%, $P < 0.01$), but increased both milk yield and milk protein yield (2.5% and 2.8%, respectively; $P < 0.05$). Milk yield, content and yield of both milk protein and milk fat were unaltered by either protein treatment alone or in combination with CLA. Overall, results demonstrate that CLA supplementation when cows are energy-limited may allow for increases in yield of milk and milk protein, and this may occur without the need for additional dietary protein.

Key Words: Conjugated Linoleic Acid, Milk Fat Depression, Milk Protein

70 Effect of transition diet on metabolism of Holstein cows in the periparturient period. J. Guo*, R. Peters, E. Russek-Cohen, and R. Kohn, *University of Maryland, College Park.*

The objectives were to characterize the homeorhetic change in blood metabolites and to evaluate the effect of transition diet on ketone body accumulation in periparturient cows. Twenty-eight multiparous Holstein cows were listed in order of their anticipated due dates and assigned to one of two groups with or without transition diet. The cows in treatment group received a transition diet (1.67 Mcal/kg NEL, 17% CP, 31% NDF) from 14 d before expected parturition to 14 d after calving and were fed the same diets as the cows in control group during the rest of experiment period. The cows in control group received a dry diet (1.38 Mcal/kg NEL, 11% CP, 53% NDF) from 28 d before expected due date, and a lactation diet (1.72 Mcal/kg NEL, 17% CP, 26% NDF) after parturition. Blood from coccygeal vein was sampled three times per week from 21 d before expected parturition to 21 d postpartum for analysis of glucose, non-esterified fatty acid (NEFA), β -hydroxybutyrate (BHBA), acetoacetate (ACAC), acetone, and glycerol. Plasma levels of ketone bodies changed in parallel, after parturition ketone bodies peaked at d 7 postpartum, and then decreased but remained high compared to values during the dry period. Plasma levels of NEFA and glycerol peaked at d 3 postpartum and changed in a similar pattern to those of ketone

bodies. Plasma glucose concentrations were higher for cows fed the transition diet compared with control cows in the last week prepartum (65.2 vs 55.1 mg/dl $P < 0.01$). Areas under the curve across the first 21 days postpartum for ACAC, NEFA, and glycerol were greater for cows receiving transition diets than for control cows ($P < 0.05$). There were no significant differences ($P > 0.05$) in peak plasma concentration (Cmax) and time of its occurrence (Tmax) between the treatment and control groups for glucose, NEFA, glycerol, acetone, ACAC, and BHBA. Results indicate that plasma glycerol may be an important contributor to gluconeogenesis during the periparturient period. Feeding a transition diet had a negative impact on postpartum metabolic variables.

Key Words: Transition Diet, Ketone Bodies, Fat Mobilization

71 The effect of copper supplementation and breed on milk fatty acid profile. J. Sumner^{*1} and P. French², ¹Washington State University, Pullman, ²Oregon State University, Corvallis.

An experiment was conducted to determine the effect of dietary copper (Cu) on Cu status and lipid metabolism in Holstein and Jersey cattle. Eight Jersey and 8 Holstein cows in mid-lactation (169 ± 37) were blocked by days in milk and assigned at random to one of two diets. Cows received either a control diet (Cu-) which contained a basal level of 8 mg Cu/kg DM or a treatment (Cu+) diet that was supplemented with 16 mg Cu/kg DM from CuSO₄ for a total of 24 mg Cu/kg DM. As expected, DM intake and milk yield were greater for Holsteins and milk fat and protein percentages were greater for Jerseys. Plasma Cu was greater for Jerseys and hepatic Cu was greater at 90 days of treatment for Cu+ Jerseys compared to Cu+ Holsteins. Total C18:0 in milk was lower for both Cu+ treatment groups. On day 90 of treatment, conjugated linoleic acid (CLA) in milk was less for Cu+ compared to Cu-. Also on treatment day 90, Cu+ cows produced more total saturated fatty acids than Cu- cows for both breeds. These results indicate that Cu metabolism differs between these two breeds. In addition, Cu supplementation decreased CLA secretion possibly due to an effect on biohydrogenation in the rumen or stearyl coenzyme A desaturase, an enzyme involved in the production of CLA.

Key Words: Copper, CLA

72 Evaluation of the ability of dietary fish oil to maintain elevated conjugated linoleic acid (CLA) in milk from dairy cows through five months of lactation. M. T. Sands*, S. T. Franklin, J. A. Jackson, L. J. Driedger, and K. I. Meek, University of Kentucky, Lexington.

Most trials for enhancement of milk CLA by dietary means have been short-term. The objective of this study was to determine the long-term ability of dietary Menhaden fish oil to maintain elevated CLA in milk fat of dairy cows. Nine primiparous cows (3 Jersey and 6 Holstein) and 12 multiparous cows (3 Jersey and 9 Holstein) were blocked by breed and parity and assigned to dietary treatments. Lactating diets were 1) control (CON), 2) cottonseed (CS), or 3) fish oil (FO) at 1.5% of dry matter (DM). During the dry period, cows assigned to the CON and CS diets were fed a dry cow control diet (DCON) and cows assigned to the FO diet were fed a dry cow diet containing 0.5% FO (DFO). Cows were housed in a free stall barn with Calan head gates approximately 4 wk prepartum to allow for 1 wk of acclimation and 3 wk of data collection. Postpartum feed intake and milk yields were recorded daily. Weekly milk samples were analyzed for fat, protein, and somatic cell count (SCC). Milk was sampled weekly for the first 2 wk and then biweekly for fatty acid analysis. Body condition scores (BCS) were estimated monthly and cows were weighed weekly throughout the trial. Serum was collected weekly through wk 4, then biweekly for analysis of nonesterified fatty acids (NEFA) and β -hydroxybutyrate (BHBA). Cows fed CON consumed more ($P < 0.05$) DM compared with cows fed CS and FO diets (21.6 ± 1.5 , 17.5 ± 1.5 , and 15.4 ± 1.5 kg/d respectively). Milk and protein yield were not affected ($P > 0.05$) by diet but fat yield was lower for cows fed FO. Both CLA and TVA were elevated ($P < 0.05$) in milk from cows fed FO compared with milk from cows fed CON or CS. Mean CLA content was $1.9 \pm 0.1\%$ in milk from cows fed FO compared with $0.6 \pm 0.1\%$ in milk from cows fed CON and CS. Dry cow DM intake, NEFA, BHBA, body weight, BCS and SCC were not affected by diet. Results indicate that cows fed FO at 1.5% of DM through 5 mo of lactation were able to maintain elevated concentrations of CLA and TVA

without adverse effects on serum NEFA, serum BHBA, body weight, or BCS.

Key Words: Fish Oil, Conjugated Linoleic Acid, Dairy

73 Effects of dietary CLA on production parameters in pasture-fed transition dairy cows. J. K. Kay^{*1,2}, J. R. Roche^{2,3}, and L. H. Baumgard^{1,3}, ¹University of Arizona, Tucson, ²Dexel, New Zealand.

High dietary CLA doses inhibit milk fat synthesis in TMR-fed dairy cows by wk 2 of lactation, however, CLA effects on pasture-fed cows immediately post-partum have not been investigated. Multiparous Holstein cows ($n=39$) grazing pasture were randomly assigned to one of three treatments: 1) pasture (PAS), 2) PAS + 600 g/d rumen protected (RP) CLA (RP-CLA) and 3) PAS + 540 g/d Hyprofat (RP palm oil; HF). RP-CLA and HF treatments were isoenergetic, fed 2x/d and provided 197 and 0 g CLA/d, respectively. Treatments began 14-21 d pre-partum and continued until 36 DIM. Milk was sampled on d 1, 2, 3 and 4 post-partum and every third d (± 1) until d 36, and fatty acid composition was determined on d 4, 8 and 15 (± 2). There was no overall RP-CLA effect on protein content (3.78%) or protein or lactose yield, however RP-CLA increased ($P < 0.01$) overall milk lactose content (4.90%) compared to HF (4.75%), but did not differ from PAS (4.82%). RP-CLA reduced ($P < 0.05$) milk fat content by 6 DIM (4.16, 5.69 and 4.98% for RP-CLA, PAS and HF, respectively) and continued to inhibit milk fat synthesis as DIM progressed, with maximum ($\sim 40\%$) milk fat depression (MFD) occurring by d 21. Milk fat yield followed a similar temporal pattern although differences did not occur until d 15. There was no overall treatment effect on milk yield (20.3 kg/d), however a quadratic relationship ($R^2=0.6$) was detected between the RP-CLA induced milk yield response and extent of MFD in RP-CLA vs. HF. RP-CLA tended to increase milk yield (1.5 kg/d; $P=0.08$) until MFD exceeded 30%, after which point the increase in milk yield declined. Milk fat *trans*-10, *cis*-12 CLA content averaged 2.4 mg/g in the RP-CLA treatment, was undetectable in PAS and HF treatments and did not differ over time. RP-CLA did not affect the Δ^9 -desaturase system nor did it alter the origin of fatty acids (*de novo* vs. preformed; molar basis) until d 15. These data indicate a high RP-CLA dose decreases milk fat synthesis and tends to increase milk yield immediately post-partum in pasture-fed cows, however excessive MFD ($>30\%$) is associated with a diminished milk yield response.

Key Words: CLA, Pasture, Transition Period

74 Effect of feeding Ca salts of palm oil (PO) or of a blend of linoleic and monoenoic trans fatty acids (LTFA) on lactation and health of Holstein cows. S. O. Juchem^{*1}, R. L. A. Cerri¹, M. Villasenor¹, K. N. Galvao¹, R. G. S. Bruno¹, H. M. Rutigliano¹, A. C. Coscioni¹, E. J. DePeters¹, W. W. Thatcher², D. Luchini³, and J. E. P. Santos¹, ¹University of California, Davis, ²University of Florida, Gainesville, ³Bioproducts, Inc., Fairlawn, OH.

Holstein cows, 511, were blocked according to parity, BCS at dry off and previous lactation milk production and randomly assigned to receive (2% diet DM) either Ca salts of PO or LTFA from 23 d prepartum to 70 d in milk (DIM). Yields of milk and milk components were measured weekly, and BCS was evaluated at -43, -23, calving, and at 40, 70, 100 and 140 DIM. Blood was sampled weekly from 23 d prepartum to 21 DIM, and plasma was analyzed for glucose, NEFA and BHBA. Fatty acid profile in milk fat was analyzed at 2 and 10 wk postpartum in 30 cows/treatment. Disease incidence was recorded for individual cows. Continuous and binomial data were analyzed by the MIXED and LOGISTIC procedures of the SAS (2001), respectively. Interval from calving to an event (death, culled, disease) was analyzed by the LIFETEST procedure of SAS (2001). Yields of milk were similar for LTFA and PO (38.4 vs 38.9 kg/d; $P=0.32$). However, feeding LTFA reduced 3.5% fat-corrected milk (36.8 vs 39.1 kg/d) because of a decrease in milk fat % (3.3 vs 3.6%; $P < 0.05$) resulting in lower milk fat yield (1.24 vs 1.37 kg/d; $P < 0.01$). The negative effect on milk fat was observed after the second week of lactation. Milk protein % was increased by feeding LTFA (2.78 vs 2.74; $P < 0.01$), but milk protein yield (1.06 vs 1.06 kg/d) and SCC were similar ($P > 0.15$). Feeding LTFA increased ($P < 0.01$) the concentrations of linoleic acid (3.56 vs 2.83%), C18:1 trans 10 (1.0 vs 0.4 %), C18:1 trans 11 (1.5 vs 1.0%) and CLA cis 9, trans 11 (0.8 vs 0.5%) in milk fat on week 10 postpartum, but differences were already detected at wk 2 postpartum. BCS did not differ ($P > 0.15$) between LTFA and PO

at -43d (3.77 vs 3.80), calving (3.68 vs 3.67), 100 DIM (2.78 vs 2.79). Feeding LTFA compared to PO had no effect on incidence of clinical ketosis (8.2 vs 6.9%), displacement abomasum (3.1 vs 1.6%), and milk fever (1.9 vs 2.0%). Cows fed LTFA had reduced yields of fat and 3.5%

FCM, altered milk fatty acid profile, but changes in FCM yield did not reflect in positive effects on BCS or health. Supported by NRI/USDA Grant 2003-02742.

75 Insulin resistance in growing Thoroughbreds is affected by diet. K. Treiber^{*1}, R. Boston², D. Kronfeld¹, R. Hoffman¹, W. Staniar¹, and P. Harris³, ¹*Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg,* ²*Department of Clinical Studies, New Bolton Center, Kennett Square, PA,* ³*Equine Studies Group, WALTHAM Centre for Pet Nutrition, Melton-Mowbray, UK.*

Insulin resistance is associated with obesity and inactivity and may be a risk factor for metabolic disorder in horses. This study applied the minimal model to test the affect of diet on glucose and insulin in young horses. Twelve Thoroughbred foals were raised on pasture and supplemented twice daily with a feed high in either sugar and starch or fat and fiber. As weanlings (age 199 ± 19 d, weight 274 ± 18 kg) the subjects underwent a modified frequently sampled intravenous glucose tolerance test during which they remained in stalls and had access to grass hay and water ad libitum. Samples were collected at -60, -45, 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 19, 22, 23, 24, 25, 27, 30, 35, 40, 50, 60, 70, 80, 90, 100, 120, 150, 180, 210, 240, 270, 300, 330 and 360 min with a glucose bolus of 300 mg/kg BW at 0 min and an insulin bolus of 1.5 mU/kg BW at 20 min. Plasma was analyzed for glucose and insulin. Insulin sensitivity (SI), glucose effectiveness, acute insulin response to glucose (AIRg) and disposition index were derived using Minmod Millennium and WinSAAM software. Diets were compared using the non-parametric Kruskal-Wallis test and the sign test. Basal glucose did not differ between groups (P = 0.75). Insulin levels were higher in the sugar and starch adapted weanlings at all 36 sample points (P = 0.030). The fasting glucose:insulin ratio for the sugar and starch supplemented weanlings was lower than for fat and fiber weanlings (P = 0.025). Insulin sensitivity was lower in weanlings fed sugar and starch than weanlings fed fat and fiber (P = 0.007). Acute insulin response to glucose was inversely correlated with SI (r = -0.54; P = 0.068). The glucose:insulin ratio was directly correlated to SI (r = 0.63; P = 0.036). These results show that weanlings adapted to a supplement high in sugar and starch had lower insulin sensitivity compared to weanlings adapted to a fat and fiber feed. Weanlings adapted to sugar and starch appeared to compensate for a lower sensitivity to insulin by increasing insulin secretion. Feeding meals high in glucose equivalents may increase the risk of developing insulin resistance and associated disorders in horses.

Key Words: Horse, Insulin Resistance, Minimal Model

76 Somatotropic axis in growing Thoroughbreds is affected by diet. K. Treiber^{*1}, W. Staniar¹, D. Kronfeld¹, R. Boston², and P. Harris³, ¹*Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg,* ²*Department of Clinical Studies, New Bolton Center, Kennett Square, PA,* ³*Equine Studies Group, WALTHAM Centre for Pet Nutrition, Melton-Mowbray, UK.*

The somatotropic axis comprises a network of metabolites and hormones that link nutrition to growth. Feeds high in glucose equivalents cause exaggerated fluctuations in components of this network and may contribute to metabolic and growth disorders. This study analyzed samples from a frequently sampled intravenous glucose tolerance test (FSIGT) to determine the effect of diet on plasma concentrations of insulin, growth hormone (GH) and insulin-like growth factor-I (IGF-I) in growing horses. Twelve Thoroughbred foals were raised on pasture and supplemented twice daily with a feed high in either sugar and starch (SS) or fat and fiber (FF). As weanlings (age 199 ± 19 d, weight 274 ± 18 kg) the subjects underwent an FSIGT during which they remained in stalls and had access to grass hay and water ad libitum. Samples were collected at -60, -45, 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 19, 22, 23, 24, 25, 27, 30, 35, 40, 50, 60, 70, 80, 90, 100, 120, 150, 180, 210, 240, 270, 300, 330 and 360 min with a glucose bolus of 300 mg/kg BW at 0 min and an insulin bolus of 1.5 mU/kg BW at 20 min. The minimal model was used to estimate insulin sensitivity (Si). Plasma was analyzed for

glucose, insulin, GH and IGF-I concentrations. Feed groups were compared using the non-parametric Kruskal-Wallis test. Time interactions for IGF-I were compared by ANOVA with repeated measures. Robust linear regression was used for correlations. Growth hormone concentrations were increased from basal 19 to 180 min after the glucose dose (P < 0.05). Basal IGF-I was higher (P = 0.006) in the SS group compared to the FF group. Concentrations of IGF-I increased with time (P = 0.002) in the SS group. Basal IGF-I was inversely correlated to SI (-r = 0.52; P = 0.10). These results show that weanlings adapted to meals high in glucose equivalents have higher IGF-I secretion as compared to weanlings adapted to a fat and fiber supplement. This deviation may be associated with insulin resistance and metabolic dysfunction in horses fed concentrates high in hydrolyzable carbohydrates.

Key Words: Diet, Growth Hormone, Insulin-Like Growth Factor-I

77 Environmental factors and nutrient composition of pasture in northern Virginia. T. A. Cubitt^{*}, W. B. Staniar, and D. S. Kronfeld, *Department of Animal and Poultry Science, Virginia Polytechnic Institute and State University, Blacksburg.*

Greater than 90% of horses in Virginia receive all or part of their nutrition from pasture (USDA/APHIS, 1988). The objective of this study was to test for association between environmental factors and pasture variables, and to compare equine requirements for growth and reproduction, as recommended by the NRC (1989), to nutrient content determined by proximate analysis of pasture samples taken at monthly intervals for 5 y in northern Virginia. Day length (DL, h) and temperature (T, C) were measured. Statistical analysis included Pearson correlations, linear regressions and quadratic curves (SAS, 2000). Significant associations were found between DL and CP (r = -0.16, P = 0.02), ADF (r = 0.24, P = 0.0004), and NSC (r = -0.15, P = 0.04). Temperature significantly correlated with DM (r = 0.76, P = 0.0001), CP (r = -0.23, P = 0.0007), ADF (r = 0.32, P < 0.0001), and NSC (r = -0.19, P = 0.004). A quadratic relationship was fit between CP and T with an R² = 0.20, P < 0.0001. A linear regression fit to ADG (kg/d) versus CP resulted in an R² = 0.11, P < 0.0001. The data was adjusted for the delay in change in ADG as compared to CP, to give a clearer indication of the strength of the association and the resulting R² = 0.23, P < 0.0001. In comparison to the requirements for growth and reproduction the pastures tested were deficient in Zn, Cu and P. Crude protein was above the requirements set by the NRC (1989). This study presents a temporal relationship between environmental factors, nutrients in the pasture, and growth variables. We suggest that certain minerals are below the recommended minimums listed in the NRC for horses at certain times of year. This data is useful in developing sound management practices for horses raised on pasture.

78 The effects of age, breed, gender and use on gastric ulceration in the horse. K. Chamero^{*}, J. Nadeau, S. Bushmich, J. Dinger, and T. Hoagland, *University of Connecticut, Storrs.*

Gastric ulceration in horses has been identified as a serious health concern. The goal of this study was to determine if there was an effect on the occurrence of ulcers among a genetically diverse population of horses composed of several different ages, breeds, gender, and use. Eighty horses ranging in age from 2 years to 23 years were used. Their breeds consisted of Morgans, Quarter horses, Warmbloods, Thoroughbreds, and grade horses. Mares and geldings were included. All horses were used in one of three different capacities: polo, lessons, or training. Horses were examined by endoscopic examination, visible ulcers were scored according to an accepted gastric ulcer scoring system. Comparisons of the distribution of the occurrence of ulcers, lesion number, and lesion severity scores were made with chi square analyses using an expected occurrence of 30% based on two previous studies. Nine of the 80 horses

(11%) had ulcers located in the nonglandular squamous epithelial mucosa. The mathematical mean of the lesion number score was 2.22 and the mathematical mean of the lesion severity score was 2.67. For all age groups, the occurrence of ulcers was not different than expected. Occurrence of ulcers was not different in Morgans, Quarter horses, and Warmbloods. Thoroughbreds and grade horses had fewer ($P < 0.05$) ulcers than expected. The occurrence of ulcers among all breeds was lower ($P < 0.01$) than expected. Geldings had fewer ($P < 0.01$) ulcers than expected, while the occurrence of ulcers was not different than expected in mares. The occurrence of ulcers for both genders was lower ($P < 0.01$) than expected. Occurrence of ulcers was less than expected in horses used in lessons ($P < 0.01$) and in polo ($P < 0.05$). The occurrence of ulcers was not different in horses in training. For all three use categories, the occurrence of ulcers was lower ($P < 0.01$) than expected. Among all categories, lesion number and lesion severity was not different than expected. Since overall percent and occurrence of ulcers in this population was lower than in previous studies, it may be suggested that such things as management practices, length of turnout, and overall contact may play an important role in the occurrence of ulcers.

79 Evaluation of feeding bee pollen to horses in training. K. K. Turner*, B. D. Nielsen, C. I. O'Connor, and J. L. Burton, *Michigan State University, East Lansing.*

"Bee pollen" is often fed to horses but few studies have evaluated its use. Our hypothesis was feeding bee pollen would positively influence nutrient digestibility, and indices of immunological status and physical fitness in horses in training. Ten Arabians (6 geldings, 4 mares) underwent a standardized exercise test (SET). Horses were pair-matched by sex and fitness and randomly assigned to P (receiving 118 g of bee pollen (Dynamic Trio 50/50) daily) or C (control receiving 73 g of a placebo) for a supplementation period of 42 d. A total collection period was conducted on geldings from d 18 to 21 to determine effects of bee pollen on nutrient retention and digestibility of NDF and ADF. Horses were exercise conditioned during the 42-d trial and completed another SET on d 42. V_{160} and V_{200} were calculated from SET heart rates (HR). Lactate, glucose, hematocrit (HT) and hemoglobin (HB) concentrations were determined from SET blood samples. Total and percent leukocytes, T and B lymphocytes, monocytes, neutrophils, and eosinophils, as well as IgG, IgM and IgA concentrations were determined from rest and recovery samples from both SETs. Geldings in P ate more feed than C on every day of the collection period. P had 80 % less phosphorus excretion ($P = 0.003$), and tended to retain 90 % more nitrogen ($P = 0.08$). P tended to digest more NDF ($P = 0.06$) and ADF ($P = 0.09$). P had lower NDF digestibility ($P = 0.002$) and tended to have lower ADF digestibility ($P = 0.07$). Although no treatment differences existed, V_{160} and V_{200} increased ($P < 0.05$), and HR ($P = 0.002$), blood lactate concentration ($P < 0.0001$), HT ($P < 0.0001$) and HB ($P = 0.0003$) decreased from d 0 to 42. Few treatment differences were seen in immunological parameters. There was a trend for percent monocytes to increase in C while decreasing in P ($P = 0.1$) from rest to recovery on d 42. Percent

Milk Protein and Enzymes

81 Composition of the air interface in ice cream as affected by protein and emulsifier content. Z. Zhang* and D. Goff, *Department of Food Science, University of Guelph, Guelph, ON, Canada.*

Emulsifiers and proteins interact during the production of ice cream to form the fat interface, which in turn controls the extent of partial coalescence and hence fat structure formation in the frozen product. The interaction of these ingredients at the air interface, however, has not been as well investigated. We have examined the effect of saturated or unsaturated mono-glyceride and the effect of protein from skim milk powder or whey protein isolate on the composition of the air interface by immuno-gold labeling and transmission electron microscopy. When ice cream was made from skim milk powder in the absence of emulsifier, casein micelles, non-micellar b-casein and b-lactoglobulin were found at the air interface. When emulsifiers were used, more fat was seen at the air interface, especially with unsaturated mono-glyceride. When whey protein isolate was used, fat globules were seldom found at the air interface, regardless of emulsifier presence. As the fat interface is formed

neutrophils increased from rest to recovery on d 42, with P increasing more ($P = 0.04$). Percent neutrophils was increased on d 42, compared to d 0, with the greatest increase in P ($P = 0.04$). Bee pollen supplementation, while not affecting measured fitness variables, may have a positive effect on performance by helping meet increased metabolic demands of equine athletes by increasing nutrient retention and feed intake.

Key Words: Pollen, Horse, Exercise

80 Potassium supplementation affects plasma $[K^+]$ during an 80 km endurance exercise test on the treadmill. T. M. Hess*¹, K. Treiber¹, D. S. Kronfeld¹, J. N. Waldron², C. A. Williams¹, M. S. Freire¹, A. M. G. B. Silva¹, L. S. Gay¹, D. A. Ward¹, and P. A. Harris³, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Rectortown Equine Center, Rectortown, VA, ³Equine Studies Group, Waltham Centre for Pet Nutrition, Melton-Mowbray, UK.

During exercise plasma $[K^+]$ increases and can lead to increased neuromuscular excitability and related clinical signs. Supplementation of K during exercise can further increase plasma $[K^+]$. A K-free electrolyte mixture (EM-K) was tested and compared to a K-rich mixture (EM+K) during an 80 km simulated endurance exercise test (EET) on a treadmill. Twelve horses were tested in a cross over design performing four bouts (B) of 20 km at 45% of their maximum heart rates with three 30-minutes of rest (R) between bouts. Before the start of EET and during each R horses were supplied with EM-K or EM+K. Blood samples were collected before (PRE), at 10 km of each B, at 20 minutes of every R and 10 minutes after B4 (REC) and analyzed for hematocrit (Hct), and plasma for pH, PCO_2 , lactate ($[La^-]$), phosphate ($[PO_4^-]$), albumin (alb), CK and AST and electrolytes. Horses were weighed and electrocardiograms done at PRE, every R, and REC; weights were also measured in the morning after (MA) EET. Effects of stage (PRE, B1, B2, B3, B4, R1, R2, R3, R4, REC, MA) treatment (EM-K vs EM+K) and their interactions were evaluated by ANOVA in a mixed model with repeated measures. Body weight losses during EET increased up to 4.96% at REC, and were 2.3% below PRE at MA ($P < 0.001$). Hct increased during B, returned to PRE at every R ($P < 0.001$). Plasma alb increased during EET ($P < 0.001$), returning to PRE values at REC. Plasma CK and AST increased progressively during EET ($P < 0.001$). Plasma pH increased with exercise, decreased with R and REC ($P < 0.001$). Plasma PCO_2 and $[Ca^{++}]$ decreased during exercise and increased during R periods, however $[Ca^{++}]$ was lower than PRE at REC ($P < 0.001$). Plasma $[Mg^{++}]$ decreased initially with exercise, but then was higher than PRE at REC ($P < 0.001$). Plasma $[Na^+]$, $[Cl^-]$, $[La^-]$, and PO_4^- increased progressively during the EET ($P < 0.0001$). No abnormalities were observed on the EKG results. A treatment effect was found for plasma $[K^+]$ ($P = 0.014$), where horses that received EM-K had lower values than EM+K. Lower plasma $[K^+]$ during exercise could help maintain resting membrane potential and prevent signs of neuromuscular hyperexcitability.

Key Words: Potassium, Equine, Exercise

first during ice cream processing, the composition of the air interface was found to be a direct consequence of the composition of the fat interface.

82 Evidence that the major novel disulfide bond in heated cows milk is between β -lactoglobulin Cys160 and κ -casein Cys88. E. K. Lowe¹, S. G. Anema^{1,2}, M. J. Boland¹, R. Jiménez-Flores³, and L. K. Creamer*¹, ¹Fonterra Research Centre, Palmerston North, New Zealand, ²Riddet Centre, Massey University, Palmerston North, New Zealand, ³Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.

Heat treatment of milk causes the milk proteins to interact irreversibly with one another, primarily caused by disulfide bond interchange. Early studies have shown that heating β -lactoglobulin (BLG) in solution invokes Cys-mediated disulfide bond interchange to give BLG polymers and BLG molecules with non-native disulfide bonds. Some of these molecules and polymers contain Cys66 or Cys160 in the reduced state.

It has long been known that both BLG and κ -casein (KCN) are present in the complexes formed as a consequence of heat treatment. BLG contains five Cys residues and KCN contains 2 Cys residues, and thus there is a large number of combinations of possible disulfide bondings. Reacting reduced KCN with DTNB (dithiobisnitrobenzoic acid) gives KCN molecules containing activated Cys groups. Reacting partially reduced BLG with these derivatives gave a range of products. These were separated and the fraction that contained material with a mass of about 35 kDa was hydrolyzed with trypsin. Among the products were peptides with masses corresponding to the peptides BLG148-162 SS KCN87-97 and BLG148-162 SS KCN11-16. The identity of the peptides was verified by partial sequencing of both the intact peptides and the reduced peptides using ESI-MS-MS. A heated milk sample was analyzed and these peptides were identified in a trypsin-treated sample of the mixture of proteins and there was significantly more disulfide-bonded KCN87-97 than KCN11-16 in the mixture. The existence of other possible disulfide bonding patterns involving Cys 66, 106, 119, or 121 of BLG, and Cys 11 or 88 of KCN are being explored.

Key Words: Heat-Induced Complex, Whey Protein, Casein

83 Application of novel gel electrophoresis to analyze native, heat-, and pressure-treated milk protein systems. H. A. Patel^{1,2}, H. Singh³, and L. K. Creamer^{*1}, ¹Fonterra Research Centre, Palmerston North, New Zealand, ²Institute of Nutrition, Food and Human Health, Massey University, Palmerston North, New Zealand, ³Riddet Centre, Massey University, Palmerston North, New Zealand.

The invention of gel electrophoresis presaged great advances in all protein sciences and has been particularly useful in dairy protein science. Incorporation of urea into the gels allowed clear separation of the caseins from one another and reduction of the disulfide bonds allowed the clarification of the polypeptides that comprise the native α_{s2} - or κ -casein (KCN). Addition of other solutes, such as magnesium chloride or SDS, meant that the basis of separation could be changed. The advent of two-dimensional electrophoresis in polyacrylamide gels gave even greater power because the two separations could be under very different conditions; for example, the alkaline urea PAGE followed by SDS PAGE. The best-known 2D method uses isoelectric focussing followed by SDS PAGE, is very powerful technique and is used extensively in proteomics research. Our group has been using electrophoresis to study some particular problems, such as: Does β -lactoglobulin (BLG) bind preferentially to α_{s2} -CN or KCN during heat treatment carried out in non-native conditions? In the whey protein scene, 2D PAGE as modified by our group allowed the identification of the pathways leading to BLG and whey protein aggregation and gelation during heat treatment. These techniques, with some added

Nonruminant Nutrition: Finishing Pigs - Additives & Energy

85 Effect of L-lysine-HCl addition in late finishing gilts fed ractopamine HCl (Paylean®). B. W. Ratliff^{*1}, A. M. Gaines¹, P. Srichana¹, G. L. Allee¹, and J. L. Ustry², ¹University of Missouri, Columbia, ²Ajinomoto Heartland LLC, Chicago, IL.

The objective of this 21 d experiment was to evaluate the effect of L-lysine-HCl addition on growth performance of pigs fed ractopamine HCl (Paylean®). A total of 966 gilts (TR-4 × C22; 98.2 ± 0.2 kg) were randomly allotted to one of six dietary treatments with seven replicate pens/treatment and 23 pigs/pen. Dietary treatments included five levels of L-lysine-HCl that corresponded to concentrations of 0.10, 0.20, 0.30, 0.40, and 0.50% lysine, respectively. With the exception of L-threonine and Alimet® feed supplement (88% L-methionine activity), additional synthetic amino acids were not supplied to meet the minimum amino acid profile. To evaluate the effect of maintaining a minimum amino acid profile, additional synthetic amino acids (L-tryptophan, L-isoleucine, and L-valine) were supplemented to a diet containing 0.50% L-lysine-HCl. All diets were corn-soybean meal-based with 2% choice white grease formulated at a 0.93% TID lysine and contained 7 ppm Paylean®. Increasing the L-lysine-HCl inclusion resulted in a decrease (quadratic, P < 0.04) in ADG (1,016, 1,016, 1,016, 1,043, and 966 g/day, respectively) and lowered (quadratic, P < 0.02) G:F (0.352, 0.357, 0.353, 0.352, and 0.338, respectively). There were no differences (P = 0.40) in ADFI. Use of two slope-broken line analysis indicated a maximum L-lysine-HCl inclusion of 0.41% for ADG and 0.39% for G:F. The addition of synthetic amino acids to the diet containing 0.50% L-lysine-HCl did not restore growth performance. Collectively, these data demonstrate

refinements, have now been applied to a range of dairy protein problems of varying complexity. For example, the examination of heat and pressure treated milks which has led to an even greater clarification of the relative roles of α_{s2} -CN or KCN in their reaction with the aggregating whey proteins

84 Effects of genetic modification, pressure, and heat on the binding of various probes to β -lactoglobulin. K. A. N. S. Ariyaratne¹, G. B. Jameson¹, T. S. Loo², G. E. Norris², H. A. Patel^{4,3}, T. Considine^{4,5}, H. Singh⁵, L. K. Creamer^{*4}, and R. Jiménez-Flores⁶, ¹Institute of Fundamental Sciences, Massey University, Palmerston North, New Zealand, ²Institute of Molecular Biosciences, Massey University, Palmerston North, New Zealand, ³Institute of Nutrition, Food and Human Health Massey University, Palmerston North, New Zealand, ⁴Fonterra Research Centre, Palmerston North, New Zealand, ⁵Riddet Centre, Palmerston North, New Zealand, ⁶Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.

Native β -lactoglobulin (BLG) has been shown to bind a number of hydrophobic and amphipathic molecules within the central calyx. Examples are: hexane, retinol (vitamin A), cholesterol, 12 bromo-dodecanoic acid, palmitic acid, and cis-parinaric acid (CPA) but not anilino-naphthalene sulfonate (ANS). The binding of retinol and CPA can be followed by induced circular dichroism or increased fluorescence. This has allowed the determination of the displacement of CPA or retinol by dodecyl sulfate (SDS) or palmitate, but not by ANS. Heat treatment denatures the BLG, and the binding of CPA and retinol decreases in proportion with the extent of denaturation while ANS fluorescence increases. Pressure treatment has a similar effect. Addition of these ligands of BLG increases the stability of the protein under increased temperature and pressure. ANS does not have this effect. Polynucleotides were synthesized and expressed to give fusion proteins, corresponding to both the A and B variants of BLG. These were subsequently cleaved to obtain synthetic BLG A and BLG B. Modification of the polynucleotide allowed the preparation of a number of different BLG mutants. Some of these were modifications close to the binding site of retinol and the fatty acids. In particular the change of lysine to glutamic acid at residues 60 and 69 showed dramatic differences in behavior. These two residues are close spatially but the change at residue 60 prevents binding of retinol or CPA while that at residue 69 does not.

Key Words: Lactoglobulin Binding, Mutant Protein, Pressure Treatment

that up to 0.40% L-lysine-HCl can be added in Paylean® diets without compromising growth performance, provided the diets are supplemented with L-threonine and a methionine source. Furthermore, maintaining a minimum amino acid profile in Paylean® diets containing 0.50% L-lysine-HCl does not restore growth performance indicating that another nutrient may be limiting.

Key Words: Ractopamine, Lysine, Pigs

86 Threonine to lysine ratio in ractopamine treated pigs. D. M. Fernandez^{*1}, N. Rosas², A. I. Soria¹, and J. A. Cuarón³, ¹Universidad Nacional Autónoma de México, ²Patronato de Apoyo a la Investigación y Experimentación Pecuaria en México A.C. Queretaro, MX, ³Instituto Nacional de Investigaciones Forestales Agrícolas y Pecuarias Queretaro, MX.

Previously we titrated the digestible lysine requirement of finishing pigs in the presence or absence of 5 ppm ractopamine (RAC). The objective of this study was to determine the threonine to lysine ratio (T:L, %) required to maximize growth performance of finishing pigs fed diets containing either 5 or 10 ppm RAC. One hundred individually penned crossbred pigs (Landrace × Duroc) were used in a 28-d trial. Initial body weight averaged 77.2 ± 4.04. Dietary treatments included 1) a control diet (CON) formulated to .67% digestible lysine (DL) and 3.20 Mcal

ME/kg (T:L=70), 2) As 1 + 5ppm RAC (T:L=70), 3) CON supplemented with L-lysine-HCl to .82% DL and L-threonine to .47% digestible threonine (DT), and 5 ppm RAC (T:L=57), 4) As 3 + .041% DT (T:L=62); 5) As 3 + .082% DT (T:L=67), 6) As 3 plus .123% DT (T:L=72), 7) CON supplemented with L-lysine-HCl to .92% DL and L-threonine to .53% DT, and 10 ppm RAC (T:L=57), 8) As 7 + .046% DT (T:L=62), 9) As 7 + .092% DT (T:L=67), and 10) As 7 + .138% DT (T:L=72). The experiment was conducted as a randomized complete block design with 10 replicates per treatment. Pigs were fed ad libitum twice a day and voluntary feed intake (FI) was measured. Pigs were weighed at d0, d7, d14, d21 and d28. Backfat depth, muscle depth, and loin eye area were measured between the 10th and last rib 6.5 cm off the midline using real-time ultrasound at d0, d14, and d28 to calculate fat-free-lean gain (FFLG). Diets with RAC decreased FI (P<.11), but most of the effect was due to the 10 ppm dose (2.69, 10 ppm vs. 2.88 kg/d at 5 ppm). The T:L ratio at 5ppm RAC showed a quadratic effect (P<.01) in ADG: .79, .95, .90 and .77 kg/d for the 57 to 72% T:L ratio. From these data the best T:L ratio was calculated at 64% (range of 62 to 67%). The RAC effect was evident (P<.01) in FFLG and primal cuts. The RAC response in FFLG and primal cuts to the T:L ratio was only detected at 5 ppm. At 10 ppm, FFLG and primal cuts were higher in CON compared to RAC at all T:L levels.

Key Words: Pigs, Threonine, Ractopamine

87 Effects of increasing total sulfur amino acid:Lys on performance and carcass characteristics of gilts fed a ractopamine step-up program. A. Yager*, L. Wilson, K. Sadoris, L. Peddireddi, R. Hinson, M. Walsh, D. Sholly, B. Richert, A. Schinckel, and J. Radcliffe, *Purdue University, West Lafayette, IN.*

One hundred eighty crossbred (Dekalb 45 x EB) gilts (initial BW = 80 kg) were used in a 5-wk study to determine the effects of increasing total sulfur amino acid to Lys ratio (TSAA:Lys) in ractopamine fed pigs. Gilts were blocked by BW and randomly assigned to diets within block (6 pens/diet). Diets met or exceeded all nutrient requirements (NRC, 1998) except true ileal digestible (TID) TSAA. Dietary treatments were fed across two phases (P1, d 1-18; P2, d 18-35). Diets 1-4 contained 1.03/0.93% (P1/P2) TID Lys, 5/10 ppm ractopamine, and TID TSAA:Lys of 0.52, 0.57, 0.62, and 0.67, respectively. Diet 5 (control), contained TSAA:Lys of 0.67 similar to diet 4, but with lower inclusion of Lys-HCl (0.10 vs. 0.30%) and L-Thr (0.08 vs. 0.17%). Individual BW and pen feed intake were recorded on d 0, 9, 18, 27, and 35. Last and 10th rib backfat (BF) and loin eye area (LEA) were determined ultrasonically (4 pigs/pen) at d 0, 18, and 35. Gilts were harvested at the end of the experiment (BW = 117 kg), and carcass ultrasound fat depth, loin depth, and % lean estimates were recorded. The TSAA:Lys had no effects (P > 0.10) on overall ADG or G:F. Pigs fed higher levels of synthetic AA (diet 4 vs. 5) consumed less feed (P < 0.05) during P2 and overall. During P2, G:F tended to improve as TSAA:Lys increased, except for pigs fed a TSAA:Lys of 0.62, which decreased G:F (quadratic, P < 0.10). Tenth rib LEA increased to a TSAA:Lys of 0.62 (quadratic, P < 0.05) during P1, but the 0.62 ratio had the smallest increase during P2. Overall change in 10th rib LEA increased (linear, P < 0.10) 15.7, 16.3, 17, and 18 cm² as TSAA:Lys increased. TSAA:Lys had no effect (P < 0.10) on live ultrasound 10th rib BF thickness, carcass ultrasound fat depth, loin depth, or estimated carcass lean. Carcass ultrasound fat depth decreased (P < 0.05) and loin depth increased (P < 0.05) for pigs fed diet 4 compared to diet 5. Increasing the TSAA:Lys had minimal effects on growth and carcass traits. However, using increased TID TSAA:Lys and synthetic amino acids may improve ADFI and carcass ultrasound fat and loin depth estimates.

Key Words: Pig, Amino Acid Ratio, Growth

88 Efficacy of SUPROL[®] as a growth promotant for grow-finish pigs. R. C. Thaler*¹, B. D. Rops¹, B. T. Christopherson², and E. Cerchiani³, ¹*South Dakota State University, Brookings*, ²*SODA Feed Ingredients LLC, Brookings, SD*, ³*SODA Feed Ingredients Ltd., IRL.*

One hundred high lean-gain barrows weighing approximately 20 kg were utilized in a grow-finish trial to determine the efficacy of SUPROL[®] as a growth promotant. SUPROL[®] is a microencapsulated mixture of organic acids and essential oils that is used as a natural growth promotant. Five dietary treatments were used (Control (Con); Con + SUPROL[®]; Con + SUPROL[®] + BMD; Con + Tylan; Con + Mecadox) in a 4-phase

feeding program. There were 5 pigs/pen and 4 replicates/treatment. The trial was terminated at a final weight of 114 kg BW. From 20-36 kg (Grower 1), there were no differences (P>.05) in ADG, ADFI, or G/F. Midway through the Grower 1 phase, a mild PRRS outbreak occurred. However, it appeared all treatment groups were affected by it. For the Grower 2 phase (36-59 kg), pigs on the Mecadox or SUPROL[®] + BMD treatments consumed more feed (P<.05) than pigs fed the other dietary treatments, and pigs fed the SUPROL[®] or Con diets were more efficient (P<.05) than pigs fed the other 3 treatments. For the Finisher 1 (59-86 kg), and Finisher 2 (86-114 kg) periods, there were no differences in performance (P>.10). In the overall period from 20-114 kg BW, daily gain and feed intake were unaffected (P>.10) by treatment but feed efficiency was affected by treatment with the pigs fed the SUPROL[®] diets being the most efficient (P<.05). Based on these results, SUPROL[®] is an effective, natural feed additive that improves grow-finish pig performance.

Key Words: SUPROL[®], Organic Acids, Essential Oils

89 Effect of wheat sample, particle size and xylanase on energy digestibility of wheat fed to grower pigs. R. T. Zijlstra*¹, T. N. Nortey¹, D. Overend³, R. Hawkes¹, M. D. Drew², J. Fledderus⁴, J. F. Patience¹, and P. H. Simmins⁵, ¹*Prairie Swine Centre Inc., Saskatoon, SK, Canada*, ²*University of Saskatchewan, Saskatoon, SK, Canada*, ³*Ridley Inc., Mankato, MN*, ⁴*De Schothorst, Lelystad, The Netherlands*, ⁵*Danisco Animal Nutrition, Marlborough, UK.*

The DE content of wheat is variable, being caused by constraints in energy digestibility. These constraints may be reduced by feed processing, e.g., grinding and xylanase supplementation. The responses from three wheat samples (W1, high; W2, medium and W3, low DE; predicted using NDF, 20.1, 29.3, and 35.7% DM, respectively), at three particle sizes (fine, FPS; medium, MPS and coarse, CPS), to control or *Trichoderma* xylanase (2625 U/kg diet) on energy digestibility were studied in a 3 x 3 x 2 factorial arrangement. Pigs (54; 29.4 ± 2.4 kg) were fed two diets (96% wheat, 0.4% chromic oxide) each at 3-x maintenance in subsequent periods for 6 pigs per diet. Feed and feces were analyzed to determine apparent total-tract energy digestibility. Energy digestibility was affected by wheat sample, particle size, xylanase, sample x particle size, and sample x xylanase (P<0.01). Energy digestibilities were different for W1, W2 and W3 (P<0.001; 85.1, 77.4 and 76.7%, respectively) and confirmed the predicted DE ranking. Based on *in-vitro* analyses, starch in all three wheat samples was rapidly degradable (P > 0.10), indicating that NDF was not related to starch digestion. Overall, energy digestibility for FPS was 2.3 and 3.0% higher than for MPS and CPS (P<0.001; 81.1, 79.3 and 78.7%, respectively), and was 0.9% higher for xylanase than control (P<0.01). Xylanase improved energy digestibility 2.0% for W2 and 1.4% for W3 (P<0.01), but not for W1 (P>0.10), and FPS improved energy digestibility 4.8% for W2 and 3.8% for W3 compared to CPS (P<0.01), but not for W1 (P>0.10), together indicating that beneficial effects of processing depended on wheat sample. Prediction of wheat quality prior to processing and subsequent adjustments in processing may be components in a decision model to achieve consistent dietary DE content.

Key Words: Wheat, Particle size, Xylanase

90 Hydration properties of different cereal grains before and after enzymatic digestion as affected by thermal treatment and grinding. M. Anguita, E. Creus*, and J. F. Perez, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Physicochemical properties of feed structures are nutritionally relevant during their passage in the digestive tract. Amongst these properties, the hydration capacity has been extensively studied in relation with the gastrointestinal function and microbial composition. We measured water retention capacity (WRC; Table) of three cereals (wheat, barley and oats) as the amount of water retained after centrifugation (3,500 x g) by the insoluble substrate (g water/g incubated DM). The cereals were processed by hydrothermal cooking (100C; 60 min) or extrusion (75 rpm; 70 atm; 145C), and ground in a hammer mill (0.8 and 3.0 mm). The WRC was measured using an *in vitro* model, which simulates the gastric (pepsin; pH = 2.0; 4 h; Gastric WRC) and small intestine (SI) digestion [Pancreatine (pancreas extract); pH = 7.0; 4 h; SI WRC]. Average values of WRC were similar for Gastric and SI digestion of raw and cooked ingredients, suggesting that WRC may be mainly determined by the

content of insoluble and undigested substrate (IUS). The relationship between SI WRC and IUS was: $WRC = 0.0279 IUS + 0.7047$ ($R^2 = 0.654$). On the other hand, extrusion of cereals promoted a significant increase in Gastric WRC, probably due to the gelatinization and dispersion of starch. Extrusion and grinding promoted decreases in SI WRC, which was associated with a decrease on the amount of IUS rather than a variation on the feed particle size. Further studies are required *in vivo* to evaluate the influence of processing on the physicochemical properties of digesta and the gastrointestinal microbial population.

91 Response of growing and finishing pigs to dietary energy concentration. J. F. Patience^{*1}, A. D. Beaulieu¹, R. T. Zijlstra¹, and N. H. Williams², ¹*Prairie Swine Centre Inc., Saskatoon, SK, Canada*, ²*PIC USA, Inc., Franklin, KY*.

Achieving the full genetic potential for swine growth requires an understanding of the response to dietary energy in all phases of growth. This experiment was designed to develop an energy response curve for growing and finishing pigs. Barley and soymeal based diets were formulated with increasing wheat and canola oil to contain 3.05, 3.19, 3.33, 3.47, or 3.61 Mcal DE/kg. Separate diets were formulated with appropriate dLys:DE ratios for barrows and gilts within 3 phases of growth (25 to 50, 51 to 80 and 81 to 115 kg BW). Offspring of C22 females and L337 boars (n=300) were blocked according to gender, weight per day of age and BW and randomly assigned to treatment. Light (28.8 kg mean BW) and heavy (33.6 kg mean BW) blocks allowed the determination of differential animal response to energy according to initial weight. Pigs were weighed on d0, d14 and at the end of each phase. ADG averaged 0.97, 1.07 and 1.07 kg/d in phases 1, 2 and 3, respectively, and was unaffected by diet DE concentration ($P > 0.05$). Lighter pigs grew 50 g/d slower than heavier pigs ($P < 0.001$). Block by DE interactions did not exist ($P > 0.05$). Overall feed intake decreased from 2.76 to 2.49 kg/d (linear, $P < 0.001$) and feed efficiency improved from 0.36 to 0.42

Physiology and Endocrinology: Factors Affecting Embryonic and Fetal Mortality

95 Effect of elevated systemic concentrations of ammonia and urea on amino acid concentrations in oviduct fluid in cattle. D. A. Kenny^{*1}, P. G. Humpherson³, D. G. Morris², H. J. Leese³, M. G. Diskin², and J. M. Sreenan², ¹*Department of Animal Science and Production, Faculty of Agriculture and Food Science, University College, Dublin, Ireland*, ²*Teagasc Research Centre, Athenry, Co. Galway, Ireland*, ³*Department of Biology, University of York, York, UK*.

It has been suggested that elevated systemic concentrations of urea and ammonia may compromise early bovine embryo development in the oviduct. The objective of this study was to determine the effect of elevated systemic ammonia and urea on amino acid (AA) concentrations in cattle oviduct fluid. Heifers (n=25) were allocated to one of three intravenous infusion treatments; saline (C), urea (U) or ammonium chloride (AC) at either 2 or 8 d after oestrus. Treatment solutions were infused over a 7 h period and oviduct fluid was collected during mid

(linear, $P < 0.001$) as DE increased from 3.05 to 3.61 Mcal DE/kg. DE concentration did not affect lean thickness (average 61.3 mm; $P > 0.05$), however, backfat increased from 16.8 to 19.4 mm when DE increased from 3.05 to 3.61 Mcal/kg (linear, $P < 0.05$). In conclusion, a positive response to dietary energy concentration is confirmed for feed conversion, but not ADG. Further research is required to understand why pigs do not always respond to increased dietary energy concentration with improved growth.

94 Palm oil and hydrogenated fat as alternative oil sources for fattening pig diets. P. Medel^{*1}, J. I. Fernández², J. Peinado¹, J. C. González¹, and C. López-Bote⁴, ¹*Imasde Agropecuaria, S.L. Spain*, ²*Norel, S.A. Spain*, ³*Universidad Complutense de Madrid, Spain*.

A total of 96 Large White × Landrace*Large White pigs of 29.0 ± 3.2 kg of initial BW, 50 % males and females, were used to study the influence of type of fat source on productive performance and carcass quality. Feeding program consisted of three phases offered *ad libitum* (1.08 % lys from 29 to 63 kg BW, 1.03 % lys from 63 to 78 kg BW, and 0.89 % lys from 78 to slaughter at 96 kg BW). There were 4 treatments based on fat source (5 % of inclusion): T1 and T2, containing respectively lard or palm oil throughout the whole period, T3, containing soy oil from 29 to 63 kg and hydrogenated palm stearin thereafter, and T4, containing soy oil from 29 to 78 kg and hydrogenated palm stearin thereafter. Each treatment was replicated four times (12 pigs housed together), and biopsies from 2 pigs per pen were taken at every change of diet. For the whole period, feeding lard improved growth and feed conversion relative to T3, showing all the other dietary treatments intermediate results (754, 717, 670, 704 g/d and 2.56, 2.71, 2.76 and 2.70 g feed/g gain for T1 to T4, respectively, $P < 0.05$). Fatty acid profile (FAP) was similar for T1 and T2 and presented low variation throughout the trial, with T2 showing slightly higher values for palmitic and stearic acids at the end of the trial. From 63 kg or 78 to slaughter, palmitic, oleic and stearic acids were increased in T3 and T4, respectively, reaching the T1 and T2 range for palmitic acid, but showing higher stearic and lower content of oleic and linoleic acids than control diets. Type of fat did not affect dressing percentage, backfat depth, or carcass pH and temperature. It is concluded that: i) palm oil can be used efficiently as an alternative to lard, and ii) hydrogenated fats may be used to increase fatty acids positively related to fat consistency when unsaturated fat sources has been previously fed, but administration should begin at least at 60 kg and productive performance could be affected.

Key Words: Hydrogenated Fats, Fatty Acids, Fattening Pigs

ventral laparotomy over the final 3 h of infusion. Oviduct and blood plasma samples were analysed for concentrations of ammonia, urea and 17 AA. There was no treatment × day interaction for any of the plasma or oviduct fluid AA measured ($P > 0.05$). The concentration of all AA was similar between oviducts ipsi- or contralateral to the corpus luteum. Plasma and oviductal urea were elevated by infusion with U ($P < 0.001$) and AC ($P < 0.05$). Plasma and oviductal ammonia were elevated by AC ($P < 0.001$) but not by U ($P > 0.05$). There was no effect of day on plasma concentrations of any AA ($P > 0.05$). Plasma and oviductal glutamine, histidine and valine were similar ($P > 0.05$) while the concentration of all other AA was lower in plasma than oviduct fluid ($P < 0.01$). Plasma glutamine was higher in animals on AC than on C (0.29 ± 0.03 v 0.19 ± 0.03 ; $P < 0.05$) while plasma isoleucine was lower in animals on AC than on C (0.04 ± 0.008 v 0.06 ± 0.008 ; $P < 0.05$). There was no effect of infusion treatment on the plasma concentration of any of the other AA measured ($P > 0.05$). Across treatments, oviductal isoleucine was higher on day 2 than 8 (0.06 ± 0.004 v 0.05 ± 0.004 ; $P <$

0.05) and there was a tendency for oviductal concentrations of histidine and lysine ($P = 0.06$) and isoleucine and phenylalanine ($P = 0.07$) to be higher on day 2 than 8. These data, in combination with previous studies from this laboratory, show that elevated systemic concentrations of ammonia or urea *per se* are unlikely to reduce embryo survival in cattle, particularly through disruptions to the oviductal environment.

Key Words: Oviduct, Amino Acids, Urea

96 Initial characterization of abortigenic activity associated with mare reproductive loss syndrome. K. J. McDowell^{*1}, N. M. Williams¹, J. M. Donahue¹, M. D. Lindemann¹, K. E. Newman², and B. A. Webb¹, ¹University of Kentucky, Lexington, ²Venture Laboratories, Lexington, KY.

A newly recognized abortigenic disease, now known as mare reproductive loss syndrome (MRLS), struck the Ohio Valley in Spring, 2001. Abortion rates exceeded 60% on some farms, and epidemiological surveys (Dwyer et al., 2003, JAVMA 222:613-619) linked abortions with eastern tent caterpillars (ETC; *Malacosoma americanum*). Previous studies demonstrated that feeding mares ETC causes abortion, the abortigenic activity is stable to freezing but not autoclaving, it is not extracted with aqueous solutions, and is confined to the insect cuticle (Webb et al., 2004, J Insect Physiol 50:185-193). Therefore, these studies were designed to test the hypothesis that ETC abortigenic activity can be extracted with an organic solvent, and to determine if ETC produce lesions in animals that ingest them. Pregnant mares ($n = 5/\text{group}$) were fed ETC cuticle (+ control), corn oil (- control), ground cuticle, corn oil containing lipids extracted from cuticle with methylene chloride (MC), or cuticle after extraction (treatments were equivalent of 50g insect/mare/day for 10 days). Abortion rates were 3/5 ($P < 0.05$), 2/5, and 1/5 for mares fed cuticle only, cuticle after MC extraction, or ground cuticle. No mares fed MC extract or corn oil alone aborted. All abortions were typical of MRLS including increased echotexture of fetal fluids and presence of streptococci or actinobacilli in aborted fetuses. This study provides new information that the abortigenic activity does not reside in extractable lipids of the cuticle, and that disrupting physical integrity of the cuticle reduces the abortigenic activity. In subsequent trials, mares or gilts fed ETC had lesions containing ETC setae in the submucosal region of their GI tracts, while control animals fed the same diet had no lesions. These findings led to the hypothesis that ETC cuticular setae penetrate the intestinal lining and allow bacteria from the GI tract to invade the circulatory system. Fetal infections then lead to fetal death and abortion.

Key Words: Equine, Caterpillar, Abortion

97 Developmental competence of oocytes fertilized in vitro with semen from bulls grazing tall fescue pastures. G. M. Schuenemann^{*1}, J. L. Edwards¹, J. L. Lawrence¹, R. R. Payton¹, F. N. Scenna¹, J. C. Waller¹, J. W. Oliver², and F. N. Schrick¹, ¹Department of Animal Science, University of Tennessee, Knoxville, ²Department of Comparative Medicine, University of Tennessee, Knoxville.

During a two-year study, developmental competence of oocytes fertilized in vitro with semen of yearling beef bulls grazing Kentucky 31 tall fescue (*Festuca arundinacea* Schreb.) infected with *Neotyphodium coenophialum*, an ergot alkaloid-producing fungal endophyte (E+; $n = 3/\text{yr}$), or Jesup tall fescue infected with the non-ergot alkaloid-producing endophyte strain MaxQ#8482 (MaxQ; $n = 3/\text{yr}$) was determined. Bulls were grouped by scrotal circumference, BW, breed composites, and age to graze E+ or MaxQ pastures from November to July. Each year, semen was collected from the same bulls in May and June by electroejaculation. After motility and morphology examinations, semen was diluted with Bioxcell extender and maintained at 4°C until fertilization of oocytes (26 h after semen collection). Oocytes were matured for 22.5 h and fertilized with the identical number of motile percoll-prepared sperm for each treatment. Number of putative zygotes that cleaved and developed to blastocysts (including nuclei number) was evaluated on d 3 and 8 post-fertilization, respectively. Data were arranged in a randomized block design and analyzed using mixed models of SAS. Percent normal sperm morphology ($86.8 \pm 3.8\%$) recorded at time of collection did not differ between pasture types. Motility at semen collection (72.5 ± 7.2 and $75.4 \pm 6.5\%$), immediately prior to (48.7 ± 7.6 and $53.3 \pm 6.7\%$), and after (56.8 ± 5.4 and $59.9 \pm 5.9\%$) percoll preparation was not different between E+ and MaxQ treatments, respectively. Semen from E+ bulls decreased cleavage rates (73.5 ± 3.1 vs $84 \pm 2.4\%$; $P = 0.02$)

compared to MaxQ bulls. Development to 8-cell (85.4 ± 10.3 vs $82.3 \pm 8.7\%$), blastocysts (32.4 ± 5.5 vs $30.1 \pm 4.7\%$), and nuclei number (72.9 ± 4.8 vs $76.5 \pm 4.5\%$) of cleaved embryos did not differ between treatments. In conclusion, use of semen from bulls grazing tall fescue containing the ergot alkaloid-producing fungal endophyte decreased embryonic cleavage rates and may lower reproductive performance due to reduced fertilization ability.

Key Words: Tall Fescue, Bull, Fertility

98 The association between early luteal phase concentrations of progesterone and embryo survival in heifers and dairy cows. M. G. Diskin^{*1}, A. J. H. Stronge¹, D. G. Morris¹, D. A. Kenny², and J. M. Sreenan¹, ¹Teagasc Athenry, Co. Galway, Ireland, ²University College, Dublin, Ireland.

There is evidence of an association between systemic progesterone (P4) and embryo survival in cattle but not all studies are in agreement on the timing of this association. A retrospective analysis of two large-scale data sets was carried out to clarify the temporal associations between early luteal phase P4 and subsequent embryo survival for both beef heifers and dairy cows. In study 1 beef heifers ($n = 368$) were inseminated (day 0) by one inseminator using semen from one high fertility bull. Two blood samples were collected on day 7 (am and pm) and subsequently assayed (RIA) for P4. In study 2 milk samples were collected on days 5, 6 and 7 post AI from dairy cows in 6 herds (total inseminations=871). The concentration of P4 was measured by enzyme-immunoassay. In both studies pregnancy diagnosis was carried by ultrasonography at about 40 days post AI. Logistic regression was used to evaluate the relationship between the post insemination concentration of P4 and embryo survival rate. Sixty-eight and 48% of the inseminated animals in studies 1 and 2, respectively, were pregnant at 40 days post AI. In study 1 there was a positive linear ($P < 0.01$) and quadratic ($P < 0.01$) association between plasma P4 on day 7 and subsequent embryo survival rate. In study 2 there were positive linear and quadratic relationships ($P < 0.05$) between milk P4 on days 5, 6 and 7 and between the change in P4 between days 4-7 inclusive and embryo survival rate. This analysis indicates an optimum concentration of P4 during the early luteal phase above or below which embryo survival or conception rate is reduced.

Key Words: Progesterone, Embryo, Survival

99 Effect of ovulatory follicle size on pregnancy rates and fetal mortality in beef heifers. G. A. Perry^{*1,2}, M. F. Smith³, A. J. Roberts¹, M. D. MacNeil¹, and T. W. Geary¹, ¹USDA-ARS Miles City, MT, ²Department of Animal & Range Science, South Dakota State University, Brookings, ³Department of Animal Science, University of Missouri, Columbia.

Ovulatory follicle size at time of GnRH/TAI significantly influenced pregnancy rates and fetal mortality following timed AI (TAI) in postpartum cows. Our objective was to assess the relationships between ovulatory follicle size and pregnancy rates or fetal mortality in beef heifers bred in one of two breeding groups: 1) heifers ($n = 108$) were inseminated following the CO-Synch protocol (TAI), subsequently 2) heifers ($n = 154$) were inseminated after detection in standing estrus by electronic mount detectors during a 23-d breeding season (EAI). Transrectal ultrasonography was used to determine ovulatory follicle size at AI and pregnancy status on d 27, 41, 55, and 68 after TAI. The relationship between follicle size and pregnancy status was quadratic for both TAI ($P < 0.01$) and EAI ($P = 0.04$), indicating predicted maximum pregnancy rates of $69.3 \pm 5.8\%$ at a follicle size of 12.7 mm and $73.6 \pm 4.8\%$ at a follicle size of 13.3 mm, respectively. Interactions between breeding group and follicle size did not affect pregnancy rate or fetal mortality ($P > 0.20$). Pooled across breeding groups, the relationship between pregnancy rate and follicle size was quadratic ($P < 0.01$) and indicated an intermediate predicted maximum pregnancy rate of $71.2 \pm 3.8\%$ at a follicle size of 13.1 mm. Follicles < 11.5 mm or > 16 mm were less likely ($P < 0.05$) to support pregnancy than an optimal sized follicle (13.1 mm). Fetal mortality between d 27 and 68 was independent of follicle size ($P > 0.20$), but was only 2% in these data. Ovulation of smaller than optimal sized follicles are a more serious problem than ovulation of larger than optimal sized follicles, as 47% of heifers ovulated follicles #8804 11.5 mm but only 3% ovulated follicles > 16.0 mm. Ovulatory

follicle size is a strong indicator of fertility and management practices that influence ovulatory follicle size may significantly influence fertility.

Key Words: Follicle Size, Pregnancy Rates, Fetal Mortality

100 Follicular phase events and the postovulatory progesterone rise in dairy cows. G. Mann* and G. Starbuck, School of Biosciences, University of Nottingham, Sutton Bonington Campus, Loughborough, UK.

In dairy cows, the timing of the postovulatory progesterone rise is critical to early embryo development. The aim of this study was to determine how variation in the timing of follicular phase events contributes to the timing of the postovulatory progesterone rise. The study was performed on 18 mature, non-lactating Holstein-Friesian cows in which plasma concentrations of progesterone, oestradiol and LH and the timing of oestrus and ovulation were determined at 8h intervals following induction of luteolysis. Ovulation was determined through ultrasound scanning at 8h intervals commencing at the onset of oestrus. Four animals were excluded on the basis of abnormal reproductive function. The remaining 14 cows showed normal reproductive function with oestrus occurring 57.4 ± 4.5 h and the LH surge 58.2 ± 5.1 h following luteolysis (progesterone fall to <1 ng/ml). The LH surge was followed by a fall in circulating oestradiol concentration at 64.6 ± 4.4 h. Cows ovulated at 88.0 ± 4.7 h with the postovulatory progesterone rise (to >1 ng/ml) occurring 167.4 ± 7.2 h after luteolysis. Cows were split on the basis of interval from progesterone fall to progesterone rise giving groups with long (188.6 ± 6.7 h; $n=7$) and short (146.3 ± 5.7 h; $n=7$) intervals from luteolysis to post ovulatory progesterone rise. Both the interval from progesterone fall to ovulation (106.3 ± 6.9 h vs. 85.7 ± 3.4 h; $P < 0.05$) and the interval from ovulation to progesterone rise (82.3 ± 4.2 h vs. 60.6 ± 5.5 h; $P < 0.01$) were longer in long interval cows. While the time from onset of oestrus to progesterone rise was also longer in the long interval group (82.3 ± 4.2 h vs. 60.6 ± 5.5 h; $P < 0.01$) the time from oestrus to ovulation did not differ (long 27.4 ± 3.0 h vs. short 34.3 ± 3.4 h). Thus in cows with an extended period from luteolysis to the subsequent progesterone rise, a delay in the time from luteolysis to ovulation and a delay in the time from ovulation to the progesterone rise appear to contribute equally to the overall delay while the interval from oestrus to ovulation is similar to that seen in cows with a shorter interval. Supported by MAFF and MDC under the Link Sustainable Livestock Production Programme.

Key Words: Cow, Ovulation, Progesterone

101 Effect of hCG on d 5 of the estrous cycle on luteal function and pregnancy rates (PR) in lactating cows receiving embryos from gossypol fed donor heifers. K. N. Galvao*, A. C. Coscioni, S. O. Juchem, M. Villasenor, and J. E. P. Santos, University of California, Davis.

Objectives were to determine the effects of hCG treatment on day 5 of the estrous cycle on luteal function and PR in lactating cows receiving frozen/thawed embryos from gossypol fed donor heifers. Holstein cows, 269, were blocked by parity, days in milk (DIM) and body condition score (BCS) and randomly assigned to one of six treatments in a 2x3 factorial design. Recipient cows were treated with either hCG (3,300 IU) or kept as controls on d 5 and received an embryo on day 7 collected from heifers fed 0, 20, or 40 mg of free gossypol/kg of BW resulting in consumption of 0, 8, and 16 g/d of free gossypol. Recipients were synchronized with the Ovsynch protocol. Ovaries were examined by ultrasonography every injection of the Ovsynch, and at 2, 5 and 12 days after the last GnRH to determine ovulation, and size of follicles and CL. Pregnancy was diagnosed on gestation days 28 and 42 (21 and 35 d after embryo transfer). Data were analyzed by the LOGISTIC and GLM procedures of SAS (2001). Because fertility responses were similar for embryos from heifers fed 20 and 40 mg of free gossypol/kg of BW, data were combined. Treatment with hCG on d 5 increased the proportion of cows with an accessory CL on day 12 (92.6 vs 3.0% ; $P < 0.001$). Number of CL on day 5 was similar for control and hCG cows (1.1 vs 1.1 ; $P = 0.61$). The luteal area was increased by hCG (921.6 vs 766.0 mm²; $P < 0.001$) because of increased number of CL (2.20 vs 1.1 ; $P < 0.001$). Pregnancy rates on days 28 and 42 were not affected by hCG ($P > 0.60$). However, embryos from donor heifers fed gossypol resulted in lower PR at 28 (23.3 vs 33.3% ; $P = 0.07$) and 42 (20.5 vs 29.6% ; $P = 0.08$) d of gestation. Treatment with hCG induced an accessory CL, but did not improve pregnancy rates. However, consumption of 8 to 16 g/d of free gossypol by embryo donor heifers reduced pregnancy rates despite grade

quality of embryos. Our data suggest that the negative effects of gossypol on fertility in cows are mediated by changes in embryo viability in spite of similar morphology.

102 Influence of duration of proestrus on circulating estradiol, the LH surge and luteal function in cattle. G. A. Bridges*, M. L. Mussard, C. L. Gasser, D. E. Grum, and M. L. Day, The Ohio State University, Columbus.

Previous research from our lab suggests that length of proestrus preceding an induced ovulation can influence subsequent pregnancy rates. The present objective was to compare the endocrinology associated with a GnRH-induced ovulation in cows with either a short or long proestrus. On d -6.25 (d 5.8 of the estrous cycle), transvaginal follicular aspiration was used to remove all ovarian follicles > 4 mm from non-lactating beef cows ($n = 16$). Cows received PGF_{2 α} on either d -2.2 or -1.2 to induce either a long (2.2 d; LP) or short (1.2 d; SP) proestrus before a GnRH-induced ovulation on d 0 and AI on d 0.5. Ovarian ultrasonography was performed on d -6.25, -3, -2, -1, 0, 2, 6 and 12 to evaluate follicular and luteal development. Blood samples were collected at 8-hr intervals from d -2.2 to 0, at 0, 0.5, 1, 2, 4, 6, 8, and 12 h after GnRH, then daily from d 3 to 8 and every 2 d thereafter until d 26. Diameter of the largest ovulatory follicle on d 0 did not differ between treatments (LP; 12.4 ± 0.3 mm, SP; 11.8 ± 0.3 mm). Plasma concentrations of estradiol (E2) were greater ($P < 0.05$) in the LP than SP treatment from d -1.5 to 0. Pregnancy rate did not differ (56%), however across treatments, cows with E2 > 10 pg/ml on d 0 had increased ($P < 0.05$) pregnancy rates compared to cows with E2 $\#8804$ 10 pg/ml (88.9 vs 14.3%, respectively). The GnRH induced LH surge pattern did not differ between treatments, but cows that conceived tended ($P = 0.10$) to have an LH surge of greater magnitude. Cows in the SP treatment tended ($P = 0.10$) to have increased incidences of short-lived CL (50 vs 12.5%) and decreased ($P = 0.06$) concentrations of progesterone from d 3 to 14 than cows in the LP treatment. In conclusion, cows with a shorter proestrus had decreased preovulatory concentrations of E2 and in the ensuing estrous cycle, luteal function tended to be compromised compared to cows with a longer proestrus. The putative role of these endocrine differences in determining the likelihood of pregnancy requires further investigation.

Key Words: Cattle, Estradiol, Progesterone

103 Factors influencing fetal loss in dairy cattle. F.D. Jousan*, M. Drost, and P.J. Hansen, University of Florida, Gainesville.

Since reproductive function in dairy cattle has declined coincident with increased milk production, fetal loss may be greatest for high-producing cows. Heat stress, which compromises early embryonic survival, could also conceivably affect fetal loss. The purpose of this study was to evaluate effects of lactation number, milk yield and somatic cell count score (scs) at breeding, number of times bred, season of breeding, and the interval from calving to breeding (days open) on fetal loss. Holstein cattle at the University of Florida Dairy Research Unit were palpated to determine pregnancy status between d 40-50 of gestation and again at d 70-80. Early fetal loss was defined as loss that occurred after d 40-50 but before d 70-80. Mid-to-late fetal loss represented losses after d 70-80 but before expected calving. Lactating females ($n = 950$) had higher early and mid-to-late fetal loss than non-lactating heifers [$n = 386$; $6.3 \pm 0.7\%$ vs $3.6 \pm 1.1\%$ for early fetal loss ($P = 0.05$) and $3.7 \pm 0.6\%$ vs $1.1 \pm 0.9\%$ for mid-to-late fetal loss ($P < 0.05$)]. For lactating animals, early fetal loss was affected by days open ($P < 0.05$; < 75 d: $5.8 \pm 3.8\%$, 75-150 d: $2.6 \pm 1.8\%$, 151-300 d: $10.0 \pm 2.0\%$, and > 300 d: $7.9 \pm 3.0\%$). Similarly, mid-to-late fetal loss was affected by days open ($P < 0.05$; < 75 d: $1.9 \pm 2.9\%$, 75-150 d: $4.2 \pm 1.3\%$, 151-300 d: $4.4 \pm 1.6\%$, and > 300 d: $10.5 \pm 2.3\%$) and scs ($P < 0.01$; $\#8804$ 2.5: $2.7 \pm 1.4\%$, > 2.5 -5.0: $3.6 \pm 1.3\%$, and > 5.0 : $9.3 \pm 1.7\%$). Early and mid-to-late fetal loss for lactating animals was not significantly influenced by season, milk yield, lactation number, or times bred. Similarly, there was no significant effect of times bred or age at breeding on early or mid-to-late fetal loss for heifers. In conclusion, days open and scs at breeding influence the lactating cow's ability to maintain pregnancy, and lactating females are most likely to suffer early or mid-to-late fetal loss. However, increased

milk yield or heat stress was not associated with increased fetal loss. (Research Support: USDA IFAFS grant 2001-52101-11318).

Key Words: Dairy Cattle, Fetal Loss, Pregnancy

104 Effect of a CIDR insert and flunixin meglumine administered at the time of embryo transfer on pregnancy rate and resynchronization of estrus in beef cattle. S. H. Purcell*¹, B. E. Beal¹, and K. R. Gray², ¹Virginia Polytechnic Institute and State University, Blacksburg, ²Cross Country Genetics North, Westmoreland, KS.

The objectives of this study were to evaluate the effects of flunixin meglumine (FM), an inhibitor of PGF_{2α} synthesis, administered at the time of embryo transfer (ET) and insertion of an intravaginal progesterone-releasing device (CIDR) at the time of ET on pregnancy rates (PR) and the resynchronization of estrus. Beef cows (n = 552) and heifers (n = 160) in three locations were assigned randomly within age to one of four treatments: FM = injection of FM (500 mg i.m.; Phoenix Scientific; St. Joseph MO) 2 to 12 min prior to ET; CIDR = insertion of a CIDR

(1.38 g progesterone; Pfizer; New York, NY) for 13 d immediately following ET; FM + CIDR or untreated control. Fresh or frozen embryos were randomly assigned to be transferred to recipients on d 6 to 9 of the estrous cycle. At one location, recipients (n = 493) were observed for signs of return to estrus beginning 9 d after ET. Recipients that returned to estrus were bred by AI or received an embryo 7 d after estrus. Pregnancy was diagnosed (d 28 to 60) by ultrasonography or palpation per rectum. PR were analyzed using the LOGISTIC procedure of SAS. Variation in the timing of the return to estrus was determined by an F-test for heterogeneity of variances. PR following the initial ET was not affected by CIDR administration (P > 0.05; 69% with CIDR, 76% without CIDR). There was a significant FM x location interaction on PR (Location 1, 89 vs 57%; Location 2, 70 vs 66%; Location 3, 74 vs 77% for FM vs no FM, respectively). The timing of the return to estrus was less variable (P < 0.01) for recipients fitted with a CIDR, but PR following AI (69 and 64%) or second ET (74 and 82%) did not differ (P > 0.05) in cows receiving or not receiving a CIDR, respectively. Effects of FM on PR varied among locations and CIDR insertion at ET reduced variation in timing of the return to estrus.

Key Words: Embryo Transfer, Flunixin Meglumine, CIDR

PSA-Environment and Management-Enteric Bacteria

105 Utilization of an experimental chlorate product in reduction of necrotic enteritis in broiler chickens. J. L. McReynolds*¹, J. A. Byrd¹, R. C. Anderson¹, T. S. Edrington¹, T. L. Poole², R. W. Moore², L. F. Kubena¹, and D. J. Nisbet¹, ¹USDA-ARS, Southern Plains Agriculture Research Center, College Station, TX, ²USDA-ARS, Russell Research Center, Athens, GA.

Clostridium perfringens (CP) is one of the etiologic agents of Necrotic Enteritis (NE). The clinical signs of this disease include depression, decreased appetite, diarrhea, and severe necrosis of the intestinal tract. Development of new technologies to combat this costly disease is needed in the commercial poultry industry. In the present investigation, in vitro and in vivo studies were conducted to determine the effects of an experimental chlorate product (ECP) on CP. In the in vitro study intestinal contents were obtained from single comb White Leghorn laying hens and diluted (1:1) with thioglycollate enrichment medium. The contents were divided into six 10 mL aliquots and assigned to the following experimental groups: a control, ECP with a 5 mM chlorate ion equivalent, or ECP with a 10 mM chlorate ion equivalent (2 replicates/group). The effects of ECP were evaluated in vitro over time. By 3 h there was a significant reduction in CP (P < 0.05) in the 5 mM ECP (3.88 Log₁₀), and 10 mM ECP (3.29 Log₁₀) when compared to the control (5.51 Log₁₀). In the in vivo experiment, evaluations of the ECP administered in the drinking water and in the feed (1X ECP is equivalent to a 15 mM chlorate ion concentration) showed reductions in clinical signs associated with NE. Lesion scores were reduced significantly in birds fed the ECP (1.25) when compared to the controls (2.1). The incidence of CP and mortality were also reduced significantly in birds fed the ECP. Populations of generic *E. coli* were significantly lower in all of the treatment groups compared to the controls. These results indicate that an ECP may provide the poultry industry with an additional management tool for controlling NE.

Key Words: *Clostridium perfringens*, Experimental Chlorate Product, Necrotic Enteritis

106 The use of biodegradable pellets for the control of *Salmonella* in broilers during feed withdrawal. J. A. Byrd*¹, L. H. Stanker², J. L. McReynolds¹, and D. J. Nisbet¹, ¹USDA-ARS, Food & Feed Safety Research Unit, College Station, TX, ²USDA-ARS, Foodborne Contaminants Research Unit, Albany, CA.

Poultry undergo a feed withdrawal (FW) prior to transport to the processing plant. During FW, poultry tend to peck at floor litter that may be contaminated with *Salmonella* and *Campylobacter*. These pathogens could be transported to the processing plant in the upper gastrointestinal of poultry which may leak out during slaughter and cross contaminate other carcasses. One approach would be to supply a disinfectant and another source of nutrition that would not physically fill the upper gastrointestinal tract. Presently, we evaluated the use of a novel biodegradable starch extruded pellet (BP) that can be treated with bactericidal or bacteriostatic compounds. The BP was provided to market-age broilers during an 8 h FW. All broilers were challenged with 10⁸

Salmonella Typhimurium (ST) by oral gavage 6 days prior to FW. One h after the onset of FW, 454 g of BP containing either 2% lactic acid (LA), citric acid (CA), or D-limonene + CA + diosulfosuccinate (DSS) were placed on the litter in each pen. In two experiments, broiler provided BP containing LA caused a significant decrease (P < 0.05) in the incidence of ST in crop contents (40%) as compared to the controls (65%). Similarly, broilers provided BP containing LA (0.8 Log₁₀ ST/g crop content) caused a significant decrease (P < 0.05) in the number of ST recovered in the crop compared to controls (1.87 Log₁₀ ST/g). The material is environmentally compatible in that it will degrade in poultry grow-out houses thus providing beneficial bacteria a food source without physically filling the gastrointestinal tract. These studies suggest that incorporation of this biodegradable material in the broiler grow-out house during pre-transport feed withdrawal may reduce *Salmonella* and *Campylobacter* contamination of crops and broiler carcasses at processing.

Key Words: Salmonella, Biodegradable, Crop

107 Apparent absence of horizontal transmission of *Campylobacter* among caged broiler breeder roosters. R. J. Buh¹, N. A. Cox¹, J. S. Bailey¹, J. L. Wilson², L. J. Richardson^{1,2}, D. E. Cosby¹, and D. V. Bourassa^{1,2}, ¹USDA-ARS Russell Research Center, Athens, GA, ²University of Georgia, Athens.

This study was undertaken to evaluate the potential for horizontal transmission of *Campylobacter* between adjacent caged broiler breeder roosters. Feces and semen from individually caged roosters at 41 wk of age were sampled for the presence of *Campylobacter* for 3 consecutive wk and determined to be negative. Three roosters were challenged with a marker strain of *Campylobacter jejuni* either orally using 1.0 mL of suspension (1.4 10⁶ / mL). Three additional roosters were challenged by dropping 0.1 mL of suspension on the everted phallus immediately after semen collection. Six non-challenged roosters were placed in wire-floored cages interspersed between the challenged roosters. Roosters were meal fed daily in individual feed troughs and provided individual nipple drinkers per cage. Feces and semen samples were collected weekly from each rooster for a period of 5 wk post-challenge. The 6 non-challenged adjacently caged roosters were consistently negative for both feces and semen from 1 through 5 wk. At 6 wk roosters were necropsied and samples collected from the thymus, spleen, liver/gall bladder, and ceca, and all were negative for non-challenged roosters. Challenged roosters all produced *Campylobacter* positive feces and semen at 1 and 2 wk post-challenge. At 3 wk post challenge all fecal samples were positive for *Campylobacter*, but 2 semen samples were negative, one from each challenge route. At 4 wk post-challenge all semen samples were negative for *Campylobacter*, and only 3 fecal sample remained positive (2 for oral and 1 for phallus challenge routes). At 5 wk post challenge all semen and fecal samples were negative for *Campylobacter*. Necropsy samples from challenged roosters were negative for the thymus, spleen, and liver/gall bladder at 6 wk post-challenge. Two ceca samples were found to contain *Campylobacter*, one from each challenge route. These results indicated

that *Campylobacter* is not readily transferred horizontally between adjacently caged roosters. At 6 wk the presence of *Campylobacter* in the ceca was undetected in 4 of the 6 challenged roosters.

Key Words: *Campylobacter*, Broiler Breeder Roosters, Horizontal Transmission

108 Effects of *Aspergillus* meal prebiotic on gut development and ascites mortality. F. Solis*¹, J. M. Balog², G. Tellez¹, S. Higgins¹, A. Torrez¹, A. M. Donoghue², and N. B. Anthony¹, ¹University of Arkansas, Fayetteville, ²USDA/ARS/PP&PSR, Fayetteville, AR.

We hypothesize that the developing gastrointestinal tract of rapidly growing broilers has a significant impact on the eventual development of ascites syndrome. Since the addition of *Aspergillus* meal (AM) prebiotic to poultry feed has been shown to improve gut development, the objective of this study was to determine if AM would reduce the negative effects of hypoxia on the gut and reduce ascites incidence. Four hundred (200 commercial and 200 susceptible) day old chicks were randomly assigned to either a control feed or a feed with 0.2 % AM added. Groups were reared at either local altitude (390 meters above sea level) or simulated high altitude (2900 meters above sea level). Mortality was checked twice daily and necropsied for ascites. Birds and feed were weighed weekly. At 6 wk the remaining birds were weighed, killed and organs were weighed. There were no significant effects due to prebiotic feeding for any of the variables evaluated. As previously shown, chickens reared at sea level were heavier (2.01 kg) than those at high altitude (1.13 kg). Also, chickens grown at high altitude showed 84.8% ascites mortality compared with 1.3% at local altitude. Of particular interest in this study was the finding that susceptible chickens had heavier relative gut wt (0.0575), when compared to the commercial birds (0.0511, $P < 0.05$). Interestingly, when measurements were made of the villi length, it became apparent that although susceptible birds have heavier relative gut wts, the duodenal villi were significantly shorter (204.4 μ at high altitude), when compared with the commercial birds (229.4 μ at high altitude). Villi height was also influenced by altitude alone, with both commercial and susceptible birds combined mean duodenal villi height at high altitude was 195.1 μ , while at sea level the mean was 227.4 μ . The results showed that hypobaric hypoxia results in a significant reduction in gut development.

Key Words: Ascites, Prebiotic, Gut Development

109 *Salmonella* and lactobacilli growth in a simulated crop model using chicken or turkey feeds. A. D. Wolfenden*¹, S. N. Henderson¹, R. L. Jarquin¹, G. M. Nava¹, L. R. Bielke¹, J. L. Vicente¹, G. I. Tellez¹, D. J. Donoghue¹, A. M. Donoghue², and B. M. Hargis¹, ¹University of Arkansas, Fayetteville, ²PPPSRU, ARS, USDA, Fayetteville, AR.

The chicken crop is a well known source of *Salmonella* contamination of carcasses at processing. Very recent evidence has been presented suggesting that *Salmonella* may amplify and perhaps colonize the crops of poultry. Presently, we evaluated *Salmonella enteritidis* (SE) or Lactobacilli spp. (LAB) growth (known to produce bacteriocin-like agents inhibitory to SE growth), alone or in combination, in either chicken or turkey feeds, using a previously-published simulated crop model *in vitro*. In exp. 1, 1.25 g of either chick starter or turkey starter were added to tubes and autoclaved. Sterile saline (4.5 ml) was added to each tube. Tubes were divided into 6 groups; chick starter+SE, chick starter+SE+LAB sprayed on feed (1.1x10⁴ cfu/g), chick starter+SE+LAB (10⁶ cfu/ml), turkey feed+SE, turkey feed+SE+LABS (2.0x10⁵ cfu/g) sprayed on feed, turkey feed+SE+LABS (10⁶ cfu/ml). 0.5 ml of 10⁵ SE was added to each tube in groups containing SE. Tubes were individually shaken for 2 sec. and incubated for 2.5 hr at 40C. At 1 or 2.5 hr, cfu of SE or LAB were determined by plating serially on appropriate agar. A significant ($p < .05$) increase in SE was observed in chick starter at 1(4.26 log₁₀ cfu) and 2.5 hr(5.66 log₁₀ cfu) regardless of LAB presence. Interestingly, very little SE amplification occurred when turkey starter was used as the substrate (< 1 log₁₀ cfu), regardless of LAB presence. Experiment II was similar in design. Again, SE was observed to amplify at either 1(4 log₁₀ cfu) or 2.5 hr(6 log₁₀ cfu) in chick starter, with no consistent effect of LAB addition. Very little SE amplification (< 1 log₁₀ cfu) was observed in commercial turkey starter, and addition of LAB at these concentrations did not affect SE recovery. Potential explanations

for amplification of SE in chick starter, but not turkey starter, are currently being explored and may be an important aspect related to the role of crops for contamination of chicken but not turkey carcasses.

Key Words: Crop, *Salmonella*, Lactobacilli

110 Effect of dietary administration of *Aspergillus* meal on broiler chick performance with low protein diets. A. Torres-Rodríguez*¹, C. D. Sartor¹, S. E. Higgins¹, A. D. Wolfenden¹, L. R. Bielke¹, C. M. Pixley¹, A. M. Donoghue², G. Tellez¹, and B. M. Hargis¹, ¹University of Arkansas, Fayetteville, ²PPPSRU, USDA-ARS, Fayetteville, AR.

Aspergillus meal (Fermacto[®], F) is a prebiotic feed additive. In two experiments we evaluated the effect of F with low protein diets on chick performance. In Experiment I, two levels of crude protein (CP), 23 and 19%, with or without F (0.2%) were evaluated. Chickens fed 19%+F were heavier ($p < 0.05$) than 19% alone (243.3 \pm 5.16 vs 205.8 \pm 4.06 std.err., respectively) at 14 days of age. Chickens fed 23% were heavier than both 19% groups (311g \pm 5.49 std.err.). In Experiment II, two levels of CP, 21 and 19%, with and without F (0.2%), were evaluated with 100% and 90% NRC lysine, methionine and tryptophan requirements for 21% and 19% diets, respectively. Both 21% groups were heavier ($p < 0.05$) than 19% groups, whereas 19%+F chickens were heavier than 19% alone (640.46 g \pm 4.98, 656.91 g \pm 5.39 std.err., for 19 alone, and 19%+F, respectively; $p < 0.05$) at 21 days of age. Results from these trials indicate that F may offer a protein sparing effect, potentially allowing for diets with lower levels of protein and amino acids. *Aspergillus* meal might offer better results when protein and amino acid levels are lower than those recommended by NRC or applied in some commercial flocks.

Key Words: *Aspergillus* Meal, Prebiotic, Low Protein Diets

111 Evaluation of an organic acid mixture to reduce *Salmonella enteritidis* in the chicken crop. R. L. Jarquin*¹, A. D. Wolfenden¹, G. M. Nava¹, J. L. Vicente¹, C. D. Sartor¹, A. M. Donoghue², and B. M. Hargis¹, ¹University of Arkansas, Fayetteville, ²PPPSRU, ARS, USDA, Fayetteville, AR.

An organic acid mixture (OAM) consisting of tannic (.024%), lactic (.042%), butyric (.048%) and acetic (.048%) acids (final concentrations) were evaluated in 4 experiments. Each experiment utilized an *in vitro* simulated crop assay which has been described. Briefly, 1.25 grams of chick starter was measured into 13 x 100 mm borosilicate tubes (n=10/replicate) and autoclaved. Sterile saline (4.5mL) was added to each tube with 0.5mL of SE inoculum (1 x 10⁵). In EXP 1 and 2, 0.5x OAM, 1x OAM, or 2x OAM significantly reduced SE recovery by at least one log₁₀ ($p < 0.05$) during a 2 hr incubation at 37° C. However, no effect of higher or lower concentrations of the OAM were observed. Tannic acid alone (.024%) did not reduce SE recovery in these experiments. After *in vitro* testing, water consumption (WC) in the presence of feed or during feed withdrawal (FW) using the OAM or tannic acid alone were measured in market age broilers (4-8 weeks of age) in EXP 3 and 4. Two pens (40 birds/pen) were randomly assigned to each treatment, with treatments consisting of no treatment (control), 1x, 2x, or 3x OAM, or 0.02%, 0.1%, 0.25%, or 0.36% of tannic acid alone in the drinking water (DW). WC was measured at 8 hours. In the presence of feed, no differences in water consumption were observed between the control, 1x OAM, or tannic acid concentrations of 0.02% or 0.1%. However, WC apparently decreased when 2X or 3X OAM or 0.25% or 0.36% tannic acid were administered. During FW, water consumption was decreased (40-70%) in groups receiving either 1X, 2X, or 3X OAM. No effect of 0.02% tannic acid was observed, although 0.25% or 0.36% tannic acid decreased WC (27-52%). Ongoing studies are aimed at evaluation of the effect of DW treatments with selected OAM concentrations on *Salmonella* recovery from market-aged broilers.

Key Words: *Salmonella*, Crop, Organic Acids

112 Cell yield and genetic response in *Salmonella* Typhimurium in a continuous culture during shifts in pH. K. D. Dunkley^{*1}, M. M. Kundinger¹, C. S. Dunkley^{*1}, T. R. Callaway², R. C. Anderson², D. J. Nisbet², and S. C. Ricke¹, ¹Texas A&M University, College Station, ²USDA-ARS, College Station, TX.

Salmonella Typhimurium is attracting world wide attention as it continues to cause foodborne illness to human beings. The organism is resistant to a wide range of anti-infectious agents and as a result the illness is more difficult to treat. The objective of this study was to analyze the expression of specific virulence and stress genes (*hilA* and *rpoS*) in *Salmonella* Typhimurium at various nutritional stress and pH in a continuous culture system. *Salmonella* Typhimurium cells were propagated in continuous cultures with a total volume of 0.50 liter LB minimal medium at 98% turnover rate. Two chemostats were used for adjusting dilution rates and pH levels. Dilution rates were 0.0125 h⁻¹, 0.025 h⁻¹, 0.05 h⁻¹, 0.1 h⁻¹, 0.27 h⁻¹, 0.54 h⁻¹, 1.08 h⁻¹, and 1.44 h⁻¹, while pH levels were 6.1 through 8.0. Results indicated that cell protein increases as dilution rates (D) increase (D 0.0125 h⁻¹, =1184 g cell: 0.27 h⁻¹, =1431g cell, however, at 0.54 h⁻¹, there was a decline in the g/cell protein quantity. This suggests that when dilution rate reaches washout in the chemostat, the cell mass decreases. Changes in glucose yield (Y_{glc}) also indicated that as the pH increases so does the Y_{glc} (pH 7.29=243±14g cell/mol glucose utilized: pH 6.15= 30±13g cell/mol glucose utilized (P>0.05)). To analyze gene expression, samples were stored in RNAsprotect (Qiagen, Valencia, CA) in duplicate. Real-time PCR reactions were performed on an ABI Prism 7700 Sequence Detection System (Perkin-Elmer Applied Biosystems, Foster City, CA). Samples were analyzed using the Comparative Ct ($\Delta\Delta C_t$) method by normalizing to the endogenous control gene (*rsmC*). Both *hilA* and *rpoS* expression appeared to change in response to corresponding pH and Y_{glc} transitional changes in the continuous culture.

Key Words: *Salmonella*, Continuous Flow Culture, Virulence

113 Isolation and prevalence of *Campylobacter* in the reproductive tracts and semen of commercial turkeys. K. Cole^{*1}, J. S. Holliman¹, P. J. Blore¹, A. M. Donoghue², and D. J. Donoghue¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²Poultry Production and Product Safety Research Unit, ARS, USDA, Fayetteville, AR.

Campylobacter is one of the leading causes of human gastroenteritis in the United States and epidemiological evidence has implicated raw poultry products as a significant source of human infection. *Campylobacter* frequently colonizes the avian intestine but recent research indicates that this organism can also colonize the oviduct of laying hens and broiler breeders. The present studies were undertaken to determine if *Campylobacter* is present in the reproductive systems of commercial turkeys. In the first study, the reproductive tracts of 11 hens and 17 toms were aseptically excised and the segments (female: vagina, shell gland, isthmus, magnum, and infundibulum; male: ductus deferens and testes) were swabbed with a dry cotton sterile swab. The swabs were incubated for 24 h in *Campylobacter* enrichment broth and 0.1 mL of

the enriched sample solution was streaked onto *Campy*-line agar plates and incubated at 42°C for 48 h in a microaerophilic environment for detection of *Campylobacter*. Of the 11 hens sampled, *Campylobacter* was isolated from the vagina (10/11), the shell gland (7/11), the isthmus (8/11), the magnum (6/11), and the infundibulum (3/11). Of the 17 toms sampled, *Campylobacter* was isolated from the ductus deferens (8/17) and the testes (2/17). In a second study, pooled semen samples from 7 separate farms were randomly collected by abdominal massage over a period of 13 weeks. The pooled semen samples were serially diluted and 0.1 mL of each dilution was plated on *Campy*-line agar and incubated at 42°C for 48 h in a microaerophilic environment for enumeration. *Campylobacter* was isolated from 57 of the 59 pooled semen samples and levels ranged from <10¹ to 1.58 x 10⁶ cfu/mL of semen. Naturally occurring *Campylobacter* is present in the reproductive tracts and semen of commercial turkeys and may enable vertical transmission of *Campylobacter* from the hen to the poult.

Key Words: *Campylobacter*, Turkeys, Reproductive Tract

114 Evaluation of the effect of fish meal supplementation on *Salmonella enteritidis* growth in chick starter *in vitro*. S. N. Henderson^{*1}, A. D. Wolfenden¹, R. L. Jarquin¹, G. M. Nava¹, J. A. Byrd², and B. M. Hargis¹, ¹University of Arkansas, Fayetteville, ²USDA-ARS-SPARC, College Station, TX.

While the contents of chicken crops are well known to play an important role in contamination of carcasses at processing, recent evidence has been presented suggesting that *Salmonella* may amplify and perhaps sometimes colonize the crop *in vivo*. *Salmonella* infections have been associated with the use of animal/fish meal supplementation, probably because of the known increased contamination frequency of these feedstuffs. Presently, we evaluated the ability of *Salmonella enteritidis* (SE) to amplify in a simulated *in vitro* crop assay, using either an all vegetable chick starter diet or a similar diet supplemented with fish meal (5%). In three replicate experiments, three different chick starter formulations, two with all vegetable protein sources, and one with fish meal (5%) supplementation, were compared for ability to support *Salmonella* growth *in vitro*. Briefly, for each experiment, 1.25 g of each feed type was measured into 13 x 100 mm borosilicate tubes (n=10/replicate) and autoclaved. Sterile saline (4.5mL) was added to each tube with 0.5mL of SE inocula at initial concentrations of 6.75x10³, 1.15x10⁵, and 8x10⁴ colony forming units (cfu)/mL, for each experiment, respectively. The tubes were then incubated at 40°C for 1 or 2.5 hrs, and cfu/ml were determined by serial dilution and spread plate enumeration on selective medium. Each of the feed types, in each of three experiments, supported the apparent amplification of SE by > 1 log₁₀ cfu/ml during the 2.5 hr incubation. Inclusion of fish meal did not affect the ability of SE to grow in the feed substrates in any of the 3 experiments. Since inclusion of fish meal did not enhance the ability of *Salmonella* to grow in this *in vitro* crop model, these data suggest that fish meal may not be important for supporting *Salmonella* growth in the crops of chickens.

Key Words: *Salmonella*, Crop, Fish Meal

PSA-Nutrition: Amino Acids and Vitamin/Mineral Nutrition I

115 Evaluation of guar by-products in high production laying hen diets. C. Zhang^{*}, A. L. Cartwright, J. B. Carey, and C. A. Bailey, Department of Poultry Science, Texas A&M University, College Station.

Guar (*Cyamopsis tetragonoloba*) is a drought-tolerant annual legume grown for its high concentration of galactomannan gum. Guar seeds are split to produce guar gum and both a high protein germ fraction and a lower protein hull fraction, which are usually recombined to create guar meal. The price of guar meal in the United States is about half that of soybean meal and therefore of potential value poultry diets. A 5 x 5 Latin square experiment was conducted to evaluate using low concentrations of guar germ or a combination of guar germ and hull (guar meal) in high production laying hen diets. A total of 125 Lohmann laying hen pullets (21-week-old) of similar body weight were assigned to 5 groups of 5 replications with 5 birds in each replication. Hens were fed either a non-guar control diet, or a diet with 2.5 and 5% guar germ, or 2.5 and 5% guar meal for 20 weeks. There was no difference (P >0.05) in hen-day egg production which averaged 96.09, 94.43, 94.34, 94.38 and

96.31%, or feed consumption which averaged 99.2, 101.2, 101.5, 103.0 and 103.0 g/day per hen, respectively. The grams feed consumed per gram egg (FCR) were 1.798, 1.856, 1.855, 1.940 and 1.834, respectively, with the 2.5% guar meal-fed group higher than the other groups. Feeding guar did not affect yolk color or shell quality (shell thickness, egg breaking force and specific gravity), but decreased Haugh units. A guar fraction x concentration interaction was detected with respect to FCR which decreased in birds fed guar meal as concentrations increased from 2.5 to 5%. The results showed that both guar germ and guar meal can be fed to high production laying hens at up to 5% without adverse effects on laying hen performance and egg quality.

Key Words: Guar, Laying Hen, Egg Production

116 Effect of dietary nutrient density, feed form, and lighting on the growth performance of broiler chickens. K. E. Brickett* and H. L. Classen, *University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this research was to examine the main and interactive effects of dietary nutrient density (2800, 2950, 3100 kcal/kg ME), feed form (mash, crumble/pellet) and lighting program (20L:4D, 12L:12D) on production characteristics of broilers raised to a young age (35 days). Diets (starter, grower and finisher) were formulated so that amino acid levels were in proportion to diet energy level. Lighting programs were initiated at 4 days of age and maintained until trial end. Body weight was not affected by nutrient density when diets were fed in a crumble/pellet form but decreased in a linear fashion with density when fed as a mash. Final body weight for birds fed mash diets were smaller than for those fed crumble/pellet diets. Feed to gain ratio decreased with increasing nutrient density but was not affected by feed form. Feed intake decreased with increasing nutrient density and was lower for birds fed mash. The effect of nutrient density on feed intake was less when birds were fed mash in contrast to crumble/pellet diets as indicated by a significant interaction. Diet nutrient density did not affect mortality but feeding a mash diet decreased death loss (3.83%) in comparison to feeding processed feed (5.63%). The increase in mortality can be attributed to an increase in the number of culls due to leg abnormalities. Mean gait scores suggested an increase in leg abnormalities for birds fed processed feed (0.756), as compared to those fed a mash (0.342). Use of 12L:12D reduced body weight, feed to gain ratio, feed intake and mortality in comparison to the use of 20L:4D. Overall there were no interactions between lighting program and diet main effects. The data demonstrate the importance of treatment effects and their interactions on broiler performance and provide data that permits selection of nutrition and management programs on the basis of economic and animal welfare considerations.

Key Words: Energy, Mash, Photoperiod

117 Satellite cell mitotic activity of broilers receiving lysine deficient diets. S. Pophal*^{1,2}, P. Mozdziaik², and S. Vieira¹, ¹*Universidade Federal do Rio Grande do Sul*, ²*North Carolina State University, Raleigh.*

Myofiber growth is dependent upon the contribution of new nuclei from the mitotically active satellite cell population. The effect of starvation or feeding with different levels of amino acids within different ideal protein levels on satellite cell mitotic activity was studied using 3-day old male broiler chicks. The experiment consisted of one starved group and 4 fed groups (n=10 per group) receiving differing levels of digestible lysine 0.82%, 0.99%, 1.16% and 1.33%. The feeds were formulated to contain 2,950 ME kcal/kg and an ideal balance for essential amino acids. All other nutrients met NRC recommendations (1994). Birds were housed in battery cages, receiving feed and water ad libitum, except for the starved group, from hatch to 3 days of age. All chicks were injected with 5-Bromo-2'-deoxyuridine (BrdU) 2 hours before being killed. By the end of experiment, each bird was killed and the Pectoralis thoracicus was removed, fixed, dehydrated, cleared and embedded in paraffin. Mitotically active satellite cells were identified in the Pectoralis thoracicus using BrdU immunohistochemistry and enumerated using computer-based image analysis. Mitotic activity in the starved group was significantly lower than the fed groups. Within the fed groups the satellite cell mitotic activity was highest for the treatment with 0.82% digestible lysine. Myofiber cross sectional area was also reduced on the starved group compared to fed treatments. The higher satellite cell mitotic activity observed for the 0.82% group, at day 3, may reflect a longer period for satellite cell activation. This activation delay may be a result of a deficiency, because a level of 0.82% of digestible lysine can be insufficient for early pectoral muscle growth. The results of the current study suggest that a satellite cell pathway may be sensitive to early nutritional supplementation.

Key Words: Muscle, Satellite Cell, BrdU

118 Synthetic methionine and feed restriction effects on performance and meat quality of organically-reared broiler chickens during fall months. N. P. Buchanan*, A. S. Parsons, N. J. Baker, and J. S. Moritz, *West Virginia University, Morgantown.*

Synthetic methionine has received scrutiny in organic production due to its extraction process and a belief that it is used for growth promotion rather than bird health. Organically reared poultry have access to pasture that may supply additional nutrients. The objective of the current study was to evaluate the extent in which birds will utilize nutrients, especially methionine, from forage and the subsequent effects on performance and carcass quality. Three hundred and eighty 1-day old Ross 308x344 broilers were reared from 0-to-3-weeks in floor pens. On day 21, 240 birds were randomly selected and moved into houses with access to pasture for five weeks. Experimental grower diets consisted of two different methionine levels (including or excluding crystalline methionine) arranged in a factorial structure with two different levels of feed access (*ad libitum* or 50% intake of *ad libitum*). In addition, fifty-six birds were withheld pasture access and fed similar diets. Birds with access to forage and comparable feed access had similar live weight gain (P=0.4676) and feed intake (P=0.5182) despite variation in dietary methionine. These birds also had similar hot carcass weight (P=0.0850), fat pad weight (P=0.6806), and breast weight (P=0.0345). A comparison of birds with and without access to pasture showed that birds without access to pasture had an increase in LWG (P=0.0001) and FI (P=0.0001). Feed efficiency did not differ between groups. Carcass weight (P=0.0001) and fat pad weight (P=0.0001) were larger for birds without access to pasture. However, these birds had smaller breast weight (P=0.0001). These results demonstrate that birds given access to pasture during the fall, with no synthetic methionine supplementation, can adequately meet their nutrient requirements. Furthermore, providing access to forage may improve carcass quality by decreasing fat pad weight and increasing breast yield.

Key Words: Organic Production, Broiler Production, Methionine

119 Synthetic methionine and feed restriction effects on performance and meat quality of organically reared broiler chickens in the summer months. A. S. Parsons*, N. J. Baker, and J. S. Moritz, *West Virginia University, Morgantown.*

Organic broiler production addresses consumer concerns with drug/animal by-product use and bird welfare. Synthetic methionine is typically added to corn-soybean based diets to meet broiler methionine requirements. However, the use of synthetic methionine in organic feed has recently become a concern to consumers. Research focusing on the removal of synthetic methionine from corn-soybean based diets for organically-reared birds does not exist. The objective of the current study was to determine the effects of synthetic methionine use as well as feed restriction on performance and meat quality of organically-reared broiler chickens. Diets consisted of two different methionine levels (excluding and including synthetic methionine) each provided for *ad libitum* or restricted access. Diets were fed to four replicate pens of 15 straight-run 308x344 Ross broilers, each having free access to pasture during the day. Additionally, broilers were reared without pasture access, but given similar diets. Birds given *ad libitum* feed and pasture access had similar live weight gain (LWG), feed intake (FI), and feed efficiency (FE) (P#88050.05) despite variation in dietary methionine. In addition, these birds did not differ in carcass characteristics (P#88050.05). Birds without pasture access, had increased LWG (P<0.05), decreased FI (P<0.05) and increased FE (P<0.05) compared to pastured birds fed similar diets. Pastured birds had decreased fat pad weights relative to carcass weight (P#88040.05), while all other carcass characteristics remained similar to birds without pasture access. Birds given restricted feed and pasture access had similar LWG and FI despite methionine level; however FE varied (P#88040.05) based on period of measurement (21-38d) or (38-56d). These results suggest that birds fed diets without synthetic methionine could compensate for the methionine deficiency if diets are provided for *ad libitum* consumption and summer forage is accessible.

Key Words: Organic Production, Broiler Production, Methionine

120 Effect of dietary copper source on broiler chicken performance and immune responses. Vanessa J. Arias* and Elizabeth A. Koutsos, *California Polytechnic State University, San Luis Obispo.*

Dietary copper sulfate (CS) and Tri-Basic copper chloride (TB) were examined to test their effects on broiler body weight (BW) and immune responses. Experiment 1 was a 6 x 2 factorial design using 6 diets containing a basal diet with no additional copper (Neg. control), 125ppm CS or TB, 188ppm CS or TB, or a basal diet + bacitracin (Pos. control). Birds were housed in Petersime batteries at 8 chicks/rep, 8 reps/diet. At 3 wk all diet groups were weighed, then placed into 1 of 2 treatments; chicks were either vaccinated with lipopolysaccharide (LPS, 100 µg/kg BW) or unvaccinated and sampled 24 h later. BW was significantly affected by diet at 3 wk ($P < 0.05$). Broilers fed Pos. control diet weighed significantly less than birds fed 125ppm CS, 188ppm TB, and 188ppm CS ($P < 0.05$). Plasma Zn was significantly reduced by LPS ($P < 0.01$) for all birds, except for birds fed 125 ppm CS or TB ($P < 0.05$). There was a significant increase in plasma Cu and liver weights in LPS versus unvaccinated birds ($P < 0.01$ for each). Experiment 2 was a completely randomized block design with four diets using a basal diet containing no additional copper (Neg. control), 188ppm TB or CS, or basal diet + bacitracin and roxarsone (Pos. control). Birds were housed in floor pens at 65 chicks/pen, 8 pens/diet. At 13 d, TB and CS diets had significantly increased BW compared to Neg. control ($P < 0.05$). At 31 d CS diets had significantly increased BW compared to Neg. control ($P < 0.05$). Diet significantly affected carcass weight ($P < 0.01$); specifically TB and CS-fed birds had significantly increased carcass weight compared to Neg. control ($P < 0.03$, $P < 0.01$, respectively). Finally, TB diet had greater plasma Cu compared to Neg. or Pos. control ($P < 0.05$). These data demonstrate that dietary copper sources have some positive effects on broiler performance, similar to bacitracin control. Effects on inflammation are variable, but 125ppm CS or TB demonstrate some anti-inflammatory properties. Further effects on immune response will be discussed in relation to gut histology and antibody titers.

Key Words: Copper, Inflammation, Broiler

121 Effects of copper source and concentration on phytate phosphorus hydrolysis by Phytase in vitro. Y. Pang* and T. Applegate, *Department of Animal Science, Purdue University, West Lafayette, IN.*

Higher concentrations of copper (Cu) in the diet may decrease phytate phosphorus (PP) hydrolysis because of the chelation of Cu with the phytin molecule. Different sources of Cu may affect the activity of phytase at different pH conditions. Therefore, five Cu sources (Cu sulfate (Cu Sul), Cu chloride (Cu CL), tri-basic copper chloride (TBCC), Cu lysinate (Cu Lys) and Cu citrate (Cu CIT)) were studied in vitro at pH 2.5, 5.5 and 6.5 to determine how Cu from each of these sources affects PP hydrolysis by phytase. Five Cu concentrations were used for these studies (0, 62.5, 125, 250 and 500 ppm), and were incubated at 40-41°C for 60 min. The values were expressed by the relative percentage of PP hydrolysis of the 0ppm Cu treatment from separate assays. At pH 2.5, 500ppm Cu Sul inhibited PP hydrolysis (≤ 0.05), whereas, both 250 ppm and 500ppm Cu from Cu CL inhibited PP hydrolysis. No concentrations of Cu from TBCC, Cu Lys or Cu CIT inhibited PP hydrolysis. At pH 5.5, addition of either Cu Sul or Cu CL between 62.5 and 500 ppm inhibited PP hydrolysis from 23.1 to 78.0% (≤ 0.05). Increasing pH to 6.5 increased the extent of inhibition for Cu Sul and Cu CL treatments such that 62.5ppm to 500ppm caused an 89.8 to 95.4% inhibition (≤ 0.05). 500 ppm Cu from TBCC inhibited PP hydrolysis at pH 2.5, 5.5 and 6.5 by 0%, 13.4% and 51.5%, respectively (≤ 0.05). Cu Lys did not affect PP hydrolysis at both pH 2.5 and 5.5, however, increasing pH to 6.5 caused around 39.7 to 48.6% inhibition (≤ 0.05). Cu CIT did not affect PP hydrolysis at pH 2.5, but it inhibited PP hydrolysis at pH 5.5 (≤ 0.05). Increasing pH to 6.5 greatly increased the inhibition such that 500 ppm Cu inhibited PP hydrolysis by 92.1% (≤ 0.05). In conclusion, pH had an important effect on how Cu affects PP hydrolysis in that inhibition occurred much more at pH 5.5 and pH 6.5 than at pH 2.5; Among five Cu sources, TBCC and Cu Lys and Cu CIT inhibited PP hydrolysis much less than Cu Sul and Cu CL.

Key Words: Copper Source, Phytate Phosphorus, Phytase

122 Evaluation of 25-hydroxycholecalciferol as a cholecalciferol substitute for broiler breeders. A. Atencio*, H. M. Edwards, and G. M. Pesti, *University of Georgia, Athens.*

An experiment was conducted to determine the relative bioavailability (RBV) of 25-hydroxycholecalciferol (25(OH)D₃) in comparison to cholecalciferol for hen day egg production (HDEP), hatchability (HAT), embryo mortality during the early (1-10 days of incubation EEM) and late stages (11-21 days LEM). The study was conducted with 77 to 90 week old molted Ross broiler breeders in an environment excluding UV light. A basal D₃ deficient diet and this diet supplemented with three levels of D₃ (125, 500, and 2,000 IU/kg of diets) and two level of 25(OH) D₃ (125 and 500 IU/kg of diets) were fed. Three repetitions of seventeen hens were used for each treatment group. No D₃ source was used in the vitamin premix and no animal byproduct was used in the corn, soybean meal and wheat middlings basal diet to guarantee that no unintentional vitamin D activity was present in the experimental diets. Data were collected weekly for HDEP, HAT, EEM and LEM. Slope ratio analyses were performed using the logarithm of 0, 125 and 500 plus 1 with the data from 81 to 88 weeks of age. The RBVs found were 140, 132, 122 and 127% for HDEP, HAT, EEM and LEM, respectively. The HDEP during the 14 weeks of the experiment was 2.09 times higher for 25(OH) D₃ when compared with D₃ at the 125 IU/kg level. However, at the 500 IU/kg level the difference was only 1.05 higher for 25(OH) D₃. Hatchability was also 1.67 times higher for 25(OH) D₃ at 125 IU/kg level than D₃; however, no difference was observed between the sources at 500 IU/kg. Late embryo mortality was reduced 4 times by 25(OH) D₃ when compared with D₃ at 125 IU/kg level and only 1.26 times at 500 IU/kg level. The potency of 25(OH) D₃ in relation to D₃ depends on the levels tested. When comparing vitamin D sources, 25(OH) D₃ has greater potency than D₃ only at very low levels of supplementation.

Key Words: Broiler Breeders, Vitamin D₃, 25-Hydroxycholecalciferol

123 Decreasing the time required for the auxotroph *Lactobacillus rhamnosus* assay by adaptation to microtiter plates. J. L. Golbach*, C. L. Woodward, V. I. Chalova, and S. C. Ricke, *Texas A&M University, College Station.*

Riboflavin is an essential part of animal diet by playing a significant role in the metabolism of carbohydrates, fatty acids, and amino acids. Riboflavin is also required for the utilization of oxygen, red blood cell formation, antibody production, and growth. Some specific sources of riboflavin are organ meats, nuts, cheese, eggs, milk, lean meat, green leafy vegetables, fish, legumes, whole grains, and yogurt. The objective of this research was to reduce time of the assay by scaling it down into a microtiter plate while still maintaining the precision of the original tube assay. The organism that is used most commonly to quantify riboflavin is *Lactobacillus rhamnosus* ATCC 7469 formerly known as *Lactobacillus casei*. The Bacto Riboflavin Assay Medium from *The Difco Manual* was used as a guideline for transferring the riboflavin assay from a tube assay to a microtiter plate assay. Micro Inoculum Broth was inoculated with *L. rhamnosus* and grown overnight at 37°C. The bacteria were washed three times with sterile 0.85 percent saline solution. Riboflavin Assay Medium was prepared and riboflavin standard was added to achieve concentrations that range from 2.5 ng/mL to 30 ng/mL. The solutions were autoclaved and transferred to a microtiter plate. The microtiter plates were inoculated and incubated at 37°C for 8 hours and values were read by a Spectra Flour Plus microtiter plate reader. The standard growth curve for the riboflavin assay was linear from 0 ng/mL up to 10 ng/mL with an average R² value of 0.99. The average variance for the optical density A₆₀₀ values between 0 ng/mL and 10 ng/mL was $\pm 4.48 \times 10^{-5}$ A₆₀₀. The microtiter assay reduced the amount of time required for sufficient bacterial growth response to generate linear standard curves from 22 hours down to 8 hours. This scaled-down assay can be utilized for the determination of riboflavin in more samples of potential nutritional sources such as poultry feeds and poultry products.

Key Words: *Lactobacillus Rhamnosus*, Riboflavin, Microtiter Plate Assay

124 Effect of anticoccidial medication upon broilers infected with eimeria species during the starter or grower phase of production. P. M. Matsler*¹, H. D. Chapman¹, and M. W. Lavorgna², ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²Alpharma.

The effect of salinomycin and roxarsone upon broilers infected with *Eimeria* species during the starter phase (18 days of age) or grower phase (35 days of age) of production was investigated. Birds medicated for 6 weeks and infected during the grower phase produced fewer oocysts than birds medicated for 4 or 5 weeks whether infected during the starter or grower phase. Feed conversion at 6, 7 and 8 weeks of birds infected during the starter phase was lower if medicated for 6 rather than 4 or 5 weeks. Feed conversion of birds infected during the grower phase was less if medicated for 6 rather than 5 weeks. It is concluded that medication beyond 5 weeks may be advantageous whether birds are exposed to infection during the starter or grower phase of production.

Key Words: Anticoccidial Drug, *Eimeria*, Broiler

125 Evaluation of an exogenous enzyme (Avizyme®) as feed additive to enhance immunity against *Eimeria* spp and replace antibiotics and ionophores in broiler diets. J. Parker*¹, S. Clemente-Hernandez¹, J. Remus², E. Pierson², B. Clack¹, and E. O. Oviedo-Rondón¹, ¹Stephen F. Austin State University, Nacogdoches, TX, ²DANISCO Animal Nutrition, St. Louis, MO.

Changes in gut microflora and crude protein levels have been linked to enhance immunity against coccidia. The objective of this trial was to evaluate the utilization of a combination of amylase, protease, and xylanase designed for corn-soybean meal diets (Avizyme® 1502) as a feed additive to enhance immunity against coccidia, and replace antibiotics and ionophores in broiler starter diets with different levels of crude protein. This trial was conducted in Petersime brooding units with 504 day-old male Cobb-500 chickens distributed in 72 cages. Twelve treatments as a result of a 3 x 3 factorial, plus 3 negative controls (No additives-No challenge) within each protein level were distributed. Crude protein levels (19, 21, 23%) and anticoccidial control program (Cocci-Vaccine, Antibiotic + Ionophore, and Vaccine+Enzyme) were evaluated as main effects in the factorial. All chickens, but those in the negative and positive control (antibiotic + ionophore) treatments were vaccinated at 1 d of age with Advent® vaccine. All chickens, but those in negative control treatments were challenged at 17 d of age with a mixed oral inoculum of *E. acervulina*, *E. maxima*, and *E. tenella*. Lesion scores and oocyst counts were evaluated at 24 d of age. Body weight and feed intake were recorded at 17 and 24 d. Feed conversion ratio was determined and corrected by mortality weight. Significant differences ($P < 0.05$) due to the interaction crude protein x anticoccidial program were observed in post-challenge FI and BWG. Crude protein levels affected ($P < 0.01$) BW, FCR in pre- and post- challenge periods. Anticoccidial programs affected ($P < 0.05$) BW at 17 d, BW, FI and FCR at 24 d. The enzyme product improved BW in vaccinated birds at 19 and 21% crude protein diets, but not at 23% CP. Lesion scores were affected ($P < 0.05$) by anticoccidial programs. Vaccinated chickens fed diets with enzyme had the lowest lesion scores in the caecum, while the antibiotic+ionophore group had the lowest lesion scores in midgut. Enzyme may help in responses against coccidiosis, especially by *E. tenella*, and this response is dependent upon dietary protein level.

Key Words: Enzyme, Coccidia, Protein

126 Enhancement of homologous vaccination to *Eimeria acervulina* via CpG-ODNs. K. Ameiss*¹, J. El Attrache¹, A. Barri¹, A. McElroy², and D. Caldwell¹, ¹Texas A&M University, College Station, ²Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg.

Synthetic oligodeoxynucleotides containing CpG motifs (CpG-ODN) have been demonstrated to be effective oral mucosal adjuvants in mice. Recent studies in chickens have shown that CpG ODNs can improve the immune response to protein antigens as well as pathogens. The goal of this study was to determine whether oral administration of a single dose of CpG-ODNs could increase the efficacy of trickle vaccination to a homologous challenge with *Eimeria acervulina* (EA). Chicks were immunized with 500 oocysts of EA strain #12 per day from days 1 to 5

post hatch with and without 50 µg of CpG-ODN or a control non-CpG ODN. They were then challenged with 1.25 X 10⁴ oocysts of the same strain on day 19 post hatch. Body weight and feed consumption were measured on days 12, 19, and 25. Lesions scores were taken on day 25. Mean feed conversion ratios (grams feed consumed/gram gain) during the immunization period, days 1-12, revealed that both the CpG and non-CpG treated groups had significantly lower ($P < 0.001$) feed conversion ratios (2.9 ± 0.14 and 3.1 ± 0.14 , respectively) than the vaccination only group (3.5 ± 0.12). Mean feed conversion ratios during the challenge period, days 19-26, revealed that all immunized groups, CpG, non-CpG and vaccination only (2.05 ± 0.06 , 2.08 ± 0.10 , and 2.19 ± 0.05 , respectively), were significantly lower ($P < 0.001$) than the unimmunized birds (2.4 ± 0.09). Mean lesion scores also revealed a significant difference ($P < 0.001$) between groups receiving either CpGs or non-CpGs (0.40 ± 0.09 and 0.52 ± 0.09 , respectively), immunization only (0.81 ± 0.07), and unimmunized (2.21 ± 0.12) birds. These findings indicate that a single oral administration of CpG ODNs can improve protection from a homologous challenge of *Eimeria acervulina*, improving feed conversion ratio during immunization and reducing lesion score upon challenge.

Key Words: *Eimeria acervulina*, Immunization, CpG-ODNs

127 Egg characteristics of commercial egg laying hens between 20 and 58 weeks of age when inoculated with the S6-strain of *Mycoplasma gallisepticum* 10, 22, or 45 weeks of age. E. Y. Basenko¹, S. W. Park*¹, E. D. Peebles¹, S. L. Branton², D. V. Maurice³, S. K. Whitmarsh¹, and P. D. Gerard⁴, ¹Department of Poultry Science, Mississippi State University, Mississippi State, ²USDA-ARS, SCPL, Mississippi State, MS, ³Clemson University, Clemson, SC, ⁴Experimental Statistics Unit, Mississippi State University, Mississippi State.

The effects of S6-strain *Mycoplasma gallisepticum* (S6MG) inoculation and its timing on egg characteristics were investigated using a total of 160 Hy-Line W36 hens in each of two trials. In each of 16 biological isolation units 10 birds were housed, with four replicate units in each of four treatments. Control birds received sham inoculations at 10 wk of age and treated birds received S6MG inoculations at 10, 22, or 45 wk. Egg weight (EW) was determined weekly between 21 and 60 wk in Trial 1, and between 21 and 53 wk in Trial 2. Eggshell weight per unit of surface area (SWUSA), percentage egg yolk (PY), albumen (PA), and shell (PSW) weights, and yolk moisture (YM) and lipid (YL) contents were determined at 24, 32, 43, 47, and 58 wk, whereas yolk cholesterol (YCHOL) and fatty acid (YFA) contents were determined at 47 and 58 wk in both trials. Hen age influenced EW, PA, PY, PSW, YM, YL and YFA in both trials, but influenced SWUSA only in Trial 2. EW was increased across 46-60 wk by S6MG inoculation at either 10, 22, or 45 wk in Trial 1, and was decreased across 22-45 wk by S6MG inoculation at 22 wk in Trial 2. In Trial 2, PSW and SWUSA were decreased across 47-58 wk by S6MG inoculation at 45 wk. YL was increased at 58 wk in Trial 1 by 45 wk S6MG inoculation, and was decreased at 24 wk in Trial 2 by 22 wk S6MG inoculation. Across 47-58 wk, the 22 and 45 wk inoculations decreased yolk myristic and oleic acid concentrations in Trial 1, but increased yolk stearic and arachidonic acid concentrations in both trials. S6MG inoculation during production may increase egg weight, decrease eggshell quality, and influence yolk total lipid and fatty acid contents during post-peak production.

Key Words: Egg Characteristics, Lipid, *Mycoplasma gallisepticum*

128 Reduction of *Salmonella enteritidis* infection by therapeutic administration of *Lactobacillus* probiotic culture. G. M. Nava*¹, C. M. Pixley¹, R. L. Jarquin¹, C. D. Sartor¹, J. L. Vicente¹, G. Tellez¹, A. M. Donoghue², and B. M. Hargis¹, ¹Center of Excellence for Poultry Science, University of Arkansas, ²PPPSRU, ARS, USDA, Fayetteville, AR.

These studies evaluated the therapeutic effect of a *Lactobacillus* probiotic culture (LPC) producing bacteriocin-like inhibitory substances on *Salmonella enteritidis* PT-13a (SE) infected chicks. All chicks were challenged at day of hatch with approximately 10³ CFU of SE orally, and 2 hr later were randomly assigned to floor pens (n=40) and treated.

Treatments were control group (CG), *Lactobacillus casei* probiotic culture (LCa), *Lactobacillus cellobiosus* probiotic culture (LCE), combination of *L. casei*-*L. cellobiosus* (LCC) and probiotic culture that contained 11 *Lactobacillus* spp isolates (L11). Groups LCa, LCE, LCC and L11 received 10^6 cfu/ml of drinking water; CG received tap water only. Twenty chicks per group were killed at 24 and 72 h post-challenge and cecal tonsils were aseptically collected for SE isolation. Administration of LPC significantly ($p < 0.05$) reduced SE recovery from chicks when compared to the CG (LCa, 59% and 62% reduction; L11, 94% and 63% reduction, 24 or 72 h, respectively). However, LCC reduced SE recovery by 82% only at 24 h). The design of EXP II was similar with CG, LCa, LCa-10x (107 cfu/ml), L11, and L11-10x. LPC treatment significantly ($p < 0.05$) reduced SE recovery when compared to the CG (LCa, 53% and 41%; LCa-10x, 100% and 100%; L11, 81% and 85%; L11-10x, 82% and 100% reduction at 24 and 72 h respectively). In EXP III, CG, LCa-10x and L11-10x were compared and samples obtained only at 72 h. LPC administration significantly ($P < 0.05$) reduced SE recovery when compared to the CG (LCa-10x 81% and L11-10x 81% reduction). These studies suggest that in addition to their better known prophylactic effects, appropriately selected defined Lactobacilli cultures may be useful for actually displacing *Salmonella* infections.

129 Experimental induction of tibial dyschondroplasia in chickens using a short regimen of feeding with thiram. N. Rath*, W. Huff, J. Balog, and G. Huff, *USDA, ARS, Poultry Science Center, University of Arkansas, Fayetteville.*

Tibial dyschondroplasia (TD) is characterized by the presence of a plug of unresolved cartilage in the growth plate that fails to form bone. Because the etiology of the naturally occurring TD is unknown, it has been difficult to determine the mechanisms of its pathogenesis. Naturally occurring lesions have limited potential to provide insight into the initiation and the progression of TD. The objective of our study was to develop an experimental model that can help understand the mechanisms of TD and should be amenable to screen for the factors that may protect against the disease. To address this objective we tested whether it is feasible to induce TD using a short duration of feeding with thiram, a fungicide. One wk-old-broiler chickens were fed diets containing 0-100 ppm of thiram for 24-48 h and the growth plates were examined for the presence of TD at the end of treatment or 5, 12, and 17 days after feeding. The lesions were given an evaluation score ranging from 0 (none) to 1 (moderate), and 2 (severe) based on growth plate width. The results showed that as little as 10-20 ppm of thiram fed for only a 24 h period increased the incidence TD which was augmented as the concentration was raised up to 100 ppm where most chickens were affected with severe TD. The TD index (severity x incidence) showed to plateau with 100 ppm of thiram fed for 48 h. A dose of thiram between 80-100 ppm appeared reasonable to study the early changes leading to TD. Under this condition the growth plate showed little visual demarcation at 48 h after feed treatment but sustained a progressive pathogenesis of TD during subsequent periods with both morphological and histological changes in spite of the fact that the birds no longer received thiram. There was no cell division in the maturing zone cartilage but an accumulation of chondrocytes with many cells showing nuclear blebbing, and shrinkage was accompanied by an extensive degeneration of blood capillaries. We conclude that this optimized protocol to induce TD by short feeding of thiram or similar compounds may be valuable to understand the initiation and progression of TD and to develop screening methods for its control.

130 *Salmonella typhimurium* Felix-O1 and P22 bacteriophage host range and viability under gastrointestinal conditions. P. Herrera*, E. M. Kozhina, and S. C. Ricke, *Texas A&M University, College Station.*

Salmonella typhimurium is both a human and veterinary health problem. The traditional method of control is the use of antibiotics as a feed supplement. However the increased rate of antibiotic resistance has for alternative methods. Bacteriophage have several advantage over antibiotics including being host specific and self replicating. However, in order to use phage, it must be able to survive potential denaturation in the gastrointestinal tract. The purpose of these experiments are to test the

stability of two phage specific to *Salmonella typhimurium* under conditions they would encounter in the gastrointestinal tract. Felix-O1, a lytic bacteriophage that infects most smooth phenotypes of *Salmonella*, was tested along with P22, a temperate *Salmonella* phage. Phage lysates (10 μ l) with concentrations of 10^5 PFU/ml were spotted on lawns of 10 strains of *Salmonella typhimurium*. Felix lysed 7 of the 10 strains as compared to P22 which only lysed 4 strains. Felix was able to infect *Salmonella typhimurium* strains ATCC 14028, ATCC 13311, UK-1 and serovars Javiana, Muenchen, Rubislaw, and Texas. To test the stability of phage under environmental conditions seen in the cecum of a chicken, 1 ml of a Felix-O1 suspension (10^9 PFU/ml) was dispensed in tubes containing 5 ml of 1:100 dilution of cecal contents and 0.25 g of ground alfalfa. The tubes were incubated at 37°C under anaerobic conditions for 1, 3, 6, 12, and 24 hours at which times phage concentration was titrated using the soft agar overlay method. Within one hour of incubation, the phage was reduced below measurable levels. Felix-O1 suspension (1 ml) was added to 1 ml of a pepsin solution (32,100 units/ml) and incubated with agitation at 37°C for three hours. Addition to the acidic proteinase solution produced an decrease in phage viability of six orders of magnitude. Pepsin produced only a modest decrease in phage numbers over the 3 h period. These results suggest that Felix-O1 might be an effective anti-*Salmonella typhimurium* agent if its stability under gastrointestinal condition can be improved.

131 Rapid detection of infectious bursal disease virus using one-step RT-PCR in clinical samples in Pakistan. M. A. Zahoor*¹, I. Hussain¹, M. K. Mansoor¹, S. Masood¹, and Q. M. Khan², ¹University of Agriculture, Faisalabad, Pakistan, ²NIBGE, Faisalabad, Pakistan.

A SuperScript One-Step reverse transcriptase polymerase chain reaction (RT-PCR) technique was used for the detection of infectious bursal disease virus in clinically affected bursal tissue specimens. The viral RNA was isolated using TRIzol One-step RNA isolation kit (LS Reagent, Life Technologies). A set of primers was used that amplified a 743-bp fragment of VP2 gene hypervariable region from the nucleotides 701 to 1444. An amplified fragment was found in 21 samples out of 26 whereas none was obtained in case of unrelated virus or IBDV negative samples. Results showed that SuperScript One-Step RT-Taq system can be used for the rapid detection of IBDV in tissue specimens.

Key Words: One STEP RT-PCR, IBDV, Pakistan

132 Very virulent strains of infectious bursal disease virus in Pakistan. M. A. Zahoor*¹, I. Hussain¹, M. K. Mansoor¹, S. Masood¹, and Q. M. Khan², ¹Faculty of Veterinary Science University of Agriculture, Faisalabad, Pakistan, ²NIBGE, Faisalabad, Pakistan.

Nine bursa samples were collected from a severe outbreak of infectious bursal disease in two commercially reared broiler farms in Oct 2003. The gross lesions particular of IBD and the presence of high mortality speculated the presence of very virulent strains of infectious bursal disease virus (IBDV) in Pakistan. The bursa samples were subjected to reverse transcriptase-polymerase chain reaction (RT-PCR) and restriction fragment length polymorphism analysis. A primer pair that amplified a 743-bp fragment from the nucleotides 701-1444 was used. Seven bursa samples were found to contain the IBDV. The PCR product was further digested with SspI restriction enzyme to identify the very virulent phenotype. Results indicated that three of the tested bursa samples were SspI positive i.e. vvIBDV. This first report describes that there exist vvIBDV strains in Pakistan and SspI restriction enzyme could be used as virulent marker.

Key Words: Very Virulent Strains, IBDV, Pakistan

133 RT-PCR Based diagnosis of infectious bursal disease virus in Pakistan. M. A. Zahoor*¹, I. Hussain¹, M. K. Mansoor¹, S. Masood¹, and Q. M. Khan², ¹University of Agriculture, Faisalabad, Pakistan, ²NIBGE, Faisalabad, Pakistan.

A total of 26 bursa samples collected from different outbreaks of infectious bursal disease, were tested at Molecular Virology Lab (EBD, NIBGE, Faisalabad) for the presence of infectious bursal disease virus using a highly sensitive method i.e. reverse transcriptase polymerase

chain reaction (RT-PCR). Viral RNA was extracted from the bursal tissue samples using Proteinase K digestion method. A 5 ug of the viral RNA was used for the synthesis of cDNA using RevertAid TM First Strand cDNA Synthesis Kit (MBI, Fermentas). The VP2 hypervariable region of the IBDV was amplified using specific primers. A single band

of PCR product of the expected size was visualized on 1.5% agarose gel after ethidium bromide staining. Results indicated that PCR is a sensitive method for the rapid detection of IBDV.

Key Words: RT-PCR, IBDV, Pakistan

PSA-Physiology: Poultry Digestion and Metabolism

134 Compromised liver mitochondrial function and complex activity in low feed efficient broilers associated with higher oxidative stress and differential expression of proteins within a single male line. M. Iqbal*¹, N. R. Pumford¹, Z. X. Tang¹, K. Lassiter¹, W. Bottje¹, T. Wing², and M. Cooper², ¹University of Arkansas, Fayetteville, ²Cobb-Vantress, Inc., Siloam Springs, AR.

Two experiments were carried out to determine the relationships of; a) mitochondrial function and activities of various complexes, b) production of reactive oxygen species (ROS) and its subsequent effect on protein oxidation, and c) protein expression in liver of male broilers with low and high feed efficiency (FE, n =5-8 per groups). Mitochondrial function and complex activities were measured polarographically and spectrophotometrically, respectively. Hydrogen peroxide (H₂O₂) was measured fluorometrically, while oxidized protein (carbonyls) and immunoreactive mitochondrial proteins were analyzed using Western blots. Mitochondrial function (ETC coupling) and activities of all respiratory complexes (I, II, III, IV) were higher in high FE compared to low FE broilers. H₂O₂ and protein carbonyls were higher in the liver of low compared to high FE broilers. Whereas the expression of four immunoreactive proteins [NAD3 (Complex I), QPC (Complex III), COX II and COX IVb (Complex IV)] were higher in low FE liver mitochondria and two proteins [70S (Complex II) and alpha-ATPase (Complex V)] were higher in high FE birds, there were no differences between groups in the expression of 18 other respiratory chain proteins. SDS-PAGE revealed several proteins (ranging from 20 to 180 kDa) that were differentially expressed between the low and high FE groups. In conclusion, taken together with our previous findings in breast muscle (Iqbal et al., 2004, Poult. Sci. 83:474-484), the differential expression of certain mitochondrial proteins might be a compensatory response aimed to maintain the compromised respiratory chain activity and/or to overcome the increased protein oxidation in low FE birds. Funded in part by USDA-NRI grant (#2001-03443).

Key Words: Feed Efficiency, Mitochondrial Complex Activity, Oxidative Stress

135 Membrane potential and hydrogen peroxide production in duodenal mitochondria in broilers with low and high feed efficiency. C. Ojano-Dirain*¹, N. Tinsley¹, M. Iqbal¹, T. Wing², M. Cooper², and W. Bottje¹, ¹University of Arkansas, Fayetteville, ²Cobb Vantress Inc., Siloam Springs, AR.

Increased hydrogen peroxide (H₂O₂) production was observed in duodenal mitochondria obtained from broilers with low feed efficiency (FE). As a decrease in mitochondrial membrane potential (MMP) due to stimulation of uncoupling of oxidative phosphorylation reduces reactive oxygen species (e.g., H₂O₂) production, this study was conducted to evaluate the effect of uncoupling on MMP and H₂O₂ production in duodenal mitochondria from broiler breeder males with low and high FE. Duodenal mitochondria were isolated from broilers with low (0.48 ± 0.02, n = 8) and high (0.68 ± 0.01, n = 7) FE. H₂O₂ production and membrane potential were measured fluorometrically using dichlorofluorescein and tetramethylrhodamine methyl ester probe, respectively, in the presence of different levels (0, 200, 400, 600, 800 and 1,000 nM) of an uncoupler, carbonylcyanide p-trifluoromethoxyphenylhydrazone (FCCP). The MMP was higher (P < 0.05) in the high FE mitochondria at 0 to 600 nM FCCP. A decrease in MMP was observed at 600 and 800 nM FCCP for the low and high FE groups, respectively. H₂O₂ generation was higher in the low FE mitochondria at all FCCP levels except at 200 nM. Adding 200 to 800 nM FCCP caused a decrease in H₂O₂ production in low but not in high FE mitochondria. The results indicate that FCCP-induced uncoupling lowered H₂O₂ production in low FE but not in high FE duodenal mitochondria and indicate that mitochondrial membrane

potential may influence reactive oxygen species production in broilers with low FE. Supported in part by USDA-NRI #2001-03443.

136 Evidence of protein oxidation in mitochondrial respiratory complexes in broilers with low and high feed efficiency. J. P. Higgins*¹, N. R. Pumford¹, M. Iqbal¹, T. Wing¹, M. Cooper¹, and W. G. Bottje¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²Cobb-Vantress, Inc., Siloam Springs, AR.

We have observed increased mitochondrial radical production, increased protein oxidation and lower activities of respiratory chain complexes in broilers with low feed efficiency (FE) compared to broiler breeders with high FE. As radical-mediated protein damage could cause the reduction in complex activities, the purpose of this experiment was to determine if there is evidence of protein oxidation that is specifically associated with respiratory chain complexes. Mitochondria were isolated by differential centrifugation from breast muscle obtained from broiler breeder males identified as either low (0.62 ± 0.01, n = 8) or high (0.80 ± 0.01, n = 8) FE. Respiratory chain complexes were separated using a non-denaturing gradient polyacrylamide blue native gel. Protein carbonyl levels were measured with an immunochemical assay in which proteins are reacted with 2,4 dinitrophenylhydrazine to produce a corresponding hydrazone. The hydrazone is then detected by Western analysis using anti-dinitrophenyl antisera. Preliminary results indicate that Low FE mitochondria exhibited higher levels of protein carbonyls (indicating increased protein oxidation) in Complex III compared to levels in High FE mitochondria. These findings suggest that increased protein oxidation may be responsible in part for the lower respiratory chain activities observed in broilers with Low FE. Further research is being conducted to ascertain protein oxidation in other mitochondrial complexes and other mitochondrial proteins in relation to the phenotypic expression of feed efficiency in broilers. Supported in part by USDA-NRI (#2001-03443).

137 Dietary phytates may noncompetitively inhibit intestinal mucosa phytase in broiler chicks. E. M. Onyango*¹, E. K. Asem², J. S. Sands³, and O. Adeola¹, ¹Department of Animal Sciences, Purdue University, West Lafayette, IN, ²Basic Medical Sciences, Purdue University, West Lafayette, IN, ³Danisco Animal Nutrition, Marlborough, Wiltshire, UK.

The role of dietary phytate in the regulation of intestinal mucosa phytase was investigated in broiler chicks. One hundred and eight 7-d-old male broiler chicks were grouped by weight into six blocks of 3 cages with six birds per cage. Three chemically defined diets were randomly assigned to cages within each block. The three diets were a chemically defined casein diet; chemically defined casein diet plus sodium phytate (20 g/kg diet), and a chemically defined casein diet plus sodium phytate (20 g/kg diet) and microbial phytase (1000 U/kg diet). The chicks were fed experimental diets from 8 to 22 d of age. At the end of the study, chicks were weighed, killed, and duodenal mucosa and left tibiae removed. Tibiae were defatted and ashed overnight at 600 °C. Phytase activity in brush border vesicles prepared from the duodenal mucosa was determined by measuring the amount of inorganic phosphorus released from sodium phytate. Addition of phytate to the chemically defined diet reduced (P < 0.05) weight gain, feed intake, feed efficiency and percentage ash. However, addition of microbial phytase fully restored (P < 0.05) feed efficiency but weight gain was only partially restored (P < 0.05). Addition of phytate to the chemically defined diet reduced (P

< 0.05) the V_{max} of the intestinal mucosa phytase but the K_m of the enzyme was not affected. By comparison, the addition of microbial phytase to the diet did not restore the V_{max} . Phytate may noncompetitively inhibit intestinal mucosa phytase.

138 Absorption of 2-hydroxy-4(methylthio) butanoic acid (HMTBA) (5-50mM) is equal to or greater than d,l-methionine (DLM) uptake in chicken intestinal slices. J. D. Richards*, C. Atwell, and J. J. Dibner, *Novus International, Inc., St. Louis, MO.*

The rates of intestinal HMTBA vs. DLM absorption have been controversial. DLM is absorbed mostly by active transport; HMTBA uptake is mainly by diffusion. *In vitro* membrane vesicle systems under-represent diffusion and, therefore, HMTBA uptake. Here, everted rings of chicken jejunum and ileum were used. Cobb broilers were grown on corn-soy diets supplemented with equimolar amounts of HMTBA (Alimet® feed supplement, Novus International, Inc.) and DLM (0.1% each). Birds (day 13-30) were sacrificed, and their intestines sliced into rings and everted. Sections were cultured at 37°C at pH 7 for 0.5 min, 1 min, 1.5 min, 2 min or 5 min in the presence of glucose; KCl or NaCl (to test Na-dependence); and 5, 10, 20 or 50mM 14C-HMTBA or 14C-DLM (both 2.5 μ Ci/100 μ mol). 3H-inulin (0.5 μ Ci/ml) was included (non-specific binding control). Slices were rinsed and scintillation counted. 3H-corrected HMTBA and DLM counts were calculated, and absorption of HMTBA or DLM per mg of tissue was determined (SAS, LSMEANS). No source by ion interactions existed, so KCl and NaCl data were combined. Absorption of each source was time and concentration dependent. In general, HMTBA uptake was equal to or greater ($P < .05$) than DLM uptake. The exception was at 1.5 minutes, where 5mM DLM absorption (ileum) was greater than 5mM HMTBA (jejunum) ($P < .05$). At 5 minutes, however, absorption of 5mM DLM (jejunum) was less than that of HMTBA or DLM absorption (ileum). No other significant differences existed at 5mM. At 10mM, absorption of HMTBA (ileum) was greater ($P < .05$) than that of DLM (jejunum or ileum), but there were no significant differences between HMTBA (jejunum) and DLM (either tissue). At 20mM and 50mM, absorption of HMTBA in both tissues was greater than or equal to DLM absorption at all time points. In contrast to data from *in vitro* membrane vesicles, this study provides further evidence that HMTBA availability is not limited by intestinal absorption.

Key Words: 2-Hydroxy-4(Methylthio) Butanoic Acid, Methionine, Absorption

139 Isolation and partial characterization of pancreatic alpha-amylase in turkey. E. Blair*, J. Firman, and S. Zhang, *University of Missouri, Columbia.*

White nicholas tom turkey α -amylase was purified by $(NH_4)_2SO_4$ fractionation, dialysis against a $C_2H_3O_2Na$ gradient, and β -cyclodextrin affinity chromatography from an aqueous pancreatic extract. The effects of pH and temperature on amylolytic activity were studied. The ideal pH for pancreatic amylase was determined to be approximately 5.9, with a conservative range of 5.7 to 6.2. The optimal range of temperature was determined to exist between 20 and 30 degrees Celsius. The homogeneous mixture was subjected to SDS-PAGE to determine approximate molecular weight. A 10 kD protein marker was used as a standard. The approximate molecular weight of the amylase was determined to be 40 kD. Isoelectric focusing with a pH gradient of 5 to 8 was run to determine if any isozymes exist. From the IEF it was determined that at least 2 isoforms exist for pancreatic amylase in the turkey.

140 Unique responses of pancreatic phospholipid metabolism of broiler hens in response to increased plasma glucose and lipid concentrations. S.-E. Chen*¹, R. L. Walzem¹, and J. P. McMurtry², ¹Department of Poultry Science, Texas A&M University, College Station, ²ARS Growth Biology Laboratory, Beltsville, MD.

Higher caloric intake (twice the recommended 145 g/day/hen; T or free access to feed; F, n=15 for each) for 10 days in broiler hens (Cobb 500 Fast Feathering, age=35 wks) caused 500 grams body weight (BW) gain when compared with hens consuming recommended feed intakes (R, n=15) or with hens necropsied at the start of feeding trial as basal references (BR, n=15). Rapid BW gain was associated with an increase ($p \leq 0.05$) of relative liver (50%) and abdominal fat weights (30%), and elevated preprandial plasma insulin (45-60%), NEFA (40%), glucose (43%), VLDL-TG (27%), and total cholesterol (TC) concentrations (60-80%) but a decreased HDL-TC (45%) concentration, suggesting metabolic dysregulations similar to those of mammalian obesity and type-II diabetes. Higher caloric intake also increased ($p \leq 0.05$) relative pancreas weight (25-30%), pancreatic protein content (25%) and protein/DNA ratio (20%), and all classes of pancreatic phospholipids (average 35%), indicative of pancreatic hypertrophy. Notably, phosphatidylethanolamine increased 75% in concert with increased D9 desaturase activity (18:1n9/18:0, mol/mol) (15-30%) and a general enhancement of unsaturation in pancreatic PL fatty acids (12-35%) ($p \leq 0.05$) when compared with group R and PR hens. These observations indicate that specific changes in pancreatic lipid metabolism accompany the acceleration of endocrine/exocrine functions in response to food intake above the amount needed for optimal egg production. Hen pancreatic cells may mount specific metabolic responses to prevent cytotoxicity resulting from excessive glucose and saturated fatty acid availability.

141 Efficacy of injected gluconeogenic supplementation on the performance of broilers from young breeders. E. D. Peebles*¹, W. D. Berry², R. W. Keirs³, L. W. Bennett³, and P. D. Gerard⁴, ¹Department of Poultry Science, Mississippi State University, Mississippi State, ²Department of Poultry Science, Auburn University, Auburn, AL, ³College of Veterinary Medicine, Mississippi State University, Mississippi State, ⁴Experimental Statistics Unit, Mississippi State University, Mississippi State.

It has been reported that gluconeogenic supplementation using hydrolyzed casein augmented the early performance of broilers from a single young breeder flock at 29 wk of age. In an effort to further explore this concept and determine the efficacy of various other practical nutrient sources, injections (0.2 mL) containing physiological saline or a gluconeogenic energy source (casein hydrolysate, ovalbumin hydrolysate, or crude ovalbumin) were given subcutaneously (in the back of the neck) to 320 broiler chicks at hatch. Concentrations of gluconeogenic substances in solution were approximately 200 g / L. Biotin was added to injected crude ovalbumin solutions. Chicks were hatched from eggs that were obtained from a single young breeder flock at 27 weeks of age. At hatch, chicks were divided into 16 floor pens with 20 chicks in each of four replicate pens per treatment group, and were brooded under commercial conditions. Tissue condition at the site of injection, growth, feed consumption, feed conversion, water intake, livability, and liver weight were determined through 16 days post hatch. Treatment injection caused no local histological reaction. Body weight and relative liver weight at Day 16 were not affected by treatment. Furthermore, daily mortality, and average feed consumption, feed conversion, water consumption, and BW gain per bird over the entire 16 day period and at various shorter consecutive intervals were not affected by treatment. In this study, the use of injected casein hydrolysate, ovalbumin hydrolysate, or crude ovalbumin for gluconeogenic supplementation did not affect the performance of chicks from young parents that were provided adequate brooding conditions.

Key Words: Broiler, Chick, Gluconeogenesis

142 Carcass scratches and growth rate of microwave toe-treated broiler chickens. B. Wang*¹, J. L. MacIsaac², and B. M. Rathgeber¹, ¹*Nova Scotia Agricultural College, Nova Scotia, Canada*, ²*Atlantic Poultry Research Institute, Truro, Nova Scotia, Canada*.

Lighting programs that provide longer daylength as a broiler ages reduce the incidence of ascites and sudden death syndrome. Birds given this type of program often have an increased incidence of carcass scratches due to increased bird activity. The turkey industry uses microwave technology to restrict claw growth and reduce carcass scratches. One concern is that the treatment may reduce bird growth rate. The objective of this study was to determine if microwave toe-treatment would reduce growth rate of chickens if used to reduce carcass scratches for broilers on an increasing photoperiod program. Two replicate trials were conducted with 728 female and 728 male broilers in each trial. Half of each sex was toe-treated using microwave energy upon delivery from the hatchery. The birds in each trial were randomly assigned to four rooms with 8 pens per room. Two rooms were given 23 h of light per day from start to finish and the other two rooms were on a lighting program with short daylength after the first three days, which increased to 23 h by day 31. Light intensity was the same for each lighting program. For half the pens, the bird's growth rate was measured by catching and weighing each bird in the pen on day 7, 14, 24, 31. On day 38, the birds from all the pens were removed and weighed. For six pens per room, computerized bird scales were installed to continually monitor bird weight. Five birds per pen were shipped for slaughter and carcass scratches monitored. Toe-treatment reduced carcass scratches for both lighting programs of which increasing photoperiod had the higher incidence ($p < 0.05$). Based on the traditional weighing method, toe-treatment reduced bird weight on day 14 and 31 ($p < 0.05$). The computerized scales indicated that the toe-treated birds were lighter on day 14 and 24. For both sources of bird weight, the birds given an increasing photoperiod were lighter than those with continuous light on day 7, 14, 24 and 31 ($p < 0.05$). On day 38, there were no lighting and toe-treatment effects ($p > 0.05$). Collectively, the present results demonstrated that microwave toe-treatment and the increasing lighting program didn't influence body weight of broiler chickens at market age.

Key Words: Microwave Toe-Treatment, Lighting Program, Scratches

143 Effect of lighting and handling technique on breast fillet dimensions and meat quality. N. A. McKee*¹, R. J. Lien², J. B. Hess², S. F. Bilgili², and S. R. McKee*², ¹*Auburn University*, ²*Auburn University*.

This study was designed to determine the effect of lighting and handling on growth and meat quality factors. Male Ross 508 broilers (total $n=1050$) were housed in light-tight rooms and subjected to step-up lighting of either, bright (15.0 foot-candles) or dim (0.1 foot-candles). Within these lighting treatments, birds were further divided into 3 handling groups by the legs (L), wings (W), or no handling (NoH) at days 37 and 44 (20 sec. at each age) to determine the effect of handling on the incidence of deep thigh bruises and deep pectoral myopathy (DPM). Birds were reared to 51 d of age. After birds were processed and chilled, a sample of 288 birds were further divided into 2 groups based on deboning time post-mortem (PM). Breast fillets were deboned at 2 h and 4 h PM and fillet weights, fillet dimensions (length, width, and height), cook-loss, and tenderness were evaluated. Shear values were measured using a (TA.XT2i) Texture Analyzer (Texture Technologies Corp., Scarsdale, NY/ UK). Birds subjected to dim lighting had greater live weights ($P < 0.05$), post-chill weights, and fillet weights compared to birds reared in bright light. The increase in fillet weights observed for the dim light treatment was likely due to an observed increase in fillet length, as all other fillet dimensions were similar regardless of lighting or handling. The incidence of DPM and other carcass defects did not vary among the handling or lighting treatments. Cook-loss was affected by a light by handling interaction with the greatest percentage cook-loss observed in the fillets from the bright light NoH, dim light L, and dim light W ($P < 0.05$) compared to other groups. Fillets deboned at 2 h PM had higher shear values than those deboned at 4 h PM, regardless of lighting or handling. Within the 2 h PM deboning period, dim lighting resulted in an increase in shear values compared to bright light treatments. This trend was not observed in the fillets deboned at 4 h PM.

In conclusion, dim lighting treatment resulted in greater bird and fillet weights but slightly tougher meat when fillets were deboned at 2 h PM.

Key Words: Lighting, Handling, Meat Quality

144 Meat quality evaluation of minimally aged broiler breast fillets from five commercial genetic strains. J. M. Mehaffey*¹, J. L. Emmert¹, J.-F. C. Meullenet¹, S. R. McKee², and C. M. Owens¹, ¹*Department of Poultry Science, University of Arkansas, Fayetteville*, ²*Department of Poultry Science, Auburn University, Auburn, AL*.

A total of 1040 birds from 5 common commercial genetic broiler strains were raised and processed in order to analyze the effect of strain and deboning time on meat quality. The birds were processed at either 6 or 7 weeks of age in two replications each. Replications consisted of 26 birds of each strain deboned at 2 h postmortem (PM) and 4 h PM. Carcass and breast weights were measured on each bird in order to calculate breast yield. Fillets deboned at 4 h PM were then measured for length, width, and height at 3 points along the fillet to evaluate footprint analysis. At time of deboning, the caudal tip was taken from one fillet per bird for muscle pH determination using the iodoacetate method. Fillets were individually bagged and stored at 4 C overnight. At 24 h PM, fillets were weighed in order to calculate drip loss, and color ($L^*a^*b^*$) was also measured. The fillets were then cooked to 76 C and cook loss was calculated. One fillet per bird was then subjected to shear analysis using the razor blade shear method where shear energy (N.mm) was calculated in order to evaluate tenderness. The strains in this study were chosen for differences in growth rate and yield; therefore, as expected, breast yield was significantly different among strains. Higher yielding birds exhibited higher shear energy (more tough), higher drip and cook loss, and higher muscle pH when deboned at 2 h PM compared to lower yielding birds. However, at 4 h PM, fewer differences among strains existed in meat quality characteristics (tenderness, water holding capacity, and pH). At 6 and 7 wks, deboning at 2 h PM resulted in higher shear energy, muscle pH, and lower L^* value compared to deboning at 4 h PM in all but one strain. However, water holding capacity was not affected by deboning time at either age interval. Footprint analysis showed that most differences among strains were apparent in heights measured at the fillet midpoint and caudal end. These results suggest that early deboning may impact meat quality of broiler strains differently resulting in greater variation within the industry.

Key Words: Tenderness, Strain, Aging

145 Comparison of Sensory Qualities of Poultry Meat from Alternative Slow-Growing Breeds and a Commercial Breed Grown with or without Outdoor Access. A. C. Fanatico*, P. B. Pillai, L. C. Cavitt, J. F. Meullenet, J. L. Emmert, and C. M. Owens, *University of Arkansas, Fayetteville*.

An experiment was conducted to assess the impact of breed and outdoor access on meat quality of broilers. One slow-growing breed (S), two medium-growing breeds (M1 and M2) and a commercial fast-growing breed (F) were raised for 12, 10, or 8 weeks, respectively, in an attempt to achieve similar body weights. The birds were straight-run, and the placement date was staggered such that all breeds were processed on the same day. Each breed was assigned to three pens of 24 birds each and raised in indoor floor pens; the S and F breeds were also assigned to two floor pens with outdoor access (during daylight hours) containing 36 birds each. All birds were provided with the same starter (0 to 4 weeks for S and M; 0 to 3 weeks for F), grower (4 to 8 weeks S and M; 3 to 6 weeks for F) and finisher (8 to 12 weeks for S; 8 to 10 weeks for M; 6 to 8 weeks for F) feeds. Birds were commercially processed; Pectoralis samples were collected at 6 h postmortem. Thighs were vacuum packed and frozen for 5 months. Consumer panels evaluated breast meat pieces and ground thigh meat patties. There was little difference in texture in breast meat samples among genotypes, although the breast meat from medium-growing broilers was perceived as more tender than breast meat from the fast-growing broilers (indoors) ($P < 0.05$). The thigh meat of the medium-growing broiler (M2) was more intense in flavor than that of the slow-growing broiler (indoor) ($P < 0.05$). The flavor of thigh meat from the medium-growing broilers and the fast-growing broilers was more liked than the slow-growing broilers (indoors) ($P < 0.05$). These data indicate that meat quality differences

may exist among breeds with different growth rates and reared with or without outdoor access.

Key Words: Broiler, Slow-Growing, Free-Range

146 The effect of blood removal, oxidation and shelf-life in broiler meat. C. Z. Alvarado*¹, S. F. O'Keefe², and M. P. Richards³, ¹Texas Tech University, Lubbock, ²Virginia Polytechnic and State University, Blacksburg, ³University of Wisconsin, Madison.

Blood components, especially hemoglobin, are powerful catalysts of lipid oxidation and may cause a decrease in shelf-life of the product. Therefore, this study examined the effect of different slaughter techniques (CO₂ kill and non-bled, no stun and bled, electrical stun and bled, CO₂ stun and bled, and no stun and decapitation) to determine their effect on pH (24 hr), L*a*b* value (24 hr), oxidation, residual hemoglobin concentration (24 hr), and sensory evaluation (day 1 and day 4 postmortem) in the broiler breast fillets. The birds were conventionally processed and analyses were performed at 24 hr PM except residual hemoglobin where the samples were frozen (-80 °C) until analyses (< 2 months). There were no significant differences in pH or b* values at 24 hr postmortem among any of the treatments. L* values were significantly higher indicating lighter fillets in the electrically stunned (56.99) and decapitated birds (56.29) compared to the darker fillets from the CO₂ stunned and bled birds (53.88). The CO₂ kill and non-bled birds (4.18) had significantly higher a* values, indicating more red color, when compared to the electrically stunned and bled (3.09) and decapitated birds (2.80). There were no significant differences in the residual hemoglobin content in the broiler breast muscle when comparing all of the treatments except CO₂ kill non-bled which was significantly higher (10.04). Overall TBARS (raw, cooked 24hr and cooked 72hr PM) indicate that ES and bled had the lowest TBARS when compared to the remaining treatments. Consumer panels detected a difference in both aroma (chicken meaty and warmed-over) and flavor (chicken meaty and warmed-over) at 24 hr PM. However, by 72 hr PM, there were no significant differences in either aroma or flavor. Therefore, different slaughter and bleeding methods may affect color and sensory properties of the broiler breast fillets.

Key Words: Oxidation, Blood Removal, Shelf-Life

147 Dietary supplementation of functional ingredients improves quality of irradiated raw turkey breast. H. Yan*, K. Nam, E. J. Lee, B. Min, K. S. Park, H. Ismail, and D. U. Ahn, Iowa State University, Ames.

The effect of dietary functional ingredients - vitamin E, selenium (Se), conjugated linoleic acid (CLA) - alone or combination on the quality of irradiated turkey breast meat was evaluated. Four hundred eighty male turkeys (12-week-old, raised on a corn-soybean basal diet) were randomly allotted to 32 pens (4 pens/treatment) and fed 8 experimental diets (A, B, C, D, E, F, G, H) supplemented with none (Control, Diet A), 200 IU/kg diet vitamin E (Diet B), 0.3 ppm Se (Diet C), 2.5 % CLA (Diet D), combination of Vitamin E and Se (Diet E), combination of Vitamin E and CLA (Diet F), combination of CLA and Se (Diet G), combination of vitamin E, Se, and CLA (Diet H). At 15-week age, all birds were slaughtered and breast muscle from 8 birds per each pen was separated and grounded. Raw meat patties were either aerobically or vacuum packaged and irradiated using a Linear Accelerator to a dose of 0 or 1.5 kGy absorbed dose. Lipid oxidation, color, and volatile changes of meat were measured after 0 and 7 days of storage at 4 °C. Vitamin E, Se, and fatty acids composition were also determined. Dietary supplementation of vitamin E and CLA increased their deposit in turkey breast. Dietary supplementation of CLA increased monosaturated fatty acids in meat. Irradiation increased ($p < 0.05$) lipid oxidation and hunter color a value, produced specific volatiles such as dimethyl disulfide and hexanal involved in off-odor. Dietary Vitamin E, Se, CLA alone and their combination decreased ($p < 0.05$) lipid oxidation caused by both irradiation and storage. Off-odor volatiles from irradiation were significantly ($p < 0.05$) decreased by dietary functional ingredients. It was concluded that dietary supplementation of functional ingredients improved the quality of irradiated turkey breast meat, lipid oxidation and off-odor caused by irradiation and storage.

Key Words: Dietary Functional Ingredients, Irradiation, Meat Quality

148 Na⁺ migration and quality parameters in turkey fillets using different marination techniques. C. Z. Alvarado*¹ and H. Wang^{2, 1}, ¹Texas Tech University, Lubbock, ²Virginia Polytechnic and State University, Blacksburg.

Marination with salt and phosphate is used as a method of improving quality and extracting salt soluble proteins in turkey meat. However, there are several marination methods available that can affect penetration of marinade and therefore affect meat quality. The objectives of this research were to determine the quality parameters (pH, L* value, marinade pick up (%), marinade retention (%), protein solubility, shear value, cook loss (%), and Na⁺ migration) of the turkey fillet when marinated by several commercial methods. A total of 160 fillets were marinated (20% wt/wt, 94% water, 3.6% NaCl, and 2.4% STP) by multi-needle injection at 4°C, vacuum tumbling (25 mmHg, 4°C, 14 RPM for 1 hour), injection + tumbling or were left as non-marinated controls. There were no significant differences in pH or L* value among the fillets prior to marination. However, by 24 hr post-marination, the pH and L* value of injected + tumbled (6.14, 51.12) and injected (6.13, 50.97) fillets were significantly higher than the control fillets (6.04, 48.91). Injected + tumbled (24.30%) and injected (24.25%) fillets had higher pickup than the tumbled (18.15%) fillets while the tumbled (98.93%) and injected + tumbled (98.23%) had higher retention than injected (95.58%) fillets. There were no significant differences in tenderness, protein solubility or cook loss among any of the treatments. The injected treatment had no differences in sodium ion content throughout the fillets while the injected + tumbled and tumbled treatments had varying levels of Na⁺ migration throughout the fillet. Overall, the injected + tumbled and injected fillets had the highest concentrations of total Na⁺ followed by tumbled and control which were significantly different. Therefore, marination method may affect Na⁺ migration throughout the turkey fillet but this difference may not cause a negative effect on quality.

Key Words: Marination, Sodium, Turkey Fillets

149 Utilizing marination and vacuum tumbling techniques to optimize tenderness of breast fillets deboned early post-mortem. L. J. Bauermeister* and S. R. McKee, Department of Poultry Science, Auburn University, Auburn, AL.

This study was designed to determine the effectiveness of marination, injection marination and/or vacuum tumbling as a means of alleviating the toughness associated with early deboning of breast. Broilers (n=480) 48-60 days of age were conventionally processed. Experimentally, a 2 X 2 X 8 factorial arrangement was used, in which replicates were considered different processing days. Fillets deboned at 2 and 4 h post mortem (PM) were subjected to the following treatments (n=15/treatment): 1. control, 2. tumble (T), 3. marination (M), 4. marination, tumbling (MT), 5. dry injection (I), 6. injection marination, tumbling (IMT), 7. dry injection, tumbling (IT), 8. injection marination (IM). When marinade was applied either by injection or brine-soaked, the marinade pick-up was 10% of the fillet weight to give a final concentration of 0.7% sodium chloride and 0.45% sodium tripolyphosphate per fillet. Biochemical parameters measured (n=80) included pH, sarcomere length, R-value. In addition, cook-loss and shear values were evaluated. Shear values were measured using the (TA.XT2i) Texture Analyzer (Texture Technologies Corp., Scarsdale, NY/Stable MicroSystems, Godalming, Surrey, UK). In the fillets deboned at 2 h PM, injection marination treatments (IMT and IM) decreased cook-loss. In the fillets deboned at 4 h PM, all marination treatments (M, MT, IMT and IM) lowered the cook-loss compared to other treatment groups. At 2 h PM, the injection marination treatments (IMT and IM) lowered shear values compared to shear values of other treatments and the 4 h PM control. Also, in fillets deboned at 4 h PM, the marination treatments (M, MT, IMT and IM) lowered shear values below the 4 h PM control. This study suggests that the use of marination and injection marination could be an effective means of alleviating toughness associated with deboning fillets as early as 2 h PM.

Key Words: Marination, Tenderness, Early Deboning

150 The correlation of razor blade shear, Allo-Kramer shear, Warner-Bratzler shear, and sensory tests to changes in tenderness of broiler breast fillets. L. C. Cavitt*¹, R. Xiong², J.-F. C. Meulenet², and C. M. Owens¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²Department of Food Science, University of Arkansas, Fayetteville.

This study was conducted in order to evaluate the efficacy of the razor blade shearing method and various other instrumental shearing methods (Allo-Kramer and Warner-Bratzler) as a means for developing models for predicting tenderness in broiler breast fillets. Breast fillets were deboned at various times postmortem (0.25 to 24 h) to yield a vast assortment of tenderness levels. Breast fillets were cooked to 76°C and subjected to either shear analysis or sensory analysis (trained or consumer). A trained descriptive panel was used to evaluate samples for attributes including initial hardness and chewdown hardness and a consumer panel for evaluation of attributes including overall acceptability and intensity of tenderness. Relationships between instrumental and descriptive sensory attributes exhibited correlations of $0.53 < R^2 < 0.73$ for initial hardness and chewdown hardness while correlations between instrumental and consumer sensory attributes of acceptability of tenderness and intensity of tenderness revealed coefficient of determination values ranging from $0.71 < R^2 < 0.97$. For both descriptive and consumer sensory analysis, razor blade, Warner-Bratzler, and Allo-Kramer shear tests performed similarly for predicting the tenderness of cooked broiler breast meat. When comparing all three instrumental shearing methods, the razor blade shear test is more advantageous in predicting tenderness as compared to the other instrumental methods due to the fact that no sample cutting or weighing is required in order to execute the test, nor is it excessively destructive as only a small incision (8.9 mm in width) is made in the sample. The razor blade shear test is also advantageous over the other testing methods in that results could be obtained two times as fast as opposed to the other testing methods with very similar or greater precision for predicting tenderness of cooked broiler breast meat.

152 Blood ketone levels of young postpartum range cows increased after supplementation ceased. R. L. Endecott*, C. M. Black, K. A. Notah, and M. K. Petersen, *New Mexico State University, Las Cruces.*

Young beef cows grazing dormant native range experience weight loss and nutrient imbalances postpartum. Due to high acetate production from ruminal fermentation and low metabolic glucose supply, ruminal acetate is cleared slowly and may be converted to β -hydroxybutyrate (β HB). As a chute-side measure of nutrient status, whole-blood β HB levels of two- and three-year-old postpartum range cows ($n = 45$) were measured with a handheld ketone sensor (MediSense/Abbott Laboratories, Abingdon, UK). Measurements were taken in May and July when cows were grazing dormant range. In May, cows were also receiving one of three 30% CP supplements containing increasing quantities of glucogenic precursors (57, 124, or 192 g/d glucogenic potential). For each ketone reading, β HB in the blood is oxidized to acetoacetate in the presence of hydroxybutyrate dehydrogenase with the concomitant reduction of NAD^+ to NADH. The NADH is reoxidized to NAD^+ by a redox mediator. The current generated is directly proportional to the β HB concentration. After 30 s, the β HB concentration (mmol/L) is displayed on the meter. Data were analyzed using physiological state, time of measurement and their interaction in the model. Cows had higher ($P < 0.01$) β HB in July than they did in May (0.34 vs 0.16 ± 0.02 mmol/L, respectively). Levels of β HB did not approach subclinical ketosis. However, the differences between the two measurements may suggest that the glucogenic precursors in the supplements may have improved utilization of acetate arising from ruminal fermentation. Cows were at an earlier stage of lactation (avg 53 d postpartum), presumably producing more milk, but gaining weight (0.11 ± 0.10 kg/d) in May, while in July were further along the lactation curve (avg 124 d postpartum) and producing less milk, but losing weight (-0.22 ± 0.10 kg/d). Protein sup-

151 Functional analysis of turkey breast muscle. M. S. Updike*¹, M. Lilburn², G. Kaletunc¹, H. Zerby¹, and M. Wick¹, ¹The Ohio State University, Columbus, ²The Ohio State University, Wooster.

Data from recent publications suggest that there is a decrease in turkey breast muscle functionality in further processing. This reduced functionality is hypothesized to be associated with changes in the salt soluble proteins extracted from the breast muscle prior to cooking. To test this hypothesis, salt soluble proteins were extracted from breast muscles obtained from three distinct turkey genotypes. These genetic lines were as follows: 1) the RBC2 line, representative of the 1960s era commercial turkeys; 2) F-line, a subline of RBC2 selected only for 16 week body weight; 3) C-line, representative of present day commercial turkeys selected for body weight and increased breast muscle yield. The rationale for using the three genotypes was to create an extremely variable genetic pool of muscle samples from which to correlate protein composition and functionality relationships. Myosin heavy chain concentrations in the salt soluble protein solutions, as determined by electrophoresis and image analysis, were not different among the genotypes ($P < 0.05$). Rheological analysis was conducted on thermally induced meat gels generated from all the breast muscles sampled ($n=5$ per line). There was a 50-fold difference in the storage modulus (G) between the highest and lowest values obtained from the final step of a programmed temperature ramp from 40°C to 80°C. Breast muscles from the RBC2 line had the highest gel strength at 131 Pa, followed by the F-line (89 Pa), and the C-line (54 Pa; $P=0.09$). A reverse stepwise linear regression analysis was used to associate staining intensities of bands obtained from a 1-D proteomic fingerprint of the salt soluble proteins with the rheological variability observed in the thermally induced meat gel strengths. This analysis showed that two bands were associated with the ultimate gel strength ($R^2 = 0.87$, $P < 0.01$). These findings are unique in showing that variations among the salt soluble proteins, other than myosin, affect the functionality of thermally induced meat gels. Further characterization of these bands will give further insight into the mechanisms underlying the functionality of turkey breast meat.

Key Words: Thermally Induced Meat Gel, Rheology, Proteomic Fingerprinting

plementation may have decreased β HB produced by improving acetate clearance due to a greater supply of glucogenic precursors.

153 Effect of step-up program during grain adaptation on ruminal pH and fermentation in feedlot cattle. D. W. Bevens*^{1,2}, K. S. Schwartzkopf-Genswein¹, T. A. McAllister¹, K. A. Beauchemin¹, and J. J. McKinnon², ¹Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, Canada, ²University of Saskatchewan, Saskatoon, SK, Canada.

Effects on ruminal parameters of rapid vs. gradual adaptation to a high concentrate feedlot diet were compared in a completely randomized study ($n = 6$) using 12 ruminally cannulated heifers (384 ± 25 kg BW). The heifers were housed individually and feed was delivered once daily for ad libitum consumption. Dietary transition from 40 to 90% concentrate was accomplished in 3 d using one step-up diet (rapid adaptation, RA) or in 15 d with five step-up diets (gradual adaptation, GA). The initial diet comprised 35% dry-rolled barley, 45% barley silage, 15% grass hay and 5% supplement (DM basis). These ingredients were used to formulate diets containing (DM basis) 48.3, 56.7, 65.0, 73.3, 81.7, and 90% concentrate. For treatment GA, each diet was fed for 3 d; for RA, only the 65% and 90% concentrate diets were fed. Ruminal pH was monitored continuously for 20 d via indwelling electrodes, and ruminal fluid was sampled 8 h after feeding on days of diet change. On days of change to 65 or 90% concentrate, treatment effects on minimum, maximum, or mean pH, or on the area of $pH \times$ time curves falling below 5.6 or below 6.2, were not observed ($P > 0.10$). Over the 3 d following introduction of 65% concentrate diets, the area of $pH < 5.6$ was greater ($P = 0.08$) with RA than with GA. No other effects ($P > 0.10$) of treatment on pH variables were observed during the 3 d of feeding 65% or 90% concentrate diets. Treatment did not affect ($P > 0.10$) total VFA concentrations or ruminal fluid osmolality, but in some samples, acetic

acid concentrations tended to be higher with RA than with GA. Acute acidosis (ruminal pH <5.2 for 10.1 h; 22.8 mM ruminal lactate 8 h after feeding) was observed in one RA heifer upon introduction of the 90% concentrate diet. In this study, recognized indicators of acidosis were only minimally increased by rapid step-up to a high grain diet. However, rapid adaptation to grain may cause acidosis in a small proportion of cattle.

Key Words: Acidosis, Barley, Volatile Fatty Acids

154 A comparison of whole animal energy expenditure by Angus, Holstein, and Wagyu heifers. K. A. Ross¹, C. T. Gaskins¹, J. J. Michal¹, D. H. Keisler², and K. A. Johnson^{*1}, ¹Washington State University, Pullman, ²University of Missouri, Columbia.

Angus, Holstein and Wagyu heifers (N=8/breed; 10 mo) were used to compare and evaluate variation in maintenance energy requirements (ME_m) among and within these breeds. Open-circuit, indirect respiration calorimetry chambers were used to determine heat production (HP) at 3 levels of intake balanced for 0.17 Mcal NEm/kg<.75> (HIGH), 0.13 Mcal NEm/kg<.75> (LOW), and fasting (FAST). A total collection digestion trial was used to determine the digestibility (DE) and metabolizability (ME) of the LOW diet that contained 24% rolled barley, 66% alfalfa hay, and 10% alfalfa haylage (DM-basis). Blood was collected and serum was harvested from heifers at HIGH and LOW intakes for leptin analysis. Assuming a semilog relationship between HP and ME intake (MEI), ME_m was determined by iteratively solving for the point where MEI equals HP. Heifers gained 0.78 ± 0.05 and 0.56 ± 0.04 kg/d when fed HIGH and LOW diets, respectively. The LOW diet contained 68% DE and 57% ME. Methane loss at the LOW intake averaged 7.5 ± 0.2 % of gross energy intake. Angus (113.5 kcal/kg<.75>) and Wagyu (105.2 kcal/kg<.75>) had lower (P<0.01) ME_m requirements than Holstein (137.1 kcal/kg<.75>). Retained energy (RE) was not different among breeds and averaged 61.4 ± 4.7 kcal/kg<.75> at HIGH and 36.7 ± 4.2 kcal/kg<.75> at LOW. Wagyu tended to have slightly higher RE (42.4 kcal/kg<.75>) at LOW intake. There was more variation in ME_m between breeds (72%) than within breed (28%). Serum leptin at HIGH averaged 7.3 ± 0.47 ng/ml and was not different between breeds. Leptin concentrations in Angus and Holstein heifers did not change when switched to the LOW diet, but serum leptin of Wagyu decreased to 3.1 ± 0.47 ng/ml, which was significantly lower (P<0.01) than the other breeds. Serum leptin concentrations were not correlated to ME_m or HP at any level of intake. Growing Wagyu heifers have energy requirements similar to those observed in Angus heifers of the same age.

Key Words: Wagyu, Maintenance Energy Requirements, Leptin

155 Effects of intravenous infusions of acetate, propionate, lactate, or glucose on lipogenic enzyme activity in bovine adipose tissue. J. D. Arseneau*, M. E. Spurlock, J. R. Townsend, L. A. Horstman, and R. P. Lemenager, *Purdue University, West Lafayette, IN.*

The objective of this study was to evaluate the differential effects of intravenous infusions of acetate, propionate, DL-lactate, or glucose on lipogenic enzyme activity in bovine subcutaneous (SQ) and intramuscular (IM) adipose tissue. Thirty Angus-sired intact heifers (576 ± 48 kg) were allotted to treatments by BW and ultrasound intramuscular fat percentage and intravenously infused for 48 h with either 1) 0.9% NaCl (CON), 2) acetate (ACE), 3) propionate (PROP), 4) DL-lactate (LAC), or 5) glucose (GLU). Heifers were fed a finishing diet formulated for 12% CP and 2.88 Mcal/kg ME. Heifers were fed twice daily and average daily ad libitum DMI was determined on d -5 to d -1. During infusion, CON heifers were fed at their previously determined ad libitum DMI levels. Heifers on the remaining treatments were fed at levels that provided 90% of daily ME from feed, while the remaining 10% of ME was provided by the appropriate infusion media. All heifers were infused at a rate of 150 ml/hr. Blood samples were collected prior to initiation of infusion and before each feeding. Immediately following exsanguination, SQ and IM adipose tissue were removed from the longissimus dorsi for determination of lipogenic enzyme activity. Heifers infused with GLU exhibited higher levels (P<0.05) of NADP-malate dehydrogenase (MDH) in IM compared to LAC (nmoles/minute/g adipose tissue). Activities of glucose-6-phosphate dehydrogenase (G6P), 6-phosphogluconate dehydrogenase (6PG), and acetyl-CoA carboxylase (ACC) in IM were not different (P>0.10) between treatments. Similarly, activities of MDH,

G6P, 6PG and ACC in SQ adipose tissue did not differ (P>0.10) between infusion treatments. During infusions, plasma glucose concentrations were numerically higher in GLU than CON, however, the difference was not significant (P>0.10). In summary, levels of acetate, propionate, lactate and glucose infused in this study were ineffective for enhancing IM or SQ lipogenic enzyme activity in market-ready cattle consuming a high concentrate finishing diet.

Key Words: Bovine, Adipose Tissue, Enzyme Activity

156 Effects of energy supply on methionine utilization by growing steers. G. F. Schroeder*, E. C. Titgemeyer, M. S. Awawdeh, and D. P. Gnad, *Kansas State University, Manhattan.*

We evaluated the effect of energy supply on methionine (Met) utilization in growing steers. Six ruminally cannulated Holstein steers (228 kg BW) were used in a 6 x 6 Latin square, housed in metabolism crates, and fed 2.8 kg DM/d of a diet based on soybean hulls (83%), wheat straw (7.6%), and cane molasses (4.1%). Treatments were abomasal infusion of two amounts of Met (0 or 3 g/d) and supplementation with three levels of energy (0, 1.3, and 2.6 Mcal ME/d) in a 2 x 3 factorial. The 1.3 Mcal/d treatment was supplied through ruminal infusion of 90 g/d acetate, 90 g/d propionate, and 30 g/d butyrate as well as abomasal infusion of 30 g/d glucose and 30 g/d fat. The 2.6 Mcal/d treatment supplied twice these amounts. Periods were 6 d with 2 d for adaptation and 4 d for sample collections. All steers received basal infusions of 400 g/d of acetate into the rumen and a mixture (125 g/d) of all essential amino acid except Met into the abomasum. No interactions between Met and energy level were observed. Nitrogen balance was increased (P<0.05) by Met supplementation from 23.6 to 27.8 g/d indicating that Met limited protein deposition. Nitrogen retention increased linearly (P<0.05) with energy from 23.6 to 27.6 g/d. Increased energy supply also linearly reduced (P<0.05) urinary N excretion from 44.6 to 39.7 g/d and plasma urea concentrations from 2.8 to 1.5 mM. Total tract OM and NDF digestibilities were reduced linearly (P<0.05) by energy supplementation from 78.2 and 78.7% to 74.3 and 74.5%, respectively. Whole body phenylalanine flux was not affected by treatment. Energy supply linearly increased (P<0.05) serum IGF-I from 694 to 818 ng/mL and quadratically increased serum insulin level (0.38, 0.47, and 0.42 ng/mL for 0, 1.3, and 2.6 Mcal/d, respectively). In growing steers, N retention was improved by energy supplementation even when Met limited protein deposition, suggesting that energy supply affects the efficiency of amino acid utilization. (Supported by NRI Competitive Grants Program/CSREES/USDA, Award No. 2003-35206-12837).

Key Words: Methionine, Energy Supply, N Retention

157 Evaluation of soybean hulls and protein sources of varying degradability on steer performance in feedlot receiving diets. C. J. Mueller*, R. H. Pritchard, and D. L. Boggs, *South Dakota State University, Brookings.*

A 52 d feedlot receiving study was used to evaluate the use of soybean hulls (SBH) in conjunction with protein sources of various degradability on gain performance and health status. Diets based upon oat silage (40%) were formulated for 11.75% CP. The control diet contained rolled corn and soybean meal (CO), while the test diets substituted SBH for corn and were supplemented with either soybean meal (SBM), dried corn gluten feed (DCGF) or dried distillers grains plus solubles (DDGS). All diets were predicted to have a negative degradable intake protein (DIP) balance. Performance was evaluated using 200 Angus steers (BW = 268 ± 2 kg) in a randomized complete block design utilizing orthogonal contrasts for treatment comparisons. Steers were blocked by previous origin and processed within 24 h of arrival. Steers within block were stratified by BW and randomly assigned to pen (8 to 11 steers). Pens (n = 5) were then assigned to dietary treatment. Intake was greater (P < 0.05) for SBM compared to CO during the initial 28 d (6.67 vs 6.29 kg) and overall (8.01 vs 7.58 kg), while ADG (1.53 ± 0.02 kg) and gain efficiency (195 ± 4 g gain/kg feed) were similar between the two treatments (P > 0.10). No differences were detected for intake, ADG or gain efficiency between SBM and corn co-products (DCGF and DDGS; P > 0.10). Steers fed the DDGS had greater ADG compared to DCGF during the initial 28 d (1.87 vs 1.69 kg; P < 0.05), but were not different after 52 d (1.52 vs 1.58 kg; P > 0.10). Intake and gain efficiency were similar between DDGS and DCGF during the initial 28 d and overall (P > 0.10). Morbidity and mortality were similar among treatments (11.1% and 0.5%, respectively; P > 0.10). This study indicates that

soybean hulls are a viable replacement for rolled corn in 40% roughage feedlot receiving diets. The use of corn co-products as a protein source with soybean hulls does not seem to limit performance, even though DIP balance varies among sources.

Key Words: Feedlot Steers, Receiving Diets, Co-Products

158 Effect of dietary crude and degradable protein concentration on feedlot performance, estimated nutrient excretion, and carcass characteristics. T. J. Biggs^{*1}, M. S. Brown^{1,2}, L. W. Greene^{2,1}, E. M. Cochran¹, E. A. Lauterbach¹, and J. R. Cortese¹, ¹West Texas A&M University, Canyon, ²Texas Agricultural Experiment Station, Amarillo.

Continued efforts are needed to refine dietary N needs to optimize feedlot cattle performance and promote environmental sustainability. Yearling steers (n = 315) were used to evaluate the effects of dietary CP and degradable protein on feedlot performance, nutrient excretion, and carcass characteristics. After adaptation to a 90% concentrate diet over 28 d, steers (375.5 ± 15.6 kg of BW) were fed one of three CP concentrations (11.5, 13, or 14.5% of DM) provided by one of three proportions of supplemental degraded intake protein (50, 75 or 100% of CP) in a 3 X 3 factorial (5 pens/treatment, 7 steers/pen) for 135 d. Urea and cottonseed meal were used in ratios of 100:0, 50:50, and 0:100, N basis. Diet CP and protein degradability did not interact (P > 0.15) for performance or carcass data. Steer ADG increased (P < 0.01) with diet CP (1.91, 2.03, and 2.23 ± 0.07 kg/d for 11.5, 13.0, and 14.5%, respectively), and gain:feed was improved as both diet CP and degradable protein increased (P < 0.07) from d 29 to 56 (immediately after reimplant). However, ADG tended (P = 0.14) to decrease as diet CP increased from d 85 to 112, and gain:feed increased as dietary CP decreased and as degradable protein increased (P < 0.09) from d 85 to 112. Thus, overall ADG, DMI, and gain:feed did not differ. Daily N and P retention, estimated by NRC equations, was not influenced (P > 0.10); steers retained 30.2 ± 0.5 g of N and 7.4 ± 0.1 g of P/d. Daily N excretion was not altered by degradability, but N excretion increased (P < 0.01) with dietary CP (143, 169, and 193 ± 5 g/d). Daily P excretion increased as CP increased and as degradability decreased (P < 0.01); P excretion ranged from 18 to 30 g/d. The number of low Choice or greater carcasses was reduced (Chi-square, P < 0.10) as dietary CP increased (64.1, 54.3, and 54.3), but other carcass attributes did not differ. Performance by yearling steers was not improved by a formulated CP above 11.5% or by altering the proportion of degradable protein, whereas carcass quality was enhanced by lower CP.

Key Words: Protein, Feedlot Performance, Nutrient Excretion

159 Oscillating protein concentrations of finishing beef cattle diets improves nitrogen retention by improving nitrogen digestibility. S. L. Archibeque^{*1}, H. C. Freely¹, N. A. Cole², and C. L. Ferrell¹, ¹USDA-ARS; U.S. Meat Animal Research Center, Clay Center, NE, ²USDA-ARS; Conservation and Production Research Laboratory, Bushland, TX.

We hypothesized that oscillating dietary CP concentrations would improve N efficiency and thus decrease overall N requirements and minimize contribution of nutrients to environmental systems. Eight Charolais-cross steers (358 kg BW) were used in a replicated 4x4 Latin Square design. The steers were allowed ad libitum access to the following finishing diets: 1) Low (Lo; 9.1% CP), 2) Med (11.8% CP), 3) High (Hi; 13.9% CP), or 4) Lo and Hi diets oscillated on a 48 h interval (Osc). Dry matter intake did not differ between treatments (P > 0.05), but N intake varied (P < 0.01) from 94 (Lo) to 131 (Med), 142 (Hi), and 133 g/d (Osc). Dry matter digestibility increased (P < 0.01) from 71.8 (Lo) to 75.8 (Med), 77.7 (Hi), and 77.5 % (Osc). Nitrogen digestibility increased (P < 0.01) from 62.2% (Lo) to 67.2 (Med), to 70.9 (Osc) and 70.1 (Hi). Nitrogen retention was greater (P < 0.01) in the steers fed the Osc diet (55.0 g/d) than either the steers fed the Lo (34.8 g/d) or Hi (40.2 g/d) diets. However, N retention of steers fed the Med diet (49.8 g/d) differed (P < 0.02) only from the steers fed the Lo diet. Urinary urea N was not different (P > 0.10) between steers fed either the Med (19.5 g/d) or Osc (21.3 g/d) diet. Similarly, urinary urea as a percentage of total urinary N did not differ (P > 0.10) between steers fed the Med (48.4) and Osc (51.5%) diets. Daily heat production tended (P < 0.09) to be less for the steers fed the Lo (177) diet than those fed the Med (189), Hi (188), or Osc (182 kcal/BW^{0.75}) diets. These data indicate that oscillating dietary protein will improve the N retention of finishing steers

compared to those in both excessive and deficient N states, while steers fed a similar daily concentration of dietary N in a static form only improved N retention compared to steers deficient in dietary N. Digestive mechanisms may play a greater role in this improvement in N retention than endogenous handling of nonprotein N.

Key Words: Heat Production, Oscillation, Metabolism

160 Prediction of ammonia release coupled to ammonia consumption. E. Venable^{*}, K. Ladyman, and M. Kerley, University of Missouri, Columbia.

Five dual-cannulated (rumen and duodenum) cross-bred beef steers were used in a 5x5 Latin square design experiment. The hypothesis of the experiment was that ammonia uptake by ruminal microbes could be estimated and that the estimated ammonia uptake could be coupled with ammonia release in the rumen. Diets were developed to fluctuate ammonia concentration in the rumen by using the degradation rates of rumen degradable protein (RDP). The objective of this experiment was to determine if the release rate of ammonia within the rumen could be managed to maintain an optimum level of ammonia concentration (2 mM) over a 12-hour period. Diet formulations were as follows: diet 1) 87% corn; diet 2) 85.5% corn, 1.25% SBM, 0.2% urea; diet 3) 84.1% corn, 2.5% SBM, 0.4% urea; diet 4) 82.7% corn, 3.75% SBM, 0.6% urea and diet 5) 81.3% corn, 5% SBM, 0.8% urea. All treatments contained 10% cottonseed hulls, 0.5% lime, 1.5% fat, and 1% vitamin and mineral mix. Diets 1 and 2 should be limiting in ammonia (< 2 mM) and diets 4 and 5 should have excess ammonia (> 2 mM). Diet 3 was expected to maintain an optimum ammonia concentration (2 mM). Samples were taken and analyses performed for volatile fatty acids (VFA), and ammonia. Additional samples were taken to measure both liquid and solid passage rate, total urinary nitrogen (N), and ruminal pH. Data were analyzed using PROC GLM of SAS. Total VFA production was greatest for diet 3 (P < 0.05). Acetate to propionate ratio was lowest for diet 5 (P < 0.05). Ammonia production increased with increasing levels of SBM and urea in the diet (P < 0.05). Ammonia concentration was optimized (2 mM) for diet 3 (P < 0.05) with diets 1 and 2 having lower (P < 0.05) and diets 4 and 5 having greater (P < 0.05) ammonia concentrations. These data illustrate that it is possible to use predictive equations relating protein degradability characteristics to ammonia release and consumption in the rumen. The potential to synchronize ammonia release to uptake in the rumen, thus lowering excessive ammonia production without reducing fermentative efficacy, would reduce N content of waste.

Key Words: Ammonia, RDP

161 Evaluation of RUP amino acid levels on lean tissue growth and carcass composition of beef steers fed a roughage-free diet. A. L. Mueller^{*}, W. H. Kolath, J. W. Golden, and M. S. Kerley, University of Missouri, Columbia.

Feeding RDP above what is needed for optimal microbial growth and efficiency results in inefficient use of CP for lean tissue growth. Previous research conducted in our laboratory demonstrated the potential of using RUP to optimize feed efficiency. Results from feeding levels of RUP above required predictions have not been studied. Therefore, we hypothesized that feeding a diet balanced in absorbable AA composition needed for lean tissue growth would maximize energy use for growth and that additional AA availability would not improve gain or efficiency. The objective of this study was to determine the optimum RUP AA level to maximize lean tissue growth of beef steers. Four diets contained increasing amounts of RUP and were fed to crossbred Angus steers in randomized complete block design. Treatment diets contained 70 % whole shelled corn and a pelleted supplement consisting primarily of blood meal (BM) and ground corn. The diets contained 6 (6BM), 9 (9BM), 12 (12BM), and 15 (15BM) % BM. The treatments were formulated to be isocaloric and contained different levels of CP and RUP AA. There were no differences in ADG (P > 0.05) among RUP treatments. The feed to gain ratio was highest for the 9BM and the lowest for the 6BM and 12BM treatments (P < 0.05). There were no difference in back fat and rib eye area among treatments (P > 0.05). Calves fed a roughage-free diet, but not optimized for AA flow had poorer feed conversion (P < 0.05). Using the NRC (2000), individual intakes and body weights were modeled for each diet. The lack of treatment effect on growth parameters in the presence of increased RUP AA was caused by energy limiting growth in all treatments and AA being supplied at

or above requirements. Using actual intakes the Mcal of NEg required for the observed gains were calculated to be within the NRC normal limits for lean tissue accretion. The 6BM treatment had similar gains and increases in carcass composition and a lower feed to gain than the

other treatments indicating it balanced the AA and energy for lean tissue growth. Supplying an AA profile that is balanced for growth relative to available energy, maximizes lean tissue growth and minimizes excess CP.

Ruminant Nutrition: Dairy - Minerals

162 Impact of minerals in water on ruminant production. J. G. Linn* and M. L. Raeth-Knight, *University of Minnesota, St. Paul.*

Water is an essential nutrient for all animals. In the consumption of water to meet this requirement, animals often consume significant amounts of various minerals. The effects of the minerals contained in water on animal performance or health are not well researched or documented with the exception of sulfates, salinity and nitrates. Most studies or reports relating water quality to animal performance and even EPA water guidelines have only considered the total mineral content of the water and not the chemical form and the availability of minerals from the water. It is well documented in the animal sciences literature that the chemical form of a mineral used in feed supplementation affects the availability of the mineral supplemented. In water, pH along with the chemical form of the mineral, affect the potential availability of the mineral from water. Magnesium for example is found as Mg^{+2} in most natural waters. When water pH is greater than 10, magnesium is usually combined with hydroxide to form MgOH. In water containing 1000 mg/L or more sulfate, significant amounts of Mg are combined with sulfate to form $MgSO_4$, whereas in waters low in sulfate, Mg complexes with bicarbonate or other anions. Routine water analysis only list total concentrations of minerals such as calcium, magnesium, chloride, sodium, sulfate, copper, iron, manganese and zinc along with pH. The chemical form or the availability of the mineral from water is not described. The objective of this presentation is to review what is known about the chemical forms of common minerals in water, the relationship between water pH and chemical form, the availability of minerals from water and ultimately relate this to requirements and potential affects on animal performance.

Key Words: Water Quality, Ruminant, Minerals

163 Quality water for dairy operations. K. Mancl*, *Ohio State University, Columbus.*

Water quality is determined from the beneficial use of the water. In dairy operations water is used both for cleaning equipment and drinking water for the animals. Each use has its own requirements. To ensure that water meets quality requirements, regular water testing is necessary. A good water test is not a waste of money. Annual water tests present a record of the water system that is critical to every dairy operation. If the water supply is damaged through human activity, evidence of a safe, adequate water supply is required to present an effective legal case.

If regular testing reveals a water quality problem, dairy operators have 4 options to solve it. 1. Improve water supply protection. 2. Find and eliminate sources of contamination. 3. Develop a new source of water. 4. Treat water to remove contaminants.

Key Words: Water Treatment, Water Testing

164 Effects of inorganic and organic (4-Plex^R) trace mineral supplementation on milk production and reproduction. J. D. Ferguson*¹, D. Tomlinson², and M. Socha², ¹*University of Pennsylvania, Kennett Square*, ²*Zinpro Corporation, Eden Prairie, MN.*

A total of 138 pregnant Holstein cows were blocked by parity, production and season of calving and randomly assigned within block to one of two dietary treatments: daily supplementation with 443 mg of Zn, 444 mg of Mn, 261 mg Cu, and 25 mg of Co as inorganic sulfates (control) or a combination of inorganic salts and complexed trace minerals (treatment, 14 g of 4-Plex/day; containing 360 mg Zn from zinc methionine,

200 mg Mn from manganese methionine, 125 mg Cu from copper lysine, and 25 mg Co from cobalt glucoheptonate). Diets were fed from -60 d from projected calving date through 250 d postcalving. Liver biopsy and claw examination were performed at -60 d, 30 d, and 250 d relative to calving. Serum was collected at 30 d postcalving for analysis of NEFA, cholesterol, betahydroxy butyrate, and total protein. Milk production was measured twice daily. Insemination and health events were recorded as they occurred. Milk composition for fat, protein, SNF, MUN and SMSCC was analyzed weekly from composite of consecutive a.m. and p.m. samples. Milk production and composition were analyzed with a repeated measures model, covariately adjusted for EPA and previous milk production, where appropriate, using the PROC MIXED procedure in SAS statistical software. Reproduction was analyzed using PROC LIFEREG. Milk production, milk fat and MUN were not significantly different between supplement groups. Milk protein was significantly different between supplement groups (control, 2.91 sem .01; treatment 2.95 sem .02, $p < .04$). First service conception rate was not different between the supplement groups (33% overall), however pregnancy occurred more rapidly in the treatment cows after first insemination (hazard .194 sem .119 $p < .10$). There was no effect of treatment on any health variables or cows culled for health problems. To more closely exam reproductive effects of the organic trace mineral supplementation, a large trial across several farms would be valuable.

Key Words: Trace Minerals, Production, Reproduction

165 Effects of inorganic and organic (4-Plex^R) trace mineral supplementation on claw lesions. J. D. Ferguson*¹, D. Tomlinson², and M. Socha², ¹*University of Pennsylvania, Kennett Square*, ²*Zinpro Corporation, Eden Prairie, MN.*

A total of 138 pregnant Holstein cows were blocked by parity, production and season of calving and randomly assigned to one of two dietary treatments: daily supplementation with 443 mg of Zn, 444 mg of Mn, 261 mg Cu, and 25 mg of Co as inorganic sulfates (control) or a combination of inorganic salts and complexed trace minerals (treatment, 14 g of 4-Plex/day; containing 360 mg Zn from zinc methionine, 200 mg Mn from manganese methionine, 125 mg Cu from copper lysine, and 25 mg Co from cobalt glucoheptonate). Diets were fed from -60 d from projected calving date through 250 d postcalving. Cows were housed in a free stall barn with concrete alleys. Examination of claws and surrounding soft tissues was made by a trained clinician at -60 d, 30 d, and 250 d relative to calving. Cows were confined into a restraining stall for examination. Feet were washed and hoof detritus removed with a knife blade. Lesions were classified according to Toussaint (R.E. Toussaint, 1989) based on macroscopic examination of hoof and tissues. All feet were examined by one trained veterinarian throughout the study. Keratinous lesions were classified as follows: dorsal wall ridges, erosion of the heel bulb, abaxial wall lesions, double soling, white line separation, sole abscess, sole hemorrhage, sole ulceration or sole erosion. Lesions of the surrounding soft tissue were classified as follows: digital dermatitis, pododermatitis of the digit or interdigital area, interdigital fibroma, or hairy heel wart. Lesions were mapped for location on the claw and surrounding soft tissues and graded as to severity (.5, 1, 1.5, 2, 2.5, 3, .5 being mild and 3 being the most severe). A repeated measures, multinomial model was used to examine hoof lesions using PROC GENMOD in SAS statistical software. A total of 3160 claw examinations were made. Heel erosions were the most frequent claw lesion across all treatments and time periods. Supplementation with organic trace minerals was associated with a reduction in solar lesions at 30 d postcalving. By 250 d postcalving lesions were not different.

166 Effect of exogenous phytase on phosphorus digestibility in dairy cows and calves. D. Garikipati and R. Kincaid*, *Washington State University, Pullman.*

Two digestibility studies were conducted to determine if exogenous phytase improved phosphorus (P) digestibility in cattle fed diets containing barley. The first study evaluated exogenous dietary phytase on P digestibility in growing calves. Dietary treatments were: 0.37% P + no phytase; 0.37% P + 225 FTU/kg; 0.37% P + 450 FTU/kg; and 0.48% P + no phytase. Calves were fed the treatment diets from 6 to 12 wk of age. The diets contained an average of 0.86 mg phytate P/g of DM, i.e., about 23% of the dietary P was as phytate P. Growth rate (1.0 kg/d) and feed intake (1.2 kg/d) were not affected by dietary treatment. Plasma inorganic P (Pi) and the % P in the feces were increased ($P < 0.05$) by the high P diet but not by the exogenous phytase. Phosphorus digestibility, based upon lignin as an internal marker, was 81% in the calves and tended ($P = 0.1$) to be improved by exogenous phytase. The feces contained an average of 0.14 mg phytate P/g of DM and was not affected by exogenous phytase. In a second study, 16 lactating Holstein cows were arranged in 4 replicates of a Latin square with two grains (barley and corn), no or added exogenous phytase (427 FTU/kg TMR), and 4 periods of 21-d. Phytate P comprised about 50% of the total P (0.46%) in the TMR. Plasma Pi was higher ($P < 0.05$) in cows fed diets with exogenous phytase (5.7 vs 6.3 mg/dL). Using lignin as an internal marker, digestibility of phytate P (79.4% vs 85.3%) was increased ($P < 0.05$) by exogenous phytase. Although considerable phytase activity occurs in the rumen, physical properties of the diet and ruminal passage rates may prevent total hydrolysis of phytate. Whereas in young calves, exogenous phytase had little effect on P digestibility, exogenous phytase appears to increase absorption of P from dietary phytates in lactating cows.

Key Words: Phosphorus, Phytase, Cattle

167 Tissue selenium content and whole-blood glutathione peroxidase activity of lactating cows are increased by two organic forms of dietary selenium. M. R. Waldron*¹, T. L. Ward², M. T. Socha², and T. R. Overton¹, ¹*Cornell University, Ithaca, NY*, ²*Zinpro Corporation, Eden Prairie, MN.*

Forty lactating Holstein cows (90-170 DIM) were fed one of two organic forms of added dietary selenium (Se), an inorganic form, or placebo as a daily topdress to determine the effects of Se source on tissue selenium content and whole blood glutathione peroxidase (GPX) activity. All cows were fed a total mixed diet devoid of added Se. Following an initial 8-week depletion period, daily rations were topdressed with 7.5 mg of N-succinyl-L-selenomethionine (SSM; n=9), 7.5 mg of zinc-L-selenomethionine (ZSM; n=10), 7.5 mg of sodium selenite (NaSe; n=10), or 0 mg of added Se (CTL; n=10) in 25 g of sugar carrier. Treatments were continued for 8 wk and were then followed by a second four-week depletion period. Of the timepoints sampled, maximal tissue Se content occurred after 8 wk of supplementation; however, maximal whole blood GPX activity occurred 12 wk after the initiation of treatments, perhaps reflecting the time necessary for red blood cell turnover. Tissue Se content was increased by NaSe relative to CTL; however, both SSM and ZSM increased tissue Se content to a greater extent than NaSe. Whole blood GPX activity was increased by Se supplementation but was not different between NaSe, SSM, or ZSM. These results indicate that the SSM and ZSM forms of organic selenium have greater bioavailability and are thereby retained in tissues at higher concentrations than NaSe.

Tissue	CTL	NaSe	SSM	ZSM	SEM
Liver (ng/g dry wt)	660 ^a	1185 ^b	1709 ^c	1647 ^d	96
Plasma Se (ng/ml)	28.9 ^a	56.8 ^b	65.9 ^c	64.3 ^c	3.5
Whole blood Se (ng/ml)	92.6 ^a	119.1 ^b	137.1 ^c	139.6 ^c	5.6

168 Effects of molasses- versus corn-based supplements on the accumulation of selenium. J. D. Arthington* and F. M. Pate, *Range Cattle Research and Education Center, University of Florida, Ona.*

Results from previous studies indicate that the S component of molasses interferes with Cu accumulation into the liver of cattle. Selenium can also combine with S to form insoluble complexes. Therefore, the objective of this study was to investigate the accumulation of Se into the liver of growing steers provided molasses- or corn-based supplements. Twenty-four crossbred (Brahman x British) steers were stratified by BW and randomly assigned to individual pens (two steers/pen). Two supplemental treatments (6 pens/treatment) were formulated using corn and cottonseed meal or molasses and cottonseed meal. Each supplement was formulated to provide 1.5 kg of TDN and 0.3 kg of CP/hd. Supplemental Se (sodium selenite) was provided at a rate of 3.0 mg/hd daily. Supplements were fed 3 times weekly. To assess the effect of supplement composition on steer performance and Se status, individual steer weights, jugular blood, and liver biopsy samples were collected on d 0, 30, 60, and 90. Although intake of TDN did not differ among treatments, steers fed corn-based supplements tended ($P = 0.07$) to have a higher ADG compared to steers fed molasses-based supplements (0.10 and 0.24 kg/d for molasses- and corn-based supplements, respectively; SEM = 0.05). There was a significant ($P < 0.01$) sampling day x supplement source interaction for liver Se concentration. Steers fed molasses-based supplements had greater initial liver Se concentrations than steers fed corn-based supplements ($P = 0.02$). However, steers fed corn-based supplements had a greater overall increase in liver Se accumulation resulting in greater ($P < 0.01$) final liver Se concentrations vs molasses supplemented steers on d 90 (1.47 and 0.50 ppm; SEM = 0.18). There was no sampling day x supplement source interaction for plasma Se concentration or plasma glutathione peroxidase enzyme activity. These data suggest that components within molasses, namely S, inhibit the accumulation of Se into the liver of growing beef cattle.

Key Words: Selenium, Molasses, Corn

169 Manganese for lactating and dry dairy cows. W. P. Weiss*¹ and M. T. Socha², ¹*Ohio State University, Wooster*, ²*Zinpro Corporation, Eden Prairie, MN.*

The Mn requirement for lactating and dry dairy cows are 50 to 70% lower in NRC (2001) compared with the 1989 version. A Mn balance study (Exp. 1) was conducted using 18 dry Holstein cows to determine the intake of Mn needed to prevent body loss of Mn. These data were combined with a large data set (143 observations) in which Mn balance was measured using lactating (average milk yield = 30 kg/d) dairy cows (Exp. 2). In Exp. 1, dry Holstein cows were fed a standard diet (47 ppm Mn) starting at dry-off (approximately 60 d before parturition) and either given no supplemental Mn, or a daily bolus that provided 200 mg of Mn in the form of Mn sulfate or Mn methionine (Zinpro Corp., Eden Prairie MN). After approximately 30 d of receiving the treatments cows were moved to metabolism stalls for total collection of feces and urine for 4 d. Dry matter intake was not affected by treatment (11.8 kg/d). Intake of Mn for cows on the control, Mn sulfate, and Mn-met treatments were 471, 707, and 646 mg/d (control < supplemented; $P < 0.01$). Apparent digestibility of Mn (-2.6, 4.7, and 5.2% for control, Mn sulfate and Mn-met) was not different between supplemented groups but was higher ($P < 0.02$) for the supplemented groups than for the control group. Urinary excretion of Mn was not affected by treatment and was extremely low (< 0.5 mg/d). Apparent retention of Mn (-9.5, 20.2, and 24.5 mg/d for control, Mn sulfate, and Mn-met) was not affected by the form of supplemental Mn but was increased ($P < 0.06$) by Mn supplementation. When intake of Mn was regressed on Mn retention, tissue retention was 0 when the diet contained approximately 50 ppm Mn (approximately twice as high as the NRC requirement for dry cows). In Exp 2. Mn balance data measured in lactating dairy cows were regressed using Mixed Models procedures with trial included as a random variable to determine the average intake of Mn required to obtain 0 tissue retention. The resulting equation was: Mn balance (mg/d) = -190 + 0.29*Mn Intake (mg/d). Based on that equation an intake of 655 mg of Mn/d was required for 0 retention. That value corresponds to an average dietary concentration of 31 ppm of Mn which is approximately twice as high as the NRC recommendation for lactating cows.

Key Words: Manganese, Mineral, Requirement

170 Effect of glutamine supplementation on immune responsiveness and milk production in dairy cattle. L. Doepel¹, N. Gagnon¹, M. Lessard¹, G. E. Lobley², J. F. Bernier³, and H. Lapierre¹, ¹AAC Dairy and Swine R & D Center, Lennoxville, QC, Canada, ²Rowett Research Institute, Aberdeen, UK, ³Université Laval, QC, Canada.

Sixteen multiparous Holstein cows were used to determine the effect of glutamine (Gln) on immune responsiveness and milk production during the immediate postpartum period, when there are competing demands from the gut, mammary gland, and immune system. Cows received abomasal infusions of either 300 g/d Gln delivered in 10 L of water (8 cows) or water alone (8 cows) for 21 d following calving. During d14-21, treatments did not affect milk yield (39.3 vs. 40.5 kg, P = 0.66), protein content (2.99 vs. 2.98%, P = 0.87) or fat content (3.92 vs. 3.73%, P = 0.46), for water and Gln, respectively. Peripheral blood mononuclear cells (PBMC) were isolated from blood collected by jugular venipuncture on d -25, 4, 11, and 18 relative to calving. Interferon- γ concentrations, the lymphocyte proliferative response to concanavalin A (0.5 μ g/ml), and cell subpopulations were determined on the PBMC. Leukocyte counts and differential analysis were also performed on these days plus on d -12, -3 and 1 relative to calving. Interferon- γ concentration did not change over time (P=0.35). Lymphocyte proliferation was not affected by treatment (0.84 vs. 0.71 for water and Gln, respectively; P = 0.38), or by time (P = 0.44). There was a tendency (P=0.09) for a treat*time interaction for the CD4 population, due to a reduction at

d4 for the water treatment compared to d 11 and 18, while there was no change for Gln treatment. Leukocyte and neutrophil counts changed over time (P < 0.001), with the counts being higher on d1 than during the treatment period. The data from this study suggest that Gln supplementation does not improve the immune status of postpartum dairy cows.

Breeding and Genetics: Genetics of Efficient Feed Utilization

171 Mechanisms regulating feed intake: role of appetite-regulating peptides. M. G. Thomas* and K. L. Shirley, *New Mexico State University, Las Cruces.*

Feed intake, or appetite, is a multifaceted physiological event. Regulation of feed intake can be attributed to, or modulated by, energy expenditure, the interaction of diet with the digestive system, and (or) central mechanisms influenced by flux of neurotransmitters and neuropeptides. The latter directs discussion towards the basal hypothalamus as a focal point by which the brain receives input of the body's metabolic state and interprets this information for appetite and modulation of other systems such as growth, reproduction, or lactation. Discovery and research of gut and appetite-regulating peptides has been increasing for almost a century. In the last decade, considerable emphasis has been placed on hormones derived from adipose tissue, such as leptin and adiponectin. Leptin is a physiologic antagonist to a potent orexigenic brain peptide, neuropeptide Y (NPY). The leptin receptor is co-localized with NPY on neurons within the ventro-medial hypothalamus of the ruminant. Intracerebroventricular (ICV) infusion of NPY stimulates appetite and infusion of leptin suppresses appetite. Suppression of appetite has also been observed with central infusion of insulin. These types of studies were effective for evaluating neuro-regulation of appetite; however, they may only explain gross effects of these neuropeptides on appetite, as concomitant to ICV infusion studies, increases in serum concentrations of leptin parallel increases in daily feed intake level and body weight in growing animals. Thus, fine control of appetite may be more related to gene regulation or receptor binding affinity for factors such as NPY and leptin. For example, as ruminants age and fatten, leptin receptor expression levels appear dynamic within the hypothalamus and pituitary. Development of marker assisted selection programs are challenging, especially for polygenic traits such as level of feed intake or residual feed intake. Further understanding of the influences of environmental and intrinsic factors are needed to narrow this search for candidate genes. Physiologic knowledge of signals of adiposity, neuropeptides, and their receptors could aid this process.

Key Words: Appetite, Neuropeptide Y, Leptin

172 Genetic variation in feed utilization: selection responses in mice. M. K. Nielsen*, *University of Nebraska, Lincoln.*

Selection for high (MH) or low (ML) heat loss per unit size (kcal/kg^{0.75}/d), measured in direct calorimeters, and no selection (MC), have been practiced in mouse lines as a proxy measure for feed energy requirement for maintenance. Selection was only in males. All selection lines were present in 3 independent replications making a total of 9 lines.

Selection ceased after 16 generations. All 9 lines were maintained without intentional selection for 26 generations. Selection recently resumed and is practiced again for the same criterion (high or low or no selection) in each of the lines. During the original selection, realized heritability of heat loss was 0.28. After initial selection, feed intake was 9% greater in MH and 11% less in ML, both as compared to MC. After re-initiating selection, feed intake is 7% greater in MH and 15% less in ML, both as compared to MC. Differences in heat loss and feed intake persist through very mature ages. No difference in longevity has been detected. Genetic correlations with heat loss, and probably maintenance energy requirement, are: positive with ovulation rate and locomotor activity, negative with body fatness. Locomotor activity of MH mice was twice that of ML, and MC mice were intermediate. Locomotor activity differences explained 36% of the differences in maintenance feed intake between lines. When reared in hot or cold environments, there was no line x environment interaction for feed intake, body weight or fatness. MH mice had reduced litter size in the cold, but performance of ML mice relative to MC did not interact with environment. ML mice are adaptable to chronic stressors, but MH mice are not, as measured by serum corticosterone level. Estimates of energy costs per unit of gain (total, or fat and non-fat) do not appear to be different between the lines. Thus, genetic variation in feed intake, after accounting for possible differences in rate and composition of gain, appear to be mostly if not totally explained by differences in maintenance energy costs per unit size. Selection to reduce energy for maintenance was successful; non-desirable responses were a reduction in ovulation rate and an increase in body fatness.

Key Words: Selection, Feed Intake, Mice

173 Genetic evaluation of efficient feed utilization in beef cattle. D. H. Crews, Jr.*, *Agriculture and Agri-Food Canada Research Centre, Lethbridge, Alberta, Canada.*

The wide range of traits for which most beef breed associations predict EPD focus on increasing the outputs of the production system, thereby increasing the genetic potential of cattle for reproductive rates, weights, growth rates, and end product yield. Feed costs represent a large proportion of the variable cost of beef production and genetic improvement programs for reducing input costs will likely include traits related to feed utilization. Feed conversion ratio, defined as feed inputs per unit output, is a traditional measure of efficiency that has significant phenotypic and genetic correlation with feed intake, growth rate, and mature size. One limitation is that favorable decreases in feed to gain as correlated response to increased growth rate does not necessarily relate to specific improvement in efficiency. Residual feed intake is defined as the difference between actual feed intake and that predicted on the basis of requirements for maintenance of body weight and production. Phenotypic

independence of residual feed intake with growth rate, body weight, and other energy depots can be forced, however, genetic associations may remain when phenotypic regression is used. Heritability estimates for phenotypic residual feed intake have been moderate, ranging from 0.26 to 0.43. Genetic correlations of phenotypic residual feed intake with feed intake have been highly positive, suggesting that improvement would produce the correlated response of decreasing feed intake. Residual feed intake estimated by genetic regression results in zero genetic correlation with its predictors thus alleviating concerns over long term antagonistic response in increased mature size and maintenance requirements. The genetic regression approach requires knowledge of genetic covariances of feed intake with growth rate and weight. Cost of individual feed intake measurement on potential replacements will be a consideration for implementation of national cattle evaluations for efficiency of feed utilization. These costs must be compared to expected and, if possible, realized rates of genetic progress and associated reductions in feed input requirements.

Key Words: Genetic Evaluation, Beef Cattle, Feed Efficiency

174 Realities of measuring feed intake on individual pigs to genetically improve feed efficiency. D. S. Casey*¹ and P. W. Knap², ¹*Pig Improvement Company, Franklin, KY*, ²*Pig Improvement Company, Germany*.

Feed efficiency is an important economic trait to the swine industry. Most improvement has been made indirectly by selecting on lean growth rate, but can also be improved by selecting for growth when feed intake is restricted. Neither of these methods involves measuring feed intake on the pig, but if done would result in a direct measurement of feed efficiency. The objective of this review was to discuss issues involved in measuring feed intake on individual pigs. Feed intake can be obtained by penning pigs individually, but pigs in this situation tend to eat more, grow faster, and are fatter than pigs housed in groups. To avoid this genotype x housing system interaction, electronic feeders were developed to measure individual feed intake on group-housed pigs. These feeders are single-spaced and offer some protection from competition, whereas conventional feeders offer no protection. These feeder differences did not affect performance of boars, but gilts on electronic feeders ate less, grew slower, and deposited less backfat and loin muscle area. Data from electronic feeders have also been found to contain substantial amounts of errors that require editing. Different editing methods have been shown to affect the accuracy of feed intake estimates, which in turn affect heritability estimates. Operating these feeders takes time and requires highly trained personnel. They are also costly, which usually limits the number of pigs that can be evaluated. Testing strategies can be adapted to increase the number of pigs measured during a test period with minimal impact on accurately estimating feed intake. This

Combined Animal, Dairy, and Poultry Extension Workshop

176 Development of model biosecurity programs. J. Shutske*, *University of Minnesota, St. Paul*.

Bio- and agricultural security programs designed to protect animal health and minimize risk often contain components such as facility access control, personal hygiene, sanitation, and animal quarantine/isolation protocols. Biosecurity protocols are often implemented using checklists that guide the user in the process of evaluating current practices and environmental/equipment conditions. These checklists provide a basis for continuous improvement. We have learned in other areas of risk control that the most effective measures to reduce risk/loss involve efforts to eliminate potential hazards through equipment and system-level design rather than heavy reliance on human action and behaviors which can be highly variable and subject to competing motivations. This becomes increasingly important as animal agriculture becomes more reliant on a labor force that may include individuals with limited knowledge of animal production, animal health, or even a basic understanding of personal health behaviors and practices. Workers themselves may, in fact, be the most crucial link within a successful production security program. Being on the front lines of an operation, workers are in the best position to monitor environmental conditions, observe changes in animal health, suggest improvements, and provide an ongoing evaluation of an operation's biosecurity program. Other industries have recognized and embraced the role of the workforce in implementing quality control and improvement. Workers are also the ones who will have the first expo-

sure to hazardous biological and chemical agents that could impact an operation. Thus, an effective biosecurity program should also have some means of monitoring and protecting worker health. Based on the few events in the U.S. where there have been intentional breaches of security within the food system, it is also clear that those in the labor force could also be involved in facilitating (or preventing) an event whether intentionally or otherwise. So, biosecurity programs, educational materials, and checklists created in the future should encourage producers to engineer out potential hazards and should holistically consider the role of workers in implementing and providing continuous evaluation of biosecurity programs.

Key Words: Swine, Feed Efficiency, Feed Intake

175 Methods of editing errors in data from electronic swine feeders impact heritability estimates of average daily feed intake. D. S. Casey* and L. Wang, *Pig Improvement Company, Franklin, KY*.

Methods of editing errors in data from electronic swine feeders affect accuracy of estimating average daily feed intake (ADFI), which will impact genetic improvement of feed efficiency. The objective of this study was to measure the effect of two editing methods on heritability estimates of ADFI. FIRE[®] electronic feeders were used to measure feed intake for 7,106 boars from approximately 73 to 163 d of age. Feed intake data were edited using two methods (EM1, EM2). For EM1, errors were identified in daily feed intake (DFI), occupation time per day, and mean DFI for a pen. Corresponding DFI records were replaced with a missing value. Data for a pig were discarded if the percentage of missing DFI was >75. DFI records were regressed on test day for each pig using a 4th order polynomial. Estimates of DFI from this model were used to calculate ADFI. Unreasonable values for ADFI from individuals and off-test groups were discarded. For EM2, 16 criteria were used to identify errors in visits. A linear model was used to adjust error-free DFI for the effect of errors. Unreasonable values of DFI were replaced with a missing value. Data for a pig were discarded if the percentage of missing DFI was >85. Adjusted DFI were regressed on test day for pigs in an off-test group using a random regression model that included a 3rd order polynomial for the fixed curve for each line (n=10) and a 1st order polynomial for the random curve for each pig. Missing values of DFI were replaced with estimates from this model. A sire model was fit to ADFI from the two editing methods. The model included on-test weight x line, herd-line-year-season, and herd-off-test group. After editing there were 6,197 (87.2%) and 6,861 (96.6%) pigs with an estimate of ADFI from EM1 and EM2. Mean ADFI for EM2 was 51 g/d larger and the standard deviation was 29 g/d smaller. Heritability estimates were .18 and .27 for EM1 and EM2 and the phenotypic correlation was .88. Methods of editing errors in data from electronic swine feeders impact estimates of heritability thus affecting genetic improvement of feed efficiency.

Key Words: Feed Intake, Editing Methods, Heritability

177 Catastrophic Composting: Is it safe and effective? J. M. DeRouchey*, J. P. Harner, and J. P. Murphy, *Kansas State University, Manhattan*.

Key Words: Biosecurity, Engineering, Labor

Composting of animal mortalities has increased in popularity in recent years due to decreased availability and increased costs associated with the traditional animal rendering industry. However, with increasing foreign animal disease and transmission concerns, composting has received considerable more attention as a potential method for mass mortality disposal. Limited research has shown composting can reduce pathogens

and parasites up to 99.99% when heated to 55°C for 3 consecutive days, such as *E. coli* and *Salmonellae*. Also, composting has been shown to effectively eliminate the highly pathogenic avian influenza virus after 10 d of composting and tissues from chickens infected with egg drop syndrome-76 virus after 20 d. However, little other data is available on effectiveness on other animal diseases. A number of challenges are present that operators must overcome properly compost large masses of diseased mortality animals. First, in areas of large animal density, there may be a lack of adequate carbon sources (straw, hay, silage, sawdust, etc.) to adequately cover and compost mortalities. Composting sites need proper drainage and collection areas, security from predators and setback distances to not jeopardize public health if the disease is transferable. Water addition for maintaining the compost with adequate moisture (50-60%) is imperative. For large carcasses turning the piles may be necessary to thoroughly degrade tissue and bones. However, this may expose transmittable pathogens to the air during turning if they had not been properly heated for the desired treatment time. All activities with composting will require human activity, which may have direct health concerns if the disease is highly contagious and proper handling procedures are not followed. Composting mass mortalities may be effective in certain instances. However, numerous challenges will prevent its widespread use in catastrophic mortality events.

Key Words: Composting, Mortality, Livestock

178 What are extension's roles in the early detection of agro-terrorism events? R. M. Smith*, *USDA, CSREES, Washington, DC.*

The early detection of an agro-terrorism event is essential to help contain the damage and to decrease any adverse economic impact. Across the United States extension will be expected to play an important role in early detection through the development and implementation of training and educational programs. The dissemination of accurate and timely information by extension agents to people working within the agricultural sector will enhance our nation's ability to rapidly and accurately detect an intentional agro-terrorism event. Extension personnel will be integrated into the National Animal and Plant Diagnostic Laboratory Network system as it matures. Their involvement with these networks will help to ensure a more rapid submission of suspected plant and animal samples to these state and university diagnostic laboratories. This presentation will review a few of the current or proposed national initiatives to support the role of extension personnel in the early detection of agro-terrorism events.

Key Words: Extension, Diagnostics, Agro-terrorism

179 Use of antibiotics and alternatives in the animal industries: What is extension's role? R. B. Phillips*, *Animal Health Institute, Washington, DC.*

The use of antibiotics to keep food animals healthy is a continuing source of controversy despite several lines of evidence that producers and the public benefit from the practice and that these benefits outweigh the very small risk of antibiotic resistance transfer via the food chain. Recent reductions in the use of antibiotics can be attributed to several factors, including the observation of judicious use principles and increased management. Confinement and increased biosecurity, while derived by some as factory farming, has several benefits including disease prevention. The search for other alternatives to antibiotics is limited by research funding and a lack of flexibility in the regulatory approval process. Extension can assist producers in evaluating the benefits of antibiotics, the alternatives, and by helping them implement judicious use principles.

Key Words: Antibiotics, Judicious Use

180 Country of origin labeling: update and path forward. J. D. Lawrence*, *Iowa State University, Ames.*

Country of Origin Labeling was part of the 2002 Farm Bill and was scheduled to become mandatory September 30, 2004. The House and Senate voted to delay it for 2 years. While debate rages over how it should be implemented by both opponents and proponents, producers, markets, and processors remain confused about what to do and where to start. Parallel to COOL is movement toward a national animal identification system. National ID is not COOL, but it will make COOL

more practical to implement. Extension has a significant role in helping producers understand what is required under both programs, how they differ, and the motivation behind them.

Key Words: COOL, National ID, USAIP

181 Opportunities for extension professionals in international education. J. P. Blake*, *Auburn University, Auburn, AL.*

There are numerous opportunities for international colleagues bound by a common thread to share in the exchange of information. Numerous organizations support agricultural based projects overseas, with a major source of funding originating from U.S. Agency for International Development (USAID) via the US Farm Bill. Partner organizations that share in this funding through the Farmer-to-Farmer program include: ACIDI/VOCA (Agricultural Cooperative Development International and Volunteers in Overseas Cooperative Assistance), Citizen's Network for Foreign Affairs, Land O'Lakes, Inc., Partners of the Americas, and Winrock International. These programs rely on the expertise of volunteers from U.S. farms, land grant universities, cooperatives, private agribusiness' and nonprofit farm organizations to provide assistance to individual farm enterprises, cooperatives, farmer's associations, agribusiness', rural credit institutions, universities, and agricultural youth groups overseas. Commodity groups such as the American Soybean Association (ASA) and U.S. Grains Council (USGC) also recruit experts that are involved with technical programs that teach livestock and poultry producers how to use feed grains effectively and manage operations efficiently. The Fulbright Scholar Program administered by the Council for International Exchange of Scholars (CIES) offers opportunities for international educational exchange. Fulbright grants are awarded to U.S. citizens and nationals of other countries for a variety of educational activities which may include, university lecturing, advanced research, graduate study, and teaching in elementary and secondary schools. The primary mission of extension is to "take the university to the people". Whether the scope is local, regional, national, or international, the essence of extension supports key projects, which may include the building of partnerships, improvement of business practices, increasing productivity and profitability, and introducing new technologies. In addition, opportunities for scientific exchange contribute to an increased understanding of history, culture, politics, and social structure.

Key Words: International, Extension, Fulbright

182 Cultural issues in processing plants and on farms. W. V. Jamison*, *Dordt College, Sioux Center, IA.*

Latino immigration is prominent in the US poultry industry and carries with it profound cultural manifestations. It is a result of increasing globalization which is defined as the flow of labor and capital across market concentration gradients, e.g. either the money goes to where the poor are or the poor come to where the money is. Anecdotal evidence and LIUNA estimates indicate that over 50% of workers in many plants and 10% of farm labor are now Latino. Immigration will continue to define human resource management in the poultry industry, and the proposed blanket amnesty and worker permit program will exacerbate immigration trends. Also, the influx of Latinos will provide a ready labor supply that both artificially suppresses wages and antagonizes native residents. While Huntington argues that Latinos are poorly assimilated and increasingly strident in rebuffing enculturation in favor of aggressive Latino identity, Brooks argues that assimilation can and will occur as American culture adapts to and compromises with Latino immigrants. However, both views are incomplete. More accurately, Bohon argues that assimilation will be episodic and dependent on ethnicity, regional social factors, and the existence of successful Americanized kinship networks. These findings imply that immigrant labor is successfully suppressing wages while subtly reshaping American culture. In processing plants, cultural, ethnic and religious conflicts between Anglos and Latinos, as well as Latinos and other racial and ethnic groups, will continue to intensify. In poultry processing regions increasing immigration will strain social and economic infrastructures, and the development of a permanent ethnic underclass entrenched in barrios is indicated. Finally, on-farm day labor will pose an increasing biosecurity risk as a

largely invisible labor force transits from farm to farm unrestricted by biosecurity protocol.

Key Words: Latino, Immigration, Assimilation

183 Extension's role in conflict resolution and consumer education. M. M. Schutz* and J. S. Ayres, *Purdue University, West Lafayette, IN.*

The role of extension dairy, poultry, and livestock educators is evolving rapidly; and to be relevant, we must continue to provide science-based information to an ever-broadening clientele. Campus-based specialists have remained insulated from this shifting paradigm longer than field-based staff that often facilitate disputes involving agriculture. Examples of conflicts involving animal agriculture include disagreements over manure or odor regulations, animal welfare, animal cloning, and food safety (for example sales of raw milk). The situational framework of Heifetz and Sinder describes three situations that illustrate the shifting paradigm faced by extension specialists. In the first situation, both a problem and a solution are clear, which characterizes the traditional role

of extension specialists as experts in a particular field. The second situation, where a problem is clear but a solution is not; is familiar ground for those of us trained as scientists. But the third situation, where both the problem and solution are unclear, will become more common as we tackle the larger societal issues facing animal agriculture. In 1988, Carpenter and Kennedy put forth the concept of a spiral of unmanaged conflict. Initially, the problem arises, sides form, and positions harden. But as the conflict spirals out of control, communication stops, resources are committed, conflict spills outside the community, perceptions become distorted, and a sense of crisis emerges. As livestock, dairy, or poultry extension specialists, our best opportunity is to be involved and to provide science-based solutions or alternatives before the conflict begins to spiral out of control. Once communication stops, even science-based information may be misinterpreted as advocacy. Unfortunately, in most cases we are not properly trained and do not feel comfortable in dispute resolution; and our reward systems within our universities do not properly recognize efforts in public issues education, conflict resolution, or consumer education.

Key Words: Extension, Conflict Resolution, Consumer Education

Dairy Foods: Perspectives on Raw Milk Cheeses

184 Survival of *Escherichia coli* in Cheddar and Colby cheese. D. R. Henning*, *South Dakota State University, Brookings.*

Trials evaluating survival of *Escherichia coli* in Cheddar cheese provided data indicating this organism will survive 60 days of curing if present in sufficient numbers and cheese composition is favorable for the organisms survival. Cheddar cheese manufacturing and curing were used for two treatments utilizing a cocktail of three strains of *E. coli* O157:H7. The target for treatment one was 10^3 colony forming units per mL (cfu/mL) in pasteurized cheese milk; treatment two was 1 cfu/mL of cheese milk. Cheeses were analyzed at 0, 14, 28, 42, 60, and 74 d, and at 28 d intervals thereafter until *E. coli* O157:H7 could no longer be detected in two successive sampling periods. When no cfu/g were detected by plating, 25 g of cheese were enriched to detect viable *E. coli* O157:H7. Treatment one resulted a two log reduction in cfu/g after 60 days of curing with viable *E. coli* O157:H7 being detected in 25 g of cheese after 150 days. Treatment two resulted in reduction of *E. coli* O157:H7 numbers to 1 or <1 cfu/g in 60 days with none detected in 25 g of cheese at 150 days. Both treatments permitted the survival of *E. coli* O157:H7 for more than 60 days of curing. The second study mathematically described the decline of viable biotype 1 *E. coli* during the curing of cheese. Pasteurized milk was inoculated with 10^2 to 10^9 cfu/ml for making Cheddar and Colby cheeses. Multiple regression was employed to determine the effects of low to high levels of composition and curing temperatures in typical cheese [moisture (34 to 40%), pH (5.0 to 5.6), curing temperature (4 to 13C), and salt level (0.8 to 1.7%)] on survival of *E. coli* during cheese curing. A total of 56 survivor curves representing combinations of the parameters were generated during four-months of curing. The model for surviving biotype 1 *E. coli* can be described as: $\text{Log}(\text{Days}4\text{D}) = -74.64881 + 28.5745^*P - 0.00098^*M^*T + 2.64579^*P^*P$, where Days4D = time, in days, needed to reach 99.99% inactivation, P = pH, M = moisture, and T = temperature. $R^2 = 0.532$.

Key Words: Cheese Curing, *Escherichia coli* Survival, Survival Model

185 Use of heat-treated cheesemilk to make high quality Cheddar cheese. B. Luth*, *Tillamook County Creamery Assn., Tillamook, OR.*

The primary argument in favor of creating cheese from heat-treated milk is to retain the quality and flavor characteristics of the cheese as it ages. This process is used because natural enzymes in the milk, essential for producing quality cheddar cheese, suffer during full pasteurization. One of the distinguishing attributes of Tillamook Cheddar Cheese is the consistent ability to age cheddar cheese for two years or more without the development of bitter or atypical flavors. Studies have been conducted using commercial vats of cheesemilk that have been pasteurized compared to commercial vats of cheesemilk heat-treated at 150° F. These were sampled over time for blind analysis by trained panels. Results show that pasteurized cheese only five months old was determined to be significantly different in flavor and texture when compared to heat-treated control samples made at the same time. The panels noted flavor

attributes of bitter, bland and flat and the texture deficiency of pasty body for the pasteurized product. The process of pasteurization of milk at 161° F for 15 seconds was designed and implemented for the control of pathogenic and spoilage microorganisms. Studies have demonstrated, however, that many organisms are inactivated by heat treatments of 148° F or above for 16.2 seconds and that heat-treatment of cheesemilk is but one of the technologies and practices which contribute to the manufacture of safe cheese. It is recommended that the heat-treatment process be recognized for cheesemaking based on the following parameters: 1. Raw Milk intended for heat-treatment meets the following requirements on a daily average: SPC < 15,000 cfu/ml; SCC < 250,000 cells/ml, indicating that the milk was from healthy animals. 2. Raw milk is heated to 148° F or greater and held for a minimum of 16 seconds. 3. Finished cheese produced under these conditions will be cured at a temperature of greater than 35° F for a period of at least 60 days.

Key Words: Cheese, Heat-Treatment, 60 Day Hold

186 Approaches to ensuring the safety of raw milk cheeses. C. Donnelly*, *The University of Vermont, Burlington.*

Although cheeses have been linked with documented outbreaks of foodborne illness, epidemiological evidence collected from around the world confirms that this occurs infrequently. Cheeses can become contaminated with bacterial pathogens as a result of their presence in raw milk used for cheesemaking and subsequent survival during the cheesemaking process. Alternatively, bacterial pathogens can contaminate cheese via post-processing contamination if sanitation and other measures in the processing plant are not sufficient to prevent re-contamination. The characteristics of the specific cheese variety will dictate potential for growth and survival of microbial pathogens, with ripened soft cheeses presenting a higher risk for growth and survival of pathogens in comparison with aged hard cheeses where a combination of factors including pH, salt content and water activity interact to render cheeses microbiologically safe. This presentation will compare and contrast approaches used worldwide to insure the safety of raw milk cheeses. The 1996 European Union Statutory Instruments contain regulations for hygienic production and marketing of milk and milk based products. EU regulations establish limits for pathogens in raw milk cheese, where presence of *S. aureus* and *E. coli* would indicate poor hygiene. The relative merits of such approaches in the context of assuring cheese safety will be reviewed.

Key Words: Cheese, Safety, Pasteurization

187 Survival of a five strain cocktail of *Escherichia coli* O157:H7 during thermalization and the 60 day aging period of hard cheese made from unpasteurized milk. J. Schlessler*, *Food and Drug Administration, NCFST, Summit-Argo, IL.*

Cheeses have been cited as vehicles for outbreaks of foodborne illness. The standard of identity for hard cheeses requires pasteurization of the milk or as an alternative treatment, a minimum 60-day aging for cheeses

made from unpasteurized milk, to eliminate the foodborne pathogens. From 1948 to 1988, there were 6 confirmed foodborne disease outbreaks in the U.S. transmitted with domestically produced hard cheeses as the food vehicle. Various research reports have raised concerns about the public health protection provided by the current 60-day aging period in the manufacture of hard cheeses made with unpasteurized milk. The objective of this study was to investigate the adequacy of the 60-day minimum aging to eliminate the foodborne pathogens and evaluate milk thermalization as a process to improve the safety of hard cheeses made from unpasteurized milk. Hard cheese was made from unpasteurized milk inoculated with a five-strain cocktail of acid-tolerant *E. coli* O157:H7. Samples of unpasteurized milk, curd and whey were collected during the cheese manufacturing process. After pressing, the blocks of hard cheese were packaged into plastic bags, and sealed with a vacuum-packaging machine, and aged at 7 °C. After 1 week, the cheese blocks were cut into smaller uniform-sized pieces, and vacuum sealed in clear plastic pouches for ease of sampling at the various aging intervals. Samples were plated and enumerated for *E. coli* O157:H7. Populations of *E. coli* O157:H7 increased during the cheese making operations. Population of *E. coli* O157:H7 in cheese aged for 60 and 120 days at 7 °C, decreased less than 1 log and 2 logs, respectively. Experiments were conducted at 64.4 °C for 16 seconds on milk inoculated with *E. coli* O157:H7 at 10⁵ CFU/ml. Supply milk and thermalized milk were taken at 0, 45 and 90 minutes to determine the levels of *E. coli* O157:H7. Thermalization runs resulted in a 5-D *E. coli* O157:H7 reduction.

Key Words: Thermalization, *Escherichia coli* O157:H7, Raw Milk Cheese

188 An integrated approach to the safety of raw milk cheeses. P. S. Kindstedt*, *University of Vermont, Burlington.*

In the ongoing quest to reduce the risk of foodborne illness associated with cheese, the goal should be to achieve the appropriate level of

safety using approaches that are both effective and practical, and that avoid placing unnecessary burdens and restrictions on cheesemakers and cheese consumers. Among the possible approaches that could be implemented to enhance cheese safety, mandatory pasteurization of all milk for cheesemaking stands out as being exceptionally burdensome and restrictive to producers and consumers of raw milk cheeses. Expanding mandatory pasteurization to include all cheeses should not be pursued if the appropriate level of safety already exists under current regulations or can be achieved through other practical and effective but less burdensome and restrictive approaches. Recent research strongly suggests that some raw milk cheeses, such as the highly cooked hard Italian and Emmental-types, present very low microbiological risks when made and aged properly. A strong argument can be made that these raw milk cheeses achieve the appropriate level of safety as a consequence of the high heat treatment that they receive during manufacture, their chemical composition and their long ripening times. Therefore, the safety emphasis for these cheeses should be on insuring that cheesemakers are adequately trained in cheese technology, hygiene and safety and held to appropriately high standards, rather than on mandatory pasteurization. For other raw milk cheeses that pose greater microbiological risks and which are deemed to fall short of the appropriate level of safety under current regulations, at least two different approaches should be evaluated and compared for overall merit: 1.) mandatory pasteurization; 2.) a combination of other safety approaches such as mandatory technical and safety training for cheesemakers (e.g. via a cheesemakers certification or licensing requirement), mandatory implementation of an approved risk-reduction (e.g. HACCP-like) program, and mandatory finished product testing for pathogens. The latter approaches have been used for raw milk cheesemaking in some European countries with apparent success.

Key Words: Cheese, Safety, Pasteurization

Extension Education: Applied Reproductive Management Symposium: Beef and Dairy Cattle Topics

189 Using melengestrol acetate (MGA)-based protocols to synchronize estrus prior to fixed-time artificial insemination in postpartum beef cows. D. J. Patterson*, F. N. Kojima, and M. F. Smith, *University of Missouri, Columbia.*

Beef producers are often restricted in their operations from implementing production-enhancing technologies, including estrus synchronization and AI, due to a lack of time and labor. The inability to predict time of estrus for individual cows in a herd often makes AI impractical to use because of the labor required for detection of estrus. The development of methods to inseminate beef cows at a fixed time with high fertility should result in a dramatic increase in the adoption of AI in beef herds. Although hormonal treatment of cows to group estrous periods has been a commercial reality for over 30 yr, producers have been slow to adopt this management practice. Perhaps this is because of past failures, which resulted when females that were placed on estrus synchronization treatments failed to resume normal estrous cycles following calving, and the reality that early estrus synchronization protocols failed to synchronize follicular waves, resulting in more days in

the synchronized period. These factors collectively precluded the application of fixed-time AI with acceptable pregnancy rates. We proposed the general hypothesis that progestin treatment prior to the GnRH-PG estrus synchronization protocol would successfully: 1) induce ovulation in anestrus postpartum beef cows; 2) reduce the incidence of a short luteal phase among anestrus cows induced to ovulate; 3) increase estrous response, synchronized conception and pregnancy rates; and 4) increase the likelihood of successful fixed-time AI. This review considers recently developed methods to control estrous cycles of postpartum beef cows with MGA. New methods of synchronizing estrus in beef cows with the MGA Select or 7-11 Synch protocols prior to fixed-time AI present the opportunity to enhance results from AI and eliminate the need to detect estrus entirely. These new protocols provide an opportunity for the beef cattle industry to expand the application of this important reproductive technology by making the implementation of an AI program feasible.

Key Words: Beef Cow, Estrus Synchronization, Progestin

PSA Air Emissions & Poultry Production

190 Air emissions in poultry production: Current challenges and future directions. R. Angel¹, W. Powers², and T. J. Applegate³, ¹*University of Maryland, College Park*, ²*Iowa State University, Ames*, ³*Purdue University, West Lafayette, IN.*

In the last few years, regulatory focus has been on nutrient management from animal feeding operations (AFOs) with recent emphasis on air emissions. Concerns are with air-borne emissions of nitrogenous compounds as well as with small particulate matter (PM 2.5). Of specific interest to the Environmental Protection Agency and specific states include ammonia, hydrogen sulfide, nitrogen oxides, sulfur oxides, nitrous oxide, and volatile organic compounds but the main challenges are establishing current emission levels and determining best methodologies for measuring these accurately. Currently methodologies to measure air emissions under field and research conditions exist and are being further developed but extensive challenges exist as to both accuracy and

precision of the different analytical methods. Current best estimates are based on a mass balance modeling approach (Air Emissions From Animal Feeding Operations, NRC 2003) but due to lack of current biologically generated data to use in the models, nutrient excretion and emission levels appear to be overestimated by these models. Extensive work is being done on dietary strategies to reduce nitrogenous excretions from poultry but the impact of these on air emissions is not always defined. Litter management strategies that reduce volatilization of nitrogenous and other compounds have shown promise and are being further developed. Flock, house, and whole farm management strategies are also being successfully implemented and further developed. The magnitude of the potential impact on air emissions of each of these strategies is still in question. There is no question, though, as to the need for the use of whole farm systems that implement different strategies at all

management levels if large decreases in air emissions from AFOs are to be achieved.

191 Air emissions from layer houses. A. J. Heber*, T. Lim, and J. Ni, *Purdue University, West Lafayette, IN.*

Measurements of air emissions from confined animal buildings are perhaps more challenging for laying hens than any other species. Modern laying houses typically have the greatest volume, the greatest mean live mass density, the greatest number of exhaust fans, the highest ridge, the largest particles, and the highest concentrations of ammonia and particulate matter (PM). This paper describes a comprehensive air emission measurement program carried out for over six months at a 250,000-hen high-rise caged-hen building. Continuous measurements of gas and particulate matter (PM₁₀, PM_{2.5}) concentrations, building static pressure and airflow, inside and outside temperature and humidity, wind speed and direction, and barometric pressure were conducted. Extractive air sampling was used to provide continuous gas streams to two sets of gas analyzers and to fill sample bags for odor evaluations. Ammonia (NH₃), hydrogen sulfide (H₂S), carbon dioxide (CO₂), and odor were measured using chemiluminescence, pulsed fluorescence, photoacoustic infrared detectors, and olfactometry, respectively. PM was measured in the exhaust air using three tapered element oscillating microbalances. Ventilation rates were assessed by monitoring fan operation and static pressure, and testing fans with a portable fan tester, and a certified fan testing lab. During 6 days in June, the average daily mean ($\pm 95\%$ c.i.) concentrations and emissions were 39 ± 8.0 , 518 ± 74 , and 1887 ± 563 $\mu\text{g}/\text{m}^3$ and 1.1 ± 0.3 , 16 ± 3.4 , and 63 ± 15 g/d-AU for PM_{2.5}, PM₁₀, and total suspended particulates (TSP), respectively. PM emission was correlated to ventilation, ambient and exhaust temperatures, and relative humidity ($P < 0.05$). Ventilation inlet and exhaust odor concentrations ranged from 43 to 74 and 216 to 451 European odor units (OU_E) per m³, and averaged 51 and 316 OU_E/m³, respectively. Mean H₂S concentrations of ventilation inlet and exhaust air were 3.1 and 19.7 ppb, respectively. Mean H₂S emission rate was 5.6 $\mu\text{g}/\text{s-AU}$. The overall mean odor emission rate was 65.6 OU_E /s-AU. Odor emissions were correlated to ventilation rate, and building temperatures. The average NH₃ emission rate was about 200 g per day per 500 kg live mass.

Key Words: Ammonia, Particulate Matter, Odor

192 Ammonia emissions from broiler houses. A.J. Pescatore*, K.D. Casey, and R.S. Gates, *University of Kentucky, Lexington.*

Ammonia levels in poultry houses are a concern due to the impact on bird performance including poor feed efficiency, blindness and respiratory problems. Recently, there has been increased interest in ammonia as it relates to emissions. EPA through its safe harbor program and third party lawsuits under CERCLA and EPCRA regulations has increased the concern of the poultry industry. Ammonia emissions are a function of the level of ammonia in the exhaust air and the ventilation rate. Accurate measurements of both ammonia concentration and rate of ventilation is essential for determining ammonia emissions. A study was conducted over five consecutive flocks to determine ammonia emissions from four commercial broiler houses with built up litter. Ammonia levels in exhaust air were determined by using Portable Measuring Units (PMU) equipped with two Drager PAC III electrochemical gas monitors. A Fans Assessment Numeration System (FANS) was used to determine exhaust fan capacity. Placement densities were either 10.75 or 13.44 birds per square meter depending on final body weight. The results of this study indicated that there is seasonal variation in the pattern of ammonia levels in the exhaust air from broiler houses. The fall and winter flocks had increasing ammonia levels in the exhaust air with increasing bird age. While the two summer flocks demonstrated a decreasing ammonia level with regard to bird age. The one spring flock was highly variable. Ammonia levels for the five flocks ranged from 1 to 40 ppm. During all five flocks, ammonia emissions which are a function of ammonia level and ventilation rate increased linearly with bird age. Average maximum ammonia emissions (g/bird/day) were .93, 1.01, 1.45, 1.73, and 1.27 for the five consecutive flocks. The lowest level for ammonia emissions occurred early in the flock and ranged from .01 to

.45 g/bird/day. Results from this study indicate that the rate of ventilation as opposed to ammonia level had a greater effect on ammonia emissions.

Key Words: Ammonia Emissions, Broiler, Ammonia Levels

193 Dietary strategies to lower nitrogen load in poultry. D. J. Burnham*, *Ajinomoto Heartland LLC, Chicago, IL.*

The poultry industry has made tremendous strides over the past 50 years to meet the demands of the retail and foodservice industries for increasing supplies of inexpensive and safe meat and eggs. The pressure to lower cost and increase supply has led to higher efficiencies which have only been possible through larger more integrated facilities. In certain areas these facilities with higher concentrations of livestock has resulted in some environmental concerns which include ammonia and odors. The poultry industry is now being challenged to reduce emissions by some of the same groups that have driven the industry into expansion and consolidation. The move toward mandating lower nitrogen emissions in the United States is inevitable. To meet these limits the poultry industry will need to either reduce the number of birds placed or implement feeding practices that minimize the feeding of excess nitrogen (crude protein). The first step in reducing ammonia emissions is to more accurately define the amino acid needs of a bird. With more accurate requirements we are able to design feeds with reduced levels of excess protein in the feed. The second step in reducing ammonia is to develop procedures that allow for more frequent feed changes. Current practices of changing broiler feeds every 14 to 20 days results initially in underfeeding followed by overfeeding of nutrients. Changing diets more frequently will reduce nitrogen emissions by improving efficiencies and reduced feeding of excess nutrients.

Tools available to nutritionist in their pursuit of reduced nitrogen emissions include commercially available crystalline amino acids. Making full use of them to more accurately balance feeds can significantly reduce excess crude protein. Unfortunately, there is still a common belief that lowering of the crude protein level of feeds negatively affects performance. The research presented in this paper strives to demonstrate to the poultry industry in the US that by embracing these technologies we can move toward lower crude protein, more efficient feed formulation and achieve the same level of performance with lower nitrogen emission at a lower cost of meat and eggs

Key Words: Nitrogen, Low Protein, Amino Acids

194 Management strategies to reduce air emissions: emphasis ammonia. P. H. Patterson*, *Department of Poultry Science, The Pennsylvania State University, University Park.*

Air emissions generated by poultry production are numerous and can include odors, dust, endotoxins, and nitrogenous compounds. Ammonia (NH₃) emissions have the potential to contaminate surface waters, while, nitric oxide and nitrous oxide lead to the formation of nitric acid, a principle component of acid rain. These emissions in and around poultry production facilities can be a health and performance issue for birds and their caretakers, and an environmental concern on both a local and global scale. Dietary strategies can aid in the reduction of many airborne emissions including NH₃. Management techniques to quell, capture or eliminate these air contaminants are numerous but vary in their cost, effectiveness and practicality. Many strategies that control dust also control the release of odorous compounds, microorganisms and NH₃ that can adhere to dust particles. Techniques for dust control include cleaning and vacuuming, fogging with water and oil, ionization, electrostatic filtration, air scrubbing techniques, and vegetative shelterbelts. Impermeable covers for manure reduce emission rates by reducing radiation and wind velocity. Biofilters trap and treat exhaust air from mechanical ventilation systems combining filtration (woodchips, or straw) with biological conversion in compost to capture emissions. Litter and manure amendments include those that inhibit microbial growth and conversion of nitrogenous compounds to NH₃; clays that absorb moisture, odors and NH₃; and acidifying agents such as ferrous sulfate, ferric chloride, and aluminum sulfate that convert NH₃ to NH₄⁺. Rapid drying techniques for litter and manure can significantly reduce NH₃ volatilization. These include slotted floor systems for turkeys, ventilated floors for broilers and new cage systems for layers each reducing litter and

manure moisture and NH₃ losses compared to conventional systems. Although many strategies are available to address NH₃ and other air emissions, ultimately regulations and costs will be determining factors guiding implementation.

Key Words: Ammonia, Air Emissions, Management

195 Emissions, regulations and impact in the EU and The Netherlands. H. Ellen*, *Applied Research of Animal Sciences Group of Wageningen, Lelystad, The Netherlands.*

Air pollution has been one of Europe's main political concerns since the late 1970's. The aim of EU-policy is to develop and implement appropriate instruments to improve air quality. The Sixth Environment Action Programme, "Environment 2010: Our future, Our Choice" regards the period from 2001 until 2010. One of the important issues of the EAP is the reduction of greenhouse gasses. This also supports the aims of the Kyoto-Protocol, because EU-countries have promised to decline their emissions with 8% in total in 2010 in comparison with 1990. In the EAP each country of the EU has an Emission Ceiling for gasses as SO₂, NO_x and NH₃. According to an EU-directive these emission

ceilings have to be reached in 2010. In addition to the EU-rules, each country have to implement its own national programme for a progressive reduction of the national emissions. For poultry, the reduction of NH₃-emission is the most important issue in the EAP. Already there was EU-directive in 1996 concerning the integrated pollution prevention and control (IPPC). According to this directive no new poultry farm larger than 40,000 bird places may be operated without a permit. From 2007 all farms need a permission and have to use a so called BAT. These are techniques that aim to reduce emission of ammonia at acceptable costs. Large farms have to make a Environmental Impact Assessment when they apply for a new permit. For already many years in Holland poultry farms require a permit in which also the amount of ammonia and odour emission is registered. Lists of ammonia and odour emission factors for all the housing systems in the different poultry categories has been established. To fulfil the EU-directive 2001/81/EC, the Dutch government has set maximum values for the ammonia emission from farms. Together with the environment regulations, poultry farmers also have to deal with EU-directives on animal welfare. Most of the housing systems that give good welfare, have higher emissions of ammonia. These systems also consume more energy, which doesn't harmonise with the need to reduce the emission of CO₂.

Key Words: Ammonia Emission, Environment, Poultry

Food Safety in Animal Production

196 A USDA multi-agency project: Collaboration in animal health, food safety & epidemiology (CAHFSE). R. R. Kraeling*¹, E. J. Bush², D. A Dargatz², N. E. Wineland², S. Ladely¹, and P. J. Fedorka-Cray¹, ¹ARS, USDA, Athens, ²APHIS-VS, USDA, Fort Collins, CO.

The emergence of antimicrobial resistant zoonotic bacteria continues to be a global concern. In response to growing surveillance needs, USDA-ARS, APHIS and FSIA collectively developed CAHFSE. CAHFSE will enhance our overall understanding of pathogens that pose a food-safety risk by tracking these organisms from farm to plant. Risk analysis, antimicrobial use information, resistance and animal health will also be assessed. The first commodity of CAHFSE is pork. Currently, blood and fecal samples are being collected quarterly on sentinel farms in four states. Herd health and management data are also being collected from these farms. To date, fecal samples from 48 site visits have been collected and cultured for Salmonella, Campylobacter and E. coli. Salmonella was recovered from 8.1% (146/1811) of the samples. Sixteen serotypes were identified, of which the predominant serotypes included; S. derby (31.5%), S. typhimurium var. copenhagen (26%), S. heidelberg (8.9%) and S. give (7.5%). Across all serotypes, resistance was most commonly observed for tetracycline (90.4%), streptomycin (63.5%), sulfamethoxazole (43.5%) and ampicillin (43.5%). Among generic E. coli, resistance to tetracycline (92.2%), sulfamethoxazole (27.2%), streptomycin (27.1%) and ampicillin (25.4%) was most common. All Campylobacter isolated to date were identified as C. coli. Resistance to tetracycline (73.6%), azithromycin (60.3%) and erythromycin (60.1%) were observed most often. Determination of risk factors related to prevalence and antimicrobial resistance of these organisms will lead to practical methods of mitigating food borne illness.

Key Words: Swine, Food Safety, Antimicrobial Susceptibility

197 Monitoring the safety of edible poultry tissues: Antibiotic residue concentrations can vary between different muscle tissues. I. Reyes-Herrera*¹, M. J. Schneider², K. Cole, P. J. Blore, and D. J. Donoghue, ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²USDA/ARS/ERRC, Wyndmoor, PA.

The use of veterinary antibiotics is an important tool for the treatment of disease in poultry. However, misuse of these antibiotics can create antimicrobial residues in edible animal tissues exceeding the FDA established safety tolerances. To ensure the safety of the U.S. food supply, the Federal Government monitors foods, including poultry, for illegal residues. For the veterinary antibiotic enrofloxacin (Baytril®), the FDA, in the Code of Federal Regulations, has listed muscle as the tissue to be monitored in poultry, irrespective of the type of muscle tissue. This study was conducted to determine if either breast or thigh meat is a better indicator of the highest enrofloxacin concentrations. One

hundred and sixty five, 5-wk old chickens were dosed with the FDA approved dose of enrofloxacin in water. The 4 treatment groups were: 25 ppm for 3 days, 25 ppm for 7 days, 50 ppm for 3 days and 50 ppm for 7 days. Five chickens from each treatment group were randomly selected and samples of breast and thigh muscle tissue were collected prior to dosing (controls, n=5), during the dosing (n=5/group/day) and for a 3-day withdrawal period (n=5/group/day). Each sample was prepared and assayed using an agar diffusion microbiological method (Schneider and Donoghue, Poultry Science, 2004). The results demonstrated that greater overall concentrations of enrofloxacin were present in breast versus thigh muscle tissues during the dosing period (443 ± 22 ppb vs. 386 ± 24 ppb. P < 0.05). These data indicate that, at least for enrofloxacin, not all muscle tissues incorporate antibiotics at the same concentrations. Therefore, the Federal Government should consider monitoring specific muscle tissues to ensure established safety tolerances are not being exceeded.

Key Words: Enrofloxacin Residues, Muscle Tissues, Chicken

198 Survival of Salmonella species following sodium hypochlorite treatment during commercial broiler processing. R. M. Lipscomb*, L. T. Walker, W. L. Hurlock, L. L. Williams, and M. Verghese, *Alabama A&M University, Normal.*

Technological advances and mass production in poultry processing present new challenges for providing a microbiologically safe product. Research has shown that Salmonella can survive acidic conditions. The objective of this study was to determine the effect of Acidified Sodium Hypochlorite (ASH) on survival of Salmonella species on commercially produced broiler carcasses. Broiler carcasses were sampled from four processing steps (rehang, reprocessing, prechill, and postchill) to determine the effect of ASH against Salmonella. Ten carcasses were sampled at each processing step. Carcasses were dipped (20 secs) in an ASH solution dip tank at prechill and rinsed (1 min) with 400ml Butterfield's Phosphate Dilution water (BPD). A 1:10 dilution was plated onto Brilliant Green and Bismuth Sulfite agars, incubated for 24 hours at 37C, and Salmonella counts were determined. Salmonella O Poly A and H Poly A antigens were determined by serotyping. Salmonella species were confirmed by PCR analysis. The experiment was replicated three times over three periods. The results showed that average Salmonella counts were 1.2888 log cfu/ml (rehang), 0.9403 log cfu/ml (reprocessing), 0.9779 log cfu/ml (prechill), and 0.2039 log cfu/ml (postchill). Means for 48 and 72 hours were not significantly different at p#88050.05. Of a total of 53 suspect Salmonella isolates (including all reps), 37 were positive for the Salmonella O Poly A antigen, and 50 samples were positive for the Salmonella H Poly A antigen. PCR analysis confirmed 32 samples to be Salmonella species.

Although ASH was effective in reducing microbial contamination, *Salmonella* species survived ASH treatment. Several factors can influence the effectiveness of ASH such as pH, temperature, and ASH concentration. Regulation of pH, temperature, and ASH concentration is the key to ASH achieving its full potential as a disinfectant used in the poultry industry.

Key Words: Salmonella, Broilers, Sodium Hypochlorite

199 Herd-level factors associated with cow and calf *Salmonella* shedding in a multi-state study of 129 dairy farms. C. P. Fossler¹, S. J. Wells¹, J. B. Kaneene², P. L. Ruegg³, L. D. Warnick⁴, J. B. Bender¹, L. E. Eberly¹, S. M. Godden¹, and L. W. Halbert², ¹University of Minnesota, St. Paul, ²Michigan State University, East Lansing, ³University of Wisconsin, Madison, ⁴Cornell University, Ithaca, NY.

This study evaluated associations between herd characteristics and the isolation of *Salmonella* from dairy cows and calves. 129 conventional and organic farms in Minnesota, Wisconsin, Michigan, and New York were enrolled without regard to previous *Salmonella* history. Herds were sampled up to 5 times at 2-month intervals over one year. *Salmonella* was detected in fecal samples from 4.9% of 20,089 cows and 3.8% of 4,673 preweaned calves. Risk factors were evaluated using multivariable logistic regression with the generalized estimating equations approach, and within-herd prevalence by visit in cows and calves was the outcome used for cow and calf models, respectively. Factors associated with an increased odds for *Salmonella* shedding in the final cow model ($p < 0.05$) included lack of use of tiestall or stanchion facilities for lactating cows, not storing all purchased concentrate or protein feeds in an enclosed building, not using monensin in weaned calf or bred heifer diets, cow access to surface water, disposal of manure in liquid form (slurry or irrigation, as opposed to broadcast/solid spreader) on owned or rented land, and eating or grazing roughage by cows from fields having surface application of manure during the growing season. Factors associated with an increased odds for *Salmonella* shedding in the final calf model ($p < 0.05$) included lack of routine feeding of medicated milk replacer, and use of calving pen as a hospital area for sick cows > once a month. Herd size and farm type (organic vs. conventional) were not associated with *Salmonella* shedding in the final cow or calf models. A number of herd-level risk factors were identified in this study that could potentially be implemented in *Salmonella* control programs on dairy farms.

Key Words: *Salmonella*, Dairy Cattle, Risk Factors

200 Investigation of cattle feedlot management practices to reduce *Escherichia coli* O157. J. R. Ransom*, K. E. Belk, J. A. Scanga, J. N. Sofos, and G. C. Smith, Colorado State University, Fort Collins.

Studies have shown that prevalence of *Escherichia coli* O157 on/in cattle entering the packing plant range from 10 to >70%. The objective of this study was to determine the effectiveness of single and multiple preharvest pathogen intervention strategies on the prevalence of *E. coli* O157 on/in cattle before transport to harvest. Cattle from 24 pens [approximately 200 head of cattle (419 kg) per pen] were randomly allocated (3 pens/treatment) to one of 8 treatment groups: Control (CT; No treatment), Bovamine (Bov; a *Lactobacillus acidophilus* product), NEOMIX (Neo; neomycin sulfate), an *E. coli* O157:H7 bacterin vaccine (Vac) and all combinations of the single treatments. Treatments of Bov and Vac began 60 d preharvest, and Neo was administered for 3 d before harvest with a 24 h withdrawal period. Twenty-five cattle per pen were randomly sampled using rectal fecal collection and by sponge-swabbing 500 cm² of the dorsal-thorax region. Cattle were sampled within a 10 d timeperiod and samples were collected no more than 48 h before harvest. Results showed that CT cattle had the highest pathogen prevalence levels (45.8 and 40.3%, for fecal and hide samples, respectively), and cattle receiving treatments had a lower prevalence of *E. coli* O157 than did CT. Trends suggested that Neo was the most effective single intervention, reducing *E. coli* O157 prevalence levels to 0.0 and 8.5%, in feces and on hides, respectively. Bovamine and Vac used singly, were equally effective, as pathogen prevalence was reduced to 22.7 and 20.0%, respectively, on hide samples and to 13.3 and 14.7%, respectively, for fecal samples. When Bov, Vac and Neo were used in

combination, pathogen prevalence for fecal and hide samples were reduced to 2.7 and 6.7%, respectively. In general, combinations of interventions resulted in lower pathogen prevalence than when a single intervention was used. This study demonstrated that preharvest mitigation strategies used singly or in combination can be effective in reducing the prevalence of *E. coli* O157 in market-ready feedlot cattle.

Key Words: Cattle, Preharvest, *Escherichia coli* O157

201 Colicin E1, N and A treatment inhibits growth of *Escherichia coli* O157:H7 strains in vitro. T. R. Callaway¹, C. H. Stahl², T. S. Edrington¹, K. J. Genovese¹, L. M. Lincoln², R. C. Anderson¹, R. B. Harvey¹, and D. J. Nisbet¹, ¹USDA/ARS, Food and Feed Safety Research Unit, College Station, TX, ²Department of Animal Science, Iowa State University, Ames.

Escherichia coli O157:H7 is a highly virulent food-borne pathogen that causes severe human illnesses and inhabits the intestinal tract of ruminants. Although abattoir do an excellent job of controlling the cross-contamination of pathogens, too many human illnesses linked to animal-derived food products still occur. Therefore, researchers have investigated methods to reduce the overall burden of *E. coli* O157:H7 entering the abattoir within the live animal. Antibiotic treatment has been proposed to reduce *E. coli* O157:H7 populations in the live animal; however, with the growing worldwide concern over the prophylactic use of antibiotics in food animals, alternative strategies to the use of traditional antibiotics must be explored. Colicins are antimicrobial proteins produced by some *E. coli* strains that are inhibitory or bactericidal against other *E. coli*. In the present study, the efficacy of three pore-forming colicins E1, N and A were quantified in vitro against *E. coli* O157:H7 strains 86-24 and 933. All three colicins reduced the growth of *E. coli* O157:H7 strains, but the efficacy of each colicin varied between strains. Colicin E1 was most effective against strain 86-24 and 933. Colicin N, while less effective than E1, was very effective against strain 86-24, however, it was unable to produce more than a 50% reduction in growth against strain 933. Colicin A did not show more than 50% of the efficacy of either of the other colicins, even when added to incubations at 10-fold or greater protein concentrations. Colicin E1 was more effective against both strains of *E. coli* O157:H7 than colicins A and N, and reduced populations of *E. coli* O157:H7 more than 1000-fold at concentrations less than 5 µg/ml. Colicin N reduced populations of strain 86-24, but not 933; and colicin A did not affect the populations of either *E. coli* O157:H7 strain tested. These potent antimicrobial proteins may potentially provide an effective and environmentally sound pre-harvest strategy to reduce *E. coli* O157:H7 populations in ruminant animals.

Key Words: *E. coli* O157:H7, Intervention Strategy, Colicin

202 Effects of lactic acid treatments on microbiological, chemical, and sensory properties of stored fresh beef trimmings. S. E. Rose*, K. E. Belk, J. N. Sofos, J. A. Scanga, K. L. Hossner, and G. C. Smith, Colorado State University, Fort Collins.

The objective of this study was to evaluate the effectiveness of warm (55°C) lactic acid (LA) at various concentrations (1.25, 2.00, or 2.50%) on microbiological, chemical, and sensory properties of fresh beef trimmings stored at 4°C for 0, 2, 5, or 8 d on Styrofoam™ trays wrapped with air-permeable cellophane film. Two replicates of four beef short plate (BSP) pieces (5 cm x 2.5 cm x 1 cm; 40 cm²) per treatment were immersed in treatment solutions or water control at 55°C for 30 s. Aerobic plate counts (APC) were determined using Petrifilm™ Aerobic Count Plate (ACP), and Total Coliform Count (TCC) and *Escherichia coli* (ECC) populations were determined using Petrifilm™ *E. coli*/Coliform Plate (ECCP). Lactic acid concentrations of the BSP pieces were determined by conducting enzymatic colorimetric assays. A sensory panel was used to determine differences in odor of BSP pieces after treatment and during storage. A MiniScan XE was used at each storage time to evaluate color (L*, a*, and b* values) of muscle and adipose tissue. Bacterial populations associated with BSP pieces treated with 1.25% LA were not different ($P > 0.05$) from controls; however, 2.00 or 2.50% LA reduced ($P < 0.05$) APC, but did not ($P > 0.05$) reduce TCC, when compared to controls for all storage days. All ECC were below the detection limit in all treatments and the control at all storage days. Lactic acid concentrations associated with BSP pieces treated with 2.00 or 2.50% LA at all storage days were higher ($P <$

0.05) compared to control BSP pieces. There were no differences ($P > 0.05$) in odor between treatments and the control BSP pieces for all storage days. Lactic acid treated BSP pieces were more likely to be lighter, greener, and more yellow throughout the storage period when compared to control BSP pieces. Lower microbial counts and indistinguishable odor differences were achieved with 2.00% LA treated BSP pieces. Using 2.00% LA in beef trimmings may provide a microbiologically cleaner product to the consumer without major adverse effects on quality.

Key Words: Lactic Acid, Beef Trimming, Residue

203 Influence of aflatoxin B1 on milk production and health in dairy sheep. G. Battacone¹, M. Palomba², M. Pascale³, A. Mazzette¹, and G. Pulina^{*1}, ¹*Dipartimento di Scienze Zootecniche, University of Sassari, Italy via Enrico de Nicola 9, 07100 Sassari, Italy*, ²*Dipartimento Farmaco Chimico Tossicologico, University of Sassari, Italy via Muroni, 07100 Sassari, Italy*, ³*CNR Istituto di Scienze delle Produzioni Alimentari, Bari, Italy via le Einaudi 51, 70125 Bari, Italy*.

The transfer of aflatoxin B1 in the diet of lactating sheep into the milk were investigated, and also its effects on milk yield and animal health. Twenty lactating Sarda sheep were divided into four groups of five. Three groups were used for the experiment and the fourth was a control group. The experimental design was a 33 Latin square with one additional group. The experimental groups were given 32, 64 or 128 μg per

day of pure aflatoxin B1 (AFB1) in two daily doses, given immediately before milking at 7:00 a.m. and 7:00 p.m.. The treatment continued for 7 days, followed by a 5 day clearance period. The control group was fed an aflatoxin-free diet. Individual milk production was recorded and milk sampled at each milking. Blood samples were collected after 7 days. Aflatoxin M1 (AFM1) levels in milk were determined using an immunoaffinity column - HPLC method. AFM1 appeared in the milk of all treated groups 12 h after the beginning of administration. No AFM1 was found in the milk of the control group. AFM1 concentrations above the EC tolerance level (0.05 $\mu\text{g}/\text{kg}$) were detected even in the milk of the group that received only 32 $\mu\text{g}/\text{d}$ of AFB1. The mean AFM1 concentration in milk reached a steady state after 2-3 days. At this point AFM1 concentration did not differ at morning and evening milking. The AFM1 concentration was linearly related to the dose. No AFM1 was detected 3-4 days after the end of treatment with AFB1. This suggests that the Latin square is an appropriate experimental design for mycotoxicological studies. The milk production traits of the AFB1 groups were no different from those of the control group. These doses of AFB1 had no effect on hematological and biochemical blood parameters. The results indicate that the level of AFB1 used did not adversely affect animal health and milk production traits, while considerable amounts of AFM1 were excreted in the milk. (Partly supported by MIUR-MiPAF SISPROLAT project)

ADSA-ASAS Northeast Graduate Student Competition

204 Fractional removal of amino acids by the small intestines and whole gastrointestinal tract of sheep remains constant across levels of protein supply. S. W. El-Kadi*, N. E. Sunny, M. Oba, S. L. Owens, and B. J. Bequette, *University of Maryland, College Park*.

We hypothesized that the net removal of amino acids (AA) by the mesenteric (MDV; small intestine) and portal (PDV; whole gut) drained viscera of sheep would remain fixed in amount, even with increasing supply of protein to the gastrointestinal tract (GIT). Wethers ($n=4$, 33 ± 2.0 kg) were fitted with catheters for duodenal infusion of casein and for measurements of PDV and MDV appearance of AA. Animals were fed a forage-based diet low in protein (9.5 % CP) to 1.4 \times maintenance and given 5-d duodenal infusions of casein (0, 35, 70 and 105 g/d) in a 4 \times 4 Latin square design. On day 5 of each period, a blood flow marker was infused and blood continuously withdrawn over 1-h intervals during a 4-h period. Plasma concentrations of AA were determined by isotope dilution with mass spectrometry. Net absorption of AA across the PDV and MDV were calculated as the product of veno-arterial difference and blood flow. Regression analyses were performed to establish equations describing net appearance of AA in relation to AA infusion rate as casein. Regression curves were found to best fit a first-order model ($R^2 = 0.60-0.95$; at least $P < 0.05$) for all AA except Val ($R^2 = 0.50$; $P = 0.06$). The large removals of the branched chain AA (43-51%; $P < 0.05$) by the GIT probably relates to their catabolism for energy production. For Lys, however, it is unclear why the GIT net metabolizes (33%; $P < 0.05$) this potentially limiting AA to a much greater extent than for His, Phe and Met, whose fractional removals by the GIT were lower (7-19%). Our data indicate that AA removal by the GIT is not fixed in amounts, but rather that the amount removed increased with greater protein supply. The fates and factors affecting AA metabolism by the GIT have yet to be elucidated. However, if AA are metabolized by the GIT to provide energy then perhaps there may be opportunity to reduce catabolism by providing energetically equivalent non-AA substrates.

Key Words: Amino Acid, Sheep, Gastrointestinal Tract

205 Regulation of urea recycling to the gastrointestinal tract and ammonia metabolism in ruminants. N. E. Sunny*, L. H. Hanus, S. W. El-Kadi, S. L. Owens, and B. J. Bequette, *University of Maryland, College Park*.

Urea recycling is the main N salvage mechanism allowing ruminants to maintain positive N balance on poor quality diets. Our aim was to determine the extent ruminants control urea recycling to the GIT, independent of rumen microbial metabolism. Thus, four wether lambs (28.1 kg BW) were fed to 1.5 \times maintenance energy a pelleted diet containing

(kg^{-1} , as-fed) 1.7 Mcal ME and only 68 g CP. Animals were assigned to four levels of urea-N infusion (0, 3.8, 7.5, 11.3 g/d) arranged in a 4 \times 4 Latin square design. Urea was infused into a jugular vein for 10-d periods, and urea kinetics determined by continuous infusion of [¹⁵N¹⁵N]urea over the last 80 h. During [¹⁵N¹⁵N]urea infusion, total urea was collected by suction and feces by harness. Isotope enrichment of urinary urea (¹⁵N¹⁵N, ¹⁴N¹⁵N and ¹⁴N¹⁴N) and fecal total ¹⁵N was determined by mass spectrometry. Urea-N entry rate (UER) increased (5.1 to 21.8 g/d; $P < 0.0001$) with level of urea infusion, whereas the proportion of UER entering the GIT decreased progressively (80 to 61%; $P < 0.01$). The amount of urea-N partitioned to the GIT (recycling; 4.1 to 13.2 g/d; $P < 0.0001$) increased with each level, as did the amount excreted in urine (1.0 to 8.6 g/d; $P < 0.0001$). However, the proportion (44 to 69%; $P < 0.001$) and amount (1.8 to 9.2 g/d; $P < 0.0001$) of the GIT entry that returned to the liver for ureagenesis was greater with urea infusion. In consequence, the amount of urea-N used for anabolism (rumen microbial protein synthesis) reached a maximum (2.3 g/d) at the second level of urea infusion. Concurrently, fecal urea-N excretion reached a maximum (1.5 g/d) at the third level of infusion. The present study suggests that the ability of ruminants to partition urea-N to the GIT is less a limitation than the rumen environment. Thus, rather than up-regulating urea entry to the GIT, there appears to be more potential to improve N efficiency of ruminants by manipulating the rumen environment (eg. fermentable energy, pH) for optimal capture of recycled N.

Key Words: Urea Recycling, Ruminant, Metabolism

206 Urea supplementation increased rumen function in lactating dairy cows fed a corn silage based diet deficient in rumen-degradable feed protein (RDP). S. E. Ferguson*, R. S. Ordway, N. L. Whitehouse, P. J. Kononoff, and C. G. Schwab, *University of New Hampshire, Durham*.

Four lactating Holstein cows fitted with ruminal and duodenal cannulae were used in a 4 \times 4 Latin square to determine the efficacy of adding urea to a corn silage based diet on ruminal fermentation and microbial protein synthesis. Dietary treatments were 0, 0.3, 0.6, and 0.9% urea in diet DM; urea was top dressed and manually incorporated into the diet. The basal diet contained (DM basis) 32% corn silage, 16% grass silage, 4% alfalfa hay, 19% corn, 6% barley, 4.5% soybean hulls, 3% citrus pulp, 3% beet pulp, 7% soybean meal, 1.3% ProvAAITM, 1.7% Megalac[®], and 2.7% vitamin/mineral mix. The basal diet was formulated to meet NRC (2001) requirements for energy and all nutrients except RDP. Cows were fed 3 times daily. Experimental periods were 14 d with a 9-d adaptation. Duodenal digesta ($n=16$), rumen samples ($n=16$), and milk samples were

collected over the last 5 d. The consumed diet contained 9.2% RDP in DM and had a predicted RDP balance of -170 g/d (NRC, 2001). Feeding increasing amounts of urea increased mean rumen ammonia N concentrations (9.0, 11.9, 12.8, and 17.4 mg/dl; linear, $P < 0.001$), passage of microbial N (quadratic, $P < 0.01$), and microbial N as a percent of nonammonia N (quadratic, $P < 0.05$). Total ruminal volatile fatty acid (VFA) concentrations ($\mu\text{mole/ml}$) and butyrate as a percent of total VFA increased with increasing urea level (linear, $P < 0.05$); there was a trend for a linear increase in acetate as a percent of total VFA ($P = 0.06$). There were no treatment effects on DM intake (20.8 kg/d), milk yield (32.2 kg/d), milk protein yield (903 g/d), or on ruminal true digestibility of organic matter (59.7%), neutral detergent fiber (41.3%), or acid detergent fiber (47.6%). Urea supplementation increased milk urea N concentrations (11.0, 11.0, 12.5, and 13.2 mg/dl; linear, $P < 0.05$). The results of this study indicate positive effects of adding urea to the described lactating dairy cow diet, and that microbial protein synthesis was maximized at an average rumen ammonia N concentration of 12.8 mg/dl.

Key Words: Lactating Cows, Urea, Microbial Protein

207 Mechanisms of transport of vitamins into colostrum: A potential role of megalin and low density lipoprotein receptor. D. G. Martinez^{*1}, G. E. Dahl², and T. B. McFadden¹, ¹University of Vermont, Burlington, ²University of Illinois, Urbana.

Previous studies have shown that IgG1 is concentrated in ruminant colostrum through active and selective transport by the neonatal Fc receptor (FcRn). It has been speculated that vitamins such as vitamin A and β -carotene are also transported into colostrum through a receptor-mediated mechanism. We hypothesized that the endocytic receptors, megalin and low density lipoprotein receptor (LDL-R), are responsible for transport of vitamin A and β -carotene, respectively. To test this hypothesis, blood samples and mammary secretions were collected from 12 pregnant, multiparous cows and mammary biopsies were obtained on days -40, -20, -7 and +7 relative to calving. Expression of megalin and LDL-R mRNA in biopsy samples were measured by real-time PCR. Expression of α -lactalbumin mRNA was measured as a functional marker of lactogenesis. Concentrations of IgG1 and β -carotene were measured in blood and secretion samples. The mixed procedure of SAS was used for statistical analysis. Expression of megalin and LDL-R mRNA was low at 40 d, peaked during colostrum formation (-7 d; $P < 0.05$) and then declined markedly ($P < 0.01$) during lactation. Expression of α -lactalbumin increased sharply from day -7 to day +7 relative to calving ($P < 0.01$). Plasma IgG1 and β -carotene decreased from 3 weeks before parturition reaching minimal concentrations around parturition ($P < 0.01$). In contrast, IgG1 and β -carotene in secretions increased to maximal concentrations around parturition and then decreased during lactation ($P < 0.01$). Similar patterns have been previously reported for vitamin A. These results imply that, like IgG1, β -carotene and vitamin A are depleted from maternal plasma as they are concentrated in colostrum. Temporal changes in mammary expression of megalin and LDL-R suggest that they may mediate the transfer of these components into colostrum.

Key Words: Colostrum, Megalin, Low Density Lipoprotein Receptor

208 Quantifying the effect of dietary sodium bicarbonate on ruminal pH. N. Singh^{*} and R. A. Kohn, University of Maryland, College Park.

Dairy cattle are fed sodium bicarbonate (NaHCO_3) to reduce fluctuation in ruminal pH. However, we do not know whether NaHCO_3 acts through increasing the cation-anion difference in the rumen or by increasing the liquid turnover rate or volatile fatty acid (VFA) absorption from the rumen. A meta-analysis was conducted using studies where NaHCO_3 was used as a dietary supplement. Treatment means ($n=38$) from 14 studies with ruminally fistulated cows were used to evaluate the effect of dietary NaHCO_3 on ruminal pH, VFA concentration and calculated strong ion difference (SID) of ruminal fluid. The model included levels of NaHCO_3 and the random study effect. Analysis of studies revealed that addition of NaHCO_3 to diet increased ruminal pH ($P=0.0065$) and SID ($P < 0.001$). A decrease in ruminal [VFA] was evident in three studies but was not a general trend across studies. A single compartmental model was fit using two zero-order inputs to the ruminal sodium pool,

(saliva and dietary sodium), and sodium outflow as a first order reaction with respect to rumen sodium concentration [Na]. The model can predict a final ruminal pH of 6.04 on addition of 0.03 moles/l-d of NaHCO_3 for a given initial pH of 5.5. Rumen fractional outflow rate was 0.19/h for sodium ion equivalent (Na^+) equivalent. The model predicted changes in ruminal SID as affected by dietary changes in NaHCO_3 and the changes in ruminal SID were in turn used to predict ruminal pH. There was no significant mean bias or linear bias for SID (RMSPE=0.76) or pH (RMSPE=0.19). Predictions from formulation data set demonstrated that the model accurately estimated rumen [SID] and pH in the data set. Across all studies, addition of NaHCO_3 to the diet increased ruminal pH by increasing ruminal SID, but within 3 studies it decreased rumen [VFA]. The model can be used to predict the effect of dietary NaHCO_3 on rumen pH from a given starting pH.

Key Words: Sodium Bicarbonate, Strong Ion Difference, Ruminal pH

209 Trans-10, trans-12 conjugated linoleic acid (CLA) reduces the Δ^9 -desaturase index without affecting milk fat yield in lactating dairy cows. J. W. Perfield II^{*1}, P. Delmonte², A. L. Lock¹, M. P. Yurawecz², and D. E. Bauman¹, ¹Cornell University, ²Center for Food Safety and Applied Nutrition.

Trans-10, cis-12 CLA is a potent inhibitor of milk fat synthesis and the magnitude of the milk fat depression (MFD) often corresponds to the milk fat content of this CLA isomer. However, in certain situations the *trans-10, cis-12* CLA content of milk fat does not correspond to the MFD observed with some diets and with CLA supplements. An increase in the milk fat content of *trans-10, trans-12* CLA has been observed in some of these situations. In the present study we synthesized *trans-10, trans-12* CLA (purity > 90%) and investigated its effect on milk fat. Three rumen fistulated Holstein cows (168 \pm 80 DIM, mean \pm SE) were randomly assigned in a 3 X 3 Latin square experiment. Treatments were abomasal infusion of 1) ethanol (control), 2) *trans-10, cis-12* CLA supplement (positive control), and 3) *trans-10, trans-12* CLA supplement. CLA supplements supplied 5 g/d of the CLA isomer of interest and the daily dose was provided by infusion at 6 h intervals. Treatment periods were 4 d in length with a 7 d washout interval. Milk yield ($P < 0.69$), DMI ($P < 0.50$) and milk protein yield ($P < 0.50$) were unaffected by treatment. The *trans-10, trans-12* CLA isomer had no effect on milk fat yield whereas *trans-10, cis-12* CLA reduced milk fat yield by 28% ($P < 0.01$). Milk fat content (percent of total fatty acids) of specific CLA isomers was elevated within respective treatment groups, 0.11% for *trans-10, trans-12* CLA and 0.18% for *trans-10, cis-12* ($P < 0.001$). Changes in specific fatty acids indicated that Δ^9 -desaturase was reduced significantly for both CLA treatments, but to a greater extent for the *trans-10, trans-12* CLA treatment. Overall, abomasal infusion of *trans-10, cis-12* CLA altered desaturase ratios and reduced milk fat synthesis, whereas *trans-10, trans-12* CLA altered desaturase ratios but had no effect on milk fat synthesis. This indicates that the mechanism for the reduction in milk fat synthesis by *trans-10, cis-12* CLA does not directly involve the reduction of Δ^9 -desaturase.

Key Words: Conjugated Linoleic Acid, Milk Fat Depression, Stearoyl-CoA Desaturase

210 Altering dry matter intake affects the nutritional efficiency of dairy heifers. G. I. Zanton^{*} and A. J. Heinrichs, The Pennsylvania State University, University Park.

The objective of this experiment was to elucidate the effects of differing intakes of dry matter on the nutritional and nitrogen efficiency in growing, postpubertal dairy heifers. A grass-based, total mixed ration (49.1% NDF, 13.0% CP) was administered to eight rumen cannulated Holstein heifers (340 \pm 5 kg) in a replicated 4x4 Latin square design at levels of intake formulated to equally span the region between maintenance and ad libitum consumption. Treatments consisted of one ration fed at 1.25, 1.50, 1.75, and 2.00 kg per 100 kg body weight with energy being the first-limiting dietary component. Rumen fluid was sampled every two hours for 24 hours and total fecal and urine collection was made over six days. Rumen pH was linearly reduced and total VFA concentration linearly increased as DMI increased ($P < 0.05$), but molar proportions of acetate, propionate, and butyrate and rumen concentrations of ammonia were unaffected by treatment. Bacterial nitrogen flowing to the duodenum, estimated by quantifying the excretion of urinary purine derivatives, was linearly increased by increasing levels of

DMI ($P < 0.05$), however the bacterial nitrogen produced per unit organic matter consumed was not altered by treatment. Organic matter digestibility was linearly increased ($P < 0.05$) by decreasing levels of DMI, while NDF digestibility was unaltered by treatment. Nitrogen excretion in the feces and urine increased linearly ($P < 0.05$) with increasing intake of nitrogen and dry matter. Nitrogen was apparently more digestible for those heifers receiving a lower amount of dry matter compared to those receiving a greater amount ($P < 0.05$). While apparently absorbed nitrogen increased linearly as intake increased ($P < 0.05$), apparently retained nitrogen increased linearly but with a decreasing rate as the intake of dry matter approached the highest level of intake (linear and quadratic, $P < 0.05$). Nitrogen retained as either a proportion of nitrogen consumed or nitrogen absorbed was quadratically affected by treatment ($P < 0.05$) with nitrogen efficiency peaking at intermediate levels of intake.

Key Words: Nitrogen Efficiency, Dairy Heifers, Bacterial Nitrogen

211 The effect of essential plant oils on milk production and composition from lactating dairy cows and on silage fermentation and aerobic stability of corn silage. R. J. Schmidt^{*1}, D. H. Kleinschmit¹, J. M. Ladd¹, J. E. Lynch¹, L. Kung, Jr.¹, P. G. Williams², and R. Losa³, ¹University of Delaware, Newark, ²Akzo Nobel LLC, Davis, CA, ³CRINA S.A. Switzerland.

Alternative feed additives have been studied and the use of plant secondary compounds is a promising option. A blend of essential oil components (CRINA Ruminant, CRINA S.A., Switzerland) was fed to lactating cows to study its effect on intake and milk production. Cows were fed a TMR of 15% alfalfa silage, 10% alfalfa hay, 25% corn silage, and 50% concentrate (DM basis). For a 2-wk pretreatment period all cows were fed 50 g of a limestone/CRINA blend that was mixed into the TMR to provide a daily intake of 0.6 g of CRINA/cow/d. At the start of an 8 wk treatment period cows were blocked on lactation number, pretreatment milk production and days in milk, and randomly allocated to one of two treatments: 1) 100 g of limestone or 2) 100 g of limestone/CRINA (1.2 g CRINA/cow/d). Cows fed CRINA ate 1.9 kg more DM/d and produced 2.7 more kg of 3.5% FCM/d than did cows fed the control diet ($P < 0.05$). Milk composition was unaffected by treatment. CRINA was also added to chopped corn forage (30% DM) to evaluate its effect on silage fermentation and aerobic stability. Treatments were: 1) no additive, 2) 2.5 g of CRINA/25 kg of wet forage, 3) 5.0 g CRINA/25 kg of wet forage, or 4) a buffered propionic acid based product, 4 lb/ton of wet forage (Kemin Industries, West Des Moines, Iowa). After ensiling, addition of CRINA had no effect on silage fermentation or the aerobic stability of corn silage. As expected, addition of the buffered propionic

acid based product increased the concentration of propionic acid ($P < 0.05$) and decreased the yeasts in silage (4.45 vs. 5.16 log cfu/g, $P < 0.05$) but only numerically improved aerobic stability (47.5 vs. 59.5 h) when compared to untreated silage. The findings of this study show that CRINA was unable to affect silage fermentation or aerobic stability but it increased DM intake and milk production in dairy cows.

Key Words: Essential Oils, Milk Production, Silage

212 The effects of *Lactobacillus buchneri* 40788 and damage to the corn ear on the fermentation, aerobic stability, and production of mycotoxins in corn silage. R. S. Teller^{*}, R. J. Schmidt, and L. Kung, Jr., University of Delaware, Newark.

We examined the effects of damaging ears of corn and microbial inoculation on the fermentation, aerobic stability, and production of mycotoxins in whole plant corn silage. Ears of corn on several plants were slashed, exposing damaged kernels to the environment. Seven days later, whole plant corn was harvested at 35% DM and ensiled in 20-L laboratory silos (packing density of 227 kg DM/m³ or 14 lb/ft³) in quadruplicate as one of the following treatments: 1) no inoculation and undamaged ears of corn (CC), 2) inoculation with *L. buchneri* 40788 (400,000 cfu/g of fresh forage) and *Pediococcus pentosaceus* (100,000 cfu/g) (Lallemand Animal Nutrition, Milwaukee, WI) and undamaged ears of corn (IC), 3) no inoculation and damaged ears of corn (CD), 4) inoculation and damaged ears of corn (ID). After 126 d of ensiling, regardless of damage to the ear, inoculated silages had higher concentrations of acetic acid (1.59 vs. 0.87%, $P < 0.05$), lactic acid (4.39 vs. 3.47%, $P < 0.05$), and 1,2 propanediol (0.87 vs. 0.0%, $P < 0.05$) than did uninoculated silages. Inoculated silages had fewer yeasts (0.61 vs. 3.33 log cfu/g) and thus were more aerobically stable (74 vs. 43.3 h, $P < 0.05$) than were uninoculated silages. Although initial numbers of yeasts and molds and concentrations of deoxynivalenol (DON) and fumonisin B1 (FB1) toxins were not different in fresh corn forage, between forage with damaged and undamaged ears, silage with damaged ears had higher concentrations of DON (3872 vs. 1009 ppb, $P < 0.05$) and FB1 (9.05 vs. 4.07 ppm, $P < 0.05$). Silages made from corn with damaged ears tended to have higher concentrations of ethanol (5.40 vs. 4.31, $P < 0.06$). Addition of *L. buchneri* 40788 and *P. pentosaceus* altered silage fermentation and improved the aerobic stability of the corn silage, regardless of damage to the ear before ensiling, but it was not able to prevent an increase in the production of mycotoxins during ensiling.

Key Words: Aerobic Stability, *Lactobacillus buchneri*, Mycotoxins

National ADSA Production Only (Graduate) II

213 Effects of providing supplemental methionine (Met) in the form of SmartamineTM M or 2-hydroxy-4-methylthio butanoic acid isopropyl ester (HMBi) to prepartum and early lactation dairy cows on feed intake and lactational performance. R. S. Ordway^{*1}, N. L. Whitehouse¹, A. M. McLaughlin¹, C. G. Schwab¹, and B. K. Sloan², ¹University of New Hampshire, Durham, ²Adisseo USA, Inc., Alpharetta, GA.

Sixty primiparous (n=18) and multiparous (n=42) Holstein cows were blocked according to parity and expected calving date and assigned randomly to one of three dietary treatments: 1) basal diet, 2) basal diet plus HMBi, or 3) basal diet plus SmartamineTM M. Treatments were initiated 21 d before expected calving and continued through 140 d postpartum. Methionine supplements were added to the diet of each cow in amounts needed to achieve predicted concentrations of Lys (7.19%) and Met (2.37%) in metabolizable protein of 3.0:1.0 (NRC, 2001). It was assumed that 50% of the HMBi in dietary HMBi is converted to metabolizable Met and that 80% of the Met in SmartamineTM M is absorbed. Prepartum DM intake (13.5 kg/d), body weight (687 kg), and body condition score (3.81), and postpartum milk yield (42.0 kg/d), milk fat yield (1549 g/d), milk fat content (3.66%), milk true protein yield (1192 g/d), and milk urea nitrogen content (12.9 mg/dl) were not different among treatments. Postpartum DM intake and body condition score were greater and milk/DM intake and milk N/feed N ratios were less for cows fed HMBi than for cows fed the control and SmartamineTM M diets (22.9 vs. 22.0 and 21.4 kg/d; 3.37 vs. 3.26 and 3.28; 1.92 vs. 2.00 and 1.98; 0.32 vs. 0.33 and 0.34, respectively). Milk protein content

was greater for SmartamineTM M (2.87%) and HMBi (2.81%) than for control (2.72%). Concentrations of Met and Met+Cys in total plasma AA were different among treatments with values for SmartamineTM M being the highest followed by HMBi and control (2.10, 1.43, and 1.15% and 3.92, 3.12, and 2.73%, respectively). The results indicate that both HMBi and SmartamineTM M are effective in providing metabolizable Met, but clarification of their relative contributions to metabolizable Met is still needed.

Key Words: Lactating Cows, Rumen Protected Methionine, Methionine Analogs

214 Comparison of Holstein, Brown Swiss and Jersey cows for age at first calving and first calving interval. T. B. Garcia-Peniche^{*1}, B. G. Cassell¹, I. Misztal², and R. E. Pearson¹, ¹Virginia Polytechnic Institute and State University, Blacksburg, ²University of Georgia, Athens.

The objective of this study was to examine breed differences due to geographic location and birth season on age at first calving and first calving interval, and the effect of season of first calving on first calving interval in Holsteins and Jerseys and Holsteins and Brown Swiss housed on the same farm. Data were analyzed for five (R5) or seven regions (R7) within the United States. The geographic division definition influenced the effect of season of first calving on first calving interval in Holstein-Jersey farms ($P = 0.68$ in R5 and $P < 0.01$ in R7). Holsteins housed with Jerseys (HJ) had shorter first calving intervals and calved at younger

ages than Holsteins housed with Brown Swiss (HB). Data from seven states (California, Oregon, Arizona, Texas, Florida, Ohio and Wisconsin) were also analyzed (S7). In general, Jerseys had the youngest age at first calving and shortest first calving interval, except in the Northwest for age at first calving, and in Florida, Texas and California for first calving interval. Holsteins and Brown Swiss did not differ for first calving interval ($P=0.98$ in R5, $P=0.33$ in R7, and $P=0.09$ in S7). Cows in Texas and Florida had the longest first calving interval (HB 481.4 \pm 20.4, Brown Swiss 448.7 \pm 23.7, HJ 482.9 \pm 20.7, and Jerseys 461.2 \pm 20.9 for Florida, and 487.9 \pm 11.4, 475.9 \pm 11.6, 491.9 \pm 16.1, and 477 \pm 16.8 for Texas, respectively). Brown Swiss had the shortest first calving interval in Texas, Florida and California. Conclusions: Brown Swiss showed evidence of heat stress resistance, the geographic definition affected some of the results, and management practices changed Holsteins' performance depending on their herdmates' breed. Longer calving intervals might not be entirely due to lower fertility, but also due to longer voluntary waiting period to breed the cows.

Key Words: Breed Comparison, Age at First Calving, First Calving Interval

215 One-time oral nucleotides enhance immune function of newborn beef calves. C. E. Oliver*¹, F. Philippe², G. Gaillard², R. B. Danielson¹, W. L. Keller¹, C. Rupprecht³, M. L. Bauer¹, and C. S. Park¹, ¹North Dakota State University, Fargo, ²Ecole Supérieure D'Agriculture D'Angers, France, ³Rabies Laboratory, Centers for Disease Control and Prevention, Atlanta, GA.

The aim of this study was to determine the effect of a one-time oral dose of nucleotides at birth on calf health and immune status. Twelve colostrum-deprived, newborn, beef calves (36.9 \pm 1.4 kg initial body weight) were assigned randomly to either milk replacer only or milk replacer plus nucleotides. Nucleotides were supplemented at 10 times the level found in cow milk (monophosphate form of adenosine = 0.08, cytidine = 2.28, guanosine = 0.96, inosine = 1.28, and uridine = 20.6 μ mol/kg body weight per d). Milk replacer was fed by dry powder weight at 0.7% of the birth weight of each calf. Milk replacer was fed reconstituted with 2 quarts warm water within 2 h of birth. Treatment calves received nucleotides in the milk replacer at the first feeding only. Other feedings in first 24 h for both groups were milk replacer only. Thereafter, calves were allowed to suckle dams. A rabies vaccine was administered at birth. Calves were weighed on d 0, 7, 14, and 21. Scours incidence was scored [2-point scale (0 = normal; 1 = scours)] daily for 3 wk. Morbidity, mortality, and treatment were recorded. Jugular blood was drawn from each calf immediately after birth (prior to feeding or other post-partum processing); at h 6, 12, 24, and 48; and d 7, 14, and 21, and analyzed for glucose, nonesterified fatty acids (NEFA), haptoglobin, immunoglobulins G (IgG) and M (IgM), and rabies vaccine titer. Nucleotide supplementation did not affect ($P \#8805$ 0.25) body weight, scours score, mortality, or serum glucose, NEFA, haptoglobin, or rabies titer. Nucleotide-fed calves tended to have higher IgG levels ($P = 0.08$) than controls (251.7 \pm 26.8 vs 175.0 \pm 28.3 mg/dL). IgM was higher ($P = 0.03$) in nucleotide-fed calves than in controls (70.0 \pm 9.9 vs 34.0 \pm 10.2 mg/dL). Results suggest that a one-time oral dose of nucleotides at birth may enhance immune status of neonatal beef calves by increasing immunoglobulin levels.

Key Words: Nucleotide, Calf, Immune Function

216 Insulin sensitivity in lactating dairy cows and neonatal calves: Comparison of the minimal model and the hyperinsulinemic euglycemic clamp. C. C. Stanley*¹, C. C. Williams¹, H. G. Bateman, II¹, D. T. Gantt¹, J. C. Roberts¹, P. T. Richardel¹, J. C. Lovejoy², and E. Ravussin³, ¹LSU AgCenter, Baton Rouge, LA, ²Bastyr University, Kenmore, WA, ³Pennington Biomedical Research Center, Baton Rouge, LA.

Nine neonatal calves and twelve lactating cows were used to compare the minimal model (MM) computer analysis of the frequently sampled

glucose tolerance test (FSIGT) to the hyperinsulinemic euglycemic glucose clamp (EC) in assessing insulin sensitivity (S_I). During the FSIGT glucose was administered (0.3g/kg BW) followed 20 min later by insulin administration (0.03 IU/kg BW) through a jugular catheter. Blood samples were collected relative to glucose administration for a 6 hr period for measurement of plasma glucose and insulin concentrations which were used in the MM to derive S_I . The EC used a variable rate of glucose infusion to achieve euglycemia (defined as basal glucose concentrations measured prior to the test) while infusing insulin at 1 mU/kg \cdot min⁻¹ in calves or 6 mU/kg \cdot min⁻¹ in cows. Insulin and glucose were infused through a jugular catheter. Blood was collected every 5 min, and glucose concentrations were measured using a handheld glucometer. Glucose disposal rate (GDR) was calculated from the glucose infusion rate after euglycemia was achieved. The GDR was converted to S_I by factoring the change in plasma insulin from basal to hyperinsulinemia and plasma glucose at euglycemia. The S_I from the MM and EC were converted to a common index of insulin sensitivity (S_C). Spearman correlation coefficients were calculated between S_I from the MM and EC. In calves the mean S_C was 0.22 \pm 0.17 and 0.34 \pm 0.21 dL/min \cdot μ U⁻¹ \cdot mL⁻¹ from the MM and EC, respectively. In cows the mean S_C was 0.29 \pm 0.25 and 0.42 \pm 0.15 dL/min \cdot μ U⁻¹ \cdot mL⁻¹ from the MM and EC, respectively. The tests tended to be correlated in calves ($r = 0.42$) but not in cows ($r = -0.08$). The MM and EC do not seem to be directly comparable in cattle and should not be interchanged. Both tests are adequate for measuring differences in S_I when evaluating treatments.

Key Words: Minimal Model, Hyperinsulinemic Euglycemic Clamp, Insulin Sensitivity

217 Effects of colostrum feeding time and sex on serum leptin and fatty acid metabolism in newborn Holstein calves. L. J. Driedger*, J. A. Jackson, K. Meek, and S. T. Franklin, University of Kentucky, Lexington.

Serum leptin has been shown to be negatively correlated to non-esterified fatty acids (NEFA) in adult Holstein cows. Leptin is also a stimulator of the thermogenic capacity of brown adipose tissue, the main source of body heat production earliest in the baby calves life. The objectives of this experiment were to measure the effects of feeding or withholding colostrum and sex on serum leptin and fatty acid metabolism in newborn calves. Eighteen Holstein calves were divided into three experimental groups. Group 1 consisted of 6 male calves that were withheld from colostrum for 12 hours after birth (Not Fed = NF). Groups 2 and 3 consisted of 6 male or 6 female calves that were fed colostrum as soon as they could suckle (Fed Male = FM, Fed female=FF). Immediately after birth, all calves were separated from dams to prevent maternal suckling. Calves were weighed and an initial 0 hour blood sample was drawn. Calves from the FM and FF groups were then fed 2.13 L of maternal colostrum. Additional blood samples were drawn at 3, 6, and 12 hours after feeding. Blood samples were drawn from NF calves at 0, 3, 6 and 12 hours after birth. The NF calves were fed 2.84 L of maternal colostrum immediately following the 12-hour blood sample. Blood was analyzed for serum leptin, NEFA, and β -hydroxybutyrate (BHBA). Data were analyzed using the PROC MIXED procedures of SAS. There were no significant effects of colostrum treatment (NF vs. FM) on serum leptin ($P=.6708$). However, leptin was significantly higher and increased over time for the FF group compared to the FM group at 3, 6, and 12 hours ($P<.01$). Effects of sex were not significant on NEFA for any time period ($P=.7580$) when comparing the FM and FF groups. However, NEFA was significantly lower and decreased over time for the FM group compared to the NF group at 3, 6, and 12 hours ($P<.01$). BHBA concentrations were not different according to sex (FM vs. FF, $P=.8099$), but were significantly higher for the FM group compared to the NF group at the 12 hour sampling time ($P<.0001$). Serum leptin appears to be negatively correlated to NEFA in baby calves from 0 to 12 hours after birth.

Southern Branch ADSA Graduate Student Paper Competition

218 Effect of length of cut and degree of kernel processing of corn silage on production characteristics of lactating Holstein cows. K. M. Cooke* and J. K. Bernard, *The University of Georgia, Tifton.*

Forty mid-lactation Holstein cows were used in a 9-wk randomized block trial to determine the effect of the degree of kernel processing (KP) and theoretical length of cut (TLC) on nutrient intake and digestibility and milk yield and composition. Corn was harvested at 3/4 milk line stage of maturity at either 1.90 or 2.54-cm TLC. At each TLC, corn was processed at either 2 or 8-mm roll clearance. A control was harvested at 1.90-cm TLC without processing. All treatments were stored in 2.4 m plastic bags and allowed to ferment approximately 5 mo before feeding. Corn silage provided 38% of the DM in the experimental diets which were fed once daily behind Calan doors. No differences in DM or nutrient intake were observed among treatments. Milk yield tended to be higher ($P = 0.07$) for cows fed processed versus unprocessed corn silage (36.0 vs. 35.4 kg/d, respectively). No differences were observed in milk fat (3.88%) or protein (3.10%) due to TLC or KP. However, an interaction between TLC and KP was observed for yield of milk ($P = 0.09$), fat ($P = 0.09$), protein ($P = 0.01$), and energy-corrected milk ($P = 0.03$) because of high yield for cows fed diets containing corn silage processed at 2 mm versus 8 mm at 2.54-cm TLC. Whole tract NDF digestibility tended to be higher ($P = 0.06$) for cows fed processed versus unprocessed corn silage (60.9 vs. 50.1%, respectively) and for animals fed corn silage chopped at 2.54 vs. 1.90-cm (64.4 vs. 54.9%, respectively). Starch digestibility was greater ($P = 0.003$) for corn silage processed at 2 versus 8-mm (92.1 vs. 86.0%, respectively). These results indicate that as TLC increases, the degree of KP becomes more critical for maintaining fiber digestibility and milk yield.

Key Words: Corn Silage, Kernel Processing, Theoretical Chop Length

219 Evaluating the effectiveness of decreasing the dosage of GnRH for ovulation synchronization and timed AI in dairy cows. L. E. McKee*, W. M. Graves, and J. D. Clark, *The University of Georgia, Athens.*

The objective of this study was to determine the effectiveness of decreasing the dose of GnRH (Cystorelin, Merial Limited, Duluth, GA) used in the ovulation synchronization (Ovsynch) protocol. First service lactating Holstein cows ($n=100$) at the University of Georgia Dairy Center in Athens were randomly assigned to 1 of 4 treatment groups (25/trt). All cows received 25 mg of PGF 2α (Lutalyse, Pfizer Animal Health, New York, NY) 11 days (d -11) prior to starting Ovsynch. Cows in treatment 1 received 100 μ g GnRH on day 0, 25 mg PGF 2α on day 7, and 100 μ g GnRH on day 9. Treatment 2 received 50 μ g GnRH on day 0, 25 mg PGF 2α on day 7, and 100 μ g GnRH on day 9. Treatment 3 received 100 μ g GnRH on day 0, 25 mg PGF 2α on day 7, and 50 μ g GnRH on day 9. Treatment 4 received 50 μ g GnRH on day 0, 25 mg PGF 2α on day 7, and 50 μ g GnRH on day 9. All injections were given i.m. Blood samples were collected on days -11 and 0 for progesterone analysis. All cows were artificially inseminated (AI) 16-20 hours after the second GnRH injection. Pregnancy was checked via ultrasound at 35-40 days and 55-60 days after AI. Data was analyzed by Chi Square. The 100 cows averaged 2.3 lactations, 68 days in milk and 88 lb of milk on DHIA. Pregnancy rates at 35-40 days were 52%, 32%, 44%, and 56% for treatments 1, 2, 3, & 4 respectively ($P>.05$, NS). At 55-60 days, the rates were 36%, 28%, 36%, and 48% (NS). Embryonic losses between days 40 and 60 were 16%, 4%, 8%, & 8%. Overall pregnancy rates were 46% at 40 days and 37% at 60 days (NS). A total of 14 of the 100 cows were considered to be noncyclic (both samples < 1.0 ng/ml), and only 2 of these were pregnant at 35-40 days versus 44 of the 86 cyclic cows (either or both samples $> \text{ or } = 1.0$ ng/ml). A total of 28.8% of 28 were pregnant at 55-60 days when the highest temperature-humidity index (THI) on the day bred was $> \text{ or } = 80$, 45.2% of 31 when the THI was between 70-79 and 36.6% of 41 when the THI high was 69 or $<$ (NS). During the 11 months of this study, days open on DHIA decreased 34 days.

Physiology of Lactation

220 Use of serial analysis of gene expression (SAGE) for gene transcript profiling in lactating bovine mammary gland. E. E. Connor*, A. V. Capuco, and T. S. Sonstegard, *USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD.*

Serial analysis of gene expression (SAGE) methodology permits quantitative analysis of global gene expression in a given tissue and is useful for comparison of gene expression patterns across physiological states and identification of novel transcripts. At present, only three SAGE libraries have been produced in cattle from cultured kidney, cultured aorta and immature B cells, and are publicly available in the NCBI SAGEmap database (<http://www.ncbi.nlm.nih.gov/SAGE/>). Our interest is in characterizing gene expression in bovine mammary parenchyma during lactation; however, the disproportionate abundance of milk protein transcripts during this physiological stage hinders the use of microarrays for transcript profiling. To evaluate gene expression during early lactation, a SAGE library was produced from pooled RNA ($n=3$ multiparous Holstein cows) isolated from biopsied mammary parenchyma at approximately Day 7 of lactation. Preliminary sequencing of SAGE tags identified the greatest abundance of α -, β - and κ -casein, α -lactalbumin, β -lactoglobulin and ribosomal protein transcripts, as expected. However, a number of tags corresponding to bovine expressed sequence tags and genes involved in metabolism, intracellular signaling and proteolysis were detected in lower abundance. Our results suggest that SAGE is a feasible approach to study gene expression in lactating mammary gland.

221 Differential effects of ovarian hormones on epithelial proliferation in the porcine mammary gland. A. S. Barndollar*, J. M. Scudder, J. F. Trott, and R. C. Hovey, *University of Vermont, Burlington.*

Development of the mammary gland (MG) architecture in gilts must occur prior to pregnancy and lactation. Ultimately this development is of major importance as it influences a sows milk production and growth of her piglets. Here we investigated the regulation of cell division in the MG of gilts by ovarian steroid hormones. Based on data from other species, we hypothesized that estrogen (E) would stimulate greater proliferation of mammary epithelial cells compared to progesterone (P). Five-month-old female Yucatan miniature pigs were treated with either E (0.1mg/kg), P (0.25mg/kg) or saline (SAL) by daily sc injection ($n=4$ per group) for five days. Prior to euthanasia, animals were injected with bromodeoxyuridine (BrDU, 5mg/kg), a nucleotide analog incorporated into newly synthesized DNA. MG tissues were sampled, fixed and prepared as paraffin sections. In order to localize dividing cells, an immunohistochemical procedure was developed using a biotinylated anti-BrDU antibody, followed by chromogenic detection of a red precipitate (Vector Red) in nuclei of hematoxylin-counterstained sections. To determine cellular proliferation rates, two hundred cells were counted from each of five ducts in two MGs for each pig. The percent of cells dividing was determined as the proportion of total cells counted that were BrDU-positive. Hormone treatment significantly altered epithelial cell proliferation in the mammary ducts. Proliferation rate following treatment with SAL, E or P was $5.77\pm 1.8\%$, $13.7\pm 8.8\%$ and $1.5\pm 0.9\%$, respectively, indicating that proliferation was increased by E ($P=.007$) and decreased by P ($P=.078$). These changes were also accompanied by alterations in both parenchymal morphology and histology. Taken together, these results indicate a positive effect of E and a negative effect

of P on epithelial proliferation in the MG of gilts. This knowledge may be lead to enhanced mammary growth in gilts and milk production by sows.

Key Words: Mammary Gland, Estrogen, Progesterone

222 Effects of continuous milking and bST on mammary cell proliferation, milk yield and composition in primiparous cows. E. L. Annen*, A. C. Fitzgerald, P. C. Gentry, and R. J. Collier, *University of Arizona, Tucson.*

Continuous milking (CM) of bST-treated cows resulted in no loss of production in multiparous cows, but a 20 to 25% loss in primiparous cows suggesting mammary development in primiparous cows is inhibited by CM. Objectives were to determine effects of CM and bST 1) on mammary epithelial cell (MEC) proliferation during late gestation and early lactation and 2) on milk yield and composition. Primiparous cows were randomly assigned to either continuous (throughout late gestation and early lactation) bST (+bST; n=4) or no bST (-bST; n=4) treatment. Within each animal, udder halves were randomly assigned to CM or a 60-d dry period (CTL) treatment. CTL glands were dried 60 d prior to expected parturition date. CM glands were milked twice daily and yield recorded until parturition or spontaneous dry-off. In the subsequent lactation, daily milk yield and weekly milk composition was measured until 30 d postpartum. Mammary biopsies were taken at -20, -8, +2, +7, and +20 d relative to parturition. CTL+bST and CTL-bST udder halves were dry for 54.4 and 63.3 d and CM+bST and CM-bST halves were dry for 5.6 and 3.1 d due to spontaneous dry-off. Prepartum half-udder milk yield was greater ($P < 0.01$) in +bST cows than -bST cows (11.0 vs. 8.9 kg/d). Postpartum half-udder milk yields (10.6 vs. 22.2 kg/d) were dramatically reduced ($P < 0.01$) in CM halves compared to CTL halves, regardless of bST treatment. Postpartum milk yield in CM and CTL udder halves was not altered by bST treatment. Milk composition (fat, protein, SCC linear score) was not affected by CM or bST treatment. MEC proliferation (Ki67 antigen index) was greater in CM than CTL glands at d -20 (3.7 vs 2.3%; $P < 0.05$), but less at d -8 (4.6 vs. 2.7 %; $P < 0.05$). MEC proliferation was not affected by CM at d +2, +7, and +20 and was not altered by bST at any time point. Results indicate that CM reduced subsequent half-udder milk yield in primiparous cows and MEC proliferation near parturition (-8 d). Negative effects of CM were not overcome by bST supplementation.

Key Words: No Dry Period, Continuous Milking, bST

223 Effects of continuous milking and prostaglandin E₂ on milk yield and composition. E. L. Annen*¹, C. M. Stiening¹, M. E. Dwyer¹, B. A. Crooker², A. C. Fitzgerald¹, and R. J. Collier¹, ¹University of Arizona, Tucson, ²University of Minnesota, St. Paul.

Continuous milking (CM; no dry period) of primiparous cows reduces milk yield in the subsequent lactation regardless of bST treatment while CM of multiparous cows results in no decrease in yield when treated with bST. This parity effect may be caused by CM inhibiting mammary development in primiparous cows. Reduced mammary epithelial cell (MEC) growth has been demonstrated in CM glands. Stimulation of mammary development in CM glands may alleviate reduced milk yields. Prostaglandin E₂ (PGE) in mammary secretions rises during the last 3 wk of gestation and returns to basal levels by 2 d postpartum (PP). This rise in PGE corresponds with a period of rapid MEC growth and differentiation. Prepartum (PR) intramammary infusions (IMI) of PGE were mammary in late-pregnant heifers. The objectives of this study were to determine effects of CM and PGE on milk yield and composition. The study used first or second lactation cows (n=8). Within each cow, udder halves were randomly assigned to CM or a 60-d dry period (CTL) and PP IMI of PGE (+PGE) or no PGE (-PGE). Cows were on study from 67 d PR to 28 d PP. At 60 d PR the CTL udder half was dried. Milk yield was recorded daily and milk composition determined weekly. PGE treatment (875 µg/10 ml medium chain triglyceride oil) was administered by IMI at parturition and at 72 h PP. CTL halves were dry 64.0 d and CM halves were dry 12.6 d as a result of spontaneous dry-off of some CM halves. Milk yield was reduced ($P < 0.01$) in CM udder halves compared to CTL halves (13.2 vs. 22.1 kg/d), but reductions were less substantial in second lactation cows compared to first lactation cows (33% vs. 53%). Milk composition (fat, protein, SCC linear score, and lactose)

was unaltered by CM. No effect of PGE on milk yield or composition was detected in CTL or CM glands. Results confirm that CM reduces milk yield of cows with a mammary growth requirement. Reduced milk yield was not alleviated by PGE suggesting PGE concentrations in CM glands are not limiting mammary growth or milk synthesis.

Key Words: No Dry Period, PGE₂

224 Influence of leptin single nucleotide polymorphism on lactation curve traits for lactating dairy cows. H. W. Soita*, D. A. Christensen, F. C. Buchanan, T. L. Heck, and J. J. McKinnon, *University of Saskatchewan, Saskatoon, SK, Canada.*

DHI test day records of milk production of 48 cows (TT=15, TC=14, CC=19) from the University of Saskatchewan dairy research unit during the years 2000 to 2001 were used to study the influence of leptin single nucleotide polymorphism (C/T transition that results in an Arg25Cys)) on lactation curve traits. Phenotypic traits of the milk yield lactation curve were estimated by fitting Woods (1967) gamma function to data recorded monthly by DHI. The traits of interest included rates of incline to reach peak yield b, rates of decline after peak yield c, peak yield, days to peak yield, persistency and total yield. Only data from animals with lactation period over 280d were included. The genotype structure of the herd based on leptin SNP showed that of the 134 cows genotyped 27.6, 44.0 and 28.4 % were TT, TC and CC respectively. Days to peak yield was defined as b/c, Peak yield was calculated as a (b/c)^{be}-b, persistence was calculated as -(b+1)ln(c). The area under the lactation curve was taken to represent the total yield of the 305d lactation. The influence of leptin SNP on lactation curve's rate of incline, days to peak and persistency depended on parity. The TT/TC cows in their first lactation exhibited steeper ($P < 0.05$) incline rates consequently they (TT/TC) reached peak lactation earlier ($P < 0.05$) as compared to the CC. Persistency tended to be higher ($P < 0.1$) for the first calf TT/TC cows as compared to the CC. Similarly total 305-d lactation milk yield showed trends for higher yields for the TT/TC younger cows. We also note here that total 305-d milk yield is negatively correlated with rate of decline c implying that the TT/TC cows with less steep decline have higher milk production potential. It is concluded that a phenotypic variation with reference to lactation curve exists due to the leptin SNP in dairy cows in the first lactation.

225 Identifying positive effectors of milk protein synthesis: amino acids and glucose. C. A. Toerien*, D. R. Trout, and J. P. Cant, *University of Guelph, Guelph, ON, Canada.*

In eukaryotic cells, nutrients play an important role in activating the cell signalling cascades that regulate protein synthesis. To assess the effect of amino acids and glucose in the mammary gland, Holstein cows were fasted to quench protein synthesis before re-supplying nutrients. In a 6x6 Latin Square design, cows (initial: 69±4 DIM; 43.4±0.5 kg milk/d) were subjected every 14 d to a 31-h fast. For the last 9 h of the fast, cows were infused iv with EAA+Glc (positive control), Glc, Met+Lys, His, Leu, or saline (Sal; negative control). Blood samples were collected at 1 d, -1 min and hourly during the infusion, and at +1 d. Milk production response to infusion was calculated from milk produced in the front quarters between +1 and +7 h of the 9-h infusion. At +9 h, an approximately 1.5-g biopsy sample of mammary tissue was harvested from a hindquarter (HQ). In successive periods, HQs were alternated so that each HQ was allowed 28 d to recover. Post-biopsy, cows were refed and infused with AA+Glc for 5 h. Relative to Sal, infusion of EAA+Glc increased ($P < 0.05$) total milk, lactose and protein yields by 83, 106 and 45% respectively. Infusion of glucose alone resulted in similar responses (83, 98 and 41% respectively; $P < 0.05$), implicating Glc as a powerful activator of protein synthesis. Infusion of His elevated milk (29%) and lactose (36%) yields above Sal ($P \# 88040.07$). Met+Lys-, His- and Leu-stimulated protein yields did not differ from Sal ($P > 0.05$). Nor did His-stimulated protein yield differ from EAA+Glc ($P > 0.05$). The effect of His on protein yield equalled 57% of the effect of EAA+Glc, which was far greater than its 5% proportion in the EAA of the EAA+Glc infusate. In conclusion, both glucose and His affected changes in milk synthesis

that implies responses in signal cascades in the mammary epithelial cell.

Milk	Treatments					
	Sal	EAA+Glc	Glc	Met+Lys	His	Leu
Total, kg	1.71 ^a ±0.1	3.13 ^b ±0.1	3.13 ^b ±0.1	2.06 ^a ±0.1	2.2 ^a ±0.1	1.95 ^a ±0.1

226 Cloning and expression of bovine glucose transporter GLUT8. F. Zhao*, P. Miller, E. H. Wall, Y. Zheng, B. Dong, and T. McFadden, *Lactation and Mammary Gland Biology Group, Department of Animal Science, University of Vermont, Burlington.*

GLUT8 is a new member of the facilitative glucose transporter family, exhibiting high-affinity glucose transport activity. The expression of GLUT8 has been shown to depend on gonadotropin secretion and may be regulated by insulin. To study the role of GLUT8 in glucose uptake and maintenance of glucose homeostasis in lactating bovine tissues, we cloned and sequenced the full length cDNA of bovine GLUT8 (GenBank accession no. AY208940) by RACE (rapid amplification of cDNA ends). The 2073 base pair cDNA sequence is predicted to encode a protein of 478 amino acids, with a molecular weight of approximately 51 kDa. The deduced amino acid sequence of bovine GLUT8 has 90%, 84%, 84% and 58% identity to human, mouse, rat and chicken GLUT8, and is 26%, 27% and 24% identical with bovine GLUT1, GLUT3 and GLUT4. Bovine GLUT8 retains the characteristic structural features of GLUT8 proteins previously identified from other species including membrane spanning helices, glucose transporter motifs, an N-linked glycosylation site on loop 9 and a putative dileucine internalization motif. The major in vitro transcription and translation product of bovine GLUT8 cDNA migrated at an apparent molecular weight of 38 kDa similar to the sizes reported for GLUT8 from other mammalian species. In the presence of canine microsomal membranes, the translation product increased to 40 kDa suggesting glycosylation. Transient transfection studies in COS-7 and MAC-T 11A cells using a FLAG epitope tagged construct revealed that bovine GLUT8 is localized to the cytoplasm in non-stimulated conditions. A 2.1 kb GLUT8 mRNA transcript was detected at the highest levels in bovine testes, at medium levels in lactating bovine mammary gland, lung, kidney, spleen, intestine and skeletal muscle, and at lower levels in bovine liver. GLUT8 mRNA expression in bovine mammary gland increased about ten-fold ($P < .001$) during late pregnancy and early lactation, similar to changes in expression of GLUT1. These results indicate that GLUT8 expression may be regulated by lactogenic hormones and GLUT8 may play a role in glucose uptake in the lactating bovine mammary gland.

Key Words: Glucose Transport, Glucose Uptake, Mammary Gland

227 Effects of a shorter duration of photoperiod treatment during the dry period on cellular immune function in dairy cattle. T. L. Auchtung*, E. D. Reid, D. E. Morin, and G. E. Dahl, *University of Illinois, Urbana.*

The periparturient period is a time of increased immunosuppression and risk of mastitis in cows. Previously, our laboratory has observed an enhanced cellular immune function in cows treated with short day photoperiod (SDPP) while dry, relative to long day photoperiod (LDPP). However, comparisons have not been made with natural photoperiod, or with further manipulations of photoperiod during the dry period. The objective of this experiment was to determine the effect of natural photoperiod during the dry period on cellular immune function, relative to current photoperiod management practices. In addition, we were interested in investigating the effects of modifications of the standard SDPP during the dry period. Holstein cows ($n = 30$) were assigned randomly to one of four dry period treatments: LDPP (16 h light: 8 h dark), SDPP (8 h light: 16 h dark), AMB (natural lighting schedule during dry period), and SD21 (AMB until 21 d prepartum followed by SDPP). After parturition, cows were exposed to AMB. Blood was collected at dry off and every 4 wk until 21 d prepartum, at which time sampling occurred weekly until calving. Mitogens used were concanavalin A and pokeweed mitogen. Neutrophil chemotaxis was measured in response to interleukin-8. At dry off, there was no difference for either lymphocyte proliferation or neutrophil chemotaxis. After 4 wk on treatment, SDPP

had enhanced ($P < 0.05$) neutrophil chemotaxis and lymphocyte proliferation than cows on LDPP or AMB. Cows on SD21 at 4 wk were on the same photoperiod treatment as AMB and had similar responses to AMB and LDPP groups. In conclusion, SDPP improves cellular immune function compared with both LDPP and AMB treatments. These data suggest that SDPP has beneficial effects on cellular immune function during the first month of the dry period, whereas LDPP has no effect on immune function of the dry period. The consequences of shortening the duration of SDPP during the dry period on immune function is being examined.

228 Comparison of gene expression changes in the two subunits of bovine IgG1 receptor during colostrogenesis. D. G. Martinez*, R. Thomason, and T. B. McFadden, *University of Vermont, Burlington.*

Massive transfer of IgG1 into bovine colostrum is mediated by the mammary Fc receptor. This receptor consists of two light and two heavy chains, β_2 -microglobulin and FcRn, respectively. Previous studies have suggested that FcRn is up-regulated three weeks before parturition to facilitate the transfer of plasma IgG1 into colostrum. Conversely, another study has reported that β_2 -microglobulin is the regulated component of the receptor. To resolve this discrepancy we quantified changes in gene expression of the two units of FcRn receptor in heifers undergoing colostrum formation. Twelve non-pregnant Holstein heifers were fed melengesterol acetate (.5 mg/day) for 14 d to synchronize estrus and were then induced into lactation by treatment with estrogen and progesterone (E+P; .1 and .25 mg/kg/d) for 7 d. Twice-daily milking was initiated 21d after the initial E+P injection. Mammary biopsies were obtained at 0, 5 and 10 d relative to the initial E+P treatment. Gene expression of FcRn and β_2 -microglobulin in mammary tissue was measured by quantitative real time PCR and normalized to β -actin mRNA expression. IgG1 concentrations were determined in plasma and secretion as colostrogenesis markers. Circulating IgG1 concentrations began to decrease from about day 5 (3.7 ± 3 mg/ml) relative to the initial injection of E+P to reach a minimum around day 12 (2.8 ± 3 mg/ml; $P < .01$). A high concentration of IgG1 in secretions was detected on day 12 (54.6 ± 4.3 mg/ml) and then decreased progressively through the initiation of milking (14.9 ± 3.5 mg/ml; $P < .01$). Abundance of β_2 -microglobulin mRNA did not change over time ($P > .05$). In contrast, FcRn gene expression increased about tenfold on day 5 ($P < .01$), coinciding with the initial decrease of plasma IgG1, and then declined about sixfold by day 10 ($P < .01$). We conclude that FcRn (heavy chain) is the hormonally regulated unit of the bovine mammary epithelial Fc receptor during colostrum formation whereas β_2 -microglobulin is constitutively expressed.

Key Words: FcRn, β_2 -Microglobulin, Colostrum

229 Changes in expression of vitamin receptors in bovine mammary gland during hormone induced colostrogenesis. D.G. Martinez*, R. Thomason, and T.B. McFadden, *University of Vermont, Burlington.*

The objective of this study was to quantify changes in gene expression of megalin, low-density lipoprotein receptor (LDL-R) and folic acid receptor during hormone-induced colostrum formation to determine whether they may be involved in the transport of their ligands (vitamin A, β -carotene and folic acid) from maternal circulation into colostrum. Twelve non-pregnant Holstein heifers were fed melengesterol acetate (0.5 mg/day) for 14 d to synchronize estrus and were then induced into lactation by treatment with estrogen and progesterone (E+P; .1 and .25 mg/kg/d) for 7 d. Twice-daily milking was initiated 21d after the initial E+P injection. Mammary biopsies were obtained at 0, 5 and 10 d relative to the initial E+P treatment. β -carotene concentrations were determined in plasma and mammary secretions as an indicator of colostrogenesis. Concentrations of α -lactalbumin in plasma were measured for use as a functional marker of lactogenesis. Expression of megalin, LDL-R, and folic acid receptor mRNA in mammary tissue was determined by quantitative real time PCR and normalized to β -actin mRNA expression. Plasma β -carotene concentrations declined between -2d (3.6 ± 3 ug/ml) and 10d (3.1 ± 3 ug/ml; $P < .01$) relative to initial E+P injection, indicating colostrum formation. Concentrations of β -carotene in mammary secretions averaged $.78 \pm .09$ ug/ml at 12d, then decreased through the initiation of milking ($.49 \pm .08$ ug/ml;

$P < .01$). Plasma α -lactalbumin concentrations increased about fivefold from 10d to 15d ($P < .01$), indicating onset of lactation. Megalin expression increased about 3-fold from 0d to 5d ($P = .01$), then decreased 2.8-fold by 10d ($P = .01$). Gene expression of LDL-R decreased 4.5-fold ($P < .06$) from 5d to 10d while folic acid receptor mRNA decreased about twofold ($P < .05$). We conclude that temporal changes in expression of

megalin, LDL-R and folic receptor mRNA during colostrogenesis may be related to the transport of their ligands into colostrum. Hormonal induction of lactation provided a useful model for studying the regulation of colostrogenesis.

230 Conjugated linoleic acid (CLA) concentrations in beef tissues from cattle finished on pasture initially with limited grain. R. N. Sonon Jr.*¹, D. C. Beitz¹, A. H. Trenkle¹, J. R. Russell¹, and R. Rosmann², ¹Iowa State University, Ames, ²Rosmann's Family Farms.

Thirty Red Angus cross yearling steers and heifers (initial BW = 394 ± 54 kg) were fed to choice grade in an on-farm study to compare the concentrations of CLA in beef tissues and to evaluate beef quality of cattle finished on pasture initially or on drylot diet entirely. The cattle on the pasture group grazed by rotation forages consisting primarily of endophyte-free tall fescue grass for 207 d and then, were shifted to the drylot diet for 59 ± 15 d, whereas the drylot cattle were fed ground alfalfa-orchardgrass hay for 183 ± 16 d. In addition to the basal forage, a corn-soybean concentrate mixture was fed at 0.5 to 1.0% of BW to the pasture group of cattle while grazing, and at 2.0% of BW to the drylot group of cattle. After harvest of cattle, steaks were removed from the 12th-13th rib of the carcasses of sixteen animals for fatty acid analysis and sensory evaluation. Results showed that cis9, trans11 CLA concentration in ribeye steak of pastured cattle (0.44 g/100 g of fatty acids) was significantly higher ($p = 88040.05$) than in steak of cattle fed the drylot diet (0.17 g/100 g of fatty acid). Linolenic acid (C18:3n-3) concentration in ribeye steak of pastured cattle (0.79 g/100 g of fatty acids) was significantly higher ($p = 88040.05$) than in the ribeye steak of drylot cattle (0.61 g/100 g of fatty acids). The Warner-Bratzler shear test of tenderness of ribeye steak from pasture-fed cattle was 2.85 ± 0.61 kg and did not differ with that of the drylot cattle (2.60 ± 0.65 kg). Sensory evaluation of ribeye steaks (pasture vs drylot) included juiciness (5.83 vs 5.43), tenderness (6.61 vs 7.00), chewiness (3.14 vs 2.43), flavor (2.08 vs 2.43) and off-flavor (5.56 vs 5.55) and these attributes were not different ($p > 0.05$) between the two groups of cattle. Data from this on-farm study indicate that pasture-feeding contributed to the production of a potentially healthier beef without diminishing eating qualities.

Key Words: CLA, Beef Quality, Pasture

231 Effects of two supplementation levels of linseed combined with CLA or tallow on meat quality traits and fatty acid profile of adipose tissue and longissimus muscle in pigs. G. Bee*, S. Jacot, G. Guex, and W. Herzog, *Swiss Federal Research Station for Animal Production and Dairy Products 1725 Posieux, Switzerland.*

Linseed is an efficient dietary supplement to increase 18:3n-3 concentration in meat and adipose tissue in pigs. Increased concentration of highly unsaturated PUFA can lead to quality deterioration due to lipid oxidation. We hypothesize that inclusion of conjugated linoleic acids (CLA) or tallow could limit the potential for lipid oxidation. In the present study we evaluated the effect of CLA or tallow combined with linseed on carcass characteristics, longissimus muscle (LM) quality traits, and the fatty acid profile of the LM and adipose tissue. From 18 to 104 kg BW, 32 Swiss Large White barrows were fed a grower finisher diet supplemented either with: 1) 3% linseed (L3); 2) 2% linseed (L2); 3) 2% linseed + 1% CLA (L2C); or 3) 2% linseed + 1% tallow (L2T). The amount of omental fat was higher ($P < 0.05$) in the L3 (2.09%) compared to the L2 and L2T group (1.60% for each). Initial pH in the LM was higher ($P < 0.05$) in the L2T (6.30) compared with the L2 (6.06) and L2C (6.03) group, but did not differ from the L3 group (6.14), whereas no dietary effects were observed for ultimate pH, color, drip, cooking losses, and shear force values. Inclusion of CLA (L2C) did not affect PUFA level but increased ($P < 0.05$) the concentration of saturated and decreased ($P < 0.05$) that of monounsaturated fatty acids in the tissues compared to the other treatments. Neither CLA nor tallow altered the concentration of 18:3n-3, 20:3n-3, 20:5n-3, and 22:5n-3 compared to the L2 group. Consequently, in the 3 dietary groups the n-6/n-3 ratio was similar in the LM (2.9) and adipose tissue (3.6). As expected, the higher linseed supply (L3) resulted in increased ($P < 0.05$) 18:3n-3 and

20:3n-3 concentrations in the tissues, whereas from the higher unsaturated fatty acids of the n-3 family only 22:5n-3 level was increased ($P < 0.05$) in the adipose tissue compared to the L2, L2C, and L2T group. The present results indicate, that CLA, but not tallow, combined with linseed could help reduce the potential for lipid oxidation by decreasing the unsaturation level without affecting the improved n-6/n-3 ratio.

Key Words: Linseed, CLA, Pig

232 Consumer acceptance of beef from steers finished on ryegrass forage or a high-concentrate diet. C. R. Kerth*, K. W. Braden, R. B. Cox, and J. Alexander, *Department of Animal Sciences, Auburn University, Auburn, AL.*

Charlais-Angus crossbred steers were fed one of three finishing diets to determine consumer acceptance of forage-fed or concentrate-fed beef. When steers ($n = 30$) reached 340 kg, they were randomly assigned to one of three finishing treatments consisting of ryegrass only for 178 d (RG), ryegrass for 125 d followed by 98 d of a high-concentrate, feedlot-type diet (RGC), or a high-concentrate, feedlot-type diet for 82 d (CON). Steers from RGC and CON groups were harvested when estimated backfat thickness reached 1.0 cm and steers from the RG group were harvested when the amount of forage was insufficient to maintain animal growth. To determine consumer acceptance, 153 consumers at an outdoor festival in Auburn, AL were asked to taste steaks from each of the three treatments. Boneless, strip loin steaks were cooked (71C) on clam-shell-style electric grills, cut into 1.0 X 1.0 cm cubes and placed in double boilers kept warm over a small flame. Overall acceptability scores were determined by marking an "X" on a continuous line anchored with frowning (score of 0) and smiling (score of 100) faces and scored by interpolation. Pricing acceptability was determined in the same manner with \$7.46/kg and \$16.26/kg anchoring the line and \$11.86/kg as the midpoint of the line, representing the typical market value of a strip loin steak at the time. Consumers were then asked which steak they preferred. The demographics of those participating in the survey were evenly distributed across income levels and gender, with almost half (46.6%) being younger than 30 y and the remainder evenly distributed from 31-80 y of age. Overall acceptability scores and price per pound were higher ($P < 0.05$) for steaks from cattle finished on CON compared to steaks from cattle finished on RG or RGC. Additionally, a higher ($P < 0.05$) percentage of consumers preferred steaks from CON (63.9%) compared to RGC (13.9%) or RG (22.2%). Consumers that preferred RG beef were willing to pay \$1.17/kg more for RG beef compared to CON beef. These results indicate that a significant market exists for forage-fed beef and consumers are willing to pay a premium for it.

Key Words: Grass-Fed Beef, Consumer Acceptance, Price

233 Mechanisms of beef carcass tenderness. R. Johnson*, J. Sawdy, J. M. Reddish, M. S. Uptide, and M. Wick, *The Ohio State University, Columbus.*

This study advanced a model that was developed to investigate the potential for relating changes in electrophoretic protein patterns derived from the L. dorsi of beef cattle 36 hr postmortem with tenderness at 7 d. Previous research done in this lab showed a significant association ($R^2 = 0.82$) between tenderness at 7 days, as determined by Warner Bratzler Shear analysis, and the relative intensities of 7 bands from L. dorsi myofibrillar fingerprints of proteins/peptides derived from the same tissue at 36 hr postmortem. Mass spectrometric analyses was used to identify one of the bands, significantly associated with tenderness, as bovine fast myosin light chain-1 (bMLC1) ($P < 0.001$). The method was previously used to identify fragments of bovine myosin heavy chain as being associated with tenderness. These combined findings suggest the presence of at least two distinct mechanisms contributing to tenderness. One mechanism proposes a relationship between myosin heavy chain proteolysis and tenderness. The most recent finding indicates a positive correlation with the amount of intact bMLC1 and tenderness.

This information has the potential of increasing our understanding of the mechanisms regulating beef carcass tenderness.

Key Words: Proteomic Fingerprinting, Beef Tenderness, Myosin Light Chain 1

234 Effects of ractopamine and dietary fat source on performance and carcass characteristics of growing-finishing swine. J. K. Apple^{*1}, B. R. Kutz¹, C. V. Maxwell¹, M. E. Davis¹, L. K. Rakes¹, Z. B. Johnson¹, and T. A. Armstrong², ¹University of Arkansas, Fayetteville, ²Elanco Animal Health, A Division of Eli Lilly and Company, Greenfield, IN.

To test the interactive effects of ractopamine (RAC) and dietary fat source on performance and carcass characteristics, crossbred pigs (n = 216) were blocked by BW (78.1 ± 6.5 kg), and allotted randomly to pens (6 pigs/pen). After a 1-wk adjustment period when a common diet devoid of RAC was fed, pens within blocks were assigned randomly to 1 of 4 dietary treatments arranged in a 2 × 2 factorial design with 5% fat (beef tallow or soy oil) and RAC (0 or 10 mg/kg). All diets were formulated to contain 3.1 g lysine/Mcal of ME and 3.48 Mcal/kg of ME. Individual pig weights and feed disappearance were recorded weekly to calculate ADG, ADFI, and G:F. At conclusion of the 35-d finishing period, pigs were slaughtered at a commercial pork packing plant, and carcass weight, 10th rib fat and LM depths, and fat-free lean yield (FFLY) were recorded prior to chilling. During fabrication, right-side loins were collected for pork quality determinations. Across the entire trial, pigs fed RAC had greater (P < 0.001) ADG and G:F, but RAC did not affect (P > 0.10) ADFI. Neither tallow nor soy oil affected (P > 0.10) pig performance. Carcass weight, LM depth and FFLY were increased (P < 0.002), whereas fat depth was decreased (P < 0.06), in carcasses from RAC-fed pigs; however, carcass composition measures were similar (P > 0.10) between fat sources. The LM from pigs fed RAC had higher pH values (P < 0.01) and received higher American (P < 0.01) and Japanese (P < 0.04) color scores. Although L* values were not affected (P > 0.10) by RAC, the LM from RAC-pigs had lower a* (P < 0.002) and b* (P < 0.005) values. The LM of pigs fed soy oil received higher (P < 0.05) American color scores than pigs fed tallow; otherwise pork quality was not (P > 0.05) affected by dietary fat source. Pigs fed RAC and beef tallow had higher (P < 0.05) marbling scores than all other treatment combinations (RAC × fat source; P < 0.04). Results indicate that feeding 10 mg/kg RAC will improve rate and efficiency of gain, carcass composition, and LM quality; however, dietary fat source had little to no impact on performance or carcass composition and quality.

Key Words: Dietary Fat, Pork Quality, Ractopamine

235 Effects of ractopamine and dietary fat source on quality characteristics of fresh pork bellies. J. K. Apple^{*1}, B. R. Kutz¹, C. V. Maxwell¹, M. E. Davis¹, L. K. Rakes¹, Z. B. Johnson¹, and T. A. Armstrong², ¹University of Arkansas, Fayetteville, ²Elanco Animal Health, A Division of Eli Lilly and Company, Greenfield, IN.

To test the interactive effects of ractopamine (RAC) and dietary fat source on fresh pork belly quality, bellies (n = 167) from pigs fed 1 of 4 dietary treatments arranged in a 2 × 2 factorial design with 5% fat (beef tallow or soy oil) and RAC (0 or 10 mg/kg), were collected during carcass fabrication. Subjective belly firmness was measured using the bar-suspension method by measuring the distance between belly ends when the length of the belly was suspended perpendicular (skin-side down and up) and parallel (skin-side up) to the bar. Color (L*, a*, and b* values) of the rectus abdominus muscle and belly fat was measured, and two 5.1-cm diameter cores were removed from the center of each belly. Cores were subsequently compressed 50% their thickness with an Instron testing machine equipped with a 400-kg load-cell and a crosshead speed of 100 mm/min. There were no (P > 0.10) interactions between RAC and dietary fat source for any pork belly quality trait. Neither RAC nor fat source affected (P > 0.10) belly thickness. Subjective (bar-suspension) or objective (compression test) measures of belly firmness were not (P > 0.05) affected by the inclusion of RAC in the diet; however, bellies from pigs fed soy oil were softer (P < 0.01) than those from pigs fed tallow, as indicated by perpendicular suspension (11.66 vs. 15.40 cm, skin-side down, respectively; 17.58 vs. 20.70 cm, skin-side up, respectively) and parallel suspension (16.04 vs. 19.50 cm, respectively). Additionally, bellies from tallow-fed pigs required more (P < 0.01) force to compress 50% their thickness than bellies from soy oil-fed pigs (52.47 vs. 43.02 kg, respectively). Neither lean nor fat color was affected (P > 0.10) by RAC, and fat source had no (P > 0.10) effect on

lean color. However, the belly fat of pigs fed tallow was lighter (higher L* values; P < 0.04) and redder (higher a* values; P < 0.02) than the fat of bellies from pigs fed soy oil. Results of the present study indicate that, as expected, dietary fat source impacts the firmness of fresh pork bellies; however, feeding RAC during the late-finishing period does not affect the firmness and color of fresh pork bellies.

Key Words: Dietary Fat, Pork Bellies, Ractopamine

236 Effect of slaughter weight on pork quality of castrated females. J. Peinado^{*1}, D. García², F. Baucells¹, G. G. Mateos³, and P. Medel¹, ¹Imasde Agropecuaria Madrid, Spain, ²Estación Tecnológica De La Carne De Guijuelo Salamanca, Spain, ³Universidad Politécnica De Madrid Madrid, Spain.

A total of 150 Pietrain*Large White × Landrace*Large White females of 23.3 ± 1.5 kg of initial BW were used to study the influence of slaughter weight (SW) on meat quality. Females were castrated at 30 kg BW and slaughtered at 105, 115 or 120 kg BW. Each of three treatments was replicated five times (ten pigs housed together). Feeding program was common for all the pigs and consisted of three diets offered *ad libitum* (2.3, 2.4, and 2.4 Mcal NE/kg and 0.97, 0.70, and 0.67 % lys from 30 to 65, 65 to 95, and 95 kg BW to slaughter, respectively). At 45 min postmortem, *longissimus* muscle samples were obtained from the last rib from four pigs per replicate. Intramuscular fat content and Warner-Bratzler force of loins were determined by using a Near Infrared Transmittance meat analyzer and a texture meter, respectively. Loins from pigs slaughtered at 120 kg BW had more intramuscular fat and higher shear force values than loins from pigs slaughtered at 105 kg BW, with loins from pigs slaughtered at 115 kg BW in an intermediate position (1.99, 2.50, and 2.70 % of intramuscular fat and 6.34, 6.57, and 7.24 kg of Warner-Bratzler values for 105, 115, and 120 kg BW; P < 0.05 and P < 0.10, respectively). Defrosting and cooking losses decreased with SW (12.8, 9.2, and 11.7 %, P < 0.05; 26.0, 24.9, and 24.4 %, P < 0.10, for 105, 115, and 120 kg BW, respectively). Increasing SW increased meat color (a* value of 3.42, 4.78, and 5.07 for 105, 115, and 120 kg BW, respectively; P < 0.05). In addition, linoleic acid content of subcutaneous fat was higher for pigs slaughtered at 105 kg BW than for pigs slaughtered at 115 or 120 kg BW (11.56, 10.64, and 10.10 % for 105, 115, and 120 kg BW, respectively; P < 0.05). It is concluded that increasing slaughter weight from 105 to 120 kg improves intramuscular fat content and color of meat from heavy pigs destined to the dry-cured industry.

Key Words: Pork Quality, Castration, Slaughter Weight

237 Strategies based on gender and slaughter weight to modify carcass quality for cured product industry. J. Peinado^{*1}, A. Fuentetaja², J. Sánchez¹, G. G. Mateos³, and P. Medel¹, ¹Imasde Agropecuaria Madrid, Spain, ²CIPIESE Segovia, Spain, ³Universidad Politécnica De Madrid, Madrid, Spain.

A total of 336 Duroc × Landrace*Large White pigs of 28.4 ± 2.3 kg of initial BW were used to study the influence of sex (castrated females, CF; entire females, EF; castrated males, CM) and slaughter weight (SW) (119 vs 131 kg BW) on productive performance and carcass quality. Each treatment was replicated four times (14 pigs housed together). Males were castrated at birth and females at 30 kg BW. All pigs received a common feeding program that consisted of three diets offered *ad libitum* (2.3, 2.4, and 2.4 Mcal NE/kg and 0.97, 0.70, and 0.67 % lys, from 30 to 60 kg BW, 60 to 90 kg BW, and 90 kg BW to slaughter). For the whole period, neither gender nor SW affected productive performance, although CM and CF pigs ate 4 % more and had 4 % worse feed conversion rate than EF. Backfat and fat thickness at *Gluteus medius* muscle (GM) were greater for CF than for EF or CM (31.4, 25.2, and 28.7 mm at P2, and 20.7, 18.1, and 18.7 mm at GM for CF, EF, and CM, respectively; P < 0.05). The percentage of pigs with a fat thickness at GM equal or greater than 20 mm was 70, 42, and 48 % for CF, EF, and CM, respectively (P < 0.05). In addition, backfat thickness increased 19 % when SW increased from 119 to 131 kg (P < 0.05). Loin yield was greater for EF than for CM, with an intermediate value for CF (7.13, 7.22, and 6.91 % for CF, EF and CM, respectively; P < 0.05). It is concluded that castration of females and increasing SW from 119 to 131 kg improves carcass fat content without impairing productive performance of pigs destined to produce cured hams.

Key Words: Carcass Quality, Pig Performance, Castration

238 Evaluating the fatty acid distribution of bratwurst in retail products and of fat in Fertiliium treated sows. L. Gordon*, A. Cox, A. Schinckel, and M. Latour, *Purdue University, West Lafayette, IN.*

The objective in Experiment 1 was to investigate the fatty acid distribution of fourteen different brands of bratwurst available in retail stores. For Experiment 2, the investigators examined the fatty acid profile in the middle and outer fat layers of sows which were fed either a control diet (n=5) or a diet enriched with Fertiliium (n=5), a supplement added to swine diets in low concentration and contains a protected n3 polyunsaturated fatty acid source. Results of Experiment 1, suggest that major fatty acids (C16:0, C18:0, C18:2, as well as the n6/n3 ratio and iodine value [IV]) varied significantly (P<0.01) between brands. The levels C16:0, C18:0, C18:2, n6/n3 ratio and IV ranged between 20-27%, 33-41%, 9-19%, 8:1-37:1 and 53-70, respectively. Collectively these results would suggest that retail brand of bratwurst exhibit tremendous variability in fatty acid composition. In Experiment 2, there were significant differences (P<0.03) in the fatty acid distribution between control and Fertiliium enriched sows as well as between fat layers; more specifically and across both fat layers, enriched sows displayed a significantly lower (P<0.05) n6/n3 ratio when compared to controls. Furthermore, control sows displayed a significantly higher (P<0.05) level of n6/n3 ratio in the outer layer when compared to the middle layer. These data would suggest that enriched sows display a fatty acid profile unlike controls and may provide a better source of n3 fatty acids in ultimate products.

Key Words: Fat, Bratwurst, Sows

239 Fascicular structure as a quantitative trait for bovine and ovine skeletal muscles. G. S. Harper*¹, M. E. McKay¹, M. Taylor², T. Reverter-Gomez³, P. G. Allingham², and R. Seymour³, ¹*Cattle and Beef Quality Cooperative Research Centre, Armidale, Australia*, ²*Australian Sheep Industry Cooperative Research Centre, Armidale, Australia*, ³*CSIRO Livestock Industries, St. Lucia, Australia.*

Connective tissues (endomysium and perimysium) are important contributors to growth and development of the muscle, being the site of capillary invasion, adipogenesis and age maturation. Perimysium is also an important contributor to meat toughness, though its contribution is difficult to quantify due to the inability of extraction techniques to account for three dimensional distribution. Here we describe a morphometric technique for quantification of the amount and frequency of perimysial seams. Longissimus dorsi muscle samples were collected by biopsy or necropsy and then either chemically fixed or frozen for histological sectioning. Muscle fascicular structure (FS) was visualised at low magnification, and morphological features were measured using image analysis tools. The features included perimysial seam width (SW) and average fascicular bundle width (BW). Our data suggest that FS measurements were robust and repeatable, and stable across divergent sarcomere lengths. *Bos indicus* (10 animals) and *Bos taurus* (10) muscles could be differentiated by SW, even though the number of seams per cm of tissue did not differ (42 ± 2.3 , *Bos indicus*; 46 ± 3.8 , *Bos taurus*). Animals came from similar nutritional backgrounds. Although SW values were vastly skewed, the residuals of the fitted mixed-model were normally distributed. *Bos indicus* animals were found to have significantly fewer fine connective tissue seams than did the *Bos taurus* animals (P<0.05). *Bos indicus* also had significantly larger BW than did the *Bos taurus* animals (P<0.05). Apart from the gross phenotypic and enzymic differences between these cattle breed types, there are also finer structural differences that have resulted from the evolutionary divergence of these breeds. Measurements on FS from sheep longissimus dorsi muscle differentiated animals of divergent EBV for muscling (control muscling EBV, SW, 9.7 ± 0.4 ; high muscling EBV, SW, 8.3 ± 0.3 ; P<0.01), when nutrition was comparable. We propose that muscle fascicular structure is a heritable and developmentally regulated phenotype of mammalian skeletal muscle.

Key Words: Meat, Connective Tissue, Tenderness

240 Growth characterization of callipyge myoblasts. J. N. Fleming*, S. P. Jackson, and J. R. Blanton, Jr., *Texas Tech University, Lubbock.*

The objective of this study was to compare the growth rates of isolated myoblasts from both *callipyge* and normal (non-*callipyge*) lambs. *Callipyge* is a mutation found in sheep that causes muscle hypertrophy in the loin and hindquarters of lambs after they reach four to six weeks of age. Myoblasts, or satellite cells, are important factors in postnatal muscle growth, as they are located beneath the basement membrane and contribute to muscle fiber hypertrophy and repair. Lambs ranging from two to eight weeks of age were euthanized and the semimembranosus muscle was excised. Myoblasts were isolated by Pronase[®] digestion and a series of differential centrifugations. Cells were plated on 0.1% gelatinized round culture plates and grown in MEM- α media supplemented with ten percent fetal bovine serum. Plates were incubated at 37°C, 5% CO₂, and media was changed every two days. All plates were counted and replated using trypsin digestion. Primary plates were counted and replated at a level of one million cells per secondary plate. Secondary plates were counted every 24h, 48h, and 72h for all *callipyge* (n=13) and normal (n=19) lambs. Percent gain did not differ across genotypes at 24h (P=0.9361), or 48h (P=0.9739). However, a significant difference was seen at 72h (P=0.0135), with the average gain in *callipyge* plates at $307\% \pm 46\%$ gain, versus the normal rate of $152\% \pm 41\%$ gain. This increase in growth rate could be attributable to either an upregulated mitotic cellular division rate in *callipyge* cells, or perhaps an increased secretion of growth factors from the *callipyge* cells, promoting cell proliferation. In conclusion, there is an increase in *callipyge* myoblast growth rates *in vitro* when compared to normal ovine myoblast growth rates.

Key Words: Sheep, *Callipyge*, Myoblasts

241 Integration of myostatin-null alleles in leptin db/db mice does not alter body composition. A. C. Dilger*, A. L. Grant, M. E. Spurlock, and D. E. Gerrard, *Purdue University, West Lafayette, IN.*

Mutation in the myostatin gene and disruption of the leptin axis in animals leads to excessive accumulation of muscle and fat, respectively. Recent reports indicate that when myostatin and leptin genes are rendered nonfunctional in mice, fat accumulation in leptin obese (ob/ob) mice is suppressed; however, it is unknown whether fat accumulation is decreased when the myostatin and db/db mutations are combined. Therefore, pups from double heterozygous breeding pairs were weaned at 21 d of age and housed individually. Standard mouse chow and water were provided ad libitum. Animals were euthanized at 9 wk of age for body composition analysis. Mice were genotyped as myostatin null (MKO), leptin db/db (LKO), wild type (WT) or myostatin/leptin db/db double knock-out (DKO). At weaning (21d), LKO mice were heaviest (P < 0.05). At 6 wk of age, BW of MKO, DKO, and LKO was 22%, 41%, and 61% heavier (P < 0.05) than WT, respectively. At 9 wk of age, BW of MKO, DKO, and LKO was 26%, 98%, and 51% heavier (P < 0.05) than WT, respectively. A significant time and genotype interaction (P < 0.001) existed for BW. Percent body fat of DKO and LKO was 150%, whereas MKO body fat was 50% of WT (P < 0.001). No differences were observed in percent body fat of DKO and LKO mice. Percent protein of MKO was 10% greater (P < 0.05) whereas LKO and DKO percent protein was 41% less than WT. No differences in percent protein were observed between LKO and DKO mice. Fat mass was 4.62 g greater (29%; P < 0.05) and protein mass was 0.72 g less (13%; P < 0.05) in DKO than in LKO and MKO, respectively. These data show that mice lacking both functional myostatin and leptin axes become as obese as those mice possessing the leptin db/db mutation alone suggesting that the muscle growth potential associated with the loss of myostatin function may not be sufficient to alter body composition.

Key Words: Myostatin, Leptin, Mouse

Nonruminant Nutrition: Weanling Pig Nutrition and Health

242 Potassium source and level influence performance day 21 42 post-weaning. B. V. Lawrence*, J. D. Hahn, and S. A. Hansen, *Hubbard Feeds Inc, Mankato, MN.*

Two trials with terminal cross Duroc sired pigs were conducted to evaluate the influence of potassium (K) source and inclusion level in post-weaning diets. In Exp 1, 1,712 pigs (11.9 ± 0.3 kg) were assigned to either a control diet (0.22% Na, 0.44% Cl, and 0.78% K), or the Control diet supplemented to 0.96% K from KCl (0.23% Na, 0.56% Cl), KHC03 (0.22% Na, 0.33% Cl), or KCl balanced to the same Na and Cl (KCl Low Cl) as the KHC03 treatment (n = 8). Pens were weighed on d-0 and 21. In Exp 2, 950 pigs (13.0 ± 0.9 kg) were fed one of five diets. The control diet from Exp 1 was used and was supplemented with 0.09% or 0.18% K from KCl or KHC03 (n = 8). All diets contained 0.22% Na. Diets were formulated to 0.40, 0.48, 0.56, 0.33, and 0.33% Cl for the control, 0.09 and 0.18% added K from KCl and 0.09 and 0.18% added K from KHC03 respectively. During Exp. 2, pens were weighed on d-0, 14, and 28. In both experiments, Na and Cl levels were manipulated by altering levels of dietary NaCl and NaPO4. Data was analyzed using the GLM procedures of SAS with pen as the experimental unit for gain, intake and feed conversion. In Exp 1, intake was unaffected by treatment (P>0.10). Gain increased in a KCL Low Cl<KHC03<KCl=control manner. Lower gains of the KCl Low Cl fed pigs at similar intakes resulted in a poorer gain to feed compared to the other treatments. During the first 14-d of Exp 2, gain and intake were not statistically different (P>0.10). Gain, however, was numerically higher for the 0.18% added K treatments resulting in an improvement (P<0.001) in gain to feed. From day 14 28, intake was not affected by treatment (P>0.10), however, gain and gain to feed were poorer (P<0.0001) when K level was increased compared with the controls. Gain and gain to feed were significantly lower (P<0.05) for the pigs fed diets with 0.18% added K from KHC03. These results suggest benefit to short-term (<14-d) K supplementation at 21-d post-weaning, however, long-term (> 21-d) K supplementation may be detrimental to gain and gain to feed, particularly if the supplemental K (0.18%) is supplied as KHC03.

Key Words: Potassium, Growth, Pigs

243 Inorganic anions (Animate® concentrate) stimulate growth in nursery pigs fed diets without antibiotics regardless of diet buffering capacity. T. D. Crenshaw*¹ and D. E. Axe², ¹University of Wisconsin, Madison, ²IMC, Lake Forest, IL.

Diets with low buffer capacity (LB) have stimulated growth and altered ingesta microflora of nursery pigs compared with pigs fed diets with high buffer capacity (HB), or sub-therapeutic antibiotics in a herd with chronic salmonella problems. LB diets involved shifts in sources (calcium tribasic phosphate and calcium sulfate) and levels of Ca and P. The current objective was to determine if shifts in cation-anion balance, or the source of inorganic anions altered growth. A complex basal diet was altered to provide HB (0.80 % Ca, 0.80 % P) or LB (0.55 % Ca, 0.65 % P) diets with 3 sources, CaCO₃, CaSO₄, or Animate (a concentrated formulation of Animate for pigs as a source of Cl and SO₄). Antibiotics were not added to any diets. Crossbred (PIC Cambrough X Line 19) pigs (n = 96, 4 pigs per pen) were weaned (3 wk) and randomly allotted to 6 diets for a 32-d trial (P1, 15 d; P2, 17 d). In P2 and the entire trial pigs fed Animate gained more (P < 0.02) than pigs fed CaCO₃ or CaSO₄ regardless of diet buffering capacity. Feed intake increased (P < 0.02) in pigs fed Animate. No differences were observed in feed efficiency. The lack of response to diet buffer capacity is not consistent with earlier results and may be related to lower initial prevalence (< 20 %) of salmonella-positive pigs. Improved growth of pigs fed Animate was likely due to Cl rather than cation-anion balance or buffer capacity. Growth and feed intake responses to inorganic anions

244 Effects of diet acidification and buffering capacity on weanling pig growth. M. Walsh*, D. Sholly, K. Saddoris, R. Hinson, A. Yager, A. Sutton, S. Radcliffe, B. Harmon, and B. Richert, *Purdue University, West Lafayette, IN.*

A study utilizing 192 weanling pigs evaluated the effects of diet acidification and buffering capacity on pig growth. Pigs (19.1 d average age) were assigned to one of three dietary trts: 1) Basal control diet (NC); 2) Diet 1 + 55 ppm carbadox (CB); 3) Dietary acid (DA): diet 1 + .4% organic acid based blend (fumaric, lactate, citric, propionic, and benzoic acids) for d 0-14 followed by .2% inorganic acid based blend (phosphoric, fumaric, lactic, and citric acids) for d 14-28. Each trt was formulated with either limestone or calcium sulfate as a calcium source to change the buffering capacity. Pigs were allotted based on genetics, gender, and initial BW (average of 5.9 kg) and were housed at 6 or 7 pigs/pen. Pen feed intake and individual BW were recorded weekly. Treatments were fed throughout the trial in two phases: d 0-14 and 14-28. During phase 1, pigs fed CB had greater ADG (P<.10) and BW (P<.03) than pigs fed the NC with pigs fed DA being intermediate. During phase 2 and overall, pigs fed CB had greater ADG (P<.01) than pigs fed NC and DA (Overall ADG: 298 vs 252 and 268 g/d, respectively). Pigs fed CB had greater ADFI (P<.04) during phase 2 and overall than pigs fed the NC with pigs fed the DA being intermediate. On d 28, pigs fed CB were heavier than pigs fed NC or DA (14.3 vs 12.9 and 13.4 kg, respectively; P<.001). Overall G:F was greater (P<.06) for pigs fed CB than pigs fed the NC with DA pigs being intermediate. During phase 1, pigs fed diets with limestone as a calcium source tended to have greater ADG (P<.09) than pigs calcium sulfate. During phase 2, pigs fed calcium sulfate had greater G:F (P<.05) than pigs fed limestone. Overall, there was no effect of calcium source on pig growth. In conclusion, pigs fed CB were 1.4 kg heavier and pigs fed DA were 0.5 kg heavier at d 28 post-weaning than the NC pigs. Altering diet buffering capacity had its greatest influence on pig growth during phase 2 when the simplest diet was fed, but did not affect the response to CB or DA.

Key Words: Pigs, Acidification, Buffering Capacity

245 Effects of diet and water acidification on weanling pig growth and microbial shedding. M. Walsh*¹, D. Sholly¹, K. Saddoris¹, R. Hinson¹, A. Sutton¹, S. Radcliffe¹, B. Harmon¹, R. Odgaard², J. Murphy², and B. Richert¹, ¹Purdue University, West Lafayette, IN, ²Kemin Americas, Inc., Des Moines, IA.

This study utilized 205 pigs in a 34 d nursery trial. Pigs (19.2 d of age) were assigned three dietary trts: 1) Basal control diet (NC); 2) Diet 1 + 55 ppm carbadox (CB); 3) Dietary acid (DA); diet 1 + .4% organic acid based blend (fumaric, lactate, citric, propionic, and benzoic acids) for d 0-7 followed by .2% inorganic acid based blend (phosphoric, fumaric, lactic, and citric acids) for d 7-34. These three diets were factored with or without water acidification (WA) of 2.48 mL/L of a propionic acid based blend (KEM SANTM). Pigs were allotted based on genetics, sex, and initial BW (Avg=5.54 kg) with 6 or 7 pigs/pen. Pen FI and individual BW were recorded weekly. Treatments were fed

in three phases: d 0-7, 7-21, 21-34. Feces were collected on d 6, 20 and 33 (3 pigs/pen) for measurement of pH and *E. coli*. No trt effects ($P > .05$) were observed during phase 1. During phase 2, pigs fed CB had greater ADG ($P < .03$) and G:F ($P < .06$) than pigs fed DA and tended ($P < .10$) to have greater ADG than pigs fed NC. During phase 3 and overall, pigs fed CB had greater ($P < .0001$) ADG (overall; 389 vs 348 and 348 g/d, respectively), ADFI and d 34 BW (18.8 vs 17.3 and 17.3 kg, respectively) than pigs fed NC and DA. Phase 3 G:F was greater for pigs fed DA than pigs fed NC ($P < .05$). Phase 3 ADG was improved by WA across all diets ($P < .01$), while WA increased ADFI only in pigs fed CB and NC but not DA ($P < .04$). Pigs receiving no WA had greater overall G:F ($P < .03$) than pigs receiving WA. Feeding CB tended to reduce *E. coli* on d 33 compared with pigs fed DA ($P < .10$). Pigs fed DA tended ($P < .10$) to have lower fecal pH than pigs fed CB on d 20. Pigs receiving WA tended ($P < .10$) to have lower fecal pH than pigs receiving no WA on d 33. In conclusion, pigs fed CB were 1.5 kg heavier at d 34 post-weaning than both NC and DA. The combination of DA with WA resulted in decreased ADFI and overall growth performance, while all other treatment combinations improved pig growth above the NC alone.

Key Words: Pigs, Carbadox, Acidification

246 Effects of diet acidification and antibiotics on weanling pig growth and microbial shedding. M. Walsh*, D. Sholly, K. Saddoris, R. Hinson, A. Yager, A. Sutton, S. Radcliffe, B. Harmon, and B. Richert, *Purdue University, West Lafayette, IN.*

Two hundred ten weanling pigs were used in a 35 d trial to evaluate the effects of a dietary acid and/or antibiotics in nursery pig diets. Pigs (18.3 d of age) were assigned to three dietary trts: 1) Basal control diet (NC); 2) Diet 1 + 55 ppm carbadox (CB); 3) Diet 1 + 38.6 ppm Tiamicin + 441 ppm Chlortetracycline (CTC) d 0-7 followed by 110 ppm CTC d 7-35 (TC). These three trts were factored with or without a diet acidification (DA); .4% organic acid based blend (fumaric, lactate, citric, propionic acid, benzoic acid) for d 0-7 followed by .2% inorganic acid based blend (phosphoric, fumaric, lactic, citric acid) for d 7-35. Pigs were allotted based on genetics, sex, and initial BW (Avg=5.6 kg) with 7 pigs/pen. Pen FI and individual BW was recorded weekly. Three diet phases were fed: d 0-7, 7-21, 21-35. Feces were collected on d 6, 20 and 33 (3 pigs/pen) for measurement of pH and *E. coli*. During phase 1, ADG, ADFI, G:F and d 7 BW for pigs fed CB and TC were greater than pigs fed NC ($P < .04$). During phase 2 pigs fed CB and TC had greater ADG and ADFI and d 21 BW ($P < .01$) than pigs fed NC. During phase 3, CB fed pigs had greater ($P < .06$) ADG and ADFI than NC fed pigs. Overall, pigs fed CB and TC had greater ADG ($P < .004$; 315 and 303 vs 270 g/d respectively), ADFI ($P < .01$) and d 35 BW (16.74 and 16.23 vs 15.08 kg, respectively; $P < .002$) than pigs fed NC. Pigs receiving DA tended to have greater G:F ($P < .09$) than pigs receiving no DA during phases 2 and 3. Overall ADG tended ($P < .07$) to improve with DA and NC or TC diets, but decreased when DA was added to the CB diets. Pigs fed CB shed lower counts of *E. coli* on d 33 compared with pigs fed TC or NC ($P < .0001$). Pigs fed CB and TC tended to have lower fecal pH on d 6 compared to pigs fed NC ($P < .002$). Feeding DA reduced fecal pH on d 6 and *E. coli* shedding on d 33 compared to pigs receiving no DA ($P < .10$). DA tended to increase growth performance above NC and TC diets alone. However, overall growth performance was greatest when CB was fed alone and not with DA.

Key Words: Pigs, Antibiotics, Diet Acidification

247 Use of δ -aminolevulinic acid in swine diet: effects on growth performance, behavioral characteristics and hematological/immune statuses in nursery pigs. R. D. Mateo*, F. Ji, and S. W. Kim, *Texas Tech University, Lubbock.*

Certain amino acids are essential precursors of a variety of important biomolecules in addition to their major function as protein building blocks. δ -aminolevulinic acid (ALA) is synthesized from the condensed form of succinyl-CoA with glycine after decarboxylation catalyzed by δ -aminolevulinic synthase. The objective of the study was to determine effects of ALA supplementation on growth performance, behavioral characteristics and hematological/immune statuses in nursery pigs. A total of 144 pigs weaned at 21 days of age were allotted to 3 dietary treatments representing (-) control (w/o antibiotics), (+) control (w/ Carbadox at 50 mg/kg as pure form or 1% as diluted form), and treatment group with ALA supplementation (0.05%). Each treatment had 6 pens (replicates) with 8 pigs per pen. Pigs were fed Phase 1 (21.86%

CP, 1.4% Lys) and 2 (20.6% CP, 1.15% Lys) experimental diets for 3 and 2 wks, respectively. Feed intake and weight gain were measured weekly during Phase 1 and at the end of Phase 2. At the end of Phase 2, blood samples were taken and analyzed using an automated hematology analyzer. Skin color and activity of pigs (48 hrs) from all pens in each treatment were measured at the second week of Phase 2. Growth performance was not affected ($P > .05$) by the dietary supplementation of ALA during nursery phases. Pigs in the ALA and (+) control groups had a higher ($P < .05$) number of red blood cells than pigs in the (-) control group (6.46, 6.68, and 6.15 $\times 10^6$ cell/ μ L, respectively). Pigs in the (+) control had a higher ($P < .05$) hemoglobin level than pigs in the (-) control and ALA groups (12.16, 11.29, and 11.47, respectively). Pigs in the ALA and (+) control groups had darker ($P < .05$) and less ($P < .05$) yellow skin color than pigs in the (-) control group. Pigs in the (+) control tended to be less active ($P < .10$) than pigs in the other groups. There was no difference in behavioral characteristics between (-) control group and ALA group. The data suggest that ALA improves red blood cell counts which can be beneficial to pigs.

Key Words: Aminolevulinic Acid, Antibiotics, Nursery Pigs

248 The effect of dietary protein on growth performance and fecal consistency of 9 to 24 kg pigs following an enteric challenge with K88 *E. coli*. D. C. Kendall*¹, R. W. Fent¹, S. X. Fu¹, J. L. Usry², J. A. Carroll³, and G. L. Allee¹, ¹University of Missouri, Columbia, ²Ajinimoto Heartland LLC, Chicago, IL, ³ARS-USDA Animal Physiology Research Unit, Columbia, MO.

Two experiments were conducted to determine the effect of dietary protein on growth performance and fecal consistency of 9 to 24 kg pigs following an enteric challenge with K88 *E. coli*. In Exp. 1, 96 barrows (10.2 kg; PIC C-23) were allotted by weight in a randomized complete block design and fed one of four dietary treatments with eight replicates of three pigs per pen. Diets contained 25.5, 23.6, 21.8, and 20.1% CP, achieved by decreasing the level of soybean meal inclusion and increasing crystalline amino acid use while maintaining 1.32% TID Lys. Diets contained no growth promoting antibiotics or copper sulfate. Following a 7d acclimation period, pigs were enterally dosed with 3.95 $\times 10^8$ CFU K88 *E. coli*. Fecal consistency was measured daily with subjective fecal scores (0-3) where 0 = normal, 1 = mild, 2 = moderate, or 3 = severe diarrhea. In addition, fecal samples were collected on d 2, 3, 4, 6, and 8 for moisture determination. From d 2 to 8, fecal scores ($P < .003$) and fecal moisture ($P < .05$) declined linearly with decreasing dietary protein (.65, .45, .27, and .26 units; 74.3, 73.1, 72.6, and 72.3% moisture, respectively). For the 14 d following challenge, there was no effect of dietary treatment on growth performance. In Exp. 2, 188 barrows (9.0 kg; TR-4 X PIC C-22) were allotted by weight in a randomized complete block design and fed one of four dietary treatments with 10 replicates of four or five pigs per pen. Dietary treatments and procedures were the same as Exp. 1. Fecal consistency was measured on a subset of pigs (n = 96) on d 0, 2, 4, 6, 8, 10, 12, and 14. For the first 7 d following challenge, fecal scores ($P < .001$) and fecal DM ($P < .001$) declined linearly with decreasing dietary protein (1.36, 1.07, .86, and .53 units; 80.8, 79.0, 77.4, and 74.5% moisture, respectively). Similar to Exp. 1, dietary treatment did not influence post-challenge growth performance of pigs. These experiments clearly demonstrate that dietary protein negatively influences fecal consistency but does not affect growth performance during an enteric challenge.

Key Words: Pigs, *E. Coli*, Protein

249 The effect of lactose and inulin on intestinal morphology, microbiology and volatile fatty acids of the weanling pig. K. M. Pierce*¹, J. J. Callan¹, P. O. Brophy¹, P. McCarthy², T. Sweeney¹, E. Fitzpatrick¹, C. Byrne¹, S. Ni Cheallaigh¹, and J. V. O'Doherty¹, ¹University College, Dublin University, Dublin, Ireland, ²Volac International Ltd..

Twenty piglets (21 d, 8.0 kg BW) were used in a 2 x 2 factorial to investigate interactions between lactose and inulin on intestinal morphology, microbiology, and VFA production of the weanling pig. The piglets were fed the following diets for 6 d and sacrificed: (T1) 100 g/kg Lactofeed 70 (LF70; 860 g whey permeate and 140 g soy bean meal/kg; Volac International, UK), (T2) 100 g/kg LF70 + 15 g/kg inulin, (T3) 350 g/kg LF70, and (T4) 350 g/kg LF70 + 15 g/kg inulin. Tissue samples were taken from the duodenum (Duo), jejunum (Jej), and ileum for morphological measurements. Digesta samples were taken from the ileum, caecum, and

colon. There was an interaction ($P < 0.001$) between LF70 and inulin in villous height (VH) in the Duo, Jej, and the ileum. In the Duo and ileum, the inclusion of 350 g/kg LF70 increased VH compared to 100 g/kg LF70. However, there was no difference between 100 g/kg and 350 g/kg LF70 when the diets were supplemented with inulin. In the Jej, the inclusion of inulin at 100 g/kg LF70 increased VH compared to 100 g/kg LF70 without inulin. However, inulin had no effect on VH at 350 g/kg LF70. The inclusion of 350 g/kg LF70 increased lactobacilli (+15%) and reduced coliforms (-10%) in the caecum and colon. The inclusion of 350 g/kg increased ($P < 0.05$) total VFA compared to 100 g/kg LF70 (143.0 vs 105.6 mmol/L; SEM, 11.4) in the caecum. There was an interaction ($P < 0.05$) between LF70 and inulin for total VFA concentration in the colon. The pigs receiving 350 g/kg LF70 had a higher total VFA concentration compared to pigs on 100 g/kg LF70. However, there was no difference between 100 g/kg and 350 g/kg LF70 when the diets were supplemented with inulin. In conclusion, high levels of LF70 increased total VFA concentrations and improved gut morphology and gut microflora. Inulin inclusion resulted in improvements in these parameters at the low LF70 level.

Key Words: Pigs, Lactose and Inulin, Intestinal Morphology

250 Effects of lactic acid and lactose on the digestive tract of nursery pigs. M. F. Palacios*, E. A. Flickinger, C. M. Grieshop, C. T. Collier, and J. E. Pettigrew, *University of Illinois, Urbana*.

The objective of this study was to measure the effects of lactose (L) and (or) lactic acid (A), on gastrointestinal tract characteristics of pigs during a 4-wk experiment. A total of 96 pigs were weaned and blocked on the basis of litter. The experiment was carried out as a RCBD, with six blocks, and four diets. The experiment was conducted as a 2 x 2 factorial arrangement of treatments, with factors being L and A. Pigs were fed one the following diets: 1) Basal (B), 2) B + L, 3) B + A, or 4) B + L + A. A 3-phase feeding program was employed for this experiment with phases 1, 2 and 3, corresponding to week 1, week 2, and weeks 3 and 4 respectively. Each of the B diets contained corn starch, which was replaced or not by L and A according to the dietary treatment. The levels of L varied according to the phase: 21% for phase 1, 14% for phase 2, and 7% for phase 3. The A was added to provide 0.75%. Half of the pigs were euthanized for collection of gastrointestinal data, utilizing 24 pigs on each of days 7 and 28. The following characteristics were measured from the tract: wet weight of organs, pH, concentration of lactate, concentration of VFA, bacterial culture of *Lactobacillus* and total anaerobes, quantitative PCR for *Lactobacillus* rDNA and total bacterial rDNA. No differences among treatments were found in wet weight of organs at 7 or 28 days post-weaning. The pH measured in all gastrointestinal segments was reduced ($P=0.01$) at 7 days post-weaning by the incorporation of A. Concentrations of lactate along the tract were not affected by treatment. Concentrations of VFA were altered, most notably reductions in terminal ileum on day 7 and distal colon on day 28 with A. The number of total anaerobes was reduced by A in stomach, terminal ileum contents and mucosa on day 7 ($P=0.01$). Also on day 7, *Lactobacillus* rDNA concentration was reduced ($P=0.02$) when both L and A were added to the diet, and *Lactobacillus* rDNA as a proportion of total bacteria rDNA concentration was reduced ($P=0.01$) when L was added to the diet.

Key Words: Pig, Lactic Acid, pH

251 Effects of lactic acid on growth performance of nursery pigs. M. F. Palacios*, K. T. Soltwedel, G. R. Hollis, and J. E. Pettigrew, *University of Illinois, Urbana*.

A 6-wk experiment was conducted to evaluate the effect of increasing levels of lactic acid (A) to improve growth performance and health status of nursery pigs in a commercial farm. The experiment was carried out as a randomized complete block design with four treatments. Overall, four rooms were used, with 12 blocks, 48 pens, and 1584 pigs. Pigs were weaned at an average of 17.3 d of age and 5.42 kg BW. The feeding program was divided into four phases: Phase 1 (wk 1), Phase 2 (wk 2), Phase 3 (wks 3 and 4), and Phase 4 (wks 5 and 6). Diets contained corn, whey, oat groats, soybean meal, fish meal, blood plasma, and soy protein concentrate; and corn starch, which was replaced or not by a lactic acid product according to the dietary treatment. Pigs were fed one of the following dietary treatments: 1) Basal (B), 2) B+0.75% A (0.75A), 3) B+1.50% A (1.50A), and 4) B+2.25% A (2.25A). During the last two

wks (Phase 4), all pigs received the same basal diet, with no addition of lactic acid to the diet. None of the diets contained antimicrobials. Performance criteria including ADG, ADFI, and G:F were measured for each phase of the experiment. In addition, medical treatments, and pig removals were recorded daily as measures of health status. The experimental treatments did not affect ADG, G:F or health status. Daily feed intake showed a quadratic response ($P=0.04$). The quadratic responses showed the greatest ADFI on the extreme treatments, and lower ADFI on the lower lactic acid inclusions. The results for this experiment did not show clear responses to increasing levels of lactic acid.

Diet	B	0.75A	1.50A	2.25A	SEM	Linear	Quadratic
						P-value	P-value

Treatments, %	1.35	1.44	1.40	1.58	0.13	0.37	0.66

Key Words: Pig, Lactic acid, Performance

252 Comparison of the effect of direct-fed microbials and antibiotic supplementation on the growth response of weanling pigs. M. S. Dirain*¹, M. E. Davis¹, D. C. Brown¹, C. V. Maxwell¹, Z. B. Johnson¹, and T. Rehberger², ¹University of Arkansas, Fayetteville, ²Agtech Products Inc., Waukesha, WI.

Pigs (n=252) from 30 litters were used to compare the effect of direct-fed microbials and antibiotic supplementation on the growth of nursery pigs. Beginning at farrowing, pigs were provided milk supplementation with or without the addition of *Lactobacillus brevis* (1E-1) via an in-line system. These treatments were continued during the nursery period, in which pigs that were administered 1E-1 via milk supplementation continued to receive 1E-1 through the watering system. At the start of the nursery phase, pigs were fed a basal diet, the basal diet with *Bacillus* cultures, or the basal diet with antibiotics. These dietary treatments were administered during Phase 1 (d 0 to 14 after weaning), Phase 2 (d 14 to 28), and Phase 3 (d 28 to 38), in a 2 x 3 factorial design during the nursery period. Data were analyzed using the GLM procedure of SAS, and the effects of 1E-1 supplementation, dietary treatments, and their interaction were evaluated. No interaction was observed between 1E-1 supplementation and the dietary treatments ($P > 0.15$). Pigs supplemented with 1E-1 had greater ADG ($P < 0.05$) during Phase 2 and the overall nursery period (d 0 to 38), greater ADFI ($P < 0.05$) during Phase 3 and the overall nursery period, and tended to have improved gain:feed ($P < 0.10$) during Phase 3. Pigs supplemented with antibiotics during the nursery had greater ($P < 0.01$) ADG during Phase 2 and the overall nursery period, and greater ($P < 0.01$) ADFI during Phase 3 than pigs fed the basal diet or pigs fed *Bacillus*. Although pigs supplemented with antibiotics had greater ($P < 0.05$) gain:feed than pigs fed *Bacillus* during Phase 2, pigs fed *Bacillus* had greater ($P < 0.01$) gain:feed during Phase 3 than pigs fed the basal diet or those fed antibiotics. Pigs fed antibiotics during the nursery were 2 kg heavier at the end of the nursery than pigs fed the basal diet or *Bacillus*, whereas 1E-1 supplementation resulted in a 1.5 kg improvement ($P < 0.01$) in body weight at the end of the nursery period compared to pigs not receiving 1E-1. This study indicates that 1E-1 supplementation during lactation and the nursery phase improves the growth response of pigs during the nursery period.

Key Words: Swine, *Lactobacillus*, Feed Supplements

253 Efficacy of mannan oligosaccharides supplementation of both sows and piglet diets on the performance of weaned piglets. M. I. Gracia*¹, J. Morales², J. Pickard³, J. Sánchez¹, and F. Baucells¹, ¹Imasde Agropecuaria, S.L. Spain, ²PigChamp Pro Europa Spain, ³Alltech Inc., Ireland.

A trial was conducted to study the effect of supplementing piglet diets with a source of mannan oligosaccharides (MOS, Bio-Mos[®]) on performance of weaned piglets from weaning at 28 d to 60 d of age. Five hundred and thirty two crossbred piglets (Large White x Large White*Landrace), half male and half female, were allocated randomly to 28 replicates of 19 piglets each. A completely randomized block (room) design was applied using four experimental treatments arranged as a 2

× 2 factorial with main effects of piglet origin: 1) control sows, and 2) sows receiving 1 g/kg of MOS during lactation, and dietary treatment: 1) basal diet (control), and 2) basal diet with MOS at 2 g/kg in prestarter and 1 g/kg in starter diets. The experimental design was applied in both the prestarter (28 to 44 d of age) and the starter (44 to 60 d of age) periods. Nutritive value of the diets was 2.5 Mcal NE/kg and 14.8 g/kg lysine for prestarter, and 2.5 Mcal NE/kg and 13.3 g/kg lysine for starter, and were based on barley, corn, and wheat. Data were analyzed as a completely randomized block design with piglet origin and dietary treatment as main effects and weaning weight as a covariate. For the overall period (28 to 60 d of age), piglets coming from sows eating MOS during their lactation period grew more than piglets from control sows independently from their dietary treatment after weaning (339 vs 363 g/d; $P < 0.05$). On the other hand, piglets supplemented with MOS tended to have better feed conversion ratio than control piglets independently from their origin (1.50 vs 1.39 g feed/g gain; $P = 0.059$). No interactions were detected between main effects for any of the parameters studied. It was concluded that: i) the supplementation of lactation diets with MOS improved growth of piglets during the post-weaning period with independence of dietary treatment within this period, and ii) addition of MOS to post-weaning piglet diets improved feed efficiency.

Key Words: Mannan Oligosaccharides, Lactation, Piglets

254 Impact of spray-dried plasma with or without antimicrobials on nursery pig performance. P. Srichana^{*1}, A. M. Gaines¹, B. W. Ratliff¹, G. L. Allee¹, J. D. Crenshaw², J. M. Campbell², J. D. Quigley², and L. E. Russell², ¹University of Missouri, Columbia, ²APC Inc., Ankeny, IA.

An experiment was conducted at a commercial research site to evaluate the impact of spray-dried plasma (SDP) with or without antimicrobials (AM) on nursery pig performance. A total of 792 pigs (TR-4 × C22; 5.66 ± 0.05 kg) were used in a completely randomized block design with 6 replicate pens/treatment and 22 pigs/pen. Growth performance was evaluated during four dietary phases: Phase 1 (d 0-7), Phase 2 (d 7-14), Phase 3 (d 14-28) and Phase 4 (d 28-50). Diets were formulated to contain 1.60% and 1.50% total lysine in phase 1 and 2, respectively and 1.42% and 1.32% true digestible lysine in phase 3 and 4, respectively. Treatments were as follows: 1) 0% SDP without AM (d 0-50); 2) 0% SDP with AM (d 0-50); 3) SDP (6% Phase 1, 3% Phase 2, 1.5% Phase 3, 0.75% Phase 4) without AM; 4) same as treatment 3 with AM; 5) SDP (6% Phase 1, 3% Phase 2); 6) same as treatment 5 with AM. For diets containing AM, the Phase 1 and 2 diets contained 3000 ppm ZnO and 55 ppm Mecadox, while Phase 3 and 4 diets contained 27.5 ppm Mecadox and 100 ppm CuSO₄. In Phase 1, pigs fed SDP and (or) AM had improved ADG ($P < 0.05$) as compared to pigs not fed SDP. Improvements in ADG were due to improvements in ADFI ($P < 0.05$). In Phase 2 and 3, pigs fed AM had improved ($P < 0.05$) ADG, which

Production, Management and the Environment: Health and Miscellaneous

256 The use of statistical process control capability indices to estimate subclinical mastitis prevalence and new infection rates. J. Lukas^{*1}, M. L. Kinsel², and J. K. Reneau¹, ¹University of Minnesota, St. Paul, ²Agricultural Information Management, Ellensburg, WA.

The objective of this study was to calculate a capability index (Cpk) measuring the capability of a herd to meet a desired SCC standard based on the BTSCC (bulk tank somatic cell count) and determine its correlation with subclinical mastitis prevalence (SM) and new infection rate (NIR) estimates. BTSCC data collected daily or every other day for 12 months (January until December 2003) from 694 Minnesota dairies were used to compute the linear score. The mean of individual values, and the average moving range was used to calculate four different Cpk indexes (Cpk400, Cpk500, Cpk600, Cpk750 based on the 400000, 500000, 600000, 750000 SCC standards, respectively) for each of the herds. The SM and NIR values of 272 herds on the Minnesota DHI program were transformed by natural log, merged by farm name with the Cpk indexes and used to examine the relationship between the calculated Cpk indexes and SM and NIR (dataset three, n=269). One hundred eighty herds from dataset three were randomly selected, linear regression models were developed and validated by taking the SM and NIR values observed for the remaining 89 herds and regressing them against the SME (estimated subclinical mastitis values) and NIRE (estimated new infec-

tion rates) calculated from the four linear regression models that were developed. High R² values (0.70, 0.64, 0.58, 0.49 for SM vs Cpk400, Cpk500, Cpk600, Cpk750, respectively) indicated a strong correlation between the BTSCC and herds SM. According to models developed, SM in herds that are able to meet the SCC standard (Cpk ≥ 1), is less or equal to 26%, 30%, 34%, 38% for the 400000, 500000, 600000 and 750000 standard, respectively. The relatively low correlations between NIR and Cpk indexes (R²=0.34, 0.31, 0.28, 0.24 for NIR vs Cpk400, Cpk500, Cpk600 and Cpk750, respectively) indicate that the single DHI test day estimate of NIR was insufficient to accurately describe NIR dynamics.

Key Words: Spray-Dried Plasma, Antimicrobial, Pigs

255 Effect of flaxseed fractions and sub-therapeutic antibiotic inclusion on microbial ecology in small intestine of growing pigs. L. F. Smith^{*1}, R. T. Zijlstra², M. D. Drew¹, and A. G. Van Kessel¹, ¹Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, ²Prairie Swine Centre Inc., Saskatoon, SK, Canada.

Increasing pressure to discontinue the feeding of growth-promoting antibiotics has prompted examination of novel feed ingredients and their effect on intestinal microbial ecology. The impact of antibiotic inclusion, flaxseed, or flaxseed fractions on small intestinal microbial profiles was investigated in growing pigs. Eighteen ileal-cannulated barrows (33.1±2.4 kg) were fed one of six diets (A, basal diet with wheat, peas and soybean meal, 3.40 Mcal/kg DE and 2.65 g dig. lysine/Mcal DE; B, basal diet plus 20% ground flaxseed; C, basal diet plus 18% ground hot-water extracted flaxseed; D, basal diet plus 4% ground flaxseed hulls; E, basal diet plus 8% flaxseed oil; F, basal diet plus 22 mg/kg tylosin phosphate) during each of three 18-d periods in a change-over design for a total of nine observations per treatment. Experimental periods included 16 d for diet acclimatization and ileal contents were collected on d 17 and 18. Diets were provided in a wet mash form at 2.8 x maintenance. Approximately 100 ml of ileal digesta was collected in plastic bags containing N₂ following the AM-feeding. Serial dilutions were prepared in sterile peptone and plated on selective media for enumeration of total aerobes and anaerobes, *Clostridium perfringens*, *Lactobacillus* spp., *Bifidobacterium* spp., *Streptococcus* spp., and Enterobacteria. Data were analyzed using the repeated measures procedure in SPSS. *Lactobacillus* spp. plate counts were 7.97, 8.13, 8.52, 7.95, 8.41, and 8.40 log cfu/g for diets A through F respectively, and were increased ($P \# 88040.05$) by flaxseed hulls, oil, and tylosin. Diet composition did not affect plate counts for any other growth media employed. Inclusion of tylosin increased the number of lactobacilli in pig ileum contents as reported by others. Flaxseed fractions also affected ileal bacterial colonization; however, precise identification of compositional changes will require molecular based analyses.

257 Evaluation of the DHI hot list as a tool to reduce bulk tank somatic cell counts. J. E. Belsito^{*}, A. de Vries, and R. P. Natzke, University of Florida, Gainesville.

Many dairy producers in the Southeast find it difficult to keep their bulk tank somatic cell count (SCC) below the legal limit (750,000 cells/ml) throughout long periods of hot weather. DHI has developed a hot list to assist farmers in identifying high SCC cows in the herd. The hot list identifies the 20 cows that are the greatest contributors of SCC to the

bulk tank on the test day. This list was developed to assist producers in making decisions to cull, treat, withhold milk, or early dry-off to reduce the bulk tank SCC. The objective of this study was to determine the repeatability of cows on the DHI hot list from test day to test day and draw conclusions about its value for the dairy producer. DHI records that have been collected from 1989 (300 cows) to 2001 (500 cows) from one farm tested monthly were analyzed. The herd manager never used the SCC data to make management decisions. The 20 cows on the hot list accounted on average for 46.4% of the cells in the bulk tank (SD 7.7%). Cows on their first test day after calving had a 6.6% (SD 5.7%) chance of being on the list. Second test day cows had an 8.1% (SD 6.2%) chance of being on the hot list while third test day cows had a 7.6% (SD 6.4%) chance. Of the cows that were on the hot list in any given month, 27% (SD 12%) were on the list the following month, 60% (SD 13%) were tested but dropped off the list and 14% (SD 10%) had missing data (not tested). Cows that were not on the hot list had only a 3% (SD 1%) chance of being on the list the following month, 81% (SD 7%) were tested and stayed off the list and 16% (SD 7%) had missing data. If culling decisions were based on the hot list we would expect to observe a higher percentage of cows on the hot list with missing data the following month. We concluded that cows on the hot list did not persistently have the highest SCC in subsequent months. These results indicated that refinement is needed to make the hot list a more valuable tool for the dairy producer.

Key Words: Somatic Cell Count, Hot List, Repeatability

258 Evaluation of the Association between Bulk Tank Somatic Cell Count and Management Practices on U.S. Dairy Operations; Results from the NAHMS Dairy 2002 study. J. E. Lombard^{1,2}, R. P. Dinsmore², J. R. Wenz^{*2}, and C. Tapp², ¹USDA:APHIS:VS; Centers for Epidemiology and Animal Health, Fort Collins, CO, ²Integrated Livestock Management, Colorado State University, Fort Collins.

The National Animal Health Monitoring Systems Dairy 2002 study surveyed dairy operations in 21 states representing 82.8% of U.S. dairy operations and 85.5% of U.S. dairy cows. Producers completed two separate interviews between December 2001 and July 2002. Producers were asked to estimate their mean bulk tank somatic cell count (BTSCC) for the three months prior to the second interview. Responses from 916 operations were represented in the analysis. Variables from both interviews having a priori potential for an association with BTSCC were identified and examined by chi-square testing (SAS, PROC FREQ). Variables with $p < 0.2$ were used to construct two logistic models using 200,000 and 400,000 BTSCC as cut-offs between groups (SUDAAN, PROC LOGIST). Significant variables (p value of Wald F statistic < 0.10) were retained. Percentage of operations reporting $< 200,000$; 200-400,000; or $> 400,000$ BTSCC was 24, 62 and 16 percent, respectively. Operations in the Southeast region of the U.S. were significantly more likely to have higher BTSCC compared to other regions. Higher rolling herd average milk production, having a closed herd and use of shredded newspaper as bedding were associated with lower BTSCC in both models. Milking procedures typically associated with decreased risk of mastitis such as teat disinfection were not retained in either model, except for forestripping prior to milking which was associated with higher BTSCC compared to operations that didn't forestrip any cows. These results of producer reported data suggest our understanding of the association between management practices and BTSCC may be incomplete.

Key Words: Milk, SCC, Management

259 Comparison of paired milk and serum ELISA for diagnosis of Johnes disease in dairy cattle. J. E. Lombard^{*1,2}, T. Byrem³, and B. J. McCluskey¹, ¹USDA:APHIS:VS, Centers for Epidemiology and Animal Health, Fort Collins, CO, ²Integrated Livestock Management, Colorado State University, Fort Collins, ³Antel Biosystems, Inc., Lansing, MI.

Paired milk and serum samples from 35 dairy herds in 17 states were evaluated for cow level and herd level test agreement. Evaluation of 6,349 paired samples suggested moderate cow level agreement between the milk and serum ELISA with a calculated kappa value of 0.50. At both the cow and herd level, the milk ELISA performed equivalent to the serum ELISA using conventional, radiometric and non-radiometric culture methods as a reference for Johnes disease. Cow level sensitivity (Se) and specificity (Sp) on 21 dairy operations with 2,173 animals were

evaluated. The relative cow level Se and Sp of the milk ELISA was 21.2 percent and 98.6 percent, respectively. Cow level relative Se and Sp of the serum ELISA was 23.5 percent and 98.1 percent, respectively. Logistic regression models revealed no association between parity and testing ELISA positive. Milk ELISA tests were more likely to be positive in the first 2 weeks of lactation and then after week 28 of lactation, while cows greater than 45 weeks in lactation were most likely to test positive with the serum ELISA. Milk production at or above herd average was negatively associated with testing ELISA positive. Substantial agreement between ELISA methods at the herd level was found with kappa values greater than 0.6 for comparisons using 1 animal testing positive or greater than 2 percent ELISA prevalence to consider a herd infected. With fecal culture as the reference, point estimates for herd-level Se and Sp for the milk ELISA ranged from 55-83 percent and 67-100 percent, respectively, depending on the ELISA prevalence cutoff. Serum ELISA estimates were similar with Se ranging from 61-83 percent but Sp remained at 33 percent for both prevalence cutoff values. The milk ELISA performed similar to the serum ELISA and has the advantage of decreased labor costs on farms that use DHIA milk testing services.

260 Financial costs of Johnes disease on U. S. dairy operations. J. E. Lombard^{*1,2}, B. J. McCluskey¹, S. L. Ott¹, and F. B. Garry², ¹USDA:APHIS:VS; Centers for Epidemiology and Animal Health, Fort Collins, CO, ²Integrated Livestock Management, Colorado State University, Fort Collins.

Dairy production records from 38 herds in 16 states were evaluated for mature equivalent (ME) 305 day milk, fat and protein production, ME maximum milk, lactation number, days in milk, days open, and average lactation linear score to determine current lactation marginal costs associated with serum ELISA test status for Johnes disease (JD). A mixed effects model was used to account for herd level clustering with production parameters as dependent variables. Significant production losses associated with JD in dairy cattle included decreased milk production in those animals that tested strong positive by serum ELISA, decreased pounds of milk fat production in those animals that tested strong positive and decreased days in milk for the inconclusive and strong positive compared to the negative and positive test group. Lactation milk production was approximately 6000 pounds less for cows that tested strong positive compared to test negative cows, resulting in a \$720 decrease in potential gross milk revenue. Information on animal removal from herds was evaluated using logistic regression models. Relative herd milk production, lactation number, body condition score and serum result were covariates in the models. Prior to producer knowledge of test outcome, cattle with elevated antibody levels were not at a significantly increased risk of being removed from the herd after accounting for relative herd milk production. Cattle with strong positive and positive test results were at a significantly increased risk of removal, even after adjusting for relative herd milk production once results were released to herd owners. Based on the results of this financial study, cattle that test strong positive on a serum ELISA test for JD should be considered for removal from the herd.

261 Financial drivers of profitability in dairy businesses. B. J. Hilty^{*}, L. A. Holden, and J. Hyde, Pennsylvania State University, University Park.

Return on assets (ROA) is an important indicator of dairy farm profitability. Although profitability is affected by many factors, ROA is driven by two financial characteristics, financial efficiency and capital efficiency. The operating expense ratio (OER) and asset turnover ratio (ATR) are primary indicators of financial and capital efficiency, respectively. The objective of this study was to identify the primary drivers of profitability of dairy businesses. Financial data from 1998 to 2001 was collected from 46 Pennsylvania dairies through personal interviews. The dairies were nominated for the study by industry professionals. Average herd size of these dairies ranged from 241 cows in 1998 to 273 cows in 2001. Average annual milk production ranged from 20,442 pounds per cow in 1998 to 21,236 pounds per cow in 2001. Average ROA was summarized by herd size and quartile rankings for each year of the study. High profit (HP) dairies were defined as those dairies generating an ROA of 8.0 percent or higher in the year being examined. Although dairies of all sizes were in the HP group, herds greater than 400 cows consistently

generated ROAs greater than 8 percent. High profit herds were classified as capital efficient, financially efficient or a combination of each to varying degrees, with a management matrix. Three of twenty-one HP dairies in 1998 were capital efficient (ATR >.70), while seven were financially efficient (OER < 60%). In 2000, a year of lower milk prices, there were only twelve HP dairies. Of the twelve, two were capital efficient (ATR >.70) and two were financially efficient (OER < 60%). The remaining dairies in both years relied on a combination of capital efficiency and financial efficiency to operate at high profit levels. Several factors that impact financial efficiency, including milk production per cow, feed expense and labor expense, were also examined by profitability group. The HP dairies performed better, numerically, in each area than dairies in the low quartile ranking. High profitability in this non-random farm sample was achieved through various strategies.

Key Words: Dairy, Profitability, Management

262 Economic and environmental feasibility of a continuous four-year lactation model. D. L. Zartman^{*1}, C. A. Rotz², and K. L. Crandall³, ¹Ohio State University, Columbus, ²USDA-ARS, University Park, PA, ³DHI Computing Services, Inc., Provo, UT.

More competitive dairy production systems are needed to improve the sustainability of our dairy industry. To test a perennial lactation concept, a set of 4,259 DHI records demonstrates that about 1% of dairy cows have produced over 20 kg/day for more than four years of continuous lactation. A dairy farm simulation model was used to evaluate the long-term performance, environmental impact, and economics of a conceptual typical dairy farm in Pennsylvania converted to a perennial system. In this system, cows lactated continuously for 4-yrs. Compared to a traditional 100-cow dairy farm with replacement heifers produced on the farm, use of 120 perennial cows with purchased replacements reduced supplemental protein feed purchases 11%, increased annual milk sales 20%, reduced manure production 17%, reduced soil N leaching loss 25%, and increased annual net return to farm management by \$14,200 while maintaining a long-term phosphorus balance for the farm. Compared to a traditional 125-cow dairy farm where replacement heifers were purchased, use of 120 perennial cows with purchased replacements reduced supplemental protein feed purchases 12%, reduced annual milk sales 4%, reduced manure production 7%, reduced N leaching loss 7%, and increased the annual net return to farm management by \$1,600. The economic feasibility of the perennial cow dairy farm was relatively insensitive to assumptions for herd replacement rate and cow mortality, moderately sensitive to milk and heifer prices, and very sensitive to the milk production maintained by the perennial herd. Thus, a perennial cow system can improve the economic and environmental sustainability of traditional dairy production if a similar level in annual milk production per cow can be maintained.

Key Words: Perennial, Lactation, Long-Term

263 Tracing pigs by using conventional and electronic identification devices. D. Babot^{1,2}, M. Hernández-Jover^{*3}, G. Caja³, C. Santamarina², and J. J. Ghirardi³, ¹Area de Producció Animal, Centre UdL-IRTA Lleida, Spain, ²Departament de Producció Animal, UdL, Lleida, Spain, ³Universitat Autònoma de Barcelona, Bellaterra, Spain.

With aim of evaluating the traceability achieved by different identification systems from birth to slaughter, a total of 1,032 pigs were used. Devices were: 1) plastic button ear tags (PET, n = 352); 2) half-duplex (EEH, n = 333) and full-duplex B (EEF, n = 347) electronic button ear tags; and, 3) half-duplex (IPH, 32 mm, n = 340) and full-duplex B (IPF, 34 mm, n = 335) intraperitoneally injected glass encapsulated transponders. Piglets were randomly assigned to treatments and reared under intensive conditions during suckling, growing and fattening periods and harvested in a commercial slaughterhouse. Readability of electronic devices was recorded during the farm period and throughout the harvesting process with full-ISO handheld transceivers. No negative effects or animal health alterations were reported after the identification.

No differences (P > 0.05) in losses between devices were observed during fattening (PET, 2.7%; EEH, 3.8%; EEF, 3.8%; IPH, 1.3%; and, IPF, 2.1%), and no electronic failures were recorded except for the EEF (0.7%). Losses obtained during the harvesting process were greater (P < 0.05) for the EEF (5.7%) than the EEH (4.4%) and PET (1.7%), the two last not differing. Electronic failures during harvesting averaged 1.5% for both electronic ear tags. Intraperitoneal transponders were not affected by the harvesting process and 97.1% were recovered at evisceration. The rest (2.9%) were lost on the slaughterhouse ground and no transponders were found in carcasses. Intraperitoneal transponders showed the greatest traceability values (IPH, 98.7%; and, IPF, 97.9%), the last not differing from conventional ear tags (PET, 95.7%). The lowest traceability values were obtained with electronic ear tags (EEH, 90.6%; and, EEF, 88.6%). In conclusion, the intraperitoneal injection seems to be an efficient system for the identification and traceability of pigs in the food chain.

264 Initial and terminal implant strategy for heavy weaned Canadian calves. K. S. Eng^{*1}, R. Bectel², and D. P. Hutcheson³, ¹Eng, Inc. San Antonio, TX, ²Advance Agricultural Testing, Baden, ON, Canada, ³Animal-Agricultural Consulting, Inc., Amarillo, TX.

With recent implant clearances, a broad range of implant types of Estrogen (E) only or Estrogen-Tremblone Acetate (ETA) combinations and dose rates are available. This trial was designed to evaluate four different initial implants followed by two combination terminal implants. Experimental animals were approximately 400 head of heavy weaned steer calves weighting approximately 300 kg from Saskatchewan Canada. They were allotted at random at the beginning of the trial to pens of 8 head each and there were 6-12 reps per initial implant treatment. During the initial phase, the cattle fed were fed an intermediate energy ration consisting of silage, wet corn gluten, steamflaked corn and premix. The initial phase was terminated at 91 days, the cattle check weighed and re-implanted with a terminal combination implant of either Synovex Choice or Synovex Plus. During the final 112 day feeding period the cattle were fed a high energy ration consisting of the same ingredients and there were 15 pen reps (8 head) in each implant treatment. The performance results are shown in Table 1. During the initial implant period, cattle receiving Synovex Choice gained more rapidly and tended to converted more efficiently. Calves receiving Synovex C consumed less feed, but had similar conversions. During the final implant phase, cattle receiving Synovex Plus compared to Synovex Choice gained faster and converted more efficiently. Carcass data was not obtained because problems associated with the occurrence of BSE, made it impossible to harvest of the cattle in a timely fashion.

Grow Phase Implant

	Synovex C	Synovex S	Revalor S	Synovex Choice	Prob- ability
Day 0 BW, kg	297.1	304.4	318.0	320.7	NS

265 Heavy tom strains fed low calcium and phosphorus diets supplemented with phytase 1. Growth performance and carcass yield. R. M. Hulet*, P. H. Patterson, and T. L. Cravener, *Department of Poultry Science, The Pennsylvania State University, University Park.*

Nicholas, BUTA-B6 and BUTA-T2 strains (A, B, and C) were reared in a total of 24 floor pens (0.309m²/bird) and fed commercial diets until 19 wk of age. The basal feeding program (calculated analysis) included a pre-starter (0-3 wk; 28.3% CP; 1.51% Ca; 1.04% tP), starter (3-6 wk; 27.8% CP; 1.50% Ca; 1.03% tP), grower-I (6-9 wk; 24.5% CP; 1.48% Ca; 1.00% tP), grower-II (9-11 wk; 22.5% CP; 1.39% Ca; 0.92% tP), finisher-I (11-14 wk; 18.9% CP; 1.15% Ca; 0.72% tP), and finisher-II (14-19 wk; 17.4% CP; 1.04% Ca; 0.64% tP). From 11-14 wk half the birds were fed a diet 15% lower in Ca and P (LCP) compared to the control birds (CON). From 14 - 19 wk half the birds were fed a diet 30% lower in Ca and P (LCP) compared to the CON birds. Both diets were supplemented with 0.06 % phytase from 11- 14 and 14 - 19 wk. Dietary treatment did not affect feed intake (FI), feed conversion (FC), 19 wk body weight (BW) or overall mortality. BW at 14 wks and overall BW gain (BWG) were significantly greater for birds fed CON diets. Dietary treatment did not affect processing weight (wt) or wt as a percent of the bled carcass wt. However, LCP diets did result in significant feed savings on a /kgcarcass(CON, .431 versus LCP, .419)and/kg breast basis (Con, 1.857versusLCP,1.749). BW at hatch and wk 3, 6, 9, 11, 14, and 19 were significantly affected by strain, with the C strain males having greater BWG than males from strain A or B. Cumulative FI was significantly different, with the C strain birds consuming more feed than birds from either strain A or B. Overall FC and mortality were not affected by strain. Processing wt was significantly affected by strain, with the wt of the carcass, neck, wing, and breast being greater for C strain carcasses. No difference in processing yield (% of carcass wt) was found for strain. The results suggest that diets 15 and 30% lower in Ca and total P, supplemented with phytase, resulted in similar growth performance and carcass yield and were cost efficient in comparison to CON fed birds. Strain C males were significantly heavier than strain A and B males for much of the study.

Key Words: Turkey, Phosphorus, Strain

266 Heavy tom strains fed low calcium and phosphorus diets supplemented with phytase 2. Impact on litter total P, soluble P and bone integrity. P. H. Patterson*¹, R. M. Hulet¹, T. L. Cravener¹, P. Y. Hester², P. J. Kleinman³, and A. N. Sharpley³, ¹*Department of Poultry Science, The Pennsylvania State University, University Park,* ²*Department of Animal Sciences, Purdue University, West Lafayette, IN,* ³*USDA-ARS, University Park, PA.*

Nicholas, BUTA-B6 and BUTA-T2 strains were reared in a total of 24 floor pens (0.309m²/bird) and fed commercial diets until 19 wk of age. The basal feeding program (calculated analysis) included a pre-starter (0-3 wk; 28.3% CP; 1.51% Ca; 1.04% tP), starter (3-6 wk; 27.8% CP; 1.50% Ca; 1.03% tP), grower-I (6-9 wk; 24.5% CP; 1.48% Ca; 1.00% tP), grower-II (9-11 wk; 22.5% CP; 1.39% Ca; 0.92% tP), finisher-I (11-14 wk; 18.9% CP; 1.15% Ca; 0.72% tP), and finisher-II (14-19 wk; 17.4% CP; 1.04% Ca; 0.64% tP). From 11-14 wk half the birds were fed a diet 15% lower in Ca and P (LCP) compared to the control birds (CON). From 14-19 wk the LCP birds were fed a diet 30% lower in Ca and P compared to the CON birds. Both diets were supplemented with 0.06% phytase from 11-14 and 14-19 wk. Litter water extractable P (WEP) increased during the study from 0.30, 0.48, 2.33, 3.22, 3.66 and 6.04g/kg of litter, respectively, at 3, 6, 9, 11, 14, and 19 wk. From 3 to 19 wk litter total P (TP) and Ca levels increased 2-fold, however, litter WEP was 20-fold greater at 19 wk. Litter WEP from LCP, CON treatments was 3.18, 4.04g/kg (P = 0.2060) at 14 wk and 5.84, 6.25g/kg (P = 0.2863) at 19 wk, respectively. Humerus bone mineral density (BMD) for LCP, CON birds was 0.368, 0.336 g/cm² at 14 wk (P = 0.0617) and 0.371, 0.371 g/cm² at 19 wk. Femur BMD for LCP, CON birds was 0.324, 0.317 g/cm² at 14 wk (P = 0.3844) and 0.372, 0.378 g/cm² at 19 wk (P = 0.6053). There was no difference in litter WEP, TP or Ca levels or humerus or femur BMD between tom strains (P > 0.05). Dietary P levels and costs were reduced by the LCP treatments compared to CON. Litter TP and WEP were reduced 5.8 and 6.6% in the LCP pens

compared to CON at the end of the study. No adverse effect of the LCP diets was observed on tom live performance or bone integrity.

267 Examining if the hole created by egg injection improves late embryonic survival. B. L. Kumpula* and G. M. Fasenko, *Department of AFNS, University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to determine if the hole produced by egg injection at 18 days of incubation has an effect on egg shell conductance and late incubation embryonic mortality. Broiler hatching eggs (n=864) from a Ross 308 flock at two ages (Trial 1 34 wk and Trial 2 42 wk) were incubated in a single stage incubator. At 7 and 14 days of incubation, all eggs were candled, eggs with non-viable embryos removed and broken open to assess fertility, and if fertile, approximate day of embryonic death. At transfer (18 d) half the eggs (Hole - n=432) had a hole made in the shell at the large end of the egg using an 18-gauge needle to simulate egg injection. The needle was inserted to a maximum depth of 2 mm. No injectables were deposited through the needle into the egg. The other half of the eggs (No Hole) were transferred without a hole being made. Twenty-four groups of 18 eggs represented the experimental unit. At 21 d (Trial 1) and 21.5 d (Trial 2) all saleable chicks were counted and any unhatched eggs opened so that hatchability production parameters could be calculated. Concurrently with the hatchability trials, the egg shell conductances of Hole and No Hole eggs (n=15 per treatment) were determined. The data were analyzed using the GLM procedure of SAS, all percentage data were transformed using Arc-sine transformations prior to analysis, and probability was assessed at P #8804 0.05. As expected, the conductance of the Hole (16.0 ± 0.4) versus No Hole (14.8 ± 0.4) eggs was significantly greater (P = 0.0420). However, number of culled chicks, hatchability, and embryonic mortality, including late incubation mortality were not influenced by the increased conductance created by the hole (late mortality Hole = 8.5 ± 1.7; No Hole = 8.3 ± 1.7; P=0.9494). This data indicates that the increased gas conductance provided by the egg injection hole does not reduce late embryonic mortality as was hypothesized. Future studies should focus on effects of the egg injection hole on eggs with poor shell conductance, and on the potential effects on post-hatch survival and growth.

Key Words: Embryo Survival, Egg Injection, Egg Shell Conductance

268 Effect of hatch pull time, protein and methionine on bobwhite quail performance. J. P. Blake*, J. B. Hess, and W. D. Berry, *Auburn University, Auburn, AL.*

Limited information exists concerning management and nutritional requirements for commercially produced bobwhite quail. An experiment investigated the effects of delayed placement after hatching on livability and performance. Bobwhite quail eggs (500) were incubated on two consecutive days and all hatchlings were removed on the 25th day and identified as either early (ES) or late (LS) set of eggs. Bird numbers were c.a. 54 birds/pen with 8 reps/set. In addition, 4 reps/set were offered a top-dressed feed supplement (Oasis) for three days post-hatch. Birds were fed a 26% corn-soybean meal starter diet containing 2,811 kcal/kg ME. Brooding temperature was 35 C (95 F) for the first week and reduced 2.8 C (5 F) weekly through four weeks of age. Results indicate that LS hatchlings (day 0) were significantly (P<0.0001) heavier as compared to ES hatchlings (6.95 vs. 6.15 g/bird). However, by 7-d of age ES birds were significantly (P<0.001) heavier than LS birds (17.60 vs. 15.31 g/bird). This effect carried through to the 28th day, where ES birds were significantly (P<0.01) heavier than LS birds (85.54 vs. 81.85 g). Bodyweight gains exhibited a similar pattern where ES birds exhibited greater period or overall gains than LS birds. Feed consumption was also significantly greater (P<0.01) for the ES versus LS birds during the 28-d experimental period (173.5 vs. 167.0 g/bird, respectively). Using a feed scattered additive had a slight influence on reducing early mortality (P<0.10) and reducing feed requirements (P<0.05) from 0-14 days posthatch. At four weeks of age birds were congruently assigned to one of four nutrient regimens: 22% CP/0.50% met; 22% CP plus methionine; 18% CP/0.41% met; 18% CP plus methionine resulting in an increased methionine level of 0.12 and 0.09% for the 22 and 18% diet, respectively. No differences in bodyweight, bodyweight gain, feed

consumption, or feed efficiency occurred due to treatment. Qualitative feather scores obtained at termination of the experiment at ten weeks of age indicated that the 18% CP plus methionine group had a significantly lower ($P < 0.05$) score as compared to the other treatments.

Key Words: Bobwhite Quail, Incubation, Protein

269 Influence of light intensity and handling on live and processing performance of male broilers. R. J. Lien*, J. B. Hess, S. R. McKee, B. A. McCrea, and S. F. Bilgili, *Auburn University, Auburn, AL.*

To determine effects on live and processing performance, broilers were subjected to step-up lighting of either bright or dim intensity, and either no handling or handling by the legs or wings to evaluate susceptibility to deep pectoral myopathy and deep thigh bruising. Male broilers (Ross 508) were placed in 12 light-tight rooms (90 per room). Step-up lighting (23L:1D, 1-9 d; 12L:12D, 9-16 d; 14L:10D, 16-23 d; 17L:7D, 23-30 d; 20L:4D, 30-37 d; and 23L:1D, 37-51 d) was provided. Six rooms were provided a light intensity of 15 footcandles (FC) (bright). The other 6 were provided an intensity of 0.5 FC to 9 d and 0.1 FC thereafter (dim). Birds were gently handled by the body during weighings at 9 and 23 d. At 23 d, birds in each room were randomly divided into 3 equal groups, assigned to either no handling, leg handling, or wing handling treatments, and marked accordingly. At 37 and 44 d, leg and wing handling birds only were each held for 20 s by their legs or wings and then weighed. At 51d, all birds were gently handled by the body as they were quickly and carefully weighed. Relative to bright light, dim light increased BW by 5% from 23 to 51 d and total feed consumption per bird from 30 to 51 d by 4%; however feed conversion was unaffected. Handling did not influence BW. Uniformity was not influenced significantly by treatments. Mortality averaged 3.6% and was unaffected by treatments. Since carcass and parts yields were consistently the same in the two intensity treatments, differences in live weights carried over through processing. Therefore, lean carcass, wing, leg, breast fillet, tender, and total breast weights were all increased by dim light. Leaf fat weights did not differ between lighting treatments, but fat yield was greater due to bright light. Handling did not affect carcass and parts weights or yields. Providing 0.1 FC throughout most of the growing period increased BW and feed consumption, which resulted in greater carcass and parts weights without any impact on feed conversion or parts yields.

Key Words: Broiler, Light Intensity, Handling

270 Impact of genotype, growth profile and photostimulation age on the reproductive efficiency of female broiler breeders. R. A. Renema*¹, M. J. Zuidhof², and F. E. Robinson¹, ¹*University of Alberta, Edmonton, AB, Canada,* ²*Alberta Agriculture, Food and Rural Development, Edmonton, AB, Canada.*

A 3 X 4 X 2 factorial design trial, with 3 broiler breeder strains, 4 target BW profiles and 2 photostimulation (PS) ages was performed to test the impact of strain and growth profile on sexual maturation traits. A total of 560 pullets from each strain (Hubbard Hi-Y, Ross 508, and 708) were housed in 24 pens. The BW profiles separated at 3 wk and converged at 32 wk of age as follows: STANDARD (approximates mean target BW profile of breeder strains used); LOW (12 wk BW target = 25% lower than STANDARD followed by rapid gain to 32 wk); MODERATE (12 wk BW target = 150% of STANDARD followed by lower rate of gain to 32 wk); and HIGH (12 wk BW target = 200% of STANDARD followed by minimal growth to 32 wk). Birds were photostimulated at 18 or 22 wk. Twelve birds per interaction were individually caged at 17 wk and monitored for egg production and fertility traits to 58 wk. The BW profiles converged at 32 wk and were similar thereafter. The LOW growth profile delayed onset of lay, particularly in 18 wk PS-age birds. There was no effect of growth history on initial egg weight. However, an 18 wk PS-age resulted in production of 16.0 small eggs (<52 g) compared to 7.9 in 22 wk birds. A settable, 52 g egg weight was reached earliest by STANDARD birds (26.7 wk of age). Prime laying sequence length was reduced by 7.0 eggs, on average, in MODERATE and HIGH birds (mean = 15.0 d) compared to other profiles ($P < 0.0001$). The 18 wk PS-age birds yielded 8 more eggs (170) than 22 wk PS-age birds, with no effect on unsettable eggs. On average, total egg production was similar among growth profile treatments. However, Ross 708-HIGH hens under-performed (138 eggs) compared to the other profiles (mean = 166.3). Alternatively, Ross 508-HIGH birds laid the same number of

eggs as Ross 508-STANDARD birds (mean = 178.7). Feeding profiles affected egg production traits differently among strains, with little effect of PS-age.

Key Words: Broiler Breeder, Growth Curve, Egg Production

271 Relationship of physical traits at hatch with growth traits to 14-d of age in male chicks of selected parent stock and pure line products. F. E. Robinson*¹, N. J. Wolanski¹, R. A. Renema¹, G. M. Fasenko¹, V. L. Carney², and B. Fanher², ¹*University of Alberta, Edmonton, AB, Canada,* ²*Aviagen, Huntsville, AL.*

Current commercial boiler breeder products are the result of specific strain crosses. This trial measured the relationship between chick morphology and quality with early male growth traits. Chicks of 8 strains (specialized and commercial lines) (110 birds/strain) were wing-banded and weighed at hatch. Chick length, shank length, navel score and abdominal score (for yolk-sac retention) were recorded. Fifty chicks/strain were dissected and breast muscle and yolk sac weighed. Remaining chicks of each strain were divided among 2 pens and reared under commercial conditions. At 14-d of age, 50 randomly selected chicks were dissected to assess the impact of strain on BW, frame size, breast muscle, and residual yolk-sac. The d0 chick weights varied, averaging a high of 40.6 g in Strains 1, 2, 4, and 9, 38.7 g in Strains 3 and 6, and a low of 37.1 g in Strains 7 and 8. Their abdominal score (range of 1-3) correlated with actual yolk-sac weight ($r = 0.50$; $P < 0.0001$). Once residual yolk sac (range of 5.8 g [Strain 4] to 3.0 g [Strain 8]) was removed, variability in chick weight dropped from 4.2 to 2.4 g among Strains. Yolk-sac weight did not impact rate of BW-gain to 14 d. Strains 1 and 4 (mean yolk-sac weight of 14.5%) grew fastest and slowest, respectively, with an identical breast muscle yield at d14 (12.0%). Residual yolk at d14 was low (0.04 [Strain 8] to 0.43 g [Strain 1]), but with a similar profile to d0 values. Both shank length ($r = 0.43$) and chick length ($r = 0.38$) at d0 correlated better with d14 BW than initial chick weight did ($r = 0.34$). The BW:shank ratio and BW:length ratio at d0, which may adjust for some strain or size differences, were no better correlated with d14 BW than d0 BW was (mean $r = 0.33$). Good navel condition at hatch was linked with improved relative growth to 14 d ($P = 0.009$), while red hocks did not affect growth ($P = 0.29$). This trial demonstrated variability in the effect of chick traits on early growth patterns in current stocks.

Key Words: Chick Quality, Growth Rate, Strain Variation

272 Growth potential and carcass characteristics of eight strains of broiler breeder stocks. M. E. Rustad*¹, F. E. Robinson¹, R. A. Renema¹, M. J. Zuidhof², and V. L. Carney³, ¹*University of Alberta, Edmonton, AB, Canada,* ²*Alberta Agriculture Food and Rural Development, Edmonton, AB, Canada,* ³*Aviagen, Huntsville, AL.*

Over the past 30 years there has been an increase in genetic progress of growth rate and breast meat yield of broiler stocks. This has led to the development of market specific strains which provide challenges for managing breeder stocks. This trial was carried out to determine the relative growth and breast yield potential of commercial and specialized broiler lines to aid in development of effective weight management strategies. Eight strains of broiler pullets (12 birds/strain) were placed in eight pens (96 birds/pen). Birds were provided ad libitum access to feed and water, and given a constant 23L:1D of light. Weekly pen weights were taken from 0 to 84 d. At 42d and 84d, six birds from each strain were removed from each pen and assessed for external fleshing traits, processed, and weights of the P. major, P. minor, and fatpad were determined.

At 6 wk and 12 wk, the heaviest strain was Strain 1 (2.59kg & 5.24kg) and the lowest was Strain 4 (1.78kg & 3.66kg). Strain 4 birds had the highest % breast muscle at both testing periods (12-wk: 27.3% of the live BW). Strain 3 and 6 were the lowest yielding strains at 6 and 12wk (20% of live BW). At 6 & 12 wk strain 3 showed the smallest breast depth (1.3 & 2.2mm). Strain 4 showed the lowest % fat pad (1.82% of live BW), while Strain 3 was the highest (4.30%). Strain 1 had consistently higher values for chest girth, keel and shank length than all other strains, but ranked fourth in breast yield (24.2%). Because strain 4 show the highest percentage of breast yield with the smallest frame size and a large breast width, this indicates that these birds are increasing breast muscle in adding width rather than by linear growth of the keel. This trial demonstrated the variability of breast muscle deposition, growth

patterns, fat deposition and carcass traits of differing broiler breeder genotypes.

Key Words: Broiler Growth, Breast Muscle Yield, Strain Variation

273 The effects of supplemental enzyme (AVIZYME 1502) and phytase (PHYZYME) on phosphorus nutrition in broiler breeders. M. S. Lilburn*¹, A. Mitchell², and E. E. M. Pierson³, ¹Ohio State University, Wooster, ²Growth Biology Lab, USDA, Beltsville, MD, ³Danisco Animal Nutrition, St. Louis, MO.

Broiler breeder pullets were fed diets with two levels of phosphorus and supplemental amylase or phytase or the combination. A Control diet was formulated to contain 0.40 available phosphorus with no added enzymes. A second series of diets were formulated to contain 0.30% available phosphorus with either supplemental PHYZYME (phytase), supplemental AVIZYME (avizyme) or PHYZYME plus AVIZYME (combination). Pullets were restrict fed beginning at 14 days of age. At 6 weeks, 12 pullets per dietary treatment were put into individual cages in Petersime growing batteries. The pullets were put in the cages on an off-feed day. They were individually fed 72 grams of the respective diets and excreta was collected from individual pullets over the next 48 hours. The phytase and combination diets resulted in a significant drop in total excreta dry matter (Control, 17.6 gm; phytase, 16.7 gm; avizyme 17.7 gm; combination, 16.5 gm). All three enzyme treatments resulted in a significant drop in excreta phosphorus concentration but this was expected as available phosphorus was also lower in these treatments (Control, 17.6 mg P per gm excreta; phytase, 14.5; avizyme, 15.1; combination, 13.1). Total phosphorus output was as follows: Control, 311 mg P; phytase, 243 mg P; avizyme, 267mg P; combination, 215 mg P. In conclusion, the use of low available phosphorus diets together with supplemental phytase and the combination of phytase resulted in a linear decline in total excreta phosphorus output by restrict broiler breeder pullets

Key Words: Broiler Breeders, Phosphorus, Phytase

274 Detection of *Campylobacter* and *Salmonella* in the mature and immature ovarian follicles of late-life broiler breeder hens. N. A. Cox¹, J. S. Bailey¹, L. J. Richardson*¹, R. J. Buhr¹, K. L. Hiatt¹, D. E. Cosby¹, J. L. Wilson², G. R. Siragusa¹, D. V. Bourassa², and M. T. Musgrove¹, ¹USDA-ARS, Russell Research Center, Athens, GA, ²Department of Poultry Science, University of Georgia, Athens.

Campylobacter and *Salmonella* are known to cause acute bacterial gastroenteritis in humans. Poultry products have been implicated as a significant source of these infections. Four trials were conducted to determine if *Campylobacter* and *Salmonella* spp. exist naturally in the mature and immature ovarian follicles of late-life broiler breeder hens. Broiler breeder hens ranging from 60-66 weeks of age were obtained from four different commercial breeder operations. For each trial, the hens were removed from the commercial operation and held overnight at the University of Georgia processing facility. The hens were euthanized, de-feathered and aseptically opened. To reduce the possibility of cross-contamination between samples, the mature and immature ovarian follicles were aseptically removed, then the ceca. Individual samples were placed in sterile bags, packed on ice and transported to the laboratory for evaluation. Overall, *Campylobacter* was found in 5/43 immature follicles, 9/35 mature follicles and 30/43 ceca. *Campylobacter* was found in at least one of each sample type in each of the four trials. *Salmonella* was found in 0/43 immature follicles, 1/35 mature follicles and 8/43 ceca. In this study the recovery rate of *Salmonella* from late-life broiler breeder hen ovarian follicles was relatively low. However, the recovery rate of *Campylobacter* from the hen ovarian follicles was reasonably high suggesting that these breeder hens could be infecting fertile hatching eggs. Determining how *Campylobacter* contaminated these ovarian follicles and how many chicks may become colonized from this source are the next steps in helping to elucidate a better understanding of this ecology and control of *Campylobacter* in poultry production.

Key Words: *Campylobacter*, *Salmonella*, Ovarian Follicles

275 The effect of daily photoperiod on growth of commercial broilers. 1. Body weight and breast yield. M. S. Lilburn*, Ohio State University, Wooster.

The broiler industry has successfully used daily photoperiod as a tool in the control of growth related anomalies ranging from leg disorders to ascites. There is an increasing trend, however, to impose restricted photoperiods at increasingly younger ages and this may have negative effects on other aspects of live production. Eggs were purchased from an integrated company that was experiencing excessive 7 and 14 day mortality. Each egg was weighed at set (n=1060 eggs) and transfer (19 days). Moisture loss at 19 days was 11.75% and shell weight determined on a random sample of eggs was above 9% of egg weight. At hatch, chicks were equally divided among two light controlled rooms. In Room A, the daily photoperiod was 24 hours through 4 days of age and then decreased to 16 hours on Day 5. In Room B, the photoperiod was decreased to 23 hours on Day 5. All the birds in each room were weighed at 7, 14, 21, and 28 days of age. On days 42 and 43, half the birds in each photoperiod were weighed and processed for pectoralis major and minor breast muscle determination. The sex of each bird was visually determined and recorded. The 23 hour photoperiod resulted in a significant increase in body weight at 14,21 and 28 days of age. At processing, the 23 hour photoperiod resulted in significantly heavier body weight (2605 vs 2555 gm) and increased weight of the pectoralis major (197 vs 189 gm). The males weighed 2826 gms versus 2337 gm for the females with corresponding pectoralis major weights of 213 and 174 gms. In summary, a reduction in daily photoperiod from 24 to 16 hours at a very young age resulted in a significant reduction in body weight from 14 through 42 days of age. The proportional reduction in body weight was less than the proportional reduction in relative weight of the pectoralis major breast muscle.

Key Words: Photoperiod, Growth, Broilers

276 The effect of daily photoperiod on growth of commercial broilers. 2. Feeding behaviour. K. Huffman* and M. S. Lilburn, Ohio State University, Wooster.

Two experiments were conducted with broilers to study the effects of different photoperiods on feed intake behaviour during the first hour of the daily photoperiod. Twenty broiler chicks were randomly allotted, at a day of age, to litter floor pens (4.64 m²) in each of two light controlled rooms. The pens were arranged in observation groups of three pens, two pens with chicks (A,B) on either side of an empty observation pen There were three observation groups in each room. At 4 days of age, the daily photoperiod in one room was decreased from 24 to 16 hr beginning at 0900 hrs. In the second room, the daily photoperiod was decreased to 22 hrs beginning at 1300 hrs. This allowed each room to be observed on the same day and weekly observations were done on Monday, Wednesday, and Friday of each week beginning at 7 days of age. The first hour of the daily photoperiod was divided into 10, 6 minute periods. The number of chicks feeding was visually determined in Pen A (4 to 5 min) and Pen B (5 to 6 min) during each of the 10 observation periods. The data for each week was the average of the three observation days X two pens per day (n=6 total observations per week per room). Experiment 2 was conducted to increase the number of replicate pens observed per week. The data was analyzed using the Proc GLM procedure of SAS. The main effects tested were experiment, photoperiod, age (week) and the interactions of experiment X week and photoperiod X week. In both treatments, the greatest feeding activity occurred during the first 6 minutes of the daily photoperiod. There were significantly more birds eating in the 22 hr treatment during the initial 6 minute observation period (16 hr = 7.4; 22 hr = 8.9; P < .002) and these numbers were almost halved during the second observation period (16 hr = 4.3, 22 hr = 4.7; P > .05). During each of the remaining 8 observation periods, there were significantly more birds from the 16 hr treatment consuming feed (range 4.1 to 4.8) than in the 22 hr treatment (range 2.4 to 3.4). There were significant experiment effects for most of the observation periods but no consistent experiment X week or photoperiod X week interactions

Key Words: Feed Intake, Photoperiod, Behaviour

277 The effect of daily photoperiod on growth of commercial broilers. 3. Skeletal development. M. S. Lilburn*¹ and A. Mitchell², ¹Ohio State University, Wooster, ²Growth Biology Lab, USDA, Beltsville, MD.

Broiler starter diets from three commercial feed mills (same company, different locations) were fed to day-old Hubbard Hi-Y broiler chicks along with a Control diet manufactured at Ohio State University. The analyzed calcium levels were as follows: Source 1, .76% ; Source 2, .97% ; Source 3, .81% ; Control, .98%. Each of the diets was fed to 5 replicate pens of broiler chicks in Petersime battery brooders in each of two light controlled rooms. In Room A, the chicks were exposed to a 24 hr photoperiod from 0 to 4 d and 22 hr from 5 to 21 d whereas in Room B, the photoperiod was decreased to 16 hr at 5 d of age. At the end of the study, each chick was weighed and the tibia and femur were removed for length, width @ 50% of length, defatted dry weight and bone mineral content. Chicks exposed to 16 hr of light weighed significantly less than those chicks exposed to 22 hr (706 vs 747 g; P < .0001). The 16 hr photoperiod also resulted in a significant decrease (P < .01) in all bone measurements: tibia wt, 1.58 vs 1.78 g; tibia length, 6.34 vs 6.48 cm; tibia width, 5.8 vs 6.0 mm; femur length, 4.82 vs 4.93 cm; femur width, 6.7 vs 7.1 mm. Tibia and femur bone mineral content and bone mineral density were significantly greater in birds fed the Source 2 and Control diets compared with birds fed the Source 1 and Source 3 diets. These same bone mineral measurements were consistently higher in the 22 h. photoperiod though the differences were not always significant. In conclusion, variability in commercial starter diets combined with early photoperiod restriction may have a negative effect on skeletal development in broilers.

Key Words: Bone, Photoperiod, Calcium

278 Spatial disparity of ammonia flux within a broiler house at one and 21 days of age. D. M. Miles*¹, P. R. Owens¹, D. E. Rowe¹, and S. L. Branton², ¹USDA-ARS, Waste Management and Forage Research Unit, Mississippi State, MS, ²USDA-ARS, Poultry Research Unit, Mississippi State, MS.

Ammonia concentrations greater than 25 ppm in broiler houses have been linked to emaculated birds. The objectives of this study were to measure ammonia and other gas fluxes in a commercial broiler house and assess any spatial variabilities. Application of these findings include the development of optimum sampling methods as well as the identification of characteristics of modern tunnel ventilated houses that contribute to gas emissions. Researchers hypothesize that litter age, moisture, pH, temperature, and airflow patterns affect gas flux values and these parameters vary spatially. Ammonia, nitrous oxide, carbon dioxide, methane, and carbon monoxide were measured using a photoacoustic multigas analyzer along with flux boxes. Samples (n=36) were collected systematically throughout the house along a set grid. Twenty-eight flocks had been grown on the litter prior to the summer flock sampling with chicks in the house at one (placement) and 21 (mid-growout) days of age. At one day of age during half-house brooding, average NH₃ flux was 498 mg/m²-hr for the brood area and 372 mg/m²-hr for the vacant end of the house with peak areas near the middle of the cool cell end (where airflow is not well established) and near the north side wall (an area of high litter moisture, 37%). At 21 days of age, litter temperatures were reversed from those at chick placement and were greater near the fan end of the house. Both ranged from about 25.6 to 31.9 C. Litter pH was greater in the nonbrood half of the house at placement and mid-growout. Average NH₃ flux for the mid-growout was 136 and 310 mg/m²-hr for the brood and fan ends. A peak area for NH₃ flux in mid-growout was evident approximately 7 m past the midpoint of the house (towards the fans) and correlated to high pH (8), high litter moisture (33%), and high CO₂ flux (12500 mg/m²-hr). The spatial variability of these parameters demonstrates that increased NH₃ flux relates to high litter moisture as well as greater litter temperatures and CO₂ flux and NH₃ flux decreases on average from placement to mid-growout.

PSA Immunology

279 Salmonella vaccination programs in broiler breeders. I. Humoral and mucosal immune response. A. Rolon*¹, J. S. Bailey², P. S. Holt², C. L. Hofacre³, J. L. Wilson², D. E. Cosby², L. J. Richardson², and N. A. Cox², ¹Department of Poultry Science, University of Georgia, Athens, ²U. S. Department of Agriculture Russell Research Center, Athens, GA, ³Department of Avian Medicine, University of Georgia, Athens.

Although vaccination against *Salmonella* has been used more frequently in broiler breeders in recent years, there is a paucity of information in the literature demonstrating the immunological response of treatments that combine live and autogenous killed cell vaccines. The present research was designed to assess the immunological response that was generated by three vaccination protocols. Treatment vaccines consisted of a live Aro-A mutant commercial *Salmonella* Typhimurium (ST) vaccine and an autogenous killed vaccine consisting of a pool of *Salmonella* serovars Berta, Heidelberg, and Kentucky prepared by a commercial company. Four groups of 250 Cobb x Cobb breeder chicks were vaccinated as follows: A) 2 live (day 1 and 21) and 2 killed (day 77 and 126); B) 3 live (day 1, 21, and 77) and 1 killed (day 126) and ; C) 2 killed (day 77 and 126); and D) untreated controls. To assess humoral and mucosal immune response, samples of serum (SER), crop lavage (CL), gut lavage (GL), hatchling serum (HSER), and egg yolk (EY) were tested to measure IgA and IgG. ELISA for IgA and IgG on *Salmonella* Enteritidis and *Salmonella* Typhimurium lypopolysaccharide (SELPS and STLPS) as capture antigen were conducted. Overall, immunological response was stronger on STLPS than SELPS. IgA of SER, CL and GL as well as IgG of CL were short-lived peaks after first killed vaccine. Strong GL IgG after first live and both killed vaccine events were measured with the killed response enduring longer. SER IgG responses were observed after killed vaccine events, and lasting throughout 40 wk of age. HSER and EY IgA were negligible, and IgG comparable among all treatments throughout time. These results show that killed antigen is vital in eliciting adequate IgG in serum and gut. Live vaccination with Aro-A mutant

ST vaccine enhances gut IgG and possibly aids in conferring adequate immunity during the breeder's first weeks of life.

Key Words: *Salmonella*, Vaccination, Immune Response

280 Salmonella vaccination programs in broiler breeders. II. Resistance to challenge under a multiple marker strain model. A. Rolon*¹, J. S. Bailey², P. S. Holt², C. L. Hofacre¹, J. L. Wilson², D. E. Cosby², L. J. Richardson², and N. A. Cox², ¹University of Georgia, ²U. S. Department of Agriculture.

Resistance to *Salmonella* challenge of breeders and their chicks under three vaccination programs was assessed. Vaccine protocols combined a live Aro-A *Salmonella* Typhimurium (ST) vaccine and an autogenous 3-serovar killed vaccine. Treatments combined: 2 live and 2 killed or 3 live and 1 killed vaccines delivered at 1 d and 3, 11 and 17 wk of age; 2 killed vaccines given at d 77 and 126; and a non-vaccinated control (C). Breeders were gavaged with 10⁷ cells of a 3-strain cocktail (*Salmonella* Enteritidis (nalidixic acid resistant, Nal-SE), Typhimurium (rifampicin resistant, Rif-ST) and Thompson (ampicillin resistant, Amp-STH)), at wk 3, 6, 10 18 and 22. Chicks from eggs laid at wk 29, 34 and 40 of breeder age (BA) were challenged at one day-of-age. Chicks were divided in two groups per treatment, one given a commercial competitive exclusion culture (CE), and both were challenged with 10⁷ cells of a Nal-SE + Rif-ST + Amp-STH cocktail and kept in isolation units for one and two wk. Ceca and Liver-Heart-Spleen (LHS) samples were cultured for each marker strain on BGS + antibiotic (Nal, Rif, or Amp) plates and colonies counted after 24h incubation. Log₁₀ data were analyzed under a factorial design. Breeder *Salmonella* counts showed significant differences between (live) vaccinates and non-vaccinates at 3 and 6 wk challenges. By 10 wk, there were no discernible difference in *Salmonella* level in challenge and control chicks, indicating protection by (1d and 3 wk) live vaccines had diminished at this time. All programs reduced breeder *Salmonella* counts compared to controls at 22 wk. Chick *Salmonella* counts showed little consistency between vaccine treatments. At 34 and

40 wk BA, no difference was observed in susceptibility of chicks from vaccinated and control breeders. Passive immunity did not show consistent decrements on challenged chicks *Salmonella* counts. These results show that live vaccination with the Aro-A ST vaccination decreases *Salmonella* counts during the first 6 wk of age of the breeder, as do all programs by 22 wk of age, and that competitive exclusion is the most effective treatment in reducing *Salmonella* counts.

281 Construction and evaluation of recombinant *Salmonella* vaccine expressing *Eimeria* sporozoite and merozoite antigen. V. Konjufca*, S.-Y. Wanda, and R. Curtiss III, *Washington University, St. Louis, MO.*

Coccidiosis is a poultry disease caused by ubiquitous protozoan parasite *Eimeria* sp. and is characterized by intestinal lesions, poor growth, morbidity and mortality. Efforts to produce an effective vaccine against this disease have been with limited success and the need for an effective vaccine is still evident. *Eimeria* is an intestinal parasite, thus a vaccine capable of inducing both mucosal and systemic immune responses would be most effective in protecting against this parasite. Our approach uses the *Salmonella* Type Three Secretion System (TTSS) to deliver an antigen directly into the cell cytoplasm of the immunized host to result in MHC class I antigen processing for induction of antigen-specific CTL responses. To accomplish this goal, *Eimeria* genes encoding antigens EASZ240 and EAMZ250 were fused to *Salmonella* effector protein gene *sptP* in the parental Asd⁺ pYA3653 vector, yielding pYA3657 and pYA3658, respectively. SptP effector protein is secreted by TTSS of *Salmonella* and translocated into the cytosol of immunized host cells. The host-strain chromosomal copy of the *sptP* gene was deleted and replaced by a reporter gene *xylE*. Newly constructed pYA3657 and pYA3658 were introduced into host strain χ 8879 (Δ phoP233 Δ sptP1033::xylE Δ asdA16). This strain is an attenuated derivative of highly virulent *S. typhimurium* UK-1 strain. In vitro experiments show that EASZ240 is secreted into the culture medium by TTSS without contact with eukaryotic cells. In addition, EASZ240 is delivered into the cytoplasm of Int-407 cells by TTSS, making this protein a good model antigen for evaluation of TTSS as an antigen delivery system. Colonization of bursa, spleen and liver by all three vaccine constructs were observed in immunized day-old chicks with peak titers at 6 to 9 days post-immunization. In vivo experiments indicate that both humoral and cell-mediated immune responses were induced in vaccinated chickens.

Key Words: *Eimeria*, Vaccine, *Salmonella*

282 Rous sarcoma growth in lines congenic for major histocompatibility (B) complex recombinants. E. S. Schulten¹, W. E. Briles², and R. L. Taylor, Jr.*¹, ¹University of New Hampshire, Durham, ²Northern Illinois University, DeKalb.

Six congenic lines of chickens with major histocompatibility (B) complex recombinant haplotypes were examined for Rous sarcoma virus (RSV) tumor growth. These lines were created by crossing a male bearing each B complex recombinant (R¹ - R⁶) to highly inbred Line UCD 003 (B¹⁷B¹⁷) females, which constitute the genetic background. Backcrosses were made by crossing recombinant heterozygous males (R^{B17}) to UCD 003 females. After the tenth backcross, heterozygotes for each recombinant were mated to produce homozygous progeny for one of six different recombinants with 99.9% of their background genome from Line UCD 003. The MHC recombinant haplotypes for these lines were: R¹=B-F/B-L²⁴, B-G²³; R²=B-F/B-L², B-G²³; R³=B-F/B-L², B-G²³; R⁴=B-F/B-L², B-G²³; R⁵=B-F/B-L²¹, B-G¹⁹; and R⁶=B-F/B-L²¹, B-G²³. R², R³, and R⁴ (all B-F/B-L², B-G²³) are distinct recombinants because each haplotype arose from separate recombinational events. Chicks from each line were challenged with 10 pfu of subgroup A RSV. Tumors were assigned tumor size scores at 2, 3, 4, 6, 8, and 10 weeks post-inoculation. Each bird was assigned a tumor profile index (TPI) number based on the six tumor size scores. Hatch and B genotype were main effects in the statistical analysis. Least squares ANOVA was used to evaluate rank transformed TPI values and mean tumor sizes through a repeated measures design. Fisher's Protected LSD at P < 0.05 separated significant means. R¹R¹ and R⁴R⁴ chickens had greater tumor growth and significantly higher TPI than the other four recombinant lines. R¹R¹ has B-F/B-L²⁴, a previously characterized progressive haplotype. The higher tumor growth and TPI of R⁴R⁴

indicates the presence of different genes affecting RSV tumors compared to the serologically-similar R²R² and R³R³. The similar tumor growth of R⁵R⁵ and R⁶R⁶ shows no B-G region effect.

283 Demonstration of Carboxypeptidase E protein and mRNA in the diffuse neuroendocrine system of the chicken thymus. X. Zhang*², J. J. Zhu¹, and L. R. Berghman¹, ¹Departments of Poultry Science and Veterinary Pathobiology, Texas A&M University, College Station, ²Department of Poultry Science, Texas A&M University, College Station.

In previous studies, we have described a complex neuroendocrine cell population within the chicken thymus using a monoclonal antibody against avian chromogranin A (CgA). CgA is considered an on/off switch in neuroendocrine cells, controlling the biogenesis of large dense-core vesicles (LDCV) and essential for the regulated secretory pathway. Here, we report that most of the CgA-positive cells are also immunoreactive for carboxypeptidase E (CpE), a processing enzyme present in the Golgi and secretory granules of neural/neuroendocrine cells that is necessary for the post-translational maturation of prohormones into bioactive peptides. Our immunofluorescent dual staining experiments used antisera against the conserved C- and N-terminal portions of CpE, respectively, (kindly donated by Dr. Peng Loh, NIH) and a monoclonal antibody against avian chromogranin A on chicken thymus sections. Surprisingly, the antisera against the respective CpE termini did not produce identical staining patterns. Co-localization of C-terminal CpE immunoreactivity was observed in most, if not all, CgA positive cells. In contrast, the antiserum against N-terminal CpE clearly identified cells but also nerve fibers, and N-terminal CpE immunoreactivity was generally not co-localized with CgA. This seems to suggest the existence of different CpE isoforms in the chicken thymus. Based on chicken genome sequence data, the synthesis of both CgA- and CpE-specific mRNA in the chicken thymus was confirmed by RT-PCR. The observed neuroendocrine cells were located predominantly in the transition zone between the cortex and the medulla of the thymic lobules, which is known to be heavily innervated by the autonomic nervous system. These findings fit with our current working hypothesis that some of the locally produced neuroendocrine molecules are processed and released through the regulated neuroendocrine secretory pathway, potentially under the control of the autonomic nervous system.

Key Words: Chicken, Thymus, Carboxypeptidase E

284 Cationic amino acid transport (CAT) expression in immune tissue and the effect of lysine on lymphocyte function. B. Humphrey* and K. Klasing, *University of California, Davis.*

Lysine and arginine are transported into cells by cationic amino acid transporters (CAT). Two experiments determined the effect of the acute phase response (APR) on CAT expression and the effect of lysine levels on lymphocyte proliferation. The first experiment was designed as a 2 x 2 factorial with fasting or feeding and 2 levels of LPS (+/- LPS; 1mg/kg BW s.q.). Treatments were initiated when broiler chicks were 2 weeks of age and samples were collected 12-h later. Plasma amino acids were determined and bursa, thymus and liver CAT1-3 mRNA levels were assayed by quantitative PCR. Plasma lysine and arginine levels were increased by both LPS and fasting (P<0.05). Bursa and thymus CAT-1 levels did not change with fasting (P>0.05) and increased 5-fold with LPS (P<0.05). Bursa and thymus CAT-2 levels did not change with fasting (P>0.05) and decreased below the limit of detection with LPS. Thymus CAT-3 levels in fasting chicks decreased 1.4-fold with an LPS injection (P=0.05). Bursa CAT-3 levels in fasting chicks decreased 2-fold with an LPS injection (P<0.05). Experiment two determined thymocyte proliferation in response to 4 lysine levels (no lysine, 0 μ M; lysine deficient, 50 μ M; lysine adequate, 500 μ M; lysine APR, 1500 μ M) and 2 levels of PHA (0 or 30 μ g/ml). In vitro lysine levels were similar to in vivo lysine levels for each indicated physiological state. Thymocytes proliferated in response to PHA at all lysine levels except for 0 lysine (P<0.05). Proliferation at 500 μ M lysine was greater than 50 μ M (P<0.05) and tended to be greater than 1500 μ M (P=0.06). During the APR, the bursa and thymus increase their transport capacity for lysine and arginine while the levels of these nutrients increase in plasma. In addition to providing increased lysine and arginine for use in nitrogen metabolism, increased transport capacity of lysine by the thymus may also serve to suppress T

lymphocyte responses since thymocyte proliferation tended to be lower with lysine concentrations at 1500 μ M.

Key Words: Acute Phase Response, Lysine, Lymphocyte

285 Effect of testosterone and lead on T cell maturation in the developing thymus. I. Hussain*, M. Piepenbrink, and R. Dietert, *Department of Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, NY.*

The developing immune system is particularly sensitive to environmental and hormonal influences. Genders can differ in this sensitivity as well. Because the heavy metal, lead, can suppress Th-1 associated function among perinatal thymocytes and cause a systemic loss of postnatal Th-1 function, we investigated the ability of *in ovo* administered lead and testosterone to alter thymocyte maturation. Cornell K-strain chick embryos were injected via the air sac on embryonic (E) day 8 with either testosterone (12.5 μ g/egg in ethanol) or 15% ethanol in 100 μ l volume. The groups then received either lead acetate (200 μ g/egg) or sodium acetate (control) on E 12 of incubation by the same route. On E 20, thymuses from 4-5 female embryos per group were harvested in sterile Hanks balanced salt solution on ice, and thymocytes were separated using Ficoll. Tri-color flow cytometry was performed with fluorescent-conjugated antibodies against chicken-CD3, CD4, CD8, TCR1 and TCR2 surface molecules and data were analyzed using the MIXED procedure of SAS. Lead did not induce changes among the cell surface markers measured in this study. However, testosterone administration caused changes in both the CD4+CD8+ and CD4+CD8- cell populations ($P \#8804$ 0.05). Testosterone treatment followed either by sodium or lead acetate injection caused a statistical increase in CD4+CD8+ cells (73.23 ± 2.77 % and 79.85 ± 2.77 % with sodium or lead acetate, respectively) compared either with ethanol and sodium acetate or ethanol and lead acetate treatments (69.68 ± 2.77 % or 68.98 ± 2.77 %, respectively). Additionally, testosterone treatment significantly lowered the percentage of CD4+CD8- cells from 7.61 ± 1.3 % (control)

to 4.2 ± 1.3 % or 4.63 ± 1.3 % (for testosterone with either sodium acetate or lead acetate, respectively). Therefore, sex hormonal balance can modulate thymocyte maturation, but cellular validation of lead-induced alterations would require the use of additional Th-specific markers. Supported by USDA grant NE-60/NE-1016.

286 Immunocompetence measurements of frizzle and normally feathered genotypes issued from different maternal lines of chicken. M. M. Fathi, S. A. El-Safy*, and A. Galal, *Poultry Prod. Dept, Faculty of Agric., Ain Shams University.*

An experiment was conducted on frizzled and normally feathered genotypes issued from two different maternal lines either Golden-Montazah (GM), an Egyptian local breed, or Brown Hy-Line strains during the summer season of Egypt. The immunocompetence parameters that were assessed for the offspring were lymphoid organ weights, cell-mediated immune response (PHA-P), globulin level in serum and heterophil/lymphocyte ratio. The results of CBH response showed that the frizzled genotypes had a significantly greater dermal swelling response to PHA-P compared to normally feathered sibs. The frizzled genotypes also exhibited larger bursa and thymus (as a percentage of body weight) compared to the normal genotypes in the two dam lines. A significantly genotype-dam line interaction for globulin level was observed. However, the frizzle gene increased globulin level in chickens issued from GM dams and the reverse was true in chickens issued from Hy-Line. The H/L ratio was significantly higher in both genotypes of Hy-Line dams compared to counterparts of GM ones. We concluded that under the conditions of the current study, the frizzle chickens are hyper-responders compared to normal plumage birds, especially those issued from Golden-Montazah breed.

287 *In vitro* and *in vivo* evaluation of simultaneous supplementation of α -galactosidase and citric acid on nutrient release, digestibility and growth performance of broiler chicks. T. Ao*¹, A. H. Cantor¹, A. J. Pescatore¹, M. J. Ford¹, and J. L. Pierce², ¹University of Kentucky, Lexington, ²Alltech Biotechnology Center, Nicholasville, KY.

Experiments were conducted to evaluate the effects of simultaneous supplementation of α -galactosidase and citric acid on 1) *in vitro* nutrient release from soybean meal, and 2) *in vivo* nutrient digestibility and growth performance of broiler chicks fed a corn-soy diet. In Experiment 1, an *in vitro* model was used to simulate the chicken's digestive process in the crop and from the crop through the small intestine. Graded levels of α -galactosidase (0 to 13,792 units/kg) and citric acid (0 or 20 g/kg) in a factorial arrangement were added to soybean meal, which was used as the substrate. Reducing sugars were measured at the end of both phases. Increasing enzyme levels linearly ($P < 0.001$) increased release of reducing sugars in both phases. Addition of citric acid with α -galactosidase further increased enzyme activity, resulting in a significant interaction ($P < 0.001$). In Experiment 2, 144 1-d-old male broiler chicks were randomly distributed among 24 replicate cages of six chicks contained in three blocks, to provide six replicate groups for each of four treatments. Two levels of α -galactosidase (0 or 1724 units/kg) and of citric acid (0 or 20 g/kg) were added in a factorial arrangement to a low-energy (2730 Kcal ME/kg) corn-soy diet. Alpha-galactosidase ($P < 0.05$) increased body weight gain, feed intake, NDF digestibility and dietary AME_n. Citric acid increased ($P < 0.05$) the digestibility of DM, NDF and CP. Compared with the unsupplemented diet, weight gain and feed intake were depressed ($P < 0.01$) by adding citric acid alone, but not by the addition of both citric acid and α -galactosidase. Simultaneous supplementation of α -galactosidase and citric acid increased ($P < 0.05$) dietary AME_n and digestibility of DM, NDF, and CP, and improved ($P < 0.05$) feed to gain ratio. These results suggest that acidification of poultry diets may improve the effectiveness of exogenous α -galactosidase.

Key Words: Alpha-Galactosidase, Citric Acid, Broilers

288 Effect of virginiamycin in diets with adequate or reduced dietary calcium or available phosphorus for 0 to 18 d-old broilers. T. O'Connor-Dennie* and L. L. Southern, *LSU Ag Center, Department of Animal Science, Louisiana State University, Baton Rouge.*

Based on previous research in our laboratory, the addition of virginiamycin (Vm) to diets with reduced available P (aP) or Ca improved the negative effects associated with deficiencies of these minerals. To further investigate this response, two additional experiments (EXP) were conducted to evaluate the effect of Vm in diets with adequate or reduced Ca (EXP 1) or aP (EXP 1 and 2) on daily gain (ADG), daily feed intake (ADFI), gain:feed, bone breaking strength, bone ash percentage, and mg of ash in 0 to 18 d-old chicks. In EXP 1, there were six treatments with six replications of five chicks per replicate. The dietary treatments were: 1) a corn-soybean meal (C-SBM) diet with 1.00% Ca and 0.45% aP; 2) C-SBM with 0.70% Ca and 0.45% aP, 3) C-SBM with 1.00% Ca and 0.25% aP; Diets 4 to 6) as Diets 1 to 3 with 9 ppm Vm. Reducing dietary aP decreased ADG, ADFI, and BS ($P < 0.01$). Reducing dietary Ca decreased BS and gain:feed ($P < 0.06$) but had no effect on ADG or ADFI. The addition of Vm to the low aP diets tended to decrease BS (aP x Vm, $P < 0.06$) but had no effect on ADG or ADFI. The addition of Vm to the low Ca and control diets increased BS ($P < 0.03$). In EXP 2, there were twelve treatments with six replications of six chicks per replicate. The dietary treatments were: Diets 1 to 4) C-SBM with 1.00% Ca and 0.15, 0.25, 0.35, 0.45% aP; Diets 5 to 8) as Diets 1 to 4 with 11 ppm Vm; and Diets 9 to 12) as Diets 1 to 4 with 22 ppm Vm. Daily gain, ADFI, gain:feed, BS, bone ash percentage, and mg of ash per tibia were increased ($P < 0.01$) as dietary aP levels were increased. The addition of Vm, regardless of supplementation level, increased ADG and BS in chicks fed diets with 0.35% and 0.45% aP, but Vm had no effect or decreased ADG and BS at the 0.15 and 0.25% aP levels (aP x Vm, $P < 0.05$). These results indicate that Vm, added at 11 or 22 ppm, will partially overcome the negative effects associated with aP deficiency at dietary levels of 0.35% aP or greater.

Key Words: Chicks, Phosphorus, Virginiamycin

289 Intestinal bacterial populations in broiler chickens fed on high protein diets with and without added guar gum. J. P. Dahiya*, D. C. Wilkie, A. G. Van Kessel, B. Laarveld, and M. D. Drew, *University of Saskatchewan, Saskatoon, SK, Canada.*

Necrotic enteritis is a worldwide poultry disease caused by *Clostridium perfringens*. An experiment was conducted to study the effects of dietary protein level and source and a soluble non-starch polysaccharide (guar gum) on the intestinal populations of various microbes in broiler chickens. Six groups of 12 birds (in duplicate) were provided with a medicated ideal protein-balanced corn-based starter crumble from day 0 to 21 of age. From d 21 onwards, six experimental diets (23, 40, 40% crude protein) with fish meal and soybean meal as main protein sources and with and without added 1% guar gum were fed in a 2 X 3 factorial arrangement of treatments. All birds were orally challenged with *C. perfringens* type A both culture from d 21 to 27. Total anaerobes, *C. perfringens*, total aerobes and *Lactobacilli* spp. were enumerated in ileal and cecal contents on d 35, 39 and 42. Nine (6.25%) birds died during the first 4 days of diet shift, but lesions typical of necrotic enteritis were seen in only three of them. There was a significant ($P < 0.05$) increase in the *C. perfringens* and total anaerobes count in cecum, but not in ileum due to guar gum addition. There were no significant effects of protein on the *C. perfringens* numbers except on d 42 in cecum where counts were significantly ($P < 0.05$) higher in birds fed SPC-based diet. Viscosity and the clostridial counts were significantly ($P < 0.05$) correlated in the cecum on d 35, 39 and 42, and in ileum on d 35. There were no significant differences in the *Lactobacilli* and total aerobic counts between different treatment groups. The viscosity and the pH of ileal contents were significantly higher and lower, respectively in birds fed diets with added guar gum. The pH of ileal contents was significantly ($P < 0.05$) higher in SPC-fed birds compared to control and fish meal-fed birds. Hence, it was concluded that the guar gum was associated with increase in *C. perfringens* and total anaerobes but the protein level had little effect on populations of these bacteria.

290 Organic acids improve phytate phosphorus utilization in chicks fed a corn-soybean meal diet. K. A. Rafacz*¹, C. M. Parsons¹, and R. A. Jungk², ¹*University of Illinois, Urbana*, ²*PMP Fermentations Products Inc., Peoria, IL.*

Previous research from our laboratory has shown that citric acid improves phytate phosphorus (P) utilization in chicks fed a P-deficient corn-soybean meal diet. The current study was conducted to determine if other organic acids are effective, with emphasis on gluconic acid. Two experiments were conducted in which four replicate groups of five crossbred chicks (New Hampshire X Columbian) were fed a P-deficient (0.16%) nonphytate P diet from 8-21 days of age. In Experiment 1, a completely randomized design was utilized to evaluate the effects of two levels of sodium gluconate (Na Glu), calcium gluconate (Ca Glu), and glucono-delta-lactone (GDL) and one level of HMB (2-hydroxy-4-methylthio butanoic acid as Alimet[®]). The diets were formulated to contain 1.5% or 3% of the gluconates or 1% HMB. Chick weight gain and tibia ash were significantly increased ($P < 0.05$) by Ca Glu (1.5%), Na Glu (1.5 and 3%), GDL (1.5 and 3%), and HMB (1%). In Experiment 2, a 4x2 factorial design was used to evaluate the effect of 2% of Na Glu, Ca Glu, and citric acid (CA) in two diets containing either 0.16 or 0.45% nonphytate P. All diets were formulated to be isocaloric and equal in Ca, Na, and Cl. Tibia ash was significantly increased ($P < 0.05$) by all three organic acids in chicks fed the 0.16% nonphytate P diet but not in chicks fed the 0.45% nonphytate P diet indicating that the responses were due to increased P utilization. The results of this study show that Na Glu, Ca Glu, GDL, HMB, and CA improve phytate P utilization in chicks fed a corn-soybean meal diet.

Key Words: Organic Acids, Chicks, Phosphorus

291 Phytase and 1 α -OH cholecalciferol (1 α -OH D₃) supplementation to broilers during the starting and growing/finishing phases. J. P. Driver*, G. M. Pesti, R. I. Bakalli, and H. M. Edwards, Jr., *The University of Georgia, Athens.*

There is considerable data in the literature on the efficacy of exogenous phytase supplementation for very young, starting, broiler chickens. However there is limited information on exogenous dietary phytase for growing/finishing broilers older than 21 days. Supplemental 1 α -OH D₃ has been shown to have qualitatively similar and quantitatively additive effects to exogenous phytase supplementation. An experiment was

conducted with 4 replicate pens per treatment of 30 broiler chicks from 0 to 35 days of age in litter covered floor pens. All birds were fed corn, soybean meal and soybean oil based diets and raised in houses which precluded any UV light penetration. From 0 to 18 days the birds were fed a 23% protein diet with 0.6% Ca, 0.5% total P (tP) and 0.24% non-phytate P (nPP). From 19 to 35 days the birds were fed a 19% protein diet with 0.3% Ca, 0.37% tP and 0.14% nPP. Eight replicates were fed a control diet with 0.9% Ca, .71% tP and .45% nPP 0-18 days, and 0.8% Ca, .71% tP and .45% nPP from 18-35 days. A supplement of 1000 FTU Natuphos 5000[®] phytase and 5 μ g/kg 1 α -OH D₃ (P+1A) was supplemented during the starter (0-18 days) or grower/finisher (18-35days) phases. The incidences of rickets and tibial dyschondroplasia were measured at 18 and 35 days. Un-supplemented chicks performed well but had considerable leg problems (1705 g gained and 2.096 g feed/g gain). Chicks fed P+1A during the starter (1886 g and 1.97 g/g) or grower/finisher phases (1733 g and 2.12 g/g) did not perform as well as those fed P+1A throughout (1933 g and 1.92 g/g). Boilers fed P+1A throughout performed as well as the controls (1940 g and 1.92 g/g) without any indication of increased leg problems. It is concluded that properly supplemented diets with as little as 0.3 % Ca and 0.14% nPP may be fed to broilers older than 18 days of age if properly supplemented with exogenous phytase and 1 α -OH D₃.

Key Words: Broiler, Phytase, 1-alpha-OH Cholecalciferol

292 Efficacy of an *Escherichia coli* phytase on growth performance, nutrient utilization and bone characteristics in broiler chicks. E. M. Onyango*¹, M. R. Bedford², and O. Adeola¹, ¹*Purdue University, West Lafayette, IN*, ²*Zymetrics Inc., Marlborough, Wiltshire, UK.*

An *Escherichia coli*-derived phytase was compared to that of a commercially available *Peniophora* phytase in order to evaluate its efficacy in improving growth performance and nutrient utilization of broiler chicks. One hundred and forty four 7-d-old male broiler chicks were grouped by weight into six blocks of six cages with four birds per cage. Six corn-soybean meal-based diets were randomly assigned to cages within each block. The six diets were adequate P and low P diets containing (g P/kg diet) 7.7 and 3.9, respectively; and low P diet plus either the *Escherichia coli*-derived phytase or the *Peniophora* phytase at 500 or 1000 units/kg of feed. The chicks were fed the experimental diets from 8 to 22 d of age. Excreta samples were collected between 17-21 d of age. At the end of the study, chicks were killed and left tibiae removed from the birds. The *Escherichia coli*-derived phytase compared with *Peniophora* phytase was more efficacious in improving weight gain ($P < 0.01$), feed intake ($P < 0.001$), toe ash ($P < 0.05$), tibia ash ($P < 0.001$) and total tract phosphorus retention ($P < 0.001$). There was a linear response to the *Escherichia coli* phytase in weight gain ($P < 0.05$), feed intake ($P < 0.01$), and tibia ash ($P < 0.01$) and phosphorus retention ($P < 0.001$). Both phytase sources improved total tract amino acid retention ($P < 0.05$). The *Peniophora* phytase improved ileal retention of most amino acids ($P < 0.05$). The *Escherichia coli*-derived phytase was efficacious in improving broiler growth performance, bone characteristics, and total tract retention of phosphorus and amino acids.

Key Words: Broiler Chick, *Escherichia coli* Phytase, Nutrient Utilization

293 Dietary Phytates Increase Endogenous Losses in Ducks and Chickens. E. M. Onyango*¹, E. K. Asem², J. S. Sands³, and O. Adeola¹, ¹*Department of Animal Sciences, Purdue University, West Lafayette, IN*, ²*Basic Medical Sciences, Purdue University, West Lafayette, IN*, ³*Danisco Animal Nutrition, Marlborough, Wiltshire, UK.*

The role of different forms of phytate on the regulation of endogenous losses in ducks and chicken was investigated. Forty eight 10-wk-old male ducks or broiler chickens were grouped by weight into eight blocks of 6 cages with one bird per cage. On the first day of experimentation, birds were fed by intubation the following six diets: dextrose alone or dextrose plus either phytic acid, magnesium-potassium-phytate, phytase (1000 U), phytic acid plus phytase, or magnesium-potassium-phytate plus phytase. All excreta were collected continuously during the 54 h following feeding and frozen until analyzed. Excreta were freeze-dried, ground and analyzed for dry matter, and their content of energy, nitrogen, mucin and sialic acid. Ducks fed magnesium-potassium-phytate excreted more nitrogen ($P < 0.05$) than those fed dextrose alone but

the amount excreted was similar to that excreted by ducks fed phytic acid. This however was not true for chickens. The highest amount of crude mucin was excreted by ducks and chickens fed magnesium-potassium-phytate followed by those fed phytic acid ($P < 0.05$). Ducks and chickens fed either phytic acid or magnesium-potassium-phytate excreted higher ($P < 0.05$) amounts of sialic acid than those fed dextrose alone. Addition of phytase to the diets did not reduce the endogenous losses observed in the ducks or chickens. In conclusion, presence of either phytic acid or magnesium-potassium-phytate in diet induces an increase in endogenous losses in ducks and chickens.

Key Words: Chicken, Duck, Endogenous Loss

294 The effect of phytase on performance of broilers fed high and low phytate phosphorus diets. M. Manangi* and C. Coon, *Department of Poultry Science, University of Arkansas, Fayetteville.*

A 42-d broiler experiment was conducted to determine the effect of added microbial phytase (Phyzyme#8482XP 5000G) to low and high phytate phosphorus (P) diets on broiler performance, ileal P retention and % tibia ash. The experiment consisted of 12 treatments with 2 levels of phytate P; 1) low phytate (LP) group-0.24% and 2) high-phytate (HP) group-0.32%. Both LP and HP groups had respective positive controls (PCs) and 5 basal diets with graded levels (0, 250, 500, 750 and 1000 FTUs/kg diet) of added phytase. A total of 1536 one day old male Cobb 500 broiler chicks were allotted to 48 pens with 32 chicks per pen and 4 pens per diet. A significant ($P < 0.001$) phytase effect was found for body weight gain, feed intake, feed: gain ratio, ileal P retention and tibia ash % for both LP and HP groups on day 42. Supplementation of 250 FTUs phytase/kg diet for both LP and HP basal diets produced equivalent body weights ($P > 0.05$) to comparable respective PCs. Supplementing 500 FTUs phytase/kg diet in both LP and HP groups resulted in a comparable ($P > 0.05$) % tibia ash to respective LP and HP positive control groups. The LP basal diet supplemented with 250, 500, 750 and 1000 FTUs phytase/kg diet was fed to broilers from 1-42d. The phytase produced increased body weights of 365, 403, 440 and 240 grams, increased ileal P retention by 9.83, 9.12, 8.17 and 15.76% and increased tibia ash % by 4.29, 6.4, 8.42, and 7.93, respectively. The same phytase supplementation in the HP basal diets increased body weights by 478, 568, 570 and 395 grams, ileal P retention increased by 7.21, 9.93, 10.91 and 20.62% and tibia ash % increased by 4.46, 10.67, 10.12, and 10.79, respectively. Based on body weight gain and % tibia ash, feeding 500 units of phytase/kg diet from 1-42d replaced 0.14% of non-phytate P in both LP and HP diets. An additional increase in body weight, ileal P retention and tibia ash % in the HP supplemented groups compared to LP groups due to increase in phytase levels/kg diet could be attributed to more substrate (phytate P) concentration.

Key Words: Phytase, Phytate P, Ileal P

295 Effects of various phytase concentrations in diets with low-phytate corn on broiler chick performance and metabolizable energy. N. J. Baker*, A. S. Parsons, N. P. Buchanan, and J. S. Moritz, *West Virginia University.*

Research indicates a reduction of phosphorus content in fecal excreta with the supplementation of phytase to corn-soybean based diets or with the use of low phytate corn (LPC) in broilers. This study examined how 0 to 3 wk broiler chicks are impacted by concomitant phytase supplementation with LPC (0.136% phytate P by analysis) in the diet. Various levels of phytase (250, 500, 750, 1000, 2000 FYT/kg) from either 2500 or 5000 FYT/g of dry *Peniophora lycii* phytase product were used as experimental treatments. Efficacy of treatments was determined using a response curve created with monocalcium phosphate providing 0.23%, 0.28%, 0.33%, and 0.38% levels of available phosphorus. All diets that included phytase contained 0.23% available phosphorus, 0.8% calcium and LPC. Following a 6-day pre-test, 576 broiler chicks were randomly assigned to one of the 12 dietary treatments, with 8 replicates and 6 birds per cage. Measurements of live performance, tibia ash, mineral digestibility, and apparent metabolizable energy (AME) were obtained. Increasing phytase concentration led to a linear increase in live weight gain ($P = 0.0309$) and a linear decrease in feed conversion ($P = 0.0010$). At enzyme levels greater than 250 FYT/kg, digestible phosphorus, calcium, and AME increased ($P < 0.05$). The two *Peniophora lycii* products, when used to make similar experimental treatments, did not differ regarding performance, mineral digestibility and AME ($P > 0.05$). Thus,

phytase supplementation in diets containing LPC had a positive impact on broiler chick growth.

Key Words: Broiler Chick, Low Phytate Corn (LPC), Phytase

296 Performance and phosphorus excretion of chicks fed conventional or low-phytate corn-soybean meal diets without or with phytase. E. G. Xavier, G. L. Cromwell*, and M. D. Lindemann, *University of Kentucky, Lexington.*

An experiment was conducted to assess diets containing normal (N) corn and N soybean meal (SBM) or low-phytate (LP) corn and LP, low-oligosaccharide SBM, without or with phytase (Natuphos[®], BASF; 750 units/kg), on performance and excretion of total and soluble P by chicks. The two corns were near-isogenic and the two SBM were from near-isogenic soybeans. They were provided by Pioneer Hi-Bred International. The N-corn, LP-corn, N-SBM and LP-SBM contained 0.25, 0.26, 0.70, and 0.77% total P and 0.05, 0.17, 0.22, and 0.55% non-phytate P. Chicks (3-d-old, 63 g initial weight) were fed 10 diets for 14 d. Diets 1 to 5 were N-corn + N-SBM with 0.75, 0.66, 0.66, 0.57, and 0.57% total P, respectively, with Diets 3 and 5 containing phytase. Diets 6 to 10 were LP-corn + LP-SBM with 0.60, 0.51, 0.51, 0.42, and 0.42% total P, with Diets 8 and 10 containing phytase. Diets 1 and 6 contained the same amount of non-phytate P (0.47%) and similar amounts of bioavailable P (0.45 and 0.43%). Diets were fed to five replications of six chicks/pen in batteries. Daily gain was reduced as dietary P was decreased to the lowest level ($P < 0.05$), and phytase did not overcome the reduction in growth (25.6, 24.7, 24.7, 22.5, 22.7, 26.4, 25.4, 26.0, 23.7, 23.0 g/d for chicks fed Diets 1 to 10, respectively). Tibia strength and ash followed similar patterns (11.2, 9.2, 9.9, 6.3, 7.3, 12.5, 10.5, 11.1, 7.8, 8.0 kg; 41.2, 39.3, 40.7, 35.0, 36.1, 42.2, 40.2, 41.0, 37.3, 37.3%). Daily excretion of total P (112, 100, 95, 87, 80, 58, 48, 45, 40, 34 mg/d) and soluble P (2.9, 1.3, 1.6, 1.0, 1.4, 1.7, 0.8, 0.8, 0.9, 0.7 mg/d) both decreased ($P < 0.05$) as dietary P decreased and the amounts were less ($P < 0.05$) in chicks fed the LP-diets. Inclusion of phytase tended ($P < 0.10$) to decrease total P excretion, but phytase did not affect soluble P excretion ($P > 0.05$). Compared with the conventional diet at the NRC level of non-phytate P (Diet 1), feeding LP-corn and LP-SBM in combination with phytase (Diet 8) reduced total P excretion by 60% and soluble P excretion by 72% without negatively impacting performance or bone traits.

Key Words: Chicks, Phosphorus, Phytase

297 Effects of dietary organic acid and phytase supplementation on performance and calcium and phosphorus utilization in laying hens. M. Sari, A. G. Onol, M. Daskiran*, and O. Cengiz, *Adnan Menderes University Faculty of Veterinary Medicine, Adnan Menderes University, Aydin, Turkey.*

An experiment was conducted to determine the effects of dietary organic acid and phytase supplementation on performance and calcium and phosphorus utilization in laying hens. Two hundred 23-wk-old Brown Nick layers were randomly allocated into 50 cages (42x50 cm) each containing 4 birds. Corn-soybean meal based rations were used. Five dietary treatments were formed as followed: (1) a basal ration with no supplemental P (- control) (2750 kcal ME/kg, 17% CP, 0.34% total P, 3.8% Ca), (2) basal ration supplemented with dicalcium phosphate (1.4%) (+ control), (3) basal ration supplemented with 0.035% phytase (ZY Phytase II-5), (4) basal ration supplemented with 1.0% organic acid (Salstop SD) and (5) basal ration supplemented with both 0.0035% phytase and 1.0% organic acid. Water and feed were provided for ad libitum consumption and a lighting program of 16 h light : 8 h dark was applied throughout the study. Each dietary treatment had 5 replications and each replication comprised two adjacent cages. Basal diet with no supplemental P resulted in body weights that were lower ($P < 0.05$) than those of hens fed diets supplemented with phytase, organic acid, or both. Hens fed diets supplemented with dicalcium phosphate, phytase, and organic acid and phytase had higher egg production ($P < 0.001$) (91.3, 86.1, and 93.7% respectively) compared to hens fed either basal diet (78.5%) or basal diet with organic acid supplementation (78.6%). Additionally, the unsupplemented or organic acid supplemented corn-soybean meal diet had lower feed consumption and higher feed conversion ratio ($P < 0.01$). Hen tibia ash and serum calcium levels were not affected by the dietary treatments whereas diets supplemented with dicalcium phosphate, phytase, and phytase + organic acid had higher ($P < 0.01$) serum inorganic phosphorus. The results of this study indicate that dietary phytase improves P utilization in corn-soybean meal based

diets with no supplemental P and acidification of gastrointestinal tract may further improve this utilization.

Key Words: Organic Acid, Phytase, Laying Hen

298 Effect of a thermo-tolerant phytase on performance and bone ash in broilers fed variable levels of dietary nutrients. C. W. Wyatt*¹, M. R. Bedford¹, T. Parr², and S. Davis², ¹Zymetrics Inc., Golden Valley, MN, ²Colorado Quality Research, Wellington, CO.

Two studies investigated the effect of a thermo-tolerant E.coli-derived phytase (QuantumTM) on performance and bone parameters of broilers fed diets varying in content of available phosphorus (AP), metabolizable energy (ME) and total lysine (TLYS). A 48-day floor pen trial used 80 pens of 16 male broilers fed corn/soya/meat-bone meal based diets formulated to commercial averages (AS) or below. A four phase positive control (PC) diet was fed with .91, .82, .76, .69% calcium (CA) and .45, .39, .34, .30% AP, and two negative control (NC) diets were formulated to contain less AP(.09% or .12%), ME(26 or 45kcal/kg) and TLYS(.01 or .03%), respectively for each phase. 250, 500 or 1000 U phytase/kg diet were supplemented to each NC resulting in 10 treatments. At day 40 and 48, the initial reduction in AP, ME and TLYS did not affect performance, but further nutrient removal reduced performance compared to the PC. Supplementing all NC diets with at least 250U/kg phytase improved performance to equal or better than the PC. Lowering AP significantly reduced 48 day femur ash, but this was restored to equal or better than the PC on adding phytase. A second 50-day floor pen trial using 88 pens of 16 male broilers was conducted to determine the impact of phytase on growth, bone ash and breast yield in corn/soya/meat-bone meal based diets varying in ME. As above, a four phase PC diet was fed and three NC diets were formulated to contain less AP(.12%) and TLYS(.01%) and ME lowered by 30, 45 and 60kcal/kg, respectively. 500 or 1000 U phytase/kg of diet were supplemented to the three NC diets resulting in 8 treatments. At day 40 and 50, reducing the amount of dietary AP, ME and TLYS resulted in significantly poorer BWT and cFCR, but further reduction in ME did not result in additional losses in performance. Adding 500 U/kg and 1000U/kg phytase to the NC equilibrated performance with that of the PC for the 45 and 60kcal reduced diet respectively. In these studies. EC phytase was able to return NC performance to that of the commercial PC, although the level of phytase needed would depend on the reduction in dietary nutrient levels.

Key Words: Broiler Chick, Escherichia Coli Phytase, Performance

299 The influence of an E.coli derived phytase on performance of turkeys fed phosphorus deficient diets. M. R. Bedford* and C. L. Wyatt, Zymetrics Inc., Golden Valley, MN.

The effect of a thermo-tolerant E.coli-derived phytase (Quantum) on performance of turkeys fed phosphorus deficient diets to 84d was investigated. In experiment 1, each treatment consisted of 6 replicates of 15 BUT T8 birds. A positive (PC) and negative control (NC) corn/wheat/soya based ration containing 0.7, 0.5 then 0.5 or 0.35, 0.2 then 0.2% AvP in the starter, grower and finisher was employed. All other nutrients met or exceeded NRC requirements. 0, 100, 300, 900 or 2700 units/kg of an E.coli derived phytase (QuantumTM) was added to the NC to give 6 diets. Performance was monitored at 28, 56 and 84 d of age. At 28 d of age, intake and gain were depressed on feeding the NC but were restored to values equivalent to the PC at 900 units/kg feed.

301 Effect of heat stress on production, reproduction hormone levels, acid-base status, and liver expression of heat shock protein-70 observed in three varieties of laying hens. D. J. Franco*, L. Robeson, and M. M. Beck, University of Nebraska, Lincoln.

Thirty-two hens of each strain (Brown, W98, W36) at 38 weeks of age, were allowed to acclimatize for two weeks at 22C, and then were exposed to heat stress (HS) at 35C for two weeks with two additional weeks at 22C to recover. Production parameters (PP) and mortality rates (MR) were collected for each phase. Reproductive hormone levels (RHL) were obtained from blood collected at each phase. Acid base status (AB), Intestinal calcium uptake rate (CaT), and liver expression of HSP70 data

At 56d of age, intake, gain and FCR deteriorated on feeding the NC, and only on feeding 2700 U/kg was performance restored to PC levels. At 84 days of age, performance on the NC was poorer than the PC and was not restored even on the 2700U/kg treatment. In experiment 2, 11 male Nicholas turkeys were assigned to 6 replicate pens per treatment. There were 5 treatments, a PC, (meeting all NRC requirements) and a NC which contained 0.14% less AvP in each of the 4 phases fed supplemented with 0, 200, 500 or 1250 units of an E.coli derived phytase (Quantum). At 21d the NC performed significantly worse than the PC in terms of FCR only, and this was restored on use of 500 units of phytase or more. By 84 days gain was marginally depressed on feeding the NC and restored on use of even the lowest level of phytase. FCR was unaffected by treatment. Intake tended to drop on feeding the NC and was restored on feeding phytase. These data suggest that the use of moderate levels of phytase can easily compensate for moderate dietary reductions in AvP, but if severe reductions are made, then the subsequent losses in performance are not readily apparent until late on in the growth phase. As a result, short term tests on the bioequivalency of phytase for replacement of inorganic P are likely flawed in their conclusions when applied to full production periods.

Key Words: Phytase, Turkeys, Performance

300 Efficacy of Phyzyme[®] XP phytase in broiler diets containing different levels of calcium and non-phytate phosphorus: performance, bone ash and mineral retention. D. R. Ledoux*¹, J. N. Broomhead¹, and J. S. Sands², ¹University of Missouri, Columbia, ²Danisco Animal Nutrition, Marlborough, Wiltshire, UK.

A six-week floor pen study was conducted to determine the efficacy of Phyzyme[®] XP, in corn-soybean meal-based diets containing different Ca & P levels, on performance, tibia ash, and P retention in broiler chickens. A 3 X 4 factorial arrangement of dietary treatments from hatch to week 3 included 3 Ca & non-phytate P (npP) levels (0.80 & 0.25%, 0.85 & 0.30%, and 0.90 & 0.35%) and 4 levels of Phyzyme[®] XP (0, 250, 500, and 750 U/kg diet). From week 3 to 6, dietary phytase levels were kept the same but Ca & npP levels were reduced (0.70 & 0.15%, 0.75 & 0.20%, and 0.80 & 0.25%). The starter basal diet contained 21.74% CP and 2920 kcal ME/kg, and the grower basal diet contained 19.5% CP and 3010 kcal ME/kg. Six pens of 25 chicks each were assigned to each dietary treatment from day 1 to 42. Significant (P < 0.05) Ca & npP level by phytase interactions were observed for feed intake (FI) at weeks 3 and 6, and for body weight gain (BWG) at week 6. Feed intake, BWG, and FCR were also affected (P < 0.05) by phytase treatment at both weeks 3 and 6, with chicks fed phytase outperforming chicks fed no phytase. Chick performance was not affected (P > 0.05) by Ca & npP at 3 weeks, but were affected (P < 0.05) at 6 weeks, with the best performance observed in chicks fed the 0.90% Ca & 0.35% npP combination. Significant interactive and main effects were observed for tibia ash (%) at 6 weeks, with the response to phytase differing among the Ca & npP levels. Both 3 and 6 week P retention were improved (P < 0.05) by phytase supplementation. Combination of Ca & npP did not affect P retention (P > 0.05) at week 3, but did affect P retention (P < 0.05) at week 6. No Ca & npP by phytase interaction for P retention occurred at either weeks 3 or 6. Results indicate that Phyzyme[®] XP was effective in improving phytate P utilization, and efficacy was influenced by Ca & npP level.

Poultry Reproductive Physiology

were obtained from samples collected before and during HS exposure. The data for PP and RHL were analyzed using the SAS program 1999 version 8.0 as repeated measure in a 3x3 factorial experiment with a level of significance of 0.05. The data for liver expression of HSP70, AB, and CaT were analyzed in a 3x2 factorial experiment with a level of significance of 0.1. Differences among means were obtained based on LSD test. Brown birds performed least well during subsequent HS, with a higher reduction in egg production and a lower CaT. Most of the PP were reduced in all the birds during HS; however, the highest reduction in egg weight was observed in the W36 hens. AB was characterized by an increase in blood pH and a reduction in PCO₂ during HS. PO₂ showed a small positive increment during HS only for the W36 and HCO₃ levels

were reduced during HS except in W98. HSP70 expression was higher after HS exposure and estrogen was reduced during HS in all strains. Progesterone levels were not affected and LH levels were lower in the W98 birds. In general, the Brown hens fared worst in all parameters measured during HS, while W98 hens performed best; W36 was almost always intermediate. However, Brown birds had higher MR (16%), W36 the lowest (4%) with the W98 (8%) intermediate. Some physiological parameters responded differentially by strain, suggesting that further investigation in gene expression might yield markers that could be incorporated into breeding programs for increasing HS resistance in laying hens.

Key Words: Laying Hens, Heat Stress, Production Parameters

302 Melengestrol acetate (MGA) as an alternative method to induce molting in hens. J. M. Koch^{*1}, J. S. Moritz¹, D. C. Lay Jr.², and M. E. Wilson¹, ¹WVU, WV, ²USDA-LBRU, IN.

Inducing hens to molt increases egg quality, egg production and extends the productive life of hens. Molting is normally accomplished by feed withdrawal, which has received criticism, and alternatives described thus far have resulted in poor post-molt performance. The process of molting leads to cessation of lay, regression of large yellow follicles (LYF) and results in loss of steroidogenic support for the oviduct. MGA, an orally active progestin, may decrease gonadotropic support for the ovary and cessation of lay. Hyline W-36 laying hens (n=104) at 40 wk-of-age were fed either 0 or 8 mg/d MGA for 28 d in a balanced diet and then returned to a normal diet. Four birds on d 0 and 4 birds/treatment on d 1, 2, 4, 8, 12, 16, 20, 24, 28, 32, 36, 40 and 44 were euthanized. The weight (g) of ovary with LYF, magnum, isthmus, shell gland and the length (cm) and weight of the intact oviduct were determined. By d 19, egg production in the MGA treated hens (M) had decreased to 24% where it remained until d 28 compared to 88% in the controls (C). The weight of the ovary with LYF, the oviduct and the magnum decreased ($p < .05$) by day 8 in M compared to C (33 ± 15 vs 62 ± 7 , 39 ± 10 vs 71 ± 1 and 19 ± 6 vs 41 ± 2). Furthermore, oviduct length, isthmus and shell gland weight decreased ($p < .05$) by d 20 in M compared to C (54 ± 7 vs 78 ± 3 , 1.2 ± 0.5 vs 3.3 ± 0.3 and 11 ± 3 vs 23 ± 2). From d 28 to 40, egg production in M increased until similar to C at 83%. Oviduct length, isthmus weight and LYF recrudescence in 3 out of 4 M was similar ($p > .05$) to C by d 32 (59 ± 10 vs 70 ± 3 , 2.0 ± 0.5 vs 2.8 ± 0.4 , 36 ± 12 vs 54 ± 5). By d 36 the shell gland weight in M was similar ($p > .10$) to C and 4 out of 4 hens had recrudescence of LYF (14 ± 2 vs 21 ± 1 , 47 ± 8 vs 40 ± 10); however, it was not until d 40 that the weight of the oviduct and magnum in M was similar ($p > .05$) to C (61 ± 8 vs 64 ± 1 , 33 ± 5 vs 37 ± 1). MGA, when fed to hens in a balanced layer diet, can cause regression of LYF on the ovary, leading to loss of steroidogenic support for the oviduct. Removal of MGA led to recrudescence of LYF, leading to steroidogenic support for the oviduct and return to lay.

Key Words: Hen, Molting, Melengestrol Acetate

303 Incidence of bone breakage of processed White Leghorn hens monitored for skeletal integrity during the second cycle of egg laying. H. Mazzuco^{*1,2} and P. Y. Hester¹, ¹Purdue University, West Lafayette, IN, ²CNPQ, Brasilia-DF, Brazil, ³EMBRAPA Concordia-SC, Brazil.

Hens housed in cages experienced a 29% broken bone incidence after transport and immediately before the water bath stunner (Gregory and Wilkins, 1989, Br. Poult. Sci. 30:555). The current study was carried out to determine the correlation between bone mineral density (BMD) and bone mineral content (BMC) measured in live birds (85 to 125 wk of age) and excised tibia (at 126 wk of age only) with the incidence of broken bones in carcasses of processed 126-wk-old White Leghorn hens. Twenty-seven hens out of a total of 207 White Leghorns of a pedigree line were monitored for BMD and BMC of the tibia and humerus using a dual energy X-ray absorptiometer during a second cycle of egg production. At 126 wk of age, the 207 birds were processed and the bones (femur, tibia, fibula, humerus, radius, ulna, keel, scapula, coracoid, ribs, clavicle, ischium and pubis) were examined for breakage. Values for in vivo BMD and BMC were averaged over the age of the hens and averaged over both bones (humerus and tibia). Correlation coefficients for the incidence of broken bones with the average in vivo BMD during the second cycle of lay and with the excised tibial BMD at 126 wk of age were -0.39 ($P < 0.05$) and -0.54 ($P < 0.01$), respectively. Correlation value for the incidence of broken bones with excised tibia BMC at 126

wk of age was -0.53 ($P < 0.01$) and with the second cycle in vivo BMC was not significant ($r = -0.20$). The percentage of broken bones of the total bones examined per bird at the end of processing at 126 wk of age averaged 34% with a range of 0 to 61%. These results show that BMD monitored in live birds during a second egg laying cycle (85 to 125 wk of age) as well as in the excised tibia at 126 wk of age were negatively and significantly correlated with the incidence of bone breakage in processed carcasses. It is concluded that as BMD decreased in White Leghorns, the incidence of breakage increased.

Key Words: Spent Hens, Bone Mineral Density, Bone Breakage

304 Impact of supplemental L-carnitine in broiler breeder diets on subsequent egg hatchability and progeny embryogenesis. J. P. Tanksley^{*1}, E. D. Peebles¹, M. T. Kidd¹, C. D. McDaniel¹, S. K. Whitmarsh¹, H. M. Parker¹, and P. D. Gerard², ¹Department of Poultry Science, Mississippi State University, Mississippi State, ²Experimental Statistics Unit, Mississippi State University, Mississippi State.

The impact of supplemental L-carnitine in broiler breeder diets on subsequent egg hatchability and progeny embryogenesis were investigated in this study. Beginning at 21 weeks of age, hens were fed diets supplemented with either 0 (control) or 25 ppm L-carnitine (treated) through 40 weeks of age. In each of 16 breeder floor pens, 20 hens were housed, with 8 replicate pens assigned to each of two treatment groups. At 27, 32, and 38 weeks of age 15 eggs from each replicate pen were set at random according to treatment in a single incubator for determination of set egg weight (SEW) and relative embryo (REMW; % of set EW), yolk sac (RYSW; % of set EW), and liver (RLW; % of embryo weight) weights at 18 days of incubation. Similarly, at 25, 30, 32, and 38 weeks of age, approximately 70 eggs from each replicate pen were set in a separate single incubator for determination of hatchability and embryonic mortality. Breeder hen age significantly affected percent hatchability of fertile eggs set, percent early dead mortality, REMW, and RLW, but did not influence percent late or piped embryo mortalities, and RYSW. Dietary treatment did not significantly affect any of the aforementioned parameters except SEW. At Week 27, supplemental carnitine reduced SEW by 3.1 %. In this study, 25 ppm supplemental dietary L-carnitine decreased SEW at 27 wk, but did not impact subsequent egg hatchability and progeny embryogenesis between 25 and 38 weeks of breeder hen age.

Key Words: Broiler breeder, Carnitine, Embryogenesis

305 Chicken sperm motility and metabolism are altered immediately by semen dilution. H. M. Parker^{*} and C. D. McDaniel, Mississippi State University, Mississippi State.

The Sperm Quality Index (SQI) is most predictive of rooster semen quality and fertility when semen is diluted no more than 10-fold prior to analysis. The present study was conducted to determine why the SQI was not as predictive of fertility at higher semen dilutions by examining the effects of semen dilution on sperm motility and metabolism. Semen from 15 roosters was collected, pooled and then diluted with 0.85% saline to achieve sperm concentrations from 30 to 1300 million sperm/mL. For each vial of diluted semen, oxygen and ATP content as well as the SQI and sperm viability were measured within one minute of dilution. To examine motility of individual sperm cells the SQI was expressed as SQI/million sperm. Viability was not affected by semen dilution. As expected, the SQI declined logarithmically with increasing semen dilution or decreasing number of live sperm. However, as semen dilution increased, motility of individual sperm cells was accelerated. Also, no free oxygen was present in the neat semen sample, but the partial pressure of oxygen for the fresh diluent was 218 mmHg. Therefore, as semen was diluted, the oxygen present/sperm increased exponentially resulting in a greater rate of sperm motility ($r^2 = 0.93$). Additionally, as semen was diluted, the sperm utilized more oxygen resulting in a positive correlation ($r = 0.93$) of the SQI/sperm with oxygen utilization. Furthermore, at lower dilutions, ATP present/sperm declined with dilution. This decline was most likely due to the sperms dependence on anaerobic metabolism, because of the lack of oxygen, and the slow increase in sperm motility. However, at higher dilutions ATP/sperm increased rapidly with dilution most likely due to greater available oxygen and aerobic metabolism. Apparently, diluting semen samples alters oxygen utilization, ATP metabolism, and therefore sperm motility. These

changes in sperm metabolism and motility are most likely the reason the SQI is not very predictive of fertility at dilutions greater than 10-fold.

Key Words: Sperm Quality Index, Semen Dilution, Sperm Metabolism

306 Expression of the mRNA for zona pellucida proteins 1 and 3 in two genetic lines of turkey hens that differ in fertility. A. P. Benson^{*1}, A. J. Davis¹, B. D. Fairchild¹, and V. L. Christensen², ¹University of Georgia, Athens, ²North Carolina State University, Raleigh.

The inner perivitelline layer of avian species contains zona pellucida protein-1 (ZP1) and zona pellucida protein-3 (ZP3) and these two proteins may be involved in sperm binding. ZP1 is produced by the liver and transported to the developing follicle, while ZP3 is synthesized and secreted by granulosa cells of the preovulatory follicle. The expression of mRNA for ZP1 and ZP3 was investigated in two lines of turkey hens selected for over 40 generations for either increased egg production (E) or increased body weight (F). Total RNA was extracted from the liver and from 1 cm² sections of the granulosa layer around the germinal disc (GD) or a nongerminal disc (NGD) area of the F₁ and F₂ follicles of six, 48 week-old hens from each genetic line. In order to obtain enough RNA for subsequent Northern analysis, the granulosa samples had to be pooled for two birds for each follicle size (n = 3). Northern analysis for ZP1 and ZP3 was performed using chicken cDNA probes. Equality of RNA loading and transfer was verified with a cDNA probe of chicken GAPDH for ZP1 and with a cDNA probe of mouse 18S ribosomal RNA for ZP3. Hepatic expression of the mRNA for ZP1 tended (P = 0.07) to be greater in turkey hens from the E-line than the F-line. The expression of the mRNA for ZP3 was equal between the two genetic lines of turkeys and within each line between the GD and NGD regions of the F₁ and F₂ follicles. The results suggest that the higher rates of fertility previously observed for eggs from the E-line versus the F-line of turkeys may be related to the higher expression of the potential sperm binding protein ZP1.

Key Words: Zona Pellucida Proteins, Turkeys, mRNA Expression

307 Follicular development and expression of the mRNA for the inhibin/activin subunits in two genetic lines of turkey hens that differ in total egg production. J. B. Hoffman^{*1}, A. P. Benson¹, A. J. Davis¹, B. D. Fairchild¹, and V. L. Christensen², ¹University Of Georgia, Athens, ²North Carolina State University, Raleigh.

Inhibin and activin appear to play key roles in follicular maturation in avian species. The expression of mRNA for the inhibin/activin subunits and the activin binding protein follistatin was investigated in the developing follicles of two lines of turkey hens selected for over 40 generations for either increased egg production (E) or increased body weight (F). Individual bird weights and follicle weights were obtained from six birds of each genetic line at 46 and 58 weeks of age. Total RNA was extracted from individual granulosa layers of the F₁ through F₄ follicles and from the combined theca and granulosa layers of the small yellow follicles (SYF, 5-10 mm) and large white follicles (LWF, 2-5 mm). Chicken cDNA clones were used in the Northern analysis of the inhibin α -subunit, inhibin/activin β_A - and β_B -subunits and follistatin. Average body weight was 3 times greater for the F-line birds, however, total follicular weight relative to body size was significantly less for these hens compared to the E-line hens. Although total follicular weight was less in the F-line hens, the preovulatory hierarchy for these birds contained 5-7 more follicles than the hierarchy for the E-line hens. Furthermore, the total relative mass of both the SYF and LWF was the same for both genetic lines of turkeys, however, the number of these follicles was significantly greater for the F-line hens. Thus, the decrease in total relative follicular mass in the F-line hens results from significantly smaller relative to body weight F₁ through F₄ follicles when compared to the E-line. The inhibin/activin β_B -subunit and follistatin were expressed very strongly in the large white follicles. Expression of the β_A -subunit was limited to the hierarchical follicles. The inhibin α -subunit was expressed in all follicles examined. The lack of a well defined preovulatory follicular size hierarchy in the F-line hens contributes to the decreased production and fertility observed in these birds compared to the E-line hens.

308 Progesterone injections induce a polycystic ovarian follicle syndrome (PCOF) in young turkey hens. W. L. Bacon^{*} and H.-K. Liu, *The Ohio State University, Wooster.*

An arrest in laying associated with a PCOF syndrome has been reported in turkey hens photostimulated with constant light. The ovaries of PCOF hens contained a normal number of hierarchical follicles (7 to 10), and 5 or more larger follicles, some of which were cystic. Comparing PCOF hens to laying hens, the oviduct was of equal weight, plasma concentrations of estradiol-17 β (E₂) were equal, luteinizing hormone (LH) slightly lower, and progesterone (P₄) several fold higher. We hypothesized that constant lighting overstimulated the ovary, inducing a high level of P₄ secretion which blocked ovulations but not entrance of follicles into the hierarchy, resulting in the PCOF syndrome. Experiments to examine effects of P₄ injections (0.17 to 1.50 mg kg⁻¹d⁻¹ for 7 to 14 d), duration of egg production (6 to 38 wk), and photoperiod (14L:10D or constant light) on egg production, ovarian follicles, and oviduct weight were conducted. In 6 experiments, hens were necropsied immediately after the last P₄ injection. Egg production was decreased by about 50% with injection of 0.17 mg kg⁻¹d⁻¹, and ceased with injection of 0.33 mg kg⁻¹d⁻¹ or greater. In hens of < 15 week of production ovarian follicle number was slightly increased, oviduct weight was unaffected, and atretic follicle number increased. At 38 wk of production, ovarian follicle number and oviduct weight decreased, and atretic follicle number increased. No hens presented with the PCOF syndrome. Two additional experiments were conducted with young hens, with the hens necropsied 3 wk after last P₄ injections. In these experiments most of the hens given constant lighting and P₄ (0.33 mg kg⁻¹d⁻¹) presented with the PCOF syndrome at necropsy. The PCOF presenting hens had several fold higher P₄ levels at necropsy, slightly lower levels of LH, and normal levels of E₂ in comparison to laying hens. We concluded that P₄ injection for 12 d of hens that had been photostimulated with constant light and were early in the reproductive period could initiate the development of the PCOF syndrome at necropsy 3 wk later.

309 Programming of photorefractoriness: The turkey breeder hen is not like a tree sparrow. J. A. Proudman^{*1} and T. D. Siopes², ¹USDA, ARS, Biotechnology & Germplasm Laboratory, Beltsville, MD, ²Department of Poultry Science, North Carolina State University, Raleigh.

Photostimulation (PS) with a long photoperiod is thought to both initiate egg laying and to program the onset of the photorefractory (PR) response by the presence of thyroid hormone, probably thyroxine (T₄), in the brain during the early weeks following PS. We have conducted three experiments to estimate when programming of the PR response by long days occurs in turkey hens. In Experiment 1, we tested the hypothesis that hormone levels (T₄, T₃, or prolactin) during the first week of lighting may program PR. We retrospectively compared hormone levels at 7, 0, 1, 3, and 7 days from PS of hens that did or did not become PR during 50 wk of lay. Results showed no differences in any hormone considered likely to be involved in programming PR. In Experiments 2 and 3, we attempted to estimate when programming for PR occurs by subjecting hens to long days for differing lengths of time and then returning them to a photoperiod (12L:12D) that is known to support egg production but not induce PR. Each experiment included a long-day control and a control group that would remain photosensitive (constant 12L:12D). All hens were tested for PR by an increase in photoperiod at the end of a lay cycle. Hens that had been programmed for PR should not respond to the increased photoperiod. In Experiment 2, treated hens received 1, 14, or 28 d of 16L:8D followed by 12L:12D until 20 wk of PS. Programming for PR was then assessed by providing 20L:4D for 8 wk. All treatment groups (but not the long day control group) responded to the light change, indicating that programming for PR does not occur within the first 4 wk following PS. In Experiment 3, treated hens received 1, 5, or 9 wk of 18L:6D followed by 12L:12D to 18 wk of PS. We then tested for photosensitivity by restricting light to 8L:16D for 2 wk and then stimulating with 22L:2D for 6 wk. Only 6 of 18 control (18L:6D) hens remained photosensitive at the end of this experiment, while all hens in the 12L:12D control group and all treated hens remained photosensitive. We conclude from these experiments that programming for PR in the commercial turkey hen does not occur within the first 9 wk following photostimulation.

Key Words: Photorefractoriness, Turkey, Photoperiod

310 Photoperiod effects on spontaneous ovarian adenocarcinoma in the domestic turkey breeder hen. C. B. Moore and T. D. Siopes*, *Department of Poultry Science, College of Agriculture & Life Sciences, North Carolina State University, Raleigh.*

The effect of photoperiod or melatonin treatments on ovarian adenocarcinoma in turkey breeder hens was investigated. In Experiment 1, photoperiod effects were tested by exposing turkeys with ovarian tumors to 8 wks of short days (8:16LD) followed by a 12 wk period of long days (16:8LD). In Experiment 2, exogenous melatonin was administered to turkeys during long day-induced development of ovarian tumors. In both experiments, the stage of tumor growth was scored weekly on a subjective scale of 0 to 4. It was clear that exposure to short days produced complete regression of tumors, with a mean time to score 0 of 4.4 wks. Following re-exposure to a long photoperiod, all of the same birds showed re-growth of the ovarian tumor with a mean time to first palpable detection of 5.4 wks. When melatonin was administered daily during the long photoperiod (Experiment 2), there was a significant delay in the re-growth of tumors. It was concluded that the growth of solid ovarian tumors in the turkey breeder hen was promoted by long photoperiods and ceased, to the point of remission, on short photoperiods. Thus, ovarian adenocarcinoma in turkeys can be completely manipulated by photoperiod. In addition, treatment with melatonin attenuates tumor growth in the turkey hen. The results suggest that the domestic turkey hen may be a useful *in vivo* model for studying spontaneous ovarian adenocarcinoma.

Key Words: Cancer, Photoperiod, Ovary

311 The distribution and change in the number of gonadotropin-releasing hormone neurons in chicks following an increase in photoperiod plus administration of sulfamethazine. W. J. Kuenzel* and C. D. Golden, *University of Arkansas, Fayetteville.*

Gonadotropin-releasing hormone-1 (GnRH-1) neurons are well known to be critical for the regulation of gonadal development due to their stimulation of luteinizing hormone and follicle stimulating hormone release from the adenohypophysis. One consistent finding for GnRH-1 neurons is that their cell number remains relatively stable over the life cycle of a particular avian species. In addition, many studies have suggested that the principle location of GnRH neurons occurs in the medial preoptic hypothalamic region. A study was designed to determine whether significant increases in GnRH-1 neurons could be induced after treatment with a compound, sulfamethazine (SMZ), known to stimulate early sexual maturation. A two-by-two factorial [two diets (SMZ and control) and two photoperiods (shortday, LD8:16 and longday, LD16:8)] experiment was designed to determine whether photoperiod and/or SMZ could alter the number of GnRH neurons in male chicks. A set of sections extending from the septopallio-mesencephalic tract (TSM) to the end of the septal region was completed for each bird (n=5/treatment). Results showed that regarding the distribution of GnRH neurons, a low percentage were actually found to occupy the preoptic, hypothalamic region. In

contrast, the vast majority of the neurons (75%) occurred in the subpallial brain region while the remainder was partitioned among three subgroups found in the diencephalon. No significant changes were noted in total GnRH-1 neurons among the four treatment groups, however, in one of the largest sub-groupings of GnRH neurons, the bed nucleus of the pallial commissure (NCPa), a significantly larger number of neurons were found in long-day SMZ fed birds compared to chicks raised in a short photoperiod (LD8:16) and fed a standard ration. Results suggest the importance of the NCPa, located in the subpallial region, as containing GnRH neurons that appear most responsive to manipulations of photoperiod in birds. Supported in part by NSF Grant # IBN-0315793 to W.J.K.

312 Changes in eggshell of Japanese quail during embryogenesis. S. Westmoreland*¹, P. Hester², and T. Halupnik¹, ¹*The University of Texas at Arlington, Arlington,* ²*Department of Animal Science, Purdue University, West Lafayette, IN.*

The avian eggshell is a source of calcium for the developing embryo. Movement of calcium from the shell to the embryo occurs once the chorioallantois is in place and functional. At the blunt end of the egg the chorioallantois has no contact with the shell due to the airspace and no calcium loss occurs. The purpose of the current study was to investigate changes that occur in shells of fertile Japanese quail eggs during incubation in order to have a baseline study for comparison to eggs that were incubated at the MIR space station. It was hypothesized that when eggs reached the stage at which the chorioallantois was in place, shell samples from the equator region (largest shell diameter) would show signs of calcium loss and reduced shell thickness, while samples from the airspace would not. Fertile Japanese quail eggs were collected from a breeding colony at Purdue University. Incubation of the eggs was interrupted at six different intervals: 3, 7, 10, 12, 14, and 16 days. Eggshells were shipped to The Center for Electron Microscopy at The University of Texas at Arlington for analysis. Shells of three eggs for each incubation date were sampled in two regions, the airspace and equator. From each region five radial samples and one inner shell surface sample were prepared for viewing on the scanning electron microscope. Digital micrographs were taken to document shell changes. Measurements were collected of shell thickness for each radial sample. No changes were observed in shell samples from either airspace or equator in eggs incubated 12 days or less. In eggs incubated 14 or 16 days voids were seen in the mammillary cones of equator samples; no voids were found in airspace samples. For any given day of incubation, the equator region shell samples were consistently and significantly thicker than airspace samples. In eggs that had been incubated 14 and 16 days, the equator samples approached the thickness of the airspace samples. This trend is interpreted to indicate that shells are normally thicker at the equator than the airspace region, but the relative shell thickness changes at day 14 of incubation when the equator region becomes thinner due to calcium loss.

313 Bacterial load of the crop of turkeys offered a feed supplement during preslaughter feed withdrawal. B. M. Rathgeber*¹, M. E. MacKenzie¹, and J. L. Maclsaac², ¹*Nova Scotia Agricultural College, Nova Scotia, Canada,* ²*Atlantic Poultry Research Institute.*

Normally, feed is withdrawn from broiler turkeys several hours prior to the initiation of catching and shipping, allowing contents of the gut to pass through. This reduces the chance of bacterial contamination due to gut breakage during the evisceration process. During the starvation period there is an increased incidence of litter consumption increasing the bacterial load of the upper digestive tract. The objective of this study was to evaluate the use of a highly digestible supplement during preslaughter feed withdrawal as a means to reduce litter consumption and the bacterial load in the crop of turkeys. For each of two trials 480 female turkeys were grown in 8 pens (60/pen) at a density of 0.18m² / bird. At 9 weeks of age 80 birds from half of the pens were shipped for processing (20 birds/pen). At 10 weeks of age 40 birds from the other four pens were shipped (10 birds/pen). Commercial feed was withdrawn

6 h prior to catching from each pen. A highly digestible nutritive supplement was offered in half of the pens for 5 h in duration. Water only was provided for the last hour before shipping. All birds were slaughtered 9 h after conventional feed was withdrawn. At 9 weeks, after feather removal the crops of 5 birds/pen were removed, placed in sterile bags and placed on ice. At 10 weeks 3 crops per pen were sampled. The number of aerobic bacteria as well as E. Coli, coliformes and salmonella were determined for each crop sampled. There was no difference between the numbers of bacteria in these groups for crops at 9 weeks old compared to 10 weeks. Salmonella was not found in any of the crops in these trials. The total number of aerobic bacteria in the crop was not influenced by the use of the nutritive supplement. Both E. coli and total coliformes were reduced in crops from birds offered the nutritive supplement prior to slaughter (p<0.01). This reduction was more than one log for each of these two categories. The results of this project indicate that populations of bacteria in crop of commercial turkeys can be re-

duced through administration of a highly digestible supplement during the normal preslaughter feed withdrawal period.

314 Effect of a commercial inside-outside bird washer (IOBW) on *Campylobacter*, *Salmonella*, *E. coli*, and aerobic plate counts (APC) of uncontaminated, contaminated, and cross-contaminated broiler carcasses. D. P. Smith*, J. K. Northcutt, and M. T. Musgrove, *USDA, ARS, Russell Research Center, Athens, GA.*

Processors are washing carcasses with one or more in-line inside-outside bird washers (IOBW) due to zero fecal tolerance regulations. This study was conducted to determine the effect of an IOBW on *Campylobacter*, *Salmonella*, *E. coli*, and aerobic plate counts (APC) of uncontaminated (control), contaminated, and cross-contaminated broiler carcasses at two different IOBW water pressure settings. Three trials of 12 commercially processed carcasses each (two replications of six birds) were conducted as follows: two control carcasses, two carcasses contaminated with cecal contents (inoculated with *Campylobacter* and *Salmonella*) and allowed to dry on carcass skin for 12 min, and two carcasses uncontaminated and placed adjacent to contaminated birds during washing (to determine cross contamination) were prepared (n=36). Whole carcass rinses were conducted on each carcass prior to contamination or washing, then repeated after washing. Carcasses were washed with an in-line commercial IOBW set at 160 bpm (5 s) and either 40 or 80 PSI water pressure. There were no significant effects (P<0.05) from contamination with feces or from cross contamination, nor from IOBW pressure on any microbiological counts. The overall effect of washing was a slight (but not biologically) significant reduction in *E. coli* (3.2 to 3.0) and APC (4.9 to 4.8) log₁₀cfu/ml rinsate. The IOBW decreased the incidence of *Campylobacter* from 14/36 positive carcasses to 1/36 positives, but *Salmonella* incidence for contaminated carcasses increased from 0/12 to 3/12 after washing. The IOBW removed carcass contamination to levels equivalent with control levels without cross contaminating other carcasses. The incidence of *Campylobacter* was decreased, though *Salmonella* was not reduced.

Key Words: Inside-Outside Bird Washer, Fecal Contamination, Broiler Carcass

315 Effects of spray washing with various chlorine levels and water temperatures on skin color and microbiology of broiler carcasses. J. K. Northcutt*, D. P. Smith, M. T. Musgrove, K. D. Ingram, and A. Hinton, Jr., *USDA, Agricultural Research Service, Russell Research Center, Athens, GA.*

A study was conducted to investigate the effects of chlorinated (sodium hypochlorite) spray washing using various water temperatures on breast skin color and microbiology of broiler carcasses. The experiment was a 2 x 3 randomized block design using 0 or 50 ppm added chlorine in tap water at a temperature of 21, 43 or 54°C. Breast skin color was measured and carcasses were subjected to a whole carcass rinse (WCR) before washing (Pre-treatment). Broiler cecal contents (4.95 g) were inoculated with a co-suspension (0.1 mL) containing 10⁷ cells of *Campylobacter* and nalidixic acid resistant *Salmonella*, and 0.1 g were applied to each carcass. Inoculated carcasses were held at room temperature for 12 min before washing in a cabinet washer (80 psi for 5 sec). Immediately after washing, carcasses were subjected to a WCR, and breast skin color was measured again (Post-treatment). Tap water pH ranged from 7.2 to 7.6, and contained an average of 0.5 ppm free chlorine. After the addition of 50 ppm chlorine, water pH increased to 8.2 to 8.4. Washing temperature and additional chlorine had no effect on the breast skin color, with average values of L* = 66.6; a* = -0.09; b* = -0.05. Moreover, washing temperature and additional chlorine had no effect on total aerobic bacteria, *E. coli*, and *Campylobacter* levels on carcasses. Pre- and Post-treatment counts were found to be 4.6, 3.6, and 3.5 log₁₀ cfu/mL rinse for total aerobic bacteria, *E. coli*, and *Campylobacter*, respectively. No nalidixic acid resistant *Salmonella* were found on Pre-treatment carcasses, and average Post-treatment levels were 3.1 log₁₀ cfu/mL rinse irrespective of treatment. Under the conditions outlined in the present study, chlorine level and water temperature had no effect on skin color or broiler carcass microbiology.

Key Words: Inside-Outside Bird Washer, Chlorine, Carcass Contamination

316 Enrichment pH impact on salmonellae recovery from TSP-treated broiler carcasses. D. V. Bourassa*^{1,2}, R. J. Buhr², D. L. Fletcher¹, M. E. Berrang², and J. A. Cason², ¹*University of Georgia, Athens,* ²*USDA-ARS Russell Research Center, Athens, GA.*

Trisodium phosphate (TSP) has been reported to reduce the recovery of salmonellae from processed poultry carcasses. It has been suggested that the high pH of TSP solutions as well as the detergent-like properties are responsible for the reduction in salmonellae recovery. This project was conducted to determine the efficacy of TSP and modified enrichment pH on the recovery of salmonellae. Carcasses were obtained from a commercial processing plant immediately after the final inside-outside carcass washer prior to chilling. Carcasses were subjected to one of four treatment groups; 1) TSP and neutral-peptone (pH 7.0), 2) TSP and acidified-peptone (pH 5.5), 3) no TSP and alkali-peptone (pH 8.5), 4) no TSP and neutral-peptone. Carcasses were individually placed into plastic bags, 500 mL of the pH adjusted peptone was added, the carcasses shaken for 1 min, and pre-incubation pH measured. Carcasses with rinse solution were incubated at 37 C for 24 h and presence of salmonellae determined. The pH of the pre-incubation enrichment peptone was 8.4 for the TSP neutral-peptone, 7.2 for the TSP acidified-peptone, 8.7 for the no TSP alkali-peptone, and 7.1 for the no TSP neutral-peptone. Salmonellae were detected from 50% of the TSP neutral-peptone carcasses, 50% of the TSP acidified-peptone carcasses, 63% of the no TSP alkali-peptone carcasses, and 43% of the no TSP neutral-peptone carcasses.

Key Words: Trisodium Phosphate, Salmonellae, pH

317 Recovery of bacteria from broiler carcasses rinsed 0 or 24 hours after chilling. J. A. Cason*, M. E. Berrang, and D. P. Smith, *Russell Research Center, Athens, GA.*

The PR/HACCP rule for poultry processing requires that selected carcasses be tested for numbers of *E. coli* or presence of *Salmonella* in carcass rinse samples taken immediately after chilling. The results are compared against microbiological standards or criteria based on the 1996 broiler chicken baseline data, but carcasses in that study were shipped to a lab and were rinsed the following day. To test whether carcass rinses done immediately after chilling are comparable to rinses 24 h after chilling, 20 whole broiler carcasses exiting the chiller of a poultry plant were sampled on 3 days. Carcasses were bagged aseptically and rinsed for 1 min in 400 ml of sterile water. Recovered rinse liquid was poured into a sterile container, rinsed carcasses were placed in clean plastic bags, and all materials were held overnight at 4 C. On the following day all carcasses were rinsed again in 400 ml of sterile water as before, and all rinse samples were cultured by standard methods to enumerate coliforms, *E. coli*, and *Campylobacter*, and to determine incidence of *Salmonella*. Statistical analysis used paired comparisons between the same carcasses rinsed at 0 or 24 h after chilling, with numbers of bacteria expressed as log cfu/ml of rinse. Significantly higher numbers of coliforms (3.0 versus 2.7) and *E. coli* (2.7 versus 2.4) were found in the rinse samples taken immediately after chilling versus rinse samples done at 24 h. There were no differences in numbers of *Campylobacter* (mean 1.8) or incidence of *Salmonella* between rinses taken at 0 or 24 hours. More study is required to determine whether rinse sampling of carcasses done at 0 and 24 h after chilling are microbiologically equivalent.

Key Words: Carcass Rinse, Coliforms, *E. coli*

318 Comparison of plate media for direct enumeration of *Campylobacter* spp. from carcasses rinses. K. S. Macklin*, R. S. Miller, and O. A. Oyarzabal, *Auburn University, Auburn, AL.*

Six plate media, Campy-Cefex (CC), modified Campy-Cefex (mCC), Campy-FDA (CF), charcoal cefoperazone deoxycholate agar (CCDA), Campy-Line (CL), and Karmali agar (K) were compared for their effectiveness in isolating *Campylobacter* spp. from commercial broiler carcass rinses. The modifications in mCC were as follows, the replacement of cyclohexamide with amphotericin B and the use of locally available whole lysed horse blood instead of commercially obtained laked horse blood. Carcass rinses were taken post-chill from four different processing plants (A, B, C, D), with 20 carcass rinses collected per plant visit. A standard rinse technique with 400 ml of buffered peptone water and one minute shaking was used for all samples collected. For each sample and each plate type, two 0.10-ml spread plates and four 0.25-ml spread plates were made. Plates were incubated at 42C under microaerophilic

conditions for 48 h. Suspect colonies were counted, examined under phase contrast microscopy and confirmed with a multiplex PCR for differentiation of *C. jejuni*/*C. coli*. The mean log CFU/ml count for each plate medium and for each plant was analyzed using GLM ($P < 0.05$), and means analyzed for differences with Tukey's. Preliminary results from two visits to each plant indicate that the total number of positive plates for five of the media ranges between 41.3 to 48.8%; however the number was significantly lower for CL (28.1%). Mean log CFU/ml for the same five media as above were also similar (0.61 to 0.77), but again counts were significantly lower for CL (0.35). It appears that the composition of CL makes the medium too selective for isolation of low-temperature-stressed *Campylobacter*. The average percent positive for each plant was: A 95%, B 80 %, C 50% and D 0.5%. Mean log CFU/ml for each plant was: A 0.82, B 0.95, C 0.82 and D 0.01. More samples will be collected to determine if the low count and incidence of *Campylobacter* spp. in plant D remains consistent.

Key Words: *Campylobacter* spp., Media, Processing

319 Transfer of *Salmonella* and *Campylobacter* from stainless steel to a ready-to-eat food. C. M. Moore¹, B. W. Sheldon*², and L. Jaykus¹, ¹Department of Poultry Science, North Carolina State University, Raleigh, ²Department of Food Science, North Carolina State University, Raleigh.

The degree of transfer of *Campylobacter jejuni* and *Salmonella enterica* serovar. Typhimurium was evaluated from a stainless steel contact surface to a ready-to-eat food (RTE, lettuce). Stainless steel coupons (25 cm²) were inoculated with a 20 μ l drop of either *C. jejuni* or *S. Typhimurium* to provide an inoculum level of ca10⁶ CFU per 28mm². Wet and dry lettuce (*Lactuca sativa* var. *longifolia*) pieces (9 cm²) were placed onto the inoculated stainless steel surface for 10 s after the designated inoculum drying time (0 to 80 min for *C. jejuni*; 0 to 120 min for *S. Typhimurium*), which was followed by recovery and enumeration of transferred pathogens (lettuce) and residual surface pathogens (stainless steel coupons). For transfers of *S. Typhimurium* to dry lettuce, there was an increase from 36% to 66% in the percent transfer of the initial inoculum load over the first 60 min of sampling followed by a precipitous drop from 66% to 6% in percent transfer. The transfer of *S. Typhimurium* to wet lettuce ranged from 23 to 31%, with no statistically significant difference between recoveries over the entire 120 min sampling period. For *C. jejuni*, the mean percent transfer ranged between 16 to 38% for dry lettuce and 15 to 27% for wet lettuce during the 80-min sampling period. The results of this study indicate that relatively high numbers of bacteria may be transferred to RTE foods such as poultry and red meat products even 1 to 2 hours after surface contamination. These findings can be used to support future projects aimed at estimating the degree of risk associated with poor handling practices of RTE foods.

320 Effect of packaging and electron beam irradiation on poultry safety and quality during extended storage. T. M. Preder*, S. J. Lewis, A. Velasquez, and S. R. McKee, Auburn University, Auburn, AL.

Electron beam irradiation (EB) combined with packaging was investigated as a means of extending the shelf-life of skinless, boneless chicken breast fillets (n=240 packages) stored at 4 C. Fillets were subjected to EB dose of 0.8 kGy and stored under aerobic or vacuum-packaged conditions for up to 42 days at 4 C. Weekly up to day 42, 5 packages of breast fillets (4 fillets per package) were randomly selected from each treatment group and subjected to microbial and sensory analyses. At day 0, EB completely eliminated coliforms and generic *E. coli* as well as *Salmonella* and *Campylobacter*. During storage, coliforms increased in non-EB fillets, but generic *E. coli* began to decline in non-EB fillets by day 21 of storage. Psychrotrophs and total aerobic bacteria were not completely eliminated by EB, but levels were lower ($P \#8804 0.05$) in EB samples when compared to non-EB samples. As fillet storage time increased, psychrotroph and aerobic bacteria levels increased in both non-EB and EB fillets. However, increases in population counts for EB fillets were lower ($P < 0.05$) when compared to non-EB. Color determination indicated that EB fillets had higher "a" values when compared to non-EB fillets. As storage time increased, aerobically packaged non-EB fillets had higher "a" values than EB fillets. Consumer taste panels

were conducted up to 42 days for EB fillets, but non-EB fillets were only tested up to 14 days because of high microbial levels. Results suggested that EB did not affect the appearance, flavor, or overall acceptability of fillets compared to non-EB fillets. Overall, the shelf-life in the irradiated fillets was three times higher when compared to the non-irradiated fillets.

Key Words: Electron Beam Irradiation, Shelf-Life, Vacuum-Packaging

321 The relationships among measures of albumen height, pH, and whipping volume. F. G. Silversides*^{1,2} and K. L. Budgell³, ¹Pacific Agri-Food Research Centre, Agassiz, British Columbia, Canada, ²Crops and Livestock Research Centre, ³Nova Scotia Agricultural College.

Defining quality has posed difficulties for the egg industry and measures of albumen height have been used extensively because albumen height is easily measured and decreases with time in storage. The association between albumen height and functional characteristics of the albumen is less clear. A total of 2,123 eggs were obtained from Brown Leghorn, unselected since 1965, ISA-Brown, a commercial brown egg layer, and Babcock B300, a commercial white egg layer, hens at 32, 50, and 68 weeks of age and used to investigate relationships among measures of albumen quality and a functional property of albumen. The eggs were sampled fresh and after storage for five and 10 days. At sampling, eggs were weighed and broken, and albumen height, pH, and volume after whipping for 80 seconds were measured. The yolks and dried shells were weighed, and albumen weight was determined by difference. Egg weight and the weights of the albumen and yolk increased with increasing age of the hen, with yolk weights increasing proportionately more. With storage, egg and albumen weights decreased, while yolk weight increased. Eggs from Brown Leghorn hens were smallest, but had proportionately the largest yolks. Albumen height decreased with time in storage and albumen pH and whipping volume both increased. Differences between lines suggested that commercial selection has changed the proportion of the yolk, albumen, and shell, and increased the albumen height. Albumen height and whipping volume were negatively correlated ($r = -0.29$), and differences between lines (whipping volume of albumen from Brown Leghorn eggs was greater than that of the other two lines) suggest that selection for increased albumen height could have decreased the foaming ability of albumen, which is a principal reason for including eggs in many processed food products.

Key Words: Albumen Quality, Layer Strain, Egg Storage

322 National Egg Temperature Survey: 3. Transport. K. E. Anderson*¹, P. H. Patterson², K. W. Koelkebeck³, M. J. Darre⁴, J. B. Carey⁵, D. U. Ahn⁶, R. A. Ernst⁷, D. R. Kuney⁸, and D. R. Jones⁹, ¹North Carolina State University, Raleigh, ²Penn State University, University Park, ³University of Illinois, Urbana, ⁴University of Connecticut, Storrs, ⁵Texas A&M University, College Station, ⁶Iowa State University, Ames, ⁷University of California, Davis, ⁸University of California, Riverside, ⁹USDA-ARS, Athens, GA.

The Egg Safety Action Plan, raised many questions concerning egg temperature patterns used in the risk assessment model. Therefore, a national study was initiated to determine the extent of egg temperature changes from oviposition through distribution. Researchers composed of Extension Specialists and USDA-ARS, in CA, CT, GA, IA, IL, NC, TX, and PA gathered data on internal and external egg temperatures from commercial egg production, processing, and distribution facilities. The main effects were: geographic region, season, and type of operation. Transport data were recorded from lots of eggs from the processor to the point of resale or distribution. Comparisons between long and short hauls, and seasons were evaluated and geographic region was eliminated due to the movement between regions. A mixed model design was used; random effect of season, and the fixed effect for the transport duration (long or short haul). Information on the use of refrigerated transport trailers as short-term storage was evaluated. Egg temperature was not reduced during short term storage. The decrease in egg temperature was smaller ($P < 0.0001$) during short hauls 0.6 C than during long hauls 7.8 C. There was a significant season by haul interaction ($P < 0.01$) for internal egg temperatures. In the winter, egg temperatures during long and short deliveries were very similar at 10.5 and 13.4C compared to summer when egg temperatures were 11.0 and 22.7 C, respectively. Mean egg temperatures declined during transport similarly during the summer and winter and the temperature differential between

ambient and egg temperatures was only 0.4 C from the start to the end of the delivery. Refrigerated trailers used for short-term storage should be critically evaluated since egg temperatures are not appreciably reduced during this time period. These data suggest that the season of year affects the temperature of eggs during transport and are appreciably cooled on the truck, during the delivery phase. This should be a component in future assessments of egg safety.

Key Words: Egg transport, Egg temperatures, Shell eggs

323 Impact of commercial processing on the microbiological safety and quality of shell eggs. M. T. Musgrove^{1,2}, D. R. Jones¹, J. K. Northcutt¹, M. A. Harrison², and N. A. Cox¹, ¹USDA-ARS, ²University of Georgia, Athens.

Egg shell microbiology has been studied extensively over the years though little of it describes how modern U.S. processing conditions impact bacterial populations. As food safety regulations (e.g., sanitation/HACCP) are being drafted for the industry, such information can be important in determining processing steps most critical to product safety. Five different shell egg surface populations (aerobic, yeasts/molds, *Enterobacteriaceae*, *E. coli*, and *Salmonella* spp.) were monitored at 12 points along the processing line (accumulator, pre-wash rinse, washer one and two, sanitizing rinse, dryer, oiler, scales, re-wash belt entrance and exit, and two packer lanes). Three commercial in-line facilities were visited 3 times allowing for the sampling of 990 eggs that subsequently yielded 5,220 microbial samples. Variations existed in levels recovered from plant to plant but the patterns of fluctuations were similar for each population. Aerobes, yeasts/molds, *Enterobacteriaceae*, and *E. coli* populations were reduced by 30%, 40%, 75% and 50%, respectively, by the end of processing. Log₁₀ counts/ml rinse on eggs collected from packer lanes were decreased by 3.2, 0.8, 1.4, and 0.5, respectively, when compared to rinses from eggs collected at the accumulator. *Salmonella* were recovered from 0 to 48% of pooled samples in the nine replications. More *Salmonella* were recovered from pre-processed (accumulator, pre-wash, re-wash belts) than in-process (washers, sanitizing rinse, dryer, oiler) or ready to pack eggs (scales, packing lanes). These data demonstrate that current commercial practices decrease microbial contamination of egg shell surfaces.

Key Words: Shell Eggs, Processing, Bacteria

324 Identification of *Enterobacteriaceae* and related organisms from rinses of eggs collected during processing in commercial shell egg processing plants in the southeastern United States. M. T. Musgrove^{1,2}, D. R. Jones¹, J. K. Northcutt¹, N. A. Cox¹, and M. A. Harrison², ¹USDA-ARS, ²University of Georgia, Athens.

Shell egg processing guidelines have been established to ensure that external and internal egg characteristics are of suitable quality. However, less is known about shell egg safety. To determine which enteric bacteria enter egg packing plants and persist through processing, eggs were collected from 3 commercial shell egg in-line processing plants on 3 separate visits. During each plant visit, 12 eggs were collected from each of 12 sites along the processing line: accumulator, pre-rinse, 1st and 2nd washer, sanitizing rinse, blower, oiler, check detection/scales, 2 egg packer lanes, re-wash belt entrance and exit. Each egg was sampled by a rinse technique and rinsate was plated onto violet red bile glucose agar with overlay for the detection and enumeration of *Enterobacteriaceae*. From each positive plate, up to 5 colonies were randomly selected and isolated for further analysis. Using biochemical tests, isolates were identified to genus or species. Sites for which the greatest numbers of isolates were identified were those collected from eggs during pre-processing. Sites yielding the least number of isolates were those during or at the end of processing. *Escherichia coli* and *Enterobacter* spp. were isolated from all of the nine plant visits. Other genera isolated from at least one of the three plants included *Cedecea*, *Citrobacter*, *Erwinia*, *Hafnia*, *Klebsiella*, *Kluyvera*, *Leclercia*, *Morganella*, *Proteus*, *Providencia*, *Rahnella*, *Salmonella*, and *Serratia*. Non-*Enterobacteriaceae* isolated and identified included *Aeromonas*, *Chryseomonas*, *Listonella*, *Pseudomonas*, *Sphingobacterium*, *Vibrio*, and *Xanthomonas*. All genera and species were recovered less frequently from processed eggs than from unwashed or in-process eggs. These data indicate that shell egg

enteric bacteria are reduced as a result of commercial processing procedures currently being used.

325 Specific activity and stability of β -n-acetylglucosaminidase and lysozyme in extracted egg shell membranes as influenced by layer breed and storage variables. G. J. Ahlborn* and B. W. Sheldon, North Carolina State University, Raleigh.

In past studies, eggshell membrane (ESM) bound enzymes (lysozyme and β -N-acetylglucosaminidase, BNAG) or other components successfully reduced the thermal resistance of bacterial pathogens (83-87% reduction in D-values for *S. Typhimurium*, *S. Enteritidis*, and *E. coli* O157:H7). The ESMs are readily extractable and might be used as "natural" processing adjuvants for reducing bacterial heat resistance in foods or pharmaceuticals. Our objective was to investigate how layer breed, age, and processing methods affected ESM enzyme activity over time. Fifty eggs each from White Leghorn (WL) and Rhode Island Red (RIR) layers were washed, emptied, and rinsed. Membranes were carefully removed and twenty 4.7 mm dia. samples cut from each egg. Pooled samples were treated as follows: storage at 4°C, at -20°C, lyophilized, or dried at ambient temperature (ca23°C for 72 h) or at 50°C for 36 h in a convection oven. Samples were stored in airtight containers and enzymatic activity determined at 24 h post processing and after 1, 2, 4 and 6 months. Colorimetric change of 4-nitrophenyl N-acetyl- β -D-glucosaminide was used to evaluate BNAG activity and change in OD at 450 nm with *Micrococcus lysodeikticus* was used to evaluate lysozyme activity. After 24 h, BNAG activity was greatest in frozen samples. Fresh, refrigerated, and freeze-dried ESM exhibited slightly lower but similar activities. Both air and oven drying yielded significant reductions in activity (22 and 34% respectively) but remained constant thereafter. During extended storage (1 to 6 mo), the freeze-dried samples had no significant reduction in activity, while the frozen samples had a 20% loss after 6 mo. Fresh samples quickly degraded and were spoiled after two months. Lysozyme activities were similar to BNAG. Moreover, eggs from WL had up to 20% more enzymatic activity than those from RIR layers. These findings will be useful in further assessing the potential value of and applications for using ESM.

Key Words: Eggshell Membrane, Beta-N-Acetylglucosaminidase, Lysozyme

326 The effect of layer age, storage and strain of hen on egg quality during summer season under Sohag conditions. T. El-Sheikh*, Faculty of Agriculture, South Valley University, Sohag, Egypt.

A total of 600 eggs from 32 and 60 week old Hy-line-White, Hy-Line-Brown and Fayoumi hens were used after lay and after periods of storage of 0, 3, 6, 9 and 12 d at room temperature (30.2°C). Eggs were individually weighed. The yolk of each egg was cautiously separated from albumen and dried. Albumen weight was calculated by difference. Shell thickness was measured using a shell thickness gauge at three different locations on the egg shell. Albumen height was measured using a micrometer. Longer periods of storage resulted in significantly (P<0.05) lower albumen weight (64.28, 63.55, 62.69, 61.94, and 61.62 % for 0 to 12 d of storage) and albumen height (9.46, 8.10, 6.69, 5.45, and 4.58, for 0 to 12 d of storage) and higher albumen pH (7.35, 8.49, 9.10, 9.35, and 9.47, for 0 to 12 d of storage) across the two age groups. Eggs from Hy-line-Brown hens had more albumen and shell than those from Hy-line-White and Fayomi hens. The lower albumen weight and height with increased days of storage were not as pronounced in Fayoumi eggs compared to Hy-line-White and Hy-Line-Brown. Within each line and storage period, the egg weight was more closely associated with albumen weight than with yolk or shell weight. The albumen height of eggs from Hy-line-White hens was lower than those of Hy-line-Brown and Fayomi hens at all storage times, but the albumen pH was higher in either Hy-line-White and Hy-line-Brown compared to Fayoumi. The loss in weight from shell, albumen and yolk was increased with age. The changes in egg composition with storage time and age were solely the consequence of weight loss from the albumen.

Key Words: Fayoumi, Egg Quality, Egg Components

327 Effect of pasteurization of potato slurry in corn or barley finishing diets for beef cattle. J. I. Szasz*¹, C. W. Hunt¹, O. A. Turgeon², and P. A. Szasz*¹, ¹University of Idaho, Moscow, ²Koers-Turgeon Consulting Service, Inc., Amarillo, TX.

Pasteurization of vegetable byproducts, such as potato slurry (PS), may be necessary to prevent spread of pathogens and beef carcass blemishes. We hypothesized pasteurization would increase ruminal fermentability of PS. Four ruminally cannulated crossbred beef steers were used in a 4 x 4 Latin square experiment with a 2 x 2 factorial arrangement of treatments to examine the main effects and interactions of PS pasteurization (54.4o C for 2 h) and grain type (GT; dry rolled barley or corn) on ruminal and total tract digestion. Diets contained 7% alfalfa hay and 14% PS (DM basis) and were fed ad libitum three times daily. Corn-containing diets had 71.7% corn while barley diets had 60% barley and 11.7% corn. Acid detergent insoluble ash was used as an internal digestibility marker. Steers fed barley diets had greater ($P < 0.05$) intake but lower ($P < 0.05$) total tract digestibility of DM, OM, and ADF than steers fed corn diets. Treatment differences were not observed for starch digestibility. Ruminal fluid pH was lower ($P < 0.05$) for pasteurized compared with non-pasteurized PS treatments, and was lower ($P < 0.05$) for corn compared with barley treatments at 0200 and 2100 sample times. Ruminal fluid pH was lower at 0200, 1400, 2100, and 2300 sample times for the corn plus pasteurized PS treatment compared with other treatments (sampling time x PS x GT interaction, $P < 0.05$). Minimum ruminal pH was lower ($P = 0.07$) for pasteurized than non-pasteurized PS diets. Maximum ruminal pH was greater ($P < 0.05$) for barley than corn diets. Steers consuming corn diets had less ($P = 0.06$) time with ruminal pH less than 6.0 than barley diets. Ruminal fluid ammonia concentration was greater ($P < 0.05$) for non-pasteurized than pasteurized PS treatments and for corn than barley treatments. Pasteurizing PS increased ruminal fermentation but was generally not interactive with GT. Also, the effect of pasteurization of PS on ruminal fermentation did not impact total tract digestion.

Key Words: Feedlot, Byproduct, Fermentation

328 Replacing corn or barley with potato processing by-product in beef finishing diets improves feed conversion efficiency and alters carcass fat distribution. J. Duynisveld*¹, E. Charmley¹, I. Mandell², and J. Aalhus³, ¹Agriculture and Agri-Food Canada, Nappan, NS, Canada, ²University of Guelph, Guelph, ON, Canada, ³Agriculture and Agri-Food Canada, Lacombe, AB, Canada.

The effects of replacing corn or barley in beef finishing diets with potato processing by-product (PPB) on beef cattle performance, feed conversion efficiency, carcass traits and meat quality were examined using 100 cross-bred British x exotic steers. The PPB comprised steamed potato peel and cull potatoes, cull French fries and potato starch. Ten pens of 10 steers each were assigned to one of five concentrate-grass silage diets comprised on a dry matter (DM) basis of 80% concentrate and 20 % silage. The five concentrates comprised either, all barley, all corn, equal parts barley and PPB (DM basis), equal parts corn and PPB (DM basis) or all PPB. Cattle were supplemented with 500 IU d⁻¹ alpha-tocopherol. Results were analyzed using mixed models procedure, examining linear and quadratic responses when PPB was substituted in barley- or corn-based concentrates. Linear declines ($P < 0.05$) in dry matter intake (kg and % body weight basis) were present when PPB was substituted into either corn or barley-based concentrates. The replacement of corn with PPB did not affect ($P > 0.05$) average daily gain (ADG; 1.4 kg d⁻¹), but there was a negative quadratic effect ($P < 0.05$) on ADG when PPB replaced barley. The replacement of corn or barley with PPB improved ($P < 0.05$) feed conversion efficiency, with a linear effect ($P < 0.05$) on feed efficiency as corn was replaced with PPB. In both barley- and corn-based diets, PPB substitution improved feed conversion efficiency ($P < 0.05$). Marbling scores tended to decline linearly ($P < 0.10$) with increased PPB in both corn and barley groups. Back fat thickness increased ($P < 0.10$) in corn-fed cattle with PPB substitution. In barley-based diets back fat thickness was unaffected but there were quadratic effects of PPB on dissected lean muscle and intermuscular fat, suggesting that inclusion of 50% PPB resulted in fatter carcasses

Key Words: Beef, Potato, Carcass

329 Corn milling byproducts and alfalfa levels in cattle finishing diets. P. L. Loza*, K. J. Vander Pol, G. E. Erickson, R. A. Stock, and T. J. Klopfenstein, University of Nebraska, Lincoln.

ABSTRACT: An experiment was performed with the objective of evaluating the performance of beef steers on diets consisting of increasing levels of corn milling by-products (BP) (50% wet corn gluten feed, 50% wet distillers grains; DM basis) and different alfalfa hay levels. 280 yearling steers (370 kg BW) were blocked (3 blocks) by weight, stratified within block and assigned to 35 pens (8 steers/pen). Pens were assigned randomly to one of seven treatments (5 pens total/treatment) in a 3 x 2 plus 1 experimental design. Treatments consisted of a control diet (0%BP, 7.5% alfalfa) and three BP levels at 25%, 50% and 75% diet DM, in combination with two levels of alfalfa. Alfalfa level was kept constant at 7.5% of DM or formulated for equal eNDF of control, i.e., 7.5, 5.0, 2.5, and 0% alfalfa for the 0, 25, 50, and 75% BP, respectively. Steers were fed for an average of 113 d and harvested at a commercial abattoir. Interactions were only observed between BP and Alfalfa level ($P < 0.05$) for marbling and YG. Quadratic responses ($P < 0.05$) to the BP level (0, 25, 50, and 75%BP, respectively) were observed for DMI (11.1, 12.0, 11.7, and 10.6 kg DM/d), ADG (1.81, 2.10, 2.07, and 1.77 kg/d), and G:F (0.162, 0.177, 0.176, and 0.167). Improved feedlot performance was observed at the 25 and 50% BP levels, without significant ($P < 0.05$) differences between 25 and 50% BP inclusion. These results suggest that the BP utilization in feedlot diets up to 50% will enhance production performance.

Key Words: Cattle Feeding, Distillers Grains, Maize Byproducts

330 Effect of corn bran and steep inclusion in finishing diets on performance and nitrogen balance of open dirt feedlots. K. M. Sayer*, G. E. Erickson, T. J. Klopfenstein, C. N. Macken, and K. J. Vander Pol, University of Nebraska, Lincoln.

Two experiments using calves fed 167 d from November to April (WINTER) and yearlings fed 126 d from May to September (SUMMER) were fed to evaluate the effects of decreasing digestibility of a finishing diet by replacing dry rolled corn (DRC) with corn bran and steep, on performance and nitrogen (N) balance in open feedlots. Cattle were stratified by weight and assigned randomly to one of four treatments. Dietary treatments for both trials included Control (CON), 30% Corn Bran (30/0), 30% Corn Bran/15% Steep (30/15), and 45% Corn Bran/15% Steep (45/15) with byproducts replacing DRC in the diet (DM basis). WINTER calves were implanted with Synovex-S and re-implanted with Revalor-S, and SUMMER yearlings were implanted with Revalor-S on d 21. Pens were cleaned four times in WINTER and three times during SUMMER, across all treatments. WINTER cattle on CON tended to eat less than cattle on byproduct diets (10.5 kg/d vs. 11.1 kg/d, $P = 0.06$), however no differences in final weight (600 kg) or feed efficiency (0.157) were detected ($P > 0.05$). SUMMER cattle were also not different in final weight (604 kg, $P > 0.05$) however, CON yearlings had lower DMI than those on the byproduct diets (10.9 kg/d vs. 11.6 kg/d, $P < 0.01$) and cattle on 30/0 were less efficient than other treatments (0.135 vs. 0.144, $P = 0.05$). WINTER percent N losses from the pen floor surface were 63.9%, 50.7%, 51.9%, and 35.8% for CON, 30/0, 30/15, and 45/15, respectively, ($P = 0.01$). SUMMER percent N loss of total N excreted was not different ($P > 0.05$) across treatments (averaging 60.1%) however, more N was removed in the manure from byproduct pens than CON pens (13.3 kg N/hd vs. 10.1 kg N/hd, $P = 0.01$). Adding steep with bran negates any negative impacts on animal performance while still reducing N losses from feedlot pens and increasing manure N removal. Byproduct diets may prove valuable in increasing N removed in manure and lowering percent N lost from the pen floor surface.

Key Words: Maize Byproducts, Nitrogen, Nutrient Management

331 Timing of flax supplementation for finishing cattle. E. J. Good*, J. S. Drouillard, T. J. Kessen, E. R. Loe, M. J. Sulpizio, M. A. Greenquist, S. P. Montgomery, J. J. Sindt, B. E. Depenbusch, and K. A. Hachmeister, Kansas State University, Manhattan.

An experiment was conducted with finishing beef heifers (n=80; 365 kg initial BW) to determine the optimal time and duration for supplementation of ground flaxseed (0 or 5% of DM). Treatment periods included:

0% flax fed for 109 d (AllControl), 5% flax fed for 109 d (AllFlax), 5% flax fed for 60 d followed by 0% flax fed for 49 d (FlaxEarly), and 0% flax fed for 60 d followed by 5% flax fed for 49 d (FlaxLate). At the end of the finishing period, hot carcass weight, USDA yield and quality grades, marbling score, subcutaneous fat thickness, longissimus muscle area, and percentage of kidney, pelvic and heart fat (KPH), were determined for each animal. Retail display life, 2-thiobarbituric acid reactive substances (TBARS), fatty acid composition, tissue vitamin E concentration, and sensory attributes of longissimus steaks also were evaluated. FlaxEarly increased ADG ($P < 0.05$) compared with AllFlax or FlaxLate, but neither DMI nor gain:feed were affected. Feeding FlaxEarly increased fat over the 12th rib ($P < 0.05$), but there were no differences in KPH, USDA quality grade, or TBARS among any of the treatments. A trained sensory panel evaluated myofibrillar tenderness, juiciness, flavor intensity, connective tissue amount, overall tenderness and off-flavor intensity of steaks, but detected no differences among treatments. Moreover, there were no differences among treatments with respect to Warner-Bratzler shear force, retail display life, or tissue vitamin E concentrations of longissimus steaks. Feeding flax increased ($P < 0.05$) levels of α -linolenic acid in the longissimus dorsi both pre- and post cooking, as well as in plasma. The α -linolenic acid content of plasma from cattle fed FlaxEarly returned to levels similar to those of AllControl cattle in response to removal of flax from the diet after 60 d. Feeding ground flaxseed resulted in no negative effects on meat quality, and may be most beneficial during the early finishing phase.

Key Words: Flaxseed, Meat Quality, α -Linolenic Acid

332 Effects of forage level and corn processing method in beef finishing diets containing wet corn gluten feed on finishing steer performance. P. L. Loza*, K. J. Vander Pol, G. E. Erickson, R. A. Stock, and T. J. Klopfenstein, *University of Nebraska, Lincoln*.

ABSTRACT: Sixty steer calves (398 kg BW) were individually fed for 101 d to evaluate two corn processing methods with two different levels of alfalfa (ALF) in finishing diets containing 25% wet corn gluten feed (DM basis). Steers were stratified by initial BW and assigned randomly to one of the four treatments in a 2 x 2 factorial design. Factors included corn processing as dry rolled (DRC) or reconstituted high-moisture corn (HMC), and ALF level of 0 or 7% of diet DM. No corn processing by ALF level interactions were observed ($P > 0.05$), thus only main effects are discussed. Steers fed HMC had lower ($P < 0.01$) DMI, lower ($P < 0.01$) ADG, but similar gain efficiency (ADG:DMI) as steers fed DRC. Alfalfa level did not affect ADG. A trend ($P = 0.14$) for an interaction between corn processing and alfalfa level was observed for ADG:DMI. The addition of ALF tended to decrease efficiency in the DRC diet, but ALF appeared to be beneficial in HMC diets, although not significant. In finishing diets containing wet corn gluten feed, the value of inclusion of forage such as alfalfa, may depend on corn processing method.

	DRC		HMC		SEM	<u/> P Values		
	0%	7%	0%	7%		Corn*	Corn	ALF
ALF	ALF	ALF	ALF	ALF		ALF	Corn	ALF
DMI	10.4	11.1	9.0	9.6	0.2	0.75	<0.01	0.01
ADG	1.71	1.68	1.36	1.47	0.05	0.31	<0.01	0.57

333 Using a dynamic ruminant model to understand the differences in performance of cattle fed rations based on barley and/or a potato processing-by-product. B. N. Nagorccka*, E. Charmley², and J. Duynisveld², ¹CSIRO Livestock Industries, Canberra, Australia, ²Crops and Livestock Research Centre Agriculture and Agri-Food Canada.

To assess the efficacy of barley Vs potato processing by-product, cattle were fed a background ration containing 31% barley and 60% silage for 85 days, and were finished for 79 days on a ration containing 18% forage and one of five combinations of rolled barley and potato (table). The observed feed conversion ratio (FCR) show a small but significant difference in favour of potato, however, the observed average intake and body weight (BW) gain decreased with increasing dietary content of potato. To understand these differences a mechanistic, dynamic ruminant model (AusBeef, supported by CSIRO) with a voluntary intake sub-model, was

used to simulate the experiment. The different time trends in the periodic observations of body weight (BW) gain and intake in treatments 1 to 5 could only be explained by including an adaptation time when potato was introduced into the ration. An adaptation time proportional to the amount of potato in the finishing ration resulted in predictions that accounted for 95% and 75% of the observed variance in DM intake and FCR, respectively (table). The adaptation time in treatment 5 could be removed by replacing barley with potato in the background ration, in which case simulations (for 80% potato) predict an average BW gain of 1.86 kg/d, an average intake of 10.10 kg/d, and an FCR of 5.43. It is concluded that cattle should perform 10% better on potato by-product compared to barley (treatment 1).

Treatment	1	2	3	4	5	
Potato/barley (%DM)	0/80	20/60	40/40	60/20	80/0	SE
DM intake (kg/d)						
observed	10.56 ^a	10.77 ^{ab}	9.98 ^b	9.13 ^c	8.16 ^d	.31
predicted	10.82	10.68	9.80	9.47	8.70

334 Digestion of pasture in response to fumarate in continuous culture. E. S. Kolver¹, P. W. Aspin¹, G. N. Jarvis², K. M. Elborough², and J. R. Roche*¹, ¹Dexcel Ltd., Hamilton, New Zealand, ²ViaLactia Biosciences (NZ) Ltd., Auckland, New Zealand.

This experiment tested the hypothesis that addition of an organic acid (fumarate) would increase energy capture from a pasture diet during ruminal fermentation. Pasture was fermented with 0, 10, 20, or 30 mM of fumarate constantly infused into four dual-flow continuous culture fermenters. Samples of digesta and gas emissions were collected during the last 3 d of four, 9-day experimental periods, according to a 4 x 4 Latin square design. Digestion characteristics responded linearly ($P < 0.05$) as fumarate increased from 0 to 30 mM. Concentrations of propionate and total volatile fatty acids increased by 74% and 19%, respectively as fumarate increased from 0 to 30 mM. Increasing fumarate reduced the ratio of acetate:propionate (2.4 v.s. 1.5) and reduced ($P = 0.057$) methane production by 38%. These results were consistent with fumarate acting as an electron-accepting intermediary in the succinate-propionate pathway. Although 30 mM fumarate increased ruminal pH by 0.16 units compared to 0 mM fumarate (pH 6.23), the digestibility of neutral detergent fibre and acid detergent fibre was not changed. Concentration of lactate was low (0.12 ± 0.03 mM) and was not affected by fumarate supplementation. Fumarate did not influence nitrogen digestion, but true dry matter and organic matter digestibilities were reduced by 3.9 and 3.2 percentage units, respectively at 30 mM fumarate. The increased concentration of propionate appears to be a direct response to additional substrate (fumarate), rather than by an indirect improvement in lactate utilisation or fibre digestibility. The addition of fumarate increased energy capture from a pasture diet by improving the supply of glucogenic compounds and reducing losses to methane emissions.

Key Words: Fumarate, Pasture, Methane

335 Effect of gossypol from cottonseed meal consumption on performance of fallow does (*Dama dama*). S. Mapel*, D. Neuendorff, A. Lewis, and R. Randel, Texas A&M University, Texas Agricultural Experiment Station, Overton, TX.

The objectives of this study were to determine the effects of gossypol ingestion on reproductive function and productivity of female fallow deer (*Dama dama*) by measuring endocrine function, pregnancy rates, and BW of does and fawns. A group of multiparous fallow does were randomly allocated by BW into three treatments and placed on separate 0.809 ha Coastal bermuda grass pastures. Two bucks, fitted with marking harnesses, were housed with each doe group for the duration of the experiment. The treatments varied the amount of free gossypol (FG) in the diet. Animals were fed daily from 6/16/03 until 11/20/03.

The soybean meal group (SBMG; n = 17) was supplemented daily with 362 g of soybean meal (SBM)/animal. The low cottonseed meal group (CSML; n = 17) was supplemented with a mixture including 181 g of SBM and 227 g cottonseed meal (CSM; 0.09 % FG). The high cottonseed meal group (CSMH; n = 16) was supplemented with 454 g CSM/animal. The daily intake of FG/animal for SBMG, CSML, and CSMH was 0.0, 0.20, and 0.41 g, respectively. Beginning 8/14/03, BW, BCS, and serum blood samples were collected weekly, until 11/20/03. Ultrasonography, for pregnancy detection, was performed for all does on 11/20/03 and 12/15/03. The SBMG (-49.83±4.08 g/animal/d) lost less (P<.01) BW than CSML (-73.84±4.08 g/animal/d) or CSMH (-77.01±4.08 g/animal/d). Average daily BW loss did not differ (P>.1) between CSML and CSMH. Body condition score (5.36±0.09), pregnancy rates (100%), and time between weaning and conception did not differ (P>.1) among treatments. Doe serum progesterone concentrations were reduced (P<.05) in CSMH relative to SBMG and CSML. Among lactating does, BW and BCS at weaning was correlated (P<.01, R=-0.50 and P<.05, R= -0.41, respectively) with time between weaning and conception. Despite reductions in BW gains and serum progesterone concentrations, consumption of CSM (8.1 mg FG/kg BW; 0.41 g FG/animal/d) did not affect reproductive performance of fallow deer.

336 Soybean hulls for finishing meat goats. M. H. Poore*, J. A. Moore, A. T. Maye, and J.-M. Luginbuhl, *North Carolina State University.*

Soyhulls (SH) have been used at high levels in goat diets, but feeding method has not been studied. Twenty-four wethers, at least 75% Boer (21 kg), were allotted to 4 treatments (trt). All trt used orchardgrass hay (10.5 % CP and 65.9% NDF). Treatment 1 (hay) was 100% hay, trt 2 (HFcorn) was 33% hay and 67% hand-fed corn/SBM mix (12.5% CP and 11.0% NDF), trt 3 (HFSH) was 33% hay and 67% hand-fed SH (12.3% CP and 64.2% NDF), and trt 4 (FCSH) was hay at 0.75% of

live wt with free choice SH. One goat on HFcorn was removed due to low intake. All goats were started slowly on concentrate (conc) with ad lib hay. Initially, loose SH were fed, but after the first wk most goats were refusing their SH, so they were changed on d 12 to a pelleted source which was acceptable to all goats. Once all goats began consuming their conc at 33% of diet DM, they were fed 50% conc for 3 d and then 67% conc for 3 d. Following that, trt 4 received SH free choice and hay intake was restricted. All goats were on final diets by d 28. Ruminal samples were taken by rumenocentesis 4 h after feeding on d 84, and goats were harvested on d 85. Contrasts determined were hay vs. the other 3 trt (C1), HFcorn vs. HFSH (C2), and HFSH vs. FCSH (C3). Due to differences in dressing %, final live wt was adjusted using carcass wt and the average dressing % for all trt to calculate ADG. The study showed that all conc trt outperformed hay, that HFcorn was similar to HFSH, and that there was little difference between HFSH and FCSH. Therefore, SH are a viable feed for finishing goats, and can be fed free-choice.

337 Effects of parity and levels of protein on production response and n-balance in holsteins. S. A. Flis* and M. A. Wattiaux, *University of Wisconsin-Madison.*

Eight Holstein cows (4 primiparous and 4 multiparous) were used in a replicated 4x4 Latin Square to determine milk production response and N balance when diets had no excess of RUP or RDP (C), 10% RUP excess (U), 10% excess RDP (D), or 10% excess of both RUP and RDP (UD) according to NRC 2001. Solvent soybean meal and soyPLUSTM made up 6.6 and 5.1, 6.1 and 7.5, 11.8 and 1.2, or 11.3 and 4.1% for the C, U, D, and UD diets, respectively. Diets were fed as a TMR with 25% alfalfa silage, 25% corn silage (DM basis) and corn grain as the primary source of dietary starch. During each 21day period, milk yield and DMI were recorded daily, and in the last 3 days of each period fecal and urinary N (UN) excretion were determined from total collection. Dietary CP averaged 17, 18, 17.6, and 18.7% for the C, U, D, and UD diet, respectively. DMI, milk and protein yield were lower in primiparous than in multiparous cows (P < 0.05). N intake (NI) was 535 and 782 g/d for primiparous and multiparous cows, respectively (P < 0.01). Total milk N (TMN g/d), fecal N and UN were lower for primiparous than for multiparous cows (P < 0.01), but N balance did not differ with parity (P = 0.2). Highest DMI and NI were in diets with excess RUP (see Table). Milk yield was lower on diets with excess RDP (D and UD) (P < 0.05). Fecal N, UN, and N balance (data not shown) were higher in diets with excess RUP. N balance was positive for all treatments. Through the trial little change in BW was observed. Results indicated that greater efficiency of N utilization on farm could be obtained by balancing rations for first and later lactation cows separately.

338 Site of digestion in dairy cows fed different sources and amounts of crude protein. I. R. Ipharraguerre*¹, J. H. Clark¹, and D. E. Freeman², ¹Department of Animal Sciences, University of Illinois, Urbana, ²Department of Veterinary Clinical Medicine, University of Illinois, Urbana.

Six multiparous Holstein cows cannulated in the rumen and duodenum that averaged 70 DIM were used in a 6x6 Latin square design with a 2x3 factorial arrangement of treatments. Two sources of CP (soybean meal (SBM) and a mixture of SBM and a commercial blend of high rumen-undergradable (RUP) CP sources) and three contents of dietary CP (about 14, 16, and 18%) were combined into six dietary treatments. Each source of CP supplied about 50% of the CP mixture used to formulate the high RUP diets. On DM basis, diets contained 25% corn silage, 20% alfalfa silage, 10% cottonseed, 26.7 to 37% corn grain, and 4 to 13.5% CP supplement. Diets were fed twice daily for ad libitum intake. Intakes of DM, OM, and NDF, and OM truly digested in the rumen were unaffected by treatments (P >.05; mean = 23.2, 21.7, 6.8, and 8.9 kg/d, respectively). As dietary CP increased from 14 to 18%, starch intake (8.0, 7.1, and 6.7 kg/d) and apparent ruminal (3.4, 2.8,

and 1.6 kg/d) and total tract digestion (7.6, 6.7, and 6.4 kg/d) decreased ($P < .01$). At 14% CP, starch intake and total tract digestion (+.7 and +.6 kg/d) were higher for the RUP diet than the SBM diet, but the opposite occurred at 16% CP (.8 and .8 kg/d, $P < .01$). Across CP sources, increasing CP in the diet from 14 to 18%, increased N intake (510, 612, and 668 g/d, $P < .01$), ruminal outflow of nonammonia N (521, 536, and 617g/d, $P < .03$), nonammonia nonmicrobial N (224, 264, and 365 g/d, $P < .01$), Lys (157, 171, and 220 g/d, $P < .02$), total essential AA (1177, 1253, and 1531 g/d, $P < .02$), and total AA (2525, 2688, and 3265 g/d, $P < .02$). Across CP percentages, replacing SBM with RUP in the diet increased Met intake (57 vs. 63 g/d, $P < .01$) but did not affect Met flow to duodenum (61 vs. 64 g/d, $P > .05$). Ruminal outflow of microbial N (mean = 270 g/d) and milk yield (mean = 30.1 kg/d) were unaffected by treatments ($P > .05$). Data suggest that SBM-corn-based diets containing about 16% CP can quantitatively optimize the supply of N to duodenum of dairy cows consuming large amounts of feed.

339 Performance of lactating dairy cows fed different sources and amounts of crude protein. I. R. Ipharraguerre* and J. H. Clark, *Department of Animal Sciences, University of Illinois, Urbana.*

Sixty multiparous Holstein cows were involved in a 210-d lactation trial using a completely randomized design with a 2x3 factorial arrangement of treatments. Two sources of CP (soybean meal (SBM) and a mixture of SBM and a commercial blend of high rumen-undergradable (RUP) CP sources) and three concentrations of dietary CP (about 15, 17, and 19%) were combined into six dietary treatments. Each source of CP supplied about 50% of the CP mixture used to formulate the high RUP diet. On DM basis, diets contained 25% corn silage, 20% alfalfa silage, 10% cottonseed, 26.7 to 37% corn grain, and 4 to 13.5% CP supplement. Diets were fed twice daily for ad libitum intake. Across the 210 d and treatments, DM intake (DMI); yields of milk, 3.5% FCM, fat, and true protein (TP); FCM/DMI; and body condition score (BCS) averaged 24.6, 37.8, 36.8, 1.26, and 1.10 kg/d; 1.51; and 2.82, respectively. Most of these variables, however, showed a significant ($P < .05$) interaction between concentration and source of CP. At 19% CP, cows fed SBM had greater DMI, yields of FCM, fat, and TP (+2.5, +2.2, +.11, and +.05 kg/d), but lower FCM/DMI (.06) and BCS (.27) than cows fed RUP. At 17% CP, cows fed RUP had higher yields of FCM, fat, and TP (+2.9, +.13, +.05 kg/d) and FCM/DMI (+.06) than cows fed SBM. At 15% CP, cows fed SBM had higher DMI (+.6 kg/d) but lower yield of TP (.07 kg/d) and FCM/DMI (.06) than cows fed RUP. Across CP sources, cows fed 15% CP compared with cows fed 17 and 19% CP showed lower ($P < .05$) yields of FCM and TP (mean = 35.8 and 1.06, 36.7 and 1.13, 37.9 and 1.13 kg/d, respectively) and tended ($P < .07$) to have lower FCM/DMI (mean = 1.49, 1.49, and 1.55, respectively). Across CP percentage, cows fed RUP showed higher FCM/DMI than cows fed SBM (mean = 1.54 vs. 1.48). As dietary CP increased from 15 to 19%, milk urea nitrogen increased on average from 8.89 to 14.48 mg/dl. Data indicate that CP content of the diet of lactating dairy cows can be decreased without decreasing milk and milk component yields if the source and amount of dietary CP and carbohydrate are properly matched.

340 Effects of different protein supplements on nitrogen utilization in dairy cows. I. Lactation performance and ruminal metabolism. A. F. Brito*¹ and G. A. Broderick², ¹University of Wisconsin, Madison, ²US Dairy Forage Research Center, Madison, WI.

Sixteen multiparous and 8 primiparous Holstein cows (8 with ruminal cannulae) were randomly assigned to six 4 x 4 Latin squares to investigate the effects of RDP source on lactation performance and ruminal metabolism. All diets contained (% of DM): 20.7% alfalfa silage and 35.1% corn silage. The following protein supplements were added to the basal diet (% of DM): urea (1.9%; diet A), solvent soybean meal [(SSBM; 12.1%); diet B]; cottonseed meal [(CSM; 14.1%); diet C]; or canola meal [(CM; 16.1%); diet D]. Diets contained 16.6% CP. Yield of milk, fat, protein, and 3.5% FCM were significantly higher for cows fed diets supplemented with SSBM, CSM, or CM. Feeding CM resulted in numerically greater responses, although not always statistically different from SSBM and CSM. Cows fed diet A had the lowest DMI while cows

on diet D had the highest; diet C was intermediate but not different from diet B. Milk fat content, total VFA, acetate, and propionate were similar among all diets whereas milk protein content was highest on diets B and D and lowest on diets A and C. Ruminal pH and butyrate also did not differ across diets (data not shown). Overall, use of true proteins improved N utilization versus NPN. However, greater protein yield indicated that SSBM and CM were more effective than CSM.

341 Effects of different protein supplements on nitrogen utilization in dairy cows. II. Digesta flow and bacterial protein synthesis. A. F. Brito*¹ and G. A. Broderick², ¹University of Wisconsin, Madison, ²US Dairy Forage Research Center, Madison, WI.

Eight multiparous Holstein cows fitted with ruminal cannulae were randomly assigned to two 4x4 Latin squares to investigate the effects of RDP source on digesta flow and bacterial protein synthesis. All diets contained (% of DM): 20.7% alfalfa silage and 35.1% corn silage. The following protein supplements were added to the basal diet (% of DM): urea (1.9%; diet A), solvent soybean meal [(SSBM; 12.1%); diet B]; cottonseed meal [(CSM; 14.1%); diet C]; or canola meal [(CM; 16.1%); diet D]. Diets contained 16.6% CP. Digesta flow (Co-EDTA and YbCl₂) and bacterial markers (¹⁵N) were continuously infused into the rumen. The omasal sampling technique was used to collect digesta from the omasal canal. Both DM and OM flows were lowest for cows fed diet A but similar among diets B, C, and D. Apparent ruminal dry matter digestibility (ARDMD) was highest on diet A, lowest on diet C, and intermediate on diets B and D. Organic matter apparently digested in the rumen (OMADR) and organic matter truly digested in the rumen (OMTDR) did not differ among diets. Fluid-associated bacteria (FAB), particle-associated bacteria (PAB), total bacterial flow, and bacterial efficiency were all higher in cows fed SSBM, CSM, or CM. Overall, bacterial non-ammonia nitrogen (NAN) flow and efficiency were increased by feeding true protein supplements rather than a NPN source (urea).

342 Evaluation of prediction equations for estimating urinary output of nitrogen in lactating dairy cows. T. D. Nennich^{*1}, J. H. Harrison¹, D. Meyer², W. Weiss³, N. R. St-Pierre⁴, R. L. Kincaid⁵, M. Wattiaux⁶, and D. L. Davidson¹, ¹Washington State University, Puyallup, ²University of California, Davis, ³The Ohio State University, Wooster, ⁴The Ohio State University, Columbus, ⁵Washington State University, Pullman, ⁶University of Wisconsin, Madison.

Previously developed prediction equations need to be validated with other data sets to verify their accuracy across various diets and environments. The objective of this study was to evaluate previously published prediction equations that estimate urinary nitrogen excretion from lactating dairy cows. A data set was assembled from total urine collection studies that used multiparous Holstein cows (n = 418). The studies were conducted by Washington State University, University of California-Davis, The Ohio State University, and the University of Wisconsin. Milk production ranged from 1.4 to 86.1 kg/d. Dietary crude protein concentration averaged 17.5±5.8 and urinary nitrogen (UN) ranged from 63 to 499 g/d. Examples of previously published equations that were evaluated included UN (g/d) = N intake (g/d) x 0.83 milk N (g/d) 97 (J. Dairy Sci. 82:1261-1273) and UN (g/d) = 0.0259 x BW (kg) x MUN (mg/dl) (J. Dairy Sci. 84:2284-2294). Equations were evaluated by plotting residuals versus predicted values. The linear regression line of these plots was used to determine if mean or slope biases were present for any of the equations. The mean bias was not significant for any of the equations evaluated. However, there were significant slope biases for each of the equations. The new regression equation developed using this data set was UN (g/d) = 0.09 x DIM 0.94 x Milk (kg) + 0.20 x BW (kg) + 6.07 x DMI (kg) + 4.70 x MUN (mg/dl) + 11.42 x Dietary CP (%) - 281.53. Evaluation and validation of prediction equations is important to develop equations that will more accurately estimate urinary nitrogen excretion from lactating dairy cows.

Key Words: Rrine, Nitrogen, MUN

343 Meta analysis of the influence of different sources of methionine on the milk protein content of dairy cows. T. Guyot¹, J. C. Robert^{*2}, and D. Sauvat¹, ¹INA Paris, Grignon, Paris, France, ²Adisseo 42 Avenue Aristide Briand - 92160 Antony.

Several experiments have been carried out to study the influence of HMBi (2- hydroxy - 4 (methyl thio) butanoic acid isopropyl ester) on the milk protein content, at different doses and in comparison with HMB and SmartamineTM M (SmartamineTM M (Sm M) Adisseo) a coated form of methionine. The aim of this work was to compare the efficiency of HMBi on milk protein content vs other sources of methionine. A meta analysis was performed on a database including data from seven experiments. The rations were formulated to be adequate in term of metabolisable lysine supply. The data set was weighted by the number of cows in the experiment and the study effect was tested in the analysis. A first meta analysis was carried out in order to predict the increase of the milk protein content (MPC, g/kg) in relation to the quantity of methionine distributed to the cows (MQ ; g /animal/day). This took into account the methionine percentage of each product (70% for HMBi, 78% for SmartamineTM M and 88 % for HMB). The relationships were: for HMBi: MPC = 0.277 ln MQ (R² =0.83;SRD=0.12) ; for HMB: MPC = 0.001 ln MQ (R² =0;SRD=0.15) and for Sm M: MPC = 0.343 ln MQ (R² =0.85 ; SRD=0.14). Furthermore the following estimates of methionine bioavailability (50% for HMBi, 40% for HMB and 80% for Sm M) were used to calculate the quantities of metabolisable methionine supplied. A second meta analysis was performed in order to predict the increase of MPC depending on the quantity of metabolisable methionine (MMQ, g/animal/day). The relationships were: for HMBi and Sm M: MPC = 0.357 ln MMQ (R² =0.77; SRD= 0.11) ; for HMB: MPC = 0.002 ln MMQ (R²=0 ; SRD=0.15). Thus, the efficiency of utilization of both HMBi and SmartamineTM M at equivalent quantities of metabolisable methionine were not found to be significantly different. Moreover this meta analysis illustrates that only by conjugating HMB with isopropanol was sufficient HMB absorbed to increase the supply of metabolisable methionine necessary to increase MPC.

Key Words: Methionine, Ruminant, Nutrition

344 Use of changes in plasma sulfur amino acid concentrations to compare the ability of methionine (Met) products to provide absorbable Met to lactating dairy cows fed a Met-adequate diet. B. J. Olley¹, R. S. Ordway^{*1}, N. L. Whitehouse¹, and C. G. Schwab¹, ¹University of New Hampshire, ²Adisseo USA, Inc.

This experiment is part of an ongoing effort to develop an accurate and repeatable approach for determining differences among Met products in their ability to provide absorbable Met to lactating cows. Fifteen multiparous Holstein cows (212 ± 162 DIM) were blocked by milk yield, DIM, and milk protein content and assigned randomly to one of three 5 x 5 Latin squares. The basal diet was formulated to meet NRC (2001) requirements for energy and nutrients, including content of Met in metabolizable protein (MP). Adequacy of Met was achieved by adding SmartamineTM M to the basal diet to increase Met in MP from 1.76% to 2.14% to achieve an approximate 1:3 ratio with lysine in MP (6.51%). Each square consisted of top-dressing the basal diet with five amounts (treatments) of a single Met source. The three Met sources were SmartamineTM M, Met-PlusTM and Mepron M85[®]. Products were added to the basal diet to provide levels of Met supplementation of 0, 0.012, 0.024, 0.036 and 0.048% of DM. Treatments had no effect on concentration of total free AA in deproteinized plasma. Percent of Met and Met+cysteine (Cys) in total plasma AA for the five treatments were: SmartamineTM M (1.95, 2.06, 2.23, 2.48, 2.44; linear, P < 0.01 and 3.21, 3.42, 3.62, 3.84, 3.89; linear, P < 0.01), Met-PlusTM (1.88, 1.91, 1.99, 2.05, 1.98; P = 0.27 and 3.25, 3.40, 3.41, 3.41, 3.49; P = 0.168) and Mepron M85[®] (1.81, 2.16, 2.11, 2.03, 2.23; linear, P = 0.03 and 3.29, 3.65, 3.57, 3.48, 3.62; P = 0.168). Concentrations of Met and Met+Cys in total plasma AA were regressed on levels of Met supplementation. The slopes for Met-PlusTM and Mepron M85[®] were divided by the slope for SmartamineTM M to obtain a Met-bioavailability relative to that of SmartamineTM M. The described approach indicates that Met-PlusTM was 24% and 28% as effective as SmartamineTM M and Mepron M85[®] was 51% and 28% as effective as SmartamineTM M using changes in plasma Met and Met+Cys concentrations, respectively, in providing absorbable Met to lactating cows.

345 A simplified *in vitro* incubation medium with the potential to evaluate amino acid degradation in ruminants. F. L. Mould^{*}, R. Morgan, and K. Kliem, *Department of Agriculture, The University of Reading.*

Most *in vitro* assays use a modified Goering and Van Soest [1970] incubation medium [GVS]. However as some of the components are hazardous, difficult to obtain [developing countries] or of little impact [e.g. trace minerals] their omission should be examined. Hungate [1966] considered osmotic potential and buffering capacity to be more vital than composition, while Tilley and Terry [1963] argued that sufficient trace elements and growth stimulants were provided by the inoculum or substrate and that fermentation maintained anaerobic conditions. A modified [MOD] N-free medium based on GVS was prepared without the reducing solution or trace minerals and with NH₄HCO₃ replaced with NaHCO₃. The Reading Pressure Technique was used to compare these media with respect to the fermentation of maize starch and where MOD was supplemented with urea up to N levels equivalent to that supplied by GVS. The rumen fluid inoculum provided 10 mg N per flask. Cumulative gas values 4, 8, 12 and 24 h post-inoculation of 5.3, 27.6, 68.9 and 103.6 and 6.0, 32.8, 77.7 and 112.7 ml were recorded for GVS and MOD + nitrogen, respectively. The similarity between the two profiles indicates that a highly simplified, non-reduced medium is sufficient. With the urea dose titration, peak rate of gas release occurred 10 h post-inoculation and corresponded with the time point with the greatest differentiation between levels. Using the assumption that the urea-N was totally available, a highly significant regression between these 10 h gas values and supplemental N [r²=0.929, P>0.0001] was obtained. This indicates that gas release kinetics from the fermentation of a N-free substrate can be used as a complement assay to estimate supplemental N availability. Further, the comparison of gas profiles from known N sources with those of amino acids should permit the extent of their utilisation by rumen microorganisms to be determined, and subsequently the

degree to which commercial preparations confer amino acids protection against rumen degradation to be assessed.

Key Words: In Vitro, Simplified Medium, Amino Acids

346 Ruminant degradation of amino acids assessed using a complement *in vitro* technique. F. L. Mould*, K. Kliem, and R. Morgan, *Department of Agriculture, The University of Reading.*

Lysine and methionine are considered the first limiting amino acids in ruminant nutrition, however consistent treatment responses have generally only been found with maize-based diets offered to high-yielding dairy cattle. The potential loss of "protein value" or decreased efficiency of use following microbial degradation led to the concept of protecting free amino acids from rumen microbial degradation. However the extent of this degradation is unclear. A novel complement *in vitro* methodology was used to examine amino acid utilisation by rumen microorganisms. This technique uses the highly significant relationship between supplemental nitrogen availability and the rate of fermentation gas release.

Nine amino acids [Ala, Gln, Glu, Gly, His, Lys, Phe, Met and Ser] were compared to urea at 8, 12 and 16 mg N g⁻¹ maize starch. Each flask contained 1.0 g starch with the rumen fluid inoculum supplying 10 mg N. Each treatment was replicated five times with 16 h cumulative gas values obtained using the Reading Pressure Technique. Fermentation gas release [ml] for the three N inclusion levels [8, 12 and 16 mg] were 114, 118, 159, 97, 90, 85, 104, 92, 131 and 182; 120, 126, 174, 89, 91, 85, 102, 95, 136 and 216; and 111, 132, 197, 91, 86, 89, 91, 103, 135 and 246 for the amino acids, respectively. Compared with the control [0 mg N] value of 85 ml these results suggest that Gly, Hist, Lys and Phe were stable, Met marginal with only Gln and to a lesser extent Glu, Ala and Ser labile. AA-N utilisation, estimated by expressing gas release less the control values, relative to that of urea gave efficiencies of 0.243, 0.314, 0.712, 0.064, 0.035, 0.007, 0.125, 0.084, 0.391 for Ala, Gln, Glu, Gly, His, Lys, Phe, Met and Ser, respectively. If these results are confirmed *in vivo* where factors such as rumen absorption and outflow are considered, it is hypothesised that, provided adequate quantities are supplied [e.g. Met 120 % of requirement] "rumen protection" may not be needed to deliver sufficient levels of specific free amino acids post-ruminally.

Contemporary and Emerging Issues

T1 Effect of inulin on the microflora of an ABT-type fermented milk during refrigerated storage. L. Varga*, B. Gyenis, N. Molnár, and J. Szigeti, *Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.*

The purpose of this research was to investigate the influence of inulin on the microbial flora of a probiotic fermented dairy product during refrigerated storage. Inulin-supplemented and control fermented acidophilus-bifidus-thermophilus (ABT) milks were produced using a fast fermentation starter culture as the source of *Lactobacillus acidophilus* (A), bifidobacteria (B), and *Streptococcus thermophilus* (T), and were then stored at 4°C for 42 d. Microbiological analyses and acidity measurements were performed at weekly intervals. Our results showed that the presence of inulin at 1.0% to 5.0% (w/v) did not significantly influence ($P > 0.05$) the survival of either *S. thermophilus* or *L. acidophilus* during storage. The viable counts of bifidobacteria fell more sharply than did those of lactobacilli and streptococci; however, the addition of inulin at 5% had a significantly beneficial effect ($P < 0.05$) on their viability after 28 d of refrigerated storage. No spoilage organisms were detected at any sampling time, indicating the high degree of sanitation during processing and packaging of the fermented milk products. In conclusion, the commercial inulin product tested was found to have prebiotic properties for bifidobacteria and, thus, it might be used for improving the viability of bifidobacteria in refrigerated fermented dairy foods. **Acknowledgments:** This work was funded by a grant (FKFP 0197/2001) from the Ministry of Education, Hungary. László Varga is grateful to the Hungarian Academy of Sciences for the award of a János Bolyai Research Scholarship.

Key Words: Inulin, Prebiotic, Bifidobacteria

T2 Evaluation of methods for detection of *Escherichia coli* O157:H7 in milk and occurrence of *Escherichia coli* O157:H7 in ex-farm raw milks in Hungary. A. Hucker¹, I. Mike-Schummel¹, L. Varga*², and A. Unger¹, ¹Hungarian Dairy Research Institute, Mosonmagyaróvár, Hungary, ²Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.

Escherichia coli O157:H7 poses a significant threat to public health. The main objective of this study was to evaluate the efficacy of classical protocols and an automated immunoassay system (mini-VIDAS) for detection of *E. coli* O157:H7 in raw milks containing background coliforms and *E. coli*, and in UHT milks deliberately spiked with non-pathogenic *E. coli* strains at various levels. In addition, the incidence of *E. coli* O157:H7 in Hungarian ex-farm raw milks was determined. As for the traditional protocols, PHLS Method 1 and FDA-BAM Method C were found to be highly suitable for detection of *E. coli* O157:H7 in non-pathogenic *E. coli*-spiked UHT milk and real raw milk samples, respectively. However, the mini-VIDAS *E. coli* O157 (ECO) system proved to be superior to the classical methods, with sensitivity, specificity, and accuracy percentages of 100, 97.9, and 99.3, respectively. Two hundred and fifty ex-farm raw milk samples were tested then in mini-VIDAS-ECO and in parallel by the FDA-BAM traditional protocol. The latter method gave 65 negative and 185 uncertain results, which required further identification, whereas mini-VIDAS-ECO gave one positive and 249 negative results. With both methods, only one out of the 250 samples tested was finally confirmed positive. The Duopath *E. coli* O157 test showed that this single positive sample contained an *E. coli* O157:H7 strain, which did not produce verocytotoxin. In conclusion, mini-VIDAS-ECO appears to be a potent tool for detection of *E. coli* O157:H7 in raw milk. With this system, 0.4% of Hungarian ex-farm raw milk samples were found to contain *E. coli* O157:H7.

Key Words: *Escherichia coli* O157:H7, Raw Milk, Immunoassay

T3 Use of powdered microalgae to stimulate acid production and growth of *Lactobacillus plantarum* and *Enterococcus faecium* in milk. B. Gyenis, L. Varga*, J. Szigeti, and N. Molnár, *Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyaróvár, Hungary.*

The objective of this research was to test the capability of microalgal biomasses to stimulate selected lactobacilli and enterococci in milk. Microalgae are photosynthetic microorganisms that can be used to produce high value compounds. Spray-dried microalgal biomasses typically contain 3% to 7% moisture, 46% to 63% protein, 8% to 17% carbohydrates, 4% to 22% lipids, 2% to 4% nucleic acid, 7% to 10% ash, 8% to 10% fiber, and a wide range of vitamins and other biologically active substances. *Chlorella vulgaris* is a green algal species that produces astaxanthin, canthaxanthin and, in minor amounts, β -carotene and lutein. *Arthrospira (Spirulina) platensis* is a planktonic cyanobacterium belonging to prokaryotic algae. It produces γ -linolenic acid in large amounts. The effect of powdered *A. platensis* and *C. vulgaris* biomasses, added at a concentration of 3 g/L, on growth and acid production of *Lactobacillus plantarum* and *Enterococcus faecium* strains primarily used for feed fermentation purposes was evaluated in milks with total solids contents ranging from 12% to 30%. The growth rate of and acid development by *L. plantarum* and *E. faecium* were found to be stimulated significantly ($P < 0.05$) by both *A. platensis* and *C. vulgaris* in all culture media formulations used. Microalgal biomasses had a more stimulatory effect on *E. faecium* than on *L. plantarum*. However, the dry matter content of milks did not influence the growth and acidification properties of the starter organisms tested. In conclusion, the *Chlorella* and *Arthrospira* biomasses rich in bioactive compounds are potentially suitable for use in cost-effective production of milk-based functional fermented feeds.

Key Words: Microalgae, *Lactobacillus plantarum*, *Enterococcus faecium*

T4 Do dairy producers market and manage dairy cows to improve beef quality? P. R. Tozer, G. A. Varga, D. Kniffen*, and W. R. Henning, *Pennsylvania State University, University Park.*

A survey of dairy producers in Pennsylvania was undertaken to ascertain the management of market cows and identify practices to improve the quality of beef from these animals. Ninety progressive dairy producers in Pennsylvania were selected based on recommendations from financial advisers and consultants. Of these 90 producers surveyed 69 provided usable responses to the survey. Producers were asked questions regarding how market cows were sold; condition of cows sold; drug residue notifications; vaccination and injection administration; foot trimming frequency and perceived mobility of market cows. Average herd size of respondents was 250 ± 218 cows, which is much larger than the Pennsylvania state herd average of 69 cows. The results of the survey indicated that most producers still market cattle through auction markets, however, the method of marketing varied across herd size, with smaller producers favoring auctions while larger producers preferred direct sales to the packer. The survey also showed that producers did not use marketing strategies to take advantage of seasonal cow beef price variability. The average number of injections given annually to dairy cows was 19.4 ± 12.4 . The percentage of injections given in the neck varied across strata, very few producers gave all injections in the neck, with a majority of injections (65%) given in other sites, with the tailhead or the hip/rump/flank area being identified as the most common site. Producers also reported an annual rate of 5% of the cows in the herd as downer cows. A downer cow is defined as one that cannot move without assistance. The principal cause of downer cows was metabolic disorders, although again there were differences observed across the different herd size strata. Smaller herds reported metabolic disorders as the principal cause of downer cows, whereas larger herds reported injuries as the major cause of downer cows. The results of this survey suggest that dairy producers have not identified the value in undertaking on-farm meat quality assurance programs.

T5 Effect of using aqueous extracts of Neem (*Azadirachta indica* A. Juss) seeds and leaves on oocyst count in calves. S. Pietrosemoli* and R. Olavez, *La Universidad del Zulia, Maracaibo, Venezuela.*

Aqueous extracts of seeds (AES) and leaves (AEL) of Neem tree were prepared in order to evaluate its potential effect on the oocyte counts (OPG) of grazing calves. Twenty-four crossbred *B. taurus* * *B. indicus* calves (45.6 ± 7.3 kg BW and 38.5 ± 2.49 d) naturally infected were allocated into 4 groups of 6 each; control (T0), 3 cc sulfonamide (25%) / kg BW (T1), AES (T2) 15 cc/ kg BW, and AEL (T3) 15 cc/ kg BW. Aqueous extract were prepared with 60 g of grounded Neem seeds (T2) and 300 g of freshly ground Neem leaves (T3), per liter of water, soaked during 12 hours before being filtered and orally administered once. Calves were fed milk (2 l/d), commercial concentrate (16% CP) *ad libitum*, and handled in *Brachiaria humidicola* pens. Pre and post treatment oocyst counts were performed by using the McMaster modified method on days -3, 7, 14, 21 and 28. Experimental design was a split plot, with treatment as main plots, and days of parasites count as split plots. Initial infestation ($4956,52 \pm 2127,74$) was used as covariate. Data were Log transformed as Log (n+1). Differences between treatments ($p \leq .03$) and days ($p \leq .004$) were found with T0 having the highest OPG count ($p \leq .05$). Although no statistic differences were observed between T1, T2 and T3, lowest OPG was recorded in T3 group. It was concluded that AES and AEL can reduce the oocyst count in calves.

T6 Neem's (*Azadirachta indica* A. Juss) leaves as feeding substrate for vermicomposting earthworm (*Eisenia andrei*). J. Hernández^{1,2}, S. Pietrosemoli^{1,2}, R. Palma², C. Tang*², C. Perozo², and R. Romero², ¹La Universidad del Zulia, Maracaibo, Venezuela, ²Proyecto S1-2000000792 FONACIT, Venezuela.

Four mixtures were tested in a small scale laboratory study, to evaluate Neems leaves potential to be used as feeding substrate for vermicomposting earthworm. Substrates tested were: 100% horse manure M, as substrate for comparison (S1); 100% Freshly-ground Neems leaves FN (S2); 50% M : 50% FN (S3) and 50% M : 50% 15 days shade dried Neems leaves (S4). Before being inoculated, all substrates were composted during 21 days. Four clitellated earthworm were maintained in cylindrical, covered, plastic containers (350 cc) during 84 days, with five replicates for treatment. Biomass and Total cocoon production were recorded weekly. Experimental design used was a split plot design, with substrates as main plot, and days of measurement as split plot. Initial weight (260.5 ± 3.1 mg / earthworm) was used as covariate. Cocoons production data were Log (Log (n+1)) transformed. All substrates supported growth and reproduction, and were successfully vermicomposted. Statistical differences were established between treatments for biomass ($p \leq 0.0001$) (407.0 ± 9.2 ; 844.9 ± 18.1 ; 490.1 ± 17.9 ; 497.0 ± 16.3 mg/ earthworm for S1, S2, S3 and S4 respectively), and for Total cocoon production ($p \leq 0.01$) (14.2 ± 1.2 ; 19.9 ± 1.4 ; 16.9 ± 0.6 and 13.6 ± 1.3 cocoons/earthworm, for S1, S2, S3 and S4 respectively). Earthworm biomass was higher in S2 substrate than in manure only substrate, which showed the lowest value, S3 and S4 achieved intermediate values. S2 showed also the highest values for cocoon production with statistical differences ($p \leq 0.05$) with the other substrates. The 100% Freshly-ground Neems leaves treatment (S2) was considered the best substrate for vermicomposting. It is concluded that Neems leaves can be vermicomposted successfully.

T7 Development and reproduction of *Eisenia andrei* using mixtures of cattle manure and Neems (*Azadirachta indica* A. Juss.) leaves. J Hernández^{1,2}, S Pietrosemoli*^{1,2}, C Contreras², R Palma², and A Faria^{1,2}, ¹La Universidad del Zulia, Maracaibo, Venezuela, ²Proyecto S1-2000000792, Venezuela.

Two laboratory scale experiment were performed in order to evaluate the suitability of use of freshly Neems leaves (NL), alone or mixed with cattle manure (M) to obtain vermicompost. In the first trial, biomass and reproduction were measured during eight weeks. The experimental design was a completely randomized, with 6 treatments and 7 replicates. Pairs of adult earthworms (767.78 ± 274.0 mg BW) were located in plastic containers (350 cc) with six different substrates: 100, 80, 60, 40, 20 and 0% of NL : M, which was used as control. Substrates were composted during 20 days before starting the trial. Weight gain and

cocoon numbers were recorded weekly. Statistical differences between substrates were not found. In the second trial, lasting 10 weeks, newborn earthworms (< 50 mg) from cocoons of the previous experiment were placed in plastic containers (950 cc; 10 per container) with the same substrates tested previously. Weight gain and established growth stage (Juvenile, Preclitellate, clitellate and regression of clitellum) were recorded weekly. The experimental design used was a completely randomized, with 6 treatments and 10 replicates. Statistical differences were observed between treatments; with highest biomass recorded in 80 % NL (535.3 ± 101.0 mg /earthworm), and the lowest in 100 % NL (302.6 ± 124.0 mg /earthworm). Reproductive activity started in week 5 and was observed until week 8. Substrates with 80 and 40 % NL showed highest total cocoon production (22.2 ± 16.88 and 31.0 ± 22.89 cocoons /earthworm respectively); meanwhile the lowest was registered with 100 % NL (4.2 ± 3.27 cocoons /earthworm). All substrates tested were completely vermicomposted. Success with these substrates, suggest that manures offer a well balanced nutrient content, able to satisfy growth and reproduction requirement.

T8 Acquisition and persistence of a high level macrolide resistant *Veillonella* sp. without selection pressure. T. Poole*, J. McReynolds, T. Callaway, and D. Nisbet, *USDA, ARS, College Station, TX.*

High level resistance to macrolide antibiotics, but not lincosamide or streptogramin antibiotics, is characteristic of enzymatic drug inactivation by macrolide phosphotransferase (*mph*) or esterase (*ere*) gene families. A *Veillonella* sp (VL2) was found to have acquired high level resistance to tylosin (a macrolide antibiotic), but not lincomycin, in a closed population of chicken cecal bacteria cultured anaerobically without antibiotic selection pressure. This suggests that a gene, or gene complex, conferring high-level macrolide resistance was acquired from a bacterial species present in the mixed anaerobic population. PCR amplification of VL2 genomic DNA with primers specific to known macrolide, lincosamide, and streptogramin resistance genes (*erm*, *ere*, *vat*, *mef*, and *msr* gene families) were negative. However, PCR amplification with *mph* A/B primers generated a DNA fragment of approximately 750 bp with tylosin resistant (TY^r) VL2, but not tylosin susceptible (TY^s) VL1 DNA. PCR amplification of genomic DNA from three *E. coli* isolates present in the same culture generated the expected (836bp) *mph* specific fragments. To date sequence alignments of the 750 bp fragment have shown partial amino acid identity with a *Salmonella* tyrosine kinase, but very little homology to published sequences of macrolide phosphotransferases. Additional studies are underway to determine the protein responsible for high level macrolide resistance by VL2, as well as the source of gene acquisition. To determine the competitive fitness of VL2, 10⁷ CFU/ml was inoculated simultaneously with 100ml of reconstituted PREEMPT (devoid of high-level tylosin resistant veillonella) to three continuous-flow fermentation devices. To date, two cultures have maintained VL2 for four months at 10³ CFU/ml without selective pressure. These preliminary experiments suggest a low metabolic cost from the acquisition of high level macrolide resistance.

Key Words: Antibiotic Resistance, Macrolide, Anaerobe

T9 Predation survival in rumen protozoa enhances *Salmonella* virulence. M. A. Rasmussen, S. L. Franklin*, and S. A. Carlson, *National Animal Disease Center, ARS,USDA, Ames, IA.*

The objective of this study was to determine if there is a relationship between predation by rumen protozoa and the enhancement of virulence in *Salmonella*. Previous research indicates that intracellular bacterial pathogens can become more pathogenic after engulfment, survival and release from free-living eukaryotic micro-organisms such as amoeba. In order to investigate if such relationships exist within the rumen microbiota, we determined the virulence of *Salmonella* strains after recovery from lysed preparations of mixed rumen protozoa. Virulence was determined using a tissue culture invasion assay (HEp-2 human carcinoma cells) and by monitoring disease progression after oral inoculation of *Salmonella* into calves. Laboratory cultured *Salmonella* isostrains not exposed to protozoa served as controls. Of the strains of *Salmonella* investigated (n=30), only those possessing the DT104 gene cluster encoding antibiotic resistance were found to be hyperinvasive (5-10 x greater than controls) after recovery from lysed rumen protozoa. The hyperinvasive strains included *S. typhimurium* DT104, U302 and multiple antibiotic resistant *S. infantis* and *S. agona*. When inoculated into calves, *S. typhimurium* DT104 recovered from rumen protozoa caused

a more rapid disease progression, including pyrexia (increased body temperature spikes), greater recovery of the bacteria from lymph nodes and spleen, and a more unfavorable prognosis resulting in earlier euthanasia. We conclude that intracellular bacterial/protozoal interactions in the rumen can enhance *Salmonella* virulence. The molecular mechanisms (and their relationship to antibiotic resistance) which contribute to intracellular survival and subsequent bacterial release from protozoa merit further investigation. These observations have implications for mechanisms of disease pathogenesis, rumen microbial ecology, fecal shedding of food borne pathogens from ruminants, and pathogen reservoir status of the rumen.

Key Words: *Salmonella*, Rumen Protozoa, Virulence

T10 More than grass: Organizing the emerging grass-fed beef market. L. Gwin*, *University of California, Berkeley.*

The U.S. market for grass-fed beef has gradually increased over the last decade, most recently spurred by public concern about food safety and the environmental impacts of conventional beef. Numerous challenges exist to the further expansion of grass-fed beef production, yet research on overcoming those challenges is scant. While many producers wish to remain small and sell via direct marketing methods (farmers markets, e.g.), others are attempting to bring grass-fed beef to larger, more mainstream markets. A major challenge is creating the economies of scale and consistency in supply and quality to meet the needs of large buyers such as retail stores, hotels, restaurants, and similar institutions. Managing pasture quality and forage availability though the year, and matching breeds to that forage, are other key challenges. In response, many grass-fed beef producers around the country have formed new programs. Interviews with program participants and review of documents from six such programs, each in a different region of the country, reveal similarities and differences in history, organizational structures, motivations and goals, and basic characteristics. Goals are often similar, yet models vary widely, from vertical integration to producer cooperatives. Programs are also typically rooted in their regions. While conventional commodity markets tend to create standardized products, often erasing regional variation, these programs take advantage of regional assets, both physical and socioeconomic. Yet balancing regional variation with market demand for consistency is addressed in different ways. One program sources nationally and favors the development of national standards for grass-fed, while another has partnered with county government to develop local certification. Consideration of regional assets is critical not only to program design and evolution but also to their future prospects. Understanding which strategies are being used to develop what is currently a niche market into a more mainstream sector will aid in the further development of grass-fed beef into a more widespread production scheme.

T11 Meat carcass inspection using fluorescence of dietary porphyrins. M. A. Rasmussen*¹, T. A. Casey¹, and J. W. Petrich², ¹*National Animal Disease Center, ARS,USDA, Ames, IA,* ²*Iowa State University, Ames.*

Feces on animal carcasses are an important source of food borne pathogens. Imaging devices that could assess the general level of carcass contamination would help to provide high quality meat products to consumers. Inspection procedures have relied upon unaided visual examination of carcasses but it is difficult to thoroughly inspect all carcasses in high speed processing plants using visual means. Imaging technology with real time capabilities and automated inspection would improve current procedures. In our research we have examined several fluorescent markers that could be used to optically detect fecal material. Excitation and emission spectra and fluorescent lifetime measurements were obtained for a variety of ingesta and fecal samples from cattle and other livestock species. Our analysis found that the most useful markers for fecal detection were the highly fluorescent metabolites of chlorophyll (pheophorbide and pyropheophorbide). These metabolites have peak excitation and emission wavelengths near 420 nm and 675 nm respectively. These metabolites are normally present in the G.I. tract of herbivorous animals consuming green plant material. These markers are particularly useful because the background fluorescence of meat is low in the far-red region of the visible spectrum. We have exploited the fluorescent properties of these chemical markers in the development of instruments,

which can detect fecal contamination on meat animal carcasses. Although diet can influence the fluorescent signal obtained, instruments have been designed with adequate sensitivity for the detection of feces from animals consuming a variety of commercial feedlot rations. This imaging technology has been developed through intellectual property protection and technology transfer into commercially produced instru-

ments, which are currently being manufactured and used by the meat processing industry. These instruments augment more time consuming microbiological testing methods and can assist slaughter plant operators and meat inspectors in their efforts to minimize contamination on meat.

Key Words: Feces, Fluorescence, Carcass Inspection

PSA - Nutrition 1

T12 Consequence of meeting non-phytin phosphorus (nPP) requirements with or without feed additives on broiler performance, litter P concentration and processing losses. A. S. Dhandu*¹, R. Angel¹, and W. W. Saylor², ¹Department of Animal and Avian Sciences, University of Maryland, College Park, ²Department of Animal and Food Sciences, University of Delaware, Newark.

Male Ross 308 broilers (56 birds/pen) were raised from hatch to 49 d of age in floor pens containing built up litter from two previous trials of identical design and dietary treatment (DT) allocation. Four feed phases were followed: starter, 1 to 18 d; grower, 18 to 32 d; finisher, 32 to 42 d; and withdrawal, 42 to 49 d. Six DT were tested (9 or 10 pens/DT). The nPP levels of DT 1 were in accordance with NRC (1994) recommendations: 0.45, 0.35, 0.35 and 0.30% nPP in the four feed phases. Following Univ. of Maryland recommendations, the nPP levels for DT 2 were 0.45, 0.31, 0.23 and 0.18%. In DT 3 and 4, nPP levels in the four phases were DT 2 levels reduced by 0.064 and 0.09%, respectively. For DT 5, the DT 1 nPP levels were lowered by 0.1%. The negative control was DT 6 and contained $\leq 90\%$ of DT 2 nPP levels. All diets in DT 3, 4 and 5 contained 600 U of phytase/kg diet. In addition, DT 4 contained 70mg of 25-hydroxycholecalciferol/kg diet. Pine shavings were weighed into pens before the first trial and litter was weighed out after the third trial. At 49 d of age, 22 birds per pen were selected at random, caught and transported by a commercial catching crew and then processed at a commercial plant following existing plant protocols. Tibiae and femurs of processed birds were analyzed for dry-defatted ash. The 49 d BW of birds fed DT 1, 2, 3 and 5 were greater ($P \leq 0.05$) than those fed DT 6. The total P excreted (per bird) by broilers fed DT 3 (12.73 g) and DT 4 (11.37 g) was lower ($P \leq 0.05$) than that of birds fed either DT 1 (19.53 g) or DT 5 (14.68 g). There was no effect ($P > 0.05$) of reducing dietary nPP on carcass yield, incidence of broken wings and legs or bruised back, breast, wings and legs. Tibia and femur ash of birds fed DT 1 was greater ($P \leq 0.05$) than that of those fed DT 6. Lowering dietary nPP concomitant with supplementation of feed additives achieved maximum reduction in litter total P without any negative impact on performance or on processing losses.

Key Words: Broilers, Phosphorus, Processing Loss

T13 The use of low-phytate soybean meal to reduce phosphorus excretion from poultts raised to 18 days of age. J. L. Godwin*, J. L. Grimes, A. G. Gernat, and M. J. Wineland, North Carolina State University, Raleigh.

An experiment was conducted to determine if feeding genetically modified low-phytate (LP) soybean meal (SBM) to turkey poultts would support growth performance equal to or better than those fed diets containing normal SBM and reduce phosphorus (P) excretion from poultts raised to 18d. A phytase enzyme (E) (Alltech; Kentucky) was also incorporated into the trial. One hundred and eighty eight Nicholas male turkey poultts were housed in Petersime batteries with 30 pens (6 birds per pen) at day of hatch with 5 pens per treatment. Five starter rations were fed to poultts in mash form. Treatments consisted of normal SBM+Ca and P at 100% of recommended NRC values (SBM100), LP+Ca and P at 100, 85, and 70% of recommended NRC (LP100, LP85, LP70, respectively) and LP70+enzyme (LP70E). Feed and water were provided ad libitum for 18d. The following parameters were measured; growth performance, AMEn, and apparent nitrogen retention (ANR). Feed consumption and feed to gain, by pen, and individual BW were determined at 6 day intervals to 18d. Also measured at 18d: percent toe and tibia ash, tibia breaking strength, and P levels in fecal samples. Neither mean BW, feed conversion, cumulative feed conversion, toe ash nor tibia ash were significantly affected by treatment. There was a significant linear decrease in tibia breaking strength and increase in AMEn as diets containing LP decreased from 100 to 70%. Tibia breaking strength for LP70E was not different from LP100. ANR and fecal P were significantly affected by

treatment. Fecal P decreased as NRC Ca and P level decreased in LP diets. Fecal P for SBM100 was higher than for LP100 while fecal P for LP70 and LP70E were not different. Using LP resulted in performance equal to SBM while providing reduced fecal P.

Key Words: Low-Phytate SBM, Phosphorus, Turkey Poultts

T14 Phytase activity and phytate hydrolysis along the digestive tract of broiler chicks: A comparative study of two phytase sources. E. M. Onyango*¹, M. R. Bedford², and O. Adeola¹, ¹Purdue University, West Lafayette, IN, ²Zymetrics Inc., Marlborough, Wiltshire, UK.

Residual activity of an *Escherichia coli*-derived phytase and a commercially available *Peniophora* phytase along the digestive tract of broiler chicks was compared in order to evaluate their relative resistance to hydrolysis in the digestive tract. Seventy two 7-d-old male broiler chicks were grouped by weight into six blocks of 3 cages with four birds per cage. Three corn-soybean meal-based diets were randomly assigned to cages within each block. The three diets were a low P diet containing 3.9 g P/kg diet; and low P diet plus either *Escherichia coli*-derived phytase or the *Peniophora* phytase at 1000 units/kg of feed. The chicks were fed experimental diets from 8 to 22 d of age. At the end of the study, chicks were killed and contents from the crop, proventriculus and gizzard, jejunum and ileum were collected, freeze-dried, ground and analyzed for phytase activity and phytate content. *Escherichia coli*-derived phytase had more residual activity at the crop ($P < 0.01$), proventriculus and gizzard ($P < 0.05$), jejunum ($P < 0.001$) and ileum ($P < 0.0001$) when compared with the *Peniophora* phytase. Less phytate remained in the digesta collected from the proventriculus and gizzard ($P < 0.05$), jejunum ($P < 0.01$) and ileum ($P < 0.05$) in birds fed *Escherichia coli*-derived phytase compared with those fed *Peniophora* phytase. The *Escherichia coli*-derived phytase may be more resistant to hydrolysis in the digestive tract when compared with the *Peniophora* phytase, and may be related to the superior phytate hydrolysis observed.

Key Words: Broiler Chick, *Escherichia coli* Phytase, Residual Phytase Activity

T15 Requirement of methionine of broilers during finishing period. F. Liu*, Z. Niu, and S. Zhai, College of Science & Technology, Northwest Sci-Tech University of Agriculture & Forestry.

The objective of this experiment was to evaluate the requirement of broilers during four to six weeks of age. Five hundred male broiler chicks from Arbor Acres commercial strains were divided into five groups, each of five replicates. The diets were based on corn-soybean meal which the level of methionine was 0.25%, 0.30%, 0.35%, 0.40%, 0.45% respectively. Each group of birds was fed one kind of the five diets above for two weeks. The results showed that there were significant effects of different levels of dietary methionine on growth performance and plasma uric acid content. BW and FC were significantly decreased at lower methionine (0.25% 0.30%), but uric acid level of plasma increased significantly. The BW and FC were not increased significantly at higher dietary level, but uric acid content was greatly increased. This study indicated that the requirement of methionine of broilers during finishing stage was 0.35% 0.40% in the diet.

Key Words: Methionine, Growth Performance, Broiler

T16 Impact of methionine source and excess choline on growth performance of broilers during the starter period. P. B. Pillai*¹, A. C. Fanatico¹, J. C. Townsend¹, K. W. Beers², and J. L. Emmert¹, ¹University of Arkansas, Fayetteville, ²Safe Foods Corporation, Rogers, AR.

Experiments were conducted to assess the impact of excess choline (CHO) or betaine (BET) on growth performance of broilers fed graded levels of DL-methionine (DLM) or 2-hydroxy-4-methylthiobutanoic acid (HMB) during the starter period. In experiment 1, a corn-peanut meal diet deficient in methionine (MET; 0.23% digestible) and cysteine (CYS; 0.25% digestible) was fed; treatments consisted of graded levels (0, 0.04, or 0.08%) of MET from DLM or HMB (additions adjusted for 88% purity) that were fed in the presence or absence of excess isomethyl CHO (0.25%) or BET (0.28%). In the experiment 2, identical treatments were used, but the basal diet was adequate in CYS (0.42% digestible). There was no overall impact of CHO or BET on growth performance in experiments 1 and 2 ($P > 0.05$); a significant improvement ($P < 0.05$) in weight gain and feed efficiency did occur with CHO and BET addition to basal diet in experiment 2. In both experiments, weight gain increased linearly ($P < 0.05$) with the addition of graded levels of DLM or HMB. Slope ratio methodology was used to assess HMB efficacy. In experiment 1, efficacy was 64.7% when HMB was fed without excess CHO or BET. Efficacy was significantly improved ($P < 0.05$) by excess CHO (79.2%) and numerically improved by excess BET (74.1%). In experiment 2, presence of adequate CYS improved HMB efficacy to 92.1%; addition of excess BET did not impact HMB efficacy (90.7%). However, addition of excess CHO to the CYS-adequate diet significantly reduced ($P < 0.05$) HMB efficacy (77.3%). In conclusion, excess CHO and BET appeared to improve HMB efficacy when added to a diet deficient in both MET and CYS, but not when added to a diet deficient in MET only. Further, presence of adequate CYS appeared to improve HMB efficacy relative to chicks fed a diet deficient in both MET and CYS. These data suggest that levels of CHO and BET and type of SAA deficiency impact HMB efficacy.

Key Words: Choline, Betaine, Sulfur Amino Acids

T17 The effect of dietary factors on induction of fatty liver-hemorrhagic syndrome and its diagnosis methods with use of serum and liver parameters in laying hens. M. Yousefi*¹, M. Shivazad², and I. Sohrabi Hafhdooost³, ¹Ph.D Student of Islamic Azad University, Science & Research Campus, Tehran, Iran, ²Department of Animal and Poultry Science, University of Tehran, Karaj, Iran, ³Department of Pathobiology, Islamic Azad University, Science & Research Campus, Tehran, Iran.

An experiment was conducted to determine: The effect of dietary factors on induction of fatty liver-hemorrhagic syndrome (FLHS) and its diagnosis methods with use of selected serum enzymes on Hy-Line W-36 hens. The experiment was conducted in completed random design (CRD) with 6 dietary treatments and 4 replicates pen each with ten hens from 94 to 106 wk of age. Three 28-d periods used from different dietary factors including: 1) control (C) 2) Low Methionine (LM) 3) Low Linoleic Acid (LLA) 4) High Energy (HE) 5) Low Methionine, Linoleic Acid, Choline and High Energy (LM-LLA-LCH-HE) and 6) Low Choline (LCH). Feed intake, body weight, egg production (EP), egg weight, egg quality, serum and liver parameters were measured the end of each 28-d periods. Overall feed intake was significantly ($P < 0.05$) lower for the hens fed HE diets compared to the control. Body weight was lower for all dietary treatments throughout the experiment compared to the control. Overall egg weight was significantly ($P < 0.05$) lower for the hens fed LM and LM-LLA-LCH-HE compared to the control. EP and egg quality were not significantly affected by dietary treatments. Overall liver hemorrhage score (LHS) was greater for the hens fed all dietary treatments except HE diet compared to the control. LHS was positively correlated ($P < 0.05$) with liver weight. Serum enzyme activities including: aspartate amino transferase (AST), alanine amino transferase (ALT), lactate dehydrogenase (LDH) were not significantly affected by dietary treatments. Although the AST enzyme activity was not significantly different, but it was numerically higher for all dietary treatments except HE diet. The results showed the effectiveness dietary factors on induction of FLHS in laying hens. AST enzyme activity could be used for diagnosis of FLHS in laying hens.

Key Words: Fatty Liver Hemorrhagic Syndrome, Dietary Factors, Enzyme

T18 The effect of dietary treatments flaxseed, yeast, soy fatty acid on fatty liver-hemorrhagic syndrome in laying hens. M. Yousefi*^{1,3}, M. Shivazad², and I. Sohrabi Hafhdooost³, ¹Department of Animal and Poultry Science, Islamic Azad University of Saveh, Saveh, Iran, ²Department of Animal and Poultry Science, University of Tehran, Karaj, Iran, ³Department of Pathobiology, Islamic Azad University, Science & Research Campus, Tehran, Iran.

An experiment was conducted to determine: 1) The effect of dietary treatments on fatty liver-hemorrhagic syndrome (FLHS) in Hy-line W-36 hens. The experiment was conducted in completed random design with 6 dietary treatments and 4 replicates pen each with ten hens from 106 to 110 wk of age. In experiment: different dietary treatments including: 1) Control (C)- 4% Soy Fatty acid + Methionine (4% SFA)- Linoleic Acid (LA)- 0.05% Yeast (*Saccharomyces Cerevisiae*) + Balanced Energy (0.05% SC)- Methionine + Linoleic Acid + Choline + Balanced Energy (M + LA + CH + BE) - 5% Flaxseed + Choline (5% FS) were compared for treatment of FLHS during 28-d period. In experiment: Body weight was lower for the hens fed all dietary treatments compared to the control. Egg weight was significantly ($P < 0.05$) lower for the hens fed 5% FS compared to the control. Liver weight was lower for the hens fed 0.05% SC and 5% FS compared to the control. Liver hemorrhage score was positively correlated ($p < 0.05$) with liver weight. The results showed body weight and liver weight are 2 of the inducing factors for FLHS that which were decreased by yeast and flaxseed.

Key Words: Fatty Liver-Hemorrhagic Syndrome, Dietary Treatments, Liver

T19 Efficiency of folate deposition in eggs throughout the production cycle of Hyline W98 and W36 laying hens. K. Hebert*¹, J. D. House, and W. Guenter, University of Manitoba, Winnipeg, MB, Canada.

With previous research to document that supplementing diets with 4 mg crystalline folic acid/kg yielded 90% maximal egg folate concentrations, a study was designed to determine the age and rate of production effects of laying hens on egg folate level, and the potential for differences due to strain of birds. Hyline W36 and W98 hens ($n = 156$ /treatment) received a barley-based ration, containing 0 and 4 mg/kg of crystalline folic acid for eleven 4-week periods. Response criteria included production parameters, egg quality measurements and measures of egg folate content. There was no significant difference ($P < 0.05$) in performance parameters or egg quality measurements due to folate supplementation. Hyline W98 had significantly ($P < 0.05$) higher feed consumption (FC), egg weight, yolk weight, body weight and lower percent yolk of egg weight than the W36 strain. Throughout the production cycle egg production (EP) and feed efficiency (FE) increased to peak and then decreased. FC, egg weight, yolk weight and percent yolk of egg weight significantly ($P < 0.05$) increased, and specific gravity significantly ($P < 0.05$) decreased throughout the production cycle. A significant ($P < 0.05$) ration x strain interaction was evident for EP and FC, as Hyline W98 hens exhibited higher EP and FC than W36 with supplementation level of 4 mg/kg. A significant ($P < 0.05$) strain x period interaction was evident for EP, FC, FE, egg weight and yolk weight. A significant ($P < 0.05$) ration x period interaction was evident for FC and FE. Overall, performance was not affected by long-term folate supplementation.

T20 Effects of supplemental dietary Vitamin E and selenium from two sources of egg production and vitelline membrane strength in laying hens. D. Monsalve*, G. Froning, M. Beck, and S. E. Scheideler, University of Nebraska, Lincoln.

Separation of the egg yolk from the albumen is extremely important in order to avoid yolk contamination; the strength of the vitelline membrane (VMS) is a key factor in this step. Information concerning effects of vitamin E and selenium (Se) supplementation in hens on VMS, whipping performance, and production parameters during heat stress is limited. Two hundred eighty eight, 26 wk old Bovan laying hens were assigned to 48 cages (6 hens/cage) in a 3x2x2 factorial arrangement of 3 levels supplemental α -tocopherol E (50 or 100 or 150 IU/Kg), 2 levels of Se (0.25 ppm or 0.50 ppm), and 2 sources of Se (inorganic or organic) added to corn-soybean meal based diets. Birds were maintained

at environmental temperatures during the summer months of July, August, and September. Egg production, feed intake were recorded daily, egg weights were determined weekly, and body weight on a monthly basis. Eggs collected from each treatment were analyzed for vitamin E and Se content in the yolk, yolk pH, albumen pH, angel cake volume, foam stability, yolk viscosity, and Haugh units. An Instron universal testing machine (4500 series) equipped with back-extrusion food cell, with a 2-kg tension load and crosshead speed 10mm/min, was used to measure VMS of fresh and aged (2 weeks) eggs. Results showed that hens fed diets with 0.50 ppm of Se laid 1.68% more eggs, weighed 19 more grams, and consumed 2.58 g more feed than those fed the same diets with 0.25 ppm of Se. Addition of 150 UI/kg vitamin E in the diet significantly ($P \leq .05$) increased VMS of fresh eggs by 0.05 and 0.08 kg/mm, respectively, in contrast to 100 and 50 UI/kg vitamin E in the diet. A similar trend was observed with aged eggs, in which VMS was significantly ($P \leq .05$) greater for eggs from hens on diets supplemented with 150 UI/kg compared to 100 and/or 50 UI/kg vitamin E. This study suggests that addition of vitamin E and Se diets during summer time improved VMS for both fresh and aged eggs.

Key Words: Vitelline Membrane, Vitamin E, Selenium

T21 Performance of broilers fed diets containing 2-hydroxy-4-methylthiobutanic acid at different inclusion rates. A. B. Batal¹, J. L. Emmert², P. B. Pillai², B. L. Lumpkins*¹, and M. E. Blair³, ¹University of Georgia, Athens, ²University of Arkansas, Fayetteville, ³Adisseo, Alpharetta, GA.

Three experiments were conducted to evaluate the effects of feeding different methionine sources, 2-hydroxy-4-methylthiobutanic acid (RhodimetTM AT88, Adisseo) or DL-methionine (RhodimetTM NP 99, Adisseo) to broilers on performance and carcass yield. AT88 was added to the experimental diets on a weight basis according to assigned efficacy values (88, 82, and 70% in Experiment 1; 88, 82, 75, and 70% in Experiments 2 and 3). As the AT88 efficacy value decreased, the level of supplemented AT88 increased to meet the methionine requirement (e.g. DLM, 0.27%; AT88-88%, 0.307%; AT88-70%, 0.39%). Each of the dietary treatments was fed to 6 replicate pens of 45 (Experiment 1) or 25 chicks per pen (Experiments 2 and 3). Experiments 2 and 3 followed the same experimental design, protocol, and diets were mixed simultaneously at one location while the experiments were conducted at two different research facilities. A methionine-deficient basal diet was manufactured for each of the feeding periods; Experiment 1, 3 periods, starter (0-22 d), grower (22-42 d) and finisher (42-56d); Experiments 2 and 3, 4 periods starter (0-16 d), grower (16-32 d), finisher (32-40 d), and withdrawal (40-50 d). The basal diet was based upon the current Agri Stat commercial baseline values for nutrients, with supplemental methionine omitted (practical-type diet). In Experiment 1, growth rate and carcass yield of birds fed AT88 with an efficacy value of 88% was similar to birds fed DLM. However, birds fed AT88 with an efficacy value of 70% (such that more AT88 is added to the diet) had slightly reduced weight gain through out the study and numerically lower carcass yield relative to birds fed DLM or AT88 with an efficacy value of 88%. In Experiments 2 and 3, no effect on performance, carcass or breast meat yield were observed due to any AT88 efficacy level employed. The results suggest that even at a calculated efficacy of 88%, growth rate and carcass yield of broilers fed AT88 was similar to that of birds fed DLM and that lowering the efficacy of AT88 may depress carcass yield (Experiment 1).

Key Words: Methionine hydroxyl analog (AT88), DL-methionine, Broiler chicks

T22 The effects of dietary herbal extracts for broiler chickens. M. R. Lewis*¹, S. P. Rose¹, A. M. Mackenzie¹, and J. Smith², ¹National Institute of Poultry Husbandry, Harper Adams University College, UK, ²Braes Feed Ingredients Limited, UK.

Limitations concerning the use of antibiotics in poultry feed in Europe have stimulated the search for alternatives in order to remain competitive. Herbs contain many active components that have a wide range of pharmacological properties. However, as yet limited data have been presented to support their efficacy or elucidate mode of action in practical poultry diets. Initial screening experiments investigated the effects of 6 herbs (garlic, yarrow, horseradish, milk thistle, juniper and oregano) on growth performance. Birds fed yarrow supplemented diets (1800mg/kg) showed improved FCE ($P < 0.05$) in the latter growth stage (17-27 days

of age) compared with birds fed the unsupplemented control diets. Further experiments have focused on how yarrow exerts its performance effects. It was thought that antibacterial components found in yarrow (such as 1,8-cineole) might exert a positive effect on gut microflora. A large floor pen experiment was therefore conducted, and caecal populations of *Escherichia coli*, *Bacteroides fragilis* group and lactic acid bacteria were enumerated anaerobically. Consistent performance effects were seen in birds fed diets containing yarrow: higher weight gains, $P < 0.001$ and increased feed intake $P < 0.05$ relative to unsupplemented controls; 18-36 days of age. However, no differences were observed in caecal microflora populations, indicating that yarrow does not mediate its effects through moderation of gut flora. The latest in this series of experiments has concentrated on the effects of yarrow on nutrient digestibility in chicks fed adequate and diluted (10% less nutrient dense) diets with and without yarrow. There was a diet x yarrow interaction: birds fed diluted diets supplemented with yarrow showed higher feed intake ($P < 0.05$) and a tendency for higher weight gain ($P = 0.08$) than their non-supplemented counterparts. Initial evidence indicates that both diet dilution and yarrow supplementation increase pancreas weights. More detailed measurements of ileal pancreatic enzyme activity are currently underway. These data should provide a valuable insight into the *in vivo* mode of action of yarrow.

Key Words: Herbal, Yarrow, Digestibility

T23 Effects of organogermanium on performance and immune response in broilers. Z. Niu*, X. Liang, F. Liu, M. Xie, and Y. Wang, College of Animal Science & Technology, Northwest Sci-Tech University of Agriculture & Forestry, Yangling, China.

The objective of this experiment was to study the effects of carboxyethyl germanium sesquioxide (Ge-132) on the growth performance and immune response of broilers. 240 Avian broiler chicks were assigned to one of four dietary treatments which was supplemented with 0mg/kg, 30mg/kg, 80mg/kg, and 120mg/kg Ge-132 resp.. The birds were reared for 7 weeks. The result of the experiment indicated that: (1) There were no significant efficacy of supplemented with Ge-132 in diets on body weight, feed intake, growth rate, and feed efficiency of broilers at 49 days old of age; (2) The weight of immune organs, including bursa of Fabricius, thymus, and spleen, weren't affected significantly by supplementation of Ge-132, but the level of the antibody of NDV was significantly higher as compared with the control group at 28 days of age.

Key Words: Germanium, Immune Function, Growth Performance

T24 Justifying effects of grain particle size on broiler performance and carcass quality. A. S. Parsons* and J. S. Moritz, West Virginia University, Morgantown.

Corn particle size has been suggested to affect broiler performance. However, a specific understanding of particle size effects has not been determined. In a previous study, experimental treatments consisted of five similarly formulated mash diets varying in corn particle size (781 μ m, 950 μ m, 1042 μ m, 1109 μ m, 2242 μ m). Each of these diets was fed to 13 replicate floor-pens of 21 straight-run 308x344 Ross broilers during the growing period. Regression analysis showed an increasing trend in feed intake ($P = 0.0016$) and gizzard weight ($P = 0.0001$) as particle size of mash diets increased; however, feed efficiency ($P = 0.0058$) and percent breast yield ($P = 0.0250$) decreased. The objective of the current study was to explain these trends via true metabolizable energy (TME), particle size preference and passage rate studies using similar diets. Regression analysis of a six replicate TME study showed a quadratic trend ($P = 0.0049$) as dietary particle size increased. Particle size preference was determined by feeding diets to broilers (4.5 wk) over a 12 hr period with particle size determined at 3 hr intervals. Preference varied due to a treatment by time of collection interaction ($P = 0.0282$). Diet particle size either significantly or numerically increased during the initial 3 hr period, while remaining similar to initial diet particle size for the second 3 hr period ($P \geq 0.05$). Particle size of diets containing fine, small or coarse corn (864 μ m, 927 μ m, 1515 μ m respectively) decreased over the final 3 hr period ($P \leq 0.05$) suggesting that size preference decreased as availability of larger particles decreased. Particle size of diets containing medium or large corn (943 μ m and 1065 μ m respectively) decreased for the remaining 6 hr period ($P \leq 0.05$) suggesting again, there was a preference for larger particles. Despite an initial preference for smaller

particles, it was necessary for birds in the floor-pen study to also consume larger particles to allow replenishment of feed in the trough. Diets containing larger particles showed a decrease in TME, which may explain the increase in FI and the decrease in FE observed in the floor-pen study.

Key Words: Particle Size, TME, Preference

T25 Effects of pelleting protein concentrate pellets on feed mill throughput and electrical efficiency. P. M. Clark* and K. C. Behnke, *Kansas State University, Manhattan.*

The efficacy of blending cracked corn and a pelleted protein concentrate to improve feed mill throughput, with emphasis on electrical consumption and pellet quality, was studied. A complete, pelleted corn-soybean meal-based broiler grower diet (Diet 1) was compared to pelleted protein supplements blended with two levels of cracked corn (15% and 30%; Diet 2 and Diet 3, respectively). All diets were formulated to be isocaloric and isonitrogenous. No. 2 yellow dent corn was cracked on a Roskamp three-high roller mill. Roll gaps were set at 2.46 mm for the top rolls with the bottom two sets of rolls being left open to achieve a particle size of 75% of the corn + #10 U.S. screen. The roller mill and hammer mill were set for equivalent production rates and electrical consumption was collected on both machines. The sifted fines from the cracked corn were then returned to the diet as part of the corn fraction. The complete diet and protein pellets were formed on a CPM pellet mill using a 4 mm x 32 mm (5/32" x 1") die, conditioned at 82 °C (180 °F). Treatment comparisons were analyzed by ANOVA using the Proc Mixed procedure of SAS (2001). The roller mill consumed 4.4 kWh/ton less electricity than the hammer mill. This can be calculated to be approximately \$0.28/ton. The pelleted protein concentrates, Diet 2 and 3, were not significantly different ($P < .05$) than Diet 1 in pellet durability (PDI), % fines produced, and electrical energy consumption. PDI for Diets 1, 2, and 3 were 80.19, 80.74, and 82.49 respectively. Fines percentages for the diets were 7.1, 6.96, and 6.56% for Diets 1, 2, and 3. Electrical consumption of the pellet mill was 3.19, 3.19, 3.36 kWh for Diets 1, 2, and 3, respectively. Overall, throughput in a feed mill can be increased to approximately 20% without sacrificing pellet quality with minimal influence on electrical energy consumption.

Key Words: Pellet Quality, Electrical Consumption

T26 Effects of feeding blends of grains naturally-contaminated with *Fusarium* mycotoxins on performance and metabolism of turkeys. S. R. Chowdhury* and T. K. Smith, *University of Guelph, Guelph, ON, Canada.*

There is a lack of information in the literature regarding the effect of feeding turkeys grains naturally-contaminated with *Fusarium* mycotoxins. Studies were conducted, therefore, to characterize the toxicity to turkeys of grains naturally-contaminated with *Fusarium* mycotoxins and to determine the efficacy of a polymeric glucomannan mycotoxin adsorbent (GMA). Two hundred and twenty-five day-old male turkey poults were fed corn, wheat and soybean meal based starter (0-3 wks), grower (4-6 wks), developer (7-9 wks) and finisher (10-12 wks) diets for 12 wks. The diets included: (1) control (2) contaminated grains (3) contaminated grains + 0.2% GMA. The feeding of contaminated grains decreased weight gain compared to controls in the starter, developer and finisher period. Weight gains increased, however, when contaminated grains were fed in the grower period. Supplementation of contaminated grains with GMA, moreover, increased body weight gain compared to unsupplemented contaminated grains throughout the experiment. There were no significant effects of diet on feed consumption. Feed efficiency increased in the grower period but decreased in the developer period compared to controls when birds were fed contaminated grains. Plasma concentrations of calcium, total protein, albumin, globulin, and uric acid were decreased after 4 wks of feeding contaminated grains compared to controls. The feeding of contaminated grains increased plasma cholesterol concentration and decreased bilirubin and uric acid concentrations after 8 wks compared to controls. Plasma phosphorus concentrations increased after 4 wks, however, decreased after 8 and 12 wks of feeding contaminated grains compared to controls. It was concluded that turkeys are sensitive to the feeding of combinations of *Fusarium* mycotoxins as seen in the reductions in performance and the alterations in

plasma chemistry and that the feeding of GMA could largely prevent the mycotoxicosis from occurring.

Key Words: Turkey, *Fusarium* Mycotoxins, Performance and Metabolism

T27 Effect of Avizyme® 1502 on increasing protein and energy retention when feeding to Bovans White pullets. C. Troche*¹, X. Sun¹, C. Novak¹, and J. Remus², ¹*Virginia Tech, Blacksburg,* ²*Danisco Animal Nutrition.*

Bovans white leghorn pullets (n = 768) were used to determine the effect of Avizyme® 1502 (AZ 1502) on protein (PR) and energy retention (ER). Diets were formulated according to the management guide for the starter (S -0 to 6 wks), grower (G -6 to 10 wks), developer (D -10 to 15 wks) and pre-lay (P -15 to 18 wks) periods. The 18-wk 2 x 2 x 2 factorial experiment consisted of 2 levels of energy (ME 2980, 2970, 2960, 2842 kcal/kg for S, G, D, P vs 3% energy reduction per period), dietary protein (CP 20, 18, 16, 15 % for S, G, D, P vs 1% unit protein reduction per period) and AZ 1502 (w/wo). Enzyme was added at 0.05 % to 8 wks and at 0.0375 % from 9 to 18 wks. Each trt was replicated 8 times (12 birds per replicate pen). During the D period, feed consumption was reduced ($P < 0.05$) by the inclusion of enzyme (2205.4 vs 2141.6 g/b/period). No differences were seen in cumulative weight gain at 18 wks, while cumulative F:G was improved ($P < 0.05$) by the supplementation of AZ 1502 (4.64 vs 4.72). Pullets fed the high energy diets had superior ER ($P < 0.05$) in the S (82.8 vs 81.7%) and D periods (79.1 vs 76.3%), but reduced ($P < 0.05$) ER (82.0 vs 80.9%) during the G period compared to pullets fed the reduced energy diets. Pullets consuming high protein diets had improved ER ($P < 0.05$) in the S (83.0 vs 81.4%) and G periods (82.0 vs 80.9%) compared to the reduced protein group. AZ 1502 supplementation increased ER ($P < 0.003$) in the S (82.7 vs 81.8%) and G periods (81.8 vs 81.1%), but reduced ($P < 0.05$) it during the P period (77.7 vs 76.3%). PR also improved in the S and G periods with AZ 1502 addition but decreased in P. Feeding various levels of protein and energy w/wo enzyme had no affect on most growth performance criteria evaluated, but did influence nutrient retention. When evaluating production cost, AZ 1502 supplementation decreased overall cost by as much as \$0.01/kg of gain, making enzyme supplementation a worthwhile consideration for raising pullets.

Key Words: Corn-Soy Enzymes, Retention, Pullets

T28 Fermenting sludge from a broiler processing plant: Effect of different levels of cane molasses . R. Sanabria León*, S. Pagán Riestra, A. A. Rodríguez, H. Santiago, and M. Pagán, *University of Puerto Rico, Mayagüez Campus, Mayagüez, PR.*

An experiment was conducted to determine the optimum level of addition of cane molasses as carbohydrate source on the fermentation characteristics of sludge from a broiler processing plant (SBPP). The SBPP was inoculated with lactic acid-producing bacteria applied at 106 cfu/g of fresh material. Inoculated SBPP was mixed with 5 five levels of cane molasses (0, 5, 10, 20, and 30%, w/w), placed into 1 kg capacity silos fitted with valves for gas release, and maintained at room temperature (28-30°C). Three silos per treatment were opened after 6 fermentation periods (0, 4, 7, 9, 14 and 21 d) and silage was analyzed to determine pH, chemical composition, and fermentation products. A completely randomized design with a 4 (levels of cane molasses) x 6 (fermentation periods) factorial arrangement of treatments was used for the correspondent statistical analysis. Mean separation was performed by Bonferroni t-test. Control sludge had higher ($P < .05$) pH than SBPP fermented with cane molasses. Sludge treated with 10, 20 and 30% cane molasses had lower pH (4.46, 4.49, and 4.58, respectively) than SBPP ensiled with a 5% level during the complete fermentation period. Also, dry matter and organic matter were higher ($P < .05$), and crude protein was lower ($P < .05$) as the levels of cane molasses increased. For all fermentations, lactic acid production was higher ($P < .05$) for treatments containing 10, 20 and 30% cane molasses. Propionic acid content was lower ($P < .05$) for treatments with a 20 and 30% cane molasses as compared to the other mixtures. Butiric acid content was higher ($P < .05$) for a 5% cane molasses treatment than sludge with a 0, 10, 20, and 30%. These results suggest that it is possible to ferment SBPP using cane molasses as a carbohydrate source. Levels higher than 10% of the sugar did not result in a better fermentation.

T29 The amino acid ideal pattern for Pekin ducks during early growing period. Y. Wang*, Z. Niu, and F. Liu, *Northwest Sci-Tech University of Agriculture & Forestry, Yangling, China.*

Five experiments were conducted to set up the ideal pattern of amino acid requirement of Pekin ducks. In experiment 1, the digestibility of some amino acids in the basal diet were determined, including lysine (Lys), methionine (Met), tryptophan (Trp), threonine (Thr), and isoleucine (Ile). In experiment 2, the growth performance was investigated to effect of different levels of Lys, Met, and Trp, and their interaction under a 3×3 factorial arrangement. The experiment 3 was conducted to evaluate the influence of different levels of Trp, Thr, and Ile, and their interaction. The experiment 4 was carried out to investigate the efficacy of different levels of Trp, Thr, and Ile in a lower protein-diet. In experiment 5, based on the results above, six amino acid models were used to test in order to select a ideal model. The results showed that Lys, Met, Trp, Thr, and Ile requirement of Pekin ducks during 0-2 week was 1.10%, 0.46%, 0.24%, 0.42%, and 0.53% resp., and the digestive amino acid requirement was 1.02%, 0.44%, 0.21%, 0.38%, and 0.47% resp. The total amino acid ideal pattern for duckling was: Lys:Met:Trp:Thr:Ile=100:41:21:38:48, and the digestive amino acid ideal pattern was: Lys:Met:Trp:Thr:Ile=100:43:21:37:46.

Key Words: Pekin Duck, Amino Acid, Ideal Pattern

Nonruminant Nutrition: Grow/Finish - Energy & Protein

T31 Advantages of formulating diets based on net energy on pig performance, carcass characteristics and production economics. M. Rademacher*¹ and L. Hagemann², ¹Degussa AG, Hanau, Germany, ²State Office for Consumer Protection and Agriculture of Brandenburg, Teltow, Germany.

The objective of this study was to determine the effect of dietary energy formulation system on performance, carcass quality and production cost. A total of 126 pigs were used in a three phase-feeding program (phase I: 32 to 50 kg, phase II: 50 to 80 kg, phase III: 80 to 112 kg) in the weight range 32 to 112 kg. Pigs were housed in groups of 14 on a partially slatted floor. Feed was offered ad libitum via a FIRE system (Feed Intake Recording Equipment). Water was provided from low pressure nipple drinkers. Wheat-barley-rye and soybean meal based diets were formulated. Within each growth phase (Phase I, II and III), three diets (A, B, C) were formulated to provide similar digestible amino acid contents. Diets A within each phase were formulated on ME basis and standard dietary CP levels. Diets B were reduced CP diets formulated on ME basis. Diets C were formulated to the same CP contents as Diets B but taking into account the net energy (NE) values of the ingredients. During the overall growing-finishing period, feed intake and feed efficiency were not affected ($P > 0.05$) comparing the 3 experimental groups. Growth rate was significantly affected ($P < 0.05$) with group B having a lower ADG compared with group C (836 vs 868 g/d) and group A (854 g/d) being intermediate. Lean gain of groups A, B and C was 422, 411 and 432 g/d ($P > 0.05$), respectively. The economic impact of comparing group A with group C resulted in a reduction in feed cost per pig by 0.63 EUR (30.62 vs 29.99 EUR), carcass value was improved by 1.10 EUR (109.63 vs 110.73 EUR) and carcass value minus feed cost was improved by 1.73 EUR per pig. Dietary CP can be reduced in growing-finishing diets without affecting growth rate, feed intake, feed efficiency and carcass quality as long as diets are formulated based on the NE concept in combination with digestible amino acids and limiting amino acids supplemented according to the ideal protein concept. This will further result in higher profit due to improved pig performance, better carcass quality and savings in feed costs.

Key Words: Pigs, Energy Systems, Performance

T32 The effects of dietary oil inclusion and oil source on apparent digestibility, fecal volatile fatty acid concentration and manure ammonia emission. A. G. B. Leek¹, V. E. Beattie², and J. V. O' Doherty*¹, ¹Department of Animal Science and Production, University College Dublin, Dublin, Ireland, ²Devenish Nutrition Ltd., Belfast, North Ireland.

An investigation was conducted to test the hypothesis that dietary oil inclusion increases ammonia nitrogen (NH₃-N) emission from the ma-

T30 Transgenic chickens expressing beta-galactosidase hydrolyze lactose in the intestine. S. Pophal*^{1,2}, P. Mozdziak¹, S. Borwornpinyo¹, and J. Petite¹, ¹North Carolina State University, Raleigh, ²Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Chickens do not possess the necessary enzymes to efficiently hydrolyze lactose into glucose and galactose. The bacterial enzyme beta-galactosidase can convert lactose into glucose and galactose. Transgenic chickens that carry the E. coli lacZ gene and express beta-galactosidase could potentially employ lactose as an energy source. The objective of this study was to determine the ability of the small intestinal mucosa from transgenic chickens to hydrolyze lactose into glucose and galactose. Lactase activity was examined in the intestinal mucosa from wild-type chickens and two lines of chickens that carry the lacZ gene and express beta-galactosidase. Lactase activity was significantly ($P < 0.05$) higher in both transgenic lines compared to wild-type birds. The presence of the beta-galactosidase enzyme was revealed via X-gal staining in the intestine of transgenic chickens, while it was not present in the wild-type chickens. Overall, it appears that inserting the lacZ gene, which encodes beta-galactosidase has resulted in a chicken that can utilize lactose as an energy source. This study demonstrates that transgenic technology can be used to modify nutrient utilization in domestic poultry.

Key Words: LacZ, Lactase, Transgenic

nure, due to a negative effect of either unsaturated or saturated oil on microbial activity in the intestine. Dietary oil was included at 45 g/kg, as either crude palm oil (PO), soya oil (SO) or a 50:50 PO:SO blend (OB), to a basal barley-soya-wheat diet (control) at the expense of dextrose and maize starch. Diets were formulated to contain 13.2 MJ DE/kg and 11.0 g/kg lysine. Four boars were assigned to each dietary treatment, and were transferred to metabolism crates (mean live weight, 74.0 kg ± 2.89) following 14 days dietary acclimation. Urine and feces were collected separately over a 5-day digestibility/nitrogen (N) balance period and a 2-day manure collection period. Inclusion of dietary oil increased apparent digestibility of oil ($P < 0.01$) and decreased the apparent digestibility of dry matter ($P < 0.01$) and gross energy ($P < 0.05$). Dietary oil did not affect the apparent nitrogen, acid detergent fibre, neutral detergent fibre or hemicellulose digestibility. Apparent digestibility of oil was lower when oil was included as PO compared to SO and OB ($P < 0.001$). The concentration of faecal volatile fatty acid (VFA) was similar in all treatments, although the acetic:propionic acid was lower when oil was included as PO and OB compared to SO ($P < 0.05$). N balance, manure N concentration and NH₃-N emission was not affected by oil inclusion or oil source. In conclusion, dietary oil inclusion reduced apparent dry matter and energy digestibilities, although no effect on fermentation was indicated by digestibility of fibre or faecal VFA content. Consequently, ammonia emission was not affected by dietary oil included at 45 g/kg.

Key Words: Pigs, Oil, Ammonia

T33 Influence of lipid source in diets on the performance, meat quality and lipid profile for finishing pigs. R. V. de Sousa¹, E. T. Fialho*¹, J. A. F. Lima¹, P. V. R. Logato¹, and J. I. A. Leite², ¹University Federal of Lavras - UFLA- Brazil, ²University Federal of Minas Gerais-UFMG-Brazil.

Two experiments were conducted to evaluate lipid sources for finishing pigs. Exp. 1 utilized a total of 44 barrows and 44 gilts (LD × LW; 68.5 ± 1.45 kg BW) while Exp. 2 used a total of 66 hybrid barrows (33 with 73.65 ± 1.56 kg initial BW and 33 with 88.50 ± 1.11 kg initial BW). The experiments were conducted to evaluate different sources of lipids at 2% (soybean oil, canola oil, linseed oil and commercial PUFA oil) in Exp. 1 and different levels (2.0, 2.5, 3.0 and 3.5%) of canola oil in Exp. 2 upon lipid metabolism, growth, carcass characteristics and meat quality. Experimental diets were isocaloric, isoprotein and isolysinic, and formulated with corn and soybean meal as base ingredients. There were no effects of sources and levels of canola oil tested on the performance. However, lean meat percentage and longissimus muscle area was improved ($P < 0.01$) by the addition of 2% linseed oil in the diet. The pigs fed diets with linseed and canola oil had higher content of protein and ash in longissimus muscle in comparison with those fed diets with

soybean oil. The biceps muscle of animals fed diets with linseed oil had higher content of protein in the same tissue of animals fed soybean oil. The different levels (2.0, 2.5, 3.0, and 3.5%) of canola oil decreased linearly ($P < 0.01$) the level of ash in longissimus muscle. The fatty acid composition of intramuscular fatty of longissimus muscle reflected the dietary fatty acid composition. Blood lipids (total cholesterol, triglycerides and total cholesterol fractions [HDL, LDL and VLDL]) did not differ ($P > 0.10$) for the sources and levels of lipids added to the diets. In conclusion, the linseed oil at 2.0% in the finishing pig diet improved lean tissue accretion at the expense of lipogenesis. In addition fatty acid deposition follows the dietary fatty acids profile.

Key Words: Lipids, Oils, Cholesterol

T34 Utilization of pearl millet in substitution for corn in diets for growing pigs - metabolism assay and performance. E. T. Fialho*, M. da S. M. Pinheiro, J. A. F. Lima, P. B. Rodrigues, and R. T. F. de Freitas, *University Federal of Lavras - UFLA, Brazil.*

To evaluate the technical viability of substitution of corn by pearl millet in an isometric way for growing pig diets, two metabolism assays and one performance trial were conducted. The metabolism assays utilized 12 crossbred (LD x LW) barrows (31.8 ± 2.2 kg BW) for the feedstuffs (corn ground, whole pearl millet and ground pearl millet) and 10 barrows (42.1 ± 2.10 kg/BW) for diets with 0, 25, 50, 75 and 100% substitution of corn by ground pearl millet. A 7 d period for adaptation and 5 d period for total collection of feces and urine with ferric oxide (2%) as the indigestible marker was used for both metabolism assays. A total of 120 crossbred (LD x LW) barrows and gilts (30.7 ± 1.2 kg BW) were utilized in the performance trial. Pigs were allotted by weight and gender with five treatments (the same as used in the metabolism assay) and 12 replicates. The experimental unit was represented by the pen (1 barrow and 1 gilt/pen). The metabolism data from both whole and ground pearl millet revealed no differences ($P > 0.05$) for apparent digestibilities of nutrients or energy values; on average the DDM, ADCP, DP, DE and ME of pearl millet were 87.14%, 86.25%, 11.49%, 3166 kcal/kg and 3040 kcal/kg, respectively. The substitution of pearl millet at 100% for corn did not affect ($P > 0.05$) the digestibility coefficients of CP or nitrogen retention. But the digestibility coefficients of DM, as well as the dietary DE and ME values decreased linearly ($P < 0.01$) as corn was substituted by pearl millet. The performance data did not show any effects ($P > 0.05$) by totally replacing corn with pearl millet in the diet (ADG, kg - 100% corn 0.872 vs 100% pearl millet 0.889; ADFI, kg - 100% corn 2.30 vs 100% pearl millet 2.38; Feed/gain - 100% corn 2.67 vs 100% pearl millet 2.69). In conclusion, it is technically feasible to substitute up to 100% of corn with pearl millet in an isometric way for growing pigs from 30 to 60 kg.

Key Words: Swine, Pearl Millet, Corn

T35 Energy, protein, and amino acid digestibility in different sources of rice bran for growing pigs. C. Kaufmann¹, W. Sauer¹, M. Cervantes², M. Rademacher³, and J. He¹, ¹University of Alberta, Edmonton, AB, Canada, ²Universidad Autónoma de Baja California, Mexicali, Mexico, ³Degussa-Huls AG, Hanau-Wolfgang, Germany.

A study was conducted to determine the fecal GE digestibility and apparent ileal digestibilities (AID) of AA in five samples of rice bran (RB). Six barrows (36.5 kg average initial BW) fitted with a simple T-cannula at the distal ileum were used according to a 6 x 6 Latin square design. Five different sources of RB were evaluated: RB 1: Canadian source; RB 2: Riceland Foods Inc., Stuttgart, AR, US; RB 3: Italy; RB 4: Phillipines; and RB 5: Agribbrands/Tradico, Greenville, MS, US. Six diets were formulated to contain 18% CP. Diets A, B, C, D and E contained 53.8% corn, 19.9% soybean meal (SBM) and 23.1% of each RB source. Diet F (reference diet) contained 71.03% corn and 26.3% SBM. The fecal energy digestibility of RB 4 (86.9%), which was the lowest in NDF content, was higher ($P < 0.05$) than those of RB 1, 2, 3, and 5 (60.5, 64.1, 62.6, 65.8%, respectively). The AID of CP and AA in RB 1, 2, 3, 4, and 5 were: CP, 61.3, 38.3, 48.3, 65.3, 67.3; Arg, 85.1, 75.7, 79.7, 83.1, 83.3; His, 81.7, 66.0, 75.8, 79.8, 76.7; Ile, 73.2, 53.9, 67.7, 73.4, 72.0; Leu, 72.0, 50.9, 63.7, 73.5, 67.2; Lys, 82.2, 62.6, 72.7, 70.5, 73.1; Met, 76.0, 61.4, 66.9, 72.2, 74.0; Phe, 71.9, 52.5, 65.2, 76.8, 70.6; Thr, 82.8, 58.4, 73.9, 86.1, 75.9; Val, 76.2, 60.2, 71.1, 76.9, 75.3; Trp, 82.6, 58.8, 69.7, 70.0, 73.3, respectively. There was considerable variation in

the amino acid digestibilities among the RB samples. The ileal CP and amino acid digestibilities were lowest in RB 2, a defatted source of RB. The values for amino acid digestibility were highest in RB 4 (which has the lowest NDF content), in RB 5 (an extruded source of RB), and RB 1. There were significant relationships ($P < 0.05$) between the content of fat (positive), or CP (negative) and the AID of Lys and Trp. No significant correlations were observed between the NDF or ash contents and the AID of AA. This study shows that there is considerable variation in fecal GE, and CP and AA apparent ileal digestibility values in RB, and that it is rather difficult to specify an overriding factor responsible for the variation.

Key Words: Rice Bran, Pigs, Digestibility

T36 Comparison of growing swine performance when fed diets containing cull chickpeas in substitution of soybean meal and corn. J.F. Obregon, J.M. Uriarte*, R. Barajas, and H.R. Guemez, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico.*

To determine the effect of substitution of soybean meal and corn for cull chickpeas on growth performance and carcass traits in finishing pigs, 72 pigs (BW = 27.48 ± 0.97 kg; Large White x Landrace x Large White x Pietrain) in groups of six were placed in 12 concrete floor pens (1.5 x 6 m). Pens were fed one of three diets: 1) Diet with 17.2% CP and 3.36 Mcal ME/kg, containing corn 73%, soybean meal 23%, and premix 4% (CONT); 2) Diet with 17.1% CP and 3.35 Mcal ME/kg with corn 60.5%, cull chickpeas 20%, soybean meal 15.5%, and premix 4% (CHP20), and 3) Diet with 17.1% CP and 3.33 Mcal ME/kg with corn 47.2%, cull chickpeas 40%, soybean meal 8.8%, and premix 4% (CHP40). Pig were weighed at days 0 and 45 of the experiments and feed intake was recorded daily; ADG and feed intake/gain ratio were calculated from these data. Body weight at day 45 (59.41, 61.62 and 58.51 kg) were not affected ($P = 0.16$) by CONT, CHP20 and CHP40, respectively. ADG (0.71, 0.75 and 0.69 kg) was similar ($P = 0.15$) between dietary treatments. Feed intake (1.83, 1.90 and 1.89 kg) was not modified ($P = 0.13$) by treatments. Feed/gain ratio (2.58, 2.53 and 2.67) was similar ($P = 0.33$) between treatments. It is concluded, that cull chickpeas can be used up to 40% in diets for growing pigs without affecting growth performance.

Key Words: Chickpeas, Growth Performance, Pigs

T37 Effect of the substitution of soybean meal and corn for cull chickpeas in the diet on growth performance and carcass traits of finishing pigs. J. F. Obregon, H. R. Guemez*, F. G. Ríos, R. Barajas, and J. M. Uriarte, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Masatlan, Mexico.*

To determine the effect of substitution of soybean meal and corn for cull chickpeas in the diet growth performance and carcass traits of finishing pigs, 72 pigs (BW = 62.81 ± 2.63 kg; Large white x Landrace x Large white x Pietrain) in groups of six were placed in 12 concrete floor pens (1.5 x 6 m). Pens were fed one of three diets that consisted of the treatments: 1) Diet with 13% CP and 3.88 Mcal ME/kg, containing corn 81.7%, soybean meal 14.3% and premix 4% (CONT); 2) Diet with 13.1% CP and 3.34 Mcal ME/kg with corn 61.7%, cull chickpeas 30%, soybean meal 4.3% and premix 4% (CHP30), and 3) Diet with 15.1% CP and 3.30 Mcal ME/kg with corn 36%, cull chickpeas 60% and premix 4% (CHP60). Pigs were weighed at days 0 and 42 of the experiment and feed intake was recorded daily; ADG and feed/gain ratio were calculated from these data. After 42 days eight pigs from each treatment were killed in a slaughterhouse and carcass traits measured. Body weight at day 42 (92.33, 92.45 and 91.49 kg) was not affected ($P = 0.80$) by CONT, CHP30 and CHP60, respectively. ADG (0.721, 0.723 and 0.698 kg) were similar ($P = 0.84$) between dietary treatments. Feed intake (2.67, 2.69 and 2.56 kg) was not modified ($P = 0.35$) by treatments. Feed/gain ratio were similar ($P = 0.42$) between treatments. Hot carcass weight (81.37, 79.37 and 77.56 kg) was similar ($P = 0.26$) and carcass yield was not affected ($P = 0.35$) by the treatments. Back fat (1.64, 1.46 and 1.60 cm) were not affected ($P = 0.42$), rib eye area, weights of loin and leg was similar ($P = 0.39$). It is concluded, that cull chickpeas can be used up to 60% in diets for finishing pigs without affecting performance and carcass traits.

Key Words: Chickpeas, Carcass Traits, Pigs

T38 Effect of diets formulated based on ileal lysine digestibility and alternative feeds for finishing pigs - metabolism and performance assay. M. L. F. Silva, E. T. Fialho*, J. A. F. Lima, R. V. de Sousa, and L. D. S. Murgas, *University Federal of Lavras - UFRA-Brazil*.

Two experiments were conducted to evaluate the digestibility of dietary nutrients, performance and carcass characteristics of pigs fed finishing diets based on corn, soybean meal and alternative ingredients with the same total dietary content of true digestible lysine (NRC, 1998). The treatments in both experiments were: T1 diet formulated with corn and soybean meal; T2 corn, soybean meal, peanut meal solv. and cottonseed meal solv. 41% CP; T3 - corn, soybean meal, meat and bone meal 45% CP, and fish meal 60% CP; T4 sorghum, defatted rice bran and soybean meal. The metabolism assay used 24 barrows (62 kg BW). A 7 d period for adaptation and 5 d period for total collection of feces and urine with ferric oxide (2%) as the indigestible marker was used. In the performance assay, 64 commercial hybrid barrows (61.9 ± 3.10 kg BW) were used. The pigs were housed in pairs in pens with pen as the experimental unit. For the two assays, a total of 6 and 8 replications were used, respectively. The apparent fecal digestibility of DM, nitrogen retention, as well as DE and ME of the diets did not differ (P>0.05) among the treatments tested. However, the digestibility of CP was better (P<0.05) for T2 (86.65%) and T3 (87.24%) than T1 (85.78%) and T4 (85.82%). The performance of finishing pigs as well as the carcass characteristics did not differ (P>0.05) for the diets tested. In conclusion diets for finishing pigs formulated with alternative feeds and based on the same amount of true digestible lysine have been shown to be technically viable.

Key Words: Performance, Digestible Lysine, Metabolism Assay

T39 Energy and protein values of some Brazilian feedstuffs for pigs as determined by metabolism assay. E. T. Fialho*, Z. A. S. Santos, J. A. F. Lima, R. T. D. Freitas, and A. G. Bertechini, *University of Lavras-UFLA, Brazil*.

Assays were conducted to determine the chemical composition and digestibility of protein and energy of 16 Brazilian feedstuffs in growing pigs. Five metabolism trials were conducted with a total of 60 LDxLW barrows (40.4 ± 2.2 kg). During each trial, pigs were penned individually in stainless steel metabolism cages with a 7 d period for adaptation and 5 d period for total collection of feces and urine. Ferric oxide (2%) was utilized as the indigestible marker. The basal diet was an 18% CP corn-soybean meal diet in each metabolism assay. The experimental diets consisted of 70% basal diet plus 30% of the test feedstuff, except for the oils and lards which were added at 15% for evaluation. In each metabolism trial three feeds plus the basal diet were tested. Digestible protein and digestible and metabolizable energy values were calculated by using the Matterson et al., 1968 (Agric. Exp. Station Research Report, Univ. Connecticut) equation. These data indicate that there are differences in digestibility protein and energy among Brazilian feedstuffs in relation to those referenced by the foreign feed composition tables (NRC, 1998 and Feedstuffs, 2003). We conclude that reliable estimates of digestibility values can significantly improve the precision of pigs diets formulation.

Chemical composition and digestibility of protein and energy of some Brazilian feedstuffs determined by metabolism assays¹

FEED-STUFFS	DM, %	CP, %	NDF, %	ADF, %	CP Digest, %	DE, kcal/kg	ME, kcal/kg

T40 Comparison of a diet containing food waste with a corn/soybean diet fed to swine. J. Jones, M. L. Westendorf*, and J. E. Wohlt, *Rutgers, The State University of New Jersey, New Brunswick*.

Recycled food waste can provide an acceptable and nutritious feed for swine. Although pigs will readily consume wet food waste, the high moisture content contributes to spoilage and feeding management problems. The use of a dry, processed food waste product was compared to a traditional corn/soy diet using growing swine in two performance trials and one digestibility trial. The food waste diet contained 30-35% processed food waste on a dry matter basis. In Trial 1, 24 gilts (76.4 kg) were fed in a six-week trial. Intake, gain, feed efficiency, and carcass characteristics were compared. Feed intake and gain averaged 3.4 and 3.6 kg of DM/d and .87 and .85 kg/d for gilts fed traditional and food waste diets, respectively. There were no differences in these or any other measurements (P#88050.05). In Trial 2, 12 barrows (84.3 kg) were fed in a six-week trial. Intake, gain, feed efficiency, and carcass characteristics were compared. Feed intake and gain averaged 3.1 and 3.3 kg of DM/d and .62 and .71 kg/d for barrows fed traditional and food waste diets, respectively (P#88050.05). There were no differences in carcass characteristics (P#88050.05) except in Trial 2 when belly weight in food waste-fed pigs was greater (P#88040.05) than control pigs (10.7 vs 9.6 kg). In Trial 3, four growing gilts (68.2 kg) were used to compare digestibility in a crossover design. There were no differences (P#88050.05) for DM, CP, ADF, or NDF digestibility when feed intake averaged 1.9 kg of DM/d for both food waste and corn/soy diets. The use of up to 35% processed food waste may be suitable in commercial swine diets.

T41 Evaluation of protein dispersibility index as an indicator for soybean meal protein quality in growing pigs: II. Feeding trial. H. S. Lee*¹, J. G. Kim², Y. W. Shin², Y. H. Park², and K. Y. Whang², ¹*American Soybean Association, Seoul, Korea*, ²*Korea University, Seoul, Korea*.

A 42-d feeding trial was conducted to verify the plausibility of using the protein dispersibility index (PDI) as an indicator of soybean meal protein quality. Soy flake treatments (Trt) used in this experiment were: 1) raw; 2) steamed for 5 min at 95°C; 3) 5 min at 110°C; 4) 15 min at 110°C; and 5) 60 min at 110°C. A total of 120 pigs (YxLxD) weighing 12.2 ± 0.8 kg were assigned to five dietary treatments with 6 replicates. Experimental diets containing various heat-treated soy flakes included 3390 kcal/kg ME, 19.1% CP, and 1.05% lysine. The ADG of Trt 4 was

higher ($P < .05$) than those of Trt 1, 2, and 5. Feed efficiency (G/F) and feed intake of pigs in Trt 1 were lower ($P < .05$) than those in other treatments. Although pepsin digestibility and urease activity index were not correlated with growth performance, the KOH protein solubility and PDI measurements were highly correlated with ADG ($r^2 = 0.659$, $P < .001$ and $r^2 = 0.649$, $P < .001$, respectively) and G/F ($r^2 = 0.719$, $P < .001$ and $r^2 = 0.739$, $P < .001$, respectively). These results suggest that PDI is as effective as KOH protein solubility as an indicator of soybean meal protein quality in growth performance of growing pigs.

T42 Evaluation of protein dispersibility index as an indicator for soybean meal protein quality in growing pigs: I. Metabolic study. H. S. Lee^{*1}, Y. W. Shin², J. G. Kim², Y. H. Park², and K. Y. Whang², ¹American Soybean Association, Seoul, Korea, ²Korea University, Seoul, Korea.

Five differently heat-treated soy flake treatments (Trt), 1) raw; 2) steamed for 5 min at 95°C; 3) 5 min at 110°C; 4) 15 min at 110°C; and 5) 60 min at 110°C, were prepared and used as a major dietary protein source to verify the plausibility of using protein dispersibility index (PDI) as an indicator of soybean meal protein quality in a nitrogen balance trial with growing pigs. Twenty castrated pigs (Y×L×D) weighing 14.1 ± 0.9 kg were randomly assigned to dietary treatments and fed experimental diets containing various heat-treated soy flakes. Pigs were adjusted for three days prior to fecal and urinary sample collection for four days. Pigs fed the diet containing soy flake heat-treated for 15 min at 110°C (Trt 4) had the highest nitrogen retention among pigs in this experiment. Nitrogen retention was increased as the heat-treatment was applied from Trts 1 to 4, and then decreased in Trt 5. Both KOH protein solubility ($y = -0.0153x^2 + 1.9191x + 13.957$, $r^2 = 0.893$, $P = 0.001$) and PDI measurements ($y = -0.0067x^2 + 0.3033x + 66.2127$, $r^2 = 0.841$, $P < 0.001$) were correlated with the nitrogen retention of the pigs. It is found however that urease activity index and pepsin digestibility were not correlated with nitrogen retention in this experiment. This result suggests that PDI is as effective as KOH protein solubility as an indicator of soybean meal quality in nitrogen retention of growing pigs.

T43 Effects of altering bed depth in the desolventizer/toaster used in soybean meal preparation on nutrient digestibility by ileally cannulated pigs and cecectomized roosters. L. Pope^{*}, K. Bruce, L. Karr-Lilienthal, C. Grieshop, N. Merchen, C. Parsons, and G. Fahey, *University of Illinois, Urbana.*

Soybean meal (SBM) has been a major contributor of dietary amino acids for the poultry, swine, and aquaculture industries for many years, and it is widely known that processing conditions used to prepare SBM have an impact on its nutrient composition. In an attempt to determine

the optimal processing conditions for preparation of SBM that maximize amino acid digestibilities, six lots of high protein SBM were produced under different toasting conditions. Specifically, the bed depth in the desolventizer-toaster was varied (4.0, 4.5, 5.5, 6.0, 7.0, and 8.0 in.). All soybeans were acquired from the same producer, and the preparation and extraction conditions were held constant for all lots. The SBMs then were incorporated into semipurified diets and fed to ileally cannulated pigs in a 7 × 7 Latin Square design to determine ileal and total tract nutrient digestibility. A low-protein casein diet also was fed to estimate endogenous losses of amino acids, and to allow for an accurate determination of true amino acid digestibilities. Each experimental period was seven days, with a five-day adaptation period and a two-day ileal collection. The SBMs were also fed to cecectomized roosters in order to determine true amino acid digestibilities by poultry. When fed to pigs, there were no differences ($P > 0.05$) among treatments in apparent or true ileal lysine digestibilities, with values ranging from 87.3 to 90.2% and 90.7 to 93.5%, respectively. Additionally, there were no differences ($P > 0.05$) in ileal apparent or true total amino acid digestibilities, but the dietary amino acids were highly available (true average total amino acid digestibility = 92.2%). For cecectomized roosters, no differences ($P > 0.05$) were observed in true lysine digestibility with values ranging from 83.2 to 87.0%. Alteration of the bed depth in the desolventizer-toaster had little effect on nutrient digestibilities of SBM by swine and poultry.

Key Words: Swine, Soybean Meal, Poultry

T44 Utilization of sunflower meal in diets of finishing pigs - performance and digestibility. D. de C. Carellos, J. A. F. Lima, E. T. Fialho^{*}, R. T. F. Freitas, and E. P. Filgueiras, *University Federal of Lavras, UFLA, Brazil.*

The objective of this study was to evaluate the influence of increasing levels of solvent extracted sunflower meal (SFM - DM 92.71%, CP 27.50%, NDF 43.57%, ADF 32.96%, CF 25.91%, EE 3.08%, GE 4,390kcal/kg) on the digestibility, performance and carcass characteristics of finishing pigs. A total of two experiments were conducted. The metabolism trial was conducted to evaluate the digestibility of Dry Matter (DDM), crude Protein (DCP), gross Energy (DGE) and fiber detergent neutral (DFDN) of SFM nutrients in diets containing 0, 4, 8, 12 and 16% SFM by utilizing 15 crossbred barrows (LD × LW; 55.1 ± 4.8 kg). The experimental unit was represented by the metabolism cage. A 7 d period for adaptation and 5 d period for total collection of feces and urine with ferric oxide (2%) as the indigestible marker was used. The digestibility values for SFM (as fed basis) were 54.40% DM, 77.73% CP, and 53.80% GE resulting in a digestible nutrient content of 50.43% DDM, 21.38% DCP, 2,365 kcal/kg DE and 2,289 kcal/kg ME. A linear effect ($P < 0.01$) was found for DDM and DFDN, a quadratic effect ($P < 0.01$) for DGE (higher value with 13.5% of SFM), DCP (higher value 11.55% of SFM) and NR (higher value 17.45% of SFM). In the performance trial, 80 crossbred pigs (LD × LW; 62.0 ± 4.2 kg BW) were utilized. Pigs were allotted by weight and gender to treatment and replicate. The experimental unit was represented by the pen (1 barrow and 1 gilt/pen). The five dietary treatments were increasing levels of SFM (0, 4, 8, 12 and 16%). At the end of the performance trial (99.80 ± 6.91 kg), the pigs were slaughtered for carcass evaluation. The increasing levels of SFM resulted in a linear decrease ($P < 0.05$) for feed intake. In carcass evaluation, the increasing levels of SFM inclusion did not affect ($P > 0.05$) any variable evaluated. However, it was found that the barrows had higher P2 values, carcass weight and percentage carcass lean, and the gilts had greater ham weight. It was concluded that inclusion levels of SFM up to 16% in a isonutritive diet should be technically feasible for finishing pigs from 65 to 98 kg BW.

T45 Effect of dry skim milk on fecal bacterial populations and *Salmonella* shedding in growing-finishing swine. J. E. Wells^{*}, J. T. Yen, and D. N. Miller, *USDA-ARS; U.S. Meat Animal Research Center, Clay Center, NE.*

Dry skim milk (DSM) contains approximately 55% lactose and lactose has been suggested to have prebiotic effects in the mammalian digestive system. Barrows were fed growing, growing-finishing, and finishing diets from age 10-14 wk, 14-18 wk and 18-22 wk, respectively. For each feeding phase, diets were formulated to contain 0 or 10% DSM (balanced with ME and apparent ileal digestible AA). Animals were weighed every

two wk. DSM did not alter animal gain, feed intake, or feed conversion ($P>0.05$). Fecal samples were collected from 40 animals (20 with DSM and 20 without DSM) at wk 10 (d 0 on diets), 14, 18, and 22, and were analyzed for *Lactobacillus* sp. (LAB), Enterobacteriaceae (EB), coliforms (CF), generic *Escherichia coli* (EC), and *Salmonella* sp. At week 10, fecal bacterial counts (\log_{10} CFU/g feces) were 9.55, 7.26, 7.01, and 6.93 for LAB, EB, CF, and EC populations, respectively. The EB, CF, and EC populations decreased through wk 14 and 18 ($P<0.05$), but were still higher with the DSM diet ($P<0.05$). The LAB population decreased over time in the absence of DSM in the diet, whereas DSM sustained higher LAB counts ($P<0.05$). At wk 22, populations of EB, CF, and EC were higher ($P<0.05$) than wk 18 for the diet without DSM, but no change was observed with DSM. As a result, no differences between the diets were observed at week 22. *Salmonella* were detected in 70% of the animals at wk 10 and 14, but only 20% at wk 18 and 22. DSM did not affect *Salmonella* shedding, but pooled analysis indicated that fewer recurring incidences of *Salmonella* shedding occurred in animals with higher LAB bacteria. Nonetheless, weight gain for individual animals was not affected by *Salmonella* shedding in this study. It is concluded that 10% DSM affects fecal bacterial populations, but not *Salmonella* shedding in growing-finishing pigs.

T47 Response of pigs to dietary phytase and calcium-to-phosphorus ratio. J. A. Jendza^{*1}, R. N. Dilger¹, M. R. Bedford², and O. Adeola¹, ¹*Animal Sciences, Purdue University, West Lafayette, IN*, ²*Zymetrics, Golden Valley, MN*.

Pigs were fed corn-soybean meal-based basal diets containing 0.71% Ca and 0.40% P to determine response to phytase and Ca-to-total P ratio (Ca:tP) in two 4-wk experiments. Pigs were blocked by weight and gender such that the average weight across treatments was similar with 1 barrow and 1 gilt receiving each treatment within each block, housed in individual pens, and allowed ad libitum access to diets and water. In Exp. 1, 48 10-kg crossbred pigs were used to evaluate the efficacy of an experimental microbial phytase. Diets consisted of the basal, basal plus 3.4 or 6.7 g/kg monosodium phosphate (MSP), basal plus 500 or 1,000 phytase units (FTU)/kg of the experimental or control phytase, and a positive control with adequate Ca and P. Supplemental MSP resulted in linear increases in wk 1 ADFI ($P < 0.05$), ADG in all periods ($P < 0.05$), final weight and ASH ($P < 0.0001$). Experimental phytase increased percent bone ash (ASH), apparent P digestibility ($P < 0.0001$), final weight, overall ADG, wk 4 ADG and wk 4 ADFI ($P < 0.05$). Bone ash (51.1%) in the 1,000 FTU experimental phytase/kg diet was similar to the 6.7 g/kg MSP diet (51.5%). Control phytase improved ASH and apparent P digestibility ($P < 0.01$). In Exp. 2, 48 11-kg crossbred pigs, were randomly assigned to treatments in a 3 x 2 factorial arrangement. The respective factors were Ca:tP (1.8, 1.5, or 1.2) and supplemental experimental phytase (0 or 1,000 FTU/kg). Phytase increased ($P < 0.01$) average BW at 2, 3 and 4 wk; ADG at 2, 3, 4 wk and overall; ADFI at 4 wk and feed efficiency (G:F). Lowered Ca:tP improved ($P < 0.05$) BW and ADG in all periods; ADFI at 3, 4 wk and overall; and G:F at 2, 3, 4 wk and overall. Interaction was significant for ADFI at 3, 4 wk and overall ($P < 0.05$). Results indicate that the experimental phytase is effective at liberating phytate P for uptake and utilization, while decreasing Ca:tP from 1.8 to 1.2 improves ADG, ADFI and G:F.

Key Words: Phosphorus, Phytase, Pig

T48 Growth performance and meat quality changes from trace mineral manipulation of finishing pig diets. B. V. Lawrence^{*}, D. Overend, S. A. Hansen, J. D. Hahn, and J. Hedges, *Hubbard Feeds Inc., Mankato, MN*.

A total of 257 terminal Duroc cross gilts (Compart Boar Store Line 442 X D100; 32.5 ± 1.9 kg) were compared between 2 treatments: a corn-soybean meal control diet (CTRL), or the CTRL diet for 63-d followed by the CTRL diet supplemented with Yield Pak (a blend of vitamins and trace minerals, YPC) from day 63 - 91. Pens ($n = 6$) were weighed on d-0, 63 and 91. Gain and gain:feed during the 91-d was not different between treatments despite the YPC pigs having higher ($P<0.05$)

T46 Metabolizable energy value of meat and bone meal for pigs. S. A. Adedokun^{*} and O. Adeola, *Purdue University, West Lafayette, IN*.

The metabolizable energy (ME) values of six samples of meat and bone meal (MBM) were determined in barrows. Twenty four pigs with an average weight of 34 kg were used for each of the MBM samples. The gross energy (GE), crude protein (CP), fat, and ash contents of the MBM samples ranged between 3.49 to 4.75 kcal/g, 44.81 to 61.38%, 8.44 to 13.27%, and 18.87 to 35.37%, respectively. The CP and GE of diets ranged from 17.6 to 19.2% and 4.26 to 4.44 kcal/g, respectively. Each diet was randomly assigned to each block of three crates giving a total of eight blocks for each sample of MBM. Diets were formulated by replacing the same ratio of corn and soybean meal in the basal diet with MBM at 0, 5, or 10%. The digestibility assay employed a 5-d acclimation followed by a 5-d period of total but separate collection of feces and urine. The ME of each of the MBM sample was calculated by regressing the MBM contribution to ME intake against amount MBM intake. The slope of the regression gave the ME content of the MBM sample. The ME of the MBM ranged from between 2.43 and 3.28 kcal/g. Meat and bone meal ME increased as both the GE and fat contents of the different MBM samples increased while MBM ME decreased with an increase in MBM ash content.

Key Words: Metabolizable Energy, Meat and Bone Meal, Pigs

intakes from day 63 - 91. At day 91, 80 gilts per treatment (116.2 ± 6.6 kg) were scanned using real-time ultrasound for 10th rib backfat and loin eye area as well as last rib fat. There was no effect ($P>0.10$) of YPC inclusion on carcass composition. A total of 40 gilts per treatment were individually tagged, tattooed, and weighed prior to shipment (123.0 ± 4.5 kg). After 8-h of transit to a commercial abattoir, live weights (119.7 ± 4.1 kg) and hot carcass weights (HCW) were obtained (91.9 ± 3.2 kg). Weight prior to shipment, abattoir live weight, and HCW were not different ($P>0.10$) between treatments. Fat and muscle depth and lean percentage were similar between treatments ($P>0.10$). Loin pH was measured at 1 and 22-h post-mortem and was not different at 1-h post-harvest, however, 22-h pH (5.62 vs. 5.70) was higher ($P<0.05$), and 22-h pH drop loss (0.49 vs. 0.60 units) lower ($P<0.05$) for the YPC pigs. At 22-h a 40 - 50 g loin core was taken between the 7th and 8th ribs and held for 7-d for determination of drip loss. The reduction in 22-h pH drop was associated with a tendency ($P<0.15$) toward a reduction in 7-d drip loss (3.93 vs. 4.86%). NPPC measures of loin color, firmness, and marbling, as well as ColorTec L*, A*, and B* values were not different ($P>0.10$) between the CTRL and the YPC pigs. The results of this experiment suggest that short term supplementation of the diet with an appropriate blend of vitamins and trace minerals may improve pig growth via stimulation of feed intake and may reduce drip loss via a reduction in the rate of post-mortem pH decline.

Key Words: Minerals, Pigs, Meat Quality

T49 Performance of pigs fed grain sorghum-based diets supplemented with phytase. J. Yáñez¹, M. Cervantes^{*1}, M. A. Barrera¹, W. Sauer², and N. Torrentera¹, ¹*Universidad Autónoma de Baja California, Mexicali, Mexico*, ²*University of Alberta, Edmonton, AB, Canada*.

An experiment was conducted to evaluate the effect of phytase supplementation to sorghum-soybean meal diets on the performance of growing pigs. Twenty-eight pigs (average initial BW 22.9 kg) were randomly distributed in 4 dietary treatments (7 replicates/treatment), according to a RB design. Treatments were: T1) sorghum-soybean meal, basal diet, 0.67% apparent ileal digestible lysine; T2) basal diet plus 350 units of phytase activity (FTU)/kg diet; T3) basal plus 700 FTU/kg diet; T4) basal diet plus 1 050 FTU/kg diet. All were formulated to contain 90% (0.77%) of the requirement of apparent ileal digestible lysine, and 100% the requirement of available phosphorus for pigs ranging in BW from 20 to 50 kg. All diets were supplemented with vitamins and minerals to meet or exceed the requirements for the 20 to 50 kg pigs. Daily weight gain (ADG), feed intake, lysine intake, threonine intake, and feed conversion for treatments 1 to 4 were: 0.67, 0.60, 0.61, 0.66 kg/d; 1.39, 1.29, 1.33, 1.47 kg/d; 12.4, 11.5, 11.9, 13.1 g/d; 9.3, 8.6, 8.9, 9.8 g/d; 2.09, 2.18, 2.17, 2.17. There was no effect of phytase supplementation on the

ADG ($P = 0.93$), feed intake ($P = 0.37$), lysine intake ($P = 0.37$), threonine intake ($P = 0.37$), or feed conversion ($P = 0.54$). However, pigs fed the diet supplemented with 350 FTU/kg tended to have a lower ($P = 0.10$) ADG as compared with the basal diet. The results from these experiments indicate that phytase supplementation does not affect the performance of pigs fed sorghum-soybean meal diets.

Key Words: Pigs, Sorghum, Phytase

T50 Paylean® did not compromise bone traits of finishing pigs fed diets formulated with phytase. C. E. Pardo*, J. N. Trower, D. K. Schneider, and T. D. Crenshaw, *University of Wisconsin, Madison.*

Improved performance of pigs fed ractopamine (Paylean®, Elanco Animal Health) is well established, but concerns have arisen over the combined use of Paylean and phytase in diets with no supplemental inorganic P (iP). The combination of Paylean and phytase (Natuphos®, 9400 G-concentrate, BASF) was evaluated in finishing pigs to determine if additional iP was required. One hundred twenty crossbred (D x LW x LR) pigs were initially (50.5 ± 0.4 kg) fed diets with phytase (0 or 500 FTU/kg) for 4 wk, then (82.0 ± 1.0 kg) fed one of five diets for an additional 4 wk. Diets provided Paylean (0 vs. 10 mg/kg, diets 1,2 vs. 3,4,5), phytase (0 vs. 500 FTU/kg, diets 1,3,5 vs. 2,4) and iP (0.45 vs. 0.65% total P, diets 1,3 vs. 5). Total lysine was increased from 0.70 to 0.90% in Paylean diets. As expected, ADG, feed efficiency, and carcass traits improved ($P < 0.05$) with inclusion of Paylean, but no benefits from iP were observed (data not shown). Metacarpal bone ash, percentage ash and mechanical properties (Force and Stress) were suppressed ($P < 0.06$) in pigs fed diets with phytase regardless of Paylean additions. Bone traits from pigs fed Paylean + phytase diets were compromised to the same extent as traits from pigs fed phytase without Paylean. The responses are consistent with a limitation due to phytase, but not Paylean. In pigs fed Paylean, additional iP improved bone traits ($P < 0.02$) over pigs fed diets with minimal P or phytase. In conclusion, growth, feed efficiency, carcass traits and bone traits of finishing pigs fed Paylean can be maintained with minimal supplemental P levels from either iP or phytase sources.

T51 Utilization of phytase in diets of growing pigs - ileal AA digestibility, performance and mineral excretion. H. O. Silva, E. T. Fialho*, J. A. F. Lima, L. D. S. Murgas, and R. T. F. de Freitas, *University Federal of Lavras - UFLA, Brazil.*

Exp. 1 evaluated the effect of level of phytase on the apparent ileal digestibility of protein and AA (AIDCP and AIDAA). The treatments were: T1- corn + soybean meal + defatted rice bran (DRB); T2 - corn + soybean meal; T3 - soybean meal + DRB; and T4 - soybean meal. All diets were supplemented with four levels of phytase (0, 400, 800 and 1200 FTU/kg diet from Natuphos 5000). Eight pigs with a simple T-cannula were used. The pigs were allocated to a 4 x 4 Latin Square design. Supplementation with phytase yielded a higher AIDCP and AIDAA of the diets, the level of 483 FTU/kg ($Y = 83.81 + 0.0029X - 0.000003X^2$,

$R^2 = 0.946$) was computed to yield the higher ileal digestibility values. These data show that phytase supplementation in the range of 440-900 FTU/kg diet is adequate in growing pig diets. Exp. 2 was designed to verify the effect of phytase on performance, bone mineralization and plasma urea content in growing pigs. A total of 80 crossbred (LD x LW; 30 ± 3.1 kg BW) barrows and gilts were allotted to four treatments and five replications. The treatments consisted of diets based on corn, soybean meal and DRB supplemented with four levels of phytase (0, 400, 800 and 1200 FTU/Kg). Over the 42 d experimental period, every eight days, blood of two animals per pen was collected. At the end of the experimental period, two animals were slaughtered for the collection of the metacarpal bone. Supplementation with the enzyme phytase up to the level of 1200 FTU/kg diet yielded a linear improved feed conversion and the content of Ca and P in the bone ($P < 0.05$). Phytase supplementation resulted in a quadratic effect on plasma urea and Mn ($P < 0.05$). It was concluded that supplementation with the enzyme phytase in growing pig diets should be beneficial as demonstrated by improved pig performance as well as increased bone mineralization of Ca, P and Mn. This would also contribute to the reduction of the environmental impact caused by pig excrement.

Key Words: Bone Mineralization, Phytase, Amino Acid Digestibility

T52 Use of betaine and conjugated linoleic acid as growth promotants in growing Iberian pigs. I. Fernandez-Figares*, I. M. Lachica¹, R. Nieto¹, E. Gonzalez Sanchez², and J. F. Aguilera¹, ¹Consejo Superior de Investigaciones Cientificas, ²Universidad de Extremadura, Spain.

Dietary betaine (BET) and conjugated linoleic acid (CLA) are associated with decreased lipid deposition and may improve feed efficiency in swine. We hypothesized that BET and/or CLA could have an impact as growth promotants on genetically unimproved purebred Iberian pigs. Gilts ($n=20$) were fed control, 1% CLA (CLA-60), 0.5% BET or 1% CLA+0.5% BET isoenergetic diets from 20 to 50 kg BW. Animals were fed diets containing 120 g crude ideal protein, and 15.4 MJ ME /kg DM at 80% of ad libitum intake. Dietary treatments and individual pen locations were assigned at random to experimental gilts. Pigs were weighed and feed intake was adjusted weekly according to BW. At 50 kg, pigs were electro-stunned, exsanguinated and organs were removed and weighed. Carcasses were chilled for 24 h to obtain carcass measurements. Fat depths along the midline and at P1, P2, P3 sites at 10th rib were determined. Compared to controls, pigs fed on BET+CLA had greater ($P < 0.05$) daily weight gain (602 vs. 540 g/day) although BET or CLA treatments were not different from control. Feed/Gain ratio was not influenced by the diets tested. Drip loss was increased when pigs were fed on the CLA+BET diet compared to control ($P < 0.05$; 2.39 vs 1.72%). There was a trend towards higher Loin Eye Area/EBW ratio when BET fed pigs were compared to controls ($P = 0.075$; 9.97 vs 8.83 cm²/kg). BET and BET+CLA fed pigs had 20% lower P1 than controls ($P < 0.05$). A nonsignificant 12% decrease in P2, P3, first rib, last rib, 10th rib back fat was observed in BET+CLA fed pigs compared to controls ($P > 0.10$). Livers from animals fed on BET+CLA were 17% heavier than controls ($P < 0.05$) while other organs were not affected by dietary treatments ($P > 0.10$). These preliminary data suggest that use of BET+CLA mixture is more effective than BET or CLA individually as growth promotants in growing Iberian gilts.

Key Words: Betaine, Conjugated Linoleic Acid, Iberian Pig

T53 Effects of dietary levels of tylosin on digestive and post-absorptive utilization of dietary nutrients in growing pigs. K. Bregendahl*, X. Yang¹, Y. Shen¹, G. Vessie², R. Bagg², T. C. Rideout¹, T. Archbold¹, P. Dick², and M. Z. Fan¹, ¹University of Guelph, Guelph, ON, Canada, ²Elanco Animal Health, Guelph, ON, Canada.

This study was conducted to examine effects of various dietary levels of tylosin on digestive and post-absorptive utilization of dietary crude protein (CP), calcium (Ca), and phosphorus (P) in growing pigs. Thirty-five Yorkshire barrows, with initial and final BW of 35 and 50 kg, were surgically fitted with a T-cannula, and fed five diets for five periods according to a completely randomized block design. The five diets were corn and soybean meal-based, and formulated to contain five levels of tylosin at 0, 11, 22, 44, and 110 ppm, respectively. Each experimental period lasted 25 d with 6-d adaptation and surgery, 6-d recovery, 10-d adaptation to diets, and 4-d collection of total urine excretion, and

digesta and fecal samples. Partitioned as the percentage of the total nutrient intake, post-absorptive metabolic urinary loss (19.1-25.1%) was the major route of N excretion followed by indigestible fecal loss, and the endogenous fecal loss (9.9-18.8%). Fecal loss (23.5-69.5%), and the post-absorptive metabolic urinary loss (0.4-1.1%) were the major routes of Ca losses. Fecal loss (37.7-67.7%), and the post-absorptive metabolic urinary loss (3.6-5.5%) were the routes of P losses. Orthogonal polynomial contrasts suggested that dietary levels of tylosin affected ($P < 0.05$) the nutrient retention through changing the nutrient losses at the ileal and the fecal levels but not ($P > 0.05$) at the post-absorptive urinary level. Dietary inclusion of tylosin at 11 ppm was optimal and improved ($P < 0.05$) the efficiency of digestive utilization of the nutrients and reduced ($P < 0.05$) the fecal excretion of these nutrients by about 10 percentage units. In conclusion, dietary supplementation of tylosin at 11 ppm resulted in the best efficiency of digestive utilization of the nutrients under the research environment. This optimal level of tylosin supplementation is likely to be affected by sanitary conditions.

Key Words: Growing Pigs, Nutrient Utilization, Tylosin

T54 Effects of dietary antibiotics on growth performance in pigs. J. W. Hong^{*1}, O. S. Kwon¹, B. J. Min¹, W. B. Lee¹, K. S. Son¹, J. H. Kim², B. C. Park³, and I. H. Kim¹, ¹Dankook University, Cheonan, Korea, ²Agribands Purina Korea, Inc., Seoul Korea, ³CTC Bio Inc., Seoul, Korea.

For Exp. 1, a total of 80 pigs (20.94 ± 0.85 kg average initial BW) were used in a 42-d growth assay to determine the effects of dietary chlortetracycline and sulfathiazole complex, oxytetracycline, and tylosin on growth performance in growing pigs. Dietary treatments included 1) CON (Basal diet : without antibiotic), 2) CTC (CON diet + 100 ppm chlortetracycline and sulfathiazole complex), 3) OTC (CON diet + 100 ppm oxytetracycline), 4) CTC+OTC (CON diet + 100 ppm chlortetracycline and sulfathiazole complex + 100 ppm oxytetracycline) and 5) TYL (CON diet + 44 ppm tylosin). For d 0-21, pigs fed TYL (471 g) diets had greater ADG than pigs fed CTC (366 g), OTC (416 g) and CTC+OTC (425 g) diets ($P < 0.04$). However, for the overall period, ADG, ADFI and Gain/feed were not significantly differences among the treatments. For the Exp. 2, a total of 80 pigs (52.04 ± 1.02 kg average initial BW) were used in a 42-d growth assay to determine the effects of dietary chlortetracycline and sulfathiazole complex, oxytetracycline and tylosin on growth performance in finishing pigs. Dietary treatments included 1) CON (Basal diet : without antibiotic), 2) CTC (CON diet + 100 ppm chlortetracycline and sulfathiazole complex), 3) OTC55 (CON diet + 55 ppm oxytetracycline), 4) OTC110 (CON diet + 110 ppm oxytetracycline) and 5) TYL (CON diet + 22 ppm tylosin). For the overall period, ADG of pigs fed CTC, OTC55, OTC110 and TYL diets were greater by 11% than pigs fed CON diet ($P < 0.03$). However, ADFI and Gain/feed were not significantly different among the treatments. In conclusion, the results obtained from these feeding trials suggest that dietary oxytetracycline and tylosin are an effective means of improving growth performance in growing and finishing pigs.

Key Words: Antibiotic, Growth, Pigs

T55 Effect of dietary natural herb extract (Biomate[®]) supplementation on growth performance, IGF-1 and carcass characteristics in growing-finishing pigs. O. S. Kwon^{*1}, B. J. Min¹, W. B. Lee¹, K. S. Son¹, J. H. Cho¹, J. H. Kim², I. H. Kim¹, and J. C. Ra³, ¹Dankook University, Cheonan, Korea, ²Agribands Purina Korea, Inc., Seoul, Korea, ³RNL Life Science Ltd., Korea.

A total of 86 pigs (LYD, 20.92 kg average initial BW) were used in a 112-d growth assay to determine the effects of dietary natural herb extract (Biomate[®]: extracts of growth promoter in *Artemisia capillaris*) on growth performance, IGF-1 of serum and carcass characteristics in finishing pigs. Dietary treatments included: 1) CON (basal diet; Control), 2) BM1 (basal diet with 0.02% of Biomate[®]), 3) BM2 (basal diet with 0.04% of Biomate[®]) and 4) BM3 (basal diet with 0.06% of Biomate[®]). Through the entire experimental period, as Biomate[®] increased, there was a decrease (linear, $P < 0.08$) in average daily feed intake and an increase (linear, $P < 0.02$; quadratic, $P < 0.08$) in gain/feed. Backfat thickness tended to decrease in pigs fed BM diets compared to pigs fed the CON diet (linear, $P < 0.09$; quadratic, $P < 0.01$). Increasing Biomate[®] tended to increase in IGF-1 content in serum (linear, $P < 0.09$). Hunter

a*(redness) (linear, $P < 0.01$) and b*(yellowness) (linear, $P < 0.02$) values of longissimus muscle were affected by the dietary Biomate[®] treatments. Color of longissimus muscle was higher in the dietary Biomate[®] treatments than pigs fed control diet (linear, $P < 0.03$). In conclusion, the results obtained from this feeding trial suggest that the Biomate[®] supplementation of diets for growing-finishing pigs can be improved growth performance, IGF-1 and meat quality.

Key Words: Pig, Herb Extract, Meat Quality

T56 Different isoflavone contents in soy-based diets are without influence on growth performance and carcass quality in pigs. G. Kuhn¹, K. Ender^{*1}, U. Hennig¹, C. Kalbe¹, S. Moors², G. H. Degen², and C. Rehfeldt¹, ¹Research Institute for the Biology of Farm Animals, Dummerstorf, Germany, ²University of Dortmund, Germany.

A weaner-grower-finisher performance trial with thirty-eight pigs was designed to compare the growth performance and carcass quality of pigs fed diets containing either soybean meal or soy protein concentrate in a pair-feeding design. Soybean meal (SM) and soy protein concentrate (SPC) differed in isoflavone (daidzein plus genistein) content (782 µg/g in SM and 125 µg/g in SPC, respectively). During the experiment, all pigs were fed four-phases-diets characterized by decreasing protein concentrations with increasing age (weaner I, weaner II, grower, finisher diets). Rations of control and experimental groups were isoenergetic, isonitrogenous, and isoaminogen. The weaning pigs with an initial live weight of 8.4 ± 1.1 kg were allotted to flat deck boxes. During the growing/finishing period (days 70 - 170 of age), the pigs were housed in single boxes. Both, the weaning and the grower/finishing performances (daily body weight gain, feed intake, feed conversion ratio) were similar in both groups. No differences were found between the groups in carcass composition (percentages of cuts, tissues, and protein/fat), and meat quality of pigs ($P > 0.05$). Moreover, the IGF-1R mRNA expression in longissimus muscle was not influenced by the kind of soy product ($P > 0.05$). However, circulating levels of isoflavones between pigs fed SM (genistein 239 ± 44; daidzein 162 ± 22; equol 12 ± 4 ng/mL plasma) and animals fed SPC (genistein 22 ± 9 and daidzein 8 ± 3, and equol 10 ± 3 ng/mL plasma) were clearly different (genistein: $P < 0.001$; daidzein: $P < 0.001$; equol: $P > 0.05$). The results confirm the expected differences in the bioavailability of soy isoflavones. Yet, there were no significant differences in performance of pigs fed either soybean meal or soy protein concentrate.

Key Words: Soybean Isoflavone, Pigs, Carcass Quality

T57 Effect of supplementation with natural tranquillizers in the diet of the pigs on the behavior of the animals and the technological quality of loin meat. M. Font i Furnols^{*}, N. Panella, E. Fàbrega, A. Velarde, M.A. Oliver, J. Soler, and M. Gil, *Institute for Food and Agricultural Research and Technology, Monells, Spain.*

Pork quality is greatly affected by the stress which pigs experience *ante mortem* (a.m.). This depends on the handling and behavior of the animal a.m., as well as on the genotype, especially the presence of the halothane gene (Hal). The aim of the project was to test, in nonstressful conditions, whether the diet supplemented with natural tranquillizers [magnesium (Mg) or tryptophan (Trp)] affected the technological quality of pork meat in two different genotypes [homozygous positive (nn) and negative (NN) for the Hal gene]. Thirty-six nn animals and 36 NN animals were reared with the same diet. However, 5 days before the harvest 12 pigs of each genotype were fed a diet supplemented with Mg (3.2 g elemental Mg per day), 12 pigs of each genotype a diet with Trp (12.5 g L-Trp per day) and the rest had no supplement in the diet (control pigs). Hot carcass weight was 78.1 ± 9.2 kg. Meat quality measurements and behavior observations of aversiveness to CO₂ stunning were taken. Diet and genotype effects were analyzed, the interaction being not significant ($P > 0.05$). The diet had no influence ($P > 0.05$) on any of the parameters of meat quality determined. However the pH measured at 45 minutes *post mortem* in the *longissimus* (LT) muscle was lower in nn than in NN animals ($P < 0.05$; 5.70 vs 6.45, respectively) and the electrical conductivity higher ($P < 0.05$; 7.34 vs 4.37 µS). There were no differences in the ultimate pH. The drip losses measured in LT were higher in nn than NN ($P < 0.05$; 10.13 vs 5.89). Both parameters showed that nn animals produced more exudative meat with implications of economical losses. There were no differences between genotypes and diets in the behavior

of the animals during the inhalation of CO₂. It can be concluded that, in a nonstressful a.m. treatment, the supplementation with elemental

Mg or Trp did not affect the meat quality parameters, the genetic of the animals being the most influential factor.

Key Words: Magnesium, Tryptophan, Pork quality

Swine Species

T58 Additional heat behind farrowing sows to reduce the number of stillborn piglets. Y. Gao, H. Y. Zhang, B. Szkotnicki, and R. R. Hacker*, *University of Guelph, Guelph, ON, Canada.*

Additional heat behind a sow at farrowing might help rendering a more relaxed labor in the sow and reduce the number of stillborn pigs at parturition. To examine the hypothesized heat effect, two trials were conducted. Parturient sows were moved to farrowing crates by day 109 of gestation, and fed a 14 (in trial I) or a 16% (in trial II) CP corn-soybean meal diet (3.2-5.5 kg) twice daily. The farrowing room was maintained at 21°C or above and the creep zone was maintained above 35°C with a 175W IR heat lamp. In total, 294 sows (86 Yorkshire in trial I and 208 Hay Bay F1 York/Landrace in trial II) were randomly assigned into either a Heat (an additional 100W IR heat lamp hovered behind the sow at farrowing) or a Non-Heat group. To distinguish stillborn pigs from other pigs that were born alive and died after birth, a lung flotation test was performed on all dead piglets after completion of farrowing. In addition, 20 sows (10 from each group) from trial I were observed for the farrowing behavior. The length of time sows spent sitting, standing and lying down, average delivery interval and position change frequency were recorded. Results showed that additional heat behind a sow at farrowing did not significantly reduce the number of stillborn pigs. On average, there was one stillborn piglet per litter for either the Heat or the Non-Heat group. However, Heat did appear to make live born piglets move readily to the sows udder. Furthermore, there was no difference between the Heat and the No-Heat group for the time farrowing sows spent lying down (85.8 vs. 85.8 min), sitting (9.5 vs. 10.1 min) or standing (4.6 vs. 4.2 min). Additional heat did not significantly decrease the average piglet delivery interval (16.9 min for the Heat group and 17.2 min for the Non-Heat group), however, it significantly decreased ($P < 0.05$) position change frequency (24 vs. 30 times). Less sow movement reduces the risk of the neonatal pigs being crushed by the sow.

Key Words: Additional Heat, Stillborn, Sow Farrowing Behavior

T59 Addition of heat at birth and supplementation of energy and IgG products on improving survivability in neonatal pigs. Y. Gao, H. Y. Zhang, B. Szkotnicki, and R. R. Hacker*, *University of Guelph, Guelph, ON, Canada.*

The objective of this study was to reduce piglet mortality during the first 7d of life by providing additional heat at birth and orally administering cream (C), (10% Half-and-Half cream, Parmalat Canada), and IgG, as Porcine plasma IgG concentrate (P), (American Protein Corp. Inc., IA, USA), to provide supplemental heat, energy and immunoglobulin to neonatal pigs. The farrowing room was maintained at 21°C or above and the creep zone was maintained above 35°C with a 175W IR heat lamp. In two trials, 294 litters (86 litters from Yorkshire sows in trial I and 208 litters from Hay Bay F1 York/Landrace sows in trial II) were randomly assigned into either a Heat (an additional 100W IR

heat lamp hovered behind a sow at farrowing, maintaining the farrowing zone temperature above 30°C) or a Non-Heat group. Within 12h after farrowing, the four smallest (minimum birth body weight of 0.6 kg) newborn piglets were selected from each litter and randomly assigned to one of the following four treatments: Control, C (6ml), CP-1 (7ml, 120mg/ml IgG) and CP-2 (8ml, 210mg/ml IgG) in trial I; Control, C (6ml), CP-3 (6ml, 60mg/ml IgG) and CP-4 (6ml, 120mg/ml IgG) in trial II. Results showed that the addition of heat at birth did not show any significant effect on piglet mortality at birth. There was not a significant effect on 3d or 7d piglet mortality associated with supplementation of energy or IgG to newborn pigs in this study. In addition, there was no difference for piglet weight gain from birth to 7d of life. Further investigations need to be conducted on the transfer and absorption of the supplemented IgG in neonatal pigs.

Key Words: Energy and Immunoglobulin Supplementation, Additional Heat, Piglet Mortality

T60 Effects of stocking rate and feeder space on pig performance in a wean-to-finish system. J. M. DeDecker*¹, M. Ellis¹, B. F. Wolter², and B. A. Peterson¹, ¹*University of Illinois, Urbana,* ²*The Maschhoffs, Inc., Carlyle, IL.*

The objective of this study was to determine the effects of feeder space and stocking rate during the first 8 wk post-weaning on pig performance from weaning (4.8 ± 0.03 kg BW; 15 ± 1d of age) to 23 wk post-weaning. Twenty pens of crossbred pigs (n = 960) were used in a randomized complete block design with a 2 × 2 factorial arrangement of treatments: 1) stocking rate (Single [32 pigs/pen] vs Double [64 pigs/pen]) and 2) feeder space (two spaces [81.3 cm/pen] vs three spaces [121.9 cm/pen]). The stocking rate treatment was imposed for 8 wk post-weaning, thereafter pigs on all treatments had the same group size of 32 pigs/pen. Floor spaces/pig during the treatment period were 0.66 m² and 0.33 m² for the single- and double-stocked treatments, respectively. There were no ($P > 0.05$) stocking rate by feeder space interactions. During the 8 wk double-stocking period, daily weight gain was higher ($P < 0.001$; 494 and 467 ± 4g/d) for the single-stocked pigs resulting in heavier ($P < 0.001$; 32.3 and 30.8 ± 0.23kg) BW at the end of wk 8. Providing three feeding spaces compared to two tended ($P = 0.08$) to improve daily weight gains (485 and 476 ± 4g/d) resulting in a trend ($P = 0.09$) for heavier BW (31.9 and 31.2 ± 0.23kg) at the end of wk 8. From the end of the double-stocking period to slaughter, there was a trend ($P = 0.06$) for average daily gain (839 and 862 ± 7g/d) to be higher for the double-compared to the single-stocked pigs resulting in similar ($P = 0.77$) BW at slaughter. There was no effect of feeder space during this period and BW were similar ($P = 0.71$) at slaughter. In summary, these results suggest double-stocking pigs for 8 wk post weaning reduces growth performance and BW at 8 wk, but that difference is not maintained to slaughter. Adding an additional feeder space did not significantly improve performance of double-stocked pigs in this study.

Key Words: Pigs, Stocking Rate, Feeder Space

Animal Health

T61 Dose-dependent cytokine expression in lipopolysaccharide activated bovine alveolar macrophages. J. A. Mills*, J. E. Campanicki, and R. M. Dyer, *Dept. of Animal and Food Sciences, University of Delaware, Newark.*

Pro- and anti-inflammatory cytokine gene expression in bovine alveolar macrophages could be reflected by level of lipopolysaccharide (LPS) challenge. Lavage procured alveolar macrophages (n=4) were exposed to 0, 1, 10, 100 and 1000 ng/ml of LPS (*E. coli*; O111:B4) for 6 hours. Levels of mRNA expression for IL-1 α , IL-1 β , TNF α , IL-10, IL-12, IL-18, TGF β and iNOS were determined by real time QPCR.

Expression of IL-1 α , IL-1 β and iNOS and peaked at 2.5, 11.3 and 13.0 fold higher ($P < 0.05$) than levels in unexposed cells, respectively at 100 ng/ml of LPS. TNF α expression changed within LPS stimulated alveolar macrophages, but differences between LPS treatments were only significant between 1 ng/ml and 100 ng/ml ($P < 0.05$), and tended to differ between 1 ng/ml and 1000 ng/ml ($P < 0.10$). In contrast, expression of IL-10, IL-12, IL-18 and TGF β decreased ($P < 0.05$) at all levels of LPS exposure with the greatest decrease appearing at 100 and 1000 ng/ml of LPS. These findings suggest the balance of inflammatory and anti-inflammatory cytokine expression is dependent upon levels of LPS

exposure and is strongly biased toward a pro-inflammatory response at higher doses of LPS exposure.

Key Words: Cytokines, Lipopolysaccharide, Alveolar Macrophages

T62 Cytokine and growth factor expression is regionally distributed in Holstein claws. J. A. Mills*, R. J. Grant, and R. M. Dyer, *Dept. of Animal and Food Sciences, University of Delaware, Newark.*

Horn tissue of healthy and diseased bovine claw is generated by keratinocyte replication and differentiation in the epidermal layer of the sensitive lamina. Since dermal-epidermal structures express cytokines and growth factors that regulate keratinocyte activity in other species we proposed bovine sensitive lamina expressed cytokine and growth factors. Accordingly, mRNA expression of IL-1 α , IL-1 β , IL-10, IL-12, IL-18, TNF α , TGF β , KGF, and GM-CSF was determined in sensitive lamina of normal coronary band, wall, sole and heel bulb using real time PCR. Expression of IL-1 α , IL-1 β , IL-10, IL-12, IL-18, TNF α , TGF β , KGF and GM-CSF was detected in the sensitive lamina and differed (P<0.05) between and within regions. Cytokine and growth factor expression was lowest overall in the heel bulb (P<0.05). Expression of IL-1 α and GM-CSF were similar across regions and levels of IL-10 were extremely low or not detected across all regions. Levels of IL-1 β expression were greatest (P<0.05) in the coronary band and wall, intermediate in the sole and lowest in the heel bulb. Expression of TNF α and KGF was highest (P<0.05) in the coronary band, intermediate in the wall and lowest in the bulb and sole. Levels of IL-12 and TGF β expression were greatest (P<0.05) in the coronary band and wall and lowest in the bulb. IL-18 expression was greatest (P<0.05) in the coronary band, intermediate in the sole and wall and lowest in the bulb. Thus the results indicated growth factors and many pro- and anti-inflammatory cytokines are expressed in normal bovine sensitive lamina. Their expression differed depending upon anatomic location of the sensitive lamina.

Key Words: Cytokines, Growth Factors, Sensitive Lamina

T63 Extracellular pH alters the innate immune response by enhancing phagocytosis and decreasing reactive oxygen species production. D. C. Donovan*¹, A. J. Reber¹, R. Parks¹, L. O. Ely², and D. J. Hurley¹, ¹*College of Veterinary Medicine, University of Georgia, Athens,* ²*Department of Animal and Dairy Science, University of Georgia, Athens.*

Intensive feeding management of today's feedlot and dairy cattle often results in systemic acidosis and an increase in respiratory disease. Previous research in our laboratory demonstrated that a slight change in venous pH lead to altered adaptive immune responses in steers fed acidogenic diets. In the present study, in vitro experiments were conducted on the innate immune response by evaluating the effects of media pH on phagocytosis and radical production of neutrophils and monocytes. Sixty milliliters of blood was obtained by jugular venipuncture from late lactation multiparous Holstein cows housed at the Athens Dairy Research Center of UGA (331 +/- 81 DIM) with an average body condition score of (3.2 +/- 0.3) for use in ROS assays (n = 12) and (337 +/- 82 DIM) with an average body condition score of (3.22 +/- 0.36) for phagocytic activity of neutrophils and macrophages (n = 12). Phosphate Buffer Saline was supplemented with 0.5% Bovine Serum Albumin and 5 mM Glucose and adjusted to pH 6.0, 6.4, 6.8, 7.2, 7.6, & 8.0. Data were analyzed by mixed procedures of SAS 8.2 (2002) with pH as the main effects. After stimulation with phorbol myristate acetate (PMA) for 1 h incubation at 37 C, the production of reactive oxygen species (ROS) was evaluated using a response ratio (PMA stimulated cells/unstimulated cells). Statistical analysis indicates that pH (P < 0.01) greatly effects the production of ROS, and acidosis decreased (P = 0.031) the production of ROS relative to alkalotic conditions. Additionally, phagocytosis of bodipy labeled E. coli and S. aureus tended (P = 0.12) to be increased under acidotic pH compared to alkalotic pH. Preliminary finding suggest nitric oxide production, after stimulation with lipopolysaccharide, also appears to be decreased at acidic conditions. These results suggest that acidotic pH alters the innate immunity.

Key Words: Acidosis, Immunity, Phagocytosis

T64 Elevation of tumor necrosis factor- α and α_1 -acid glycoprotein in lambs with consolidation of lung tissue. J. A. Daniel*¹, T. H. Elsasser², and W. Epperson¹, ¹*South Dakota State University, Brookings,* ²*USDA-ARS Growth Biology Lab.*

Previous research in cattle and sheep has indicated that lung lesions result in decreased animal growth, but mechanisms by which lung lesions result in decreased growth have not been identified. The objective of this research was to identify possible changes in circulating mediators of inflammation associated with lung lesions. As part of a study to determine timing of the onset of lung lesion development, lambs were slaughtered at three time points after weaning (day 1 n=21, day 50 n=20, and day 71 n=21). Serum was harvested and stored at -80°C until analysis. Percentage consolidation of each lobe of the lung was estimated for each lamb. Lambs were classified as having normal (<5 % consolidation of any lobe), moderate lesions (5-50% consolidation of any lobe) or severe lesions (>50% consolidation of any lobe). Circulating concentrations of tumor necrosis factor- α (TNF) were determined by RIA and circulating concentrations of α_1 -acid glycoprotein (AGP) were determined by radial immunodiffusion. For statistical analysis, sheep with AGP levels below the minimum detectable concentration (50 μ g/ml) were assigned an AGP concentration of 50 μ g/ml; effect of lesion scores and level of severity on circulating concentrations of TNF and AGP were tested using one-way ANOVA. Lambs with lesions, moderate or severe, had elevated circulating concentrations of TNF and AGP relative to normal lambs (75.9 \pm 2.3 vs. 68.7 \pm 2.2 pg TNF /ml and 183.6 \pm 44.6 vs. 76.0 \pm 21.3 μ g AGP /ml respectively, P < 0.05). Circulating concentrations of TNF and AGP did not differ between lambs with moderate or severe lesions (76.4 \pm 3.14 vs. 75.3 \pm 3.52 pg TNF /ml and 139.3 \pm 74.2 vs 232.3 \pm 45.3 μ g AGP /ml respectively, P > 0.05). These data indicate that circulating concentrations of TNF and AGP are elevated in lambs with lung lesions. Elevations in circulating concentrations of TNF and AGP in lambs with lung lesions are consistent with an inflammatory state that compromises health and growth.

Key Words: Lambs, Tumor Necrosis Factor-Alpha, Alpha₁-Acid Glycoprotein

T65 Failure to down regulate tumor necrosis factor- α (TNF- α) responses to repeated endotoxin (LPS) challenge in subpopulations of cattle constitutes a pathophysiologically relevant marker of risk for increased morbidity to disease. T.H. Elsasser* and S. Kahl, *USDA, Agricultural Research Service, Beltsville, MD.*

The tolerance phenomenon is a progressive physiological downregulation of the cytokine cascade responses to repeated challenge with inflammatory stimuli like LPS. Tolerance is considered necessary to attenuate the development of multiorgan failure that occurs from the formation of oxy-nitrogen free radicals and initiation of the complement C9 membrane attack complex (MAC) pathway. Using repeated, graded doses of *E. coli* 055:B5 LPS, we have identified and characterized subpopulations of cattle who fail to develop tolerance in their presentation of significantly greater changes in the immune response event-initiating proinflammatory cytokine TNF- α and corresponding indicators of increased morbidity and disease response. Crossbred beef heifers (n = 32, avg BW 323 kg) were injected twice in five days with LPS (0.8 μ g/kg BW^{0.75}) with representative blood samples obtained for measurement of plasma TNF- α by RIA. The TNF- α response index (T_{IND}, area response to the first challenge divided by the area response to the second challenge) for each heifer was ranked (Z-score) and outliers identified and grouped (tolerance failure heifers, TFH, n = 6) and retested with a contemporary group of tolerant heifers (TH, n = 6) at 9.46 μ g LPS/kg BW^{0.75}. T_{IND} responses to LPS were highly repeatable across dose and correlated (P<0.02). Replenishment of lost BW following LPS was delayed (P<0.02) in TFH vs TH. Plasma acute phase proteins (APP: serum amyloid-A and haptoglobin) concentration changes were greater and temporally prolonged (P<0.01) after the repeated LPS challenge in TFH vs TH. Immunohistochemical quantification indicated an increased number of cells and greater intensity of staining positive for MAC at 24 h post LPS in TFH vs TH (P<0.05). The data indicate that TNF- α and APP responses to repeated LPS challenge testing can identify animals at risk of greater morbidity response to disease vector challenge.

Key Words: Endotoxin, Immune tolerance, Regulation

T66 Exogenous testosterone (T) modulates tumor necrosis factor- α (TNF- α) and acute phase proteins (APP) responses to repeated endotoxin (LPS) challenge in steers. S. Kahl* and T. H. Elsasser, *USDA, Agricultural Research Service, Beltsville, MD.*

Clinical responses to some disease agents differ between sexes and this dimorphism has been attributed to the immunomodulating effects of estrogens and androgens. Our objective was to determine in steers the effect of T treatment on circulating concentrations of immune response mediators after two consecutive LPS challenges (LPS1 and LPS2, 5 d apart; 0.25 $\mu\text{g}/\text{kg}$ BW, i.v., *E. coli* 055:B5). Crossbred steers (n=16; 328 \pm 6 kg), fed a forage-concentrate diet (15% CP) to appetite, were assigned to control (C) or T treatment (n=8). Testosterone cypionate (100 mg/m² body surface, i.m.) was injected 12 and 2 d before LPS1. Mean plasma concentrations of T before LPS were 0.02 \pm 0.01 and 3.9 \pm 0.17 ng/ml in C and T, respectively. For each challenge, jugular blood samples were obtained at 0, 1, 2, 4, 7, and 24 h relative to LPS injection. The response to LPS challenge was calculated as area under the time \times concentration curve (AUC) for the parameter measured. After LPS1, TNF- α AUC was greater in T than C (3.17 vs 1.91 ng/ml \times h, P<0.05). Serum Amyloid-A (SAA) and plasma haptoglobin (HG) concentrations increased (P<0.01) after LPS1 and LPS2. In all steers SAA AUC was greater after LPS1 than LPS2 (P<0.01) but the response was augmented over C with T treatment (2.70 vs 2.05 mg/ml \times h, P<0.05). HG response to LPS1 within 24 h was not affected by T. However, 5 d after LPS1 mean plasma HG concentration remained higher in T than C (0.95 vs 0.27 mg/ml, P<0.01). HG response to LPS2 was greater in T than C (17.7 vs 9.7 mg/ml \times h, P<0.01). Results indicate that the presence of circulating T increases the magnitude of the TNF- α response to LPS challenge as well as the subsequent increases in APP. Effects of T on increases in TNF- α and APP may underlie a differential presentation of disease symptoms. The data also suggest a role for T in the development of tolerance to repeated immune challenge through its effect on the increased magnitude and duration of HG response.

Key Words: Acute Phase Proteins, Endotoxin, Testosterone

T67 Concomitant dual wavelength fluorescence evaluation of inducible nitric oxide synthase (iNOS) and cytokine responses to endotoxin (LPS) stimulation of bovine peripheral blood mononuclear cells (PBMC). C. Li*, D. Carbough, S. Kahl, and T. Elsasser, *Animal and Natural Resources Institute, Beltsville, MD.*

Cytokines exert autocrine and paracrine effects on the tissue response to immune challenge. Characterization of induced cytokine proteins and intracellular response mediators like nitric oxide (NO) can be used to characterize specific aspects of host responsiveness or resistance to disease challenge. LPS induces rapid formation of proinflammatory cytokines like tumor necrosis factor-alpha (TNF) and many TNF actions are mediated by NO generated from arginine through protein kinase b/AKT- mediated TNF upregulation of the iNOS gene promoter. Once formed, the 17 kD form of TNF is rapidly released from cells making it difficult to evaluate the cellular level of cytokine produced as well correlate its production to that of iNOS. In the present work, we optimized an immune challenge protocol, to rapidly evaluate TNF and iNOS responses in individual beef cattle. LPS (*E. coli*,055:B5) was added to whole blood (jugular, heparinized) to a final concentration of 2.0 $\mu\text{g}/\text{ml}$. Brefeldin-A, an antibiotic that blocks vesicular protein transport out of cells (Golgi-Block (tm), BD Scientific) was added at 1.0 $\mu\text{l}/\text{ml}$ blood. After discrete time periods, subsamples of the whole blood were permeabilized to permit passage of antibodies into cells; blood was incubated with anti-bovine TNF or anti-mouse iNOS. Red blood cells were eliminated by hypotonic lysis. PBMC TNF and iNOS responses were quantified by specific immunofluorescent staining using a dual wavelength fluorescence flow cytometer (Beckman-Coulter Cytomics Fc 500). Our data indicate that upon activation, the intracellular levels of TNF accumulate in the cells treated with brefeldin-A and iNOS increases significantly with a differential time course to that of TNF. The levels of TNF and i-NOS are correlated in PBMCs (P<0.01). By rapidly evaluating the functional interactions between iNOS and cytokines using whole blood in vitro challenge, we can develop strategies to more closely monitor animal health status.

Key Words: Endotoxin, iNOS, Cytokines

T68 The effects of anti-inflammatory agents on expression of cyclooxygenase-2 by bovine neutrophils. N. Cunningham*, P. Matterson, and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro.*

Neutrophils (PMN) play a very important role in the inflammatory response of mammals. Cyclooxygenase-2 (COX-2) is one of two isoforms of the enzyme that catalyzes the production of prostaglandins. Bovine PMN release the COX-2 enzyme when stimulated with *Escherichia coli* lipopolysaccharide (LPS). Nonspecific steroidal anti-inflammatory drugs (NSAIDs) have been very effective at inhibiting COX-2 gene expression in man. The objectives of the present study were to evaluate the effect of commonly used NSAIDs on COX-2 gene expression in resting and stimulated bovine PMN. Blood collected from the jugular vein of four lactating Holstein cows was used to isolate PMN by differential centrifugation and hypotonic lysis of red blood cells. Viability was determined by Trypan blue dye exclusion, purity by differential cell counts and cell concentrations by using a hemacytometer. Subsequently, untreated or LPS stimulated PMN (5 \times 10⁶ cells/ml) were incubated for 30 minutes in the presence of either naproxen sodium, flunixin meglumine, acetaminophen, Ibuprofen, sodium salicylate, nordihydroguaiaretic acid, Indomethacin, Dexamethasone, or NS-398. Each NSAID was diluted to a final concentration of 1.0 μM / treatment. Cells were harvested, lysed and fractionated using SDS-PAGE. Cyclooxygenase-2 was positively identified on LPS treated samples using a specific antibody for western blot analysis. A band of 72 Kd was detected by enhanced chemiluminescence. All NSAIDs tested inhibited the expression of COX-2 on LPS stimulated bovine PMN. The tested reagents may be useful in targeting COX-2 gene expression for modulation of inflammatory diseases such as Mastitis.

Key Words: Neutrophil, Cyclooxygenase-2, NSAID

T69 Extracts of shitake mushrooms modulate receptors for immunoglobulins on bovine neutrophils. K. Gye-nai*, M. Worku, O. Ishekhumen, and P. Matterson, *North Carolina Agricultural and Technical State University, Greensboro.*

Phagocytic destruction of opsonized bacteria by bovine neutrophils (PMN) is mediated by receptors (FcR) binding IgM and IgG₂. Receptor-specific induction of genes ultimately determines cell fate. Binding of ligand to FcR results in signal transduction through the action of mediators. Expression of FcR by PMN is a marker of apoptosis. The aqueous extract of the Shitake mushroom (*Lentinus edodes*) decreases production of inflammatory mediators and apoptosis in human PMN. Two different extracts were evaluated for their effect on the modulation of immunoglobulin binding to and FcR expression on bovine PMN. Blood PMN from a Holstein cow were isolated by differential centrifugation and hypotonic lysis of red blood cells. Extracts of 20 grams of Shitake were prepared in phosphate buffered saline (PBS) and incubated at room temperature (RT) or at 90 °C for six hours. Isolated, viable PMN were treated with 100 μl of extracts in the presence of *E. coli* lipopolysaccharide (LPS) or PBS. Cells were then incubated with FITC labeled bovine IgG₂ or IgM for flow cytometric analysis of 10,000 cells in duplicate. The mean is presented. The percentage of untreated PMN binding IgM was 76%. Treatment with LPS or RT extract slightly decreased IgM binding 69% and 68% respectively. Treatment with the 90 °C extract decreased binding (44%). Expression of FcR for IgM in untreated PMN was 112. Treatment with LPS increased receptor expression to 180 and to 107 with the RT extract. The 90 °C extract decreased expression of FcR for IgM to 93. The percentage of untreated PMN binding IgG₂ was 44%. Treatment with LPS or mushroom extract prepared at 90 °C had no effect on IgG₂ binding (47% and 45% respectively). The RT extract increased binding (54%). Expression of FcR for IgG₂ in untreated PMN was 88. Treatment with LPS and the 90° C extract did not change receptor expression (72). The RT extract up-regulated expression of FcR for IgG₂ to 165. Extracts of Shitake mushroom differentially modulated binding and expression of receptors for IgM and IgG₂ on bovine PMN. Methods of extraction may determine the effect of mushroom derived compounds for therapeutic use in animal health. Further studies are warranted.

Key Words: Neutrophil, Fc Receptor, Mushroom

T70 Expression of 5'-lipoxygenase on bovine blood neutrophils. T. Harris*¹, M. Worku¹, P. Matterson¹, and D. Fargo², ¹North Carolina Agricultural and Technical State University, ²University of North Carolina at Chapel Hill, Chapel Hill.

Exposure to bacterial products such as endotoxin (LPS) results in activation of neutrophils (PMN) and associated inflammation. Studies have shown that following exposure to LPS components of somatic cells express genes for 5'-lipoxygenase (5'-LOX) a key enzyme in the synthesis of leukotrienes. Bovine PMN contribute to the Somatic cell count in milk in response to LPS exposure. The objectives of this study were to determine if bovine PMN express the gene for 5'-LOX and to assess the effect of exposure to LPS. Blood collected from the jugular vein of two lactating Holstein cows was used to isolate PMN by differential centrifugation and hypotonic lysis of red blood cells. Viability was determined by Trypan blue dye exclusion, purity by differential cell counts and cell concentrations by using a hemacytometer. Cells were exposed to *E. coli* LPS (10ng LPS for 30 minutes at 37°C or unexposed. RNA from unexposed and LPS exposed PMN was isolated using TRI-Reagent (Sigma). Specific forward and reverse primers for 5'-LOX were used. RNA was reverse transcribed to cDNA and amplified, observed on a 2% agarose gel and documented. The PCR product was sequenced commercially and Genbank and the Basic Local Alignment System (BLAST) were used to determine homology. The PCR product appeared as a band of 332 base pairs. Two sequences of length 320 and 349 were isolated and consequently showed homology with sequences from *Bos Taurus* partial mRNA, *Mus musculus*, and *Homo sapiens*. The PCR results and sequence information confirm that bovine PMN express 5'-LOX. The results indicate that the gene is expressed in LPS exposed and unexposed cells. Quantitative studies will be conducted to assess the levels of gene expression following LPS exposure. Bovine PMN may contribute to the production of leukotrienes in inflammatory diseases such as mastitis through 5'-LOX gene expression. The gene for 5'-LOX is an ideal target for the design of therapeutics based on 5'-LOX inhibition to block leukotriene synthesis.

Key Words: 5'-lipoxygenase, Neutrophil, Sequence

T71 Ergovaline transport across human gastrointestinal cells (Caco-2). N. W. Shappell* and D. J. Smith, *USDA-ARS Biosciences Research Laboratory, Fargo, ND.*

The gastrointestinal (GI) cell model Caco-2 (derived from human colon carcinoma) was used to assess ergovaline transport. Cells were grown in transwell inserts until monolayers were established (~day 20 in culture). A pre-equilibrated mixture of ergovaline/ergovalinine (60:40; 10 and 40 μ M concentrations) was added to the apical wells (equivalent to mucosal side) in media containing phenol red. Basal media (equivalent to serosal side) contained no phenol red or ergovaline/inine. Diffusion of compounds through filters with no cells present was also measured. Apical and basal media were extracted, and isomer concentrations were determined by HPLC with fluorescence detection. Monolayer integrity was maintained throughout the 12h experimental period, as assessed by the absence of phenol red in basal media. Kinetics of isomers were identical. In the absence of cells, basal accumulation of isomers was essentially linear for three h at 10 and 40 μ M concentrations, after which basal accumulation plateaued (regression curves best described by ln equation; R^2 from 0.85 to 0.96). A second order polynomial equation best described the regression analyses of basal isomer accumulation in the presence cells (R^2 from 0.94 to 1.00). The linear phase of accumulation extended to 240 min with cells. Little change in basal accumulation was observed from 6 to 12 h. After six h in the presence of cells, ~25% and 40% of dose had accumulated in the basal compartment for 10 and 40 μ M ergovaline, respectively. These experiments show that both ergovaline and its naturally occurring isomer, ergovalinine, readily cross GI mucosal cells intact and with similar kinetics. Because both isomers were transported, either isomer, or a combination of both, could be involved in the pathogenesis of fescue toxicosis at sites distal to the G.I.

Key Words: Ergovaline, Fescue Toxicosis, Caco-2

T72 Assessment of TascoTM and YCWP on ergovaline toxicity in Caco-2 cells. N. W. Shappell* and L. O. Billey, *USDA-ARS Biosciences Research Laboratory, Fargo, ND.*

The seaweed extract TascoTM and yeast cell wall preparation (YCWP) were tested to evaluate efficacy in attenuation of ergovaline toxicity to Caco-2 cells. Initially cells were treated with 0.1% to 0.001% Tasco, to identify potential TascoTM toxicity. By ~24h at 37 °C in the presence of media (with or without cells) globules formed. After consultation with manufacturers, it was concluded that calcium and magnesium concentrations present in the medium were causing coalescence of the alginates present in TascoTM resulting in globules. TascoTM was toxic at high concentrations (72h, 0.001% to 0.1% yielded ~66% to 1% of control values, respectively, as assessed by metabolic activity (using the alamarBlueTM assay) and total protein. Ergovalines toxicity (100 μ M) was tested +/- TascoTM (0.0001% and 0.00005%, 72 h) on undifferentiated cells. At these concentrations, TascoTM was non-toxic and it did not alter the toxicity of ergovaline (~40% reduction of metabolic activity and/or total protein relative to control cells with ergovaline treatment). As YCWP is not water soluble, DMSO extraction was used (0.1g/ml). The cellular effect of YCWP in DMSO (ranging from 0.1-0.5%) was evaluated on cells. DMSO alone was found to reduce metabolic activity and total protein at concentrations greater than 0.2%. Therefore YCWP was tested in 0.05% and 0.1% DMSO. At the 0.05% DMSO/YCWP there was a slight amelioration of the toxicity caused by ergovaline (10-20%). At the 0.1% concentration, no amelioration was seen and ergovaline toxicity may have been increased slightly (<10%). Further investigation of TascoTM and YCWP at different concentrations may be warranted. An unexpected finding was the reduction of ergovaline toxicity when cells were treated in the presence of DMSO.

Key Words: Ergovaline, Yeast Cell Wall Prep, Tasco

T73 Effects of an oral rehydration solution with added bovine serum proteins on small intestinal absorptive capacity. S. I. Kehoe*¹, J. D. Quigley, III², and H. D. Tyler¹, ¹Iowa State University, Ames, ²American Protein Corporation, Ames, IA.

Calves commonly become infected with viruses and bacteria that damage the intestinal lining. Although calves cannot absorb IgG after 48 h of age, oral IgG may bind to intestinal lining. This IgG binding may decrease the levels of pathogens in the gut. To enhance recovery of small intestinal function following a coronavirus challenge, bovine serum proteins, containing IgG, TGF- β and other growth factors, were added to an oral rehydration solution (ORS) for 16 Holstein and Jersey calves. Calves were housed individually and offered water ad libitum and milk replacer at 10% of BW. Treatments consisted of a control ORS (CON) and ORS with added bovine serum proteins (GFR). After a 2 d adjustment, calves were orally challenged with bovine coronavirus. Xylose (0.5 g/kg) was administered orally once daily for 6 d and jugular blood was sampled at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4 h post-dosing. Hematocrits, fecal dry matter, rectal temperatures, attitude scores and dehydration scores were recorded once daily. Concentrations of serum xylose were numerically higher on d 6 (27.1 ± 4.9 mg/dl for CON and 24.9 ± 5.3 mg/dl for GFR) than d 3 (13.7 ± 4.6 mg/dl for CON and 17.0 ± 4.7 mg/dl for GFR) but treatments did not differ significantly. Hematocrits and other scores were not significantly different between treatments. In this model, bovine serum proteins did not enhance intestinal recovery from a coronavirus challenge when added to ORS.

Key Words: Calves, Oral Rehydration Solution, Bovine Serum Proteins

T74 Effects of small intestinal absorption in calves treated with an oral rehydration solution supplemented with fat-soluble vitamins. S. I. Kehoe*¹, H. D. Tyler¹, M. L. O'Brien², K. J. Touchette², and J. A. Coalson², ¹Iowa State University, Ames, ²Merrick's, Inc., Middleton, WI.

Young calves commonly become infected with viruses and bacteria that damage the intestinal lining. Deficiencies in fat-soluble vitamins also occur in young calves and may impair the rate of differentiation of intestinal epithelial tissues, especially following enteric infections. To enhance recovery of small intestinal function following a coronavirus challenge, fat-soluble vitamins were added to an oral rehydration solution (ORS) for 16 Holstein and Jersey calves. Calves were housed individually and

offered water ad libitum and milk replacer at 10% of BW daily. Treatment one consisted of a control ORS (CON). Treatment two consisted of added antioxidants, to provide 70,000 IU of vitamin A and 300 IU of vitamin E per day (VIT). After a 2 d adjustment, calves were orally challenged with 5×10^6 plaque-forming units of a moderately virulent bovine coronavirus isolate. Xylose (0.5 g/kg of BW) was administered orally once daily for 6 d and jugular blood was sampled at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4 h post-dosing. Hematocrits, fecal dry matter, rectal temperatures, attitude scores and dehydration scores were recorded once daily. Serum xylose concentrations were higher on d 6 (27.1 ± 4.9 mg/dl for CON and 20.2 ± 3.7 mg/dl for VIT) than on d 3 (13.7 ± 4.6 mg/dl for CON and 14.9 ± 4.2 mg/dl for VIT) but were not significantly different between treatments. Hematocrits and other clinical scores were not significantly different between treatments. In this model, antioxidant vitamins did not appear to enhance intestinal recovery from a coronavirus challenge when added to ORS.

Key Words: Calves, Oral Rehydration Solution, Fat-Soluble Vitamins

T75 Effectiveness of ground endophyte-infected tall fescue seed in production of fescue toxicosis in cattle. L. E. Wax*, D. E. Spiers, G. E. Rottinghaus, and T. J. Evans, *University of Missouri, Columbia.*

Cattle fed endophyte-infected tall fescue (E+) in the form of whole seed during heat stress experience increased hyperthermia, and reduction in both feed intake and weight gain. This study determined if intake of diet containing ground infected fescue seed would increase fescue toxicosis as a result of increased absorption of toxin. Steers (n=18; 300kg avg. BW) were housed in the Brody Climatology Laboratory and randomly assigned to daily diet treatments of either E+ (20-40 μ g ergovaline/kg BW) or control (endophyte-free, E-) seed. Animals were exposed to a 14 day heat challenge (HC) reaching 36°C during the day and 26°C at night and fed twice daily at 0800 and 1600 with water available *ad libitum*. Core temperature was measured continuously using telemetric, temperature transmitters (CowTemp, Model BV-010) with respiration rate, skin and rectal temperatures recorded four times daily. Ground E+ decreased feed intake below control by day 7 at thermoneutral (TN) (p<.0001). Maximum reduction in feed intake at TN was 25% from pre-treatment with an additional 46% decrease during HC. By the end of HC, E+ feed intake increased to E- levels, suggesting there is a recovery from the effect. In contrast to previous studies using whole seed, there is no evidence of change in core temperature from control levels. A preliminary study was done using fistulated steers to determine if this level (20 μ g ergovaline/kg BW) of seed is capable of producing an increase in core temperature above the E- level. Steers were fed E- seed for 3 days switched to E+ seed for 5 days followed by E- seed for 3 days, during HC. Peak rectal temperature rose 1.3°C from E- to E+ treatment periods. Therefore core temperature response and feed intake are independent of each other with feed intake being more sensitive. Ground fescue seed elicits a robust temperature response, once the large effect on feed intake is overcome.

Key Words: Cattle, Endophyte, Heat Challenge

T76 Effect of Eprinex® on subsequent 90-day production in Virginia Holstein herds. K. L. Rossini*¹, M. L. McGilliard¹, and R. H. Nutt², ¹Virginia Tech, Blacksburg, ²Valley Feed Co., Staunton, VA.

One trial involving four Holstein herds and 270 total dairy cows was conducted to determine if cows treated once with Eprinex® (Merial) produced more milk in subsequent months than did untreated cows. Cows were generally confined and averaged 33 kg/d of milk. Odd-numbered cows in each herd were treated with Eprinex® (1 ml/10 kg body weight) whereas even-numbered cows were left untreated. A single treatment was administered on or near one DHI test day in March, April or May. Test-day data were down-loaded for that initial test day and the next 3 monthly tests. Change in production from month zero was analyzed with a model containing effects of treatment, herd (random), month (repeated), parity (first and older), and initial days in milk (<90, 90-270, >270 d). Variables analyzed were test-day milk, percentages of fat and protein, and SCC score. A total of 211 cows remained for all four test days. Change in milk per cow from mo 0 to 1 was 2.7 kg/d (0.5 SE) greater for treated cows. The advantage was maintained at 2.7 kg/d (0.8 SE) to mo 2, and 3.1 kg/d (0.8 SE) to mo 3 (cumulative from mo 0). For cows in milk less than 90 d, treated cows had an advantage of

5.4 kg/d (1.1 SE) to mo 1, 6.6 kg/d (1.7 SE, NS) at mo 2, and 6.5 kg/d (1.7 SE) at mo 3. For cows in early lactation, 7 of 13 untreated cows increased in milk from mo 0 to 1, whereas 10 of 11 treated cows increased. Initial days in milk were 72 and 69 d for those untreated and treated groups. The advantage for cows more than 90 d in milk at treatment was not significant at less than 2 kg/d. Fat changed 0.33% more by the mo 2 for cows dosed in mid-lactation. Change in percentage protein and somatic cell score did not differ between treated and untreated cows. At a cost of \$4.00 per cow for product and labor, 0.35 kg of feed dry matter consumed for each kilogram of additional milk, \$0.15/kg of dry matter, and \$0.28/kg milk, the net value for 90 d of 3.1 kg/d would be \$0.66/d per cow (\$0.86 milk - \$0.04 product and labor - \$0.16 feed).

Key Words: Eprinex, Milk Yield, Eprinomectin

T77 Frequencies of calving-related diseases of Holstein dairy cows injected with low doses of bovine somatotropin during the transition period. M. Liboni*, M. J. Hayen, M. S. Gulay, T. I. Belloso, and H. H. Head, *Department of Animal Sciences, University of Florida, Gainesville.*

Objective was to evaluate effects of injecting bST (0.4 mL, 10.2 mg/d, POSILAC®) during the prepartum and/or early postpartum periods on incidence rate of calving-related disorders of dairy cows during the first 60 d postpartum. Multiparous Holstein cows (n=150) were assigned randomly to a 2x2 arrangement of treatments to give four groups (I=no bST, n=26; II=bST postpartum, n=25; III=bST prepartum, n=27; IV=bST prepartum and postpartum, n=25) plus a group of cohorts (V=cohort, n=47). Biweekly injections of bST were in left or right ischio-rectal fossa beginning 3 wk before expected calving through 70 DIM. Disease frequencies were collected from farm records, and incidence rates (number of diseased cows divided by the total number of cows) were reported for each group. Across all TRT groups (n=150) the observed incidence rates were: retained fetal membranes (RFM, 15%), metritis (MET, 36%), clinical mastitis (MAT, 22%), digestive problems (indigestion [DIG], 11%), ketosis (KET, 4%), milk fever (MF, 1.3%), displaced abomasum (DA, 3.3%) and lameness (LAME, 4.6%). Incidence rates of RFM, MET, MAT and DIG for TRT I, II, III, IV and V were 19.2, 16, 7.4, 0.0 and 25.5 %; 42.3, 32.0, 37.0, 32.0 and 42.5%; 30.7, 28.0, 14.8, 20.0 and 21.2%; and 19.2, 16, 11.1, 0.0 and 8.5 %, respectively. The proportions of sick cows in a group (number of cows that had one or more cases of disease divided by the total number of cows) were 76.9, 64.0, 59.2, 48.0 and 65.9 %, respectively. Significant Chi-Square values were detected between TRT I vs. TRT IV cows for RFM and DIG (P<0.028). In addition, there tended to be greater number of healthy cows on TRT IV than on TRT I (P<0.0649). No differences were detected between TRT I and cohorts. Results indicated that bST injected during the transition period did not increase the incidence of calving-related disorders. Furthermore, cows on TRT IV were less likely to have RFM, DIG and tended to be healthier than non-injected cows.

Key Words: bST, Transition Period, Diseases

T78 The effect of Johne's disease on culling and milk production in nine Ontario dairy herds. S. H. Hendrick*¹, T. F. Duffield¹, D. F. Kelton¹, K. E. Leslie¹, K. D. Lissimore¹, and M. Archambault², ¹Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, ²Animal Health Laboratory, University of Guelph, Guelph, ON, Canada.

The objective of this study was to evaluate the influence of Johne's disease (JD) on culling and milk production on Ontario dairy herds. During the summer of 2002, 9 Holstein dairy herds with a previous history of JD were enrolled in this study. Blood and fecal samples were collected from all milking and dry cows (868 cows). Serum samples were submitted to the AHL, for a commercial ELISA. Fecal samples were sent to AntelBio Systems for traditional fecal culture. Milk samples were collected from all milking cows at the herds next DHI test day (690 cows). The milk samples were sent to AntelBio for an in-house milk ELISA. Test results were not returned to the producers until January 2003. Milk production and culling data were retrieved from the DHI database. 305-day milk production was compared to JD status as predicted by the three diagnostic tests. A separate model was made for each test with the effects of mastitis, DIM, parity and herd controlled in each of the models. Culling data was collected between the farm visit date and Dec. 31, 2002. Proportional hazards models were used to evaluate the days to culling stratified by JD status with separate model

for each test, and controlling for herd, DIM, parity, pregnancy status and linear score. Fecal culture positive cows produced 548 kg less milk than fecal culture negative cows. Similarly, milk ELISA positive cows had a decrease of 457 kg versus milk ELISA negative cows. There was no statistical difference in 305-day milk production in seropositive cows. Survival analysis showed that fecal culture positive cows were 3.16 times more likely to be culled than non-shedding cows. Milk ELISA positive cows were 2.27 times more likely to be culled than milk ELISA negative cows. There was a tendency for serum ELISA positive cows to be culled 1.72 times more than seronegative cows. For the 9 herds in this study, JD significantly limited milk production and cow longevity.

Key Words: Paratuberculosis, Culling, Milk Production

T79 *Escherichia coli* and *Staphylococcus aureus* elicit differential innate immune responses following intramammary infection. D. Bannerman¹, M. Paape¹, J.-W. Lee², X. Zhao², J. Hope³, and P. Rainard⁴, ¹Bovine Functional Genomics Laboratory, USDA-Agricultural Research Service, Beltsville, MD, ²Department of Animal Science, McGill University, Ste-Anne-de-Bellevue, QC, Canada, ³Institute for Animal Health, Berkshire, UK, ⁴Institut National de la Recherche Agronomique, Nouzilly, France.

Staphylococcus aureus and *Escherichia coli* are among the most prevalent species of Gram-positive and Gram-negative bacteria, respectively, that induce clinical mastitis. The innate immune system comprises the immediate host defense mechanisms to protect against infection and contributes to the initial detection of and pro-inflammatory response to infectious pathogens. The objective of the current study was to characterize the differential innate immune response to experimental intramammary infection with *E. coli* and *S. aureus*. The cytokine response and changes in the levels of soluble CD14 (sCD14) and lipopolysaccharide (LPS)-binding protein (LBP), two proteins that contribute to host recognition of bacterial cell wall products, were studied. Intramammary infection with either *E. coli* or *S. aureus* elicited systemic changes that were statistically significant including decreased milk output, a febrile response, and induction of the acute phase synthesis of LBP. Infection with either bacteria resulted in significantly increased milk levels of IL-1 β , IFN- γ , IL-12, sCD14, and LBP. Significantly higher levels of the complement cleavage product C5a, and the anti-inflammatory cytokine IL-10, were detected at several time points following *E. coli* infection, whereas, *S. aureus* infection elicited a slight but significant increase in these mediators at a single time point. Significant increases in IL-8 and TNF- α were only observed in quarters infected with *E. coli*. Together, these data demonstrate the variability of the host innate immune response to *E. coli* and *S. aureus* and suggest that the limited cytokine response to *S. aureus* may contribute to the well-know ability of this bacterium to establish chronic intramammary infection.

Key Words: Mastitis, Innate Immunity, Inflammation

T80 Ultrasonographic characteristics of the uterus of Holstein cows with late endometritis. J. K. Haskell¹, D. S. Hammon², and G. R. Holyoak³, ¹Department of Forest, Range and Wildlife, Utah State University, Logan, ²Department of Animal, Dairy and Veterinary Sciences, Utah State University, Logan, ³Department of Clinical Sciences, College of Veterinary Medicine, Oklahoma State University, Stillwater.

Endometritis in dairy cows is common during the prebreeding period and has a profound negative impact on reproductive efficiency. Further characterization of endometritis and easily utilized, non invasive, and accurate methods to diagnose endometritis are needed. The objective of this study was to determine the potential for using ultrasonography as a method for diagnosing subclinical endometritis in early lactational dairy cows. To assess subclinical endometritis, primiparous and multiparous Holstein dairy cows were examined 40 to 60 days postpartum. The reproductive tract of each cow was examined using transrectal ultrasonography, and measurements of uterine horn diameter, and endometrium height were obtained by electronic caliper. Frozen ultrasound images of uterine horn transverse sections were recorded for later evaluation to determine the presence of endometritis, based on echoid particles and fluid within the uterine horn lumen. Uterine cytology was performed as a definitive diagnosis of endometritis for each cow. Specificity and sensitivity of ultrasound were established based upon the results of two investigators and compared to uterine cytology. Specificity was 97%

and 64%; and sensitivity was 53% and 57% for evaluator 1 and 2, respectively. Measures of uterine endometrium height difference between horns, and maximum endometrium height were significantly associated with the presence of endometritis. This finding supports the use of ultrasound to accurately detect endometrial changes, which are associated with endometritis.

Key Words: Subclinical Endometritis, Uterine Cytology, Ultrasonography

T81 Antimicrobial Susceptibility Of Coagulase-Negative Staphylococci Isolated From Hands Of Urban Children, Farm Workers, and Dairy Cow Teat Skin. M. M. Pol^{*}, C. C. M. Hulland, and P. P. L. Ruegg, University of Wisconsin, Madison.

There is increasing concern that antimicrobial use in animals can create a reservoir of resistant bacteria that could be transferred to humans. The aim of this study was to compare results of antimicrobial susceptibility tests of coagulase-negative staphylococci (CNS) isolated from teat skin of cows, and hands of children and farm workers. Swabs (Quick Swab, 3M) were obtained from hands of farm workers (n = 39), urban children (n = 36), and from teat skin of dairy cows (n = 32). Swabs were cultured on blood agar plates and incubated at 37 C. CNS were speciated using a commercial microbial identification system. MIC values were obtained using a commercial microdilution system (Sensititre, Westlake, OH). Isolates classified as intermediate were reclassified as resistant for statistical analysis. MIC values were obtained for CNS isolated from children (n = 57), farm workers (n = 64), and teat skin (n = 42). There were no significant differences in MICs of CNS isolated from farm workers among farms. MICs of CNS obtained from teat skin varied among farms for erythromycin and sulfadimethoxine (P #8804 0.05). For most antimicrobials, there were no significant differences in MIC based on source of the isolate. MICs for erythromycin and sulfadimethoxine were significantly higher for farm workers as compared to urban children (P #8804 0.05). MICs for tetracycline were significantly higher for CNS obtained from farm workers as compared to CNS obtained from children and teat skin (P < 0.001). Source of isolate was significantly associated with resistance for ampicillin (P = 0.04), penicillin (P = 0.02), erythromycin (P = 0.03), pirlimycin (P < 0.001), sulfadimethoxine (P = 0.04), and tetracycline (P < 0.001). The probability of resistance was 0.3, 0.4, 0.1 and 0.2 for children as compared to farm workers for ampicillin, erythromycin, pirlimycin and tetracycline respectively. The probability of resistance was 0.3, 0.2 and 0.04 for children as compared to teat skin for erythromycin, penicillin, and pirlimycin, respectively.

Key Words: Antimicrobial Susceptibility, Coagulase-Negative Staphylococci

T82 Heel erosion in dairy cattle. L. G. Baird¹, L. C. Pinheiro Machado Filho², M. A. G. von Keyserlingk¹, D. M. Weary¹, and K. A. Beauchemin³, ¹Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, ²Universidade Federal de Santa Catarina, Brazil, ³Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.

Heel erosion, one of the most common hoof disorders in dairy cattle, begins as shallow irregular grooves in the heel horn and can progress to deep oblique grooves resulting in major loss of heel structure. Although some research is available for European farms, to date no published studies have addressed this disorder for North American dairy herds. The objective of this study was to monitor the progression of heel erosion in a cohort of Holstein cows, examining the effects of parity and stage of lactation. The hind hooves of 20 heifers and 38 multiparous cows were scored at least once pre-calving, in early lactation (0-100 DIM) and in mid-lactation (100-200 DIM). Specifically, we noted any grooving on the four hind claws (medial and lateral, left and right), and if these grooves were irregular or oblique. Any claw with oblique grooves or major loss of heel structure was classified as having severe erosion. During pre-calving observations, the average number of claws per cow with severe heel erosion was 0.59 \pm 0.12, but by mid-lactation this score had increased to 2.7 \pm 0.20 (P < 0.001). Erosion was also related to parity, with the older cows experiencing higher scores (P < 0.001), especially in early and mid-lactation (P < 0.02 for period by parity interaction). The

results of this study indicate that heel erosion is a common affliction, especially for mid-lactation multiparous cows.

T83 Identification of a c-reactive protein gene in cardiomyopathic turkeys: A possible genetic marker for turkey cardiomyopathy. A. E. Hauser* and M. M. Corley, *Tuskegee University, Tuskegee, AL.*

C-reactive protein (CRP) is an inflammatory protein released by the body in response to infection and injury. Elevation of this serum protein has been linked to increased risks of heart disease through inflammation that is believed to play a key role in the hardening of arteries resulting in a heart attack or stroke. Consequently, CRP could serve as a genetic marker for an eminent cardiac event. Thus far, the poultry industry has experienced considerable loss due to turkey cardiomyopathy. Furthermore, the gross and microscopic lesions in tissue from cardiomyopathic turkeys, have been shown to be very similar to human cardiomyopathic heart tissue. Therefore investigation of those genes involved in turkey cardiomyopathy can lead to further insight of cardiovascular disease and thus benefit both the poultry industry and the human population. In this study, we attempted to identify a crp gene from turkeys that carry a genetic trait (unknown) that renders them susceptible to cardiomyopathy. The identification and expression of this gene as it relates to heart disease in these turkeys has not been investigated. The reverse transcriptase polymerase chain reaction (RT-PCR) was used to target this gene. Total RNA, extracted from frozen heart tissue (0.1g) of a cardiomyopathic turkey was used to generate turkey cDNA, and oligonucleotide primers were designed from a partial crp gene sequence derived from a chicken liver cDNA library to amplify the crp gene. The expected 504 bp RT-PCR product was successfully amplified. Identification and analysis of the gene that codes for CRP in turkeys will lend further insight into the etiology of turkey cardiomyopathy.

Key Words: Cardiomyopathic, C-reactive Protein, Turkeys

T84 Identification and analysis of an apolipoprotein- A gene in cardiomyopathic turkeys. T. A. Dugger* and M. M. Corley, *Tuskegee University, Tuskegee, AL.*

Apolipoprotein A is a major constituent of high-density lipoproteins, which aids in the regulation of high cholesterol levels in the blood and peripheral tissues. If this process is defective, cholesterol molecules can accumulate in arteries, result in arterial blockage, thereby leading to a cardiac event (heart attack). The turkey cardiomyopathic heart resembles that of humans in gross and microscopic morphology. Therefore analysis of genes implicated in turkey cardiovascular disease may be beneficial to both poultry and human health. Heart tissue from cardiomyopathic turkeys was used to identify an apoA gene and its possible involvement in cardiovascular disease. The role of this gene as it relates to turkey cardiomyopathy has not been investigated. To isolate this gene, total RNA was isolated from heart tissue samples and purified. Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) was performed using primers designed from the chicken apoA-1 gene. The RT-PCR product was visualized via agarose gel electrophoresis (1.5% w/0.5 µg/ml ethidium bromide). The expected 519 bp RT-PCR product was observed, indicating successful amplification of the apoA gene from cardiomyopathic turkey heart tissue. Identification and analysis of the turkey apoA gene will lead to further knowledge of the etiology of turkey cardiomyopathy.

Key Words: Apolipoprotein, Cardiomyopathy, Turkeys

T85 Isolation and characterization of an anti-Salmonella phage collection for use as antibacterial agents. E. Kozhina*, P. Herrera, and S. Ricke, *Texas A&M University, College Station.*

Interest in phage therapy has increased in the past several years due to the rise in the antibiotic resistance. There are several problems to overcome before bacteriophages can be routinely used as antibacterial agents. One problem is that most bacteriophages are highly specific

infecting only a few host strains of bacteria. However some bacteriophages exhibit a wider host range. Another problem is the maintenance of the stability and viability of a phage collection. Our objective is to isolate a stable phage collection capable of lysing a number of different *Salmonella* strains. First, we isolated phages from the environmental water samples. This was followed by five consecutive step propagation procedures in a mixture of *Salmonella* strains and in four different *Salmonella* strains. A number of plaques grew on a bacterial lawn containing the 4 *Salmonella* strains. The largest and clearest plaques were chosen for further study. We investigated stabilizer (YT media supplemented with 10 mM MgSO₄, 1% BSA and 5% sucrose) for storage of phage collection. We found that it result in 100% recovery of newly isolated phage collection stored for a month in 4°C (compare to 98% of recovery in SM buffer (100 mM NaCl, 8 mM MgSO₄, 50 mM Tris-Cl, pH 7.5). The DNA from these phages were isolated, digested with EcoRI restriction enzyme, and the banding patterns analyzed by agarose electrophoresis. In order to select for the most stable phage isolates, the mixtures of primary phage isolates were stored for 5 months at 4°C. Phages isolated from these mixtures were tested for their ability to survive while incubated in non-sterile bovine rumen fluid at 37°C. Stabilizers, such as 1M MgSO₄ and 1% gelatin, were added to determine if they could enhance the bacteriophages survival. In all cases phages were isolated from rumen fluid after 3 days of incubation. The presence of stabilizer did not influence phage stability in rumen fluid. Initial results indicate that these procedures, with minor modification, can be used routinely to generate a useful and stable anti-*Salmonella* phage collection.

Key Words: *Salmonella*, Phage, Isolation

T86 Pathology of listeriosis resulting from respiratory infection of turkey poults with *Listeria monocytogenes* Scott A. G. R. Huff*¹, W. E. Huff*¹, J. N. Beasley², M. G. Johnson², R. Nannapaneni², J. M. Balog¹, and N. C. Rath¹, ¹USDA/ARS/PPPSRU, ²University of Arkansas.

The pathogenesis of a human epidemic strain of *Listeria monocytogenes*, Scott A, was studied by challenging day-old turkey poults with air sac inoculation of 10⁰ (Control), 10⁴, 10⁵, 10⁶, 10⁷, or 10⁸ cfu. Respiratory challenge with all levels resulted in listeriosis. Mortality at 2 wk post-infection ranged from 25-100% and was directly correlated with level of challenge. Gross pathology included enlarged gall bladders and pale livers, some of which were also yellowish, mottled, or cooked in appearance. Ruptured yolk sacs were common. Lungs were necrotic and hearts were swollen and surrounded by fluid. Sections of liver, heart, spleen, bursa, lung, and brain were fixed in 10% buffered formalin. Paraffin-embedded sections were cut at 5µ, stained with hematoxylin and eosin as well as Gram stain and were examined for histological lesions. Lesions were observed in liver, heart, spleen, bursae, and lung, however no significant changes were present in brain. The myocardial lesions consisted of large infiltrations of mononuclear cells deep in the myocardium and were associated with Gram positive rods. In the liver, focal infiltrations of mononuclear cells were small and scattered and were also associated with Gram positive rods. Congestion and reticuloendothelial hyperplasia were prominent in the spleen and there was necrosis of scattered cells. Lymphocytes and mononuclear cells infiltrated areas surrounding bronchi in the lung. In the bursae there was depletion of lymphocytes in bursal follicles. *Listeria* challenge also resulted in significantly decreased relative weight of the bursa of Fabricius and increased relative weight of the spleen. *L. monocytogenes* was isolated by direct plating of liver, gall bladder, pericardium, brain, yolk sac, lung, cecal tonsil, and both left and right knee synovium cultures on UVM *Listeria* selective agar. These results suggest that respiratory infection with *L. monocytogenes* can be invasive in young turkeys and may be responsible for some unexplained cases of early poult mortality as well as the initiation of chronic infection leading to product contamination.

Key Words: *Listeria Monocytogenes*, Respiratory Infection, Turkeys

T87 Aspirin and selenium influence on bordetellosis in turkey poults. A. M. Tyner*, F. W. Edens, and G. H. Luginbuhl, *College of Agriculture & Life Sciences, Dept. of Poultry Science, North Carolina State University, Raleigh.*

Bordetellosis, caused by *Bordetella avium* infection, is characterized by tracheal inflammation, epithelial cell degeneration, and tracheal distortion. The inflammation results from dermonecrotic toxins produced by *B. avium*. Inflammatory reactions are accompanied by generation of reactive oxygen metabolites (ROM) that kill cells. Antioxidant enzyme activity associated with either sodium selenite (SS) or organic selenium (SP, Sel-Plex, Alltech, Inc., Nicholasville, KY) elevates cellular redox status to reduce ROM. Aspirin (AS) can be an antioxidant because it inhibits synthesis of oxidative prostacyclins that induce ROM. The objective of this work was to examine the influence of AS with either SS or SP on development of bordetellosis in female poults. Experiments were conducted with day of hatch poults given intranasally 107 cfu of W strain *B. avium* or no challenge and monitored for 21d post challenge. Challenged and non-challenged poults were given 6 experimental diets made with poult starter- 1. SS (0.3 ppm), 2. SP (0.3 ppm), 3. no selenium or AS, 4. SS (0.3 ppm)+AS (.05%) 5. SP (0.3 ppm)+AS (0.05%), 6. AS (0.05%). At 9 and 14d, 5 poults (1/rep of 7 poults/rep) were killed and necropsied. Regardless of dietary treatment, lower BW ($P<0.05$) was observed in infected groups. In one experiment, AS prevented epithelial cell degeneration in infected poults. In control groups, SP alone and SP+AS increased thymus weight (g/100 g BW) over other treatments ($P<0.06$). With infection, SP only was associated with a smaller thymus, but addition of AS maintained thymus wt equal to the other treatments. Bursa and spleen wt were not altered significantly by selenium source, AS, or infection. Abdominal exudate macrophage IL-1 was elevated significantly ($P<0.0001$) by SS but not by SP or AS, and infection elevated IL-1 ($P<0.001$). It was concluded that SP and AS can alter the course of developing bordetellosis

Key Words: Selenium, Aspirin, Bordetellosis

T88 Silymarin PHYTOSOME against AFB₁ in broilers: effects on serum biochemistry. D. Tedesco¹, S. Galletti¹, L. Ravarotto², M. Tameni¹, S. Steidler¹, and P. Morazzoni³, ¹Department of Veterinary Sciences and Technologies for Food Safety, Milan, Italy, ²Istituto Zooprofilattico Sperimentale delle Venezie Via dell'Università, Legnaro, Italy, ³Indena S.p.A., Milan, Italy.

Silymarin, the bioactive extract of *Silybum marianum*, is a natural hepatoprotector and a potent anti-hepatotoxic agent. In poultry, silymarin has shown to be effective against toxic effects of AFB₁, preventing the negative repercussions on performance of broilers. This study focused on the effects of silymarin on serum biochemistry in AFB₁ intoxicated broiler chickens. Twentyone 14-d-old male commercial broilers (377±34g body weight) were randomly allotted into 3 groups and treated for 35 days as follows: control group on a basal diet alone; AFB₁ at 0.8mg/kg of feed; AFB₁ at 0.8mg/kg of feed plus silymarin PHYTOSOME*, a silymarin complexed form with phospholipids from

soy, at 600 mg/kg body weight. Before slaughter, blood samples were collected from the brachial vein and total protein, albumin, globulin, glucose, urea, total bilirubin, direct bilirubin, indirect bilirubin, aspartate amino transferase (AST), gamma glutamil transferase (GGT), alanine amino transferase (ALT), calcium, and phosphorus were analyzed on sera. No differences were evidenced in any of the biochemical parameters evaluated, except for the level of ALT. The serum ALT activity was lower ($P<.05$) in AFB₁ treated animals with respect to control (6.16 vs 18.65 U/L, SEM=3.12). In animals receiving AFB₁ plus silymarin PHYTOSOME there was no difference in ALT serum activity in respect to control (26.14 vs 18.65 U/L, SEM=3.12). The decrease in serum ALT content is due to a recognized hepatotoxic effect of AFB₁. We can affirm that silymarin PHYTOSOME prevented these change in ALT activity, supporting the suggestion that these compound may achieve a protection against toxic effects of AFB₁. *PHYTOSOME is a trademark of Indena S.p.A.

T89 Supplemental dietary 1,4-diaminobutane (putrescine) on growth and development of small intestine in broiler chicks challenge with *E. acervulina*. F. A. Santoyo¹, T. K. Smith*², and J. R. Barta², ¹Universidad Autonoma de Nuevo Leon, Monterrey, Mexico, ²University of Guelph, Guelph, ON, Canada.

Dietary putrescine (1,4-diaminobutane, DAB) the mammalian polyamine has been shown to play a regulatory role in growth, cellular development, division and anabolic processes including synthesis of DNA, RNA and protein. The high turn over rate of intestinal epithelium, as well as healing following mucosal damage resulting from luminal exposure to deleterious compounds or parasites, is dependent on sustained supplies of putrescine, spermidine and spermine. An experiment was conducted with one hundred and twenty eight, day-old male broiler chickens fed a corn and soybean meal based control diet. Experimental diets were formulated by adding putrescine (0.0, 0.15, 0.30 and 0.45%). Experimental diets and water were offered ad libitum for 21 days. Birds were housed at the Isolation Unit of the University of Guelph, in four rooms with 8 battery cages each with external drinker and feeder, with 4 birds/cage (4 diets with 2 cages per room each for a total of 8 birds/diet/room). On day 11, in each room 16 birds (4cages/4 birds/diet) were inoculated with *Eimeria acervulina* Guelph strain, with a dose of 1,000,000 oocysts per ml per bird. At day 17, and at day 21, the end of the experiment, 12 birds randomly selected by wing band number per diet were killed by cervical dislocation. Excreta were collected per pen in both rooms from days 11-13 for determination of fat and energy. Lesions in the small intestine were scored (0 to +4 scale). There was a significant quadratic increase in excreta fat content with increasing dietary putrescine in control birds. There was significant effect of diet on excreta energy content. Overall, the infection did influence growth rate and feed intake of broiler chicks, these levels of putrescine supplementation were inadequate to overcome the protozoal challenge.

T90 Development of an antigen specific indirect ELISA for *Eimeria* using recombinant antigen EASZ240 from *Eimeria acervulina*. K. Ameiss*¹, M. Jenkins², H. Danforth², A. Barri¹, and D. Caldwell¹, ¹Texas A&M University, College Station, ²USDA/ARS, Beltsville, MD.

The etiological agents of chicken coccidiosis are a number of *Eimeria* species including *E. acervulina*, *E. tenella* and *E. maxima*. While a cellular response to these parasites has been shown to be important, our laboratory is investigating the mucosal humoral response after both immunization and infection. In order to perform these studies an indirect ELISA was developed based upon the recombinant antigen EASZ240. EASZ240 was isolated from *E. acervulina* strain #12 and inserted into an expression vector containing both an arabinose promoter and a His tag for purification. This clone represents an immunodominant sporozoite surface antigen which also has high sequence homology to antigens from both *E. maxima* and *E. tenella*. The goal of this study was to develop and verify an indirect ELISA assay for the detection of antibodies to this antigen. The clone pBADSZ240 was grown using standard microbiological methods and then the protein purified using low pressure

chromatography with a Ni-NTA column. Purity was confirmed using SDS-PAGE. Positive control serum was obtained by hyper-immunizing chickens with the antigen and collecting and pooling serum. Mean absorbance of positive control serum as compared to normal chicken serum and pre-immune serum revealed a more than 20 fold increase when diluted at 1:2560. Validation of the assay was done by testing serum from birds challenged with both *E. acervulina* strain #12 and *E. tenella* WLR-1 strain. Mean absorbance revealed that, at six days post challenge, challenged birds (0.437 ± 0.03) were significantly ($P<0.001$) higher than non-challenged birds (0.15 ± 0.03). In addition birds immunized with Coccivac[®]-B revealed significantly higher ($P<0.001$) mean absorbance (0.33 ± 0.03) as compared to non-immunized birds (0.05 ± 0.01). These finding indicate that this indirect ELISA may be useful in examining the humoral response to *Eimeria* species.

Key Words: Indirect ELISA, *Eimeria*, Recombinant Antigen

T91 Dietary lutein and fat interact to modify macrophage nitric oxide production in chicks hatched from carotenoid depleted eggs. R. K. Selvaraj* and K. C. Klasing, *University of California, Davis*.

An experiment was conducted to study the interaction between dietary lutein and fat in broiler chicks hatched from lutein depleted eggs. Six dietary treatments in a 2 X 3 factorial (fat at 3 and 6% and lutein at 0, 25 and 50 mg /Kg feed) were fed to 18 birds per treatment (in 3 replications) for 23 days. Anti-DNP-KLH serum antibodies were measured on d 22 by ELISA. Peripheral blood monocytes were collected on d 17 for macrophage phagocytosis assay. On d 19, blood lymphocytes were stimulated with either Con-A or PHA-P and proliferation index was measured. On d 23, peripheral blood macrophages were stimulated with lipopolysaccharide in vitro and nitric oxide (NO) production was measured at 16 and 40 hours of stimulation. The anti-DNP-KLH serum antibody titer and macrophage phagocytotic index did not differ among treatment groups ($P > 0.05$). The Con A and PHA-P proliferation index was increased ($P < 0.05$) in birds fed 50 mg of lutein and 3% fat compared to all other treatments. Macrophage NO production at 16 hours was increased ($P < 0.05$) in birds fed lutein compared to the birds fed no lutein, independent of the level of dietary fat. Among the birds fed lutein at 25 or 50 mg/Kg feed, birds in the 3% fat group had increased NO production compared to the birds fed 6% fat group. At 40 hours, macrophage NO production in birds fed 25 and 50 mg lutein with 3% fat was increased ($P < 0.05$) compared to all other treatments. Thus, in birds hatched from lutein depleted eggs, modulation of macrophage NO production by lutein is dependent on the level of dietary fat.

Key Words: Lutein, Fat level, Macrophage

T92 Construction of a naïve chicken antibody library using phage display. Daad Abi-Ghanem*¹, Suryakant D. Waghela^{1,2}, and Luc R. Berghman², ¹*Department of Poultry Science, Texas A&M University, College Station*, ²*Department of Veterinary Pathobiology, Texas A&M University, College Station*.

Phage display technology has emerged in recent years as a powerful tool for the creation of antibody libraries. It is based on the possibility of linking the displayed antibody phenotype on the phage surface to the encapsulated genotype. This approach was used to create a naïve chicken combinatorial antibody library. Total RNA was extracted from the bursa of Fabricius of ten 9-week old Leghorn layers. Messenger RNA was purified and used for the synthesis of cDNA. First-strand cDNA was then used in a primary PCR to amplify VH and VL genes. The VH forward primer and the VL reverse primer included complementary linker sequences that were used in the secondary overlap PCR to link the VH (400 bp) and VL (350 bp) fragments, thus creating a single chain Fv fragment (scFv, 750-800 bp). The primers used in the overlap PCR incorporated the cloning sites of the restriction endonuclease *Sfi* I, thus allowing for subsequent cloning into the phagemid pComb3X vector (provided by Dr. C. Barbas, The Scripps Research Institute, CA). Vector and scFv were digested with *Sfi* I. Digests were loaded on a 1% agarose gel, and bands corresponding to the double-cut vector (3,400 bp), the stuffer fragment (1,600 bp), and the digested scFv (700 bp) were excised. Three ligation reactions using T4 DNA ligase were then carried out, including either insert and vector, vector and stuffer, or vector alone. Ligations were incubated overnight at room temperature, followed by transformation into XL1-Blue Supercompetent cells. Cells were plated onto LB/carbenicillin plates and incubated overnight at 37°C. About 5×10^7 transformants/ μ g of vector DNA were obtained from the vector-insert ligation. More than 10^8 cfu/ μ g of vector DNA were obtained from the vector-stuffer ligation, indicating good vector quality. Background ligation was determined by self-ligation of the vector, and was found to be minimal ($< 5\%$). The scFv antibody library thus produced will be used to select for antibodies that bind to surface antigens of chicken enteric pathogens.

Key Words: Phage Display, scFv, Chicken

T93 Cellular uptake of the triamilide tulathromycin by bovine and porcine phagocytic cells in vitro. T. W. Siegel¹, D. L. Earley², C. D. Smothers³, F. Sun¹, and A. P. Ricketts*¹, ¹*Pfizer Inc., Groton, CT*, ²*Pfizer Inc., Terre Haute, IN*, ³*Pfizer Inc., Kalamazoo, MI*.

Tulathromycin (Draxxin[®]) is the first of a new class of veterinary macrolide antimicrobial, the triamilides. This study explored the accumulation of tulathromycin by bovine and swine phagocytes in vitro. Bovine blood polymorphonucleocytes (PMNs) incubated in a range of tulathromycin concentrations from 0.5 to 5 μ g/ml concentrated the antibiotic to an internal/external (I/E) ratio of approximately 28. These antibiotic concentrations are within the plasma and lung tissue concentration ranges achieved in tulathromycin-treated animals. When tulathromycin-loaded bovine PMNs were transferred to antibiotic-free media, by 1 h 50% of the intracellular tulathromycin remained, and by 4 h 40% of the intracellular antibiotic remained intracellular. Bovine alveolar macrophages (M Φ) accumulated tulathromycin to a lesser extent (I/E = 19.3), as did porcine blood PMNs (I/E = 16.6) and porcine alveolar M Φ (I/E = 8.1). This pattern of accumulation is distinct from that of other macrolides. Recruitment of tulathromycin-loaded phagocytes to infected lungs could contribute to in vivo efficacy observed for this antibiotic in livestock. Accumulation of tulathromycin by bovine PMNs was influenced by time, temperature, pH, and formalin fixation, but was insensitive to metabolic inhibitors (NaF, KCN). Efflux of tulathromycin was slower than for erythromycin. An active carrier system has been proposed for macrolides and its molecular identity is under active investigation; for the tribasic tulathromycin reversible protonation of amines is probably also important in membrane penetration. In summary, the triamilide tulathromycin represents a new class of macrolide antibiotics that accumulates within phagocytes from cattle and swine; this may contribute to in vivo efficacy for this compound.

Key Words: Tulathromycin, Neutrophil, Macrophage

T94 Valine needs for immune responses in male broilers from day 21 to 42. S. A. Thornton*¹, G. T. Pharr¹, A. Corzo¹, S. L. Branton², and M. T. Kidd¹, ¹*Mississippi State University, Mississippi State*, ²*United States Department of Agriculture*.

A number of studies have evaluated the impact of Met, Arg, Lys, and Thr on immune responses of broilers. Although a limited amount of research exists evaluating Val needs for immunity in broilers, these studies point to its adequacy as being important to support normal immunity. Because Val can become limiting in broiler diets, especially those based on vegetable protein sources, two experiments were conducted to evaluate Val needs for cellular and humoral immunity in Ross 508 male broilers from 21 to 42 d. Birds in Experiment 1 were fed 3 dietary treatments with Val levels at 0.72%, 0.82% (accomplished by adding L-Val), and 0.82% (corn and soybean meal control equaling NRC (1994)). Experiment 1 measurements included: a hypersensitivity test to phytohemagglutinin-P (PHA-P) on d 35 and 36 (2 birds/pen); relative immune organ weights at d 42 (1 bird/pen); and a primary antibody response to SRBC on d 34 and 41 (2 birds/pen). Birds in Experiment 2 were fed 3 dietary treatments with Val levels at 0.64%, 0.73%, and 0.78%. Experiment 2 measurements included: a hypersensitivity test to Concanavalin A and Pokeweed mitogen on d 40 and 41 (2 birds/pen); relative immune organ weights at d 42 (1 bird/pen); a primary antibody response to SRBC on d 34 and 41 (2 birds/pen). Cell quantification of BU1 receptors on splenic cells at d 42 (1 bird/pen) was measured in treatments with 0.64% and 0.78% Val. In Experiment 1 there was a decrease ($P = 0.08$) for relative spleen weight in birds fed the 0.72% Val diet compared to birds fed the 0.82% corn and soybean meal control diet, however; significant differences did not occur for relative bursa and thymus weights. There were no significant differences in SRBC or PHA-P responses in Experiment 1. In Experiment 2, significant differences did not occur for any parameter tested. The results indicate that as CP is reduced in broiler diets to the extent of a marginal Val deficiency, the immune system of the birds should not be compromised.

Key Words: Broiler, Immunity, Valine

T95 Anti-rbosCD14 monoclonal antibodies (mAb) inhibits in vitro production of tumor necrosis factor- α (TNF- α) by bovine monocytes following stimulation with LPS. E. J. Sohn^{*1}, M. J. Paape², R. R. Peters¹, and D. D. Bannerman², ¹*Department of Animal and Avian Sciences, University of Maryland, College Park*, ²*Bovine Functional Genomic Laboratory, USDA-ARS, Beltsville, MD*.

Endotoxin (lipopolysaccharide, LPS) from Gram-negative bacteria activates host innate immune responses that promote bacterial clearance. Paradoxically, such a response also contributes to septic shock, a clinical problem occurring with high frequency during Gram-negative septicemia. CD14 is a glycoprotein which binds LPS and initiates cell activation. The production of TNF- α by monocytes stimulated with LPS is mediated, in part, by the interaction of LPS with CD14 on mono-

cytes. The objective of the present study was to investigate whether anti-rbosCD14 mAb could block the production of TNF- α by bovine monocytes stimulated with LPS. The concentration of LPS used ranged from 1 to 100 ng/ml. The inhibition of anti-rbosCD14 mAb on the LPS induced production of TNF- α by adherent monocytes during a 24 h of incubation was dose dependent. The greatest inhibition (61%) was achieved when 100 ng/ml of LPS was used to stimulate the monocytes. With 1 and 10 ng of LPS/ml, inhibition averaged 37% and 54%, respectively. The inhibition of TNF- α secretion by anti-rbosCD14 mAbs can be explained by the binding of mAb to membrane bound CD14 on the monocytes, thus blocking interaction of LPS with mCD14. The anti-rbosCD14 mAb has the potential for neutralization of TNF- α during acute coliform mastitis.

Key Words: Endotoxin, CD14, TNF- α

Companion Animals

T96 Serum and urine indice comparisons between llamas and alpacas fed three forages. M. Sharp^{*}, C. Horey, T. F. Robinson, and B. L. Roeder, *Brigham Young University, Provo, UT*.

The objective of this experiment was to determine species differences for serum and urine indices between llamas and alpacas fed three forages of differing quality. Four llamas (115 kg BW; 3yrs old) and four alpacas (58 kg BW; 3 yrs old) were housed in metabolic crates, given ad libitum water and grass hay initially. Three forage treatments of alfalfa (AH), barley (BH) and grass (GH) were fed in random order to each animal. Treatment periods were for 14 d; d1 to d12 for forage adjustment and d13 to d14 for collection. Animals were fitted with a urine collection harness and a jugular venous catheter. Forages were fed ad libitum and feed intake determined. Blood and urine were collected at 4-hr intervals on d13 and 14. Serum and urine aliquots were analyzed for electrolytes (Na, Cl, K, Ca and P), urea N, creatinine. Feed intake differed between species and forage ($P < .05$), alfalfa the highest and llamas consuming more than alpacas. Serum electrolytes, osm and creatinine were not different. Glucose levels were higher ($P < .01$) for llamas than alpacas, 7.7 to 7.2 mmol/L. Total serum protein was higher for llamas than alpacas ($P < .05$; 6.6 to 5.8 g/dL), while PUN was affected ($P < .01$) by forage: 7.8, 4.7 and 3.9 for AH, BH and GH. Urine results are expressed on a metabolic weight basis ($\text{kg}^{-.75}$). AH urine excretion was highest ($P < .005$) at 70.9, and 42.2 and 32.8 ml/d/mwt for BH and GH. Urine electrolyte excretion differed for diet ($P < .05$; Na: 3.0, 3.6, 1.6 mmol/d/ $\text{kg}^{-.75}$; Cl: 27.2, 22.1, 18.9 mmol/d/ $\text{kg}^{-.75}$; K: 11.4, 5.9, 6.1 mmol/d/ $\text{kg}^{-.75}$ for AH, BH and GH). PUN excretion differed for species, forage and the interaction ($P < .03$), 281, 126 and 87 mmol/d/ $\text{kg}^{-.75}$ for AH, BH and GH and 189 vs.140 mmol/d/ $\text{kg}^{-.75}$ for llamas and alpacas. Creatinine excretion was not different. It has been hypothesized that llamas and alpacas are similar in physiology and respond to diets in a similar fashion. These data demonstrate that the two species responded similarly to the three forages, with the exception of serum glucose and total protein and urine urea N. Diet did affect urine indices.

Key Words: Alpaca, Llama, Forages

T97 Affect of water deprivation on plasma and urine analytes of alpacas. A. Peterson^{*}, J. A. Anderson, T. F. Robinson, and B. L. Roeder, *Brigham Young University, Provo, UT*.

Four male alpaca (62 kg BW, 3 yrs old) were housed in metabolism crates and given ad libitum water and grass hay. The alpacas were fitted with a urine collection harness and a jugular catheter. Urine and plasma were collected at 4-hr intervals during the 14 d baseline, 120-hr water dehydration (Dh) and 160-hr rehydration (Rh) periods. Plasma and urine were analyzed for electrolytes (Na, Cl, K and Ca), total protein, urea N and creatinine. Data are presented as a mean of the baseline samples at the 4-hr interval times, while Dh and Rh data were analyzed as repeated measures using SAS Proc Mixed. Water intake was 24.4 ml/d/ $\text{kg}^{-.75}$ while urine output was 7.1 ml/d/ $\text{kg}^{-.75}$. Pack cell volume increased ($P < .001$) during Dh from 24 to 32%, returning to 23% for Rh. Plasma osm increased ($P < .001$) from 312 to 356 mmol/kg with the Dh/Rh, while COP increased ($P < .001$) from 21 to 24 mmHg. Plasma electrolytes increased ($P < .001$). Na and Cl increased from 149 and 121 mmol/L to 161 and 133 mmol/L, respectively. K increased from

4.9 to 5.4 mmol/L ($P < .001$). Glucose increased ($P < .001$) from 7.1 to 8.4 mmol/L, with PUN increasing from 2.7 to 8.6 mmol/L ($P < .001$). Creatinine was not affected and TPP increased ($P < .001$) from 5.6 to 6.1 g/dL. Urine osm increased from 1100 to 1800 mmol/kg ($P < .001$). Urine electrolyte excretion was affected by Dh. Na increased from 0.30 to 1.30 mmol/d/ $\text{kg}^{-.75}$. Cl was unchanged during Dh and increased from 1.5 (baseline and Dh) to 3.0 mmol/d/ $\text{kg}^{-.75}$ during the Rh period. K decreased from 1.1 to 0.13 mmol/d/ $\text{kg}^{-.75}$ during the Dh period. PUN excretion increased from 5.7 to 12.5 mmol/d/ $\text{kg}^{-.75}$, and creatinine increased from 1.1 to 8.0 mg/d/ $\text{kg}^{-.75}$ ($P < .001$). Alpacas respond similarly to Dh/Rh as do llamas, with the exception being increased urine urea N excretion. This implies that alpacas do not recycle urea N to Cl during Dh. Glucose may have been elevated from endogenous glucocorticoid release during Dh and during Rh rebounded due to realimentation. Rh elicited a diuresis affect with increased Na and very large Cl excretion.

Key Words: Alpaca, Dehydration, Analytes

T98 Affect of water deprivation on plasma and urine analytes of llamas. J. A. Anderson^{*}, A. Petersen, T. F. Robinson, and B. L. Roeder, *Brigham Young University, Provo, UT*.

Four male llama (123 kg BW, 3 yrs old) were housed in metabolism crates and given ad libitum water and grass hay. The llamas were fitted with a urine collection harness and a jugular catheter. Urine and plasma were collected at 4-hr intervals during the 14 d baseline, 120-hr water dehydration (Dh) and 160-hr rehydration (Rh) periods. Plasma and urine were analyzed for electrolytes (Na, Cl, K and Ca), total protein, urea N and creatinine. Data are presented as a mean of the baseline samples, while the Dh and Rh data were analyzed as repeated measures using SAS Proc Mixed. Water intake was 17.8 ml/d/ $\text{kg}^{-.75}$ while urine output was 3.7 ml/d/ $\text{kg}^{-.75}$. Pack cell volume increased ($P < .001$) during the Dh period from 24 to 28%, returning to 23% for Rh. Plasma osm increased ($P < .001$) from 315 to 354 mmol/kg with the Dh/Rh, while COP increased ($P < .001$) from 22 to 24 mmHg. Plasma electrolytes increased ($P < .001$) with the exception of K. Na and Cl increased from 151 and 125 mmol/L to 166 and 133 mmol/L, respectively. Glucose increased ($P < .001$) from 6.6 to 7.7 mmol/L, with PUN increasing from 4.3 to 7.8 mmol/L ($P < .001$). Creatinine was not affected. Urine osm increased from 2500 to 3000 mmol/kg ($P < .001$). Urine electrolyte excretion was affected by Dh. Na increased from 0.11 to 1.40 mmol/d/ $\text{kg}^{-.75}$. Cl was unchanged during Dh and increased from 2.5 (baseline and Dh) to 6.0 mmol/d/ $\text{kg}^{-.75}$ during Rh. K decreased from 1.1 to 0.4 mmol/d/ $\text{kg}^{-.75}$ during Dh. PUN excretion was not affected by Dh, while creatinine increased from 0.6 to 9.4 mg/d/ $\text{kg}^{-.75}$ ($P < .001$). These data indicate that llamas respond to Dh/Rh with similar increases followed by decreases in PCV, PUN, plasma Na, urine Osm, and urine electrolytes. Exceptions were plasma K and creatinine which did not change. Glucose may have been elevated from endogenous glucocorticoid release during Dh and during Rh rebounded due to realimentation. Rh elicited a diuresis affect with increased Na and very large Cl excretion. Unlike other species during Dh, llamas recycle large quantities of urea N to Cl, avoiding pre-renal azotemia.

T99 Differential expression of mitochondrial and extra-mitochondrial proteins in heart of low and high feed efficient broilers within a single male line. N. Tinsely*¹, M. Iqbal¹, N. R. Pumford¹, K. Lassiter¹, C. Ojano-Dirain¹, J. P. Higgins¹, W. Bottje¹, T. Wing², and M. Cooper², ¹*Department of Poultry Science, Center of Excellence for Poultry Science, University of Arkansas, Fayetteville, 2Cobb-Vantress, Inc., Siloam Spring, AR.*

The objectives of this study were to determine the relationships of low or high feed efficiency (FE) with expression of mitochondrial and extra-mitochondrial proteins, and protein oxidation in heart muscle. Tissue homogenate was prepared from hearts of broilers with High (0.80 ± 0.01 , $n = 7$) and Low FE (0.62 ± 0.02 , $n = 5$). The levels of specific electron transport chain (ETC) immunoreactive proteins and protein oxidation (carbonyls) were analyzed using Western blots with a chemiluminescence detection system. A proteome from the pooled heart muscle homogenate in each group was obtained using two-dimensional electrophoresis (2DE). The intensity of each protein spot was quantified using Image Master 2D software. The expression of six mitochondrial proteins [CII 70 S (Complex II), ISP, cyt b, cyt c1 (Complex III), COX II (Complex IV)] and adenine nucleotide translocator 1 (ANT1) were higher in low FE heart mitochondria, but one protein [NAD6C (Complex I)] was higher in high FE birds, and there were no differences between groups in the expression of 18 other respiratory chain proteins. The levels of protein carbonyl (protein oxidation) were higher in the heart of low compared to high FE broilers. 2DE revealed several proteins that were differentially expressed between the low and high FE groups. These findings of differential expression of some mitochondrial and extramitochondrial proteins in Low FE tissues are similar to a recent report in breast muscle (Iqbal et al., 2004, *Poult. Sci.* 83:474-484) and may either be due to inherent genetic differences or represent a compensatory response to overcome the increased protein oxidation in low FE birds. Funded in part by USDA-NRI grant (#2001-03443).

Key Words: Feed Efficiency, Mitochondrial Proteins, Protein Oxidation

T100 Differential expression of mitochondrial and extra-mitochondrial proteins in lymphocytes of low and high feed efficient broilers within a single male line. K. Lassiter*¹, M. Iqbal¹, N. R. Pumford¹, C. Ojano-Dirain¹, N. Tinsley¹, W. Bottje¹, T. Wing², and M. Cooper², ¹*Department of Poultry Science, Center of Excellence for Poultry Science, University of Arkansas, Fayetteville, 2Cobb-Vantress, Inc., Siloam Springs, AR.*

The objectives of this study were to establish relationships of a) mitochondrial and extramitochondrial protein expression, and b) protein oxidation (carbonyls) in lymphocytes with feed efficiency (FE) in broilers. Lymphocytes were isolated from a single line of male broilers with low (0.48 ± 0.02 , $n=8$) and high (0.68 ± 0.01 , $n=7$) FE. Protein bands were separated by electrophoresis (10% SDS-PAGE) and stained with Coomassie Blue. The band intensities were scanned with an Agfa (Arcus II) scanner and quantified using Scion software. Mitochondrial proteins, and oxidized protein (carbonyls) were analyzed using Western blots with chemiluminescence detection. A proteome from the pooled lymphocyte homogenate in each group was obtained using two-dimensional electrophoresis (2DE). The intensity of each protein spot was quantitated using Image Master 2D software. The expression of three mitochondrial proteins (core I, cyt c 1 [Complex III], and ATPase [Complex V]) were higher and lower for one protein (CII 30 [Complex II]) in High FE compared to Low FE lymphocytes, but there were no differences between groups for six other proteins. 2DE analysis showed a difference in the expression of several other proteins between groups. The levels of protein carbonyl were higher in High compared to Low FE birds. These results extend our reports in several tissues including breast muscle (Iqbal et al., 2004, *Poult. Sci.* 83:474-484) indicating that differences in protein expression may be involved in the phenotypic expression of feed efficiency. Supported in part by USDA-NRI grant (#2001-03443).

T101 Steady-state levels of mitochondrial phosphoproteins in broilers with and without pulmonary hypertension syndrome. C. R. Cisar*¹, J. M. Balog¹, J. O. Lay Jr.², N. B. Anthony², and A. M. Donoghue¹, ¹*Poultry Production & Product Safety, ARS, USDA, Fayetteville, AR, 2University of Arkansas, Fayetteville.*

Pulmonary hypertension syndrome (PHS), also known as ascites syndrome, is a metabolic disease associated with the rapid growth rate of modern broilers. PHS symptoms include chronically elevated pulmonary blood pressure leading to right ventricular hypertrophy and eventually heart failure. Broilers resistant to PHS have elevated levels of several mitochondrial electron transport chain proteins in their right ventricles. Phosphorylation of mitochondrial proteins regulates respiratory activity and other mitochondrial functions. Therefore, we examined steady-state levels of mitochondrial phosphoproteins in broilers with and without PHS. Mitochondria were prepared from right ventricle cardiac muscle and mitochondrial proteins were separated by two-dimensional gel electrophoresis. Gels were stained with Pro-Q Diamond[®], a fluorescent phosphoprotein-specific stain, and images were acquired using a laser scanner. Twenty putative phosphoproteins were detected. Four of these proteins appeared to be less phosphorylated in broilers without PHS than in broilers with PHS. Two proteins appeared to be more phosphorylated in broilers without PHS than in broilers with PHS. We are currently attempting to identify these six phosphoproteins from their peptide mass fingerprints as determined by MALDI-TOF mass spectrometry.

Key Words: Pulmonary Hypertension Syndrome, Mitochondria, Phosphoprotein

T102 Aorta pulse wave velocity is reduced by intravenous injections of L-arginine in female, but not male, white leghorn chickens. C. A. Ruiz-Feria*¹ and H. Nishimura², ¹*McGill University, Ste. Anne de Bellevue, QC, Canada, 2University of Tennessee, Memphis.*

Chickens (males more so than females) have higher blood pressure that most mammals and develop neointimal lesions in the distal abdominal aorta (AbA). We found that L-arginine (Arg) reduced neointima plaque size in chicks (6-10 wks), but increased plaque size in older birds (12-16 wks), presumably due to endothelial damage in older birds. We evaluated the effect of an i.v. injection of Arg (160 mg/kg BW) on pulse wave velocity (PWV, m/s), mean arterial pressure (MAP, mm Hg) and pulse pressure (PP, systolic-diastolic BP, mm Hg) in 13-wk-old anesthetized male ($n = 7$) and female birds ($n = 9$). A Mikrotip[®] catheter with two intravascular pressure transducers was advanced to the AbA and pressure waves electronically recorded. PWV was calculated as the distance between the two transducers divided by the time delay at the foot of a pulse wave recorded at the two transducers. Data was analyzed using a one way repeated measure ANOVA, and significance declared at $P < 0.05$. PWV, MAP, and PP were not different between male and female chickens before Arg injection (control). In females, PWV increased 30 s after Arg (11.4 ± 0.9 Vs 13.2 ± 0.8), returned to control levels between 60 and 90 s, was lower than control levels after 120 s (8.0 ± 0.7), and returned to control levels after 11 min. PWV in males did not change with Arg. In females, MAP was lower 120 sec after Arg (87.5 ± 4.9) compared with control levels (100.0 ± 5.3), and remained lower up to 15 min after Arg. Again, no change was observed in males. PWV and MAP were lower in females than in males from 120 sec through 11 min after Arg. PP increased in both male (31.4 ± 3.1 and 43.5 ± 4.6 , before and 120 s after Arg, respectively) and female (26.1 ± 2.4 and 43.3 ± 2.6 , in the same order) chickens, but in males PP returned to control levels after 11 min whereas in females PP remained higher up to 15 min after Arg. Age-matched male and female chickens show a different response in aortic elasticity parameters to Arg, and this may be related to differences in endothelial integrity and capacity to synthesize nitric oxide.

Key Words: Pulse Wave Velocity, L-Arginine, Nitric Oxide

T103 Pulmonary and systemic hemodynamic responses to prostacyclin in broilers. R. F. Wideman* and M. E. Chapman, *University of Arkansas, Fayetteville.*

The vasodilator prostacyclin (PGI₂) reduces the resistance to pulmonary blood flow and attenuates pulmonary hypertension in mammals, however no information is available regarding the responsiveness of the avian pulmonary vasculature to PGI₂. Accordingly, in three experiments we evaluated the pulmonary vascular responses to PGI₂ in male broilers. In Experiment 1, infusing PGI₂ (10 µg/min) into clinically healthy broilers did not reduce their pulmonary vascular resistance (PVR) but did reduce the pulmonary arterial pressure (PAP) by lowering the cardiac output (CO). Within 4 min after stopping the PGI₂ infusion, the CO and PAP returned to pre-infusion levels. In Experiment 2, the responses to PGI₂ were evaluated after arachidonic acid (AA) had been infused to pre-constrict the pulmonary vasculature. The AA infusion (400 µg/min) consistently triggered dramatic, sustained pulmonary vasoconstriction (increased PVR) and pulmonary hypertension (increased PAP). Concurrent PGI₂ infusions did not reduce the PVR, but did reduce the PAP by lowering the CO. After the PGI₂ infusion was terminated, the PAP and CO returned to their previous (hypertensive) levels attributable to the ongoing AA infusion. In Experiment 3, PGI₂ was infused into clinically healthy (PAP ≤24 mmHg) or sub-clinically hypertensive (PAP ≥27 mmHg) broilers. Throughout this experiment broilers in the hypertensive group had higher PAP values than broilers in the healthy group. The PGI₂ infusion reduced the PAP in both groups, but did not reduce the PVR. Instead, the pulmonary hypotension in response to PGI₂ infusion was associated with a reduction in CO in both groups. In each of these experiments PGI₂ reduced the PAP by reducing the CO rather than by reducing the PVR. There was no evidence that PGI₂ acts as an effective pulmonary vasodilator in broilers regardless of whether their pulmonary vasculature was apparently normal (clinically healthy), had been pharmacologically pre-constricted (AA infusion), or initially exhibited the vasoconstriction that is typical of the pathogenesis of pulmonary hypertension syndrome in broilers.

T104 Pulmonary hypertensive responses of broilers to lipopolysaccharide: evaluation of source and dose, and impact of pre-existing pulmonary hypertension and cellulose micro-particle selection. M. E. Chapman*, W. Wang, and R. F. Wideman, *University of Arkansas, Fayetteville.*

Previous studies show that bacterial lipopolysaccharide (LPS) triggers pulmonary vasoconstriction leading to pulmonary hypertension (PHS) in broilers. The lungs of broilers are constantly challenged with LPS that can trigger thromboxane A₂- and serotonin-mediated pulmonary vasoconstriction. Among broilers from a single genetic line, some individuals respond to LPS with large increases in pulmonary arterial pressure (PAP), whereas others fail to exhibit a response to the same supra-maximal dose of LPS. It is possible that broilers are more likely to exhibit pulmonary hypertension when LPS elicits the production of more vasoconstrictors than vasodilators such as nitric oxide. In the present study we evaluated the impact of a variety of factors on the magnitude of the PAP response of male broilers to LPS, including: a) The role of the initial PAP (Low vs. High initial PAP); b) The source of the LPS (*S. typhimurium* vs. *E. coli*); c) The dose of LPS (0.02, 0.1, and 0.5 mg/kg BW); and d) The role of micro-particle selection for improved pulmonary vascular capacity (Cellulose survivors vs. Saline controls). Broilers with a low initial PAP did not differ in their pulmonary hypertensive response to LPS when compared with broilers having a high initial PAP. LPS from *S. typhimurium* elicited pulmonary hypertensive responses similar to those elicited by *E. coli* LPS. The results revealed that a dose of 0.1mg/KgBW LPS elicits a maximal pulmonary hypertensive response in broilers, and broilers selected for a robust pulmonary vascular capacity by micro-particle injection did not differ in their pulmonary hypertensive response to LPS when compared with saline injected controls. This confirms that the variable pulmonary hypertensive responses among broilers cannot be attributed to the source or dosage of LPS, or to differences in the baseline PAP or micro-particle selection prior to injecting LPS. This is consistent with the hypothesis that innate rather than acquired variability influences the chemical mediators released during the inflammatory cascade.

Key Words: Ascites, Vasoconstriction, LPS

T105 Effect of selection of sires and dams for growth or egg production on embryonic cardiac physiology. V. L. Christensen*, D. T. Ort, J. L. Grimes, and M. J. Wineland, *College of Agriculture & Life Sciences, North Carolina State University, Raleigh.*

Poult cardiac tissue may appear normal at hatching, yet ventricular hypertrophy can increase the size of the heart and confers a round shape called spontaneous cardiomyopathy (SCM). The SCM might result from selection for economically important traits. The hypothesis was proposed that lines selected for increased egg production (Egg) or body weight (F) might affect embryo cardiac physiology. Lines of turkeys selected for either trait as well as their randombred control populations (R1 and R2, respectively) were studied. At sexual maturity, hens were assigned randomly to pens by line. Half of each line was mated to males of the same line whereas the remaining half was mated to males of the appropriate randombred strain in reciprocal crosses. Progeny resulting from the crosses were observed for heart rate and weight, cardiac glycogen and lactate concentrations and creatine kinase (CK) and lactate dehydrogenase (LDH) activities that are indicators of cardiac insufficiency. Data were analyzed comparing dam and sire effects of the Egg only with the R1 and the F only with R2. In the Egg/R1 comparison, Egg dams increased embryo heart rate compared to R1 and also depressed embryo heart weight compared to R1 dams. Sire effects were negligible. Tissue oxygen debt was indicated in poults from R1 dams and Egg sires at hatching. F sires and dams compared to R2 decreased embryonic heart rates and increased heart weights, but when observed relative to body mass, F sires increased heart weights. Selection for growth in dams decreased tissue oxygen debt as indicated by CK. Thus, selection for egg production has increased heart rates and depressed weights relative to body mass. F embryo tissue oxygen debt and reduced heart rates were also evident. Selection for growth also decreased poult tissue oxygen debt for 3 days posthatching. In conclusion, the data indicate that selection for both egg production and growth have affected embryo cardiac physiology divergently and may play roles in the increased incidence of SCM in turkeys.

Key Words: Turkey, Embryo, Heart

T106 Effect of excess dietary vitamin D supplementation as a management adjustment to reduce the effect of heat stress on three varieties of laying hens. D. J. Franco*, L. Robeson, and M. M. Beck, *University of Nebraska, Lincoln.*

Thirty-two hens of each strain (Brown, W98, W36) were randomly selected and allowed to acclimatize for two weeks at 22C. Sixteen birds from each strain received a commercial layer diet plus 22,000 IU/Kg feed of vitamin D₃; the rest of the birds were fed the commercial layer diet. Birds were exposed to heat stress (HS) at 35C for two weeks with two additional weeks at 22C to recover. Production parameters (PP), mortality rates (MR) and reproductive hormone levels (RHL) were measured for each phase. Acid base status (AB) and intestinal calcium uptake rate (CaT) data were obtained from samples collected before and during HS exposure. The data for PP and RHL were analyzed using the SAS program 1999 version 8.0 as a repeated measure ANOVA in a 3x3x2 factorial experiment with a level of significance of 0.1. The data for CaT, and AB were analyzed in a 3x2x2 factorial experiment with a level of significance of 0.05. Differences among means were obtained based on LSD test. The results showed less decrease in egg production (EP) during HS in all the varieties given the extra vitamin D₃ than birds receiving the regular diet. The rest of PP were negatively affected by HS with small differences among strains and diet. Blood pH and PO₂ levels increased, with a reduction in PCO₂ and HCO₃ levels in the three strains during HS. LH and estrogen blood levels were significantly lower during HS for the three strains, and progesterone levels showed a large increase after HS exposure. CaT was enhanced by vitamin D₃ during HS with the W36 and the W98 showing the higher rate compared to the Browns. Based on these results we can conclude that the addition of excess dietary vitamin D₃ in the diet did not reduce the effect of HS on egg weight, eggshell quality and other PP. However, the addition of this vitamin in the diet allowed the birds to maintain high EP and CaT. Even though vitamin D₃ improved CaT, utilization of calcium was not increased, likely because of the alkalosis noted, which was not affected by vitamin D₃.

Key Words: Laying Hens, Heat Stress, Vitamin D₃

T107 Heat stress suppresses 3 β -hydroxysteroid dehydrogenase activity differentially by strain in granulosa cells of laying hens. H. Taira* and M. M. Beck, *University of Nebraska, Lincoln.*

Heat stress (HS) is known to disrupt egg production and to suppress circulating progesterone (P₄), luteinizing hormone (LH), and estrogen. It has been shown that strain differences exist in response to HS (Franco et al., 2002, 2003). HS suppresses secretion of P₄ by granulosa cells (GC) *in vitro*, even when stimulated by addition of LH (Novero et al., 1990), and decreases activity of 3 β -hydroxysteroid dehydrogenase (3 β -HSD) in GC of laying hens (Alodan, 2001) and in testis of Japanese quail (Taira et al., 2003). In this study, two experiments were conducted to determine the effects of HS on estrogen receptor- α (ER α) localization and 3 β -HSD activity. Comparisons were made among 3 types of Hy-Line hens (W-36, W-98 and Brown), with birds of each strain divided into 3 groups: thermoneutral (22C, 50% RH; TN), acute (A) HS (36C, 50% RH; 24h), and chronic (C) HS (36C, 50% RH; 2wk) conditions. Effect of HS on ER α staining in kidney, duodenum and shell gland by immunocytochemistry was inconclusive. Activity of 3 β -HSD was determined by incubating GC in the presence of pregnenolone and nitroblue tetrazolium. To determine percentage of 3 β -HSD active cells, a total of 200 cells per bird was counted. 3 β HSD activity was suppressed by both AHS or CHS; AHS reduced 3 β -HSD by 42.6% (P<0.01) and 36.2% (P<0.01), respectively compared to TN. Under CHS, 3 β -HSD activity was lower in GC from Brown birds compared to W-98 (P<0.01); activity in cells from W-36 birds was intermediate. In addition, in Brown hens, CHS suppressed 3 β -HSD to a greater extent than did AHS (P<0.01). The results of the 3 β -HSD study suggest a possible mechanism by which the strain effects of HS may be mediated; earlier studies have shown that W-98 hens maintain production significantly better than either W-36 or Browns and that W-36 are always intermediate in response between W-98 and Browns. Because P₄ is the main ovarian ovulatory/oviposition hormone in birds, decreased activity of 3 β -HSD by HS, particularly since it is differentially suppressed by strain, may be a logical point at which to investigate genomic aspects of the response.

Key Words: 3 β -HSD, Granulosa Cells, Heat Stress

T108 Duration of follicular development increases with advancing duration of the reproductive period in broiler breeder hens. H.-K. Liu* and W. L. Bacon, *The Ohio State University, Wooster.*

Settable egg production of broiler breeder hens is increased by feed restriction, but declines as the duration of the reproductive period increases. We hypothesized that the decrease in egg production with advancing duration of the reproductive period is associated with a longer duration of follicular development. The objective of the current study was to document the duration of ovarian follicular development early (Early, at 3 to 6 wk of egg production) and late (Late, after egg production had declined by about 25% at 19 to 31 wk of egg production) in broiler hens that were full-fed during both growth and reproductive periods (FF), restricted-fed during growth but full-fed after photostimulation (RF), or restricted fed during both growth and reproduction periods (RR). Photostimulation was at 23 wk of age. Sudan IV (R; 100 mg/hen/d) and Sudan Black B (B; 50 mg/hen/d) were suspended in canola oil and 1.0 mL day fed alternatively to measure the duration of follicular development. The total egg production rate (74-84% and 52-56%, respectively) was not different between feeding treatments within Early and Late hens. The duration of ovarian follicular development (8.7-9.1 d and 9.8-10.2 d, respectively) was not different between feeding treatments within Early and Late hens. Early hens in each feeding treatment had a higher (P<0.01) total egg production rate but shorter (P<0.005) duration of follicular development in comparison to Late hens. We concluded that longer duration of ovarian follicular development in Late hens was associated with lower total egg production rate in broiler breeder hens.

Key Words: Follicle, Broiler, Feed Restriction

T109 Bone characteristics of laying hens as a function of age, diet and strain. J. Wardell*, N. Heywood, and M. M. Beck, *University of Nebraska, Lincoln.*

Many factors have been investigated, but none have been shown to function alone in the etiology of osteoporosis in the hen. The occurrence of

medullary bone as the labile calcium reserve for shell formation complicates the picture. Trabecular bone is found in the middle of the ends of the long bones and in the vertebrae and contributes more to stress resistance. The partitioning of bone between medullary and trabecular components is of interest. Comparisons between younger (first egg) and older birds (70-72 wk) indicate that medullary bone formation and remodeling occur partly at the expense of trabecular bone (Whitehead, 1991). In this study, two strains of Hy-Line birds, W36 and W98, were started as chicks receiving NRC requirement diets or a diet supplemented with HyD[®]. Chicks were fed to achieve target body weight or 15% greater or less than target. Bones were sampled at 20 and 60 wk of age. The right tibia from two birds in each treatment was removed, cleaned, decalcified, cut into eight pieces (two halves of the proximal head, four pieces of the shaft, two halves of the distal end), embedded in paraffin, sectioned at 7 μ m, and stained with hematoxylin and eosin. Two slides per bird were used for histological examination and measurement of cortical bone diameter and percent trabecular bone. Cortical diameter (CD) was measured at one location on both sides of the bone; percent trabecular bone (%TB) was obtained by dividing TB area by total bone area. Measurements were made using Scion Image analysis program. Data were analyzed using SAS. Comparisons were age (A), strain (S), body weight (BW), and diet (D). For cortical bone, there were effects of age, SxBW, SxD, and AxBWxD. At 60 wk, CD was less than at 20 wk (P=0.0001). At 20 wk, addition of HyD[®] enhanced CD in W36 birds but not in W98; at 60 wk, there was no effect of D but W98 birds had greater CD than W36 birds (P=0.0175). For %TB, there were effects of A, S, BW, D, AxBW, SxBW, AxBWxD, SxD, BWxD, and AxBWxD. Considering the most complex interaction, it appeared that S, BW and A contributed most to %TB, and that there was relatively little effect of D.

Key Words: Osteoporosis, Trabecular Bone, Cortical Bone

T110 Yolk-related gene transcription by estrogen in the liver of Japanese quail. A. M. Hanafy^{1,2}, T. Sasanami¹, and M. Mori^{*1}, ¹Shizuoka University, Shizuoka, Japan, ²United Graduate School of Agricultural Science, Gifu University, Gifu, Japan.

The avian liver is known as a target tissue for estrogens. In the previous study, we have demonstrated that diethylstilbestrol stimulates the expression of ZP1, perivitelline membrane glycoprotein, in the liver of immature male quail, and ZP1 gene has been shown to be a sensitive biomarker for estrogenic compounds. In the present study, we compared the sensitivity of transcription of ZP1 with those of vitellogenin II (VTG II) and very-low-density apolipoprotein II (apoVLDL). Immature male quail were treated with single intraperitoneal injection of estrogenic compounds dissolved in corn oil. Total RNA extracted from liver was reverse-transcribed with oligo (dT) primers. The cDNA was subjected to real-time PCR performed with the gene-specific sets of primers (ZP1: AB061520, VTG II: AF499027, apoVLDL: S82591, GAPDH: Z19086) and TaqMan probes. Cycling conditions were 10 min at 95°C followed by 40 cycles of 15 sec at 95°C and 1 min at 60°C. The standard curves were almost linear between 10⁹ to 10⁵ copies for all genes. Levels of mRNA of each gene were expressed in relation to house-keeping GAPDH mRNA levels. Expression of ZP1, VTG II, and apoVLDL genes are highly specific for mature female, and no significant expression was observed in the mature and immature male quail. Of the three female-specific genes measured, apoVLDL was the most sensitive for estrogenic compounds. Administration of ethinyl estradiol or diethylstilbestrol at 1 μ g per 100 g body weight caused more than a ten-fold increase in the mRNAs. All three genes were induced by ethinyl estradiol or diethylstilbestrol at 100 μ g per 100 g body weight, although the increase in the mRNA was prominent only one day after the administration. The present study shows that effects of estrogenic compounds vary in the induction of female-specific gene transcription, and apoVLDL was more responsive to the estrogenic compounds than ZP1 and VTG II as a biomarker gene. These results suggest that the expression of avian female-specific genes may be differentially regulated.

Key Words: Liver, Estrogen, Vitellogenesis

T111 Identification of endocrine phenotypes of chicken pituitary cells expressing the vasotocin VT2 receptor subtype. A. Jurkevich^{*1}, L. R. Berghman², L. E. Cornett³, and W. J. Kuenzel¹, ¹Department of Poultry Science, University of Arkansas, Fayetteville, ²Poultry Science Department, Texas A&M University, College Station, ³University of Arkansas for Medical Sciences, Little Rock.

Hypothalamic neurohormones of vasotocin/vasopressin family have long been shown influencing the endocrine and behavioral response to stress. The regulatory effects of these hormones are achieved by modulating neuronal processes in the brain and by controlling hormone release from the pituitary gland. Effects of vasotocin (VT) on pituitary hormones in the domestic fowl are mediated, at least in part, by the VT2 vasotocin receptor highly expressed in the pituitary. Immunohistochemical localization of VT2 receptor-expressing cells revealed that they are prevalent in the cephalic lobe of the anterior pituitary. The objective of this study was to identify the endocrine phenotypes of chicken pituitary cells containing immunoreactive VT2 receptor protein using a dual labeling immunohistochemical approach. The obtained results confirmed our previous finding that, at the subcellular level, the VT2 receptor is predominantly associated with the cell membrane. Dual immunofluorescent labeling demonstrated that virtually all corticotrophs are VT2 receptor-immunoreactive. The immunoreactive VT2 receptor was also found in a relatively small subpopulation of lactotrophs. Preliminary assays did not reveal extracellular membrane-associated VT2 receptor on gonadotrophs (visualized with the antibody to chicken LH β -subunit) and somatotrophs; however these findings are being verified on a larger amount of samples. Our results provide the first morphological evidence supporting the hypothesis that VT could be the primary ACTH secretagogue in birds acting directly on corticotrophs. Moreover, the data obtained suggest that the known stimulatory effects of VT on prolactin release in poultry species are likely to be mediated primarily by VT2 and perhaps other VT receptor subtypes.

Key Words: Vasotocin, Pituitary Gland, Stress

T112 Characterization and expression of the avian ghrelin gene. M. Richards^{*}, S. Poch, and J. McMurtry, *USDA, ARS, Growth Biology Laboratory, Beltsville, MD.*

Ghrelin (GHR), a peptide hormone produced by the stomach in mammals, stimulates growth hormone (GH) release and food intake. Recently, GHR was identified and characterized in chicken proventriculus and shown to stimulate GH release but inhibit feed intake. The purpose of this work was to identify and characterize the GHR gene in Leghorn (LC) and broiler (BC) chickens and in turkeys (T). Using molecular cloning techniques we have sequenced cDNAs corresponding to LC and T GHR mRNAs. A total of 844 (LC) or 869 (T) bases including the complete coding regions (CDS), and the 5'- and 3'-untranslated regions (UTRs) were determined. Nucleotide sequence (CDS) predicted a 116 amino acid precursor protein for both LC and T that demonstrated complete conservation of an N-terminal active core (GSSF) including a serine (position 3) known to be a modification (acylation) site important for GHR bioactivity. Additional nucleotide sequence was found in the 5-UTRs of both LC and T cDNAs that was not present in BC. The T GHR gene, sequenced from genomic DNA templates, contained 5 exons and 4 introns, a structure similar to mammalian and chicken GHR genes. GHR was highly expressed in proventriculus with much lower levels of expression in other tissues such as pancreas, brain and intestine. RT-PCR was used to quantify GHR gene expression relative to 18S rRNA in 3 wk-old male BC. GHR expression in proventriculus increased in response to fasting but did not decline with subsequent refeeding. Plasma GHR, determined by RIA, did not change significantly in response to fasting or refeeding and did not reflect changes in proventriculus GHR gene expression. GHR expression declined in pancreas after a 48 hr fast and increased upon refeeding. Expression of the gene encoding the receptor for GHR (GH secretagogue receptor, GHS-R) was detected in pancreas possibly suggesting autocrine/paracrine effects. These results offer new insights into the avian GHR gene and the potential role of GHR in regulating feed intake and energy balance in poultry.

Key Words: Ghrelin, Gene Expression, Feed Intake

T113 The effect of dosimetric levels of dietary L-carnitine on semen traits of White Leghorns. Wei Zhai^{*1}, S. L. Neuman², C. D. McDaniel³, M. A. Latour¹, and P. Y. Hester¹, ¹Purdue University, West Lafayette, IN, ²Astra Zeneca, Raleigh, NC, ³Mississippi State University, Mississippi State.

Feeding 500 ppm of dietary L-carnitine to young and aging White Leghorns for 5 wk improved sperm concentration and reduced sperm lipid peroxidation during the last half of supplementation (Neuman et al., 2002, Poultry Sci. 81:495). The current study examined the effect of feeding dosimetric levels of L-carnitine on semen traits of White Leghorns. An 8-wk trial was conducted with 48 White Leghorn roosters, 46 to 54 wk of age. Feed was formulated to contain to 0, 125, 250, and 500 mg of carnitine/kg of feed, but analyzed values were higher (3, 167, 357, and 674, respectively). Diets were fed ad libitum to 12 birds/treatment with the semen of two roosters pooled per rep per treatment to form 6 experimental units per treatment. Data were analyzed using ANOVA with repeated measurements using the mixed model procedure of SAS. Dietary carnitine did not affect feed consumption, body weight, and sperm viability. Sperm concentration of roosters fed 125 mg/kg of carnitine was significantly higher than the controls ($P < 0.05$). Dietary carnitine effects on semen volume varied over time (dietary treatment age interaction, $P < 0.003$). Semen volume increased in roosters consuming 125 mg/kg at 6 wk as compared to 2 wk post treatment ($P < 0.002$). An increase in semen volume was noted in roosters consuming 500 mg/kg of carnitine at 6 ($P < 0.0002$), 7 ($P < 0.02$), and 8 ($P < 0.007$) wk when compared to 2 wk post-treatment. Circulating levels of free and total carnitine were elevated in roosters consuming 500 mg of carnitine/kg of feed as compared to controls ($P < 0.04$). It is concluded that White Leghorns consuming 125 mg/kg of carnitine for 8 weeks as compared to controls showed an increase in sperm concentration without affecting sperm viability or having a deleterious effect on semen volume. Research supported by the U. S. Poultry and Egg Association & Lonza Group Ltd.

Key Words: L-carnitine, Semen Traits, Sperm Concentration

T114 Time course of thyroid hormone replacement and lipogenic enzyme gene expression in broilers. R. W. Rosebrough^{*}, B. A. Russell, S. M. Poch, and M. P. Richards, *Growth Biology Laboratory, ARS, USDA, Beltsville, MD.*

The purpose of this experiment was to determine the possible relationship between certain indices of lipid metabolism and specific gene expression in chickens fed methimazole to produce a kind of artificial hypothyroidism. Male, broiler chickens growing from 7 to 28 days of age were fed diets containing 18% crude protein and either 0 or 1 g methimazole per kg of diet. At 28 days, these two groups were further subdivided into groups receiving 18% crude protein diets containing either 0 or 1 mg triiodothyronine (T3) per kg. Birds were sampled at 28, 30 and 33 days. Measurements taken included in vitro lipogenesis (IVL), malic enzyme (ME) activity, the expression of the genes for ME, fatty acid synthase (FAS) and acetyl coenzyme carboxylase (ACC). Hypothyroidism decreased IVL and ME at 28 d of age; however, T3 supplementation for 2 d restored both IVL and ME. Paradoxically, continuing T3 replenishment for an additional 3d decreased IVL without affecting ME activity. In contrast, supplemental T3 decreased IVL in euthyroid birds, regardless of the dosing interval, but had no effect on ME activity. Methimazole decreased plasma T3, T4, and uric acid. Although methimazole decreased ME gene expression, there was only a transitory relationship between enzyme activity and gene expression when plasma T3 was replenished with exogenous T3. These data may help to explain some of the apparent reported dichotomies in lipid metabolism elicited by changes in the thyroid state of animals. In addition, most metabolic changes in response to feeding T3 occurred within 2 to 5 d, suggesting that changes in intermediary metabolism preceded morphological changes. In conclusion, the thyroid state of the animal will determine responses to exogenous T3.

Key Words: Lipogenesis, Thyroid, Gene

T115 Evaluation of oils and polyethylene glycol as vehicles in a nine-day chick embryo xenobiotic assay. M. E. Persia*, T. Carro, and W. W. Saylor, *University of Delaware, Newark.*

The goal of this research was to evaluate procedures and vehicles that could be used in a xenobiotic metabolism assay utilizing an embryonating egg model. In four experiments, fertile Single-Comb White Leghorn eggs were incubated for 6 d and then injected with various oils or polyethylene glycol (PEG) to determine their effects on egg, embryo and shell weight and embryo mortality. Each treatment consisted of 10 replicate eggs sampled and analyzed on d 15. In Experiment 1, 500 μ l of corn, soybean, sesame and mineral oil were compared to control eggs that did not receive injections. None of the oil treatments significantly affected egg, embryo or shell weight or embryo mortality. Autoclaved samples of corn and soybean oil were compared with non-autoclaved oil samples and controls in Experiment 2. No significant differences in weight or mortality were noted among the autoclaved, non-autoclaved and control eggs. In Experiment 3, PEG was injected into eggs at levels of 0, 250, 500, 750 and 1000 μ l. Embryos in all eggs that received 1000 μ l of PEG died by 9 d post injection. A linear increase in embryo mortality was seen with increasing PEG injection. Injection of eggs with 500 μ l of PEG resulted in 50% survivability and will be utilized in subsequent experiments. Soybean oil and PEG were both tested at 500 μ l in Experiment 4. Soybean oil did not differ from control values for any weight or embryo mortality, but 500 μ l of PEG significantly reduced embryo weight and increased mortality (50%). The results of these experiments indicate that injecting fertile eggs with corn, soybean, sesame and mineral oils resulted in similar egg, embryo and shell weights and embryo mortality as control eggs, but PEG reduced embryo weight and increases mortality. Autoclaving oil samples did not alter egg, embryo or shell weight or affect mortality.

T116 Bone density measurements in broiler chickens. A. Mitchell*¹ and R. Angel², ¹USDA-ARS, ²University of Maryland, College Park.

The bone status of chickens can be measured by numerous techniques, providing a variety of parameters for evaluation. By the use of dual energy X-ray absorptiometry (DXA) it is possible to measure bone mineral content (BMC, g) and bone mineral density (BMD, g/cm²) either in vivo or on excised bones. The purpose of this study was to evaluate the relationships between DXA measured BMC and BMD in broiler chickens in vivo and in the excised bones. In two separate studies, a total of 2244 broiler birds of diverse nutritional background were scanned by DXA. In one study consisting of 1542 birds (1922 to 4091 g body weight, BWT) DXA scans were analyzed for total body and in vivo tibia BMC and BMD. In a second study of 702 birds (470 to 4110 g BWT) DXA scans were analyzed for total body BMC and BMD, and the excised tibia and femur were scanned separately and analyzed for BMC and BMD. Linear regression analysis was used to compare total body to bone measurements. For tibiae analyzed in vivo, the correlation (R²) between tibia BMC and total body BMC was 0.52 and the R² for BMD was 0.29. For excised bones, the R² with total body BMC was 0.65 for the tibiae and 0.56 for the femur, and the R² with total body BMD was 0.21 for the tibiae and 0.17 for the femur. The correlation between femur and tibia BMD was 0.58. Polynomial regression analysis was used to compare relationships among total body BWT, BMD and BMC. Combining the results of both studies, for the relationship between BWT and BMC the R² was 0.66, for BWT and BMD the R² was 0.13, and for BMC and BMD the R² was 0.58. In conclusion, the results of these studies indicate that in vivo and in vitro measurements of tibia BMC and BMD correlate similarly with total body measurements of BMC and BMD. In general, measurements of BMD, in the total body or in the individual bone showed low correlation with other parameters.

Key Words: Bone Mineral, Chickens, DXA

T117 Differentiation of chicken adipocytes in vitro. R. M. Morales*¹, M. S. Mayes², T. W. Huiatt², and C. G. Scanes^{1,2}, ¹Program in Toxicology, Iowa State University, Ames, ²Department of Animal Science, Iowa State University, Ames.

Control of excess amounts of adipose tissue are important to the animal industry. It is well established that the differentiation of mammalian

adipocyte is modulated hormonally. There is, however, little information on the hormonal control of differentiation of the chicken adipocyte. The present study examined the conditions necessary for differentiation of chicken preadipocytes in cell culture and, hence, the hormonal control of differentiation. Computer-assisted image analysis was used to analyze size of adipocytes and adipocyte clusters and the amount of lipid accumulation. Chicken preadipocytes cultured in serum free media for 3 and 5 days failed to show complete differentiation (e.g. clusters of at least five cells with abundant lipid droplets as stained with oil red O). Complete differentiation was allowed in the medium containing a combination of 1ug/ml insulin, 25ug/ml transferrin, 25ng/ml sodium selenite (ITS). The presence of triolein in the ITS media increased lipid accumulation as indicated by increased cell cross-sectional area of lipid droplets. The cocktail ITS also increased the size of clusters with <5 cells. A model to examine differentiation of chicken preadipocytes has been developed. The present data support the fundamental control of the differentiation of avian preadipocytes being similar to that in mammals.

Key Words: Chicken, Adipocyte, ITS

T118 Enhancing enterocyte enzymatic function by prebiotic feed supplementation. V. Davila¹, A. Diaz², A. Lopez-Mungia³, M. P. Castaneda¹, and G. M. Nava*^{1,4}, ¹CEIEPA, FMVZ-UNAM, Mexico City, Mexico, ²Departamento de Nutricion Animal, FMVZ-UNAM, Mexico City, Mexico, ³Instituto De Biotecnologia-UNAM, Mexico, ⁴University of Arkansas, Fayetteville.

Manipulation of the intestinal microflora with prebiotic products may affect the enterocyte physiology given that the intestinal mucosa maturation depends on beneficial bacterial colonization in neonatal animals. The objective of the present study was to evaluate the effect of inulin prebiotic administration on enterocyte enzymatic activity (maltase and sucrose) in the intestinal tract of neonatal broiler chickens. Arbor Acres chicks (1-day of hatch) were fed during 15 days with a standard diet (SD) or a standard diet supplemented with 0.2% of inulin prebiotic (SDI). At day 7 of age, intestinal samples (n=5) were taken and processed. Briefly, samples of duodenum and ileum were collected and intestinal mucosa was scraped in order to collect the enterocytes. Enterocyte homogenates (EH) were physically removed and brush border membrane vesicles (BBMV) were isolated. Enzymatic activity assays were performed using the EH and BBMV. Additionally, values of nucleotidase were analyzed. Inulin diet supplementation significantly (p<0.05) increased the concentration of intestinal maltase in the BBMV isolated from ileum at 7 days of age when compared to control diet (SD, 0.445 \pm 0.04 and SDI, 0.608 \pm 0.02 μ g of disaccharide metabolized/mg of protein/minute). Additionally, inulin supplementation during 14 days significantly (p<0.05) increased the concentration of intestinal sucrose in the BBMV isolated from duodenum when compared to control diet (SD, 0.555 \pm 0.053 and SDI, 0.816 \pm 0.027 μ g of disaccharide metabolized/mg of protein/minute). The low concentration of nucleotidase observed during this assay indicates that BBMV were isolated properly. Prebiotics stimulate the establishment of beneficial bacterial populations in the intestinal tract. It is possible that the early development of beneficial communities enhance the development of intestinal functions. The data from the present study support this hypothesis given that inulin prebiotic supplementation enhanced intestinal enzymatic activity in the BBMV section of the enterocyte.

Key Words: Prebiotic, Enterocyte, Inulin

T119 Developmental changes of plasma insulin, glucagon, IGF-I, IGF-II, thyroid hormones, and glucose concentration in chick embryo. J. Lu*¹, J. P. McMurtry², and C. N. Coon¹, ¹University of Arkansas, Fayetteville, ²USDA-ARS Growth Biology Laboratory, USDA-ARS, Beltsville, MD.

Hatching eggs from a flock of Cobb 500 females were collected and incubated. Plasma samples were obtained daily from day 10 of embryogenesis (10E) through hatch. The developmental changes of plasma insulin, glucagon, insulin-like growth factor-I and -II (IGF-I, IGF-II), triiodothyronine (T3), thyroxine (T4), and glucose concentration were investigated at different ages of the chick embryos. A significant increase in plasma insulin levels was observed from 130pg/ml at 10E to 389pg/ml at 16E. The insulin levels showed two peaks during embryogenesis (460pg/ml at 17E; 488pg/ml at hatch). Plasma glucagon levels increased from 59pg/ml at 10E to 428pg/ml at hatch; however, there was a decrease

from 12E to 19E with the lowest level of 60pg/ml at 15E. The molar ratios of insulin to glucagon (I/G) from 14E to 17E ranged from 1.8 to 2.2 which were significantly greater than normal I/G ratio in the post-absorptive state in avian species (1.2-1.7). The results indicate that insulin is an important promoter of chick embryo growth by anabolic drive to promote protein deposition especially during the embryonic rapid growth period. There also was a significant increase in plasma glucose from 13E to 18E suggesting glucose is an important regulator of protein anabolism in the chick embryo via suppression of amino acid oxidation. Plasma IGF-1 and IGF-II levels increased from 10E to 14E and then IGF-1 slowly decreased until hatch, while IGF-II remained constant. IGF-II levels were about 10 fold greater than IGF-1 suggesting IGF-II is an important functionary for chick embryonic development. Plasma T3 and T4 levels showed a significant increase during the third week of incubation and reached a peak at 19-20 E. The findings are consistent with previous research showing a sharp rise in T3 and T4 activities when the embryo switches to lung respiration.

Key Words: Chick Embryo, Hormones, Developmental Change

T120 Developmental changes of hepatic enzyme activities involved in methionine metabolism for chick embryo. J. Lu* and C. N. Coon, *University of Arkansas*.

Developmental changes in hepatic methionine adenosyltransferase (EC 2.5.1.6, MAT), cystathionine β -synthase (EC 4.2.1.22, CBS), cystathionase (EC 4.4.1.1, C-ase), 5-methyltetrahydrofolate-homocysteine S-methyltransferase (EC.2.1.1.13, MFM) and glycine

N-methyltransferase (E.C.2.1.1.20, GNMT) were determined in 11, 14, 17 and 19 day-old chick embryos and hatched chicks. Enzyme activities were expressed as nmole of product formed /min/mg of protein. The methionine-activating enzyme (MAT) activity was present at low level at day 11 of incubation but increased 8-fold to a maximum at day 19 and remained 6-fold at hatch. The MAT enzyme developmental pattern resembles the pattern observed in the rat fetus suggesting additional SAM (S-adenosyl-Methionine, sole product of MAT enzyme) is needed for rapid growth in the development of the chick embryo. Hepatic CBS activities did not change much during embryogenesis except the activity decreased to a low at day 19. High levels of hepatic C-ase were detected from day 11 through hatch. The developmental pattern of C-ase resembles the pattern observed in the rat fetus, although C-ase activity is absent from human fetal liver. Cystine can not be produced in pre-mature human infants but chick embryos do not have this limitation. Hepatic MFMT activity was higher during embryogenesis than that at hatch suggesting remethylation of homocysteine through MFMT may be a priority for the chick embryo. Previous studies indicate MFMT activity in rat liver decreases with age. MFMT is one of two methionine-conserving enzymes in broilers and layers. Chick embryos have a higher GNMT activity at day 14 than that at day 17, 19 and hatch suggesting the enzyme is more important for regulating the intrahepatic ratio of SAM to SAH (S-adenosyl-homocystine) during the middle of the incubation period. GNMT is considered the main enzyme for maintaining methyl group availability for more than 200 methylation reactions in mammals and birds.

Key Words: Chick Embryo, Enzyme Activities, Methionine Metabolism

Physiology and Endocrinology: Nutrition, Growth and Stress

T121 Effects of injecting transition cows with low doses of bovine somatotropin (bST) on milk yield, IGF-1, glucose and hepatic gene expression of gluconeogenic enzymes. M. Liboni*, M. S. Gulay, L. Badinga, M. J. Hayen, T. I. Belloso, C. J. Wilcox, and H. H. Head, *Department of Animal Sciences, University of Florida, Gainesville*.

Objectives were to evaluate effects of supplemental bST (0.4 mL, 10.2 mg/d, POSILAC[®]) during the prepartum and/or early postpartum periods on milk yield (MY), plasma concentrations of IGF-1 and glucose, and on steady state mRNA concentrations of hepatic gluconeogenic enzymes pyruvate carboxylase (PC) and phosphoenolpyruvate carboxylase (PEPCK). Multiparous Holstein cows were assigned randomly to a 2x2 factorial arrangement of treatments (TRT) to give four groups (I=no bST, n=26; II=bST postpartum, n=25; III=bST prepartum, n=27; IV=bST prepartum and postpartum, n=25). Biweekly injections of bST were in left or right ischiofemoral fossa beginning -21 d from expected calving through 70 DIM. Blood samples were collected from all cows thrice weekly throughout experiment, and liver biopsies were taken from 9 cows per TRT at -21, +2, +14 and +28 d from calving. Supplemental bST increased daily MY in all bST groups through 28 DIM (P<0.019) compared to TRT I; increases were 13.9, 12.7, and 26.6% for TRT II, III and IV, respectively. From 28 through 70 DIM, only TRT IV cows had greater daily milk yield than controls (18.7%, P<0.019). For IGF-1, significant increases were detected only during the postpartum period for cows on TRT II and IV (0-70 DIM, P<0.045); TRT group means were 107.0, 120.0, 102.8, and 132.6 ng/mL, respectively. No differences were detected in glucose concentrations (P=0.52). Hepatic levels of PC mRNA did not differ among TRT (P=0.47); PEPCK mRNA differed (P<0.01); mean levels were 165.9, 168.2, 162.7 and 161.2 arbitrary units, respectively. Results indicated that supplemental bST caused increased MY and postpartum plasma IGF-1 concentrations, but did not affect plasma glucose, or hepatic PC mRNA. Despite a small, but significant down-regulation of PEPCK mRNA for cows in TRT III and IV, these cows produced more milk than controls, and maintained similar plasma glucose concentrations.

Key Words: bST, Transition Period, Liver Gluconeogenesis

T122 Effect of insulin and growth hormone administration to mature miniature Brahman cattle on circulating concentrations of metabolic hormones and metabolites. C. C. Chase, Jr.*¹, D. G. Riley¹, T. H. Elsasser², L. J. Spicer³, M. C. Lucy⁴, S. W. Coleman¹, and T. A. Olson⁵, ¹USDA, ARS, Brooksville, FL, ²USDA, ARS, Beltsville, MD, ³Oklahoma State University, Stillwater, ⁴University of Missouri, Columbia, ⁵University of Florida, Gainesville.

The objective of this study was to determine the effect of administration of GH, insulin (INS), and GH plus INS to mature miniature Brahman cows (n = 6; 9.7 \pm 2.06 yr; 391 \pm 48.6 kg) and bulls (n = 8; 9.4 \pm 2.00 yr; 441 \pm 54.0 kg) on plasma concentrations of metabolic hormones (GH, INS, IGF-I) and metabolites (glucose, urea nitrogen [PUN]). We hypothesized that IGF-I secretion could be enhanced by concomitant administration of exogenous GH and INS, but not by either hormone alone. Animals were allotted to a modified crossover design that included four treatments: control (CON), GH, insulin (INS), and GH+INS. At the start of the study, one-half of the animals were administered GH (POSILAC; 14-d slow release) and the other one-half served as controls (CON) for 7 d. Beginning on day 8 and for 7 d, insulin (Novolin L) was administered (0.125 IU/kg BW) twice daily (0700 and 1900) to all animals; hence the INS and GH+INS treatments. Animals were rested for 14 d and then were switched to the other treatment combination. Blood samples were collected at 12-h intervals during the study. Sex affected (P < 0.05) plasma concentrations of metabolic hormones but not (P > 0.15) blood metabolites. Compared to CON, GH treatment increased (P < 0.01) mean plasma concentrations of GH (11.1 vs 15.7 \pm 0.94 ng/mL), INS (0.48 vs 1.00 \pm 0.081 ng/mL), IGF-I (191.3 vs 319.3 \pm 29.59 ng/mL), and glucose (73.9 vs 83.4 \pm 2.12 mg/dL), but decreased (P < 0.05) PUN (14.2 vs 11.5 \pm 0.75 mg/dL). Compared to INS, GH+INS treatment increased (P < 0.05) mean plasma concentrations of INS (0.71 vs 0.96 \pm 0.081 ng/mL), IGF-I (228.7 vs 392.3 \pm 29.74 ng/mL) and glucose (48.1 vs 66.70 \pm 2.12 mg/dL), decreased (P < 0.01) PUN (13.6 vs 10.4 \pm 0.76 mg/dL), and did not affect GH (13.5 vs 12.7 \pm 0.95 ng/mL). In the miniature Brahman model, using mature animals, both GH and GH+INS treatments dramatically increased circulating concentrations of IGF-I.

Key Words: Miniature Cattle, GH, IGF-I

T123 Influence of low doses of bovine somatotropin (bST) on plasma NEFA, and β -Hydroxybutyrate, hepatic lipid metabolism and gene expression of Holstein transition cows. M. Liboni*, M. J. Hayen, M. S. Gulay, L. Badinga, T. I. Belloso, and H. H. Head, *Department of Animal Sciences, University of Florida, Gainesville.*

Multiparous Holstein transition cows (n=103) were assigned randomly to a 2x2 arrangement of treatments (TRT) based upon biweekly injections of bST (0.4 mL, 10.2 mg/d, POSILAC[®]), which began 21 d before expected calving and continued through 70 DIM. The TRT were I=no bST, n=26; II=bST postpartum, n=25; III=bST prepartum, n=27; IV=bST prepartum and postpartum, n=25. During the transition period (-21 d through 28 DIM), blood samples were collected thrice weekly from all cows for quantification of non-esterified fatty acids (NEFA) and β -hydroxybutyrate (β -HBA) concentrations in plasma. Liver biopsies (9 cows per TRT) were conducted on d -21, +2, +14 and +28 from calving for the determination of total fat (FAT) and triglyceride (TG) accumulation, and the steady state expression of microsomal triglyceride transfer protein I (MTP-I) mRNA. No TRT effects were detected on NEFA (p=0.91); means ranged from 794.3 to 840.1 μ eq/L. For β -HBA, a trend for TRT effect was detected, but only during the postpartum period (P<0.07); means were 8.3, 12.6, 10.7 and 8.3 mg/dL, respectively. No TRT effects were detected on liver FAT (p=0.45) or TG (p=0.39). However, liver fat content of TRT II cows was greater than for cows on TRT II and IV (P<0.042), and also, TRT II cows had greater TG concentrations (P<0.038) than TRT I, III and IV cows on d 28; FAT and TG means were 8.45, 13.04, 8.04 and 8.31%; 1.89, 4.49, 2.32 and 1.90%, respectively. For MTP-I, significant TRT effects were detected (P<0.045); mean values were 178.6, 179.1, 174.2, 171.4 arbitrary units. As for FAT and TG, on d 28, TRT II cows had greater expression of MTP-I than TRT III (P<0.089) and IV (P<0.01) cows. In conclusion, when bST was injected only during the postpartum period (TRT II), β -HBA was increased. Despite the small but significant up-regulation of MTP-I of TRT II cows, FAT clearance from the liver was not greater than for cows on TRT I, III and IV after calving.

Key Words: bST, Transition Period, Liver Lipids

T124 Muscle and liver IGF-I mRNA expression and plasma IGF-I levels in channel catfish administered rbGH over time. B. Peterson*, G. Waldbieser, and L. Bilodeau, *USDA/ARS Catfish Genetics Research Unit Thad Cochran National Warmwater Aquaculture Center, Stoneville, MS.*

We have reported previously increased growth rates of 48% in as little as 6 wk in channel catfish administered recombinant bovine growth hormone (rbGH). Identifying genes involved in regulating growth may prove important to selecting fish for efficient lean growth. Research was conducted to examine plasma IGF-I and IGF-I mRNA expression in the muscle and liver of catfish administered rbGH. Ninety-six fish (41.1 \pm 1.5 g) were assigned randomly to one of two treatments with four replicates each. The treatments were: 1) Sham-injected control (needle puncture/week) and 2) rbGH (30 μ g/g BW/week, Posilac). Eight fish per treatment (2 fish/tank) were sampled on d 0, 1, 2, 7, 14, and 21. The fish were bled and muscle and liver samples were excised on each of the 6 sampling d. Relative expression of IGF-I mRNA was determined by real time RT-PCR. Circulating levels of IGF-I increased (55.5 \pm 2.5 ng/ml vs 22.2 \pm 1.7 ng/ml; P = 0.03) in rbGH-injected fish compared to sham-injected controls only at d 14. Expression of muscle IGF-I mRNA was not different in rbGH-injected fish compared to controls throughout the 21-d study. Liver IGF-I mRNA was increased 6-fold by d 1 in rbGH-injected fish compared to controls (P = 0.05). However, expression of liver IGF-I mRNA was not different from controls on d 2, 7, 14, and 21. Results of this study show that the growth promoting effects of rbGH were not mediated by the expression of IGF-I in the muscle. Instead, the results suggest that rbGH promotes growth by stimulating plasma IGF-I release, probably through its direct effect on the liver to synthesize IGF-I. The changes in expression and protein levels of IGF-I support IGF-I's role in growth regulation of channel catfish.

Key Words: IGF-I, Real Time PCR, Channel Catfish

T125 Cloning, expression and functional analysis of the porcine prolactin receptor. J. F. Trott, N. R. Farley, and R. C. Hovey*, *University of Vermont, Burlington.*

Prolactin (PRL) is an important reproductive hormone in pigs that functions through the prolactin receptor (PRLR) protein that is present in tissues such as the mammary gland, ovary and uterus. PRL may be of particular significance for reproduction in pigs due to their lack of placental lactogens that can bind the PRLR. Our objective was to clone the full length pPRLR cDNA and study its function. Using 5' RACE we have cloned the full-length pPRLR that encodes a mature protein of 601 amino acids. As anticipated, the pPRLR transduced a differentiation signal to the β -casein milk protein gene promoter *in vitro* following PRL treatment. Analysis of different ligands in this assay revealed that human growth hormone (hGH) and pPRL effected a greater transcriptional response (P#8804.0005) compared to oPRL. Transfection of CHO-K1 cells with the pPRLR revealed binding of hGH at high affinity (Kd=1.75 nM), similar to characteristics for the hPRLR (Kd=3.6 nM). The pPRLR also displayed higher affinity (P#8804.01) for pPRL compared to oPRL. Under normalized transfection conditions, the number of active receptor sites per cell was higher for the pPRLR than the hPRLR (P#8804.001), consistent with results from western blotting experiments. While both the pPRLR and hPRLR showed perinuclear intracellular distribution in transfected CHO cells as determined by immunocytochemistry, the pPRLR primarily localized to the cytoplasm whereas the hPRLR was more concentrated in vesicles (P#8804.05). Expression of pPRLR mRNA in miniature pig tissues as determined by quantitative RT-PCR was lowest in the ovary and highest in the mammary gland (P#8804.05). Our data indicate that the pPRLR demonstrates several unique characteristics at the post-transcriptional, post-translational and functional level.

Key Words: Prolactin, Pig, Prolactin Receptor

T126 Fluctuation of plasma ghrelin and growth hormone in fed and fasted cattle. A. E. Wertz*¹, T. J. Knight², A. Kreuder², M. Bohan², D.C. Beitz², and A. Trenkle², ¹South Dakota State University, Brookings, ²Iowa State University, Ames.

Four steers (450 \pm 28.5 kg) were used in a crossover design to determine fluctuation of plasma ghrelin and growth hormone (GH) concentrations in fed and fasted beef cattle. Cattle were adapted to a once daily feeding schedule over an 11-d period. Feed, sufficient to result in 10% weight-back, was offered at 0800 h and removed at 2000 h. After adaptation, two steers continued the once daily feeding schedule (FED) whereas; feed was withheld from the other two steers (FAST). Steers were fitted with indwelling jugular catheters 24 h before sampling. Serial blood samples were collected at 10-min intervals from 1800 to 2000 h (22 to 24 h fasting) and from 0600 to 0800 h (34 to 36 h fasting). From 0815 to 2000 h (36 to 48 h fasting), steers were sampled at 15-min intervals. A 5-d crossover period was used between sampling periods to re-establish the once daily feeding schedule. Treatment groups then were switched, and the sampling period was repeated. Plasma ghrelin and growth hormone concentrations were quantified using radioimmunoassays. Data were analyzed statistically as repeated measures using the mixed procedure of SAS. Peak concentrations were defined as concentrations that were two standard deviations greater than the baseline using PEAK software. Average plasma ghrelin concentrations were elevated (P<0.001) in FAST (648 \pm 10.4 pg/mL) compared with FED (115 \pm 3.5 pg/mL) steers. Plasma ghrelin concentration for FED steers reached a maximum just prior to feeding and then returned to baseline post-feeding, whereas ghrelin concentrations for FAST steers did not exhibit this pattern during the time period. Episodic ghrelin peaks, however, were detected for FAST steers beyond 40 h fasting. Plasma GH peaks tended to be more frequent (P=0.06) just prior to feeding, from 0600 to 0800, for FED compared with FAST steers. In contrast, FAST steers had more frequent (P#8804.02) GH peaks beyond 40 h of fasting. Plasma ghrelin concentrations fluctuated when feed intake was restricted, and differences in ghrelin concentrations correspond to difference in GH peak frequency.

Key Words: Ghrelin, Growth Hormone, Beef Cattle

T127 Plasma hormones and expression of growth hormone receptor (GHR) 1A and IGF-I mRNA in hepatic tissue of feed-restricted peri-parturient dairy cows. R. P. Radcliff^{*1}, B. L. McCormack¹, B. A. Crooker², and M. C. Lucy¹, ¹University of Missouri, Columbia, ²University of Minnesota, St. Paul.

The primary GHR mRNA transcript in liver (GHR 1A) is decreased at parturition and then gradually increases. We hypothesized that decreased food intake after parturition inhibits normal postpartum up-regulation of GHR 1A mRNA expression. Liver was biopsied from Holstein cows (n = 11) on d 10 ± 1, 1, 7, 14 and 21 postpartum. Blood samples were collected during the biopsy period. Cows were offered feed ad libitum prepartum. After parturition, six cows were fed 70% of their expected feed intake (feed-restricted; FR) for 14 d and five cows were fed ad libitum (Control). Both groups had ad libitum feed after d 14. Total cellular RNA was isolated from liver samples and GHR 1A and IGF-I mRNA were measured using quantitative real-time polymerase chain reaction. Dry matter intake (7 vs. 11 ± 1 kg/d; *P* < 0.03), milk yield (29 vs. 34 ± 2 kg/d; *P* = 0.1), and energy balance (-18.5 ± 0.7 vs. -15.4 ± 0.8 Mcal/d; *P* < 0.02) were less for FR compared to control cows (d 1 to 14). Plasma NEFA concentrations were greater (1190 ± 105 vs. 715 ± 115 µEq/L; *P* < 0.02) and plasma glucose concentrations tended to be less (50.2 ± 3.4 vs. 59.1 ± 3.7 mg/dL; *P* = 0.1) for FR vs. control cows (d 1 to 14). Amounts of GHR 1A mRNA decreased after parturition (*P* < 0.001). A treatment by day interaction for GHR 1A was detected because GHR 1A mRNA was less for FR cows on d 21 (7 days after FR ended; 986 ± 107 vs. 421 ± 97 fg/25 ng RT; *P* < 0.001). Amounts of IGF-I mRNA and plasma IGF-I concentrations decreased after parturition. Postpartum plasma IGF-I concentrations tended to be lower (51 vs. 65 ± 5 ng/ml; *P* = 0.09) but postpartum liver IGF-I mRNA concentrations were similar for FR vs. control. Feed-restriction decreased GHR 1A mRNA. The decrease in GHR 1A mRNA was present 7 days after the end of FR. We conclude that feed intake partially controls GHR 1A mRNA expression in early postpartum dairy cows and that the effect of FR may persist for at least one week.

Key Words: Growth Hormone Receptor, Feed Intake, Parturition

T128 Effect of naloxone, an opioid antagonist, on serum calcium concentrations immediately after parturition in multiparous Holstein cows. F. Frago¹, A. Ahmadzadeh^{*1}, R. Manzo¹, M. A. McGurie¹, and J. C. Dalton², ¹University of Idaho, Moscow, ²Research and Extension Center, University of Idaho, Caldwell.

This experiment was conducted to investigate the effect of naloxone, an opioid receptor antagonist, on serum calcium (Ca) homeostasis and pH, within the first 24 hours post-partum, in Holstein cows. Prior to parturition cows received a close up ration that met the NRC requirements for dry cows. Shortly after parturition and the first milking, cows were weighed and assigned randomly to receive either saline (n = 6), or 0.01 mg/kg of BW of naloxone (n = 6). Blood samples were collected at 10-minute intervals for 20 min before and 50 min after treatments. Mean serum Ca was not different between groups before treatments (8.6 vs. 10.4 mg/dL; SEM = 1.0). Naloxone caused a transient increase (*P* < 0.05) in serum Ca concentrations within 20 min after injection (from 10.4 to 14.8 mg/dL; SEM = 1.0). Mean serum Ca was not altered in saline-treated cows. There was no change in the mean serum pH in naloxone- or saline-treated groups. These results suggest that endogenous opioid peptides (EOP) play a role in Ca homeostasis in lactating Holstein cows and its inhibitory action is mediated through opioid receptors. Therefore, EOP may play a part in milk fever.

Key Words: Opioid Antagonist, Early Postpartum, Calcium

T129 Effects of short-term fasting on channel catfish growth and nycthemeral concentrations of plasma GH, IGF-I, and cortisol. B. C. Small^{*}, USDA/ARS Catfish Genetics Research Unit, Thad Cochran National Warmwater Aquaculture Center, Stoneville, MS.

Short-term fasting is a common management tool for controlling enteric septicemia of catfish; however, little is known concerning the physiological ramifications of short-term fasting. In many animals, long-term starvation affects the somatotrophic and the corticotrophic axes, often resulting in increased plasma concentrations of growth hormone (GH) and cortisol, and decreased concentrations of circulating IGF-I. This study

was conducted in order to characterize the effect of short-term fasting on plasma concentrations of GH, IGF-I, and cortisol over a 24-h period. Channel catfish fingerlings (mean=14.8 g) were stocked into forty-eight 76-L aquaria and acclimated for two wk. A photoperiod of 12L:12D was maintained throughout the study, with lights coming on at 0600 h daily. Treatments were assigned randomly such that fish in 24 aquaria were fed twice daily to satiety and fish in the remaining aquaria were fasted. The study was conducted for 21 d. On d 21, fish in the fed treatment were fed at 0650 h. Beginning at 0700 h and continuing every 2 h for 24 h, fish from two tanks per treatment were bled and plasma collected. After 3 wk, weight of fed fish increased an average of 65.7%, while fasted fish lost 21.3% on average. Nycthemeral concentrations of plasma GH were not significantly (*P*>0.05) different between fed (24.7 ng/mL) and fasted (26.8 ng/mL) fish. Paradoxically, nycthemeral IGF-I concentrations were different (*P*<0.05) between fed (23.4 ng/mL) and fasted (17.8 ng/mL) fish, and not different for times within treatments. Nycthemeral plasma cortisol concentrations were also different (*P*<0.05) between fed (14.5 ng/mL) and fasted fish (11.0 ng/mL), and different (*P*<0.05) for times within treatments. The present study indicates little or no effect of short-term fasting on plasma GH levels, but does demonstrate fasting-induced suppression of plasma IGF-I levels, and a correlation between feeding and cortisol secretion in channel catfish.

Key Words: Channel Catfish, Fasting, Hormone Profiles

T130 Microarray analysis of gene expression in ovarian dominant follicles (DF) following heat stress (HS). S. J. Kolath^{*1}, P. M. Coussens², S. S. Sipkovsky², S. J. Wilson¹, D. E. Spiers¹, J. N. Spain¹, and M. C. Lucy¹, ¹University of Missouri, Columbia, ²Michigan State University, East Lansing.

Heat stress decreases follicular growth and causes infertility in cattle. Our objective was to compare gene expression in DF from heifers exposed to HS or thermoneutral (TN) environments. Estrous cycles were synchronized (estrus = d 0) in Holstein heifers assigned randomly to HS (n=3) or TN (n=3) treatment. On d 5, heifers were moved into the Brody Environmental Chambers (19°C). Ambient temperature for HS heifers was increased on d 10, 3°C per day to 33°C on d 14. Ambient temperature for TN heifers remained at 19°C. The second wave DF was collected after ovariectomy on d 15. Total RNA was isolated, amplified using MessageAmp aRNA Kit (Ambion Inc., Austin, TX), reverse transcribed, labeled, and hybridized to the NBFGC microarray (18,263 unique ESTs) from the Center for Animal Functional Genomics (<http://gowhite.ans.msu.edu>). Follicular cDNA was labeled with Cy5 and a reference sample cDNA (comprised of mRNA from 29 bovine tissues) was labeled with Cy3 (n=10 microarrays). Fluorescence was measured using the GenePix 4000B scanner (Axon Instruments Inc., Union City, CA) and data were analyzed using GeneSpringTM software (Silicon Genetics, Redwood City, CA). A Student's t-test was performed using a Benjamini and Hochberg False Discovery Rate. Genes whose mRNA was enriched in DF had a fluorescent signal greater (*P*<.05) than the reference sample. There were 1,354 candidate genes whose mRNA was enriched in DF; 179 of which were increased greater than two-fold above the reference. Genes with greater than two-fold up-regulation encoded cell structural components (FMOD, ACTA2, GNB2L1), were involved in cell growth (VSGP/F-spondin, SPARC) and hormone transport (SHBG), and were transcription factors (ATF1, HIF-1, TFIID). Some of the discovered genes had not been reported previously in ovary. Heat stress increased body temperature (*P*<.01) but had no effect on follicle-specific mRNA. We conclude that microarray analysis with a reference design can be used to identify novel mRNA in ovary.

Key Words: Microarray, Ovary, Heat Stress

T131 Effects of conjugated linoleic acid on culture of adipose tissue explants of growing pigs. A. A. F. B. V. José, M. A. S. Gama, and D. P. D. Lanna^{*}, LNCA-ESALQ-USP, Brazil.

The objective of this study was to evaluate the effects of conjugated linoleic acid (CLA; 94.5% of t10,c12 CLA) on lipogenesis (measured as rates of 14C labeled glucose incorporation over a subsequent 2 h incubation), lipolysis (release over a subsequent 2 h incubation of non-esterified fatty acid - NEFA), and activities of lipogenic enzymes in explants of adipose tissue collected from growing pigs. Adipose tissue explants from nine pigs (78±3 kg) were cultured in medium 199 with insulin, dexamethasone and antibiotics for 4, 12, 24 and 48 hours. Treatments were: Control: 100 µM of PVA (polyvinyl alcohol); CLA

200: 200 μ M of CLA; CLA50: 50 μ M of CLA; LA: 200 μ M of linoleic acid and pGH: 100 ng/mL (porcine growth hormone - Reporcin, Southern Cross Biotech). Free fatty acids were complexed to PVA (2:1) as a carrier. After each culture period explants were collected and assayed for lipogenesis. After 48 h in medium 199 samples were analyzed for NEFA release (Krebs-ringer buffer, for 2 h) and explants taken for measurement of fatty acid synthase (FAS), glucose 6-phosphate dehydrogenase (G6PDH), 6-phosphogluconate dehydrogenase (6PGDH) and NADP-malate dehydrogenase activities. Glucose incorporation was significantly decreased ($P < 0.05$) in response to pGH treatment. The activity of FAS was consistently decreased by pGH ($P = 0.07$). Linoleic acid had no effect on any parameter evaluated. Lipid synthesis was decreased after culture; Control = 5390 and 2333 nmoles/2h.g; and CLA200 = 4296 and 1900 nmoles/2h.g, respectively. However, the effect of CLA was not statistically significant. Despite the lack of a significant effect of CLA on lipogenesis, FAS activity was decreased in response to CLA at 200 μ M ($P < 0.05$). The NADPH generating enzymes were not affected by any of the treatments. The pGH treatment increased basal lipolysis ($P < 0.05$), but CLA treatment had no effect ($P > 0.05$) on NEFA release after 48 h of culture. These data suggest CLA decreases FAS activity in cultures of pig adipose tissue explants.

T132 Somatotropic axis components following administration of exogenous bovine somatotropin to neonatal beef calves having an IGF-I promoter polymorphism. E. F. Jones*, K. E. Govoni, T. A. Hoagland, G. W. Kazmer, and S. A. Zinn, *University of Connecticut, Storrs.*

In cattle, serum concentrations of components of the somatotropic axis and its response to bovine somatotropin (bST) are age dependent. In addition, changes in serum concentrations of insulin-like growth factor (IGF)-I are associated with a polymorphism in the promoter region of IGF-I. To determine the response of components of the somatotropic axis and the association of the polymorphism with concentrations of IGF-I in neonatal calves, 44 newborn beef calves (22 males, 22 females) were utilized. Within 24 hr of birth, blood samples ($n=3$, 10 mL, 30 min apart) were collected via venipuncture of a jugular vein. Following collection of the third blood sample, half of the males and half of the females were administered bST (500 mg; d 0). Blood samples ($n=3$, 10 mL, 30 min apart) were collected from each animal on d 1, 3, 5 and 7. Concentrations of ST and IGF-1, and IGF binding protein (BP) -2 and -3 were determined by RIA and ligand blot, respectively. Calves were genotyped using single stranded conformational polymorphism techniques. Concentrations of ST, IGF-I, IGFBP-2 and IGFBP-3 averaged 14 ± 4 ng/mL, 104 ± 16 ng/mL, 20 ± 1 AU (arbitrary units) and 25 ± 2 AU, respectively. Concentrations of ST (18 ± 6 vs 94 ± 6 ng/mL) and IGF-I (114 ± 24 vs 142 ± 22) were increased ($P < 0.01$) on d 1 and 3 by bST treatment, after which increased concentrations of ST and IGF-I were maintained. Neither serum IGFBP-2 (17 ± 1 vs 17 ± 1 AU) nor IGFBP-3 (23 ± 1 vs 23 ± 1) were altered ($P > 0.10$) by bST treatment. Response to bST was greater in males than females (91 ± 7 vs 53 ± 7 ng/mL), but no gender differences ($P > 0.10$) in IGF-1 or IGFBP-2 and -3 were found. Frequencies were 24%, 52% and 24% for AA, AB and BB genotypes, respectively. Concentrations of IGF-1 in AA (179 ± 17 ng/mL), AB (201 ± 12 ng/mL) and BB (211 ± 17 ng/mL) calves were not different ($P > 0.37$). As early as 1 d of age IGF-I concentrations in calves increased in response to bST, but no association between IGF-I concentrations at this age and IGF-I promoter polymorphism was found.

Key Words: Somatotropic Axis, Beef Cattle, IGF-I Polymorphism

T133 Microarray analysis of hepatic gene expression from dry-off through early lactation in dairy cows fed at two intakes during the dry period. J. J. Loor*, N. A. Janovick, H. M. Dann, R. E. Everts, S. L. Rodriguez-Zas, H. A. Lewin, and J. K. Drackley, *University of Illinois, Urbana.*

A bovine cDNA microarray was used to study gene expression during the periparturient period in response to restricted or ad libitum DMI during the dry period. Liver from four Holstein cows with ad libitum (ca. 150% of NRC requirements; AA) or restricted (80% of requirements; RR) DMI of far-off and close-up diets was biopsied at -65, -30, -14, 1, 14, 28, and 49 d relative to parturition. All cows had ad libitum access to the same lactation diet. A microarray consisting of 7,872 cDNA inserts was used for transcript profiling. Annotation was based on similarity

searches using BLASTN and TBLASTX against human and mouse UniGene databases and the human genome. Cy3- and Cy5-labelled cDNA from liver and a reference standard (derived from a mixture of cattle tissues) were used for hybridizations (106 microarrays). Loess-normalized log-transformed ratios (liver/standard) were used to detect differential gene expression. Using Benjamini and Hochberg's False Discovery Rate ($P = 0.10$) to determine effects of prepartum DMI, day, or their interaction on differential gene expression resulted in 2,537, or 29 significant genes, respectively. Among those with significant interactions were genes associated with lipid metabolism, signal transduction, and insulin action. Genes differentially expressed by day relative to parturition included some involved in cell proliferation, carbohydrate metabolism, and protein catabolism. Hierarchical clustering showed that expression patterns on d -14, 1, and 14 were grouped in two clusters according to prepartum DMI. RR resulted in greater number of genes being upregulated 1.5 fold or greater ($P = 0.05$) on d 1 vs. d -14 (AA, 21; RR, 286). A similar trend was observed when comparing d 14 (AA, 31; RR, 139), d 28 (AA, 334; RR, 910), and d 49 (AA, 398; RR, 1,036) vs. d 1. Our data indicate that prepartum plane of nutrition alters hepatic gene expression during the peripartum period. (Supported by award 2001-35206-10946 from NRI Competitive Grants Program/CSREES/USDA).

Key Words: Liver, Microarray, Gene Expression

T134 Mammary and hepatic gene expression analysis in peripartal dairy cows using a bovine cDNA microarray. J. J. Loor*, H. M. Dann, R. E. Everts, S. L. Rodriguez-Zas, H. A. Lewin, and J. K. Drackley, *University of Illinois, Urbana.*

Simultaneous analysis of mammary and hepatic gene expression in peripartal dairy cows was studied using cDNA microarray technology. Mammary and liver tissue were collected at -14, 1, and 14 d relative to parturition from two multiparous Holstein cows fed according to current NRC recommendations. A microarray consisting of 7,872 cDNA inserts was used for transcript profiling. Annotation was based on similarity searches using BLASTN and TBLASTX against human and mouse UniGene databases and the human genome. Cy3- and Cy5-labelled cDNA from liver and a reference standard (derived from a mixture of cattle tissues) were used for hybridization (24 microarrays). Loess-normalized log-transformed ratios (tissue/standard) were used to detect differential gene expression. Benjamini and Hochberg's False Discovery Rate ($P = 0.05$) and a global gene error model, to account for the dependence of variation on signal intensities, were used to determine differential gene expression for the effect of tissue (1,040), day (20), and tissue by day (392) interactions. Among genes with a significant tissue by day interaction, expression ratios greater than 5-fold in liver compared with mammary were found for 15, 12, and 13 genes on d -14, 1, and 14, respectively. Among those showing tissue-specific expression, there were 26 genes with >5-fold expression in mammary compared with liver, and 44 genes with >5-fold expression in liver compared with mammary. Expression patterns in liver clustered together on d -14 and 14, and in mammary on d 1 and 14. Differences in expression patterns within these clusters ranged from 11% (liver) to 30% (mammary). Results show the power of microarrays to dissect gene expression patterns in tissues during the peripartum period. (Supported by award 2001-35206-10946 from NRI Competitive Grants Program/CSREES/USDA).

Key Words: Liver, Mammary, Microarray

T135 Adipose, mammary, and hepatic gene expression profiling in lactating dairy cows using a bovine cDNA microarray. J. J. Loor*, N. A. Janovick, R. E. Everts, S. L. Rodriguez-Zas, H. A. Lewin, and J. K. Drackley, *University of Illinois, Urbana.*

Simultaneous analysis of gene expression in four adipose depots [mesenteric (MS), omental (OM), subcutaneous (SQ), perirenal (PR)], mammary (MG), and liver (LV) of lactating cows was performed using cDNA microarray technology. Tissues were collected at slaughter from multiparous cows around peak (50 DIM), mid (95 DIM), and late (245 DIM) lactation. A microarray consisting of 7,872 cDNA inserts was used for transcript profiling. Annotation was based on similarity searches using BLASTN and TBLASTX against human and mouse UniGene databases and the human genome. Cy3- and Cy5-labelled cDNA from liver and a standard reference (derived from a mixture of cattle tissues) were

used for hybridizations. Loess-normalized log-transformed ratios (tissue/standard) were used to detect differential gene expression. Clustering analysis of gene expression around peak lactation (12 microarrays) showed that SQ had expression patterns that differed by 57% from other tissues. LV gene expression differed from MG and adipose by 50%; whereas expression in MG differed from adipose by 44%. Among adipose depots, gene expression in PR differed from MS and OM by 17%. Using Benjamini and Hochberg's False Discovery Rate ($P = 0.05$) and a global gene error model, to account for the dependence of variation on signal intensities, we detected differential expression of 355 genes across tissues. The same 24 genes were >5-fold ($P = 0.05$) in SQ than LV or MG. Some of these genes were associated with intracellular signaling, inflammatory responses, and apoptosis. One gene involved in the regulation of glucose oxidation was 3-, 5-, and 20-fold greater ($P = 0.05$) in MS, OM, and PR, respectively, than SQ. Thirteen genes were >5-fold in LV than MG, and 10 were >5-fold ($P = 0.05$) in MG than LV. Genes with >5-fold ($P = 0.05$) expression in LV than other tissues included one of the mitochondrial lipid oxidation pathway and one of unknown function. Our results reveal previously unknown tissue-specific gene expression patterns during established lactation.

Key Words: Tissue, Gene Expression, Lactation

T136 Gene expression profiles in liver of dairy cows in response to feed restriction using a bovine cDNA microarray. J. J. Looor*, D. B. Carlson, R. E. Everts, S. L. Rodriguez-Zas, H. A. Lewin, and J. K. Drackley, *University of Illinois, Urbana.*

Dairy cows decrease DMI around parturition but little is known about associated changes in tissue gene expression. We studied the effects of acute feed restriction on hepatic gene expression using cDNA microarray technology. During a 14-d period, six Holstein cows in mid-lactation (132 ± 38 DIM) had ad libitum access to a TMR (NR) or were restricted to 50% of previous 5-d DMI (FR) from d 10 through 14. Liver was biopsied on d 14. A microarray consisting of 7,872 cDNA inserts was used for transcript profiling. Annotation was based on similarity searches using BLASTN and TBLASTX against human and mouse UniGene databases and the human genome. Cy3- and Cy5-labelled cDNA from liver and a reference standard (derived from a mixture of cattle tissues) were used for hybridizations (24 microarrays). Loess-normalized log-transformed ratios (liver/standard) were used to detect differential gene expression. Ninety-nine differentially expressed genes were found using Benjamini and Hochberg's False Discovery Rate ($P = 0.10$) and a global gene error model (to account for the dependence of variation on signal intensities). Forty-six were 0.9- to 0.5-fold lower and 53 were 1- to 5-fold greater with FR. Genes associated with intracellular acyl-CoA ester transport, stress responses, and the tricarboxylic acid cycle were among those downregulated by FR. In contrast, FR increased hepatic expression of genes with links to immune responses, antioxidant activities, signal transduction, and apoptosis. Our results demonstrate that hepatic gene expression is altered in response to plane of nutrition. (Supported by award 2001-35206-10946 from NRI Competitive Grants Program/CSREES/USDA).

T137 Accuracy and precision of commercially available glucometers for use in dairy cattle. C. C. Williams*, A. M. Ponson, C. C. Stanley, H. G. Bateman, II, P. T. Richardel, and D. T. Gantt, *LSU AgCenter, Baton Rouge, LA.*

An experiment was conducted to validate two commercially available glucometers for use in dairy cattle. Six female Holstein calves approximately one mo of age, six Holstein steers approximately 4 mo of age, and six lactating Holstein cows were subjected to intravenous glucose tolerance tests (IVGTT) and insulin tolerance tests (ITT). These tests induced glucose concentrations ranging from very high (IVGTT) to very low (ITT) to test the sensitivity of the glucometers. In both tests, conducted on consecutive d, animals were fitted with indwelling jugular catheters 1 h prior to testing. In the IVGTT, glucose (0.5 g/kg BW) was infused at once, while in the ITT bovine insulin (0.03 units/kg BW) was infused at once. Relative to the glucose or insulin bolus, blood samples were collected at -10, 0, 5, 15, 25, 35, 45, and 60 min. Blood glucose concentrations were immediately measured in duplicate using the Accu-Chek® Glucometer (Roche, Inc.) and the Glucometer Elite® (Bayer Corp.). At each time point a blood sample was collected and plasma was frozen for glucose analysis using commercial spectrophotometric kits. Correlation coefficients were calculated to determine the

degree of linear association between glucometer readings and plasma glucose concentrations. Both glucometers were strongly correlated with plasma glucose concentrations in calves ($r = 0.975$ and 0.979), steers ($r = 0.992$ and 0.989), and cows ($r = 0.993$ and 0.996) for Accu-Chek® and Elite®, respectively. Glucometers were strongly correlated with plasma glucose in the IVGTT ($r = 0.980$ and 0.985 for Accu-Chek® and Elite®, respectively). However, in the ITT the correlations decreased ($r = 0.873$ and 0.754 for Accu-Chek® and Elite®, respectively) as plasma glucose concentrations were reduced. Coefficients of variation were 3.60% and 3.51% for the Accu-Chek® and Elite®, respectively, in the IVGTT, and 1.85% and 1.79% for the Accu-Chek® and Elite®, respectively, in the ITT. These data indicate that commercially available glucometers are valid for measuring blood glucose concentrations in dairy cattle.

Key Words: Glucometers, Blood Glucose, Dairy Cattle

T138 Effects of bovine somatotropin (bST), pregnancy and a diet enriched in omega-3 fatty acids on the uterine GH/IGF system in lactating dairy cows. T. R. Bilby*¹, F. Michel¹, T. Jenkins², C. R. Staples¹, and W. W. Thatcher¹, ¹University of Florida, Gainesville, ²Clemson University, Clemson, SC.

The objective was to examine the effects of bST, pregnancy and dietary fatty acids on the GH/IGF system in lactating dairy cows. Two diets were fed, starting 18 days postpartum (PP), in which the oil of whole cottonseed (15% of dietary DM; control diet; n=19) was compared to calcium salts of fatty acids containing fish oil (FO), high in eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA; 1.9% of dietary DM; n=8). All cows started an Ovsynch protocol between d 5 and 12 of an estrous cycle and were assigned randomly to be time inseminated (d 0; ~ 77 d PP) or not, and to receive either a bST (500 mg) injection on d 0 and 11 d later or not. On d 17, cows were slaughtered and uterine luminal flushings (ULF), endometriums and conceptuses were recovered. The number of cows in each group was as follows: control diet had 5 bST-treated cyclic (bST-C), 5 non bST-treated cyclic (C), 4 bST-treated pregnant (bST-P), and 5 non bST-treated pregnant (P) cows; FO diet had 4 bST-treated (bST-CFO) and 5 non bST-treated cyclic (CFO) cows. GH receptor mRNA was undetectable in the endometrium of all cows. Endometrial IGF-I mRNA was reduced in pregnant cows ($P \# 88040.01$) and tended to decrease in FO fed (+/- bST) versus C (+/- bST) cows ($P \# 88040.06$). IGF-II mRNA was increased in the endometrium of P and bST treated cows on the control diet ($P \# 88040.01$). Cows fed FO had increased concentrations of IGF-II mRNA, regardless of bST treatment ($P \# 88040.05$). IGFBP-2 mRNA was increased in bST-P cows ($P \# 88040.05$), whereas bST decreased the IGFBP-2 mRNA in all cyclic cows ($P \# 88040.05$). Treatments did not differ in endometrial IGFBP-3 mRNA or for ULF content of IGFBP-3, IGFBP-4, GH and IGF-I. EPA and DHA were increased in the endometrium and liver ($P \# 88040.01$), and DHA was increased in the milk of FO fed cows vs. control cyclic cows ($P \# 88040.01$). In conclusion, bST, pregnancy, and FO can have differential effects on the GH/IGF system.

Key Words: Pregnancy, Somatotropin, Fish Oil

T139 Unique effects of ovarian steroid hormones on parenchymal morphology in the mammary glands of swine. J. M. Scudder*, A. S. Barndollar, J. F. Trott, and R. C. Hovey, *University of Vermont, Burlington.*

Sufficient milk production by sows is a major limitation for piglet growth. The main structural component in the mammary glands of gilts is a lobular structure referred to as the terminal duct lobular unit (TDLU) that arises from mammary ducts. These can be classified as a TDLU-1, -2, or -3, depending on the number of ductules present. Separately, end buds (club-like structures) are also present in the mammary gland to direct ductal elongation. We hypothesized that the proportion of different structures in the mammary glands of gilts is regulated by ovarian steroid hormones. Ovary intact, sexually-mature Yucatan miniature swine were treated with estrogen (E2), progesterone (P4), or saline for 5 days. Mammary gland tissues were prepared as semi-thick sections and mounted on slides before staining to identify the various structures. Other sections were prepared at 4µm and stained with hematoxylin and eosin. We used a histomorphometric approach to quantify the number of different structures in the mammary glands of each animal. Across treatments we found that TDLU-1, -2 and -3 structures in

the mammary glands of gilts contained an average of 11, 35 and 81 ductules, respectively. In saline treated animals, 37.4%±10%, 59.2%±8% and 3.4%±2.5% of the structures were present as TDLU-1, -2 and 3, respectively (TDLU-1 vs TDLU-2, P#8804.16; TDLU-1 vs TDLU-3, P#8804.02). These proportions were not altered by hormone treatment (P#8805.05). We did however find hormone-induced changes in the number of end buds within the mammary gland. The number of end buds per gland following treatment with saline, E2 or P4 was 4.75±2.8, 16.5±5 and .5±.5 (SAL vs E2, P#8804.03; SAL vs P4, P#8804.09). Separately, histological examination revealed increased secretory activity with E2 treatment. Taken together, our results show that ovarian steroid hormones have pronounced effects on parenchymal morphology and cell proliferation in the mammary glands of gilts that may influence a sows milk production potential.

Key Words: Mammary Gland, Morphology, Ovarian Hormones

T140 Effects of bovine somatotropin (bST), pregnancy and a diet enriched in omega-3 fatty acids on reproduction in lactating dairy cows. T. R. Bilby*¹, A. Sozzi¹, M. Lopez¹, F. Silvestre¹, A. Ealy², C. R. Staples¹, and W. W. Thatcher¹, ¹University of Florida, Gainesville, ²The Pennsylvania State University, University Park.

The objective was to examine effects of bST, pregnancy and dietary fatty acids on reproductive responses in lactating dairy cows. Two diets were fed, starting 18 d postpartum (PP), in which oil of whole cottonseed was compared to calcium salts of fatty acids containing fish oil (FO). The Ovsynch protocol was administered between d 5 and 12 of the estrous cycle, and cows were assigned randomly to be time inseminated (d 0; ~ 77 d PP) or not, and to receive a bST (500 mg) injection on d 0 and 11 or not. Daily blood samples were taken from d 0 d 17, and ovarian responses were measured by ultrasound on d 7, 9, 11, 13, and 15-17. Cows were slaughtered on d 17, and uterine luminal flushings (ULF), conceptuses and CL were recovered. Number of cows in each group was as follows: control diet had 5 bST-treated cyclic (bST-C), 5 non bST-treated cyclic (C), 4 bST-treated pregnant (bST-P), and 5 non bST-treated pregnant (P) cows; FO diet had 4 bST-treated (bST-CFO) and 5 non bST-treated cyclic (CFO) cows. The bST increased pregnancy rate (83% [5/6]>40% [4/10]; P#8804.10), conceptus length (45>34 cm; P#8804.10) and INF- τ in the ULF (9.4>5.3 μ g; P#8804.05) with no effect on INF- τ mRNA concentration in the conceptus. The CL tissue volumes tended to be higher in P cows versus C cows (P#8804.10) and was higher at slaughter (P#8804.05). Pregnancy altered (P*; P#8804.05) size of the second wave dominant follicle and number of Class 2 follicles indicative of a less active dominant follicle in P cows. Treatment with bST increased plasma GH and IGF-I (P#8804.01); among control fed cows (cyclic and pregnant) bST decreased P4 (P#8804.05). The FO (+/-bST) cows had lower plasma insulin than C cows (+/-bST; P#8804.05), and FO altered (FO*d) the GH (bST-CFO>bST-C; P#8804.01) and IGF-1 (bST-C>bST-CFO; P#8804.05) responses to bST injections. In summary, bST and FO appear to modulate reproductive responses that may be beneficial to the developing conceptus.

Key Words: Pregnancy, Somatotropin, Fish Oil

T141 Effects of ambient temperature and solar radiation on skin evaporative water loss in dairy cattle. B. C. Pollard*, M. E Dwyer, A. C. Fitzgerald, P. C. Gentry, D. A. Henderson, and R. J. Collier, *University of Arizona, Tucson.*

To determine effects of ambient temperature and solar radiation on total evaporative water loss (TEWL) in cattle, non-lactating, Holstein cows (n=6) and heifers (n=6) were randomly assigned to one of two treatments in a climate control facility and given ad libitum access to feed and water. Both treatments were provided a dry bulb temperature at 0500 h of 27.8°C and a maximum temperature of 39.4°C at 1500 h to mimic the average for Summer Solstice (SS) in Tucson, AZ. The two treatments differed by either the addition of SS levels of solar radiation (S) or high ambient temperature alone (NS). Sunrise began at 0600 h, sunset at 1950 h, with maximum irradiation (1,061 Wh/m²) at 1200 h. At two hour intervals, rectal temperature (RT), respiration rate (RR), and skin temperature (ST) were estimated by infrared reflection and TEWL were determined at five points (rump, loin, udder, rib and neck). Closed-chamber TEWL was determined with a Vapometer® (Delfin Technologies, Finland) calibrated and validated according to the

manufacturers instructions. Solar radiation S increased (P<0.05) RR and ST at all locations. Average TEWL rose as ambient heat load increased and was greater in S (94.3 vs. 77.1 g/m²; P < 0.01) compared to NS. Correlations between skin temperature and TEWL were highly significant for the loin (r = 0.55, P < 0.001), rib (r = 0.62, P < 0.001) and neck (r = 0.42, P < 0.001) while a tendency was noted for the rump (r = 0.23, P = 0.0807). There was no detectable relationship between udder ST and TEWL (P > 0.10). This study begins to address the solar radiation component contributing to individual parameters of heat stress. Further, closed-chamber TEWL provides a novel method to determine sweating rate in dairy cattle.

Key Words: Heat Stress, Dairy Cattle, Solar Radiation

T142 Effect of growth hormone on the expression of liver-enriched transcription factors in the bovine liver. S. Eleswarapu* and H. Jiang, *Virginia Tech, Blacksburg.*

Growth hormone (GH) plays an important role in a variety of physiological processes. A major target organ of GH is the liver, where GH regulates the expression of many genes involved in metabolism, detoxification and other functions of the liver. A possible mechanism by which GH affects gene expression in the liver is that GH alters the expression of liver-enriched transcription factors (LETFs), which in turn change the expression of other genes in the liver. As part of the long-term goal to investigate this possibility, we determined the effect of GH on the expression of nine LETFs, including hepatocyte nuclear factor (HNF)-1 α , HNF-1 β , HNF-3 α , HNF-3 β , HNF-3 γ , HNF-6, CCAAT/enhancer-binding protein (C/EBP)- α , C/EBP- β , and albumin D-element binding protein (DBP) in the bovine liver. Eighteen non-lactating and non-pregnant Angus cows were assigned randomly to three groups (n = 6 per group) and each cow received a single intramuscular injection of 500 mg of recombinant bovine GH. Liver biopsy samples were taken from group 1 cows 6 h after GH administration, group 2 cows 24 h after GH administration, and group 3 cows 1 wk after GH administration. Liver biopsy samples were also taken from group 3 cows 1 d before GH administration. Levels of the nine LETF mRNAs in these liver samples were quantified using ribonuclease protection assays. The levels of HNF-3 γ and HNF-6 mRNAs were higher (P < 0.05) in the liver samples taken from cows 24 h and 1 wk after GH administration than in the liver samples taken from cows 1 d before GH administration or 6 h after GH administration. The levels of other LETF mRNAs, including HNF-1 α , HNF-1 α , HNF-3 α , HNF-3 β , C/EBP- α , C/EBP- β and DBP mRNAs, were not different (P > 0.05) between these liver samples. Thus, GH can increase the expression of HNF-3 γ and HNF-6 mRNAs in the liver and these two LETFs may play a role in GH regulation of the expression of other genes in the liver.

Key Words: Growth Hormone, Liver, Transcription Factor

T143 Liver expression of growth hormone receptor 1A mRNA is decreased in dairy cows but not in beef cows at parturition. H. Jiang*¹, M. C. Lucy², B. A. Crooker³, and W. E. Beal¹, ¹Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg, ²Department of Animal Sciences, University of Missouri, Columbia, ³Department of Animal Sciences, University of Minnesota, St. Paul.

Growth hormone receptor (GHR) mRNA in the liver of cattle is composed of variants that differ in the first exon. The expression of a major GHR mRNA variant, GHR 1A, is down-regulated in the liver of dairy cows at parturition. As part of the effort to understand the mechanism by which GHR 1A mRNA expression is decreased at parturition, we determined in this study if GHR 1A mRNA expression was also decreased in the liver of beef cows at parturition. Liver biopsy samples were taken from multiparous Angus (n = 6) and Holstein cows (n = 6) 7 to 23 d before parturition, within 24 h after parturition (i.e., at parturition), and 8 to 18 d after parturition, and the levels of GHR 1A and insulin-like growth factor-I (IGF-I) mRNA in these samples were measured by ribonuclease protection assays. As expected, the expression of GHR 1A mRNA in the liver of dairy cows was decreased at parturition (P < 0.05). The expression of IGF-I mRNA in the liver of dairy cows was also decreased at parturition (P < 0.05), perhaps as a result of decreased expression of GHR 1A mRNA. However, neither the expression of GHR 1A mRNA nor that of IGF-I mRNA was decreased in the liver of beef cows at parturition (P > 0.1), when compared to that in the prepartum or postpartum periods. These results suggest that the decrease in GHR

1A mRNA expression in the liver of dairy cows at parturition is not caused by ending of pregnancy or by initiation of lactation *per se*.

Key Words: Growth Hormone Receptor, Cows, Liver

T144 A miniature condition in Brahman cattle is associated with a single nucleotide mutation within the growth hormone gene. B. L. McCormack¹, C. Agca¹, C. C. Chase, Jr.², T. A. Olson³, T. H. Elsasser⁴, A. C. Hammond⁵, T. H. Welsh, Jr.⁶, and M. C. Lucy¹, ¹University of Missouri, Columbia, ²USDA, ARS, Brooksville, FL, ³University of Florida, Gainesville, ⁴USDA, ARS, Beltsville, MD, ⁵USDA, ARS, Athens, GA, ⁶Texas A&M University, College Station.

Miniature Brahman cattle at the USDA, ARS in Brooksville, FL have normal proportioned growth but are approximately 70% of normal mature height and weight. Pedigree analyses suggest that the condition is inherited as a recessive gene. The objective was to clone the GH cDNA from miniature cattle and compare its sequence to normal cattle. Messenger RNA was isolated from pituitary and a cDNA for the protein coding region of the GH gene was amplified by reverse transcription PCR from each of two miniature cattle. The cDNA were cloned into

plasmid vectors and the top and bottom strands were sequenced by automated DNA sequencing. Both cDNA clones contained a nucleotide polymorphism in which base number 641 of GenBank AF034386 (*Bos indicus* GH) was mutated from a cytosine (C) to a thymine (T). The C to T change encodes a mutation (threonine to methionine) at amino acid 200. The threonine is located in the fourth alpha helix of GH and is one of nine amino acids that participate directly in binding of GH to the GH receptor. Amino acid mutations at this location are associated with dwarfism in humans. Four miniature and four normal stature cattle from the Brooksville herd were tested for the polymorphism by using restriction fragment length polymorphism (RFLP) analysis of PCR-amplified GH gene with BsmBI restriction enzyme (specific for mutated nucleotide). The four miniature cattle were homozygous for the mutation (-/-). Two of the normal stature cattle were homozygous for the wild type allele (+/+) and two were heterozygous (+/-) ($P < .05$). Miniature Brahman cattle were homozygous for a single nucleotide polymorphism that encodes a mutation in an amino acid involved in binding of GH to the GH receptor. Normal stature cattle had at least one copy of the normal GH allele. We conclude that threonine 200 in bovine GH is required for normal growth in cattle.

Key Words: GH, Mutation, Growth

ASAS - Growth and Development

T145 Effect of gender and feeding program on productive performance and carcass quality of heavy pigs. J. Peinado^{*1}, M. Nieto², J. C. González¹, G. G. Mateos³, and P. Medel¹, ¹Imasde Agropecuaria Madrid, Spain, ²Copese Segovia, Spain, ³Universidad Politécnica de Madrid, Madrid, Spain.

A total of 252 Duroc x Landrace*Large White pigs of 28.3 ± 2.1 kg of initial BW was used to study the influence of sex and a 10 % lysine restriction from 30 to 60 kg BW on productive performance and carcass quality. There were six treatments arranged factorially with two types of feed from 30 to 60 kg BW (LL, 0.89 % lys vs HL, 0.97 % lys) and three sexes (castrated females, CF; entire females, EF; castrated males, CM). Energy:lys ratio was maintained constant in all the diets, and each treatment was replicated three times (14 pigs housed together). Males were castrated at birth and females at 30 kg BW. From 60 kg BW to slaughter all pigs received a common diet *ad libitum* (2.4 Mcal NE/kg and 0.70 and 0.67 % lys from 60 to 90 and from 90 to 119 kg BW, respectively). From 30 to 60 kg BW pigs fed the LL diet had worse feed conversion than pigs fed the HL diet (2.12 vs 1.97 g/g; $P < 0.05$). However, from 60 to 90 kg BW pigs fed the LL diet ate more and grew faster than pigs fed the HL diet (1,982 vs 1,815 g/d; and 688 vs 619 g/d for LL and HL diet, respectively; $P < 0.05$). For the whole period, pigs fed the LL diet ate 5.5 % more feed than pigs fed HL diet (1,983 vs 1,879 g/d; $P < 0.05$) but gains and feed conversion were not affected. Gender did not influence productive performance. Backfat was higher for CF than for EF with CM in an intermediate position (28.3, 23.3, and 25.4 mm, respectively; $P < 0.05$). Fat thickness at *Gluteus medius* muscle (GM) was higher for CF than for EF or CM (20.2, 17.9, and 18.6 mm, respectively; $P < 0.05$). Feeding program did not affect backfat or GM fat. It is concluded that a reduction of 10 % of lysine from 30 to 60 kg BW increased feed intake in the global period without affecting growth or feed conversion. Also, castration of the females might improve some quality carcass parameters of pigs destined to the cured ham industry.

Key Words: Pig Performance, Castration, Lysine Level

T146 Effect of protein from placental bovine tissue on puberty and growth mice. F. A. Nunez¹, J. A. Garcia-Macias¹, J. A. Lopez², and F. G. Rios^{*2}, ¹Facultad de Zootecnia - Universidad Autonoma de Chihuahua (Mexico) Periferico F. R. Almada, Mexico, ²FMVZ - Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico.

Our aim was to evaluate activity of protein from placental bovine tissue partially purified by chromatographic column with Sephadex 50-40#8482. Sixty Balb/C pubertal mice, (thirty females and thirty males), were used in a randomized design experiment with 3 x 4 factorial arrangement to test two sex (females and males), two placental proteins (PI and PII) and four placental proteins (25, 50, 75 and 100 μ g/mice/day of the placental protein). We compared this to a positive

control (100 μ g/mice/day) of bovine serum albumin (BSA) and negative control group (100 μ L/mice/day) of ammonium bicarbonate (AB). Four groups (three males and three females) received four dose, 25, 50, 75 and 100 μ g/mice/day of the placental protein PI (MW ranks 17 to 30 kDa), and four groups (three males and three females) received four dose, 25, 50, 75 and 100 μ g/mice/day of the placental protein PII (MW ranks 31 to 97 kDa). Body weight and feed intake were measured daily for a ten day experimental period. The experiment was analysed as factorial design randomised with three factors; means comparison performed by contrast. Feed efficiency (FE) of female mice (0.095g:g) and male mice (0.091) were not affected ($P \#88050.05$), by sex and treatments. The rate of growth (RG) observed a effect of sex; the male mice were heavier ($P \#88040.01$) in 44.82% than female mice (2.61 \pm 0.23 vs. 1.17 \pm 0.23). RG in the mice group injected with AB was less ($P \#88040.05$) than mice group injected with BSA (1.54 \pm 0.25 vs. 2.16 \pm 0.24), average daily gain (ADG) was different in male mice ($P \#88040.05$) in 29.1% than female mice (0.51 \pm 0.01 vs. 0.36 \pm 0.09g/d). In the mice group injected with AB and the mice group injected with 50 μ g/mice/d of PII proteins, ADG was less than the other treatments in the same sex ($P \#88040.05$). The female mice injected with 100 μ g/mice/d were less ADG. The carcass composition was not affected ($P \#88050.05$) by sex and treatments, 41.96 \pm 1.56 for male vs. 41.57 \pm 1.59, for female, however dressing carcass percentage observed lineal tendency ($P \#88040.05$) in PI and PII for male mice. It is concluded that proteins from placental bovine tissue partially purified, not improve growth in pubertal mice.

Key Words: Placental Protein, Mice, Growth

T147 Maternal undernutrition changes angiotensin type 1 and 2 receptors in ovine fetal heart. H.-C. Han^{*1}, K. J. Austin¹, S. P. Ford¹, P. W. Nathanielsz², and T. R. Hansen¹, ¹University of Wyoming, Laramie, ²New York University, New York.

Nutrient restriction during early gestation causes compensatory growth of both the left and right ventricles of the ovine fetal heart by day 78 of gestation (Biol Reprod 69:133). Angiotensin II mediates cardiovascular pathologies through its effects on the type 1 (AT1) and type 2 (AT2) receptors. AT1 has been shown to mediate deleterious effects such as vasoconstriction, cellular growth, and endothelial cell damage in adult systems. Very little is known about fetal heart angiotensin receptors and the consequences of activation. Previously we reported that AT1 mRNA was down regulated in fetal left ventricle (LV) from nutrient restricted ewes when compared to control fed ewes. It was hypothesized that maternal undernutrition (energy and protein) would adversely affect AT1 and AT2 protein expression in the fetal LV. Pregnant ewes were randomly assigned to control (n = 8, 100% NRC requirements) or nutrient-restricted groups (n = 8, 50% NRC requirements). Ewes were maintained on diets from day 28-78 of gestation. Fetal LV was

snap frozen on day 78 of gestation. Protein was extracted in a reducing environment (beta mercaptoethanol) using Laemmli buffer. Protein (100 µg) was separated using SDS-15% 1D-PAGE and transferred to nitrocellulose membranes. AT1 and AT2 were detected using antibody against AT1 or AT2. Immunoreactive bands were detected using chemiluminescence substrate. Data represent arbitrary units. AT1 was down regulated in fetal LV from nutrient restricted when compared to control fed ewes (1630 vs 1345 ± 78.72, pooled standard error; P < 0.05). A 50-kDa form of AT2 was also down regulated in nutrient restricted LV (3290 vs 2814 ± 149.52; P < 0.05) while a lower molecular weight form of AT2 (22kDa) was upregulated (7672 vs 11044 ± 880.69; P < 0.05) when compared to control fed ewes. It is concluded that hypertrophy of fetal LV in response to maternal undernutrition is associated with decreased AT1 and 50-kDa AT2, and increased 22kDa AT2 protein expression. Fetal LV gene expression in response to changes in the angiotensin receptors may have longer-term implications in development of cardiovascular disease during post-natal life. NIH P20RR16474.

Key Words: Ruminant, Fetal Heart, Angiotensin

T148 Microarray analysis of gene expression during ovarian development in swine. C. Agca^{*1}, K. M. Whitworth¹, J.-G. Kim¹, C. N. Murphy¹, A. Rieke¹, G. K. Springer¹, L. J. Forrester¹, J. A. Green¹, N. Mathialagan², R. S. Prather¹, and M. C. Lucy¹, ¹University of Missouri, Columbia, ²Monsanto Company, St. Louis, MO.

The objective was to measure global changes in porcine ovarian gene expression by using microarray analysis. cDNA clones from porcine reproductive tissues were isolated and sequenced. The cDNA insert from individual clones was amplified by PCR and arrayed onto polylysine-coated slides (n = 20,000 clones per slide). Clones were represented either once (75%) or multiple times (25%) on individual slides. Total RNA was isolated from fetal ovary (60 d of gestation), neonatal ovary (22 d of age), prepubertal ovary (150 d of age), or adult ovary [ovary or corpus luteum (CL)]. Duplicate samples from four animals per developmental stage were used in the analysis (n = 40 microarrays). A reference sample was generated by pooling total RNA from ovarian follicles and CL. Each microarray slide was hybridized to cy5 labeled test sample and cy3 labeled reference sample. The arrays were normalized and filtered using GeneSpring™ software (Silicon Genetics, Redwood City, CA). Statistical analysis was done using Welch t-test and Bonferroni multiple testing correction with 0.01% false discovery rate. A Tukey post-hoc test was used to determine differential expression among the developmental stages. Approximately 16,500 clones passed the filtering and 1148 genes (7%) showed evidence of differential expression in ovarian tissues (P < 0.01). Examples of genes found to be differentially expressed were: synaptonemal complex protein 3 and transportin 3 (fetal ovary); zona pellucida glycoprotein 3 and H19 (neonatal ovary); insulin-like growth factor binding protein 5 (fetal and neonatal ovary); connexin 43 (prepubertal ovary); apolipoprotein D (adult and prepubertal ovary); 3β hydroxysteroid dehydrogenase (adult ovary and CL); betamicroseminoprotein and major histocompatibility complex genes (CL). Distinct differences in gene expression across ovarian development were shown. This research was funded by the Monsanto Company.

T149 Hormonal regulation of leptin receptor expression in primary cultures of porcine hepatocytes. T. J. Caperna^{*}, A. E. Shannon, S. M. Poch, W. M. Garrett, and M. P. Richards, USDA, Agricultural Research Service.

Leptin, a polypeptide hormone primarily produced by fat cells, has been shown to regulate energy metabolism in monolayer cultures of rodent hepatocytes and hepatic tumor cell lines. However, in porcine hepatocytes, we and others have demonstrated that leptin plays a minimal role, if any, in cellular energetics. The goals of this study, were to establish the presence of porcine hepatocyte leptin receptors and to determine the influence of regulatory hormones on leptin receptor gene expression. Hepatocytes were prepared from 30-70 kg pigs and seeded into T-25 flasks coated with pig tail collagen. Monolayers were established in Williams E medium containing fetal calf serum for one day and switched to serum-free medium with basal hormone conditions (1 ng/ml insulin and 10 nM dexamethasone) for an additional two days. For the final 24 hr, insulin (1 or 100 ng/ml) or glucagon (100 ng/ml), were added in the presence or absence of 100 nM T3. RNA was extracted and quantitative

RT-PCR was performed with primers specific for porcine long form and total leptin receptors. Leptin receptor expression was calculated relative to 18S rRNA expression. The expression of the long form of the leptin receptor was confirmed under basal conditions. Insulin, glucagon and recombinant human proteins at 100 ng/ml (ghrelin, GLP-1 and leptin) had no influence on leptin receptor expression, however, the addition of T3 was associated with a marked increase (P < 0.001) in total and long forms of the leptin receptor, 1.6 and 2.3 fold, respectively. Despite the presence of up-regulated leptin receptor expression in T3 treated cells, addition of leptin to these cultures confirmed the lack of effect of leptin on glycogen turnover or glucagon-induced cAMP production. These data suggest that porcine hepatocytes are insensitive to leptin even when leptin receptor expression is enhanced by T3.

Key Words: Pig Hepatocytes, Leptin Receptor, T3

T150 Regulation of leptin and leptin receptor expression in porcine subcutaneous adipose tissue. T. G. Ramsay^{*} and M. P. Richards, USDA-ARS, Beltsville, MD.

The present study was performed to examine the response of the leptin gene to hormonal stimuli in porcine adipose tissue from finishing pigs. Ten Yorkshire gilts (approximately 150 kg BW) were used in this study. Dorsal subcutaneous adipose tissue samples were acquired and adipose tissue explants (approximately 100 mg) were prepared using sterile technique. Tissue slices were then transferred to 12 well tissue culture plates containing 1 mL of media 199 with 25 mM Hepes, 0.5 % BSA, pH 7.4 and various hormone supplements of interest. Triplicate tissue slices were incubated with either basal medium or hormone supplemented media in a tissue culture incubator at 37° C with 95% air/5% CO₂. Following 24 h of incubation, tissue samples from these incubations were blotted and transferred to microfuge tubes with subsequent freezing in liquid nitrogen and storage at -80° C prior to analysis for gene expression by RT-PCR and subsequent quantification of transcripts by capillary electrophoresis with laser-induced fluorescence detection. Media from these incubations was collected in microfuge vials and stored at -20° C prior to analysis for leptin content by RIA. Dexamethasone (1 µM) reduced leptin secretion by 25% (p < 0.05), while the combination of insulin and dexamethasone stimulated leptin secretion into the medium by 60% (p < 0.05). Porcine growth hormone (GH) inhibited leptin secretion by 33% (p < 0.05). Neither triiodothyronine (T3, 10 nM) nor IGF-1 (250 ng/mL medium) had an effect on leptin secretion from adipose tissue slices (p > 0.05). Dexamethasone produced a 35% increase in leptin mRNA expression relative to insulin (p < 0.05). Incubation of tissue cultures with GH, T3 or leptin for 24 h had no effect on leptin mRNA expression (p > 0.05). Dexamethasone induced a 34% decrease in total leptin receptor expression, relative to insulin treated adipose tissue slices, following 24 h of incubation. Porcine GH, T3 and leptin had no effect on total leptin receptor expression (p > 0.05). These data suggest that leptin secretion is a regulated phenomenon and that post-translational processing may be significant.

Key Words: Leptin, Leptin Receptor, Adipose

T151 Secreted and signaling genes and proteins in fetal and neonatal pig adipose tissue and stromal-vascular cells. G. J. Hausman^{*1}, S. P. Poulos¹, L. R. Richardson¹, R. Barb¹, T. Andacht², R. Mynatt³, H. Pecot³, D. Crandall⁴, and A. Hreha⁴, ¹USDA-ARS, Athens, GA, ²University of Georgia, Athens, ³Pennington Biomedical Research Center, Baton Rouge, LA, ⁴Wyeth Research Labs, Philadelphia, PA.

Although microarray studies indicate unique and unexpected genes in human and rodent adipose tissue similar studies of meat animal adipose tissue have not been reported. Total RNA was isolated from 90 day fetal stromal-vascular (S-V) cell cultures (n=4; 2 arrays, 2 cultures / array) and subcutaneous adipose tissue from two 105 day-old fetuses and neonatal pigs. Dye labeled cDNA probes were hybridized to custom microarrays (70 mer oligonucleotides) representing 600 pig genes involved in growth and reproduction. Each of the four adipose tissue arrays represented RNA from a fetus and a pig with duplicate arrays / fetus and pig. Relative intensities of 25 irrelevant or reproductive oriented genes were averaged for both S-V cell culture arrays (150 ± 20) and all adipose tissue arrays (200 ± 40) and used to represent basal gene expression. A total of 391 and 340 genes were expressed 10 fold and 200 and 160 genes expressed 40 fold over basal in S-V cultures and adipose tissue, respectively. Relative intensities in adipose tissue arrays

(n = 4) included $20,360 \pm 2700$ for IGFBP-5, $19,800 \pm 2,800$ for relaxin, $7,360 \pm 1,260$ for leptin and $2,390 \pm 355$ for APO-A1. Collectively, 21 secreted protein genes and 40 signaling protein genes were expressed 40 fold in S-V cultures and adipose tissue. Additionally, the agouti gene was detected by RT-PCR in S-V cultures and adipose tissue. Proteomic analysis of adipose tissue and S-V culture conditioned media and cells identified several secreted and signaling proteins including APO-A1, APO-E, relaxin, IGFBP-5 and nitric oxide synthase. Another of the secreted proteins, PAI-1, was identified by ELISA in S-V culture media. These studies demonstrate for the first time the expression of several major secreted and signaling proteins in pig adipose tissue which may influence local and overall metabolism and growth.

Key Words: Adipocytes, Microarrays, proteomics

T152 IGF-I mRNA levels in bovine satellite cell cultures: Effects of fusion and anabolic steroid treatment. E. Kamanga-Sollo*, M. S. Pampusch, G. Xi, M. E. White, M. R. Hathaway, and W. R. Dayton, *University of Minnesota, St. Paul.*

Anabolic steroids enhance muscle growth in cattle; however, their mechanism of action is not known. The goal of this study was to determine if treatment of bovine satellite cell (BSC) cultures with 17 β -estradiol (E2) or trenbolone (T) directly affects proliferation rate or level of mRNA for estrogen receptor (ER)- α , androgen receptor, and growth factors that have been shown to affect muscle growth (IGF-I, IGFBP-3, and myostatin). BSC cultures established from semimembranosus muscles of steers were treated for 48 hours with concentrations of E2 or T ranging from 0.001 nM to 10 nM. IGF-I mRNA levels in proliferating BSC cultures were significantly increased at 0.01 (1.9 times control values, $p < 0.02$) and at 0.1, 1 and 10 nM E2 (2.9, 3.5 and 3.5 times control values, respectively, $p < 0.0001$). Both 1 and 10 nM T increased IGF-I mRNA levels to 1.7 times control values ($p < 0.02$). ER- α mRNA was detectable in BSC cultures, and levels were increased (2.3 times control levels, $p < 0.001$) in cultures treated with 0.001 nM E2 but not in cultures treated with higher concentrations of E2. Androgen receptor mRNA levels also were increased (1.5 times control levels, $p < 0.02$) in cultures treated with 0.001 nM T but not by treatment with higher concentrations of T. Levels of IGFBP-3 were increased (1.4 times control values, $p < 0.02$) by treatment with 0.001 nM E2 but not by treatment with high concentrations of E2. Myostatin mRNA levels were not affected by any concentration of either of the steroids. Although, levels of IGF-I mRNA were 10 times greater ($p < 0.02$) in fused BSC cultures than in proliferating cultures, treatment of fused cultures for 48 hours with 10 nM E2 increased IGF-I mRNA levels (2.5 times control levels, $p < 0.02$). Both E2 and T increased ^3H -thymidine incorporation rate (1.5 times control levels, $p < 0.001$) in BSC cultures in media containing serum from which IGFBP-3 had been removed. In summary, treatment of BSC cultures with either E2 or T increased IGF-I mRNA level and proliferation rate, thus, establishing that these steroids have direct anabolic effects on cells present in the BSC culture.

Key Words: Satellite Cell, Muscle, Steroid

T153 Production of recombinant porcine IGF-binding protein-5 (IGFBP-5) and its effect on proliferation of porcine embryonic myoblast cultures (PEMC) and L6 cells and on differentiation of L6 cells in the presence and absence of IGF-I. M. Pampusch, G. Xi, E. Kamanga-Sollo, M. White*, M. Hathaway, and W. Dayton, *Animal Growth and Development Laboratory, Department of Animal Science, University of Minnesota, St. Paul.*

IGF-binding protein (IGFBP)-5 is produced by cultured porcine embryonic myogenic cell (PEMC) cultures and is secreted into the medium. IGFBP-5 may play some role in myogenesis and/or in changes in myogenic cell proliferation that accompany differentiation. IGFBP-5 reportedly may either suppress or stimulate proliferation or differentiation of cultured cells depending on cell type. Additionally, IGFBP-5 has been shown to possess both IGF-dependent and IGF-independent actions in some cell types but not all. The goal of this study was to produce recombinant porcine IGFBP-5 and assess its IGF-I-dependent and IGF-I-independent actions on proliferation of PEMCs and L6 myogenic cells. To accomplish this, we have expressed porcine IGFBP-5 in the baculovirus system, purified and characterized the expressed recombinant porcine IGFBP-5 (rpIGFBP-5). RpIGFBP-5 suppressed IGF-I-stimulated proliferation of both PEMCs and L6 cells in a concentration-dependent manner ($P < 0.05$). RpIGFBP-5 also suppressed Long-R3-IGF-I-stimulated proliferation of PEMCs and L6 cells ($P < 0.05$), indicating that rpIGFBP-5 possesses IGF-independent activity in these cell

systems. Furthermore, rpIGFBP-5 stimulated differentiation of L6 cells as indicated by an increase in creatine phosphokinase (CPK) activity ($P < 0.05$). These data demonstrate that rpIGFBP-5 has the potential to affect proliferation and differentiation of both PEMCs and L6 myogenic cells during critical periods of muscle development that may impact ultimate muscle mass postnatally.

Key Words: Porcine, IGFBP-5, Muscle

T154 Effect of recombinant porcine IGFBP-3 on IGF-I and Long-R3-IGF-I-stimulated proliferation and differentiation of L6 myogenic cells. G. Xi*, E. I. Kamanga-Sollo, M. S. Pampusch, M. E. White, M. R. Hathaway, and W. R. Dayton, *Department of Animal Science, University of Minnesota, St. Paul.*

Insulin-like growth factor (IGF)-I stimulates both proliferation and differentiation of myogenic precursor cells. In vivo, IGFs are bound to one of the members of a family of six high-affinity IGF binding proteins (IGFBP 1-6) that regulate their biological activity. One of these binding proteins, IGFBP-3, affects cell proliferation via both IGF-dependent and IGF-independent mechanisms and it has generally been shown to suppress proliferation of cultured cells; however, it also may stimulate proliferation depending upon the cell type and the assay conditions. Cultured porcine embryonic myogenic cells produce IGFBP-3 and its level drops significantly immediately prior to differentiation. Additionally, IGFBP-3 suppresses both IGF-I and Long-R3-IGF-I-stimulated proliferation of embryonic porcine myogenic cells. In this study we have examined the effects of recombinant porcine IGFBP-3 (rpIGFBP-3) on IGF-I- and Long-R3-IGF-I-stimulated proliferation and differentiation of the L6 myogenic cell line. L6 cells potentially provide a good model for studying the actions of IGFBP-3 on muscle because they contain no non-muscle cells and they do not produce detectable levels of IGFBP-3. RpIGFBP-3 suppresses both IGF-I and Long-R3-IGF-I-stimulated proliferation of L6 cells, indicating that it suppresses proliferation via both IGF-dependent and IGF-independent mechanisms. Our data also show that rpIGFBP-3 causes IGF-independent suppression of proliferation without increasing the level of phosphosmad-2 in L6 cultures. Additionally, rpIGFBP-3 suppresses IGF-I-stimulated differentiation of L6 cells. In contrast, however, rpIGFBP-3 does not suppress Long-R3-IGF-I-stimulated differentiation. This suggests that rpIGFBP-3 does not have IGF-independent effects on L6 cell differentiation.

Key Words: IGF-I, IGFBP-3, Muscle

T155 Molecular cloning of untranslated regions of the porcine acid-labile subunit (pALS) gene and detection of pALS gene expression in hepatic and non-hepatic tissues. C. Y. Lee*, E. J. Jin, and I. A. Kim, *RAIRC, Jinju National University, Jinju, Korea.*

Tested primarily in this study was a hypothesis that there are untranslated regions including an intron in the gene of porcine acid-labile subunit (pALS) of the 150-kilodalton ternary insulin-like growth factor complex. The ALS gene consists of two exons separated by an intron in known species. Exons 1 and 2 code for the proximal region of the signal peptide and the rest of the pALS peptide, respectively. The nucleotide sequence of an exon 2 segment of pALS gene coding for the distal region of the signal peptide through the termination codon of pALS peptide has been previously reported from this laboratory. In the present study, the 5' and 3' untranslated regions (UT) of the gene were identified by rapid amplification of 5' complementary DNA end (5' RACE) and 3' RACE, respectively. A segment of the pALS gene spanning from the distal region of exon 1 through the proximal region of exon 2 coding for the proximal region of the pALS signal peptide was next amplified by polymerase chain reaction (PCR) using genomic DNA as template. The entire pALS coding sequence exhibited 85% and 83% homology to those of hALS and rALS genes, respectively, whereas 5' UT, 3' UT and intron sequences did not exhibit any significant homology to those of the human or rat. In-situ hybridization on pig liver slice using a pALS cDNA fragment revealed the gene expression in hepatocytes. Moreover, the ALS gene was also identified to be expressed in non-hepatic organs and tissues including the reproductive tract by reverse transcription-PCR using an intron-spanning primer pair.

Key Words: ALS, IGF, Gene

T156 Circulating levels of growth factors are influenced by physiological status in the horse. F. C. Buonomo*¹, D. L. Grohs¹, D. S. Ruffin², and J. L. Sartin², ¹Monsanto Company, St. Louis, MO, ²School of Veterinary Medicine, Auburn University, Auburn, AL.

Changes in endogenous growth factor levels have been well characterized in primates, rodents and food-producing species, but less in companion animals. While it has been demonstrated that horses respond to somatotropin by increasing insulin-like growth factor-I (IGF-I), the influence of physiological status on IGF-I and IGF-II levels in horses is not well known. Thus, we examined gender, age and breed differences on IGF-I and IGF-II in intact male and female horses over the first yr of development. A significant ($P < .02$) age effect was observed as IGF-I levels gradually declined over the first yr of life, but more rapidly between 6 & 12 mos. of age. The decline in IGF-I was similar between sexes. Effects of age ($P < .02$) and agexgender interaction ($P < .01$) were observed for IGF-II. The IGF-II developmental pattern in both genders was characterized by a spike in the otherwise relatively stable circulating levels during the first yr. IGF-II levels increased 110% in males at 3 mos. of age, followed by a decline at 6 & 12 mos. of age. A much smaller increase (17%) in IGF-II was observed in females at 6 mos. followed by a decline at 12 mos. An overall breed effect ($P < .05$) was observed for IGF-I, but not IGF-II (American Miniature < Quarter Horse < Draft Horse) during the first yr of life. IGF-I and IGF-II levels were then examined under conditions associated with reduced growth in foals by measuring serum IGF-I and -II in foals suckling mares housed on either endophyte-infected or endophyte-free fescue for 4 wks. At the end of 4 wks, mares and foals were switched to alternative pastures for 4 additional wks. IGF-I and IGF-II levels were lower ($P < .05$) in foals of mares grazing endophyte-infected pasture compared to those grazing endophyte-free pasture. Levels of both growth factors in foals on the endophyte-infected pasture did not return to normal after being transferred to an endophyte-free pasture for a period of 4 wks. These observations suggest that IGF-II, as well as IGF-I, plays an important role in growth and development during the first yr of life in the horse. Moreover, neonatal exposure to endophyte-infected fescue may have more long term consequences on subsequent growth and development.

Key Words: Growth Factor, IGF, Horse

T157 Effects of insulin, leucine, and glucose on translation rates in primary porcine satellite cells. B. A. Creamer*, J. M. Scheffler, and S. J. Jones, *University of Nebraska, Lincoln.*

Both insulin and branched-chain amino acids have shown to increase protein synthesis in rats, perfused muscle, and *in vitro* cultures of skeletal muscle myoblasts. This increase in synthesis has been shown to occur more readily at an early age, but this response declines with time. The objective of this study was to determine if insulin, glucose, and leucine caused a shift in the amount of ribosomes in the polysome state. We hypothesized that all three work independently to increase the amount of total ribosomes forming polysomes in primary porcine satellite cells (PSC) and in porcine satellite cell derived myotubes (PDM), *in vitro*. In both PSC and PDM, the addition of insulin at or above post-feeding physiological levels caused an increase in both total RNA and the percentage of ribosomes in polysome complexes when compared to controls ($p < .05$). A diminution of insulin to below physiological levels, in both PSC and PDM, caused a decline in both total RNA when reduced to half-physiological levels ($< .05$). This reduction was mimicked in polysome formation. Leucine caused similar results in both cell types; however, the increase in total RNA was much more pronounced, at 2-times control levels, in PSC than PDM (20% and 4% increase, respectively). When only glucose was excluded from the medium, total RNA and percent polysomes were reduced ($p < .05$), when compared to low (1g/L) and high (4g/L) glucose treatments. However, the increase from low to high glucose was not significantly different in either total RNA or percent polysome formation ($p > .05$). These data indicate that 1) insulin, leucine, and glucose increase total RNA production and percent polysome formation when present in increasing amounts, and 2) the absence of glucose decreases total RNA production and polysome formation, while addition, at both low and high levels, caused similar increases in both PSC and PDM.

Key Words: Translation, Insulin, Satellite cells

T158 Development of a microarray-based ELISA for the assessment of SR-associated calcium regulatory proteins in skeletal muscle. J. S. Schulz*, S. J. Jones, and M. Zeece, *University of Nebraska, Lincoln.*

A microarray-based ELISA approach was taken for development of a novel method to assess the levels of key calcium regulatory proteins in porcine skeletal muscle. Sarcoplasmic reticulum (SR) membrane preparations were generated by homogenization of longissimus muscle samples. The microarray technique is novel and has several advantages including: very small muscle sample requirement (2g), greater sensitivity (pg), lower analyte requirement ($< 50 \mu\text{L}$ per array) and capability multiplexed analysis of several target proteins on the same "chip". Membranes were solubilized by homogenization with buffer containing 30% sucrose, 5 mM imidazole pH 7.4 and protease inhibitors. Extracts (4.9 nl) were spotted onto microarray slides, and incubated at 37C for 2 hr with monoclonal antibodies to several target proteins including Ryanodine receptor (RyR) and dihydropyridine receptor (DHPR). Detection of bound antibody was accomplished using laser-induced fluorescence of a labeled secondary antibody. Microarray analysis of these targets was quantitated as fluorescence intensity per ng of protein spotted. The limit of detection has been found to be 15-20 pg of target protein. Coefficient of variation for this level of analyte ranges from 14 to 33%. Data from the protein microarrays can be compared with genomic analysis of the same animals. Microarray analysis will enable rapid determination of defects that alter levels of key proteins associated with abnormal calcium regulation and the subsequent development of PSE-like conditions in the meat.

Key Words: Microarray ELISA, Calcium, Proteomics

T159 Hormonal and metabolic responses to human handling in crossbred steers. K. Uetake*¹, T. Ishiwata¹, N. Abe², Y. Eguchi¹, and T. Tanaka¹, ¹School of Veterinary Medicine, Azabu University, Sagami-hara, Japan, ²Faculty of Agriculture, Tamagawa University, Machida, Japan.

Hormonal and metabolic responses to human handling, which can affect skeletal muscle growth, were determined with 35 Japanese Black \times Holstein steers. The steers were allocated into three pens (6.0 m \times 9.5 m each) after transport at 6-10 mo of age. They were provided commercial grain feed twice a day (830, 1500). They were allowed to access dry hay or oat straw on an ad libitum basis in the early or middle fattening stage. All steers were bimonthly driven into a crush 2 h later from the morning feeding and were weighed and blood collected. The relationships between concentrations of 7 hormones and 5 metabolites were determined using Pearsons correlation coefficients. The following integrated hormonal and metabolic responses were analyzed: In the early stage, increases in adrenaline (A) and noradrenalin (NA) secretion can cause an increase in plasma glucose (A: $r = 0.61$, $P < 0.001$; NA: $r = 0.53$, $P < 0.01$) and the depletion of serum vitamin A (A: $r = -0.38$; NA: $r = -0.42$, both $P < 0.05$), which could lead to an inhibition of insulin secretion ($r = 0.31$, $P < 0.10$). In addition, an increase in dopamine secretion might activate the depletion of serum triglyceride ($r = -0.29$, $P < 0.10$). In the middle stage, increases in the A and NA secretion can cause an increase in serum NEFA (A: $r = 0.31$; NA: $r = 0.32$, both $P < 0.05$) as well as a decrease in serum triglyceride (A: $r = -0.37$; NA: $r = -0.39$, both $P < 0.05$). It can also cause an inhibition of insulin secretion (NA: $r = -0.36$, $P < 0.05$) and the depletion of serum vitamin A (NA: $r = -0.33$, $P < 0.10$), which could lead to an inhibition of leptin secretion ($r = 0.38$, $P < 0.05$). Decreases in serum vitamin A and leptin could bring about a decrease in serum total cholesterol (vitamin A: $r = 0.35$, $P < 0.05$; leptin: $r = 0.30$, $P < 0.10$). In addition, an increase in cortisol secretion can cause steatolysis and an increase in serum NEFA ($r = 0.41$, $P < 0.05$). It is vitamin A that acts as intermediary between the stress responses and growth in steers.

Key Words: Cattle, Growth, Stress Response

T160 Skeletal development and productive performance of Italian Merino lambs as related to age. G. Maiorano*, F. Filetti, A. Ciarlariello, G. Gambacorta, and A. Manchisi, *University of Molise, Campobasso, Italy.*

To study skeletal development and productive performance of the Italian Merino sheep breed, 24 growing male lambs were slaughtered, in

groups equal for number, at 5, 30, 50 and 70 d of age. Lambs were naturally suckled, left to graze with their dams and allowed free access to a commercial diet. *In vivo* and *post mortem* performance were evaluated. Metacarpal (MC) and metatarsal (MT) bones were measured for length, diaphyseal diameter, weight, and moisture. MC growth plate width was also assessed after AgNO₃ staining. ANOVA was performed and comparisons were tested by Scheffé's test. ADG was 274, 299 and 256 g/d from d 5 to 30, 30 to 50, and 50 to 70, respectively. As age increased, slaughter weight (4.6a, 11.1b, 19.5c, 23.0d kg) and carcass (with head, thoracic organs, spleen, and liver) weight (2.9a, 7.4b, 12.2c, 14.1d kg) increased (P<0.05), but dressing (63.6a, 67.0b, 62.5a, 61.4a %) was the highest (P<0.05) at d 30. Loin eye area, indicative of carcass muscularity, increased (P<0.05) with age (3.0a, 7.6b, 10.3c, 11.2c cm²) up to d 50. Bones mainly grew longitudinally in the first month of age, with a following stop (9.8a, 11.0b, 11.5b, 11.7b cm for MC; 10.3a, 11.7b, 12.3b, 12.3b cm for MT; P<0.05). In the same period, growth plate, the site of longitudinal bone growth, has thinned (P<0.05) of about 35% (from 0.98 to 0.64 mm) and of another 24% in the following periods, reaching 0.40 mm at d 70. However, bone weight continued to increase (P<0.05) with age up to d 50, either in MC (15.5a, 24.1b, 30.2c, 32.6c g) or in MT (15.7a, 24.4b, 30.1c, 32.7c g) due to a persistence in development of transversal diameter (1.0a, 1.2ab, 1.3bc, 1.4c cm for MC; 0.9a, 1.0ab, 1.1bc, 1.2c cm for MT; P<0.05). Bone moisture, expression of bone chemical maturity, decreased (P<0.05) with age up to d 50, in both MC (49a, 38b, 29c, 25c %) and MT (49a, 38b, 27c, 23c %). The second month of age appears to be a critical period in lamb skeletal growth, which strictly related to development of muscular and adipose tissues, and influences carcass and meat quality.

Key Words: Lamb, Age, Skeletal Growth

T161 Regulation of myostatin (MSTN) and MyoD expression with acute inflammatory challenge in the channel catfish (*Ictalurus punctatus*). T. E. Weber*, D. J. Gregory, and B. G. Bosworth, *USDA/ARS, Stoneville, MS.*

In mammals, MSTN is implicated in the negative regulation of skeletal muscle growth. The muscle regulatory factor, MyoD, is important for muscle regeneration in mammals. Inflammatory mediators increase the expression of MSTN and decrease the expression of MyoD in skeletal muscle of mammalian species. Environmental stressors and glucocorticoids decrease the expression of MSTN in fish. This suggests species differences in the regulation of the expression of muscle regulatory factors in response to environmental stressors. Therefore, our aim was to determine the effect of an acute inflammatory challenge on MSTN and MyoD expression in muscle tissue, and whether alterations in mRNA abundance were related to an increase in circulating cortisol. A total of 36 fish (BW 46.1 ± 3.9 g) were randomly assigned to Control (saline; n = 18) or lipopolysaccharide (LPS, injected i.p. at 1.5 mg/kg BW; n = 18) treatments. Muscle and blood samples were collected at 3, 12, and 24 h relative to injection from six fish/treatment group at each time point. The abundance of MSTN and MyoD mRNAs was evaluated using real-time reverse transcriptase PCR procedures. Plasma cortisol was measured via a time-resolved fluoroimmunoassay. The abundance of MyoD mRNA was increased in LPS injected fish at 3 h (P = 0.05) and 10 h (P = 0.03) postinjection. At 24 h postinjection there was no (P = 0.89) difference in MyoD mRNA abundance between treatment groups. Injection with LPS did not alter the abundance of MSTN mRNA at 3 h (P = 0.85) or 10 h (P = 0.87) postinjection. However, the abundance of MSTN mRNA was decreased (P = 0.02) in fish injected with LPS at 24 h postinjection. Plasma concentrations of cortisol were not affected (P > 0.10) by LPS injection at any of the time points measured. These data suggest that MyoD is acutely upregulated, and that MSTN is downregulated in response to inflammatory stimuli in the channel catfish. In addition, these data further indicate that there are differences in the regulation of expression of muscle regulatory factors between mammals and fish in response to inflammatory stimuli.

Key Words: Catfish, MyoD, Myostatin

T162 Expression of the anti-apoptotic gene Bcl-2 during skeletal muscle development in normal and Low Score Normal chickens. C. S. Coy* and S. G. Velleman, *The Ohio State University, Wooster.*

Cell morphology and cell-extracellular matrix interactions play key roles in determining whether cells will undergo programmed cell death, apoptosis. Cell survival requires the appropriate interaction of the cell with the extracellular matrix. Low Score Normal (LSN) myogenic cells in culture exhibit a rounded morphology whereas normal myogenic cells are elongated with maximal attachment to the extracellular substrate. The rounded LSN cells undergo apoptosis most likely due to reduced contact of the cell with the extracellular matrix through the cell surface integrin receptors. In the current study, the expression of the anti-apoptotic gene Bcl-2 was measured during embryonic and posthatch pectoralis major muscle development in normal and LSN birds. During embryonic development, pectoralis major muscle tissue was analyzed every two d beginning at d 10 through 18 d, 19, 20, and 21 d. During posthatch development muscle samples were taken every two d through d 8, and then at 2, 4, and 6 wk, and 6 mo. Expression of the mRNA was measured by semi-quantitative reverse transcriptase-PCR using primers based on the chicken Bcl-2 sequence. The results from this study have shown at embryonic d 16 through 19, and posthatch d 6 and 8 that Bcl-2 expression was significantly reduced in the LSN pectoralis major muscle (P < 0.05). These data suggest that the appropriate expression of Bcl-2 is important for normal muscle development to occur by preventing cell death due to apoptosis.

Key Words: Extracellular Matrix, Bcl-2, Apoptosis

T163 Proteins were differentially expressed in the plasma from high and low feed efficient broilers. N. Pumford*¹, M. Iqbal¹, W. Bottje¹, J. Lay³, T. Wing², and M. Cooper², ¹Center of Excellence for Poultry Science, University of Arkansas, Fayetteville, ²Cobb-Vantress, Inc., Siloam Springs, AR, ³Statewide Mass Spectrometry Facility, University of Arkansas, Fayetteville.

Mitochondrial function and biochemistry have previously been linked to the phenotypic expression of feed efficiency (FE) in broilers (Bottje et al., 2002; 2003; Iqbal et al. 2004). Broilers were fed the same diet, provided same environment, and were from the same genetic line. Broilers, with low FE (g gain/g feed), though healthy, exhibit higher mitochondrial oxidative stress. In addition, proteins are differentially expressed in the mitochondria from low and high FE birds. The objective of this study was to investigate and identify proteins that expressed differentially in a readily available tissue such as plasma. Plasma from high (n=7) and low (n=7) FE broilers were initially separated using a one-dimensional sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS/PAGE). A protein with a molecular weight of 116 kDa was expressed 23% higher (p=0.03) in the plasma from the low feed efficient broilers compared to the high feed efficient broilers. To identify this protein the band at 116 kDa was excised from the gel and digested with trypsin into smaller polypeptides. The peptides were sequenced using matrix assisted laser desorption/ionization/time of flight (MALDI/TOF) mass spectrometry. The molecular masses obtained from the mass spectral analysis was compared to known masses in the Swiss Protein database using the program Protein Prospector. An antibody was obtained to the protein and the level of this protein was found to be significantly higher (p=0.01) in plasma from low feed efficient broilers in a Western blot format. The plasma proteins were also separated using a two-dimensional PAGE with the first dimension separating the proteins by charge and the second dimension by molecular weight. At least twelve plasma proteins were expressed over five fold differentially between high and low feed efficient broilers. Identification of proteins that are differentially expressed in a readily accessible tissue may aid in the development of a rapid, inexpensive, and cost effective assay to aid in progeny selection of broilers. This research was funded in part by USDA-NRI grant #2001-03443.

Lactation Biology: Lactational Physiology

T164 Effects of low doses of bST during transition period on milk component percentages and yields and milk production of Holstein cows. M. S. Gulay*¹, M. Liboni², A. Garcia³, M. J. Hayen², T. Belloso², and H. H. Head², ¹Department of Physiology, Burdur Veterinary Faculty, Akdeniz University, Burdur, Turkey, ²Department of Animal Sciences, University of Florida, Gainesville, ³Universidad del Zulia, Facultad de Veterinaria, Universidad del Zulia, Maracaibo, Venezuela.

Experiment was designed to evaluate whether supplementing Holstein cows with low doses of bST during the transition period affected milk constituent percentages and yields, and milk production. Data obtained from three hundred forty six multiparous Holstein cows from four separate trials were combined for analyses. Cows in bST supplemented group (n=177) received biweekly POSILAC[®] to provide approximately 5.1 or 10.2 mg bST/d beginning approximately 21 d (\pm 3 d) before expected calving and continued through 42 d (\pm 2 d) postpartum, whereas control cows (n=169) were not supplemented with bST during the same time period. Milk samples were collected the same day each week at three consecutive milkings during the first 9 wk of lactation for analyses of milk constituents. Proc Mixed procedure was used for data analyses and analyses were included treatment, trial, the two-factor interaction, and wk. No apparent calving problems were associated with bST. Overall, the percentages of fat and protein, and SCC were affected by trial ($P < 0.01$), but not the milk yield. During first 9 wk of lactation no differences due to bST were observed in percentages of protein (2.87 ± 0.02 vs. 2.85 ± 0.02) or fat (3.92 ± 0.04 vs. 3.92 ± 0.04). However, control cows had greater SCC than treated during the first 9 wk of lactation (438 ± 46 vs. $288 \pm 47 \times 10^3$; $P < 0.04$). Supplemented cows had greater mean yields of milk fat, milk protein and milk (1.54 ± 0.03 , 1.18 ± 0.03 and 39.4 ± 0.8 kg/d, respectively; $P < 0.01$) than non-supplemented control cows (1.41 ± 0.03 , 1.07 ± 0.03 and 36.2 ± 0.7 kg/d, respectively). The SCC of cows supplemented with a low dose of bST was significantly less even though MY of the treated cows was greater. This implies that a low dose of bST supplemented during transition period may have a potential role in reducing incidence of mastitis in dairy cows without affecting percent fat and protein in milk.

Key Words: Transition Cow, bST, Milk Constituents

T165 Response of milk yield and reproduction to bovine somatotropin (bST) in low and high producing Holstein cows. S. A. Mosley*¹, M. A. McGuire¹, W. Stouder², M. F. McGrath³, J. L. Vicini³, and S. C. Denham³, ¹University of Idaho, Moscow, ²Stouder Holsteins, Wendell, ID, ³Monsanto Co., Chesterfield, MO.

Sixty-four Holstein cows were selected on milk production from the top and bottom one-third of the herd. Cows were then blocked by parity and randomly assigned to receive bovine somatotropin (bST, Posilac, Monsanto Co.) or no injection starting the 9th or 10th wk of lactation. Biweekly bST injections continued up to 24 injection cycles. Monthly test day was used for milk yield, and body condition (5 pt scale by 0.25 units) determined by a single evaluator was recorded monthly. Reproductive data were recorded using the farms record system. The Proc Mixed procedure of SAS was used to evaluate the effects of parity, bST, production level, all possible interactions and a covariate representing the deviation from production level block. No significant effect of any interaction ($P > 0.2$) was detected for milk production but effects of parity ($P < 0.006$), production level ($P < 0.011$) and bST ($P < 0.07$) were detected. Multiparous cows produced 4.4 kg/d more milk than first lactation animals. Production levels across lactation were 34.6 and 30.6 kg/d for high and low groups. Response to bST across parities and production level was 2.9 kg/d. Over the entire lactation, average body condition was reduced in primiparous cows by both production level ($P < 0.0001$) and bST (3.20 for low control vs 3.08 for low bST compared to 3.01 for high control vs 2.96 for high bST; $P < 0.002$). In multiparous cows, average body condition was lower due to bST (0.25 points for low production cows and 0.14 points for high production cows; $P < 0.0001$). However, irrespective of production level or bST, body condition score increased from initiation of bST treatment to cessation of treatment. There were no differences in days open (primiparous = 99.6 d and multiparous = 123.9 d) or services per conception (primiparous = 2.0 services and multiparous = 2.7 services) due to production level or bST. High and low

producing cows respond to bST without any differential effects on reproduction.

Key Words: Bovine Somatotropin, Milk Yield, Body Condition Score

T166 Lactation persistence is enhanced in transgenic mice overexpressing des(1-3)hIGF-I in the mammary gland. D. L. Hadsell*^{1,2}, D. T. Torres^{1,2}, J. George^{1,2}, G. S. Shelton^{1,2}, and M. L. Fiorotto^{1,2}, ¹USDA/ARS Childrens Nutrition Research Center, Houston, TX, ²Baylor College of Medicine, Houston, TX.

Transgenic overexpression of IGFs within the mammary gland during lactation delays involution and inhibits apoptosis. The goals of this study were; 1) to determine if mammary apoptosis was associated with increased oxidative damage and decreased milk yield during prolonged lactation, and 2) to test the hypothesis that overexpression of des(1-3)hIGF-I within the mammary glands of transgenic mice (WAP-DES) would increase lactation persistence. Mammary morphology, apoptosis, proliferation and protein carbonyl content were compared among normal mice (N=3-13) during early and prolonged lactation. Persistence was compared among nontransgenic (N=9) and WAP-DES (N=13) mice by measuring the weight gain of cross-fostered litters (10 pups/litter) from day 14 to 35 postpartum. Apoptosis and proliferation were measured using immunohistochemical markers. Proliferation was highest on day 2 (6.3 ± 0.5 and 18.3 ± 1.8 % for phospho-histone H3 and BrdU, respectively) decreased dramatically on day 3 (1.8 ± 0.5 and 3.1 ± 0.2 %, respectively), and remained low throughout the rest of lactation. Apoptosis was low throughout lactation (0.3 ± 0.04 and 0.1 ± 0.01 % for TUNEL and active-caspase 3, respectively). Protein carbonyl content, as measured by dinitrophenyl-hydrazine reactivity, peaked on day 2 postpartum (0.4 ± 0.2 nmole/mg), decreased on day 5 (0.2 ± 0.1 nmole/mg), and remained low through the rest of lactation. Litter gain dropped in both nontransgenic and WAP-DES mice beginning on day 21 postpartum. By day 35, litter gain was 6.6 ± 2.6 and 2.4 ± 2.7 gm/wk for the WAP-DES and nontransgenic mice, respectively. Mammary gland wet weight at day 35 was also greater in WAP-DES mice than their nontransgenic counterparts (448 ± 24 and 346 ± 25 mg, respectively). Milk composition, however, was similar among genotypes. These data support the conclusion that neither increased apoptosis nor oxidative damage is responsible for declining milk yield during prolonged lactation. The data also support the conclusion that overexpression of des(1-3)IGF-I allows for the maintenance of a greater mammary tissue mass and enhanced lactation persistence. Supported by USDA NRI grant number 2001-35206-11145.

Key Words: IGF, Transgenic, Persistence

T167 IGF-I and TGF- α activate different upstream signaling molecules in bovine mammary epithelial cells. K. A. Hogan², U. Sivaprasad¹, G. Desury*¹, and W. S. Cohick¹, ¹Rutgers, The State University of New Jersey, New Brunswick, ²Rutgers, The State University of New Jersey and The University of Medicine and Dentistry of New Jersey, Piscataway, NJ.

IGF-I and TGF- α play critical roles in growth and development of the mammary gland. We have shown that these two growth factors stimulate DNA synthesis and IGFBP-3 expression in an additive manner in the bovine mammary epithelial cell line MAC-T. However, the molecular mechanisms by which this occurs are unknown. In MAC-T cells, IGF-I and TGF- α differentially activate Akt, a downstream signaling molecule in the phosphatidylinositol 3-kinase (PI3K) pathway, over time. TGF- α activates Akt transiently while IGF-I demonstrates a slower, prolonged activation of Akt. TGF- α also mediates the rapid and transient phosphorylation of ERK 1/2, a downstream component of the Ras/Raf/MAPK pathway. While basal activation of ERK 1/2 is readily apparent in untreated cells, further activation is not observed following IGF-I treatment. These data suggested that these two growth factors may signal through different upstream molecules. To test this hypothesis, cell lysates were collected from MAC-T cells treated with IGF-I (50 to 200 ng/mL) or TGF- α (2.5 to 100 ng/mL) over time. Activation of signaling molecules was determined by immunoprecipitation or immunoblotting using phosphospecific antibodies. Following IGF-I treatment, the IGF-I receptor was phosphorylated at 1 min, with maximal activation subsiding after 5 min. Immunoprecipitation of the IGF-I receptor docking protein IRS-1 revealed activation from 1 to 15 min,

and IRS-1 coimmunoprecipitated with the p85 subunit of PI3K. TGF- α did not activate IRS-1. Neither growth factor activated IRS-2, although total IRS-2 protein was detectable. TGF- α -mediated PI3K activation could involve direct binding of the p85 regulatory subunit with the EGF receptor (EGFR) or the Src tyrosine kinase. In contrast to IGF-1, TGF- α activated the adapter protein Shc (5 to 45 min), which explains its ability to activate ERK1/2. Therefore, the additive effects of IGF-1 and TGF- α on DNA synthesis and IGFBP-3 expression may be a consequence of divergence in the upstream signaling molecules recruited to their respective receptors.

Key Words: Mammary, IGF, TGF

T168 Expression of prolactin receptor, STAT5a, STAT5b and whey acidic protein in mammary tissue of lactating Large White and 50% Meishan sows. M. F. Palin and C. Farmer*, *Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Lennoxville, QC, Canada.*

The association between mammary gland composition and prolactin receptor (PRL-R), whey acidic protein (WAP), STAT5a and STAT5b mRNA levels were investigated in sows. Twenty lactating 50% Meishan (GM) and 15 Large White (LW) sows were slaughtered on day 25 of lactation. Their mammary glands were collected for dissection of parenchymal and extraparenchymal tissues and tissue composition analyses. Parenchymal tissue samples were also collected, frozen immediately in liquid nitrogen and stored at -80°C until mRNA analyses. Semi-quantitative RT-PCR was performed to measure PRL-R, WAP, STAT5a and STAT5b mRNA expression levels. Data were analyzed using a Student's T test with breed as the main effect. Correlation analysis were calculated using the PROC CORR procedure of SAS. Levels of PRL-R mRNA (58.0 vs 43.3 ± 5.2 , $P < 0.05$) and of STAT5a mRNA (50.5 vs 26.9 ± 5.3 , $P < 0.01$) were higher in GM than in LW sows and there was a tendency for STAT5b to be higher in GM than in LW (58.6 vs 47.1 ± 5.7 , $P < 0.10$). Correlation analyses in the overall sow population showed associations between PRL-R mRNA levels and RNA concentrations ($r=0.41$, $P < 0.01$), total RNA ($r=0.33$, $P < 0.05$) and RNA/DNA ratio ($r=0.32$, $P < 0.05$) in parenchymal tissue. Such associations were not found in GM but were present in LW sows, with correlation coefficients of 0.51, 0.48 and 0.46 for RNA concentrations ($P < 0.05$), total RNA ($P < 0.10$) and RNA/DNA ratio ($P < 0.10$), respectively. In the overall sow population, there was an association between STAT5a mRNA levels and RNA concentrations in the parenchymal tissue ($r=0.34$, $P < 0.05$), but this association was not confirmed in GM or LW sows taken separately. There was no association between mammary gland composition variables and WAP or STAT5b mRNA levels ($P > 0.05$). The positive associations between the RNA content of lactating mammary glands and PRL-R and STAT5a mRNA levels suggest a possible involvement of the PRL-R signalling pathway in protein synthesis capacity of sow mammary glands.

T169 Expression of prolactin receptor (PRL-R) mRNA in somatic cells of bovine milk. K. J. Hohmann*, T. L. Auchtung, and G. E. Dahl, *University of Illinois, Urbana.*

Determination of the cellular function of the mammary gland using non-invasive techniques has practical implications for the dairy industry. Current research techniques utilize invasive biopsies of the mammary gland that can lead to health problems such as mastitis. Our objective was to assess the ability to use bovine somatic cells as an indicator of cellular function of the bovine mammary gland. Our laboratory has observed a positive relationship between PRL-R expression and milk production. In addition, we have established the importance of PRL sensitivity in management practices such as photoperiod and frequent milking. Therefore, we examined expression of PRL-R mRNA in somatic cells of bovine milk as an initial assessment of PRL sensitivity. To isolate the somatic cell fraction from milk, a minimum of 1 L of milk was separated into 20-50 mL fractions. The fractions were centrifuged for 10 min at $500 \times g$. The pellets were re-suspended in 5 mL of PBS and combined into 2-50 mL conical tubes. The tubes were then centrifuged for 10 min at $500 \times g$ and the pellets were suspended in 5 mL of Trizol. Expression of PRL-R mRNA was performed using real-time PCR, with 18S as the endogenous reference. Somatic cells from bovine milk were found to express PRL-R mRNA. Because the somatic cell fraction contains cells of epithelial origin as well as leukocytes, the

approach is being refined to further separate the somatic cells into lymphocytes, neutrophils, and epithelial (i.e., secretory) cells. Studies are underway to determine the differential expression of PRL-R in the various fractions of bovine somatic cells from animals milked at different frequencies. Observation that the somatic cell fraction contained cells that express PRL-R suggests that this approach may be a viable, non-invasive alternative to assess mammary function in lactating cows.

T170 Mammary cytokine gene expression during lactation. C. G. Prosser*, C. S. Smith, A. J. Hodgkinson, V. C. Farr, and E. A. Carpenter, *AgResearch.*

This study examined the expression of immune related genes in the mammary epithelium as a preliminary to understand the changes in immune function within the mammary gland occurring around parturition in dairy cattle.

Mammary secretory tissue was obtained from 6 Friesian-Jersey cross cows 221-235 days of pregnancy and 6 cows within 48 h of calving. Expression pattern of different immune or immune-related genes was measured by RT-PCR on total RNA extracted from the tissue.

The mRNA for IL-2, 6 10 and TNF- α were more highly expressed in tissue from all animals 48h post-calving. Whilst expression of IL-8, 12, 15 and 18 was more variable between animals, their expression levels were usually higher at this time. Very little IL-4 or 5 were detected and there was no change from pregnancy to colostrum.

A number of the cytokine genes observed to increase at the beginning of lactation are pro- or anti-inflammatory genes. The changes in their expression would indicate inflammation occurring naturally within the gland at this time in the absence of bacterial infection.

Key Words: Cytokines, Mammary, Bovine

T171 Effect of stage of lactation and parity on mammary gland gene expression. N. Miller*¹, L. Debecchi², D. Petitclerc², B. G. Talbot¹, and P. Lacasse², ¹Université de Sherbrooke, Quebec, Canada, ²Dairy and Swine R&D Centre, Lennoxville, QC, Canada.

Milk production persistency is a function of mammary epithelial cells number and activity. Therefore, factors that affect these parameters are very important for the determination of lactation persistency. Milk production tends to be higher in multiparous compared to primiparous cows, but, persistency is usually greater in primiparous cows. In this study, we compared the expression of several genes related to metabolic activity, apoptosis and endocrine control of mammary cell growth and development in 8 primiparous and 9 multiparous cows from calving to 250 days in lactation. Mammary gland biopsies were taken at early (d 10), peak (d 50) and late (d 250) lactation for gene expression evaluation. RNA isolation from mammary tissue was performed using Trizol reagent. RNA was converted to cDNA prior to analysis with real-time PCR using SYBR Green reagent. Expression of the 14 genes was normalized with the housekeeping gene GAPDH. As expected, milk production was higher ($P < 0.001$) in multiparous cows than in primiparous cows at the early and peak periods of lactation. However, milk production was the same during late lactation (23.9 kg/d). The expression of all genes related to milk synthesis was not significantly affected by the lactation stage. However, gene expression of acetyl-CoA carboxylase ($P < 0.05$), β -casein ($P < 0.05$), lipoprotein lipase ($P < 0.05$), fatty acid synthase ($P < 0.05$), and stearoyl CoA desaturase ($P < 0.05$) was lower during early lactation in primiparous cows. Expression of both the pro-apoptotic gene *bax* ($P < 0.01$) and the anti-apoptotic gene *bcl-2* ($P < 0.05$) were higher in primiparous cows and, therefore, the ratio *bax/bcl-2* was not changed. Expression of the *fos* gene was also higher in primiparous cows. There was no main effect ($P > 0.05$) of parity and stage of lactation on gene expression of IGF-1, IGFBP-5, prolactin receptor (long and short isoforms) and TGF- β 1. In conclusion, the level of expression of genes related to metabolic activity was lower during early lactation in primiparous cows than in multiparous cows suggesting a lower degree of cell differentiation in these animals. Differences in lactation persistency could not be related to the expression of any of the genes evaluated.

Key Words: Lactation, Persistency

T172 Long days do not alter mammary growth in prepubertal heifers. E. E. Connor¹, A. G. Rius², T. L. Auchtung², D. L. Wood¹, P. E. Kendall², G. E. Dahl², and A. V. Capuco¹, ¹USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD, ²Department of Animal Sciences, University of Illinois, Urbana.

Effects of photoperiod on growth and development have been demonstrated in many species. In cattle, long-day photoperiod reduces the age at puberty, increases growth rate and increases milk yield in lactating cows. Reported effects on prepubertal mammary growth are inconsistent. Discrepancies may be the result of separate influences of photoperiod on rate of mammary growth and duration of allometric mammary growth, which terminates peripubertally. Our objective was to evaluate mammary growth after exposure to long-day (16L:8D) or short-day (8L:16D) photoperiods during the prepubertal phase of mammary growth. Calves approximately 3 mo of age were assigned to short- or long-day photoperiods. Three calves were killed prior to treatment and 4 heifers per group were killed after 2 or 4 months of treatment (5 or 7 months of age). Effect of photoperiod on mammary growth measurements was analyzed by t-test. Photoperiod did not affect the mass of mammary parenchyma or mammary fat pad ($P > 0.05$), although both increased with age ($P < 0.05$). Similarly, total parenchymal DNA and parenchymal lipid content were unaffected by photoperiod ($P > 0.05$). These data indicate that mammary growth is not influenced by manipulation of day length during the prepubertal period.

Key Words: Photoperiod, Heifer, Mammary Growth

T173 Short term effects of different milking intervals on cisternal and alveolar milk in dairy sheep. V. Castillo*, X. Such, G. Caja, E. Albanell, and R. Casals, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Changes in volume and composition of milk stored in the cisternal and alveolar udder compartments at different machine milking intervals (4-, 8-, 12-, 16-, 20- and 24-h) were studied in 24 lactating ewes (Manchega, MN; $n = 12$; and, Lacaune, LC; $n = 12$) during mid-lactation. Cisternal milk was obtained by milking after i.v. injection of an oxytocin receptor blocking agent, and alveolar milk was milked removed after i.v. injection of oxytocin. Milk samples from each fraction were analyzed for composition and SCC. Total and cisternal milk accumulated linearly up to 24 h in both breeds. Alveolar milk increased up to 16 h in MN and 20 h in LC and was steady thereafter. Cisternal milk increased from 33 to 65% (MN), and from 47 to 76% (LC) for 4- and 24-h milking interval, respectively. Fat content in cisternal milk decreased from 8.3 to 5.8% (MN), and from 7.5 to 4.9% for 4- and 24-h milking interval, respectively. Alveolar milk fat content did not vary according to milking interval in MN, but increased in LC from 7.5 to 8.8% for 4- and 24-h milking interval. Protein content in cisternal milk increased in MN from 5.7 to 6.8% for 4- and 8-h milking interval, and did not change thereafter; no change was observed in LC (average 5.6%). Protein content in alveolar milk did not significantly vary according to milking interval in both breeds. True protein and casein contents changed in a similar manner as protein contents for both breeds. SCC values in total milk varied quadratically ($P < 0.01$) with milking interval and ranged between 5.26 and 5.10. The greatest logSCC in milk was observed at the 8-h milking interval (5.44; $P < 0.01$). Alveolar milk contained higher logSCC than cisternal milk at 16- (5.03 vs 4.95), 20- (5.09 vs 4.93), and 24-h (5.10 vs 4.85) milking intervals. Our results suggest that the cistern plays an important role in accommodating milk at extended milking intervals in dairy sheep. Milking frequency affected cisternal and alveolar composition and quality.

Key Words: Milking Frequency, Dairy Ewes, Milk Partitioning

T174 The use of ¹³C labeled fatty acids to study milk fat synthesis in dairy cows. E. E. Mosley* and M. A. McGuire, *University of Idaho, Moscow.*

The objective of this study was to evaluate methodology where ¹³C labeled fatty acids are utilized to study fatty acid synthesis in lactating dairy cattle. The incorporation of ¹³C labeled fatty acids into milk lipids was determined. Potassium salts of 5 g myristic-1-¹³C acid (14:0), 40 g palmitic-1-¹³C acid (16:0), or 50 g stearic-1-¹³C acid (18:0) were separately infused into the abomasums of ruminally cannulated primiparous Holstein cows ($N=3$) during two treatment periods of either bolus administration of the ¹³C labeled fatty acids over 20 min or continuously

over 24 h. Following initial infusion, milk samples were taken by hand every 2 h for 48 h (12 samples each day). During this time, milk samples were also taken every 4 h after complete milking by machine (6 samples each day). Milk fat was extracted using chloroform:methanol. Fatty acids were converted to fatty acid methyl esters (FAME) by base catalyzed transesterification. The FAME were converted to dimethyl disulfide derivatives (DMDS). The FAME and DMDS were analyzed by gas chromatography mass spectrometry. Data obtained from hand and machine milk samples were similar. The ¹³C enrichments from the bolus infusion were 4.9, 3.0, and 2.9% for 14:0, 16:0, and 18:0, respectively, at 4 h post infusion and peaked at 8 h (5.7, 7.2, and 5.3%, respectively). Enrichments for continuous infusion were 2.0% for 14:0, 1.6% for 16:0 at 4 h and 0.7% for 18:0 at 8 h, and peaked at 28 h for 14:0 (3.8%), from 20 to 28 h for 16:0 (3.5%), and from 20 to 24 h for 18:0 (1.7%). Enrichment was also detected in delta-9 desaturase products for both bolus and continuous infusions. Bolus infusion enrichments of 5.4, 1.7, and 2.1% were detected at 4 h for 14:1, 16:1, and 18:1, respectively, and peaked at 8 h for 16:1 (2.9%) and 18:1 (3.6%), and at 4 h for 14:1 (5.4%). Continuous infusion enrichments were 1.8% for 14:1 and 1.0% for 16:1 at 8 h, and 0.7% for 18:1 at 12 h, and peaked at 28 h for 14:1 (3.2%), and at 20 h for 16:1 (2.4%) and 18:1 (1.0%). Fatty acid synthesis and desaturase activity in the mammary gland can be studied using ¹³C labeled fatty acids. Funded by the United Dairymen of Idaho and USDA-NRI.

T175 Duration of starvation required to decrease milk production in the high-producing dairy cow. C. A. Toerien* and J. P. Cant, *University of Guelph, Guelph, ON, Canada.*

Milk synthesis can be decreased through feed removal. Our objective was to determine the length of starvation required to decrease milk production in the high-producing dairy cow without inducing detrimental metabolic effects. Holstein cows ($n=3$; 49 ± 2 kg milk/d; 45 ± 2 DIM) consuming TMR with ad lib intake were starved for a 24-h period, and refed for 18 h. Cows were milked and milk, blood and urine samples were collected at 0 h relative to the start of starvation, and every 6 h thereafter. During the starvation period, each cow received alfalfa hay (kg DM) at 6 h (3.4) and 18 h (2.8) to minimize the possible occurrence of ketosis. Compared to baseline values, milk production and its components were maintained for 18 h, possibly in part through the role of cortisol in mobilizing body reserves, thereby maintaining milk precursor availability. Cortisol levels increased during starvation and at peak were 7.5 times that at baseline. However, between 18 and 24 h of starvation, cortisol (-79%) and milk production (-31%) decreased sharply. Milk production remained at the same level ($P > 0.1$) for 6 h before responding to refeeding. No clinical signs of ketosis were observed and cows consumed feed readily upon refeeding. Mean milk production (kg/d) during 3 d prior to and 3 d after the experiment, were similar (47.2 ± 2.1 vs 46.6 ± 2.6 ; $P > 0.1$). In conclusion, in the high-producing dairy cow, 42% decrease in milk production can be achieved through a 24-h starvation period.

T176 Lactational response to annual or biannual kidding in dairy goats. A. A. K. Salama*, G. Caja, X. Such, R. Casals, and E. Albanell, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Extended lactation may reduce the number of days dry within the animal lifetime and metabolic stress. The effects of an annual lactation cycle vs a two-year extended lactation were evaluated in 30 multiparous Murciano-Granadina dairy goats milked once-a-day throughout lactation. Goats were assigned to treatments at wk 29 of lactation and mated (M, n = 14) or kept open (O, n = 16). Milk yield (weekly from wk 2) and milk composition (biweekly from wk 30) were recorded up to wk 72. Cisternal and alveolar milk were evaluated at wk 39 (wk 10 of pregnancy) and 55 (wk 5 of subsequent lactation) by using an oxytocin receptor blocking agent (Tractocile, Ferring S.A., Madrid, Spain). Average milk yield during the first 29 wk was 2.28 L/d. Pregnancy reduced ($P < 0.05$) milk yield at wk 39 (1.19 vs 1.51), 40 (1.02 vs 1.53), 41 (0.55 vs 1.40), and 42 (0.30 vs 1.41) of lactation for M and O goats, respectively. From wk 43 to 50, M goats were in dry-off, whereas, O goats yielded 1.43 L/d. After kidding (wk 51 to 72), M goats produced

40% more milk than O goats (2.50 vs 1.51 L/d; $P < 0.001$). Milk of M goats contained lower ($P < 0.05$) log SCC (5.99 vs 6.49) than O goats. No significant changes were detected for fat, protein or lactose contents. Cisternal milk at wk 39 was lower for M than O goats (638 vs 1560 ml; $P < 0.01$), whereas, alveolar milk did not differ (345 ml). In the following lactation (wk 55) cisternal milk in M goats tripled (2063 ml) and was higher ($P < 0.01$) than in O goats (1218 ml). Similarly, alveolar milk doubled in M goats (680 ml) and was higher ($P < 0.01$) than in O goats (355 ml). Fat content was higher ($P < 0.05$) for alveolar milk (6.18%) than cisternal milk (3.74%) except for M goats at wk 39. No differences in percentages of protein and lactose, or in log SCC were detected between cisternal and alveolar milk, although cisternal milk of M goats contained lower SCC than alveolar milk at wk 55 (5.84 vs 6.09; $P < 0.05$). In conclusion, differences in milk yield between groups were clear in the last third of pregnancy and at the peak of the following lactation. Throughout 72 wk, extended lactation slightly decreased milk yield (6.9%) in our conditions.

Key Words: Pregnancy, Extended Lactation, Dairy Goats

Ruminant Nutrition II

T177 Feed intake, nutrient digestibility and nitrogen retention in beef steers fed a total mixed ration supplemented with monensin or different doses of essential oils. C. Benchaar*^{1,2}, E. Charmley³, and J. Duynisveld³, ¹*Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Lennoxville, QC, Canada*, ²*Nova Scotia Agricultural College, Truro, NS, Canada*, ³*Crop and Livestock Research Centre, Agriculture and Agri-Food Canada, Nappan, NS, Canada.*

Five steers (Angus x Herford, initial BW = 244 ± 21 kg) were used in a 5 x 5 Latin square design to study the effect of dietary addition of monensin (Rumensin[®]; MO) or a commercial mixture of essential oils (Vertan[®]; EO) on feed intake, nutrient digestibility and nitrogen retention. The mixture of EO consisted of thymol, eugenol, vanillin and limonene. Steers were fed once daily for *ad libitum* intake a total mixed ration consisting of 75% of grass/legume silage and 25% of rolled barley (dry matter basis), unsupplemented (Control, CO), or supplemented with MO (220 mg/d) or with different dose levels of EO (2, 3, and 4 g/d). Each experimental period consisted of three weeks of adaptation to the experimental treatment and one week for data recording and sample collection. Data were statistically analyzed as a 5 x 5 Latin square design using the PROC MIXED procedure of SAS. Specific prior contrasts were used to test differences between CO and diets supplemented with MO and EO, and to determine the linear or quadratic response to EO dose level. Dry matter intake was not affected by the addition of MO (5.8 kg/d; $P > 0.05$). However, it was higher for steers fed EO compared to those fed CO (6.3 vs 5.8 kg/d; $P < 0.05$), and linearly increased ($P < 0.05$) with increased dietary levels of EO. Apparent digestibility of dry matter was not changed by the addition of EO or MO to the diet (70.1%; $P > 0.05$). Nitrogen digestibility was not affected by feed additives (63.3%; $P > 0.05$). However, a quadratic tendency ($P = 0.08$) was observed for EO levels in the diet. Nitrogen digestibility was increased by the addition of 2 or 3 g of EO/d, but it was decreased with the highest dose of EO. Nitrogen retention was not different ($P > 0.05$) between steers fed CO and steers receiving MO or EO. Results from this study indicate that the addition a commercial mixture of EO increased DM intake and improved nitrogen utilization in beef cattle.

Key Words: Monensin, Essential Oils, Steers

T178 Effects of phase feeding of protein on performance, blood urea N, manure N:P ratio, and carcass characteristics of feedlot cattle. J. T. Vasconcelos*¹, L. W. Greene¹, N. A. Cole², and F. T. McCollum, III¹, ¹*Agricultural Research and Extension Center, Texas A&M University, College Station*, ²*USDA-ARS, Bushland, TX.*

One hundred eighty four steers (BW = 406 kg) were used in a randomized block design to determine the effects of phase feeding protein on performance, blood urea N (BUN), manure N:P ratio, and USDA carcass characteristics. Steers were assigned to 22 pens and fed *ad libitum* a finishing diet formulated to contain 10% roughage and 13% CP (DM basis). When steers reached 477 kg the diets were either maintained at

13% CP or reduced to 11.5% CP or no supplemental CP (approximately 10% CP). Steers were harvested when they had approximately 25 mm of external fat. Reducing the CP to 11.5% or no supplemental CP did not affect ($P = 0.21$) ADG of steers (1.62, 1.71 and 1.53 kg/d for 13%, 11.5% or no supplemental CP, respectively) from day of diet change to day of harvest. The ADG of steers was similar ($P = 0.09$) throughout the finishing period regardless of level of CP treatment (1.69, 1.86, and 1.74 for approximately 10% CP, 11.5% CP and 13% CP, respectively). Similarly, dry matter intake and feed efficiency did not differ ($P > 0.05$) among treatments. BUN concentrations were determined (mg/dL) on d 1, day of the diet change, and immediately before harvest. Differences ($P < .0001$) in BUN were observed only immediately before the harvest. Steers fed the 13% CP diet had greater ($P < .0001$) BUN concentration (13.85 mg/dL) than steers fed the 11.5% and no supplemental CP (12.08 and 10.04 mg/dL, respectively). Manure from the pen surface was collected and analyzed for N and P. No differences ($P > 0.05$) were observed in N ($P = 0.60$) and P ($P = 0.93$) concentrations among the different dietary treatments. The N:P ratio, however, was different ($P = 0.038$). The N:P ratio was influenced by treatment ($P = 0.04$), and was greater (3.87) for manure from 10% CP diets than for 11.5% or 13.0% diets (3.45 and 3.56, respectively). Carcass characteristics of steers did not differ ($P > 0.1$). Data indicate that under the condition of this study CP levels can be reduced during the final stages of finishing without effects on feedlot performance.

Key Words: Feedlot, Nitrogen, Environment

T179 Influence of sodium caseinate infusion on voluntary feed intake and digestive function in steer calves fed a Sudangrass-based growing diet. E. G. Alvarez*¹ and R. A. Zinn², ¹*Universidad Autonoma de Baja California, Mexicali, Mexico*, ²*University of California, Davis.*

Four medium-frame steer calves (269 kg BW) were used in a 4 x 4 Latin square experiment. Treatments consisted of infusing 300 g/d of Sodium Caseinate into: 1) the rumen (Rmn), via the rumen cannula; 2) the abomasum (AbR), via rumen cannula; 3) the abomasum (Abm), via the abomasal cannula and 4) the proximal duodenum (Ddn), via the duodenal cannula. Steers were allowed *ad libitum* access to the basal forage-diet (sudan grass, 87.6%). There were no treatment effects ($P > .20$) on dry matter intake (DMI; 97 g/kg BW^{0.75}), and flow of OM, and NDF to the small intestine. Casein infusion did not affect ($P > .20$) ruminal degradability of dietary N. There were no treatment effects ($P > .20$) on ruminal NDF digestion. However, ruminal ADF digestion was greater (5%, $P < .05$) when casein was infused post-terminally then when it was infused ruminally. There were no treatment effects ($P > .20$) on total tract digestion of OM, N, ADF, NDF, and GE. Casein infusion did not influence ($P > .20$) flow of chyme to the small intestine or ruminal turnover. Post-ruminal casein infusion increased (75%, $P < .01$) the soluble N content of duodenal chyme, but it did not affect ($P > .20$) its tonicity, averaging 264 mOsm. The relationship between tonicity and passage rate of chyme from the abomasum was small ($R^2 = .05$). Casein infusion did not affect ($P > .20$) ruminal DM content or

liquid volume, averaging 17.5 g DM / kg BW.75, and 471 g / kg BW.75, respectively. Casein infusion did not affect ($P > .20$) ruminal pH, but ruminal acetate:propionate molar ratio was greater ($P < .10$) when casein was infused ruminally. Ruminal acetate:propionate molar ratio was also greater ($P < .05$) when casein was infused into the abomasum versus the proximal duodenum. Protein content of chyme leaving the abomasum does not have an important role in the regulation of intake in steers fed forage-based diets.

Key Words: Casein, Regulation, Intake

T180 Ruminal ammonia load improves nitrogen retention of growing steers when leucine is limiting. M. S. Awawdeh*, E. C. Titgemeyer, K. C. McCuiston, and D. P. Gnad, *Kansas State University, Manhattan.*

We tested the hypothesis that ammonia loading might negatively impact amino acid (AA) utilization by cattle by increasing AA degradation in support of ureagenesis. Six ruminally cannulated Holstein steers (189 kg BW) housed in metabolism crates were used in a 6x6 Latin square to study effects of a rumen ammonia load on leucine (Leu) utilization. All steers received a basal diet (83% soybean hulls, 7% wheat straw, and 0.3% urea) twice daily at 2.7 kg DM/d, ruminal infusion of 200 g/d acetate, 200 g/d propionate, and 50 g/d butyrate, and abomasal infusion of 300 g/d glucose and a mixture containing all essential AA except Leu. Treatments were arranged as a 3x2 factorial and included Leu (0, 4, or 8 g/d) infused abomasally and urea (0 or 80 g/d) infused ruminally to provide an ammonia load. Periods were 6 d, with 2 d for adaptation and 4 d for fecal and urine collection. There was no Leu x urea interaction for fecal, urine, or retained N. Infusion of urea increased ($P < 0.05$) rumen ammonia concentrations from 9.0 to 27.0 mM and plasma urea concentrations from 4.3 to 6.8 mM. Urea infusion increased ($P < 0.05$) urinary excretion of total N from 47.1 to 80.0 g/d, urinary urea N excretion from 33.9 to 65.4 g/d, and retained N from 22.4 to 26.2 g/d. Leucine supplementation linearly decreased ($P < 0.05$) excretions of total urinary N, urinary urea N, and fecal N, and linearly increased ($P < 0.05$) retained N from 21.4 to 24.5 and 26.9 g/d for 4 and 8 g/d Leu, respectively. The efficiency of deposition of supplemental Leu ranged from 0.24 to 0.43 when steers received 0 or 80 g/d urea, respectively. Serum insulin and IGF-1 concentrations were not affected by treatments. Although environmentally unfriendly, an excess dietary N supply improved utilization of Leu for protein deposition by growing steers when Leu supply was limiting. (Supported by NRI Competitive Grants Program/CSREES/USDA, Award No. 2003-35206-12837.)

Key Words: Growth, Leucine, Ammonia

T181 Effect of fall protein supplementation with a self-feeding liquid supplement on performance of beef cows grazing tallgrass-prairie range. D. A. Llewellyn*¹, B. T. Gray¹, T. T. Marston¹, and C. A. Bandyk², ¹*Kansas State University, Manhattan*, ²*Quality Liquid Feeds, Inc., Dodgeville, WI.*

An experiment was conducted to evaluate the effect of providing a liquid, high-protein supplement during the fall on beef cow and calf performance. One hundred twenty-two mature, pregnant, spring-calving cows were assigned to supplementation treatments in a randomized complete block design. Twelve fall pastures were used providing four replications per treatment. Control cows received no fall supplementation and then a meal supplement (40% CP; as-fed basis) from 12/17 until calving. Fall supplemented cows were either allowed access to a liquid protein supplement (40% CP; as-fed basis) approximately 2 months before weaning until calving (fall supplementation from 8/14 to 12/17) or from weaning until calving (fall supplementation from 10/15 to 12/17). Supplement intake of the control cows was adjusted to match the estimated intake of the liquid-fed groups (prorated and hand-fed 3 d/wk). Fall supplementation did not affect cow body weight (BW) or body condition score (BCS) changes before weaning. Cows receiving the liquid supplement tended ($P = 0.08$) to gain BW more rapidly and had greater ($P = 0.03$) BCS gains after weaning (10/15). The rate of gain of calves suckling fall-supplemented cows (8/14 to 10/15) was not affected ($P = 0.83$) by fall supplementation. Control cows gained more BW and BCS ($P < 0.01$) during the winter (12/17 to 2/5), were heavier ($P = 0.03$), and had greater ($P = 0.04$) BCS at calving. Fall supplementation did not affect ($P = 0.39$) calf birth weight or subsequent pregnancy rate ($P = 0.36$). Calves produced by control cows gained more BW ($P < 0.01$; birth to May 2) and were heavier ($P < 0.01$) at the start of the grazing

season. In conclusion, fall supplementation increased cow BW and BCS gains from weaning until the start of the winter grazing season. Cows not supplemented during the fall had the ability to compensate for their lower previous nutrition when properly supplemented during the winter.

Key Words: Beef Cattle, Protein, Supplementation

T182 Amino acids degradation of rumen incubated feeds. M. Q. Manella¹, C. Boin², G. F. Alleoni¹, J. J. A. Demarchi¹, and L. O. Tedeschi*³, ¹*Instituto de Zootecnia, Heitor, Nova Odessa, Brazil*, ²*Esalq-Usp Av. Pádua Dias, Piracicaba, Brazil*, ³*Cornell University, Ithaca, NY.*

Six rumen-cannulated Nellore steers were used in two latin-square design with 3 treatments and 3 periods to evaluate the effects of different ratios of concentrate (20, 40, 60%) on amino acids (AA) degradation (%) after 12h of rumen incubation, corrected for ruminal microbial contamination. Six feeds were evaluated: soybean hulls (SBH), corn (C), sorghum grain (S), soybean meal (SBM), cottonseed meal (CSM) and corn gluten feed (CGF). There was a significant effect of feed ($P < 0.05$) on AA degradation in which S had the lowest and CGF had the highest degradabilities. Total ruminal degradation of the true protein for SBH, C, S, SBM, CSM, and CGF were 75.3, 76.8, 65.2, 82.4, 76.4 and 92.6%, respectively. The individual AA degradability for each feed was highly variable among feeds, depending on its characteristics, especially Ly, Met, Leu, Ile, and Val. The Met degradation compared to the mean degradation of total AA, was numerically higher (3.6 and 4.1%) for CGF and CSM, but for SBH it was significantly higher (4.8%, $P < 0.05$). The Met of C and S grains had lower ($P < 0.05$) degradability (-14.1 and -3.9%) and did not alter (1.4%, $P > 0.10$) for SBM. The Lys degradation of S were 19% ($P < 0.05$) higher ($P < 0.05$); however, it did change for the other feeds ($P > 0.05$). On average, Val, Leu and Ile had similar or even lower degradabilities than total AA, especially for Ile and Leu. On the other hand, the degradability of Val, Leu and Ile for SH was 12, 8, and 7%, respectively. Leu degraded less on S and C (-6.5 and -6.1%, $P < 0.05$) and showed no alteration to the other feeds. Ile degradability for S, CGF SBM, C, CSM were -2.8 ($P < 0.05$), 0.5, -0.2, 0.4 e -1.5%, respectively. Similarly, Val degradation was variable among feeds; it was higher for C and S (3.9 and 7.1%, $P < 0.05$), numerically lower for SBM (-3.5%), but were similar for CGF and CM compared to the total amino acid degradability (0.9 and -1.8%). The differences between AA degradability of the six feeds may be related to the protein structure for the protein feeds, and how it's associated to the protein fractions, which might have resulted on AA profile changes after rumen degradation. These interactions must be accounted for on future revisions of the feed evaluation systems.

Key Words: Aminoacids Degradation, Rumen, Protein

T183 Feedlot cattle responses to reduced levels of degradable protein. J. W. Lehmkuhler*, S. C. Arp, and D. M. Schaefer, *University of Wisconsin, Madison.*

Two feedlot trials were conducted to evaluate responses to lowered dietary crude protein level by reducing supplemental degradable protein addition. Experiment 1 involved 70 calf-fed steers (initial wt.=296 kg) that were offered rations including supplemental protein levels and forms of 0.5% urea (U), 2% Bloodmeal (BM), 2% BM + 0.5% U (BMU), or 1% U + 3% soybean meal (POS). Basal ingredients consisted of approximately 79% corn, 12% corn silage, and 9% supplement. Steers were blocked by source into 12 pens with 5-6 animals per pen. Steers were implanted with an estrogenic implant. Steers were harvested when ultrasound estimates for subcutaneous fat over the longissimus muscle approached 1.0 cm. Those not achieving this endpoint were harvested after being on trial for 197 d. Carcass data were collected following a 24-hr chill. No differences were observed for DM intake or carcass characteristics ($P > 0.05$). POS resulted in greater ($P < 0.05$) ADG in comparison to U and BM (1.77, 1.59, and 1.55 kg/d, respectively). Gain efficiency was improved ($P < 0.05$) for POS and BMU in comparison to U (20.04, 20.36, and 17.64 kg gain/100 kg DM, respectively). Experiment 2 evaluated the same treatments offered to 70 yearling steers (initial wt.=407 kg). Steers were blocked by weight to 12 pens with 5-6 animals per pen. Steers were implanted with an estrogenic implant. Cattle were offered dietary treatments for 100 d. Carcass data were collected following a 48-hr chill. Dietary treatments did not significantly ($P > 0.05$) alter any of the variables measured with ADG ranging from 1.79-2.17 kg/d and gain efficiencies of 18.00-20.08 kg gain/100kg DM. These data suggest

responses to reducing the dietary crude protein level by lowering the amount of supplemental degradable protein differs for calf-fed and yearling steers. Reducing dietary protein levels for short-fed yearling steers did not result in detrimental responses for performance or carcass traits. However, reducing dietary crude protein levels decreased ADG and lowered gain efficiency for calf-fed steers though carcass characteristics were not affected.

Key Words: Beef, Ruminant, Protein

T184 Responses of serum glucose, insulin, glucagon, and fatty acids to ruminal propionate and abomasal carbohydrates in Korean cattle. S. C. Lee¹, J. S. Eun², Y. K. Kim³, J. P. Cant⁴, and Y. H. Moon⁵, ¹National Livestock Research Institute, Suwon, Kyonggi, Korea, ²Samyang Feed Company, Suwon, Kyonggi, Korea, ³Chungnam National University, Taejon, Chung Nam, Korea, ⁴University of Guelph, Guelph, ON, Canada, ⁵RAIRC, Jinju National University, Jinju, Gyeong Nam, Korea.

The purpose of this study was to investigate responses of serum NEFA, glucose and insulin concentrations to different glucose sources. Two 4 x 4 Latin square experiments with periods of 8 d each were conducted. In experiment 1, four Korean steers (270 kg, 13 mo) were fed a ration of concentrate and rice straw at 80% of maintenance and treatments were 1 L of a 0, 0.5, 1.0 or 1.5 M propionate solution infused into the rumen between 1300 and 1400h each day for 5 consecutive days. On day 5, rumen and blood samples were collected during the infusion. Experiment 2 followed the same design with four Korean steers (304 kg, 20 mo), fed mixed hay at 1.5% of body weight, and infused abomasally between 1100 and 1800 h daily with water, or 30 g/h carbohydrate from glucose, corn starch or cane molasses. Blood samples were collected on day 6 of infusion. There was no effect of propionate dose on serum glucose or glucagon concentrations ($P > 0.05$). Insulin concentrations increased with dose ($P < 0.05$), peaking at 60 min of infusion at 20.7, 33.4, 42.4 and 53.8 mU/L for 0, 0.5, 1.0 and 1.5 M propionate, respectively. At 60 min, NEFA concentrations were reduced ($P < 0.05$) to 54, 76 and 57 μ M on 0.5, 1.0 and 1.5 M propionate, respectively, compared to 168 μ M with no propionate. Serum glucose concentrations were elevated ($P < 0.05$) during the first 100 min of abomasal infusion of glucose while starch and molasses had no effect compared to water. Serum insulin was increased and NEFA decreased by glucose infusion only. Serum glucagon was reduced ($P < 0.05$) from 78 to 53 mU/L by glucose infusion and to 64 mU/L by molasses but starch had no effect. In conclusion, propionate infusion increased insulin and decreased NEFA concentrations without affecting blood glucose level. The glycemic response to abomasal carbohydrates was greatest for glucose, intermediate for molasses and negligible for corn starch.

Key Words: Propionate Infusion, Carbohydrate Infusion, Blood Composition

T185 Hepatic mitochondrial efficiency of Angus and Wagyu heifers. J. J. Michal¹, J. J. Ramsey², K. A. Ross¹, D. E. Johnson³, and K. A. Johnson¹, ¹Washington State University, Pullman, ²University of California, Davis, ³Colorado State University, Fort Collins.

Mitochondrial proton leak kinetics were measured to explain variation in maintenance energy requirements (MEM) of two breeds of cattle. Ten-month old Angus (A) and Wagyu (W) heifers (N=8/breed) were fed a diet balanced for 0.13 Mcal NEm/kg<.75>. Liver biopsies were obtained with a Trucut biopsy needle, immediately placed in ice-cold isolation buffer with BSA, and homogenized within 30 min. Mitochondria were isolated and added (0.5 mg protein/ml) to respiration medium for simultaneous measurement of oxygen consumption and membrane potential at 37<o>C by an O₂ electrode and a TPMP+-sensitive electrode, respectively. Mitochondrial proton leak kinetics were determined by incremental additions of 0.3–10 mM malonate. Proton leak rate was calculated from respiration rate by assuming 6 protons are leaked per oxygen atom consumed. Open-circuit, indirect respiration calorimetry was used to determine heat production (HP) and MEM requirements. Angus and W heifers had identical HP (145.3 kcal/kg<.75>) and similar fasting HP (91.8 vs. 92.0 kcal/kg<.75>). There was no difference in MEM requirement between breeds, W (105.2 kcal/kg<.75>) and A (113.5 kcal/kg<.75>). Hepatic mitochondrial respiration rates were greater ($P < 0.05$) in A heifers than W (11.81 vs 7.52 nmol O/min/mg protein). Membrane potential was higher in mitochondria from W ($P < 0.001$) than

A (145.4 \pm 4.89 vs. 118.9 \pm 5.13 mV, respectively). At the same proton leak rate across all malonate levels, W mitochondria had greater membrane potentials ($P < 0.0001$) than A mitochondria. At a standardized membrane potential, A mitochondria had 2–2.5 fold higher proton leak rates than W mitochondria. Lower proton leak rates of W might indicate better efficiency of energy use than A; however, because of the large variation in proton leak rate and MEM within and across breeds, no apparent relationship to MEM was detected.

Key Words: Proton Leak, Efficiency, Oxygen Consumption

T186 Barley- versus protein supplemented corn-based diets for feedlot cattle evaluated using the NRC and CNCPS beef models. K. A. Beauchemin and K. M. Koenig*, Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.

A study was conducted to evaluate the effects of supplementing a corn-based feedlot finishing diet with degradable intake protein in the form of urea or canola meal and urea on growth, intake and carcass characteristics. Animal performances were compared to those obtained by feeding a barley-based diet typical of diets fed commercially in western Canadian feedlots. Crossbred beef steers (288 steers, 435 kg initial BW) were allocated to 24 pens (12 steers/pen) and six pens were assigned to one of four diets: 1) barley grain (13.9% CP DM basis), 2) corn grain (10.0% CP, no protein supplementation), 3) corn grain with 1% urea (13.0% CP), and 4) corn grain with 6.4% canola meal and 0.3% urea (12.8% CP). Grains were steam-rolled and all diets contained 9% silage DM. Cattle were fed for ad libitum intake, weighed at 3-wk intervals, and slaughtered after 138 d on feed. There were no differences in ADG between cattle fed barley and those fed the corn diet supplemented to a concentration of CP similar to that supplied by the barley diet (1.40 vs 1.44 kg/d, SE 0.03; $P > 0.05$). However, ADG was 10% lower (1.29 kg/d; $P < 0.05$) and DM intake was 8% lower (8.97 vs 9.77 kg/d, SE 0.13; $P < 0.05$) for cattle fed the unsupplemented corn diet compared with that of cattle fed the other corn diets. Source of protein supplementation had no effect on ADG, but providing canola meal and urea improved feed efficiency by 7% compared with urea alone (6.35 vs 6.84 kg DM/kg gain, SE 0.09; $P < 0.05$). The NRC model (levels 1 and 2) and the CNCPS model predicted the substantially lower gain of cattle fed the unsupplemented corn diet, but only after intake was reduced to reflect the negative effects of ruminal N limitation on ruminal digestion and passage rate. Neither model predicted the improvement in feed:gain ratio observed when corn diets were supplemented with a combination of canola meal and urea rather than urea alone. Western Canadian feedlots can expect similar gain and feed efficiency from cattle fed steam-rolled barley or corn grain, provided that the corn diet is supplemented with canola meal and urea to supply at least 13% CP and 8% of dietary DM as degradable intake protein.

Key Words: Feedlot Cattle, Corn Grain, Protein

T187 Ruminal mucosa and epidermis morphology of calves infused with lactate, propionate or butyrate. S. F. Costa, M. N. Pereira*, L. Q. Melo, L. A.L. Muzzi, and M. L. Chaves, Universidade Federal de Lavras, Lavras, Brazil.

Volatile fatty acids may induce undesirable morphological changes on keratinized stratified epithelial tissues. We evaluated the effect of butyrate, propionate and lactate on rumen wall, the epidermis of the nasolabial surface, the *perioplum* and the *epicera* of calves. The adequacy of tegument biopsies as an indirect evaluator of the rumen mucosa was tested. Seventeen calves were fed exclusively on a whole fluid milk diet throughout the experiment. At 45 days of age Foley catheters were surgically placed into the rumen. Starting on day 52 until being slaughtered at 89 days of age, animals received twice a day infusions of saline or 0.0744 moles of propionate or butyrate per kg of BW^{0.75} daily or 0.0636 moles of lactate. All VFA induced greater increase on the weight of the rumen-reticulum than on omasum weight, butyrate was the VFA most stimulatory of organ mass. Abomasum mass was not affected by VFA infusion. Infusion of all VFA tended to increase the weight and proportion of mucosa in the cranial sac of the rumen, however they reduced papillae number per square centimeter of rumen wall. Only propionate tended to increase papillae area and height. The positive response to lactate and butyrate on mitosis of the basal cells of the epithelium apparently occurred in response to VFA induced rumenitis.

Histopathological lesions of the rumen wall were induced by VFA infusions. Butyrate and lactate were greater inducers of rumen epithelium pathological changes than propionate. The VFA increased hind *perio-plum* mitotic index and decreased mitosis on the nasolabial surface and *epicera*. The simultaneous effect of VFA on the morphology of ruminal mucosa and other keratinized tissues suggests that damage of hoof and ruminal epithelium, frequently reported on cattle subjected to ruminal acidosis, may have a common cause. Tegument biopsies may be useful as indicators of rumen mucosa morphology.

Key Words: Papillae, Rumen Wall, Volatile Fatty Acids

T188 Evaluation of quality, quantity and timing of colostrum feeding on immunoglobulin G1 absorption in jersey calves. E. C. Johnson, D. K. Kendall, and E. H. Jaster*, *California Polytechnic State University, San Luis Obispo.*

Twenty-four Jersey calves were randomly assigned to one of four treatment groups (6 calves per group). Pooled colostrum from first milkings (high IgG1 colostrum, 84 mg/ml) of multiparous cows was fed to treatment groups 1 and 2. Pooled colostrums from second and third milkings (low IgG1 colostrum, 31.2 mg/ml) of multiparous Jersey cows was fed to calves in treatment groups 3 and 4. The quality and timing of colostrum feeding was as follows: group 1, were fed (high IgG1 colostrum) 4 L at 0 hour (birth); group 2, calves were fed (high IgG1 colostrum) 2 L at 0 hour (birth) and 2 L at 12 hour; group 3, calves were fed (low IgG1 colostrum) 4 L at 0 hour (birth); and group 4 calves were fed (low IgG1 colostrum) 2 L at 0 hour (birth) and 2 L at 12 hour. Mean serum IgG1 at 48 h of age was 38.66, 45.66, 13.81 and 9.95 mg/ml in groups 1-4, respectively. Calves fed colostrum with higher concentrations of total ingested IgG1 (group 1 and 2) had significantly higher serum protein and IgG1 concentrations than calves fed low IgG1 colostrum at 48 h of age (group 1 and 2). Mean apparent efficiency (AEA) of IgG1 absorption was measured at 48 h and calves (group 2) receiving 2 L at birth and 2 L at 12 h of high IgG1 colostrum had higher mean apparent efficiency of IgG1 absorption than calves (group 4) fed 2 L of colostrum that was low in IgG1 at birth and 12 h (31.2% and 18.2% groups 2 and 4, respectively). Results suggest that dairy management practices support feeding Jersey calves two separate feedings of high quality colostrum to maximize the colostrum IgG1 intake.

T189 Effect of time of milk replacer delivery on feed intake of calves during weaning. S. I. Kehoe*, M. L. Moody, and A. J. Heinrichs, *Pennsylvania State University, University Park.*

Recommended strategies for weaning calves attempt to reduce stress and also enhance feed intake. One common weaning method that provides this transition is to decrease milk feeding to once a day for one week. Effects of feeding frequency, feeding time, and diurnal patterns have been observed in mature cattle. However, diurnal patterns of feed intake have not been researched in preweaned calves. The objective of this study was to investigate feed intake of calves offered milk in the morning or in the afternoon. Forty two Holstein heifer calves were fed milk replacer at 10% bodyweight twice daily for 4 weeks (20% fat, 20% protein, Land OLakes, Arden Hills, MN). During the fifth week, milk was reduced to 5% of birth BW and fed once a day at 5 a.m. or 3 p.m. Calf starter (Startena, Purina, St. Louis, MO) and water were offered ad libitum and daily grain intake was monitored for 7 days, after which, calves were weaned. Statistical analysis consisted of mixed procedure of SAS 8.1 using calf nested within treatment as a random effect. Least squares means of grain intake for calves fed in the morning were 449.83 ± 75.47 grams and for calves fed in the afternoon were 455.01 ± 79.15 grams. Overall intake was not different between treatments ($P > 0.963$). There were also no significant differences between slopes of intake for either treatment over the 7-day period ($P > 0.409$). It is concluded that calves are not affected by milk replacer delivery time and consume calf starter equally whether fed milk as the morning meal or the afternoon meal.

Key Words: Calves, Feed Intake, Diurnal Effects

T190 Effects of dietary protein level and fish meal on growth and hormonal status of weaned dairy calves. P. T. Richardel*, C. C. Williams, H. G. Bateman, II, C. F. Hutchison, C. C. Stanley, Y. H. Chung, T. W. White, L. R. Gentry, D. L. Thompson, Jr., and D. T. Gantt, *LSU AgCenter, Baton Rouge, LA.*

Eight weaned Holstein calves approximately four months of age (mean BW = 119.47 ± 2.65 kg) were used in a replicated 4 x 4 Latin Square designed experiment to study the effects of protein source and level on performance of weaned dairy calves. Treatments consisted of two diets containing either 16 or 20% CP with or without fish meal. Experimental diets were corn-silage based, with soybean meal (SBM) as the source of ruminally degradable protein and fishmeal as a source of ruminally undegradable protein. The animals were fed their respective diets twice daily at ad libitum levels during each 10-day adjustment period and 4 day sample collection period. Animals were housed in individual stalls for 10 days and in metabolism crates for 4 days for each period. Total fecal and urine output were collected, weighed, and subsampled for laboratory analysis of nitrogen during the 4-day collection period. On day 4 of the collection period, animals were fitted with indwelling jugular catheters. Blood samples were collected at 15-minute intervals for 6 hours for analysis of growth hormone (GH) and at 30 minute intervals for analysis of insulin. On day 14 of each experimental period body weight, wither height, hip height, and body length were measured. Treatment did not affect ($P > 0.10$) dry matter intake. There were also no effects ($P > 0.10$) of protein level or source on nitrogen balance or on any of the growth parameters measured. Steers consuming diets containing 20% CP tended to have higher circulating concentrations of insulin ($P = 0.07$). Mean GH concentrations tended to be greater in steers fed SBM ($P = 0.07$), however the GH to insulin ratio did not differ ($P > 0.10$). These data suggest that feeding diets greater than 16% CP with or without fish meal does not improve performance in weaned dairy calves.

Key Words: Weaned Calves, Dietary Protein, Fish Meal

T191 Components of growth in Holstein heifers reared from early life on two levels of energy intake. M. J. Meyer*, D. A. Ross, D. E. Shaw, and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

The effect of two levels of energy intake initiated during the preweaning period, on composition of growth in Holstein heifers was determined in a slaughter study. Starting at 44kg, Holstein heifers ($n = 72$) were fed two levels of nutrient intake to achieve 650g (R) or 950g (E) daily gain. Six heifers were slaughtered at 46kg to establish baseline composition and treatment heifers were slaughtered every 50 kg from 100 to 350 kg. Preweaning live weight (LW), lifetime LW, and lifetime empty body (EB) weight gains were greater for E- than R-heifers (960 vs. 640g/d, 929 vs. 656g/d, and 717 vs. 491g/d, respectively, $P < 0.05$). At slaughter, heifers were separated into three components: carcass (CA); head, hide, feet and tail (HT); and blood and organs (BO). E- had more ether extract (EE) and less ash and crude protein (CP) per unit of EB weight than R-heifers ($P < 0.05$). Mean daily gains of EE, ash, and CP were all greater in E- than R-heifers ($P < 0.05$). Composition of daily EB gain was also influenced by diet as R- deposited more CP and ash but less EE per unit of EB gain than E-heifers ($P < 0.05$). Treatment effects on composition of EB gain were brought about by differences in rate of body component gain as well as changes in the composition of gain of these body components. Retention of total energy and EE energy per unit of EB weight was greater in E-heifers however retention of CP energy per unit of EB weight was higher in R-heifers ($P < 0.05$). Overall mean daily tissue energy (TE) retention was greatest in E-heifers ($P < 0.05$) reflecting the higher nutrient intake. Daily TE retained in protein ($y = 0.1621x + 0.0308$, $R^2 = 0.69$; $P < 0.05$) and EE ($y = 0.8379x - 0.308$, $R^2 = 0.98$; $P < 0.05$) as a function of total daily TE yielded equations that intersect at 0.91 Mcal/d total TE. Thus, daily retention of TE in excess of 0.91 Mcal/d will increase the proportion of TE that is deposited as EE than that deposited as CP, however, daily CP deposition will continue to increase. These data help describe nutrient requirements of the modern Holstein heifer.

T192 Urinary phosphorus and allantoin as parameters for rumen development in veal calves. A. M. van Vuuren*, N. Stockhofe, W. J. J. Gerrits, B. J. Suarez, and C. G. van Reenen, *Animal Sciences Group, Wageningen, Lelystad, The Netherlands.*

In the EU, allowance to solid feeds is prescribed for veal calves to stimulate their natural chewing behavior. However, for an optimal utilization of solid feeds, rumen fermentation is required. Allantoin (A) and phosphorus (P) in urine are potential parameters to estimate rumen development by non-invasive techniques. Urinary excretion of A is related to ruminal microbial biomass production. Urinary excretion of P is negatively related with ruminating activity. To validate the use of these parameters, 160 Holstein-Friesian male calves were allocated to 5 treatments, being milk replacer only (MILK) or milk replacer and in addition either beet pulp (PECT), soybean hulls and corn grits (NDF), corn and barley (STA), or a mix of all these ingredients (MIX). Eighty calves were slaughtered in wk 8, the remaining 80 calves in wk 12. By post-mortem examination, the development of rumen mucosa was classified as poor, moderate, or good. Urine (spot sample from each animal) was collected in wk 7 (n=160) and in wk 11 (n=80), and analyzed for A, P, and creatinin (C). No development of rumen mucosa was observed in animals receiving MILK. Less animals with poorly developed mucosa were observed when supplemented with PECT, NDF or MIX than when supplemented with STA. The P:C ratio in urine, sampled one week before slaughter, reflected the proportion of animals with poorly developed rumen mucosa. The A:C ratio was not related to rumen development. Probably, intake of fermentable OM and consequently synthesis of rumen biomass is too low to result in distinguishing amounts of allantoin in urine. It is concluded that the P:C ratio, but not the A:C ratio could be a tool to estimate rumen development in veal calves.

Effect of supplementation on rumen development and urinary components

	MILK	PECT	NDF	STA	MIX	S.E.M.
Animals with poorly developed mucosa ¹ , %	100 ^a	10 ^c	13 ^c	44 ^b	29 ^{bc}

T193 Relationship of serum metabolites and insulin to beef marbling score in Korean cattle. J. S. Eun¹, S. C. Lee², Y. K. Kim³, and Y. H. Moon⁴, ¹Samyang Feed Company, Suwon, Kyonggi, Korea, ²National Livestock Research Institute, Suwon, Kyonggi, Korea, ³Chungnam National University, Tadjon, Chung Nam, Korea, ⁴RAIRC, Jinju National University, Jinju, Gyeong Nam, Korea.

Finding blood components exhibiting a significant relationship with meat quality, particularly marbling, in beef cattle will provide valuable information to optimize appropriate feeding strategies. This study was conducted to investigate changes in concentrations of serum metabolites and insulin during fattening and their relationship with final carcass characteristics in Korean cattle. Fourteen Korean steers (310±25 kg) were fed a ration of 12% CP and 72% TDN at 1.8% of body weight between 13 and 18 mo of age (phase 1) and a ration of 11% CP and 74% TDN ad libitum between 18 and 24 mo (phase 2). Throughout, steers had free access to rice straw, water and mineral block. Blood samples were collected bimonthly from a jugular vein 2 h after feeding (1100h) during the experiment. At 24 mo, steers were slaughtered following a 24 h fast. Carcass characteristics were evaluated from ribeye muscle at the cut surface between the 13th rib and the 1st vertebra. Means for each time point were separated by the Duncan's multiple range test. Concentrations of serum glucose were lower in phase 2 than in phase 1 (average 64.9 vs. 78.9 mg/dl). In contrast, serum NEFA concentrations were higher in phase 2 than in phase 1 (average 245 vs. 398 µeq/l). Serum insulin concentrations were elevated at 20 mo of age (27.5 µU/ml) compared to at 16 mo (20.2 µU/ml) and 24 mo (17.9 µU/ml) of age (P < 0.05). The Pearson correlation coefficients indicate that serum NEFA concentration was related to marbling score (see table below).

Items	Phase 1			Phase 2		
	Glucose	NEFA	Insulin	Glucose	NEFA	Insulin
Marbling score	-0.123	0.585*	0.215	-0.169	0.747**	0.342
Back fat thickness	0.278	-0.094	-0.123	-0.099	-0.572	-0.052
Longissimus muscle area	0.091	0.401	-0.199	0.254	0.004	0.122

*P < 0.05; ** P < 0.01

Key Words: Marbling Score, Korean Cattle, Serum Composition

T194 Using a DNA marbling marker, expected progeny differences, ultrasound, and live evaluation to predict carcass composition of early-weaned Simmental steers. C. B. Rincker*, N. A. Pyatt, L. L. Berger, and D. B. Faulkner, *University of Illinois, Urbana.*

Early-weaned Simmental steers (n = 175, Simmental or greater) of known genetics were individually fed over a four-year repeated trial to determine if a combination of aDNA marbling marker (GeneSTAR[®]), real-time ultrasound (RTU), EPDs, and live evaluation can accurately predict carcass composition. Steers were fed a high concentrate diet for 249.7 ± 0.7 d and harvested at 423.3 ± 1.4 d of age. RTU scans were recorded every 60 d for ribeye area (REA), intramuscular fat percentage (IMF%), and backfat (BF) with final scan taken < 13 d prior to harvest. Yearling weight (YW), marbling (MARB), percent retail cuts (PRC), and carcass weight (CW) EPDs were calculated for each steer. Visual animal evaluations were made at < 7 d to harvest by three evaluators to estimated quality (QG) and yield grade (YG). Five-year average price data were used for dressed beef, grid premium, and discounts. Gene marker frequencies did not affect marbling score (MS), chemical IMF%, QG, or percent low Choice or higher (P > 0.10). Live YG estimate was highly (P < 0.05) correlated to harvested BF (r = 0.23), and REA (r = 0.32); however, there was no relationship (P > 0.10) between live QG and MS. Genetic, live, and carcass parameters were regressed on chemical IMF, carcass value, and profit using step-wise regression analysis. With IMF%, 67.0% of the variation was explained by RTU QG (R² = 0.585), PRC (R² = 0.030), MARB (R² = 0.028), Live YG (R² = 0.017), and GeneSTAR Marbling Test (R² = 0.011) indicating that RTU was the only major contributor. Approximately 17% of the variation in average dressed price was explained by RTU QG (R² = 0.148) and MARB (R² = 0.025). GeneSTAR marbling marker was not an efficacious indicator for carcass composition of early-weaned Simmental steers. By using RTU, EPDs, and visual evaluation prior to harvest, producers can more accurately predict carcass composition.

Key Words: Carcass Value, Early-Weaned, Composition Estimation

T195 Fermentation characteristics and fatty acid biohydrogenation in continuous cultures of mixed ruminal microorganisms fed diets containing poultry products and nutrients reclaimed from the process water of processing plants. T. C. Jenkins*¹ and C. J. Sniffen², ¹Clemson University, Clemson, SC, ²Holderness, NH.

The process water from poultry processing plants contains considerable organic nutrients that must be captured, stored, treated, and disposed of in a manner that prevents environmental contamination. As an alternative, nutrients in the process water could be recycled as a feed supplement for ruminants. Because poultry process water has a high fat content containing unsaturated fatty acids, there is concern that it could inhibit ruminal fermentation, causing reduced feed digestibility. A novel process has recently been developed to reclaim nutrients from the process water by reacting organic matter to yield a dry, free-flowing product, which possibly may reduce or eliminate negative effects on fermentation. To test how lipids in the modified product were transformed by ruminal microorganisms, the feed ingredient, known as PRO*CAL, was incubated in continuous cultures and compared to two other fat sources. Four dual-flow continuous cultures were fed 30 g/d of forage and concentrate (1:1, DM basis). Concentrates contained no added fat or were supplemented (DM basis) with 5% PRO*CAL, 1.81% soybean oil (SBO), or 2.06% calcium salts of fatty acids (CAS). The four diets were fed to the fermentors in a 4 x 4 Latin square design with 10 d

periods. The cultures were adjusted to have a 0.10/d liquid dilution rate and averaged 84.0 mM total VFA concentration, 58.7% NDF digestibility, and 6.16 pH, which were not affected by diet. The acetate to propionate ratio was lowest for the SBO diet, highest for the CAS diet, and intermediate for PRO*CAL. Biohydrogenation of oleic, linoleic, and linolenic acids were lower ($P = 0.02$) for the PRO*CAL and CAS diets than for the SBO diet. Biohydrogenation of linolenic acid was lower for CAS than for PRO*CAL ($P = 0.07$). Based on the results of this study, PRO*CAL could be used as a dairy feed supplement without significant negative effects on ruminal fermentation, and as a means to increase the post-ruminal delivery of unsaturated fatty acids.

Key Words: Biohydrogenation, Fatty Acids, Poultry Products

T196 Effects of amino nitrogen on fermentation parameters by mixed ruminal microbes in batch and semi-continuous cultures when energy or nitrogen was limiting. H. Kajikawa^{*1}, A. Kawamura², K. Tajima¹, M. Mitsumori¹, and A. Takenaka¹, ¹National Institute of Livestock and Grassland Science, Tsukuba, Ibaraki, Japan, ²Tsukuba University, Tsukuba, Ibaraki, Japan.

Supplementation of amino N improves growth efficiency of and fermentation rate by ruminal microbes on purified nutrients, but these effects of amino N have not been always observed on actual feeding conditions of ordinary diets. The inconsistent effects may be attributable to the difference in the energy and N balance for the ruminal microbes since Van Kessel and Russell (J. Dairy Sci. 1996. 79:1237) showed that the growth of ruminal bacteria improved when the energy-excess batch cultures were provided with amino N. We prepared diet TC (Timothy hay:corn = 80:20 on DM basis) and TS (Timothy hay:soybean meal = 85:15 on DM basis), on which ruminal N balances were negative and positive, respectively, according to the model evaluations by the NRC (dairy cattle, 2001) and the CNCPS (ver.5, 2003) both, assuming that the diets were fed a mature cow at maintenance level. 1) Mixed ruminal bacteria were incubated in triplicate with diet TC or TS (100 mgDM/10 ml) in batch cultures in the presence of amino N (Trypticase) or ammonium N (70 mgN/L each). Gas production was slightly (by 6% or less), but significantly higher in the presence of amino N at 8 and 24 hr of incubation on both the diet, but no significant difference was shown at 48 hr between the N sources. 2) Mixed ruminal microbes were incubated with diet TC or TS (12 gDM/0.8 L/d) in semi-continuous cultures (Rusitec, eight vessels for each treatment) at 3.5 %/h of the dilution rate in the presence of amino N (Trypticase) or ammonium N (70 mgN/L each). There was no significant difference between the N sources on both the diets in any of the fermentation parameters (productions of total and methane gas, and total and each VFA) and microbial N yield, calculated from a sum of the nonammonia N in the effluent and N in the digested feed residues released by a neutral detergent treatment. More studies would be required to define the conditions on which the positive effect of amino N on microbial synthesis and fermentation in the rumen could be clearly exhibited on an actual dietary regimen.

Key Words: Amino Nitrogen, Rumen Fermentation, Microbial Synthesis

T197 Rumen microbial degradation of amino acids from fish meal and blood meal in continuous culture. S. Gargallo, S. Calsamiglia^{*}, and A. Ferret, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Eight dual flow continuous culture fermenters (1320 ml) were used in three 8-d replicated periods to study the effects of diets containing increasing levels of fish meal (FM) or blood meal (BM) on rumen microbial fermentation, nutrient flow and relative ruminal escape of dietary amino acids (AA). Fermenters were fed isonitrogenous diets composed of a basal mix (70.6% of total dry matter) and a protein supplement (29.4% of total dry matter). The protein supplement contained 0, 33, 66 or 100% of FM or BM, and a non-protein N source (urea and tryptone). Ruminal degradation of individual AA within protein supplement was calculated as the slope of the flow of each AA vs supplemental AA intake. Relative escape of individual AA was the ratio of ruminal escape of each AA vs average ruminal escape of total AA within supplemental protein. The inclusion of increasing levels of FM or BM to diets did not affect dry matter, organic matter and fibre digestion, total volatile fatty acids concentrations and molar proportions of individual volatile fatty acids. Ammonia N concentration and protein degradation decreased, and the flow of dietary N and AA increased with the increase of FM

or BM, without affecting microbial N flow and efficiency of microbial protein synthesis. Diets supplemented with BM provided the highest flows of essential AA and Lys, and those with FM provided the highest flows of Met. Relative ruminal escape of AA indicated that Ile was the most extensively degraded AA in BM, and Asp, Glu and Tyr were the most resistant AA in both protein sources. Results suggest that the resistance to rumen degradation of individual AA within a protein supplement differs, and the use of the AA profile of the original protein source may lead to inaccurate estimates of the supply of individual AA to the small intestine.

Key Words: Ruminal Degradation, Protein, Amino Acid

T198 Effects of time at suboptimal pH on rumen bacterial fermentation in a dual flow continuous culture system. M. Cerrato, S. Calsamiglia^{*}, and A. Ferret, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Seven 1325-ml dual flow continuous culture fermenters were used in three consecutive periods (8 days each) to study the effects of increasing time at suboptimal pH on rumen microbial fermentation and nutrient flow. Fermenters were maintained at 39C, with solid and liquid dilution rates of 5 and 10%/h, respectively, and fed 95 g/d of a 60 to 40 forage to concentrate diet (18.2% CP, 35.0% NDF). Treatments were a constant optimal pH (6.4) and 6 different intervals of time during the day at suboptimal pH (5.5) ranging from 4 to 24 h (in 4 h increases). Results were analyzed for linear (L), quadratic (Q) and cubic (C) effects ($P < 0.05$). Effects were L for total VFA (highest at constant pH 6.4 = 113.2 mM; lowest after 24 h at pH 5.5 = 83.5 mM) and acetate proportion (highest at constant pH 6.4 = 59.2%; lowest after 20 h at pH 5.5 = 44.8%). Effects were Q for propionate proportion (highest after 20 h at pH 5.5 = 43.4%; lowest at constant pH 6.4 = 18.5%), branch-chained VFA (highest at constant pH 6.4 = 4.4%; lowest after 20 and 24 h at pH 5.5 = 0.15 and 0.16 %, respectively) and acetate to propionate ratio (highest at constant pH 6.4 = 3.3; lowest after 20 and 24 h at pH 5.5 = 1.0 and 1.2, respectively). Effects were L for NDF digestion (highest at constant pH 6.4 = 50.5%; lowest after 24 h at pH 5.5 = 38.3%), ADF digestion (highest at constant pH 6.4 = 50.7%; lowest after 24 h at pH 5.5 = 32.2%) and ammonia N concentration (highest at constant pH 6.4 = 4.75 mg N/dL; lowest after 20 and 24 h at pH 5.5 = 2.9 and 3.1 mg N/dL, respectively). There were no effects of increasing time at suboptimal pH on protein degradation (mean = 47.1%), the flow of nonammonia N (mean = 2.8 g/d), dietary N (mean = 1.6 g/d) and bacterial N (mean = 1.28 g/d), and efficiency of microbial protein synthesis (mean = 32.72 g N/kg OM truly digested). Results indicate that increasing time at suboptimal pH may affect rumen microbial fermentation. Changes started to be significant after 8 h, and major changes were observed after 16 h at suboptimal pH.

Key Words: pH, Acidosis, Rumen Fermentation

T199 Effect of particle size on adhesion of Ruminococcus albus and ruminococcus flavefaciens to plant cell walls in vitro. Q. Meng^{*} and W. Gao, *China Agricultural University, Beijing, China.*

Two bacteria strains of Ruminococcus albus 7 and Ruminococcus flavefaciens FD-1 were used to study the effect of particle size on adhesion of cellulolytic ruminal bacteria to plant cell walls in vitro. Corn stalk cell walls were coarsely milled by hammer mill (CM, 1 mm) or finely milled by ball-mill (FM) for 48 h to produce two particle sizes of plant cell walls. Microcrystalline cellulose (MC) was used as a positive control. The adhesion was measured by culturing bacterial suspensions and corn stalk cell walls and microcrystalline cellulose at 39 C for 60 min, then centrifuging the mixtures at 150 x g for 5 min, and measuring the optical densities of the supernatant at 600 nm. The particle size had a significant influence ($P < .001$) on adhesion of three cellulolytic ruminal bacteria to the substrates. The adhesion percentages of FM, CM and MC were 80.3, 64.0 and 80.4% for R. albus ($P < .001$), and 72.9, 77.8 and 69.0% for R. flavefaciens ($P < .08$), respectively. The adhesion abilities of R. albus 7 and R. flavefaciens FD-1 to corn stalk cell walls were significantly declined after the treatment with periodate, LiCl, trypsin and protease ($P < .001$), indicating that certain proteinoous and carbohydrate molecules may be involved in the bacterial adhesion process. The bacterial adhesion inhibition to corn stalk cell walls was found in the use of monosaccharide of galactose at the concentration of 0.5% for R. albus 7 and 5% for R. flavefaciens FD-1, respectively. The inhibition effect of

methylcellulose on the adhesion of the two cellulolytic ruminal bacteria were only detected to CM both at the concentration of 0.05% and 0.1% ($P < .01$). On the basis of our experimental results, we concluded that glycoprotein associated with the bacterial cell surface of ruminococci may be responsible for the adhesion to plant cell walls.

Key Words: Adhesion, Cellulolytic Bacteria, Plant Cell Walls

T200 Effects of a blend of essential oils and the type of diet on rumen microbial fermentation and nutrient flow from a continuous culture system. L. Castillejos¹, S. Calsamiglia*¹, A. Ferret¹, and R. Losa², ¹Universitat Autònoma de Barcelona, Spain, ²AKZONOBEL/CRINA SA, Clond, Switzerland.

Eight dual flow continuous culture fermenters (1320 ml) were used in two consecutive periods of 8 d to study the effects of a specific blend of essential oils (EOB, CRINA RUMINANTS) on rumen microbial fermentation and nutrient flow. Temperature (39°C), pH (6.4), and liquid (10%/h) and solid (5%/h) dilution rates were maintained constant. Treatments were arranged in a 2 x 2 factorial design. Main factors were type of diet (diet 10:90, forage to concentrate ratio, 15.3% CP and 20.2% NDF; vs diet 60:40, forage to concentrate ratio, 18% CP and 30.2% NDF) and the addition of EOB (0 vs 1.5 mg/L of EOB). Diets (95 g/d of DM) were fed in three equal amounts along the day. Each experimental period consisted of 5 d of adaptation and 3 d of sampling. Effluent samples were taken from a composite of the three sampling days, and bacteria were isolated from fermenter flasks on the last day of each period for chemical analysis. Differences were declared at $P < 0.05$. There were no significant interactions between diet type and the addition of EOB. There were no effects of diet type on digestion of DM (average of 58.2%), OM (average of 58%), NDF (average of 40.6%), ADF (average of 46.7%) and CP (average of 36.8%). The 10:90 diet had a higher concentration of total VFA (128.1 vs 110.9 mM) and proportion of butyrate (18.5 vs 13.9 %) compared with the 60:40 diet. The 60:40 diet had a higher proportion of acetate (61.0 vs 50.3 %), acetate to propionate ratio (2.98 vs 1.98), ammonia N concentration (8.64 vs 3.01 mg/100ml), total N flow (3.57 vs 3.26 g/d), ammonia N flow (0.27 vs 0.10 g/d) and non-ammonia N flow (3.30 vs 3.17 g/d) compared with the 10:90 diet. There were no negative effects of EOB on DM, OM, NDF, ADF and CP digestion. The use of EOB increased the concentration of total VFA (122.8 vs 116.2 mM) without affecting individual VFA proportions or nitrogen metabolism.

Key Words: Essential Oil Blend, Rumen Microbial Fermentation

T201 Effects of different doses of plant extracts on rumen microbial fermentation. M. Busquet¹, S. Calsamiglia*¹, A. Ferret¹, and C. Kamel², ¹Universitat Autònoma de Barcelona, Bellaterra, Spain, ²University of Leeds, UK.

The effects of 4 different doses (3, 30, 300, and 3000 mg/L) of 18 plant extracts were evaluated in *in vitro* batch culture rumen microbial fermentations with a 50:50 forage to concentrate diet (17.3% CP; 28.0% NDF). Treatments were: control (C, no additive), plant extracts (fennel = FG, anise oil = AO, cade oil, cinnamon oil, clove bud oil, dill oil, garlic oil = GO, ginger oil, oregano oil, pepper oil, tea tree oil = TTO, and yucca = YU), and secondary plant metabolites (benzyl salicylate, anethol, carvacrol = CA, cinnamaldehyde = CI, eugenol, and d-carvone = DC). Raw materials were provided by AXISS France SAS (France). After 24 h, the pH was determined in culture fluid and samples were collected to analyse for ammonia N and volatile fatty acids (VFA). Differences were declared at $P < 0.05$. The highest doses (3000 mg/L) of most compounds resulted in higher pH and lower ammonia N and total VFA, suggesting that rumen fermentation was reduced, except FG and YU that resulted in lower pH and no decrease in total VFA. The FG (at 300 and 3000 mg/L) decreased the ammonia N concentration (-19 and -40 %, respectively) compared to C. The GO reduced the acetate (-10% at 300 mg/L; -9% at 3000 mg/L) and increased the propionate (+12% at 300 mg/L) compared with C. Anethol, AO, DC and TTO (at 3000 mg/L) reduced the proportion of acetate (-4, -4, -12 and -5 %, respectively) and propionate (-8, -8, -25 and -8 %, respectively) compared with C. Eugenol and CI (at 3000 mg/L) increased the propionate proportion (+9 and +9 %, respectively) compared with C. When dosed at 300 mg/L, CA reduced the acetate (-4%) and propionate (-7%) proportions, but when dosed at 3000 mg/L, it increased propionate proportions (+10%). Plant extracts may help modify rumen microbial fermentation,

but effects appear dose-dependent, and attention should be given to potential interactions and the subsequent effects on rumen fermentation and animal performance.

Key Words: Plant Extracts, Rumen Fermentation

T202 Ionized calcium requirements of cellulolytic ruminal bacteria for growth and cellulose degradation. M. S. Morales* and B. A. Dehority, OARDC, The Ohio State University, Wooster.

We investigated the ionized calcium (Ca^{+2}) requirements for growth and cellulose degradation of *Fibrobacter succinogenes*, strains A3c and S85; *Ruminococcus albus*, strain 7; and *Ruminococcus flavefaciens*, strains B34b and C94. Bacteria were grown in slants and transferred to a complete medium containing one-tenth the normal concentration of Ca^{+2} . After incubation overnight, the cultures were transferred to Ca^{+2} free medium and grown to an optical density (OD) between 0.6-0.7. Inoculum was prepared by diluting the culture to 0.1 OD with divalent cation-free medium, and 0.1 ml was used to inoculate each experimental tube. Medium containing 0, 0.02, 0.04, 0.08, 0.16, 0.32, 0.4 (Normal medium), 0.64 mM Ca^{+2} concentrations were tested. Growth was monitored by OD (660nm) in liquid cellobiose medium, and cellulose degradation was determined measuring cellulose residue after different times of incubation. Data were fitted mathematically to determine growth and degradation rates as well as concentrations required for maximum growth and extent of cellulose degradation. As Ca^{+2} concentrations increased, *F. succinogenes* S85 and A3c responded with increased maximum growth and growth rates, whereas these decreased for *R. flavefaciens* C94. Other strains were not affected by Ca^{+2} concentration. *F. succinogenes* A3c and S85 showed absolute requirements for Ca^{+2} for cellulose degradation, and rate and extent of cellulose degradation increased when Ca^{+2} concentration increased. For other strains, rate of degradation was not affected, although the extent of cellulose degradation tended to be higher with higher Ca^{+2} concentrations for *R. flavefaciens* C94 and B34b. *R. albus* 7 was not sensitive to Ca^{+2} concentrations, either in growth or cellulose degradation.

Key Words: Ruminal Bacteria, Cellulose Degradation, Ionized Calcium

T203 Empirical relationships between ruminal pH and volatile fatty acid concentrations. M. Devant¹, A. Bach*¹, and J. A. García³, ¹IRTA-Unitat de Remugants, Barcelona, Spain, ²ICREA, Barcelona, Spain, ³IRTA-Unitat de Química Alimentària, Girona, Spain.

The objective of this study was to establish empirical relationships between ruminal pH and total VFA concentrations and molar proportions. A total of 167 individual rumen samples from dairy cattle from two different dairy herds were obtained by rumenocentesis conducted every three weeks during the first 100 days of lactation 4 hours after offering the TMR. Rumen pH was measured immediately following sample extraction whereas samples for $\text{NH}_3\text{-N}$ and VFA determinations were frozen until subsequent analyses. The relationships between each factor and rumen pH were evaluated by regression analyses using the fit model procedure of JMP(r). Rumen pH was negatively related with acetate ($r = -0.35$; $P < 0.001$), propionate ($r = -0.51$; $P < 0.001$), butyrate ($r = -0.50$; $P < 0.001$), valerate ($r = -0.56$; $P < 0.001$), and total VFA ($r = -0.507$; $P < 0.001$) concentrations (mM). Despite the lower pKa of acetate compared with propionate, rumen pH was positively correlated with acetate ($r = 0.42$; $P < 0.001$) and negatively correlated with propionate ($r = -0.32$; $P < 0.001$) molar proportions (mol/100 mol). As total VFA concentrations increased, molar proportions of propionate increased linearly ($r = 0.22$; $P < 0.05$), whereas molar proportions of acetate and butyrate remained more constant. No linear relationship was found between rumen pH and $\text{NH}_3\text{-N}$ ($r^2 = 0.0007$; $P > 0.70$). The results from multiple regression analysis indicate that a model containing concentrations of acetate, propionate, isobutyrate, valerate, acetate to propionate ratio, and molar proportions of butyrate was able to account for about half of the observed variance in ruminal pH ($r^2 = 0.51$; $P < 0.001$; RMSE = 0.367). It is concluded that VFA concentrations and molar proportions can only account for half of the observed variation in ruminal pH, and thus, for modelling ruminal pH it is necessary to account for other factors such as ruminal buffer capacity and concentration of other organic acids, such as lactate and malate.

Key Words: Empirical, Rumen, Rumenocentesis

T204 An empirical analysis of ruminal microbial efficiency. E. Ungerfeld* and S. Rust, *Michigan State University, East Lansing.*

Since microbial protein synthesized in the rumen is a major source of amino acids for ruminants, it is important to understand microbial synthetic efficiency. A total of 111 treatment means of efficiency of microbial crude protein synthesis in the rumen (ME) from 29 published *in vitro* and *in vivo* trials was used for multivariate analysis to determine the relationships between ME and fermentation variables. Experiments were included as random factors in the model. Treatment means were weighted by the reciprocal of their variance (n/s^2) scaled to one. Microbial efficiency was 22.4 ± 7.89 (range 9.2 - 54.0) g microbial N/kg degraded OM. Total VFA concentration was linearly and positively related to ME, while isobutyrate to propionate (iB/P) and isovalerate to propionate (iV/P) ratios had quadratic relationships with ME. This model accounted for 94% of ME variation, although fermentation variables alone (i.e., without adjustment for experiment) explained only 2% of variation. A backward stepwise procedure ($P = 0.20$) without adjustments for experiments led to a model explaining 60% of ME variation that contained total VFA, butyrate to propionate (B/P, linear and quadratic), iB/P, valerate to propionate (V/P, linear and quadratic), iV/P (linear and quadratic) and pH (linear and quadratic). Hence, the inclusion of experiments in the first model accounted for a large portion of the variation in ME that could potentially be explained by fermentation variables but was experiment-associated. Total VFA could be an indicator of energy status, although VFA concentration does not necessarily reflect production. The decline in ME at high B/P could reflect high protozoal numbers and consequently, high bacterial lysis due to predation. Low ME at high V/P and iV/P could reflect inefficiencies associated to amino acids catabolism; however, there was a linear and positive response of ME to iB/P. The increase in ME at low pH was unexpected and did not reflect an association between pH and total VFA; low protozoal numbers at low pH are a possible explanation. Results suggest that fermented substrate and N recycling are important factors affecting ME, although much still needs to be understood.

T205 *In vitro* synthesis of isopropanol from acetone by mixed rumen microbes. L. H. Rivier* and M. L. Bruss, *University of California, Davis.*

The objective was to assess the ability of mixed rumen microbes to convert acetone to isopropanol using ^{13}C -acetone *in vitro*. For this purpose, rumen fluid from four lactating and four dry, rumen-fistulated Holstein dairy cows was incubated with saline or 9.3 mmol/L $2\text{-}^{13}\text{C}$ -acetone for 0 or 8 hours and analyzed via gas chromatography and mass spectroscopy. There was negligible ^{13}C -isopropanol in the 0-hour incubates. In the 8-hour incubates, the isopropanol ^{13}C -atom percent averaged $32.5\% \pm 0.68\%$ (SE). The average transfer quotient (TQ = $100 \times$ atom percent of isopropanol/acetone) was $98.6\% \pm 2.3\%$ (SE). The atom percent and the TQ together demonstrate that all of the isopropanol detected in rumen fluid originated from the added acetone, which clearly indicates that rumen microbes are capable of directly converting acetone into isopropanol and that there is no other precursor. Other unidentified, non-acidic, unlabeled compounds were detected by gas chromatography. The average rate of synthesis of isopropanol from acetone was 2.46 ± 0.51 (SE) μmol per minute per liter of rumen fluid. There were no significant differences (t-test) between lactating and dry cows for any of the observed parameters. Isopropanol levels have been found to increase during ketosis and may be implicated in the nervous form of ketosis. Reducing equivalents generated from conversion of absorbed isopropanol back to acetone may contribute to the synthesis of glucose in the liver of ketotic cows.

Key Words: Acetone, Isopropanol, Rumen

T206 Site of digestion in dairy cows fed different soy-protein supplements. I. R. Ipharraguerre*¹, J. H. Clark¹, and D. E. Freeman², ¹*Department of Animal Sciences, University of Illinois, Urbana,* ²*Department of Veterinary Clinical Medicine, University of Illinois, Urbana.*

Four multiparous lactating Holstein cows cannulated in the rumen and duodenum averaging 209 DIM were used in a 4x4 Latin square design to evaluate the replacement of soybean meal (SBM) with soy-protein

products of reduced ruminal degradability. Diets contained 15% alfalfa silage, 25% corn silage, 34.3 to 36.9% corn grain, and 19.4% soy products; 18.2% CP, 25.5% NDF, and 35.3% starch (DM basis). In the experimental diets, SBM was replaced with expeller SBM (ESBM), non-enzimatically browned SBM (NSBM), or whole roasted soybeans (WRSB) to supply 10.2% of the dietary DM. Intakes (kg/d) of DM, OM, NDF, and starch were ($P > .05$) for SBM 19.8, 18.3, 4.8, and 6.9; for ESBM 21.4, 19.7, 5.4, and 7.7; for NSBM 20.9, 19.2, 5.2, and 7.4; and for WRSB 19.4, 18.0, 4.9, and 6.4. True ruminal digestion of OM and apparent digestion of NDF and starch in the rumen and total tract (kg/d) were ($P > .05$) for SBM 10.1, 2.4, 1.9, 4.0, and 6.7; for ESBM 10.1, 2.7, 2.4, 4.7, and 7.4; for NSBM 9.8, 2.5, 2.4, 4.2 and 7.1; and for WRSB 9.6, 2.6, 2.3, 4.0, and 6.2. Intake of N (SBM = 579, ESBM = 622, NSBM = 613, and WRSB = 567 g/d) and passage to duodenum of microbial N (SBM = 245, ESBM = 227, NSBM = 236, and WRSB = 209 g/d) were not affected by treatments ($P > .05$). Compared with SBM, the flow to duodenum (g/d) of nonammonia N (SBM = 467, ESBM = 514, NSBM = 564, and WRSB = 498) was higher ($P < .05$) for NSBM and that of nonammonia nonmicrobial N (SBM = 222, ESBM = 283, NSBM = 323, and WRSB = 289) was higher ($P < .05$) for NSBM and WRSB. Replacing SBM with ESBM tended to increase the ruminal outflow of both N fractions ($P < .09$ and $P < .08$, respectively). Among protected soy-protein supplements, ruminal escape of NAN was higher ($P < .05$) for NSBM than for WRSB (564 vs. 498 g/d). No differences were detected ($P > .05$) among treatments when the flow to duodenum of nonammonia nonmicrobial N (SBM = 48.4, ESBM = 56.0, NSBM = 58.5, and WRSB = 57.9%) and microbial N (SBM = 51.6, ESBM = 43.9, NSBM = 41.5, and WRSB = 42.1%) were expressed as percentage of N intake.

Key Words: Digestion, Rumen Undergradable Soy Protein, Dairy Cows

T207 Utilization of the mobile bag technique to determine intestinal digestibility of feedstuffs. S. K. Ivan*, H. L. Haugen, and T. J. Klopfenstein, *University of Nebraska, Lincoln.*

Our objective was to determine the effects of dietary wet corn gluten feed on intestinal digestibility of various feedstuffs. Two ruminally and duodenally fistulated steers (658 kg) were assigned randomly to a crossover design with 4-wk periods. Diets were formulated on a DM basis to consist of 12% alfalfa hay, 18% alfalfa haylage, 30% corn silage, 9% whole cottonseeds, and 31% concentrate or 38% wet corn gluten feed, 8.5% alfalfa hay, 10% alfalfa haylage, 19% corn silage, 5% whole cottonseeds, and 19% concentrate. A mobile bag technique was employed to determine the RUP, RUP digestibility, total tract digestible protein (TTDP), and total tract digestible DM (TTDD) of alfalfa hay, brome hay, alfalfa haylage, corn silage (CS), whole cottonseeds (WCS), soybean meal (SBM), non-enzymatically browned soybean meal (SP), and dried distillers grains (DDG). There was no consistent effect of diet on RUP, RUP digestibility, TTDP, or TTDD. The RUP (% of CP) ranged from 6.0% for alfalfa haylage to 75.7% for SP. The RUP digestibilities ranged from 15.3% for the alfalfa haylage to 96.5% for the SP. The RUP digestibilities for alfalfa hay (33.9%), brome hay (39.1%), alfalfa haylage (15.3%), and corn silage (19.2%) were lower than NRC reported values. The higher RUP digestibility of the SP sample is reflective of more total protein reaching the small intestine. The large range in RUP digestibility was not reflected in TTDP (% of CP) with corn silage being the lowest at 83.5% and SP the highest at 97.9%. The TTDD ranged from 53.0% for cottonseeds to 96.9% for SP. The total tract NDF digestibility of the forages ranged from 49.2% for the alfalfa haylage to 53.9% for the alfalfa hay. In this study, diet had little effect on intestinal digestibility of protein or DM. The higher the concentration of RUP reaching the small intestine the higher the RUP digestibility, leading to a smaller range in total tract CP digestibility compared with RUP digestibility.

Key Words: Mobile Bag, Wet Corn Gluten Feed, Intestinal Digestibility

T208 Effects of dietary sodium bicarbonate on ruminal and total tract digestibility of diet and diet components in dairy cows. C. S. Mooney* and M. S. Allen, *Michigan State University, East Lansing.*

Six ruminally and duodenally cannulated, mid-lactation (177 ± 12 DIM, mean \pm SD) Holstein cows were used in a replicated 3 x 3 Latin square design to evaluate effects of sodium bicarbonate on ruminal and total tract digestibility. Periods were 28 d in length with the last 14 days

for data and sample collection. Treatments were control, sodium bicarbonate at 1% of dietary DM and an isomolar concentration of sodium chloride. Diets were formulated to 20% forage NDF and 17.5% CP and contained a common base mix (95% of diet DM) to which treatment pre-mixes (5% of diet DM) were added. The control premix was composed of 50% finely ground dry corn and 50% ground rice hulls (DM basis). Sodium bicarbonate and sodium chloride were included in place of rice hulls in their respective pre-mixes. Fat-corrected milk (3.5%), DMI, and milk fat percentage were not affected by treatment and averaged 35.7 kg/d, 23.3 kg/d, and 3.51%. Liquid passage rate and valerate absorption rates were determined by analyzing disappearance curves of Co-EDTA and valerate from the rumen following a pulse dose. Duodenal flux of DM was measured using chromic oxide as a marker. Digestion and passage rates were determined using the ruminal pool and duodenal flux method. Treatments did not affect liquid passage rate or valerate absorption rate. Ruminal digestibility of DM, OM, NDF and starch were not affected by treatment. Passage rates of indigestible NDF and starch were not affected by treatment with means of 3.7 and 19.3 %/h, respectively. Digestion rates of potentially digestible NDF and starch were not affected by treatment with means of 2.0 and 19.8%/h. Furthermore, post-ruminal digestion and total tract of DM, OM, starch and NDF were not affected by treatment. These results do not support the hypothesis that sodium bicarbonate decreases ruminal starch digestibility by increasing passage from the rumen.

Key Words: Sodium Bicarbonate, Ruminal Digestibility, Passage Rate

T209 Ruminal characteristics and rate, site, and extent of digestion of dairy diets supplemented with canola fed to Holstein steers. S. E. Bedgar^{*1}, J. W. Schroeder¹, M. W. Chichlowski², M. L. Bauer¹, and S. A. Soto-Navarro¹, ¹North Dakota State University, Fargo, ²North Carolina State University, Raleigh.

Fifteen cannulated Holstein steers averaging 399 ± 21.7 kg initial body weight (BW) were assigned to treatments by BW to evaluate the effects of feeding ground canola seed (GCS) on site and extent of digestion and ruminal fermentation in a completely randomized design. Diets containing 0, 6.1, and 12.2% of the total ration dry matter (DM) as GCS were fed ad libitum for 33 d. Rations were formulated to represent high lactation diets that were isonitrogenous and equivalent to 1.74 Mcal of net energy per kg of DM. The control diet was composed of corn silage, ground ear corn, alfalfa, soybean, canola, and blood meal, vitamins, minerals, and chromic oxide as an external marker. Corn grain and canola meal were reduced as GCS (39.6% lipid) was added to the diets. Steers were acclimated to treatment for 25 d prior to collections. Duodenal and ileal samples were taken to represent every 1.5 h in a 12 h period from d 29 through 31. Total feces were collected from d 27 to 32, and rumen fluid samples were taken at 0, 2, 4, 6, 8, 10, and 12 h post-feeding on d 31. Inclusion of GCS did not affect intake or digestion of DM, organic matter (OM), fiber, and crude protein (CP). Ruminal pH and ammonia nitrogen were also similar among treatments. Concentration of ruminal volatile fatty acids (VFA) and butyrate decreased ($P < 0.01$), and propionate increased ($P < 0.01$) linearly with greater levels of GCS. Diets that contain 7% lipid with up to 4.2% added lipid from GCS, when fed to Holstein steers, did not affect the rate, site, or extent of digestion of DM, OM, fiber, and CP. These data suggest that canola can be used as an ingredient when formulating diets for high lactation dairy cows without negatively affecting digestion and ruminal fermentation.

Key Words: Canola, Digestibility, Dairy Steer

T210 Effect of a saponin-based surfactant on the processing characteristics and in vitro ruminal fermentation of barley grain. Y. Wang^{*} and T. A. McAllister, *Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, Canada.*

The effects of a saponin-based tempering agent (GrainPrep#8482) on barley grain were evaluated in two in vitro studies. In Exp. 1, barley grain was tempered at 20% moisture for 2 or 4 h. Surfactant was applied during tempering at 0, 60, 120, or 240 µL/kg DM, and the barley was processed with rollers set at a distance of 2.03, 2.22, or 2.41 mm, yielding a 4 × 3 factorial arrangement of treatments. Surfactant × roller distance interactive effects on barley processing were not observed ($P > 0.05$) at either tempering time. Applying surfactant did not affect ($P > 0.05$) the processing index (PI; vol wt after rolling/vol wt before rolling × 100%) or particle size distribution of the barley. Increasing the roller

spacing (from 2.03 to 2.41 mm) increased ($P < 0.05$) the PI and the proportion of particles sized 3.35 to 4.75 mm, but decreased ($P < 0.05$) particles >4.75 mm or <2.36 mm. In Exp. 2, barley grain was tempered for 2 h (20% moisture) with surfactant applied at 0 or 120 µL/kg DM, then processed with rollers set at 2.03 or 2.41 mm. The four preparations were incubated in buffered ruminal fluid with surfactant added at 0 or 360 µL/kg DM. Apparent IVDMD and gas production were higher ($P < 0.01$) with barley rolled at 2.03 mm than at 2.41 mm. Applying surfactant at 120 µL/kg during tempering and at 360 µL/kg prior to incubation reduced ($P < 0.05$) IVDMD and the accumulation of VFA and reducing sugars, irrespective of roller setting. When rollers were set at 2.03 mm, adding surfactant during tempering, prior to incubation, or at both times reduced ($P < 0.05$) the acetate:propionate ratio after 4 h of incubation. However, this effect was observed only with the highest dose (120 + 360 µL/kg DM) of surfactant and a roller setting of 2.41 mm. The surfactant exerted no substantial effect on the processing characteristics of barley grain, but it did reduce the initial rate, but not the extent, of IVDMD from processed grain.

Key Words: Barley Tempering, Ruminal Fermentation, Surfactant

T211 Development of an in vitro technique to determine intestinal digestion of protein supplements by a Daisy II incubator. S. Gargallo, S. Calsamiglia^{*}, and A. Ferret, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

A Daisy II incubator was used to develop an in vitro technique to estimate intestinal digestion of proteins and amino acids (AA). The objective was to adapt the three step in vitro procedure (TSP; J. Anim. Sci. 1995. 73:1459-1465) to reduce the cost and labor involved in the determination of intestinal digestion of proteins, and to obtain a residue that could be analyzed for AA content. Four tests were conducted to study the effects of the type of pepsin (Sigma P-7012 vs Sigma P-7000), the type of bags used for the incubation of samples (nylon bags, Ankom R510, vs bags for fiber analysis, Ankom F57), the amount of sample per bag (0.5, 1, 2 or 5g) and the number of bags per incubation bottle (5, 15, 20 or 30 bags) on the estimated intestinal digestion of protein. A soybean meal (SBM) sample heated at 170°C for 0, 0.5, 1, 2, 4, 6 and 8h was used in all preliminary tests to determine the optimum conditions of the technique. The intestinal digestion of 12 protein supplements was determined using the proposed DaisyII and the TSP techniques. Results using the two types of pepsin were strongly correlated ($r = 0.99$; $P < 0.0001$), indicating that the use of the cheapest (Sigma P-7000) did not affect the results. Intestinal digestion values of the SBM samples obtained from the TSP assay were highly correlated with those obtained using the DaisyII incubator with both types of bag ($r = 0.99$; $P < 0.0001$), and with an amount of sample from 0.5 to 5 g ($r = 0.99$; $P < 0.0001$). The number of bags per incubation bottle did not affect ($P > 0.10$) intestinal digestion values determined with the DaisyII incubator. Intestinal digestion values of the 12 protein supplements determined with TSP and with DaisyII technique were highly correlated ($r = 0.92$; $P < 0.0001$). These results indicate that the use of up to 30 nylon bags (Ankom R510) with 5 g of sample in each DaisyII incubation bottle could be used to estimate intestinal digestion of protein supplements.

Key Words: In Vitro, Intestinal Digestion, Protein

T212 The in vitro digestibility, gas production and fermentation characteristics of *Mucuna pruriens*, and soybean meal treated with or without L-Dopa. A. T. Adesogan^{*}, S. K. Chikagwa-Malunga, M. B. Salawu, and S. C. Kim, *University of Florida, Gainesville.*

Mucuna pruriens (velvet bean) seeds contain 25-35% CP, but concerns about possible antinutritive effects of their L-Dopa (5-6% DM), have limited their use in ruminant diets. A 3 × 6 factorial design was used to determine the rumen fermentability of *Mucuna*, seeds (M) and soybean meal treated with (SBD) or without (SB) L-Dopa (138g/kg DM). Ground (1mm) substrates were incubated in triplicate at 38°C in 9 ml media and 1 ml rumen fluid for a series of six, 48 h, consecutive batch cultures. The first culture was inoculated with rumen fluid from 2 cows fed hay and soybean meal. Subsequent cultures were inoculated with fluid from the previous culture. After each culture, gas production was measured from syringes placed in the culture tubes, in vitro DM digestibility was calculated and fermentation acids were analyzed by high performance liquid chromatography. DM digestibility (g/kg) and gas production (ml) from M were higher ($P < 0.001$) than from SB and SBD,

616 v 540, 554 and 3.7 vs. 3.2, 3.1 respectively. There were no differences ($P>0.05$) between SB and SBD in DM digestibility and gas production, suggesting that L-Dopa addition did not depress the extent of fermentation of SB. Over the sequence of cultures, DMD of M and SB were decreased ($P<0.05$) linearly and cubically respectively, but DMD remained unchanged in SBD. Whereas, gas production increased ($P<0.05$) linearly, quadratically, and cubically in M, SB and SBD respectively. Over the sequence of cultures, acetate levels were unchanged in SB, but they increased ($P<0.05$) quadratically and cubically in SBD and M respectively; propionate levels were unchanged in SBD but they increased ($P<0.05$) cubically and quadratically in M and SB respectively; and butyrate levels were unchanged in M, but they increased ($P<0.05$) linearly in SB and SBD. In conclusion, M seeds are readily fermentable in the rumen. Adding L-Dopa to SB, did not affect the extent of digestion or gas production, but changed the fermentation acid profile.

T213 Estimated dry matter, crude protein and neutral detergent fiber degradation of some feeds by in situ technique. L. Cabral^{*1}, S. Valadares Filho², J. Zervoudakis¹, A. Souza¹, and E. Detmann³, ¹Universidade Federal de Mato Grosso, Av. Fernando Corrêa da Costa, DZER-FAMEV/UFMT, Cuiabá-MT, Brazil, ²Universidade Federal de Viçosa Av. P.H. Rolfs, Viçosa-MG, Brazil, ³Universidade Estadual do Norte Fluminense CCTA, Campos Dos Goytacazes - RJ, Brazil.

The present work aimed to determine the degradation kinetic parameters of the dry matter (DM), crude protein (CP) and neutral detergent fiber (NDF) for corn silage, elephant-grass silage, Tifton-85 bermudagrass hay and soybean meal. Three rumen cannulated cattle were used (avg 400 kg body weight), in a 3x3 latin square. The feeds were weighed in nylon bags (10-20 mg/cm²) and incubated all in one time. Bags were removed 0, 2, 4, 8, 16, 24, 48 and 72 hours after of incubation for roughages, and 0, 2, 4, 8, 16, 24 and 48 hours for soybean meal. The residues in the bags were analyzed for residual dry matter, crude protein and NDF on each time and the degradation curves were adjusted using non linear models, where for DM and CP a first order assintotic model was used and for NDF a sigmoidal model was used. The data were analyzed by analysis of variance using SNK tests, calculating the average values of parameters and respective coefficients of variation (CV). The soybean meal and corn silage presented potentially digestible fraction for dry matter of 99.8% (CV = 3.02%) and 83.88% (CV = 3.22%) and potentially digestible fraction for the crude protein of 99.85% (CV = 5.74%) and 89.39% (CV = 6.92%), respectively. The soybean meal and corn silage had degradation rates for the crude protein of 0.1368 h⁻¹ (CV= 6.14%) and 0.0756h⁻¹ (CV = 7.98%), respectively. The Tifton-85 bermudagrass hay had indigestible NDF fraction of 40.89% (CV =6.28%), that affected the dry matter degradation, have been observed value of 61.9% (CV = 4.77%). The estimative of the kinetic parameters by in situ technique was a good predictor of the nutritive value of the feeds evaluated.

Key Words: Degradation Rate, Indigestible NDF, Kinetic Parameters

T214 Effect of freeze drying versus oven drying on dry matter and starch digestibility of corn mutants with Oh43 inbred line background harvested at four growth stages. D. Ngonyamo-Majee¹, R. D. Shaver¹, D. Sapienza^{*2}, J. G. Coors³, J. G. Lauer³, and C. Venhaus², ¹Dairy Science Dept., University of Wisconsin, Madison, ²Pioneer Hi-Bred Int'l Inc., Johnston, IA, ³Agronomy Dept., University of Wisconsin, Madison.

Combined effects of single gene mutations, harvest stage (HS), and sample drying technique (DT) on the proportion of corn dry matter (DM) and starch digested ruminally and post-ruminally was evaluated using four near-isogenic lines in Oh43 inbred background (*fl*, *o2*, *su2* genes and straight OH43). The inbred lines were grown at University of Wisconsin, West Madison Research Station during the summer of 2002 in 3*5m row plots in a randomized complete block design with three replications. The inbreds were harvested at four HS (HS1=1/2 milk-line; HS2=5d post HS1; HS3=10d post HS1; and HS4=black layer stage or about 15d post HS1) and samples were split in two for oven drying (OD) at 40°C for 72 hrs and freeze drying (FD) treatments. Dried kernels were ground through a Wiley mill (6 mm screen, Arthur H. Thomas, Philadelphia, PA) for measurement of ruminal in situ dry matter (RDMD) and starch digestion (RSTARCD) at 0 and 14-hr incubation (1.5g/bag x 8 replicates per time point per steer in 5x5cm bags of 50µm pore size) using two steers. Residue from the 14-hr bags proceeded

to an 8-hr enzymatic post-ruminal digestion (Pioneer Hi-bred Int.), from which the post-ruminal residue was oven dried at 62°C for 24 hours and DM and starch contents determined. Inbred by DT interactions were observed for zero-bag losses ($p<0.0001$), RDMD ($p=0.0024$) and total DMD ($p=0.0089$). Harvest stage by DT interactions were observed for bag losses ($p<0.0001$), RDMD ($p=0.0031$) and total DMD ($p=0.0551$). Inbred by HS interactions were observed for bag losses only ($p=0.0208$). Freeze dried samples were more highly degraded than OD samples, especially for earlier harvested samples (HS1 and HS2), 0-hr losses, and RDMD versus TDMD. The ranking of inbreds for decreasing RDMD and TDMD was *o2*(Oh43)>*fl2*(Oh43)=*su2*(Oh43)>Oh43. When compared to FD, OD corn samples at 40°C reduced 0-hour DM loss through bag pores, particularly for early harvested samples.

Key Words: Corn Mutants, Starch Digestibility, Drying Technique

T215 Effect of kernel vitreousness on ruminal and total tract dry matter digestibility of diverse corn germplasm sources. D. Ngonyamo-Majee¹, R. D. Shaver^{*1}, J. G. Coors², D. Sapienza³, J. G. Lauer², and C. Venhaus³, ¹Dairy Science Dept., University of Wisconsin, Madison, ²Agronomy Dept., University of Wisconsin, Madison, ³Pioneer Hi-Bred Int'l Inc., Johnston, IA.

Correlations between kernel vitreousness (V) and ruminal (RDMD) and total tract dry matter digestibility (TDMD) were evaluated using 33 germplasm sources selected for future development of corn hybrids for starch digestibility. Germplasm sources included 17 lines from the Germplasm Enhancement of Maize project at Iowa State University, 6 flint lines from North Carolina State University and the International Maize and Wheat Improvement Center (CIMMYT), 6 near-isogenic inbreds of Oh43 carrying *o2*, *fl2*, *su2*, *ae1*, *h1* and *wx1su2* alleles affecting endosperm composition, an experimental breeding population (WQS C2), and three check inbreds (B73, Oh43, and W64A). Inbreds were harvested at two growth stages; 1/2 milk-line (ML) and black-layer (BL). Kernels from middle portion of ears were oven dried at 40°C for 72 hrs and ground through a Wiley mill (6 mm screen Arthur H. Thomas, Philadelphia, PA) for measurement of in-situ RDMD after 0 and 14 hr of incubation (1.5g/bag x 8 replicates per time point per steer in 5x5cm bags of 50µm pore size) using two steers. Residue from the 14-hr bags proceeded to an 8-hr in vitro enzymatic post-ruminal digestion (Pioneer Hi-bred Int.) from which the residue was oven dried at 62°C for 24 hours and DM content determined. Inbred by harvesting stage interactions were observed for 0-hr disappearance ($P<0.0001$) and TDMD ($P=0.0066$). Vitreousness of the 33 germplasm, determined by near infrared reflectance spectroscopy (NIRS) in a previous study, was better correlated to DMD at BL stage ($R^2=0.66$; 0.52; and 0.36) than ML ($R^2=0.38$; 0.44; and 0.14) for RDMD, 0-hr disappearance and TDMD, respectively. Inbreds *su2*(Oh43) and *wx1su2*(Oh43) were outliers with high %V and also high RDMD. Their removal from the regression improved R^2 values for both harvesting stages (BL= 0.81, 0.54, and 0.46; ML= 0.72, 0.50 and 0.34) for RDMD, 0-hr disappearance and TDMD, respectively. This suggests that endosperm characteristics other than V may affect corn digestibility.

Key Words: Corn, Digestion, Vitreousness

T216 Fines in steam-flaked corn samples disrupt the relationship between flake density and gelatinized starch content. D. R. Brown^{*1} and M. K. Meilahn², ¹Agland, Inc., Eaton, CO, ²Weld Laboratories, Inc., Greeley, CO.

The relationship between flake density and gelatinized starch has been well documented under research conditions but not under field conditions. The objective of this study was to evaluate the relationship between flake density and starch gelatinization in steam-flaked corn samples received from feed manufacturers across a wide geographic region. Flake density, gelatinized starch, and fines content were determined in approximately 300 flaked corn samples from mainly the western United States and some from central Canada. Samples were received by a commercial laboratory, split, dried at 100°C for 24 h or 65°C for 48 h, and ground through a 2 mm screen using a Wiley mill and then ground to pass a 1mm screen using a udy cyclone mill. Gelatinized starch was measured using the method described by Meilahn and Brown (2003). Intact retention samples were grouped into three categories based on their fines content. Category one samples contained low levels of fines, category two had moderate levels, and category three had high levels of fines. Each fines-category contained flakes weighing from approximately

23 to 35 lb/bu. Data were analyzed using the regression and GLM procedures of Minitab (1996). Flake density across all samples averaged 31 ± 7.3 lb/bu and ranged from 22 to 42 lb/bu. The level of gelatinized starch across all samples averaged 660 ± 22 lb/ton of flaked grain (DMb) and ranged from 300 to 1100 lb/ton of flaked grain (DMb). Flake density increased slightly with increasing fines score ($P < 0.001$) but was highly variable ($r^2 = 6.2\%$). Gelatinized starch content decreased with increasing flake density and fines score ($P < 0.001$) but was highly variable ($r^2 = 15.5\%$). The regression equation was: gelatinized starch lb/ton of flaked grain (DMb) = $1145 - 61.3(\text{fines score}) - 11.9(\text{flake density})$. Fines score accounted for 65% and flake density 35% of the explained variation in gelatinized starch. These findings indicate the use of flake density as a reliable proxy for starch gelatinization (and availability) or digestion is erroneous when using samples derived from feed manufacturers across a wide geographic area.

Key Words: Steam-Flaked Corn, Gelatinization, Starch Availability

T217 Effect of dietary forage source and crude protein level on in vitro microbial protein synthesis and ruminal fermentation. J. J. Olmos Colmenero*¹ and G. A. Broderick², ¹University of Wisconsin, Madison, ²U.S. Dairy Forage Research Center, Madison, WI.

Optimizing microbial protein synthesis in the rumen is crucial because it represents more than half of the NAN that reaches the duodenum in dairy cows. A 3x5 factorial arrangement of 15 diets, three forage sources [alfalfa silage (AS); 50% alfalfa silage:50% corn silage (AS:CS); corn silage (CS)] at each of 5 CP levels (13.5, 15.0, 16.5, 18.0, and 19.5% of DM) were tested in two identical ruminal in vitro incubations. Diets contained (% of DM) 50% forage and 50% concentrate. High moisture corn was replaced with solvent soybean meal to increase CP. The marker used for microbial NAN synthesis (MNS) was ¹⁵N. After 4 and 8 h of incubation, samples were taken to obtain total solid pellets, supernatants, and isolated bacterial pellets. Supernatants were analyzed for NH₃, total AA, and VFA. Total solid and bacterial pellets were analyzed for DM, total N and ¹⁵N to estimate true dry matter digestibility (TDMD) and net MNS (i.e., blank corrected). Concentration of total AA, acetate, and total VFA were higher for AS and AS:CS compared with CS. However, propionate concentration and TDMD were higher on AS:CS than on AS and CS. Net MNS was higher on CS than on AS and AS:CS. Levels of dietary CP affected only NH₃ and total AA concentrations. As expected, NH₃ and total AA increased with dietary CP content. Under the conditions of this study CS was more effective for stimulating net MNS than AS and AS:CS; CP level had no effect on net MNS.

Item	Forage				SE	P>F	
	AS	AS:CS	CS	CP, % of DM			
NH ₃ , mM	1.90	1.85	1.98	0.04	0.06

T218 Forage mixtures to increase N-use efficiency by lactating dairy cows. R. J. Dewhurst*, L. J. Harris, and R. T. Evans, Institute of Grassland and Environmental Research, Aberystwyth, UK.

Earlier studies with white clover silage (WCS) showed increased milk production in comparison with grass silage (GS) and suggested that this may be related to high intake characteristics and/or high rumen passage rates. WCS is a high-protein forage crop (30% CP) and possible improvements in N-use efficiency that relate to inherent properties of WCS could only be achieved using mixtures with complementary low-protein forages- such as corn silage (CS). Eight multiparous Holsteins (initially in month 3 of lactation; initial BW = 640 kg) were used in a N partitioning study with three 4-wk periods. Total collections of milk, urine and feces were made in the final 6 d of each period. All cows received 8 kg/d of a standard dairy concentrate (19.9% CP in DM) and had *ad libitum* access to one of 4 forage treatments: GS, GS/CS (60/40 on a DM basis), WCS/CS (20/80 on a DM basis), and WCS/CS (40/60 on a DM basis). Diet CP contents were 18.6, 16.9, 15.2, and 17.5 % of DM respectively. WCS/CS diets led to increased DM intake (16.6, 18.1, 21.8, and 21.8 kg/d respectively; SE = 0.38; $P < 0.001$), milk yield (30.1, 30.3, 32.5, 31.7 kg/d respectively; SE = 0.50; $P < 0.05$) and milk protein % (3.03, 3.09, 3.17, and 3.25 % respectively; SE = 0.037; $P < 0.01$). Milk fat % was unaffected (mean = 4.20%). Urine output was reduced for the diets with lower N content (32.5, 26.2, 20.4, and 23.7 kg/d respectively; SE = 0.51; $P < 0.001$). Urinary N output decreased (177, 136, 118, and 146 g/d respectively; SE = 9.0; $P < 0.001$), whilst milk N yields increased (141, 145, 160, and 161 g/d respectively; SE = 2.8; $P < 0.001$). This led to a 41% increase in milk N output per g of urinary N. Urinary excretion of purine derivatives (allantoin plus uric acid; an index of rumen microbial yield) was highest for GS (37.2, 28.5, 25.2, and 30.2 mmol per kg DM intake respectively; SE = 2.01; $P < 0.001$). Consequently, it seems more likely that the improvements in N-use efficiency are the result of improving the balance of energy and protein supply to the cow than of increased rumen efficiency.

Key Words: Dairy Cow, Nitrogen Efficiency, Forage

T219 Impact of rumen protected lysine and methionine sources on yield of milk and milk components: a statistical survey of published literature. L. M. Rode*¹ and M. Vazquez-Anon², ¹Sage Biosciences Inc., Lethbridge, AB, Canada, ²Novus International, Inc., St. Charles, MO.

It is generally recognized that providing ruminally protected lysine (RPLys) and methionine (RPMet) in optimal amounts and ratios will maximize milk protein yield (NRC 2001). It is less clear what impact RPLys and RPMet supplementation has on milk volume and milk fat yield. A database of published literature was established to investigate the impact of rumen protected Lys and Met sources on yield of milk and milk components. Information from 66 diets was obtained from published literature in which RPLys (n=10), RPMet (n=21), and RPLys plus RPMet (n=35) were fed to lactating dairy cows. Results were compiled for milk yield, milk fat and protein yield and percent and expressed as absolute amounts or as a percent response relative to controls. Results were ranked according to the milk protein yield response, as a percent of controls. Studies were subdivided into two groups: lower 50 percentile (No/Low response; LOW) and upper 50 percentile (High response; HIGH). Percentage response for yields of milk, protein and fat and percentages of protein and fat were respectively 2.9 ± 2.4 , 3.8 ± 5.1 , -1.4 ± 3.8 , 0.4 ± 3.6 , -4.2 ± 4.4 for RPLys; -0.2 ± 3.0 , 2.2 ± 3.3 , 1.9 ± 4.1 , 2.6 ± 2.6 , 2.3 ± 3.3 for RPMet and 2.1 ± 4.3 , 4.8 ± 5.5 , 4.5 ± 6.9 , 2.6 ± 2.0 , 2.3 ± 3.5 for RPLys plus RPMet. For HIGH responses, RPLys increased milk and protein yield by 4.6 ± 1.2 and 7.7 ± 4.2 percent and decreased milk fat percentage by 6.6 ± 4.5 percent whereas RPMet increased milk yield, protein yield and milk fat percentage by 1.9 ± 1.9 , 4.9 ± 2.0 and 2.0 ± 2.5 respectively. Supplementing with RPLys tends to increase yield of milk and milk protein while decreasing yield and percentage of milk fat. Supplementing with RPMet tends to increase milk and protein yield as well as milk fat percentage. Results for RPLys plus RPMet were similar to RPMet alone.

Key Words: Lysine, Methionine, Rumen Bypass

T220 Effects of DL-methionine and lysine HCl on fermentation in vitro. T. W. Braud*, H. G. Bateman, II, C. C. Williams, and D. T. Gantt, *LSU AgCenter, Baton Rouge, LA.*

Previous experiments from our laboratory indicated that supplemental DL-met and lys- HCl enhanced ruminal fermentation in vitro. However, treatments in the previous study were not isonitrogenous. Therefore an experiment was conducted to determine if the enhancement was due to the added amino acids or the presence of a readily fermentable N source. Single effluent fermentors were used to determine if supplying DL-met and lys-HCl in the substrate would enhance microbial fermentation. Corn silage was dried at 55 C and ground to pass a 2 mm screen and used as the basal substrate for the fermentations. Treatments were a 2 x 2 factorial arrangement of DL-met (0 or 0.5% of DM) and lys-HCL (0 or 1% of DM). Treatments were made isonitrogenous by adding L-gln. Fermentations were conducted over a 5 d period with the final day used for sampling. Fermentor pH was maintained at 6.0 or greater by infusion of equal volumes of 0.5 M NaH₂PO₄ and NaHCO₃. Due to formulation errors, added lys resulted in decreased (P < 0.05) N, increased (P < 0.01), DM, and a tendency (P < 0.1) for decreased OM in the treatments. Total volume of effluent was not affected by treatment. Concentrations of total VFA were not affected by treatment. The proportion of propionate tended (P < 0.1) to increase when lys was added but there was no effect on the ratio of acetate to propionate. There was an interaction of met and lys for the proportion of isobutyrate (P < 0.01). Adding lys without adding met decreased the proportion of isobutyrate while the proportion increased when lys and met were added. No other proportions of VFA were affected by treatments. Ammonia concentrations were decreased (P < 0.05) by added met but were not affected by lys. Free amino acid concentrations in the effluent tended (P < 0.1) to decrease when met was added but were not affected by lys. Peptide concentrations were not affected by treatment. These data indicate that adding DL-met and lys-HCl may enhance fermentation in vitro. However, the effects are small and may not elicit a response when translated to in vivo practices.

Key Words: Rumen, Amino Acid, Fermentation

T221 Determination of undegradability and ruminal effects of HMB, HMBi, and DL-MET in lactating cows. S. Noftsker*, N. R. St-Pierre, and J. L. Firkins, *The Ohio State University, Columbus.*

The effects of Met provided as HMB, HMBi, and dl-Met were examined. Eight cows were used in a replicated 4 X 4 Latin square design. Effects on milk composition and yield, N utilization, VFA, and protozoa were determined. Samples of omasal fluid were used to determine the amount of Met supplements passing out of the rumen. Treatments were: (1) no methionine (Control); (2) 2-hydroxy-4-methylthiobutanoic acid (HMB) (3) isopropyl HMB (HMBi); and (4) dl-methionine (dl-Met). The three supplemented diets were iso-Met. Dry matter intakes and milk yields were not different and averaged 20 kg/d and 37.7 kg/d, respectively. Milk protein concentration (2.91, 2.95, 3.02, 2.96%) and fat concentration (3.34, 3.12, 3.51, 3.69%) are reported here for control, HMB, HMBi, and dl-Met. Milk protein concentration was significantly increased with the HMBi treatment. Rumen VFA profile and NH₃ concentrations were similar. Addition of Met in all forms increased ruminal digestibility of OM and NDF over the control. Passage rates of small particles (0.071/h) and fluid (0.167/h) were not affected by treatment. Protozoa were increased numerically in the omasum by HMB and HMBi treatments. Proportion of omasal N from bacterial N was not different (0.64), and g of bacterial N flow were similar between treatments. The percentage of HMB that passed into the omasum was 5.3%. Only a small amount of HMBi was found as HMB in the omasum (2.3%).

Key Words: Dairy, Methionine, 2-hydroxy-4-methylthio Butanoic Acid

T222 Intravenous histidine infusion affects milk composition in lactating dairy cows. Y. H. Moon*², P. H. Luimes¹, L. E. Wright³, C. A. Toerien¹, and J. P. Cant¹, ¹*University of Guelph, Guelph, ON, Canada,* ²*RAIRC, Jinju National University, Jinju, Gyeong Nam, Korea,* ³*Elora Dairy Research Centre, Ariss, ON, Canada.*

Controlling milk composition nutritionally is a beneficial tool sought in many farming circumstances. The purpose of this study was to evaluate the potential of histidine to influence the production and composition

of milk in lactating dairy cows. Histidine was compared to methionine and lysine, and graded doses of histidine infusion were also evaluated. Forty-one multiparous (2.9 ± 0.5) Holstein cows (33 ± 1 DIM) were assigned by a randomized block design to one of six treatments. Cows were fed, ad libitum, a corn/alfalfa silage-based TMR containing 17.7% CP and 1.7 Mcal/kg NEL on a DM basis. Feed intake was recorded daily, and milk yield was recorded and sampled for analysis of composition twice per day. Treatments were saline (n = 7), 14.3 g/d methionine (n = 8), 45.4 g/d lysine (n = 8), 7.4 g/d histidine (n = 5), 14.7 g/d histidine (n = 8) and 29.4 g/d histidine (n = 5) and were infused into a jugular vein. Infusion rates for methionine, lysine and histidine (14.7 g/d) were designed to be equivalent to 500 g/d milk protein. Solutions were infused continuously for 4 d by peristaltic pump. The day before infusion served as a covariate period, and data from the last four days of infusion were analyzed with the Mixed procedure of SAS. Treatments were compared to control using the Dunnett-Hsu adjustment for differences between least squares means. Linear effects of histidine dose were analyzed by orthogonal contrast. Milk fat, protein and lactose contents were affected by treatment (P < 0.05). Histidine (7.4 g/d) resulted in lower lactose content compared to control (4.76 ± 0.02 vs. 4.83 ± 0.02%). Milk protein yield and the protein to fat ratio were affected by treatment (P < 0.05). Milk protein yield was 1,195 ± 38.1 g/d for the methionine treatment compared to 1,108 ± 39.5 g/d (P = 0.08) on the control. Increasing level of histidine infusion resulted in a linear increase in milk protein content, yield and ratio to milk fat (P < 0.05).

Key Words: Amino Acid, Jugular Infusion, Early Lactation

T223 Use of milk ammonia nitrogen as an indicator of rumen protein degradation in dairy cows. A. B. Peterson* and R. A. Kohn, *University of Maryland, College Park.*

The prediction of rumen protein degradation in lactating dairy cow rations is critical in diet formulation and to prevent overfeeding of nitrogen (N). Milk ammonia N (NH₄-N) may be a reliable indicator of rumen protein degradation. NRC 1989 and 2001 reported two different methods to predict RDP and RUP dietary content, intake and requirement. In 1989, NRC reported the RUP% in commonly used feedstuffs that can be used to predict the overall RDP and RUP content of the ration. In 2001, NRC used a systematic set of equations including digestion and passage rates as well as protein fractions (A, B, and C) to determine the same. The objective of this study was to compare different indicators of ruminal protein degradation: milk NH₄-N, soluble protein content of the diet and NRC 1989 and NRC 2001 predictions. Detailed herd and ration information as well as a TMR and bulk tank samples were collected from eight farms across Maryland repeatedly over two years (n=17; milk yield = 27.0 ± 5 kg). Milk NH₄-N averaged 17.8 ppm (± 0.8 ppm) and there was little variation across farms ranging from 16.5 to 19.1 ppm. Milk NH₄-N was correlated with the analyzed CP% of the diet (P < 0.05; R² = 0.35) which ranged from 14.9 to 25.3% (average = 18.1 ± 2.4%). Milk urea nitrogen (12.1 ± 2.1 mg/dl) was also correlated with analyzed CP% of the ration (P < 0.05), but milk NH₄-N and MUN were not correlated (P > 0.10). Predicted intakes of both RDP (2000 ± 320g) and RUP (1270 ± 230g) were not different using either the 1989 and 2001 NRC models (P > 0.10). Milk NH₄-N was not correlated with predicted dietary RDP and RUP content, intake, or balance as determined by either NRC 1989 or 2001 (P > 0.10). Additionally, milk NH₄-N was not correlated with measured dietary soluble protein (1170 ± 180g; P > 0.10). With the current data, milk NH₄-N was not correlated with predicted rumen protein degradation or level of excess RDP using 1989 or 2001 NRC models, but was correlated with dietary CP content.

Key Words: Milk Ammonia, Rumen Protein Degradation, Milk Urea Nitrogen

T224 Ruminal degradability and intestinal digestibility of treated soybean meal products. S. I. Borucki Castro*¹, H. Lapierre², L. E. Phillip¹, P. W. Jardon³, and R. Berthiaume², ¹*Animal Science - McGill University, Ste-Anne-de-Bellevue, QC, Canada,* ²*Dairy and Swine Research and Development Centre - Agriculture and Agri-Food Canada, Lennoxville, QC, Canada,* ³*West Central Soy, Ralston, IA.*

Four Holstein cows fitted with rumen and duodenal cannulae were used to determine rumen degradability and intestinal digestibility of physically and chemically treated soybean meal (SBM): solvent extracted

SBM (SE), expeller SBM (EP) -SoyPlus[®], lignosulfonate treated SBM (LS) -Surepro[™], heat treated SBM with soy hulls (HS) -Aminoplus[®] and chemically treated SBM (CT) -Top Soy[™]. Samples were milled through a 2 mm screen and 4 g (12.3 mg/cm²) placed in N-free polyester bags (pore size 50 μ m) according to a standardized procedure (NRC 2001). Duplicate bags of each feed were hooked to a stainless steel weight, soaked in 39 °C water for 20 min, and then inserted in the ventral sac of the rumen, for 48, 24, 16, 8, 4, 2 and 0 h. Four additional bags of each feed were incubated for 16 h to estimate intestinal digestibility *in situ*, using the mobile bag technique (Hvelplund and Weisbjerg 2000). Degradation kinetics were calculated with 6% of passage rate (NRC 2001). The presence of a lag phase was detected for ruminal DM degradability of LS, HS and CT and also for ruminal CP degradability of EP, LS, HS and CT. Effective degradability of DM was higher ($P \leq 0.001$) for SE (73.5%) compared to EP (61.0%), LS (62.9%), CT (63.1%) and HS (61.7%), while effective degradability of CP was higher ($P \leq 0.01$) for SE (67.8%) compared to EP (54.7%), LS (53.3%), CT (53.9%) and HS (52.6%). Intestinal disappearance of DM was higher ($P \leq 0.05$) for SE (91.4%) compared to EP (89.5%) but lower ($P \leq 0.05$) compared to LS (93.3%) and CT (96.3%) and not different compared to HS (91.8%). Intestinal disappearance of CP was lower ($P \leq 0.01$) for SE (96.6%) compared to LS (98.7%), CT (99.0%) and HS (98.2%) but not different compared to EP (97.5%). Physical or chemical treatment of SBM decreased rumen degradability but did not negatively affect intestinal digestibility of protein. Therefore these treatments would increase RUP from SBM with the potential to enhance the supply of bioavailable amino acids in the small intestine.

Key Words: Soybean Meal, Rumen Degradability, Intestinal Digestibility

T225 Effects of ruminally-protected L-carnitine intake on plasma L-carnitine, glucose, urea, and ammonia in sheep undergoing an ammonia challenge. D. K. Walker^{*1}, B. D. Lambert^{1,2}, H. B. Rathburn³, and J. C. Woodworth⁴, ¹Department of Animal Science, Tarleton State University, Stephenville, TX, ²Texas Agriculture Experiment Station, Stephenville, TX, ³Department of Biology, Tarleton State University, Stephenville, TX, ⁴Lonza Inc., Fairlawn, NJ.

Two experiments were conducted to evaluate the effect of dietary ruminally-protected L-carnitine (RPLC) on plasma L-carnitine (LC) concentrations and ammonia toxicity in sheep. In Exp. 1, wether lambs ($n=20$; 44.3 ± 0.98 kg) were randomly assigned to one of five treatments (0.25, 1.00, 2.50, 5.00, and 10.00 g/day) of dietary RPLC. Sheep were fed 2% of BW of a complete ration and allowed 20 d for adaptation. On d 20 of the experiment, plasma was obtained at 0, 120, and 240 min after RPLC feeding for LC analysis. Plasma LC concentrations increased ($P < 0.01$) from Day 0 (baseline) to Day 20 for all levels of RPLC treatment, however, no differences were observed due to level of RPLC or time. Plasma LC concentrations were 27.05 and 57.83 μ mol/L for baseline and pooled RPLC treated sheep, respectively. In Exp. 2, wether lambs ($n=20$; 36 ± 1.2 kg) were randomly assigned to one of four treatments (0, 0.125, 1.06, 2.0 g/day) of RPLC to evaluate the protective effects of dietary RPLC on sheep undergoing an ammonia challenge. Sheep were fed and adapted as in Exp. 1. On d 20 of the experiment, sheep received 300 mg/kg of BW of urea orally as an ammonia challenge. Plasma was collected at 0, 15, 30, 60, 90, 180, 240, and 360 min after feeding for metabolite analysis. Plasma LC concentrations increased with treatment relative to control ($P < 0.01$). Plasma LC concentrations were 35.7, 44.2, 60.5, and 65.7 μ mol/L for the 0, 0.125, 1.06, 2.0 g/day treatments, respectively. Levels of RPLC tended to have different effects on plasma ammonia across time (time treatment; $P=0.10$). Plasma glucose and urea were not affected by treatment. We conclude that feeding at least 1.0 g of RPLC once daily for 20 d increased circulating plasma LC concentrations in sheep. Additionally, this level of RPLC tended to reduce plasma ammonia concentrations at some time points during an ammonia challenge.

Key Words: Ruminant, Nitrogen, Toxicity

T226 Influence of slow-release urea on nitrogen flux in steers. C. C. Taylor^{*1}, S. E. Kitts¹, N. B. Kristensen¹, K. R. McLeod¹, D. E. Axe², and D. L. Harmon¹, ¹University of Kentucky, Lexington, ²IMC Feed Ingredients, Lake Forrest, IL.

Effects of urea or slow-release urea (SRU) on gut nutrient absorption and liver metabolism were investigated. Four steers (319 ± 5 kg body weight)

were surgically prepared with ruminal cannulas and hepatic portal, hepatic venous, mesenteric venous, and mesenteric arterial catheters. The basal diet was 90% corn silage and 10% ground corn-based supplement offered once daily at 1.5% of body weight (dry matter basis). Supplemental dietary nitrogen was provided by urea or SRU (mean 92 g/head) top-dressed daily onto the basal diet. Steers were fed dietary treatments for 3 weeks prior to sampling. On the day of sampling, p-aminohippuric acid (250 mM, pH 7.4) was infused continuously into the mesenteric vein catheter (approximately 1.3 mL/min) starting 1 h prior to feeding and continuing throughout the sampling period. After 1 h of infusion, blood was sampled to obtain a time zero sample. Each blood sampling consisted of simultaneously collecting arterial, portal and hepatic blood samples (10 mL each) into heparinized syringes. Immediately following the time zero sample, steers were offered the basal diet without the top-dressed urea treatments and their daily aliquot of urea or SRU was dosed into the rumen and mixed thoroughly. Blood samples were collected 0.5, 1, 2, 4, 6, 8, and 10 h post-dosing. SRU reduced mean ruminal ammonia concentration by 72% compared to urea (3.6 versus 12.9 mM; $P < 0.03$). SRU tended to decrease net portal flux of ammonia ($P < 0.08$) compared to urea. A treatment by time interaction was detected for hepatic ammonia uptake ($P < 0.02$); hepatic ammonia uptake increased rapidly (within 0.5 h) with intraruminal dosing of urea compared to SRU. These results demonstrate that SRU possesses the ability to release N slowly in the ruminant. Slow-release urea can reduce the rate of ruminal urea hydrolysis and may increase the synchrony of N release with carbohydrate digestion.

Key Words: Urea, Non-Protein Nitrogen, Ruminants

T227 Utilization of ammonia-N by ruminal epithelial and duodenal mucosal cells isolated from growing sheep. M. Oba^{*1}, R. L. Baldwin, VI², S. L. Owens¹, and B. J. Bequette¹, ¹Department of Animal and Avian Sciences, University of Maryland, College Park, ²Bovine Functional Genomics Laboratory, Animal and Natural Resources Institute, USDA-ARS, Beltsville, MD.

To determine the capability of ruminant gut tissues to detoxify ammonia-N, ruminal epithelial cells (REC) and duodenal mucosal cells (DMC) were isolated from growing Texel-Polypay ram lambs ($n=4$) fed a mixed forage-concentrate diet. Immediately after isolation, primary cells were incubated for 60 min with glucose (1mM), glutamate (1mM), [¹⁵N]ammonium chloride (0, 5, 10, 20, or 40 mM), and one of four combinations of substrate to support urea synthesis (1 mM each; control (no additional substrates), N-carbamoylglutamate (NCG), NCG + ornithine, NCG + ornithine + aspartate) in a 5 x 4 factorial arrangement of treatments. Incorporation of ammonia-¹⁵N into Ala, citrulline, Arg, and urea (nmol / 10⁶ cells / 60 min) was determined by gas chromatography-mass spectrometry. Utilization of ammonia-N for net Ala synthesis increased quadratically from 0.73 to 1.35 nmol for DMC ($P < 0.001$) and from 0.28 to 0.69 nmol for REC ($P < 0.001$) as the ammonia concentration increased from 5 to 40 mM, regardless of substrate treatments. For both cell types, ammonia-N incorporation into Ala was lower in the presence of NCG compared to control (1.18 vs. 1.39 nmol for DMC, $P < 0.001$; 0.52 vs. 0.59 nmol for REC, $P < 0.05$). For REC, ammonia-N was not incorporated into citrulline, Arg and urea, whereas for DMC ammonia-N was incorporated into citrulline but not Arg and urea. However, ammonia-N utilization for net citrulline synthesis by DMC decreased linearly from 0.68 to 0.27 nmol ($P < 0.001$) as ammonia concentrations increased from 5 to 40 mM. Thus, in ruminant gut tissues, Ala synthesis is probably a more significant disposal pathway to detoxify ammonia-N at high ammonia concentrations compared with disposal via the ornithine-urea cycle although DMC also possess a capability to incorporate ammonia-N into citrulline.

Key Words: Ruminal Epithelial Cells, Duodenal Mucosal Cells, Ammonia detoxification

T228 An improved analytical method for the determination of urea recycling parameters. J. C. Marini^{*}, University of Illinois, Urbana.

Urea metabolism has generated considerable interest in ruminant nutrition because of the ability of rumen microorganisms to produce amino acids from urea-N, which then can meet the needs of the host. More recently, interest has also been focused on reducing N excretion from which urea is the main component. Use of ¹⁵N¹⁵N-urea allows for the determination not only of urea production and recycling, but of the urea

recycled that returns to the ornithine cycle. Because of the large size of cattle and the cost of labeled urea, the targeted enrichments can only be determined by isotope ratio mass spectrometry (IRMS). Unfortunately, sample preparation for the original analytical method (Sarraseca et al., 1998, Br. J. Nutr. 79:79-88) was very laborious and time consuming. Furthermore, sample admission into the dual inlet IRMS was done manually. We have developed a fast and convenient method of sample preparation, with minimal supervision, with a fully automated sample admission into the IRMS. In brief, samples (6 mM urea, 2 mL) were placed into Exetainer tubes (Labco, UK) and helium was bubbled to displace dissolved air. Samples were then frozen and 0.4 mL of LiOBr was added (and frozen on top). The Exetainer screw cap was tightened and the headspace pumped out by a high vacuum system. Helium was then admitted into the Exetainers to achieve positive pressure. The samples were then incubated in a heat block at 65 °C for 20 min, where the $^{15}\text{N}^{15}\text{N}$ and $^{15}\text{N}^{14}\text{N}$ -urea reacted with LiOBR to yield ^{30}N and ^{29}N gas, respectively. The N gas generated was admitted into a PDZ Europa 20/20 continuous flow IRMS with a Gilson autosampler. The $^{15}\text{N}^{15}\text{N}$ -urea standard curve generated (range 0 to 0.32 atom % excess, ape) was $Y = 1.0009 (0.012) X + 0.0006 (0.002)$, $R^2 = 0.998$ (slope not different than 1, intercept no different than 0; $P < 0.05$), where Y was the measured and X the known enrichment in ape. The occurrence of the nonmonomolecular degradation of urea was $5.5 \pm 0.2\%$. This method of sample preparation for automated continuous flow IRMS is fast, convenient, and allows for a large sample throughput (16 samples/h).

Key Words: Urea Recycling, ^{15}N , N Metabolism

T229 Use of Synchrotron-based FTIR microspectroscopy to reveal chemical features of feather protein secondary structure and its relation to protein value. P. Yu*¹, J. J. McKinnon¹, C. R. Christensen^{2,3}, and D. A. Christensen¹, ¹College of Agriculture, University of Saskatchewan, Saskatoon, SK, Canada, ²Canadian Light Source, Saskatoon, SK, Canada, ³Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, SK, Canada.

Protein secondary structures include α -helix and β -sheet. The relative percentage of the two influences protein value. A high percentage of β -sheet may reduce the access of gastrointestinal digestive enzymes to the protein. Reduced accessibility results in poor digestibility and as a result, low protein value. Feather is widely available as a potential protein supplement. It is high in protein (84%), but the digestibility is very low (5%). The objective of this study was to use synchrotron-based Fourier transform infrared (S-FTIR) microspectroscopy to reveal chemical features of feather protein secondary structure within amide I at ultra-spatial resolution (pixel size: 1010 μm), in comparison with other commonly used sources of protein barley, oat and wheat. The experiment was performed at U2B station of the Albert Einstein Centre for Synchrotron Biosciences at the National Synchrotron Light Source in Brookhaven National Laboratory, US Dept of Energy (NSLS-BNL, New York). The results indicate that ultra-spatially resolved imaging of feather protein secondary structure by stepping in pixel sized increments (10 μm) was possible. Using synchrotron FTIR microspectroscopy one can distinguish between secondary structures of protein amide I among the different feed protein sources. The results show that the secondary structure of feather protein differed from other feed protein sources in terms of the line-shape and position of amide I. The feather protein amide I band showed a peak at ca. 1630 cm^{-1} , which is consistent with absorption peak of β -sheet protein amide I. However, the other feed protein sources showed a peak at ca. 1650 cm^{-1} , which is consistent with absorption peak of α -helix protein amide I. These results indicated that the secondary structure of feather protein contains a higher percentage of β -sheet. Such a difference in the protein secondary structure likely explains the poor biological value of feather protein.

Key Words: Synchrotron Infrared Microspectroscopy, Protein Secondary Structure, Amide I (α -helix, β -Sheet)

T230 Basolateral transport of neutral amino acids in enterocytes is mediated via Systems A, ASC, L, asc, and y^{+L} . J. Knapp*, University of Vermont, Burlington.

Enterocytes take up substantial quantities of amino acids (AA) from the systemic circulation via transporters located on the basolateral surface. Immortalized bovine intestinal cell lines VIE-1 and VIE-5 were used to determine the activities and kinetic properties of neutral

AA transport systems on the basolateral cell surface using the Transwell system. Differences in transport activity between cell lines were tested using Student's t test and kinetic parameter estimates were obtained from Eadie-Hofstee plots. Leucine (Leu) influx occurs through Na⁺-dependent (15-40%) and Na⁺-independent mechanisms (60-85%) in both cell lines. Na⁺-independent Leu influx was inhibited 20 and 35% by 10mM 2-aminobicyclo-heptane-2-carboxylic acid (BCH) in VIE-1 and VIE-5 cells, respectively, indicating that System L has a significant role in basolateral Leu transport. System y^{+L} that is not inhibited by BCH would also be expected to contribute significantly to Na⁺-independent Leu influx, while System asc would not because of substrate specificity. VIE-5 cells displayed more total Leu transport activity than VIE-1 cells. In contrast, VIE-1 cells exhibited more total alanine (Ala) influx activity than VIE-5 cells, and both lines were able to transport significantly more Ala than Leu at the same concentrations. Active Ala transport occurs through Na⁺-dependent (17-37%) and Na⁺-independent mechanisms (63-83%) in both cell lines. Na⁺-independent Ala transport would be a function of Systems L, asc, and y^{+L} . α -Methylaminoisobutyric acid was not able to inhibit all Na⁺-dependent Ala transport in either cell line, suggesting that there is another Na⁺-dependent transporter in addition to System A on the basolateral surface, most likely System ASC. While Systems A and L have been reported to be the major AA transporters on the basolateral surface of enterocytes, these results demonstrate the existence of other systems (ASC, asc, and y^{+L}) that are capable of transporting significant amounts of both small and large neutral AA.

Key Words: Amino Acid Transport, Intestine

T231 Investigation of the site of absorption and metabolism of HMBi and HMB in sheep. P. Nozière¹, C. Richard², B. Graulet², D. Durand¹, D. Remond¹, and J.C. Robert*², ¹INRA URH, Clermont-Ferrand Theix, Fance, ²ADISSEO France SAS, Briand, Antony, France.

The aim of this trial was to investigate the site of absorption of HMBi (2-hydroxy - 4 (methyl thio)-butanoic acid isopropyl ester) and HMB, and the site of hydrolysis of HMBi to HMB. Four sheep, adult castrated, Texel breed were assigned in a cross over design with 2 treatments (HMBi or HMB) and 2 periods. The animals were fitted with ruminal cannula, catheters on ruminal and portal veins, artery, and blood flow probes around the right ruminal artery and portal vein. Diet was hay and concentrate (70/30) given twice a day. Products were introduced intraruminally as a single dose (7.5 g methionine equivalent) just before the morning meal. Blood was collected at min. 0, 10, 20, 30, 50, 80, 120, 180 and 240 after introduction. Ruminal and portal net fluxes of HMBi, HMB, methionine, isopropanol and acetone were calculated from plasma concentrations and flows. For HMBi treatment, no HMBi was detected in the plasma at any site or time of blood collection but net appearance of both HMB and isopropanol were detected from the very start of blood collection and were maximum in the first hour after rumen introduction at both ruminal and portal drained viscera (PDV) levels. Net appearance of HMB across rumen and PDV wall were 5 times higher with HMBi vs. HMB. This indicates that HMBi is absorbed as HMBi and hydrolysed to HMB and isopropanol across the wall of the digestive tract and particularly across rumen wall. Arterial HMB and methionine peak values occurred at 20 and 180 min following introduction, respectively, and concentrations were 6 and 5 times higher with HMBi vs. HMB treatment. This was related to a higher entry rate of HMB with HMBi vs. HMB treatment Mean Area Under Curve of portal net flux (SD) = 2730 (864) vs. 588 (403) mg rather than methionine portal net flux which remained unchanged. This is coherent with higher methionine bioavailability of HMBi vs. HMB due to its higher absorption efficiency. This study contributes to better knowledge of the HMBi metabolism for methionine supply to the ruminant.

Key Words: Methionine, Ruminant, Bioavailability

T232 Relationship between body weight, loin Longissimus dorsi and backfat measurements, and body condition score in dry and lactating Holstein-Friesian dairy cows. G. Jaurena, J. M. Moorby*, W. J. Fisher, and D. W. R. Davies, Institute of Grassland and Environmental Research, Aberystwyth, UK.

Body condition score (BCS) is widely regarded as a measure of energy reserves, but it also relates to muscle mass. The lactation cycle of the dairy cow induces large changes in body fat and protein pools, which can be

monitored through loin backfat (BF) and Longissimus dorsi (LD) measurements. Data from two experiments (Exp) using Holstein-Friesian dairy cows ($n = 32$ and 40 respectively) were used to study the association of body weight (BW), BF and LD with BCS for the last 5 wk of the dry period (DP) and the first 8 wk of lactation. Loin and tail BCS were manually assessed (0-5 scale) and BF and LD were measured by ultrasound at the 5th lumbar process. The BCS data ranged from 1.2 to 3.0 units in the DP, and from about 1.1 to 3.1 units in lactation in both experiments. An autoregressive covariance structure to account for repeated measures within cows was used for data analysis by two models: BW, LD or BF = Exp + Per (DP or lactation) + BCS + Interactions + Cow + Measure within cow + Residuals (Model 1); and BCS = Exp + Per + LD + BF + Interactions + Cow + Measure within cow + Residuals (Model 2). Regressions of BW and LD on BCS (Model 1) found pre-to-post calving intercept differences ($P < 0.001$) of 43 kg BW and -3.3 mm LD, and slope coefficients of 35 (DP) and 21 (lactation) kg BW, and 5.8 mm LD per BCS unit. Regression of BF on BCS (Model 1) showed an Exp \times Per interaction ($P < 0.001$), with 0.4 mm BF (Exp 1; $P < 0.05$) and 2.0 mm BF (Exp 2; $P < 0.001$) per BCS unit. Regression of BCS on LD and BF (Model 2) showed intercepts $\neq 0$ ($P < 0.06$), and different ($P < 0.001$) between DP and lactation; BCS increased ($P < 0.001$) by 0.027 units/mm BF and 0.05 units/mm LD, but LD had a quadratic term -0.0004 ($P = 0.02$). It is concluded that at BCS lower than 3, LD contributes to BCS following a quadratic function, whereas BF increases BCS linearly. Each unit of BCS equated to about 35 and 20 kg BW for DP and lactation periods, 5.8 mm LD, and between 0.4 and 2.0 mm BF.

Key Words: Back Fat, Body Condition Score, *Longissimus dorsi*

T233 Predicting feed protein flow to the duodenum of lactating dairy cows. H. G. Bateman, II^{*1}, J. H. Clark², and M. R. Murphy², ¹LSU AgCenter, Baton Rouge, LA, ²University of Illinois, Urbana.

A data set constructed from research trials published between 1979 and 1998 was used to derive equations to adjust tabulated values for the rumen-undegradable protein (RUP) content of feeds and better predict flow of nonammonia-nonmicrobial N (NANMN) to the small intestine of lactating dairy cows. The data set contained 150 treatment means from 35 trials. Both linear and nonlinear forms of equations were considered for making adjustments. Iterative processes were used to estimate equation parameters. A logistic equation was developed and considered optimal for adjustment of tabulated RUP values. The equation is a function of the DMI and includes terms for tabulated RUP and NPN contents of the feeds. The equation eliminated both linear and mean bias from the prediction of NANMN flow to the duodenum and maintained the apparent RUP values of the feeds within the biologically valid range of zero to 100% of the CP. The equation had a standard error of prediction (SEY) of 82.6 g NANMN/d. An independent data set was constructed from trials published between 1998 and 2003 and used to evaluate the equation. The evaluation data set contained 51 treatment means from 12 research trials. The predicted flows of NANMN did not differ from measured flows ($P > 0.8$). The SEY for the evaluation data set was 99.1 g NANMN/d and the mean prediction error was 179 g/d. Analysis of the errors of prediction revealed that 94.9% of error was attributable to random variation with 5.1% correctable through a linear adjustment and only 0.02% was associated with errors in predicting the mean flow of NANMN to the duodenum. The equation developed was superior to tabulated values for RUP in predicting flow of NANMN to the duodenum of lactating dairy cows. As data become available that quantify the effects of factors other than DMI on the apparent RUP content of feeds, they should be incorporated into an adjustment equation to better predict flow of NANMN to the duodenum.

Key Words: Dairy, Rumen-Undegradable Protein, Prediction

T234 Prepro-ghrelin mRNA in the digestive tract of undernourished pregnant ewes. H.-C. Han^{*}, K. J. Austin, B. W. Hess, S. P. Ford, and T. R. Hansen, *Department of Animal Science, University of Wyoming, Laramie.*

Ghrelin, a peptide hormone purified from the gastric mucosa, activates growth hormone release, food intake and energy homeostasis. The greatest levels of ghrelin have been found in the gastric fundus of the rat. During fasting, the synthesis of ghrelin is stimulated in gastric endocrine cells. Ghrelin mRNA has been reported in bovine rumen and abomasum. We hypothesized that undernutrition would stimulate the expression of

ghrelin in the digestive tract of ewes during midgestation. Control ewes were fed pelleted beet pulp fortified with vitamins and minerals to meet requirements of early pregnancy, whereas the nutrient restricted group received 50% of the control diet from day 28-78 of gestation. On day 78 of gestation, ewes were slaughtered, and digestive tracts were removed, stripped of digesta, and trimmed of fat. Digestive tract tissues (rumen, abomasum, duodenum, jejunum) were harvested. A subsample was collected and snap frozen and the rest of the tissue was weighed. Total RNA was purified using TRI reagent. Ovine prepro-ghrelin cDNA was amplified, sequenced and random prime labeled for use on northern blots. Data (mean \pm SEM) were analyzed as a 2x2 factorial with diet ($n = 7$ control; $n = 6$ nutrient-restricted) and offspring number ($n = 6$ singles, $n = 7$ twins) as main effects using PROC GLM procedure. No interaction and no effect of offspring number was observed. Rumen weight was decreased significantly ($1022\text{g} \pm 51.4$ vs $765\text{g} \pm 61.4$; $P = 0.03$) in nutrient restricted when compared to control fed ewes while there was no change in abomasal weight ($215\text{g} \pm 20.1$ vs $211\text{g} \pm 21.4$; $P > 0.05$). Northern blot analysis showed that prepro-ghrelin mRNA was abundantly expressed in the abomasum, while rumen, duodenum, and jejunum expressed little or no prepro-ghrelin mRNA. However, prepro-ghrelin mRNA did not differ in the abomasum of nutrient restricted ewes when compared to control fed ewes ($P > 0.05$). These results are interpreted to mean that prolonged undernutrition during pregnancy in the ewe does not alter the expression of prepro-ghrelin in the maternal abomasum. NIH P20RR16474.

Key Words: Ruminant, Nutrition, Ghrelin

T235 Effects of forage proportion in the diet on digestibility and portal nutrient flux in sheep fed to maintenance level. G. F. Mouro, A. F. Branco^{*}, S. M. Coneglian, T. F. Minella, L. P. Rigolon, L. M. Zeoula, and F. J. Maia, *Universidade Estadual de Maringa, Parana, Brasil.*

Three Suffolk wethers, weighting 50 kg, fitted with mesenteric vein, portal vein and mesenteric artery catheters were used to evaluate the effects of forage proportion in the diet on digestibility and portal nutrient flux. The design was a 3 x 3 Latin square. Treatments were as following: 30, 40 and 50% of corn silage in the diet (as dry matter basis). Digestibility was determined using total collection of feces. Portal plasma flow was determined by continuous infusion of *P*-aminohippurate, and net nutrient flux was calculated as the difference between venous and arterial concentration times blood flow. Intake, digestion and digestibility of dry matter, organic matter and crude protein were not influenced by forage level. Neutral detergent fiber intake increased linearly ($P < .05$) as result of corn silage ($y = 399.36 + 1.42(x - x)$, g/d) increase in the diet. Intake ($y = 280.21 - 4.09(x - x)$, g/d) and digestion ($y = 253.71 - 4.19(x - x)$, g/d) of non fiber carbohydrates decreased linearly ($P < .05$) as result of corn silage increase in the diets. Intake of total digestible nutrients was not affected by forage level. Forage level in the diet did not influence portal plasma flow. Portal and arterial concentrations of glucose and alpha-amino-nitrogen were not affected by forage level in the diet, and averages were 3.715 and 3.725 mM for glucose and 3.302 and 3.045 mM for alpha-amino-nitrogen. Portal flux of glucose and alpha-amino-nitrogen were not affected by forage level and were -940 and 43.208 mM/h, respectively. Portal concentration ($y = .522 - .00101(x - x) + .00074(x - x)^2$, mM) and portal flux ($y = 40.927 - .05068(x - x) + .14165(x - x)^2$, mM/h) of ammonia showed a quadratic response ($P < .05$) to forage level. Corn silage increase in the diet produced a quadratic response ($P < .05$) in portal ($y = 2.577 + .00263(x - x) + .00170(x - x)^2$, mM) and arterial ($y = 2.622 + .00122(x - x) + .002(x - x)^2$, mM) urea concentration. There was no effect of forage level on portal urea flux.

Key Words: Metabolism, Portal Drained Viscera, Forage

T236 Effects of carbohydrate source and monensin in high oil diets on nitrogen balance, digestibility and portal nutrient flux in sheep. G. F. Mouro, A. F. Branco^{*}, F. J. Maia, T. F. Minella, L. M. Zeoula, and S. M. Coneglian, *Universidade Estadual de Maringa, Parana, Brasil.*

The objectives of this research were to evaluate utilization of two carbohydrate sources (soybean hulls and corn) with and without monensin in sheep diets with high vegetable oil inclusion, and effects on nitrogen balance, digestibility and portal nutrient flux. Were used four Corriedale wethers, weighting 54 kg on average, and fitted with

catheters in mesenteric and portal vein and mesenteric artery. Digestibility and nitrogen balance were determined using total collection feces method. Portal plasma flow was determined by continuous infusion of *P*-aminohippurate, and net nutrient flux was calculated as the difference between venous and arterial concentration times blood flow. Intake, fecal excretion, digestion and digestibility of dry matter (DM), organic matter (OM) and ether extract (EE) were not affected by treatments. Intake (g/d), digestion (g/d) and digestibility (%) of neutral detergent fiber were higher ($P < .01$) for soybean hulls diets (SBHD) (757, 531.1 and 70.2, respectively) than for corn diets (CD) (392.3, 199.9 and 60, respectively). CD had higher ($P < .01$) non fiber carbohydrates intake (g/d), digestion (g/d) and digestibility (%) than SBHD (474.6 vs 148, 416.8 vs 97.8 and 87.8 vs 66.1, respectively). CD (80.2%) had higher ($P < .05$) total digestible nutrients than SBHD (76.8%). Fecal protein excretion (g/d) was lower ($P < .04$) and protein digestibility (%) was higher ($P < .02$) for CD (49.3 and 77.1, respectively) than for SBHD (61.9 and 72.6, respectively). There was no effect of monensin on nutrients digestibility and nitrogen balance. Treatments did not affect glucose concentration in arterial and portal plasma, and portal glucose flux. Alpha-amino-nitrogen concentration (mM) in arterial and portal plasma were lower ($P < .04$) for diets with monensin (3.268 and 2.992, respectively) than for diets without monensin (3.423 and 3.147, respectively). Portal concentration (mM) and portal flux of ammonia (mM/h) were lower ($P < .03$) for CD (.419 and 26.119, respectively) than for SBHD (.516 and 37.041, respectively). Treatments did not affect urea concentration in arterial and portal plasma, and portal urea flux.

Key Words: Metabolism, Portal Drained Viscera, Monensin

T237 Two techniques to determine the ruminal clearance rate of volatile fatty acids. J. C. Resende Júnior¹, M. N. Pereira^{*1}, H. Boer², and S. Tamminga², ¹Universidade Federal de Lavras, Lavras, Brazil, ²Wageningen Universiteit, Wageningen, The Netherlands.

Removal (clearance) of VFA from the rumen occurs by absorption through the rumen wall and by passage to the omasum with rumen liquid. The objective of this experiment was to compare measurements of fractional clearance rates obtained with the HVal-Co technique with measurements obtained with ¹³C labeled VFA. The exponential decay rate of the ¹³C/¹²C ratio after pulse dosing ¹³C-Acetate, ¹³C-Propionate or ¹³C-Butyrate into the rumen was compared to the decay rate of rumen valerate concentration following a pulse dose of 300 grams of valerate. Each labeled VFA, the unlabeled valerate and Co-EDTA were concurrently mixed to the evacuated ruminal content of six lactating cows in two 3x3 Latin Squares. The fractional clearance of VFA by passage to the omasum was assumed to be equal to the decay in ruminal Co concentration and was around 50% of the total clearance. The fractional clearance rates of all VFA were similar, showing that chain length was not a factor in the irreversible loss of ¹³C introduced into the rumen as each acid. Absorption rates varied from 14 to 19 %h⁻¹ and was higher for propionate than for butyrate. Linear regression determination coefficients using valerate clearance rate as estimator of the clearance rates of acetate, propionate and butyrate were 0.51, 0.56, and 0.99, respectively. In a second experiment, the decay rate of ¹³C-Valerate was similar to that obtained with unlabeled valerate by the HVal-Co technique. There was no increase in ¹³C enrichment of rumen microbes four hours after intraruminal infusion of ¹³C-Valerate. The fractional VFA absorption rates obtained with the stable isotopes technique gave results similar to that obtained with the HVal-Co technique.

Key Words: Acetate, Propionate, Butyrate

T238 Prediction of milking cows performance and use of the equations for estimating nutritional requirements in Brazil. R. P. Lana^{*1,2}, J. A. Freitas¹, and A. C. Queiroz^{1,2}, ¹Universidade Federal de Viçosa-DZO, Viçosa, MG, Brazil, ²CNPq, Brasília, DF, Brazil.

The objectives of this research were to develop prediction equations of dry matter intake, energy and protein requirements, and to validate the NRC (1989, 2001) for predict milking cows performance under typical Brazilian production conditions. Data from 33 pure Holstein to Holstein/Zebu cows were used in this study. The average body weight (BW), daily milk production (Milk), milk fat (Fat), milk protein (Ptn), daily dry matter intake (DMI) and their respective standard deviations

were 499±37 kg; 21±3 kg; 3.9±0.4%; 3.2±0.3%; and 17±2 kg, respectively. The composition (%) of dietary crude protein (CP), total digestible nutrients (TDN), ethereal extract (EE) and neutral detergent fiber (NDF) of the diet was 16.4±1.5; 69.4±5.5; 4.2±2.7; and 42.6±9.4, respectively. Prediction equations of DMI, milk production and nutritional requirements are presented below.

DMI = -100 + (0.116*BW) + (2.91*Milk) + (22.8%*Fat) - (2.6%*%Fat²) - (0.00483*BW*Milk); R² = 0.91; Eq.1

Milk = -24.4 + (0.0227*BW) + (0.891*DMI) - (0.232%*NDF) + (0.412%*TDN); R² = 0.95; Eq.2

Milk = 36.1 - (0.364%*NDF); R² = 0.59; Eq.3

%CP = -49.9 + (0.429*BW) - (35.4%*Fat) + (20.9%*Ptn) + (4.4%*Fat²) - (3.18%*Ptn²) - (0.000445*BW²); R² = 0.75; Eq.4

%TDN = [Milk + 24.4 - (0.0227*BW) - (0.891*DMI) + (0.232%*NDF)]/0.412; Eq.5

%NDF = (36.1 - Milk)/0.364 = 99.1 - (2.75*Milk); Eq.6

%TDN = (47.4 + Milk - (0.0227*BW) - (0.891*DMI) - (0.64*Milk))/0.412; Eq.7

Equations 5, 6 and 7 were derived from equations 2 and 3. Equations 1, 4, 6 and 7 allow us to estimate the nutritional requirements of DM, CP, NDF and TDN, respectively, as a function of BW, Milk, fat, and protein. These equations can be used in computer programs for ration formulation and to generate tables of nutritional requirements for milking cows under typical Brazilian production conditions. These equations are more efficient in predicting the cow's performance than NRC (1989, 2001), in which the NRC (2001) was inadequate by over-predicting milk production by 92%.

Key Words: Dry Matter Intake, Milk, Nutritional Requirements

T239 Efficiency of use of concentrate ration on weight gain and milk production by cattle under tropical pasture and intensive conditions in Brazil. R. P. Lana^{*1,2}, ¹Universidade Federal de Viçosa-DZO, Viçosa, MG, Brazil, ²CNPq, Brasília, DF, Brazil.

The feed efficiency (FE; kg of weight gain; or milk production/kg of supplement) of using concentrate rations was evaluated in cattle in pasture and intensive production conditions. The efficiency of weight gain was obtained from 25 published studies examining growing cattle receiving supplementation during the dry season, and seven studies examining growing cattle being fed different forage to concentrate ratios in feedlot conditions. FE were calculated by the coefficient of the linear regression equation of the weight gain as a function of the concentrate intake, in addition to the calculation of the gain accretion as a function of concentrate intake. The efficiency of milk production was calculated by dividing the increase in milk production as a function of the concentrate intakes from nine published pasture and one free-stall research studies. Pasture reared cattle had FE from 7 to 10:1, while feedlot cattle had FE of 10:1. When pasture-reared cattle consumed a mineral salt treatment, FE was improved by 0.1 to 0.14 kg of weight gain/kg of consumed concentrate; and in feedlot studies FE increased by 0.1 kg/kg of consumed concentrate. When dairy cows were reared on pasture FE ranged between 0.04 and 0.1 kg of weight gain/kg of concentrate consumed; milk production efficiency (MPE) was 0.65 ± 0.41 kg of milk/kg of concentrate consumed, and MPE was improved to 1.8 kg of milk/kg of concentrate consumed by feeding whole cottonseed. For dairy cows raised in free stall conditions, MPE ranged between 0.29 and 0.48 kg of milk/kg of concentrate consumed, due in part to high levels of concentrate in the control diets. The high cost of concentrate feeds compared to the pasture and the low efficiency of the concentrate conversion in weight gain and milk under tropical pastures, as verified above, can explain the low use of concentrate by Brazilian farmers, which can have greater profitability in spite of low cattle performance.

Key Words: Cattle, Concentrate Conversion, Supplement

T240 Ruminal parameters and plasma metabolites of Holstein dairy cows fed processed cottonseed. A. R. Foroughi^{*}, A. A. Naserian, R. Valizadeh, and M. Danesh mesgaran, Ferdowsi University of Mashhad, Iran.

Whole cottonseed (WCS) is of significant feeding value for average and high-yielding dairy cows. Multiparous cows (n=8) averaging 84.50±10.34 days in milk and 36.10±4.46 milk yield were used in a 4x4 Latin square design. Cows were divided into four groups, receiving one of the following treatments: 1) WCS; 2) Ground cottonseed (GCS);

3) GCS heated in 140°C and steeped for 2.5 minute (GHCS1); or 4) GCS heated in 140°C and steeped for 20 minute (GHCS2). The percentage of whole or processed cottonseed was fixed at 14%. Total mixed diets had the following composition, dry matter 79.5%, NDF 35.2%, CP 18.5% and NEL 1.58 (Mcal/KgDM). Each period consisted of 21 days and the last 7 days were used for dry matter intake (DMI). Ruminal samples were taken via stomach tube and ruminocentesis on 21d of each period at approximately 2h postfeeding. Ruminal pH was measured in fresh samples immediately, and samples were analyzed for N-NH₃. Blood samples were taken from coccygeal blood vessels at the time of ruminal sampling. The mean DMI was significantly ($P < 0.01$) affected by diets and in treatments of 1,2,3 and 4 were 25.97, 27.24, 27.63, and 27.63 (kg/d), respectively. Supplementation with HGCS2 resulted in decreased ($p < 0.01$) in ruminal N-NH₃ concentrations and in treatments of 1,2,3 and 4 were 14.63, 16.31, 12.48, and 10.52 respectively. This represented a 28% decrease between WCS and HGCS2. Blood urea showed the same pattern observed for ruminal N-NH₃. Physical processing of WCS did not affect ruminal pH and mean for stomach tube and ruminocentesis method was 6.6 and 6.1, respectively. Significant differences ($p < 0.05$) were observed in glucose and cholesterol concentrations, but processing of WCS did not affect ruminal triglycerides, albumin and low density lipoproteins.

Key Words: Processed Cottonseed, Ruminal Parameters and Plasma Metabolites

T241 NutriDense® corn grain and corn silage for dairy cows. B. C. Benefield*, I. R. Ipharraguerre, M. o Liñero, and J. H. Clark, *University of Illinois, Urbana.*

Sixteen intact multiparous Holstein cows and four multiparous Holstein cows surgically fitted with ruminal cannulas, averaging 71 days in milk, were used in a replicated 4 x 4 Latin square to compare the effects on digestibility and animal performance of feeding either NutriDense®, stacked with the “leafy” trait (NDL), or yellow dent corn control (YDC) whole plant silage; and either grain from NutriDense® corn (ND) or YDC hybrid. Diets contained 30.56% corn silage and 27.65% corn grain (DM basis) produced from one of the NDL, ND, and the YDC hybrids. Data from this experiment show that the CP, NDF, ADF, and EE content of NDL and ND were higher and NFC and starch were lower than that of the YDC hybrid. Dry matter intakes (mean = 27 kg/d) were similar ($P < .7$) for the four diets (YDC silage + YDC grain, NDL silage + YDC grain, YDC silage + ND grain, and NDL silage + ND grain). NutriDense grain and NDL silage decreased ($P < .01$) NFC and starch intake but increased ($P < .01$) EE and N intake. Feeding NDL silage increased ($P < .01$) NDF and ADF intake but did not affect DMI. These differences in nutrient intake arose from variations in the composition of the corn grains and silages. Starch digestibility was higher ($P < .05$) for the NDL silage + YDC grain diet but digestibility of other nutrients were not different among treatments. Ruminal pH and concentrations of VFA and NH₃N in rumen fluid were not different among treatments ($P > .05$). Production of milk, 3.5% FCM, fat, CP, true protein, and total solids (mean = 36.5, 37.6, 1.34, 1.21, 1.14, 4.57 kg/d, respectively), and the percentages of milk fat, CP, true protein, and total solids (mean = 3.71, 3.32, 3.13, 12.58, respectively), were not affected by treatments. Milk urea N (mean = 11.6 mg/dl) was higher ($P < .001$) for cows fed diets containing ND grain; this may be because of higher N intakes for those diets. Results indicate that NDL silage and ND corn were similar to the control hybrid for the feeding of lactating dairy cows.

Key Words: NutriDense, Corn Silage, Dairy Cows

T242 Effect of level of dietary crude protein on ruminal digestion and bacterial NAN flow in lactating dairy cows. J. J. Olmos Colmenero*¹ and G. A. Broderick², ¹University of Wisconsin, Madison, ²U.S. Dairy Forage Research Center, Madison, WI.

Ten ruminally fistulated Holstein cows were used in an incomplete 5 x 5 Latin square design with 4, 4-wk periods to assess the effects of different dietary CP levels on ruminal digestion and bacterial NAN flow. Diets contained (DM basis) 25% alfalfa silage, 25% corn silage, and 50% concentrate. High moisture corn was replaced with solvent soybean meal to increase CP from 13.7%, to 15.1%, 16.6%, 18.1%, and 19.6%. Samples of digesta were taken from the reticulo-omasal orifice and the true digesta flow was calculated using a triple marker approach (indigestible NDF, Co-EDTA and Yb-acetate). The marker used to quantify bacterial NAN

was ¹⁵N. DM and OM intakes were not different among treatments. As expected, N intake increased linearly with CP content in the diet. DM and OM flow, apparent rumen OM digestibility (AROMD), OM truly digested in the rumen (OMTDR), and liquid associated bacteria (LAB) flow did not differ. The flows of particle associated bacteria (PAB) and total bacterial NAN, and bacterial efficiency were not different but significant linear effects of CP level were detected. Under the conditions of this study, total bacterial NAN was not increased by feeding more than 16.6 % CP.

Item	CP, % DM							
	13.7	15.1	16.6	18.1	19.6	SE	P>F	Linear
DM intake, kg/d	21.9	22.9	23.8	23.5	22.5	1.2	0.50	0.37

T243 Effect of species and breed within species on forage intake and growth in hair sheep lambs and meat goat kids offered alfalfa and grass hay diets with a corn-based supplement. S. Wildeus¹, K. E. Turner*², and J. R. Collins¹, ¹Virginia State University, Petersburg, ²USDA, ARS, AFSRC, Beaver, WV.

Feed intake, growth, live grade, and blood metabolites were measured in 36 intact male hair sheep lambs, equally representing Barbados Blackbelly (BB), Katahdin (KA), and St. Croix (SC) breeds, and 36 intact male goat kids, equally representing F₂ Boer cross (BX), Myotonic (MY) and Spanish (SP) breed types in a 98-d pen feeding study. Animals were allocated to 8 pens at 3.5 mo of age stratified by species and breed type, and offered either tall fescue (*Festuca arundinacea* Shreb.; FES; 13.5% CP, 56.1% NDF, 37.9% ADF, 45.2% IVOMD) grass or alfalfa (*Medicago sativa* L.; ALF; 16.3% CP, 51% NDF, 36.1% ADF, 55.2% IVOMD) hay (4 pens/forage type) plus a corn (*Zea mays* L.)-based concentrate (16% CP) at 2% BW. Forage DMI decreased ($P < 0.01$) during the trial, and ALF DMI was higher ($P < 0.01$) initially, but similar to FES as the trial progressed. The ADG was greater ($P < 0.001$) for hair sheep (165 g/d) than goats (106 g/d), and was greater when offered ALF (153 g/d) than FES (118 g/d) diets. When offered ALF diets, blood urea nitrogen (BUN; 21 vs. 19.9 mg/dl) and glucose (71 vs. 66.9 mg/dl) were higher ($P < 0.01$) compared to FES diets. Live grade was higher ($P < 0.01$) in hair sheep than goats, and when offered ALF than FES. Within hair sheep, there were no differences in ADG and live grade between breeds, although KA had higher ($P < 0.01$) starting and final BW (42.7 vs. 36.2 and 38.2 kg, respectively) than BB and SC. In goats, BX had higher ($P < 0.001$) starting and final BW, and greater ($P < 0.01$) ADG than MY and SP (133 vs. 84 and 99 g/d). Live grade in goats was higher ($P < 0.05$) on ALF than FES, but not affected by breed. Goats had lower ($P < 0.01$) blood concentrations (mg/dl) of BUN (18.9 vs. 22.1), creatinine (0.55 vs. 0.58), and glucose (65.6 vs. 72.2) than hair sheep. Results suggest that an improved forage base in the diet uniformly increased performance independent of small ruminant species and/or breed.

T244 Productive performance of Holstein cows in early and very early lactations when injected with bovine somatotropin. M. A Tarazon*¹, J. T. Huber², A. C. Calderon³, and H. G. Garcia³, ¹Universidad de Sonora, México, ²University of Arizona, Tucson, ³Universidad Autónoma de Baja California, Mexicali, Mexico.

The objective of the current study was to evaluate the effect of bovine somatotropin (bST) on milk yield and composition of Holstein cows in early and very early lactations. Twenty-two lactating Holstein cows averaging 62 days in milk (DIM:25-115), 28.5 kg/d milk, a body condition score (BCS) of 2.87, and 648.2 kg of body weight (BW), were assigned to one of the four treatments in a completely randomized design with a treatment arrangement of factorial 2x2. Cows were fed with the regular diet during the fourteen days of pretreatment and the 56 days of treatment periods. The treatments were: 1). VE, cows in very early lactation (25-56 DIM) without bST; 2). VES, cows in very early lactation with bST; 3). E, cows in early lactation (67-115 DIM) without bST; and 4). ES, cows in early lactation with bST. Variables were adjusted for covariance effects using the data from the 28-day pretreatment period and analyzed by the General Linear model Procedure (GLM) of SAS (1990). Results showed that bST tended (P<0.09) to increase milk yield (34.8 vs. 36.4 kg/d) in cows between 25 to 115 DIM, however the increase was significant when bST was injected to cows in early lactation (67-115 DIM). Neither the stage of lactation nor the injection of bST altered milk composition nor the rest of variables measured in the experiment.

Key Words: bST, Holstein, DIM

T245 Effect of type of concentrate on milk production and composition of dairy cows. R.G. Pulido*¹, P. Aguilera¹, R. Daetz¹, F. Wittwer¹, and P. Orellana², ¹Fac. Cs. Veterinarias, Universidad Austral de Chile, Valdivia, Chile, ²Depto. Nutrición, F. Med. Veterinaria, Universidad de Concepción.

Two experiments were carried out to evaluate the effect of two sources of carbohydrate (fibrous and starchy) and two levels of crude protein in

concentrate supplements (17.0% in exp 1 and 11.9% in exp 2) on milk production and composition of spring calving dairy cows. In exp 1, 12 multiparous Friesian dairy cows (BW 529 kg), yielding 33.0 l/d and at 53 days of lactation, were assigned to a 3x3 Latin square design with periods of 21 days. In exp 2, 30 multiparous Friesian dairy cows (BW 512 kg), yielding 29.3 l/d and at 65 days of lactation, were assigned to a continuous randomized design for 45 days. For both experiments the treatments included: grazing alone (TGO), grazing plus 6 kg/d of sugar beet pulp-based concentrate (TFC) and grazing plus 6 kg/d of cereal-based concentrate (TSC). The concentrates were balanced by CP and ME. The cows were supplemented twice a day and managed under a strip grazing system on pasture consisting mainly of perennial rye grass. During the last week of each period in exp 1 and during all period, in exp 2, milk production (MY) was recorded on a daily basis and milk composition on 4 occasions during each week. Throughout the trial BW was recorded weekly. The results for (MY) during exp 1 were 24.2, 28.5 and 29.8 l/d for treatments TGO, TCF and TCS, respectively (TGO vs. TCF or TCS, P<0.05; TCF vs. TCS P>0.05). Milk fat (MF) was 3.65, 3.44 and 3.40 %, respectively (P=0.06), milk protein (MP) was 2.88, 2.99 and 3.01 %, respectively (TGO vs. TCF or TCS, P<0.05; TCF vs. TCS P>0.05) and milk urea was 43.35, 41.01 and 43.89 mg/dl, respectively (P>0.05). The results for (MY) during exp 2 were 27.0, 28.9 and 31.0 l/d for treatments TGO, TCF and TCS, respectively (TGO vs. TCF or TCS, P<0.05; TCF vs. TCS P>0.05). (MF) was 3.59, 3.58 and 3.73 %, respectively (P>0.05), (MP) was 3.07, 3.30 and 3.14 %, respectively (TGO vs. TCF or TCS, P<0.05; TCF vs. TCS P>0.05) and milk urea was 48.59, 42.72 and 44.65 mg/dl, respectively (P<0.05). The results suggest that carbohydrate source did not affect the milk production and composition of dairy cows on this experiment.

T246 Effect of substitution of alfalfa hay with sun dried pig excreta on performance of sheep feed growing diets. A. Estrada-Angulo*, C. H. Ramos, R. Barajas, and J. F. Obregon, FMVZ-Universidad Autonoma de Sinaloa, Culiacán-Mazatlan, Mexico.

With the objective of determining the effect of substitution of alfalfa hay with sun dried pig excreta on performance of sheep fed growing diets, a 56 days growing feeding experiment was conducted. Forty hair sheep (Males; BW=15±2 kg) were used in a complete randomized block experiment design. The animals were weighed and blocked by weight in groups of four. Groups were placed in eight pens (2 x 3 m) with a bare ground floor and designed to consume one of two diets that constituted the treatments: 1) Diet with 18% CP and 3.1 Mcal of DE/kg, containing 30% of alfalfa hay, sudan grass hay 10%, cracked corn 29.5%, soybean meal 13%, sugar cane molasses 14%, mineral premix 2.5% (Control); and 2) Diet similar to control, but containing 30% of sun dried pig excreta, that substituting entirely for the alfalfa hay. Diets were offered twice a day under free access condition. There was not effect (P=0.48) of treatments on end weight (23.60 vs. 23.28 kg for diet 1 and diet 2, respectively). The inclusion of pig excreta did not affect (P=0.73) the dry matter intake (0.773 vs. 0.775 kg/day for diet 1 and diet 2, respectively). The average daily gain was similar (P=0.62) for both treatments (152.25 vs. 148.75 g/day for diet 1 and diet 2, respectively). The feed intake/gain ratio was not altered (P=0.72) by treatment (5.16 vs. 5.13 for diet 1 and diet 2, respectively). It is concluded, that sun dried pig excreta can be used as partial substitute of roughage in diets for growing sheep.

Key Words: Pig Excreta, Growth Performance, Sheep

T247 Effect of substitution of sorghum grain for escobero sorghum grain (sorghum bicolor, var. Technicum, Jav.) on apparent digestibility of diets for sheep. A. Estrada-Angulo*, R. Barajas, J. F. Obregon, R. E. Lopez, and J. C. Robles, FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico.

With the objective of determining the effect of substitution of sorghum grain for escobero sorghum grain (sorghum bicolor, var. Technicum, Jav.) on apparent digestibility of diets for sheep, a digestibility experiment by total fecal collection was conducted. Four pelibuey sheep, males (BW=22.75±0.32 kg) were used in a crossover design experiment. The animals were placed in individual metabolic crates (0.6 x 1.2 m), and randomly were assigned to consume one of two diets that constituted the treatments: 1) Diet with 15% CP and 3.4 Mcal of DE/kg, containing 45% of whole sorghum grain, sudan grass hay 22.5%, sesame meal 15%, sugar cane molasses 12%, poultry fat 3%, and 2.5% of mineral premix (Control); and 2) Diet similar to control but containing 45% of whole escobero sorghum grain (Sorghum bicolor var. technicum, Jav.), that substituted for sorghum grain of the diet (ES treatment). Diets were offered twice a day (800 and 1600 h), after a six days adaptation period, samples of diet (1 kg) and the total of feces produced were collected for four days. Samples were dried, weighed, and ground. The inclusion of escobero sorghum increased (P=0.01) the amount of DM excreted in feces (151 vs. 215 g/day for control and ES, respectively) and fecal excretion of crude protein (25 vs. 32 g/day for control and ES, respectively). ES decreased (P<0.01) by 15.5% dry matter digestibility of the diet (74.45 vs. 62.94% for control and ES, respectively). The crude protein apparent digestibility was 9.5% lower (P=0.02) in ES treatment (70.8 vs. 64.06% for control and ES, respectively). Digestible energy of the diet was diminished (P<0.01) 16% by ES (3.18 vs. 2.67 Mcal/kg for control and ES, respectively). Digestible energy content of sorghum bicolor, var. Technicum, Jav. was calculated to be 2.75 Mcal/kg and the true digestibility of its protein was calculated to be near 72%. It is concluded, that inclusion of sorghum bicolor, var. Technicum, Jav. decreased digestibility and DE content of the diet for sheep.

Key Words: Sorghum Grain, Digestibility, Sheep

T248 Effect of substitution of sorghum grain with escobero sorghum grain (*Sorghum bicolor*, var. *Technicum*, Jav.) on growth performance of finishing sheep. A. Estrada-Angulo*, R. Barajas, J. F. Obregon, and F. J. Gallardo, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

With the objective of determining the effect of substitution of sorghum grain with escobero sorghum grain (*Sorghum bicolor*, var. *Technicum*, Jav.) on growth performance of finishing sheep, thirty two hair sheep (males, BW=27.85 kg) were used in a complete randomized block experiment design. The animals were weighed and blocked by weight in groups of four. Groups were placed in eight pens (2 x 3 m) with a bare ground floor, and assigned to consume one of two diets that constituted the treatments: 1) Diet with 15% CP and 3.4 Mcal of DE/kg, containing 60% of Whole sorghum grain, corn straw 10%, SBM 10%, sugar cane molasses 14.5%, and 2.5% of mineral premix (Control); and 2) Diet similar to control, but containing 60% of whole escobero sorghum grain (*Sorghum bicolor*, var. *Technicum*, Jav.), substituting for sorghum grain (ES treatment). Diets were offered twice a day under free access condition. Average daily gain was not affected ($P=0.26$) by treatments (219 vs. 202 g/day for control and ES respectively). Feed intake was increased ($P<0.01$) in 21% for escobero sorghum (1.07 vs. 1.298 kg/day for control and ES respectively). Feed/gain ratio was negatively affected ($P=0.02$) by the inclusion escobero sorghum in the diet (5.11 vs. 6.43 for control and ES respectively). It is concluded, that the inclusion of sorghum bicolor, Var. *Technicum*, Jav, substituting to sorghum grain, decreased growth performance response of finishing sheep.

Key Words: Sorghum Grain, Varieties, Sheep

T249 Effect of substitution of alfalfa hay with Clitoria hay (*Clitoria ternatea* L.) on performance of sheep feed finishing diets. A. Estrada-Angulo*, A. B. Perez-Fernandez, J. F. Obregon, R. Barajas, and E. A. Velazquez, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

To determine the effect of substitution of alfalfa hay with Clitoria hay (*Clitoria ternatea* L.) on performance of sheep fed finishing diets, a 28 day growth performance experiment was conducted. Twenty four Pelibuey sheep (males, initial BW=20.7 kg) were used in a complete randomized Block design experiment. The animals were weighed and grouped by weight. Groups of three were allocated in one of eight pens (2 x 3 m) with a bare ground floor fitted with metal feed bunks (1 x 0.33 m) and waters. The pens were randomly assigned one of two diets that constituted the treatments: 1) Diet with 18.3% of CP and 3.015 Mcal of DE/kg, containing (DM basis), alfalfa hay 50%, (18.01% CP), ground corn 27.8%, soybean meal 9.75%, sugar cane molasses 9.58%, urea 0.57%, limestone 1.15%, and mineral premix 1.15% (control); and 2) Diet same as control, but containing 50% of clitoria hay (19.09% CP), that substituted for all alfalfa hay of the control diet. The animals were weighed at day 1 and 28 of the trial. DM intake was recorded daily. The mean final weight of experiment was 26.9 kg and was not altered ($P=0.48$) by roughage source in diets. Dry matter intake was not affected ($P=0.74$) by treatment with values of 1.009 and 1.014 kg/day for alfalfa and clitoria diets, respectively. Average daily gain was similar ($P=0.20$) for both treatments with means of 0.208 and 0.190 kg/day for alfalfa and clitoria diets, respectively. There were no differences ($P=0.32$) in the dry matter intake/ADG ratio, with values of 4.92 and 5.34 kg/kg for alfalfa hay and clitoria hay diets respectively. It is concluded that clitoria hay can be included up to 50% in the diets of finishing sheep substituting for alfalfa hay without detrimental effect on performance.

Key Words: Clitoria ternatea, Alfalfa Hay, Sheep

T250 Effect of supplementation of meat meals from different non ruminant species on growth performance response in finishing sheep. A. B. Perez-Fernandez, A. Estrada-Angulo*, R. Barajas, and J. F. Obregon, *FMVZ-Universidad Autónoma de Sinaloa, Culiacan-Mazatlan, México*.

To determine the effect of supplementation of meat meals from different non ruminant species on growth performance response in finishing sheep, a 56 days feeding experiment was performed. Eighty Pelibuey sheep (males; BW=23.16 kg) were used in a complete randomized experiment design. Animals were weighed and divided in groups of five.

Groups were placed 16 pens (2x3 m) with a bare ground floor, and randomly assigned to consume one of four diets containing different kind of meat meal that constituted the treatments; protein sources were: 1) Diet with 15% CP and 3.5 Mcal of DE/kg containing Sesame meal as protein supplement (control); 2) Diet containing 6% of fish meal as protein supplement (FM); 3) Diet containing 6% of Pork meat meal (PMM); and 4) Diet with 6% of poultry meal (POM). Diets were offered twice a day (0800 and 1600 h) under free access condition. Pork meat meal reduced ($P<0.01$) feed intake (1.207 vs. 1.100 kg/day for control and PMM respectively), and tended to decreased ($P=0.07$) average daily gain (209 vs. 185 g/day for control and PMM respectively). The treatments did not affected ($P>0.20$) the feed/gain ratio. It is concluded that growth performance of finishing sheep can be altered by the source of meat meal from different nonruminant species.

Key Words: Fish Meal, Pork Meat Meal, Poultry Meal

T251 Comparative effect of tallow and dark poultry fat on apparent digestibility of diets for sheep. A. Estrada-Angulo*, J. C. Robles, J. F. Obregon, and R. Barajas, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

With the objective of comparing the effect of tallow and dark poultry fat on apparent digestibility of diets for sheep, four Pelibuey sheep (males, BW=17.62±0.27 kg) were used in a CrossOver design experiment. The animals were placed in individual metabolic crates (0.6 x 1.2 m), and randomly were assigned to consume one of two diets that constituted the treatments: 1) Diet 15% CP and 3.4 Mcal DE/kg, containing sudan-grass hay, tallow 3%, sorghum grain 45%, sesame meal 15%, sugar cane molasses 12%, and mineral premix 2.5% (Control); and 2) Diet similar to control, but containing 3% of dark poultry fat substituting for the tallow (DPF). Diets were offered twice a day (800 and 1600 h), after a six days of adaptation period, samples of diet (1 kg) and the total of feces produced were collected for four days. Samples were dried, weighed and ground. Treatments did not affected ($P=0.20$) the amount of dry matter (118 vs. 110 g/day for control and DPF respectively) and crude protein (20 vs. 18 g/day for control and DPF respectively) excreted in feces. Apparent digestibility of the diet was similar ($P=0.32$) for both treatments (73.66 vs. 75.28% for control and DPF respectively). Apparent digestibility of crude protein was equal ($P=0.14$) for both treatments (68.43 vs. 72.68% for control and DPF respectively). Digestible Energy content of the diets was not altered ($P=0.30$) by the fat sources. It is concluded, that the dark poultry fat can substituting for tallow in diet for sheep without alter its digestibility.

T252 Digestibility of fermented bagasse fed to Suffolk ewes. R. Pradhan*¹, E. Shirakabe¹, T. Nishioka¹, and K. Batajoo², ¹*School of Agriculture, Kyushu Tokai University, Kumamoto, Japan*, ²*Chubu Feed Co. Ltd., Nagoya, Japan*.

Bagasse is a fibrous byproduct remaining after the production of cane sugar. Raw bagasse as such has low feed value and is typically burned at the sugar mill for fuel. Fermented bagasse is produced by fermenting raw bagasse with molasses and special microbial culture mix. In Japan, bagasse is imported from Thailand and is fed as a fiber source to beef cattle, dairy and beef heifers. Field trials indicate that fermented bagasse increases feed intake in beef cattle. Nutrient digestibility and animal performance data of fermented bagasse are limited. Nine mature Suffolk ewes (average age 4.3±0.9 years and body weight 69.4±9.7 kg) were divided into three groups (three animals per group) and fed experimental diet for 8 weeks. Experimental diets (DM basis) were: FB (fermented bagasse 70% + tofu cake mix 30%), FB+TH (35% fermented bagasse + 35% timothy hay + 30% tofu cake mix), TH (70% timothy hay + 30% tofu cake mix). Tofu cake mix consisted of wheat bran 40%, rice bran 5%, tofu cake 10%, barley 10%, corn 15% and beet pulp 20%. Tofu cake mix contained 17% CP, 37% NDF and 36.43% nonfiber carbohydrate (NFC). Total tract digestibility, rumination time, rumen fluid pH, ammonia and VFA were measured during the last week of 8 week period. Fecal and urine sample were collected for 5 days. Rumen DM disappearance at 48 hour (conducted in fistulated dry Holstein cows) were: FB 31.5%, TH 69.1%, and tofu cake mix 87.4%. FB had lower intake, digestibility and N retention compared to TH. FB+TH showed higher intake, nutrient digestibility and similar rumination time relative

to FB. Based on this study fermented bagasse is palatable but not recommended to be fed as a sole forage source. Its inclusion in sheep diet should be less than 35% when fed along with other forages.

		FB	FB + TH	TH
Intake, g/d	DM	1356	1693	1402
Digestibility, %	DM	49 ^a	58 ^b	68 ^c

T253 Chemical diet composition and metabolizable protein intake by grazing sheep. A. S. Juarez-Reyes*, J. Arzola-Nevarez, G. Nevarez-Carrasco, R. Montoya-Escalante, and M. A. Cerrillo-Soto, *Universidad Juarez del Estado de Durango, Mexico*.

The aim of this study was to determine the chemical composition of the diet and the metabolizable protein (MP) intake by sheep grazing a scrubland in North Mexico. Three sheep (52.0 ± 7.2 kg BW) belonging to a herd of 100 animals and fitted with esophageal cannulae were used to collect monthly extrusa samples from August 2002 to May 2003. Animals were sampled two days each month at 1100 and 1530 for 45 minutes. Extrusa samples were analyzed for CP, NDF, ADF, lignin, hemicellulose, cellulose and *in vitro* digestibility with pepsine cellulase. Metabolizable Protein content was performed by the PDI (Intestinal Digestible Protein) model. Dry matter intake was estimated by: total fecal production/1-digestibility. To determine the effective degradability (ED) of CP, 5 g DM samples were incubated in nylon bags for 0, 3, 7, 12, 24, 48, 72 and 96 h, in 3 rams fed alfalfa and concentrate (70:30). The CP degradation was established by: $p = a + b(1 - e^{-ct})$, where p is CP disappearance from the bags, a the soluble fraction, b the insoluble but potentially degradable fraction, c the base of natural logarithm, t the rate of degradation of b and t the period of incubation. The data were analyzed using a completely randomized design. Mean DM intake was 1 kg/d. Chemical composition was different ($P < 0.05$) between months. Mean values of CP, NDF, ADF, lignin, hemicellulose, cellulose and *in vitro* digestibility contents were 176, 542, 369, 141, 190, 228 and 556 g/kg DM, respectively. The mean ED value was 70.8% with a range from 60.4 to 93.7% ($P < 0.05$). Microbial protein (Mp) derived from dietary nitrogen (MpN: 77 g/kg organic matter fermented in the rumen (OMFR)) was higher ($P < 0.05$) than that derived from dietary energy (MpE: 36 g/kg OMFR). Thus, the energy consumption was the limiting factor to microbial growth. The mean value of MP intake for pregnancy was 69 g/d (MpE: 36 g/kg + bypass protein: 33 g/d). Metabolizable protein requirements for maintenance (50 g/d) and late pregnancy (67 g/d) were satisfied but not the lactation requirements (115 g/d). Under the conditions of this study, to increase the utilization of degradable protein and thus, the MP consumption, an energy degradable supplement may be necessary.

T254 Effect of chromium methionine supplementation on growth performance and carcass traits of hair sheep. F. Juarez*, R. Barajas, M. A. Espino, J. F. Obregon, and F. G. Rios, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

With the objective of determining the effect of inclusion of 0.0, 0.4 and 0.8 ppm of chromium (from chromium methionine) in the diet on growth performance of hair sheep, sixty hair sheep (Males; BW= 17.3 kg) were used in a complete randomized block experiment design. The animals were weighed and blocked by weight in group of five. Groups were placed in twelve pens with earth floor (2 x 3m), and assigned to consume one

of three diets that constituted the treatments: 1) Diet with 14.1% CP and 3.0 Mcal of DE/kg, containing corn straw 15%, corn grain 55.0%, soybean meal 15.5%, sugar cane molasses 12% and mineral premix 2.5% (Control); 2) Diet similar to control but containing 0.4 ppm of Cr; and 3) Diet similar to control but containing 0.8 ppm of Cr. Animals were weighed on days 1, 28, and 56. Feed was offered twice a day under free access condition. Treatments did not affect ($P > 0.30$) end weight (29.16, 30.57, and 30.10 kg for 0, 0.4, and 0.8 ppm Cr respectively), feed intake (0.898, 0.910, and 0.902 kg of DM/day for 0, 0.4, and 0.8 ppm Cr respectively), average daily gain (0.211, 0.236 and 0.229 kg/day for 0, 0.4, and 0.8 ppm Cr respectively) or feed/gain (4.302, 3.891 and 3.962 for 0.0, 0.4 and 0.8 ppm Cr respectively). Hot carcass weight, carcass yield, rib eye area, and back fat were not affected ($P > 0.10$) by treatments. It is concluded, that the inclusion of 0.4, and 0.8 ppm of chromium methionine in the diet, does not affect growth performance and carcass traits of hair sheep.

Key Words: Chromium Methionine, Growth-Performance, Sheep

T255 Effect of chromium methionine supplementation on serum concentration of triglycerides and cholesterol of fattening sheep. F. Juarez*, M. A. Espino, and R. Barajas, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

With the objective of determining the effect of chromium methionine supplementation on serum concentration of triglycerides and cholesterol of fattening sheep, twelve Pelibuey Tabasco sheep (Males 15.46 ± 0.45 kg) were used in a complete randomized experiment design. Animals were placed in individual metabolic crates, and were randomly assigned to consume one of three diets that constituted the treatments: 1) Diet with 14.1% CP and 3.0 Mcal of DE/kg, containing corn straw 15%, corn grain 55.0%, soybeans meal 15.5%, sugarcane molasses 12%, and mineral premix 2.5% (Control); 2) Diet similar to control but containing 0.4 ppm of Cr; and 3) Diet similar to control but containing 0.8 ppm of Cr. Blood samples were collected from the jugular vein on days 1, 14, 28, 42, and 56, serum was obtained by centrifugation, and triglycerides and cholesterol analyses were performed by spectrophotometric methods. On day 14, 0.4 ppm Cr increased ($P < 0.01$) serum triglycerides level (20.5 vs. 20.7 mg/dL for control and 0.4 ppm Cr respectively), Cr 0.8 ppm had not effect ($P > 0.20$) relative to control, a quadratic effect of Cr ($P < 0.01$) was observed. On day 28, 0.4 ppm Cr decreased ($P = 0.04$) serum triglycerides (32.0 vs. 24.5 mg/dL for control and 0.4 ppm Cr respectively). Across all timepoints 0.8 ppm Cr decreased ($P = 0.07$) triglycerides serum levels (28.9 vs. 23.9 mg/dL for control and 0.8 ppm Cr respectively). Cr supplementation linearly decreased ($P = 0.09$) cholesterol on day 14 (47.5, 42.5, and 38.0 mg/dL for control, 0.4 ppm Cr, and 0.8 ppm Cr respectively). It is concluded that, chromium methionine supplementation reduced serum triglycerides concentration, and its impact on serum cholesterol level is only observed during the start of the feeding period in sheep.

Key Words: Triglycerides, Serum Cholesterol, Sheep

T256 Effect of substitution of canola meal with overcooked sesame meal on growth performance of hair sheep. J. F. Obregon*, A. Estrada-Angulo, and R. Barajas, *FMVZ-Universidad Autónoma de Sinaloa, Culiacan-Mazatlan, Mexico*.

With the objective of determining the effect of substitution of canola meal with overcooked sesame meal on growth performance in hair sheep during the finishing phase, thirty two hair sheep (males; BW=26.23 kg) were used in a complete randomized block experiment design. The animals were weighed and blocked by weight in groups of four. Groups were placed in eight pens (2 x 3 m) with a bare ground floor and assigned to consume one of two diets which constituted the treatments: 1) Diet with 15.97% CP and 3.31 Mcal of DE/kg, containing (DM) Sudan grass hay 20%, corn grain 49%, canola meal 20%, sugarcane molasses 8.4%, and mineral premix 2.6% (control); and 2) Diet similar to control, but containing 20% of sesame meal substituting for the canola meal. Animals were weighed on day 1 and day 28 at which time the trial was completed; feed was offered twice a day under free access condition. Treatments did not affect ($P > 0.2$) end weight (32.75 vs. 32.54 kg), feed intake (1.115 vs. 1.288 kg of dry matter/day), average daily gain (0.234 vs. 0.225 kg/day) or feed/gain (4.76 vs. 5.72) for canola meal and sesame meal

respectively. It is concluded, that overcooked sesame meal can be included in diets for finishing sheep, substituting for canola meal without altering performance in hair sheep in the finishing phase.

Key Words: Sesame Meal, Canola Meal, Hair Sheep
