The objective of this study was to evaluate management, sanitation and consistency of liquid diets delivered to calves via autofeeders. Ten herds in Virginia and North Carolina with sophisticated (Förster-Technik, Germany) and basic (Biotic Industries, TN) machines were asked a 60-question survey concerning calf and autofeeder management. Duplicate milk replacer samples were obtained to measure standard plate count (SPC), Brix refractometer value and temperature of liquid diet delivered by the autofeeder at the time of the survey. Dairies were also categorized based upon management strategies for the autofeeders. Producers purchased autofeeders to manipulate feeding rate, refocus labor to improved sanitation, explore new feeding options and provide better care and well-being of calves. Six dairies were visited monthly for 3 mo for continued evaluation of milk replacer from the autofeeder. Survey questions did not reveal differences related to management strategy or autofeeder type as determined by Proc Freq. Variables, SPC, Brix and temperature were analyzed by Proc Glimmix with a fixed effect of management strategy, or autofeeder type, and random effect of dairy nested in management strategy or autofeeder type, and residual. Seven herds utilizing basic machines had milk replacer liquid with a mean SPC of $6.9 \times 10^6 \pm 7.3 \times 10^6$ cfu/mL. The mean Brix and temperature readings were 12.0 ± 2.1 Brix and 38.8 ± 6.7°C. Three dairies that used sophisticated autofeeders had milk replacer liquid with a mean SPC of $1.3 \times 10^6 \pm 2.2 \times 10^6$ cfu/mL. Mean Brix and temperature readings were 10.3 ± 1.7 Brix and 38.6 ± 6.7°C. Differences could not be attributed to either management strategy or autofeeder type. This study suggests that implementation of management protocols was more important than autofeeder type or management strategy category.

Key Words: calf, automated feeder, milk replacer

W223 Performance, health, behavior and respiratory antibody production of individually vs. grouped housed dairy calves. M. S. Calvo[1], C. J. Neumeier*[1], L. E. Hulbert[1], A. Louie[2], L. J. Gershwin[3], K. E. Pinkerton[4], C. B. Tucker[1], K. C. Klasing[1], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California, Davis,* [2]*School of Veterinary Medicine, University of California, Davis,* [3]*Department of Pathology, Microbiology and Immunology, School of Veterinary Medicine, University of California, Davis,* [4]*Department of Anatomy, Physiology, and Cell Biology, School of Veterinary Medicine, Center for Health and the Environment, University of California, Davis.*

Individual calf housing systems are widely used in the US to inhibit competition for food and reduce the transmission of disease between calves. Future legislation could mandate group housing for dairy calves without identifying suitable alternatives. Therefore, the objectives were to evaluate the effects of individual housing versus group housing in modified hutches on calf performance, resting behavior, health and respiratory antibody production. The 2 housing treatments were: 1) individual housing (INV; 1.23 m^2/head; n = 18) and 2) group housing (GRP; 3 calves per hutch; 1.23 m^2/head; n = 16). Milk and starter intake were recorded daily and BW measured on d 0, 20, 45, 73, and 87. Visual health assessment scores were recorded daily and behavior loggers utilized on d 21–23, 47–49, and 74–76. In a sub-experiment, healthy calves from each treatment (n = 6, SML; n = 7, GRP) were sensitized (subQ) and challenged (aerosolized) with Ovalbumin (OVA) at age 76 ± 0.5 d. Bronchoalveolar lavage fluid (BALF) was collected at age 80 ± 0.5 d and was analyzed for OVA-specific IgG, IgG1, IgA, and IgE. All calves had increased ADG at 45 d of age compared with 20 d (INV: 0.53 ± 0.05 kg/d; GRP: 0.61 ± 0.04 kg/d). In addition, at age 73 d, INV calves tended ($P = 0.09$) to be more efficient than GRP calves (INV: 7.97 ± 0.45 Mcal/BW gained; GRP: 8.64 ± 0.35 Mcal/BW gained). The INV calves spent more time in the resting-position than GRP calves ($P < 0.01$). The GRP calves had greater percent days of nasal discharge than INV calves ($P < 0.05$). A greater percentage of days of clean hide scores were observed in INV than GRP calves ($P < 0.05$). However, GRP calves had less BALF OVA-IgE compared with INV ($P = 0.03$). Although GRP calves appeared dirtier and had more days with nasal discharge, the decreased BALF OVA-IgE suggests that early life microbial exposure may be beneficial to the respiratory antibody milieu later on in life, which warrants more investigation.

Key Words: bovine, performance, behavior

W224 Performance and welfare of high-yielding dairy cows subjected to 5 or 8 cooling sessions daily in a hot and humid climate. U. Moallem,* J. Miron, H. Lehrer, M. Zachut, and H. Honig, *Volcani Center, Bet Dagan, Israel.*

The objectives were to determine the effects of cooling frequency of high-yielding dairy cows on intake, milk yield, rumination time, and welfare parameters. Forty-two multiparous dairy cows were divided into 2 treatment groups and were housed in an open barn divided into 2 pens. The groups were subjected to different cooling schedules, in a crossover design as follows: cows were exposed to 5 or 8 cooling sessions per day (5CS and 8CS, respectively), in the holding area of the milking parlor. Each period lasted 4 wk, and then treatments were switched for another 4-wk period. Each cooling session lasted 45 min, comprising cycles of 30 s of showering and 4.5 min of ventilation. Rectal temperature (RT) and respiration rate (RR) were recorded twice per week at 0630 and 1600. Rumination and lying times were recorded automatically. RT was 0.16 and 1.08°C lower in 8CS than in 5CS cows in the morning and afternoon, respectively ($P < 0.001$). RR was lower in 8CS than in 5CS cows in the morning (49.1 and 54.6 breaths/min, respectively; $P < 0.001$), and more so in the afternoon (50.0 and 83.0 breaths/min, respectively; $P < 0.001$). DMI and milk yields were 9.3 and 9.6% higher in the 8CS than in the 5CS cows (27.0 vs. 24.7 and 40.1 vs. 36.6 kg/d, respectively; $P < 0.001$), with no differences in milk fat and protein contents. Daily rumination time was 7.4% longer in the 8CS than in the 5CS (440.1 and 409.6 min/d, respectively; $P < 0.001$). Although the 8CS cows moved 3 times more to the milking area for extra cooling sessions than the 5CS ones, they spent 9.9 min/d more than the 5CS ones in lying down (484.4 and 474.5 min/d, respectively; $P < 0.004$), and used more of their free time in resting than the 5CS cows: 52.0 and 43.9%, respectively ($P < 0.001$). In conclusion, increasing the cooling frequency of cows under hot and humid conditions from 5 to 8 times a day increased their intake and milk yield, and lowered their RR and RT. Moreover, the 8CS cows spent more time resting and ruminating than 5CS cows, an indication that increasing cooling frequency improved animal welfare.

Key Words: cooling frequency, animal welfare

W225 Effects of presynchronization with GnRH or prostaglandin F2α before the start of a resynchronization protocol on reproductive performance of dairy cows.

A. A. Scanavez[1], L. G. D. Mendonça[1], J. G. N. Moraes[1], P. R. B. Silva[1], G. Lopes Jr.[2], and R. C. Chebel*[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, Saint Paul,* [2]*Accelerated Genetics, Baraboo, WI.*

Objectives were to evaluate estrus expression, ovarian responses, and pregnancy outcomes of dairy cows submitted to different presynchronization protocols before the start of a resynchronization protocol. Cows from 2 herds (MN = 611 and WI = 307) were enrolled in the study 28 to 37 d after AI (d0). The GGPG treatment consisted of GnRH on d0 and start of the resynchronization protocol on d7. The PGPG treatment consisted of a prostaglandin (PG) F2α on d2 to 4 and start of the resynchronization protocol on d14. The resynchronization protocols were the Ovsynch56 and the Cosynch48 in the MN and WI herds, respectively. Cows submitted to the resynchronization protocol were randomly selected to receive or not a CIDR insert. Sub-sample of cows from the MN herd had ovaries scanned by ultrasound on the day of non-pregnancy diagnosis (n = 342) and on the days of the GnRH and PGF2α injections of the resynchronization protocol (n = 215). Diagnosis of pregnancy was done by ultrasound (MN herd) or by concentration of pregnancy-specific protein B (WI herd) at 33 ± 4 d after AI. Continuous data were analyzed by ANOVA, dichotomous data were analyzed by logistic regression, and time dependent dichotomous data were analyzed by Cox proportional hazard ratio. Mean and median intervals to re-insemination were ($P < 0.01$) greater for GGPG cows (14.8 ± 0.3 and 16 d) than PGPG cows (12.9 ± 0.3 and 8 d) as the former were ($P < 0.01$) less likely to be re-inseminated in estrus (16.2 vs. 61.4%). Percentage of cows with a CL on d0 was similar ($P = 0.24$) among treatments, but fewer ($P < 0.01$) PGPG cows had a CL at the start of the resynchronization (67.2 vs. 93.6%). Percentage of cows ovulating to the first GnRH ($P = 0.32$) and percentage of cows with a CL on the day of the PGF2α ($P = 0.19$) of the resynchronization were not different between treatments. Treatment ($P = 0.67$) and farm ($P = 0.38$) did not affect pregnancy outcome, but treatment by farm interaction tended ($P = 0.06$) to affect pregnancy outcome (MN–GGPG = 43.8 vs. PGPG = 36.2%; WI–GGPG = 39.9 vs. PGPG = 45.3%). Among cows re-inseminated at timed AI, pregnancy outcome did not differ between cows treated or not treated with a CIDR insert ($P = 1.0$). Presynchronization with PGF2α increased the number of cows re-inseminated in estrus and reduced AI interval, but pregnancy outcomes were dependent on farm.

Key Words: presynchronized-resynchronization, dairy cow

W226 Seasonal effect of a reduced dose of prostaglandin $F_{2\alpha}$ on estrus response in lactating dairy cows.

R. W. Silcox,* J. B. Brinkerhoff, S. Hatch, and L. T. Jacobs, *Brigham Young University, Provo, UT.*

We have previously shown that 15 mg of prostaglandin $F_{2\alpha}$ (PGF; Prostamate) injected in the ischiorectal fossa (IRF) is just as effective in inducing luteolysis in lactating dairy cows as the normally prescribed dose of 25 mg administered intramuscularly (IM). The objective of this study was to compare estrus response in lactating dairy cows treated with 15 mg PGF IRF versus 25 mg PGF IM during different seasons of the year under field conditions experienced in a single dairy herd located in Utah. The study began in February and concluded in February the following year. The study was divided into 3 seasons: Season 1-February–April; Season 2-May–August; Season 3-September–February. Five hundred seventy-seven lactating Holstein cows (lactation number 1–5) eligible for first breeding (days in milk ≥59) were selected for study based on the presence of a responsive corpus luteum as estimated by palpation performed by a field veterinarian. Selected cows were grouped each week of the study by lactation (lactation 1 versus lactation 2 versus lactation ≥ 3) and randomly assigned within group to treatment. Estrus was detected by pedometer. Overall, cows treated with 15 mg PGF IRF had an estrus response rate (161/285; 56%) lower than cows treated with 25 mg IM (200/292; 68%; $P < 0.01$). Response rate between treatments differed during Season 2 (IRF = 46/109;42% vs IM = 70/109;64%; $P < 0.01$) but did not differ ($P > 0.05$) during Season 1 (IRF = 68/107;64% vs IM = 77/111;69%) or Season 3 (IRF = 47/69;68% vs IM = 53/72;74%). Response within treatment was unaffected by season in cows given 25 mg PGF IM ($P > 0.05$) but did differ by season in cows given 15 mg IRF ($P < 0.01$). In summary, season did not affect estrus response when cows were administered 25 mg PGF IM. In contrast, lowering the dose to 15 mg injected by way of the IRF during the summer months did reduce estrus response as compared with administration during other seasons of the year and as compared with the response in cows receiving the full dose. We conclude that lactating dairy cows should not be administered a reduced dose of PGF by way of the IRF during the summer months.

Key Words: season, prostaglandin $F_{2\alpha}$, estrus

W227 Degree of agreement between the ration formulated and the ration fed on seven California dairies.

N. Silva-del-Río*[1] and A. R. Castillo[2], [1]*Veterinary Teaching and Research Center, Tulare, CA,* [2]*University of California, Cooperative Extension, Merced.*

Dairy nutritionists utilize computer models to formulate least cost rations that maximize feed to milk conversion efficiency. However, the nutrient composition of the fed ration often differs from the formulated ration as a result of errors associated with weighing ingredients into the mixer wagon, and uncertainties in dry matter content and nutrient composition of the ingredients. If large deviations exist between the formulated and the fed ration, important consequences on the environment and animal performance should be expected. The objective of this study was to evaluate the degree of agreement between the dairy cow ration formulated by the nutritionist and the ration fed at the feedbunk. A total of 7 dairies in Merced County, CA were enrolled in this study. Feedbunk samples of the total mixed ration were taken on 2 non-consecutive days from 4 (n = 1), 3 (n = 5) and 2 (n = 1) lactating groups, composited and assayed for CP, NDF, fat, Ca and P. Results are presented in Table 1. Dairies over or under fed more than 10% of CP (n = 4), NDF (n = 3), fat (n = 3), Ca (n = 6) and P (n = 2). Results from this study indicate that despite formulating rations to meet animal requirements, and implementing grouping strategies, we will not improve nutrient efficiency utilization unless best feeding management practices are implemented to minimize errors during the feeding process.

Table 1. Maximum and minimum percentage of nutrient under or over fed per dairy across the different total mixed rations (TMR)

Dairy	1	2	3	4	5	6	7

W228 Nitrogen and phosphorus utilization by dairy cows on small and medium-sized farms.

Z. Dou, J. D. Ferguson, D. T. Galligan, C. F. Ramberg, D. W. Remsburg, L. D. Baker, R. J. Munson, and Z. Wu,* *University of Pennsylvania, Kennett Square.*

Small and medium-sized dairy farms (<700 cows) are exempted from EPA nutrient management regulations, but can account for a major proportion of animals in traditional agriculture regions. Reducing nutrient loading to sensitive water bodies is a challenge that needs to be shared by animal operations of all scales. Ten dairy farms with 50 to 250 cows (900 total) were randomly selected from the Chesapeake Bay watershed in Pennsylvania and monitored for nutrient utilization for 2 yr in comparison with baseline data collected during the first 3 mo of the project. Farms were evaluated regularly for nutrition and management practices and presented with recommendations for improvement, as appropriate. Diets and feces were sampled quarterly (fecal from 5 randomly selected cows per herd) and analyzed for nutrient content. DHIA reports were collected monthly. Most of the farms used dietary P appropriately, and half of the farms reduced dietary protein during monitoring, averaging 0.38% in P and 16.5% in CP, both consistent with current industry usages and NRC standards. However, variation existed in the diets as well as fecal analysis among farms and over time within farms. Analyzed dietary P exceeded formulated concentrations, whereas the trend was the opposite for protein. Pregnancy rate (21-d) increased during the monitoring period. While combined data across farms showed that there was little change in milk production or MUN during the monitoring period, half of the farms showed improvements. Although not mandated to implement nutrient management plans, producers of small and medium farms were conscientious about dietary CP and P content, and willing to adopt new technologies to reduce excretion. Extension services for reducing nutrient excretion on small and medium farms may use the approach of identifying vulnerable farms followed by close monitoring and evaluation. Partially supported by National Fish and Wildlife Foundation.

Table 1. Protein and phosphorus utilization on small and medium dairy farms during 2-yr monitoring

Item	Baseline	Monitoring	SEM	*P*
Dietary CP, %

W229 Basic economic indexes on small and medium sized dairy farms.

D. T. Galligan,* Z. Dou, J. D. Ferguson, C. F. Ramberg, D. W. Remsburg, L. D. Baker, R. J. Munson, and Z. Wu, *University of Pennsylvania, Kennett Square.*

Ten dairy farms with 50 to 250 cows (averaging 87.7 cows/herd) were randomly selected from the Chesapeake Bay watershed in Pennsylvania and monitored for nutrient utilization and production efficiency for 2 yr in comparison with baseline data collected for the first 3 mo of project. Farms were evaluated regularly for nutrition and management practices and economic parameters were collected from herd accountants, tax reporting forms, and herd record systems. DHIA reports were collected monthly tracking production, herd demographics, culling, and reproductive performance. Farm wealth was hypothesized to be improved by selling products (milk, calves, and culls) as well as the accumulation of valued livestock over the course of the study. Nutrient efficiency was hypothesized to improve due to improved animal performance per unit of animal maintenance and replacement. Herds varied greatly in their nutritional, animal, and management practices and were offered evaluations and recommendations by participating study members. Herd parameters in yr 1 and 2 were compared with baseline values recorded in yr 1 as well as values reported for similar Pennsylvania herds at large. Basic economic metrics (milk price: \$0.352/kg milk; marginal feed cost: \$0.08/kg milk; cull values: \$600; cow value: \$1600) were set to average values observed over the study period so that changes in production efficiency could be observed. Milk production, estimated from changes in rolling herd average, improved by approximately 270 kg/cow over the 2-yr period with an estimated marginal value of \$71.35/cow. Herd value on 8 herds (cows and heifers valued at constant prices) increased by 3% in yr 1 and 5% in yr 2 compared with starting values. Estimated net income over feed cost increased by \$72.83/cow over the 2-yr period while a comparable estimate of herds with <100 cows in Pennsylvania increased by only \$4.39 over the same period. Seven of the 10 farms had increases in pregnancy rate from 20.4 to 22.7% with an estimated reproduction efficiency value of \$53.02 per cow per year (REPMON economic analysis). Improved nutrition by nutrient management strategies is synergistic with positive economic consequences on dairy herds. Partially supported by National Fish and Wildlife Foundation.

Key Words: dairy farm management, farm economic, dairy herd evaluation

W230 Technological level of Holstein cattle herds in the West and North of Mexico.

D. V. Mariscal-Aguayo,* H. Estrella-Quintero, R. Núñez-Domínguez, and G. Maldonado-García, *Universidad Autónoma Chapingo, Chapingo, Estado de México, México.*

The objective of this study was to classify family-based dairy enterprises considering their technological level (TL). Surveys following FAO´s guidelines were applied to 45 producers, located in the states of Chihuahua, Coahuila, Durango, Aguascalientes, Jalisco and Michoacán in México, to diagnose the type and use of technology. From outputs of the surveys, indexes for reproductive (RMI), health (HMI) and nutritional (NMI) management, genetic quality (GQI), and infrastructure and equipment (IEI) were calculated. Later, these indexes were combined to get the TL by weighing each index with their importance to differentiate the enterprises. FAO´s guidelines were modified getting the weights, proportional to the variation coefficients of the indexes (26.0, 19.6, 25.0, 3.6, and 25.8% for RMI, HMI, NMI, GQI and IEI, respectively). The enterprises were classified as subsistence, transition or business (transition enterprises are those moving from subsistence to business, the latter being the ones that market all their products), if the TL was ≤ 0.4, > and ≤ 0.8 or >0.8, respectively. Eighty 6 percent of enterprises were classified in transition and 14% in business. Transition enterprises averaged 7 years of school attendance, agricultural or grazing area of 26.9 ha, herd size of 98 animals, 53 cows in milk, 20.2 L of milk/cow per day, and a milk price of \$4.43/L, artificial insemination (AI) is used, 17% use bulls for mating repeated not pregnant cows, and cattle feeding is variable. Business enterprises averaged a 9 years of school attendance, agricultural or grazing area of 56.6 ha, herd size of 384 animals, 215 cows in milk, 26 L of milk/cow per day, and a milk price of \$4.68/L, AI is used, cattle are confined and the feeding is based on forage and concentrates. The TL is important to advise producers in a different manner, according to the strengths and weaknesses, to improve production efficiency of their enterprises.

Key Words: cattle, dairy enterprises, producer stratification

W231 Association of stocking density, production, and behavioral patterns of dairy cows milked in automatic milking systems.

J. A. Deming[1], R. Bergeron[2], K. E. Leslie[3], and T. J. DeVries*[1], [1]*Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada,* [2]*Dept. of Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada,* [3]*Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada.*

The objective of this cross-sectional study was to examine the associations between stocking density, production, and behavioral patterns of cows milked in automatic milking systems (AMS) under commercial management settings. Thirteen AMS farms were enrolled in the study. Average herd size was 71 ± 30 lactating cows. Farms either had 1 (n = 11) or 2 (n = 2) AMS units. All of the farms utilized free-stall barns, each set up for free cow traffic. Across farms there were, on average, 55 ± 10 cows/AMS, 0.9 ± 0.1 cows/free stall, and 0.66 ± 0.17 m/cow of feed bunk space. A random sample of 30 cows per herd was selected to monitor standing and lying behavior for 4 d using electronic data loggers. Times of feed delivery and feed push-up were recorded daily. Milking times and yield were automatically recorded by the AMS units. Data were analyzed in multivariable mixed-effect regression models. Cows were milked less frequently ($P < 0.05$) when they were further in lactation, were of higher parity, and as AMS stocking density (#cows/AMS) increased; milking frequency (#/d) = −0.003(SE = 0.0004) × DIM + −0.06(SE = 0.03) × parity + −0.02(SE = 0.009) × cows/AMS + 4.4(SE = 0.5). Milk yield increased with feed bunk space and parity ($P < 0.05$) and decreased ($P < 0.001$) with DIM; milk yield = 16.9(SE = 5.3) × bunk space (m/cow) + 1.9(SE = 0.03) × parity + −0.05(SE = 0.004) × DIM + 26.6(SE = 3.7). Lying bout lengths increased with DIM ($P = 0.02$) and tended ($P = 0.11$) to increase with more feed bunk space; bout length (min/bout) = 0.035(SE = 0.01) × DIM + 36.7(SE = 21.7) × bunk space (m/cow) + 49.0(SE = 14.8). Cows spent more time lying down ($P = 0.02$) the further along they were in lactation; lying time (h/d) = 0.004(SE = 0.001) × DIM + 7.5(SE = 0.7). Cows of higher parity stood longer after milking ($P = 0.003$); post-milking standing time (min) = 5.3(SE = 1.8) × parity + 63.2(SE = 6.7). The results suggest that within AMS herds, more milkings per cow may be achieved with having fewer cows per AMS unit. Further, in AMS herds, longer lying bouts and greater milk yield may be achieved with providing more feed bunk space per cow.

Key Words: automatic milking, behavioral pattern, stocking density

W232 Performance of dairy cows managed with automatic milking and three contrasting feeding systems.

S. A. Utsumi* and D. K. Beede, *Michigan State University, East Lansing.*

The effects of contrasting feeding systems (FS) on milk production and frequency of milkings in 2 separate herds of Holstein cows (n = 45 to 53 cows/herd) managed with automatic milking systems (AMS) was quantified in this pilot study. Feeding systems were: pasture grazing (GRASS); total mixed ration (TMR); and, pasture grazing plus supplemental TMR (pTMR) lasting 66, 51 and 96 d, respectively. Average DIM and parity of cows for the 3 FS were 169 ± 13(mean ± SE) and 2.3 ± 0.2, respectively. Cows received in addition to basal diets in the FS, 1 kg of concentrate per 4 kg of milk. Voluntary milking with one single-stall AMS per herd was applied at variable rates of 4 to 2 milkings/day based on DIM and daily milk yield. ANOVA for a completely randomized design (Proc Mixed, SAS) and path analysis (Proc Calis, SAS) of standardized regression coefficients (r) for the interrelationships among milk yield, milking frequency and concentrate intake was conducted using a total of 14,035 daily cow records. As expected, milk yield, milking frequency and body weight were greater ($P < 0.001$) for cows in TMR, intermediate for those in pTMR and lower for those in GRASS (Table 1). Conversely, cow activity in GRASS increased ($P < 0.001$) by 46% and 68% compared with pTMR and TMR, respectively (Table 1). Path analysis detected greater direct effects ($P < 0.05$) of concentrate intake on milk yield for GRASS (r = 0.52) compared with pTMR (r = 0.46) and TMR (r = 0.44) feeding systems. Conversely, the path analysis detected lower direct effects ($P < 0.10$) of milking frequency on milk yield for GRASS (r = 0.14) compared with the pTMR (r = 0.21) and TMR (r = 0.32) feeding systems. This analysis highlights the importance of proper concentrate feeding in FS, increasingly limited by low feed or energy intake, such as in GRASS, and the potential milk yield response to increased milking frequency in FS offering increasing amounts of feed or energy intake, such as pTMR and TMR.

Table 1. Cow performance in three feeding systems

Response	GRASS	pTMR	TMR
Milk yield, kg/d	23.0^{c}	27.0^{b}	30.1^{a}
Milking frequency, /d	2.4^{c}	2.7^{b}	3.1^{a}
Body weight, kg	566^{b}	574^{ab}	597^{a}
Activity, accelerometer counts	415^{a}	284^{b}	245^{c}

$^{a–c}$Means within a row with different superscripts differ ($P < 0.05$).

W233 Potential for a real-time location system for dynamic tracking of dairy cow location within dairy facilities.

R. A. Black*[1], T. S. Stombaugh[1], S. R. Luciani[2], M. P. Sama[1], R. L. Klingenfus[3], A. B. Klingenfus[3], and J. M. Bewley[1], [1]*University of Kentucky, Lexington,* [2]*AiRISTA, Sparks, MD,* [3]*Harvest Home Dairy, Crestwood, KY.*

The objective of this study was to evaluate the potential accuracy of real time location systems (RTLS), commonly used to track assets or people, within a roofed dairy facility. AiRISTA (Sparks, MD) developed a leg-based RTLS tag incorporating Wi-Fi and RFID to locate tags through received signal strength indication (RSSI). The RTLS was installed in a newly constructed 120-cow compost bedded pack barn, measuring 59.1 long (X plane) by 39.6m wide (Y plane). Six locators, mounted around the perimeter of the barn to transmit a signal, and 6 access points, mounted throughout the barn interior to send and receive signals, were installed at 4.3m high. X and Y coordinates of 43 evenly distributed locations throughout the barn were obtained with a total surveying station (Trimble SPS390 Universal Total Station, Sunnyvale, CA). Calibration was achieved using AirCalibrator software and tags and 7 reference location (RL) poles. The total surveying station determined RL coordinates. To assess system accuracy, a tag was attached to the researcher's leg while the researcher rotated among each RL 5 times to obtain X and Y coordinates for 35 samples. The mean (±SD) difference from the RL for the X coordinate was −0.08 ± 0.85m, ranging from −1.49 to 1.12m, and 0.37 ± 0.55m for the Y-coordinate, ranging from −0.46 to 1.36m. The mean (±SD) root squared error of the mean (RSEM) was 0.91 ± 0.48m. The mean (±SD) of the X and Y coordinates and RSEM for each location are depicted in the table below. A RTLS system may be able to identify animal position within a few meters, although additional validation with multiple cows is needed.

Table 1. Mean (±SD) of X and Y coordinates (m) and RSEM (m) for each RL

Location	X-coordinate	Y-coordinate	RSEM
1	50.02 ± 2.12	9.49 ± 1.91	1.22
2	43.05 ± 0.87	8.56 ± 1.64	0.87
3	34.30 ± 1.53	9.01 ± 1.49	0.39
4	26.67 ± 0.68	8.80 ± 1.46	0.49
5	19.34 ± 1.50	7.78 ± 1.67	1.36
6	14.86 ± 1.68	8.70 ± 1.03	1.56
7	6.33 ± 1.53	8.85 ± 0.95	0.46

Key Words: real time location system, animal tracking, dairy

W234 Effects of prepartum dietary energy density and postpartum extruded full-fat soybean (ESB) supplementation on energy balance and productive performance of transition dairy cows. H. Su,* F. Wang, Z. Yang, Z. Cao, and S. Li, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objective of this study was to determine the ideal energy density that could alleviate negative energy balance (NEB) without jeopardizing milk production of transition cows. Three prepartum diets of different energy levels (NEL = 5.25, 5.88 and 6.48 MJ/kg DM for L, M and H, respectively) and 2 postpartum diets (basal TMR or supplementing with 1.5 kg/d ESB in the first 30 d of lactation) were studied in a 3 × 2 factorial design experiment. Sixty multiparous dairy cows were blocked according to expected calving date, BW, BCS, parity and previous mature-equivalent milk into 6 groups, and each group was randomly allocated to one treatment. Individual feeding started 3 wk before the expected calving date and measurements were taken until 56 DIM. All data were analyzed using the PROC MIXED procedure of SAS (version 9.1). With the increase of prepartum dietary energy density, the birth weight of calves increased ($P < 0.05$), and prepartum DMI as well as energy balance of the transition cows improved ($P < 0.01$). However, compared with L and M groups, postpartum DMI of H group tended to decrease ($P < 0.079$), and postpartum BCS decreased significantly ($P = 0.007$). From 35 to 56 DIM, milk yield tended to decrease ($P = 0.061$) and milk fat and protein yields were lower ($P < 0.05$) for cows in the H group. Milk urea nitrogen (MUN) concentration ($P = 0.034$) and postpartum plasma nonesterified fatty acids (NEFA) concentration ($P < 0.10$) of M group were the lowest. By supplementing ESB during early lactation, the dairy cows had greatly improved energy balance ($P < 0.05$), less BW loss ($P = 0.09$), and a tendency for increased milk yield ($P < 0.10$). Taking all these results into account, feeding prepartum diets of low or medium energy and supplementing 1.5 kg/d ESB in the postpartum diet might be the best approach for alleviating NEB, improving productive performance and maintaining optimum health in transition dairy cows.

Key Words: transition cow, energy balance, productive performance

W235 Physiological and productive responses to seasonal variation in transition dairy cows. H. Su,* F. Wang, Z. Yang, Z. Cao, and S. Li, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objective of this study was to investigate physiological and productive responses of cows calving in summer compared with cows calving in autumn. During each season, 20 multiparous Holstein dairy cows were selected and dried off 60 d before expected parturition, and balanced according to BW (699 ± 34 kg), BCS (3.57 ± 0.17), parity (2.14 ± 1.22) and previous mature-equivalent milk (7520 ± 858 kg). The cows were monitored from the last 3 wk of pregnancy until 21 DIM. All cows were fed a TMR formulated to meet or exceed NRC (2001) requirements. The average temperature-humidity index (THI) was 75.9 ± 3.1 in summer and 52.9 ± 7.1 in autumn. Results showed that cows were experiencing heat stress for nearly 96% of the test days during summer. In comparison with the autumn group, cows in summer had significantly increased rectal temperature and respiration rates ($P < 0.01$), decreased BW, BCS and DMI ($P < 0.05$), which induced more severe negative energy balance (NEB) ($P < 0.01$). Cows that experienced transition period during summer also had lower milk yield, percentages of milk fat, protein, solids-not-fat (SNF), and feed efficiency ($P < 0.01$), but higher concentration of milk urea nitrogen (MUN) ($P < 0.01$) and a tendency for higher somatic cell count (SCC) ($P = 0.054$). In addition, plasma concentrations of insulin, leptin, glucose, triiodothyronine (T3), thyroxine (T4) and cortisol of cows calving in summer were significantly lower ($P < 0.05$), whereas the concentrations of plasma glucagon, urea nitrogen, nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) were significantly higher within 14 d postpartum ($P < 0.05$). In conclusion, compared with cows calving in autumn, cows calving in summer not only had more severe NEB and lower milk production, but also were at higher risk for health disorders. Based on our findings, we suggest producers avoid breeding dairy cows for calving during the hot season.

Key Words: transition cow, physiology, seasonal variation

Production, Management and the Environment: Environmental Quality

W236 Using dietary saponin extracts to reduce methane emissions from steers. W. Li* and W. Powers, *Michigan State University, East Lansing.*

A total of 3 experiments (Exp), in vitro and in vivo, were conducted to investigate the effects of saponin extracts from *Quillaja saponaria* (QS), *Yucca schidigera* (YS) and *Camellia sinensis* (TS) on CH_4 emissions from steers. The in vitro Exp was carried out to determine the effects of saponin inclusion on ruminal methanogenesis and fermentation parameters. Two doses (0.5% and 2.0% of substrate DM) of each saponin were added to the mixture of rumen fluid and buffer for 0, 4, 8, 12 and 24 h incubation. During the in vivo experiments (Exp 1 and 2), concentrations of saponin extracts added to the diets were determined based on the actual saponin content in the extract to provide 0.54 g/kg DM saponin in the diets. Exp 1 used a 3 × 3 Latin Square design with 4 replicates for each treatment, to compare the effects of saponin containing diets, QS (LQS, 1.5% DM) and YS (LYS, 0.64% DM), to a corn and corn silage based control (C1) treatment on enteric CH_4 emissions. Exp 2 used a 2 × 2 Latin Square design with 6 replicates to evaluate the effect of TS (LTS, 0.25%) on enteric CH_4 emissions, by comparing it to a corn and corn silage based control diet (C2). For each study, 12 Holstein steers were individually housed in environmental rooms for 14 d per period. Methane concentrations were monitored in room exhaust air. In the in vitro experiment, both inclusion rates reduced in vitro CH_4 production in all saponin treatments at 24 h incubation ($P < 0.01$), while gas production and pH were not affected ($P > 0.05$). Acetate concentration was reduced in all treatments except 0.5% QS and 0.5% YS ($P < 0.01$). With the exception of the QS 0.5% treatment, all saponin treatments reduced A:P ratio and the NH_4-N concentration compared with the control treatment, at 24hr time point ($P < 0.01$). During both in vivo Exp, feeding saponins to steers did not change ADG or manure excretion characteristics ($P > 0.05$), but decreased DMI with TS saponin supplementation ($P < 0.01$). Methane emission mass, emission factors and manure excretions were not affected by dietary saponin inclusion. Results indicated that dietary supplementation of 0.54 g/kg DM saponin did not decrease ruminal CH_4 emissions.

Key Words: saponin extracts, CH_4 emissions, Holstein steer

W237 Does total condensed tannin concentration predict rumen methane production in vitro? H. D. Naumann*[1], L. O. Tedeschi[1], J. P. Muir[2], B. D. Lambert[2,3], D. K. Andrade Silva[4], and M. A. Fonseca[5], [1]*Texas A&M University, College Station,* [2]*Texas AgriLife Research, Stephenville,* [3]*Tarleton State University, Stephenville, TX,* [4]*Federal Rural University of Pernambuco, Garanhuns, Pernambuco, Brazil,* [5]*Federal University of Viçosa, Viçosa, Minas Gerais, Brazil.*

The US EPA has indicated that 20% of total CH_4 emissions in the US are the result of enteric fermentation in domestic ruminants. Previous studies have indicated that forages containing biologically active condensed tannins (CT) may reduce the amount of CH_4 produced during rumen fermentation. The objective of this work was to verify if the concentration of total CT (TCT) from warm season perennial herbaceous legumes affects CH_4 production in vitro. Five forages commonly fed to ruminants were evaluated, including *Desmanthus illinoensis* (Illinois bundleflower), *Lespedeza cuneata* (sericea lespedeza), *Acacia angustissima* (prairie acacia), *Desmodium paniculatum* (panicled tickclover), and *Arachis glabrata* (rhizoma perennial peanut). Each of these forages was fermented for 48 h under anaerobic conditions. Perennial peanut had the least TCT at 5.69 g/kg DM and produced 110.62 mM CH_4/g DM, which was greater ($P < 0.05$) than the other species surveyed. There was no difference in CH_4 production between Illinois bundleflower and sericea lespedeza ($P > 0.05$), which produced 66.17 and 46.73 mM CH_4/g DM and had TCT concentrations of 81.49 and 82.95 g/kg DM, respectively. There was no difference in CH_4 production between sericea lespedeza and panicled tickclover ($P > 0.05$), which produced 46.73 and 23.26 mM CH_4/g DM, respectively, even though panicled tickclover had the greatest TCT concentration of all plants surveyed at 124.63 g/kg DM, suggesting the type, but not necessarily the amount, of CT might have affected CH_4 production. Prairie acacia had a TCT concentration of 84.66 g/kg DM and produced 6.93 mM CH_4/g DM. Prairie acacia suppressed CH_4 to a greater degree than sericea lespedeza, Illinois bundleflower, and perennial peanut but not panicled tickclover ($P < 0.05$). Results indicated that feeding native warm season perennial herbaceous legumes containing CT is a promising alternative to feeding introduced and potentially invasive species sericea lespedeza as it relates to reducing CH_4 production during fermentation in vitro. In addition, it appears that TCT concentration alone is not a reliable predictor of the CT biological activity relative to CH_4 production by rumen liquid in vitro.

Key Words: condensed tannins, legumes, greenhouse gas

W238 Methane production from novel oat varieties measured by gas production. J. M. Moorby,* A. A. Cowan, D. K. Leemans, and A. H. Marshall, *Institute of Biological, Environmental and Rural Sciences, Aberystwyth University, Aberystwyth, UK.*

Methane emissions from sheep fed naked oats has been shown previously to be lower than from sheep fed husked oats or barley, offering the potential of this crop as a potential mitigation option. However, the price of naked oats is significantly higher than that of husked oats, which limits their use. To improve the digestibility of husked oats, a breeding program aimed at producing low-lignin oats with a high oil content has generated several new breeding lines. The methane production potential of these lines was compared with commercial naked oat varieties using the gas production technique. Triplicate ground samples of 1 g DM of each oat whole grain (including the husk, if present) were incubated in dairy cow rumen fluid at 39°C in gas-tight bottles. Gas was removed from the bottles to equalize pressure at 3, 6, 10, 14, 20, 26, 31, 47, 71 and 81 h from the start of incubation, and the methane concentration in the recorded volume was measured. Dry matter residues were weighed to determine apparent digestion. Methane production varied from 28.3 to 46.1 (mean = 35.4, SD = 4.73) ml per g grain DM incubated, and 39.7 and 52.2 (mean = 46.3, SD = 3.68) ml per g of apparently digested DM (adDM). Methane production was negatively related to grain ADL content ($r = -0.86$; $P < 0.001$) but was positively related to DM loss ($r = 0.78$; $P < 0.001$). Methane production per g adDM was also negatively related to grain total fatty acid (FA) content ($r = -0.77$; $P < 0.001$). As the relative proportion (g FA/100g total FA) of some of the unsaturated FA increased, methane production per g adDM decreased (e.g., C18:1, $r = -0.76$; $P < 0.001$). However, because the relative proportions of individual FA did not vary greatly among the different oat lines, the relationships with methane emissions were similar to those of total FA, particularly for those FA in greatest abundance (C16:0, C18:1, C18:2 n-6). In conclusion, breeding husked oats for reduced lignin concentrations and increased FA concentrations to produce more digestible oat with a high oil content offers potential as a ruminant dietary ingredient that could help mitigate methane emissions.

Key Words: oats, methane, gas production

W239 Effect of crude glycerin on methane emissions of male beef calves finished in feedlot. J. F. Lage*[1], T. T. Berchielli[1], I. P. C. Carvalho[1], A. Berndt[2], R. T. S. Frighetto[3], E. San Vito[1], R. A. Silva[1], A. F. Ribeiro[1], L. M. Delevatti[1], E. E. Dallantonia[1], L. R. Simonetti[1], and R. A. Reis[1], [1]*Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil,* [2]*Embrapa Pecuária Sudeste, São Carlos, São Paulo, Brazil,* [3]*Embrapa Meio Ambiente, Jaguariúna, São Paulo, Brazil.*

The objective of this study was to evaluate the effects of feeding crude glycerin (CG; 80% glycerol) included as 10% of diet DM to replace corn or soybean hulls in 2 concentrade:roughage ratios (60:40 or 40:60) on enteric methane (CH4) production of young bulls finished in feedlot. Thirty 6 young bulls (Nelore breed) with 374.11 ± 24.77 initial BW, were randomly assigned to 6 treatments, with 6 replicates. The diets were: 1- corn, no CG; 2- CG and corn, 3- CG and soybean hulls. These 3 diets were formulated with 2 concentrate:roughage ratios (60:40 or 40:60), resulting in 6 treatment diets in a 2 × 3 factorial arrangement. The diets were isonitrogenous. Animals were slaughtered at 495.50 kg BW. The CH4 emissions were evaluated using the SF6 tracer gas technique. Five consecutive gas samples were collected in 24-h intervals from each animal. Data were analyzed using the GLM procedure of SAS. Characteristics evaluated in the study were daily carcass gain (CrG, kg.d-1), and CH4 emission expressed in kg of CH4 emitted per year (kg CH4.yr-1), gram of CH4 emitted per day (g CH4.d-1), gram of CH4 emitted per day per kg of metabolic BW (g CH4.d.MBW-1) and kg of CH4 emitted per kg of carcass produced (kg CH4.kg CAR-1). The CrG was not different ($P > 0.05$) among the treatments, with mean values of 0.94 kg.d-1. The CH4 emission was also not different ($P > 0.05$) among the treatments in any unit expressed, with mean values of 62.5 kg.yr-1, 171.2 g.d-1, 1.62 g.d.MBW-1, 0.22 kg.kg CAR-1, respectively. Interaction between concentrate:roughage ratios and feeding regimens was not significant ($P > 0.05$). The evaluated variables did not change ($P > 0.05$) in response to the ratio of roughage utilized (60:40 or 40:60). Animals fed with CG in diet with low or high level of concentrate showed similar enteric methane production.

Key Words: beef cattle, greenhouse, glycerol

W240 Prediction of methane emission from enteric fermentation of growing-finishing Hanwoo steers using IPCC methodology. N. C. Jo*[1], S. Y. Jeong[1], K. H. Park[2], and S. Seo[1], [1]*Chungnam National University, Daejeon, Republic of Korea,* [2]*National Institute of Animal Science, R.D.A., Suwon, Republic of Korea.*

The objectives of this study were 1) to predict methane (CH_4) emissions from enteric fermentation of Hanwoo steers using the Intergovernmental Panel on Climate Change (IPCC) Tier 2 equations and 2) to evaluate and compare the adequacy of the use of the IPCC Tier 2 and the Japanese Tier 3 equations for predicting enteric methane emissions from Hanwoo steers. The values of animal and feed characteristics required for the equations (e.g., BW, ADG, and energy content of feeds) were obtained from Kim et al. (2005). CH_4 emission was calculated by multiplying gross energy (GE) intake with constant CH_4 conversion factor as suggested by IPCC. Methane emission from enteric fermentation of Hanwoo steers was estimated to be 116.3, 93.6, and 99.1 g CH_4 /head/day for the growing, finishing, and overall, respectively. These resulted in an estimated enteric methane emission factor of 36.2 kg CH_4 /head/year for growing-finishing Hanwoo operation. The value was lower than the one estimated using IPCC Tier 1 (53 kg CH_4 /head/year) which is being used for the national inventory report of Korea. When GE intakes were replaced by the values estimated from actual feed intake, estimated enteric methane emission was significantly lower ($P < 0.01$) in the finishing period (80.3 g CH_4 / head/day) and overall (91.7 g CH_4 /head/day). Consequently, enteric methane emission factor was estimated to be 33.5 kg CH_4 /head/year. This imply the IPCC Tier 2 method may overestimate enteric methane emission from Hanwoo especially during the finishing period, which is primarily due to overestimation of GE intake. On the contrary, the Japanese Tier 3 predicted DMI of Hanwoo steers surprisingly well ($R^2 = 0.88$, root mean squared prediction error = 0.4). However, it estimated enteric methane emission factor of 69.1 kg CH_4 /head/year, which is even larger than the default value based on IPCC Tier 1. The discrepancy was due to over-prediction of a percentage of feed energy converted to methane. We concluded that either the IPCC Tier 2 or the Japanese Tier 3 method overestimated methane emissions from enteric fermentation of growing-finishing Hanwoo steers and further research to develop Korean-specific equations and parameter estimates is warranted.

Key Words: Hanwoo steers, enteric fermentation, methane emission factor

W241 Enteric methane emissions by dairy cows grazing temperate pastures. N. Nelson*[1], K. Steensma[1], S. Utsumi[1], D. K. Beede[1], S. Zimmerman[2], and P. Zimmerman[2], [1]*Michigan State University, East Lansing,* [2]*C-Lock Technology Inc., Rapid City, SD.*

Effects of grazing ryegrass (RG) or orchardgrass (OG) pasture on milk production, enteric methane (CH_4) flux and CH_4 per unit of milk by United States Holstein (USH; 552 ± 6 kg BW; n = 24) and New Zealand Friesian (NZF; 342 ± 11 kg BW; n = 6) cows managed with an automatic milking system (AMS) was quantified. Rotational grazing of RG and OR pastures was applied at conservative stocking rates (2.5 cow/ha) using pre- and post-grazing pasture biomass targets of 2400 ± 200 and 1500 ± 200 kg/ha, respectively. Voluntary milking with one single-stall AMS was applied at variable rates of 4 to 2 milkings/day based on DIM and milk yield (MY). In addition to pasture, cows received 1 kg of concentrate per 6 kg of MY. Concentrate was fed in the AMS unit. Mass flux of eructed and expired CH_4 during individual milkings (n = 1,151) was automatically recorded using nondispersive infrared sensors and tracer gas (Greenfeed system, C-Lock Technology Inc., Rapid City, SD). Repeated measures analysis of daily CH_4 fluxes and Pearson correlation of calculated CH_4 fluxes and milk production for a completely randomized design were conducted ($\alpha = 0.05$). Enteric CH_4 flux (g/d) was greater ($P < 0.001$) for USH (384 ± 8) than NZF (281 ± 22) cows, but CH_4 flux per unit of metabolic BW was not different ($P = 0.68$) between the 2 breeds (average: 3.43 ± 0.14 g/kg $BW^{0.75}$). Daily CH_4 flux was affected by a pasture by day interaction ($P = 0.002$), likely influenced by daily decreases in CH_4 flux in RG pastures. Milk yield was not different ($P = 0.84$) between RG and OG pastures (average: 20.5 ± 1.5 kg/cow per d), but MY was greater ($P < 0.001$) for USH (27.2 ± 1.0 kg) than NZF (14.1 ± 1.9 kg) cows. Differences in MY between breeds explained the diluted ($P = 0.05$) CH_4 per unit of milk in USH compared with NZF cows (15.8 ± 0.9 vs. 21.2 ± 2.5 g CH_4/kg milk). There was a positive correlation ($P < 0.001$) between MY and CH4 flux ($r = 0.20$) and a significant negative correlation ($P < 0.001$) between CH_4 emissions per unit of milk and MY ($r = -0.75$), highlighting the importance of high milk production levels as a management strategy to mitigate CH_4 emissions in pasture-based dairy systems.

Key Words: methane, pasture-based dairy, automatic milking

W242 Estimation of greenhouse gas emissions from beef cattle production systems using whole-farm models. A. W. Alemu*[1], K. H. Ominski[1], M. Tenuta[1], and E. Kebreab[2], [1]*University of Manitoba, Winnipeg, MB, Canada,* [2]*University of California, California, Davis.*

Measuring greenhouse gas (GHG) emissions from beef cattle operations is challenging as these are complex systems, composed of multiple interacting components. Whole-farm modeling integrates these components and can be used to determine the effects of change in management practices on net emissions and to develop cost-effective mitigation options. The objectives of this study were to: 1) integrate process-based models into a whole-farm GHG model and 2) compare the outputs from the integrated model with outputs from other whole-farm models under different management practices. Input data for the models were obtained from published literature including a 3-year study which examined GHG emissions associated with the following management practices: no application of liquid hog manure on pasture (baseline), application of manure in fall and spring (split) and single application of manure in spring only (single). An integrated whole-farm model (IM) was developed by integrating the process-based models, COWPOLL and manure-DNDC, as well as aspects of IPPC. Emission estimates from IM were examined along with those generated from HOLOS and the Integrated Farm System Model (IFSM). It was assumed that the simulated cow-calf operation was self-sufficient with regard to feed and bedding. Estimated whole-farm emissions were 13, 15 and 14 kg CO_2 eq/kg animal live weight for the baseline scenario using IM, HOLOS and IFSM, respectively. However, whole-farm emission estimates were higher for split (24 and 19 kg CO_2 eq/kg animal live weight) and single (29 and 19 kg CO_2 eq/kg animal live weight) application using IM and IFSM, respectively. Estimates from all models indicated enteric methane was the major contributor in the baseline scenario (68–74%) whereas enteric methane (36–54%) and soil nitrous oxide (34–51%) were the major contributors for the split and single application. In general, variation was observed among models, not only in estimating whole-farm emissions, but also in the proportion of methane and nitrous oxide produced from the different farm components.

Key Words: greenhouse gas emissions, whole-farm model, beef cattle production

W243 Isotope ratio mass spectrometry monitoring of nitrogen volatilization from cattle feces and ^{15}N-labeled synthetic urine.

F. Y. Ayadi,* E. L. Cortus, and D. E. Clay, *South Dakota State University, Brookings.*

Losses in the nitrogen cycle from manure, to fertilizer, to crops fed to the animal and back to manure are losses of valuable nutrients to the environment in form of gaseous emission or runoff. To minimize these losses, we must first understand the nitrogen source. The objective of this study was to verify the ^{15}N-labeled urea tracer method to determine the fate and origin of nitrogen in manure. A bench-scale manure storage experiment with beef feces and synthetic urine was conducted to monitor the movement of nitrogen (N) via ^{15}N-labeled urea through the system. Isotope ratio mass spectrometry (IRMS) was used to determine the ratio of fecal material vs. urine contribution to loss of ^{15}N and total nitrogen from a manure mixture. Feces were collected from beef cattle and mixed in a 1:2.2 ratio with 10 atom % ^{15}N-labeled synthetic urine. Fresh urine and feces were added daily for 4 d to jars that were connected to a vacuum pump which pulled the exhaust through a sulfuric acid trap solution. Acid traps were exchanged daily and exhausted ammonia was collected for 15 d. All samples (initial urine and feces, acid trap, and final manure mixture) were analyzed for total N and ^{15}N using IRMS. Results showed that nitrogen loss of the manure mix was highest during the first 2 to 3 d of monitoring. The majority of N loss (92.2%, SE = 0.3) occurred from the urine portion of the manure mixture on d 2. On d 15 only 68.6% (SE = 1.1) of the volatilized N was derived from urine. The average N volatilization from urine from d 1 to 15 was 83.7% (SE = 0.1). Nitrogen losses from feces were more variable, being high on d 1 (24.5%, SE = 0.5), decreased to 9.0% (SE = 0.3) on d 5 and gradually increased to 31.4% (SE = 1.2) on the last day of sampling (d 15). This study verified the applicability of IRMS measurements for beef manure mixtures that has previously been verified for dairy systems. The results suggest that further research to explain and model the ammonia/nitrogen release from fecal material is warranted.

Key Words: ammonia volatilization, gas emission, beef cattle manure

W244 Identifying ammonia hotspots on a Colorado dairy using conditional passive samplers and inverse modeling.

C. Williams,* J. Ham, and K. Shonkwiler, *Colorado State University, Fort Collins.*

Increasing pressure is being placed on concentrated animal feeding operations to reduce NH_3 emissions as the public becomes more concerned over effects on environmental and human health. The purpose of this study was to identify and monitor strong NH_3 emission zones on a northern Colorado dairy farm using a newly developed conditional sampling system. Passive samplers can be used to measure spatial variations of NH_3 near livestock operations, but results are often confounded by changing weather conditions during extended deployment periods (e.g., 1 to 2 weeks). A new type of conditional sampler was developed that only exposes the passive samplers when a user-defined set of wind and weather conditions are met. Several sampling stations were deployed on a northern Colorado dairy for an 8-wk period during late summer. Stations were placed on the downwind side of potential NH_3 sources, including; the composting area (S1, S2, and S3), lagoon and open-sided freestall barns. Each station contained 2 passive samplers. One sampler deployed whenever weather conditions were met (Full-day), while the other deployed when weather conditions were met between 1000 and 1600 h (Mid-day). Passive samplers were exchanged every 2 wk during the sampling period. Background NH_3 concentrations averaged 19.9 ppb NH_3 over the course of the study. Full-day samplers averaged 430.9, 637.0, and 588.9 ppb NH_3 for S1, S2 and S3, respectively. The sampler downwind of the 4 open-sided freestall barns averaged 321.5 ppb, while the lagoon averaged 1126.5 ppb NH_3. Analysis of all 4 sampling periods yielded similar patterns, with the lagoon consistently producing the highest NH_3 concentrations of the sources measured ($P = 0.02$). An inverse dispersion model also was used to estimate NH_3 emissions from each zone where the samplers were deployed. Deployment of the conditional sampling system on dairies or other livestock operations will help producers identify hotspots of NH_3 emissions, as well as monitor any subsequent changes in emissions resulting from implementation of best management practices. Data will also help quantify farm-specific NH_3 losses for mandatory reporting requirements.

Key Words: environment, emissions, ammonia

W245 Effects of alum and aluminum chloride on volatile fatty acid concentration and pathogen populations in Hanwoo (Korean native cattle) manure.

C. M. Kim[1], S. C. Kim[2], S. M. Amanullah[2], H. J. Lee[3], J. H. Choi[4], and I. H. Choi*[5], *[1]Department of Chemistry, Sookmyung Women's University, Seoul, South Korea, [2]Department of Animal Science (Inst. Agric. Life Sci.), Gyeongsang National University, Jinju, South Korea, [3]Division of Applied Life Science (BK 21), Gyeongsang National University, Jinju, South Korea, [4]Department of Chemistry, Hanyang University, Seoul, South Korea, [5]Department of Companion Animal & Animal Resources Science, Joongbu University, Kumsan, South Korea.*

Several recent studies have shown that treating animal manure with alum (aluminum sulfate) and aluminum chloride is one of the most effective methods of reducing odor and inhibiting microbial growth.

Of all treatments tested, alum has been intensively used in the poultry industry, but there is little information available on the effects of alum and aluminum chloride on odor and pathogen populations from Hanwoo manure. The objective of this study was to evaluate the effect of applying alum and aluminum chloride on VFA concentration and pathogen populations of Hanwoo manure. A total of 36 steers (8 mo old and averaging 300 kg in weight) were used in this trial and allotted to 9 pens (3 replication pens per group with 4 steers per experimental unit, 5 × 8 m). Chemical additives were applied as a top dressing with garden rake to a depth of 1 cm of manure with wood shavings in each treatment. The treatments were control (without chemical amendments) or 50 g of alum and 50 g of aluminum chloride/kg of Hanwoo manure. The experiment was carried out for 6 weeks. The addition of alum and aluminum chloride reduced ($P < 0.05$) volatile fatty acid concentration (6.2 mM/100 g compared with 9.7 mM/100 g for control) during the 6-wk period. Manure pH was lower ($P < 0.05$) in alum and aluminum chloride treatments (7.5 to 8.4) compared with the controls (9.2 to 9.3) during the 6-wk period. Both levels of the alum and aluminum chloride treatments tested decreased ($P < 0.05$) *Escherichia coli* and *Salmonella enterica* populations (average 4~5.7 log 10 cfu/g manure compared with average 7~7.5 log 10 cfu/g manure in untreated controls) in Hanwoo manure during the 6-wk period. It appeared that the reduction in VFA concentration and pathogen populations was primarily associated with the lower manure pH. If more strict environmental regulations are put into effect regarding VFA concentration and pathogen populations from Hanwoo facilities, treating Hanwoo manure with alum and aluminum chloride may be a good management practice.

Key Words: alum, aluminum chloride, Hanwoo manure

W246 Whole-farm balances of phosphorus and potassium on dairy farms. D. Fulawka, T. L. Garner, K. H. Ominski, D. Flaten, and J. C. Plaizier,* *University of Manitoba, Winnipeg, MB, Canada.*

Imports and exports of phosphorus (P) and potassium (K) were monitored during a 12-mo period on 10 commercial dairy farms in Manitoba. Balances were expressed per kg of milk shipped, milking cow, and ha. The farms differed in housing, feeding, manure management systems, and in the production and purchase of feeds. Imports included feed, bedding, animals, inorganic fertilizer, and manure. Exports included milk, animals, feed, and manure. A farm included the milking herd, the replacement herd, and the fields used to produce feed for these herds. Two farms purchased all their feed and exported all their manure. Results show that P and K balances varied substantially among farms. Based on these balances, P accumulated on all farms and K accumulated all but one farm. On average, the imports of P through feed, inorganic fertilizer, animals, bedding, and manure were 47.8, 47.7, 2.6, 1.7, and 0.2% of total P imports, respectively. The imports of K through feed, inorganic fertilizer, animals, bedding, and manure were, on average, 78.4, 0, 1.4, 20.1, and 0.2% of total K imports, respectively. On average, the exports of P through feed, animals, and milk were 5.4, 9.1, and 85.5% of total P exports respectively. The exports of K through feed, animals, milk, and manure were, on average, 15.3, 3.5, 78.6, and 2.6% of total K exports, respectively. The coefficients of variation (CV) for the import of P through feed, inorganic fertilizer, animals, and manure were 28, 168, 97, and 101%, respectively. The CV for the export of P through feed, animals, milk, and manure were 170, 53, 3, and 262%, respectively. The CV for the import of K through feed, animals, bedding and manure were 74, 112, 128, and 217%, respectively. The CV for the export of K through feed, animals, milk, and manure were 165, 83, 10, and 265%, respectively. This shows that the greatest opportunity to reduce the P balance is through management of inorganic fertilizer and to reduce the K balance is through the reduction of the import of bedding and increasing the export of feed that is not needed. As the largest imports of P and K occur through feed, ensuring that dietary P and K do not exceed requirements is critical in avoiding whole farm surpluses of these minerals.

Table 1.

	Minimum	Median	Maximum	SD
Milking cows	46	82	634	237
Total cows, heifers and calves	64	213	1027	332
Landbase, ha[1]	65	432	1272	446
P balance, g/kg of milk	0.3	2.4	16.8	5.1
P balance, kg/cow yr	4.2	29.1	159.1	48.7
P balance, kg/ha year[1]	1.1	10.5	112.6	37.8
K balance, g/kg of milk	−1.3	3.6	17.6	5.3
K balance, kg/cow yr	−16.9	40.5	156.3	52.1
K balance, kg/ha yr[1]	−4.2	22.7	118.0	38.8

W247 Foliar uptake and utilization of phosphorus by grazing cattle as influenced by nitrogen fertilization regime. S. L. Dillard,* W. F. Owsley, C. W. Wood, B. H. Wood, and R. B. Muntifering, *Auburn University, Auburn, AL.*

Accumulation of soil nutrients potentially restricts production and land-use options available to resource managers. Efficiency of nutrient utilization may be increased by implementation of management practices that facilitate phytoextraction of nutrients from nutrient-enriched soils. An experiment was conducted to determine the effect of different N-fertilization regimens on foliar P uptake and P utilization by grazing cattle in plots with high soil-test P. In October 2010, 6 0.28-ha plots were overseeded with triticale (*Triticum secale*) and crimson clover (*Trifolium incarnatum*) into a tall fescue (*Lolium arundinacea*)/bermudagrass (*Cynodon dactylon*) sod and assigned randomly to 1 of 3 treatments (trts) (n = 2): 100% of N recommendation for tall fescue in a split application (100N), 50% of N recommendation (50N), and 0% of N recommendation (0N). In February 2011, 6 cattle (339 ± 11 kg; 4 steers, 2 heifers) were randomly assigned to plots (1 animal/plot) until May. In June, plots were overseeded with cowpea (*Vigna unguiculata*) and maintained on the same N-fertilizer regimens, based on N recommendation for bermudagrass. In August, 6 steers (361 ± 23 kg) were randomly assigned to plots (1 steer/plot) until September. Forages were sampled biweekly, and intake and fecal excretion of P was determined for each animal in mid- and late season using Cr dilution technique by reference to forage IVDMD. Data were analyzed as a completely randomized design using a mixed-model in which intake and fecal excretion of P were treated as repeated measures. Forage DM availability ($P = 0.002$) and uptake of P ($P = 0.01$) were greater for cool- than warm-season forage (4,441 vs. 2,311 kg/ha and 8.44 vs. 5.30 kg P/ha, respectively), but were not different among trts. Foliar P concentrations were not different among trts. Daily P intake and excretion were not different among trts (12.2, 11.3 and 13.3 g /d, and 14.8, 15.0 and 11.9 g /d for 0N, 50N and 100N, respectively). Results indicate manipulation of N-fertilization regimen did not affect P removal from plots with high soil P beyond that from overseeded small-grain and annual legumes, and seasonal differences in P removal were not reflected in patterns of P utilization by grazing cattle.

Key Words: phosphorus, cattle, nitrogen

W248 Soil CO_2 emission during the dry season under different grazing intensities in Southern Brazil. L. de Figueiredo Brito, M. Vieira Azenha,* A. R. Panosso, F. H. M. de Souza, A. A. Oliveira, S. S. Santana, R. A. Reis, N. La Scala, and A. C. Ruggieri, *Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

Greenhouse gas emissions have been considered in sustainable livestock production, and the objective of this study was to monitor the soil CO_2 emission in Marandu-grass pasture submitted to continuous stocking with different grazing intensities during the drought period of the year. Three grazing intensities, defined by heights of 15, 25 and 35 cm, were studied in 6 plots (2 plots for each treatment) with 6 replications in each. Soil CO_2 emission and soil temperature were evaluated in 20 d between May 3rd and September 29th, 2011, in all plots, by using a LI-8100 portable Flux System. Data were submitted to variance analysis and Tukey test for mean comparison ($P < 0.05$). Daily soil CO_2 means varied from 0.90 to 5.58 μmol CO_2 m^{-2} s^{-1} with significant reductions probably due to reductions in soil moisture. Higher values were observed at the beginning of the dry season reflecting the importance of soil moisture to biological processes, such as biological activity and root respiration. In the last days of the study, soil respiration reached a minimum, similar to what was observed in relation to plant′s growth. Accumulated monthly precipitation along the wet period before these evaluations were 267, 202, 495 and 92 mm (January to April 2011), and in the drought period the total precipitation was 59 mm (May to September, 2011). On the other hand, while soil CO_2 emission and soil moisture declined, soil temperature increased (18.4°C in May to 22.1°C in September, 2011), indicating that soil moisture was a limiting factor to soil CO_2 production. Total mean values indicate higher grazing intensities (15 and 25 cm) resulted in higher CO_2 emissions, 2.64 and 2.59 μmol CO_2 m^{-2} s^{-1}, respectively, when compared with the lower grazing intensity (35 cm), 2.30 μmol CO_2 m^{-2} s^{-1} ($P < 0.001$). Total CO_2 emission for the period was estimated as being 4.10, 3.93 and 3.48 Mg C ha^{-1}, respectively, for heights of 15, 25 and 35 cm.

Key Words: *Brachiaria brizantha*, carbon cycle, greenhouse gases

W249 Using a batch culture system to measure volatile organic compounds as the primary substrates for methanogenesis in anaerobic digestion of dairy waste. C. L. Ross,* K. C. Das, and M. A. Froetschel, *University of Georgia, Athens.*

Cost effective anaerobic digestion of dairy excrement is limited by its relatively low energy content. As a result, anaerobic digestion of dairy waste requires a greater reactor volume and retention time for stable and efficient methane production. Processing dairy waste to concentrate its volatile organic compound (VOC) content as substrate for methanogenesis could improve digester efficiency and reduce costs associated with volume and retention time. Dairy excrement was processed using different methods to alter its concentration of VOC′s. Bio-conversion of processed dairy excrement into methane was studied in a one-way factorial designed experiment. Processing methods included: A) oven-dried (55°C for 72 h) and ground through a 1mm screen, B) freeze-dried, C) fresh whole manure in a 1:1 water dilution (with solids present), D) a water extract of fresh whole manure from a 1:1 dilution (without solids), or E) dairy excrement processed through an on-farm solid separator. All waste substrates were fermented in batch cultures for 48 h after being inoculated with a mixed culture of rumen microorganisms. Gas production was analyzed for volume and concentrations of methane (CH_4) and carbon dioxide, pH, volatile fatty acid concentration, in vitro dry matter digestion, and free-ammonia. All data were analyzed with SAS 9.2 using PROC GLM. Caloric values of volatile fatty acids and CH_4 were calculated. Process C produced the greatest volume of CH_4 gas, 33–179% more than the other methods ($P < 0.01$). Process C, D, and E had higher concentrations (mM) of acetate ($P < 0.01$) than A or B (C = 43.5, D = 22.3, E = 20.8 vs. A = 1, C = 3.5). C and D both contained more acetate calories (70% and 7%, respectively) than E ($P < 0.01$). Calories of CH_4 were also higher for the C (23.1) and D (17.1) than A (4.4), B (4.9), or E (0.8) ($P < 0.01$). Energetic data implies that substrate processed to contain more VOC′s increasingly fuels methanogenesis. The liquid fraction of dairy excrement contains the VOC′s that may be concentrated to enhance methane production during anaerobic digestion.

Key Words: volatile organic compounds, methanogenesis, anaerobic digestion

Ruminant Nutrition: Beef: Feed Additives

W250 Live yeast and adaptation protocols on finishing feedlot Nellore cattle fed high concentrate diets. P. L. Alvarez,* S. L. Silva, L. S. Martello, M. R. Mazon, L. S. Oliveira, P. H. Cancian, A. C. Ianni, L. Z. Zanoni, R. F. Carvalho, A. P. S. Silva, and P. R. Leme, *Universidade de São Paulo, Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brazil.*

Adaptation period on feedlots is a critical step for rumen stability. Inclusion of live yeast on high concentrate diets has been reported to be an alternative to reduce nutritional disorders such as acidosis and ruminitis on beef cattle. The aim of this work was to evaluate the performance and carcass traits of finishing feedlot Nellore (*Bos indicus*) cattle fed high concentrate diets with (LY) or without (CON) live yeast under 2 different adaptation protocols. Fourty-8 Nellore bulls (24 intact and 24 castrated) (372 ± 22.5kg BW; 20-mo) were distributed in individual pens in a randomized block (initial BW) and fed LY or CON diets. Diets were composed by 85% of concentrate (corn grain, corn gluten, soybean meal, mineral salt and monensin) and 15% of sugarcane bagasse as roughage source. Animals were adapted to final diets using step-up (ST) or feed intake restriction (FR) methods. The ST group started with 30% of concentrate increasing 15% each 2 d until it reached 85% while the FR group started with 4.5kg of final diet increasing one kg each 2 d. Both groups achieved the final diets after 10 d. After that, animals were fed for 56 d with LY or CON diets. Feed and orts were registered daily for DMI and F:G determinations. Animals were weighed at the beginning and at the end of adaptation period and then every 28d. Ultrasound measurements of LM area (LMA) and backfat thickness (BFT) between 12th/13th ribs were collected every 28d intervals. Fixed effects of initial BW (block), adaptation protocol, treatment and adaptation protocol x treatment interaction were evaluated using GLM procedure of SAS system. No interactions were observed for any trait. There was no effect of treatment on ADG and DMI on adaptation period. Animals fed FR protocol had higher ADG (1.121 vs 0.580 kg/day; $P = 0.0417$) and F:G (0.158 vs 0.085 kg ADG / kg DMI; $P = 0.0599$) than those fed ST but they did not differ for BW (379 kg) and DMI (6.6 kg). After adaptation period final BW (497 kg), ADG (1.72 kg), DMI (12.2 kg), F:G (0.143 kg ADG/ kg DMI) LMA (76.1 cm2) and BFT (4.1 mm) were not affected by treatments or adaptation protocols. Use of FR protocol improves performance on adaptation period but has no effect on post-adaptation period. LY does not affect feedlot performance.

Key Words: beef cattle, performance, probiotics

W251 Effect of slow release urea supplementation during the dry season on Nellore cattle performance in Brazil. D. P. Pantoni*[1], D. S. Graça[1], M. H. Ramos[2], and P. C. Molina[1], [1]*Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil,* [2]*Research Institute Flávio Guarani - Rehagro, Belo Horizonte, Minas Gerais, Brazil.*

This study was developed to synchronize the release of nitrogen from supplement with carbohydrate from pasture. Forty Nellore bulls (average weight 446 kg ± 24,6) were allowed to graze pastures of *Brachiaria brizantha* 'Marandu' during the dry season (June to September of 2010). Pastures were divided into 3 paddocks of 10 ha each with water and mineral ad libitum and managed in a rotation system. Dry matter availability averaged 5,200 kg of DM/hectare. Forage quality average 6% for CP, 69% for NDF and 51% for IVDMD. Treatments were: only mineral (T1), supplement containing 6% Urea (T2), supplement containing 3% Urea and 3% of slow release Urea (T3), supplement containing 6% of slow release Urea (T4). All supplements contained 15% soybean meal, 67% ground corn and 12% mineral with 200 mg of monensin. Pasture intake was measured using lignin as an internal marker. Cattle was brought together every day, divided by their treatments into pens, and allowed to eat the supplement (average of 1 kg/animal). Statistical analysis was performed using PROC MIXED of SAS (SAS Institute, Cary, NC) with treatment as the experimental unit for performance and animal as the experimental unit for nitrogen variables. There was no difference ($P > 0.05$) in forage consumption expressed as a percentage of BW (2.3, 2.1, 2.2, and 2.1; respectively for T1, T2, T3, and T4). There was no difference ($P > 0.05$) in ADG (316, 327, and 286 kg/d for T2, T3, and T4, respectively) and total gain (22, 23, and 20 kg, for T2, T3, and T4 respectively) between the urea treatments. Blood urea nitrogen (mg/dL) was not different ($P > 0.05$) between T2, T3, and T4. Allantoin (microbial marker) was not different ($P > 0.05$) between treatments (250, 327, 349, and 351 mg/dL, respectively for T1, T2, T3, and T4). Internal rate of return was greater for T2 followed by T3, T4, and finally T1 (19, 17, 10, and −2%, respectively). We concluded that slow release urea did not provide any benefit over conventional urea when Nellore bulls were offered low quality pastures.

Key Words: urea, braquiaria, cattle

W252 Intake, digestibility and digestion kinetics of beef steers supplemented with slow-release urea in diets with two concentrate levels. P. D. B. Benedeti, P. V. R. Paulino,* T. S. Martins, E. F. Lisboa, L. H. P. Silva, C. R. V. Teixeira, L. C. Alves, M. S. Duarte, R. Mezzomo, J. C. M. Lima, J. P. I. S. Monnerat, M. I. Marcondes, and S. C. Valadares Filho, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

This study evaluated the effects of replacing soybean meal (SBM) by slow-release urea (SRU) in beef cattle diets containing 2 concentrate levels on intake, partial and total digestibility and digestion kinetics in finishing beef steers. Eight crossbred steers were used (average BW of 418 kg) fitted with ruminal and abomasal cannulas. Total fecal collections were performed to determine digestibility and rumen evacuation was used to determine passage and digestion rates. The animals were distributed in 2 groups of 4 steers, when each group received one of the 2 levels of concentrate (40 or 80% of the total DM). The experiment was designed as a Latin square in 2 × 4 factorial scheme, with 2 concentrate levels in the diet, and within each square, 4 levels of SBM protein replacement by SRU: 0, 33, 66 and 100%. The interaction of concentrate level x SRU levels was not significant ($P > 0.05$) for any variable measured. Dry matter (DM) intake, as well as organic matter (OM) intake and crude protein (CP) intake decreased linearly ($P < 0.05$) as SBM was replaced by SRU. For each percentage unit of SRU added to the diet there was a reduction of 5.80, 5.17 and 0.58 g in DMI, OMI and CPI, respectively. The intake of non-fiber carbohydrates (NFC) was higher ($P < 0.05$) in the diet containing 80% concentrate when compared with the 40% concentrate diet, whereas neutral detergent fiber (NDF) intake was greater ($P < 0.05$) on the low concentrate diet when compared with the high concentrate diet. Ruminal digestibility coefficient of OM tented to be greater ($P < 0.074$) for the 40% concentrate diet, whereas all other ruminal, intestinal and total digestibility parameters evaluated were not statistically different ($P > 0.05$) among treatments. DM and OM passage rates (Kp) were greater ($P < 0.05$) on the 80% concentrate diet than on the 40% concentrate diet. Replacing SBM by SRU up to 100% on the diet did not lead to any modification ($P > 0.05$) on DM, OM, CP and NDF passage rate. Digestion rates (K_d) were also not affected by either concentrate level or SRU level ($P > 0.05$). The average K_d for DM, OM, CP and NDF were 3.82, 4.21, 1.13, and 2.20%/h, respectively.

Key Words: soybean meal, nonprotein nitrogen, feedlot

W253 Dose response effects of laidlomycin propionate plus chlortetracycline or monensin plus tylosin on growth performance, carcass merit and health of growing-finishing beef steers.

M. E. Branine*[1], M. E. Hubbert[2], M. L. Galyean[3], and B. D. Hunsaker[4], *[1]Pfizer Animal Health, Canon City, CO, [2]New Mexico State University, Clayton, [3]Texas Tech University, Lubbock, [4]Summit Research LLC, Wellington, CO.*

Doses of laidlomycin propionate plus chlortetracycline (LP/CTC) or monensin plus tylosin (M/T) were evaluated in an experiment with growing-finishing steers. No ionophore, low, moderate, and high levels of LP (50, 100 and 150 mg/animal per day) and M (150, 300 and 450 mg/animal per day), respectively were compared. Chlortetracycline (350 mg/animal per day) or T (90 mg/animal per day) were fed in combination with LP or M, respectively. Four-hundred 20 steers (average. initial wt. 357 kg) were randomized by initial BW to 6 blocks (7 pens/block). Steers were on feed for 153 d (3 heavy weight blocks) or 175 d (3 lightweight blocks) at a commercial feedlot facility before slaughter. Ionophores, CTC, and T were added to a non-medicated basal diet using a micro-ingredient allocation machine. Linear (L) and quadratic (Q) effects of ionophore dose were evaluated for growth performance and carcass measurements. Carcass-adjusted final BW, ADG, and hot carcass weights indicated a Q increase ($P \leq 0.05$) with dietary LP level. Dry matter intake and carcass-adjusted DM feed:gain ratio were not affected by LP dose. Neither L nor Q responses were observed for M level on DMI, carcass-adjusted BW, growth performance, or DM feed:gain ratio. Hot carcass weight was not affected by M level. Increasing M level increased number of Prime/Choice carcasses (L and Q); increased marbling score (L and Q); twelfth rib fat thickness (Q); and calculated yield grade (Q). Incidence and severity of liver abscesses were not affected by ionophore type or level. Morbidity and mortality rates from respiratory disease were minimal across treatments. Across dose levels, mean ionophore effects indicated LP increased ($P \leq 0.05$) carcass-adjusted final BW, ADG, DMI and hot carcass weight compared with M, with no difference between ionophores for carcass-adjusted DM feed:gain ratio. Growth performance responses of feedlot cattle may be modified by medicated feed additive program and dietary level of ionophore.

Key Words: ionophore level, laidlomycin propionate, monensin

W254 Adipose gene expression patterns in finishing steers fed steam-flaked corn diets supplemented with dietary *Aspergillus oryzae* extract containing α-amylase activity.

D. E. Graugnard*[1], K. M. Brennan[1], J. S. Jennings[1], and J. J. Wagner[2], *[1]Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY, [2]Southeast Colorado Research Center, Colorado State University, Lamar.*

We evaluated the effect of dietary *Aspergillus oryzae* extract on lipogenic gene expression in finishing beef cattle. Cross-bred yearling steers were randomly assigned to 2 groups (n = 135/treatment). From receiving until d21, starter and step-up diets were fed to acclimate steers to steam-flaked corn. Steers were then fed a finishing diet ad libitum until harvest that met or exceeded NRC requirements: basal diet with or without 5 g/hd/d A. oryzae extract (Amaize, Alltech Inc.) containing α-amylase (AMZ). On d70 and at harvest (d160), adipose tissue was sampled from one steer per pen (n = 15/treatment). Gene expression was profiled using the Affymetrix Bovine Genome Array. Of the 24,000 probe sets on the array, ~60% were expressed in subcutaneous adipose tissue. At d70, 270 genes were affected ($P \leq 0.05$, fold-change ≥ 1.1; 124 upregulated, 146 downregulated) and at d160, 399 genes were affected (176 upregulated, 223 downregulated) by AMZ. At both times the main functions affected were lipid metabolism, cellular development and cell-to-cell signaling/interaction. Gene classification based on gene ontology (GO) using the PANTHER database revealed the most affected GO term was metabolic processes (d70, 90 affected genes; d160, 149 affected genes). Analysis of individually affected genes showed a 1.42-fold ($P = 0.04$) increase in AMZ steers at d70 of peroxisome proliferator-activated receptor gamma coactivator 1 α mRNA, a key gene in fat and energy metabolism. Results suggest AMZ added to a steam-flaked corn finishing diet affects expression of genes involved in metabolism, growth and cellular development in steer adipose tissue. These results offer genomic support to previous findings that AMZ supplementation results in improved performance and carcass characteristics in finishing steers.

Key Words: amylase, beef, gene expression

W255 Effect of *Saccharomyces cerevisiae* CNCM I-1077 supplementation on zootechnical performances and feeding behavior of dairy bull calves during growing period.

C. Loncke[1], L. Van Nespen[1], C. Launay[1], E. Sulmont[1], L. Dussert*[2], and V. Demey[2], *[1]INZO, Chierry, France, [2]Lallemand SAS, Blagnac, France.*

The aim of this study was to evaluate the effectiveness of supplementation with *Saccharomyces cerevisiae* CNCM I-1077 (SC) in the diet of the growing period of dairy bull calves. Sixteen Montbéliarde calves aged 6 mo and weighing on average 251 ± 22 kg at the beginning of the adaptation period were used. The trial was preceded by 28 d of adaptation during which the animals all received the same ration composed of corn silage and 2.5 to 3 kg of concentrate. During the trial′s experimental phase, the animals were fed either with control diet (C), or an experimental diet supplemented with SC (5×10^9 cfu/kg feed). Both groups received corn silage as forage. Animals were fed according to the following program: 1 kg concentrate /100 kg BW and 1 kg DM forage /100 kg BW. The animals were placed in a Roughage Intake Control system (RIC) (8 animals per box, 4 animals per trough), which allowed to record individual feed intake as well as feeding behavior. The experimental period lasted for 56 d. The animals were weighed every 28 d and individual consumption was recorded. The results show that the supplementation with live yeast SC positively influenced the animals ADG compared with C (2.05 ± 0.09 kg/d vs 1.80 ± 0.28 kg/d; $P \leq 0.05$). Moreover, the homogeneity of growth was increased in the SC group. Consumption of feed was higher in the SC group (8.01 ± 0.73 kg DM/head per day vs 7.48 ± 0.49 kg DM/head per day; $P \leq 0.1$). The feed conversion ratio was enhanced by the SC in the diet (3.92 ± 0.35 kg DM/kg live weight for SC vs 4.22 ± 0.43 kg DM/kg live weight for C; $P \leq 0.1$). The SC supplemented animals also showed a different feeding behavior (higher number of visits to the RIC, shorter feeding time per visit and lower quantity ingested per visit; $P \leq 0.05$). This trial shows that the incorporation of live yeast SC stimulates the consumption of dairy bull calves, involving thus a higher weight gain of these animals. The inclusion of SC also reduces the heterogeneity of growth of young bulls during the early stage of fattening.

Key Words: fattening beef, *Saccharomyces cerevisiae* CNCM I-1077

W256 Effects of medicinal feed additive (MFA) program fed with varying levels of wet distillers grains (WDGS) on growth performance, carcass characteristics and health of growing / finishing beef steers.

M. E. Branine*[1], M. E. Hubbert[2], and B. D. Hunsaker[3], [1]*Pfizer Animal Health, Canon City, CO,* [2]*New Mexico State University, Clayton,* [3]*Summit Research LLC, Wellington, CO.*

Dose level effects of wet corn distillers grains (WDGS) and medicinal feed additive (MFA) program were evaluated. Three hundred twenty yearling steers (average initial weight 320 kg) were randomized in a 2 × 4 factorial arrangement (4 blocks / treatment) with main effects of MFA program consisting of laidlomycin propionate (LP; 11.1 g/DM ton) plus chlortetracycline (350 mg/animal per day; CTC) or monensin (M; 28 g/ton DM) plus tylosin (T; 90 mg/animal per day) and 0, 15, 30 and 45% dietary (DM basis) inclusion level of WDGS . A single source of WDGS was used throughout the study with cattle fed once daily. Cattle were on feed for a total of 179 d before being shipped to a commercial plant for slaughter where carcass and liver abscess data were collected. MFA × WDGS interactions were not observed for any growth, health, or carcass parameter. Growth rate between MFA programs did not differ ($P \geq 0.05$); however, DM intake tended to be greater ($P \leq 0.10$) for LP/CTC and feed efficiency improved ($P \leq 0.05$) by M/T. Carcass measurements and liver abscess incidence were not affected ($P \geq 0.05$) by MFA program. Linear ($P \leq 0.01$) and cubic effects ($P \leq 0.06$) of dietary WDGS were present for bodyweight, growth rate and carcass weight with 15% WDGS having greater response than the 0% diet and 30 and 45% WDGS. Feed efficiency and DM intake were not affected by WDGS level. Marbling score was linearly decreased with increased WDGS level. Overall health was not affected by MFA program; however, apparent morbidity from respiratory disease, while low, was increased ($P \leq 0.05$) with higher WDGS levels. Overall morbidity at the 30 and 45% WDGS levels was increased ($P \leq 0.01$) compared with 0 and 15% inclusion levels, with no differences among WDGS levels for mortality. Alternative MFA programs may have application in feedlot diets containing varying levels of WDGS

Key Words: Ionophore, laidlomycin propionate, wet distillers grains

W257 Basal diet affects ruminal in situ degradation rate of urea and Optigen II in steers.

V. B. Holder*[1], J. S. Jennings[2], and J. M. Tricarico[3], [1]*University of Kentucky, Lexington,* [2]*Alltech, Brookings, SD,* [3]*Innovation Center for U.S. Dairy, Rosemont, IL.*

The objective of this study was to determine whether basal diet would have an effect on the ruminal degradation of urea and a slow release urea product (Optigen II). The basal diets were 30% vs. 100% forage. The 30% forage diet was offered at 2.4% of BW and was based on fescue hay, cracked corn, cottonseed hulls, soybean meal and urea. The 100% forage diet was offered ad libitum and consisted of fescue hay plus a vitamin and mineral supplement. Intake of the 100% forage diet was approximately 2.2% of BW. Steers were fed once daily at 7am. Four Angus steers (BW = 311 kg) were used in a crossover design with 3 weeks of adaptation to diets before each in situ experiment. Experiments were conducted independently for urea and Optigen II respectively. Triplicate 10-g samples of Optigen II and urea in 5 × 10 cm polyester bags were sequentially inserted into the rumen before simultaneous removal to achieve various incubation times. Incubation times were 0, 5, 10, 15, 20, 30, 40, 50 and 60 min for urea and 0, 1, 2, 6, 10 and 24 h for Optigen II. In situ residues were processed by flash freezing in liquid N then subsequently dissolving residues in a known amount of 1 M HCl. Resulting solutions were incubated at 100°C for 25 min to ensure total dissolution of urea. The determination of urea concentration of the solutions allowed direct quantification of urea disappearance from both sources. Urea disappearance reached a maximum (100%) by 10 min of incubation. Urea disappearance was higher on the 100% forage diet than the 30% forage diet at 5 min (95.3 vs. 77.5%, $P < 0.05$). Urea disappearance from Optigen II was higher on the 100% forage diet than the 30% forage diet for all time points from 2 h onwards ($P = 0.0005$) and the difference was maximum at 24 h (78 vs. 87%, $P < 0.05$). These data demonstrate that diet does affect the degradation characteristics of protected urea. Forage:concentrate affects ruminal pH, passage, viscosity, and lipase and urease activities all of which may contribute to the observed differences.

Key Words: forage:concentrate, NPN, ruminant

W258 Effect of feeding chelated forms of Zn, Cu, and Mn in combination with methionine on growth and reproductive development of heifers.

R. Harvey*[1], Y. Wang[2], G. I. Zanton[2], T. J. Wistuba[2], and M. S. Kerley[1], [1]*University of Missouri, Columbia,* [2]*Novus International Inc., St. Charles, MO.*

Heifer production across most of the US is based upon forage-dominant diets. Methionine is typically the first-limiting amino acid in a forage-based diet. Forages can also vary widely in mineral composition, often being deficient relative to the animal's micromineral requirement. Therefore, the objective of this study was to determine the effect of 2-hydroxyl-4-methyl-thio butanoic acid (HMTBA; MFP) and/or organic trace mineral in the form of Zn, Cu, and Mn (HMTBA; Mintrex), Novus International) supplied to a forage-fed diet on growth and reproductive characteristics of developing heifers. The experiment was carried out in a 2 × 2 factorial design plus negative control. The treatments consist of Negative Control (NEG)- heifers were fed diet without additional Zn, Cu, Mn and MFP supplement; ITM- heifers were fed inorganic Zn, Cu, and Mn (30, 10, 20 mg/kg respectively); ITM + MFP- Supplemental MFP at 15 g/d with inorganic Zn, Cu, and Mn (30, 10, 20 mg/kg respectively); CTM- No MFP- Supplemental Mintrex to supply Zn, Cu, and Mn (30, 10, 20 mg/kg respectively); CTM + MFP- Supplemental Mintrex at levels delivered in Mintrex treatment, MFP was given at 15 g/d. Sixty purchased, weaned and prepubertal heifers were used in this experiment (252.3 ± 23.3 kg). Data were analyzed as a completely randomized design with repeated measurements using MIXED procedure of SAS. There was no significant treatment effect on DMI, ADG, and RTS ($P > 0.05$). Heifers fed MFP had a tendency for higher gain efficiency ($P = 0.10$), compared with no MFP^{TM} heifers. A trend for a mineral by MFP interaction was observed ($P = 0.06$) in serum antibody titer after 4 weeks of vaccination. The combination of CTM and MFP had the greatest serum antibody titers ($P < 0.05$), and CTM, and ITM+MFP treatments had the least. Therefore, supplementation of HMTBA and chelated minerals was effective at improving efficiency and health responsiveness of developing heifers.

Key Words: heifer development, methionine, microminerals

W259 The effect of combination of metal amino acid chelates, Se yeast, mannaoligosaccharides, and dietary antioxidants on the health and growth performance of high-risk calves.

T. J. Wistuba*[1], G. I. Zanton[1], D. Nuzback[1], M. Andersen[1], and E. Larsen[2], [1]*Novus International Inc., St. Charles, MO,* [2]*Larsen Nutritional Solutiions, Fowler, CO.*

Calves that are new to the feedyard are often exposed to numerous stressors (weaning, transportation, commingling, dietary restriction, etc.) that cause oxidative stress and compromise health and performance. Cu, Mn and Zn play a role in superoxide dismutase activity and Se in

glutathione peroxidase activity. Dietary antioxidants have been shown to improve overall anti-oxidant status, and mannanoligosaccharides improve the body's natural defense mechanisms. Therefore, the objective of this study was to evaluate the effects of feeding the combination of trace minerals chelated to glycine (MAAC- Zn,- Cu and -Mn), Se yeast (Zorien) dietary antioxidant (Agrado Plus), and mananoligosacharide (Zorien MOS) on growth performance, feed efficiency, and health in receiving calves. The study utilized 955 calves (742 steers and 213 bulls) that were obtained from 2 order buyers through sale barns in SE OK and SE TX with an average initial body wt of 233.6 ± 0.4 kg. The dietary supplements (Control or Treatment) were formulated to contain the same amount of supplemental Zn (320 mg), Cu (120 mg), Mn (200 mg), and Se (0.6 mg) from either organic or inorganic sources. In addition, calves consuming the Treatment supplement were fed 2 g/hd/d Agrado Plus and 20 g/hd/day Zorien MOS. After initial processing, calves were blocked by truckload (1–12), origin (TX vs OK), sex (bull vs steer), and individual body wt (light to heavy). No differences ($P > 0.14$) in body wt, gain, intake, or feed conversion were detected during the 42 d receiving period between Control and Treatment supplement supplemented calves. Calves were highly stressed as evidenced by the high morbidity (68% treated at least once). No differences ($P > 0.27$) between treatments were detected for morbidity, days between re-pulls, medicine cost, realizers, or total out. However, approximately 50% less ($P = 0.05$) calves died when fed the Treatment (1.04%) compared with the Control (2.09%). Therefore, the combination of organic trace minerals, dietary antioxidants and mannanoligosacharides was an effective way to reduce death loss in highly stressed receiving cattle.

Key Words: health, oxidative balance, receiving calves

W260 Effect of addition of increasing doses of chitosan in diets of Nellore cattle on the intake and digestibility total nutrients. R. V. Barletta,* A. P. C. Araújo, R. Gardinal, R. D. Mingoti, B. C. Ventureli, J. E. Freitas Jr., T. H. A. Vendramine, J. R. Gandra, M. C. B. Santos, B. C. Benevento, V. G. C. Lacuna, and F. P. Rennó, *1University of Sao Paulo, Sao Paulo, Brazil.*

The objective of this study was to evaluate the inclusion of different doses of chitosan in the diet of beef cattle on intake and total apparent digestibility of nutrients. Eight Nellore steers (540 ± 28.5 BW/kg of SD) cannulated in the rumen were used and divided into 2 4 × 4 balanced Latin squares with an experimental period of 21 d, being 14 d for adaptation and 7 d of sample collection. The daily doses of chitosan (0, 50, 100 and 150 mg/kg BW) were inserted directly through the rumen cannula, twice daily. Daily intake was measured individually so to be kept a percentage of orts between 5 and 10% of the total supplied in the previous day. The total apparent digestibility of nutrients, was determined by the concentration of indigestible acid detergent fiber (iADF). There was quadratic effect ($P < 0.05$) to the NDF intake with the inclusion of chitosan in the diets (2.99; 3.06; 3.09 and 2.91 to the doses CH0, CH50, CH100 and CH150 respectively). The inclusion of chitosan in the diets caused linear increase ($P < 0.05$) to the NDF digestibility (56.62, 60.19, 60.69 and 60.59% for the doses CH0, CH50, CH100 and CH150 respectively). There was increase ($P < 0.05$) to the crude protein digestibility with the inclusion of the chitosan in the diets (63.12, 64,92, 66,49 and 67,51 CH0, CH50, CH100 and CH150 respectively). The total carbohydrate digestibility was positively influenced by dose of the chitosan, probably by effects of the NDF digestibility. The inclusion of the chitosan increased ($P < 0.05$) the total nutrients digestibility, resulting in linear increase (68.07, 70.97, 71.59 and 72.10 to the doses CH0, CH50, CH100 and CH150 respectively). At the significance level of 5% in the analysis by SAS PROC MIXED the inclusion of chitosan in the diet did not affect dry matter intake and obtained positive effects on total apparent digestibility of nutrients.

Key Words: beef cattle, chitosan, metabolism

W261 Ruminal parameters, microbial protein production, protein efficiency and nitrogen balance on beef steers supplemented with slow-release urea in diets with two concentrate levels. P. D. B. Benedeti[1], P. V. R. Paulino*[1], T. S. Martins[1], E. F. Lisboa[1], L. H. P. Silva[1], C. R. V. Teixeira[1], L. C. Alves[1], M. S. Duarte[1], R. Mezzomo[1], J. C. M. Lima[1], J. P. I. S. Monnerat[1], M. I. Marcondes[1], S. C. Valadares Filho[1], and M. Manella[2], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Alltech do Brasil, Curitiba, PR, Brazil.*

This study evaluated the effects of replacing soybean meal (SBM) by slow-release urea (SRU) in beef cattle diets containing 2 concentrate levels, on ruminal parameters, microbial protein production, protein efficiency and nitrogen balance in finishing beef steers. Eight crossbred steers (average BW of 418 kg) fitted with ruminal and abomasal cannulas were used. The animals were distributed into 2 groups of 4 steers each, and each group received one of the 2 levels of concentrate (40 or 80% of the total dry matter). The experiment was designed as a double Latin square in a 2 × 4 factorial scheme, with 2 concentrate levels in the diet, and within each square, 4 levels of replacement of soybean meal protein by slow-release urea: 0, 33, 66 and 100%. The diets with different levels of concentrate were applied independently in each Latin square and were fed once daily. Ruminal fluid samples were taken every 2 h after feeding throughout a 24 h period to determine pH and ammonia concentration. A cubic effect ($P < 0.05$) of SBM replacement by SRU on ruminal ammonia ($N\text{-}NH_3$) concentration in relation to the hours of collection was detected. A quadratic effect of replacing SBM by SRU was observed ($P < 0.05$) on pH and on the excretion of urea N in urine, expressed both as g/day or mg/kg of BW. The animals had higher ($P < 0.05$) total N excretion in urine, in g/day, as the slow-release urea levels were increased in the diet, but no significant effects were observed ($P > 0.05$) for total N in urine in mg/kg BW (average of 148.56 mg/kg BW) and for the concentration of urea N in the serum (average value of 11.53 mg/dL). Nitrogen intake, N excreted in feces, nitrogen balance and efficiency of nitrogen use decreased linearly ($P < 0.05$) as the levels of SRU increased in the diet, whereas the amount of nitrogen compounds excreted in urine increased linearly ($P < 0.05$) as SRU replaced SBM in the diet. The production of microbial nitrogen and microbial efficiency were not significantly affected by the experimental treatments ($P > 0.05$) obtaining average values of 173.75 g/day and 128.36 g/kg TDN ingested, respectively. Replacing SBM by SRU decreases nitrogen efficiency utilization in beef steers.

Key Words: feedlot diet, pH, ruminal ammonia

W262 Impact of an all-natural liquid fermentation prototype on performance of feedlot cattle. M. Scott*[1], J. Miles[2], H. Vermaak[3], and S. Schalk[3], *[1]Diamond V, Cedar Rapids, IA, [2]University of Pretoria, Pretoria, Gauteng, South Africa, [3]Essential Nutrient Systems, Pretoria, Gauteng, South Africa.*

As feed costs continue to rise, new technologies that will improve feed efficiency in a safe and consistent manner will become more critical for beef cattle production. With this in mind, a randomized complete block design study utilizing 144 bonsmara-type steers (233 ± 0.8 kg BW) was conducted to examine the effect of a liquid *Lactobacillus* fermentation prototype (LFP; Diamond V, Cedar Rapids, IA) on performance of feedlot cattle. The 134 d study was conducted on a commercial beef research facility in South Africa. Upon arrival, cattle received a feedlot ID tag, were vaccinated and treated for parasites, and were allocated to a free-range pasture for 8 d. On d 9, cattle received a trial ID tag and growth implant, and were re-vaccinated, castrated, and dehorned. Steers were then blocked by arrival body weight and randomly assigned to one of 3 treatments with 8 pens per treatment and 6 steers per pen. Dietary treatments included a control diet that contained 0, 5, or 10 g LFP per head daily. Treatments were provided in the starter (d 9 to 29) and grower diets (d 30 to 43), and in the finishing diet that contained 49% hominy chop, 23% maize, 20% maize plant, 3% soya oil cake, and 5% supplement (DM basis). Data were analyzed using Proc Mixed procedures of SAS with pen as the experimental unit. Data were considered significant at $P < 0.05$ and tendency at $0.05 < P < 0.10$. No differences were detected ($P > 0.10$) among treatments for BW, ADG, or DMI. From d 107 to 134, steers supplemented with 5 g LFP had numerically higher ADG ($P = 0.11$; 1.57 vs. 1.39 kg/d) and improved F:G ($P = 0.16$; 6.54 vs. 7.03) compared with 0 g LFP. Overall (d 9 to 134), F:G was improved ($P = 0.03$) for 5 g LFP supplemented steers compared with those receiving 0 or 10 g LFP (4.70 vs. 4.82, 4.86). Results from this study suggest that LFP does improve feed efficiency of beef cattle fed a typical South African feedlot diet and that the effect was dose dependent.

Key Words: beef cattle, feedlot, *Lactobacillus* fermentation prototype

W263 Effect of β-carotene supplementation on fatty acid profile and expression of genes involved in vitamin A metabolism in beef cattle.

K. N. Condron,* J. N. Waddell, M. C. Claeys, R. P. Lemenager, and J. P. Schoonmaker, *Purdue University, West Lafayette, IN.*

Thirty Angus-cross calves allotted to 5 treatments were used to examine the effects of dietary β-carotene (βC) or vitamin A (VA) on fatty acid profile and expression of genes involved in VA and lipid metabolism. Treatments consisted of retinyl palmitate (RP) supplemented at the NRC vitamin A requirement (2200 IU/kg), synthetic βC supplemented at 1×, 5×, and 10× the NRC VA requirement, and natural βC (50/50 mix of all-trans and 9-cis-βC) supplemented at 5× the NRC VA requirement. Longissimus muscle (LM), liver, and small intestinal (SI) tissues were collected immediately after slaughter, snap frozen in liquid nitrogen, and stored at −80°C for subsequent analysis of fatty acid profile and mRNA expression by quantitative PCR. β-Carotene monooxygenase 1 (βCMO1) and β-carotene oxygenase 2 (βCO2), the enzymes responsible for symmetrical and asymmetrical cleavage of βC, respectively, were both expressed in the SI. Liver and LM tissues did not express βCMO1, but did express βCO2. Natural βC tended ($P < 0.10$) to increase expression of βCMO in the SI relative to 5× synthetic βC. Expression of βCO2 was not different among treatments ($P > 0.54$) in the liver, but in LM βCO2 expression was increased ($P < 0.01$) in 1× βC compared with VA, tended to decrease ($P < 0.10$) in 5× βC vs natural βC, and decreased linearly ($P < 0.02$) as synthetic βC concentration increased. Expression of alcohol dehydrogenase (ADH1), an enzyme that converts retinol to retinaldehyde, tended ($P < 0.06$) to decrease in the SI as synthetic βC supplementation increased, but did not differ in the liver ($P > 0.36$). The polyunsaturated fatty acid (PUFA) to saturated fatty acid (SFA) ratio increased linearly ($P < 0.05$) as dietary synthetic βC increased because of a linear decrease in SFA concentration ($P < 0.08$), including C16:0, as well as a tendency ($P < 0.10$) for a linear increase in PUFA concentration, including C18:2, as synthetic βC supplementation increased. βC fed at 1× the NRC requirement decreased ($P < 0.04$) the concentration of CLA relative to VA supplemented at the NRC requirement. In conclusion, βC supplementation seems to inhibit expression of enzymes involved in metabolism of βC and VA, potentially allowing these metabolites to accumulate in muscle, thus altering fatty acid profile and fat deposition.

Key Words: beef cattle, β-carotene, gene expression

W407 Analysis of rumen methanogen diversity in cattle divergent for residual feed intake using next generation sequencing technology.

C. A. Carberry*[1,2], D. A. Kenny[1], C. J. Creevey[1], and S. M. Waters[1], [1]*Animal and Bioscience Department, Animal and Grassland Research and Innovation Centre, Teagasc, Grange, Co. Meath, Ireland,* [2]*School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland.*

Methane (CH_4), a potent green house gas, is an undesirable end product of fermentation activity of ruminal methanogens. Production of CH_4 in the rumen represents a significant source of energy loss in cattle, accounting for up to 15% of dietary gross energy intake. Improved residual feed intake (RFI), a measure of energetic efficiency, has been associated with reduced ruminal CH_4 emissions in cattle. However there is little published information on whether the ruminal methanogenic population varies between animals of different RFI phenotype and in particular across different dietary regimen. The aim of this study was to analyze the rumen methanogen community in cattle divergent for RFI using 454 pyrosequencing. Yearling Limousin sired heifers (n = 86) were ranked on the basis of phenotypic RFI over an 80 d period while consuming a 30:70 maize silage to concentrate diet. The 7 highest (HRFI; inefficient) and 7 lowest (LRFI; efficient) ranking animals were selected for use in this study. Both groups had similar mean bodyweight and ADG but HRFI had, on average, 20% higher DMI. Following ranking on RFI all animals were offered (i) a low energy, high forage grass silage diet, followed by (ii) a high energy, low forage, concentrate based diet. Both diets were offered ad libitum for a 6-wk period. Ruminal fluid was sampled at the end of both periods using a specialized trans-esophageal sampling device. Total microbial DNA was isolated from the rumen fluid and amplified using fusion primers, which included sequencing adaptors and a unique 8-base barcode designed to amplify ca. 550-bp region of the 16S rRNA gene. Across RFI phenotype and diet *Methanobrevibacter* spp. were found to dominate, with *Methanobrevibacter smithii* the most abundant species within this genus. Rare phylotypes contributing <5% of sequences were also detected, and were influenced by both host feed efficiency and diet. Thus the rumen microbiome appears to harbour a core group of methanogens and differences in ruminal methane emissions between efficient and inefficient cattle may be due to variation in the relative abundance of specific rare microbial phylotypes.

Key Words: bovine rumen methanogens, pyrosequencing, residual feed intake

Ruminant Nutrition: Co-Products

W264 In vitro intestinal amino acid digestibility of distillers grains varies with grain source and milling process.

C. Li[1,2], J. Q. Li[1], K. A. Beauchemin[2], and W. Z. Yang*[2], [1]*College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China,* [2]*Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

A study was conducted to evaluate the in vitro intestinal digestibility of amino acids (AA) in dried distillers grains with solubles (DDGS) originating from different grain sources (corn vs. wheat) and milling processes (conventional vs. fractional). The experimental feeds were: wheat grain, wheat DDGS (wDDGS), corn grain, corn DDGS (cDDGS) and corn fractional DDGS (fDDGS). Ruminal residues were produced by incubating the feeds in polyester bags for 16 h in the rumen of 3 ruminally cannulated beef heifers fed a diet containing 60% barley silage and 40% barley-based concentrate (DM basis). In vitro intestinal digestibilities of the rumen undegradable protein (RUP) and AA were determined on the residues using a modified 3-step method. In vitro intestinal digestibilities of individual AA were similar for wheat and wDDGS, except for His ($P < 0.05$; 65 vs. 83%) and Glu ($P < 0.05$; 95 vs. 90%). The digestibilities of most AA, especially the individual essential AA (EAA), were lower ($P < 0.05$) for cDDGS than for corn, and as a result, the digestibility of CP, total AA and EAA were lower ($P < 0.05$) for cDDGS (86, 86 and 87%, respectively) than for corn (92, 92 and 91%, respectively). Digestibilities of 3 EAA (His, Met and Thr) were lower ($P < 0.05$) for cDDGS (68, 81 and 83%, respectively) compared with wDDGS (83, 87 and 87%, respectively) with no differences in the digestibility of CP, total AA, and EAA. For fDDGS, 6 individual AA (4 EAA and 2 non EAA), total AA, non EAA and CP had lower ($P < 0.05$) digestibilities compared with cDDGS. The results suggest that the AA availability of DDGS varies with the grain source used to produce ethanol and with the milling process before ethanol fermentation. Information on the intestinal digestibility of individual AA can be used to improve accuracy of diet formulation.

Key Words: AA digestibility, DDGS, in vitro

W265 In vivo determination of undegradable intake protein (UIP) of dried distillers grains with solubles (DDGS) and comparing DAPA and DNA as bacterial markers.

E. Castillo-Lopez,* T. J. Klopfenstein, and P. J. Kononoff, *University of Nebraska-Lincoln, Lincoln.*

The objectives of this trial were to determine the undegradable intake protein (UIP) of dried distillers grains with solubles (DDGS) and to compare the estimates of duodenal bacterial crude protein (BCP) flow using either DAPA or DNA as bacterial markers. Three crossbred steers fitted with ruminal and double L-shaped duodenal cannulas (average BW 780 ± 137 kg) were used in a 3 treatment, 6 period crossover design. Animals were housed in individual free stalls and fed twice daily at 0700 and 1900. Diets (DM basis) were 1) CONTROL, 0% DDGS, but with 19.5% corn bran, 20% sorghum silage, 60% brome hay, 0.5% trace minerals and 0.25% urea; 2) LOW DDGS, inclusion of 9.75% DDGS replacing equal percentage of corn bran; 3) HIGH DDGS, inclusion of 19.5% DDGS completely replacing corn bran. On d 16 to 19 of each period, 200 mL of duodenal digesta were collected every 4 h from each animal, then composited by day, by animal within period, lyophilized and analyzed for CP. Duodenal BCP flow was estimated by 2 methods, using DAPA and DNA as bacterial markers. DNA marker was part of the 16S rRNA gene. The UIP of DDGS was determined by difference of residual duodenal CP flow between HIGH DDGS treatment and CONTROL. Data were analyzed using the MIXED procedure of SAS. Average DMI was 10.5kg/d across treatments. The average value of DDGS UIP as a percent of CP was determined to be 63.0 ± 0.64%. Average duodenal BCP flow across treatments was unaffected ($P = 0.71$) by marker type and were 404 and 417 ± 83 g/d for DAPA and DNA markers, respectively. Overall, the value of DDGS UIP determined in this study will contribute to better understand the effect of this byproduct in ruminant nutrition. Duodenal BCP flow tended to decrease with DDGS inclusion, but was not affected by marker type.

Key Words: dried distillers grains with solubles, duodenal bacterial crude protein flow, undegradable intake protein

W266 Urea treatment of different levels of pistachio hull and its relation to gas production in vitro.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[2], and B. Saremi*[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agricultural Sciences & Natural Resources, University of Gorgan, Gorgan, Golestan, Iran,* [3]*Bonn University, Bonn, Germany.*

Tannins can inhibit enzymatic and microbial activity therefore affecting gas production. There is very limited information about effects of urea treatment on gas parameters in dietary of tannin. The objective of this study was to evaluate effects of processing of different levels of pistachio hull by urea on gas production in vitro. Experimental treatments were included: Control with 30% alfalfa, 20% straw and 50% concentration (0.42% tannin), T1) 15% alfalfa, 15% PH, 20% straw and 50% concentration (1.06% tannin) and T2) 30% PH, 20% straw and 50% concentration (1.83% tannin). The treatments were incubated with 0.5 and 1 percentage of urea. Gas production was measured (Theodorou et al., 1994; McDonald, 1979). The gas pressure and volume was recorded before incubation (0) and 2, 4, 6, 8, 12, 24, 36, 48, 72, 96 and 120 h after incubation. Gas production kinetics were estimated using the equation described by Ørskov and McDonald (1979), y = a + b (1-exp-ct). Statistical analysis was performed using the 3 × 2 factorial procedure of SAS ($P < 0.05$). Our data exhibited that extent of gas production in treatments incubated with 0.5% urea in T2 was significantly higher vs. T1 and control. Extent of gas production in treatments incubated with 1% urea was significantly affected i.e., the value of gas production in T1 + 1% urea was lower than T2 + 1% urea and control + 1% urea. Indeed, T2 + 1% urea was significantly higher than control + 1% urea. Rate of gas production was not affected when co-incubation was done by 0.5% urea in different treatments while by incubation with 1% urea, the rate of gas production was significantly higher in T1 than control and T2. The treatments were incubated with 0.5 vs. 1% of urea led to increase of extent and reduction of rate of gas production with the exception of T2 which extent and rate of gas production were stable. It seems that urea supplementation can eliminate the negative effects of tannins on gas production.

Table 1. Effect of urea treatment of different levels of pistachio hull gas production parameter

Gas production	Alfalfa		15% PH		30% PH			
parameters	0.5% urea	1% urea	0.5% urea	1% urea	0.5% urea	1% urea	SEM	*P*-value
Extent (ml/gDM)	199.194^{d}	204.128^{bc}	199.937^{cd}	196.598^{d}	205.317^{ab}	208.798^{a}	0.6182	0.0005

W267 Effect of different levels of pistachio hull on in vitro gas production.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[2], and B. Saremi*[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran,* [3]*Bonn University, Bonn, Germany.*

Tannins are a heterogeneous group of phenolic polymers of the plant origin that can be detrimental when consumed by herbivores. Pistachio hull (PH) is a by product that has a high tannin content. Tannins can also inhibit enzymatic and microbial activity and together with inhibition of gas production. The aim of this study was to evaluate effects of different levels of Pistachio Hull on in vitro extent and rate of gas production. The rumen fluid was obtained from 4 fistulated sheep which were fed twice daily with a diet containing alfalfa hay (60%) and concentrate (40%). Experimental treatments were included: Control consisted of 30% alfalfa, 20% straw and 50% concentration (0.42% tannin), T1) 15% alfalfa, 15% PH, 20% straw and 50% concentration (1.06% tannin) and T2) 30% PH, 20% straw and 50% concentration (1.83% tannin). Gas production was measured on procedure (Theodorou et al., 1994; McDonald, 1979). The pressure and volume of gas was recorded before incubation (0) and 2, 4, 6, 8, 12, 24, 36, 48, 72, 96 and 120 h after incubation. The linear regression equation between reading pressure and volume for determination of corrected volume of gas was estimated. Cumulative gas production data were fitted to the model of Ørskov and McDonald (1979), y = a + b (1-exp-ct). Statistical analysis was performed using the MIXED procedure of SAS (2000) using a completely randomized design. Extent of gas production decreased as the amount of tannin in the diet increased, but this decrease was significantly in treatment 2 (1.83% tannin) relative to T1 (1.06% tannin) and control (0.42% tannin; $P < 0.01$). Rate of gas production was not affected by the amount of tannin in experimental treatments. It seems that tannins could be inhibiting for microbial activity and thus reduced the amount of gas production.

Table 1.

W268 Increased dietary tannin by addition of pistachio hull and its relation to fermentation parameters and protozoa content of rumen in Balochi male lambs.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi*[2], and B. Saremi[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agriculture Sciences and Natural Resources University of Gorgan, Gorgan, Iran,* [3]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany.*

Tannins could affect rumen parameters such as pH, NH_3-N and microorganisms. The low rate and extent of protein degradation in the rumen by feeding tannin-rich feeds could lower rumen ammonia concentration. There are many reports indicating inhibitory effect of tannins on rumen protozoa. We aimed to determine the effects pistachio hull (PH) as a tannin source in the diet on rumen pH, N-NH_3 concentration, and protozoa content in Balochi male lambs. Three male lambs (35 ± 2 kg live weight) equipped with ruminal and abomasual cannula were randomly assigned into a changeover 3 × 3 design with 3 treatments: 1) control (alfalfa), 2) 15% alfalfa+15% PH and 3) 30% PH (DM basis). Rumen fluid pH was measured immediately before and every 30 min up to 8 h after the a.m. feeding. Also, rumen fluid was collected from the anterior dorsal, anterior ventral, medium ventral and posterior dorsal and posterior ventral locations within the rumen at 0, 1, 2, 4, 6 and 8 h after the 0800 h feeding for determination of NH_3-N concentration and protozoa count. Data were analyzed as a repeated measurement design using PROC MIXED of SAS ($P < 0.05$), assuming the model included treatment, time, and time × treatment as fixed effects and animal as random effect. Rumen fluid pH was not affected by PH content of diet, although tended to increase as the amount of dietary PH increased. Dietary PH content resulted in a decrease in the rumen N-NH_3 concentration. Protozoa content of rumen was not affected by the amount of PH in the diets, although a tendency to decrease was observed when dietary PH amount increased.

Table 1. Substitution of alfalfa with different levels of pistachio hull (PH) and its contribution to rumen pH, NH3-N and Protozoa count

W269 Effects using of pistachio hull and polyethylene glycol supplementation on feed intake and apparent digestibility of nutrients in Saanen dairy goats.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[2], and B. Saremi*[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran,* [3]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany.*

Tannins at low concentrations can confer nutritional advantages to ruminants by reducing protein degradation in the rumen and increasing the flow of protein and essential amino acids to the intestine. However, higher concentrations of condensed tannins have deleterious effects on animal performance, digestibility and voluntary intakes. Polyethylene glycol (PEG), react preferentially with condensed tannins and prevents the formation of tannin-protein complexes. The aim of this study was to evaluate the effects of feeding pistachio hull (PH, source of tannin) and PEG supplementation on feed intake and nutrients digestibility in Saanen dairy goats. Nine Saanen dairy goats were used in a 3 × 3 Latin square design with 21-d periods, including 14 d of adaptation followed by 7 d of sampling. Three treatments were formulated: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet and T3) 30% PH + 1% PEG (DM basis). In T2 and T3 PH was replaced with alfalfa hay. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Dry matter intake (DMI), DMI per body and metabolically weight were not affected in the experimental diets. Organic matter intake (OMI), OMI per body and metabolically weight, ADF, NDF and crude protein intake were significantly decreased in 30% PH (T2) and with the addition of PEG in T3 were significantly increased. Fat intake in T2 (168.40 g/d) and T3 (175.13 g/d) in comparison to Control (150.14 g/d) were significantly increased. DM, ADF and NDF apparent digestibility weren't significantly affected by the diets, but in T2 had a tendency to decrease and with the addition of PEG in T3 showed an increasing trend. OM and CP apparent digestibility were significantly decreased in T2 and with the addition of PEG in T3 were significantly increased. Fat apparent digestibility in T2 (84.95%) and T3 (85.98%) vs. Control (83.91%) was significantly increased. This study has shown that pistachio hull can replace alfalfa hay in diets for goats when PEG is given as a supplement.

Key Words: pistachio hull, feed intake, apparent digestibility

W270 Effects of feeding pistachio hull and polyethylene glycol (PEG) supplementation on milk fatty acids composition in Saanen dairy goats.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[2], and B. Saremi*[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran,* [3]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany.*

Decreasing the level of saturated fatty acids (SFA) and increasing monounsaturated FA (MUFA) and polyunsaturated FA (PUFA) content in ruminant's milk would be beneficial for human health and would be of commercial interest. It is also recognized that tannins affect rumen biohydrogenation therefore increase the MUFA and PUFA content of milk and meat. We aimed to evaluate the effects of feeding pistachio hull (PH, source of tannin) and PEG supplementation on milk fatty acids composition in Saanen dairy goats. Nine Saanen dairy goats were used in a 3 × 3 Latin square design. Treatments were T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g tannin per kg DM of diet, and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH replaced alfalfa hay. Milk fatty acids were analyzed on a Gas Chromatography with a flame-ionization detector and column. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Concentration of UFA, MUFA, and PUFA in treatments including of tannin (with PH) were significantly higher than control (without PH). Conversely, concentration of SFA and medium-chain FA (MCFA) in T2 were significantly lower than the control and with addition of PEG in T3 were significantly increased relative to T2. Concentration of short-chain FA (SCFA) in T2 and T3 was significantly lower than the control. Long-chain FA (LCFA) in T2 was significantly higher than the control and with addition of PEG in T3 was significantly decreased relative to T2. In conclusion, tannin has the ability to reduce SFA and to increase UFA. PEG will reverse this effect but not to the control levels.

Table 1. Effect of PH and PEG on milk fatty acids composition

Milk FA composition	Alfalfa	30% PH	30% PH+PEG	SEM	*P*-value
SFA	67.056^{a}	54.642^{c}	63.077^{b}	1.840	0.0001
UFA	32.940^{c}	46.746^{a}	37.910^{b}	2.023	0.0003

Key Words: fatty acids composition, tannin, goat

W271 Milk fatty acid profile of Saanen dairy goats fed diets containing pistachio hull tannin and polyethylene glycol supplementation.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], B. Saremi*[2], and A. Reza Shahdadi[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany,* [3]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran.*

Tannins ability to modify the fatty acid composition of milk and meat has received great attention recently. There is limited information pertaining the effects of tannins on ruminal biohydrogenation process and content of C18:1, trans-11 (vaccenic acid) and C18:2, cis-9, trans-11 CLA (rumenic acid) in ruminants meat and milk. We aimed to evaluate the effects of feeding pistachio hull (PH, source of tannin) and polyethylene glycol (PEG) supplementation on milk fatty acid profile particularly vaccenic and rumenic acid in Saanen dairy goats. Nine Saanen dairy goats were used in a 3 × 3 Latin square design. Three treatments were formulated: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH replaced alfalfa hay. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Percentage of C18:1, trans-9, C18:1, cis-9 and C18:1, trans-11 (vaccenic acid), and C18:2, cis-9, trans-11 CLA (rumenic acid) significantly increased with addition of PH in T2. Blocking of PH with PEG significantly reduced the fatty acids but not to the same level as control group. Percentage of C18:0, C18:2, trans-9, 12, C18:2, cis-9, 12, and C18:3, cis-9, 12, 15 with increasing PH in T2 significantly increased and addition of PEG in T3 could not reduce them back to levels of control group. In conclusion, addition of PH could increase the level of polyunsaturated acids content of goat milk and PEG supplementation will conserve it while blocking PH tannin content.

Table 1.

Milk FA profile (%)	Alfalfa	30% PH	30% PH+PEG	SEM
C18:0	9.901^{b}	12.454^{a}	11.566^{a}	0.381
C18:1, trans-9	4.040^{c}	9.950^{a}	7.232^{b}	0.854
C18:1, cis-9	21.620^{c}	26.837^{a}	21.965^{b}	0.869
C18:1, trans-11	3.825^{c}	5.511^{a}	4.214^{b}	0.255

W272 Effects of pistachio hull and polyethylene glycol supplementation on milk yield and compositions in Saanen dairy goats.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[2], and B. Saremi*[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Agricultural Sciences & Natural Resources University of Gorgan, Gorgan, Golestan, Iran,* [3]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany.*

Evaluation of dietary containing tannin for animal performance was very varied. We aimed to investigate the effects of pistachio hull (PH, source of tannin) and polyethylene glycol (PEG) supplementation on milk production and milk composition in early lactation Saanen goats. Nine Saanen dairy goats (average DIM, 71.5 ± 6.5 d; milk production, 1.5 ± 0.25 kg; and live body weight, 45 ± 1.75 kg) were used in a 3 × 3 Latin square design with 21-d periods, including 14 d of adaptation followed by 7 d of sampling. Three treatments were formulated: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH replaced alfalfa hay. Goats were milked 2 times in day and milk yield was recorded. Milk samples were taken at the 3 last days of sampling. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Treatment means were compared using Duncan′s New Multiple Range test. The results showed that milk, fat corrected milk (FCM), and energy corrected milk (ECM) yields together with milk efficiency were not affected by experimental diets. Milk fat, lactose and solids not fat (SNF) percentage were not affected by addition of PH and PEG. Milk protein percentage in T2 in comparison to control was significantly decreased. Fat and protein yield (kg/d) were not affected by the experimental diets. In conclusion, use of tanniniferous sources had no negative effects on milk production and composition of goats except protein percentage that can be compensated partly by addition of PEG. However, goats are able to consume large amounts of tannin-rich plant material in comparison to other ruminant species.

Table 1.

High tannin diets may increase the clinical symptoms of intoxication in ruminants. Toxic effects are reflected by damage in the liver, kidneys and the epithelium of the digestive tract. Polyethylene glycol (PEG) can neutralize the toxic effects of tannins. The aim of this study was to evaluate the effects of feeding pistachio hull (PH, source of tannin) and PEG supplementation on the liver enzymes i.e., alanine aminotransferase (ALT) and aspartate aminotransferase (AST) and blood factors such as packed cell volume (PCV), mean corpuscular hemoglobin concentration (MCHC), total white blood cells (TWBC), neutrophils, eosinophils, lymphocytes, monocytes, and hemoglobin in Saanen dairy goats. Nine Saanen dairy goats were used in a 3 × 3 Latin square design. Three treatments were formulated: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH replaced alfalfa hay. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Immune factors and liver enzymes were not significantly affected by the exprimental diets. But, plasma concentration of MCHC and hemoglobin and percentage of PCV in T2 had a tendency to decrease and was removed by PEG addition in T3 (with $P = 0.534$, $P = 0.735$ and $P = 0.732$ for MCHC, hemoglobin and PCV, respectively). Conversely, concentration of ALT and AST and number of TWBC, neutrophil, eosinophil, lymphocyte, and monocyte in T2 had a tendency to increase and was removed by PEG addition in T3 (with $P = 0.791$, $P = 0.931$, $P = 0.794$, $P = 0.399$, $P = 0.928$, $P = 0.659$, $P = 0.933$ and $P = 0.368$ for ALT, AST, TWBC, neutrophil, eosinophil, lymphocyte and monocyte, respectively).

Table 1.

W274 Effects of pistachio tannins on nitrogen metabolism in Balochi male lambs.

A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], B. Saremi*[2], and A. R. Shahdadi[3], [1]*Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran,* [2]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany,* [3]*Agriculture Sciences and Natural Resources University of Gorgan, Gorgan, Iran.*

The decreased rate and extent of protein degradation in the rumen as observed due to feeding of tannin-rich feeds could lower ammonia concentrations in the rumen and hence urea N excretion in urine. The tannins shift the site of N metabolism from rumen to the lower digestive tract and large intestine. Shifting excretion pattern of nitrogen from urine to feces and formation of tannin—protein complex are beneficial environmentally. We aimed to evaluate if tannin rich diets (pistachio hull (PH) as a tannin source) manipulate intake, digestion, excretion and retention of nitrogen in Balochi male lambs. Three male lambs (35 ± 2 kg live weight) equipped with ruminal cannula were randomly assigned into a changeover 3 × 3 design. Treatments were: 1) control (alfalfa), 2) 15% alfalfa+15% PH that provided 10.59 g/kgDM tannin, and 3) 30% PH that provided 18.28 g/kgDM tannin. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). As tannin was increased in the diets, the nitrogen intake linearly and quadratic was decreased, rumen N-NH3 concentration linearly was decreased, and nitrogen excretion from urine and digested nitrogen linearly were decreased. Nitrogen excretion from fecal linearly and quadratic and retained nitrogen linearly were increased, by increased of dietary tannin. Thus, effects of tannins to reduce the degradation of protein in the rumen and nitrogen excretion from urine and to increase the nitrogen excretion from fecal and retained nitrogen due to N metabolism in the large intestine could have important role to improve nitrogen efficiency in lambs.

Table 1.

	Alfalfa	15% PH	30% PH	SEM	*P*-value

W275 Different levels of tannin by dietary addition of pistachio hull and plasma metabolic profile in Balochi male lambs. A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], and B. Saremi*[2], *[1]Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran, [2]Bonn University, Bonn, Germany.*

Pistachio hull (PH) is a byproduct that has high tannin concentration. Tannins can reduce the digestion of nutrients, especially proteins. We aimed to evaluate the effects of diets containing tannin on plasma metabolic profile of Balochi male lambs. Pistachio hull as a tannin source (with 6.68% tannin and 9.95% total phenol content) was used in diets of 3 male lambs (35 ± 2 kg live weight) which were randomly assigned into a changeover 3 × 3 design. Treatments were: 1) control (alfalfa), 2) 15% alfalfa+15% PH and 3) 30% PH (DM basis). Blood samples were taken from the jugular vein at 0, 2 and 4 h after the 0800 h feeding for measuring glucose, total protein, blood urea nitrogen (BUN), albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT), triglycerides and cholesterol. Data were analyzed as a repeated measurement design using PROC MIXED of SAS ($P < 0.05$), assuming the model included treatment, time, time × treatment as fixed effects and animal as random effect. Blood metabolites glucose, albumin, BUN, AST and ALT were not affected by the experimental diets ($P = 0.778$, $P = 0.264$, $P = 0.281$, $P = 0.538$ and $P = 0.899$ for glucose, albumin, BUN, AST and ALT, recpectively). Total protein was decreased as the dietary PH content (Tannin source) increased ($P = 0.003$). Plasma triglyceride concentration was significantly increased ($P = 0.0008$). The fat metabolite i.e., cholesterol ($P = 0.913$) was not influenced by PH content of diet.

Table 1. Effect of different levels of tannin by dietary addition of pistachio hull on plasma metabolic profile

Plasma metabolites	Alfalfa	15% PH	30% PH	SEM
Glucose (mg/dL)	57.22	58.44	57.33	0.947
Total protein (g/dL)	7.73^a	7.50^b	7.26^c	0.082

W276 Replacing alfalfa with different levels of pistachio hull and its effects on feed intake and digestibility of nutrients in total tract, rumen and post-rumen in Balochi male lambs. A. Rahimi[1], A. Ali Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], A. R. Shahdadi[3], and B. Saremi*[2], *[1]Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran, [2]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany, [3]Agriculture Sciences and Natural Resources University of Gorgan, Gorgan, Iran.*

Dietary tannins can exert either positive or negative effects on ruminants' nutrition and performance. Pistachio hull (PH) is a by-product containing high amount of tannin. Herein we determined the effects of replacing different levels of alfalfa with PH on feed intake and digestibility of nutrients in total tract, rumen and post-rumen in Balochi male lambs. Three male lambs (35 ± 2 kg live weight) equipped with ruminal and abomasal cannula were randomly assigned into a changeover 3 × 3 design and fed the experimental diets for 35 d, 20 d adaptation, 5 d collection and 10 d break time between the 3 periods. Treatments were: 1) control (alfalfa), 2) 15% alfalfa+15% PH and 3) 30% PH (DM basis). Statistical analysis was performed using the MIXED procedure of SAS. Least squares means were separated using the LSD. Total dry matter intake (DMI), organic matter intake (OMI), DMI and OMI per kg of body and metabolic weight, CP, ADF, NDF and fat intake were not different between treatments. Total tract and ruminal digestibility for DM, OM, ADF and NDF was not significantly affected by the diets, but CP in total tract and its ruminal digestibility were linearly decreased with 66.03, 60.11 and 55.50% for total tract ($P = 0.011$ and SEM = 1.616) and 59.97, 53.67 and 49.17 for ruminal digestibility ($P = 0.022$ and SEM = 1.718) for 0, 15 and 30% PH respectively. Total tract and ruminal digestibility of fat were linearly increased with 78.97, 80.37 and 82.43% for total tract ($P = 0.025$ and SEM = 0.529) and 11.98, 17.47 and 21.98 for ruminal digestibility ($P = 0.027$ and SEM = 1.558) as the amount of PH in the diet increased. Post-ruminal digestibility of OM, Fat, ADF and NDF was not significantly affected by the diets while DM decreased ($P = 0.037$ and SEM = 0.419) from 29.03 to 28.64 and 27.31 and CP increased ($P = 0.049$ and SEM = 0.642) from 7.90 to 10.52 and 12.21 for 0, 15 and 30% PH respectively.

Key Words: pistachio hull, feed intake, digestibility

W277 Effect of increasing amounts of corn dried distillers grains with solubles in dairy cow diets on enteric methane emissions, digestibility, and milk production. C. Benchaar*[1], F. Hassanat[2], R. Gervais[2], P. Y. Chouinard[2], C. Julien[3], F. Tremblay[1], D. I. Massé[1], and H. V. Petit[1], *[1]Dairy and Swine Research and Development Centre-Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]Département des Sciences Animales-Université Laval, Québec, QC, Canada, [3]INRA-Université de Toulouse, Castanet-Tolosan, France.*

Twelve lactating Holstein cows (DIM = 99 ± 18; BW = 645 ± 49kg) were used in a triplcated 4 × 4 Latin square (35-d periods, 14-d adaptation) to examine the effect of including increasing amounts (0, 10, 20 and 30%, DM basis) of corn dried distillers grains with solubles (DDGS) in the diet on enteric CH$_4$ emissions, digestibility, and milk production. Diets were isonitrogenous (CP = 16.9%) and isocaloric (NE$_L$ = 1.64 Mcal/kg) and fed for ad libitum intake. Production of CH$_4$ was measured (3 consecutive days) using respiration chambers. Digestibility and milk performance were determined over 6 consecutive days. Linear and quadratic contrasts (Proc MIXED; SAS) were used to determine effects of dietary DDGS levels on variable responses. Significance was declared at $P \leq 0.05$. Dry matter (DM) intake increased linearly as DDGS proportion increased in the diet (23.4, 24.4, 24.8 and 25.2 kg/d for 0 to 30% DDGS, respectively). Digestibility of DM (70.7, 70.2, 69.6, and 68.1% for 0 to 30% DDGS, respectively), and energy (69.6, 69.2, 68.7, and 67.6% for 0 to 30% DDGS, respectively) declined linearly as DDGS level in the diet increased. Milk yield increased linearly (up to + 4 kg/d) with increasing levels of DDGS in the diet. Milk fat (3.93 to 3.47% for 0 to 30% DDGS, respectively) and milk protein (3.49 to 3.31% for 0 to 30% DDGS, respectively) contents decreased linearly with the addition of DDGS in the diet. There was a tendency ($P = 0.10$) for a quadratic increase in energy corrected milk (ECM) as the proportion of DDGS in the diet increased. Methane production decreased linearly with increasing levels of DDGS in the diet (495, 490, 477 and 475 g/d for 0 to 30% DDGS). When adjusted for gross energy intake, CH_4 losses also decreased linearly as DDGS proportion increased in the diet (5.53, 5.30, 5.14, 4.76% for 0 to 30% DDGS, respectively). When expressed relative to ECM, CH_4 production declined linearly as the amount of DDGS increased in the diet. Results from this study show that feeding DDGS to dairy cows can help to mitigate enteric CH_4 emissions without negatively affecting intake and milk production.

Key Words: corn DDGS, methane, dairy cows

W278 The effect of feeding canola meal on the performance of Chinese Holstein cows.

Z. G. Wang[1], C. R. Wang[1], G. L. Liu*[1,2], C. G. Zhang[1], and G. Yang[1], *[1]State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co. Ltd., Shanghai, China, [2]Shanghai Dairy Breeding Center Co. Ltd., Shanghai, China.*

The objective of this study was to evaluate the effects of canola meal (CM) on the lactational performance of Chinese Holstein cows. One hundred multiparous Chinese Holstein cows average 102 ± 38.13 d in milk were randomly assigned to one of 5 treatments. During the 8-wk periods, cows were fed total mixed diets containing 21.8% soybean meal (control), 16.4% soybean meal and 6.3% CM (CM1), 10.9% soybean meal and 12.6% CM (CM2), 5.5% soybean meal and 19% CM (CM3) or 25.3% CM (CM4) as the major protein source. All diets had a 60:40 forage-to-concentrate ratio, and were formulated to be isonitrogenous at 16.25% CP. Results showed that dry matter intake did not differ among control, CM1 and CM2 (17.54, 17.53 and 17.55 kg/d), but was lower for CM3 andCM4 (17.27 and 17.19 kg/d, $P = 0.03$). Milk yield (26.3, 26.4, 26. 5, 26.3 and 26.2 kg/d) was no different ($P = 0.11$) when CM replaced soybean meal and corn except when the percentage of CM reached 25.3% DM. Milk SNF, TS, fat and protein percentages decreased for CM4 compared with other groups, but only the percentage of milk SNF and protein reached a significant level ($P < 0.05$). Milk fat yield was higher for CM1 ($P = 0.02$) and CM2 ($P = 0.02$) compared with other groups. Milk protein yield was affected among CM1, CM2, CM3, CM4 and control (0.78, 0.74, 0.81, 0.71, 0.87 kg/d. for, CM1, CM2, CM3, CM4 and control respectively). The percentage of milk lactose was higher for control compared with the other four treatments, whereas the milk lactose yields of CM1 and CM2 were higher than control, CM3 and CM4. Results of this study showed that maximum economic payback could be obtained when the dairy ration was formulated to contain about 12.6% CM (DM basis).

Key Words: canola meal (CM), performance, Chinese Holstein cows

W279 Effects of limit-feeding dried distillers grains to ewes during mid- to late-gestation on ram progeny post-weaning performance and carcass composition.

R. L. Burgett*[1], J. R. Luther[2], D. L. Thomas[1], D. M. Schaefer[1], and A. E. Radunz[1], *[1]University of Wisconsin-Madison, Madiso, [2]University of Wisconsin-River Falls, River Falls.*

Mature Polypay and Hampshire ewes (n = 48; BW = 83.1 ± 2.7 kg) were used to evaluate the effects of maternal dietary energy source fed during mid- to late-gestation on postnatal progeny performance. Ewes were blocked by breed (n = 2) and BW (n = 3), stratified by age, sire, and fetal number, and randomly assigned to pens (n = 12). Pens were allocated to 1 of 2 treatments: ad libitum alfalfa hay (H) or limit-fed dried corn distillers grains plus solubles (D) as the primary dietary energy source from 63 to 130 ± 6 d of gestation then removed from experimental treatments and managed as 1 group until weaning (66 ± 9 d). All ram lambs (n = 25) were fed the same diet as 1 group: whole shelled corn (82.5%), commercial finishing pellet (12.5%, 150 g/t lasalocid), molasses (3.75%), calcium carbonate (0.75%) and ammonium chloride (0.5%) on DM basis. Rams were weighed bi-weekly until slaughter at 114 ± 9 d post-weaning. At slaughter, KPH was removed before collecting HCW. Carcass measurements were collected 24 h after slaughter. Ram lambs from Hampshire ewes fed D during gestation tended ($P = 0.08$) to be lighter at slaughter than lambs from Hampshire ewes fed H or Polypay ewes fed D or H, whereas ADG was similar ($P = 0.34$) for rams between treatments from weaning to slaughter. Hampshire ram progeny from ewes fed H had greater ($P = 0.05$) HCW than those from Hampshire ewes fed D and Polypay ewes fed H but not different than ram progeny from Polypay ewes fed D. Organ weights, KPH, and mesenteric fat as % HCW were similar ($P \geq 0.17$) among treatments. No differences ($P \geq 0.55$) were detected in 12th rib fat thickness, body wall thickness, intramuscular fat (% ether extract), or LM area, however, lambs from Hampshire ewes fed H had greater ($P = 0.05$) percentage of boneless trimmed retail cuts than lambs from Polypay ewes fed H. Measurements for USDA quality grade (leg score and conformation) were also similar ($P \geq 0.47$) among treatments. Feeding D versus H to ewes in mid to late gestation resulted in no difference in post-weaning growth performance but slight differences in ram progeny carcass weight.

Key Words: distillers grains, fetal programming, sheep

W280 Effect of dried distillers grains with solubles (DDGS) on duodenal microbial crude protein (MCP) flow in steers as determined with DNA microbial markers.

E. Castillo-Lopez,* T. J. Klopfenstein, and P. J. Kononoff, *University of Nebraska-Lincoln, Lincoln.*

The objectives of this trial were to evaluate the effect of dried distillers grains with solubles (DDGS) on duodenal flow of bacterial crude protein (BCP), protozoal crude protein (PCP) and yeast crude protein (YCP) in steers fed DDGS. Three crossbred steers fitted with ruminal and double L-shaped duodenal cannulas (average BW 780 ± 137 kg) were used in a 3 treatment, 6 period crossover design. Animals were housed in individual free stalls and fed twice daily at 0700 and 1900. Diets (DM basis) were 1) CONTROL, 0% DDGS, but with 19.5% corn bran, 20% sorghum silage, 60% brome hay, 0.5% trace minerals and 0.25% urea; 2) LOW DDGS, inclusion of 9.75% DDGS replacing equal percentage of corn bran; 3) HIGH DDGS, inclusion of 19.5% DDGS completely replacing corn bran. On d 16 to 19 of each period, 200 mL of duodenal digesta were collected every 4 h from each animal, then composited by day, by animal within period. Duodenal microbial crude protein (MCP) was estimated using DNA as microbial markers. For bacteria, marker was part of the 16S rRNA gene. For protozoa, marker was part of the 18S rRNA gene. For yeast, marker was part of the II chromosome of *Saccharomyces cerevisiae*. Data were analyzed using the MIXED procedure of SAS. Average DMI was 10.5 kg/d across treatments. Duodenal BCP flow tended ($P = 0.14$) to decrease with DDGS inclusion; estimates were 479, 397 and 368 ± 74 g/d for CONTROL, LOW DDGS and HIGH DDGS, respectively. However, duodenal PCP flow was unaffected ($P = 0.64$) and averaged 80 ± 12 g/d. Duodenal YCP flow increased ($P < 0.01$) with DDGS inclusion; estimates were 0.15, 1.94 and 4.80 ± 0.66 g/d for CONTROL, LOW DDGS and HIGH DDGS, respectively. Overall, when animals were fed DDGS, duodenal BCP flow tended to decrease, PCP flow was unaffected, YCP flow increased and total duodenal MCP flow tended to decrease.

Key Words: dried distillers grains with solubles, duodenal microbial crude protein flow

W281 Effect of canola meal on growth performance, carcass quality and meat fatty acid profiles of feedlot cattle.

M. L. He*[1,2], T. A. McAllister[1], D. Gibb[3], and J. J. McKinnon[2], [1]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*University of Saskatchewan, Saskatoon, SK, Canada,* [3]*Viterra Feed Products, Lethbridge, AB, Canada.*

This study investigated the effect of substituting canola meal (CM) for barley grain on growth performance, carcass quality and meat fatty acid (FA) profiles of feedlot cattle. Cross bred calves (n = 140; 285 ± 27 kg) were individually fed diets comprised of a barley grain based concentrate (including 5% supplements) and barley silage in dry matter (DM) basis at ratios of 45:55 and 92:8 during growing and finishing periods, respectively. Solvent extracted and pressed CM derived from *Brassica napus* or solvent extracted CM from *Brassica juncea* canola was compared. Pressed CM contained 11.4% residual oil. CM was substituted for 0 (control), 15, or 30% barley grain (DM basis) in the diet. There was no difference ($P = 0.54$) in average daily gain among the treatments. The inclusion of 30% pressed CM increased ($P < 0.05$) feed intake compared with the control and those 15% CM groups, but reduced ($P < 0.05$) feed efficiency as compared with the control and 15% *Brassica juncea* or 15% pressed CM. Feed efficiency of cattle fed 15% CM did not differ from those fed the control diet. Carcass quality and incidence of liver abscesses were not affected ($P > 0.05$) by inclusion of CM. Inclusion of 30% pressed CM resulted in higher ($P < 0.05$) FA of total polyunsaturated, n-3, *trans*, non-conjugated dienes, α-linolenic acid and rumenic acid, and a decrease ($P < 0.05$) in n-6/n-3 ratio in the *pars costalis diaphragmatis* muscle as compared with the control diet. In conclusion, inclusion of 15% CM did not alter the growth performance or feed efficiency of beef cattle during the growing and finishing period. However, inclusion of 30% CM in the diet decreased feed efficiency, particularly during the finishing period. The inclusion of 15% or 30% solvent extracted CM did not alter carcass quality whereas that of 30% pressed CM increased functional fatty acids (i.e., n-3 and CLA) in beef.

Key Words: canola meal, beef cattle, growth performance

W282 Effects of roughage concentration in steam-flaked corn-based diets containing wet distillers grains with solubles on nutrient digestibility by feedlot cattle.

J. S. Schutz,* C. H. Ponce, D. R. Smith, and M. L. Galyean, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Effects of concentrations of alfalfa hay (AH) and wet distillers grains with solubles (WDGS) on apparent total-tract digestibility of nutrients were evaluated with 56 beef steers (initial BW = 395.3 ± 6.9 kg) in a randomized complete block design. Treatments were arranged in a 2 × 3 + 1 factorial and consisted of steam-flaked corn-based diets with (DM basis) 6 or 12% AH and 15, 30, or 45% WDGS plus a control diet without WDGS that contained 9% AH. Diets were fed for 28 d, and 0.15% (DM) of Cr_2O_3 was included in the diet as an indigestible marker for measurement of nutrient digestibility from d 21 to 28. A WDGS × AH interaction (Linear and quadratic, $P \leq 0.02$) was detected for intake of starch. Intakes of DM, OM, NDF, ADF, and CP were greater ($P \leq 0.048$) for steers fed 12 vs. 6% AH. Increasing the dietary concentration of WDGS increased NDF, ADF, and CP intakes (quadratic, $P \leq 0.046$). Dry matter and OM digestibility were greater for the control steers vs. the average of the other treatments ($P < 0.01$). A WDGS × AH interaction was noted for apparent total tract digestibility of DM, OM, and starch ($P < 0.01$). Dry matter and OM digestibilities were decreased (AH × linear, $P < 0.03$) and increased (AH × quadratic, $P < 0.01$) with 6 and 12% AH; respectively, as WDGS increased in the diet, and starch digestibility increased (AH × quadratic $P < 0.01$) at 12% AH. Increasing WDGS in the diet resulted in a linear increase of NDF and CP digestibilities ($P < 0.01$). Results from this experiment suggest an interaction of WDGS and roughage concentrations in terms of total tract digestibility.

Key Words: alfalfa hay, digestibility, wet distillers grains with solubles

W283 Effect of sarsaponin supplementation on digestive function of steers fed a high grain distillers grain-feedlot diet.

E. Valencia[1], M. F. Montano*[1], J. Salinas[2], V. M. Gonzalez[1], O. M. Manriquez[1], J. A. Valdez[1], J. O. Chirino[1], O. J. Castillo[1], G. M. Carvajal[1], and W. G. Caceres[1], [1]*Universidad Autónoma de Baja California, Mexicali, B.C. Mexico,* [2]*Universidad Autónoma de Tamaulipas, Ciudad Victoria, Tam. Mexico.*

Six Holstein steers (132 ± 3 kg) with cannulas in rumen and duodenum were distributed in a 3 × 3 replicated Latin square design to evaluate the effect of supplementation of sarsaponin on a finishing diet with 40% of dried distillery grains plus soluble (DDGS) on the characteristics of digestion and rumen function. Treatments were a combination of an initial dose of SarStart (SarTec Corporation, Anoka, MN) via mouth on the d 1 of each experimental period plus a daily dose of SarStart DSC (SarTec Corporation) offered in the diet. Treatments were as follows: 1) 0cc of SarStart + 0 g/d of SarStart DSC; 2) SarStart 100cc + 2 g/d of SarStart DSC and 3) 200cc of SarStart + 4 g/d of SarStart DSC. Ruminal starch digestion was greater (79.6 vs 82.1%; $P < 0.05$), as well as its amount reaching duodenum (160 vs. 125 g/d; $P < 0.05$), in T2 compared with T3. There was no effect of treatment on ruminal, postruminal or total digestibility of the nitrogen components of diets, or microbial efficiency ($P > 0.05$). The treatments did not affect ($P > 0.05$) total volatile fatty acids, or its composition, or ruminal pH. It was concluded that the doses from sarsaponin used in this experiment did not significantly alter the digestive efficiency of the components of finishing diets with high levels of dried distillery grains plus soluble in cattle.

Key Words: distillery grains, sarsaponin, steers

W284 Effect of tannins extract supplementation on feedlot performance and plasma urea nitrogen of yearling bulls fed dry-ground corn-based diets containing corn-DDG and cane molasses.

R. Barajas*[1], B. J. Cervantes[2], M. A. Espino[1,3], A. Camacho[1], M. Verdugo[1], L. R. Flores[1], J. J. Lomeli[1], and J. A. Romo[1], [1]*FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México,* [3]*Pronutrient Developers, León, Guanajuato, México.*

Thirty *Bos Taurus* × *Bos indicus* yearling bulls 365 ± SE 1.10 kg, were used in a 84 d experiment to determine the effect of tannins extract supplementation on feedlot performance and plasma urea nitrogen of yearling bulls fed dry-ground corn-based diets containing corn-DDG and cane molasses. Prior to the experiment, bulls were placed in experimental pens and fed a 15.4% CP, 70% roughage diet for 90 d to homogenize previous nutritional plane. Day-1 bulls were weighed and blocked by initial weight, and in groups of 5 were placed in 6 ground floor pen (6 × 12 m). In agreement with a complete randomized block design, in each block, bulls were randomly assigned to one of next treatments: 1) Feeding with a finishing diet containing ground corn 53.37%, corn dry distiller grain 13.51%, sugar-cane molasses 12.71%, tallow 2.35%, mineral premix 2.82%, and corn straw 14.23% (Control); or 2) Diet similar to Control, added with 0.3% (dry matter basis) of a tannins extract (TE). Tannins extract was supplied as ByPRO (Pronutrient Developers; Mexico), a premix that contains 72% of a condensed (Quebracho tree) and soluble (Chesnutt) tannins blend. Bulls were weighed in d 1 and 84. In d 1 and 28, blood samples were taken from jugular vein for plasma urea nitrogen (PUN) determination. Real mean daily tannins extract intake was 36 g by bull, equivalent to 0.33% of the dietary DMI. In d 28 TE decreased ($P = 0.08$) PUN concentration in 18%. At end of the experiment TE-fed bulls were 2.9% heavier ($P = 0.04$) than Control (498.25 vs. 512.98 kg, for Control and TE, respectively). TE supplementation increased ($P = 0.02$) average daily gain by 11.8% with mean values of 1.580 vs. 1.767 for Control and TE treatments, respectively. DMI was not affected by treatments ($P = 0.91$). TE improved ($P = 0.06$) the Gain:DMI ratio by 12% (0.149 vs. 0.167 kg/kg, for Control and TE, respectively). It is concluded, that tannins extract supplementation improves feedlot performance of yearling bulls fed dry-ground corn based-diets containing corn-DDG and cane molasses.

Key Words: feedlot performance, tannins, yearling bulls

W285 Inclusion of triticale dried distiller grains and flaxseed in feedlot cattle diets increases alpha-linolenic acid in beef without affecting carcass or meat quality traits.

M. L. He*[1,2], L. M. Hernandez-Calva[1], T. A. McAllister[1], J. L. Aalhus[3], M. E. R. Dugan[3], and J. J. McKinnon[2], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]Lacombe Research Centre, Agriculture and Agri-Food Canada, Lacombe, AB, Canada.*

This study examined the effect of including triticale dried distillers grain (TDDG), with and without ground flaxseed (FS) or high oleic acid-sunflower seeds (SS), in feedlot finishing diets on carcass and meat quality and fatty acid profiles in beef. Steers (n = 90; 455 ± 31kg) were housed in individual pens and fed either: 1) control (CON) consisting of (dry matter basis) 90% barley concentrate (including 5% supplements) - 10% barley silage, or the following diets with barley grain substituted for 2) 30% TDDG; 3) 10% FS; 4) 30% TDDG – 8.5% FS (FS+DDG); 5) 10% SS; and 6) 30% TDDG – 8.5% SS (SS+DDG) over a 15 wk finishing period. Major carcass traits including grade fat depth, rib eye area and marbling (n = 15) as well as meat quality parameters including *longissiumus thoracis* (LT) pH, temperature, drip loss, shear force, cook loss and meat color (n = 8) were measured. Fatty acids in back fat, perirenal fat and LT muscle samples were analyzed (n = 8). Including TDDG, in combination with either oilseed did not affect ($P > 0.05$) carcass or meat quality except for: a higher ($P < 0.05$) post-slaughter temperature at 45 min, an increase ($P < 0.05$) in drip loss and chroma values after inclusion of TDDG; and a reduction ($P < 0.05$) in cook loss after inclusion of FS. Inclusion of TDDG decreased ($P < 0.05$) total *trans* fatty acids (excluding conjugated linoleic acids and vaccenic acid), whereas inclusion of FS increased ($P < 0.05$) α-linolenic acid (ALA) as well as associated biohydrogenation products (non-conjugated dienes (NCD)) in meat and adipose tissues. Inclusion of TDDG together with FS further increased ($P < 0.05$) ALA, but decreased ($P < 0.05$) NCD in the meat and adipose samples. Compared with inclusion of FS alone, addition of DDG+FS in feedlot diets increased n-3 fatty acid while reducing levels of *trans* fatty acids in fat and meat, without adversely impacting carcass or meat quality.

Key Words: carcass, flaxseed, triticale dried distillers grain with solubles

W286 Effects of increasing distillers grain and monensin on feed intake and ruminal fermentation in feedlot cattle diets.

L. Xu[1,2], Y. Jin[2], C. Li[1,2], and W. Z. Yang*[1], *[1]Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

It has been reported that diets that contain corn distillers grain with solubles (DG) are less responsive to monensin (M) addition in feedlot cattle. A study was conducted to determine the effects of increasing M supplementation and inclusion rates of corn DG on DMI, sorting index and ruminal fermentation. Five ruminally and duodenally cannulated beef heifers were used in a 5 × 5 Latin square design with 2 × 2+1 factorial arrangement. Treatments were control (CON; 10% barley silage, 87% barley grain, 3% supplement, and 28 mg M/kg DM), and diets substituting 20% or 40% corn DG for grain combining with 28 or 48 mg M/kg diet DM, i.e., 20DG-28M, 20DG-48M, 40DG-28M and 40DG-48M. The CON is a standard feedlot diet in western Canada. Sorting index was calculated as the ratio of actual intake to expected intake for particles retained on 19- and 8-mm sieve of Penn State Particle Separator. DMI (kg/d) was lower ($P < 0.05$) for CON (7.2) than for DG (8.3) diets. There was no interaction between DG and M on DMI, which was not affected by the level of DG (8.3 kg/d), whereas DMI was higher ($P < 0.05$) with 28M (8.9) than with 48M (7.7). Sorting index was not affected by treatments but it was 109 for the particles retained on 19 mm sieve, indicating that animals were intentionally selected for the coarse particles. Total VFA concentrations (mM), molar proportions of acetate and propionate were not different between CON (128, 52 and 29, respectively) and DG (126, 50 and 32, respectively) diets. There was no interaction of DG with M on ruminal fermentation. Total VFA concentration was greater ($P < 0.06$) for 20DG (130) than for 40DG (122) with no difference in molar proportions of acetate and propionate. Increasing the level of M increased ($P < 0.04$) proportion of acetate from 48 to 51% but did not affect other fermentation variables. These results indicate that manipulating the levels of corn DG and M in feedlot diets can change DMI, whereas the effects on ruminal fermentation appear minimal.

Key Words: distillers grain, feedlot cattle, monensin

W287 Modeling nutrient supply from combined feeds of corn with wheat dried distillers grains with solubles at different ratios in ruminants.

D. Damiran, M. Yari, L. Yang,* X. Zhang, and P. Yu, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The objectives of this study were to use modeling approach to estimate nutrient supply from combined feeds of corn with wheat DDGS at 4 different ratios of corn to wheat dried distillers grains with solubles (DDGS): 100:0, 75:25, 50:50; 25:75. Each feed treatment had 2 different replicates using 2 different DDGS sources. The parameters for nutrient supply prediction that were accessed included: truly absorbed rumen synthesized microbial protein in the small intestine; truly absorbed rumen undegraded feed protein in the small intestine; endogeneous protein in the digestive tract; total truly absorbed protein in the small intestine and degraded protein balance. Two dry Holstein Friesian cows, fitted with a flexible rumen cannula were used for measuring rumen degradation kinetics of the 4 combined feeds. Based on lab chemical analysis, in situ degradation and in vitro intestinal digestion data, the nutrient supply to dairy cattle was predicted. The data were analysis by Mixed procedure of SAS with a CRD model. The results showed that with increasing inclusion rate of wheat DDGS to corn, it did not change the truly absorbed rumen synthesized microbial protein in the small intestine with an average of 54 g/kg DM and endogenous protein with an average of 7 g/kg DM, but changed the truly absorbed rumen undegraded feed protein in the small intestine from 50 to 108 g/kg DM, total truly absorbed protein in the small intestine from 95 to 154 g/kg DM and degraded protein balance from −54 to 102 g/kg DM. These results indicated that with the inclusion of bioethanol co-product, the nutrient supply from corn grain could be further improved.

Key Words: combined feeds, modeling, nutrient supply

W288 Effects of biodiesel by-products on in vitro fermentation, digestion kinetics and methane production. S. J. Meale*[1], S. M. Olivares-Palma[1], L. G. R. Pereira[2], F. S. Machado[2], H. Carneiro[2], F. C. F. Lopes[2], and A. V. Chaves[1], *[1]Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia, [2]Embrapa Dairy Cattle, Juiz de Fora, MG, Brazil.*

Increasing interest in the biofuel industry has produced by-products which show promise as energy and protein feeds in the diets of ruminant livestock. The objective of this study was to determine the effects of biodiesel by-products, from a variety of oilseed sources on *in sacco* nutrient degradability, in vitro ruminal fermentation and CH_4 production. Beard grass (*Brachiaria brizantha*) was incubated alone (control) and in combination with 7 biodiesel by-products (i.e., moringa, castor, cotton, radish, palm kernel and sunflower press oil seeds and glycerine) at ratios of 900:100, 800:200 and 600:400 for each treatment, in a 48 h in vitro batch culture. Gas production (mL/g incubated DM) was measured at 6, 12, 24 and 48 h. Methane production (mg/g of DMD) was measured at 6 and 12 h. Data were analyzed using the MIXED procedure of SAS. After 48 h, culture pH and IVDMD were affected by level x supplement interaction ($P < 0.05$). Supplement type affected gas production, total VFA, proportions of individual VFA and CH_4 production ($P < 0.05$). Moringa produced the lowest amount of CH_4 (g/kg of DM) at 6 and 12 h of incubation, whereas glycerine had the highest CH_4 production ($P < 0.05$). The in sacco experiment examined ruminal degradation of CP and DM in moringa, castor, cotton, radish, palm kernel and sunflower press oil seeds and soybean meal (control). Three nylon bags, containing 5 g of sample, were placed into the rumen of each of the 3 lactating Holstein-Friesian dairy cows. Corresponding bags were removed at 0, 3, 6, 12, 24, 48 and 96 h (i.e., 3 replicates per cow, 9 replicates per time point) for determination of CP and DM disappearance. Moringa press oils seeds exhibited the greatest effective degradability of DM. Similarly, moringa and sunflower press oil seeds exhibited rapid degradation rates of both CP and DM and showed the greatest effective degradability of CP compared with other feed sources ($P < 0.05$). The findings suggest moringa press oils seeds may have the potential to be included in ruminant diets to reduce CH_4 production without adversely affecting nutrient degradability.

Key Words: methane, press oil seeds, ruminal fermentation

W289 Effect of replacing barley grain with glycerol in feedlot diets on nutrient digestibility, methane emissions, growth, fatty acid profiles and carcass traits of lambs. J. S. Avila[1,3], S. J. Meale*[1,2], T. A. McAllister[2], M. L. He[2], O. M. Harstad[4], K. A. Beauchemin[2], S. M. McGinn[2], and A. V. Chaves[1], *[1]Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia, [2]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [3]Facultad de Ciencias Veterinarias, Universidad de Concepción, Chillan, Chile, [4]Norwegian University of Life Sciences (UMB), Ås, Norway.*

The aim of the study was to assess the effects of replacing barley grain with increasing concentrations of glycerol on total tract nutrient digestibility, methane (CH_4) emissions, growth performance, and fatty acid (FA) profiles. The control diet (DM basis) contained 57% barley grain, 14.5% wheat dried distillers grain with solubles (WDDGS), 13% sunflower hulls, 6.5% beet pulp, 6.3% alfalfa and 3% mineral-vitamin mix. Increasing concentrations (7, 14 and 21% dietary DM) of glycerol in the diet DM were achieved by substituting it for barley grain. As glycerol was added alfalfa and WDDGS were increased to maintain similar concentrations of CP and NDF among diets. Nutrient digestibility and CH_4 emissions from 12 ram lambs were measured in a repeated 4 × 4 Latin square experiment. Additionally, 60 weaned lambs were blocked by weight and randomly assigned to one of the 4 dietary treatments and fed to slaughter weight. Data were analyzed using the mixed procedure of SAS. The model included the fixed effects of treatment (diet), day and treatment by day interactions and the random effects of period (n = 4), chamber (group) and lamb nested within treatment as random effects with day of sampling within each period treated as repeated measure. Nutrient intakes, digestibility and CH_4 emissions were not altered by inclusion of glycerol in the diets. In the growth trial, increasing glycerol in the diet linearly decreased DMI ($P < 0.01$) and linearly decreased final bodyweight ($P = 0.01$). The 7% glycerol group tended to have higher ADG ($P = 0.06$) compared with all other treatments. Feed efficiency, carcass traits and total SFA or MUFA proportions of subcutaneous fat were not affected by inclusion of glycerol, but PUFA were linearly decreased ($P < 0.01$). Proportions of 16:0, 10*t*-18:1, linoleic acid 18:2 (n-6) and the n-6/n-3 ratio were linearly reduced ($P < 0.01$) and those of 18:0 (stearic acid), 9*c*-18:1 (oleic acid) were linearly increased ($P < 0.01$) by glycerol inclusion in the diets. In conclusion, glycerol did not affect nutrient digestibility or CH_4 emissions of lambs fed barley-based finishing diets. Lamb growth performance was optimized at 7% glycerol inclusion in the diet and may improve back fat fatty acid profiles by increasing 18:0 and 9*c*-18:1, while reducing 10*t*-18:1 and the n-6/n-3 ratio.

Key Words: biofuel by-products, methane, *trans* fatty acids

W290 Crude glycerin decreases fiber digestibility in finishing Nellore bulls. E. H. C. B. van Cleef*[1], J. M. B. Ezequiel[1], J. B. D. Sancanari[1,2], A. P. D′Aurea[1], V. R. Fávaro[1], D. A. V. Silva[1], J. W. Catellan[1], and F. B. O. Scarpino[1], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]Uzinas Chimicas Brasileiras S.A., Jaboticabal, São Paulo, Brazil.*

Nellore bulls (n = 30, 277.7 ± 23.8 kg BW) were used to evaluate total tract digestibility when fed diets containing 0, 7.5, 15, 22.5, or 30% crude glycerin. Treatments (5 diets) consisted of a control diet containing 30% corn silage, 35% corn grain, 19.2% soybean hulls, 14.6% sunflower meal, and 1,2% supplement, and diets containing 7.5, 15, 22.5 or 30% glycerin (dry matter basis). In this study, glycerin replaced specifically corn grain. Bulls were vaccinated against common viral and clostridial diseases, stratified in a randomized block design, by initial BW, and assigned randomly to 30 individual feedlot pens (6/treatment). Over a period of 21 d, bulls were transitioned from diets containing 20% concentrate to their respective 70% concentrate finishing diets using 4 step-up diets that contained progressively greater proportions of concentrate. Final diets provided 12.2% CP and 2.5 MCal ME/kg. Data were analyzed using the General Linear Model procedure of SAS, with animal considered as experimental unit. Indigestible acid detergent fiber was used as internal marker to determine nutrient apparent digestibility. Five Nellore rumen-cannulated steers (approximately 400 kg BW) were adapted to experimental diets and incubated in situ with diets, orts and fecal samples from the 30 finishing study animals for 264 h. Feeding glycerin caused linear ($P \leq 0.01$) reductions in neutral detergent fiber and hemicellulose apparent digestibility, while simultaneously increased crude protein apparent digestibility ($P \leq 0.01$). Dry matter, ether extract and acid detergent fiber apparent digestibilities were unaffected ($P > 0.05$) by adding glycerin. The negative effect in digestibility was not reflected in changes in DMI ($P > 0.05$) nor ADG ($P > 0.05$). The inclusion of crude glycerin in finishing Nellore cattle diets cause significant decrease in digestibility of neutral detergent fiber and hemicellulose, suggesting caution to the level and type of roughage used. Further studies are needed to elucidate the effect of crude glycerin on mechanisms of action of fibrolytic microorganisms as well as the processes involved in the adhesion of these to fiber particles. Supported by FAPESP and CNPq.

Key Words: biodiesel, co-product, beef cattle

W291 Effect of replacing wheat offal with dried oil palm slurry on the performance and carcass traits of Ndama weaners. M. K. Adewumi* and J. A. Aderiye, *Department of Animal Science, University of Ibadan, Ibadan, Oyo State, Nigeria.*

The objective of this trial was to evaluate the effect of replacing wheat offal (WO) with dried oil palm slurry (DOPS) on performance and carcass traits of weanling Ndama calves. Sixteen calves weighing 60.00 ± 1.50 kg were used in a complete randomized design. Control (T1) diet consisted of 53.0% wheat offal (WO), 30.0% dried brewers grains (DBG), 15.0% palm kernel cake (PKC) and 2.0% of a ruminant premix on dry basis. In the test diets, wheat offal was replaced with dried oil palm slurry at 18.9% (T2), 37.7% (T3) and 56.6% (T4) on dry matter basis. The supplements were fed at the rate of 3 kg/100 kg of body weight. Animals, also had access to fresh *Panicum maximum*. The trial lasted 180 d with a 14 d adaptation. All animals were weighed at the start of the trial and subsequently every 14 d to obtain average daily gain (ADG). At the end of 180 d, 3 animals were slaughtered per treatment after fasting for 16 h and hot carcass weight (HCW) determined. Dressing percentage (DP) and rib eye area (REA) were measured after cooling the carcass. Data were analyzed using ANOVA. Dry matter intake (2.58 ± 0.04 kg/d) was similar for T1, T2 and T3 but higher ($P < 0.05$) than for T4 (2.17 ± 0.01 kg/d). Dry matter digestibility (69.88 ± 3.18%) was not different among treatments. Hot carcass weight (kg) and dressing percentage (%) were higher ($P < 0.05$) for T2 (74.20 ± 1.80 and 49.19 ± 0.76) and T3 (78.07 ± 1.76 and 50.99 ± 0.68) than T1 (52.00 ± 1.68 and 40.86 ± 0.74) and T4 (59.17 ± 1.80 and 43.45 ± 0.72) respectively. Rib eye area (cm^2) was higher ($P < 0.05$) for T3 (76.00 ± 1.78) than the average (52.33 ± 3.18) for the other 3 treatments respectively. Replacing wheat offal with not more than 37.7% dried oil palm slurry improved performance and carcass traits of Ndama weaners.

Key Words: dried oil palm slurry, Ndama, performance

W292 Glycerin from soybean biodiesel in diets with high levels of concentrate for sheep. R. L. Galati,* P. G. Paiva, L. S. Cabral, J. T. Zervoudakis, J. G. Abreu, R. S. Gomes, M. P. S. Fachin, and A. P. G. Baroni, *Universidade Federal do Mato Grosso, FAMEV/UFMT, Cuiabá, Brazil.*

The objectives of this study were to evaluate the effect of glycerin from soybean biodiesel in high-concentrate diets on intake, digestibility, rumen pH and glucose blood concentrations. Animals were housed in individual pens, randomly allocated in a 5x5 Latin square design, and the dietary treatments were: 0, 5, 10, 15 and 20% of glycerin on diet DM. The glycerin used was derived from soybean biodiesel (98% glycerol, 0.98% methanol, 0.18% ethanol, 101 mg KOH/g). Five male sheep, castrated and cannulated in the rumen, with initial body weight of 52.2 ± 5.5 kg were used in this study, and fed isoproteic diets (11.2% CP), containing 25% cotton boll and 75% concentrate, on DM basis. Water, feed, refusal and total fecal output were collected on 8 d through 13 d of each period. Rumen fluid was collected on 14 d to measure the pH values up to 8 h after feeding. The glucose blood concentrations were measured with AccuChek on 17 d of each period until 4 h after feeding. Quadratic responses ($P < 0.03$) were observed on DM (1631.16 g/d), OM (1515.69 g/d), CP (184.98 g/d), total digestible nutrients (TDN) intakes, with maximum inclusions of 12.95, 12.55, 13.01 and 15.75% glycerin, respectively. Linear response ($P < 0.01$) from 32.21 to 93.41 g/d was observed for ether extract (EE) intake, while non-fiber carbohydrate (NFC) linearly decreased from 761.79 to 501.69 g/d. Water intake was about 2.3 L/kg DM without glycerin effect ($P > 0.10$). For the most part of nutrients digestibility (DM, OM, CP, EE and NDF), a positive linear response ($P < 0.08$), without any effect on fiber carbohydrate ($P > 0.10$), were observed. Linear decreases ($P < 0.07$) were observed in NFC digestibility, and to the TDN, a positive response ($P < 0.01$) was obtained (71.55 to 75.24%). Quadratic response ($P < 0.03$) were observed on rumen pH values by glycerin and collection times, with the maximum of 5.57 for 8.63% glycerin, and minimum of 5.39 about 4.78 h after feeding The increase of glycerin did not affect ($P > 0.11$) the blood glucose concentration (63.66 mg/dL). The dry matter intake was not affected by the inclusion of 13% soybean glycerin in high-concentrate diets, and the linear digestibility response could compensate low intake, so that, 15% glycerin could be adequate without compromising nutritional parameters.

Key Words: digestibility, glycerol, soybean

W293 Nitrogen balance and microbial efficiency in sheep fed with diets containing glycerin. R. L. Galati,* P. G. Paiva, J. T. Zervoudakis, L. S. Cabral, J. G. Abreu, M. Zanchetin, L. R. Rebelo, and R. S. Fioravante Filho, *Universidade Federal do Mato Grosso, FAMEV/UFMT, Cuiabá, Brazil.*

The objective of this study was to evaluate the effect of glycerin inclusion in diets with high levels of concentrate on nitrogen balance (NB), excretion of purine derivatives, microbial production (Pmic) and efficiency (Efmic), and ruminal ammonia concentrations. The glycerin used was derived from soybean biodiesel production (98% glycerol, 19.2% fat, 0.98% methanol, 0.18% ethanol, 101 mg KOH/g). Five castrated male sheep, cannulated in the rumen, with initial body weight of 52.2 ± 5.5 kg were used in this study. Animals were housed in individual pens and fed isoproteic diets (11.2% CP), containing 25% cotton boll and 75% concentrate, on DM basis. Animals were randomly allocated in a 5 × 5 Latin square design, and treatments were 0, 5, 10, 15 and 20% of glycerin on diet DM. The total fecal collection was performed during 3 d, and urine for 24 h to enable quantification of nitrogen (N) intake, in feces, urine, and therefore the balance of this nutrient. Estimates of Pmic and Efmic were obtained from the total excretion of purine derivatives in urine. The inclusion of glycerol increased quadratically ($P < 0.08$) the intake, fecal, urinary and the uptake of nitrogen, with estimated values of 31.21, 11.71, 8.12 and 18.93 g/d for 14.22, 11.53, 11.86 and 15.52% glycerin, respectively. The nitrogen balance was not affected by glycerin ($P > 0.10$) with values of 57.97%, on average. Ammonia concentrations linearly decrease ($P = 0.01$) from 23.64 to 20.45, which corresponded to 0.16 mg/dL for each 1% of glycerin. The excretion of purine derivatives were not affected ($P > 0.10$), except for xanthine + hypoxathine which was linearly increased ($P < 0.01$), but without influences on total excretion of purine (9.85 mmol/d), which result in Pmic 55.03 g/d, and Efmic of 48.35 g CP/kg TDN. It was concluded that up to 20% of glycerin could be utilized. The nitrogen intake and losses could vary above 15% of glycerin, but without any damage in retention. Ammonia concentrations decreased with the inclusion of glycerin, but without disadvantage in microbial production and efficiency.

Key Words: ammonia concentration, glycerol, purine derivatives

W294 Blood parameters of Nelore steers fed with glycerin. V. R. Fávaro,* J. M. B. Ezequiel, A. P. D'Áurea, J. B. D. Sancanari, E. H. C. B.van Cleef, A. C. Homem Junior, and V. C. Santos, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Ruminants fed high concentrate diets frequently present metabolic disorders. Blood parameters have been used to assess the health status of animals. The viability of glycerin use in cattle diets may be indicated by the blood parameters of the animals. This study aimed to evaluate blood parameters indicators of metabolic disorders (glucose, triglycerides, cholesterol and urea). Five rumen cannulated Nelore steers (420 ± 20 kg BW) were used in a 5 × 5 Latin square design. Orthogonal contrasts were used to determine the linear, quadratic, and cubic effects of glycerin. Experimental diets (DM basis) consisted of 40% corn silage and 60% concentrate (corn grain, soybean hulls, sunflower meal, glycerin) with the following levels of glycerin 0, 5, 10, 15 and 20% of DM. Blood samples were taken on 25d of each experimental period through coccygeal vein puncture, 4h after morning feeding, using Vacutainer tubes. The samples were analyzed using commercial kits. There was no effect ($P > 0.05$) of treatment for serum triglycerides and urea. The average values (7.3 and 21.4 mg/dL, respectively) were in agreement with those suggested in the literature (0–14 mg/dL and 12–65 mg/dL). Diets promoted quadratic effect on plasma glucose concentration ($P = 0.0001$) which presented as maximum point 73.1 mg/dL (10% of glycerin) and minimum, 50.9 mg/dL (0% of glycerin), and promoted cubic effect on serum cholesterol ($P = 0.04$) which presented as maximum point 117.0 mg/dL (0% of glycerin) and minimum, 88.6 mg/dL (5% of glycerin). Although there was difference between treatments, these values were in according to those suggested in the literature (45–75 mg/dL, and 80–120 mg/L, respectively for glucose and cholesterol). The inclusion of glycerin in cattle diet affect blood concentrations of glucose and cholesterol, however, the values for all parameters obtained in this study are in agreement with the suggested in the literature.

Key Words: beef cattle, biodiesel, blood

W295 Levels of replacement of corn by glycerin in multiple supplements for Nelore steers grazing in dry season: Performance. J. T. Zervoudakis,* R. P. da Silva, L. C. R. P. Silva, A. J. Neto, J. F. W. Koscheck, R. G. F. da Silva, T. P. Trindade, A. O. Zanette, and E. R. Donida, *Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil.*

The objective of this study was to evaluate the productive performance of Nelore steers in growing on *Brachiaria brizantha* cv. Marandu during dry season and receiving supplements with partial replacement of corn by glycerin. Forty Nelore steers with initial body weight of 203. 12 ± 20.10 kg and average initial age of 12 months, divided into eight paddocks of 1.6 ha each, were used. The design was completely randomized with five replicates and eight supplements. The supplements were formulated with levels of partial replacement of corn by glycerin: 0% (G0), 10% (G10), 20% (G20), 30% (G30), 40% (G40), 50% (G50) and 60% (G60). The supplements were supplied to the animals in the level of 1 kg/animal/day. A group of animals was allotted to untreated control treatment (MM) and received exclusively mineral mix. Average daily gain (ADG) was higher ($P < 0.10$) for animals receiving supplements G30 (0.568 kg/d), G 40 (0.548 kg/d) and G60 (0.570 kg/d) in relation to supplements G0 (0.510 kg/d), G10 (0.475 kg/d), G50 (0.523 kg/d) and MM (0.208 kg/d). Significant differences ($P < 0.10$) in ADG were observed for supplemented animals as compared MM. It is concluded that supply of supplements using partial replacement for corn by glycerin in levels of 30, 40 and 60%, results in higher performance of cattle grazing in dry season.

W296 Productive response of lactating cows fed low-fat dried distillers grains with solubles in combination with rumen-inert fat. H. A. Ramirez Ramirez*[1], P. J. Kononoff[1], and K. Karges[2], *[1]Department of Animal Science, University of Nebraska, Lincoln, [2]Dakota Gold Research Association, Sioux Falls, SD.*

Twenty Holstein cows, 12 primiparous and 8 multiparous, with (mean ± SD) 91 ± 19 DIM and 594 ± 81 kg were used in replicated 4 × 4 Latin squares to compare the effects of feeding conventional dried distillers grains with solubles (DDGS) and low-fat DDGS (LF-DDGS) in combination with rumen-inert fat (RIF, as calcium salts of long chain fatty acids). In each 21-d period cows were randomly assigned to one of 4 dietary treatments (values expressed on a DM basis): control diet (CONT) that contained 0% DDGS; a second diet (DG) that contained 30% DDGS; a third diet (LF-DG) that contained 30% LF-DDGS in substitution of DDGS; and a fourth diet (COMBO) that was similar to LF-DG with the addition of 1.9% RIF. Dry matter intake was similar across treatments containing any form of DDGS, 26.0 ± 0.6 kg/d, and greater ($P < 0.01$) than CONT, 21.6 ± 0.6 kg/d. Milk yield was similar across treatments averaging 33.4 ± 0.94 kg/d. The COMBO treatment resulted in the greatest ($P = 0.05$) fat corrected milk (3.5% FCM), 35.0 ± 0.98 kg/d, and no differences were observed among the remaining treatments averaging 33.4 ± 0.98 kg/d. A reduction in milk fat percentage and yield was observed ($P < 0.01$) when cows consumed the DG diet, 3.27 ± 0.10% and 1.11 ± 0.04 kg/d, whereas these parameters were similar among CONT, LF-DG and COMBO which averaged 3.68 ± 0.10% and 1.22 ± 0.04 kg/d. Concentration of milk protein was highest ($P < 0.01$) for the DG and LF-DG treatments, intermediate for the COMBO treatment and lowest for the CONT diet, namely 3.21, 3.12 and 3.07 ± 0.05%. Milk protein yield for the CONT diet was 1.0 ± 0.03 kg/d and was lower ($P < 0.01$) compared with DG, LF-DG and COMBO which averaged 1.08 ± 0.03 kg/d. These results demonstrate that compared with typical dairy diets, feeding high proportions of LF-DDGS to lactating dairy cows results in greater DMI with no risk for milk fat depression and that the addition of RIF supports greater yield of fat corrected milk.

Key Words: milk fat depression, corn milling

W297 Production performance and ruminal fermentation of dairy cows fed diets replacing starch from corn with non-forage fiber from distillers grains. S. D. Ranathunga,* M. M. Abdelqader, K. F. Kalscheur, A. R. Hippen, D. J. Schingoethe, and D. P. Casper, *Dairy Science Department, South Dakota State University, Brookings.*

The objective was to evaluate replacing starch from corn with non-forage fiber from dried distillers grains with solubles (DG) on the intake, lactation performance, and ruminal fermentation of lactating dairy cows. Six Holstein cows with ruminal fistula were assigned to a multiple 3 × 3 Latin square design. Three diets were formulated: 1) high starch (33% starch, 0% DG), 2) medium starch (25% starch, 12% DG), and 3) low starch (17% starch, 24% DG). Ground corn, soybean feeds were replaced by DG at 2 inclusion amounts to formulate diets containing medium and low starch concentrations. Diets contained 27.5% corn silage, and 22.5% alfalfa hay, and were formulated to contain 17% CP, 4.4% fat, and 21% forage NDF. Intake of DM was not affected by the diets. As dietary starch concentrations were decreased across diets, milk yield ($P = 0.04$), milk fat percentages ($P = 0.04$), milk fat yield ($P = 0.03$), total solids (TS) yield ($P = 0.03$), and energy-corrected milk ($P = 0.02$) were increased linearly, whereas protein percentages ($P = 0.01$) were decreased linearly. Diets were similar for milk lactose, and TS percentages, protein yield, and feed efficiency. Ruminal pH (6.23) and total VFA concentrations (102 mM/L) were similar for all diets. Quadratic responses were observed for the concentrations of acetate and propionate when starch concentrates were decreased across diets. Decreasing starch concentrations in the diet by replacing corn with DG increased milk production and milk fat percentages, while altering ruminal VFA concentrations.

Table 1.

Item	High Starch	Medium Starch	Low Starch	SEM	*P*-value[1]
DMI, kg/d	22.3	21.9	22.9	1.50	NS
Milk, kg/d	30.7	31.2	32.4	2.75	L
Fat, %	3.03	3.37	3.40	0.30	L
Protein, %	3.10	3.05	3.00	0.15	L

W298 Effect of supplementing dairy cow diets with different forms of palm oil-based supplements on the fatty acid profile of milk fat. P. C. Aikman[1], K. E. Kliem[1], R. M. Kirkland*[2], A. K. Jones[1], S. L. Potterton[1], and C. K. Reynolds[1], *[1]University of Reading, Reading, UK, [2]Volac International Ltd., Royston, UK.*

Calcium salts of palm fatty acids (FA) and high palmitic acid-based products, are commonly used as rumen-protected energy supplements for high yielding dairy cows. The objective of this study was to determine the effects of including these 2 types of palm oil-based fat supplement in dairy cow diets on milk FA profile, particularly total saturated FA (SFA) and C16:0, given current interest in the effects of these on long-term human health. Forty-two cows were randomly allocated to diets from calving until wk 12 of lactation, in a completely randomized block design. Diets were total mixed rations with a forage:concentrate ratio of 50:50, with the forage portion comprising 50:50 corn silage:grass silage, wt/wt (DM). A control diet (Control) contained 32 g/kg DM molasses in the concentrate portion, and this was replaced by either calcium salts of palm FA distillate (Megalac; CPO) or a high-C16:0 (>85%) product (H16), each contributing 19 g lipid per kg ration DM. All diets were isonitrogenous. Milk FA profile (g/100 g total FA) was analyzed during wk 6 and 12. Data were analyzed as repeated measures using mixed model procedures of SAS (see Table 1). It is concluded that CPO supplementation had no effect on 16:0 but reduced total SFA concentration in milk fat, while H16 increased milk 16:0 but had no effect on SFA when compared with the Control diet.

Table 1.

g/100 g fatty acids	Control	CPO[1]	H16[1]	SEM	Diet effect (*P*)
4:0-10:0	9.29^{a}	7.91^{b}	7.68^{b}	0.171	0.001

W299 Influence of corn silage hybrid on lactation performance by dairy cows. M. S. Akins* and R. D. Shaver, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

The objective of this study was to determine lactation performance by dairy cows fed diets containing different corn silage hybrids; dual-purpose (DP; Pioneer 34A89), brown midrib (BMR; Mycogen F2F665) or NutriDense (ND; NutriDense 905823). One hundred and 28 Holstein and Holstein × Jersey cows were stratified by breed and parity and randomly assigned to 1 of 16 pens, each with 8 cows. Pens were randomly assigned 1 of 4 TMR treatments containing DP, BMR, or ND. Three treatments (DP40, BMR40 and ND40) contained 60% forage DM with 2/3rd (40% of TMR DM) from the respective corn silage and 1/3rd alfalfa silage on DM basis. The fourth treatment contained 65% forage DM entirely from ND corn silage (ND65). All diets were formulated to be isonitrogenous. A 2-wk covariate period with all pens receiving a TMR containing equal DM proportions of DP40, BMR40 and ND40 was followed by an 11-wk treatment period with pens fed their assigned treatment TMR. Contrasts were used to compare ND40 vs. DP40, ND40 vs. BMR40, and ND40 vs. ND65. Data are presented in Table 1. Dry matter intake, actual milk and 3.5% fat-corrected milk (FCM) yields, milk fat%, and yields of protein and lactose were greater ($P < 0.05$) for cows fed ND40 compared with ND65. Cows fed ND40 tended ($P = 0.08$) to produce more milk and had greater ($P < 0.05$) protein and lactose yields than DP40. Cows fed ND40 and BMR40 had similar ($P > 0.10$) actual milk and FCM yields, FCM/DMI, and milk fat% and component yields, with reduced ($P = 0.04$) MUN for BMR40. Overall, cows fed ND40 had improved lactation performance compared with DP40 and ND65, and similar performance to BMR40.

W300 Sugar cane silage for lactating dairy cows. M. I. Marcondes*[1], F. L. Andrade[1], R. A. V. Vergara[1], A. S. Trece[1], T. E. Silva[1], W. L. Cardoso[1], and A. B. Fonseca[2], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]University of New Hampshire, Durham.*

Sugar cane has strong potential to replace corn as a silage source due to its higher productivity (80–120 tons/ha), lower costs, and maintenance of nutritive value during the dry season in tropical conditions. However, previous research showed that sugar cane silage has high concentration of ethanol and significant DM losses when ensiled. This study was conducted to evaluate the effects of sugar cane silage alone or ensiled with different additives on milk production and performance of lactating Holstein cows. Thirty 5 cows averaging 110 DIM were blocked by milk production and, within each block (n = 5), randomly assigned to one of 7 treatments: 1) corn silage (CS), 2) chopped sugar cane (SC), 3) sugar cane silage (SCS), 4) SCS + 0.5% of CaO (SCCaO), 5) SCS + *Lactobacillus buchneri* (2.5×10^{10} cfu/g; SCLB), 6) SCS + *Lactobacillus plantarum* (2.5×10^{10} cfu/g) and *Pediococcus pentosaceus* (2.5×10^{10} cfu/g; SCLPPP), or 7) SCS + *Propionibacterium acidipropionici* (5×10^{9} cfu/g; SCPA). Data was analyzed as completely randomized block design using a mixed model with repeated measures over time where block and treatment were considered as fixed variables and period and animal as random variables; each experimental period (n = 5) lasted 21 d. Diets were formulated to be isonitrogenous and isocaloric with a 60:40 (CS diet) or 40:60 (sugar cane silage-based diets) forage to concentrate ratios, There were no differences ($P > 0.05$) among treatments for milk production (18.5, 22.4, 19.4, 19.7, 18.8, 19.5, and 19.5 kg/d, respectively) and milk lactose content (4.16, 4.11, 4.08, 4.18, 4.03, 4.19, and 4.18%, respectively), FCM (4% fat) (20.0, 23.0, 21.4, 21.1, 20.2, 18.7, and 20.8, respectively), DMI (16.7, 19.3, 18.1, 17.2, 17.1, 17.4, and 20.2 kg/d, respectively), feed efficiency (1.12, 1.15, 1.05, 1.11, 1.09, 1.12, and 0.97 kg of milk/kg of DMI, respectively), and average daily weight gain (0.64, 0.81, 0.55, 0.56, 0.23, 0.37, and 0.77 kg/d, respectively). Cows fed CS (4.02%), SC (4.50%), SCCAO (3.99%), and SCPA (3.92%) had the highest ($P < 0.05$) concentration of milk fat, whereas those fed CS (3.16%), SC (3.19%), SCS (3.30%), SCLB (3.28%), and SCPA (3.32%) showed the greatest ($P < 0.05$) milk protein content. Cows receiving sugar cane silage-based diets produced 20 kg/d of milk and maintained body condition throughout the study, thus suggesting that nutrient requirements were met for this low milk output. Further research is needed to investigate the effect of sugar cane silage-based diets on milk production of high-producing dairy cows. Because ensiling sugar cane with additives did not improve milk yield when compared with the SCS diet, it can be concluded that silage made from sugar cane alone can maintain reasonable milk outputs in tropical conditions. Supported by INCT-CA/FUNARBE/CNPq.

Key Words: dairy cattle, lactobacilli, sugar cane

W301 Influence of dietary starch and forage NDF concentrations on digestion and lactation performance by dairy cows. L. F. Ferraretto* and R. D. Shaver, *University of Wisconsin-Madison, Madison.*

A meta-analysis was performed to evaluate the effect of starch and forage NDF concentrations in corn grain based diets on intake, digestion and milk production by dairy cows, and assess site of starch digestion using a data set comprised of 414 treatment means from 100 peer-review articles published during 2000 - 2011. Categories for dietary starch and forage NDF concentrations were: ≤18% (VLS), >18% to 24% (LS), >24% to 27% (MS), >27% to 30% (MHS), >30% to 33% (HS), and >33% (VHS) starch (DM basis); ≤17% (LFNDF), >17% to 20% (MFNDF), and >20% (HFNDF) forage NDF (DM basis). Data were analyzed using Proc Mixed of SAS with treatment as Fixed and trial as Random effects. Digestibility of dietary starch was greater ($P = 0.03$) ruminally, but not ($P = 0.61$) total tract (TT), for HS and VHS compared with VLS, LS and MS. Conversely, increased dietary starch concentration decreased ruminal ($P = 0.02$) and TT ($P = 0.001$) dietary NDF digestibilities. The TT digestibilities of dietary DM and OM were greatest ($P = 0.001$) for VHS and lowest for VLS. A quadratic effect ($P = 0.001$) was observed for DMI, which was lowest for VLS and VHS. Actual milk yield and protein content were unaffected by dietary starch concentration ($P > 0.10$). Fat-corrected milk (FCM) yield was 2.0 kg/d lower ($P = 0.01$) for VHS than the other dietary starch concentrations. A similar response was observed for milk fat content ($P = 0.001$). Ruminal and TT nutrient digestibilities were unaffected ($P > 0.10$) by dietary forage NDF concentration. Milk fat, protein and urea-nitrogen concentrations did not differ ($P > 0.10$) either. The DMI was 0.8 kg/d greater ($P = 0.01$) and milk yield tended ($P = 0.09$) to be 2.1 kg/d greater for LFNDF. Ruminal and TT starch digestibilities were positively related (R2 = 0.84), with an increase of 0.23%-units TT per %-unit increase ruminally. Digestibility of dietary NDF decreased 0.60% units ruminally (R2 = 0.58) and 0.52% units TT (R2 = 0.45) per unit increase in dietary starch concentration.

Key Words: dairy cow, milk production, starch digestibility

W302 Processed corn stover as a corn silage replacement feed for lactating dairy cattle.

S. S. Donkin*[1], A. C. Headley[1], H. A. Tucker[1], P. H. Doane[2], and M. J. Cecava[2], *[1]Purdue University, West Lafayette, IN, [2]Archer Daniels Midland Company, Decatur, IL.*

Corn silage represents almost half of the forage used in rations for dairy cattle in the Midwest region and increased value for corn grain has increased the costs of corn silage production. Our overall goal is to determine the potential for treated corn crop residues as replacement feeds for corn silage and corn grain. The objective of this initial study was to determine the short-term impact of feeding increasing amounts of processed and chemically treated corn stover on feed intake, milk production and milk composition. Baled stover was tub-ground, hydrated to approximately 50% moisture and treated with either 5% CaO or a mixture of 3% CaO and 2% NaOH (DM basis) in a twin-screw extruder. Separately, baled stover from the same lot, was chopped through a 10.2 cm screen using a HayBuster, mixed with water to 50% moisture and CaO to 5% of DM. All stovers were stored in AgBags. Fifty-six Holstein cows were assigned to 1 of 7diets in which corn silage was replaced by treated stover. Diets were: CaOH extruded stover at 12.5 and 25% of ration DM, CaOH +NaOH extruded stover at 12.5 and 25% of ration DM, on-farm prepared stover containing 5% CaOH and fed at 12.5 or 25% of ration DM and a control diet consisting of 37.5% corn silage. Cows were fed diets for 21 d to assess initial acceptance of treated stover and impact on production parameters. Milk production averaged 28.9 ± 2.22 kg/d and DM intake was 22.3 ± 1.26 kg/d and did not differ ($P > 0.05$) between treatments. There were no differences ($P > 0.05$) in milk composition, body weight changes during the 21-d feeding period. There were treatment × day of experiment effects ($P < 0.05$) for feed intake and milk production with the greatest difference with day observed for extruded stover containing NaOH. The data indicate that chemically treated corn stover can replace corn silage in diets for lactating dairy cows to at least 25% of the ration DM and potentially more for some compositions.

Key Words: biofuels, stover, corn replacement

W303 Effects of feeding camelina meal on milk production and composition in lactating Holstein cows.

B. C. Casperson,* J. E. Williams, K. M. Hunt, K. M. Steinkamp, and M. A. McGuire, *Department of Animal and Veterinary Science, University of Idaho, Moscow.*

Meal from *Camelina sativa* is potentially available from the biofuel industry as a protein source rich in α linolenic acid for the dairy cow. The objective of this work was to determine the effects of feeding camelina meal to Holstein cows on milk production and composition. Cows (n = 15) were randomly assigned to diet after blocking for parity and milk production. Camelina meal replaced canola meal at 0, 50, and 100% so rations contained 0, 7 and 14% of the diet DM as camelina meal. Total mixed rations were formulated to meet NRC requirements for cows producing 35 kg of milk per day. Cows were fed individually in tie stalls for 6 wk. Milk production was recorded daily and composition was tested on d 41 and 42 of feeding. Results were compared using Tukey's test. Milk production (30.4, 32.0 and 29.3 kg/d for 0, 7 and 14% camelina, respectively; SEM = 1.6) for d 35–42 and milk protein percentage (3.2, 3.0 and 2.8% for 0, 7 and 14% camelina, respectively; SEM = 0.07) from d 41 and 42 were unaffected ($P > 0.05$) by diet. Milk fat percent was lower ($P < 0.05$) in milk from cows on 14% camelina meal compared with the other diets (3.8, 3.6 and 3.3% for 0, 7, and 14% camelina, respectively; SEM = 0.09). Camelina meal at 14% of diet DM reduced ($P < 0.05$) milk fat concentrations of 18:0 (10.8, 12.0 and 7.9% total fatty acids for 0, 7 and 14% camelina, respectively; SEM = 1.6), but increased ($P < 0.05$) α linolenic acid (0.1, 0.5 and 0.8% total fatty acids for 0, 7 and 14% camelina, respectively; SEM = 0.01), 18:1 trans isomers (2.6, 3.5 and 6.8% total fatty acids for 0, 7 and 14% camelina, respectively; SEM = 1.3) and c9t11 CLA (0.9, 1.1 and 2.3% total fatty acids for 0, 7 and 14% camelina, respectively; SEM = 0.18), relative to other diets. Camelina meal had no effect ($P > 0.05$) on 12:0, 14:0, 18:1c9 and linoleic acid concentrations in milk fat. In conclusion, camelina meal supported milk production similar to canola meal and enhanced the unsaturated portion of the fatty acid profile.

Key Words: camelina, milk fat, milk yield

W304 Comparison of the NRC (2001) model and the DVE/OEB system in the prediction of protein supply to dairy cows from hulless barley (*Hordeum vulgare* L.) with altered carbohydrate traits.

L. Yang*[1,3], D. Christensen[1,3], J. McKinnon[1,3], B. Rossnagel[2,3], A. Beattie[2,3], and P. Yu[1,3], *[1]Department of Animal and Poultry Science, [2]Crop Development Centre, [3]University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

The objective of this study was to predict protein supply to dairy cows from 4 hulless barley varieties (zero-amylose waxy, CDC Fibar; waxy, CDC Rattan; normal-amylose, CDC McGwire and high-amylose, HB08302) by using NRC 2001 model and DVE/OEB system. CDC Copeland was induced as a hulled control. The hulless barley breeding lines differed ($P < 0.05$) in amylose (1 to 20%DM), amylopectin (34 to 51%DM), amylose to amylopectin ratio (Ay:Ap) (0.02 to 0.59) and β-glucan contents (5 to 10% DM). In DVE/OEB system, CDC McGwire was higher ($P < 0.05$) in rumen fermented organic matter (FOM: 683 vs. 545 g/kg DM), metabolizable protein (MP: 102 vs. 82 g/kg DM), truly absorbed microbial protein in the small intestine (AMCP: 65 vs. 52 g/kg DM) and digested organic matter (DOM: 921 vs. 871g/kg DM) but lower ($P < 0.05$) in endogenous protein in the small intestine (ENDP: 5 vs. 9 g/kg DM), truly absorbed bypass protein in the small intestine (ABCP: 48 vs. 61 g/kg DM) and degraded protein balance (OEB: −35 vs. −24 g/kg DM) compared with HB08302. Highest OEB among all barley varieties was found in CDC Fibar (−14 g/kg DM, $P < 0.01$). Hulled barley was lower ($P < 0.01$) in true protein supplied to the small intestine (TPSI: 127

g/kg DM) and truly digested protein in the small intestine (DVE: 95 g/kg DM) than hulless barley lines but higher ($P < 0.01$) in undigested inorganic matter (9 g/kg DM). From NRC Dairy 2001 model, CDC Fibar was higher ($P < 0.05$) in OEB (−30 g/kg DM), microbial protein synthesized in the rumen (MCP: 76 g/kg DM), AMCP (49 g/kg DM) than the other hulless barley lines. Compared with hulless barley, hulled control was relatively lower ($P < 0.01$) in truly absorbed rumen undegraded protein in the small intestine (44 g/kg DM) and total MP (83 g/kg DM). In conclusion, altered carbohydrate traits in hulless barley varieties significantly improved the truly absorbed protein supply to dairy cattle compared with hulled barley.

Key Words: NRC dairy 2001 model, DVE/OEB system, amylose to amylopectin ratio

W305 Effect of different forage and dried distillers grains with solubles concentrations on sorting behavior of lactating dairy cows.

S. D. Ranathunga,* K. F. Kalscheur, and D. P. Casper, *Dairy Science Department, South Dakota State University, Brookings.*

The objective was to evaluate the effect of different forage and dried distillers grains with solubles concentrations on sorting behavior of lactating dairy cows. Four Holstein cows were assigned to a 4 × 4 Latin square in a 2 × 2 factorial arrangement of treatments with 4-week periods. Diets contained low forage (LF; 41% of diet DM) or high forage (HF; 60% of diet DM) and DG at 0 or 18% of diet DM. Ground corn and soybean feeds were partially replaced by DG from 0% DG diets to formulate 18% DG diets. Fresh TMR and orts were sampled for particle size analysis on the first 3 d of wk 3 and 4 of each period. Particle size distribution of samples of TMR and orts were determined using the 4-box Penn State particle size separator. The particle size separator had 3 screens (19, 8, and 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, and fine). Feed sorting was calculated as the actual intake of each particle size fraction expressed as a percentage of the predicted intake of that fraction. Average DMI was similar ($P > 0.05$) across diets (23.8 kg/d). Cows fed HF diets sorted against long (91.2 vs. 97.6%) and medium (96.6 vs. 97.8%) particles compared with LF diets. Feeding HF diets increased selective consumption of short (103 vs. 101%) and fine (104 vs. 100%) particles compared with the LF diets. These results suggest that, despite geometric mean diameter of the diet being affected by forage (LF vs. HF: 1.55 vs. 1.95 mm) and DG (0DG vs. 18DG: 1.81 vs. 1.69) concentrations, only forage concentration affected the sorting behavior of lactating dairy cows.

Table 1. Effect of forage and DDGS concentration on sorting (%)

	LF	LF	HF	HF		
Item	0DG	18DG	0DG	18DG	SEM	*P*-value[1]
Particles

Orts	2.37	1.74	3.05	3.31	0.18	F, F×D

[1] F or D = forage or DG effect; F × D = forage and DG interaction ($P < 0.05$).

Key Words: distillers grains, forage, sorting behavior

W306 Effects of sudden additions of condensed distillers solubles to diets of lactating dairy cows on milk production and milk components.

S. E. Fraley,* J. R. Townsend, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

Variability in the fat content of dried distillers grains with solubles (DDGS) in dairy diets make dairy producers hesitant to utilize this coproduct. The objective of this study was to determine the effect of sudden additions of condensed distillers solubles (CDS) on milk production, milk components and rumen parameters. Eight ruminally cannulated Holstein cows (166 ± 12 DIM) were randomly assigned to treatments in a replicated 4 × 4 Latin square design with 21-d periods. The dietary treatments, on a DM basis, were CON (10% DDGS); DDGS (20% DDGS); CDS2.5 (17.5% DDGS plus 2.5% CDS); and CDS5 (15% DDGS plus 5% CDS). Cows were fed CON diets for a 14-d adaptation period and treatments diets for a 7-d treatment period with the last 3 d used for data collection. Milk samples were collected daily to determine milk components. Rumen samples were collected via rumen cannula for determination of pH, volatile fatty acids (VFA) and NH$_3$. Data were analyzed using PROC MIXED of SAS. Milk yield and fat percentage were similar between treatments ($P = 0.66$ and 0.82, respectively). Cows fed CON had greater ($P < 0.01$) and DDGS tended ($P = 0.06$) to have greater milk protein concentrations than CDS2.5 and CDS5 (2.89, 2.83, 2.77, 2.81%, respectively). Dry matter intake was greater ($P < 0.05$) for CON than CDS2.5 or CDS5 (21.6, 20.1, 20.5 kg/d, respectively), but was similar ($P = 0.11$) to DDGS (20.7 kg/d). Rumen pH was lesser for CON than CDS5 (6.05 and 6.13, respectively; $P = 0.03$) and lesser for DDGS than for CDS2.5 and CDS5 (6.03, 6.10, 6.13, respectively; $P \leq 0.05$). Total VFA concentrations were similar among treatments ($P = 0.84$); however, CDS5 had greater butyrate concentrations than CON (11.1 and 9.7 μmol/mL; $P = 0.05$) and tended to have greater concentrations than DDGS (9.7 μmol/ml; $P = 0.08$). Rumen NH$_3$ was greater for CON and DDGS ($P < 0.03$) and tended ($P = 0.08$) to be greater for CDS2.5 than for CDS5 (18.4, 17.5, 17.1, 15.0 mg/dL, respectively). Sudden additions of up to 5% added CDS in dairy cow diets decreased milk protein concentration and DMI without affecting milk yield or milk fat.

Key Words: condensed distillers solubles, dairy cow, milk fat

W307 Occurrence and concentration of mycotoxins, molds and yeasts on corn co-products from South Dakota and Minnesota dairy farms.

F. Diaz-Royon*[1], A. Garcia[1], K. F. Kalscheur[1], K. A. Rosentrater[2], J. S. Jennings[3], and K. Mjoun[3], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Department of Agricultural and Biosystems Engineering, Iowa State University, Ames, [3]Alltech South Dakota, Brookings.*

Twenty-nine large dairies in SD and MN were visited during summer and fall 2011 to provide a comprehensive assessment of the prevalence of mycotoxins, molds, and yeasts on corn co-products. Samples were collected from every corn co-product used on these farms. Feed samples analyzed included: distillers grains (n = 13 wet, 6 dried), wet corn gluten feed (n = 11), high moisture corn (n = 2) and germ meal (n = 1). Ten subsamples (0.5 kg each) were taken from each corn co-product, pooled together and composited. This composite was split in two 0.8- to 1.0-kg samples. After vacuum sealing, one sample was stored at −20 °C for later mycotoxin analyses and the second was stored at 4 °C for mold and yeasts analyses. A total of 32 different mycotoxins were analyzed by triplicate using UPLC-MS/MS (tandem mass spectrometer coupled to liquid chromatography). Molds and yeasts counts were determined by direct plate dilution. In addition, mold isolates were identified in samples with mold growth equal to or greater than 1,000 cfu/g using the conventional microscopic tape method. Two distillers dried grains samples contained aflatoxin B2 levels (32.0 and 36.7 ppb) greater that the U. S. Food and Drug Administration (FDA) guidelines for use in feeds for dairy cows or immature animals (20 ppb). But these samples contained aflatoxin levels lower than the FDA recommendation for feeding mature beef cattle (300 ppb), swine (200 ppb) and poultry (100 ppb). The rest of the samples contained aflatoxins, deoxynivalenol, and fumonisins levels lower than the detection limit or the FDA guidelines for use in animal feeds. Mold growth was lower than 1,000 cfu/g in 25 corn co-product samples (75.7%) and greater than 2,000 cfu/g in 4 samples (12.1%). *Aspergillus* and *Mucor* were the fungi genera most frequently isolated. There were only 7 corn co-products (21.2%) with yeast counts lower than 1,000 cfu/g, with most of them containing levels greater than 105 cfu/g (63.6%). The majority of the samples analyzed in this experiment had high yeast counts not associated with the presence of detrimental mycotoxin concentration.

Key Words: corn co-products, dairy cows, mycotoxins

W308 Surveying the constraints of ethanol co-products utilization on dairy farms. F. Diaz-Royon*[1], A. Garcia[1], K. F. Kalscheur[1], K. A. Rosentrater[2], J. S. Jennings[3], and K. Mjoun[3], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Department of Agricultural and Biosystems Engineering, Iowa State University, Ames, [3]Alltech South Dakota, Brookings.*

Distillers grains (DG) originating from the corn-based fuel ethanol industry are an excellent source of energy and rumen undegradable protein, which complement well with other feedstuffs used in dairy cattle diets. However, despite the competitive pricing when compared with other protein sources and their availability in the market, DG are not always sought as dietary ingredient by nutritionists and dairy producers. A survey was mailed to every South Dakota grade A dairy farm (303) to determine current use and constraints to ethanol co-products usage in dairy cattle diets and whether dairy producers found the different co-products available in the market useful. The self-administered survey with an original cover letter and self-addressed stamped envelope were delivered to dairy farms though the US Postal Service in April of 2011. Forty-nine dairy producers (16.2%) filled out and returned the survey. The average number of years producers had been feeding corn co-products was 8, with a range between 0.5 and 21.Thirty-six producers (73% of respondents) were using ethanol co-products in their rations. Among those that did not feed them, the primary reason was price (31%). Modified distillers grains (MDG) was the ethanol co-product included at the highest percentage in lactating dairy cows and heifer rations (13.8 and 10.7% on a dry matter basis, respectively); however, distillers dried grains with solubles were mostly used in dry cow rations. In addition, MDG was the corn co-product most frequently fed in farms during 2010, with an average use of 1,048 ton/yr (as-fed basis). Outside piles were the most common storage method for wet or modified distillers grains while commodity sheds for distillers dried grains. When dairy producers were asked to rank the degree of importance of several DG issues (1 = none; 2 = low; 3 = average; and 4 = high), the majority (73%) ranked ″variability between batches″ highest, followed by price (60%), and mycotoxin content (58%). These results provide a snapshot of percent inclusion, storage methods, major concerns, amount fed and type of corn co-products used on South Dakota dairy farms.

Key Words: dairy farms, ethanol co-products, survey

W309 Effects of molasses products on productivity and milk fatty acid profile of cows fed high-DDGS diets. A. V. Siverson* and B. J. Bradford, *Kansas State University, Manhattan.*

Previous research has shown that replacing up to 5% corn with cane molasses can partially alleviate milk fat depression when cows are fed high-concentrate, low-fiber rations containing distillers grains with solubles (DGS). Our objective was to determine whether dietary molasses would alter milk fatty acid profile or improve solids-corrected milk yield in the context of a more typical lactation diet. Our secondary objective was to assess production responses to increasing RDP supply when molasses was fed. Twelve primiparous and 28 multiparous Holstein cows (196 ± 39 DIM) were randomly assigned to 8 pens. Pens were randomly allocated to treatment sequence in a 4 × 4 Latin square design balanced for carryover effects. Treatments were a control diet including 20% dried DGS, 35% NDF, 30% starch, and 5% EE (CON), a diet with 5% cane molasses (DM basis) replacing a portion of the corn grain (MOL), a diet with 3.25% (DM basis) QLF (Quality Liquid Feeds) 20% CP supplement (QLF3), and a diet with ~6.5% (DM basis) QLF 20% CP supplement (QLF6). Data were analyzed using mixed models including the fixed effects of treatment and the random effects of period, pen, period × pen interaction, and cow within pen. Diets had no significant effects on dry matter intake, milk production, milk component concentration or yield, crude feed efficiency, BW change, or somatic cell count in milk (all $P > 0.12$).Milk stearic acid content was increased by QLF6 compared with CON and QLF3 ($P < 0.05$), but the magnitude of the effect was small (12.27, 11.75 and 11.69 ± 0.29 g/100 g fatty acids). Production data revealed a dramatic effect of period on milk fat content and yield. Milk fat content dropped during the course of the experiment (3.16, 2.81, 2.93, and 2.64 ± 0.09% for periods 1–4, respectively) as did milk fat yield (1.20, 1.03, 0.98, and 0.79 ± 0.05 kg/d). Exchanging molasses-based products for corn at 3 to 6% of dietary DM did not influence productivity and had minute effects on milk fatty acid profile. The limited responses in this study may have been influenced by dietary unsaturated fatty acid content or advancing DIM of cows on the study.

Key Words: biohydrogenation, milk fat depression, sugar

W310 Effects of feeding brown midrib corn silage with a high dietary concentration of alfalfa hay during early and mid lactation on milk production of Holstein dairy cows. M. S. Holt*[1], A. J. Young[1], X. Dai[2], K. E. Nestor[3], and J.-S. Eun[1], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Utah Agricultural Experiment Station, Utah State University, Logan, [3]Mycogen Seeds, Indianapolis, IN.*

This experiment was conducted to determine the long-term effects of feeding brown midrib corn silage (BMRCS) fed with a high dietary concentration (25% DM) of good quality alfalfa hay in high-forage lactation diets on productive performance of dairy cows. Twenty 4 multiparous Holstein cows were used starting at the onset of lactation through 200 d-in-milk (DIM). Two dietary treatments were tested in a completely randomized design: TMR based on conventional corn silage (CCST) and TMR based on BMRCS (BMRCST). Intake of DM was not affected by dietary treatments throughout the experiment. During early lactation (0–60 DIM), milk yield was not different between dietary treatments, whereas milk yield during mid lactation (61–200 DIM) increased by feeding the BMRCST compared with the CCST (39.8 vs. 36.2 kg/d; $P = 0.05$), resulting in increased overall milk yield by feeding the BMRCST throughout the experiment (40.9 vs. 37.6 kg/d; $P = 0.05$). While milk fat concentration did not differ during early lactation, it tended to decrease by feeding the BMRCST compared with the CCST during mid lactation (3.51 vs. 3.82%; $P = 0.08$). During mid lactation, yield of 3.5% fat-corrected milk tended to increase for cows fed the BMRCST compared with those fed the CCST (42.5 vs. 39.3 kg/d; $P = 0.10$), but it remained similar during 200 DIM. Overall milk protein concentration was similar between dietary treatments throughout the experiment

(2.95% on average), but overall milk protein yield was higher for the BMRCST than the CCST (1.27 vs.1.14 kg/d; $P = 0.01$). Milk protein concentration and yield were similar between dietary treatments during early lactation; however, during mid lactation, milk protein yield was greater for cows fed the BMRCST than those fed the CCST (1.27 vs. 1.10 kg/d; $P < 0.01$). Feeding BMRCS with a high dietary concentration of alfalfa hay did not affect milk production during early lactation; however, cows fed the BMRCST maintained longer peak milk yield, which resulted in increased milk production during mid lactation, leading to greater overall milk production and milk protein yield.

Key Words: brown midrib corn silage, alfalfa hay, early and mid lactation

W311 Effects of harvest date and a BMR hybrid on yield and nutrient composition of corn plants harvested for silage.

P. Walker[1], M. J. Faulkner[1], T. D. Kaufman*[1], L. Brown[2], and F. N. Owens[2], *[1]Illinois State University, Normal, [2]Pioneer Hi-Bred International, a DuPont Business, Bloomington, IL.*

Maturity at harvest and the brown midrib (BMR) trait influence concentration and availability of nutrients from plants harvested for corn silage. To quantify these effects, 9 commercial elite Pioneer corn silage hybrids were planted in 12-row plots in a field near Lexington, IL on May 9, 2010 at 69K and 84K/hectare. Duplicate sets of 5 plants each were harvested 10 times (at 3 to 6 d intervals) spanning the silage harvest window (28 to 42% DM). Nutrient content and availability were estimated by calibrated NIR procedures. Averaged across hybrids, yield of DM reached a plateau at 33% plant DM, but starch content (% of DM and g/plant) continued to increase to over 40% plant DM. NDF digestibility was not altered by DM content. Per plant, grams of starch increased while grams of NDF, ADF, and sugars decreased as plant DM increased. Nutrient values for the Pioneer BMR hybrid (P1376XR) were compared with those from the non-BMR hybrids. Differences were not significant ($P > 0.05$) for starch, total sugars, hemicellulose, ash, dry matter yield per hectare (18.9 for BMR vs. 19.0 t/ha), or kg of grain per hectare estimated from starch content (8.1 vs. 7.8 t/ha). At equal moisture contents, the BMR hybrid had less ($P < 0.01$) NDF (41.4 vs. 43.7%) and ADF (23.8 vs. 25.9%) but more ($P < 0.01$) crude protein (7.9 vs. 7.4%) and greater ($P < 0.01$) digestion of NDF at 24 h (50.5 vs. 46.7%). Although it did not alter grain yield, the 21% higher planting density increased yield of DM per hectare only by 5% ($P < 0.01$) because individual plants weighed 13% less. When adjusted for DM content, the higher plant density decreased the percentage of starch and digestion of NDF at 24 h ($P < 0.05$). Harvest of modern corn hybrids below 33% DM sacrifices DM yield while harvest below 40% sacrifices yield of starch. The BMR tested had grain and NDF yields equal to elite non-BMR hybrids but greater NDF digestibility at 24 h.

Key Words: corn silage, harvest maturity, BMR

W312 Chemical and nutrient availability of hulless barley (*Hordeum vulgare* L.) with altered carbohydrate characteristics.

L. Yang*[1,3], J. McKinnon[1,3], D. Christensen[1,3], B. Rossnagel[2,3], A. Beattie[2,3], and P. Yu[1,3], *[1]Department of Animal and Poultry Science, [2]Crop Development Centre, [3]University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Four hulless barley varieties and breeding lines with altered carbohydrate composition were developed at the Crop Development Centre, University of Saskatchewan based on amylose (1 to 20% DM), amylopectin (34 to 51% DM), amylose to amylopectin ratio (0.02 to 0.59) and β-glucan (5 to 10% DM) content. The objective of this study was to compare differences in chemical and nutrient profiles among the 4 newly developed hulless barley lines (zero-amylose waxy, CDC Fibar; 5%-amylose waxy, CDC Rattan; normal-amylose, CDC McGwire and high-amylose, HB08302). CDC Copeland hulled barley was included as a hulled control. Among the hulless barley lines, CDC Fibar showed greater ($P < 0.01$) crude protein (16.2% DM), soluble crude protein (7.8% of DM) and β-glucan (10.0% DM) but reduced ($P < 0.01$) amylose (1.3% DM), intermediately degradable CHO (51.9% CHO) and slowly degradable CHO (9.9% CHO). CDC McGwire had greater ($P < 0.01$) starch (61.5% DM) but reduced β-glucan (4.7% DM) while HB08302 had greater neutral detergent fiber (13.8% DM, $P < 0.01$) than the other hulless barley lines, but reduced intermediately degradable protein than CDC Fibar (30.5 vs. 40.9% CP, $P < 0.05$). The hulled control showed greater CHO ($P < 0.01$) but a reduced rapidly degradable CHO content and Mcal/kg of NEL (1.68 vs. 1.74, $P < 0.01$) versus the hulless barley lines. Altered carbohydrate composition improved chemical, protein and carbohydrate subfractions and energy values which affected nutrient availability for ruminants.

Key Words: amylose to amylopectin ratio, β-glucan, hulless barley

W313 Effects of dietary protein content and source of grain on milk production and nitrogen efficiency in early lactating primiparous Holstein cows.

H. Mirzaei Alamouti* and A. Mohammad, *University of Zanjan, Zanjan, Iran.*

Nitrogen excretion from dairy farming systems is a major environmental challenge and formulating dairy ration to decreasing nitrogen excretion without compromising milk production and composition can be one of strategies. An experiment was conducted to determine the effects of dietary crude protein (CP) levels, source of grain and their interactions on performance and nitrogen efficiency of early lactating Holstein cows. Eight primiparous cows (BW = 560 ± 65 kg and DIM = 50 ± 15 d) were allocated to one of 4 diets in replicated 4 × 4 Latin square design. The diets containing: 1) 20% CP and barley grains as a cereal grain source (HPB), 2) 20% CP and a 50:50 ratio of barley and corn grain (HPBC), 3) 16% CP and barley grain (LPB), and 4) 16% CP and a 50:50 ratio barley and corn grain (LPBC). In 21 d periods, data collection was conducted in second and third weeks. Data were analyzed as repeated measure by using proc mixed of SAS software. The results showed that cows fed with LPBC diet had higher Dry matter intake ($P < 0.01$), dry matter digestibility ($P < 0.05$), organic matter digestibility ($P < 0.05$) and neutral detergent fiber digestibility ($P < 0.01$). Rumen fluid concentrations of total volatile fatty acids ($P < 0.05$), acetate ($P < 0.01$), propionate ($P < 0.05$), and rumen pH ($P < 0.01$) of cows fed with different source of grain was significant. Cows fed higher level of CP had greater ($P < 0.05$) urine and rumen ammonia nitrogen, blood and milk urea nitrogen, and lower nitrogen efficiency than those fed lower level of CP. There were no differences between milk production and contents. In conclusion, the results from this study showed lowered dietary nitrogen content and using a mix of barley and corn grain in dairy ration can improve nitrogen efficiency.

Key Words: cereal grains, crude protein, Holstein cow

W314 Lactational performance, chewing behavior, and ruminal fermentation of dairy cows fed diets differing in amount and digestibility of NDF from two sources of corn silage.

C. Kokko,* H. M. Dann, K. W. Cotanch, J. W. Darrah, and R. J. Grant, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Ruminally cannulated Holstein cows (n = 8, 91 ± 11 d in milk) were used in a replicated 4 × 4 Latin square design study with 21-d periods

(8-d collection periods) to evaluate intake, milk yield and components, chewing behavior, and ruminal fermentation in response to diets differing in amount and 24-h digestibility of aNDF ($NDFD_{24h}$) from 2 sources of corn silage. Treatments were 1) 53% forage, conventional corn silage (CCS)-based diet with 32% aNDF, 28% starch, 56% $NDFD_{24h}$ (Low CCS); 2) 68% forage, CCS-based diet with 36% aNDF, 21% starch, 54% $NDFD_{24h}$ (High CCS); 3) 50% forage, BMR-corn silage-based (BMR) diet with 32% aNDF, 28% starch, 62% $NDFD_{24h}$ (Low BMR); and 4) 64% forage, BMR-based diet with 35% aNDF; 24% starch; 60% $NDFD_{24h}$ (High BMR). Data were analyzed as a replicated Latin square with the MIXED procedure of SAS with fixed effects of diet, period, and replicate. Cow within square was the random effect. Intake, milk yield, and solids corrected milk (SCM) were lower on the High CCS diet. Efficiency of milk production (milk/DMI, 1.63 ± 0.04; SCM/DMI, 1.57 ± 0.03) was not affected ($P > 0.1$) by treatment. Differences in milk composition and chewing behavior reflected dietary inclusion of NDF. Chewing time per kg of NDF intake was greater for CCS diets. Mean ruminal pH was lower on the Low BMR diet, though time (min/d) below a pH of 5.8 (328 ± 89) or 5.5 (98 ± 43) did not differ ($P > 0.1$) among diets. Greater inclusion of highly digestible NDF forage promoted DMI and milk yield without compromising the ruminal environment.

Table 1.

Item	Low CCS	High CCS	Low BMR	High BMR	SE
DMI, kg/d	29.0^{a}	26.5^{b}	29.3^{a}	29.2^{a}	0.7

W315 Reduced protein for late-lactation dairy cows fed ryegrass haylage-based diets.

V. R. Moreira[1], A. B. D. Pereira*[2], L. K. Zeringue[1], C. Leonardi[3], B. F. Jenny[2], C. C. Williams[2], and M. E. McCormick[1], [1]*LSU AgCenter SE Research Sta., Franklinton, LA,* [2]*LSU AgCenter School of Animal Sciences, Baton Rouge, LA,* [3]*LSU Health Sciences Center, New Orleans, LA.*

Ryegrass is a reliable high-quality forage resource in Southeast Louisiana. In this study, 2 protein levels were compared in ryegrass-based diets fed to late lactation dairy cows. Twenty 4 lactating Holstein cows (244 ± 55 DIM and 30.7 ± 4.81 kg milk yield) were randomly distributed among 4 pens in a freestall barn equipped with Calan gates for individual TMR feeding. Higher protein TMR (HP) contained 15.4 ± 0.20% CP using soybean meal as the main protein supplement and rumen-protected Met (Metasmart, Adisseo; 0.10% DM basis). Lower protein TMR (LP) contained 13.8 ± 0.4% CP and was prepared using dry distillers' grains plus solubles (DDGS), soybean hulls, and rumen protected Lys (AminoShure-L, Balchem, 0.25% DM basis) and Met (0.18% DM basis) to offset dietary AA deficiencies. Cottonseed, corn, and minerals remained similar in both rations. Forage (ryegrass haylage) represented 41% of the rations (DM basis). Metabolizable protein (MP) balance (NRC, 2001) was estimated to be marginal (30 g/cow/d for HP) or deficient (−180 g/cow/d for LP). The experiment was analyzed as a crossover design using SAS MIXED procedure with pen as experimental unit. Cows in both treatments had similar intake (21.4 kg/cow/d for HP and 20.9 kg/cow/d for LP; $P = 0.51$) and maintained body condition score (0.03 unit/period for HP and 0.04 unit/period for LP; $P = 0.77$), but most lost weight (−18.1 kg/cow/period for HP and −14.0 kg/cow/period for LP; $P = 0.71$) mainly in the second period. Milk yield (27.5 kg/cow/d for HP and 25.9 kg/cow/d for LP; $P = 0.36$) and water intake (118 kg/cow/d for HP and 112 kg/cow/d for LP; $P = 0.47$) did not differ statistically. Cows ingested 4.3 kg of water per kg of milk output in both treatments. Milk components averaged 3.48%, 3.30%, and 4.71% respectively for fat, protein and lactose ($P = 0.12$). Milk urea nitrogen decreased ($P = 0.01$) from 9.85 mg/dL with HP to 6.40 mg/dL with LP. Results suggest late-lactation dairy cow performance can be maintained, at least in the short term (21 d-period), when fed an MP deficient diet based on ryegrass haylage and supplemented with DDGS and soybean hulls, adjusted with rumen-protected Met and Lys.

Key Words: dairy cows, protein, dry distillers grains plus solubles

W316 Energy intake of dairy cows grazing native rangeland in México.

R. Améndola-Massiotti*[1], H. Crespo-Lira[1], J. Burgueño-Ferreira[2], and M. Huerta-Bravo[1], [1]*Universidad Autónoma Chapingo, Chapingo, Estado de México, México,* [2]*CIMMYT, Texcoco, Estado de México, México.*

Energy requirements of cows for grazing on native rangeland are high; therefore determination of energy intake from grazed herbage (EIGH) is important. The aim was to estimate EIGH of dairy cows grazing native rangeland at Marcos Castellanos, Michoacán (19°59′ N, 103°01′ W, 2000 masl). The experiment took place in the dry (DS) and rainy (RS) seasons; DS measurements were taken in 2 farms and during the RS a third farm was added. Intake was measured on 6 cows during 2 (DS) and 3 (RS) cycles of 24 h. Offered and residual amounts of supplementary feed were measured and samples were taken to estimate the content of net energy of lactation (NEL) based on Acid Detergent Fiber contents. Hand-plucked samples of grazed herbage were taken for estimation of NEL content. Herbage dry matter intake (DMI) was estimated by means of fecal output (chromium oxide and acid insoluble ash). Calculation of EIGH was based on DMI and NEL content. A mixed model was used, with fixed effects of season, farm nested within season, cycle nested within farm and season, lactation stage and their interactions; the random effect of cows nested within farm was included. In Table 1 is shown that mean total energy intake was lower in DS than in RS due to lower EIGH. Total energy intake and EIGH in DS did not differ among farms and neither did EIGH in RS. Differences in RS were due to supplementary feeding. It is concluded that due to very low EIGH, accurate use of supplementary feeding is crucial in the dry season.

Table 1. Energy intake (Mcal NE_L) of dairy cows grazing native rangeland

Season	Farm			Mean
	A	B	C	
Total				
Dry		$18.5^{x,b}$	$19.5^{x,a}$	19.0^{B}
Rainy	26.4^{x}	$23.2^{xy,a}$	$19.3^{y,a}$	23.0^{A}
Herbage				
Dry		$5.1^{x,b}$	$4.3^{x,b}$	4.7^{B}
Rainy	10.8^{x}	$10.8^{x,a}$	$11.0^{x,a}$	10.8^{A}

^{x,y}Means not sharing letters within rows and within each variable are different ($P \leq 0.05$).

^{a,b}Means not sharing letters within columns and within each variable are different ($P \leq 0$ .05).

^{A,B}Means not sharing letters within columns and within each variable are different ($P \leq 0.05$).

Key Words: dry and rainy seasons, grazed herbage, net energy of lactation

W317 Feeding canola meal to dairy cows: A meta-analysis on lactational responses suggests underestimation of metabolizable protein supply by NRC (2001). R. Martineau, D. R. Ouellet, and H. Lapierre,* *Dairy and Swine R&D Centre Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada.*

The objective of this meta-analysis was to determine the effects of the substitution of a protein source by canola meal (CM) on lactational responses (Δ = CM minus control) in dairy cows. The study included 83 comparisons of isoproteic (±1.5% CP) treatments published since 1975 (42 experiments). The CM intake ranged from 0.9 to 4.0 kg/d (SD 0.75). The level of inclusion of CM (ΔCM) was expressed as 100 g/kg of diet (DM basis); therefore, the coefficient associated with ΔCM represents the response observed with a 10% increment in the dietary proportion of CM (e.g., 2 kg of CM for 20 kg DMI = ΔCM of 10%). Dietary composition was estimated using NRC (2001). Regressions were forced through the origin, weighted by sample size and controlled for differences in DMI and diet concentrations of NDF, CP and ether extract. Milk yield (MY, kg/d) and milk protein yield (MPY, g/d) responded linearly to increasing ΔCM: $\Delta MY = 0.4^{***} (\pm 0.08) \times \Delta CM$, $R^2adj = 0.55$, n = 80; and $\Delta MPY = 25^{***} (\pm 2.6) \times \Delta CM$, $R^2adj = 0.53$, n = 80. The MPY response was different ($P = 0.04$) depending on the type of protein source that was substituted. The ΔCM coefficients were 14*** (±3.8) and 26*** (±3.5) with substitutions involving only soybean meal ($R^2adj = 0.44$; n = 37) or other protein sources ($R^2adj = 0.61$; n = 35), respectively. The greater effect with other protein sources was due to an additional positive effect of ΔCM on milk protein percentage. The efficiency of N utilization (milk N yield/N intake; g/kg) also responded linearly to increasing ΔCM: $7.5^{***} (\pm 0.96) \times \Delta CM$, $R^2adj = 0.48$, n = 82. The estimated supply of metabolizable protein (MP) was examined to explain the responses to ΔCM. Surprisingly, there was a negative effect of CM inclusion on ΔMP: $-85^{***} (\pm 9.2) \times \Delta CM$, $R^2adj = 0.53$, n = 80, contrarily to the usual positive relationship between MP supply and MY or MPY. In conclusion, current results suggest that a protein supplement can be substituted by CM with positive effects on lactational performances. It also appears that there is a systematic underestimation of MP supply associated with CM inclusion in dairy rations using the NRC (2001) model.

Key Words: canola meal, meta-analysis, metabolizable protein

W318 Milk production, milk composition and blood parameters of cows fed whole flaxseed or whole linola. H. V. Petit*[1], R. N. do Prado[1,2], M. F. Palin[1], and C. Benchaar[1], *[1]Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada, [2]Universidade Estadual de Maringa, Maringa, PR, Brazil.*

A total of 28 Holstein cows were stratified by groups of 3 within parity for similar expected calving dates, and cows within group were randomly assigned to one of 3 isonitrogenous and isoenergetic diets to determine the effects of feeding different sources of fatty acids (FA) on milk production, milk composition, and blood parameters related to fatty liver. The 3 TMR contained either calcium salts of palm oil (MEG), unsaturated lipids supplied as 4.8% whole linola (WLO) rich in *n*-6 FA, or unsaturated lipids supplied as 4.8% whole flaxseed (WFL) rich in *n*-3 FA. The experiment was carried out from wk 4 before parturition to wk 12 of lactation. All cows were fed for ad libitum intake. Milk production and DMI were recorded at every milking and daily, respectively. Cows were weighed weekly and body score was recorded at the same time. Milk composition was determined on wk 1, 2, 3, 4, 6, 10 and 12. Blood was collected on wk 1 and 2 prepartum and on wk 1, 2, 4, 6 and 8 postpartum to determine NEFA, glucose and β-hydroxybutyrate. Data were analyzed as repeated measures using the PROC MIXED procedure of SAS (SAS Institute, 2000).There was an interaction ($P = 0.01$) between wk and treatment as a result of a greater increase over time in DMI, expressed as a percentage of BW, for cows fed WFL compared with those fed MEG. Cows fed MEG tended ($P = 0.07$) to produce more milk (41.7 kg/d) than those fed WLF and WLO (38.3 and 38.2 kg/d, respectively). Concentrations of protein, fat and lactose in milk were similar among diets. Treatment had no effect on BW, body condition score, blood concentration of NEFA and β-hydroxybutyrate. Cows fed WFL tended ($P = 0.09$) to maintain higher blood concentrations of glucose than those fed WLO and MEG as shown by the interaction between treatment and wk. These data suggest that feeding oilseeds that differ only for their type of FA (*n*-6 in linola and *n*-3 in flaxseed) result in similar productivity of early-lactating dairy cows.

Key Words: dairy cattle, flaxseed, linola

Ruminant Nutrition: Dairy: Rumen function and digestion

W319 In situ ruminal degradability of soybean meal (SBM), canola meal (CM), and corn or wheat dried distillers grains (DDG).

G. Maxin,* D. R. Ouellet, and H. Lapierre, *Dairy and Swine Research and Development Center, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

Different protein sources, as CM or by-products of ethanol production, are currently used in dairy rations to replace SBM. There is little data available on rumen degradation of these protein sources in a single study. Therefore, the objective of this study was to compare the dry matter (DM) and crude protein (CP) ruminal degradability of SBM, CM, high protein corn DDG with solubles (HPDDG) and wheat DDG with solubles (WDDG). In situ studies were conducted with 4 rumen-fistulated lactating Holstein cows fed a diet containing 38% grass hay and 62% corn-based concentrate. Each protein source was incubated in the rumen in nylon bags for 0, 2, 4, 8, 16, 24 and 48h according to NRC (2001) guidelines. DM and CP ruminal degradabilities were calculated from rumen-undegraded residues corrected or not for small particle loss according to Hvelplung and Weisbjerg (2000). Data were fitted to an exponential model to estimate degradation parameters and effective degradability (ED) was calculated with a passage rate of 7%/h. DM and CP contents for SBM, CM, HPDDG and WDDG were 88.7, 89.7, 92.2, 89.7% and 53.6, 40.0, 40.3, 37.2%. WDDG and SBM had higher uncorrected ED ($P < 0.05$, DM: 75.0 and 72.6%, CP: 84.8 and 66.0%) than CM and HPDDG (DM: 57.2 and 55.5%, CP: 59.3 and 48.2%). This was attributed to a higher soluble fraction in WDDG and a higher potentially degradable fraction and rate of degradation in SBM (9.0 vs. 5.8%/h for the other feeds). Small particle loss from the bags contributed to the DM and CP disappearance, being higher for WDDG (31.6% of DM, 45.7% of CP feed) than for the other feeds (11.2, 14.7, 17.3% of DM and 16.3, 19.7, 19% of CP for SBM, CM and HPDDG). Therefore, the corrected ED was lower than the uncorrected ED for all feeds, especially for WDDG where ED decreased to 53.2% (DM) and 60.8% (CP). However, this correction did not alter feed ranking, with SBM and WDDG being more degradable than CM and HPDDG. The results suggest that small particle loss correction is relevant for this type of feed ingredients and that higher RUP supply would result with CM and HPDDG substituting SBM, assuming similar intestinal digestibility.

Key Words: rumen degradation, protein

W320 Effect of carbohydrate source on performance and ruminal responses of dairy cows fed low-starch diets.

H. M. Dann*[1], K. W. Cotanch[1], C. Kokko[1], K. Fujita[2], and R. J. Grant[1], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*ZEN-NOH National Federation of Agricultural Cooperative, Tokyo, Japan.*

Fifteen multiparous Holstein cows (6 ruminally cannulated) were used in a replicated 3 × 3 Latin square design with 21-d periods (7-d collection periods) to measure the effect of forage or nonforage sources of fiber on lactational and ruminal responses when fed to cows in lower-starch diets compared with a higher-starch control diet. Treatments were: 1) control diet (CON) containing 50% forage [20% conventional corn silage (CS), 20% brown midrib CS, and 10% haycrop silage (HCS)], 2) high-forage diet (FOR) containing 63% forage (53% brown midrib CS and 10% HCS), and 3) nonforage fiber source diet (NFFS) containing 50% forage similar to CON and partial replacement of corn meal and soybean meal with beet pulp, wheat middlings, and distillers grains. CON contained 35% neutral detergent fiber (NDF) and 26% starch, FOR contained 38% NDF and 21% starch, and NFFS contained 38% NDF and 21% starch. Data were analyzed as a Latin square by ANOVA with the MIXED procedure of SAS using cow as the experimental unit, treatment, period within square, and square as fixed effects, and cow within square as a random effect. Dry matter intake (DMI), NDF intake, milk yield, and milk composition differed among treatments, which reflected the dietary NDF content. There was no treatment effect ($P > 0.10$) on solids-corrected milk (SCM), efficiency of milk production, ruminal total volatile fatty acid concentration (126 ± 4 m*M*), ammonia concentration (6.7 ± 0.7 mg/dL), or microbial N yield (594 ± 28 g/d). CON was associated with compromised ruminal pH compared with FOR and NFFS. This study demonstrates the value of both a higher forage and a NFFS strategy compared with a higher starch feeding approach.

Table 1.

Item	CON	FOR	NFFS	SE

W321 Duodenal bioavailability of quercetin and rutin in German Holstein cows.

A. Gohlke[1], C. J. Ingelmann[1], S. Wolffram[2], and C. C. Metges*[1], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*Institute of Animal Nutrition & Physiology, Christian-Albrechts-University of Kiel, Germany.*

Flavonoids were shown to have health promoting effects in vitro but evidence for in vivo efficacy is scarce. Whether they are effective depends on their bioavailability and metabolism. Since flavonoids are thought to be degraded by the rumenal microbiota we studied the bioavailability of the flavonol quercetin after duodenal administration of the aglycone and its glucorhamnosid rutin. Six German Holstein cows (>10,000 kg milk 305 d; 2nd lactation; 87 DIM) were fitted with duodenal cannulas. Bioavailability was tested at 4 different doses of each flavonoid (0 (NaCl only), 30, 60 and 90 μmol/kg BW). Before and after duodenal short-term infusion (10 min) at 0700 h, timed blood samples were taken until 24 h post-administration. Levels of plasma quercetin (Q), and its methylated (isorhamnetin, tamarixetin; I, T) and dehydroxylated (kaempferol; K) derivatives were measured after treatment with β-glucuronidase and sulfatase by HPLC with fluorescence detection. Data evaluation was performed using PROC MIXED of SAS. After rutin administration levels of plasma Q, I, T, and K did not increase above baseline. Administration of quercetin aglycone resulted in increased plasma concentrations of Q, I, T and K within 1 h ($P \le 0.05$). Although maximal plasma

Q concentrations showed high interindividual variability (331.9–842.8 nmol/L at 90 µmol/kg) peak time (115 min) did not differ ($P > 0.9$) among cows. With quercetin aglycone, Q was the main metabolite in plasma followed by I, K and T (81.5, 8.8, 5.8, 3.8% of total flavonol plasma area under curve). Flavonoids did not change DMI and plasma glucose levels but increased daily milk yield by 8% as compared with NaCl administration ($P \leq 0.05$). In contrast to findings in monogastric animals quercetin from rutin seems not to be available in cows when administered duodenally. Different intestinal microbiota composition in ruminants and monogastrics as well as differences in passage time could explain these findings. The increased milk yield upon flavonoid administration needs verification. Supported by BMBF, Germany.

Key Words: bioavailability, dairy cows, flavonoids

W322 Differences in rate of ruminal hydrogenation of C18 fatty acids in clover and ryegrass. J. Lejonklev*[1], A. C. Storm[2], M. K. Larsen[1], G. Mortensen[1], and M. R. Weisbjerg[2], *[1]Aarhus University, Department of Food Science, Tjele, Denmark, [2]Aarhus University, Department of Animal Science, Tjele, Denmark.*

The effect of forage type on ruminal hydrogenation was investigated by in vitro incubation of feed samples in rumen fluid from 2 rumen fistulated Holstein cows. Silages of red clover (RC), white clover (WC) and perennial ryegrass (PR) were produced in laboratory scale using forage harvested in primary growth and in third regrowth, resulting in 6 silages. Fatty acid content was analyzed after 0, 2, 4, 6, 8 and 24 h of incubation in triplicates to study the rate of hydrogenation of unsaturated C18 fatty acids. Initial composition of C18 fatty acids in dry matter varied between the different forages and growths. The amount of polyunsaturated fatty acids decreased with increased incubation time, whereas the amounts of monounsaturated vaccenic acid and saturated stearic acid increased. A dynamic mechanistic model was constructed assuming mass action driven fluxes between the following pools of C18 fatty acids: C18:3 (linolenic acid), C18:2 (linoleic acid), C18:1 (vaccenic acid, oleic acid, petroselidic acid) and C18:0 (stearic acid) as the end point. Longitudinal data from each single in vitro run was fitted to the final model and the rate constants (/h) of the hydrogenation were estimated using a Nelder-Mead optimization algorithm while maximizing the log-likelihood function. The estimated rate constants of hydrogenation were 0.069 (RC), 0.071 (WC) and 0.087 (PR) for $k_{C18:2->C18:1}$. 0.081 (RC), 0.077 (WC) and 0.102 (PR) for $k_{C18:3->C18:1}$. 0.046 (RC), 0.055 (WC) and 0.050 (PR) for $k_{C18:1->C18:0}$. Type of forage had a significant effect on $k_{C18:2->C18:1}$ ($P = 0.005$) and a tendency to influence $k_{C18:3->C18:1}$ ($P = 0.062$). The growth (primary or regrowth) had no effect on $k_{C18:2->C18:1}$ ($P = 0.42$) or $k_{C18:3->C18:1}$ ($P = 0.14$). Neither forage nor growth significantly affected $k_{C18:1->C18:0}$ ($P > 0.5$). Both RC and WC resulted in lower rates of hydrogenation of polyunsaturated fatty acids to monounsaturated than did PR, whereas the hydrogenation of monounsaturated to saturated fatty acids was similar between forages. This effect is present irrespective of the cutting time, i.e., primary growth or regrowth, despite large variations in fatty acid content between the cuts.

Key Words: clover, hydrogenation, rumen

W323 Corn source and dietary protein degradability: effects on ruminal measures and proposed mechanism for degradable protein effects. M. B. Hall,* *U. S. Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Effects of corn source and ruminal degradability of dietary protein (RDP) on ruminal measures was evaluated in a partially balanced, incomplete Latin square design with 3 21-d periods, 8 ruminally cannulated lactating dairy cows, and a 2 × 2 factorial arrangement of treatments (trt). Trt were corn source (corn; DG: dry ground corn, HM: high moisture corn) and RDP (+RDP: added protein from soybean meal; -RDP: heat-treated expeller soybean product partially substituted for soybean meal). Diets were formulated to be isonitrogenous and similar in starch and NDF. Data were analyzed with mixed models with cow (a random variable), period, corn, RDP, and corn x RDP as factors. Rumen concentrations over time were analyzed as repeated measures. Significance was declared at $P < 0.05$, and tendency $0.05 \leq P < 0.15$. DMI was 1 kg less on -RDP as compared with +RDP diets. Weights of total digesta and liquid tended to be greater with +RDP than with -RDP at 2 h post-feeding, with digesta DM% greater with -RDP than with +RDP (DM%: 14.6, 15.7, 14.9, and 15.3% for DG+RDP, DG-RDP, HM+RDP, and HM-RDP, respectively, SED = 0.44). Differences in the digesta DM:liquid ratio could introduce dilution effects on pH and organic acid concentrations (OA), hence, 2 h post-feeding digesta DM% for each cow in each period were used as covariates for analysis of ruminal pH and OA. *P*-values of the covariate were < 0.04. pH was greater for DG (6.27) than for HM (6.09; SED = 0.12), and tended to be affected by RDP x time with HM+RDP numerically lower than other trt after 1 h post-feeding. Corn x RDP tended to affect mean OA with +RDP 4% lower than -RDP with DG, but 9% greater with HM. Interaction of time and RDP affected OA with +RDP (155 mM) greater than -RDP (141 mM; SED = 5.9) at 2 h post-feeding and with more similar values for trt at all other times. Average lactate concentration was greater and maxima tended to be greater for +RDP than for –RDP. +RDP effects on OA and pH may be due to more immediate fermentation of starch instead of storage as microbial glycogen, but presence of dietary starch precludes measurement of glycogen. The basis for RDP effects needs further exploration.

Key Words: corn, protein degradability, rumen fermentation

W324 A meta-analysis of continuous culture rumen fermentation and digestibility data. A. N. Hristov*[1], C. Lee[1], R. A. Hristova[1], P. Huhtanen[2], and J. L. Firkins[3], *[1]The Pennsylvania State University, University Park, [2]Swedish University of Agricultural Sciences, Umeå, Sweden, [3]The Ohio State University, Columbus.*

A meta-analysis was conducted to investigate variability in ruminal fermentation and nutrient digestibility in continuous culture (CC) experiments in comparison with in vivo data. One hundred and 80 CC studies representing 1,074 individual treatments were used in the analysis. Studies were classified into 2 groups based on the type of CC used: CC system specified as RUSITEC (Rumen Simulation Technique) and non-RUSITEC CC systems. The CC data were compared with a data set of in vivo trials (INVIVO) with ruminally-cannulated lactating dairy cows (a total of 366 individual cow data). Data were analyzed using the MIXED procedure of SAS with study as random effect. Average total VFA concentration for RUSITEC and non-RUSITEC was 68 and 80% ($P < 0.001$) of INVIVO concentrations: 79.0 (SD = 30.9), 93.8 (36.3), and 116.9 (19.8) m*M*, respectively. Average concentration of acetate was also lower ($P < 0.001$) for the CC data sets compared with INVIVO and that of propionate was considerably lower for RUSITEC compared with INVIVO ($P < 0.001$), but butyrate concentrations were similar between CC and INVIVO. Average acetate:propionate ratios were lower ($P < 0.001$) for the CC data sets compared with INVIVO (2.69, 2.61, and 2.94, respectively). Variability in the VFA data was generally the highest for non-RUSITEC (higher CV and variance; $P < 0.001$), followed by RUSITEC, and was the lowest for INVIVO. Digestibilities of neutral-detergent fiber (NDF) and particularly organic matter (OM) were lower ($P < 0.001$) in the CC data sets compared with INVIVO; average NDF digestibility was 34.2 (15.9), 45.5 (17.2), and

53.0 (11.6) % for RUSITEC, non-RUSITEC, and INVIVO. A possible explanation for the considerably lower NDF digestibility with RUSITEC vs. non-RUSITEC could be the lower microbial enzymatic activities within the nylon bag vs. the surrounding rumen reported for the in situ procedure. This analysis demonstrated that in CC, total VFA and acetate concentrations were lower, protozoa were low or absent, and OM and NDF digestibilities were lower than in vivo. Overall, variability was much greater for CC vs. in vivo experimental data.

Key Words: continuous culture, rumen fermentation, meta-analysis

W325 Amount and digestibility of NDF affects rumen nutrient pool sizes and passage kinetics of dairy cows. K. W. Cotanch,* C. Kokko, H. M. Dann, J. W. Darrah, and R. J. Grant, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Ruminally cannulated Holstein cows (n = 8, 91 ± 11 d in milk) were used in a replicated 4 × 4 Latin square design study with 21-d periods to evaluate rumen pool size and turnover of organic matter (OM) and neutral detergent fiber (aNDF) of cows fed different sources and amounts of corn silage using a rumen evacuation technique. Conventional corn silage (CCS) and BMR corn silage (BMRCS) contained 37 and 39% aNDF with a 24-h aNDF digestibility (NDFD) of 38 and 51%, respectively. Treatments were 1) LCCS: 53% forage, 39% CCS, 32% aNDF, and 56% NDFD; 2) HCCS: 68% forage, 55% CCS, 36% aNDF, and 54% NDFD; 3) LBMR: 50% forage, 36% BMRCS, 32% aNDF, and 62% NDFD; and 4) HBMR: 64% forage, 50% BMRCS, 35% aNDF, and 60% NDFD. Intake was measured during d 14 to 21. Ruminal contents were evacuated manually 4 h after and before feeding on d 20 and 21, respectively. Total rumen contents were weighed and volume determined. Ten percent of rumen contents were collected, subsampled, and analyzed for OM and aNDF content. Data were analyzed as a replicated Latin square with the MIXED procedure of SAS with fixed effects of diet, period, and replicate. Cow within square was the random effect. Intake of dry matter (DMI) and aNDF were affected by treatment. Ruminal digest volume and mass were greatest for HCCS and lowest for LBMR. Pool size of OM did not differ among treatments but turnover time of OM was greater for HCCS than LBMR and HBMR. Pool size of aNDF was greater for HCCS than LBMR; LCCS and HBMR were intermediate. Turnover time of aNDF was greater for LCCS and HCCS than HBMR. The amount and digestibility of forage aNDF from corn silage affect nutrient pool size and passage kinetics of dairy cows.

Table 1.

W326 Orchard grass forage effects on bacterial communities and long-chain fatty acid profiles in the rumen of Holstein heifers. R. Mohammed[1,2], G. E. Brink[1], D. M. Stevenson[1], K. A. Beauchemin[2], and P. J. Weimer*[1], *[1]USDA-ARS, US Dairy Forage Research Center, Madison, WI, [2]AAFC, Lethbridge Research Center, Lethbridge, AB, Canada.*

The aim of this study was to determine if ruminal bacterial community composition (BCC) and long chain fatty acid (FA) profiles differed in heifers grazing orchardgrass pasture (OP) versus those fed hay (OH) harvested from the same field at the same stage of maturity. Five ruminally cannulated Holstein heifers were allotted to OP or OH with three 28-d periods. Three of these heifers were offered OP, OH and OP successively in the 3 periods while the other 2 heifers remained on OP for all periods. Ruminal digesta were collected on 3 consecutive days near the end of each period. Microbial DNA was extracted from solid and liquid phases of digesta, amplified by PCR using domain-level bacterial primers, and subjected to automated ribosomal intergenic spacer analysis (ARISA). Total ruminal volatile fatty acids (m*M*) and acetate (mol/100 mol) were greater for OH than for OP, while butyrate was less. The ARISA profiles for the OP and OH diets formed distinct clusters, indicating that ruminal BCC was affected by diet. Branched-chain FA (% total FA methyl esters) in rumen digesta (13:0 *anteiso*, 14:0 *iso*, 15:0 *iso*, 15:0 *anteiso* and 18:0 *iso* were greater for OH than OP. Total *trans* (*t*)-18:1, *t*11- and *t*10-18:1 were greater for OP than OH. Conjugated linoleic acid (CLA) isomers (*c*9, *t*11-CLA and *t*10, *c*12-CLA) were not influenced by the diets. Relative population size (RPS) of *Butyrivibrio fibrisolvens* and *Megasphaera elsdenii* in the liquid phase of rumen digesta (fraction of total 16S rRNA gene copy number), were not affected by diet. Regression analysis of ruminal *t*10-18:1 and RPS of *M. elsdenii* was not significant ($P = 0.59$; n = 8). Unexpectedly, the relationship between ruminal *t*11-18:1 and RPS of *B. fibrisolvens* was negative ($r^2 = 0.52$; $P = 0.04$; n = 8) suggesting that there are likely yet unidentified polyunsaturated FA biohydrogenating rumen bacteria. The difference in ruminal chemistry and BCC in heifers fed OP and OH reflects possible alterations in substrate availability to the rumen microflora due to differences in the form of diet (fresh vs. conserved forage).

Key Words: conjugated linoleic acid, orchardgrass, rumen bacterial communities

W327 Silicone plastination of rumen models: A room temperature technique. H. C. Puch,* K. B. Cunningham, and D. C. Brown, *LongView Animal Nutrition Center, Land O'Lakes Purina Feeds, Gray Summit, MO.*

The objective of this work was to create demonstration models of rumen tissues that are preserved and realistic compared with fresh tissues. Silicone plastination is a process that replaces tissue and cellular fluids with silicone polymers. Using this method, rumen tissue specimens can be preserved that are lightweight, flexible and anatomically correct. Random Holstein calves at 12, 20, or 24 weeks of age were euthanized and the reticulo-rumens collected for preservation. The full reticulo-rumen was placed on its right side, and an incision made around the outer circumference. The reticular fold, cranial and caudal pillars are cut at their mid points so that the reticulo-rumen can lay flat creating a symmetrical left and right side. The left side portion of the rumen was first dehydrated in cold 100% acetone at −24 C. Each rumen is stretched and attached to a customized polypropylene frame and placed into the vacuum chamber filled with silicone (NCS10 and NCS6, supplied by R.W. Henry, DVM, 1455 A. R. Davis Road, Seymour, TN. 37865). The lab made welded vacuum chamber is made from 6.5 mm steel with a chamber 810 mm long × 460 mm wide × 150 mm deep and has 170 mm

× 130 mm × 12 mm thick acrylic window in the top. Silicone replacement of tissue acetone occurs slowly in the vacuum chamber by decreasing pressure. Vacuum is controlled by adjusting inlet needle valve. Visually, the acetone will start to boil/vaporize at 22 cm Hg. Vacuum is held 22 cm Hg for 24 h. Each day the vacuum pressure is decreased by 1/2 for 3 d and the vacuum is 2 cm Hg. On d 4 the needle valve is completely closed and the vacuum held for 24 h or until acetone stops vaporizing. The rumen is removed from the silicone, allowed to drain, air dry for 24 h and removed from stretching frame. Final end chain polymerization is done by spraying tissue with the polymerizing catalyst (NCS3) and held in a closed plastic bag for 24 h. Visual differences can be observed in the plastinated rumens at different weeks of age in, papillae size, shape, color appearance and any abnormalities. This method creates preserved tissues that are ideal for teaching and demonstrations.

Key Words: model, plastination, rumen

W328 Techniques for sampling and measuring total two-dimensional surface area of rumen papillae. H. C. Puch*[1], K. M. O'Diam[2], and K. M. Daniels[2], [1]*LongView Animal Nutrition Center, Land O' Lakes Purina Feeds, Gray Summit MO,* [2]*Ohio Agricultural Research and Development Center, The Ohio State University, Wooster.*

The aim was to develop an objective method for determining total 2-dimensional (T2D) surface area of rumen papillae which can effectively be used to study rumen development. Eight Holstein steers were fed defined amounts of texturized grower concentrate with ad libitum access to alfalfa hay from 12 to 24 wk of age. Steers were euthanized at 24 wk to evaluate rumen development. The full reticulo-rumen was placed on its right side and an incision made around the outer circumference. The reticular fold, cranial and caudal pillars were cut at their mid points, so that it could be laid out flat creating a symmetrical left and right side. The right side was sampled to measure papillae development. Tissue sections (2x12 cm) were cut from 4 regions (caudal dorsal blind sac, caudal ventral blind sac, cranial dorsal and cranial ventral) and individually stapled to labeled 15 cm wooden tongue depressors and preserved in fixative for later histological analyses (data not shown). Ten representative papillae were dissected from each rumen tissue section and adhered to millimeter graph paper to determine length (L) and width (W). T2D surface area was calculated for each papilla, using an oval equation [2*(L/2*W/2 * 3.14)]. For comparison, T2D surface area of the same papillae was also determined via a digital image analysis program (CellSens Imaging; Olympus Corp.). In this method, papillae images were traced and the 2D area x2 determined. Both measurement techniques were not different (pooled across region: 32.2 vs. 31.6 mm2, SE 5.3). However, the 4 regions of caudal dorsal blind sac, caudal ventral blind sac, cranial dorsal and cranial ventral had different papillae surface area of 28.4, 30.9, 26.5, and 42.0 mm2, SE 5.4, respectively ($P < 0.001$). Both methods are effective in quantifying T2D surface area of rumen papillae; the digital method has an advantage in that it does not assume the shape of each papilla to be an oval. Both methods are helpful in evaluating dietary influences on rumen papillae size. Due to regional differences in papillae area, each region must be examined in future studies to fully characterize papillae surface area response to dietary changes.

Key Words: papilla, rumen, dairy steer

W329 Changes in rumen bacterial communities and rumen chemistry in primiparous Holstein cows during the periparturient period. R. Mohammed[1,2], D. M. Stevenson[2], P. J. Weimer[2], G. B. Penner*[3], and K. A. Beauchemin[1], [1]*AAFC, Lethbridge Research Center, Lethbridge, AB, Canada,* [2]*USDA-ARS, US Dairy Forage Research Center, Madison, WI,* [3]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The objectives were to study the changes in: 1) rumen bacterial community composition (BCC) and fermentation as influenced by feeding regimen and period; and 2) pH and VFA profiles among selected cows with minimum (stable) and maximum variation (unstable) between pre- and post-parturient periods. Fourteen Holstein heifers paired by expected calving date and BCS were allotted to 1 of 2 prepartum feeding regimens: low concentrate regimen (2 diets ranging from forage:concentrate, F:C = 80:20 to 54:46); or a high-concentrate regimen (4 diets ranging from F:C = 68:32 to 46:54). All cows received the same lactation diet postpartum. Microbial DNA extracted from 58 rumen digesta samples collected prepartum (d −50, −31, −14) and postpartum (d +14, +52) and amplified by PCR were subjected to automated ribosomal intergenic spacer analysis (ARISA). Changes in rumen chemistry (pH, VFA, and acidosis indicators at d −54, −35, −14, −3, +3, +17, +37, +58) were analyzed using principal component analysis (PCA). The ARISA profiles did not show a diet effect; however, 4 out of 14 cows showed a shift in BCC from the prepartum to the postpartum period. The PCA profiles did not show a diet effect for rumen fermentation variables. However, 4 cows (stable) showed minimal changes while 4 other cows (unstable) had greater changes in rumen fermentation when PCA profiles of individual cows were examined. The remaining cows had a PCA profile intermediate between the stable and the unstable fermentation profiles. Cows with a stable profile had greater minimum rumen pH, mean pH, less bouts under pH 5.5 and 5.2, and less duration and area of moderate (pH <5.5) and acute ruminal acidosis (pH <5.2) compared with cows with an unstable profile. Milk fat content tended to be greater for cows with a stable profile than for those with an unstable profile, with no difference in milk yield or FCM. Substantial changes in rumen chemistry occurred before and after calving with only small changes in BCC. Rumen chemistry during the periparturient period was not affected by feeding regimen but varied considerably among cows.

Key Words: ruminal acidosis, ruminal bacterial communities, periparturient period

W330 Detection of the methanol dehydrogenase structural gene *mxaF* in rumen fluid by PCR. E. T. Kim*[1], C. S. McSweeney[2], S. S. Lee[1], S. C. Kim[1], and S. H. Kang[2], [1]*Division of Applied Life Science (BK21 Program), Gyeongsang National University, Jinju, Gyeongnam, Republic of Korea,* [2]*CSIRO Livestock Industries, Queensland Bioscience Precinct, St Lucia, Qld, Australia.*

This study was conducted to demonstrate the potential possibility of methane oxidation in rumen by the *mxaF* gene, a functional gene (methanol dehydrogenase (MDH)), involved in methane oxidation pathway. The rumen fluid was collected before morning feeding from fistulated Holstein cows maintained on Leucaena and Rhodes grass diets, and on Lucerne diet. The DNA sample was amplified by PCR with the *mxaF* target primers. The expected DNA size band from PCR products was observed, and then cut for sequencing analysis. The PCR products of gDNA were ligated into the pGEM®-T Easy Vector according to the protocol of the TA Cloning Kit. Briefly, after the transformed cells had been incubated with isopropylthiogalactoside (IPTG), 192 random clones of white colonies were sequenced by an ABI 3130xl Genetic Analyzer. The amplicon sequences were compared with sequences of reference organisms from Greengenes and NCBI. The result from sequencing analysis matched *Methylobacterium sp.* which is extremely important because they can use methanol and methylamine as well as acetate, propionate and butyrate compounds to grow. *Methylobacterium* *sp.* is common in soil and on surfaces of leaves and other plant parts, and has the ability to utilize methane and other more complex organic compounds as carbon and energy sources. *Methylobacterium sp.* is known as a facultative methylotroph. *MxaF* gene, one of functional genes involved in methane oxidation pathway, was detected in rumen fluid in present study

Table 1. The result of sequencing analysis of mxaF-target from the rumen fluid

Classification	Identity (%)	
Methanol dehydrogenase alpha subunit (mxaF) gene (Methylobacterium brachiatum)	99	(527/533)
Methanol dehydrogenase alpha subunit (mxaF) gene (Methylobacterium platani strain KCTC12901)	98	(533/544)
Methanol dehydrogenase alpha subunit-like (mxaF) gene (Methylobacterium aquaticum strain DSM 16371)	98	(545/558)
Methanol dehydrogenase alpha subunit (mxaF) gene (Methylobacterium hispanicum strain DSM 16372)	97	(516/532)

W331 Evaluation of DM, NDF, and starch ruminal degradabilities of corn silage hybrids: A three-year study.

D. R. Ouellet*[1], G. F. Tremblay[3], and A. F. Mustafa[2], *[1]Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]Dept. of Animal Science, Ste-Anne de-Bellevue, QC, Canada, [3]Soils and Crops R&D Centre, Agriculture and Agri-Food Canada, Québec, QC, Canada.*

This experiment evaluated the DM, NDF, and starch ruminal degradabilities of 6 corn silage hybrids (Garst 8707 MP, Maizex leafy 2, Mycogen TMF 94, Novartis G 4106, Pickseed Exel, Pioneer 38T27) seeded at 5 different locations in Ontario, Canada, and in 3 consecutive years. Each year, corn hybrids were ensiled in duplicate in 20-L mini-silos which were sampled after more than 100 d of fermentation. All frozen silage samples were placed in nylon bags and incubated for 0 (wash only) or 16 h into the rumen of 2 fistulated cows to determine the ruminal degradation characteristics using double-point estimation (Vanzant et al. 1996 JAS 74:2773). Effective ruminal degradabilities (ED) of nutrients were estimated assuming a fractional rate of passage of 0.06 h^{-1}. There was no interaction between hybrids and production years for all parameters. Silage DM concentration varied between 32 and 36% and was affected by hybrids and years (32.4^{a}, 32.7^{a}, and 34.1^{b} % for year 1, 2, and 3, respectively). Silage NDF and starch concentrations were also affected ($P < 0.05$) by hybrids (46.2 to 49.2 and 26 to 32% of DM, respectively) and years. Degradation rates of the potentially degradable DM, NDF, and starch were not affected by hybrids averaging 1.7, 1.1, and 8.8% h^{-1}, respectively. Degradation rate of DM was affected by the production year (1.5^{a}, 2.2^{b}, and 1.3^{c} % $h^{-1}$for year 1, 2, and 3, respectively); NDF degradation rate was affected by year in the same manner. The ED of DM was affected by hybrids (53.1^{a}, 53.8^{ab}, 54.3^{ab}, 54.9^{ab}, 55.3^{b}, and 56.9^{c} for Garst 8707 MP, Pickseed Exel, Novartis G 4106, Pioneer 38T27, Maizex leafy 2, Mycogen TMF 94, respectively). The ED of NDF and starch were similar among hybrids averaging, 23.0% (SE = 1.4) and 90.1% (SE = 0.7), respectively. Years affected ED of DM (51.7^{a}, 57.1^{b}, and 55.5^{c}% for 1, 2, and 3, respectively), NDF (24.5^{a}, 25.9^{a}, and 18.6^{b}% for year 1, 2, and 3, respectively) and starch (90.6^{a}, 89.0^{b}, and 90.6^{a}% for year 1, 2 and 3, respectively). Results indicates that the production year have a significant effect on DM, NDF, and starch concentrations of silage, which in turn affected degradation rate and ED of these parameters except for degradation rate of starch. Degradation rates and ED of NDF and starch were not affected by hybrids, but the hybrid Mycogen TMF 94 had the greatest ED of DM.

Key Words: corn silages, forage degradation

W332 Rumen microorganisms growth as a function of the concentration of corn silage and soybean meal in culture medium.

C. P. Ghedini[1], R. P. Lana[1], A. S. Oliveira[2], D. C. Abreu*[1], R. M. Paula[1], C. J. Silva[1], and P. E. P. Barros[3], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Universidade Federal do Mato Grosso, Sinop, MT, Brazil, [3]Universidade Federal de Lavras, Lavras, MG, Brazil.*

The objective was to assess the effect of levels of corn silage and soybean meal on the ruminal microbial growth. Vials containing 6 mL of artificial saliva, 24 mL of inoculum and substrate (half corn silage, half soybean meal) in weights of 1.2; 0.6; 0.3; 0.1; 0.05 and 0 g were incubated in triplicate at 39°C for 72 h. Optical density (OD-600nm) and pH were measured at 0, 6, 12, 18, 24, 48 and 72 h of incubation. The experiment was analyzed as completely randomized design as a function of substrate concentration, time of incubation and the respective interaction. Microbial growth has reached the maximum value ($P < 0.01$) in the highest concentration of substrate, where it was also noted the lowest pH value (6.75). Regardless of level of substrate, the largest optical density was observed within 24 h incubation ($P < 0.01$) showing that the limiting factor was the substrate, as the pH was always above 6.9. After the time of maximum growth the microbial growth curve followed the hyperbolic model, assimptotic, being analyzed by saturation kinetics model of Lineweaver-Burk, as follows: $1/OD = y = 0.0869 + 0.5573\ (1/\text{concentration of substrate})$, $r^2 = 0.90$. The theoretical maximum growth rate was 1.79 and the substrate concentration required to achieve half of the maximum response was 0.160 g. The pH values were 6.75; 7.48; 7.93; 8.06 and 8.16 for 1.2; 0.6; 0.3; 0.1 and 0.05 g of substrate, respectively, and 7.70; 7.98; 7.80; 8.07; 7.74; 7.09; 7.36 in times of 0, 6, 12, 18, 24, 42 and 72 h of incubation, respectively. The growth of microbial population in rumen depends not only on the availability and substrate concentration, but also on fermentation products accumulation. Under the terms of this work the limiting factor was the availability of the substrate, leading to saturation of microbial growth, following the hyperbolic model. Supported by FAPEMIG (Fundação de Amparo à Pesquisa do Estado de Minas Gerais).

Key Words: fermentation kinetics of saturation, microbial growth, substrate

W333 Passage of liquid and fiber particles in dairy cows fed diets differing in NDF from conventional and bmr corn silages.

K. W. Cotanch*[1], C. Kokko[1], H. M. Dann[1], J. W. Darrah[1], R. J. Grant[1], and D. R. Mertens[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Mertens Innovation & Research LLC, Belleville, WI.*

Ruminally cannulated Holstein cows (n = 8, 91 ± 11 d in milk) were used in a replicated 4 × 4 Latin square design with 21-d periods to evaluate mean retention time (MRT) of liquid and fiber particles in cows fed diets varying in aNDF and 24-h NDF digestibility (NDFD) from conventional corn silage (CCS) and bmr corn silage (BMRCS). Treatments were 1) LCCS: 53% forage, 39% CCS, 32% aNDF, and 56% NDFD; 2) HCCS: 68% forage, 55% CCS, 36% aNDF, and 54% NDFD; 3) LBMR: 50% forage, 36% BMRCS, 32% aNDF, and 62% NDFD; and 4) HBMR: 64% forage, 50% BMRCS, 35% aNDF, and 60% NDFD. Samples of feces, haylage, CCS, and BMRCS were extracted in neutral detergent and sieved to obtain fiber particles of defined sizes. Fine fecal particles (1.59 - 4.75 mm), medium haylage particles (1.18 - 4.75 mm), and small (0.30 - 1.18 mm), medium (1.18 - 4.75 mm), and large (>4.75 mm) particles of CCS and BMRCS were labeled with Cr, La, Sm, Yb, Pr, respectively. Cows were dosed ruminally with a liquid marker (Co-EDTA) and marked particles on d 14 before feeding. Fecal samples were collected from 0 to 168 h after dosing and analyzed for marker by ICP. The MRT were calculated from areas under marker excretion curves, and included ruminal residence time plus post-ruminal transit time, which varied from 6 to 9 h based on first excretion of markers. Data were analyzed as a replicated Latin square with the MIXED procedure of SAS with fixed effects of diet, period, and replicate. Cow within square was the random effect. DMI (kg/d) was lower ($P \leq 0.05$) for HCCS (26.5) than LCCS (29.0), LBMR (29.3), and HBMR (29.2). Small corn silage particles of LCCS had shorter MRT than HCCS, but were not different between LBMR and HBMR. Conversely, medium corn silage particles of HBMR had shorter MRT than these particles in LCCS and HCCS. The lower DMI of HCCS does not appear to be related to marker MRT.

Table 1.

Mean retention time, h	LCCS	HCCS	LBMR	HBMR	SE
Liquid	20.5	20.9	20.7	19.4	0.6
Fine feces	29.5	30.7	31.2	32.2	0.8
Medium haylage	41.8	43.3	42.7	41.9	1.6
Small corn silage	36.1^{y}	39.8^{x}	37.5^{xy}	36.5^{xy}	1.3
Medium corn silage	44.9^{axy}	46.0^{ax}	43.7^{abyz}	42.1^{bz}	1.5
Large corn silage	47.5	48.8	47.9	46.8	1.6

W334 Effect of silica levels, and its location in the detergent fiber matrix, on in vitro gas production of rice straw. G. S. Cun*[1], G. A. Nader[2], and P. H. Robinson[1], [1]*University of California, Davis,* [2]*University of California Cooperative Extension, Yuba City.*

Rice straw can be used as a forage for cattle but, due to its very low net energy (NE) value, its use is generally limited to cattle whose intake potential substantially exceeds their energy need. This low NE value, driven by a low digestibility of organic matter (OM), has often been attributed to the high silica (Si) level of rice straw. This series of experiments evaluated how simulated field drying of rice straw, its Si level and location in the detergent fiber matrix, affects in vitro gas production. We also determined how in vitro gas production at 4, 24 and 72h are affected by removing Si from rice straw entirely by growing it in a Si-free hydroponic solution. In Expt. 1, rice plants grown in controlled conditions were analyzed fresh (i.e., within 60 min of harvest), and when fully dried (i.e., 25°C for 7 d), for dry matter, ash, acid detergent fiber (ADF) and acid detergent extracted neutral detergent fiber (ND/ADF) by ND extracting ADF, Si in ADF (ADF-Si) and Si in ND/ADF (ND/ADF-Si), as well as in vitro gas production. Fresh straw had a higher proportion of ADF-Si (539 versus 485 mg/g total Si; $P < 0.01$) and less Si in ND extracted ADF (196 versus 340 mg/g total Si; $P < 0.01$), than the same plants after drying, which may have caused the higher in vitro gas production of fresh straw at all times. However this was not confirmed in Expt. Two where ADF-Si, ND/ADF-Si and total Si were not predictive of any in vitro gas production in 39 field samples of rice straws collected in the Sacramento Valley (CA), possibly due to the relatively narrow range of 3.5 to 6% Si in the samples, or because the location of the Si in the fiber matrix, or Si itself, is simply not predictive of the digestibility of its OM. Indeed, in Expt. 3, rice grown under controlled conditions in Si free or Si containing hydroponic media, in 2 sub-experiments, had similar gas production unit OM. The general lack of impact of rice straw Si levels, either in total or relative to its location in the detergent fiber matrix, on in vitro gas production seems to demonstrate that Si is not causative to the low fermentability of rice straw OM.

Key Words: in vitro, silica, hydroponic

Ruminant Nutrition: General III

W335 Variation in chemical composition among breeding lines of novel oat varieties as ruminant feeds. J. M. Moorby,* A. A. Cowan, and A. H. Marshall, *Institute of Biological, Environmental and Rural Sciences, Aberystwyth University, Aberystwyth, UK.*

Previous work has shown the nutritional benefits of naked oat varieties compared with husked oats, particularly for pigs and poultry, but also for ruminants. However, crop yields of naked oats are significantly lower than those of husked oats, leading to a more expensive crop which has limited its appeal to feed compounders in least-cost ration formulations. To improve the digestibility of husked oats, a breeding program aimed at producing low-lignin oats with a high oil content has generated several new breeding lines. The chemical composition of modern oat varieties is likely to be different from previous varieties, and therefore standard 'book' values. Samples of the whole grain (including husk if present) of 4 commercial varieties of winter naked (WN) oats, together with several novel low-lignin breeding lines of spring husked (SLLH; n = 5) and winter husked (WLLH; n = 8) oats, were analyzed for standard chemical composition. Data were analyzed by ANOVA, with multiple comparisons when the effect of treatment (SN, SLLH and WLLH) was significant ($P < 0.05$). Grain oil and CP concentrations were significantly lower in the novel husked oats than the conventional naked oat varieties (Table 1), while fiber concentrations were higher, leading to lower ME densities in the husked oats than the naked oats, as expected. In conclusion, although the apparent feeding value of the novel husked oats was not as good as naked oats in some areas, some values of novel spring varieties in particular were similar to naked oats and show promise as ruminant feeds. Oat breeding work is ongoing, and these results highlight breeding targets for future lines of high yielding husked oats.

Table 1. Mean chemical composition of oat varieties; values in % DM unless otherwise indicated

	WN	WLLH	SLLH	SEM	*P*-value
DM, %	89.4	90.9	90.9	0.49	0.053

W336 Ruminal metabolism in continuous culture fermentation when administrating high concentration of inorganic selenium in mixed cultures of ruminal microorganisms. J. M. Vera[1], T. Z. Davis[2], D. N. Miller[3], K. E. Panter[2], D. R. ZoBell[1], and J.-S. Eun*[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan,* [2]*Poisonous Plant Research Laboratory, USDA-ARS, Logan, UT,* [3]*Agroecosystem Management Research Unit, USDA-ARS, Lincoln, NE.*

The current literature lacks information on ruminal microbial metabolism in response to high selenium (Se) concentration in the diet. We investigated changes in ruminal fermentation when high concentration of Se was administered in mixed ruminal cultures in fermentors. Two mature beef cows, fitted with a ruminal cannula, grazed on tall fescue pasture and were used as donor animals for ruminal contents. Filtered ruminal contents were allowed 11 d of adaptation to diets followed by 3 d of data collection. A dual-flow continuous culture system was used in a completely randomized design (n = 4) to test 2 dietary treatments: control (no Se addition) and 50 ppm Se addition. Grass hay (20 g DM/d) containing 0.12 ppm Se was added to the fermentors in 2 equal portions at 0800 and 1700 h. Selenium (sodium selenate) was added to the Se addition treatment by gradually increasing the concentration from 2 to 50 ppm over the 11 d in adaptation period. Culture pH averaged 6.04 and was not affected by treatment. Total volatile fatty acid (VFA) concentration averaged 52.2 and 55.5 m*M* in the control and Se treatment, respectively, and addition of Se did not affect the VFA concentration. Molar proportions of acetate and propionate did not differ due to Se addition, resulting in a similar acetate-to-propionate ratio. However, addition of Se tended to increase ($P = 0.09$) ammonia-N concentration. Additionally, Se addition increased methane production ($P = 0.01$). Selenate-respiring microorganisms were detected by the most probable number enumeration technique in 3 of the 4 replications receiving Se. Addition of 50 ppm Se in grass hay diet had no negative effects on ruminal fermentation, as was observed in similar culture pH and VFA concentration. However, addition of Se affected microbial N metabolism by increasing ammonia-N concentration. Overall data in this study suggest that the addition of Se up to 50 ppm would not interfere with in vitro ruminal metabolism by microbiota.

Key Words: continuous cultures, ruminal metabolism, selenium

W337 Effects of algae on ruminal fermentation and digestion in continuous culture fermenters. A. M. Gehman,* G. A. Harrison, and B. Jacobs, *Alltech Biotechnology Inc, Nicholasville, KY.*

The objectives of this experiment were to observe the effects on ruminal fermentation and digestibility when algae were included in a total mixed ration fed to continuous culture fermenters. Algae were *Schizochytrium* sp. and had a composition of 15.2% crude protein, 1.5% neutral detergent fiber (NDF), 3.9% ash, 30.9% non-structural carbohydrate, and 41.9% total fatty acids. Twelve single-flow continuous culture fermenters were used in a single-factor design with 6 dietary treatments with 2 replications per treatment. Diets were formulated to be isonitrogenous (17% crude protein) and to include algae at 0, 1, 2, 3, 4, and 5% dry matter (DM) or 0, 232, 465, 697, 930, and 1162 g equivalent for 22.7 kg DM intake. Diets were primarily comprised of corn silage, alfalfa hay, and corn grain. Cultures were fed 25 g twice daily for 6 d. Rates of flow and dilution were kept constant at 44 mL/h and 0.04/h for the duration of the study. Fermentation samples were collected from cultures before morning feeding during the last 3 d of the experiment to measure pH, ammonia, and volatile fatty acids (VFA). Composite effluent samples from each fermenter were used for DM and NDF digestibility. Data were analyzed for effects of treatment using PROC GLM of SAS. Culture pH and ammonia before morning feeding did not differ among treatments, averaging 6.21 ± 0.42 and 7.93 ± 0.32 mg/dL respectively. Molar proportions of acetate increased ($P < 0.01$) and propionate decreased ($P < 0.01$) similarly in all treatments containing algae compared with control (48.5 vs. 46.5 ± 0.5 and 26.0 vs. 29.4 ± 0.8 mol/100 mol). Butyrate, isobutyrate, isovalerate, valerate, and total VFA were not affected by treatment, averaging 18.2 ± 0.9, 1.81 ± 0.04, 1.73 ± 0.07, 2.32 ± 0.08, and 46.5 ± 2.1 mol/100 mol, respectively. Dry matter and NDF digestibility were not affected by treatment, averaging 43.4 ± 2.6 and 38.4 ± 6.4% respectively. Inclusion of algae affected the VFA profile but did not affect DM or NDF digestibility, indicating that algae modifies rumen fermentation in a manner that may not affect forage utilization.

Key Words: algae, continuous culture fermenter, rumen fermentation

W338 Digestion response of dairy heifers to the supplementation of autolyzed yeast.

D. R. Gomide[3], R. F. Lima[1], N. M. Lopes[1], R. C. Oliveira[1], A. Ganner[2], R. A. N. Pereira[3], and M. N. Pereira*[1], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Biomin Research Center, Tulln, Austria, [3]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil.*

Response to autolyzed *S. cerevisiae* supplementation (Levabon Rumen, Biomin) was evaluated. Nine ruminally cannulated heifers (510kg) received a sequence of treatments in 35-d period, 3x3 Latin Squares. Treatments were 0, 10 or 30g/d, given twice daily via cannula. A TMR was individually fed twice a day: 51.8% corn silage, 48.2% concentrate, 15% CP, 34% NDF, 39% NFC. Low ruminal pH was induced by feed removal at 12h post-morning feeding on d 34 and ad libitum feeding on d 35. Ruminal pH was evaluated on d 28 and 35 at 0, 3, 6, 9, 12, 18 and 24h post-feeding, and ruminal ammonia and PUN simultaneously on d 28. Tifton was incubated in situ over time on d 30 to 33. Total tract digestibility of DM was done by total collection of feces on d 31 to 33, simultaneously to urine sampling to estimate the relative rumen microbial yield by allantoin excretion. Statistical models had the effects of heifer, period and treatment; some had time and time by treatment interaction. Preplanned contrasts were: T0 vs. T10 and T0 vs. T30. Ruminal pH did not respond to treatments ($P > 0.20$), neither protozoa count ($P > 0.24$). Mean and minimum pH were 6.45 and 6.01 on d 28, and 6.16 and 5.38 on d 35, respectively, nadir was at 12h post-feeding. Urinary allantoin excretion was (mmoles/d): 53.3 on T0, 60.5 on T10 ($P = 0.50$), 77.6 on T30 ($P = 0.04$). There were trends for increased kd of Tifton B fraction on T30 for DM ($P = 0.07$) and NDF ($P = 0.06$). Total tract DM digestibility was (% of intake): 67.3 on T0, 68.4 on T10, 69.5 on T30 ($P > 0.28$). Days 28 to 33 DMI was increased from 11.7kg/d to 12.5 on T10 ($P = 0.04$), but T30 induced no response ($P = 0.88$). Day 35 DMI was: 17.0 on T0, 17.2 on T10, 16.4 on T30 ($P > 0.43$). Ruminal ammonia concentration did not differ ($P > 0.58$), but PUN was (mg/dL): 17.5 on T0, 18.5 on T10 ($P = 0.14$), 19.1 on T30 ($P = 0.03$). T10 induced a flattened PUN curve along the day. Ruminal ammonia peaks posterior to the morning feeding induced PUN peaks, while the evening ammonia peak was associated to decreasing PUN concentration. Autolyzed yeast supplementation induced positive dose dependent responses in rumen microbial yield, digestion and DMI. Ruminal pH regulation by yeast was not a plausible mechanism for the response.

Key Words: rumen microbial yield, *Saccharomyces cerevisiae*, yeast

W339 The effect of several sodium and potassium salts on rumen pH.

R. Garcia-Gonzalez,* C. Yunta, and H. van Laar, *Nutreco R&D, Boxmeer, the Netherlands.*

”Buffers” are broadly used in practice to counteract low rumen pH, but their mode of action is still open to question. Our work aimed to examine the rumen pH response to several Na and K salts, supplied at equivalent amounts of the cation. Two separate experiments (exp.) were conducted with Na and K salts, respectively. Each exp. was designed as a Latin square involving 5 rumen-fistulated cows in 5 periods of 2 d each. The cows were housed in a tie-stall barn, submitted to a fixed daily management schedule and fed a customary diet, but free of any mineral supplement, offered in 2 daily meals. The first day of each period, 1 of 5 possible treatments was supplied directly in the rumen, 2 h after the morning meal. Treatments were, for the Na exp.: $NaHCO_3$, Na_2CO_3, Na_2HPO_4, NaCl and none (control); and for the K exp.: $KHCO_3$, K_2HPO_4, K_2HPO_4 at double dose, KCl and none. Salts were supplied to provide 2 mol of the corresponding cation. Cows were fitted with indwelling rumen pH loggers set to record pH every 2 min for the whole duration of the exp. Every exp. was separately analyzed. First, pH data was averaged (avg.) for 3 time intervals post-administration of treatments, namely: 0 to 1 h, 1 to 3 h, and 3 to 6 h. Avg. pH were then analyzed with the mixed procedure of SAS, according to a model that included treatment, time (repeated measure), their interaction, and the pH at time 0 (covariable) as fixed effects; and cow and period as random effects. Any effects ($P < 0.05$) of these salts on pH were noticeable in the first 3 h, mostly in the first 1 h. In the Na experiment, NaCl did not cause any change in pH whereas all the other salts raised the pH. Similarly, in the K experiment KCl failed to cause any change in pH, while $KHCO_3$ rose, and the double dose of K_2HPO_4 tended to raise, pH. These results support that a positive strong cation to anion difference may be a determining factor for the salts tested to increase rumen pH.

Key Words: rumen pH, sodium, potassium

W340 Effect of polyethylene glycol on in vitro fermentation kinetics and digestibility of native tree fruits.

F. Aviles-Nova*[1], J. G. Estrada-F[2], O. Castelan-Ortega[3], B. Albarran-P[1], and A. Ramirez-O[1], *[1]Centro Universitario UAEM-Temascaltepec. Universidad Autonoma del Estado de Mexico, Temascaltepec, Edo. de Mexico, Mexico, [2]Instituto de Ciencias Agropecuarias y Rurales (ICAR) de la UAEM, Toluca, Edo. de Mexico, Mexico, [3]Facultad de Medicina Veterinaria y Zootecnia de la UAEM, Toluca, Edo. de Mexico, Mexico.*

This study evaluated the effect of polyethylene glycol on in vitro ruminal fermentation kinetics, in vitro organic matter digestibility (IVOMD), in vitro neutral detergent fiber digestibility (IVNDFD) and metabolizable energy (ME) in the fruit of native trees *Quercus hintonii* and *Quercus glaucoides* from the Mexican Central Plateau. Samples were collected in 4 sites where 3 trees were randomly selected. Three subsamples of 200g of ripe fruit were taken from each tree. They were dried at 40°C, ground in a Wiley mill with a 1mm sieve, and analyzed in triplicate. Fermentation kinetics, IVOMD and IVNDFD were evaluated with the in vitro gas production technique (GP) with and without polyethylene glycol (PEG 6000). In the former, 500 mg of substrate were added to each glass syringe plus 50 mL of buffered ruminal fluid (10 mL of ruminal fluid from forage-fed cattle: with a concentration of 80:20) and 40 mL of culture media. The syringes with PEG contained 500 mg of substrate, 1000 mg of PEG, plus 50 mL of ruminal fluid and 40 mL of culture media. All syringes were incubated at 39°C for 96 h. Gas volume was recorded from 1 to 8,12,16,20,24,36,48,72, and 96 h and was adjusted to mathematical model $Y = b(1\text{-}\exp\text{-}^{c(t\text{-}lag)})$. IVOMD and ME were determined with equations: IVOMD = 16.49+0.9042*GP+0.0492*RP+0.0587*EE, ME = 3.16+0.0695*GP+0.000730 *GP2 +0.00732*RP+0.02052*EE [RP = raw protein; EE = ether extract]. A completely randomized design was used with a 2x2 factorial arrangement. *Q. glaucoides* presented higher IVNDFD (52.7%) ($P < 0.001$), IVOMD (68.8%)($P < 0.001$) and ME (10.4 MJ/kgMS)($P < 0.010$). PEG addition between the species had a positive effect on IVNDFD, IVOMD and ME ($P < 0.02$). *Q. glaucoides* with PEG presented higher GP (200.1 mL/200mg) compared with *Q. glaucoides* without PEG (176.8 mL/200 mg)($P < 0.0001$). *Q. hintonii* presented a similar behavior with PEG (150.1mL/200mg) and without PEG (126.4mL/200mg) ($P < 0.018$). Adding PEG to the fruit had a positive effect, improving nutritional value. *Q. glaucoides* presented higher digestibility and better fermentation parameters.

Key Words: in vitro digestibility, native trees, polyethylene glycol

W341 Chemical composition and in vitro digestibility of foliage trees, and their use in feeding lambs in the dry tropics of central highlands of Mexico.

S. Rojas-Hernandez[1], D. Castelan-Ortega[3], A. Garciâ-Martinez[2], J. Olivares-Perez[1], J. G. Estrada-F[4], and F. Aviles-Nova*[2], *[1]U. A. Medicina Veterinaria y Zootecnia, Universidad Autonoma de Guerrero, Ciudad Altamirano, Guerrero, Mexico, [2]CU - Temascaltepec, Universidad Autonoma del Estado de Mexico, Temascaltepec, Edo. de Mexico, Mexico, [3]Facultad de Medicina Veterinaria y Zootecnia - Universidad Autonoma del Estado de Mexico, Toluca, Edo. de Mexico, Mexico, [4]Instituto de Ciencias Agropecuarias y Rurales, Toluca, Edo. de Mexico, Mexico.*

The objective of this study was to evaluate the chemical composition and in vitro digestibility of *C. alata* and *G. ulmifolia*, and the productive response of lambs fed diets with different levels of foliage included, in terms of dry matter intake (DMI), total weight gain (TWG), daily weight gain (DWG), feed conversion (FC) and feed efficiency (FE). Twenty lambs at 3.5 mo of age and 22.9 ± 0.88kg were randomly distributed (n = 4) in 5 treatments: T0 = control diet, T1 = diet with 15% *C. alata*, T2 = diet with 30% *C. alata*, T3 = diet with 15% *G. ulmifolia*, and T4 = diet with 30% *G. ulmifolia*. A totally random design was used, the Tukey test was applied ($P < 005$). The *G. ulmifolia* foliage had greater crude protein, IVDOM, total phenols and condensed tannins content ($P < 0.01$), with 167.2, 491.0, 41.5, and 38.2 g/kg DM, respectively, and 2.08 Mcal/kg DM of metabolizable energy. The *C. alata* foliage had greater neutral detergent fiber and acid detergent fiber content ($P < 0.001$), with 502.0 and 315.0 g/kg DM, respectively; the *C. alata* foliage, at 24, 48 and 96 h of incubation, had greater gas production ($P < 0.001$) with 66.1, 170.9 and 210.6 mL/g DM, respectively. Asymptotic gas production (b) was greater ($P < 0.05$) in T0 (293 mL g^{-1} DM). DMI was less in lambs in T0 (1061.4 g/animal/day) ($P < 0.025$). The DWG of the control diet was similar to that of diets with the different levels of inclusion of each species ($P > 0.05$), however the DWG of the diet with 15% *C. alata* (T1) was greater (295.6 g/d) ($P < 0.05$) than that of the diet with 30% *G. ulmifolia* (T4) (227.8 g/day) and was similar to T2 (30% *C. alata*) (286.7 g/d) and T3 (15% *G. ulmifolia*) (267.8 g/d). The native, non-leguminous tree foliages, *C. alata* and *G. ulmifolia*, have potential as forage for lamb production in the dry tropics. Including foliage from these species may substitute 15 and 30% of the conventional ingredients in lambs diets, since they improve dry matter intake and productive response.

Key Words: kinetics of degradation, lambs, non-leguminous tree

W342 Effect of replacing barley grain with wheat dry distillers grains with solubles on *in situ* degradation kinetics, growth, and fatty acid profiles of lambs.

J. S. Avila[1], S. J. Meale*[1], A. S. O'Hara[1], A. Horadogoda[1], D. Palmer[1], T. A. McAllister[2], and A. V. Chaves[1], *[1]Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia, [2]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

The aim of the study was to assess the effects of replacing barley grain with increasing concentrations of wheat dry distillers grains with solubles (WDDGS) in lambs diets. The control diet contained (DM basis) 62.9% barley grain, 30% alfalfa hay, 2.5% molasses, 1% canola oil and 3.6% mineral-vitamin mix. Increasing concentrations (20, 40% of DM) of WDDGS was achieved by replacing barley grain with WDDGS. Digestion kinetics of DM, CP, and NDF of diets were measured by in situ incubations using 2 rumen cannulated cows. Additionally, 39 weaned Dorper/Merino lambs were used in a trial to determine the effects of WDDGS on growth performance, feeding behavior, subcutaneous fat fatty acid (FA) profiles and wool growth. Lambs were blocked by weight and randomly assigned to one of the 3 dietary treatments (Control, 20% WDDGS and 40%WDDGS). Lambs were fed ad libitum using 3 automatic feeders per treatment and had free access to water. Lambs were slaughtered at a BW of ≈44 kg. Data were analyzed using the mixed model procedure of SAS. In the in situ study, WDDGS did not affect ($P = 0.61$) DM or NDF degradation rates (k, h^{-1}), but reduced CP degradation rate ($P = 0.02$). Effective rumen degradable protein and ruminal undegradable protein (g/kg DM) were higher ($P < 0.001$) in the WDDGS diets compared with control. In the growth trial, increasing WDDGS in the diet did not affect ($P = 0.48$) eating time (min/d), but quadratically increased ($P = 0.02$) eating rate (g/min), intake ($P = 0.02$) and daily gain ($P = 0.05$). Final bodyweights were linearly increased ($P = 0.02$) by WDDGS addition and hot carcass weight was higher ($P = 0.04$) in the 40% WDDGS group compared with other treatments. Inclusion of WDDGS did not affect feed efficiency ($P = 0.62$), wool staple length ($P = 0.32$), total SFA ($P = 0.29$), MUFA ($P = 0.32$) or PUFA ($P = 0.11$) profiles of subcutaneous fat, but increased C18:3 ($P = 0.02$). This study suggested that WDDGS included up to 40% of dietary DM as replacement of barley grain increases RDP, RUP, and lamb growth performance.

Key Words: digestion kinetics, ethanol by-products, wool yield

W343 Could essential oils of thyme (*Zataria multiflora*) and peppermint (*Mentha piperita*) improve calf growth performance?

M. Ebrahimi, M. Ganjkhanlou, and M. Dehghan-Banadaky,* *University of Tehran, Karaj, Tehran, Iran.*

This experiment was conducted to investigate the effect of feeding thyme and peppermint essence to calf starter on preweaning and postweaning calf growth performance, feed intake and blood metabolites. Following 3 d of colostrum and transition milk feeding 36 Holstein calves were assigned in a completely randomized block design with 3 dietary treatment with 12 calves (6 females and 6 males) per treatment including: 1) starter without essence (Control), 2) starter including 0.2% peppermint essence, and 3) starter including 0.2% thyme essence. Calves were housed in individual hutches, and fed whole milk at 10% of the initial body weight daily and had free access to starter and water. The weaning process defined when the calves had consumed 1 kg of starter for 2 d, consecutively. The experiment was ended 2 weeks after weaning the calves. Feed intake was measured daily. Body weight was measured at birth, at monthly throughout the study, at weaning and at the end of study. Blood samples were obtained 2 d before weaning and at the end of study. Plasma samples analyzed for glucose, urea nitrogen and β-hydroxybutyrate (BHBA) determination. Average daily feed intake and body weight gain was greater for calves fed peppermint compared with other calves (624.3 ± 43.5 vs. 526.2 ± 42.4 and 432.7 ± 44.7 g daily feed intake and 0.94 ± 0.03 vs. 0.88 ± 0.02 and 0.82 ± 0.04 g daily gain respectively for treatments 2, 3 and 1, $P < 0.05$). There were no differences between treatments for postweaning gain and feed consumption after weaning ($P > 0.05$). Plasma urea nitrogen and BHBA concentration decreased in calves fed thyme compared with other calves ($P < 0.5$). No significant difference showed in blood metabolites between calves after weaning ($P > 0.05$).The results of this study demonstrated that supplementation of peppermint essence to calf starter increased feed intake and body weight during suckling period,

but after weaning the supplementing of essence had no effect on calf growth performance. Also we concluded that supplementing of thyme essence to starter causes a decrease in blood urea nitrogen and BHBA concentrations in suckling calves.

Key Words: calf performance, essential oil, starter

W344 In vitro investigation of various adsorbents to adsorb aflatoxin B1.

M. Savari, M. Dehghan-Banadaky,* K. Rezayazdi, and M. Javan-Nikkhah, *University of Tehran, Karaj, Tehran, Iran.*

Aflatoxin B1 (AfB1) is the most important of a group of naturally occurring secondary metabolites produced mainly by *Aspergillus parasiticus* and *Aspergillus flavus* primarily in agricultural products from tropical and subtropical regions. A common way to counteract aflatoxicosis is the utilization of adsorbents added to AfB1 contaminated feed to bind the toxin in the gastro-intestinal tract before its resorption. Therefore, the aim of this study was to comparison of various adsorbents including bentonite (natural mineral), zeolite (synthetic mineral), Mycosorb (organic) and Biotox (mineral - organic) on their ability to adsorb aflatoxin B1. Hence, AFB1-contaminated rice was obtained after inoculation with the *Aspergillus parasiticus* type strain PTTC 5286 (Iranian Research Organization for Science and Technology). AFB1 was produced in 6 d at 28°C. Amounts of aflatoxin present in the contaminated rice were determined by HPLC. The result showed that the product obtained was containing aflatoxins in the following concentrations (μg/g of substrate): B1-B2-G1-G2, 13.5:0.5:0:0. AFB1 was extracted 3 times with chloroform by soaking rice in chloroform over night at room temperature and stirring rice. Adsorbents were individually mixed at 3 different ratios with AFB1 (1:1000, 1:5000 and 1:15000, w/w) in the McDougall buffer at pH 6.8 and shaken for 16 h at 39°C, centrifuged (at 3500 × g for 15min) and the supernatant evaluated for amount of aflatoxin B1 by aflatoxin B1 ELISA kit and then obtained data were analyzed using the general linear model procedure of the SAS in a 4 × 3 × 3 factorial arrangement of a completely randomized design. At the 1:15000 aflatoxin: adsorbent ratio, zeolite, Mycosorb and Biotox sequestered (adsorbed) over 0.8, 0.81 and 0.83 of the AFB1. This efficacy decreased when the amount of adsorbents was reduced. Bentonite had a lower sequestering efficacy in all of cases, with 0.38 being the maximum value obtained in the 1:15,000 aflatoxin: adsorbent ratio ($P > 0.05$). We concluded that there were significant differences between 3 ratios of aflatoxin: adsorbent and also between adsorbents for percentage of adsorption.

Key Words: aflatoxin B1, adsorbents, *Aspergillus parasiticus*

W345 Influence of *Yucca schidigera* on in vitro gas production and fermentation of rumen fluid.

K. D. Boden* and C. A. Loest, *New Mexico State University, Las Cruces.*

Several factors, including excessive foam production, may inhibit eructation and contribute to bloat in cattle. We hypothesized that saponins of *Yucca schidigera* in a commercially available feed supplement (Ruma-Just, Nova Microbial Technologies) will alter anaerobic microbial fermentation and decrease both foam and gas production in vitro. Rumen fluid was collected from 2 ruminally cannulated cows fed an 83% dry-rolled corn-based diet. Anaerobic fermentations were conducted at 39°C in 250-mL Erlenmeyer flasks containing 40 mL rumen fluid, 60 mL McDougal's buffer, and 1 g ground corn grain with treatments. Treatments were 0.00 (control), 0.01, or 0.02% Ruma-Just mixed with the ground corn grain. Gas production was recorded from 7 flasks per treatment at 0, 2, 4, 6, 8, 10, 12, 18, and 24 h. Foam height, viscosity, pH, VFA, and NH_3 were measured in 6 flasks per treatment that were incubated for 0, 6, 12, or 24 h. Results showed that gas production, VFA, and NH_3 concentrations increased ($P < 0.05$), and pH decreased ($P < 0.05$) from 0 to 24 h regardless of treatment. Rumen fluid pH tended to be greater (quadratic, $P = 0.06$) for 0.01% Ruma-Just (6.18 ± 0.10) than control (6.03 ± 0.10) and intermediate for 0.02% Ruma-Just (6.13 ± 0.10). Gas production was lower (quadratic, $P < 0.05$) for 0.01% Ruma-Just (102 ± 3.8 mL) than control (116 ± 4.5 mL) and 0.02% Ruma-Just (121 ± 3.8 mL). Similarly, foam height was lower (quadratic, $P < 0.05$) for 0.01% Ruma-Just (4.63 ± 2.85 mL) than control (8.25 ± 2.85 mL) and 0.02% Ruma-Just (8.75 ± 2.85 mL). Viscosity was lower (quadratic, $P < 0.05$) for 0.01% Ruma-Just (2.13 ± 0.06 cP) and 0.02% Ruma-Just (2.18 ± 0.06 cP) than control (2.30 ± 0.06 cP). Treatments did not affect ($P > 0.10$) VFA and NH_3 concentrations. In summary, Yucca Schidigera altered gas and foam production, rumen fluid viscosity, and pH, but did not affect VFA and NH_3 concentrations in vitro. Decreasing gas production, foam production, and rumen fluid viscosity could reduce ruminal bloat. Authors acknowledge R. Goodall, Nova Microbial Technologies and MBRS RISE Program (grant # R25GM061222).

Key Words: *Yucca schidigera*, gas production, rumen

W346 Effects of inclusion of bioethanol co-product on changes in the metabolic characteristics of the proteins in oat grain in ruminants.

D. Damiran, M. Yari, L. Yang,* Z. Niu, and P. Yu, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

This research program aims to develop a strategy to more efficiently utilize oat grain by integration with bioethanol co-products (wheat dried distillers grains with solubles) in sustainable beef and dairy production and to assist the beef and dairy industry to develop low-cost and more efficiently feeding strategies by utilizing alternative feed resources. In this study, the objectives were to investigate the effects of inclusion of bioethanol co-product of wheat dried distillers grains with solubles into oat grain on changes in the metabolic characteristics of the proteins, total truly digested and absorbed protein supply and degraded protein balance, determined with the DVE/OEB system (non-TDN based model) and NRC-2001 model (TDN-based model). Oat grains with the co-products were mixed manually to combine in ratios of 4:0, 3:1, 2:2 and 1:3. Each combined feed had 2 replications with 2 sources of the co-products. The rumen degradation kinetics and intestinal digestion were determined using 2 Holstein Friesian dairy cows. The data were analyzed by mixed model procedure of SAS with a CRD model. A significant level was declared at $P < 0.05$ and a tendency was declared at $P < 0.10$. The results showed that by using the DVE/OEB system, when the co-products was included at the different ratios into oat grain, the total truly digested and absorbed protein supply tended to be linearly increased from 76 to 137 g/kg DM ($P = 0.06$) and degraded protein balance linearly increased from 6 to 133 g/kg DM ($P < 0.01$). By using the NRC-2001 model, when the co-product was included at the different ratios into oat grain, the metabolizable protein supply was numerically increased from 100 to 154 g/kg DM ($P = 0.20$) and degraded protein balance increased from −33 to 119 g/kg DM ($P < 0.01$). In conclusion, the inclusion of bioethanol co-product changed the metabolic characteristics of the proteins and improved nutrient supply from oat grain to cattle.

Key Words: metabolic characteristics of the protein, combined oat with bio-ethanol co-products, nutrient modeling

W347 Evaluation of forage indigestible NDF and relations with analytical parameters by principal component analysis.

A. Gallo, S. Bruschi, G. Giuberti, M. Moschini, and F. Masoero,* *Università Cattolica del Sacro Cuore, Piacenza, Italy.*

The estimation of indigestible NDF (iNDF) is considered as an important parameter in dynamic nutritional models to predict energy and protein values of forages. Currently, the iNDF is predicted as 2.4 times ADL. However, recent observations suggested the use of a constant coefficient provides inaccurate estimations of the iNDF across forages. The aim of this experiment was to evaluate the iNDF of different forages and to study its relationships with chemical parameters. A set of 35 forages (10 alfalfa hays or AH, 10 grass hays or GH and 15 corn silages or CS; respectively) was randomly collected from the Po Valley of the Northern Italy. Forages were characterized for chemical composition and iNDF, the latter evaluated after 288h of in situ rumen incubation. Then, a principal component analysis (PCA) was used to study relationships between original variables and extracted principal components. Overall, the nutritive value of forages was in the ranges of those reported by the National Research Council database. The iNDF was lower in CS than GH and AH (13.4 versus 25.1 and 26.8 g/100 g DM, $P < 0.05$; respectively). The iNDF/ADL ratio was higher than 2.4 for all forage classes, being 6.2, 3.5 and 4.7 in GH, AH and CS, respectively. As a result of PCA, the first 3 principal components explained more than 85% of total variation (eigenvalues of 6.13, 3.30 and 0.78). The loading plot from PCA showed iNDF clustered with different chemical parameters. Particularly, iNDF was positively correlated ($P < 0.05$) to CP ($r = 0.41$), ash ($r = 0.59$), ADICP ($r = 0.60$), NDICP ($r = 0.72$), ADL ($r = 0.73$) and ADF ($r = 0.81$). Furthermore, ether extract and NSC clustered and were oriented in an inverse direction to iNDF. The iNDF/ADL ratio clustered with ether extract and NDF ($r = 0.53$ and $r = 0.45$, $P < 0.05$; respectively) and was negatively related ($P < 0.05$) to NSC ($r = -0.72$) and soluble CP ($r = -0.55$). Our data suggested the iNDF was related to different chemical parameters and the use of simply regression seems to be inadequate to universally predict iNDF across forages.

Key Words: indigestible NDF, forage, principal component analysis

W348 Utilization of *Yucca schidigera* to alter hydrogen sulfide gas production from rumen fluid in vitro.

J. Browne-Silva* and C. A. Loest, *New Mexico State University, Las Cruces.*

This study evaluated the effects of an additive from *Yucca schidigera* (Ruma-Just, Nova Microbial Technologies) on in vitro fermentation of ground corn grain, total gas and H_2S production, and rumen fluid viscosity. Rumen fluid was collected from a ruminally-cannulated cow fed a corn-based diet. Anaerobic fermentations were conducted in 250-mL serum bottles containing 50 mL rumen fluid, 50 mL McDougal's buffer, and 1 g of ground corn grain that was thoroughly mixed with one of 6 treatments. Treatments, in a 3 × 2 factorial arrangement, were ground corn grain substrate mixed with 0%, 0.01%, or 0.02% Ruma-Just and 0% added sulfur, or 0%, 0.01%, or 0.02% Ruma-Just with 0.6% added sulfur as sodium sulfate. Total gas production was recorded, and a sample of gas for H_2S analysis was collected after incubating 9 replicate bottles per treatment for 24 h at 39°C. Contents from in vitro fermentations were frozen at −20°C, and later filtered for IVDMD and rumen fluid viscosity measurements. Gas production decreased in response to 0.01% Ruma-Just when no sulfur was added, and gas production decreased in response to 0.02% Ruma-Just when 0.6% sulfur was added (Ruma-Just × S interaction, $P < 0.01$). Ruma-Just at both 0.01% and 0.02% increased IVDMD when no sulfur was added, but Ruma-Just did not affect IVDMD when 0.6% sulfur was added (Ruma-Just × S interaction, $P = 0.07$). Production of H_2S per gram of substrate was not affected by Ruma-Just when 0% sulfur was added, but H_2S production decreased in response to 0.02% Ruma-Just with 0.6% added sulfur (Ruma-Just × S interaction, $P = 0.01$). By design, addition of 0.6% sulfur increased ($P < 0.01$) H_2S production. Rumen fluid viscosity tended to be lower ($P = 0.10$) for 0.02% Ruma-Just than 0% and 0.01% Ruma-Just. In conclusion, *Yucca schidigera* may decrease total gas and H_2S production in ruminants consuming diets high in sulfur. Authors acknowledge R. Goodall and Nova Microbial Technologies.

Key Words: *Yucca schidigera*, hydrogen sulfide, rumen

W349 Effect of monensin and bismuth subsalicylate on hydrogen sulfide in continuous culture fermenters.

M. Ruiz-Moreno,* E. Binversie, and M. D. Stern, *Department of Animal Science, University of Minnesota, St. Paul.*

In ruminants, excess dietary S is associated with several conditions including a reduction in DM intake, negative effects on feedlot performance and carcass characteristics, and sulfur-associated polioencephalomalacia. Therefore, ruminant nutritionists are interested in methods to reduce negative effects of high S diets. Bismuth subsalicylate (BSS) has been shown to decrease fecal H_2S production in humans, while there are conflicting results about the effect of monensin (MON) on H_2S production in ruminants. Therefore, the objective of this experiment was to evaluate effects of these compounds on H_2S production by rumen microbes. Eight dual flow continuous culture fermenters were used during 2 consecutive 10-d periods with the first 7 d for stabilization followed by 3 d of sampling. The experimental design was a 2 × 2 factorial arrangement of treatments, with 2 levels of BSS (0 and 1% of DM) and 2 levels of MON (0 and 5 ppm in incubation fluid). Fermentation substrate consisted of 46% distillers dried grains, 41% ground corn, 8% hay, 2.5% $CaCO_3$, 1.5% molasses and 1% mineral premix and was provided at 75 g/fermenter/d. Addition of BSS to the diet increased ($P < 0.05$) digestion of OM, NDF and ADF but decreased ($P < 0.05$) NFC digestion and total VFA concentrations. Molar proportions of acetic and propionic acid increased ($P < 0.05$) with BSS, while butyric acid decreased ($P < 0.05$). Monensin decreased ($P < 0.05$) ADF digestion and A:P ratio, without affecting ($P > 0.05$) molar proportions of acetic, propionic and butyric acids. In regards to nitrogen metabolism, MON increased ($P < 0.05$) non NH_3-N outflow without affecting ($P > 0.05$) other parameters. BSS increased ($P < 0.05$) NH_3-N concentration, NH_3-N flow and tended to increase ($P < 0.1$) dietary-N flow, and decreased ($P < 0.05$) microbial-N outflow, CP digestion and efficiency of microbial protein synthesis. Headspace concentration of H_2S was reduced 99% ($P < 0.05$) with BSS. Conversely, a trend ($P < 0.1$) to increase H_2S headspace concentration was found following addition of MON. Only minor changes in fermentation pH were found with MON, but increases ($P < 0.05$) in mean, minimum and maximum fermentation pH were observed with addition of BSS. Results indicate that BSS can markedly decrease H_2S production in long-term in vitro rumen incubations.

Key Words: bismuth subsalicylate, hydrogen sulfide, rumen

W350 Alteration of fasting heat production during fescue toxicosis in Holstein steers.

A. F. Koontz*[1], A. P. Foote[1], D. H. Kim[1], L. P. Bush[2], J. L. Klotz[3], K. R. McLeod[1], and D. L. Harmon[1], *[1]Department of Animal and Food Sciences, University of Kentucky, Lexington, [2]Department of Plant and Soil Sciences, University of Kentucky, Lexington, [3]USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

This study was designed to examine alteration of fasting heat production (FHP) during fescue toxicosis. Six ruminally cannulated Holstein

steers (BW = 348 ± 26 kg) were weight-matched into pairs and utilized in a 2-period crossover design experiment. Each period consisted of 2 temperature segments, one each at 22°C and 32°C. During each period, one steer per pair was ruminally dosed twice daily with 0.5 kg of ground endophyte-infected fescue seed (E+), the other with ground endophyte-free fescue seed (E-) for 7 d. Animals were pair-fed with E+ animals offered alfalfa cubes at 1.5 × NE_m. On d 8 of each segment, animals were moved to individual metabolism stalls fitted with indirect calorimetry head-boxes. Rumen contents were removed, weighed and subsampled for DM determinations. The reticulorumen was then washed and filled with a buffer ($NaCl$ = 96; $NaHCO_3$ = 24; $KHCO_3$ = 30; K_2HPO_4 = 2; $CaCl_2$ = 1.5; $MgCl_2$ = 1.5 mmol/kg buffer) that was gassed with a 75% N_2 and 25% CO_2 mixture before rumen incubation. During buffer incubation, an E+ or E-fescue seed extract was added at 12 h intervals to maintain treatment presentation to the animal. After a 12-h wait, heart rate (HR), core temperature (CT), O_2 consumed, and CO_2 produced were recorded for 16 h. There was no difference ($P > 0.9$) in DMI or DMI/kg $BW^{0.75}$ between endophyte treatments by design; however, intake decreased ($P < 0.01$) at 32°C. CT was unaffected by fescue treatment or temperature. Rumen contents weight (kg/ kg $BW^{0.75}$) tended to be increased ($P < 0.15$) and DM of rumen contents as well as total rumen DM/kg $BW^{0.75}$ was increased ($P < 0.0001$) in E+ animals. Increased temperature had no effect on measurements with the exception of HR and respiratory quotient (RQ). HR increased ($P = 0.05$) at 32°C, but was unaltered by fescue treatment. RQ was elevated ($P = 0.02$) in E+ animals and tended to increase ($P = 0.1$) at 32°C. O_2 consumption decreased ($P = 0.04$) and CO_2 production tended to be reduced ($P = 0.07$) in E+ animals. FHP (kcal/kg $BW^{.75}$) was reduced ($P = 0.04$) in E+ animals. These data suggest that consumption of E+ tall fescue by cattle results in a reduction in basal metabolic rate.

Key Words: cattle, fescue, fasting heat production

W351 Influence of maternal nutrition and prenatal adenovirus-VEGF gene therapy on fetal visceral tissues and crypt cell proliferation at d 130 of gestation.

N. M. Chapel*[1], R. D. Yunusova[1], R. P. Aitken[2], J. S. Milne[2], D. J. Carr[2,3], P. P. Borowicz[1], A. L. David[3], J. M. Wallace[2], and J. S. Caton[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo,* [2]*Rowett Institute of Nutrition and Health, University of Aberdeen, Scotland, UK,* [3]*Prenatal Cell and Gene Therapy Group, UCL Institute for Women's Health, University College London, UK.*

Adenovirus VEGF (Ad.VEGF) gene therapy has been shown to increase pre- and early post-natal growth velocity in an ovine model of fetal growth restriction. Our objectives were to investigate the effects of Ad.VEGF on fetal visceral tissues and crypt cell proliferation at d 130 of gestation in this paradigm. First parity ewe lamb recipients were initially allocated to a control (CON; n = 12) or high (H; n = 45) quantity of the same diet at singleton embryo transfer. Control diets provided met requirements for specific age and stage of gestation and H ewes received approximately twice the dietary intake of CON. At 89 ± 1.5 d of gestation H ewes were randomly allocated to receive 1 of 3 injections into both uterine arteries: a) Ad.VEGF (5×10^{11} particles) gene; (n = 18), b) control Ad containing the β-galactosidase reporter gene, Ad.LacZ, same dose; (n = 14), and c) saline (n = 13). On d 130 of gestation ewes and fetuses were necropsied. Fetal visceral tissues were harvested, weighed, and perfusion fixed. At necropsy, H ewes had increased ($P \leq 0.001$) BW, condition, and perirenal fat compared with CON (81.0 vs. 65.7 ± 1.2 kg; 2.9 vs. 2.4 ± 0.03; 1,334 vs. 543 ± 91 g, respectively). Maternal measurements were not altered by any injection treatment. Fetal BW was lower ($P < 0.001$) in H compared with CON (4,186 vs. 5,084 ± 214 g). Total fetal stomach, small intestine, and large intestine weights tended ($P \leq 0.07$) to be lower in H compared with CON. Fetal liver weight was less ($P \leq 0.01$) in H compared with CON. Fetal stomach (g/kg BW) was greater ($P < 0.01$) in H compared with CON. Fetal small intestine (g/kg BW) was less ($P = 0.016$) in Ad.VEGF vs. Ad.LacZ + saline. Small intestinal crypt cell proliferation was not altered by maternal nutrition or adenovirus-VEGF gene therapy. Adenovirus-VEGF gene therapy, while having some effects on proportional fetal visceral tissue mass, does not appear to alter intestinal crypt cell proliferation at d 130 of gestation. However, intestinal vascular responses to gene therapy treatment are unknown at this time.

Key Words: intestine, maternal nutrition, VEGF

W352 Effect of dried fermentation biomass on microbial fermentation in continuous culture.

A. Carpenter*[1], E. Binversie[1], M. Ruiz-Moreno[1], J. Usry[2], I. Shinzato[2], and M. D. Stern[1], [1]*Department of Animal Science, University of Minnesota, St. Paul,* [2]*Ajinomoto Heartland Inc., Chicago, IL.*

Fermentation biomass (FB) is a dried bacterial co-product derived from lysine production (Ajinomoto Heartland Inc.). The objective of this study was to determine if FB can be used as a protein source in ruminant diets. The study consisted of one experimental period where 8 dual-flow continuous culture fermenters were inoculated with rumen fluid. The experimental period consisted of a 7-d adaptation followed by 3 sampling days. Substrate for the microbes was provided by one of 2 isonitrogenous diets, CON or DFB. In CON diet, soybean meal (SBM) provided 55% of total CP, and in DFB diet, SBM and FB provided 12 and 45% of total CP, respectively. CON contained 3% molasses, 16% ground corn, 13% grass hay, 48% corn silage, and 20% SBM on a DM basis. DFB contained 3% molasses, 18.4% ground corn, 13% grass hay, 50% corn silage, 8.5% SBM, and 6.7% FB. Fermenters were fed 75 g/d of DM divided into 8 equal portions. Anaerobic conditions were maintained by infusion of N_2; pH was maintained between 5.8 and 6.8; and temperature was set at 38.6°C. On sampling days, liquid and solid effluent outflows were collected, combined, and homogenized to be used for chemical analysis. Both treatments had an average pH of 5.9. There was no effect ($P > 0.1$) of treatment on apparent or true OM digestibility (%). Nitrogen source had no effect ($P > 0.1$) on total-N, dietary-N, and bacterial-N flows. Addition of FB decreased ($P < 0.05$) ammonia-N flow from 0.41 to 0.23 g/d and tended to decrease ($P = 0.06$) effluent ammonia concentration from 17.1 to 9.7 mg/100 mL. Histidine and methionine flows increased ($P < 0.05$) from 0.48 to 0.53 and 0.18 to 0.20 g/d, respectively, when FB partially replaced SBM in the diet, but there were no effects ($P > 0.1$) on other AA or total AA. There was a trend ($P = 0.08$) in percent change from essential AA input (CON = 68.9% versus DFB = 63.74%) and from non-essential AA input (CON = 73.62% versus DFB = 82.22%); however, there was no effect ($P > 0.1$) on percent change of total AA. Results indicate that FB elicited a similar response in N metabolism and AA flows to SBM and may be used as a protein source in ruminant diets.

Key Words: continuous culture, fermentation biomass, protein

W353 Plasma metabolites and rumen ammonia concentration in steers fed high-forage diets and supplemented non-protein nitrogen.

C. L. Cox*[1], R. H. Pritchard[1], B. P. Holland[1], and J. S. Jennings[2], [1]*South Dakota State University, Brookings,* [2]*Alltech Inc., Brookings, SD.*

The objectives were to determine if Optigen, a slow-release NPN source, has a slower N release than urea and whether pelleting affects Optigen

N release. Treatments (TRT) were 1) control non-urea pellet, 11.0% CP; 2) ruminally pulse dosed Optigen, 12.4% CP; 3) Optigen incorporated into a pellet, 11.3% CP or 4) urea ruminally pulse dosed, 12.8% CP. Diets were 50% forage (oat hay; 5.5% CP, 66% NDF) and 50% pelleted feed (beet pulp, corn, soybean meal). NPN as a percent of dietary CP (36 ± 0.5%) did not vary among TRT 2, 3, and 4. Diets were fed to 4 ruminally fistulated steers (BW 387 ± 28.9 kg), fitted with indwelling jugular catheters, in a 4x4 Latin square designed experiment. Pellet was fed at 0800 (t 0) and consumed within 20 min. Pulse doses of Optigen or Urea occurred at t 0. Blood samples were collected in 10 min intervals (0800 to 1130), 1 h intervals (1300 to 1600), and 2 h intervals (1600 to 2000). Rumen fluid samples were taken at 1 h pre-feeding and at 0, 1, 4, 8, 12 and 16 h post feeding. TRT 2 and 4 resulted in higher dietary CP than TRT 1 and 3 (12.6 v 11.2%; $P < 0.01$).Diet did not affect DMI (6.5 ± 0.2 kg). At t 0, rumen ammonia-N (RAN; 4.4 ± 5.8 mg/dl), plasma urea-N (PUN; 10.0 ± 0.9 mg/dl) and blood ammonia-N (BAN; 0.8 ± 0.03 mg/dl) were similar across TRT. RAN was greatest for TRT 4 (28.1 ± 4.6 mg/dl) and similar between TRT 1, 2, and 3 (6.4 ± 5.3, 10.8 ± 4.6, 8.5 ± 5.3, respectively; $P < 0.05$). A TRT by time interaction occurred because of 60 min post feeding RAN concentrations of 8.6 ± 12.4, 34.6 ± 10.7, 25.3 ± 12.4 and 138.9 ± 10.7 mg/dl, for TRT 1 through 4, respectively ($P < 0.001$). PUN concentrations of 11.6, 11.5, 10.9 and 14.58 mg/dl, respectively, were not affected ($P > 0.05$) by time or TRT. BAN concentrations were highest for TRT 4 ($P < 0.05$) and peaked during 50 to 80 min post feeding. TRT 3 caused lower BAN concentrations compared with TRT 2 ($P < 0.05$) which was consistent with decrease in RAN at 60 min post feeding. Optigen had a slower rate of N release than urea, and was not adversely affected by pelleting.

Key Words: beef cattle, blood ammonia, non-protein nitrogen

W354 Gossypol and total phenols of eleven varieties of whole cottonseed (*Gossypium hirsutum*) in the north of Argentina.

M. García*[1], C. Berton[1], E. Casenave[1], M. Nazareno[1,2], and J. I. Arroquy[3], [1]*FAyA, UNSE, Santiago del Estero, Argentina,* [2]*INQUINOA-CONICET, Santiago del Estero, Argentina,* [3]*INTA - EEA Santiago del Estero, Santiago del Estero, Argentina.*

Whole cottonseed (WCS, *Gossypium hirsutum*) is a feedstuff usually fed in beef and dairy cattle rations. Gossypol is a polyphenol pigment in WCS and cotton byproducts, and its concentrations depend on several factors such as genotype, temperature, and rainfall. This pigment is considered as an antiquality factor that might affect animal performance and ruminal metabolism. The objective of this study was to quantify gossypol concentration and nutritional profile of WCS from 11 varieties cultivated in Northern Argentina, and usually fed to cattle. Varieties studied were: Guazuncho 3, Pora, Poraite, New opal BT, Guazuncho 2000 RR, BT604, BT404, Cacique, Chaco 530, Oro blanco, and an experimental cultvirar. Samples were collected in 2004, 2006, 2007, 2008, 2009 and 2011 were analyzed for total soluble protein, ash, total fat, total phenolic compounds (TF; Folin-Ciocalteu), and free gossypol. Gossypol was analyzed by HPLC-DAS with external standard using a purified gossypol. Total phenolic compounds concentration in the varieties oscillates from 0.54 to 1.16% (Tannic acid equivalent). Gossypol content in WCS was 0.06–1.36%. Soluble protein varied from 0.53 to 2.24%. Total fat was 17.59–25.65%. Results from this preliminary study indicate small variation in gossypol and TF levels among 11 varieties grown in the north of Argentina.

Key Words: antiquality, cotton varieties, gossypol

W355 Influence of nitrogen fertilization and fibrolytic enzymes on digestibility and utilization of the nutrients of ryegrass (*Lolium multiflorum* var. Jumbo) hay fed to Holstein steers.

J. A. Villarreal,* J. E. Camargo, E. G. Alvarez, J. Rodriguez, E. Vazquez, B. H. Gutierrez, M. F. Montano, and V. M. Gonzalez, *Universidad Autonoma de Baja California, Mexicali, BC, Mexico.*

To evaluate the influence of fibrolytic enzyme addition × N fertilization (100, 200 or 300 kg of N/ha) on digestive function of ryegrass hay offered as basal diet, 6 Holstein steers (143 ± 5 kg LBW) equipped with cannulas in rumen and duodenum proximal were distributed in a split plot design. Orthogonal contrasts were used to test for linear, quadratic, and cubic effects of increasing N fertilization. Daily enzyme levels tested were 0 vs. 15 g/d and N fertilization levels applied to ryegrass were 100, 200, and 300 kg N/ha. Chromic oxide (0.3% as daily DMI basis) was added as digestive internal marker to basal diet. There was no interaction ($P \geq 0.05$) between enzyme and N fertilization. Enzyme addition increased N ($P \leq 0.05$; 76.6 vs. 77.4 g/d ±5.7) and microbial N flow ($P \leq 0.05$; 54.5 vs. 57.9 g/d ± 5.0) to the duodenum, N efficiency ($P \leq 0.05$; 1.34 vs. 1.42 ±0.1), microbial efficiency ($P \leq 0.01$; 24.6 vs. 26.5 ± 2.7) and postruminal OM digestion ($P \leq 0.10$; 42.1 vs. 45.5± 5.1). Nitrogen fertilization increased (linear component, $P \leq 0.01$) feed N leaving the abomasum and the OM rumen digestion ($P \leq 0.05$). Passage and digestion rates were not influenced ($P \geq 0.05$) by treatments. Fibrolytic enzymes had more influence on N metabolism in the rumen and total tract than for N fertilization.

Key Words: fibrolytic enzyme, N fertilization, rye grass

Ruminant Nutrition: Other Ruminants

W356 Diurnal pH of the first compartment stomach of alpacas fed alfalfa or grass hay supplemented with oats, corn, and corn/oats/barley.

B. Harris*[1], T. F. Robinson[1], and N. I. Bott[2], [1]*Brigham Young University, Provo,* [2]*Bott Veterinary Services and Consulting, Elk Ridge, UT.*

The purpose of this study was to determine the diurnal pH variation of the first compartment stomach (C1) of alpacas (vicugna pacos) fed grass hay (G) or alfalfa hay (A) and acute addition of grain supplements; oats (O), ground corn (C) or corn/oats/barley (COB). Three male (+3 yrs, 65 kg BW) were fitted with a C1 fistula, housed in metabolism crates and fed ad libitum grass hay or alfalfa hay and water. The treatments (TRT) included the addition of 454 g of O, C or COB to G (GO, GC, GCOB) or to A (AO, AC, ACOB). The alpacas were acclimated to A and each grain TRT was randomly administered followed by a 30 d acclimation period to G followed by the random administration of each grain so that each grain TRT was represented during each 3-d collection period. A pH probe was calibrated, fitted through the fistula plug and positioned at the anterior, ventral portion of C1 one day prior to beginning of data collection. Treatment periods included d1 to d7 diurnal pH collection of A or G. Grain TRT pH data were collected during d8-10, d 15 to 17 and d 22 to 24. Diurnal patterns for a 24-hour period are an average of the 3-d collection period. Dry matter intake (DMI) was 1415, 1142, 1146, and 1192 g for A, AO, AC and ACOB; and 1331, 1207, 1206, and 1260 for G, GO, GC and GCOB. Only A DMI was different from the alfalfa + grain treatments ($P < 0.05$). Overall pH was 6.87, 6.78, 6.78 and 6.56 for A, AO, AC and ACOB; and 6.95, 6.89, 6.76 and 6.83 for G, GO, GC and GCOB. Alfalfa pH was more acidic than G ($P < 0.05$) and was more basic than AO and AC which are more basic than ACOB ($P < 0.05$). All G TRT were different from each other ($P<0.05$). Diurnal pH patterns for each TRT showed a decrease in pH followed by a return. As indicated by overall pH, the COB pattern decreased the lowest before return. The alpaca C1 has a very effective buffering system, but acute intake of highly fermentable feeds does have a dramatic effect on pH. Support was provided by Brigham Young University and The Camelid Center.

Key Words: alpaca, compartment 1, pH

W357 Effect of castration on performance and carcass traits of crossbreed lamb on different time on feed.

M. R. Mazon*[1], P. R. Leme[1], L. S. Oliveira[1], R. F. Carvalho[2], C. A. Zotti[1], L. E. Zanoni[1], D. M. C. Pesce[2], and S. da Luz e Silva[1], [1]*Faculdade de Zootecnia e Engenharia de Alimentos (FZEA/USP), Pirassununga, São Paulo, Brazil,* [2]*Pontifícia Universidade Católica de Minas Gerais (PUC Minas), Poços de Caldas, Minas Gerais, Brazil.*

The use of non-castrated (NC) males for meat production has been an increased practice because they grow fast, utilize feed more efficiently and show high-yielding and leaner carcasses than castrated males (CM). To evaluate the performance and carcass traits of CM or NC crossbreed lambs slaughtered after different time on feed, 48 Dorper × Santa Ines males (32 ± 5.04 kg BW, 90 d old) were individually allotted in pens according to initial BW (block) and fed a diet with 75% whole corn grain, 20% of pelleted protein and mineral mix and 5% of coast cross hay. After 14 d of adaptation period 24 animals were Burdizzo castrated. Feed and orts were registered daily for DMI and feed efficiency (FE) determinations. Animals were weighed at the beginning of the trial and every 14 d. Two CM died during the trial due to urolithiasis problems. Animals were slaughtered after 36 or 78 d of feeding (half of each sex) for hot carcass weight (HCW) and *Longissimus* muscle area (LMA) and backfat thickness (BFT) at 12th rib level determinations. There was no significant sex x age interaction for any trait. BW at slaughter was greater for NC (52.2kg) than CM (46.8kg; $P = 0.005$). Non-castrated also had greater ADG (0.34 vs 0.27 kg/day; $P = 0.001$), DMI (1.2 vs 1.1 kg;$P = 0.007$) and FE (0.30 vs 0.25 kg ADG/kg DMI;$P < 0.006$), HCW (24.8 vs 22.7; $P = 0.030$), LMA (18.0 vs 16.1cm ^{2}; $P = 0.018$) with no difference in BFT (3.4 mm). Animals fed for 36 d had smaller HCW (21.2 vs 26.3 kg; $P < 0.001$), LMA (16.0 vs 18.2 cm ^{2}; $P = 0.005$) and BFT (2.9 vs 4.0 mm; $P = 0.030$) than those fed 78 d, as expected. Animals slaughtered after 78 d of feeding were heavier (54.2 vs 44.9 kg; $P < 0.001$) and had smaller ADG (0.33 vs 0.28 kg/day; $P = 0.019$) than those slaughtered at 36 d. DMI (mean = 1.15 kg DM/day) did not differ between time on feed but animals fed for 78 d had higher FE than those fed for 36 d (0.25 vs 0.29 kg ADG/kg DMI; $P = 0.020$. Non-castrated crossbreed lambs could be finished with a better performance and appropriate degree of fatness when fed high concentrate diets for short periods.

Key Words: feedlot, high concentrate, sheep

W358 Efficacy of novel feed products to reduce locoweed toxicity in wether lambs.

F. A. Allataifeh*[1], C. A. Loest[1], M. N. Sawalhah[1], L. N. Tracey[1], J. Browne-Silva[1], J. B. Taylor[2], and D. M. Hallford[1], [1]*New Mexico State University, Las Cruces,* [2]*USDA-ARS, Dubois, ID.*

Locoweed may result in impaired performance and possibly death when consumed by livestock. Novel products are needed that increase the tolerance of livestock to swainsonine, the toxicant in locoweed. The objective was to determine the efficacy of proprietary feed products to reduce locoweed toxicity in sheep. Wether lambs (n = 40; 39 ± 0.4 kg BW) were housed individually and fed 620 g/d of alfalfa hay and 100 g/d of corn-based feed in equal portions twice daily for 20 d. Lambs were equally divided into 4 BW blocks, and within block were randomly assigned to 1 of 5 treatments (randomized complete block design). Treatments were: no locoweed or feed products (CON); 20 g/d of locoweed (LOCO); 20 g/d of locoweed and 50 g/d of feed product 1 (AK1); 20 g/d of locoweed and 50 g/d of feed product 2 (AK2); 20 g/d of locoweed and 50 g/d of feed product 3 (AK3). Locoweed and feed products replaced alfalfa hay in the basal diet. Serum (from venous blood) was collected on d 0, 3, 6, 9, 12, 15, 18, and 20, and rumen fluid samples were collected on d 9 and 20. Swainsonine was detected in serum and rumen fluid of lambs fed LOCO, AK1, AK2, and AK3, but was not detected in lambs fed CON. Serum swainsonine of lambs fed LOCO, AK1, AK2, and AK3 increased ($P < 0.05$) from d 0 to d 3, and remained elevated for the remainder of the study. Serum alkaline phosphatase was greater ($P < 0.05$) in lambs fed treatments with locoweed than CON, and was less ($P < 0.05$) in lambs fed AK3 than LOCO. Serum thyroid hormones (T3 and T4), serum total iron, and serum transferrin saturation were lower ($P < 0.05$) in lambs fed treatments with locoweed than CON. Serum thyroid hormones (T3 and T4) were also lower in lambs fed AK1 than CON. Serum insulin was lower ($P < 0.05$) in lambs fed AK2 than LOCO. Serum total iron binding capacity, urea N, NEFA, and rumen fluid pH, ammonia, and total VFA were not different ($P \geq 0.10$) among treatments. In locoweed-fed treatments, rumen fluid swainsonine was not different ($P \geq 0.10$) for lambs fed AK1, AK2, or AK3 than LOCO. The results suggest that the novel feed products evaluated in the current study did not reduce symptoms of subclinical toxicity in wether lambs consuming locoweed. Authors acknowledge A. Temple and Agri-King, Inc.

Key Words: locoweed, serum, sheep

W359 Swainsonine excretion, nutrient digestibility, and nitrogen retention of lambs fed alfalfa hay, locoweed, and novel feed additives. F. A. Allataifeh,* C. A. Loest, M. N. Sawalhah, F. Castillo, A. F. Cibils, and E. J. Scholljegerdes, *New Mexico State University, Las Cruces.*

Novel products are needed that could reduce locoweed toxicity, alleviate impaired performance, and prevent possible death when consumed by livestock. This study evaluated the effect of 3 feed additives (Agri-King) on swainsonine intake and excretion, nutrient digestibility, and N retention of 40 wether lambs (39.2 ± 0.38 kg initial BW). Lambs were blocked by initial BW and assigned to 5 dietary treatments in a randomized complete block design (4 blocks). Treatments were a control diet (86% alfalfa hay and 14% corn-based supplement) fed to lambs at 1.8% of BW (as fed) for 20 d (CON), CON with 20 g/d locoweed replacing alfalfa hay (LOCO), LOCO with 50 g/d of feed additive 1 replacing alfalfa hay (AK1), LOCO with 50 g/d of feed additive 2 replacing alfalfa hay (AK2), and LOCO with 50 g/d of feed additive 3 replacing alfalfa hay (AK3). Lambs were housed individually for 14 d in pens and then for 6 d in metabolism crates for total fecal and urine collections. Statistical analysis used the mixed procedure of SAS with lamb as the experimental unit. Intake, fecal, and urinary swainsonine were greater ($P < 0.05$) for LOCO, AK1, AK2, and AK3 than CON. Intake of swainsonine was lower ($P < 0.05$) for AK3 than LOCO, fecal swainsonine was lower ($P < 0.05$) for AK1 than LOCO, and urinary swainsonine was lower ($P < 0.05$) for AK1 and AK2 than LOCO. Treatments did not affect ($P \geq 0.20$) DM intake, fecal DM, or DM digestibility. Nitrogen intake was lower ($P < 0.05$) for AK1, AK2, and AK3 than for CON and LOCO, but fecal N and urine N was not affected ($P \geq 0.11$) by treatments. Nitrogen digestibility was not different ($P = 0.26$) among treatments, but N retention was lower ($P < 0.05$) for AK1 and AK3 than CON. In summary, lamb consumption of locoweed with the feed additives evaluated in the current study does not significantly affect DM and N digestibility. Lower fecal and urinary swainsonine in lambs receiving AK1 indicated that it may affect metabolism of swainsonine in sheep. Authors acknowledge A. Temple and Agri-King Inc.

Key Words: swainsonine, nitrogen retention, sheep

W360 The serosal-to-mucosal urea flux across the cervine ruminal epithelium is not affected by mucosal ammonia or phloretin. M. E. Walpole*[1], G. B. Penner[1], M. Woodbury[2], and T. Mutsvangwa[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*Department of Large Animal Clinical Services, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Urea transporter (UT) proteins are involved in the movement of urea across the gastrointestinal tract in ruminants. Few studies with domesticated ruminants indicates that increasing ruminal ammonia concentration has inhibitory effects on urea transfer from blood into the rumen, but the exact mechanisms involved have not been elucidated. The effect of mucosal ammonia concentration on the serosal-to-mucosal flux of urea ($J_{sm\text{-}urea}$) was examined. Five white-tail deer (*Odocoileus virginianus*) bucks were killed and ruminal epithelial tissue was collected and mounted in Ussing chambers under short-circuit conditions. To simulate in vivo physiological conditions, the serosal buffer contained 1 m*M* of urea and was adjusted to a pH of 7.4, while the mucosal buffer lacked urea and pH was adjusted to 6.2. Treatments were control (no ammonia), 6.65 m*M* ammonia (as $[NH_4]_2CO_3$), and ammonia with phloretin (1 m*M*; a UT inhibitor). Fluxes of urea ($J_{sm\text{-}urea}$) and mannitol ($J_{sm\text{-}mannitol}$) were measured in parallel using ^{14}C-labelled urea (26 kBq/mL) and ^{3}H- labelled mannitol (74 kBq/mL), respectively, with $J_{sm\text{-}mannitol}$ being used as an indicator of paracellular transport. Ruminal ammonia and blood urea nitrogen concentrations averaged 12.3 and 34.4 mg/dL, respectively. The additions of ammonia or phloretin had no effect on tissue conductance (G_t) or short-circuit current (I_{sc}). Both $J_{sm\text{-}urea}$ and $J_{sm\text{-}mannitol}$ were not inhibited ($P > 0.05$) by mucosal ammonia or the serosal addition of phloretin. The $J_{sm\text{-}urea}$ and $J_{sm\text{-}mannitol}$ were highly correlated ($R^2 = 0.88$; $P < 0.001$), thus suggesting that $J_{sm\text{-}urea}$ was mediated via para-cellular pathways. Ruminal ammonia concentration was not correlated with $J_{sm\text{-}urea}$; however, blood urea nitrogen concentration was negatively correlated with $J_{sm\text{-}urea}$ ($R^2 = 0.81$; $P = 0.038$). We conclude that, because of the significant correlation between $J_{sm\text{-}urea}$ and $J_{sm\text{-}mannitol}$ and the lack of inhibitory action for phloretin, a known inhibitor of UT, urea flux across the ruminal epithelium in white-tail deer is likely via para-cellular routes.

Key Words: ammonia, rumen, urea transporter

Ruminant Nutrition: Feed Additives

W361 Effects of different feed additives on performance and carcass traits of feedlot cattle. C. A. Zotti, S. da Luz e Silva,* L. S. Martello, R. L. Meirelles, A. P. dos Santos Silva, P. L. Alvarez, P. H. Cancian, A. C. Ianni, L. E. Zanoni, and P. R. Leme, *Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de São Paulo, Pirassununga, SP, Brazil.*

Feed additives are largely used in beef cattle diets to improve performance and reduce risks of nutritional disorder diseases like acidosis and timpanism. However, some countries tend to ban the use of ionophore in animal nutrition due to the risk of resistance of some microorganisms. Therefore, alternatives to non-antibiotic additives must be studied. The objective of this work was to investigate the effects of different feed additives on performance and carcass traits of beef cattle. Twenty 2 Nellore bulls (initial BW 353 ± 20.9 kg) and 22 steers (initial BW 320 ± 1.5 kg; 21mo old) were fed high concentrate diet (85% of concentrate and 15% of sugarcane bagasse as roughage source). The animals were allotted in 4 pens equipped with calan gate system and randomly assigned within sex (block) to one of the 4 treatments: Monensin at 30 mg/kg DM (MON); Virginiamycin at 30 mg/kg DM (VIR); combination to MON (15 mg/kg DM) plus VIR (15 mg/kg DM) (MPV); Blend of Castor Oil Acid and Cashew Oil fed at 500 mg/kg DM (COC). Feed and orts were computed daily for each animal for DMI and feed efficiency calculations. Animals were weighed (BW) and ultrasound scanned at the first day of the feedlot and each 28 d. Ultrasound measurements taken were Longissimus muscle area (ULMA) and backfat thickness (UBFT) between 12th and 13th ribs. After 112 d on feed, cattle were slaughtered and hot carcass weight (HCW), kidney, pelvic and inguinal fat (KPIF) and dressing percentage (DP) calculated. Dry matter intake for treatment MON was smaller (9.7kg/day; $P = 0.04$) when compared with COC (11.1kg/day) with no differences of VIRG and MPV (10.1 and 10.4kg/day, respectively). There was no effect of treatments on ADG (1.60 ± 0.26 kg), feed efficiency (0.156 ± 0.02 kg ADG/kg DMI), final BW (510 ± 47 kg), HCW (307 ± 27.2 kg), dressing percentage (60.0 ± 1.78%), UBFT (5.9 ± 2.1 mm) and KPIF (3.12 ± 1.62%) at slaughter. Longissimus muscle area was higher for MPV (80.9cm^2; $P = 0.008$) than COC (74.4cm^2) and VIR (74.4cm^2). The additives studied can replace ionophores to beef cattle fed high concentrate diet, without affecting animal performance and most of carcass traits.

Key Words: additives, feedlot, Nellore

W362 Effect of *Propionibacterium freudenreichii* supplementation in diets containing canola or flaxseed oils on in vitro methanogenesis and lipid biohydrogenation. S. Ding[1,2], S. J. Meale*[1,2], M. L. He[2], J. Long[3], A. Y. Alazzeh[2], T. A. McAllister[2], and A. V. Chaves[1], *[1]Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia, [2]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [3]Department of Animal Science, Northeast Agricultural University, Haerbin, Heilongjiang, China.*

The addition of propionibacterium as a direct fed microbial may provide a competitive pathway to methanogenesis for H_2 disposal in ruminants. Additionally, it has the potential to inhibit the biohydrogenation of polyunsaturated fatty acids (PUFA). Flaxseed and canola oils have been shown to reduce methane formation and rumen biohydrogenation due to the dominant levels of linolenic acid (C18:3) and linoleic acid (C 18:2), respectively. However, to-date, no studies have been undertaken regarding the ability of propionibacterium to mitigate methane from diets supplemented with plant oils or its effects on PUFA biohydrogenation. Thus, a 48 h, in vitro batch culture was conducted to determine the effects of *Propionibacterium freudenreichii* (PFB) on (1) in vitro VFA production and methane and (2) fatty acid biohydrogenation, in a backgrounding diet supplemented with 2 plant oils. Treatments were: backgrounding diet (CON); CON + PFB (CPB) (4x109 cfu propionibacteria/40 mL inoculum); CON + canola oil (6% DM; CCO); CCO + PFB (CCPB), CON + flaxseed oil (6% DM; FLO) and FLO + PFB (CFPB). Methane and gas production was measured at 3, 6, 12, 24, 48 h, whereas, total ruminal VFA were determined at 0, 6, 24 and 48 h of incubation. In vitro incubations were repeated twice with 3 replicates per treatment in each run. Data were analyzed using the MIXED procedure of SAS with treatments as fixed effect, and incubation run and interaction incubation run × treatments as random effects. Cumulative gas production (mL), CH_4 production (mL/g DM) and total ruminal VFA concentration (mM) were not affected by treatment ($P \geq 0.10$). However, there was a tendency ($P = 0.07$) for both oil-based diets, with or without PFB, to reduce CH_4 production (mL/g DM) at 24 and 48 h. Additionally, oil increased ($P \leq 0.002$) the percentage of CLA+VA at 24 and 48 h. Propionibacterium did not affect ($P > 0.05$) biohydrogenation. However, flaxseed and canola oil increased ($P < 0.001$) the proportion of unsaturated fatty acids and decreased ($P < 0.001$) the proportion of saturated fatty acids in the total incubation period, thus inhibiting biohydrogenation based on oil diets. Canola oil based treatments had the highest ($P \leq 0.003$) proportion of C18:1 (cis-9) across all time points, whereas flaxseed oil groups had the greatest ($P \leq 0.04$) percentages of PUFA including C18:3, C18:1 (cis-15), biohydrogenation intermediates from C18:3 at 6, 24, 48h, and CLA (cis-9,trans-11) at 6, 24h, indicating the capability of flaxseed oil to alter biohydrogenation in favor of desirable PUFA production. In conclusion, propionibacterium did not significantly affect methanogenesis and lipid biohydrogenation based on either flaxseed or canola oil diets on current in vitro study.

Key Words: biohydrogenation, methane, lipids

W363 Efficacy of an autolysed yeast product (Levabon Rumen) for ruminants versus live yeast and yeast culture in vitro. A. Ganner*[1], C. Stoiber[1], I. Dohnal[1], K. Deckardt[2], F. Klevenhusen[2], G. Schatzmayr[1], and Q. Zebeli[2], *[1]Biomin Research Center, Tulln, Lower Austria, Austria, [2]University of Veterinary Medicine, Vienna, Austria.*

Various yeast products for ruminants have been reported to improve rumen microbial activity, feed utilization and cow performance. Increasingly, literature reports about the benefits of live yeast and yeast culture. However, little has been reported about the effect of autolysed yeasts for ruminants. Moreover, the mode of action of different yeasts, with respect to improving animal performance, is still not completely understood. Target of the present study was to evaluate the efficacy of a novel yeast derivative (Levabon Rumen) on anaerobic bacterial count (batch culture); on crude fiber, dry matter and crude protein digestibility (RUSITEC) versus yeast culture and live yeast, which are used for animal feeding. In a first in vitro batch culture study, rumen simulation reactors were filled with rumen fluid, mixed with saliva and incubated under anaerobic conditions for 24 h. The yeasts (in mg yeast/flask: Levabon Rumen 40–300; yeast culture1 300, 600; yeast culture2 200, 400; live yeast 0.5, 5) were mixed into the ration (50% hay and 50% concentrate). Total viable anaerobic bacteria (batch culture) were counted (cfu/g). In a second experiment with the rumen simulation technique (RUSITEC), different levels of the yeast products (in mg yeast/12 g dry matter: Levabon Rumen 3, 6, 12, 18, 24;

yeast culture1 12, 36; yeast culture2 6, 12; live yeast1 2.4; live yeast2 0.3) were fed daily for 14 d. The samples were mixed into a ration consisting of 50% hay and 50% concentrate. The parameters measured include nutrient digestibility (Weender analysis), pH, redox potential and volatile fatty acids. Results indicate improved digestibility in RUSITEC and increased amount of anaerobic bacteria in batch culture by the autolysed yeast as well as by the probiotic yeast and the yeast culture. Volatile fatty acids also increased. None of the yeast showed an effect on either pH or redox potential, perhaps due to continuously buffering the system and strictly anaerobic conditions. Based on these findings, Levabon Rumen represents a promising feed additive to improve cattle health and performance.

Key Words: autolysed yeast, prebiotic, ruminants

W364 Effect of monensin on methane emissions in dairy cattle can be explained by level of dry matter intake and fat content of the diet.

J. A. D. R. N. Appuhamy*[1], A. B. Strathe[1], S. Jayasundara[2], C. Wagner-Riddle[2], J. Dijkstra[3], J. France[2], and E. Kebreab[1], [1]*University of California, Davis,* [2]*University of Guelph, Guelph, ON, Canada,* [3]*Wageningen University, Wageningen, the Netherlands.*

Methane (CH_4) is an important greenhouse gas that contributes to climate change. Cattle produce the majority of CH_4 emissions from ruminants accounting for about 30% of the global emissions. Monensin improves feed conversion efficiency and increases propionic acid molar proportion in the rumen. Several studies have investigated the effects of monensin on CH_4 emission from dairy cows and the results vary widely. The objectives of the present study were to conduct a meta-analysis to infer about the overall effect of monensin feeding on CH_4 emission from dairy cows and to quantify factors explaining between-study variability of the monensin effect. Data of mean and SD of CH_4 emission (g/d) in monensin and control groups, sample size (N), treatment duration (T, d), DMI (kg/d), monensin dose (mg/kg of DMI), and basal diet nutrient contents (g/kg of DM) from 11 controlled-trials were included. The Metafor package in R was used to conduct the meta-analysis. Effect size (ES, g/d) was calculated as difference between the means of monensin feeding and control groups. A model accounting for random study effects revealed significant ES heterogeneity between trials (98%, $P < 0.001$) suggesting T, DMI, monensin dose and nutrient contents as potential covariates for explaining between-study variability. The final model including potentially significant covariates were selected using Likelihood-ratio tests. Feeding monensin was shown to have a non-significant effect (ES = −2.88 ± 3.28 g/d, $P = 0.380$) on CH_4 emission from dairy cows. Effect size was positively (covariate coefficient = 1.35 ± 0.56, $P = 0.016$) and negatively (covariate coefficient = −5.15 ± 1.51, $P = 0.001$) associated with DMI and crude fat content, respectively. Monensin dose and T did not significantly affect ES. Inclusion of DMI and fat content into the model reduced total heterogeneity of ES (τ^2) by about 70% ($\tau^2 = 322$ vs. 100). Dry matter intake and crude fat content were significant and could explain between-study variability of the monensin effect on CH_4 emission from dairy cows.

Key Words: dairy cows, methane, monensin

W365 Effects of dietary supplementation of a yeast product on performance and morbidity of newly received beef heifers.

C. H. Ponce*[1], J. S. Schutz[1], C. Elrod[2], U. Y. Anele[1], and M. L. Galyean[1], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock,* [2]*Varied Industries Corp. Inc., Mason City, IA.*

Two truckloads of beef heifers (n = 237; average initial BW = 191 kg ± 1.17) were used to evaluate the effects of a yeast culture/enzymatically hydrolyzed yeast product (Celmanax; Varied Industries Corp. Inc., Mason City, IA) included in a 65% concentrate receiving diet on performance and percentage of bovine respiratory disease (BRD) morbidity during a 35-d receiving period. Treatments included: 1) the 65% concentrate receiving diet with the addition of Celmanax; 14 g/heifer/d; mixed in a carrier; or 2) the 65% concentrate receiving diet without Celmanax (Control; 14 g/heifer/d of carrier only). No load × treatment interactions ($P > 0.157$) were detected for any measures of performance or BRD morbidity. Initial BW did not differ ($P > 0.537$) between treatments nor did d-35 BW ($P = 0.332$). Average daily gain for d 0 to 14 ($P = 0.052$) and for the overall 35-d ($P = 0.078$) period tended to be greater for Celmanax heifers than for controls. Intake of receiving diet DM was greater ($P \leq 0.025$) by the Celmanax heifers than by Control heifers at all the measurement periods during the experiment, but G:F did not differ ($P > 0.175$) between treatments. The proportion of heifers treated once for BRD tended ($P = 0.094$) to be less with the Celmanax treatment (4.1 for Control vs. 10.5% for Celmanax). Results indicate that heifers fed Celmanax ate more receiving diet DM and tended to gain more than Control heifers, with a tendency for decreased BRD morbidity during a 35-d receiving period.

Key Words: newly received beef cattle, feedlot performance, yeast product

W366 Effect of oregano, ginger and thyme oils on in vitro rumen fermentation and methane emission.

F. G. Vilela,* I. C. S. Bueno, A. S. Netto, T. S. Canaes, J. E. Freitas Jr., B. C. Venturelli, and F. P. Rennó, *University of São Paulo, Pirassununga, SP, Brazil.*

In vitro semi automated gas production technique has been used to evaluate the effects of essential oils at different levels (0, 15, 30, 45 and 60 μ/ml) on ruminal fermentation and methane production. The investigated essential oils were *Origanum vulgare* (OV_{15}, OV_{30}, OV_{45}, OV_{60}, *Zingiber officinale* (ZO_{15}, ZO_{30}, ZO_{45}, ZO_{60}) and *Thymus vulgaris* (TV_{15},TV_{30}, TV_{45}, TV_{60}). The analysis of the essential oils by gas chromatography - mass spectrometry demonstrated that the principal components were carvacrol (70%) and thymol (11%) in OV, zingiberene (33%) and zingerone (17%) in ZO, thymol (40%) and carvacrol (13%) in TV. A total mixed ration (50% roughage: 50% concentrate) was incubated with buffered rumen fluid. Data were analyzed using PROC MIXED of SAS 9.1. The inclusion of OV, TV, ZO_{15} and ZO_{30} did not affect significantly on true digestibility of dry matter and organic matter, while ZO_{45} and ZO_{60} decreased significantly ($P \leq 0.05$). The efficiency of microbial protein was estimated by partitioning factor (PF, estimated as ratio of truly organic matter degradation and gas volume produced in 24 h of incubation). There was no significant effect of investigated essential oils on PF except OV_{45}, TV_{45} and TV_{60} which improved significantly ($P \leq 0.05$) the PF. There was no significant effect of essential oils on the production methane except OV_{45} and TV_{60} which decreased significantly ($P \leq 0.05$) the methane production. The NH_3-N concentration was not altered with inclusion of essential oils at different doses. The short chain fatty acids concentration was not altered with inclusion of essential oils except OV_{30}, $TV_{45}$and TV_{60}which increased significantly ($P \leq 0.05$) the propionate concentration. This study suggested that essential oils have the potential to affect rumen fermentation and OV_{45} and TV_{60} could be a promising methane mitigating agent.

Key Words: essential oils, gas production, rumen fermentation

W367 Effect of some essential oils on rumen fermentation and methane emission in vitro. F. G. Vilela,* I. C. S. Bueno, A. S. Netto, J. E. Freitas Junior, B. C. Venturelli, T. S. Canaes, and F. P. Rennó, *University of São Paulo, Pirassununga, SP, Brazil.*

The objective of this study was to evaluate in vitro the effects of essential oils at different levels (0, 15, 30, 45 and 60 µL/100 mL buffered rumen fluid) on ruminal fermentation by semi automatic gas production technique. The selected essential oils were *Rosmarinus officinalis* (RO_{15}, RO_{30}, RO_{45}, RO_{60}), *Syzygium aromaticum* (SA_{15}, SA_{30}, SA_{45}, SA_{60}) and *Pimpinella anisum* (PA_{15}, PA_{30}, PA_{45}, PA_{60}). The analysis of the essential oils by gas chromatography-mass spectrometry demonstrated that the principal components were 1.8 cineol (28%) and p-cimeno (13%) in RO, eugenol (40%) in SA and anethol (45%) in PA. The trial was conducted in duplicates making a total of 12 bottles for each treatment. The substrate used was the basal diet consisting of corn silage and concentrate (71.66% corn, 12.12% soybean meal and 10% soybean), in ratio 50:50. Ground samples (1 g) were incubated in 100 mL of diluted rumen fluid (10 mL mixed rumen fluid + 90 mL of buffer solution mineralized) in 160 mL serum bottles. Data were analyzed using PROC MIXED of SAS 9.1. There was no significant effect of essential oils on the production methane except PA_{45} and PA_{60} which decreased significantly ($P \leq 0.05$) the methane production. The inclusion of RO_{45}, RO_{60}, SA_{15}, SA_{30} and PA did not affect on true digestibility of dry matter and organic matter, while RO_{15}, RO_{30}, SA_{45} and SA_{60} decreased significantly. The efficiency of microbial protein was estimated by partitioning factor (PF, estimated as ratio of truly organic matter degradation and gas volume produced in 24 h of incubation). There was no effect of investigated essential oils on PF except SA_{45} and SA_{60} which improved significantly the PF. The short chain fatty acids concentration was not altered with inclusion of essential oils except PA_{30}, PA_{45} which increased significantly the propionate concentration. This study suggested that essential oils could modify the rumen fermentation and have a potential in methane mitigation, which may be beneficial for animal growth.

Key Words: essential oils, methane, degradation

W368 Effect of abomasal inorganic phosphorus infusion on phosphorus absorption in lactating dairy cows. X. Feng,* J. P. Jarrett, P. P. Ray, L. Karpinski, B. F. Willing, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective of the study was to evaluate the effect of inorganic P (Pi) supply on P disappearance from the intestinal tract of lactating dairy cows. Four ruminally and ileally cannulated crossbred cows were used in a 4 × 4 Latin square with 21-d periods. Cows were fed a total mixed ration containing 0.21% P, providing 50% of the cows' P requirement. Ytterbium (Yb) labeled corn silage and Co-EDTA were used as particulate and liquid phase markers, respectively, to measure digesta flow. Omasal samples were collected every 9 h from d 10 to 13 to measure omasal P flow from the basal diet. On d 13 to 21 of each period, each cow was infused daily with 0, 20.1, 40.2, or 60.3 g Pi into the abomasum and total collection was conducted on d 18 to 21. Ileal samples were collected every 9 h on d 18 to d 21. Feed, digesta, and fecal samples were analyzed for total P and Pi using the molybdovanadate yellow method and blue method, respectively. All data were analyzed using PROC GLIMMIX in SAS 9.2 using contrasts to evaluate linear and quadratic effects of Pi infusion dose. Dry matter (DM) intake, apparent DM digestibility, milk yield and milk total P were unaffected by Pi infusion ($P > 0.05$). Ileal flow and fecal excretion of total P and Pi increased linearly ($P < 0.05$) with increasing infused Pi. In the small intestine, net disappearance of total P and absorption of Pi decreased ($P < 0.05$; 67.7 to 37.4% and 83.2 to 52.8%, respectively) with increased Pi infusion. Similarly, total tract disappearance of total P and Pi decreased with increasing Pi infusion ($P < 0.05$; 74.3 to 54.3% and 81.1 to 66.6%, respectively). In the large intestine, net Pi absorption was unaffected but increasing Pi infusion increased disappearance of total P ($P < 0.05$). Results of this study suggest limits to Pi absorption in the small intestine.

Key Words: dairy cows, phosphorus absorption, phosphorus excretion

W369 Effects of essential oils on in vitro ruminal fermentation and methane production of a mixed diet. I. Mateos[1], A. Díez[1], C. Saro[1], D. Yáñez-Ruiz[3], M. D. Carro[1,2], and M. J. Ranilla*[1,2], [1]*Dpto. Producción Animal, Universidad de León, Campus de Vegazana, León, Spain,* [2]*Instituto de Ganadería de montaña (CSIC-ULE), Finca Marzanas, Grulleros, León, Spain,* [3]*Estación Experimental del Zaidín (CSIC), Camino del Jueves, Armilla, Granada, Spain.*

The effects of 6 doses (0 (control), 40, 80, 160, 320 and 640 mg/L incubation medium) of carvacrol (CAR), thymol (TYM), eugenol (EUG) and garlic oil (GO) on in vitro fermentation of a mixed diet (65:35 alfalfa hay:concentrate) were evaluated in batch cultures of mixed rumen microorganisms from the rumen of sheep fed the same diet. Previous in vitro studies have shown the ability of these compounds to modify ruminal fermentation, but the effects could be dose and diet dependent. After 24 h of incubation, the main fermentation variables were determined. Differences among treatments were declared at $P < 0.05$. Dose 640 mg/L of all additives tested inhibited almost completely rumen microbial fermentation, confirming their antimicrobial activity at high concentrations, and therefore the values were withdrawn from the statistical analysis. GO and EUG did not modify ($P > 0.05$) rumen fermentation at any other dose. TYM at 320 mg/L decreased ($P < 0.05$) total VFA, acetate, propionate and methane production, and increased ($P < 0.05$) acetate:propionate ratio compared with control. CAR has similar effects on VFA and propionate production at dose 160 mg/L, and tended ($P = 0.08$) to reduce methane production. At 320 mg/L, CAR also increased ($P < 0.05$) acetate:propionate ratio and decreased ($P < 0.05$) ammonia-N concentrations, compared with the control. These results confirm that essential oils supplementation shows different effects on ruminal fermentation depending on the administered dose and the nature of the compound. Under the conditions of this study the doses of essential oil that modified VFA profile and reduced methane production also resulted in a reduction in VFA production, which would indicate a decrease in feed digestibility and have negative consequences on animal productivity.

Key Words: essential oils, in vitro ruminal fermentation, methane

W370 Effect of feeding *Bacillus subtilis* and *Bacillus licheniformis* on dry matter and nutrient intake and digestibility by lambs fed a low quality roughage diet. E. Martínez-Loarte,* A. A. Rodríguez, and L. C. Solórzano, *University of Puerto Rico, Mayaguez, PR.*

The objective of this experiment was to evaluate the addition of *Bacillus subtilis* and *Bacillus licheniformis* (BSL) to the diet on DM, CP, and NDF intake and digestibility in growing lambs fed a diet consisting of 50% commercial tropical grass hay (mixtures of *Panicum maximum*, *Sorghum halapense*, and *Digitaria decumbens*, 71.7% NDF, 4.9% CP;) and 50% hay of the invasive weed *Hyparrhenia rufa* (78.8% NDF, 3.5% CP). Ten crossbred lambs (11.2 kg) were randomly assigned to one of 2 dietary treatments, with or without daily addition of BSL in the diet. The daily offering of hay was at the rate of 4% of body weight on a dry basis and water was available ad libitum. The bacterial strains were mixed with calcium carbonate carrier, and were included in the additive to provide

1.33×10^9 cfu/g supplying 1.33×10^8cfu/head/d. The additive was mixed with 225 g of a commercial concentrate (15.67% CP) and fed daily to the lambs during a 49 d period. Nutrient intake and digestibility (DM, CP, and NDF) were determined from d 42 to 49. Data was analyzed using the PROC MIXED procedure of SAS using the initial lamb body weight as covariance and Tukey′s test was used for mean separation. Total DM intake and tropical grass hay intake was higher ($P < 0.05$) in lambs consuming the additive containing BSL than control animals (484.26 vs 445.23 g/d and 236 vs 218 g/d, respectively), but intake of *Hyparrhenia rufa* hay was similar (32.18 vs 52.43 g/d). Total forage intake as percentage of total DM intake, and DM intake as percentage of lamb body weight was also higher ($P < 0.05$) in lambs consuming BSL than control (59.08 vs 55.09% and 2.36 vs 2.03%, respectively). Feeding the *Bacillus* strains to lambs also improved NDF digestibility (62.48 vs 58.71%), however, the experimental treatment did not affect DM and CP digestibility. In summary, addition of BSL improved total intake by lambs fed a diet containing commercial concentrate and low quality roughage as well as the individual tropical grass hay component. Addition of BSL to the diet also improved cell-wall digestibility of low quality forage by lambs.

Key Words: *Bacillus* spp., Tropical grass hay, *Hyparrhenia rufa*

W371 Efficacy of live yeast *Saccharomyces cerevisiae* (strain Sc 47) and/or yeast cell wall on rumen fermentation and digestive utilization of corn silage-based diet in mid-lactating dairy cows.

C. Bayourthe*[1,2], C. Julien[1,2], E. Auclair[3], and J. P. Marden[3], [1]*INRA, UMR1289 Tissus Animaux Nutrition Digestion Ecosystème et Métabolisme TANDEM), Castanet Tolosan Cedex, France,* [2]*Université de Toulouse, INPT-ENSAT, INP-ENVT, UMR1289 TANDEM, Castanet Tolosan Cedex, France,* [3]*Lesaffre Feed Additives, Marquette Lez Lille, France.*

Four ruminally cannulated Holstein cows in mid-lactating (DIM = 185 d) were assigned in a 4 × 4 Latin square design. They were fed a TMR composed of 78.8% corn silage, 9.8% soybean meal, 10.9% ground corn and 0.5% minerals at 23 kg DM daily during 10 d either supplemented with 5 g of live yeast (LY) at 10^{10} cfu/g (L1), or 5 g LY + 5 g yeast cell wall (YCW; L2), or 5 g LY + 10 g YCW (L3), or not supplemented (CTRL). Ruminal fluid was withdrawn from donor cows and mixed with 100 mL artificial saliva (1:1) and 3 g TMR for 8 h-anaerobic batch incubations to determine pH, E_h, rH index, total and individual VFA, and ammonia. The same donor cows were given chromic oxide (10 g before each daily meal) as indigestible flow marker to assess the fecal excretion of the cows and thus DM, OM, NDF and ADF digestibility. In vitro results showed that pH, E_h and total VFA were significantly modified (respectively +0.12 pH unit, −24 mV and +0.97 m*M*/L/h on average when compared with CTRL) with L1, L2 and L3. Ruminal reducing power (rH) was further improved with L2. Acetate contents of L2 and L3 differed significantly with CTRL (in average +0.52 m*M*/L/h). A 36% mean decrease in rumen ammonia was observed with L3 in comparison to other treatments. Propionate and butyrate contents tended to increase ($P < 0.1$) for L2 and L1 respectively. In vivo NDF and ADF digestibility tended to increase (+8 and +9 points respectively) with L3 compared with other treatments, while DM, OM and starch digestibility showed no significant difference. Combining LY and YCW resulted in improving ruminal conditions followed by better fiber utilization in mid-lactating dairy cows.

Key Words: live yeast, mid lactation cow, yeast cell wall

W372 Effect of live yeast *Saccharomyces cerevisiae* (strain Sc 47) on nutrient digestion and ruminal fermentation in relation with rumen degradable protein content of the diet.

C. Julien*[1,2], J. P. Marden[3], E. Auclair[3], R. Moncoulon[1,2], and C. Bayourthe[1,2], [1]*INRA, UMR1289, Tissus Animaux Nutrition Digestion Ecosystème et Métabolisme (TANDEM), Castanet Tolosan Cedex, France,* [2]*Université de Toulouse, INPT-ENSAT, INP-ENVT, UMR1289 TANDEM, Castanet Tolosan Cedex, France,* [3]*Lesaffre Feed Additives, Marquette Lez Lille, France.*

Four ruminally cannulated early lactating Holstein were involved in a cross over design. Cows were fed for a 33-d period a TMR containing an adequate level of RDP (HL) or was 30% below HL (LL), by using soybean meal or tanned soybean meal, respectively: for 21 d with no live yeast (LY) addition (14 d of adaptation and 7 d of sampling) followed by 12 d when LY (5 g at 10^{10} cfu/g /cow/d) was added to the diet (5 d adaptation and 7 d sampling). The pH and redox potential (E_h) were recorded over 3 consecutive days (d 15 to 17 and d 27 to 29) using the ex vivo method (Julien et al., 2010). Ruminal fluid samples were collected on the same days, before the morning meal then 1, 2, 4, 6 and 8 h post-feeding. Feces were collected individually and quantitatively over 48h (d 20 to d22 and d 32 to d 34) and individual DMI were measured for determining apparent nutrient digestibility. Nutrients daily intake did not differ between diets. Fecal excretion of OM was greater in LL (6.7 kg/d) compared with HL (5.6 kg/d). For LL diet, LY decreased ($P < 0.05$) fecal flows of OM (−19%), ADF (−17%), and N (−20%). Fecal N amount was lower ($P < 0.0001$) for HL than for LL: 128.5 vs. 232.9 g/d. Digestibility of CP was lower ($P < 0.0001$) for LL than for HL while that of ADF was higher ($P = 0.033$). With LY, digestibility of CP and ADF were increased ($P < 0.05$): respectively +0.8 and +4.8 points for HL, and +5.9 and +6.4 points for LL. Ruminal pH and E_h were lower ($P < 0.0001$) with HL compared with LL: 5.95 and −167 mV vs. 6.13 and −144 mV. Live yeast increased ruminal total VFA (+8.6%; $P < 0.05$), C2 (+10%; $P < 0.05$), and C4 (+35%; $P < 0.05$) contents for LL and decreased that of C3 (−9.8%; $P < 0.05$) for HL. Those results suggested a specific interest in using LY in RDP deficient diets for early lactating cows.

Key Words: digestion, live yeast, rumen degradable protein

W373 Effects of difructose anhydride III supplementation on serum calcium, dry matter intake and energy status in periparturient dairy cows.

M. Teramura*[1], S. Wynn[2], M. Abe[2], S. Hisasue[2], T. Sato[1], M. Ohtani[1], C. Kawashima[2], and M. Hanada[2], [1]*Nippon Beet Sugar Manufacturing Co. Ltd., Obihiro, Hokkaido, Japan,* [2]*Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Hokkaido, Japan.*

Difructose anhydride (DFA) III is an indigestible oligosaccharide. It has been shown that DFA III promotes intestinal Ca absorption in rats and reaches the duodenum without being degraded by rumen bacteria when ingested by dairy cows. The purpose of this study was to investigate the effects of DFA III supplementation on serum Ca, dry matter intake (DMI) and energy status in periparturient dairy cows. Twenty-two multiparous Holstein cows were divided into DFA and control group, which were balanced for parity and BW. DFA group was fed 40 g/d of DFA III from 2 wk before expected calving to 1 wk postpartum (pp) and control group was received no DFA III. DMI (−2 to 3 wk pp) and milk yield (0 to 3 wk pp) were recorded daily. BW was measured weekly during the study period (−3 to 6 wk pp). Blood samples were taken weekly throughout the study period as well as on the day before calving and at 0, 6, 12, 24, 48 and 72 h pp for serum Ca, glucose, NEFA and BHBA. Rumen contractions were also counted at blood sampling (5 cows in each group). All data was compared by repeated measures ANOVA. Changes in serum Ca were compared by Tukey-Kramer method for each group. The incidence of subclinical ketosis (SCK; BHBA ≥1400 μmol/L) was compared by Fisher′s exact test. Pretreatment blood parameter levels were similar between the groups. Hypocalcemia (≤7.4 mg Ca/dL) were observed at pp period in 2 DFA and 4 control cows. Serum Ca recovered to the prepartum level in 12 h pp in DFA cows and 48 h pp in control cows. The number of rumen contractions and DMI were higher in DFA cows than control cows during the first 3 wk pp ($P < 0.05$). Milk yield and BW were not affected by the treatment. DFA cows had lower NEFA at 1 ($P < 0.05$) and 7 ($P < 0.10$) d pp with a lower incidence of SCK during the 6 wk pp (9% vs. 45%; $P = 0.07$). These results suggest that periparturient DFA III supplementation encourages DMI by assisting recovery from hypocalcemia thereby maintaining gastrointestinal motility. Increased DMI by supplement of DFA III might reduce negative energy balance and prevent SCK in early lactation.

Key Words: DFA III, DMI, hypocalcemia

W374 Effects of monensin and extracts of hops and *Yucca schidigera* applied alone or in combination on rumen fermentation in vitro.

N. Narvaez, Y. Wang,* and T. A. McAllister, *AAFC, Lethbridge, AB, Canada.*

There is increasing interest in using plant bioactive as alternative to in-feed antibiotics due to the public concerns over the possible contribution to the emergence of antibiotic resistant bacteria. One possible strategy to increase the efficacy of in-feed antibiotics and possibly circumvent the development of antibiotic resistance is to feed them in combination with plant bioactives. The objective of this study was to assess the effects of monensin (MON), and plant bioactives alone and in combination with MON on in vitro ruminal fermentation. Ethanol extracts of hops (HE; α- and β-acids) and *Y. schidigera* (YE; steroidal saponin) were used as sources of plant bioactives. Treatments were Control (no additive), MON alone (2.5, 5 and 10 µg/ml) and HE (600 µg/ml) or YE (650 µg/ml) alone or combined with the first 2 concentrations of MON. Total gas and CH_4 production were measured at 4, 8, 12, 24 and 48 h of incubation, whereas VFA, NH_3-N concentration, microbial protein (MP), true DM disappearance and ruminal bacteria were determined after 48h. All treatments decreased ($P < 0.05$) gas and CH_4 production, MP, and NH_3-N accumulation. VFA production decreased ($P < 0.05$) with addition of MON alone (10 µg/ml) or in combination with YE. Molar proportion of butyrate were reduced ($P < 0.01$) and that of propionate increased ($P < 0.01$) by all treatments. MON reduced ($P < 0.001$) the relative proportions of 16S *rRNA* copies associated with *Ruminococcus flavefaciens*, but increased those of *Selenomonas ruminantium* ($P < 0.01$) and *Ruminobacter amylophilus* ($P < 0.05$). All treatments reduced ($P < 0.01$) the relative abundance of methanogens. HE alone or in combination with MON reduced ($P < 0.01$) proportions of *R. flavefaciens*, but increased ($P < 0.05$) those of *S. ruminantium* when combined with MON. YE alone and in combination with MON increased ($P < 0.01$) *R. flavefaciens* and *S. ruminantium*. HE and YE altered rumen microbes and fermentation in a manner similar to MON with many responses being additive when applied in combination.

Key Words: monensin, plant bioactives, rumen fermentation

W375 Concentrate level and combined use of ionophore and virginiamycin on feeding behavior of Nelore steers fed high grain diets.

A. J. C. Nuñez*[1], V. V. Almeida[2], J. P. Schoonmaker[3], F. T. Mercado[1], F. Pinese[1], I. E. Borges[1], R. R. Casagrande[1], P. R. Leme[1], and J. C. M. Nogueira Filho[1], [1]*USP/FZEA, Pirassununga, SP, Brazil,* [2]*USP/ESALQ, Piracicaba, SP, Brazil,* [3]*Purdue University, West Lafayette, IN.*

The objective in this study was to evaluate feeding behavior of Zebu cattle fed 2 concentrate levels and 2 virginiamycin (VM) levels in diets containing salinomycin (SL). Eight ruminally cannulated Nelore steers (434 ± 35 kg initial BW) were randomly allocated to a 4x4 replicated Latin square design (21-d periods). Two concentrate levels (70C and 90C diets had 70 and 90% concentrate on DM basis, respectively) and 2 VM levels (0 and 15 ppm) were tested in a 2x2 factorial arrangement of treatments. Animals were housed in individual pens and fed once daily at 0800 h. The forage source was sugarcane silage (72.4% NDF on DM basis), and all diets included the ionophore SL (13 ppm). During a 24-h period, eating and ruminating activities were visually monitored every 5 min and assumed to persist for the entire 5-min interval. Total chewing time (TCT; min/d) was calculated as the sum of total time spent eating (TTSE; min/d) and ruminating (TTSR; min/d). Rate of intake (RI; g/min) was determined by dividing DM intake in the evaluation day by TTSE, and rate of rumination (RR; min/kg) was calculated by dividing TTSR by DM intake. Statistical analyses were conducted using the GLM procedure of SAS. There was an interaction ($P = 0.02$) between concentrate and VM levels only for TTSE. Within the VM treated group, steers receiving 70C spent 71.9 min/d more eating compared with 90C (234.4 ± 7.9 vs. 162.5 ± 11.7 min/d, respectively; $P < 0.01$). Due to higher NDF content of the diet, TTSR was higher for the 70C compared with the 90C treatment (427.8 ± 23.1 vs. 301.6 ± 18.9 min/d, respectively; $P < 0.01$). As a consequence, TCT increased as concentrate level decreased (643.7 ± 29.6 vs. 481.2 ± 21.3 min/d for 70C and 90C, respectively; $P < 0.01$). Because of the higher NDF content of the diet, the 70C group also showed lower RI (37.9 ± 1.7 vs. 49.7 ± 3.8 g/min for 70C and 90C, respectively; $P < 0.01$) and higher RR (53.6 ± 2.6 vs. 35.9 ± 1.7 min/kg for 70C and 90C, respectively; $P < 0.01$). In summary, feeding behavior of Nelore steers is more influenced by concentrate level than by VM supplementation in diets containing SL.

Key Words: antibiotics, beef cattle, salinomycin

W376 The effect of different doses of exogenous enzymes preparation on in vitro gas production and ruminal fermentation activities of some fibrous feeds in cows.

M. M. Y. Elghandour[1], C. G. Peñuelas-Rivas[1], M. Ronquillo[1], A. Z. M. Salem*[1], H. Gado[2], and N. E. Odongo[3], [1]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado de Mexico, Mexico,* [2]*Faculty of Agriculture, Ain Shams University, Cairo, Egypt,* [3]*Animal Production and Health Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria.*

This study was conducted to investigate effects of different doses of exogenous enzyme preparation (ENZ- 0, 0.06, 0.12 and 0.24 g/g DM) on in vitro gas production and some ruminal fermentation patterns such as truly degraded substrate (TDS), short chain fatty acids (SCFA), and microbial protein production (MP) of 4 fibrous feeds (FF - Sugarcane leaves, taiwan grass, sorghum straw and llanero grass) in cows. Rumen liquor was collected before the morning feeding from 2 cows (450 ± 6 kg BW) fitted with permanent rumen cannula. In vitro gas production (GP) was recorded at 2, 4, 6, 8, 10, 12, 24, 48 and 72 h of incubation. After 72 h, the incubation was stopped and the inoculants pH was determined and filtered to determine TDS. Ruminal fermentation parameters such as 24 h partitioning factor (PF24), gas yield (GY24), in vitro organic matter digestibility (IVOMD), metabolizable energy (ME), SCFA, and MP were also estimated. Data were analyzed as 4 (4 doses of ENZ) x 4 (4 FF) factorial experimental design. Interaction between FF × ENZ ($P < 0.05$) only occurred for gas production at 12 h (GP12) and 24 h (GP24) of incubation, but there were no interactions after 24 h of incubation. Relative to control, addition of ENZ increased ($P < 0.05$) accumulated gas volume of all FF during the 72 h of incubation compared with control (0 g ENZ/g DM). Among the FF species, gas production was higher ($P < 0.001$) in sorghum straw and lower ($P < 0.001$) in sugarcane leaves. There was no significant effect of ENZ on gas production parameters (i.e., b; asymptotic gas production, c; rate of gas production and L; discrete lag time before gas production) of all FF. Addition of ENZ doses increased ($P < 0.05$) gradually gas production and this increase was higher ($P < 0.05$) for 0.24 g ENZ/g DM. addition of ENZ was increased ($P < 0.05$) some fermentation parameters (i.e., IVOMD, ME, GY24 and SCFA) were higher ($P < 0.05$) of all FF, while the highest ($P < 0.05$) increased were in sorghum straw with a lower values in sugarcane leaves. Results indicated that exogenous enzymes preparation probably improve the ruminal fermentation activities of fibrous feeds in cows. The authors wish to acknowledge the financial support from IAEA/FAO project MEX 16307.

Key Words: exogenous enzymes, fibrous feeds, gas production

W377 Nutrient intake and ruminal parameters in response to *Bacillus subtilis* included on beef steer diet.

B. Vieira*, R. Telles, V. Naves, I. Carvalho, and R. Reis, *Universidade Estadual Paulista.*

The objective of this experiment was to evaluate the inclusion of *Bacillus subtilis* on the diet of 4 Nellore steers, with rumen cannulas and allocated on a Latin square design, with inclusion of Biotop (a probiotic product containing 10^9 colony-forming unit (cfu) *Bacillus subtilis*/g, as main plots and sampling time as subplots. The period last 20 d each and it was evaluate the dry matter (DM), organic matter (OM), crude protein (CP), ether extract (EE), neutral detergent fiber (NDF), non fiber carbohydrates (NFC) total carbohydrates (TC) and total digestible nutrients (TDN) intakes and, was measured the ruminal pH and N-ammonia. Treatments were defined as control (no addition of) and 3 doses (1, 2 and 4g.day^{-1}). The sampling times for pH and ammonia were at the time (0), at 3, 6, 9, 12 and 24 h after the morning the diet. The forage utilized was corn silage, in a 40:60 forage and concentrate ratio. The DM, OM, CP, EE, NDF and TC intakes were not different (Table 1). However, TDN intake increased with the addition of the probiotic. The pH and the N-ammonia were not affected by treatment, but a quadratic equation was adjusted as a function of sampling time, with a minimum point at 6.2 and 6.2 h after feeding for pH and N-ammonia with values of 5.88 and 24.17mg. dL^{-1}, respectively. It can be concluded that the addition of Biotop on beef cattle diet on the doses between 1 and 4g.day^{-1} do not affect ruminal pH and N-ammonia but can improve the TDN intake.

Table 1. Nutrient intake (%BW) of animals fed with Bacillus subtilis (Bs) in the diet

		Bs			
Item	C	1g	2g	4g	CV (%)

W378 Effect of exogenous fibrolytic enzymes on *in vitro* rumen fermentation of corn silage.

X. Chen, J. K. Wang, H. L. Mao, C. H. Wu, Y. M. Wu, and J. X. Liu,* *Institute of Dairy Science, MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

The aim of this study was to investigate the effect of exogenous fibrolytic enzymes (EFE) as potential additives to improve the utilization of corn silage. A total of 11 commercial EFE, including 5 cellulase and 6 xylanase products, were used. Endoglucanase and xylanase were considered as key enzymatic activities for cellulase and xylanase products, respectively. One unit of enzyme activity was expressed as the amount of enzymes needed to release 1 μmol xylose or glucose per min per gram of enzyme products at 39°C and pH 6.6. Corn silage as substrate was added without (control) or with cellulase (30 units/g DM), xylanse (40 units/g DM). Rumen content was collected from 3 donor animals before feeding in the morning. Gas pressure measurements were recorded at 3, 6, 9, 12, 24 and 48 h of incubation and then converted to gas volume. At the end of the incubation, the fluid was sampled to determine the pH and volatile fatty acids (VFA). The contents in the bottle were completely rinsed out to determine the degradation of DM and neutral detergent fiber. Methane production was determined at 6, 12 and 24 h of incubation. Addition of cellulase resulted in a decreased potential gas production ($P < 0.05$) but increased rate of gas production ($P < 0.05$) with the highest rate being 83.7% compared with the control. Total VFA concentrations were increased ($P < 0.05$) for some EFEs, but degradation of DM and neutral detergent fiber was enhanced ($P < 0.05$) for all enzyme additives with highest value at 65.4%. The enzymes showed various effects on methane production. From the results of this study, it is indicated that addition of EFEs has potential to inhibit methane production while increasing fiber digestibility of corn silage.

Key Words: corn silage, exogenous fibrolytic enzymes, rumen fermentation

W379 Effects of meat goat breed, sex, and conditions before and between measures on behavior in pens with barb wire and electric fence strands. Y. Tsukahara,* T. A. Gipson, G. D. Detweiler, T. Sahlu, and A. L. Goetsch, *Langston University, Langston, OK.*

Growing meat goats of 4 types (Boer (B) wethers and doelings, 25 ± 1.0 and 22 ± 0.7 kg BW; Spanish (S) wethers and doelings, 17 ± 0.3 and 16 ± 0.2 kg BW, respectively) were used to evaluate conditions for a method to test efficacy of electric fence strand addition to barb wire fence for cattle to contain goats. Animals were allocated to 8 sets of 20, consisting of 5 groups/set and 1 animal type/group. There were 5 2.4 × 3.7 m test pens consisting of 3 sides of metal panels and 1, adjacent to a pasture with abundant vegetation, of barb wire strands at 30, 56, 81, 107, and 132 cm from the ground. Fence treatments were electric strands at 15 and 43 (LH), 15 and 23 (LM), 15 (L), 23 (M), and 43 cm (H) at 6 kV. Adaptation procedures entailed 4 sequential weekly exposures to test pens: no electric strands, 1 strand at 0 kV, LH, and LH. Two preliminary treatments were imposed the week before the first observation period in wk 1: barb wire with no electric strands vs. LH. All sets were observed for 1 h in wk 1, and 4 sets were exposed to the same fence treatment in wk 6. During the 5 wk between observations, sets were exposed to 2 washout treatments while on pasture: without or with electric strands at ≥6 kV situated next to concentrate feeders. There were no effects of gender, preliminary, or washout treatments ($P > 0.05$). The % of animals exiting test pens differed ($P < 0.05$) among fence treatments in wk 1 (25, 47, 38, 66, and 84%; SE = 7.7) and in wk 1 and 6 (6, 22, 22, 63, and 81% for LH, LM, L, H, and M, respectively; SE = 4.9) and between breeds in wk 1 (34 and 70%) and in wk 1 and 6 (28 and 50% for B and S, respectively). The % receiving a shock was similar among fence treatments in wk 1 and in wk 1 and 6, although for the latter analysis the value was greater ($P < 0.05$) in wk 1 vs. 6 (11 vs. 1%). In conclusion, dissimilar behavior of B and S is a consideration for the testing method being developed and adaptation procedures employed appeared generally conducive to use of an experiment with one observation period, whereas repeated observations would necessitate evaluation of other washout treatments.

Key Words: goat, fence, containment

W380 GIS grid analysis of utilization of adjacent pastures by two herds of goats. T. A. Gipson*[1], S. P. Hart[1], and R. Heinemann[2], [1]*Langston University, Langston, OK,* [2]*Kiamichi Forestry Research Station, Oklahoma State University, Idabel.*

Many goat producers divide their herd into 2 or more groups for grazing in adjacent pastures with or without other livestock species. The objective of this study was to observe the spatial patterns of 2 adjacent herds of goats pastured with and without cattle. A 15.8-ha pasture was stocked with 36 Spanish goats and 12 Angus cows (GC), and a 14.1-ha pasture was stocked with 36 Spanish goats without cattle (GO). Neither group of goats had been exposed to cattle before. The pastures consisted of fescue, bermudagrass, various *Panicum* such as switchgrass, bahiagrass, and broomsedge bluestem, but areas were reverting to woody plant species such as sapling-sized trees of pecan, elm, and honey locust. Eleven goats in GC and 10 goats in GO were fitted with GPS collars that recorded a fix every 5 min in the first 2 wk. A GIS point-in-polygon analysis using a 10 × 10 m grid was conducted for each pasture. The GO had greater ($\chi2 = 858$, $P < 0.01$) explored space (65% of 1473 grids) compared with GC (13% of 1584 grids). Of the grids explored, GO had a higher percentage with a density of 100 or more fixes than did GC (55 vs. 33%; $\chi2 = 11$, $P = 0.01$), indicating a wider area of methodical exploration or habituation. Only 21% of fixes were within 100 m of the water point. Goats in GO preferred pasture locations closer ($\chi2 = 15106$, $P < 0.01$) to the water point than did GC (200 vs. 300 m); however, GC came to the water point earlier ($P < 0.01$) than did GO (0730 vs. 1000 h). The favored location in the morning for each pasture was near the water point in the eastern intersection of the pastures. During the remainder of the day GC favored the southwestern-most corner of their pasture near a central fence line. In the afternoon, GO preferred the location near GC but also had a favorite location shaded by trees in the center of the pasture. The spatial behavior of the groups of goats appeared to be influenced by each other, and presence of cattle may have inhibited GC from fully exploring their pasture.

Key Words: goats, GPS, grid analysis

W381 Ruminal methane emission by Boer and Spanish does supplemented with garlic. R. Puchala,* Z. Wang, A. L. Goetsch, and T. Sahlu, *Langston University, Langston, OK.*

Twenty Boer (B; 2–7 yr of age and 48.5 ± 2.2 kg) and 20 Spanish (S; 4–6 yr of age and 39.3 ± 1.5 kg) does were used to examine effects of garlic on ruminal methane emission and heat production. Ten does of each breed were randomly allocated to control (C) and garlic (G) treatments. All does received 200 g/d (as-fed basis) of a concentrate mixture consisting of 54.4% ground corn, 26.0% soybean meal, 12.9% molasses, and 6.7% mineral and vitamin sources. The G does also received 20 g/d (as-fed basis) of garlic powder. For at least 2 mo does grazed grass/forb pastures in the summer. Thereafter, sets of 4 does consisting of 1 doe per treatment (CB, CS, GB, and GS) were sequentially placed in metabolism crates for 2 wk, continued to receive supplements, and were fed coarsely ground alfalfa hay free-choice. Gas exchange was measured on the last day for 24 h in an indirect, open circuit respiration calorimetry system with 4 metabolism cages fitted with head-boxes. There were no interactions between breed and supplement treatment ($P > 0.10$). Alfalfa hay DMI during the calorimetry measurement period was greater ($P < 0.05$) for G vs. C (781, 742, 934, and 853 g/d for CB, CS, GB, and GS, respectively; SEM = 29). Ruminal methane emission was less ($P < 0.05$) for G than for C in g/d (12.0, 10.8, 8.5, and 6.4, respectively; SEM = 0.56) and relative to intake of DM (15.2, 14.6, 9.1, and 7.6 g/kg; SEM = 0.44) and GE (4.31, 4.12, 2.58, and 2.14% for CB, CS, GB, and GS, respectively; SEM = 0.124). Treatment did not affect ($P > 0.10$) respiratory quotient (1.012, 1.004, 1.003, and 0.994), heart rate (73, 72, 72, and 70; SEM = 1.6), heat production (450, 444, 447, and 432 kJ/kg $BW^{0.75}$; SEM = 10.7), or the ratio of heat production:heart rate (6.18, 6.19, 6.18, and 6.21 kJ/kg $BW^{0.75}$ per heart beat for CB, CS, GB, and GS, respectively; SEM = 0.056). In conclusion, supplementation with garlic decreased ruminal methane emission and increased DMI by Boer and Spanish does consuming alfalfa hay.

Key Words: goats, garlic, methane

W382 Effects of Roscovitine on maturation and fertilization of ovine oocyte in vitro. S. Nasrollahi,* A. Z. Shahneh, S. Zeinoaldini, H. Kohram, and M. Poorhamdollah, *University of Tehran, Karaj, Tehran, Iran.*

The purpose of this study was to determine the effect of Roscovitine on maturation and fertilization of Ovine oocyte. Roscovitine was added in doses of 0, 6.25, 12.5, 25, 50 and 100µM with control group to maturation culture. Ovaries were collected from abattoir in normal saline at approximately 30°C and transported to the laboratory within 2 to 3 h from collection. After washing with fresh normal saline, cumulus-oocyte complexes (COCs) were recovered by aspiration. Cumulus-oocyte complexes were collected under a stereomicroscope and washed in the passed-through washed aspiration containing HEPES-TCM-199 culture supplemented with 2% fetal Bovine serum, 2/0 µM sodium pyruvate and 1% penicillin-streptomycin and then COCs were delivered into plates containing maturation medium and cultured for 24 h in 5% CO2 at 39°C and maximum humidity. In the first step, nuclear situation was assessed by removing of cumulus cell and oocyte staining. Then, oocytes were cultured without Roscovitine for 24h to determine the inhibitory effects of treatment and then again strained. Finally, oocytes were washed with fertilization medium and the fertilized with fresh semen. Data were analyzed by ANOVA and G mode procedure of SAS (version 9.1). Results showed those expansions level and mucosal rates were not influenced by different concentrations of Roscovitine ($P < 0.05$). Although, there was no difference in nuclear maturation between control treatment and 6.25 micro molar Roscovitine, other concentrations increased the nuclear maturation in oocyte ($P < 0.05$). All of treatment increased reaching to M-II phase than control treatment ($P < 0.05$). In conclusion, treatments 6.25, 12.5 and 25 were selected for in vitro fertilization. The results obtained of these treatments indicated that the oocyte affected by Roscovitine (25µM), could make the better fertilization ability than control group.

Key Words: Roscovitin, fertilization, sheep

W383 Anthelmintic efficacy of medicinal herbs in goats infected with nematode parasites. R. Z. Zhong[1,2], Z. Wang*[2], D. Zhou[1], A. L. Goetsch[2], S. P. Hart[2], and T. Sahlu[2], [1]*Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, China,* [2]*Langston University, Langston, OK.*

Thirty high-percentage Boer does (2.9 ± 0.12 yr; 48 ± 1.9 kg BW) naturally infected with *Haemonchus contortus* from grazing pasture of Langston University were allocated to 5 groups and moved to a barn to investigate anthelmintic efficacy of 3 medicinal herbs, *Rheum palmatum* L. (rhubarb; R), *Meliae cortex* (melia bark; M), and *Quisqualis indica* L. (rangoon creeper; Q). Does were given ad libitum access to grass hay and water, along with 200 g/d per doe of a concentrate-based pelleted supplement. Treatments were control (C), R, M, Q, and a 1:1:1 mixture of the 3 herbs (RMQ). The herbs in powder form were mixed with water at 20 g/100 mL just before drenching. After being acclimated for 7 d, does were drenched with 100 mL of water alone or with the respective herbs at 20 g/d for 10 d. Fecal samples were collected on d 0, 3, 6, 9, 13, and 16 after the start of drenching for worm egg count (FEC). Blood samples were taken on d 0 and 13 for measuring packed cell volume (PCV). Initial FEC was 2,208, 3,933, 3,025, 2,350, and 3,033/g for C, R, M, Q, and RMQ, respectively (SEM = 425.2; $P > 0.05$). After 10 d of treatment, none of the herbs showed anthelmintic effects. The FEC on d 16 was 1,350, 3,058, 1,525, 825, and 2,067/g for C, R, M, Q, and RMQ, respectively (SEM = 332.9, $P > 0.05$). Change in PCV was 1.8, 20.1, 9.1, 10.7, and 13.3% for C, R, M, Q, and RMQ, respectively (SEM = 1.68). Compared with C, the PCV value increased in does treated with R and RMQ ($P < 0.05$); however, the increases may have been due to scouring in response to treatment with R. In conclusion, these herbs were not effective anthelmintics for the most problematic internal parasite of goats, *H. contortus*, in much of the US.

Key Words: goats, anthelmintic herb, *Haemonchus*

W384 The effects of confinement and protein levels on the growth and parasitic loads of kids raised under mixed-species grazing system. S. Gebrelul, L. Gray,* R. Marshall, and Y. Ghebreiyessus, *Southern University Ag Center.*

A long-term mixed-species grazing project was designed to determine the performance of goats and cattle grazing together or separately in continuous or rotational systems. To evaluate the potential of producing kids of desirable market weight of 20 kg or more, 50 kids that were born and weaned under the mixed-specie system were randomly assigned to 4 treatments in a 2 × 2 factorial arrangement. The treatments were housing (confinement vs. semi-confinement) and protein levels in the diet. Kids under confinement system were divided into 2 groups and fed ad lib rations which contained 13% or 16% CP. Kids under semi-confinement were allowed to graze on Bermuda grass pastures during the day (for 8h) and supplemented with the same experimental rations during the night. After an adjustment period of 2 weeks, initial measurements of BW, BCS, (1 = thin, 5 = fat) and FAMACHA scores (FS, 1 = red, healthy, 5 = white, anemic) were taken. These measurements were taken every 14 d for 8 wk. Data were analyzed using SAS MIXED procedure where kids were considered random effects. Kids under confinement were 1.7 kg heavier ($P < 0.05$) than kids under semi-confinement housing. Male kids were 3.0 kg heavier ($P < 0.05$) than female kids. No differences in BCS or FS were observed due to housing effect. Level of CP in the diet had no effect ($P > 0.05$) on BW, BCS or FS. Kids from pastures that were comingled with cattle had higher BW (19.1 ± 0.4 vs. 17.9 ± 0.4 kg) and BCS (2.6 ± 0.05 vs. 2.4 ± 0.05), and lower FS (1.8 ± 0.1 vs. 2.4 ± 0.1) than kids that originated from goats-alone pastures. Kids that were confined and fed 16% CP were heavier ($P < 0.05$) than any other group. BW was positively correlated (0.48) to BCS but negatively correlated (−0.34) to FS. BCS and FS were negatively (−0.28) correlated. Results showed that kids raised under mixed-species system can be confined and fed for 8 wk to achieve desirable market weights.

Key Words: mixed-grazing, FAMACHA, confinement

W385 The anthelmintic effect of Juniper and Tifton 85 on the infective larval stage of *Haemonchus contortus* in an in vitro system. S. A. Armstrong*[1], B. D. Lambert[1,2], T. R. Whitney[3], J. P. Muir[2], and A. McEwin[1], [1]*Tarleton State University, Stephenville, TX,* [2]*Texas Agrilife Research, Stephenville,* [3]*Texas Agrilife Research, San Angelo.*

This experiment tested the effect of inclusion of buffered rumen fluid with and without Tifton 85 bermudagrass (T85) or Juniper in an in vitro larval migration assay (LMI) for *Haemonchus contortus* (HC). Inclusion of a forage material in control samples is time consuming, risks introducing unknown compounds that could reduce larvae viability in the control treatment, and limits the number of test compounds that can be studied in a single assay. Rumen fluid from a mature ruminally-cannulated goat was mixed with McDougall's buffer in a 1:4 ratio. Aliquots of buffered rumen fluid were placed in an anaerobic incubator along with one of 3 forage treatments. Treatments included control (no forage material), control plus T85 or control plus dried juniper. Treatment solutions were incubated for 18 h to extract any potential bioactive anthelmintic compounds. Ivermectin (40 µg/ml) was included as a positive control treatment. Following the 18-h incubation, solutions were centrifuged. Five milliliters of supernatant was added to individual 100-mL plastic cups containing approximately 1000 ensheathed HC larvae. All treatment cups (buffered rumen fluid, buffered rumen fluid + Tifton 85, buffered rumen fluid + Juniper and buffered rumen fluid + ivermectin) were anaerobically incubated for 4 h. Following incubation, larvae were transferred onto a screen in a 96-well plate which contained the same treatment rumen fluid mixture (9 replicate wells per treatment). Larvae were incubated overnight; those which passed through a screen were considered to be viable. Percent larval migration inhibition was calculated as: % LMI = [(A − B)/A] × 100 where A is the number of viable larvae in the control wells, B is the number of viable larvae in the test wells. Juniper and ivermectin treatment resulted in similar LMI, which was greater ($P < 0.05$) than control or control plus T85. We conclude that inclusion of dried juniper was as effective at inhibiting larval migration as ivermectin at 40 µg/mL and future LMI assays need not include forage in the control treatment.

Key Words: *Haemonchus contortus*, anthelmintic, in vitro

W386 Panicled tickclover, a native herbaceous legume, suppresses internal parasites without negative effects on kid performance.

N. M. Cherry[1], M. Bullinger[3], B. D. Lambert*[1,3], J. P. Muir[1], and T. Whitney[2], [1]*Texas AgriLife Research, Stephenville,* [2]*Texas AgriLife Research, San Angelo,* [3]*Department of Animal Science, Tarleton State University, Stephenville, TX.*

This trial looked at the effects of 2 condensed tannin (CT) containing legumes, *Lespedeza cuneata* (sericea lespedeza; SL), *Desmodium paniculatum* (panicled tick-clover; PTC), and a non-CT containing legume, *Medicago sativa* (alfalfa) on growth and fecal egg counts (FEC) in goat kids. The 3 legumes were each pelleted into a complete feed that contained 3.94% CT, 18% CP and 2.8 Mcal/kg digestible energy and fed to goats at 3.5% of their BW in a 4 wk feeding trial with 36 Boer × Spanish doe kids with an average BW of 19.1 kg. Goats were weighed every 14 d, refusals were collected throughout the study and weighed on d 14 and 28, blood samples were collected on d 25 and 28, and rumen fluid was collected at slaughter. Fecal eggs counts were done every 7 d. Compared with alfalfa, SL decreased feed efficiency and ADG, and had no effect on dressing percentage, BUN, and ruminal NH3-N. In contrast, PTC had the same feed efficiency, ADG, dressing percentage, BUN, and ruminal NH3-N as alfalfa. Sericea lespedez and PTC increased feed intake overall ($P < 0.05$) by 5.1 and 4.3 kg, respectively, compared with alfalfa, and kids consuming pellets with SL and PTC also showed 44% reduced FEC ($P < 0.05$) compared with alfalfa. If PTC, native in North America from Texas to Georgia and north to Canada, can be cultivated as easily as SL and alfalfa, it may be an alternative for small ruminant systems looking for natural means of reducing internal parasites or as a protein source in regions such as central Texas where alfalfa and SL are not easily cultivated.

Key Words: goat, internal parasites, legume

W387 Relative resistance to gastrointestinal nematode parasitic infection in sheep and goats.

R. Merriott,* H. Ismail, G. Summers, and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro.*

Co-grazing of parasite resistant and susceptible animals may aid in on-farm control of parasite load and offer a system for reducing production losses in goats. An experiment was conducted to evaluate the effect of nematode infection in goats co-grazed with St Croix sheep reported to be parasite resistant under fall and summer grazing conditions. St. Croix sheep (10), Boer goats (10), and Spanish Boer cross goats (10) were co-grazed on the same pasture. A second group of Boer (5) and Spanish Boer cross (5) goats were grazed on a separate pasture. The duration of both fall and summer trials was 56 d. Fecal and blood samples were collected on d 0, 28 and 56. Fecal egg counts, packed cell volumes, FAMACHA scores, BW and white blood cell differentials were used to assess relative resistance to parasite infection using SAS PROC GLM and PROC TTEST. Goats had higher levels of infection than sheep. The parasite resistant St Croix sheep had higher percentages of eosinophils in peripheral blood when compared with co-grazed goats or goats on a separate pasture ($P < 0.05$). During the fall co-grazed sheep and goats had lower percentages of neutrophils in peripheral blood than goats grazing on a separate pasture ($P < 0.05$). Parasite resistance in sheep was associated with low fecal egg counts and increased eosinophil levels. In goats parasite burden and the neutrophil mediated inflammatory response may be influenced by management practices such as co-grazing.

Key Words: parasitic infection, parasite resistance, goats

W388 Effects of supplementing fat sources in pre-mating ewe diets on reproductive performance.

Z. Mohammadi*[1], H. Mirzaei Alamouti[1], M. H. Shahir[1], H. Amanlo[1], and M. Yavari[2], [1]*University of Zanjan, Zanjan, Iran,* [2]*University of Hamedan, Hamedan, Iran.*

A major challenge in management of most sheep breeds especially low prolific sheep is low lambing rate. Ewe feeding in pre-mating with glucogenic ingredient such as cereal grain has used as a strategy in several past years. Fat supplements have caloric and noncaloric effects that can change energy status of ewes. An experiment was conducted to determine noncaloric effect of some fat supplements in pre-mating ewe diets on reproductive efficiency of Afshari ewes. Afshari sheep are major fat-tail sheep breed in northwest of Iran. Thirty 2 estrus-synchronized Afshari ewes (62 ± 7kg) were assigned randomly to 4 diets containing a basal diet (alfalfa, barley, soybean meal, and a blend of mineral and vitamin) and different fat supplements, 3% of dry matter. Fat supplement were consisting 1) sunflower oil (SFO), 2) fish oil (FO), 3) rumen protected calcium salt of palm oil (RPO), and 4) an equal blend of SFO+FO. For adapting ewes to concentrate (35% of total diet), they were individually fed with basal diet for 7 d and then they were fed with basal diet and fat supplements for 14 d until the day of mating (d 14). Estrus-synchronizing was conducted using intravaginal progesterone releasing device (CIDR) for 12 d and a single dose injection of 400IU PMSG immediately after CIDR withdrawal. Ewes were exposed to rams 24–36 h after PMSG injection. Body weight, BCS, back fat thickness, blood sampling, and ultrasonography were conducted in initial (0), CIDR withdrawal (12), estrus days (13) and 30 d after mating. Data were analyzed using the PROC MIXED of SAS software. Three covariance structures were tested and the best was fitted. The results showed that ewes fed with fat sources had no differences in daily DMI, BW, and BCS and also glucose, cholesterol, and albumin as well in aforementioned days. The ewes fed FO compared with SFO, RPO, and SFO+FO diets had lower ($P < 0.05$) insulin concentration, 19.5 vs 19.5, 22.6, and 21.2 IU/mL respectively, on d12 and 20.4 vs 20.4, 23.2, and 21.8 IU/mL respectively, on d13, and greater ($P < 0.01$) estradiol concentration, 69.2 vs 57.5, 54.2, and 53.5 pmol/mL respectively. There was no difference in progesterone concentration among diets. The ewes fed FO diet had greater ($P < 0.05$) large follicle (>5 mm diameter) number, 1.5 and 2.25, in d 12 and 13, respectively compared with SFO, RPO, and SFO+FO (d12: 1.15, 1.13, and 0.7; d13: 1.5, 1.63, and 1.00, respectively). Also, ewes fed with FO diet had larger follicle size ($P < 0.05$) than ewes fed to other diets (5.7 vs 5.5 5.23, and 3.9 mm) in d13. Number of lambs born per ewe exposed ranked FO > SFO > RPO > SFO+FO (175, 150, 138, and 114%). It was concluded that short-term supplementing fish oil in pre-mating diets can have a beneficial effect on reproductive performance of Afshari ewes.

Key Words: fish oil, sunflower oil, pre-mating ewes

W389 Effect of equine chorionic gonadotropin dosage and administration moment on reproductive performance in Pelibuey ewes. A. González-Reyna[1], J. Hernández-Meléndez[1], F. A. Lucero-Magaña[1], J. Cedillo-Monroy[2], and J. F. Vázquez-Armijo*[2], [1]*Universidad Autónoma de Tamaulipas, Facultad de Ingeniería y Ciencias, Cd. Victoria, Tamaulipas, Mexico,* [2]*Centro Universitario UAEM Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, México, Mexico.*

This study was conducted to evaluate the effects of 4 doses of eCG and 3 application times on the estrus percentage (EP), time to estrus (TE), ovulation rate (OR), and prolificacy (PR) in hair sheep ewes, under a synchronization of estrus program. Ninety 7 Pelibuey adult ewes were treated with vaginal sponges impregnated with 40 mg of fluorogestone acetate during 12 d, at −48, −24, and 0 h before the sponge withdrawal. The ewes were assigned to the following treatments: 1 = 0; 2 = 100; 3 = 200 and 4 = 400 IU of eCG; and ewes showing estrus were mated by natural service. The statistical analysis was carried out using GLM procedure of SAS, and chi-squared tests. There was no effect of eCG dose on EP; however, the application time affected ($P < 0.01$) the EP. The application time ($P < 0.0006$) and the eCG dose ($P < 0.0001$) had important effects on TE. The dose of eCG affected ($P < 0.003$) the OR, and the OR for the dose of 400 IU of eCG was greater ($P < 0.05$) than the OR for the 0, 100 or 200 IU of eCG doses. These values were of 3.5 ± 2.5, and 2.05 ± 0.9, 1.86 ± 0.7 and 2.26 ± 1.3, respectively. The application time did not have effect on the lambing rate, but the eCG dose did ($P < 0.05$), showing superior values of 83 and 75%, respectively for the 100 and 400 eCG doses, versus 48 and 63% for the 0 and 200 eCG doses. PR was affected ($P < 0.05$) by the eCG dose, being greater for the 400 eCG dose (2.28). Based on the results of this present study, the use of eCG did not affect EP; however, it reduced the interval TE and increased the OR and PR.

Key Words: gonadotropins, reproductive behavior, hair sheep

W390 Blood metabolites and insulin concentrations during pregnancy in ewes carrying one to five fetuses and supplemented with propylene glycol. H. Honig,* A. Rozov, E. Gootwine, L. Lifshits, and U. Moallem, *Volcani Center, Bet Dagan, Israel.*

Our previous studies demonstrated the susceptibility of prolific ewes to metabolic disorders during late pregnancy. In this study we examined blood metabolites and insulin concentrations in 60 Afec Assaf ewes carrying 1 to 5 fetuses from 60 d of pregnancy (DOP), and investigated the effect of supplementation from 110 DOP of propylene glycol (PGLY) to ewes carrying ≥ 3 fetuses. Ewes were examined for number of fetuses by ultrasonography at 35 DOP. At 110 DOP ewes carrying ≥ 3 fetuses were divided into 2 groups: (i) control — ewes were fed daily with an average of 0.70 kg of grain mix, 0.35 kg of corn silage and 1.34 kg of oat hay (DM basis); and (ii) PGLY — ewes were fed similar diet which included 55 g/d ProGlyc-55 thatcontained 55% 1.2 propaniol. Blood samples were collected every 2 wk from 60 to 100 DOP and then weekly until lambing, and concentrations of glucose, β-hydroxybutyrate (BHBA), nonesterified fatty acids (NEFA) and insulin were determined. Glucose concentrations decreased gradually from 95 DOP. Insulin concentrations elevated between 70 and 100 DOP, which followed by a dramatic decline in ewes bearing 3-5 fetuses. The increase in NEFA concentrations started moderately between 80 to 95 DOP and then rose rapidly until a peak at lambing. Average concentrations of BHBA (12.2 and 11.3 mg/dL, $P > 0.10$), NEFA (866.4 and 888.1 μEq/L, $P > 0.10$) and insulin (7.3 and 5.9 μIU/ml, $P > 0.10$) during the last 40 DOP were not different between control and PGLY groups, whereas glucose concentrations were lower in PGLY than in the control ewes (50.0 and 58.5 mg/dL, respectively; $P < 0.02$). In conclusion, our results indicate that the metabolic stress in prolific ewes starts early during pregnancy, at 70 DOP, most likely due to the high metabolic demands of the placenta being in its maximal growth rate during this period. In addition, PGLY supplemented from 110 DOP was not effective in improving the metabolic status of ewes conceiving multiple fetuses.

W392 Bone morphogenetic protein 15 (BMP-15) in crossbred goat fertility. R. Hill, L. Canon, H. Ismail, R. Noble, and M. Worku,* *NC A&T State University, Greensboro.*

A study was conducted to identify bone morphogenetic protein 15 (BMP-15) in goat genomic DNA, to evaluate its role in fertility. Bone morphogenetic protein 15 is a growth factor and a member of the TGFβ superfamily that is recognized by the bone morphogenetic protein receptor. It is specifically expressed in oocytes and is important for ovulation and for increasing litter size. Blood was collected from does and their kids of 2 goat breeds, Boer (n = 3 does each) and Spanish x Boer (n = 3 does each), on FTA elute cards (Whatman Inc.). Genomic DNA was extracted from the FTA card according to the manufacturer's protocol. Specific primers for BMP-15 and the loading control GAPDH were used for PCR amplification. Amplified products were run on a 1% agarose gel with DNA markers. Gels were stained with ethidium bromide and visualized using a gel documentation system. All Boer goats and their offspring had the BMP-15 gene. The BMP-15 gene was also detected in does and twin offspring of Boer x Spanish goats. However, Boer × Spanish cross goats that did not have the BMP-15 gene had single offspring. These offspring also did not have the BMP-15 gene. This preliminary evidence indicates that BMP-15 might be a gene that influences prolificacy of crossbred goats, but further research is needed to reach a final conclusion.

Key Words: goat, bone morphogenetic protein 15, fertility

W393 Induction of sexual activity of male goats during the reproductive resting season. O. Angel-Garcia[1], J. M. Guillen-Muñoz[1], M. A. De Santiago-Miramontes[1], P. A. Robles-Trillo[1], R. Rodriguez-Martinez[1], C. A. Meza-Herrera[2], F. G. Véliz[1], and G. Arellano-Rodriguez*[1], [1]*Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México,* [2]*URUZA, Universidad Autónoma Chapingo, Gómez Palacio, Durango, Móxico.*

The aim of this study was to evaluate different protocols to induce the sexual behavior in male goats during the season of reproductive arrest in northern Mexico. Adult male goats (n = 24; dairy crossbred genotype) were divided into 4 experimental groups (n = 6, each) which were homogeneous regarding to BW, BCS, scrotal circumference and smell at the onset of the experimental period. Animals received alfalfa hay ad libitum and 200 g per animal per day of a commercial concentrate (14% CP). On May 15, one group of males (G-T4) was treated with 25mg of testosterone per male, every third day during 3 weeks. A second group (G-GnRH) was treated with 25 ug of GnRH per male every third day, during 3 weeks. A third group (G-females) of males was set in contact with 3 estrogenized females, separated by a fence that permitted visual contact between them. Each of these females received 0.3 mg of estradiol cypionate every third day. A fourth group (G-Control) of males was treated with a saline solution each every third day during 3 weeks. At the end of the experimental period (April 11) each male was submitted to a behavioral test. Each male was exposed to an estrogenized female for 15 min. The behavioral test considered the number of sniffing, vocalization, approaches, complete mounts, mounts with ejaculation as well as latency to first ejaculate. The odor of the males was measured at the end of the experimental period, considering a 0–4 scale; 0 = female odor, 4 = very active male odor. The sexual behavior data were compared with x^2. The smell intensity and latency to ejaculate were compared with ANOVA as well as paired-mean comparisons with a "t" of student test (SYSTAT 10, Evanston, IL, USA, 2000). Data regarding sexual behavior, smell and latency to the first ejaculate for all groups is shown on Table 1. The results for the present study allow us to conclude that GnRH and testosterone administration besides the exposure to estrogenized females to dairy crossbred male goats in northern Mexico during the sexual resting season can promote a clearly active sexual behavior.

Table 1. Number of registered behavior during the behavior test for the four groups exposed to an estrogenized female during 15 min

	Vocalization	Approaches	Complete mount	Mount & ejaculation	Ejaculate latency (s)	Odor (0-4 scale)
G-Control	7^{a}	53^{a}	5^{a}	3^{a}	436 ± 121^{c}	0.7 ± 0.1^{a}
G-GnRH	84^{b}	210^{b}	16^{b}	10^{b}	187 ± 89^{b}	1.4 ± 0.3^{b}
G-Female	60^{b}	168^{b}	3^{a}	2^{a}	507 ± 93^{c}	1.4 ± 0.1^{b}
G-T4	1^{a}	114^{b}	27^{b}	17^{b}	24 ± 8^{a}	1.3 ± 0.2^{b}

W394 Induction to sexual activity of goats from the Mexican semidesert during the seasonal anestrous throughout the "female-to-female effect."

J. M. Guillen-Muñoz[1], O. Angel-Garcia[1], M. A. De Santiago-Miramontes[1], G. Arellano-Rodriguez[1], C. A. Meza-Herrera[2], M. Mellado[3], F. G. Véliz[1], and R. Rodriguez-Martinez*[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]URUZA, Universidad Autónoma Chapingo, Gómez Palacio, Durango, México, [3]Universidad Autónoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

The aim of this study was to determine if administration of PMSG during the seasonal anestrous stimulates sexual activity of goats exposed to the "female-to-female effect" (FTF) in northern Mexico (26° N). The FTF effect considers that direct contact of estrus females with anovulatory females, stimulates reproductive function. Crossbred adult goats (n = 138) under grazing conditions were divided into 4 experimental groups and received alfalfa and water ad libitum. On May 13, all anestrous goats received a single i.m. injection of 25 mg progesterone in 1 mL vegetable oil, to reduce the occurrence of short luteal cycles. On May 14 (d 0), a group of females (PMSG-G; n = 30) was treated with 240 IU of PMSG and 50 ug of cloprostenol i.m. per animal, a second group of females (FTF-G; n = 39) was untreated but interacted with the first treated group. The third and fourth groups were set 300 m apart from the previous groups; while the third group (CS, n = 30) received 0.5 mL of saline i.m. per animal, the fourth group (control, CG; n = 39) remained untreated. At this time 3 males were introduced in every group of females. Female estrus activity was registered twice per day (0800 and 1800 h) during 15 d. On day-45 after male introduction, the proportion of pregnant goats was determined by ultrasonographic scanning. The percentage of estrus females, diagnosed as pregnant and giving birth were compared with a x^2. The latency of the first estrus was compared with a Student t-test (SYSTAT 10, Evanston, IL). Reproductive outcomes considering estrus females, pregnant females, first heat latency and prolificacy in the 4 experimental groups is shown in Table 1. Results of this study clearly demonstrated that anovulatory females can be induced to sexual activity by the female-to-female effect.

Table 1. Percentage of females (no./no. in parentheses) that demonstrated estral activity, diagnosed as pregnant

	Estrus females (%)	Pregnancy rate (%)	Time to onset of estrus (h)	Litter size	Kidding rate (%)
PMSG-G	97 (29/30)^{a}	83 (25/30)^{a}	54.2 ± 1.3^{b}	1.9 ± 0.1^{a}	77 (23/30)
FTF-G	95 (37/39)^{a}	85 (33/39)^{a}	72.6 ± 2.8^{a}	1.7 ± 0.1^{a}	70 (27/39)
CS	0 (0/30)^{b}	0 (0/30)^{b}			
CG	0 (0/39)^{b}	0 (0/39)^{b}			

^{a,b}Different letters between columns indicate statistical differences at $P < 0.01$.

Key Words: sexual activity, female effect, goat

W395 Influence of different GnRH treatments in an 11-d CIDR timed AI synchronization program in Santa Inês ewes.

M. V. Biehl*[3], A. V. Pires[2], I. Susin[2], R. S. Gentil[2], E. M. Ferreira[2], F. M. Abreu[1], M. V. C. Ferraz Junior[3], L. H. Cruppe[1], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]University of Sao Paulo, Pirassununga, SP, Brazil.*

The aim of this study was to determine the effect of GnRH doses at different times on reproductive performance of Santa Inês ewes (n = 299) synchronized with 11-d CIDR timed AI (TAI) program. Ewes were blocked according to BW (45.8 ± 0.39) and BCS (2.22 ± 0.03, scale 1 - 5). The treatments were: 25μg/12h (n = 52) and 10μg/12h (n = 51) which means that ewes received 25 μg or 10 μg of GnRH 12h before TAI; 25μg/TAI (n = 47) and 10μg/TAI (n = 51) which means that ewes received 25 μg or 10 μg of GnRH at time of TAI; no-GnRH (n = 46); and NM (n = 52) bred by natural mating. The CIDR was inserted on day −11 and it was removed 11d later (d 0). All ewes received 5 mg PGF (Lutalyse) and 300 IU eCG (Novormon) on d 0. Estrus detection was performed for 55 h after CIDR withdrawal. Ewes were exposed to rams 10 d after CIDR removal for rebreeding for 7 d. Pregnancy diagnoses by ultrasonography were performed 30 and 50 d after TAI. Data were analyzed using GLIMMIX procedures of SAS. Estrus detection was greater ($P < 0.05$) for 10μg/12h (96.1%) treatment compared with 25μg/TAI (74.5%), 10μg/TAI (60.8%), no-GnRH (73.9) and NM (55.8%), where the 25μg/12h (86.5%) did not differ from any of the treatments. The time of onset of estrus did not differ among treatments (29.9 ± 0.56 h). TAI pregnancy rate was greater ($P < 0.05$) in 10μg/12h (60.8%) and 25μg/TAI (63.8%) compared with 10μg/TAI (41.2%), no-GnRH (30.4%) and NM (42.3%), where the 25μg/12h (51.9%) did not differ from any of the treatments. Natural mating rebreeding pregnancy rate was greater ($P < 0.05$) in no-GnRH (47.8%) when compared with 25μg/12h (28.8%), 10μg/12h (17.6%), 25μg/TAI (19.1%) and NM (28.8%). Final pregnancy rates did not differ among treatments. In conclusion, 10 μg of GnRH 12 h before TAI was effective in promoting estrus response and had a similar AI pregnancy rate as when 25 µg of GnRH was given at TAI. However, the convenience of a single injection of GnRH at TAI makes this approach more desirable in sheep operations.

Key Words: ewes, timed AI, laparoscopy

W396 Effect of AI method on pregnancy rate following an 11d-CIDR estrus synchronization program in Santa Ines ewes. M. V. Biehl*[3], A. V. Pires[2,3], I. Susin[2], R. S. Gentil[2], E. M. Ferreira[2], M. V. C. Ferraz Junior[3], D. D. Nepomuceno[2], F. M. Abreu[1], L. H. Cruppe[1], and M. L. Day[1], [1]*The Ohio State University, Columbus,* [2]*University of Sao Paulo, Piracicaba, SP, Brazil,* [3]*University of Sao Paulo, Pirassununga, SP, Brazil.*

The objective of this study was to compare reproductive performance of nonlactating Santa Ines ewes (n = 267) synchronized using an 11-d CIDR program and a laparoscopic AI followed by different insemination methods following estrus detection. Ewes were blocked by BW (53.4 ± 0.42) and BCS (3.08 ± 0.04; scale 1 – 5). The treatments were: 1) timed AI (n = 65), when half of the ewes were detected in estrus, and AI was performed on the whole group; 2) AM/PM rule (n = 66), AI 12 h after estrus detection; 3) timed AI-48h (n = 67) AI 48 h after CIDR withdrawal; or 4) control (n = 69), ram exposure for 60 h after CIDR withdrawal. After insertion, CIDRs remained in place for 11 d. Upon CIDR removal, all ewes received 5 mg PGF (Lutalyse®) and 300 IU eCG (Folligon®), and estrus detection was performed for 60 h thereafter. Fresh semen from 5 proven rams was used for AI. Ten days after the initial AI, ewes were exposed to rams for rebreeding for 7 d. Pregnancy diagnosis by ultrasonography was performed 30 and 50 d after AI. Data were analyzed using GLIMMIX and MIXED procedures of SAS. Estrus detection within 60 h was 82.8% across treatments and was greater ($P < 0.05$) for timed AI, AM/PM rule, and control (86.2, 87.9 and 85.5%, respectively) than timed AI-48h (71.6%). The moment of AI was greater ($P < 0.05$) for the timed AI (47.1 h), AM/PM rule (46.3 h), timed AI-48h (48.8 h) compared with the control (34.4 h). Pregnancy rate of the synchronized estrus did not differ among treatments (timed AI, 41.5%; AM/PM rule, 53.0%; timed AI-48h, 41.8% and control, 59.4%). Rebreeding pregnancy rate was greater ($P < 0.05$) for the timed AI (32.3%) compared with the AM/PM rule (15.2%) or control (13.0%), however, the timed AI-48h (25.4%) group did not differ from any of the treatments. Final pregnancy rate was 70.4% and did not differ among treatments. In conclusion, timed AI was comparable to AM/PM breeding and natural mating in Santa Ines ewes.

Key Words: ewes, timed AI, laparoscopy

Swine Species III

W397 Industry productivity analysis—Sow farm traits. C. E. Hostetler*[1] and M. T. Knauer[2], [1]*National Pork Board, Des Moines, IA,* [2]*North Carolina State University, Raleigh.*

The objective of this study was to quantify US swine production benchmarks and trends for sow farm traits from a representative database. Data were provided by a data management company representing 1.8 million sows in North America. Production records were available from 2005 to 2010. Traits included piglets per mated female per year (PMFY), litters per mated female per year (LMFY), total number born (TNB), number born alive (NBA), number weaned (NW), preweaning mortality (PM), weaning age, weaning weight (WWT), replacement rate (RR), culling rate (CR), sow mortality, lactation feed intake (LFI) and gestation feed intake (GFI). Data were analyzed in SAS using PROC MIXED. Models included year and month as fixed effects. Standard errors for PMFY, LMFY, TNB, NBA, NW, PM, weaning age, WWT, RR, CR, sow mortality, LFI and GFI were 0.12, 0.010, 0.029, 0.033, 0.035, 0.27, 0.08, 0.015, 1.42, 1.17, 0.15, 0.050 and 0.016, respectively. Means for sow reproductive efficiency and sow removal traits are shown by year in Table 1. Piglets per mated female per year, LMFY and NW increased ($P < 0.05$) from 2005 to 2010 (21.5 to 23.4, 2.31 to 2.34 and 9.30 to 10.08, respectively). Replacement rate did not differ ($P > 0.05$) between 2005 and 2010 (54.1 and 52.2%, respectively) and sow mortality decreased ($P < 0.05$) from 11.2 to 10.4%. Total number born and NBA increased ($P < 0.05$) from 11.82 to 13.03 and from 10.77 to 11.83, respectively. Weaning age and WWT increased ($P < 0.05$) from 18.9 to 20.6 d and 5.46 to 5.86 kg, respectively. Lactation feed intake increased ($P < 0.05$) from 6.11 to 6.62 kg per d and GFI decreased ($P < 0.05$) from 2.33 to 2.27 kg per d. Producers and scientists can use these sow farm benchmarks to better understand industry trends.

Table 1. Sow reproductive efficiency and removal means from 2005 to 2010

	Year					
Trait	2005	2006	2007	2008	2009	2010
Reproductive Efficiency						
PMFY	21.5^{a}	21.9^{b}	22.4^{c}	22.9^{d}	23.4^{e}	23.6^{e}
LMFY	2.31^{a}	2.34^{b}	2.34^{b}	2.35^{b}	2.34^{b}	2.34^{b}
NW	9.30^{a}	9.39^{b}	9.55^{c}	9.72^{d}	9.98^{e}	10.08^{f}
PM, %	13.7^{a}	14.1^{a}	14.0^{a}	14.2^{a}	14.0^{a}	14.8^{b}
Sow Removal						
Replacement rate, %	54.1^{ab}	57.8^{c}	56.0^{bc}	56.1^{bc}	51.4^{a}	52.2^{a}
Culling rate, %	41.9^{a}	44.2^{b}	43.4^{ab}	48.2^{c}	48.7^{c}	47.5^{c}

W398 Welfare of Camborough sows in gestation crates or pens. W. Chaya*[1] and J. McGlone[2], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock,* [2]*Pork Industry Institute, Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

A randomized complete block design experiment with 2 × 2 factorial rearrangement of treatments was conducted to study the effect of 2 housing systems, group pens and crates and 2 feeding systems, single drop and trickle feeding systems on lactating sow reproductive performance, litter performance, behavior, physiology and skin lesion scores. A total of 40, Camborough (Yorkshire x Landrace) gilts were allocated into groups of 5/pen or crates. Behaviors such as feeding, drinking, standing/walking, lying, sitting, agonistic behavior, and oral-nasal-facial (ONF) behavior were video recorded for 24 h at 50 to 60 d of gestation and transformed before analyses. Behavior data were collected hourly based on a 5 min interval between scan samples. Whole blood was collected via jugular puncture over heparin for determinations of plasma cortisol, white blood cell counts, % differential WBC count, neutrophils:mononuclear cell ratio, neutrophil phagocytosis, and neutrophil oxidative burst a week after behavioral observations. No significant differences were identified among housing and feeding systems for reproductive or physiological measures (except for plasma cortisol, neutrophil phagocytosis, and neutrophil oxidative burst that had not yet been assayed). Gilt ONF behavior was higher ($P < 0.05$) among crated gilts than penned gilts (LSmeans 12.7 ± 1.13 vs. 7.6 ± 1.19%). The interaction between penning and feeding system was significant for head lesion score (LSmeans for pen-drop, pen-trickle, crate-drop, crate-trickle were, respectively: 1.0 ± 0.07, 0.0 ± 0.06, 0.0 ± 0.06, and 0.13 ± 0.06; $P < 0.01$). Crated and group-penned sows had similar reproduction. With only minor differences in skin lesion score, each sow penning/feeding system supported similar sow welfare. However, the finding that Camborough gilts had more ONF behavior in crates (than pens) and more head skin lesion score in pens (than crates) differed from our previous work with Camborough-22 gilts in which these differences were not observed. Genotypes may respond differently to group housing than individual housing.

Key Words: pigs, welfare, housing

W399 Relationships of birth weight and weaning weight on performance traits in purebred pigs. R. L. Cutshaw*[1], A. Schinckel[1], J. Fix[2], M. Brubaker[3], and M. Einstein[1], [1]*Purdue University, West Lafayette, IN,* [2]*National Swine Registry, West Lafayette, IN,* [3]*Whiteshire Hamroc LLC, Albion, IN.*

The purpose of study was to evaluate the relationships of birth weight (BTW) and weaning weight (WW) with off test performance traits: Days to 113.4kg (DAYS), real-time ultrasound backfat depth (BF), and loin muscle area (LMA). Data analyses were conducted separately for sire line (SL, Hampshire and Duroc n = 2,388) and maternal line breeds (ML, Yorkshire and Landrace, n = 11,163). The data were fitted to a model that included significant ($P < 0.05$) fixed effects for breed, parity (1–6), sex, ultrasound time period, and random effects of contemporary group and sow. Significant ($P < 0.05$) covariates including WW, WW2, BTW, BTW2 were then added to the model. It was found that pigs from parity 1 dams had 1.44 (SL) and 2.21 (ML) greater ($P < 0.05$) DAYS than pigs from parity 2 and 3 dams. When covariates were added to the model, pigs from parity 1 dams averaged 1.41 (SL, $P < 0.05$) and 0.46 (ML, $P = 0.32$) less DAYS than pigs from parity 2 and 3 dams. Effects of BTW (linear and quadratic) and WW (linear and quadratic) were significant ($P < 0$ 0.01) for DAYS and accounted for 20 and 22% of the residual variance respectively. For the BF data, in the SL only BTW linear was included (−0.013 cm per kg, $P < 0.01$) while for the ML, BTW (linear and quadratic), and WW were significant ($P < 0.01$). For LMA in the SL pigs, WW (linear and quadratic) were significant ($P < 0.01$) and for the ML pigs the effects of BTW (linear and quadratic, $P < 0.01$) were significant. The inclusion of the covariates to the LMA and BF models produced small reductions in residual variances. Pigs that were the lightest at birth or weaning had smaller LMA, greater BF and required additional DAYS.

Key Words: swine, birth weight, weaning weight

W400 Length of productive life and lifetime production of Landrace, Yorkshire and crossbred sows raised under Thai tropical conditions.

S. Koonawootrittriron[1], U. Nopibool[1], M. A. Elzo*[2], and T. Suwanasopee[1], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville.*

Length of productive life (LPL) and lifetime production of sows are important for commercial swine operations. These traits need to be considered for the improvement of sow productivity and efficiency. The aim of this study was to characterize factors affecting LPL and lifetime piglets born alive (LB), lifetime piglets loss (LL), lifetime weaned piglets (LW), and lifetime non-productive sow days (LN) in Landrace (L), Yorkshire (Y) and F1 crossbreds between L and Y (C) sows evaluated in a Thai commercial farm. Data included records of 1,239 L, 397 Y and 153 C sows born between 2001 and 2010. The LPL was defined as the number of days between sow age at first farrowing and sow age at weaning of her last farrowing. The LB, LL, LW, and LN were the sum of all individual measurements of each trait during this period. The model included year-season and breed group (L, Y, and C) as subclass fixed effects, age at first farrowing (9 to 17 mo) as a fixed covariate, and residual as a random effect. Least squares means (LSM) were estimated for all breed groups. Year-season effects were important for all traits ($P < 0.01$). Sows that began to farrow at older ages had significantly shorter LPL (−17.4 ± 7.1 d/mo; $P = 0.01$), lower LB (−1.2 ± 0.5 piglets/mo; $P = 0.03$), and lower LW (−1.2 ± 0.5; piglets/mo; $P = 0.009$) than sows that started farrowing at younger ages. Breed group effects were significant ($P < 0.05$) for LL, LW and LN, but not for LPL and LB. Yorkshire sows had the highest LL (8.5 ± 0.4 piglets) and LW (47.6 ± 1.3 piglets), L sows had the lowest LL (7.4 ± 1.0 piglets), LW (43.6 ± 0.7 piglets), and LN (30.3 ± 0.6 d), and C sows had the highest LN (33.5 ± 1.7 d) of all breed groups. Thus, Yorkshire sows were the most productive over their lifetime (highest LW) of all breed groups in this commercial herd. This study needs to be repeated with a large number of herds in Thailand to verify if results here apply to the whole swine population in this tropical country.

Key Words: pig, production, tropical

W401 In utero heat stress alters postnatal body composition parameters in growing pigs.

R. L. Boddicker*[1], N. J. Boddicker[1], J. N. Rhoades[2], S. Pearce[1], J. Johnson[1], M. C. Lucy[2], T. J. Safranski[2], N. K. Gabler[1], J. T. Selsby[1], J. Patience[1], R. P. Rhoads[3], L. H. Baumgard[1], and J. W. Ross[1], [1]*Iowa State University, Ames,* [2]*University of Missouri, Columbia,* [3]*Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) is a costly issue to the US swine industry as a result of losses in several production, reproductive, and health parameters. The study objective was to test the hypothesis that gestational HS would alter postnatal response to HS and body composition parameters. To investigate this, 48 offspring from 14 first parity crossbred gilts were exposed to 1 of 4 environmental treatments (TNTN, TNHS, HSTN, or HSHS) during gestation. TNTN and HSHS sows were exposed to thermal neutral (TN, cyclical 18–22°C) or HS conditions (cyclical 28–34°C) for all of gestation, respectively. Sows assigned to HSTN and TNHS treatments were heat-stressed for the first or second half of gestation, respectively. After a TN nursery period, at 14 weeks of age, offspring were exposed to one of 2 postnatal thermal environments for 5 weeks: constant TN (21°C) or HS (35°C). Following the subsequent thermic bouts, offspring from the HSTN group had increased back fat depth compared with all other gestational treatments (20.3, HSTN vs. 17.0, TNTN; 16.0,TNHS; and 17.5, HSHS mm, $P = 0.01$) irrespective of postnatal HS. Further, irrespective of postnatal HS, pigs from sows that experienced HS during the first half of gestation (HSHS and HSTN) had increased (13.5%) back fat depth than pigs from sows exposed to TN conditions during the first half of gestation (18.8 vs. 16.5 mm, $P = 0.03$). There was an interaction ($P = 0.04$) between gestational and postnatal environments for loin eye area, as offspring from HSHS and HSTN sows had decreased loin eye area after postnatal HS compared with the postnatal TN offspring, whereas offspring from sows in TNTN and TNHS conditions had increased loin eye area following postnatal HS compared with postnatal TN. No gestational treatment effect was observed on heat indices, feed intake, or weight gain during postnatal HS. Together, these results demonstrate prenatal heat stress alters body composition parameters during growth and development without concomitant changes in feed intake or body weight. This work was supported by USDA NIFA grant #2011-67003-30007.

Key Words: swine/porcine, heat stress, body composition

W402 Implementing a total traceability system for the pig chain based on electronic ear tags and molecular markers.

P. Grassi[1], G. Caja*[1], J. H. Mocket[1], A. Costa[1], J. Soler[2], M. Gispert[2], J. Tibau[2], M. A. Rojas-Olivares[1], and A. Sánchez[1], [1]*Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain,* [2]*Institut de Recerca i Tecnologia Agroalimentàries, Monells, Girona, Spain.*

A total of 1,540 crossbreed pigs of similar origin and production conditions (weaned 28 d, slaughtered 100 kg BW) were used in 3 experiments to assess on the implementation of a total traceability system based on electronic identification (e-ID) and molecular markers (DNA). Pigs were tagged by 3 types of electronic ear tags and carcasses audited by DNA. In Exp. 1, piglets (n = 1,033) were e-ID at birth with ear tags (EF1, plastic double button FDX-B transponder, 2.6 g), biopsied (n = 30) and slaughtered under commercial conditions. No EF1 losses were reported until weaning, but fattening losses were 6.3%. Losses of EF1 during transportation and slaughtering were 41.9%, resulting in 54.3% overall traceability. Auditing 18 carcasses by a panel of 12 DNA microsatellites showed 83.3% matching rate. In Exp. 2, 133 weaned piglets were e-ID (EH, plastic double button HDX transponder, 4.4 g) and biopsied (n = 56). Fattening and slaughtering were done under experimental conditions. On-farm losses were 1.5% and no losses were observed at slaughter, overall traceability being 98.5%. Auditing 56 carcasses by DNA microsatellites showed 98.0% matching rate. In Exp. 3, 374 weaned piglets were e-ID with 453 ear tags of 3 types: EF1 (n = 151), EF2 (plastic double button FDX-B transponder, 4.2 g; n = 140) and EH (n = 162). Biopsies for auditing were 97. Fattening was done in the farm of Exp. 1 and slaughtering in 3 commercial slaughterhouses. By ear tag type (EF1, EF2 and EH), on-farm losses were 1.7, 1.9 and 0.9%, and failures 5.0, 5.6 and 0.9%. On-farm traceability was 93.3, 92.5 and 98.3% (the last differing at $P < 0.05$), respectively. Additionally 5.3, 4.0 and 0.9% ear tags were lost or failed during transportation, respectively. Slaughtering losses were 22.1, 13.3 and 4.5% and failures were 6.3, 5.3 and 0%, resulting in 71.6, 81.3 and 95.5% slaughterhouse traceability, respectively. Overall traceability was 63.6, 70.1 and 92.4% for EF1, EF2 and EH, respectively ($P < 0.05$). Auditing 23 carcasses by DNA microsatellites resulted in 85.1% matching rate. Ten samples of each ear tag type were collected across the experiments for studying their features and performances under laboratory conditions. Separation

strength of EF1 from Exp. 1 was weaker ($P < 0.05$) than the rest of ear tags and reading distances varied dramatically according to the reader, technology and orientation toward the antenna used (0.3 to 33.4 cm). In conclusion, the EH ear tags were more efficient than EF1 and EF2 for tracing pigs under commercial conditions. On-farm traceability depended on piglet age, device used and fattening and slaughtering conditions. Traceability auditing by DNA varied by sample quality and matching rates ranged between 83.3 and 98.0%. Finally, the use of quality electronic ear tags and DNA analysis are recommended for implementing a total traceability system in the pig industry.

Key Words: traceability, electronic identification, ear tag

SYMPOSIA AND ORAL SESSIONS
Alpharma/Beef Species Joint Symposium: Redefining the Replacement Heifer Paradigm

602 Pubertal issues for beef replacement heifers. C. L. Gasser,* *Southern Utah University, Cedar City.*

Heifers that reach puberty and experience multiple estrous cycles before the onset of their initial breeding season have a greater probability for early conception and optimal lifetime productivity. Peripubertal changes include increases in LH secretion, estradiol production, follicular development, and reproductive tract size. Positive feedback stimulation from estradiol eventually causes a hypothalamic surge of GnRH, leading to a surge of LH from the pituitary and the initial ovulation. Attainment of puberty typically occurs around 12 to 14 mo of age in beef heifers but varies greatly. Genetic differences and environmental factors contribute to this variation. In typical US cow-calf operations, calves are generally weaned at approximately 200 d of age. The effect of postweaning management on age at puberty in heifers has been demonstrated, and there is considerable flexibility in the timing of gain from weaning to breeding. However, even when heifers are grown to the desired BW before the start of breeding, there remains a pronounced variation in the timing of puberty, which affects pregnancy rates. Less attention has been focused on the effect of preweaning management on age at puberty. Many changes occur during early reproductive development. Wave-like patterns of follicular development have been observed in heifer calves as early as 2 weeks of age. Some dramatic changes occur from about 2 to 5 mo of age, most notably the transient rise in LH secretion. Most components of the hypothalamic-pituitary-ovarian axis are fully competent by approximately 5 to 6 mo of age. Heifer calves with increased growth rates from birth to weaning have reached puberty at earlier ages. Precocious puberty has also been induced in most heifers with early weaning and feeding a high-concentrate diet. Nutritional control during early maturation in heifers exerts substantial influence on the timing of puberty. Understanding the mechanisms involved in reproductive development increases our ability to effectively manage replacement beef heifers for reproductive efficiency.

Key Words: heifer, puberty, development

603 Development systems for replacement beef heifers. R. N. Funston,* *University of Nebraska, West Central Research and Extension Center, North Platte.*

Studies in numerous species provide evidence that diet during development can partially control physiological changes necessary for puberty. Numerous studies have reported inverse correlations between postweaning growth rate and age at puberty and pregnancy rates in heifers. Thus, rate of postweaning growth was determined to be an important factor affecting age of puberty, which influenced pregnancy rates. This and other research conducted during the late 1960s through the early 1980s indicated puberty occurs at a genetically predetermined size, and only when heifers reach their target weight can high pregnancy rates be obtained. Guidelines were established indicating replacement heifers should achieve 60 to 65% of their expected mature body weight by breeding. Traditional approaches for postweaning development of replacement heifers used during the last several decades have primarily focused on feeding heifers to achieve or exceed an appropriate target weight, and thereby maximize heifer pregnancy rates. Intensive heifer development systems may maximize pregnancy rates, but not necessarily optimize profit or sustainability. Since inception of target weight guidelines, subsequent research demonstrated the pattern of growth heifers experience before achieving a critical target weight could be varied. Altering rate and timing of gain can result in periods of compensatory growth thereby providing an opportunity to decrease feed costs. Recent research from our laboratory has demonstrated feeding replacement heifers to traditional target weights increased development costs without improving reproduction or subsequent calf production relative to development systems where heifers were developed to lower target weights ranging from 50 to 57% of mature BW.

Key Words: beef cattle, heifer development, target weight

604 Interactions of feed efficiency with beef heifer reproductive development. R. D. Randel*[1] and T. H. Welsh Jr.[2], [1]*Texas AgriLife Research, Overton,* [2]*Texas AgriLife Research, College Station.*

The influence of nutrition on puberty in beef heifers is complex and under neuroendocrine control. The stores of body fat in mammals are a determinant of the onset and maintenance of puberty. Body fat stores are greater in heifers with higher residual feed intake than in their more efficient herdmates. A one-unit increase in residual feed intake resulted in a reduction of 7.54 d in age at puberty in *Bos taurus* beef heifers. However, *Bos indicus* influenced heifers which reach puberty at older ages were not found to have sexual maturity influenced by selection for residual feed intake. The strong influence of body fat stores on return to estrus after calving does indicate that selection for leaner beef heifers could affect reproductive performance relative to puberty and postpartum rebreeding of first calf heifers. The influence of intermediary metabolism through signals at the central nervous system regulates the GnRH pulse generator thereby influencing pituitary and ovarian function culminating with puberty and return to ovarian cydicity following calving. Tropically adapted cattle (Santa Gertrudis and Brahman) selected for low residual feed intake had a lesser response of insulin to a glucose challenge than their less efficient herdmates. These studies indicate the possibility that animals with differing residual feed intake (efficiencies) may have differing intermediary metabolism and therefore differing rates of reaching puberty.

Key Words: heifers, feed efficiency, reproduction

605 Enterprise level implications of heifer development. R. L. Endecott*[1], A. J. Roberts[2], and J. T. Mulliniks[3], [1]*Department of Animal and Range Sciences, Montana State University, Miles City,* [2]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT,* [3]*Department of Animal and Range Sciences, New Mexico State University, Las Cruces.*

Research emphasis has been placed on heifer development strategies in recent years, comparing traditional, more intensive systems to more extensive systems using less feed and relying on compensatory gain to reach a target BW. Recent research has suggested that developing heifers to a lighter target BW at breeding (50–57% of mature BW compared with 60–65% BW) reduced development costs while not impairing reproductive performance. One limitation of most research concerning influences of nutrition on heifer development and cow reproductive performance is little or limited consideration of long-term implications. Longevity has a relatively low heritability; thus heifer development and other management strategies have a greater potential to affect cow retention. While limited information exists about the effects of heifer development strategies on cow longevity, data from other species implies that limiting caloric intake during juvenile development can increase lifespan. Establishing the effect of heifer development protocols on longevity is complex, requiring consideration for nutritional factors following the start of breeding and through subsequent calvings. Factors to consider include the resulting maintenance requirements and behavior traits associated with development protocols. For example, developing to lighter target weights may be advantageous in maintaining positive energy balance or adapting to negative energy balance through the breeding season in many range settings. Likewise, heifers developed under a range setting may be better adapted to maintain desired metabolic status during breeding than heifers reared in a pen or developed at a high rate of gain. Adequate growth and development to ensure little calving difficulty can be of critical importance for longevity; however, providing additional supplemental feed during postweaning development to accomplish this may be less efficient than later in development. Ultimately, financial requirements of any development system must be evaluated in conjunction with duration of production to establish implications on production enterprises.

Key Words: replacement heifers, feed inputs, cow longevity

Breeding and Genetics: Beef Cattle Breeding II–Applied Genomics

606 Genomic technologies to increase production of Certified Angus Beef (CAB). J. D. Nkrumah*[1], P. Boddhireddy[1], M. Kelly[1], S. L. Northcutt[2], M. McCully[3], K. Anderson[1], J. Rumph[1], W. Herring[1], J. Osterstock[1], and S. DeNise[1], [1]*Pfizer Animal Genetics, Kalamazoo, MI,* [2]*Angus Genetics Inc., St Joseph, MO,* [3]*Certified Angus Beef, Wooster, OH.*

Genomic technologies can be used as part of genetic improvement strategies to allow Angus cattle producers to both improve growth performance and increase the potential for animals to achieve the Certified Angus Beef (CAB) brand quality specifications. We applied data mining and machine learning methods to genotype and phenotype data on a total of ~4,000 animals with AAA marbling and postweaning gain EPDs and ~9,600 animals with feedlot growth and carcass marbling phenotypes to select an optimum subset of markers from the Illumina BovineSNP50 chip. Selected SNPs predict the genetic potential of Angus cattle to qualify for the CAB brand due to superior genomic merit for marbling, and to affect profitability through growth. Marker effects estimated based on cross-validations using 2/3 of each data were used to compute molecular breeding value predictions, which were then tested in the remaining independent 1/3 of each data set. The independent internal validation results showed that the markers explained between 17 to 36% of the genetic variation in both the EPDs and phenotypes for marbling and growth, depending on the trait. Subsequently, the SNP effects were used to generate predictions on a second completely independent set of ~5,400 animals with genotypes. These new molecular breeding value predictions were sent to Angus Genetics Inc. (AGI), where they were combined with their respective phenotypes and evaluated for their genetic correlations with phenotypes using single-trait animal models. The estimated genetic correlations in the AGI analysis ranged from 0.40 to 0.50, depending on the trait. These predictions provide commercial cattlemen the opportunity to use simple and cost-effective genomic tools to inform early selection, management, and marketing decisions related to genetic potential for marbling and growth.

Key Words: Certified Angus Beef, genomic technologies, molecular value predictions

607 Genomic selection for dry matter intake using a combined European and Australian reference population. Y. de Haas*[1], J. E. Pryce[3], M. P. L. Calus[1], E. Wall[2], M. P. Coffey[2], H. D. Daetwyler[3], B. J. Hayes[3], and R. F. Veerkamp[1], [1]*Animal Breeding and Genomics Centre of Wageningen UR Livestock Research, Wageningen, the Netherlands,* [2]*Sustainable Livestock Systems Group at Scottish Agricultural College, Easter Bush, Midlothian, United Kingdom,* [3]*Biosciences Research Division of Department of Primary Industries Victoria, Bundoora, VIC 3083, Australia.*

Dairy cow dry matter intake (DMI) data from Australia (AU), the United Kingdom (UK) and the Netherlands (NL) were combined (1801 cows) for this study. The aim was to explore the impact on the accuracy of genomic estimated breeding values of pooling data across key reference populations. A total of 843 Australian growing heifers with records on DMI measured over 60 to 70 d at approximately 200 d of age, 359 Scottish and 599 Dutch lactating heifers with records on DMI during the first 100 d in milk were included in the data set. Genotypes were obtained using the Illumina BovineSNP50 BeadChip for European (UK+NL) cows, and Illumina High Density Bovine SNP chip for AU heifers. The AU and EU genomic data were matched on SNP-name and genotypes were compared for quality control using 40 bulls that were genotyped in both data sets. This resulted in a total of 30,949 SNPs being used in the analyses. Genomic predictions were with both single-trait and multi-trait genomic REML models, using ASReml. The accuracy of genomic prediction was evaluated in 11 single-country validation sets, and the reference set (where animals had both DMI phenotypes and genotypes) were either a reference set within AU or EU, or with a multi-country reference set consisting of all data except the validation set. When DMI was considered to be the same trait for each country, using a multi-country reference set, the accuracy of genomic prediction for DMI increased for EU and UK, but not for AU and NL. Extending to a bivariate (AU-EU) or trivariate (AU-UK-NL) model increased the accuracy of genomic prediction for DMI in all countries. The highest accuracies were estimated for all countries when data was analyzed with a trivariate model, with increases of up to 5.5% compared with a single-trait analysis with a multi-country reference set.

Key Words: genomic selection, dry matter intake, international collaboration

608 Whole transcriptome sequencing of seven bovine tissues reveals gene expression profiles, splicing variants, and novel coding regions to improve genome annotation. J. Thomson*[1], U. Basu[1], Y. Meng[1], X. Liao[1], S. Moore[2], and P. Stothard[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*University of Queensland, Brisbane, Qld, Australia.*

A comprehensive annotation of the transcriptome is essential for understanding the genome biology of cattle. The objectives of this work include characterizing the transcriptome of 7 bovine tissues with the aim of identifying additional splice variants, novel coding regions, and tissue-specific gene expression. Liver, adipose, hypothalamus, muscle, kidney, duodenum, and lung tissues were profiled using RNA-Seq Reads were mapped to the bovine reference sequence using TopHat and gene expression values normalized as FPKM (fragments per kilobase of exon per million fragments mapped) were generated using Cufflinks. A total of 24,617 genes were identified and quantified in at least 1 of the 7 tissues. Several thousand transcript variants were also identified. Functional annotation of the expressed genes will provide insight into tissue functions and may stimulate future lines of research. This work adds to the current knowledge base by identifying expressed transcripts and quantifying their expression in several important tissues. Novel transcribed regions that are not currently available in the database may be identified. Additional information about gene function can be used to improve our understanding of ruminant biology.

Key Words: gene expression, genomics, physiology

609 An ensemble-based approach to imputation of high-density genotypes for genomic selection with application to purebred Angus cattle.

C. Sun*[1], X.-L. Wu[1,2], K. A. Weigel[1], G. J. M. Rosa[2,3], S. Bauck[4], B. W. Woodward[4], R. D. Schnabel[5], J. F. Taylor[5], and D. Gianola[2,3], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]Department of Animal Sciences, University of Wisconsin, Madison, [3]Department of Biostatistics and Medical Informatics, University of Wisconsin, Madison, [4]Merial Limited, Duluth, GA, [5]Division of Animal Sciences, University of Missouri, Columbia.*

Imputation of high-density genotypes from low-density panels is of increasing interest in genomic selection because it can reduce genotyping costs markedly. Imputation software packages vary in imputation accuracy, and imputed genotypes may be inconsistent among procedures. Hence, an AdaBoost-like approach is proposed to combine imputations from several different software packages. Six such packages were used: Beagle (v3.3), IMPUTE (v2.0), fastPHASE (v1.4), AlphaImpute, findhap (v2), and Fimpute (v2), each serving as a basic classifier in an ensemble-based system. This method computed weights sequentially for all classifiers, and then combined results from the component methods via weighted majority voting, to produce a final vote for unknown genotypes. The data included 3,078 purebred Angus cattle, each genotyped with the Illumina BovineSNP50 BeadChip. SNP genotypes on 3 chromosomes (BTA1, BTA16, and BTA28) were used to compare imputation accuracy among various methods, and the application involved imputation of 50k genotypes covering 29 chromosomes based on a set of 7k SNPs contained on the Illumina BovineLD chip. Beagle and Fimpute had the greatest accuracy, which varied between 0.87 and 0.99, among the 6 imputation softwares. The ensemble method outperformed the independent packages; however, the sequence of independent packages in voting affected imputation accuracy. The ensemble systems yielding the best imputation accuracies were those that had Beagle as the first classifier, followed by one or 2 methods that utilized pedigree information. A salient feature of the ensemble method is that it provides a way of solving imputation inconsistencies among different imputation methods, hence leading to a more reliable system for imputing genotypes relative to any of the individual procedures.

Key Words: AdaBoost, imputation, ensemble-based system

610 Gene expression analysis of longissimus and semitendinosus muscle from Angus and Charolais finishing steers.

J. W. Buchanan*[1], A. K. Sexten[2], J. W. Dillwith[1], C. R. Krehbiel[1], and R. G. Mateescu[1], *[1]Oklahoma State University, Stillwater, [2]Kansas State University, Manhattan.*

Fatty acid profile is an important component in determining the healthfulness of beef products. However, the fatty acid profile of beef is variable among breeds and within different cuts in the same breed. Genetic regulation of fatty acid profile is known to vary among breeds and within different muscles. The objective of this study was to analyze gene expression in both longissimus and semitendinosus muscles in 6 Angus and 6 Charolais heifers finished on concentrate for 140 d. Expression of *ADIPOQ* (*adiponectin*), *FASN* (*fatty acid synthase*), *DGAT2* (*diglyceride acyl transferase 2*), *PPARG* (*peroxisome proliferator activated receptor gamma*), and *GPAM* (*glycerol-3 phosphate acyltransferase muscle type*) were analyzed for differences between both muscle and breed. Total RNA was extracted from intramuscular samples and gene expression was quantified using SYBR Green real-time PCR. Delta CT (threshold cycle) values for each gene were analyzed for differences between breed and muscle using the GLM procedure in SAS (Cary, NC) and means were separated with the PDIFF option. In Angus cattle, *ADIPOQ* and *FASN* were upregulated 6.7- and 4.1-fold respectively in semitendinosus compared with longissimus muscle ($P < 0.05$). In Charolais, *PPARG* was upregulated 43-fold in semitendinosus compared with longissimus ($P < 0.05$). In longissimus, *ADIPOQ*, *FASN*, *PPARG*, and *DGAT* were upregulated 7.6-, 6.0-, 5.0-, and 6.1-fold in Charolais compared with Angus ($P < 0.05$). In semitendinosus, *PPARG* was upregulated 35.8-fold in Charolais compared with Angus ($P < 0.05$). Significant differential expression differences across both muscle and breed indicates these genes are likely affecting fatty acid metabolism in the tissues analyzed.

Key Words: beef, fatty acid, gene expression

611 Single nucleotide polymorphisms in the NPY, leptin, and IGF-1 genes in Angus cattle: I Effects on feed efficiency.

A. I. Trujillo,* A. Casal, and P. Chilibroste, *Universidad de la Republica, Facultad de Agronomia, Montevideo, Montevideo, Uruguay.*

Single nucleotide polymorphisms (SNP) that showed associations with residual feed intake (RFI) may be useful for marker-assisted selection. There is limited research about specific gene mutations and RFI. Neuropeptide Y (NPY), leptin (LEP), and insulin-like growth factor-1 (IGF-1) are candidate genes due to their role in the regulation of feed intake, growth and energy balance. Thus, our aim was to study the associations of SNP previously identified in NPY (A/G, intron 2), LEP (C/T, exon 2) and IGF-1 (C/T, promoter region) genes to dry matter intake (DMI), metabolizable energy intake (MEI), average daily gain (ADG) and RFI. Female Angus calves carrying 3 putative favorable alleles simultaneously (V = validation group; n = 19; 187 ± 33 kg BW, 260.6 ± 34 d old at the beginning of test (BT)) and calves carrying 3 putative unfavorable alleles (C = control group, n = 19, 185 ± 33 kg BW, 263.9 ± 17 d old at BT) were fed a TMR diet (60:40 concentrate: alfalfa hay, as fed) twice a day during 56 d. DMI was estimated by the difference between feed offered and refused; BW was recorded every 2 wk. RFI_{K} was residual from a regression of DMI on ADG and mid-test $\text{BW}^{0.75}$. RFI_{SCA} was residual from regressing DMI on DMI predicted from Australian feeding standards. RFI_{NRC} was residual from regressing DMI on DMI expected from net energy system (NRC_{1984}) and RFI_{ME} was the same as RFI_{NRC} but expressed in ME values. Mean DMI, MEI, ADG and RFI_{K} were 7.16 ± 1.08 kg DM, 18.53 ± 2.78 Mcal ME, 1.24 ± 0.19 kg BW, and 0.00 ± 0.41, respectively. Mean values for RFI_{SCA}, RFI_{NRC}, and RFI_{ME} were 0.00 ± 0.49, 0.00 ± 0.50, 0.00 ± 1.27, respectively. Calves of V group had lower DMI and MEI ($P = 0.046$, $P = 0.032$, respectively) and similar ADG ($P = 0.195$) than calves of C group when initial BW (covariate) and age (random effect) were included in a linear mixed model. Calves of V group were more efficient ($\text{RFI}_{\text{NRC}} = -0.181$, $\text{RFI}_{\text{SCA}} = -0.171$, $P < 0.05$; $\text{RFI}_{\text{ME}} = -0.3279$, $\text{RFI}_{\text{K}} = -0.111$, $P < 0.1$) than calves of C group. Spearman rank correlation between RFI methods was highly significant ($P < 0.001$). These results indicate that there is an association between the SNP of NPY, LEP and IGF-1 and RFI.

Key Words: beef cattle, residual feed intake, single nucleotide polymorphism

612 Single nucleotide polymorphisms in the NPY, Leptin, and IGF-1 genes in Angus cattle: II Effects on serum IGF-1 and leptin concentrations.

A. I. Trujillo,* A. Casal, and P. Chilibroste, *Universidad de la Republica, Facultad de Agronomia.*

Single nucleotides polymorphisms (SNP) in the leptin (LEP) and insulin-like growth factor (IGF-1) genes or its promoters, have been associated with differences in serum LEP and IGF-1 concentrations and others relevant traits including residual feed intake (RFI). The aim of the study was to evaluate the relationship of the SNP, previously identified in NPY (A/G, intron 2), LEP (C/T, exon 2) and IGF-1 (C/T, promoter region) genes, with serum LEP and IGF-1 concentrations. Female Angus calves, genotyped at mentioned SNP, were classified as carrying 3 putative favorable alleles simultaneously (n = 19; 187 ± 33 kg BW; 260.6 ± 34 d old; V = validation group), or 3 putative unfavorable alleles (n = 19; 185 ± 33 kg BW; 263.9 ± 17 d old; C = control group). Calves were fed a TMR diet (60:40 concentrate: alfalfa hay, as fed) during 56 d. Dry matter intake (DMI) was estimated as the difference between feed offered and refused; BW was recorded every 2 weeks. RFI_{ME} was residual from regressing energy metabolizable intake (EMI) on EMI expected from net energy system (NRC1984). Blood samples were collected by jugular venipuncture at sampling date at the beginning (SD1) and at the end of test (SD2). Data was analyzed as a repeated measure using a mixed model and means were considered to differ when $P < 0.05$. Mean serum concentration of IGF-1 and LEP were 281.8 ± 110.8 and 2.92 ± 0.97 ng/mL, respectively. IGF-1 concentration did not differ between groups, was affected by initial BW (iBW; $P < 0.0001$) and was greater in SD2 than in SD1 (348.8 vs. 214.9 ± 12.2 ng/mL, respectively). LEP concentration did not differ between groups and tended to be affected by iBW ($P < 0.1$). In addition, IGF-1 concentration was moderate and positively correlated with DMI (r = 0.40, $P < 0.05$) while LEP concentration was moderate and negatively correlated with RFI_{ME} (r = −0.40, $P < 0.05$). Although the SNPs considered were not associated with any of the studied hormones our data show a correlation between LEP concentration and RFI_{ME}. Further studies are needed but these results suggest that LEP serum concentration could be use as an indicator of efficiency in beef cows.

Key Words: single nucleotide polymorphism, IGF-1, leptin

613 A distributed parallel computing approach for tuning Bayesian regression models for genomic selection with application to Angus cattle.

X.-L. Wu*[1,2], H. Okut[2], C. Sun[1], G. J. M. Rosa[2], S. Bauck[3], B. W. Woodward[3], R. D. Schnabel[4], J. F. Taylor[4], and D. Gianola[1,2], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]Department of Animal Sciences, University of Wisconsin, Madison, [3]Merial Limited, Duluth, GA, [4]Division of Animal Sciences, University of Missouri, Columbia.*

Predicting genetic merit of candidates for breeding purposes using an optimal subset of whole-genome markers is a model selection problem. A BayesCπ model, for example, postulates that a portion, π, of all SNP markers have no effect on the quantitative trait. Inferring π, however, adds extra complexity to the Bayesian regression model, which is dependent on the extent of data and the underlying trait genetic architecture, and requires more computing time. It is also questionable whether the π parameter optimized in training data necessarily leads to best prediction when generalized to testing data particularly for traits governed by the infinitesimal model. Here, we propose a distributed parallel computing (DPC) approach to choose optimal π values in Bayesian regression models, based on their cross-validation performance in testing data sets. Several Bayesian regression models were computed in parallel in computer clusters, each assuming a distinct value of π. These 2 approaches to choosing π were applied to prediction of marbling score in 3,078 registered Angus bulls. It was found that the π values obtained directly from BayesCπ fitted to the training data were smaller than those obtained from the DPC approach as supported by testing data. This reflected that BayesCπ fit more SNP markers in the model than the DPC approach. In general, the π obtained from BayesCπ was > 95% with a 50K SNP panel, and it was moderate (40–70%) with a 3k SNP panel. In contrast, the DPC approach consistently yielded the best predictions using from 600 to 900 SNP markers. Hence, a model that describes variation in a training set well does not necessarily lead to the best predictions when generalized beyond the training set. With a low-density SNP panel, however, interpretation of SNP markers having putatively nonzero effects should be done with caution, because many could be distant from functional genes or quantitative trait loci.

Key Words: distributed parallel computing, genomic selection, single nucleotide polymorphism

614 Quantitative traits and genomics of heterosis in Wagyu × Angus F_1 progeny.

L. F. Zhang[1,2], J. J. Michal[1], J. V. O'Fallon[1], Z. X. Pan[1,3], C. T. Gaskins[1], J. J. Reeves[1], J. R. Busboom[1], M. V. Dodson[1], R. W. Wright Jr.[1], and Z. Jiang*[1], *[1]Department of Animal Sciences, Washington State University, Pullman, [2]College of Animal Sciences, Zhejiang University, Hangzhou, Zhejiang, China, [3]College of Animal Sciences and Technology, Nanjing Agricultural University, Nanjing, Jiangsu, China.*

The objective of the present study was to understand the genetic complexity of economically important traits in beef cattle. A total of 91 genes were investigated for their associations with 6 carcass and 24 fatty acid composition traits in a Wagyu × Angus population, including 43 Wagyu bulls and their potential 791 F1 progeny. Parentage assignment was performed using the Cervus package, while the association analysis was conducted using the PROC MIXED procedure of SAS. All significant markers along with their quantitative trait modes (QTMs) for each phenotype were then integrated into a linear regression analysis to identify genetic networks. Of the 182 SNPs evaluated, 102 SNPs that were in Hardy-Weinberg equilibrium with minor allele frequencies (MAF) > 0.15 were selected for parentage assignment. Linkage disequilibrium analysis further identified 75 of these 102 SNPs derived from 54 genes as tagged SNPs for association analysis. After Bonferroni correction, single-marker analysis revealed a total of 113 significant associations between 44 genes and 29 phenotypes (adjusted $P < 0.05$). Multiple-marker analysis confirmed single-gene associations for 10 traits, but revealed 2-gene networks for 9 traits and 3-gene networks for 8 traits, respectively. These associations/networks were orchestrated by only 19 genes, including ATP-binding cassette A1, apolipoprotein B, ankyrin repeat and SOCS box-containing 3, calpains 1 and 12, calpastatin, corticotropin releasing hormone, dermatan sulfate epimerase-like, EGF containing fibulin-like extracellular matrix protein 1, fatty acid desaturase 2, guanine nucleotide binding protein gamma 3, lipase, hormone-sensitive, phospholipid transfer protein, regulator of calcineurin 1, solute carrier family 27 A1 and A2, tumor necrosis factor, transcription factor B2, mitochondrial and urotensin 2 receptor. In addition, we observed an interesting phenomenon that crossbreeding of different breeds might change gene actions to dominant and overdominant modes, thus explaining the origin of heterosis in their F1 progeny. The present study further confirmed that these pathway-based genes are useful targets for improving meat quality traits and healthful beef products in cattle.

Key Words: quantitative traits, genetic networks, beef cattle

Companion Animals

615 Use of genomic biology to study companion animal microbiota. K. S. Swanson,* *University of Illinois, Department of Animal Science, Urbana.*

The gastrointestinal (GI) tract of dogs and cats contains a complex and dense population of microbiota, including bacteria, archaea, fungi, protozoa, and viruses. Depending on its composition, the microbiota may be beneficial or harmful to the host. Commensal microbes may be a burden in some respects, but is outweighed by the role they play in GI immunity, resistance to pathogenic colonization, short-chain fatty acid production, and epithelial gene expression. The knowledge pertaining to GI microbiology and health has largely been obtained using traditional (i.e., plating) techniques over the past several decades. A hindrance to this field has been the inability to effectively identify and quantify microbial species. Molecular tools, such as quantitative polymerase chain reaction (qPCR), fluorescent in situ hybridization (FISH), denaturing gradient gel electrophoresis (DGGE), quantitative dot blot hybridization, restriction fragment length polymorphism (RFLP), and high-throughput DNA sequencing, have dramatically changed the research landscape. Our lab has recently used such techniques to characterize the phylogeny and functional aspects of canine and feline GI microbiota and identify the effects of diet and age on these communities. Several hundred phylotypes, predominated by members of *Firmicutes*, *Fusobacteria*, *Proteobacteria*, *Bacteroidetes*, and *Actinobacteria*, inhabit the dog and cat gut. Although these populations are quite stable over time, our data have demonstrated that dietary macronutrient profile (e.g., dietary protein: carbohydrate ratio), fiber amount and type, and form of food (e.g., raw vs. extruded) may affect the number and/or metabolism of the colonic microbiota. Continued use of DNA-based techniques to characterize microbial phylogeny and metabolic capacity, along with other technologies to analyze microbial RNA, protein, and metabolite profiles, will increase our understanding of host-microbe relationships. Despite the challenges that surround this field, these powerful tools will enhance our ability to understand GI health and diseases in pets on a molecular level, leading to improved disease diagnosis and treatment in coming years.

616 Pheromones and interomones that change heart rate and behavior of anxious dogs. G. Thompson* and J. J. McGlone, *Texas Tech University, Lubbock.*

Pheromones are species-specific odors used in communication. Interomones are pheromones in one species, but have diverse effects on other species. The objective of this study was to assess efficacy of pheromones/interomones to modulate heart rate and behavior in adult anxious dogs (trembling, cowering, shy). The dogs (8.1 ± 0.18 kg; estimated 5–12 yr intact males) were obtained from a local research facility. Body weights and feed intake were recorded. Each dog was housed in a separately ventilated room with a minimum of 12 m^2 of floor space. Heart rate (HR) and surface temperature was measured using a telemetry system (Data Science International, St. Paul, MN). Behavior was recorded on a DVR and later reviewed by a trained individual. A scan sample was used with a recording interval of 5 min over 24 h. At the end of 24 h with a given pheromone collar, each dog was startled with a 110 db foghorn 12 cm from the dog's head while behavior and heart rate were recorded. Each dog received each treatment in a Latin square design with repeated measures over time. This model allowed evaluation of effects of treatment, dog, treatment by dog, time, treatment by time and dog by time. Treatments were given in the form of a collar containing each pheromone/interomone and included placebo (collar without pheremone), Sergeant's (SERG), 2-methylbut-2-enal–Rabbit Pheromone (RP), or a SERG+RP combined collar. Baseline HR did not differ among treatments (avg = 110.1 ± 13.3 bpm). After startle, the RP lowered ($P < 0.01$) HR compared with placebo (124.5 ± 7.2 vs. 157.8 ± 7.2 bpm); however, the treatment by dog interaction ($P < 0.01$) indicated certain dogs were more responsive than others. Dogs with RP collars spent more time lying down (87.4 ± 5.4 vs. 63.2 ± 4.8% of time, $P = 0.01$) and less time pacing (3.0 ± 0.2 vs. 3.8 ± 0.02%, $P < 0.05$) than placebo-treated dogs. Pace/walk changed differentially among treatments and dogs (dog by RP and SERG effects for pace/walk, $P = 0.05$). In summary, RP lowered HR while SERG and SERG+RP did not change dog HR. However, pheromone/interomone treatments had differential effects on individual dog behavior and HR. Pheromones/interomones can cause meaningful changes in dog behavior and HR among certain anxious dogs.

Key Words: pheromone, behavior, dogs

617 Genome-wide linkage scan for loci associated with canine hypoadrenocorticism. A. M. Oberbauer* and J. M. Belanger, *University of California-Davis, Davis.*

Canine hypoadrenocorticism (Addison's disease) results from reduced adrenal production of corticosteroids and mineralocorticoids. Within the dog population, the disease is relatively uncommon but some breeds, bearded collie, great danes, leonbergers, Portuguese water dogs, standard poodle, and west highland white terriers are at increased risk for developing hypoadrenocorticism. This disease can be lethal or require lifelong hormonal therapy. Prior studies have indicated a genetic component to the expression of the disease in these breeds. The aim of this study was to employ a genome-wide linkage scan to interrogate the canine genome and identify genomic regions associated with hypoadrenocorticism in the dog. Extracted DNA from bearded collies (43), great danes (11), leonbergers (4), Portuguese water dogs (11), standard poodles (91), and west highland white terriers (11) were genotyped using the newly developed high-density genotyping array consisting of over 170,000 evenly spaced single nucleotide polymorphisms (SNP). Association analyses were conducted using the software package PLINK. Dogs were classified as having a positive diagnosis of hypoadrenocorticism if they failed to respond to an adrenocorticotropic hormone stimulation test and unaffected controls if they were over 7 years of age and healthy. The analysis included 96 confirmed cases and 75 control dogs. When considered in this manner, based on 50,000 permutations, 4 chromosomal regions reached genome wide significance: chromosomes 3 ($P < 0.006$), 6 ($P < 0.008$), 16 ($P < 0.04$), and 30 ($P < 0.04$). Chromosome 3 appears to be associated with a protective allele while 6, 16, and 30 confer a 3- to 4-fold risk. Each chromosomal region encompasses several genes that will require additional fine mapping to resolve the region that contributes to expression of the disease. Identifying the underlying causal mutations and implementing genetic testing will reduce the incidence of hypoadrenocorticism in dogs.

Key Words: hypoadrenocorticism, genome scan, dog

618 Effects of dietary macronutrient composition on postprandial endocrine response in domestic cats.

P. Deng*[1], T. K. Ridge[2], T. K. Graves[2], J. K. Spears[4], and K. S. Swanson[1,3], [1]*Department of Animal Sciences, University of Illinois, Urbana,* [2]*Department of Veterinary Clinical Medicine, University of Illinois, Urbana,* [3]*Division of Nutritional Sciences, University of Illinois, Urbana,* [4]*Nestlé Purina PetCare, St. Louis, MO.*

Obesity is now the most common metabolic disease in cats, having adverse effects on quality of life. Identifying dietary effects on appetite-regulating hormones in cats may enhance our understanding of appetite control and obesity development in this species. The objective of current study was to investigate the effects of dietary macronutrient composition on appetite-regulating hormone release. Twelve neutered male adult domestic shorthair healthy cats were fed 4 nutritionally complete diets [control, high-fat (HF), high-protein (HP), high-carbohydrate (HC)] at amounts to maintain ideal BW and body condition score. The control diet provided 33% kcal from each macronutrient, while the other provided 50% of kcal from the macronutrient highlighted. Cats were randomly allotted to diets in a 4 × 4 Latin square design experiment for a total of 64 d (four 16-d periods). After a 15-d adaptation phase, blood samples were collected before (0 min) and 10, 20, 30, 60, 90, 120, 150, 180, 240, 300, 360, 720 min after the morning meal was consumed. Glucose, insulin, total ghrelin, and leptin concentrations were measured. Data were analyzed by comparing change from baseline and postprandial incremental area under the curve (IAUC) among treatments. Baseline concentrations of glucose, insulin, leptin, and ghrelin were not different among treatments. However, glucose $\text{IAUC}_{0\text{–}6\ \text{h}}$ and $\text{IAUC}_{0\text{–}12\ \text{h}}$ were higher ($P = 0.028$) in cats fed control and HC compared with those fed HF and HP. $\text{IAUC}_{0\text{–}6\ \text{h}}$ and $\text{IAUC}_{0\text{–}12\ \text{h}}$ of insulin, leptin, and ghrelin were not different among treatments. In conclusion, while diets containing higher carbohydrate content increased blood glucose, they did not appear to affect appetite-regulating hormone concentrations. More studies on macronutrients are required to identify any effect they may have on appetite.

Key Words: appetite-regulating hormones, macronutrients, cat

619 Digestibility of day-old, whole ground, extruded, and canned chicken-based diets in African wildcats.

K. R. Kerr*[1], C. L. Morris[3], S. L. Burke[3], L. M. Garner[1], and K. S. Swanson[1,2], [1]*Division of Nutritional Sciences, University of Illinois, Urbana,* [2]*Department of Animal Sciences, University of Illinois, Urbana,* [3]*Henry Doorly Zoo, Omaha, NE.*

Small captive exotic cats are commonly fed whole prey to supplement traditional diets, such as raw-meat based, canned, and extruded diets. Data regarding the digestibility of these diet types is lacking. The objective of this study was to compare apparent total tract macronutrient digestibility differences of whole chicks [WHO; 24% DM, 76% crude protein (CP)], ground chicken (GRO; 31% DM, 43%CP), chicken-based canned diet (CAN; 40%DM, 47% CP), and chicken-based extruded (EXT; 92%DM, 36% CP) diets fed to captive African wildcats. Four animals were utilized in a crossover design. Apparent DM digestibility (81 to 85%) was not affected by treatment; however, apparent organic matter (OM) digestibility was higher ($P < 0.05$) in cats fed GRO (94%) compared with those fed WHO, CAN, and EXT (85 to 87%). Apparent CP digestibility was higher ($P < 0.05$) in cats fed GRO (91%) compared with those fed EXT (80%). Because the GRO had high digestibility and low levels of fiber or bulking materials (i.e., feathers), cats fed this diet had high fecal DM (68%), which was reflected in the fecal scores (1 out of 5; 1 = hard, dry pellets). Cats fed the other diets had fecal scores close ideal (2.6 to 3.6; 3 = ideal). In conclusion, all diets had high digestibility (>85% OM digestibility), maintained BW and health short-term. Inclusion of whole-prey (WHO and GRO) as dietary items for AWC is appropriate; however, if fed as the sole dietary item additional nutrient supplementation, including fiber or fiber-like material, may be necessary. Further research is needed on the ability of whole prey to meet the nutritional needs of small exotic cats, including compositional analysis, bioavailability, and research including more species.

Key Words: digestibility, feline, whole prey

620 Dietary protein:carbohydrate ratio alters kitten fecal microbiota as analyzed by 454 pyrosequencing.

S. Hooda*[1], B. M. Vester Boler[1], K. R. Kerr[1], S. E. Dowd[2], and K. S. Swanson[1], [1]*University of Illinois, Department of Animal Sciences, Urbana,* [2]*MR DNA Molecular Research LP, Shallowater, TX.*

The dietary protein: carbohydrate ratio may affect the gut microbiota of growing kittens, but this aspect of the diet has not been well studied. This study was conducted to test the effects of moderate and high protein intake on the composition of the gut microbiota of growing kittens using 454 pyrosequencing. Male domestic shorthair kittens were raised by mothers fed moderate-protein, moderate-carbohydrate (MPMC; n = 7) or high-protein, low-carbohydrate (HPLC; n = 7) diets, then weaned at 8 wk of age onto the same diet. Fresh fecal samples were collected at 8, 12 and 16 wk of age; DNA was extracted, followed by amplification of the V4-V6 region of the 16S rRNA gene using barcoded primers for pyrosequencing. Pyrosequencing of barcoded amplicons resulted in a total of 384,588 sequences, with an average of 9,374 sequences per sample. The difference in protein:carbohydrate ratio resulted in dramatic differences in fecal microbiota, primarily in the *Actinobacteria* and *Fusobacteria* phyla; the abundance of fecal *Actinobacteria* being greater ($P < 0.05$) in MPMC-fed kittens and increased with age ($P < 0.05$). In contrast, the proportion of fecal *Fusobacteria* was greater in HPLC-fed kittens ($P < 0.05$). Among the well-characterized genera *Clostridium*, *Fecalibacterium*, *Ruminococcus*, *Blautia*, and *Eubacterium* predominated ($P < 0.05$) fecal samples of HPLC-fed kittens. In contrast *Dialister*, *Acidaminococcus*, *Bifidobacterium*, *Megasphaera*, *Mitsuokella*, and *Subdoligranulum*, were greater ($P < 0.05$) in MPMC-fed kittens. Kittens fed MPMC also had higher ($P < 0.05$) fecal Lactobacillus at 8 wk of age and then decreased ($P < 0.05$) at 12 and 16 wk of age. Further research is required to identify the physiological relevance of these diet-induced changes in gut microbiota during the nursing and weaning period, and test how important the weaning diet is on long-term microbiota populations and gut health-related outcomes.

Key Words: protein carbohydrate ratio, gut microbiome, 454 pyrosequencing

621 Influence of indigestible starch content in dry expanded diets on stool characteristics of dogs differing in body size.

R. Goudez*[1,2], M. Weber[2], L. Martin[1], V. Leray[1], V. Biourge[2], H. Dumon[1], and P. Nguyen[1], [1]*LUNAM University, Oniris, National College of Veterinary Medecine, Food and Science and Engineering, Nutrition and Endocrinology Unit, Nantes, France,* [2]*Royal Canin Research Center, Aimargues, France.*

Large breed dogs are known to be more sensitive to diet than smaller ones, and consequently to produce feces of poorer quality. This could be due to larger amounts of indigestible residues reaching the large bowel and leading to increased fermentative activity. The aim of this study was 1/ to determine whether variation in dietary indigestible starch level could affect fecal characteristics in small and large dogs and 2/ to assess if large dogs have a higher digestive sensitivity to indigestible starch than small ones. Five German shepherds (GS), 5 beagles (BE), and 5 miniature schnauzers (MS) were used in the study. Two dry expanded diets were tested in a crossover design. They only differed in their source of corn starch: purified (CS) or high-amylose (HA), and contained respectively 0.4 and 3.6% of indigestible starch (i.e., resistant starch). Fecal quality, nutrient digestibility and fermentation by-products (SCFA and lactate) were measured. Effects of diet or breed on fecal parameters were statistically tested (Wilcoxon and Kruskal-Wallis tests). Contrary to CS diet, HA diet tended to modify fecal characteristics in the 3 tested breeds ($P < 0.059$). When HA diet was fed, higher fecal SCFA (GS, BE) or lactate (GS, BE, MS) concentrations, lower pH (GS), and poorer fecal quality (GS) were observed, and animals presented a lower apparent digestibility of starch. Compared with small ones, large dogs fed with the HA diet presented stools with lower consistency ($P < 0.003$) and higher moisture ($P < 0.003$). Fecal SCFA and lactate concentrations were higher ($P < 0.003$ and $P < 0.014$ respectively), and stool pH tended to be lower pH ($P < 0.055$). Starch apparent digestibility was higher in GS ($P < 0.01$). Those results show that indigestible starch level tends to increase colonic fermentative activity in all dogs whatever their size. However, small and medium dogs showed less sensitivity to indigestible starch based on fecal scores, while large dogs were quite responsive. These results suggest that indigestible starch content (strongly affected by source and processing) is a critical step for petfood manufacturer, especially regarding diets for large breed.

Key Words: dog, starch, fermentation

622 Influence of fresh citrus pulp and apple pomace on the digestibility of nutrients in dogs.

S. Brambillasca,* C. Deluca, A. Britos, and C. Cajarville, *Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

Six adult cocker spaniel dogs were used to evaluate whether the dietary inclusion of fresh citrus pulp and apple pomace affect the digestibility of nutrients. Dogs (3 female, 3 male; BW: 12.7 ± 0.7 kg) were assigned randomly to treatments in a double 3 × 3 Latin square design (3 treatments, 3 experimental periods). Treatments consisted in a commercial dog food (CON) with or without the addition of 70 g/kg of either fresh citrus pulp (CIT) or fresh apple pomace (APP). Each experimental period consisted in a 5-d diet adaptation phase and 3-d for fecal collection. Diets and feces were analyzed for DM, OM, CP, NDF and ADF, and digestibility of each fraction calculated. Data was analyzed by PROC MIXED considering the treatment and period effects and means were separated by orthogonal contrasts. Digestibilities of nutrients were higher when dogs received CON than when fed diets containing both citrus and apple. Dogs fed CIT presented higher digestibility values than dogs fed APP for most of the nutrients analyzed. Despite there was a reduction in digestibility values with the inclusion of fiber in the diets, overall digestion was widely acceptable.

Table 1. Effect of diets on coefficients of total tract apparent digestibility of nutrients

	Treatment				Contrast (*P*-value)[1]	
	CON	CIT	APP	SEM	Fiber	Source
DM	0.850	0.811	0.804	0.011	0.005	0.020
OM	0.888	0.845	0.841	0.012	<0.001	0.003
CP	0.863	0.835	0.817	0.011	0.012	0.081
NDF	0.777	0.680	0.649	0.022	<0.001	0.001
ADF	0.575	0.383	0.340	0.030	<0.001	<0.001

[1] Fiber = effect of fiber inclusion (CON vs CIT+APP); Source = effect of fiber source (CIT vs APP).

Dairy Foods: Microbiology and Chemistry

623 Impact of NaCl substitution with KCl on cell-wall extract and cell-free supernatant proteinase activities of *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus* and *Lactobacillus acidophilus* and *Lactobacillus casei* at different pH and salt levels. M. M. Ayyash[1], F. Sherkat[2], and N. P. Shah*[1,3], [1]*Victoria University, Melbourne, Vic, Australia,* [2]*RMIT University, Melbourne, Vic, Australia,* [3]*The University of Hong Kong, Pokfulam, Hong Kong.*

To reduce salt concentration in cheeses by substitution with KCl, it was important to study the effect of salt substitution on starter culture proteinases which play a vital role in ripening and texture profile of cheeses. The objective of this study was to examine the effect of NaCl substitution with KCl at different pH levels (6.0, 5.5, and 5.0) and salt concentrations on proteinases activity of cell-wall and supernatant of *Lactobacillus delbrueckii* ssp. *bulgaricus* 11824, *Streptococcus thermophilus* MS as well as of *Lactobacillus acidophilus* and *Lactobacillus casei* was investigated. MRS broths were mixed with 4 salt substitutions at 2 different concentrations (5% and 10%) and incubated individually at 37°C for 22 h. The collected cell pellets were used to prepare cell-wall proteinases and the cell-free supernatants were used as source of supernatant proteinases. The proteolytic activities and protein contents of both portions were determined. The supernatants after incubation of both portions with 3 milk caseins (α, β, kappa-casein) were subjected to ACE-inhibitory activity and proteolytic activity by OPA method. Significant differences were observed in ACE-inhibitory activity and OPA between salt substitutions of cell-wall extract and cell-free supernatant of LB and ST at same salt concentration and same pH level. The conclusion is that there were significant effects of pH and salt substitution on all measured variables.

Key Words: salt substitution, proteinase activity, ACE-inhibitory activity

624 Survival of microencapsulated probiotic *Lactobacillus paracasei* LBC-1e during manufacture of Mozzarella cheese and simulated gastric digestion. F. Ortakci,* J. R. Broadbent, W. R. McManus, and D. J. McMahon, *Western Dairy Center Department of Nutrition, Dietetics, and Food Science, Utah State University, Logan.*

An erythromycin resistant strain of probiotic *Lactobacillus paracasei* ssp. *paracasei* LBC-1 (LBC-1e) was added to part skim Mozzarella cheese in alginate microencapsulated or free form at a level of 10^8 and 10^7 cfu/g respectively. The objective of this study was to investigate the survival of LBC-1e and total lactic acid bacteria through the pasta filata process of cheese making where the cheese curd was heated to 55°C and stretched in 70°C-hot brine, followed by storage at 4°C for 6 wk and subjected to simulated gastric and intestinal digestion. This included incubation in 0.1 *M* and 0.01 *M* hydrochloric acid, 0.9 *M* phosphoric acid and a simulated intestinal juice consisting of pancreatin and bile salts in a pH 7.4 phosphate buffer. There were some reductions in both free and encapsulated LBC-1e during heating and stretching with encapsulated LBC-1e surviving slightly better. Changes in total lactic acid bacteria losses during heating and stretching did not reach statistical significance. During storage there was a decrease in total lactic acid bacteria but no statistically significant decrease in LBC-1e. Survival during gastric digestion in HCl was dependent on extent of neutralization of HCl by the cheese with more survival in the weaker acid in which pH increased to 4.4 after cheese addition. The alginate microcapsules did not provide any protection against the HCl. Interestingly, there was greater survival of the encapsulated LBC-1e during incubation in H_3PO_4. Proper selection of simulated gastric digestion media is important for predicting delivery of probiotic bacteria into the human intestinal tract. Neither free nor encapsulated LBC-1e was affected by incubation in pancreatin/bile solution. It was concluded that based on survival during simulated gastric digestion, the level of probiotic bacteria that would need to be added to cheese to provide a beneficial health benefit is lower than is generally assumed for other fermented dairy foods or when consumed as supplements.

Key Words: microencapsulation, probiotic, Mozzarella

625 Characterization of *Lactobacillus* sp. GF103 as potential probiotics in vitro. X. L. Dong[1], Q. Y. Diao*[1], N. F. Zhang[1], Y. Tu[1], M. Zhou[1,2], L. H. Zhao[1], and X. H. Gao[1], [1]*Key Laboratory of Feed Biotechnology of Ministry of Agriculture/Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Animal Science Xinjiang Agricultural University, Urumqi, China.*

Probiotics are living microbial feed supplements which beneficially affect the host animal by improving its intestinal microbial balance. A potentially probiotic strain is expected to have several desirable properties to exert its beneficial effects. The purpose of this study was to characterize the strain *Lactobacillus* sp. GF103 as potential probiotics. The strain was identified as *Lactobacillus plantum* by 16S rRNA sequence analysis (GenBank accession number: JQ411248). It was further characterized for acid and bile salt resistance, simulated gastrointestinal fluid tolerance and antibacterial activity. Results showed that *Lactobacillus* sp. GF103 can fully resist to pH 3 and 0.3% bile salts. The percentage of bacteria viable count was 85% during 3 h under the conditions of the simulated gastric fluid. Viability was not affected during 3-h culture in the simulated intestinal fluid. Antibacterial activity found the strain has ability to inhibit the growth of 2 pathogens, *Escherichia coli* K88 and *Staphylococcus aureus*. The results suggest that the strain *Lactobacillus* sp. GF103 has potential probiotics properties. It can survive and propagate in animal intestinal tract as probiotics additives.

Key Words: probiotics, 16S rRNA, characterization

626 Microbial safety assessment of Juustoleipa cheese manufacture. B. Ganesan,* D. Irish, and C. Brothersen, *Western Dairy Center, Utah State University, Logan.*

Juustoleipa cheese is manufactured by direct acidification of milk and stored either refrigerated or frozen. The cheese has a shelf life ranging from 2 weeks to over several months depending on mode of storage. The cheese is cooked (either toasted or mildly sautéed) before use in foods, which is a post-manufacture step that helps destroy unwanted bacteria. However, even such heat treatments do not exclusively limit bacterial load. To understand microbial quality, spoilage-, and safety-related issues arising from Juustoleipa cheese-making, we hypothesized that survival of unwanted bacteria in Juustoleipa cheese is reduced by frozen storage, thereby altering its shelf life, quality and safety. The objective of the study was to understand how storage conditions and pre-storage baking of Juustoleipa cheese affect its microbial quality. Juustoleipa cheese was made in 3 replicates. *Escherichia coli* and *Pseudomonas fluorescens* were added to separate cheese portions at an initial level of 10^4 cfu/g cheese along with a control (bacteria not added). Bacterial addition was performed 30 min after salting and cheeses were further pressed for 1.5 h and stored refrigerated or frozen with or without pre-storage cooking in a pizza oven (internal temperature of 82°C). We compared the survival of these bacteria by plate counts on selective media in refrigerated and frozen storage conditions that were sampled at a) 0, 14, and 28 d for refrigerated cheese and b) 0, 30, and 90 d for frozen cheese. Bacterial survival was reduced ($P < 0.05$) by 1,000 to 10,000-fold when samples were stored frozen, justifying our hypothesis. Pre-storage cooking of cheese reduced *E. coli* and *Pseudomonas* below detection by plate counts, but aerobic thermoduric bacteria that were incident during manufacture survived cooking at 82°C. As expected, microbial counts in cheeses that were not cooked were higher ($P <$ 0.05) by 10- to 1000-fold compared with those in cooked samples. Characterization of the thermoduric bacteria is underway to comprehend their survival mechanisms. We concluded that pre-storage cooking and frozen storage reduce survival of but do not fully eliminate thermoduric bacteria in Juustoleipa cheese, which might affect its shelf life and microbial quality.

Key Words: Juustoleipa cheese, *E. coli*, *Pseudomonas*

627 Viability of probiotic bacteria and yeasts in traditional and commercial kefir following frozen storage. K. V. O'Brien,* C. A. Boeneke, K. J. Aryana, and W. Prinyawiwatkul, *Louisiana State University, Baton Rouge.*

Kefir is a fermented milk traditionally made from a unique starter culture, which consists of numerous bacteria and yeast species bound together in an exopolysaccharide matrix produced by certain lactic acid bacteria. Many health benefits are associated with traditionally produced kefir; however, bulging and leaking packaging, caused by secondary yeast fermentation during storage, has limited large-scale manufacture of traditionally produced kefir. Commercial kefir products have been designed to reduce these effects by using a pure starter culture consisting of a mixture of bacteria and yeast species that give a flavor similar to traditional kefir; however, some health benefits may be lost in commercial production such as reduced microbial diversity and lack of beneficial exopolysaccharides. The objective of this study was to examine the effects of various periods of frozen storage on the survival of probiotic species in traditional and commercial kefir. The traditional kefir was prepared by inoculating 1 L of pasteurized whole goat milk with approximately 30 g of kefir grains. Commercial kefir was prepared by inoculating 1 gallon of full fat, pasteurized goat milk with a commercial kefir starter (Lifeway Foods, Morton Grove, IL). The milk was allowed to ferment at room temperature (24–28°C) until pH 4.6 was reached. Samples were frozen (−8 to −14°C.) immediately following the completion of fermentation and were thawed and plated for lactobacilli, lactococci and yeasts on d 0, d 7, d 14 and d 30 of frozen storage. Statistical analysis was performed using the variance analysis (ANOVA) F-test ($P < 0.05$). Means were compared by the least squares difference (LSD) test. Lactobacilli, lactococci and yeasts were significantly reduced in number during frozen storage ($P < 0.05$); however, the traditionally produced kefir was shown to have significantly higher counts of bacteria and yeast at each sampling ($P < 0.05$). It was concluded that the development of frozen kefir products would eliminate most packaging concerns associated with large-scale production of traditionally produced kefir, resulting in increased manufacture and marketability of this healthful product.

Key Words: kefir, probiotics, frozen dairy

628 Probing the foaming characteristics of milk proteins. J. A. Stankey*[1] and J. A. Lucey[1,2], [1]*University of Wisconsin-Madison, Department of Food Science, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

The strength of protein-protein interactions in foams gas-liquid interface dictate stability and formation of the dispersed gas phase. Molecular properties of proteins determine its overall foamability. Intermolecular interactions within and between casein can be modulated through the addition of salts, which affect the hydrophobic interactions. The Hofmeister salt (HS) series modifies hydrophobic interactions by strengthening (Na_2SO_4) or weakening (NaSCN) protein-protein interactions due to their preferential interactions with water or protein. Comparisons were made with the Hofmeister-neutral NaCl. This study evaluates the importance of hydrophobic interactions in milk protein foams by modifying casein interactions with HS. Mechanisms responsible for foam structure are of practical interest within the food industry. Foams were made from milk protein concentrate solutions (5% protein, w/w; pH 6.6) and HS were added (0.05–1.0 *M*) at 22°C. Protein solutions were whipped in a KitchenAid mixer for 5, 10, 15, or 20 min at the highest speed. Yield stress of foams was measured immediately after 20 min whipping using a rheometer with a vane attachment. Foam overrun and stability were measured at each time point. Foams made with high levels (≥0.5 *M*) HS exhibited salt-specific effects. Foams made with HS that decreased hydrophobic interactions (≥0.05 *M* NaSCN) formed quicker and were more voluminous, less stable, and weaker (yield stress) foams than the other treatments ($P < 0.05$). Foams made with HS that increased hydrophobic interactions (0.05–0.75 *M* Na_2SO_4) required longer time to foam, and produced denser, stronger, and overall more stable foams ($P < 0.05$). At high levels (1.0 *M*) of Na_2SO_4, foams formed slowly due to the high ionic strength and its salting-out effect on proteins. Overrun of foams made with NaCl decreased with increasing concentrations but stability and yield stress increased. Fluorescence microscopy was performed after whipping 20 min. Foams with 0.5 *M* NaSCN had fewer, larger air cells compared with foams made with 0.5 *M* NaCl or Na_2SO_4, which had smaller, more numerous air cells. Hydrophobic interactions between milk proteins at the gas-liquid play an important role in the strength and stability of foams.

Key Words: milk protein concentrate, foaming, Hofmeister series

629 The influence of Bactoscan total bacteria counting (TBC) and preliminary incubation (PI) counting on subsequent infrared milk component results. K. L. Wojciechowski and D. M. Barbano,* *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objective was to determine if sampling and sample handling for TBC and PI counting using a Bactoscan FC influences milk component test results by mid-infrared (IR) milk analysis. Raw milk was gravity separated for 22 h at 4°C. After 22 h, the lower 90% of milk was removed from the cone bottom gravity separation tank and then the cream layer was collected in 6 sequential fractions. The cream from the upper most fraction (highest bacteria count) was used to blend with a portion of the lower 90% (gravity skim about 2% fat) to produce milks with 3, 4, and 5% fat in addition to the gravity separated milk with no added cream. Milk at each fat concentration was mixed and split into 60 vials. If the removal of a test portion from a sample container by the auto-sampler of the Bactoscan when the milk was cold removed a non-representative portion of fat, then the effect of sampling on IR results would be expected to increase progressively with increasing fat concentration. The TBC count is done on fresh cold milk while the sample for the PI is incubated for 18 h at 14°C before testing. Within each fat level, 20 vials of milk were tested by IR only, 20 vials by Bactoscan TBC followed by IR, and 20 vials by Bactoscan TBC and PI, followed by IR. This was replicated 3 times with a new batch of milk and the samples were tested using a different Bactoscan FC in a different laboratory in each replicate. Running TBC with a Bactoscan first followed by IR milk analysis had minimal effect (<0.01%) on milk component tests when milk bacteria counts were within Pasteurized Milk Ordinance limits <100,000 cfu/mL. For milks with bacteria counts of > 500,000 cfu/mL, there was an effect on the fat test results. Running PI counts had an effect ($P < 0.05$) on IR component tests. The effect on component testing by IR was due to microbial growth in the samples, not the physical process of sampling by the Bactoscan. The effect of microbial growth was the largest on fat tests. The direction and magnitude of change in component tests will vary depending on the bacteria count, the type of bacteria that grow and the compounds they product in the milk.

Key Words: milk payment testing, bacteria testing, Bactoscan

630 Protective action of serum amyloid A3 against *Salmonella* Dublin infection.

A. Domènech*[1], A. ArÍs[1], A. Bach[1,2], and A. Serrano[1], [1]*Institut de Recerca i Tecnologia Agroalimentària (IRTA), Caldes de Montbui, Barcelona, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.*

Milk is an important source of antimicrobial compounds. Serum amyloid A3 (SAA3) is an acute phase protein expressed at high levels in colostrum and may be an important candidate for the protection of calves against intestinal infections. Previous studies have explored its protective role in the gastrointestinal tract indicating that it inhibits the binding of enteropathogenic bacteria in cell cultures. However, the SAA3 potential at regulating the intestinal immune response has been poorly explored. The objective of this study was to evaluate the SAA3 effects in infected and non-infected tissues ex vivo, quantifying the associated immune response and bacterial internalization. A total of 28 punches of 8-mm diameter from jejunal bovine Peyer patches were cultured in 24-well plates with Krebs media and assigned to 2 different treatments: with or without recombinant SAA3 (n = 14 per treatment). Tissues were incubated for 3 h at 37°C and 5% CO2. After the first hour of incubation, jejune explants were challenged with 10^2 cfu/well of *Salmonella* Dublin (n = 20), according to previous optimization of the ex vivo enteropathogenic model, or incubated with media (n = 8). For cytokine quantification, total RNA was extracted from the tissue and IL-8 and INF-γ levels were quantified by qPCR. To determine internalized bacteria, tissue fragments were homogenized and viable cell counts were enumerated by colony counting after serial dilution plating. Data were analyzed using an ANOVA test. In non-infected tissues, pro-inflammatory IL-8 response increased ($P < 0.05$) with the presence of SAA3. Moreover, the SAA3 treatment tended ($P = 0.08$) to double the expression of IL-8, and increased ($P < 0.05$) the expression of INF-γ in infected tissues. Furthermore, SAA3 clearly decreased ($P < 0.05$) *Salmonella* Dublin infection ($5.1 \times 10^3 \pm 1.3 \times 10^3$ cfu/mL versus $1.6 \times 10^3 \pm 0.46 \times 10^3$ cfu/mL with SAA3). In conclusion, SAA3 enhances inflammatory immune response in the gastrointestinal tract and suggests a direct protective effect against intestinal infections such as that caused by *Salmonella* Dublin.

Key Words: SAA3, intestine, *Salmonella* Dublin

Dairy Foods: Physico-Chemical Properties

631 Development of whey protein concentrate incorporated dietetic kulfi. H. G. Ramachandra Rao*[1] and A. Giri[2], [1]*Dairy Science College, Bangalore, Karnataka, India,* [2]*National Dairy Research Institute, Karnal, Haryana, India.*

Kulfi, a traditional Indian frozen dairy product has a similar composition to that of ice cream. Kulfi is made by concentrating whole milk (5% fat and 8.5% SNF) by 2 fold and then added with sugar, sodium alginate, glycerol monosterate and cardamom. The mix is then pasteurized, placed in molds and hardened to the consistency of ice cream. The objective of our study was to produce kulfi with reduced sugar and enriched with whey protein concentrate without compromising the sensory quality. Stevia, non-caloric natural sweetener, which is about 300 times sweeter than sucrose and heat stable up to 200°C was used as a sugar replacer to an extent of 50, 60 and 70 by 0.05, 0.06 and 0.07% respectively. At higher levels of sugar replacement, there was significant decrease of specific gravity, melting rate, and significant increase of freezing point, hardness and fat, protein, ash and moisture percentage. 50% sugar replaced kulfi was adjudged by a panel of 5 experts (using ice cream score card) on par with the control in sensory characteristics. Above 50% sugar replacement there was lack of brownish appearance, increased bitterness and presence of icy texture. Further, the study was conducted with incorporation of different levels of whey protein concentrate (WPC) at 0, 2, 3 and 4% respectively on the basis of concentrated milk and mixing thoroughly and hardening at −20°C for 8 h. When the levels of WPC addition increased there was significant decrease of freezing point (due to higher levels of soluble constituents - whey protein, lactose and mineral from WPC), melting rate (for improved water binding ability and stability for whey proteins), hardness (for water binding property which imparts reduced iciness) and moisture percentage but significant increase of specific gravity (for increase water binding ability of WPC), protein percentage and total calorie content. Among control and treated samples up to 3% addition of WPC overall acceptability score increased due to increase body and texture for excellent functional properties of whey protein but above 3% addition of WPC there was detectable whey flavor and excess softness. Statistically significance was tested by employing ANOVA and comparison between means was made by critical difference (CD) value. It was concluded that kulfi made with 50% replacement of sugar using stevia and 3% WPC incorporation was acceptable.

Key Words: kulfi, stevia, whey protein concentrate

632 Application of ultrasound spectroscopy to monitor lactose crystallization. J. K. Amamcharla*[1], L. E. Metzger[1], and R. Tweedie[2], [1]*Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings,* [2]*Industrial Tomography Systems plc, Manchester, UK.*

Lactose accounts for about 75 and 85% of the solids in whey and deproteinized whey, respectively. Production of lactose is usually carried out by a process called crystallization. Several factors including rate of cooling and mixing speed influence the crystal characteristics. Therefore, it is important to monitor the crystallization process. The objective of the present work was to use ultrasound spectroscopy as a tool to monitor the lactose crystallization process. Unlike conventional optical spectroscopy techniques, ultrasound spectroscopy can be used to characterize highly concentrated or optically opaque samples. An in situ ultrasound probe operating in pulse-echo mode connected to an ultrasound spectrometer (U2s, Industrial Tomography Systems, Manchester, UK) was used to acquire attenuation and velocity of ultrasound over the frequency range 5 and 20 MHz. In the first preliminary experiment, it was found that the attenuation of ultrasound in under-saturated lactose solutions was not influenced by temperature and lactose concentration. In the second preliminary experiment, it was found that the ultrasound attenuation increased along with an increase in the amount of crude lactose crystals. Lactose crystallization studies were conducted in a batch crystallizer (1000 mL). Supersaturated lactose solutions (70 g/100 g water) were prepared and crystallized using an isothermal batch process at 25°C. At regular intervals, 1mL of the crystal suspension was removed from the crystallizer and centrifuged to separate the crystals from the aqueous phase. The dissolved lactose in the aqueous phase was measured using a refractometer to determine crystallization kinetics. The separated crystals were washed with cold water (<5°C) and an image was acquired under 10× magnification using a camera attached to a microscope. As soon as the crystals appeared (20 μm), the ultrasound attenuation increased at frequency 12 MHz. Subsequently, the attenuation at other frequencies also increased as the concentration of lactose in soluble phase decreased. Overall ultrasound spectroscopy shows potential for monitoring the lactose crystallization process.

Key Words: ultrasound, lactose crystallization, in situ

633 Heat induced aggregation of whey proteins as influenced by shear, pH, and protein concentration. M. Dissanayake, L. Ramchandran, and T. Vasiljevic,* *Advanced Food Systems Faculty Research Unit, School of Biomedical and Health Sciences and Institute for Sustainability and Innovation, Victoria University, Werribee Campus, VIC, Australia.*

Microparticulation of whey proteins (WP) is understood to improve their functional properties that could enhance their utilization. However, shear forces used in microparticulation of WP can modulate their functional properties by altering their structure. The main objective of this study was to monitor the effect of simultaneous heating (90°C/20 min) and shearing (100, 500 or 1000/s) on WP aggregation at different protein concentrations (5, 10, 17.5 or ~25% w/w) and pH (3, 5 or 7). WP retentates (Warrnambool Cheese and Butter Factory, VIC, Australia) were simultaneously subjected to shear and heat using rheometer geometry. The sheared and heat treated WP were then analyzed for the conformational and structural changes by measuring turbidity, gel color, PAGE and surface hydrophobicity. Results from these tests indicated that application of shear reduced the formation of molecular associations including covalent bonds particularly at pH 7 while the reverse was true at pH 5. Surface hydrophobicity of WP increased significantly ($P < 0.05$) when sheared at pH 5 suggesting greater denaturation than the control and at pH 3 and 7, which further increased significantly ($P < 0.05$) with increase in shear rate at protein concentrations up to 10%. Turbidity tests indicated that shear forces significantly increased ($P < 0.05$) aggregate growth at pH 5, while at pH 3, protein concentration significantly increased ($P < 0.05$) the size of aggregates. Thus, the rate of denaturation and size of resulting aggregates was dependent on pH, protein concentration, and intensity of the shear forces applied. However, shear rate alone did not affect ($P > 0.05$) the color (lightness, L*) of the shear heat-induced WP gels but the effect was significant ($P < 0.05$) along with changes in pH and protein concentration. It was concluded that simultaneous heating and shearing of WP could modify the surface properties of the WP that could change the direction and extent of heat-induced WP denaturation and aggregation.

Key Words: whey proteins, aggregation, heat/shear

634 Effect of pH and protein concentration on denaturation kinetics of whey proteins.

M. Dissanayake, L. Ramchandran, and T. Vasiljevic,* *Advanced Food Systems Faculty Research Unit, School of Biomedical and Health Sciences and Institute for Sustainability and Innovation, Victoria University, Werribee Campus, VIC, Australia.*

Microparticulation of whey proteins (WP) has been implied to help overcome the loss of protein functionality accruing from traditional heat processing. This study examined the reaction kinetics of WP aggregation as a function of pH (4–6) and protein concentration (10, 17.5 and 25%, wt/wt) to help devise a more feasible pathway to produce microparticulated WP powder having small particle size. WP retentates (Warrnambool Cheese and Butter Factory, VIC, Australia) were heat treated at 140°C for 5–20 s in an oil bath. The thermal behavior of the WP was assessed using differential scanning calorimeter while the kinetics of denaturation was examined using capillary electrophoresis. The extent of protein aggregation was monitored by measuring solubility and turbidity. The denaturation and aggregation of β-Lg appeared to follow the first order reaction kinetics under steady state conditions. The reaction rate constant (k) obtained suggested distinctly higher rate of denaturation and aggregation when WP dispersions having 10% protein concentration were heated at pH 5. Also, the decline in k values was more noticeable at pH 4 than at pH 6 indicating a slower rate of denaturation at pH 4. At higher concentrations of protein, the rate of aggregation was not prominent at pH 5. Heat induced changes at low protein concentration reduced the solubility of WP regardless of pH, the reduction being significant ($P < 0.05$) during the first 5 s of heating at pH 5 and 6. The rate of decrease in solubility was significantly ($P < 0.05$) greater at pH 6 than at pH 4 and 5. The turbidity of WP dispersions at pH 4 were significantly higher ($P < 0.05$) than those at pH 5 and 6, suggesting that WP were most stable against heat induced denaturation at high protein concentration and low pH. Results from differential scanning calorimetric studies indicated that rate of WP denaturation varied with protein concentration and pH, being highest at 10% concentration and pH 5. It was concluded that microparticulation of WP at low pH and high protein concentration could produce heat stable WP ingredients.

Key Words: whey proteins, kinetics, denaturation

635 Comparison of heat stability of bovine milk subjected to UHT and in-container sterilisation.

B. Chen,* F. Ren, A. Grandison, and M. Lewis, *University of Reading, Reading, UK.*

The objective of this study was to compare how the heat stability of bovine milk was affected by the UHT and in-container sterilization. In addition, stabilizing salts are added to bovine milk to decrease ionic calcium concentration in milk and the roles of different stabilizing salts (di-sodium hydrogen phosphate and tri-sodium citrate) in both heat treatments were evaluated. Heat stability was assessed by measuring the amount of sediment in the bovine milk. Sediment formation provides a robust way of measuring heat stability during in-container sterilization, as standard deviations were small for replicated determinations of the same sample. Without stabilizing salts, bovine milk produced more sediment when subjected to UHT processing compared with in-container sterilization. Addition of up to 12.8 m*M* stabilizing salts resulted in a significant ($P < 0.05$) increase in sediment for in-container sterilization. This arises due to the considerable increase in measured casein micelle size during in-container sterilization. The existence of this lower heat stability region has not been specifically pointed out previously, since it is not intuitive that reducing ionic calcium will decrease heat stability. In contrast, adding 6.4 m*M* DSHP (di-sodium hydrogen phosphate) initially reduced sediment formation in UHT treated milk but this increased on addition of 12.8 m*M* DSHP. However, Adding up to 12.8 m*M* TSC (tri-sodium citrate) resulted in a continuous increase in sediment in UHT processing. Adding these stabilizing salts to bovine milk increased pH, decreased ionic calcium and increased casein micelle size. Adding up to 2 m*M* calcium chloride increased sediment formation significantly ($P < 0.05$) more after UHT treatment than after in-container sterilization. These results for bovine milk are in agreement with trends found for heat stability of caprine milk, which have been published previously. It was concluded that there is no single mechanism or set of reactions that cause milk to produce sediment during heating and that the kinetics are different for UHT and in-container sterilization processes. Poor heat stability could be induced by both increasing and decreasing ionic calcium.

Key Words: heat stability, UHT, in-container sterilization

636 Investigating the influence of phospholipids on the viability of *Streptococcus thermophilus* and *Bifidobacterium lactis.*

B. Chinnasamy* and S. Clark, *Food Science and Human Nutrition, Iowa State University, Ames.*

The potential health benefits and improved extraction methods of dairy phospholipids from by-products such as buttermilk and whey have opened new avenues for dairy phospholipids (PL) application in foods; one such application is fortification of yogurt with PL. However, before fortification, it is critical to evaluate if PL inhibit common lactic acid bacteria (LAB) used in yogurt. The objective of this research is to determine the influence of PL on viability of *Streptococcus thermophilus* (ST), *Bifidobacterium lactis* (BL), *Lactobacillus delbrueckii* ssp. *bulgaricus* (LB) and *Lactobacillus acidophilus* (LA) in yogurt. In preparation for work in yogurt, ST and BL were grown in M17 and MRS broth respectively, fortified with one of 5 PL: phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylinositol (PI), phosphatidylserine (PS), and sphingomyelin (SM). Growth was monitored at a) optimum growth temperatures and b) 5°C above the optimum growth temperatures (42°C ± 1and 47°C ± 1 for ST and 37°C ± 1 and 42°C ± 1 for BL, respectively). The temperature spike of 5°C from optimum growth temperatures was selected to "stress" bacteria in a way that may occur during yogurt processing. The PL were fortified at the rate of 0.01% wt/vol. The LAB were enumerated at 0, 3, 6 and 9 h time intervals using the pour plate technique. At optimum temperature, after 9 h, ST and BL counts tended to be higher when media were fortified with PL than when not. At elevated temperatures, most PL showed a similar trend, except ST, which was slightly inhibited by PS and PI, and BL by PE. No statistically significant differences ($P > 0.05$) were recorded in the viability of ST and BL in the presence or absence of PL or across temperatures. The results suggest that phospholipids do not have profound beneficial or inhibitory influences on ST and BL. However, viability studies in yogurt and on the remaining lactic acid bacteria must be conducted to determine fortification of PL in yogurt is a promising venture.

Key Words: phospholipids, *Streptococcus thermophilus*, *Bifidobacterium lactis*

637 Elucidating the role of α_{s2}-casein in the superior functionality of acid gels prepared from high-pressure-treated milks compared with heat-treated milks.

H. Patel*[1], P. Salunke[3], L. Creamer[2], and H. Singh[2], [1]*Fonterra Research Centre, Palmerston North, New Zealand,* [2]*Riddet Institute, Massey University, Palmerston North, New Zealand,* [3]*South Dakota State University, Brookings, SD.*

The objective of this study was to compare the functional properties of heat- and high-pressure-treated milks and elucidate the mechanisms

for differences in their functionality. Samples of low heat skim milk powder reconstituted to 10% total solids (wt/wt) were heat treated at 90°C for 10 min or pressure treated at 600 MPa for 3 min. Acid gels were prepared from these heat- and pressure-treated milk samples and rheological measurements (G′, G″, tanδ) were carried out. Samples were also centrifuged into a soluble (serum) phase and an insoluble casein micelle (pellet) phase and analyzed using PAGE techniques to study the interactions of proteins as affected by heat and pressure treatments of the samples. Both the heat- and pressure-treated samples generated a range of disulfide-linked aggregates, which were much larger in the heat-treated samples than the pressure-treated samples. The acid gel strengths were significantly greater in pressure-treated samples (1000 Pa) compared with heat-treated samples (200 Pa). The PAGE techniques suggested that the casein-whey protein (WP) complexes in the soluble phase consisted mainly of disulfide-linked complexes of κ-casein with β-lactoglobulin and other WPs, with little evidence of the presence of α_{s2}-casein, in the heat-treated samples, but contained significantly higher proportions of both α_{s2}- and κ-casein in the pressure-treated samples. The higher acid gel strengths of the pressure-treated samples, compared with the heat-treated samples, can be explained by the presence of greater amounts of soluble casein-WP complexes and the involvement of α_{s2}-casein (in addition to κ-casein) in the disulfide-linked interactions with WPs. Generally, α_{s2}-Casein is buried inside the casein micelles and is not easily accessible for casein-WP interactions whereas κ-casein protrudes outside the micelles and is readily available. High-pressure treatment affects the colloidal calcium phosphate complex; it dissociates/solubilizes the casein micelles, therefore exposing α_{s2}-casein and making it readily available, whereas only the κ-casein is accessible in heat-treated samples. These results clarify that α_{s2}-casein has a special role to play in improving the functional properties of high-pressure-treated milks.

Key Words: high pressure, heat, casein

638 Coagulation properties of the casein micelle by combination of ultrafiltration and dilfiltration measured using rheology and diffusing wave spectroscopy. J. G. Luo*[1,2], E. Kristo[1], and M. Corredig[1], *[1]Department of Food Science, University of Guelph, Guelph, ON, Canada, [2]Gay Lea Foods Co-operative Ltd., Guelph, ON, Canada.*

The objective of this work is to understand how casein micelles (CM) are affected during milk protein concentrates (MPC) manufacturing and what effect this may have on its coagulation properties. The changes in structure function of the CM occurring in MPC are a topic of great interest in dairy technology. There is limited research of coagulation properties of the casein micelle during MPC manufacturing. This study investigates the changes in the renneting functionality of fresh retentates and reconstituted retentates by combination of ultrafiltration and dilfiltration. Reconstitution was carried out in milk or milk serum (permeate). The rennet gelation behavior of reconstituted retentate was also compared with a control reconstituted freeze-dried skim milk powder (6% protein level). The renneting behavior of the CM was followed using rheology and diffusing wave spectroscopy (DWS). The release of caseinomacropeptide was also quantified. Soluble calcium and total calcium were measured to understand the effect of this ion on the mechanism of the gelation. Concentrated fresh retentate and reconstituted MPC (17.5% protein) formed significantly stiffer gels than regular samples (6% protein) due to increased number of bonds in the network. There were no significant difference in casein micelle size between fresh retentate and reconstituted retentates. The reconstituted retentates at 6% protein were dialyzed against skim milk to ensure the ionic equilibrium of the samples were similar to skim milk. The release of the caseinomacropeptide during renneting was also not significantly different among the samples tested at the same protein concentration. No significant differences were noted in the rennet coagulation time as tested by both DWS and rheology. After dialysis against milk, the gelation time of the samples was shorter and the gel modulus higher than for the nondialyzed samples. Based on our result, we conclude that ionic equilibrium is important in the reconstitution of MPC for rennet-induced gelation of milk.

Key Words: ultrafiltration, dilfiltration, rennet

639 Composition and physical properties of dairy products in the UK. B. Chen,* A. Grandison, and M. Lewis, *Univerisity of Reading, Reading, UK.*

The objective of this study was to investigate the effect of raw milk composition on some selected properties of milk products. Raw bulk cow milk was collected and its composition and physical properties were measured every 2 weeks. This milk was then converted to a range of products using standardized methodology and selected properties of these products were measured. Products include evaporated milk, soft cheese, skim milk powder, whipping cream, UHT milk and in-container sterilized milk. Results presented are those from the first 6 batches of raw milk, collected over the period August to December 2011. This project is ongoing and will be replicated with a minimum of 25 batches of raw milk. The range of values for fat and protein were 4.04 to 4.77% and 2.89 to 3.29% respectively. Ranges for lactose (4.26 to 4.69%), total solids (12.45 to 13.32%), pH (6.74 to 6.78), buffering capacity (pH change from 0.83 to 0.88) and ethanol stability (87 to 94%) were narrower. Ca^{2+}concentration ranged from 1.75 to 2.55 m*M*. Sediment in raw milk was very low, ranging from 0.10 to 0.12% (dry weight basis). Viscosity ranged from 1.56 to 2.31 cp and density from 1.026 to 1.031 g/cm^3. Casein micelle size ranged from 160 to 200 nm and freezing point depression from −0.525 to −0.514. The longest foaming times were 75 and 61 s for raw and skim milk, respectively, and the shortest were 24 s and 19 s. Foam stability was more variable, ranging from 76 s and 72 s to 213 s and 435 s for raw and skim milk, respectively. The viscosity range for evaporated milk was wide and was also affected by the level of added stabilizer. The range of for sediment for UHT and in-container sterilized milk was from 0.16 to 0.29% and from 0.18 to 0.31% respectively. Sediment formation was always accompanied by an increase in casein micelle size. For the whipping cream, the overrun and hardness were constant, ranging from 151 to 153% and 0.13 to 0.15 N, but the range of stability was more variable (14.63 to 18.75 mL). The heat stability of skim milk powder showed considerable variability. The ranges of the moisture content and hardness in soft cheese were 55.5 to 59.1% and 1.27 to 2.26 N respectively. It was concluded that variations in raw milk composition influence the properties of manufactured milk products.

Key Words: raw milk quality, physico-chemical properties, best use for milk

Extension Education II

640 Assessing a team-based educational program designed to build communication skills for practicing dairy veterinarians. G. M. Schuenemann*[1], D. J. Klingborg[2], D. A. Moore[3], and J. D. Workman[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*School of Veterinary Medicine, University of California, Davis,* [3]*Department of Veterinary Clinical Sciences, Washington State University, Pullman.*

The purpose of the study was to assess the effectiveness of a team-based educational module designed to build communication skills for practicing dairy veterinarians. A comprehensive program on leadership and communication skills was developed and participants from 11 veterinary practices located in 5 states (IN, NY, PA, NM, and OH), serving an estimated 186,150 dairy cattle in 469 herds, attended the advanced module (~2 d and ~20 h of learning) in 2011. The program consisted of the following topics: insights of participants; communication styles; personality influences; group dynamics/effective teams; rationale and interpersonal skills in team problem solving; communication lab-survival; communication model; re-write messages; elements of effective listening; conflict management; critical thinking, decision making and priority setting; elements of effective management of meetings and facilitation; message mapping; and communication limitations. Educational materials were delivered through in-class lectures followed by case-based learning, group discussions, and participant presentations resulting from an out-of-class assignment. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained during the module. Participants evaluated the program and provided feedback at the conclusion of each module. Veterinarians (100%) reported that the overall program, presentations, and discussions were useful. Attendees found the presented information relevant for their work (neutral = 2.3%, agree = 38.3% and strongly agree = 59.4%), and of great immediate use to them (neutral = 1.7%, agree = 43.9% and strongly agree = 54.4%). The presented materials and the implemented educational delivery methods substantially increased the knowledge level of the attendees (13.6% points increase from pre- to post-test scores; $P < 0.05$). Importance of teamwork and communication styles, developing and improving messages, elements for effective management of meetings, and conflict management styles were listed as learned concepts that participants can apply in their practices. This program has important implications for dairy veterinarians because they are a vital source of information for dairy producers.

Key Words: communication, veterinary, continuing education

641 Assessing a team-based educational program on nutrition and reproductive management for small dairy producers. G. M. Schuenemann*[1], W. P. Weiss[2], and J. D. Workman[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Animal Sciences, The Ohio State University, Wooster.*

The purpose of the study was to assess the effectiveness of a team-based educational program designed to enhance the transfer of applied research-based practices to dairy producers and their veterinarians to enhance sustainability of small dairy operations. A comprehensive program on nutrition and reproductive management was developed and participants from 2 veterinary practices and 69 dairy producers (<100-cow herds), attended the on-farm modules (~6 h of learning). The nutrition program consisted of the following topics: corn silage harvesting (moisture content, particle size, cut length, and inoculants); silage management (spoilage); choosing feeds; and maintaining ration consistency. The reproductive program consisted of the following topics: estrous cycle, synchronization strategies (estrus detection and compliance to protocols); factors affecting reproductive performance; record analysis; and AI technique. Educational materials were delivered through on-farm lectures followed by case-based learning, and group discussions. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained during the module. Participants evaluated the program and provided feedback at the conclusion of each module. Dairy producers (100%) reported that the overall program, presentations, and discussions were very useful. Attendees found the presented information relevant for their work (neutral = 3%, agree = 45% and strongly agree = 52%), and of great immediate use to them (neutral = 13%, agree = 43% and strongly agree = 44%). The presented materials and the implemented educational delivery methods substantially increased the knowledge level of the attendees (23 percentage point increase from pre- to post-test scores; $P < 0.05$). Additionally, >80% of participants indicated that they were highly confident (>75%) that they will apply the new learning into their operations. Handling corn silage, value of reproductive management, effect of nutrition and health management on herd performance, assessment of feed prices before buying, and teamwork and communication were listed as learned concepts that participants can apply in their operations. This program has important implications for small dairy operations and their sustainability.

Key Words: small dairy herd, reproduction, nutrition

642 I. Interactive index to identify and rank risk factors affecting reproductive performance of lactating dairy cows under field conditions. S. Bas*[1], P. Federico[2], and G. M. Schuenemann[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Mathematics, Computer Science, and Physics, Capital University, Columbus, OH.*

Many factors influence the reproductive and productive performance of dairy herds, thus, profitability. It is common to observe large between-herd variation in pregnancy rate (PR) of lactating dairy cows. Successful identification of factors affecting reproductive performance at herd level can be challenging due to their multi-factorial nature. The objective was to develop an interactive dairy herd index (DI) to aid in decision making about reproductive management of dairy cows. The DI was developed to identify and rank risk factors (stillbirth, retained fetal membranes, metritis, mastitis, lameness, body condition score, estrus detection, conception risk, labor-cow ratio, and stocking density) affecting PR according to their weights. Novel components of the DI included: 1) Desirable values for the selected risk factors (DV; estimated from the literature as reference for desirable PR), 2) Contribution weights for individual risk factors (CW; computed using linear regression), 3) Relative difference [RD = (DV-value of individual risk factor from herd to be assessed)/DV], and 4) DI by component (DI = RD*CW), 5) Ranking of risk factors according to their DI, 6) Overall DI for the herd (Positive or negative values move around the DV). The incidence of selected risk factors, collected from on-farm records, is compared with the DV and their individual CW to obtain individual and overall DI. Additionally, the regression nature of the DI helps the decision makers to be aware of the CW of each risk factor on PR due to herd management. Often time dairymen, consultants, and veterinarians trouble-shoot poor reproductive performance within-herd and the incidence of risk factors and their CW on PR varies greatly from farm-to-farm. Therefore, ranking within-herd risk factors with greater CW on PR is critical to implement corrective strategies step-by-step. Through a mechanistic approach, we ranked real herd risk factors affecting PR according to their CW (e.g., stocking density).

Key Words: dairy herd index, risk factor, pregnancy

643 Using real-time futures market simulation to teach dairy risk management. M. E. Sowerby* and J. J. VanSickle, *University of Florida, Gainesville.*

Less than 5% of all dairy producers use hedging strategies to manage price risk on their operations. To help producers gain knowledge, experience and confidence in using futures and options, a program featuring FACTSim, a financial and agricultural commodity trading simulator which uses real-time market data, was developed. FACTSim gives producers the opportunity to apply risk management concepts without losing real money. By using FACTSim, producers have gone beyond concepts to put together marketing goals to service farm debt needs and profit strategies to realize their farm goals. In the process of learning the fundamentals behind primarily milk, corn and soybean market movement, dairy producers have also become better at advanced ordering feed and using livestock gross margin (LGM)-Dairy insurance. Producers who have been involved in the program are now using futures options to hedge, gaining savings on advanced ordered feed and finding peace of mind using LGM-Dairy insurance.

Key Words: risk management, futures market, FACTSim

644 A decision support tool for investment analysis of new dairy housing facility construction. R. A. Black* and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this research was to develop a decision support tool, in the form of a user-friendly dashboard, for investment analysis of new dairy housing facility construction. User inputs included milking herd size, daily milk yield per cow, long-term milk price (MP), daily lactating cow feed cost, hourly labor cost, time to move cows, SCC bonus structure, SCC, and clinical mastitis and lameness incidence rate. New facility inputs included per cow barn cost (CBC), bedding cost (BC) and usage rate, tax rate, discount rate, interest rate, predicted daily increase in production per cow (PPC), predicted time to move cows, predicted time to stir the pack or rake stalls, and predicted reduction in SCC (PSCC), lameness incidence (PL) and clinical mastitis incidence (PCL). Investment analysis outputs included net present value (NPV), internal rate of return (IRR), breakeven barn cost, and payback period (PP). Model assumptions were obtained from published literature and farm surveys. This dashboard did not account for manure handling or culling costs. To compare alternative facilities with all model assumptions held equal except CBC, CBC were set at $850 per cow space for a compost bedded pack barn (CBP), $1,306 for a freestall barn with mattresses (FSM), and $1,021 for a freestall barn with sand (FSS). The NPV, IRR, and PP for the alternative facilities were CBP: $5,042, 9%, and 6.1y, respectively; FSM: $5,673, 9% and 6.8y, respectively; and FSS: $27,844, 13%, and 5.1y, respectively. A breakeven analysis was conducted for each of the 3 systems that would return a NPV of zero by changing BC, CBC, MP, PPC, PSCC, PL, or PCL. Results are depicted in the table below.

Table 1. Breakeven analysis for each of the 3 systems

System	BC	CBC	MP	PPC	PSCC	PL	PCL
CBP	$566	$909	$18.24	1.9kg	22.8%	44.1%	29%
FSM	$167	$1,061	$21.80	2.4kg	NA	NA	NA
FSS	$578	$1,214	$16.67	1.8kg	55.2%	80.8%	29%

Key Words: economic dashboard, compost bedded pack barn, freestall barn

645 Quantifying the effect of an extension programme (InCalf) on the reproduction performance of New Zealand dairy herds using a randomized controlled study. T. S. Brownlie*[1,2], J. M. Morton[3], C. Heuer[2], and S. McDougall[1], *[1]Cognosco, Anexa Animal Health, Morrinsville, New Zealand, [2]Epicentre, Institute of Veterinary, Animal and Biomedical Sciences, Massey University, Palmerston North, New Zealand, [3]Jemora Pty Ltd., Geelong, Victoria, Australia.*

There has been a national decline in the herd average reproductive performance and an increase in between herd variation of the New Zealand dairy herd. A national reproductive extension program (InCalf) has recently been introduced. A study was established to quantify the effects of this program on the reproductive performance of enrolled herds as well as benchmarking the reproductive performance of the national herd. The study was a multi-herd, multi-year randomized controlled study in 4 key dairy regions of New Zealand. In total, 168 herds were ranked based on estimates of the proportion of cows pregnant in the first 6 weeks of the seasonal breeding programs ("6-wk in-calf rate") and randomly allocated to either 1 of 2 control groups (n = 95) or the treatment group (n = 73) that received a 12 mo series of structured meeting with trained advisors ('farmer action groups'). The herds were monitored in the year of the farmer action group and the subsequent year. Monitoring included collection of cow demographic data, BCS, heifer weights, all breeding and disease events and 180,000 pregnancy tests. Social science interviews were conducted to capture the attitudes, priorities and constraints perceived by farmers. Preliminary results indicate that the mean 6-wk in-calf rate for the control group remained similar across years at 67% (95% CI: 66–68). The median 3 week submission rate (i.e., proportion of the herd bred in the 1st 3 weeks of the breeding program) remained at 81% (95% CI: 80–82) across years but the median conception rate to first breeding declined to 48% (95% CI: 47–49). A multivariable model including biophysical and demographic explanatory variables (including region and season) found allocation to treatment was associated with a small but not statistically significant increase in 6-wk in-calf rate. More variation was explained by reproductive performance at allocation and variation between herds was greater than between years. Determinants of changes in herd reproductive performance will be explored to refine expectations and strategies for delivery of extension programs.

Key Words: dairy, extension, reproduction

646 Stochastic simulation of the impact of commodity price variation on mastitis costs. D. Liang*[1], M. M. Schutz[2], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Purdue University, West Lafayette, IN.*

The objective of this research was to evaluate the impact of varying commodity prices on 2012 mastitis costs. The dynamic, stochastic, simulation farm-level model described by Bewley et al. (2010) and constructed using Microsoft Excel (Microsoft, Seattle, WA) and the @ Risk Monte Carlo simulation add-in (Palisade Corp., Ithaca, NY) was used to calculate mastitis costs and associated sensitivities. Baseline milk, replacement cow, slaughter, corn, soybean, and alfalfa prices were established using USDA NASS prices from 1971 to 2011 and stochastic predicted prices were modeled using FAPRI (Food and Agricultural Research Institution, Columbia, MO) estimates for 2012 to 2021. Feed cost was calculated using corn, soybean and alfalfa prices based on the USDA feed cost formula. A 163 cow US dairy, with default herd parameters established using DairyMetrics (Dairy Records Management Systems; Raleigh, NC) and published literature, was simulated through 5000 iterations. Mean (±SD) mastitis costs for parity 1 (P1) and later parity (P2) cows were \$240.98 ± 31.95 and \$192.08 ± 24.28 per case, respectively. For P1, costs (mean ± SD) were as follows: veterinary and drug costs (\$18.33 ± 1.83), labor costs (\$20.00 ± 2.00), discarded milk (\$55.21 ± 8.55), lost milk (\$93.78 ± 21.96), reduced days open (\$0.98 ± 1.78), culling (\$43.45 ± 10.80), and death (\$9.24 ± 1.27). In P1, mastitis costs were highly correlated with milk price ($r = 0.81$), moderately correlated with replacement price ($r = 0.464$) and feed cost ($r = -0.47$), and lowly correlated with slaughter price ($r = -0.18$). For P2, costs were as follows: veterinary and drug costs (\$18.33 ± 1.83), labor costs (\$20.00 ± 2.00), discarded milk (\$55.21 ± 8.55), lost milk (\$62.53 ± 16.56), reduced days open (\$0.98 ± 1.78), culling (\$25.11 ± 5.43), and death (\$9.93 ± 1.36). In P2, mastitis costs were highly correlated with milk price ($r = 0.88$), moderately correlated with feed cost ($r = -0.43$) and replacement price ($r = 0.28$), and lowly correlated with slaughter price ($r = -0.09$). These estimates may be used in on-farm mastitis decisions reflecting varying commodity prices.

Key Words: mastitis economics, commodity prices, stochastic simulation

647 A model: The Alabama Coalition for Farm Animal Care and Well-Being–A unified approach to animal care and well-being.

R. Owen,* L. W. Greene, W. F. Owsley, and D. Wolfe, *Auburn University, Auburn, AL.*

The purpose of the Alabama Coalition for Farm Animal Care and Well-Being is to provide a unified approach to animal care and well-being across all farm animal species in Alabama. The Coalition serves as a body of knowledge for legislators and political groups on issues of farm animal care and well-being; provides a unified approach on animal care and well-being; is an advocate for a safe and abundant food supply; serves as a spokes-group for animal care in Alabama; is proactive in education for producers, consumers, and policy makers on animal care and well-being; provides a science perspective on issues affecting animal agriculture; provides training forums on issues of animal agriculture to producers, and regulators; is a forum of consensus building on animal agriculture. The governance of the Coalition is by a board of trustees (BOT) with an executive committee (EC) supported by a well-founded membership. The BOT consists of one voting member from each of the full-member partners of the Coalition. The EC consists of a president, vice-president, secretary-treasurer, and 4 directors at large. The Coalition membership consists of 1. full member: farm animal related organizations directly involved with animal agriculture and Alabama Land Grant Universities agriculture programs and Colleges of Veterinary Medicine, and 2: associate member: organizations indirectly involved with animal agriculture. Two major standing committees of the Coalition are (1) Education and (2) Legislative. The education committee works for the development of educational programs for stakeholders. The legislative committee provides a linkage to the state's legislative activities effecting farm animal care and well-being. Through the educational efforts of the Coalition, the Animal Agriculture 101 program, a training course in basic concepts of animal care and well-being, was delivered to educate law enforcement on adequate farm animal care. The course creates a resource for local officials in dealing with animal care complaints. The Coalition member organizations were an integral part in passing Alabama's HB561: Animal Industry Bill, a bill which strengthens the authority of the state veterinarian regarding setting the standards and procedures for animal protection within the state.

Key Words: well-being, coalition, welfare

Food Safety: Advances in Food Safety

648 Antimicrobial use in preweaned calves: Effects on fecal *E. coli* resistance.

D. A. Moore,* D. Barone, A. C. B. Berge, T. E. Besser, and W. M. Sischo, *Washington State University.*

Antimicrobial use in food animals can potentially lead to resistant bacteria and future inability to use some antimicrobials for humans. The objective of this study was to determine the effect of fed antimicrobials and antimicrobial treatment on resistance in calf fecal *E. coli*. Newborn calves (n = 118) were allocated to 1 of 4 groups and monitored for 28 d. Calves in the conventional therapy group were treated as per dairy protocol with trimethoprim-sulfa, spectinomycin, penicillin, and bismuth-pectin for diarrhea. The targeted therapy group included a physical examination and treatment with bismuth-pectin for diarrhea and ceftiofur and trimethoprim-sulfa in cases of fever. Within treatment groups, calves were equally assigned to receive neomycin and tetracycline in their milk for the first 2 weeks of life or not. Daily health evaluations and treatments were recorded. Fecal swabs, taken on d 1 and at 2 and 4 weeks were cultured for *E. coli*, 3 isolates of which were tested for susceptibility to 12 antimicrobials. Resistance patterns were designated susceptible; resistant to at least streptomycin, sulfa and tetracycline (SSuT); or resistant to all β-lactams and SSuT. On the first sampling, 86% of isolates were mostly susceptible but by 14 d only 7 isolates were susceptible. Isolates were 3.1 times more likely to have β-lactam/SSuT resistance at 2 weeks compared with 4 weeks ($P < 0.001$). Using ordinal logistic regression, feeding antibiotics in milk did not result in higher levels of antibiotic resistance ($P = 0.52$). However, at the 14-d sampling, an isolate was 10 times more likely to have a higher level of resistance (either SST or β-lactam/SSuT) if the calf had been treated compared with no treatment (95% CI 3.7, 30.7). At 4 weeks, neither antibiotics in the milk for the first 14 d nor treatment were associated with resistance patterns seen ($P = 0.12$). In conclusion, antimicrobial treatment has a significant effect on recovery of multidrug resistant fecal *E. coli*, but the effect is not completely sustained over time.

Key Words: antimicrobial, resistance, calf

649 Effect of pre-slaughter stressors on intestinal microbial populations of pigs.

M. H. Rostagno*[1], B. T. Richert[2], and D. C. Lay Jr.[1], [1]*USDA-ARS, Livestock Behavior Research Unit, West Lafayette, IN*, [2]*Purdue University, Department of Animal Sciences, West Lafayette, IN.*

The swine intestinal microbiota is a complex ecosystem, which may be disturbed by many factors. Studies have focused on the relation between antimicrobial use and resistance in intestinal microbial populations, whereas the effect of non-antimicrobial factors, such as stress, remains unknown. During the process of being transported from production farms to abattoirs, market pigs are exposed to several stressors. The occurrence of antimicrobial resistance in market pigs is critical, since the most likely transmission route from animals to humans is through contamination of carcasses. Therefore, 2 experiments were conducted to determine the effect of common pre-slaughter stressors (feed withdrawal, transportation, and lairage) on levels of antimicrobial resistance in commensal coliforms and lactobacilli in market pigs. In the first study, no effect of transportation and lairage on total fecal coliforms or its subpopulations resistant to antibiotics was observed ($P > 010$). Also, no effect was observed on total fecal lactobacilli populations, as well as on subpopulations resistant to tetracycline and erythromycin ($P > 0.10$). However, a significant increase of the fecal levels of ampicillin-resistant lactobacilli was caused by transportation and lairage ($P < 0.05$). In the second study, while total ileal coliforms were not affected by feed withdrawal and/or transportation ($P > 0.10$), populations of lactobacilli resistant to tetracycline and erythromycin decreased ($P < 0.05$) in response to the stress of feed withdrawal and transportation. Interestingly, no effects of the investigated stressors were observed in any of the cecal microbial populations analyzed. These studies show that stress does affect intestinal microbial populations in market pigs with lactobacilli being more susceptible to the effects of stressors compared with coliforms. Moreover, it was revealed that interactions between type of stress, region of the intestinal tract, and microbial population analyzed may influence the pattern of antimicrobial resistance observed. There is a critical need for further investigation of the quantitative effect of stressors on intestinal microbial populations of pigs, and its food safety implications.

Key Words: swine, stress, microbial ecology

650 Screening of antimicrobials and salt substitutes for use in reduced sodium dairy products.

T. Taylor,* A. Lathrop, N. Farkye, and A. Lammert, *California Polytechnic State University, San Luis Obispo.*

Pressure has been put on the food industry to reduced sodium levels. Since reduction or elimination of salt from dairy products could potentially change the microbial stability an alternative antimicrobial agent may be needed. In addition to the use of antimicrobials salt replacers could be used to maintain acceptable flavor. To determine which antimicrobials have potential for success in reduced sodium dairy products, this study evaluated 8 commercially available antimicrobials (lauric arginate, natural enzyme systems and various fermentates). Antimicrobials were also tested in combination with 6 commercial sodium reduction agents to determine if their use would interfere with antimicrobial activity. Sodium reduction agents contained one or more of the following components calcium salt, potassium salt, sodium chloride, cultured corn sugar and trehalose. Milk and low-sodium cheese agar systems were used as the growth medium for screening. Antimicrobials with and without sodium reduction agents were added to the agar systems, then a 5-strain cocktail of *Listeria monocytogenes*, *Salmonella* or *Escherichia coli* O157:H7 was spread plated at 3 concentrations: 10^1, 10^2 and 10^4 cfu/plate. Samples were then incubated at 30°C and observed for growth after 24 and 48 h. A nisin-containing antimicrobial blend, lauric arginate, a natural enzyme system and a fermentate inhibited growth of all pathogens on milk agar after 48 h. In the cheese agar, pathogen growth was observed after 48h with the nisin-containing antimicrobial blend, and the fermentate, whereas while lauric arginate showed pathogen growth in 48 h or less. No pathogen growth was observed in the cheese agar containing the enzyme system. When the nisin-containing antimicrobial blend, lauric arginate and fermentate were tested in combination with sodium reduction agents containing potassium chloride, growth of *Salmonella* and *E. coli* O157:H7 was observed within 48h. Regardless of the salt substitute, there was no pathogen growth when the natural enzyme system was tested. Results from this study can aid in the selection of antimicrobials and sodium reduction agents for use in dairy products. However, testing in the dairy product itself is needed to confirm screen results and ensure a safe product.

651 Control of native microbiota in skim milk by pulsed electric fields and tangential-flow microfiltration versus high-temperature short-time pasteurization. D. Khanal,* A. Chugh, M. Walkling-Ribeiro, L. Duizer, and M. W. Griffiths, *University of Guelph, Guelph, Ontario, Canada.*

Conventional high-temperature short-time pasteurization (HTST) is the established food preservation technology for commercial processing of milk. However, during HTST treatment degradation of valuable nutrients and loss in sensory quality in milk occurs due to substantial heat exposure. Pulsed electric fields (PEF) and tangential-flow microfiltration (TFMF) are emerging food processing technologies that could represent a non-thermal alternative to heat pasteurization for skim milk processing. This study investigated the effect of non-thermal technologies on the reduction of native microbiota in skim milk and compared PEF and TFMF efficacies to that of HTST. Fresh raw skim milk (0.05% fat) was incubated at 8°C for 96–120h to promote the native microbial growth up to 10^8 cfu/mL. Incubated milk was treated with PEF for electric field strength, product flow rate and maximum processing temperature combinations using 28 kV/cm, 20 mL/min and 40°C (PEFL), 40 kV/cm, 35 mL/min, and 55°C (PEFM), and 40 kV/cm, 25 mL/min, and 65°C (PEFH) that led to respective treatment times of 2805, 1122, and 1571 µs, while TFMF-treated milk was processed at a flow rate of 300 mL/min and 35°C with membranes of different pore sizes (0.2, 0.45, and 0.65 µm). Thermal control treatments were carried out with HTST at 75 and 95°C for respective holding times of 20 and 45 s. ANOVA was used for all treatments ($n = 3$). Microbial loads in stand-alone PEFL- and PEFM-treated milk were reduced by respective 1.3 and 2.3 log10 ($P < 0.05$), in contrast to higher inactivation ($P < 0.05$) of 4.5 and 3.7 log10 achieved by similarly effective PEFH and 0.65 µm pore-sized TFMF ($P \geq 0.05$), respectively. However, these treatments were all less effective for microbial decontamination than microfiltration at 0.2 and 0.45 µm ($P < 0.05$) inactivating respective 6.0 and 5.9 log10, which was comparable to the low and high HTST treatments ($P \geq 0.05$) that led to 5.7 and 5.8 log10 reductions of native microbiota in skim milk, respectively. Results obtained in this study highlight the potential of TFMF and heat-assisted PEF for skim milk processing and suggest their combination in a hurdle technology as non-thermal processing alternative to HTST.

Key Words: pulsed electric field, tangential-flow microfiltration, high-temperature short-time

Horse Species Symposium: Equine-Assisted Therapies: Incorporation into university programs

652 Partnering therapeutic riding and higher education. C. Burke,* *University of New Hampshire, Durham.*

The field of equine-assisted activities and therapies (EAAT) is a growing segment of the equine industry in the US. Research in this area continues to support anecdotal evidence that EAAT works as a treatment modality for individuals with a wide range of disabilities. As a result, the need for knowledgeable, qualified, and diversely educated individuals with practical experience in EAAT is rising. Additionally, as the breadth and depth of this field increases, so do career opportunities, and therefore more college students wishing to pursue this course of study. Since 1969, the Professional Association of Therapeutic Horsemanship International (PATH Intl; formally NARHA) served as the primary educational body in this field. Today, there are increasing educational opportunities at the collegiate level available for the pursuit of EAAT as a degree option. In 2010, PATH Intl developed Higher Education memberships for colleges and universities in an effort to aid in curriculum development for EAAT. Many institutions are in the process of evaluating whether to offer EAAT as a course of study and if so how best accomplish this goal. In this session career options in EAAT will be explored and many related questions answered. What job opportunities are available for graduates with a 2- or 4-year degree in EAAT? How can universities best prepare students to succeed in this industry? Should institutions of higher education partner with a local EAAT center or start their own program? What other university resources are required to incorporate EAAT and what are some benefits to the university? What opportunities for cross-disciplinary studies exist? How would a PATH Intl Higher Education Membership fit into the curriculum and is it a worthwhile endeavor? Questions of liability, legal structure, and faculty qualifications will also be explored.

Key Words: equine-assisted activities and therapies (EAAT), PATH International Higher Education

653 Equine-assisted therapy and recovery from combat trauma. J. M. Kouba*[1], B. L. McDaniel[1], E. A. Eason[2], and K. G. Odde[1], [1]*Kansas State University, Manhattan,* [2]*Fort Riley, KS.*

After more than a decade of conflict in the Middle East, the number of soldiers being diagnosed with posttraumatic stress disorder (PTSD) and mild traumatic brain injury (mTBI) is steadily increasing. Population surveys on post-deployment soldiers report a prevalence rate of 10 to 20% for some type of combat-related stress disorder. The diagnosis of PTSD and mTBI presents challenges for mental health providers, and relies heavily on screening instruments and clinician interviews. Treatment options for soldiers routinely involve various types of counseling or psychotherapy, along with psychotropic medications. Despite these established approaches, a need still exists for novel treatment interventions. Although equine-assisted therapy (EAT) has been used as an adjunct therapy for a variety of health conditions, it is gaining popularity as an alternative treatment modality for veterans at private EAT facilities and some military institutions. Despite the positive results reported by these facilities, research supporting the effectiveness of EAT on alleviating the symptoms of PTSD or mTBI in our military population is limited. Therefore, a 14-wk study will examine the efficacy of EAT with active-duty military personnel who have experienced psychological and/or physical injury in a tour of duty and been diagnosed with PTSD or mTBI. Twenty-four subjects from the Warrior Transition Battalion at Ft. Riley, Kansas, will be randomly assigned to either a treatment (T, n = 12) or control (C, n = 12) group, each consisting of 6 soldiers diagnosed with PTSD and 6 with mTBI. The T group will be taught basic horsemanship skills in weekly small group sessions. The participants mental status will be assessed several times during the trial using survey instruments. Salivary cortisol will also be measured. The T group will also complete an EAT questionnaire and be interviewed upon completion of the trial to evaluate their perceptions of the program. We anticipate that the results will demonstrate a benefit of EAT in reducing symptoms associated with PTSD and mTBI, and help improve the quality of life of soldiers transitioning to the next phase of their military or civilian career.

Key Words: equine-assisted therapy, posttraumatic stress disorder (PTSD), mild traumatic brain injury

654 Research in equine-assisted activities and therapies. E. L. Berg,* *North Dakota State University, Fargo.*

A growing body of evidence exists supporting the benefits of equine assisted activities and therapies (EAAT) for individuals with a wide range of diagnoses including cerebral palsy, autism, stroke, multiple sclerosis, spinal cord injury, and attachment disorder. Research in the field of EAAT is necessary to demonstrate effectiveness of EAAT for individuals with disabilities, to validate and standardize industry practices, to garner support from the medical community, and to work toward reimbursement for these services from insurance companies. The objective of this session will be to highlight research in the field of EAAT, examine collaborative opportunities for institutions of higher education with industry and private organizations, discuss who would be integral members of a research team, as well as available funding sources in the area of EAAT.

Key Words: equine-assisted therapy, higher education, research

Meat Science and Muscle Biology Symposium: Pre-Slaughter Stress, Postmortem Glycolysis, and Biophysical Mechanisms of Meat Quality

655 Preslaughter stress and pork meat quality. L. Faucitano,* *Agriculture & Agri-Food Canada, Sherbrooke, Canada.*

At all times before slaughter pigs may experience stress from a range of handling practices, such as feed withdrawal, loading and transport, mixing, human interventions and slaughter. Frequently used welfare indicators for preslaughter treatment are behavioral and physiological (heart rate, hormones, and body temperature) responses. However, preslaughter stress is not only an animal welfare issue but also a meat quality issue as it may have short- and long-term effects on ante-mortem muscle metabolism and thereby on meat quality. The 2 major preslaughter stress-induced meat quality defects are PSE (pale, soft, exudative) and DFD (dark, firm, dry) pork. Acute short-term stress, such as no or short rest time after transport, rough handling while moving pigs toward the stunning area and the stunning process itself, can stimulate sympathetic arousal and adrenaline release triggering a rapid glycogenolysis and excessive lactate and heat production. This muscle metabolic condition may result in the formation of PSE pork depending on the glycogen content at the time of slaughter. A major effect of long-term stress, such as too extended feed withdrawal, transport and lairage times, and mixing of unfamiliar groups of pigs, is the reduction of muscle glycogen levels at slaughter leading to an insufficient acidification of the meat (higher ultimate pH) and production of DFD pork. However, the relationship between behavioral and physiological variables and meat quality parameters is sometimes conflicting. This discrepancy might depend on the different reaction to physical and psychological stressors of muscles differing in muscle fiber contractile properties, being the glycolytic muscles more prone to develop PSE pork and the oxidative ones to develop DFD pork. The objective of this review is to overview research findings related to the effects of preslaughter practices on ante-mortem animal physiological response, including muscle metabolism, and to provide recommendations aiming at limiting the effect of preslaughter handling on pork quality variation.

Key Words: meat quality, pigs, stress

656 Muscle glycogen and postmortem glycolysis. E. Poulanne,* *Department of Food and Environmental Sciences, University of Helsinki, Helsinki, Finland.*

Glycogen is a branched polysaccharide with linear chains of 12 to 14 glucosyl groups linked by 1,4-bonds. Glycogen has a variable molecular weight from about 600 000 up to 10^7 with 55,000 glucosyl units and 4000 chains, of which 2100 chains are on the outermost tier. The structure is optimized to provide the maximum number of available branches in a minimum volume. The chains (B chains) have 2 branching points where further chains are linked by 1,6-bonds to form the next tier up to 12 tiers. On the outermost tier, the chains are unbranched (A chains). Glycogen phosphorylase is able to degrade glycogen at a very high speed thus providing the energy substrate, glucose-1-phosphate, in periods of intensive exercise and stress. Glycogen phosphorylase can cleave the glucosyl units down to the fourth unit from the 1,6-bond. Following this, the glycogen debranching enzyme is required first to remove 3 glucosyl units and move them to another A chain, and then to degrade the 1,6-bond resulting in one free glucose molecule, which allows the further action of glycogen prosphorylase. In glycolysis, glucose-1-phosphate is converted to glucose-6-phosphate and then broken down to pyruvate by 9 different enzymes, yielding 3 ATP per glucose-1-phosphate (2 ATP of glucose molecules coming from the action of the glycogen debranching enzyme). Pyruvate is used oxidatively in the citric acid cycle or non-oxidatively to regenerate NAD+, resulting in 2 lactate molecules and the binding of 2 protons per glucosyl unit. Simultaneously, there is a net production of 2 protons per glucosyl unit which originate from the glycolytic pathway from different intermediates, depending of the pH of the medium at a given time.

657 Biophysical approaches for improving our understanding of meat quality. A. Karlsson* and D. Brüggemann, *University of Copenhagen, Frederiksberg C, Denmark.*

The texture and water-holding of meat are of utmost importance for consumer acceptance. Meat consists of approx. 70% water and approx. 20% protein, the latter being crucial for holding the myo-water in place. Proteins are also the main constituents that make up the structure of meat and meat products. Even minor structural and chemical changes as well as degradation of the proteins post-mortem, are therefore very important for the major meat quality attributes, including water-holding, color and texture. The proteins also undergo structural changes on heating, resulting in protein denaturation, which includes among other processes protein unfolding, and protein-protein interactions leading to protein aggregations. Therefore the quality of meat products, which is mainly governed by the meat structure, also changes drastically after cooking. Due the complexity of muscle tissue and meat raw material, our knowledge in this field is far from complete, and therefore there is a need for research to understand basic and underlying mechanisms involved to explain the variation of the important meat quality attributes, thereby making it possible to control the meat quality. Biophysics, where physical methods are used to explain and study biological phenomenon, has the potential for being a new way for a meat science paradigm shift, thereby making it possible to increase our understanding of mechanisms involved in the development of meat quality attributes, and also to obtain a more detailed understanding of the complex matrix of raw and processed meat. In this presentation we will show some preliminary results of biophysical approaches for improving our understanding of meat quality attributes using techniques including fluorescence lifetime microscopy, second harmonic generation microscopy, differential scanning calorimetry and high field NMR.

Key Words: meat quality, biophysics

Nonruminant Nutrition: Amino Acids and Energy

658 Influence of net energy content of the diet on productive performance and carcass merit of gilts, boars, and immunocastrated males fed barley-based diets and slaughtered at 119 kg of BW. L. Cámara[1], M. Romero[1], M. P. Serrano[1], J. L. Sánchez[2], E. Alcázar[2], and G. G. Mateos*[1], [1]*Departamento de Producción Animal, Universidad Politécnica de Madrid, Madrid, Spain,* [2]*SAT Vallehermoso S.A, Ciudad Real, Spain.*

In total, 540 crossbred pigs with an initial BW of 28.5 ± 4.1 kg were used to investigate the effects of increasing the level of NE of barley based diets (2.450, 2.410, 2.370, 2.330, and 2.290 Mcal/kg) on growth performance and carcass and meat quality traits of gilts, boars, and immunocastrated males (IMC) slaughtered at 119 kg BW. The IMC pigs were immunized against GnRF with Improvac at 90 and 143 d of age (18 and 71 d on trial). Each treatment (5 × 3) was replicated 3 times (12 pigs per pen). Gilts, boars, and IMC pigs responded similarly to NE concentration of the diet. For the entire experimental period, an increase in NE concentration of the diet improved linearly NE intake ($P < 0.05$), ADG ($P < 0.05$), and feed efficiency ($P < 0.001$) but ADFI and NE efficiency (g of ADG/ Mcal NE intake) were not affected. Backfat depth (linear, $P < 0.05$, quadratic; $P = 0.078$), fat at m. *Gluteus medius* (linear, $P < 0.05$), and trimmed ham yield (linear, $P < 0.05$) increased as the NE concentration of the diet increased but carcass yield was not affected. The IMC pigs had higher ADFI ($P < 0.001$) and ADG ($P < 0.05$) than gilts and boars. Net energy efficiency was higher for boars than for gilts with IMC being intermediate ($P < 0.001$). Carcass and loin yields were higher for gilts than for boars and IMC ($P < 0.001$). Backfat depth ($P < 0.01$) and fat at m. *Gluteus medius* ($P < 0.001$) were higher for gilts and IMC than for boars. The results indicate that an increase in NE concentration of the diet improved growth performance and increased the amount of fat carcass independent of gender. The IMC pigs had higher ADG, backfat, fat at m. *Gluteus medius*, intramuscular fat, and similar carcass and primal cut yields than boars. The use of diets with NE content above 2.330–2.370 Mcal /kg is recommended for the production of pigs destined to the dry cured industry because of its beneficial effects on growth performance, backfat depth, and intramuscular fat that improved the quality of the final products.

Key Words: growth performance and carcass merit of pigs, inmunocastration, net energy

659 Influence of increasing levels of lysine in the diet on growth performance and carcass quality of entire and inmunocastrated females. L. Cámara[1], M. P. Serrano[1], A. López[2], J. M. González[2], F. Ortin[2], and G. G. Mateos*[1], [1]*Departamento de Producción Animal, UPM, Ciudad Universitaria, Madrid, Spain,* [2]*Piensos Jiménez S.L., Lorca, Murcia, Spain.*

In total, 320 crossbred pigs (70 d of age) were used to study the influence of increasing levels of standarized ileal digestible lysine (Lysd) in the diet on growth performance and carcass and meat quality of gilts and inmunocastrated gilts (IMG). The IMG were immunized against GnRF at 89 and 161 d of age. The feeding program consisted of 3 periods with 5 dietary Lysd levels used within each period. Diets within period were formulated to have the same net energy (NE) content (2,470 kcal/kg) but differed in Lysd concentration (control diet and ± 5% and ± 10% over the control diet). The Lysd concentration of the control diets was 1.01% from 70 to 89 d of age, 0.95% from 89 to 140 d of age, and 0.83% from 140 to 185 d of age. All the other indispensable amino acids were formulated on an ideal protein bases. Each treatment was replicated 4 times and the experimental unit was the pen for all traits (8 pigs each for growth performance variables and 4 carcasses chosen at random for carcass and meat quality traits). From 70 to 89 d of age, ADFI was similar for pigs fed diets with −5% to +5% Lysd and decreased with −10% (linear, $P = 0.088$; quadratic, $P = 0.003$). Pigs fed −10% Lysd diet had worse G:F than pigs fed −5% to +10% Lysd diets (linear, $P < 0.001$; quadratic, $P = 0{,}010$). From 161 to 185 d of age, IMG had higher ADFI ($P < 0.001$) and ADG ($P = 0.023$) than gilts. Cumulatively, neither Lysd content of the diet nor inmunocastration of gilts had any influence on growth performance of the pigs. Inmunocastrated gilts tended ($P = 0.073$) to have higher fresh ham yield than gilts but none of the other carcass quality variables measured, were affected by Lysd content of the diet or inmunocastration of the gilts. An increase in Lysd concentration in the diet increased protein content (linear, $P = 0.0185$) and reduced (linear, $P = 0.0373$) fat content of the meat measured at m. *Longissimus dorsi*. It is concluded that, under the conditions of the current experiment, the use of 1.01%, 0.86%, and 0.74% digestible Lys is recommended in each of the 3 feeding periods considered, in diets containing 2,470 kcal NE/kg.

Key Words: carcass quality of pigs, digestible lysine, inmunocastration

660 The standardized ileal digestible (SID) tryptophan to lysine ratio to optimize performance of 25 to 50 kg pigs fed low protein diets. G. Zhang[1], S. Qiao[1], and J. K. Htoo*[2], [1]*China Agricultural University, Beijing, China,* [2]*Evonik Industries AG, Hanau, Germany.*

Published data about the optimal SID Trp:Lys ratios for growing pigs fed low CP, AA-supplemented diets are rather inconsistent. Two 35-d experiments were conducted to estimate the optimal SID Trp:Lys in 25–50 kg pigs under commercial conditions. In Exp. 1, 144 pigs (Landrace × Large White; initial BW of 25.3 kg) were used to identify a diet deficient in Lys. Pigs were fed either a corn, soybean meal based high CP (18.6%) diet with 1.02% SID Lys or one of 2 low CP diets (14.6% CP but supplemented with Lys, Thr, Met, Thr, Trp, Val and Ile) to contain 0.90 or 1.02% SID Lys, respectively. All diets were formulated to contain 2400 kcal/kg NE and AA except Lys were adequate. Each diet was assigned to 6 pens with 4 barrows and 4 gilts per pen. The ADG (688 g/d) of pigs fed the low CP diet containing 0.90% SID Lys was lower ($P < 0.05$) than that of pigs fed the diet containing 1.02% SID Lys with a high (758 g/d) or low (747 g/d) CP content confirming that 0.90% SID Lys was deficient for these pigs. In Exp. 2, 300 pigs (same genetic and BW as used in Exp. 1) were allotted to 5 diets with 5 barrows and 5 gilts per pen and 6 replicates per treatment. Diets 1 to 5 contained SID Trp content of 0.12, 0.14, 0.17, 0.20 and 0.23%, respectively and the same suboptimal SID Lys level of 0.90% (dietary SID Trp:Lys of 13, 16, 19, 22 and 25%). The ADG increased linearly ($P < 0.05$) as the SID Trp:Lys increased while a linear effect of ADFI ($P < 0.05$) and a quadratic effect of FCR ($P < 0.05$) were observed. The d 36 plasma Trp concentration was highest ($P < 0.05$) at 25% SID Trp:Lys while plasma urea N concentration was lowest ($P < 0.05$) at 22% SID Trp:Lys. The SID Trp:Lys to optimize ADG, FCR and plasma urea N were 19.7, 20.0 and 20.8% using a linear broken-line model, and 22.6, 23.2 and 23.6% using a curvilinear-plateau model, respectively. On average, the optimal SID Trp:Lys was estimated at 22% for 25 to 50 kg pigs fed low CP, AA-supplemented diets under commercial conditions.

Key Words: growing pigs, lysine, tryptophan

661 Changes in amino acid accretion during immune activation of the chicken immune system by *E. coli*.

V. J. Iseri* and K. C. Klasing, *University of California, Davis.*

The immune system requires appropriate levels of nutrients to support changes in leukocyte numbers and effector proteins during immune activation. However, a quantitative estimate of the amount of nutrients needed for maintenance and the additional amounts needed for a robust response has yet to be attempted. Thus, we quantified the total amino acid content of leukocytes in blood and tissues, protective plasma proteins, liver and pectoralis muscle in adult chickens before and after injected intravenously with dead *E. coli*. The amount of amino acids accreted during the early (first 2 d) and late (first 21d) response were calculated. When comparing amino acids used for leukocytes and protective proteins relative to that in skeletal muscle, lysine was limiting during the early response and leucine, threonine, and valine were limiting for the late response. For liver, phenylalanine, asparagine, lysine, and valine were limiting relative to muscle during the early response and phenylalanine during the late response. Summing accretion for expansion of leukocytes, protective proteins and liver showed that lysine and asparagine were limiting during the early response and leucine, threonine, and valine were limiting during the late response. Supported by USDA Regional Research project 1013.

Key Words: chicken, *E. coli*, amino acids

662 Restricting sulfur amino acid intake in immune system stimulated pigs decreases plasma protein and albumin synthesis.

N. Litvak* and C. F. M. de Lange, *University of Guelph, Guelph, ON, Canada.*

Chronic sub-clinical levels of disease occur frequently in intensive pork production and compromise nutrient utilization efficiency. Sulfur amino acids (Met+Cys; SAA) are involved in the pig's response to immune system stimulation (ISS) as substrates for generating compounds involved in the immune response, such as glutathione and acute phase proteins (APP; haptoglobin, fibrinogen, albumin). This study was conducted to determine the impact of ISS and SAA intake (high vs. low; 4.0 vs. 2.2 g/d) on the fractional synthesis rate (FSR) of albumin and protein in blood plasma, liver, and small intestine (SI) of pigs. Fifteen pigs (9.8 ± 1.4 kg BW) were allotted to one of 3 treatments: 1) Control (ISS-; high SAA), 2) ISS+ and high SAA, or 3) ISS+ and low SAA. For inducing ISS, pigs were injected intramuscularly twice, with a 48 h interval, with increasing doses of *E. coli* lipopolysaccharide (LPS); an ISS protocol that has been proven effective in previous studies. One day after the second LPS injection, FSR was determined using an intravenous infusion of a flooding dose of L-[ring-2H5]-Phe. Plasma levels of APP were not affected by ISS ($P > 0.10$; Control vs. ISS+ and high SAA). Only plasma albumin levels decreased with reduced SAA intake (29.0 vs. 24.2 g/L; ISS+ and high SAA vs. ISS+ and low SAA; SEM = 1.26; $P = 0.02$). Molar enrichment of free Phe in the liver and SI ranged from 86 to 91% of that in plasma, indicating adequate flooding. In plasma, total protein FSR was increased during ISS (50.3 vs. 56.9%/d, SEM = 1.64; $P = 0.01$) and plasma FSR tended to decrease with reduced SAA intake (56.9 vs. 52.5; SEM = 1.64; $P = 0.08$); albumin FSR was not affected by ISS ($P > 0.10$), but decreased with reduced SAA intake (49.5 vs. 41.9%/d, SEM = 1.57; $P = 0.01$). There were no treatment effects on FSR in liver and SI. The FSR of plasma proteins appears a more sensitive indicator of liver protein synthesis. Overall, these results suggest that restricting SAA intake during ISS decreases total plasma protein and albumin synthesis, implicating SAA as important nutrients involved in the immune response.

Key Words: immune system stimulation, protein synthesis, sulfur amino acids

663 Response to dietary L-glutamine supplementation in weaned piglets: A serum metabolomic comparison and hepatic metabolic regulation analysis.

Y. Xiao,* A. Chen, T. Wu, L. Yang, and Q. Hong, *College of Animal Sciences, Zhejiang University, Hangzhou, Zhejiang, China.*

A novel metabolomic method based on gas chromatography/mass spectrometry was applied to investigate the serum metabolite in response to dietary L-glutamine (Gln) supplementation in piglets. Sixteen 21-d-old piglets were weaned and randomly assigned into 2 groups, one with the Gln group and the other with the control group, representing 1% Gln (wt:wt) and isonitrogenous L-alanine, respectively. Serum samples were collected to characterize metabolites after a 30-d treatment. Additionally, 4 liver samples per group were collected to examine the enzyme activity and genes expression involved in metabolic regulation. Results showed 12 metabolites were significantly altered by Gln treatment, including carbohydrates, amino acids, and fatty acid. A leave-one-out cross-validation of random forest analysis indicated that proline and glycerol were the most important metabolites among the 12 different metabolites. These data demonstrated that the control and Gln-supplemented pigs showed a wide range of metabolic difference across carbohydrate metabolism, arginine and proline metabolism, tyrosine metabolism, and glycerophospholipid metabolism. Principal component analysis yielded separate clustering of profiles between the 2 treatment groups. Metabolic enzyme activity of alanine aminotransferase and hexokinase increased by 26.77% ($P = 0.026$) and 26.18% ($P = 0.004$), respectively, in the liver of Gln-supplemented pigs over the control, whereas pyruvate kinase (PK) activity decreased by 29.08% ($P = 0.001$). The mRNA level of PK decreased by 66.10% ($P = 0.034$) in the liver. No significant difference was observed for the mRNA level of mammalian target of rapamycin and peroxisome proliferator-activated receptor gamma. Based on the data, correlation networks for the Gln-supplemented and control pigs revealed that Gln treatment changed carbohydrate, lipid and amino acid metabolism in the whole body of the early weaned piglets. These findings provide fresh insight into specific metabolic pathways and lays the groundwork for the complex metabolic alteration in response to dietary Gln supplementation in pigs.

Key Words: glutamine, metabolomics, piglets

664 Effects of dietary glutamine supplementation on nutrient absorption and activity of enzymes involved in glutamine metabolism and energy production in the jejunum of weaned piglets.

A. Chen,* Y. Xiao, T. W. Wu, Q. Hong, and C. Yang, *College of Animal Sciences, Zhejiang University, Hangzhou, Zhejiang, China.*

The influence of L-glutamine (Gln) on the coefficient of total tract apparent digestibility (CTTAD) and apparent ileal digestibility (AID), the jejunal enzyme activity associated with nutrient absorption, and the energy production in weaned piglets has not been sufficiently studied. The aim of the present paper is to provide a profile of the effects of Gln on CTTAD, AID, the activities of jejunal enzymes in connection with nutrient digestion and absorption and energy production. The piglets were weaned at 21 d of age. There were 2 groups in Exp. 1 and Exp. 2, representing supplementation with 0 or 1% Gln to the basal diet. In Exp. 1, the CTTAD of the dietary components and energy was assessed at 3, 5, 10, 15, and 30 d after weaning. In Exp. 2, productive performance, AID, jejunal enzyme activities, and expression of peroxisome proliferator-activated receptor gamma (PPARγ) were measured at 10 and 30 d post-weaning. Results showed that dietary Gln supplementation significantly improved the CTTAD of DM, OM, GE, and AA, and the CTTAD increased significantly with the extension of days after weaning. For the entire experiment, the average daily gain increased by 12.40% ($P = 0.049$) in the Gln group. Dietary Gln supplementation increased the AID of GE, Leu, Lys, Cys, and Pro by 12.50 ($P = 0.047$), 7.03% ($P = 0.041$), 5.95% ($P = 0.036$), 9.30 ($P = 0.025$), 11.17% ($P = 0.009$), respectively, at 10 d post-weaning; Pro by 6.11% ($P = 0.044$) at 30 d post-weaning. Jejunal brush border membrane-bound alkaline phosphatase activity increased in the Gln-supplemented pigs by 30.36% ($P = 0.048$) and 6.21% ($P = 0.30$) at 10 and 30 d post-weaning, respectively. Compared with the control pigs, the mRNA level of PPARγ decreased by 10.85% ($P = 0.14$) and 41.88% ($P = 0.023$) after the administration of 1% Gln for 10 and 30 d, respectively. The activity of glutamine synthetase decreased by 48.89% ($P = 0.044$) at 10 d post-weaning, and pyruvate kinase by 13.13% ($P = 0.036$) at 30 d post-weaning in the Gln-supplemented pigs. In conclusion, 1% Gln supplementation to the post-weaned piglet diet enhanced the CTTAD and AID of diet, improved intestinal absorption, and modified jejunal enzyme activities related to Gln metabolism and energy production.

Key Words: L-glutamine, nutrient absorption, weaned piglets

665 Effects of oral supplementation with glutamate or combination of glutamate and N-carbamylglutamate on intestinal mucosa morphology in weanling piglets. W. Xin[1,2], P. Zhangzhi[1,2], L. Zhiqiang[1], L. Tiejun[1], and Y. Yulong*[1,2], [1]*Key Laboratory for Agro-ecological Processes in Subtropical Region, Institute of Subtropical Agriculture, Chinese Academy of Sciences, China,* [2]*State Key Laboratory of Food Science and Technology and College of Life Science and Food Engineering, Nanchang University, China.*

To evaluate the effects of glutamate (Glu) or combination of glutamate and N-carbamylglutamate (NCG) on intestinal mucosa in weanling piglets, 18 Duroc × Landrace × Yorkshire piglets weaned at 28 d (BW 5.56 ± 0.51 kg) were grouped into 3 treatments, and fed one of the following diets for 30 d: a standard diet (SD), SD+Glu (1%), SD+Glu (1%)+NCG (0.05%). All the piglets were killed for blood and tissue collection. The results showed that compared with the control group, Glu increased concentration of blood glucose and glucagon ($P < 0.05$) and reduced plasma insulin ($P < 0.05$) in weaned piglets. Both of Glu or combination of Glu and NCG decreased serum urea nitrogen and ammonia concentration ($P < 0.05$), and Glu+NCG increased average intestine weight significantly ($P < 0.05$). Compared with the control group, adding Glu to the diet resulted in a higher villus height ($P < 0.05$) in both of duodenum and jejunum. However, there was no difference in crypt depth at the 2 different locations, and the villus height/crypt depth ratio was unaltered ($P > 0.05$). The RT-PCR results showed that combination of Glu and NCG significantly increased PCNA mRNA abundance in both jejunum and ileum ($P < 0.05$), while they also significantly increased β-catenin and decreased VEGF in ileum ($P < 0.05$). There were no differences in expression of these genes between the Glu and Glu+NCG groups ($P > 0.05$). Only Glu increased ($P < 0.05$) PCNA mRNA abundance in jejunum. and Glu+NCG significantly decreased VEGF mRNA in jejunum ($P < 0.05$). These results indicated that oral supply of Glu improved intestinal mucosa morphology, and combined Glu and NCG had more favorable effects on self-renewing of intestinal mucosa than supply of glutamate alone.

Key Words: glutamate, N-carbamylglutamate, mucosal morphology

Physiology and Endocrinology I

666 Gram-negative or gram-positive toxin-induced subclinical mastitis affects preovulatory follicle responses in cows. O. Furman[1], G. Leitner[2], Z. Roth[1], Y. Lavon[3], S. Jacoby[4], and D. Wolfenson*[1], [1]*Faculty of Agriculture, Food and Environment, the Hebrew University, Rehovot, Israel,* [2]*The Veterinary Institute, Bet Dagan, Israel,* [3]*Israel Cattle Breeders Association, Caesarea, Israel,* [4]*Institute of Animal Science, Agricultural Research Organization, Bet-Dagan, Israel.*

Long-term, subclinical mastitis lowers conception rate. The objective of this study was to induce subclinical mastitis by gram-positive (G+) exosecretions (*S. aureus* ex.) or gram-negative (G-) endotoxin (*E. coli* LPS), and examine its effects on preovulatory follicle responses. Throughout the study, cows were synchronized with series of GnRH and $PGF_{2\alpha}$ administered every 8 d. Cows received intramammary injections every 48 h for 20 d with minimal doses of either G+ (10 µg, n = 10) or G- (0.5 µg, n = 6) toxin, or saline (n = 6). Follicular fluids were aspirated before, at the end of (immediate effect), and 16 and 32 d after toxin exposure (carryover effect). Data were analyzed by ANOVA. During G+ or G- exposure, somatic cells count was higher ($P < 0.05$) than in controls, but body temperature (38.8 ± 0.1°C), plasma cortisol and haptoglobin concentrations did not differ among groups. In the G- group, a 50 to 60% immediate and 16 d-carryover decrease ($P < 0.05$) in plasma estradiol concentration relative to controls (11.0 ± 1.0 pg/ml) was noted; in the G+ group, only a 16 d-carryover decrease of 25% in plasma estradiol was noted ($P < 0.05$). Neither toxin induced an immediate drop in follicular steroids; however, an immediate decrease in the number of medium-size follicles was noted in the G+ group compared with controls (1.3 ± 0.2 vs. 3.0 ± 0.7 follicles;, $P < 0.05$). Most G- group cows (5/6) exhibited a 32 d-carryover decrease ($P < 0.05$) of 70% and 62% in estradiol and androstenedione concentrations, respectively, in the follicular fluids. In the G+ group, only half of the cows exhibited a 33% and 60% carryover decrease in follicular estradiol and androstenedione concentrations, respectively ($P < 0.05$); in the other half, steroid levels were not altered. Results indicate that growth dynamics of medium-size follicles is attenuated mainly by *S. aureus* ex. Small, pre- to early antral follicles are susceptible to both *S. aureus* ex. and *E. coli* LPS toxins, and the induced damage is then carried over to the preovulatory follicles; this corresponds well with the long-term chronic nature of subclinical mastitis.

Key Words: mastitis, steroid, follicles

667 Blood constituents in milk due to changed blood-milk barrier integrity during mastitis. O. Wellnitz, M. Lehmann, and R. M. Bruckmaier,* *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.*

Mastitis is accompanied by changes in milk composition. Besides changes of mammary secretions the blood-milk barrier integrity is impaired and molecules can cross the border from blood into milk or vice versa. This study aimed to investigate the transfer of several blood constituents into milk during a mammary immune response due to intramammary endotoxin challenge. Five cows who received a β-hydroxybutyrate (BHB) clamp infusion to increase BHB in blood to a steady concentration (1.5 to 2.0 mmol/L) were challenged intramammarily into one quarter with 200µg *E. coli* lipopolysaccharide (LPS). They were immunized against bluetongue virus (BTV) 2 years before. Blood and milk were analyzed hourly. Changes were considered significant if $P < 0.05$. Blood concentrations of LDH, IgG, and specific antibodies against BTV did not change. In milk the somatic cell count increased in LPS challenged quarters within 4h but not in controls. Lactate dehydrogenase (LDH), BHB, lactate, and immunoglobulin (Ig) G was 33 ± 8 U/L, 0.08 ± 0.01 mmol/L, 8 ± 2mg/L, and 0.1 ± 0.0 mg/L, respectively, and increased within 3 h and continued to increase through 8h to concentrations of 326 ± 146 U/L, 0.56 ± 0.01 mmol/L, 182 ± 26 mg/L, 0.72 ± 0.24 mg/L, respectively, in milk of LPS challenged quarters but not of control quarters. IgG increase in milk was paralleled by an increase of antibodies against BTV. Lactate concentrations in blood and milk of control quarters increased 2h after challenge and were correlated (r = 0.74). The blood constituents LDH, BHB, IgG, and lactate increase in milk after LPS challenge. The increase of antibodies against BTV in milk suggests that the primary mechanism of IgG transfer is opening of the blood-milk barrier and not specifically targeted to mastitis pathogens. In conclusion, opening of the blood-milk barrier during mammary inflammation increases the presence of blood constituents including antibodies in milk, and this does not appear to be a specific immune function response.

Key Words: blood-milk barrier, mastitis, antibody

668 Characterizing the temporal and seasonal pattern of plasma lipopolysaccharide binding protein during the transition period. A. Nayeri*[1], N. C. Upah[1], M. V. Sanz-Fernandez[1], E. Sucu[1,2], A. L. Gabler[1], R. L. Boddicker[1], D. B. Snider[1], J. M. Defrain[3], and L. H. Baumgard[1], [1]*Iowa State University, Ames,* [2]*Uludag University, Turkey,* [3]*Zinpro Corporation, Eden Prairie, MN.*

During the periparturient period and heat stress (HS), dairy cows are more susceptible to rumen acidosis, which may compromise the gastrointestinal tract's (GIT) barrier function. Infiltrating lipopolysaccharide (LPS) is bound by LPS binding protein (LBP), but the role of LBP in dairy cow physiology is not well known. To investigate this, production data and blood samples were collected on lactating Holstein cows (n = 40) housed in a freestall barn and fed individually from −21 to 21 DIM. Two analyses were conducted: 1) good vs. poor transition cows and 2) winter vs. summer (July 2011) calving cows. It is important to note that data from 5 of the 40 cows were used as part of the winter and good transition analyses. Poor transition cows (n = 7) were defined as those treated for ketosis within 22 d after parturition. Conversely, good transition cows (n = 9) were void of a diagnosed health problem during the transition period. Cows included in the winter (n = 24) vs. summer (n = 5) analysis did not experience a diagnosed health event. Irrespective of classification, plasma LBP levels were lowest before calving and peaked at 3 DIM then slowly returned to pre-parturition concentrations by 21 DIM. Overall, poor transitioning cows had increased (21%, $P = 0.04$) circulating LBP compared with good transition cows and the difference was most pronounced (>2 fold) on 3 DIM. Nonesterified fatty acid and BHBA levels were not different between good and poor transitioning cows. However, we observed strong correlations between peak LBP and the transition success measures, milk yield slope ($r = -0.58$, $P < 0.05$) and BHBA area under the curve ($r = 0.72$, $P < 0.01$). Interestingly, winter calving cows had 52% ($P = 0.05$) greater LBP than summer calving cows and the difference was most pronounced (82%) at 3 DIM. In these cows, peak LBP was also negatively associated with average milk yield ($r = -0.49$, $P < 0.01$) and d 1–21 dry matter intake slope ($r = -0.57$, $P < 0.05$). Taken together, we hypothesize that circulating LBP concentration may play a role in determining seasonal and transition period success, or at least is closely associated with periparturient performance.

Key Words: dairy cow, LPS, transition

669 Effect of dry period length on rumen adaptation in dairy cows.

R. M. A. Goselink*[1], J. T. Schonewille[2], G. van Duinkerken[1], and A. T. M. van Knegsel[3], [1]*Wageningen UR Livestock Research, Lelystad, the Netherlands,* [2]*Utrecht University, Utrecht, the Netherlands,* [3]*Wageningen University, Wageningen, the Netherlands.*

The objective of this study was to evaluate the effect of length of dry period on rumen papillae dimensions of dairy cows around parturition. Twelve rumen-cannulated Holstein dairy cows were assigned to a dry period length of 60 (G60), 30 (G30) or 0 (G0) days. The experiment started 60 d before expected calving date and lasted until wk 8 postpartum for each individual cow. Cows received ad libitum forage mixtures of corn silage, grass silage and straw (containing 12% CP, 5.3 MJ NEL/kg DM for dry cows and 15% CP, 6.4 MJ NEL/kg DM for lactating cows). Concentrates were fed individually starting 10 d antepartum with 1.0 kg/d, gradually increasing up to 8.5 kg/d at d17 postpartum. Milk yield and DMI were recorded daily. The rumen contents of each cow were evacuated at wk-9, wk-6, wk-2, d3, d7, d14, d28 and d56 relative to parturition. At each time, biopsies were taken to determine papillae dimensions at 3 locations: the right dorsal sac cranially of the dorsal coronary groove (DS), the right wall of the caudodorsal blind sac (DB) and the ventral wall of the caudoventral blind sac (VB). Treatment effects were tested by mixed model analysis using REML procedure. Data are presented as means ± SE. Mean DMI postpartum was 21.2, 22.2 and 23.7 (±0.6 kg/d) for G60, G0 and G30 respectively ($P < 0.05$). Average daily milk yield postpartum was significantly lower for G0 ($P < 0.05$) compared with G30 or G60 (35.1 vs. 41.4 and 41.8 ± 3.1 kg/d, respectively). For cows with a dry period (G30 and G60), papillae surface area decreased prepartum ($P < 0.05$). More importantly, during the first 2 weeks postpartum the papillae growth was significantly delayed for G60 compared with G30; mean papilla surface was 42.5, 58.6 and 60.6 (±7.1, $P < 0.05$) mm^2 for G60, G30 and G0 respectively. Irrespective of treatment, rumen papillae were largest at VB and smallest at DS and papilla surface increased approximately 50% postpartum ($P < 0.05$). In conclusion, a shortened dry period of 30 vs. 60 d increases papillae surface in the first weeks of lactation and herewith may improve absorption capacity of volatile fatty acids, without a negative effect on milk yield as found with 0 d dry.

Key Words: dairy cow, rumen papillae, dry period length

670 Sodium salicylate administration during the first 7 days of lactation has effects that extend through the entire lactation in dairy cattle.

J. K. Farney*[1], L. K. Mamedova[1], J. F. Coetzee[2], J. E. Minton[1], and B. J. Bradford[1], [1]*Kansas State University, Manhattan,* [2]*Iowa State University, Ames.*

Inflammation has been proposed as a contributor to fatty liver disease, and this disorder has negative effects on milk production in dairy cattle. Our objective was to determine if administration of sodium salicylate (SS), a non-steroidal anti-inflammatory drug (NSAID), in the first week of lactation changes whole-lactation productivity and retention in the herd. At calving, 78 cows (n = 39 primiparous [1P]; n = 24 2nd lactation [2P]; n = 15 ≥ 3 lactations [3P]) were alternately assigned to either control (CON) or SS treatment for 7 d postpartum. SS treatment was administered via individual water bowls at a concentration of 1.68 g/L, delivering a mean of 113.5 ± 6.8 g SS/d during the 7 d of treatment. Cows were followed through the lactation by monthly milk yield and component testing, and the effects of treatment on the risk of leaving the herd and on 305-d milk, fat, and protein yields were determined by Fisher's exact test and mixed model analysis, respectively. Predicted transmitting abilities (PTA) for milk, fat, and protein yields were not influenced by treatment or treatment by parity interaction (all $P > 0.17$); nevertheless, PTA values were included as covariates in the statistical models. Treatment by parity interactions were detected for 305-d milk and fat yields, and a tendency for an interaction was detected for protein yield. Milk yield was 2,469 ± 646 kg greater over the lactation in 3P SS cows compared with 3P controls (21% increase, $P < 0.01$), but milk yield tended to be 980 ± 375 kg less for 1P SS cows compared with 1P controls (8% decrease, $P = 0.07$); no effects were detected in 2P cows. Furthermore, 3P SS cows produced 130 ± 23 kg more milk fat over the lactation (30% increase, $P < 0.001$) and tended to produce 49 ± 18 kg more protein (14% increase, $P = 0.06$). No effects on fat or protein yield were detected for 1P or 2P. A treatment by parity interaction was observed for the risk of leaving the herd. First parity cows treated with SS cows tended to have greater risk of leaving the herd than controls (30% vs. 6% risk, $P < 0.10$). However, treatment did not alter herd retention in 2P or 3P groups, and SS had no effect on the risk of leaving the herd overall ($P = 0.59$). Results indicate that sodium salicylate has long-term effects on lactation of aged cows, particularly on fat metabolism, but has potential negative effects for primiparous cows.

Key Words: inflammation, milk production, non-steroidal anti-inflammatory drug

671 Responses to a nutritional challenge in early and late lactation.

N. C. Friggens*[1,2], C. Duvaux-Ponter[1,2], J. Tessier[1,2], and P. Schmidely[1,2], [1]*INRA UMR 791 Modélisation Systémique Appliquée aux Ruminants, Paris, France,* [2]*AgroParisTech UMR 791 Modélisation Systémique Appliquée aux Ruminants, Paris, France.*

Characterizing robustness at the level of the individual animal would be valuable for refining management and selection strategies. Accordingly, to explore differences in adaptive capacity we studied responses of animals to a short-term nutritional challenge. Measurements of performance, milk composition and plasma metabolites were made in 16 dairy goats exposed to a 2-d nutritional challenge (underfeeding), at 2 different stages of lactation. Each challenge consisted of a 1-wk control period with standard TMR, 2 d of straw feeding, and a 1-wk recovery period on the TMR. All feeds were offered ad libitum. The 1st challenge was in late lactation (mean DIM, intake, milk yield: 280, 2.55 kg/d, 1.85 kg/d, respectively), the 2nd challenge was early in the following lactation (mean DIM, intake, milk yield: 26, 3.07 kg/d, 3.99 kg/d, respectively). Relative to the control periods, the challenges (means in late and early lactation, respectively) resulted in large drops in DMI (−1.78, −2.48 kg/d) and milk yield (−1.32, −2.46 kg/d) with increases in milk fat (+3.71, +4.65%) and milk protein (+0.91, +0.55%). For intake and milk yield, the size of the drop was strongly related to the pre-challenge values indicating that these 2 measures were tightly clamped by the challenge. For all other measures (milk fat, milk protein, NEFA, BHB, glucose, urea, insulin) the pre-challenge values had no significant effect, except for BHB in early lactation. Significant within animal repeatability between lactation stages in size of response for intake, milk yield, plasma urea, and BW were found (i.e., significant regression slopes; early vs late). Responses in milk fat, milk protein and the plasma metabolites (other than urea) were not significantly related, indicating that the metabolic adaptations to nutritional challenge vary not only between animals but also between stages of lactation. This was confirmed by principle components analysis which revealed different response patterns between individuals with regard to energy partitioning in milk. In conclusion, there is significant variation between individuals in response to a nutritional challenge and this can be used to develop a quantitative description of adaptive capacity.

Key Words: robustness, individual variation, ruminant

672 Supranutritional levels of antioxidants maintains feed intake and reduces heat stress in sheep. S. Chauhan[1,2], P. Celi[3], B. Leury[2], and F. Dunshea*[2], *[1]CSK, HP Agriculture University, Palampur, Kangra, India, [2]The University of Melbourne, Parkville, Victoria, Australia, [3]The University of Sydney, Sydney, Australia.*

The present study was undertaken to investigate the impact of heat stress and dietary antioxidant supplementation on the oxidative status and physiology of sheep. Twenty-four Merino × Poll Dorset crossbred sheep were housed in one of 2 climatic chambers and offered either a control (10 IU Vitamin E and 0.24 mg Selenium/kg DM) or high antioxidant [100 IU Vitamin E and 1.20 mg Se (as SelPlex)/kg DM] diet. The sheep were subjected to 2 thermal treatments [Thermoneutral (TN): 18 to 21°C and 26–30% relative humidity and Heat Stress (HS): 28–40°C and 40–50% relative humidity] for 2 weeks in a single reversal design. After one week of dietary treatment, animals in one chamber were subjected to HS for one week, with the temperature being increased to 40°C between 9.00 h to 17.00 h and then maintained at 28°C overnight. Those sheep in the TN group were maintained at 18–21°C. Physiological parameters (respiration rate, rectal temperature, skin temperature and heart rate) were recorded 4 times a day (9.00 h, 13.00 h, 17.00 h and 21.00 h and blood samples were collected on d 1 and 7 of heat treatment at 0hr, 8hr and 12hrs of start of heat. The temperature treatments were then reversed. The data was analyzed by undertaking REML (restricted minimum likelihood) variance component analysis using GenStat for windows (12th edition). All the physiological parameters recorded were elevated significantly ($P < 0.001$) by heat treatment. Respiration rate was reduced by antioxidant supplementation as indicated by a diet x temperature x time interaction ($P = 0.010$). There was 13% decline ($P = 0.014$) in feed intake of the control animals during heat stress whereas feed intake was maintained in sheep supplemented with antioxidants. Therefore, these data demonstrated that the negative effect of heat stress on feed intake and respiration rate can be reversed when sheep receive dietary antioxidant supplementation.

Key Words: heat stress, antioxidants, sheep

Ruminant Nutrition: Beef: Feed Additives

673 Feeding monensin or functional oils in high corn finishing diets for Nellore bulls. L. J. Chagas, R. S. Marques, C. Sitta, C. Guerra, V. N. Gouvea, J. Souza, F. Batistel, and F. A. P. Santos,* *University of São Paulo, Piracicaba, SP, Brazil.*

A feedlot experiment was conducted to evaluate the effects of functional oils in substitution of monensin on feedlot cattle performance and carcass characteristic. Two hundred forty Nellore bulls (339 ± 18 kg initial BW) were blocked by initial BW and allotted to 40 dry lot pens (6 head/pen). The animals received their respective dietary treatment for 124 d (including 21 d of adaptation). Treatments were: 1) control (CON), no additives; 2) monensin (MON), 30 mg/kg of DM (Rumenpac); 3) Functional oil (FO3), 0.3 g/kg of DM (commercial additive extracted from castor and cashew oils, Essential); and 4) Functional oil (FO5), 0.5 g/kg of DM. The diets contained 80.6% ground corn, 12% Tifton 85 hay, 4% soybean meal, 0.9% urea, and 2.5% minerals (DM basis). During the 21 d adapting period (step up), when comparing CON, MON, FO3 and FO5 treatments respectively, monensin (MON) decreased ($P < 0.01$) DMI (7.96, 6.49, 7.83, 7.71 kg/head/d) and ADG (0.95, 0.76, 1.11, 1.12 kg/head) ($P < 0.06$) compared with other treatments. Supplementing functional oils at 0.3 g/kg of DM (FO3) increased ($P < 0.06$) G/F (Gain/Feed) (0.120, 0.105, 0.141, 0.145) compared with MON treatment. Supplementing functional oils at 0.5 g/kg of DM (FO5) increased ($P < 0.06$) G/F compared with CON and to MON treatments. Considering the whole feedlot period (124 d), when comparing CON, MON, FO3 and FO5 treatments respectively, no treatment effects ($P > 0.05$) were observed for DMI (9.84, 9.52, 10.28, 10.26 kg/head/d), for ADG (1.27, 1.24, 1.31, 1.34 kg/head), for G/F (0.129, 0.131, 0.128, 0.131) and for carcass characteristics. In conclusion, functional oils from castor and cashew oils may have some beneficial effect on cattle performance during the first 21 d adapting period to high grain diets. In this trial the feed additives tested did not improve cattle performance during the whole feedlot period.

Key Words: antibiotics, feedlot, ionophores

674 Feeding monensin, functional oils and combination of feed additives in high by-products finishing diets for Nellore bulls. L. J. Chagas, R. S. Marques, C. Sitta, C. Guerra, V. N. Gouvea, J. Souza, F. Batistel, and F. A. P. Santos,* *University of São Paulo, Piracicaba, SP, Brazil.*

Monensin, functional oils and a combination of both were evaluated in diets for feedlot cattle for 102 d. One hundred seventy-six Nellore bulls (310 ± 29 kg initial BW) were blocked by initial BW and allotted to 16 dry lot pens. The animals were fed once a day and treatment diets were restricted to 1.5% of BW at the first experimental day. The amount fed was increased 0.4 kg of DM/head per day whenever the feedbunk was clean. Treatments were: 1) control (CON), no additives; 2) monensin (MON), 25 mg/kg of DM (Rumensin); 3) Functional oil (FO5), 0.5 g/kg of DM (commercial additive extracted from castor and cashew oils, Essential); and 4) (M+FO3) monensin, 25 mg/kg of DM plus functional oil, 0.3 g/kg of DM. The 4 treatment diets contained 5% sugar cane bagasse, 50% wet corn gluten feed, 43.5% soybean hulls and 1.5% mineral-vitamin mix and the respective fee aditive. Data were analyzed using the mixed procedure of SAS (1999) with pen as experimental unit. During the first 34 experimental days, comparing CON, MON, FO5 and M+FO3 respectively, cattle fed FO5 diet presented greater DMI (8.95, 8.62, 9.38, 8.69 kg/animal per day) than cattle fed MON and M+FO3 diets ($P < 0.05$). The ADG (1.66, 1.60, 1.75, 1.79 kg/animal per day) was greater for FO5 and M+FO3 than for MON ($P < 0.08$). No differences ($P > 0.05$) were observed for G/F (ADG/DMI) (0.186, 0.186, 0.187, 0.206). During the 102 d of the whole experimental period, comparing CON, MON, FO5 and M+FO3 respectively, DMI (10.30, 10.30, 10.54, 10.46) was not affected by treatments ($P > 0.05$), ADG (1.73, 1.86, 1.77, 1.82 kg/animal per day) was greater for MON and M+FO than for CON treatment ($P < 0.05$) and G/F (0.171, 0.183, 0.171, 0.177) was greater for MON than for CON and FO5 treatments ($P < 0.08$). In conclusion, during the adapting period to high concentrate diets, feeding functional oils or the combination of both feed additives was superior to feeding monensin alone. During the whole feedlot period, monensin was superior to control and to functional oils as a feed additive for feedlot cattle fed high by-product diets.

Key Words: antibiotics, feedlot, ionophores

675 Effect of Rumensin, Micotil, and Component TE-G with Tylan on health, growth performance, and carcass merit of stocker cattle grazing wheat pasture. E. D. Sharman*[1], P. A. Lancaster[1], B. D. Wallis[1], G. W. Horn[1], and G. D. Hufstedler[2], [1]*Oklahoma Agricultural Experiment Station, Stillwater,* [2]*Elanco Animal Health, Guthrie, OK.*

Crossbred steers (n = 207; 200 ± 22 kg) were used in a split plot design to determine the additive effects of metaphylactic treatment with Micotil on arrival, inclusion of Rumensin in an energy supplement, and use of a combination grazing implant on wheat pasture growth performance and carcass merit. On arrival, half of the steers were randomly treated with Micotil (1.5 mL/cwt BW) and held in receiving pens for 42 d. Following receiving, steers were stratified by BW and randomly assigned to 1 of 16 wheat pastures (7.3 to 9.7 ha) at a stocking rate of 1.5 steers/ha for a 112-d winter grazing phase. Pastures were blocked and randomly assigned to 1 of 2 supplement treatments that consisted of a corn and wheat middling-based energy supplement that contained 0 or 220 g/metric ton monensin fed at a rate of 0.91 kg/steer per day. Prior to turnout, half of the steers within each pasture and within Micotil treatment were implanted with Component TE-G with Tylan. Steers were then transported to a commercial feedlot, implanted with Component TE-S with Tylan and fed in a single pen for 137-d before harvest. Growth performance and carcass merit were analyzed using PROC MIXED procedure of SAS. The model included Rumensin treatment as the whole-plot and Micotil and implant treatments as the sub-plot. The 2- and 3-way interactions were not significant ($P > 0.10$). There were no differences ($P > 0.87$) in receiving health parameters or economic impact among Micotil treatments, but no steers were treated for respiratory issues. Inclusion of Rumensin in the supplement increased ($P < 0.01$) final BW and grazing ADG compared with the non-medicated supplement (349 vs. 340 kg; 1.07 vs. 1.01 kg/d, respectively). The grazing ADG of implanted steers was 0.13 kg/d greater ($P < 0.01$) than non-implanted steers (1.10 vs. 0.97 kg/d). Steers implanted during grazing had greater HCW and REA compared with non-implanted steers with no differences in backfat, marbling score, or quality grade distribution. Since the interactions between Micotil, Rumensin, and implant were not significant, we conclude that these technologies are independent and, therefore, additive.

Key Words: grazing implant, Micotil, Rumensin

676 Effects of dietary *Aspergillus oryzae* extract containing α-amylase activity on feedlot performance and carcass characteristics of finishing beef cattle fed steam-flaked corn-based diets.

K. A. White*[1], J. J. Wagner[2], T. E. Engle[1], D. R. Woerner[1], T. C. Bryant[3], J. S. Jennings[4], and K. M. Brennan[4], *[1]Animal Sciences Department, Colorado State University, Fort Collins, [2]Southeast Colorado Research Center, Colorado State University, Lamar, [3]JBS Five Rivers Cattle Feeding, Greeley, CO, [4]Alltech Inc., Nicholasville, KY.*

Two hundred seventy crossbred yearling steers were used in a randomized block study to evaluate the effects of supplementing steam-flaked corn-based finishing diets with *Aspergillus oryzae* extract containing α-amylase activity on feedlot performance and carcass characteristics. Steers were ranked by weight and allocated into 15 weight block replicates (9 steers/pen). Within each weight block replicate, steers were randomly assigned to one of 2 treatments. The treatment diet (AMZ) contained 5 g/head daily *Aspergillus oryzae* extract containing α-amylase (Amaize, Alltech Inc., Nicholasville, KY). The control diet (CON) provided 5 g/head daily of a corn meal placebo. Each gram of Amaize provided 750 fungal α-amylase units (FAU) which was defined as the amount of enzyme that will dextrinize soluble starch at the rate of 1 mg/min at 30°C and pH 4.8. Individual full weights were obtained on d −1, 0, 33, 70, 105, 159, and 160. All weight data were subjected to a 4% pencil shrink before analysis. Treatment differences for final BW, ADG, DMI, and gain-to-feed ratio were not significant ($P > 0.10$). Steers consuming AMZ achieved greater ($P < 0.07$) dressing percentage (63.7 versus 63.2%); greater ($P < 0.05$) hot carcass weight (358.4 versus 352.1 kg); and greater ($P < 0.08$) kidney, pelvic and heart fat (2.08 versus 1.99%) as compared with controls. Steers fed the AMZ diet also exhibited a reduced ($P < 0.10$) liver abscess rate (17.7 versus 27.7%) as compared with steers receiving the CON diet. Remaining carcass variables were not affected ($P > 0.10$). Data indicate that AMZ supplementation has minimal effects on live cattle performance but alters dressing percentage and carcass weight. Additional research studying the mode of action for this response is warranted.

Key Words: beef feedlot, carcass merit, α-amylase

677 Accelerated step-up regimens for feedlot heifers following oral dosing with Lactipro (*Megasphaera elsdenii*).

K. A. Miller,* C. L. Van Bibber-Krueger, and J. S. Drouillard, *Kansas State University, Manhattan.*

A finishing study was conducted using crossbred heifers (n = 378; 385 ± 10.9 kg BW) to evaluate the potential for employing accelerated step-up regimens following oral dosing with *Megasphaera elsdenii* (Lactipro; MS-Biotec, Inc., Wamego, KS). Upon arrival at the feedlot cattle were given *ad libitum* access to alfalfa hay, and 36 h later were stratified by weight and randomly assigned to 54 pens (7 cattle/pen) within strata. Pens were randomly assigned to one of 6 step-up regimens that utilized between 1 and 5 diets. Diet 1 = 50% corn silage (CS) and 50% concentrate; 2 = 40% CS and 60% concentrate; 3 = 30% CS and 70% concentrate; 2 = 20% CS and 80% concentrate, and the final finishing diet (F) contained 10% CS and 90% concentrate. The control treatment (1234F; no Lactipro) consisted of feeding diets 1 through 4 for 5 d each before feeding F on d 21 and thereafter. Accelerated regimens consisted of a single oral dose (100 mL; 109 cfu/mL) of Lactipro drench administered at processing, followed by the following diet regimens: 234F, 34F, 3F, 4F, and F. Diets 2 through 4 were fed 5 d each before progressing to the next diet in sequence. All diets were based on dry-rolled corn and wet corn gluten feed. Treatment tended (quadratic effect, $P = 0.07$) to influence DMI, with cattle started on intermediate diets (3F and 34F) having lower DMI than other groups. Heifers fed 1234F or F tended to have greater ADG (quadratic, $P = 0.10$) and were more efficient than other groups (quadratic, $P < 0.01$). Treatments did not differ with respect to liver abscess incidence or severity, HCW, dressing percentage, yield grade ($P > 0.10$) or digestive upsets. Treatment affected LM area (quadratic, $P = 0.01$), and was smallest for carcasses from heifers fed the 4F regimen. Marbling score generally increased with the accelerated step-up regimens (linear, $P = 0.12$; quadratic $P = 0.02$) with the greatest improvement in carcasses of heifers placed directly onto the finishing diet. Heifers can be transitioned rapidly to high concentrate diets following oral administration of *Megasphaera esldenii* without compromising performance or carcass quality.

Key Words: diet adaptation, *Megasphaera elsdenii*

678 Oral dosing with Lactipro (*Megasphaera elsdenii*) decreases roughage required for feedlot finishing.

K. A. Miller,* C. L. Van Bibber-Krueger, and J. S. Drouillard, *Kansas State University, Manhattan.*

A completely randomized study with crossbred steers (n = 443; initial BW = 400 ± 2.4 kg) was used to evaluate performance and carcass traits after oral dosing with *Megasphaera elsdenii* (Lactipro; MS-Biotec, Wamego, KS) and placed directly onto finishing diets. Steers grazing pastures in Wells, NV were transported to the Beef Cattle Research Center in Manhattan, Kansas, placed into feedlot pens, and provided ad libitum access to brome hay and water. Approximately 24 h after arrival, steers were weighed and randomly assigned to one of 2 treatments based on order of processing. Steers were placed in 36 pens, 24 containing 14 or 15 steers/pen and 12 containing 7 or 8 animals/pen (18 replicates/treatment). A traditional, 4-diet step-up regimen (control) utilizing 3 step-up diets (40, 30, and 20% corn silage and the balance as concentrate) fed for 6 d each, followed by a finishing diet (10% corn silage and 90% concentrate) fed for the remainder of the study was compared with a Lactipro treatment, which consisted of a single oral drench of Lactipro (100 mL, providing 109 cfu/mL *Megasphaera elsdenii* strain NCIMB 41125) and direct placement onto the finishing diet. Diets contained steam-flaked corn and wet corn gluten feed, and were fed once daily ad libitum. Lactipro steers consumed 17% less silage than control steers over the 115-d feeding period ($P < 0.01$). Dry matter intake tended to be lower for steers in the Lactipro group ($P = 0.07$), but gain and gain efficiency were not different ($P > 0.10$). Dressing percentage, HCW, LM area, 12th-rib fat thickness, and incidence of liver abscess were unaffected by diet regimen. Percentage of YG 1 carcasses tended to be higher for steers in Control group ($P = 0.10$) compared with cattle placed directly onto the finishing diet. Dosing with Lactipro and placing cattle directly onto the finishing diet yielded more Choice ($P = 0.07$) and fewer Select carcasses ($P = 0.06$) compared with the control treatment. Steers receiving Lactipro at processing can be placed directly onto a finishing diet, decreasing roughage use while maintaining acceptable cattle health, performance, and carcass quality.

Key Words: diet adaptation, Lactipro, roughage

679 Effect of Optaflexx level on growth performance and carcass characteristics of feedlot steers.

J. W. Homm,* G. J. Vogel, N. A. Pyatt, and R. L. Botts, *Elanco Animal Health, Greenfield, IN.*

Three thousand and twenty-four steers (588 kg) were allotted to 40 pens in a randomized complete block design of 4 treatments at 2 trial sites with 5 replications per site to evaluate the effects of differing levels of Optaflexx on growth performance and carcass characteristics of finishing steers. Experimental treatments included: 1) Non-medicated control; 2, 3 and 4) Optaflexx fed continuously at 10.0, 20.1 and 30.1

mg/kg of the diet DM, respectively. Optaflexx was fed during the final 28 d before harvest. The basal diet contained Rumensin at 36.7 mg/kg and Tylan at 9.8 mg/kg of the diet DM. Data were analyzed using a mixed model with treatment as a fixed effect and site, block and site by block as random effects. Pen served as the experimental unit and initial weight was used as a covariate. Feeding Optaflexx resulted in improved ($P < 0.01$) average daily gain, harvest weight, feed conversion, carcass weight, dressing percentage and LM area compared with control. Feeding 20.1 or 30.1 mg/kg diet DM Optaflexx increased ($P < 0.05$) daily gain, harvest weight, feed conversion and carcass weight compared with 10.0 mg/kg diet DM. Optaflexx fed at 30.1 mg/kg diet DM resulted in increased dressing percentage and LM area compared with 10.0 and 20.1 mg/kg diet DM. Marbling score, quality grade and yield grade were not affected by feeding Optaflexx. Feeding Optaflexx increases daily gain, harvest, and carcass weight and improves feed efficiency while having minimal effects on carcass quality.

Table 1. Effect of Optaflexx level

	Treatments					
Item	Control	10.0 mg/kg	20.1 mg/kg	30.1 mg/kg	SEM	P-value
Final BW, kg	618.2^{a}	622.3^{b}	626.9^{c}	627.3^{c}	2.5	<0.01
DM Intake, kg/d	9.36	9.28	9.36	9.24	0.16	0.38
Daily gain, kg	1.08^{a}	1.23^{b}	1.38^{c}	1.41^{c}	0.09	<0.01
Feed/gain	8.71^{a}	7.63^{b}	6.84^{c}	5.70^{c}	0.33	<0.01
Carcass Wt, kg	397.8^{a}	401.2^{b}	404.0^{c}	406.3^{c}	0.9	<0.01
Dressing percent	64.3^{a}	64.5^{a}	64.5^{a}	64.8^{b}	0.1	0.02
LM area, cm^2	91.0^{a}	92.5^{b}	93.2^{b}	94.8^{c}	1.7	<0.01
Marbling	small^{29}	small^{22}	small^{24}	small^{19}	3.7	0.07

$^{a–c}$Row means without a common superscript differ ($P < 0.05$).

680 Effect of an injectable amino acid solution in calves fed barley-based rations with supplemental lysine and methionine during a 65-d preconditioning program.

C. F. O'Neill*[1], C. L. Maxwell[1], S. L. Parr[2], M. L. May[2], E. J. Behlke[2], C. W. Booker[2], G. K. Jim[2], C. R. Krehbiel[1], and L. O. Burciaga-Robles[2], *[1]Department of Animal Science, Oklahoma State University, Stillwater, [2]Feedlot Health Management Services Ltd., Okotoks, Alberta, Canada.*

High-risk steer calves (n = 160; BW = 297 ± 10.6 kg) were allocated to evaluate the effect of an injectable amino acid solution in combination with supplemental lysine and methionine in barley-based rations during a 65-d preconditioning program. The trial was conducted in Alberta, Canada. Animals were randomly assigned to a 2 × 2 factorial arrangement of treatments: saline × injectable amino acid (INJ-AA) versus control (CON) × dietary amino acid (DIET-AA) in a completely randomized block design. Animals were blocked by placement weight. Administration of saline or Vitamaster-NF (NF; Vétoquinol N.A. Inc., Lavaltrie, QC, Canada) was done intramuscularly at a dosage of 1 mL/45 kg of BW. Cattle receiving DIET-AA were fed supplements providing 15 mg/steer per day of both methionine (MetaSmart, Adisseo, Alpharetta, GA) and lysine (AminoShure-L, Balchem Corporation, Animal Nutrition and Health, New Hampton, NY). Cattle from the same treatment group were randomly allocated to one of 4 pens (40 steers/pen) equipped with individual feed intake data collection systems (GrowSafe Systems Ltd., Airdrie, Canada) and fed for 65 d. Performance was calculated with deads (2) and removals (6) excluded; only 6.0% morbidity and 1.3% overall mortality was experienced with no health differences across treatments ($P > 0.10$). Animal performance was analyzed using PROC GLIMMIX (SAS Institute, NC). Animal was the experimental unit, and the model included the fixed effect of treatment and the random effect of block nested within pen. There were no differences in placement BW ($P > 0.30$) or 65-d BW ($P > 0.30$). There were no effects of treatment on ADG ($P > 0.26$) or G:F ($P > 0.60$), throughout the 65-d period. A decrease in DMI was observed in animals receiving DIET-AA compared with CON (5.97 vs. 6.40 kg; $P < 0.01$) in the 65-d preconditioning program. These data indicate that dietary supplementation of amino acids resulted in a decrease in DMI in high-risk steer calves without hindering ADG. However, it should be noted that morbidity was only 6.0%.

Key Words: amino acids, cattle, feedlot performance

Small Ruminant: Production and Reproduction

681 Fabricated carcass measurements in terminally sired F_1 lambs. M. R. Mousel*[1], D. R. Notter[2], T. D. Leeds[3], H. N. Zerby[4], S. J. Moeller[4], and G. S. Lewis[1], [1]*USDA, ARS, U.S. Sheep Experiment Station, Dubois, ID,* [2]*Virginia Tech, Blacksburg,* [3]*USDA, ARS, National Center for Cool and Cold Water Aquaculture, Kearneysville, WV,* [4]*The Ohio State University, Columbus.*

Scientific data for carcass traits of terminal-sire sheep breeds can be used to improve the value of market lambs, but information is lacking for modern terminal-sire breeds in the United States. Thus, the effects of terminal-sire breed on 14 fabricated carcass measurements were determined in F_1 wether lambs. Columbia, USMARC-Composite (Composite), Suffolk, and Texel rams were mated with mature Rambouillet ewes over 3 yr. From weaning until harvest each year, F_1 lambs ($n = 518$) were fed a step-up finishing diet and harvested in 3 groups at targeted mean BW of 54.5, 61.4, or 68.2 kg. Carcasses were fabricated according to Style A of Institutional Meat Purchase Specifications. Weights were collected for the following carcass subprimal cuts: neck, foreshank, breast, square-cut shoulder (SCShoulder), rack, roast ready rack (RRR), loin, trimmed loin (TLoin), sirloin, boneless sirloin (BSirloin), flank, leg, boneless leg (BLeg), and hindshank. All traits were analyzed individually with a mixed model that included fixed effects of sire breed, year of harvest (YR), harvest group (HG), weight-on-test deviation from the breed mean, and random effects of sire and maternal grandsire. The YR and HG were significant ($P < 0.01$) in all models. Sire breed was significant ($P < 0.01$) for all traits except flank ($P = 0.05$). Suffolk-sired lambs had the heaviest neck (0.86 kg), breast (4.1 kg), SCShoulder (6.5 kg), rack (3.4 kg), RRR (1.5 kg), loin (3.2 kg), sirloin (3.1 kg), leg (10.6 kg), and BLeg (4.6 kg) compared with the other F_1 lambs. Suffolk-sired lambs had the heaviest foreshanks (1.7 kg) and TLoin (2.7 kg); then Columbia-sired, 1.5 and 2.6 kg, respectively; and Texel-sired lambs had the lightest, 1.4 and 2.4 kg, respectively. Suffolk-sired lambs had heavier BSirloin (1.7 kg) than Composite-sired lambs (1.5 kg), but Suffolk- and Composite- did not differ from Texel- (1.6 kg) or Columbia-sired (1.6 kg) lambs. Columbia- and Suffolk-sired lambs had heavier hindshanks than Texel-sired lambs, 0.94, 0.97, and 0.88 kg, respectively. Producers can use data such as these to select a terminal-sire breed of sheep that will improve the carcass value of market lambs.

Key Words: lamb, terminal sire, carcass

682 Awassi sheep productivity in central Anatolia region of Turkey. H. Üstüner* and M. Ogan, *Uludag University, Faculty of Veterinary Medicine, Department of Animal Science, Bursa, Turkey.*

The objective of this study was to investigate the reproductive and production performance of Awassi sheep in central Anatolia region of Turkey. A total 147 ewe production and reproductive performance records between January 2003 and December 2005 were used for this experiment. The data consisted of parity, birth type and year for reproductive and production performance, and birth type, birth date, sex and weight of lamb for growth performance. Growth and milk yield were recorded fortnightly. Average live weight of Awassi lambs at birth, 30th, 60th (weaning), 90th, and 120thday were found 4.5 ± 0.2, 9.9 ± 0.2, 17.3 ± 0.4, 23.3 ± 0.5, and 29.1 ± 0.7 kg, respectively. Average live weights of female Awassi lambs at d 150 and 180 were 32.8 ± 0.5 and 38.1 ± 0.7 kg, respectively. The effects of parity, birth year, sex, birth type (single or twin) and all interactions on growth performance were investigated using PROC MIXED of SAS. The birth weight was affected by sex ($P < 0.01$) and birth type ($P < 0.01$) but the effects of parity and year were not significant ($P > 0.05$). The average survival to weaning was 88.3%, representing a loss of 18 lambs. Lactation milk yield was found to be 196.5 ± 5.6 kg in 184.3 ± 2.1 d. The effects of year and parity and all interactions on milk yield were investigated using PROC MIXED of SAS. The effects of year and parity were found statistically significant ($P < 0.01$). Greasy wool production and mating weight of Awassi ewes were found 2543.0 ± 59.6 g and 58.8 ± 0.7 kg, respectively. General mortality rate was found 8.2% throughout research period. Greasy wool production was affected by year (first or second research year; $P < 0.001$) but not by parity ($P > 0.05$). The effects of parity and mating year on ewes' mating weight were highly significant ($P < 0.001$). As a result of this study, Awassi sheep can be successfully raised under central Anatolia conditions.

Key Words: Awassi, lactation yield, environment

683 Effect of lithium chloride for mid-term conditioned aversion to olive tree leaves in penned and grazing goats. C. L. Manuelian, E. Albanell, M. Rovai,* A. A. K. Salama, and G. Caja, *Grup de Recerca en Remugants (G2R), Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

With the aim of allowing the selective grazing of goats in olive tree fields, conditioned aversion was created by using 2 doses of lithium chloride (LiCl). Treatments were C (water blank), AV1 (175 mg LiCl/kg BW) and AV2 (200 mg LiCl/kg BW). Fifteen dry Murciano-Granadina does were randomly assigned to the 3 treatments, in which voluntary intake of olive leaves (used as novel feed) was individually measured after 1 h of allowance during the aversion induction period (d 1 to 3). A single dose of LiCl was orally administered by a drenching gun. Repeated exposure to the olive leaves for memory evaluation was performed in double-choice feeding (Italian rye-grass and olive leaves) tests of 60 min (d 4 to 8) and 30 min (d 16, 24, 31, 38 and 53). On d 9 a new dose of LiCl was administered to does consuming > 10 g/d olive leaves. No more LiCl was administered during the memory evaluation period. Thereafter, all groups were exposed (d 59, 90, 121 and 182) to simulated olive trees, placed in a rye-grass prairie for 30 min. Moreover, C and AV2 groups grazed (d 146, 211 and 363) on a commercial olive tree field with natural weeds for 30 min. Olive leave intake slightly increased during the memory evaluation period being greater on d 53 in the C does (99 ± 1 g; $P < 0.05$) than in the averted does (AV1, 42 ± 14 g; AV2, 34 ± 16 g) which did not differ. Four AV1 does needed a new LiCl dose to re-establishing the aversion. In addition AV1 does spent more time eating olive leaves under simulated field conditions than AV2 (333 ± 53 s and 149 ± 60 s; $P > 0.05$). A year after the induced aversion, AV2 does still presented greater preference (approaching, eating and climbing) for olive leaves than C does, when grazing in the commercial field. In conclusion, 200 mg LiCl/kg BW was the preferred dose for inducing an effective mid-term (12 mo) conditioned aversion in goats. The use of LiCl was considered as a useful tool for selective grazing and use in ecological bio-agriculture system.

Key Words: aversion, lithium chloride, goats

684 Milk production losses in early lactating dairy goats under heat stress. S. Hamzaoui, A. A. K. Salama,* G. Caja, E. Albanell, C. Flores, and X. Such, *Group de Recerca en Remugants (G2R), Universitat Autònoma de Barcelona, Bellaterra, barcelona, Spain.*

In a previous work we observed that heat-stressed goats at late lactation suffered no reductions in milk yield and milk fat, despite the lower milk protein. However, this response during early lactation remains unclear. Eight multiparous Murciano-Granadina dairy goats (43.3 ± 1.6 kg BW; 81 ± 3 DIM) were used. Goats were kept in metabolic cages and randomly assigned to 2 climatic treatments according to a crossover design (35 d periods). Treatments were (temperature, °C; humidity, %; THI, Thorn heat index):1) thermal neutral (TN, 15 to 20°C; 35 to 45%; THI = 59 to 64), and 2) heat stress (HS, 12 h/d at 37°C and 45%, and 12 h/d at 30°C and 45%, THI = 86 and 77, respectively). Goats received TMR and water ad libitum. Feed intake and milk yield were recorded daily. Milk, blood, and urine samples were collected weekly for the osmolality measurements. Additionally, blood samples were taken at d 7 and 28 of each period for the creatinine analysis. Urine uric acid concentration was used as an index (uric acid:creatinine × $BW^{0.75}$) of microbial protein synthesis. Feces and urine for digestibility and N balance (d 31 to 35) were also collected in each period. Compared with TN, HS goats had lower ($P < 0.01$) feed intake (1.75 vs. 2.47 kg/d), milk yield (1.53 vs. 1.68 L/d), milk fat (3.76 vs. 4.26%), and milk protein (3.26 vs. 3.74%). Osmolality (mosm/kg) of blood plasma (334) and urine (1449) was similar in both groups, but milk of HS had lower ($P < 0.05$) osmolality than TN (309 vs. 321). Creatinine concentration in blood was greater ($P < 0.05$) in HS than TN (0.81 vs. 0.62 mg/dL), which might indicate muscle degradation under HS conditions. The HS goats had lower ($P < 0.05$) microbial protein synthesis index (6.5 vs. 10.0). Digestibility of DM, OM, ADF, and NDF did not differ between TN and HS. Moreover, both TN and HS retained similar ($P = 0.557$) amount of N (19.3 g/d). In conclusion, early lactating dairy goats under HS suffer losses in milk yield, milk fat and protein contents. The reduced milk protein content under HS might be related to the lower microbial protein synthesis.

Key Words: heat stress, digestibility, dairy goat

685 Long-term effects of intrauterine rivalry on the reproductive performances of co-twin ewe-lambs.

J. Casellas and G. Caja,* *Grup de Recerca en Remugants (G2R), Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Intrauterine environment may permanently alter the genome expression through fetal programming. We hypothesized that the birth weight difference (BWD) between co-twins may be a representative measure of their experienced rivalry. With this regard, we tested the effect of variations in the BWD of co-twin ewes on their further average litter size. Data analyses were performed on 1,449 lambing records from 331 Ripollesa breed ewes averaging 1.502 ± 0.01 lambs per litter (singletons, 51.8%; twins, 46.2%; triplets, 2.0%). Ewes born as twins were classified in groups using BWD = 200 g as a discriminating threshold; i.e., equal twins (T0, BWD ≤ 200 g), and heavier (TH) and lighter (TL) co-twins of litters with BWD > 200 g. Ewes born as singletons were grouped in an additional control category (S). A mixed linear model accounting for BWD, ewe age (<3, 3, 4, 5 and > 5 yr), year of lambing (21 yr) and the random permanent effect of each ewe, was implemented with the Mixed procedure of SAS (SAS Institute, Inc., Cary, NC). Both the effects of birth weight and co-twin sex (male or female) were discarded ($P > 0.1$), whereas remaining effects reached statistical significance ($P < 0.05$). Singleton (n = 94; 1.49 ± 0.03 lambs), T0 (n = 73; 1.509 ± 0.03 lambs) and TH (n = 64; 1.52 ± 0.032 lambs) ewes showed similar reproductive performances ($P > 0.05$) whereas litter size decreased ($P < 0.05$) for TL ewes (n = 100; 1.40 ± 0.03 lambs). Indeed, TL ewes experienced a 6 to 8% reduction in the realized litter size along their whole productive life. Although physiological pathways underlying these reproductive departures were not elucidated, current knowledge on fetal programming postulates permanent alterations in the hypothalamic-pituitary-adrenal axis as the causal mechanism. In conclusion, fetal programming due to intrauterine competition is a fact that must be dealt with in sheep, with relevant economic consequences in the ovine sector worldwide.

Key Words: fetal programming, litter size, sheep

686 Fixed-time laparoscopic AI with frozen-thawed goat semen in progesterone and PMSG supplemented Cosynch protocol.

Z. Nur[1], B. Üstüner*[1], Y. Nak[2], S. Alcay[1], Y. Yaman[3], and H. Sagirkaya[1], [1]*Department of Reproduction and Artificial Insemination, Uludag University, Faculty of Veterinary Medicine, Gorukle, Bursa, Turkey,* [2]*Department of Obstetrics & Gynecology, Uludag University, Faculty of Veterinary Medicine, Gorukle, Bursa, Turkey,* [3]*Marmara Animal Breeding Research Institute, Bandirma, Balikesir, Turkey.*

The effects of progesterone and PMSG supplemented Cosynch (GnRH on d 0, PGF2α on d 7, with GnRH and timed AI (TAI) on d 9) on the estrus synchronization, follicular development and pregnancy rates (PR) after TAI were evaluated during the breeding season. The multiparous Saanen does (>40 kg BW) were used and assigned to 4 synchronization treatments. In group I, II and IV; all does received Cosynch plus intravaginal sponges on d 0 (choronogest) for 7 d. For the Groups I (n = 18) and III (n = 15) all does were received PMSG at PGF2α injection. The Groups I and II (n = 20) were laparoscopically and the Groups III and IV (n = 19) were intracervically inseminated with 50 × 10^6 motile spermatozoa after 2nd GnRH injection. The onset of estrus was determined with teaser bucks at 12-h interval for 30 min during 72h. Follicular development was monitored at d 7 and 9 by transvaginal ultrasonography (US) with 4–8 MHz endocavity array transducer. The data were subjected to Fisher′s exact test and the 95% significance level was noted. The mean time of the estrus onset, the mean of observed estrus, the biggest follicle diameters and follicle numbers (>0.3 cm) at the sponge removal and at the 2nd GnRH injection were 28.5h, 89%, 0.6cm, 2.6, 0.8cm, 2.2; 28.2h, 85% 0.8cm, 3.1, 0.8cm, 1.3; 24.0h, 27%, 0.7cm, 2.8, 0.7cm, 3.3 and 29.3h, 84%, 0.8cm, 2.2, 0.7cm, 2.9 for the Groups I, II, III and IV, respectively. Cosynch plus PMSG (Group III) was not successful to induce estrus ($P < 0.001$). There were no significant difference between evaluations for the follicle diameters ($P > 0.05$). The follicle numbers of the Group II were lower at the 2nd GnRH injection than at sponge removal ($P < 0.001$). PR were ultrasonographically determined as 56, 41, 0, and 33% for Groups I, II, III, and IV on d 35, respectively. The PR of Group III was the lowest ($P < 0.05$). Although, there was no difference between insemination protocols for PR of Groups II and IV; the laparocopically inseminated groups was higher than the intracervically inseminated groups. Choronogest supplementation of Cosynch improved the reproductive parameters.

Key Words: Cosynch, goat, laparoscopic AI

687 Pregnancy diagnosis in sheep using fecal near infrared reflectance spectroscopy.

M. A. D. Bomfim*[1,2], S. Prince[2], J. Angerer[2], O. Faco[1], J. de L. Gonçalves[3,1], R. T. De Souza[3,1], F. E. P. Fernandes[1], A. M. F. Fernandes[3,1], and M. Ponciano[1], [1]*Embrapa Goats and Sheep, Sobral, Ceara, Brazil,* [2]*Blackland Research Center/Texas A&M University, Temple,* [3]*State University of Acarau Valley, Sobral, Ceara, Brazil.*

The development of quick and accurate methods for early pregnancy diagnosis is a key factor for livestock exploitation. Fecal near infrared reflectance spectroscopy has shown potential to be used to identify pregnancy in cattle. One hundred ten Brazilian

Somalis and 100 Morada Nova ewes' fecal spectra were used to evaluate the fecal NIRS for pregnancy identification in sheep. Fecal spectra were collect from the same animals in two different physiological stages: 67 ± 7 days of pregnancy and 30 days after weaning. Discriminant analysis with PCA/MDR algorithm coupled to Mahalanobis distance (MD), were used to identify pregnancy through spectra similarity, assuming three or more as dissimilar spectra. Spectra of pregnant or non-pregnant ewes from one breed were not consistently similar to other breed in the same reproductive stage, with a range of 33 to 89% of prediction accuracy in the spectral match. Greater breed effect was observed for pregnant ones, probably reflecting prolificacy differences. Spectra from pregnant animals were different from non-pregnant ones and vice versa (98 to 100% of prediction accuracy), regardless of the breed, suggesting they may be used to classify animals based on pregnancy. To minimize breed effect, all spectra were pooled to create two databases (pregnant and non-pregnant). From these data sets, a randomized subset of 42 fecal spectra, not used to equation calibration, were selected and used for validation of procedure. Both pregnant and non-pregnant discriminant equations were able to identify and classify the animals according to pregnancy with 100% of accuracy, confirming the potential of fecal NIRS to identify pregnancy in livestock. However, a statistical significant difference was observed for diet CP and organic matter digestibility (OMD) between pregnant and non-pregnant ewes (T-test, P <0,001), reflecting changes in pasture quality during data collection. Thus, the potential effect of season on pregnancy-related spectral differences remains to be investigated and also a larger database need be evaluated before this technique is recommended for early pregnancy diagnosis in sheep.

Key Words: discriminant analysis, gestation, NIRS

688 Ability to culture of cells from postmortem goat skin tissues stored at room temperature for different time intervals.

M. Singh* and X. Ma, *Fort Valley State University, Fort Valley, GA.*

Animal cloning technology has renewed the interest in postmortem tissue storage, since these tissues can be used to reintroduce the lost genes back into the breeding pool in animal agriculture, preserve the genetic diversity, and revive endangered species. Several studies have demonstrated that cell survival decreases with increasing postmortem tissue storage. However, the limits of time interval within which live cells can be recovered from dead animals is not adequately studied. Cell viability and their potential to in vitro culture ensure nuclear integrity, a requirement for successful cloning of animals. To test the postmortem storage limits of animal tissues, 2–3 mm^2 skin pieces (n = 70) from ears of 3 breeds of goats (n = 7) were cultured after 0, 2, 4 and 6 d of postmortem storage at 24°C. After 10 d of culture, outgrowth of fibroblast-like cells (>10 cells) around the explants was scored. All the explants irrespective of breed displayed outgrowth of cells on the dish containing fresh tissues (d 0). However, the number of explants exhibiting outgrowth reduced with increasing time interval. Only 53.8% explants displayed outgrowth after 2 d of tissue storage. The number of explants displaying outgrowth was much smaller after 4 d (16.7%) and 6 d (13.3%) of storage. In general, the number of outgrowing cells per explant, on a given day, also decreased with increasing postmortem storage time interval. To test the differences between cell cultures, obtained from postmortem fresh and stored tissues, secondary cultures were established from one of the goats exhibiting outgrowth of cells after 6 d of tissue storage. Comparison of both the cell lines revealed similar cell morphology and growth curves, and had doubling times of 23.0 h and 22.6 h, respectively. These results suggest that live cells can be recovered from skin tissues of goats and perhaps other animals even after 6 d of their death with comparable growth profiles.

Key Words: fibroblasts, postmortem tissue storage, goat skin

Symposium: Recent Advances in Swine Genomics

689 Pigs, feed intake, and genes. J. P. Cassady*[1], S. Jiao[1], C. Maltecca[1], K. A. Gray[2], and J. W. Holl[1], [1]*North Carolina State University, Raleigh,* [2]*Smithfield Premium Genetics.*

The objective of this research was to develop genomic strategies for improving nutrient utilization by identifying genomic regions affecting feed intake, growth rate, and ultrasound traits in a Duroc terminal sire population. Individual feed intake, growth rate, and ultrasound data were available on 1022 Duroc boars. Boars were genotyped at GENESEEK using the Illumina Porcine SNP60 BeadChip. The criteria for screening the genomic data was a call rate per animal of 0.9, call rate per SNP marker of 0.9, Hardy Weinberg equation test with $P < 0.001$, and minor allele frequency >0.01. After editing, 40,008 SNPs were retained for genome wide association analysis. The Bayes B and C options in GenSel 4.0.1 were used with pen and contemporary group included as fixed effects for all traits. A preliminary analysis of average daily feed intake, intramuscular fat, and muscle depth was completed. Regions on chromosomes 1, 6, 9, 10, 12, 15, and X were identified affecting average daily feed intake, intramuscular fat, and muscle depth. Additional regions affecting average daily feed intake were found on chromosomes 3, 4, 5, 7, 8, 11, 13, and 17. The markers explained 16% of the total variance for average daily feed intake, 44% for intramuscular fat, and 49% for muscle depth. Analyses of ADG and feeding behavior are currently in progress. Markers identified on chromosome 1 effecting average daily feed intake were in the general region of MC4R. Several other markers were also located in regions where QTL have previously been reported. It was concluded that opportunities exist to use genomic markers to increase accuracy of selection in a Duroc terminal sire population.

Key Words: denomics, SNP, Duroc

690 A review of swine genome-wide association studies at USMARC. J. F. Schneider,* *USDA, ARS, USMARC, Clay Center, NE.*

Reproductive efficiency has a great effect on the economic success of pork production. Traits including age at puberty (AP), ovulation rate, number born alive (NBA), and average piglet birth weight (ABW) contribute greatly to reproductive efficiency. To better understand the underlying genetics of reproductive efficiency, a series of GWAS were undertaken. Samples of DNA were collected and tested using the Illumina PorcineSNP60 BeadChip (Illumina Inc., San Diego, CA). The first analysis included total number born (TNB), NBA, number born dead (NBD), number still born, mummies, litter birth weight (LBW), and ABW taken from 1,152 first parity females. Chromosome and position assignments were based on Build 10. A total of 41,151 SNP were tested using a Bayesian approach. Beginning with the first 5 SNP on SSC1 and ending with the last 5 SNP on the SSCX, SNP were assigned to groups of 5 consecutive SNP by chromosome-position order and analyzed again using a Bayesian approach. These selected 5-SNP non-overlapping groups were defined as QTL. Of the available 8,814 QTL, 124 were found to be statistically significant ($P < 0.01$). Multiple testing was considered using the probability of false positives. QTL were found for litter traits on SSC1, SSC4, SSC6, SSC10, SSC11, SSC13, SSC14, SSC15, and SSC17. QTL were found for LBW and ABW on all chromosomes except SSC16 and SSCX. Several candidate genes have been identified that overlap QTL locations among TNB, NBA, NBD, and ABW. A second analysis measured AP on 752 gilts that showed estrous before 230 d of age. Chromosome and position assignments were made based on Build 10.2. Seventy-two QTL were found to be statistically significant ($P < 0.01$) and were found on all chromosomes except SSC17. One hundred fifty-seven gilts that failed to reach puberty were added to the data set and the 909 gilts were analyzed as a binomial trait. A similar number of QTL were found on all chromosomes except SSC11, SSC16, and SSC18. The results of these analyses demonstrate that opportunities exist to introduce QTL into genetic improvement programs designed to improve reproductive efficiency. USDA is an equal opportunity provider and employer.

Key Words: Bayes, GWAS, reproduction

691 The genetic basis of host response to experimental infection with the PRRS virus in pigs. J. Dekkers*[1], N. Boddicker[1], E. Waide[1], J. K. Lunney[2], R. R. R. Rowland[3], D. J. Garrick[1], and J. Reecy[1], [1]*Iowa State University, Ames,* [2]*USDA, ARS, BARC, Beltsville, MD,* [3]*Kansas State University, Manhattan.*

Porcine reproductive and respiratory syndrome (PRRS) represents the most costly disease in the US pig industry. Caused by an RNA virus, vaccination strategies have generally been ineffective. Thus, to investigate opportunities for genetic improvement of pigs for increased resistance or tolerance to the PRRS virus, the PRRS Host Genetics Consortium (PHGC) was established. Among others, the PHGC involves experimental challenge of piglets provided by commercial breeding companies with a specific strain of the PRRS virus shortly after weaning, evaluating piglet response in terms of viremia and weight gain, genotyping each piglet with the Porcine 60K SNP panel, and conducting genome-wide association studies to identify genomic regions associated with host response. The purpose of this presentation will be to review results of the first 6 challenge trials of 200 piglets each, with specific reference to a major QTL identified on chromosome 4, and to discuss future plans and implications. This work is supported by the PRRS CAP, USDA NIFA Award 2008-55620-19132, the National Pork Board, USDA ARS and the NRSP-8 Swine Genome and Bioinformatics Coordination projects.

Key Words: porcine reproductive and respiratory syndrome (PRRS), genetic markers, swine

Teaching/Undergraduate and Graduate Education Symposium: Giving Employers What They Want–How Ready is Today's Animal Science Graduate?

692 The animal sciences curriculum of 2025. M. A. Wattiaux,* *University of Wisconsin-Madison, Madison.*

A curriculum reflects subjects and experiences in a plan of study intended to prepare students for professional success in a chosen career. The core animal sciences curriculum has hardly changed in the last 50 years, but it has adapted to changes in scientific discoveries, departmental priorities, student and instructor demographics, and employers' demands. As the 21st century unfolds, our graduates will be asked to solve increasingly complex problems and address societal concerns, many of which will not have unique disciplinary answers. How can we capitalize on our strengths to prepare students for jobs that, in many cases, do not exist yet? How do we structure programs that foster skills and aptitudes that offer students with a degree that has long-term value? Animal sciences curricula will continue to expand (e.g., genomics, animal welfare) and interface with other disciplines (e.g., environmental, international, human health and social studies), but more importantly, our classrooms will become microcosms of society, and students will be challenged to face problems as they will encounter them in the workforce. Students will have to become critical thinkers and evaluators of information as the latest scientific facts and figures will be readily available through the World Wide Web. Because embracing diversity is an essential component of broad understanding, creativity and innovation, our students must be challenged with the conflicting perspectives of multiple stakeholders. Requiring multiple capstone-like experiences whereby a student addresses relevant real-world problems through properly structured internships, service learning, labs or undergraduate research projects, study abroad, and computer-based simulations will become ever more essential to our future pedagogy. Communication skills and leadership experiences will no longer suffice, as metacognitive and self-directed learning skills will be vital to one's successful career path. In short, learning how to learn is a lasting, transferable and life-long learning skills that will be as important as equipping our students with the latest knowledge at the time of graduation. These inevitable changes are already occurring in spite of numerous challenges.

Key Words: undergraduate, instruction, curriculum

693 Creating animal scientists from scratch–Meeting industry needs with today's students. J. A. Sterle,* *Iowa State University, Ames.*

Changing demographics of students majoring in animal science (AN S) are no surprise. However, coupled with decreased interest of AN S undergraduates in food production species, continued demand for "industry-ready" graduates, and the increased enrollment that many AN S departments are experiencing (along with decreasing resources), it becomes apparent that AN S faculty, departments and curriculum must adjust. Questions arise about changing goals and objectives of traditional departments, and the best use of available resources to meet these diverse interests and needs (and increasing student numbers). Incoming students today need more introduction to the livestock industry, including terminology, industry structure, heritage, and contributions to society. Safety around livestock and animal handling also need to be covered. These topics are not only necessary to provide frame of reference and perspective, they also draw the interest of students. There is pressure to create broader curricula to meet students' interest in species other than livestock. A department must consider whether the job market supports graduates in a new specialized area. If the answer is yes, then the question of available resources must be addressed. For example, many students come to AN S with a strong interest in zoo animals or exotics, but the job market makes it difficult to justify specific courses in this area. Many employers of animal scientists have expectations that graduates have some basic knowledge, experiences and skills (such as being comfortable around large animals), regardless of the position. Basic handling courses, experiential labs throughout the curriculum, and intense internship/student worker positions can prepare students who do not enter college with such experience. Over 95% of Iowa State AN S graduates, 55% of which would not be considered "traditional" or from a farm background, are placed within 6 mo of graduation, in a wide variety of positions. This suggests that AN S programs can still meet the needs of a variety of employers, regardless of the background of students entering the curriculum.

Key Words: teaching, undergraduates, non-traditional students

694 Critical skills and characteristics expected by employers of animal science graduates and strategies for equipping them. S. Robinson*[1] and D. Mulvaney[2], [1]*Oklahoma State University, Stillwater,* [2]*Auburn University, Auburn, AL.*

Employers and professional schools desire graduates in animal science programs who possess human capital (i.e., technical competencies, employability skills, and experiences) in the animal agriculture industry. Specifically, in addition to technical competencies, employers seek prospective employees who have evidence of practiced leadership and previous work experience that has enabled them to experience real-life issues, such as dealing with difficult people, resolving conflicts, making decisions and thinking at higher levels of cognition. According to employers, colleges of agriculture are effective in preparing prospective employees with technical skills and knowledge within a specific discipline; however, the development of interpersonal and emotional intelligence (EI) skills is not perceived as highly. Yet, in terms of importance, employers rank these latter skills ahead of disciplinary knowledge and technical skills. It is believed that disciplinary knowledge, skills and ability (KSA) are expected of all prospective employees, while "soft" cluster skills are those that differentiate the best from the rest. A recent study released by the Association of Public and Land Grant Universities (APLU) analyzed the importance of 7 "soft skill" clusters. Employers ranked them in importance from highest to lowest: (1) communications, (2) decision making/problem solving, (3) self-management, (4) teamwork, (5) professionalism, (6) experiences, and (7) leadership. These data provoked a call for more intentional integration of leadership and EI development into curricula and the establishment and promotion of leadership minors and/or certificates. Authors will address the readiness of the animal science graduate and offer strategies for developing the KSA expected by employers. Results of a study using the Delphi method to reach consensus of agreement among animal science industry experts on their thoughts regarding the skills college graduates need for employability in various sectors of the animal agriculture industry will be compared with other survey results and the APLU report. Additional inputs derived from interview processes conducted by prospective employers with applicants provide details about which aspects of human capital result in job offers. Of concern is how do programs reconstruct the frameworks of the higher education experience so that learning outcomes of soft skills, critical thinking skills, problem solving, experience and abilities needed for acquisition and access of information, knowledge and the contextual application are not mere aspirations in a strategic plan but tangible and measured. Classroom pedagogy may need to be changed - shifting from the emphasis on delivering content knowledge to a more robust intentional, experiential engagement of students around the acquisition of the desired skills. Based on these collective inputs, authors will offer suggestions for teaching and learning practices and curricular revision, which will lead to effective preparation of students for a dynamic, complex, global world of work.

Key Words: employer expectation, student development, animal sciences curricula

695 Custom tailoring class information to each student for their eventual use in the workplace.

T. G. Rozell,* *Kansas State University, Manhattan.*

Teaching required classes within the animal sciences often involves students from a wide range of backgrounds and diverse future career interests. Thus, some class material may seem of more relevance to some than to others, and engagement and comprehension suffers among students who do not see an immediate need for learning the information. As a result, opportunities for critical thinking are lost and the student is subsequently ill-prepared for critical thinking after entering the workplace. To address this, 2 different strategies have been employed in 2 different courses. The first involves the use of comprehensive oral final exams in Anatomy and Physiology. This required class includes about 80 students each semester, with career interests ranging from family farming to veterinary medicine. Students take the oral final in groups of 4 to 6, and are first asked their career interests. As each student takes a turn answering questions about major class concepts, they are asked to describe the information in the context of their future career choice. The future farmer may be asked about heat stress and managing animal comfort in a feedlot, while the future veterinarian might be asked about the same concepts in the context of an animal recovering from surgery. Students are made aware frequently during the semester that they will be asked to apply the basic concepts during the oral final, and the idea of doing so in front of peers provides increased motivation for learning basic mechanisms. The second strategy involves an industry-style R&D team project in Physiology of Lactation. Students work in small groups of 3 or 4 and are asked to develop a business proposal focused on some aspect of lactation, and which uses class material on anatomy and function of the mammary gland in their chosen species. Critical thinking skills are practiced at numerous times as students are required to present a legitimate business model for their lactation-based business to the rest of the class at the end of the semester. Each strategy allows individual students to develop the context in which to apply basic course information and practice critical thinking in their chosen occupation area.

Key Words: critical thinking, oral final exam, industry-style project

Contemporary and Emerging Issues

696 Web forums as a method for engagement on contentious issues in dairying: Should pain relief be provided during disbudding and dehorning of dairy calves? D. M. Weary,* C. S. Schuppli, and M. A. G. von Keyserlingk, *University of British Columbia, Vancouver, BC, Canada.*

Many people have positive views about dairy farming but this goodwill may be eroded if industry practices fall out of step with changing public expectations. Previous work has indicated that a particularly contentious topic is the use (or lack thereof) of pain control during painful management procedures. To better understand the expectations of different stakeholders to the use of pain control during routine painful procedures, we used web-based virtual "town hall" meetings to provide some background information describing the procedures and issues and allow people to respond to the question: "Should pain relief be provided when disbudding and dehorning dairy calves"? Anybody with access to the Internet could participate, and individuals working in dairy industry were targeted via a short article and link to the forums published in Progressive Dairyman. Over 200 people participated in 5 different web forums; 36% were students or teachers, 10% animal advocates, 25% farmers, veterinarians, and industry professionals, and 29% had no involvement in the dairy industry. The majority (86%) responded "Yes"; 7% "Neutral" and 7% "No." Participants in any one forum could not see the responses in other forums, allowing the discussions to proceed independently. Despite this independence, the majority of respondents in every forum (varying from 82% to 90%) indicated that pain control should be provided (i.e., chose "Yes"). Responses varied with participant demographics; for example, only 64% of producers chose "Yes" versus 90% of veterinarians. However, within every demographic category measured (e.g., sex, age, etc.) the majority argued that pain control should be provided. These results suggest that practice on farms that do not routinely provide pain mitigation for these procedures is out of step with widely held values (including those of dairy producers), suggesting the need for new policy and better incentives to encourage use of appropriate methods of pain control.

Key Words: animal welfare, analgesic, survey

697 Preliminary assessment of graded *Garcinia kola* seed meal on the performance, hematology and serum enzymes of broilers. O. A. Ogunwole, E. A. Iyayi, M. D. Olumide,* O. Arinola, and O. A. Adebiyi, *University of Ibadan, Ibadan, Oyo State, Nigeria.*

A preliminary assessment of the incorporation of graded levels of *Garcinia kola* seed meal (GKSM) and a commercial symbiotic Biovet YC on the performance, serum enzymes, hematology and organ weights of broilers was undertaken in a trial lasting 6 weeks. One hundred and 50 chicks of Arbor acre strain were randomly assigned to 6 treatments comprising of 25 birds per treatment and 5 birds per replicate. Diets 1, 2, 3, 4, and 5 contained *Garcinia kola* meal at 0, 2.5, 5.0, 7.5 and 10.0g/100g and the sixth diet had Biovet-YC at 0.1g/100g of feed. Routine antiviral vaccinations were administered on the birds but without any medication throughout the course of the trial. Feed intake and weight gain were significantly ($P < 0.05$) lowered by increasing GKSM inclusion above in the feed. Values obtained for serum alkaline phosphatase (19.82, 21.40, 21.20, 21.05, 20.82 and 22.90 μg/L for birds on treatments 1, 2, 3, 4, 5 and 6 respectively) were significantly ($P < 0.05$) higher with increasing inclusion of test ingredient. The red blood cell counts and the weight of kidney were significantly ($P < 0.05$) higher for birds on treatment 5. *Garcinia kola* meal should be incorporated at lower levels below 2.5g/100g in broilers diet. The bioactive component of *Garcinia kola* could be extracted, characterized and exploited for poultry production.

Key Words: *Garcinia kola* meal, serum indices, organ weight

698 Water usage and discharge volumes on New Mexico dairy operations. T. M. Vander Dussen*[1], G. R. Hagevoort[1], J. Lazarus[2], E. Naumburg[2], R. Ganta[2], and K. D. Casey[3], *[1]Agricultural Science Center at Clovis, New Mexico State University, Clovis, [2]Glorieta Geoscience Inc., Santa Fe, NM, [3]Texas AgriLife Research, Texas A&M System, Amarillo.*

Water usage on western dairies has become a topic of much debate in recent years. Much of the debate is fueled by incomplete information about the volume of water pumped (total water diversion) and its subsequent distribution for dairy purposes or for irrigation. Water diverted to the dairy is consumed by the cows, used for cooling of milk or cows, or utilized for cleaning. The large majority of the cooling and cleaning water is discharged into the lagoon system and recycled as irrigation water. In New Mexico a discharge permit (DP) is required to discharge "green water" into the lagoon system, and the maximum allowed discharge volume is defined in the permit. Metered discharge volumes into the lagoon system are reported monthly. A review of New Mexico's State Engineer and Environment Department records attempted to determine how much water is actually discharged. Average discharge volumes varied largely depending on the waste water management practices, in particular the use of a flush system. Based on the average herd size in NM (2,293), the average discharge volume per milking cow in 2011 was 28 GPD. Dairies with direct land application or total evaporation systems (19% of DP's) discharged lowest water volumes, typically well below 10,000 GPD. Since individual herd sizes are not reported, it is unknown if large discharge volumes (>100,000 GPD) were simply due to a large herd size, a large flush-system, or poor water management. Over the 2006–2011 reporting period, average discharge volumes peaked in 2008 at 87,000 GPD but have since decreased 27%. Some of the noted measures producers have taken to reduce water usage are: switching from water- to air-cooling systems, abandoning the practice of flushing alleys, reducing hose sizes in barns and wash pens, installation of timers on hoses for wash pen cleaning, etc. Dairies surrounding the Rio Grande watershed reported lower discharge volumes than dairies along New Mexico's East side with little or no nearby surface water. A lower discharge volume ultimately reduces: 1) the risk of accidental non-permitted discharges to waters of the US, 2) the costs of production, and 3) the total water footprint of the dairy operation.

Key Words: water usage, discharge volume, water footprint

Beef Species

699 Evaluation of selecting half-sibling beef cows to increase calf crop uniformity.

B. Nichols,* R. Reuter, and B. Cook, *The Samuel Roberts Noble Foundation Inc., Agriculture Division.*

Increasing calf crop uniformity has long been regarded as a means to increase sale price in beef cattle operations. A lack of uniformity has also been reported as one of the top quality defects in the US beef industry according to the National Beef Quality Audit. In 2004, 200 half-sibling (HS) yearling heifers and 200 yearling heifers of similar phenotype (PS) but unknown genetic relationship were used to determine if selection of half-siblings would increase uniformity of the calf crop under commercial management. Females were bred by AI to either Angus or Limousin bulls and exposed to full brothers of the AI bull. Cows were managed in one herd under commercial conditions. Calf weaning weights were measured for 5 calf crops (calves born in 2005 – 2009). Adjusted weaning weights (BIF adjustments) were available for 853 calves (393 calves from 158 HS cows; and 460 calves from 156 PS cows). These adjusted weaning weights were evaluated in a repeated-measures ANOVA (PROC MIXED) with year, cow type, calf sire breed, calf sex and their interactions as fixed effects and cow as the repeated subject with an autoregressive covariance structure. Least squares means for adjusted weaning weight were 506 and 526 lb for HS and PS cows, respectively. Adjusted weaning weight residuals from the model were evaluated for homogeneity of variance with Levene's test in PROC GLM of SAS. Adjusted weaning weight SD was 49.4 and 47.7 for HS and PS cows, respectively ($P = 0.56$). Lifetime weaning weight production was calculated for each cow by summing all observed actual weaning weights across all 5 years. Lifetime production was 1358 ± 706 lb for HS cows and 1635 ± 705 lb for PS cows, and variances were not different ($P = 0.97$). A subset of calves from each year was finished in a commercial feedlot. Variance of HCW and REA of calves from HS cows tended to be less ($P < 0.14$) than variance of calves from PS cows. The opposite was true for finishing-period ADG variance ($P = 0.14$). Considering half-sibling relationships when selecting commercial cows, over and above phenotypic selection, appears to have limited ability to reduce variability of calf crops.

Key Words: calf crop uniformity, beef cows

700 Performance, residual feed intake, and carcass quality of progeny from Red Angus sires divergent for maintenance energy EPD.

C. M. Welch*[1], J. K. Ahola[3], G. K. Murdoch[1], D. H. Crews[3], J. I. Szasz[1], L. C. Davis[1], M. E. Doumit[1], W. J. Price[2], L. D. Keenan[4], and R. A. Hill[1], [1]*Department of Animal and Veterinary Sciences, University of Idaho, Moscow,* [2]*Statistical Programs, University of Idaho, Moscow,* [3]*Department of Animal Sciences, Colorado State University, Fort Collins,* [4]*Red Angus Association of America, Denton, TX.*

The maintenance energy (ME_M) EPD was developed by the Red Angus Association of America and is used as an indicator of energy expenditure, which may be closely associated with residual feed intake (RFI). The objectives of this study were to evaluate and quantify the following using progeny of Red Angus (RA) sires divergent for ME_M EPD: 1) post-weaning RFI and finishing phase feed efficiency (FE), 2) post-weaning RFI and carcass quality, and 3) post-weaning RFI and sire ME_M EPD. Studies were conducted over a period of 3 years (cohorts), and sires divergent for ME_M EPD were identified before breeding. Post-weaning RFI and finishing phase FE of steer progeny tended to be positively correlated ($r = 0.38$; $P = 0.06$) in cohort 1 and were positively correlated ($r = 0.50$; $P = 0.001$) in cohort 3. In addition, post-weaning RFI was not correlated ($P > 0.05$) with any carcass traits. Sire ME_M EPD was correlated ($P < 0.05$) with carcass traits in cohort 1 (HCW, LM area, KPH, fat thickness, and yield grade) and cohort 2 (KPH and fat thickness). Most correlations between sire ME_M EPD and carcass quality were explained by the genetic potential of the sires; however, variation in measured LM area was not explained by the genetic potential of ribeye area EPD, and therefore, the observed correlation between sire ME_M EPD and measured LM area may suggest an association between ME_M EPD and LM area. In addition, no relationship was observed ($P > 0.05$) between progeny post-weaning RFI and sire ME_M EPD. Therefore, results suggest the following: 1) RFI measured during the post-weaning growth phase is indicative of FE status in the finishing phase, 2) neither RFI nor sire ME_M EPD negatively affected carcass quality, and 3) RFI and sire ME_M EPD are not associated.

Key Words: maintenance energy, residual feed intake, carcass quality

701 The effect of limiting feed intake on concentration of proteins associated with energy balance in the pregnant beef cow.

K. M. Wood*[1], C. J. Fitzsimmons[2,3], S. P. Miller[1], B. W. McBride[1], and K. C. Swanson[4], [1]*Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Agriculture and Agri-Food Canada, Edmonton, AB, Canada,* [3]*Dept. of Agriculture, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada,* [4]*Dept. of Animal Sciences, North Dakota State University, Fargo.*

Twenty-two multiparous pregnant beef cows were used to investigate the effect of dietary restriction on the abundance of selected proteins regulating energy metabolism. Cows were fed at either 85% (n = 11; LOW) or 140% (n = 11; HIGH) of NEm. The diet consisted of a haylage-based total mixed ration containing 20% wheat straw. Cows were slaughtered by block (date of parturition), beginning on 83 d after the initiation of dietary treatments and every wk thereafter for 6 wks, such that each block was slaughtered at approximately 250 d of gestation. Tissue samples from liver, kidney, sternomandibularis muscle, ruminal papilli (ventral sac), pancreas, and small intestinal muscosa were collected at slaughter and snap frozen in liquid N_2. Western blots of total protein isolated from these tissues were conducted to quantify abundance of: PCNA, ATP synthase, ubiquitin, and Na/K+ ATPase for all tissues; PGC1α, PPARγ, AMPKα and phosphorylated AMPKα for liver, muscle, and rumen; and PEPCK for liver and kidney. Statistical analysis was conducted using proc Mixed in SAS and included the fixed effects of dietary treatment, cow age, block, and the random effect of pen. Pearson correlations were conducted within treatment to investigate relationships between protein abundance and performance characteristics. Dietary treatments resulted in cows fed HIGH having greater ($P \leq 0.04$) ADG and final BW then cows fed LOW. Abundance of ubiquitin in muscle was greater ($P = 0.009$) in cows fed LOW, and PCG1α in liver was greater ($P = 0.03$) in cows fed HIGH. In cows fed HIGH, DMI was negatively correlated ($P < 0.03$) with small intestinal PCNA, ATP synthase and Na/K+ ATPase abundance. This data indicates that feed intake can influence the quantity of important metabolic proteins. These results will further the understanding of maintenance requirements and feed efficiency in pregnant beef cows.

Key Words: beef cows, cellular energy metabolism, feed intake

702 Heifers with low antral follicle counts have low birth weights and produce progeny with low birth weights.

A. F. Summers*[1], R. A. Cushman[2], and A. S. Cupp[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]USDA-ARS U.S. Meat Animal Research Center, Clay Center, NE.*

Research has demonstrated that heifers with increased numbers of ovarian antral follicle counts (AFC) have improved hormonal profiles and improved fertility. Interestingly, heifers with low AFC had lower birth weights, suggesting that genes influencing growth and development also influence the development of the reproductive tract and establishment of the ovarian reserve. To determine the relationship of AFC to heifer BW, reproductive tract characteristics, and first calf performance, composite (MARC III x Red Angus) heifers (n = 362) were used over a 4 yr period. In yr 1 heifers grazed winter range or corn stalk residue and were offered no supplement or 0.45- 0.90 kg/d (31%CP, DM Basis) during development. In yr 2 and 3 heifers grazed winter range and were fed a dried distillers grain-based (DDG) or corn gluten feed-based supplement offered at 0.59% and 0.78% BW, respectively, throughout development. Supplements were formulated to be isocaloric but differed in undegradable protein. In yr 4 heifers were fed either 0.59% or 0.46% BW of the DDG based supplement offered in yr 2 and 3. All heifers in yr 2 to 4 were fed ad libitum meadow hay while grazing dormant pasture. Prior to breeding, heifers were transrectally ultrasounded to determine AFC and classified as high (≥26 follicles; HIGH) moderate (16–25; MOD) or low (≤15; LOW). There was no diet x AFC classification interaction. HIGH heifers have greater ($P \leq 0.05$) birth, weaning, and adjusted 205-d weaning BW compared with LOW. Pre-breeding BW, total AFC, and proportion of mature BW at breeding were greater ($P < 0.01$) for HIGH compared with LOW heifers. Overall pregnancy rate was similar ($P = 0.36$) among AFC classifications. Progeny birth BW was greater ($P = 0.03$) for calves born to HIGH compared with LOW heifers. Taken together these data indicate a relationship between AFC and BW through the first breeding season and progeny calf BW. The low birth BW in heifers with low AFC and in their progeny continues to support a possible link between genes that influence growth and development and establishment of the ovarian reserve. USDA is an equal opportunity provider and employer.

Key Words: beef, progeny, antral follicle count

703 Prediction of HCW of individual steers from partial live weight collected with an in-pen weighing device.

R. Reuter* and C. Moffet, *The Samuel Roberts Noble Foundation Inc., Agriculture Division.*

Accurately and precisely predicting HCW of individual cattle several days before slaughter would enable more efficient management and marketing of slaughter cattle. Technology (GrowSafe Beef system, GrowSafe, Inc.) has been developed that estimates a partial body weight (pBW) by weighing the fore feet of an animal as it drinks water. Weights are measured at 1-s intervals. Our objective was to determine the degree to which pBW could predict HCW in steers. Four hundred and five steers (BW: 309 ± 28.5 kg) were fed in a commercial feedlot near Calgary, AB in the winter of 2010 – 2011. Steers were housed in dirt-surfaced pens equipped with the pBW measuring device. Cattle were slaughtered (HCW: 360 ± 33 kg) in 2 groups (n = 203 and 202). Cattle were on feed for 209 d, and recorded ADG of 1.21 kg, indicative of commercial management. Number of pBW observed ranged from 0 to 4,620 and averaged 602/steer per day. These pBW were filtered to remove extreme 1-s data points. The filtering algorithm removes 1-s observations were the residual pBW is more than 200 kg from the predicted pBW predicted from the linear regression of pBW over time. The filtering algorithm continues iteratively refitting the linear regression, decreasing the residual threshold in 5-kg increments in each iteration, and discarding the extreme observations until all the observed pBWs are within 25 kg of the predicted pBW. For each steer, this filter was applied to pBW from d −40 to −10 (relative to slaughter = d 0), and used to predict pBW at d 0 (slaughter). On average, this filtering algorithm removed 12% of the pBW data. Predicted pBW was then regressed on measured HCW ($r^2 = 0.86$). The Limit of Agreement was 25.2 kg, indicating that a 30-d history of pBW measurements could predict HCW of an individual steer 10 d before slaughter within 25.2 kg, 95% of the time. Theoretically, using this device and prediction method, mean HCW of a group of 100 steers could be predicted within 2 kg of the actual HCW 10 d before slaughter, 95% of the time. Further, if a large population of steers were available such that 100 steers could be identified that all had the same predicted pBW, mean HCW of that group would still be within 2 kg of the prediction and 95 of the steers would have a HCW within 25.2 kg of the predicted HCW.

Key Words: partial body weight, carcass weight prediction, technology

704 Effect of various feeding regimens pre-shipment on shrink and subsequent weight recovery in feeder calves.

J. Starnes* and D. Rankins, *Auburn University, Auburn, AL.*

Shrink is a major factor in the marketing of feeder cattle. It is especially important for long hauls (20+ h) from southeastern backgrounders to Midwestern feedlots. Shrink occurs in 2 forms: 1) loss of body fill and 2) loss of tissue fluids, which is observed during longer periods of transport. Objectives of this research were to compare the effects of various pre-shipment feeding regimens on shrink and subsequent BW gain in shipped and unshipped feeder calves. Forty-eight British cross steers (initial BW 351 kg) were fed high moisture (HM) or dry feed (DF) for 45 d and then offered hay or no hay 48 h before shipment. Factors were imposed factorially (2 × 2), 3 pens/group and 4 steers/pen. Daily gain during the backgrounding period was not different for HM versus DF ($P > 0.10$) and averaged 0.93 kg/d. On d 45, 2 steers from each pen were shipped, while their 2 pen-mates remained in the pen of origin (24 shipped; 24 un-shipped). Steers were loaded on 2 trailers ($11.3m^2$; 12 steers/trailer; one from each pen) with an average stocking density of $413kg/m^2$. Average shipping BW was 393 kg. Transported calves remained on the trailers for 21 h during which the minimum temperature was 7.2°C and the maximum temperature was 11.6°C. Upon arrival, BW were decreased ($P = 0.02$) for transported steers (365 kg) versus their pen mates (392 kg). Neither HM nor DF or hay affected shrink ($P > 0.10$). Within 12 h, BW were similar for the shipped and un-shipped calves ($P = 0.08$; 371 and 392 kg, respectively). Pre-shipment diets or 48-h hay offering did not affect BW post-shipment ($P > 0.10$). Within 5 d of shipment BW of the transported calves (384 kg) and un-transported calves (393 kg) remained similar ($P = 0.36$). Following 21 h of trailer transportation feeder calves shrank 7.1% during mild temperatures (7.2°C to 11.6°C). Feeding HM or DF or offering hay 48 h before shipment had no effect on shrink or subsequent BW gain after transportation.

Key Words: shrink, transportation, feeder calves

705 Comparison of different feed additives for backgrounding of weaned beef calves.

A. Imler[1], M. Hersom*[1], T. Thrift[1], J. Yelich[1], and J. Arthington[2], *[1]University of Florida, Department of Animal Sciences, Gainesville, [2]Range Cattle Research and Education Center, Ona, FL.*

The use of feed additives in supplements is one means to positively affect the health status of newly weaned calves during backgrounding.

Our objective was to evaluate the response of weaned calves to different feed additives in a supplement (CP = 14.6%, TDN = 67%) to improve calf performance and mitigate the stress response observed during the backgrounding period. Following stratification by BW, calf gender, previous castration status, and breed, 160 calves (203 ± 2.3 kg) were randomly allotted to 1 of 4 treatments (n = 40 calves/treatment): 1) control (CON) were supplemented without additives; 2) supplement with added chlortetracycline, 350 g/d (CTC); 3) supplement with added Rumensin, 175 mg/d (RUM); 4) supplement with added Actigen, 10 g/d (ACT). Calves were held in 1 of 4 drylot treatment pens (n = 40 calves/pen) for 1 wk and offered ad libitum access to hay and 1.8 kg of supplement before placement in 1 of 32 0.8-ha pens (5 calves/pen) for a total of 8 pens/treatment. Calves had BW and blood samples collected on d 0, 1, 4, 7, 11, 14, 51 and 52. Data were analyzed by the MIXED procedure of SAS. The model included the main effects of treatment. All variables quantified by day were analyzed using repeated measures. Over the 52-d period, ACT resulted in the greatest ($P = 0.002$, 0.325 kg/d) gain response. CTC calves exhibited similar ($P = 0.35$) gains to ACT, which were both greater ($P \leq 0.005$) than RUM (0.228 kg/d). CON calves were similar ($P \geq 0.13$) to both medicated treatments, but did not gain more ($P = 0.02$) than ACT. Plasma concentrations of haptoglobin and ceruloplasmin were similar ($P \geq 0.70$) among treatments; however, a day effect ($P \leq 0.001$) was observed in both acute phase proteins measured. Feed cost of gain was not significantly different ($P = 0.19$, mean = \$2.93/kg) among treatments. Profitability for ACT and CTC were similar ($P = 0.16$, mean = \$23.84/calf) and more ($P = 0.002$) profitable than RUM (\$-3.66/calf), CON was intermediate. ACT may improve calf performance as effectively as CTC during a backgrounding period of this duration, but neither additive was effective at mediating stress post-weaning.

Key Words: backgrounding, stress, supplement

706 Comparison of different feeding levels of a recycled-product supplemented to weaned beef calves. M. Hersom,* T. Thrift, and J. Yelich, *University of Florida, Department of Animal Sciences, Gainesville.*

The objective of this study was to evaluate different feeding levels of dehydrated food products and recycled poultry bedding supplemented to weaned beef calves. In Exp. 1, 160 Angus and Brangus steers and heifers (218 ± 2.2 kg) were utilized. In Exp. 2, 160 steers and heifers (245 ± 3.6 kg) of Angus, Brahman, and 4 combinations of Brahman × Angus were utilized. For both experiments all calves grazed 0.81 ha bahiagrass-bermudagrass pastures and supplement was offered as a percent of initial pen mean BW. Treatments were 1) no supplementation (CON); 2) 1.0% of BW; 3) 1.5 of BW; 4) 2.0% of BW and calves were fed daily in the morning. In both experiments calves were stratified by BW, breed, gender, and implant status in Exp. 1, and randomly allotted to 1 of 4 treatments. Each treatment was replicated in 4 pastures for each experiment. All pastures were fertilized 7 d before the initiation of the experiment with 56 kg/ha of N. Calf BW were collected on d −7 for allotment, and d −1, 0, 22, 46 and 47. Data were analyzed as a randomized complete block design with a split-plot; supplement treatment was the whole plot and implant or breed type was the split-plot for Exp. 1 and 2, respectively. Forage mass decreased linearly ($P < 0.05$) from 3,839 to 1,998 kg/ha across the 46 d experiment. In both Exp. 1 and 2, final BW was greater ($P < 0.05$) for supplemented compared with CON. In Exp. 1, 46-d ADG was greater ($P < 0.05$) for supplemented compared with CON and calves supplemented at 2.0 had greater ($P < 0.05$) ADG than the 1.0 and 1.5 level. In Exp. 2, 46-d ADG was different ($P < 0.05$) among all treatment levels. Breed type affected 46-d ADG; 0.5:0.5 and 0.25:0.75 Angus:Brahman crossbred calves had greater ($P < 0.05$) compared with Angus, Brangus and 0.75:0.25. In both Exp. 1 and 2, final calf value (\$/calf) and profit/loss (\$/calf) were greater ($P \leq 0.005$) for supplemented compared with Con calves (Exp. 1: \$644.25 vs 601.64 and \$35.16 vs 6.33, respectively; Exp. 2: \$725.74 vs 648.31 and \$54.56 vs 6.36, respectively). Available forage and supplement level had a direct effect on calf BW gain, value, and weaned calf profitability.

Key Words: backgrounding, pasture, supplement

Breeding and Genetics: Dairy Cattle Breeding III–Genetic Evaluation

707 Extension of Bayesian procedures to integrate and to blend multiple external information into genetic evaluations. J. Vandenplas*[1,2] and N. Gengler[1], [1]*University of Liege - Gembloux Agro-Bio Tech, Gembloux, Belgium,* [2]*National Fund for Scientific Research, Brussels, Belgium.*

Current genetic evaluations are mostly based on local data, potentially followed by an international second step, as it is performed by Interbull (Uppsala, Sweden) for dairy breeds. However, reliability of estimated breeding values (EBV) for animals with few local data may be limited. Furthermore, the current development of genomic selection makes this issue more important and the blending of those multiple sources more necessary. Current methods are based on selection index and Bayesian procedures were proposed for a single external source. The aim of this research was to extend these methods to integrate information from multiple sources outside a given evaluation system, i.e., external information, into this genetic evaluation, i.e., internal evaluation, and to assess its potential to blend multiple sources of information when only external information is available. To allow simplifications of the computational burden and the propagation of all external information through the whole pedigree, all animals were considered as animals associated to external information thanks to the prediction of external information from available one for internal animals, i.e., animals with no external information. Multiple considerations of contributions due to relationships among animals were also taken into account. Two dairy cattle populations were simulated across 5 generations. Internal females were randomly mated with internal and 50 external males. Milk production for the first lactation for each female was simulated in both populations. Results for 100 replicates showed that average rank correlations among Bayesian EBV and EBV based on the joint use of external and internal data were close to 1 for both external and internal animals. The respective correlations for the internal evaluation were equal to 0.54 and 0.95. Mean squared error, expressed as a percentage of the internal mean squared error, was close to 0% for both external and internal animals. Thereby, the Bayesian procedure has the potential to integrate and to blend multiple sources of external information to evaluate animals more reliably.

Key Words: Bayesian, integration, multiple

708 Are in-line measurements of somatic cell counts equally or more useful for genetic evaluations as those from DHI? L. P. Sørensen* and P. Løvendahl, *Department of Molecular Biology and Genetics, Center for Quantitative Genetics and Genomics, Aarhus University, Tjele, Denmark.*

The aim was to estimate and compare genetic parameters for log-transformed somatic cell counts (SCC) based on in-line measurements (OCC, DeLaval) in automatic milking systems with monthly test-day SCC from traditional herd testing schemes. Data was collected during a 29-mo interval from 6 herds and 1294 first parity cows (5 to 305 d in milk). Cell counts were analyzed using a 2-trait linear animal model. There were a total of 298,988 records for OCC and 7779 for test-day SCC. The fixed part of the model included lactation curves fitted as a Wilmink function, and the random parts included animal and herd-test-day effects. Age at calving and days in milk was included as covariates. Estimates of heritability were similar for the 2 traits, $h^2 = 0.26$ and 0.25 for OCC and SCC, respectively, and the genetic correlation between the 2 traits was close to unity ($r_g = 0.98$). The results suggest that somatic cell counts based on in-line measurements are similar but not preferable to traditionally obtained SCC despite several OCC measurements per cow per day.

Key Words: dairy cattle, somatic cell count, genetic parameters

709 Prediction of residual feed intake for first and second lactation dairy cows. G. H. Manafiazar,* T. McFadden, E. Okine, L. Goonewardene, and Z. Wang, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Individual daily feed intake of 77 heifers from calving to the end of their second lactation was recorded at the Dairy Research and Technology Centre of the University of Alberta. Individual milk yields, and milk composition data of these cows were obtained from Dairy Herd Improvement (DHI) program and their body weights were recorded on the same days as the DHI milk sampled. Daily animal solutions for metabolic body weight (MBW), milk production energy requirements (MPER), and empty body weight changes (EBWC) were predicted from 5 to 305 d in milk using random regression Legendre polynomial. Total MBW, MPER, and EBWC over 301 d were predicted as the summation of their respective daily solutions. The total actual energy intake (AEI) over 301 d was linearly regressed on total 301-d predicted MBW, MPER, and EBWC to develop expected energy intake (EEI) prediction equation. The EEI prediction equation for the first and second lactation had R^2 of 0.82 and 0.81, respectively. Individual RFI over 301 d was calculated as the difference between total AEI and EEI over 301-d. The averaged daily RFI value ranged from −3.95 to 5.11 MJ NE_L d^{-1} and −4.86 to 4.34 MJ NE_L d^{-1} for the first and second lactation period, respectively. The animals were grouped into 3 classes of Low (<0.5 SD), medium (±0.5 SD), or high (>0.5 SD) from the mean (0) based on SD of RFI within lactation. The results showed that 30% of animals remained their respective RFI group between lactations, 54% of animals changed their RFI by less than 0.5 SD, and 15% of animals changed their RFI group by 1 SD. The results indicate that the developed RFI prediction equations could be used to calculate RFI in the first and second lactation; however, reranking exists between animals in the first and second lactation.

Key Words: dairy, residual feed intake, random regression

710 Random forest approach for SNP effects of residual feed intake in dairy cattle. C. Yao*[1], D. M. Spurlock[2], K. A. Weigel[1], L. E. Armentano[1], C. D. Page[1], and M. J. VandeHaar[3], [1]*University of Wisconsin, Madison,* [2]*Iowa State University, Ames,* [3]*Michigan State University, East Lansing.*

The objective of this study was to identify significant associations between single nucleotide polymorphisms (SNP) markers and residual feed intake (RFI) in dairy cattle using a random forest (RF) algorithm. Genomic data included 54,609 SNP genotypes for 395 Holstein cows, whereas phenotypic data included RFI measurements from 50 to 150 d postpartum. Residual feed intake was defined as the difference between observed dry matter intake (DMI) and predicted DMI after accounting for year and season of calving, year and season of measurement, age at calving nested within parity, days in milk (DIM), milk yield, body weight (BW), and body weight change (ΔBW). Measurements of BW were smoothed by using the fitted value of a quadratic function of weekly weights regressed on DIM, whereas ΔBW was calculated as the difference between fitted values for BW on adjacent days. Random Forest is an ensemble-based machine learning algorithm that uses a collection of tree predictors and can be adapted to classification and regression problems. Variable importance scores of RF, which were based on increases in mean squared error after permutation, were used to rank individual SNPs with large effects. Important combinations of SNPs, which may indicate the presence of epistasis even in the absence of significant main effects, were identified by examining the structure of trees. A 2-step RF algorithm was implemented, and parameters were tuned through 5-fold cross validation. A total of 4411 SNPs were selected at the first step based on importance scores; in the second step, individual SNPs with the largest importance scores and pairs of SNPs that appeared most repeatedly in combination within decision trees were evaluated relative to previously published studies of RFI in livestock. Among the 15 SNPs that were identified in our study, 7 are located within reported quantitative trait locus intervals for RFI in beef cattle, 6 are associated with annotated genes, and 5 are located in the introns of known genes. Based on these results, RF algorithms may be an effective method for identifying individual SNPs with large additive effects and combinations of SNPs with epistatic effects for quantitative traits.

Key Words: feed intake, random forest, SNP

711 Use of milk fatty acids to substitute for body condition score in breeding purposes.

C. Bastin*[1], D. P. Berry[2], H. Soyeurt[1,3], and N. Gengler[1], [1]*University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium,* [2]*Teagasc Moorepark Dairy Production Research Center, Fermoy, Co. Cork, Ireland,* [3]*National Fund for Scientific Research (F.R.S.-FNRS), Brussels, Belgium.*

The general objective of this research was to investigate whether fatty acids (FA) profile in milk could substitute for body condition score (BCS) as an indicator of energy balance status in genetic evaluations. First, genetic correlations between BCS and the content in milk of 10 major FA predicted by mid-infrared spectrometry (C4:0, C6:0, C8:0, C10:0, C12:0, C14:0, C16:0, C17:0, C18:0, and C18:1 *cis-9*; in g/dL of milk) were estimated using 10 2-trait random regression models. Data included from 36,964 to 37,239 FA records depending on the trait and 30,500 BCS records collected in 85 herds from 7,623 first-parity Holstein cows. Genetic correlations among BCS and FA were at the highest in early lactation. At 5 d in milk, genetic correlations with BCS ranged from 0.26 to 0.32 for C4:0 to C14:0 and were 0.15 for C16:0, −0.01 for C17:0, 0.05 for C18:0, and −0.15 for C18:1 *cis-9*. These results could be explained by the release of long chain FA in milk in early lactation due to the body fat mobilization and the consequent inhibition of de novo FA synthesis in the mammary gland. Also, results indicated that FA contents in milk in early lactation would impact BCS during the whole subsequent lactation: genetic correlation between C18:1 *cis-9* at 20 d in milk was −0.14 with BCS at 20 d in milk and −0.25 with BCS at 305 d in milk. Second, the part of the genetic variance in BCS explained by FA contents in milk along the lactation was calculated using selection index theory. Results indicated that the part of genetic variance in BCS explained by FA was 38% at 5 d in milk, was at the highest (56%) at 150 d in milk, and then decreased to 44% at 305 d in milk. Future studies will aim at estimating the part of the genetic variance in fertility explained either by BCS or FA contents in milk or both and will further investigate if FA contents in milk could substitute for body condition score.

Key Words: fatty acid, body condition score, genetic correlation

712 Genetics of the mid-infrared prediction of lactoferrin content in milk for Holstein first-parity cows.

C. Bastin*[1], G. Leclercq[1], H. Soyeurt[1,2], and N. Gengler[1], [1]*University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium,* [2]*National Fund for Scientific Research (F.R.S.-FNRS), Brussels, Belgium.*

Lactoferrin is an iron-binding protein present in bovine milk. Interests taken to this protein are related to its therapeutic properties. Lactoferrin can be isolated from whey and used as a specialty food ingredient or as an antimicrobial agent. Furthermore, lactoferrin content in milk has been demonstrated to be higher in (sub)clinical mastitic cows. The objective of this study was to assess the genetic variability of the mid-infrared prediction of lactoferrin content in milk (MIRLf) and to estimate its genetic correlations with milk, fat, and protein yields, somatic cell count (SCS), and contents in milk (g/dL) of 7 groups of fatty acids (FA) predicted by mid-infrared spectrometry (saturated, monounsaturated, polyunsaturated, unsaturated, short chain, medium chain, and long chain). Data included more than 88,000 milk, fat, and protein records, 85,000 SCS records, and 61,000 FA and MIRLf records from 9878 first-parity Holstein cows. Co(variances) were estimated using 11 2-trait random regression models. Heritability for MIRLf increased from 0.20 at 5 d in milk to 0.40 at 250 d in milk. Genetic correlations of MIRLf with milk, fat, and protein yields decreased along the lactation; from 0.50 to −0.50 for milk, from 0.40 to −0.10 for fat yield, and from 0.55 to −0.25 for protein yield. Genetic correlation between MIRLf and SCS increased along the lactation from 0.10 at 5 d in milk to 0.30 at 305 d in milk. This positive correlation substantiated the potential interest of MIRLf as an indicator of udder health. Finally, for all FA groups, genetic correlation with MIRLf increased along the lactation. Average daily genetic correlations between MIRLf and FA ranged from 0.25 to 0.40 and were higher for unsaturated FA, indicating that selection for higher MIRLf would increase the content of unsaturated FA in milk to a larger extent than saturated FA. Concomitant selection of MIRLf and unsaturated FA is therefore feasible and this could be considered as beneficial for the genetic improvement of nutraceutical properties of milk.

Key Words: lactoferrin, mid-infrared prediction, genetic correlation

713 Genetic parameters for methane indicator traits based on milk fatty acids in cows.

P. B. Kandel*[1], A. Vanlierde[2], F. Dehareng[2], E. Froidmont[2], N. Gengler[1], and H. Soyeurt[1,3], [1]*Animal Science Unit, Gembloux Agro Biotech, University of Liège, Passage des Deportes, Gembloux, Belgium,* [2]*Valorisation of Agricultural Products Department, Walloon Agricultural Research Centre, Gembloux, Belgium,* [3]*National Fund for Scientific Research (FNRS), Brussels, Belgium.*

Dairy production is pointed out for its large methane emission. Therefore, currently studies of factors affecting emission and methods to abate methane emission are numerous. However, an important issue is the development of easily obtainable indicators, because they would also allow estimating animal genetic variability of methane emission. Recently methane indicators were proposed using gas chromatography based milk fatty acid composition. We derived these published methane indicators using 1100 calibration samples directly from mid-infrared (MIR). For the published indicator showing the highest relationship ($R^2 = 0.88$) with sulfur hexafluoride (SF_6) methane emission data, genetic parameters for this MIR based indicator were estimated by single trait random regression test-day models from 619,272 records collected from 2007 to 2011 on 71,188 Holstein cows in their first 3 lactations at Walloon region of Belgium. The average daily heritability was 0.35 ± 0.01, 0.35 ± 0.02 and 0.32 ± 0.02 for the first 3 lactations, respectively. Similarly, the lactation heritability was 0.67 ± 0.02, 0.72 ± 0.03 and 0.62 ± 0.03. As expected, methane production was higher during the peak milk production depicting the normal lactation curve. The largest differences between estimated breeding values (EBV) of sires having cows in production eructing the highest and the lowest methane content was 21.80, 22.75 and 24.89 kg per lactation for the first 3 parities, the variances of the EBV of the sires with daughters were 10.67, 12.46, 12.18 kg^2. Results were similar for other indicators. This study suggested that methane indicator traits can be predicted by MIR. Genetic parameters also indicated a rather high heritability and genetic variability exist for these published indicators and consequently a potential high genetic variability of methane eructation by dairy cows. Therefore, these first finding might open new opportunities for animal selection programs that include the reduction of methane emission.

Key Words: methane, mid-infrared (MIR), heritability

714 Comparison of daughter performance of New Zealand and North American sires in US herds. H. D. Norman*[1], J. R. Wright[1], R. L. Powell[1], T. J. Lawlor[2], and C. W. Wolfe[3], *[1]Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD, [2]Holstein Association USA Inc., Brattleboro, VT, [3]American Jersey Cattle Association, Reynoldsville, OH.*

To improve fertility or other desired traits, some US graziers have chosen bulls from New Zealand (NZ), which relies extensively on seasonal calving and grazing. To compare performance of daughters of NZ and North American (NA; Canadian and US) AI Holstein (HO) and Jersey (JE) bulls, the model included fixed effects for US herd-year-season, parity (≤5) and semen source. Cows that calved between January 2000 and July 2010 in all US herds were included as well as in a subset of seasonally calving herds (≥60% of calvings in February through April). First-lactation HO data included records from 438 herds with 1,443 daughters of 54 NZ bulls and 26,444 daughters of 3,055 NA bulls; JE first-lactation data included records from 538 herds with 2,714 daughters of 65 NZ bulls and 76,281 daughters of 1,631 NA bulls. The seasonal calving subset included 22 HO and 26 JE herds. All differences mentioned were significant ($P < 0.05$) unless designated otherwise. Mean milk and protein yields across all parities were higher for NA daughters than for NZ daughters (497 kg milk and 6 kg protein for HO; 264 kg milk and 3 kg protein for JE); mean fat yield was nearly equal for HO but lower (2 kg) for NA JE daughters. Mean somatic cell scores were higher for NZ than NA daughters (0.15 for HO; 0.08 for JE). Mean days open were fewer for HO (9.9 d) and JE (1.3 d, nonsignificant) NZ daughters. Difference between NZ and NA HO daughters for calving ease and stillbirth rate was small and nonsignificant. Results for seasonally calving herds were similar. For 17 HO type appraisal traits, NA daughters scored higher for stature, fore udder attachment, rear udder height, and udder depth. For 13 JE type appraisal traits, NA daughters scored higher for stature, dairy form, fore udder attachment, rear udder height and width, and udder depth but lower for strength and thurl width. Overall, NA HO bull daughters produced more milk and protein but were less fertile than NZ bull daughters. For JE, fertility was not different between NA and NZ daughters. Overall merit of various selection alternatives should be judged on performance of all traits with economic value considered.

Key Words: daughter performance, New Zealand, seasonal calving

715 Genotype environment interaction of Holstein-Friesian dairy cattle in eastern Libya. S. A. M. Bozrayda,* R. S. Gargoum, and I. A. S. Al-Drussi, *Department of Animal Production, University of Benghazi, Benghazi, Libya.*

Breeding values (BV) for some productive and reproductive traits of Holstein Friesian sires (6 North American, 57 European and 7 Libyan) under eastern Libyan conditions were estimated and compared with those estimated under, European, and North American conditions in an attempt to assess the genotype environment interaction. To investigate the effect of managerial conditions on the same traits, the heritability coefficients were also estimated under Libyan and Dutch managements. The trait's variance and covariance components and the breeding values of animal were computed using mixed model containing the fixed effects of month of calving, year of calving, management and generation and animal as random effect. The lactation period and age at calving were used as covariates. Genetic correlation values of sires BV for the milk yield under Libyan and European and North American conditions was less than 1. Differences in heritability estimates due to the management system and or to environmental factors reflect genotype × environment interaction. Milk yield traits except dry period had a higher BV during the Libyan than Dutch management. Reproductive traits except age at first calving also had a higher BV during Dutch than Libyan management. Correlations between BV for milk yield ranged between 0.16 and 0.56 under Libyan, European and North American conditions. Breeding values of both North American and European sires were medium, low and negatively ranked under Libyan environment. Breeding values of milk yield traits showed higher variability under the Libyan environment. Sires with low BV (≥ 500) revealed negative ranking under the Libyan conditions.

Key Words: breeding values, genetic correlations, genotype × environment interaction

716 Casein and fatty acid content in milk of crossbred dairy cows under grazing conditions. V. Artegoitia*[1,2], M. Carriquiry[1], A. Meikle[2], J. Dutur[1], L. Olazabal[3], J. Bermudez[1], A. Torre[3], and P. Chilibroste[1], *[1]Facultad de Agronomía, Universidad de la República Oriental del Uruguay, Montevideo, Uruguay, [2]Facultad de Veterinaria, Universidad de la República Oriental del Uruguay, Montevideo, Uruguay, [3]Laboratorio Tecnológico del Uruguay, Montevideo, Uruguay.*

Nutritional, physical, and flavor properties of milk are influenced by its casein and fatty acid (FA) content and they might have an effect on the consumer acceptance of dairy products. Therefore, the manipulation of their content in milk would have an effect on consumer demands, and on health recommendations [e.g., choosing between milks with greater proportion of conjugated linoleic acid (CLA)]. The objective of this study was to evaluate the casein and FA content of milk on Uruguay Holstein cows (UH; North American genetics), New Zealand Holstein and UH (NZH×UH), Jersey and UH (J×UH), and Swedish Red and UH (SRB×UH) under the same feeding strategies and herbage allowance. Forty primiparous cows were selected from a commercial Uruguayan dairy farm (UH, n = 8; HNZ×UH, n = 10; JXH×UH, n = 10; SRB×UH, n = 12). Milk samples were collected at wk 12 of lactation. Means were considered to differ when $P \leq 0.05$. Milk yield was greater in UH than RBS×UH and J×UH cows, while NZH×UH was greater than J×UH. Milk fat yield was greater in J×UH than the rest of the groups. Although milk protein yields were not affected by genotype, total casein production was greater in J×UH than UH cows and no other differences were found. Casein content was not affected by genotype. Saturated FA was greater and monounsaturated were less in milk fat of J×UH and HNZ×UH than RBS×UH. Polyunsaturated FA tended to have a lower concentration in J×UH than in the other groups ($P = 0.09$). Trans FA in milk fat were greater in RBS×UH, than J×UH. No differences among cows were found in CLA concentrations in milk. The results indicate that differences in genotype have an impact on the total casein production, as well as, saturated, monounsaturated, polyunsaturated and *trans* FA concentrations in milk from dairy cows under grazing conditions.

Key Words: crossbreeding, milk composition, grazing

717 Effect of the milk recording time on the genetic parameters of milk production and mid-infrared milk components in Luxembourg dairy cattle. V. M.-R. Arnould*[1,2], H. Soyeurt[2,3], and N. Gengler[2,3], [1]*CONVIS s.c., Ettelbruck, Luxembourg,* [2]*University of Liège, Gembloux Agro Bio-Tech, Animal Science Unit, Gembloux Belgium,* [3]*National Fund for Scientific Research (F.N.R.S.), Brussels, Belgium.*

Reducing the frequency of official milk recording and the number of recorded samples per test-day (vs. the conventional twice-a-day sampling) would have some advantages for dairy herd management. However, phenotypic variations in milk composition between morning (AM) and evening (PM) milkings are known and documented for major milk components but poor literature exist about genetic differences between AM and PM milkings. Therefore, the objective was to study the effect of milking time (AM or PM) on the estimation of the genetic parameters of milk yield, and mid-infrared milk components such as protein and fat yields and saturated and unsaturated fatty acids groups. A total of 44,833 milk samples were collected between October 2007 and November 2011 (from 9,602 Holstein cows in first lactation belonging to 491 Luxembourg dairy herds): 23,046 records from AM milking and 21,787 from PM milking. All milk samples were analyzed by mid-infrared spectrometry. The model included as fixed effects: herd × date of test, 3 classes of age, 24 classes of days in milk and month of test × year of test. Random effects were permanent environmental, additive genetics, and residual effects. Expect for milk yield ($P = 0.88$), it was observed that the evolution of the daily heritability among the first lactation was different according to the milking time for all studied traits ($P < 0.0001$). Preliminary results based on breeding values of bulls with daughters having records showed a rank correlation of 0.77 (milk yield). Given these results, genetic parameters of milk yield and studied milk components were affected by AM/PM milking.

Key Words: genetic evaluation, alternate milking recording scheme, milk component: heritability

718 Integration of experimental designs and analytical approaches to co-ordinate efficiency of global efforts to optimize environmental and genetic effects on reproductive performance of dairy cattle. E. Block[1], B. Bradford[2], W. M. Chalupa[3], I. J. Lean*[4], S. LeBlanc[5], M. C. Lucy[6], J. McNamara[7], J. Morton[8], A. R. Rabiee[4], J. E. P. Santos[9], W. W. Thatcher[9], M. Van Amburgh[10], and M. J. VandeHaar[11], [1]*Church & Dwight Co, Princeton, NJ,* [2]*Kansas State University, Manhattan,* [3]*University of Pennsylvania, Kennett Square,* [4]*SBScibus, Camden, New South Wales, Australia,* [5]*Population Medicine Ontario Veterinary College University of Guelph, Guelph, ON Canada,* [6]*Division of Animal Sciences, University of Missouri, Columbia,* [7]*Department of Animal Sciences, Washington State University, Pullman,* [8]*Jemora Pty Ltd., Geelong Victoria, Australia,* [9]*Department of Animal Sciences, University of Florida, Gainesville,* [10]*Department of Animal Sciences, Cornell University, Ithaca, NY,* [11]*Department of Animal Sciences, Michigan State University, E. Lansing.*

Our present knowledge of genetic and environmental processes that influence reproductive functions demands a systematic approach to design, conduct and analyze basic and applied studies of dairy cattle reproduction. The effects of genetic selection and population variation, nutritional intake and composition, climate and housing all interact to affect reproductive functions at cellular and molecular levels. Therefore, experiments must be designed to address specific mechanisms within a defined systems framework such that data will be integrated efficiently into knowledge bases, utilizing compilation methods such as meta-analysis and regression. Researchers with interests in reproduction have undertaken a project to produce guidelines to assist in efficient design, conduct, and analysis of experiments. The intent of the guidelines is to provide for design of studies that best fill the most critical knowledge gaps, enhance opportunities for research interaction, and provide new knowledge that can be integrated into our present understanding through appropriate data analyses and pooling methods. Similar guidelines have been developed for randomized controlled clinical studies in medicine, veterinary and animal science using a process of review and consensus. The guidelines will provide 1) clear definitions of experimental conditions, which include dietary, environmental, and reproductive conditions and responses, and 2) appropriate statistical designs and analyses to reduce bias, pseudoreplication, and the risks of Type I and Type II statistical errors. Critical knowledge gaps include the influence on reproductive outcomes of genetic selection and random genetic variation, diet content and intake, reproductive management and environmental conditions. Standardization is being developed for definitions of expression and detection of estrus and ovulation, cyclicity, fertilization, embryonic development, establishment and maintenance of pregnancy, and time to events such as pregnancy and for appropriate minimal sample sizes to detect economically or biologically important outcomes.

719 Associations between candidate gene polymorphisms and milk production traits in Alpine goats farmed in Italy. P. Crepaldi[1], E. Mlanesi[1], B. Coizet[1], L. Nicoloso[1], P. Fresi[2], S. Murru[2], R. Steri[3], and N. P. P. Macciotta*[3], *[1]Università di Milano, Milan, Italy, [2]ASSONAPA, Rome, Italy, [3]Università di Sassari, Sassari, Italy.*

Milk fat yield and composition have a great economic importance in the goat industry being most of milk destined to cheese processing. The identification of genes associated with these traits could provide useful indications for breeding programs. In this work, an association study between 11 SNP polymorphisms at 3 candidate genes (acetyl-coenzyme A carboxylase, ACACA; stearoyl-CoA desaturase, SCD; lipoprotein lipase, LPL) was carried out on 59 Alpine bucks. Data from 13,331 daily records, for milk, fat, and protein yields (kg/d) and fat and protein contents (%) of 2,220 lactations were recorded on 946 goats, daughters of the 59 bucks. Associations were tested with a mixed linear model that included the fixed effects of flock, date of the test, lactation stage, kidding season, age of the goat at kidding, SNP genotype of the sire and the random effect of the goat. Four SNPs were found to be significantly associated to milk production traits (Bonferroni gene-wide adjusted significance $P < 0.01$). The GC substitution at exon 1 of the LPL locus had the highest effect on milk yield (difference of about 0.6 kg/day between the 2 homozygotes CC and GG, respectively, $P < 0.01$). The CT substitution at exon 45 of the ACACA locus affected milk yield and fat percentage. The deletion at the 3′ untranslated region of the SCD locus affected milk, and protein (undeleted homozygotes produced about 16 g/d more than deleted ones) yield and fat percentage. Finally, the CT mutation at exon 5 of the SCD gene was associated to milk yield. These interesting associations should be obviously validated on a larger sample. Moreover, effect on other traits as milk fatty acid composition could be considered in future analyses

Key Words: goat, candidate genes, dairy traits

720 Single nucleotide polymorphisms identified in polygenic traits through the use of the Ovine SNP50 BeadChip. R. R. Cockrum*[1], N. K. Pickering[2], R. M. Anderson[2], D. L. Hyndman[2], M. J. Bixley[2], K. G. Dodds[2], R. H. Stobart[1], J. C. McEwan[2], and K. M. Cammack[1], *[1]University of Wyoming, Laramie, [2]AgResearch Limited, Mosgiel, New Zealand.*

High-density single nucleotide polymorphism (SNP) chips have shown promise in genome wide association studies (GWAS) to target genomic regions that play key roles in traits of economic interest. The objective of this study was to use GWAS to identify SNPs affecting polygenic traits including backfat (BF), loin eye area (LEA), ADG, birth type (BT), and scrotal circumference (SC) in sheep. Phenotypic measurements were collected on rams from 2 separate ram tests (Dual Purpose Ram Test and Blackface Ram Test) at the University of Wyoming Ram Test ($n = 328$) from 2009 to 2011. Blood was collected via the jugular and DNA was isolated and diluted. Single nucleotide polymorphisms in ram DNA were genotyped using the Ovine SNP50 BeadChip on the Illumina Infinium HD BeadChip Assay. Percentage loci scored per animal and locus, Hardy Weinberg deviations, animal information comparison, replicate sample reproducibility, and unusual allelic ratio analyses were conducted through Genome Studio and R for quality control analysis. A GWAS analysis was conducted in R using the GenABEL package where a polygenic model, $Y = \mu + G + e$, where μ is the intercept, G is the polygene, and e is the random residual, was used to identify SNPs. The SNP associated with *RXFP2* was used to confirm the accuracy of the polygenic model resulting in a high association ($P = 9.283^{-04}$) with the horn phenotype. There were 11 and 5 SNPs for BF and ADG, respectively, that reached the genome-wide threshold ($P \leq 9.359^{-04}$). Genes associated with SNPs identified in BF include *EPHBA* and *B* family, *ANK* family, *REL, XDH, RPAIN*, and *FRMPD4*, while only *KLF12* was linked to ADG. Genome-wide threshold was reached ($P \leq 0.092^{-04}$) for BT (i.e., single, twin, or triplet) resulting in 10 SNPs. Genes linked to BT SNPs were *ODZ1, ODZ3, LTBP3*, and *DSCAM*. The top SNPs for SC and LEA did not reach optimum threshold as in BF, ADG, or BT; however, 3 SNPs for SC and 1 SNP for LEA achieved moderate threshold levels ($P \leq 0.0003$). No genes were associated to SNPs for SC, but one gene, *AAK1*, corresponded to the SNP for LEA. Results indicate that SNPs can be identified for polygenic traits using GWAS. However, further research and validation studies will be required before implementation of marker-assisted selection strategies.

Key Words: polygenic, sheep, single nucleotide polymorphism

721 Genetic parameter estimates for birth weight in three Yemeni indigenous sheep breeds. S. Al-Shorepy*[1], M. Al-Karmah[1], and Ab. Albial[1], *[1]United Arab Emirates University, Al Ain, United Arab Emirates, [2]Sana'a University, Sana'a, Yemen, [3]Agricultural Research & Extension Authority, Sana'a, Yemen.*

Genetic parameters for birth weight were estimated for 3 indigenous Yemeni sheep breeds (White Boni, Barri, and Black Boni breeds), using animal model. Data were analyzed by restricted maximum likelihood (REML) using MTDFREML program. Five different animal models were fitted. Model 1 considered the animal as the only random effect. Models 2 and 3 included in addition to the additive direct effect of the animal, the additive maternal and the permanent maternal environmental effects, respectively. Model 4 fitted both the additive maternal and permanent environmental effects. Model 5 was the same as model 4, except that a covariance between the direct and the maternal additive effects. Estimates of additive direct heritability were 0.19, 0.36, and 0.38 for White Boni, Barri, Black Boni lambs, respectively. Judged by log L, introducing either additive maternal effects (model 2) or permanent environmental effects (model 3) resulted in a similar fitting as compared with model 1 in the 3 breeds. Fitting additive maternal and permanent environmental effects (model 4) resulted in a significantly better fit ($P < 0.05$) compared with models 1, 2, and 3 for White Boni lambs only. Estimates of total heritability (h^2t) from model 5 were 0.14, 0.17, and 0.53 for Barri, White Boni and Black Boni lambs, respectively. These results indicate that moderate to high estimates of direct heritability suggest further scope for improvement due to selection for higher birth weight.

Key Words: birth weight, direct and maternal effects, Yemeni indigenous sheep breeds

722 Increased lean growth rate does not extend days to harvest in crossbred lambs. G. C. Márquez*[1], W. Haresign[2], M. H. Davies[3], D. R. Notter[1], R. Roehe[4], L. Bünger[4], G. Simm[4], and R. M. Lewis[1,4], *[1]Virginia Tech, Blacksburg, [2]Aberystwyth University, Aberystwyth, UK, [3]ADAS Rosemaund, Preston Wynne, UK, [4]Scottish Agricultural College, Edinburgh, UK.*

A lean growth selection index (LI) was designed for terminal sire sheep in the UK to increase lamb carcass lean weight while decreasing fat at a constant age end point. The purpose of this study was to investigate if lambs sired by high (leaner) versus low LI rams take longer to reach target harvest condition (fat cover). Data on 6,350 crossbred lambs sired by Charollais, Suffolk and Texel rams were available. From 1999 to 2002, 15 high and 15 low LI sires from each breed were mated to 1,984 crossbred ewes at 3 farms in the UK. Most rams were used for 2 mating seasons, and some were rotated among farms to create genetic links. Lambs were reared on pasture and, from 10 weeks of age, were visually assessed bi-weekly for fat cover until they reached a target condition of 11% subcutaneous fat (estimated) for harvest. The mean days to harvest (DTH) were 180 (SE 1.1) for high LI sires, 176 (SE 1.0) for low LI, 182 (SE 1.2) for Charollais, 182 (SE 1.3) for Suffolk, and 170 (SE 1.3) d for Texel. A semiparametric Cox proportional hazard model was fitted to DTH. The analysis was stratified by lamb rearing type because the hazard for DTH differed for single and twin reared lambs. Fixed effects were sire index, sire breed, dam breed, sex, age of dam, fat class (visual classification of harvest condition), birth year, farm, and birth year-farm interaction. Random effects were sire (considering the relationship matrix among sires) and rearing dam. Likelihood ratio tests indicated that all fixed effects were significant ($P < 0.001$) except sire index ($P = 0.5$) and dam breed ($P = 0.1$). There was no difference in hazard ratio (HR) between lambs sired by high and low index sires, or between lambs sired by Charollais and Suffolk rams ($P = 0.8$). However, Texel-sired lambs had fewer DTH than Suffolk-sired lambs (HR = 1.44, $P < 0.001$). No significant interaction between sire index and breed was found. The HR increased with increasing age of the dam. Heritability of DTH was estimated as 14%. The similar DTH in lambs sired by high as compared with low LI rams is favorable, because it implies that leaner lambs reach acceptable harvest condition without extending their finishing period.

Key Words: crossbred lambs, lean index selection, survival analysis

723 Evaluation of environmental factors affecting the speed of racing camels in the United Arab Emirates.

S. Al-Shorepy,* S. Al Mansouri, and Z. Al Katheeri, *United Arab Emirates University, Al Ain, United Arab Emirates.*

Camel racing is a deep-rooted traditional sport that finds its origins in the desert culture of the Arabian Peninsula, North Africa, and the Middle East. In United Arab Emirates (UAE), camel racing is very popular and has become a part of tradition and culture. Therefore, the aim of the present study was to evaluate environmental factors affecting speed of racing camels in UAE. The data used in this study were obtained from UAE Camel Race Association, from year 2007 to 2011 and the trait evaluated was racing speed (m/s) for total distance and for the last 1000 m. Five hundred ten races with around 40 camels per race of varying distances were evaluated for which the first 10 winners were determined. The full linear model included the effect of year, age, sex, breed, racetrack, and type. In each race, 3 categories were considered for analysis; fastest 10, fastest 3, and the fastest camels. Overall average speed of the races was 10.40 m/s (SD = 0.37; range: 8.3–13.5 m/s), with a coefficient of variation of 3.6% and the effects included in the analytical model formed R^2 of 85.5%. The average speed for the last 1000 m was 10.87 m/s with maximum speed of 16.1 m/s. Speed significantly ($P < 0.05$) decreased with the age in the 3 categories (fastest 10, fastest 3 and the fastest). Females were significantly ($P < 0.05$) superior to males in the 3 categories evaluated. Similarly, purebred (thoroughbred) camels were faster ($P < 0.05$) than the crossbred camels in the tested categories. The sex by breed interaction had no significant effects on race speed in the 3 categories. Understanding the role of environmental factors in racing camels might assist owners, trainers, and others to optimize the performance of camels under their care. Moreover, determining these factors is a fundamental step in developing a selection program to improve the racing speed of racing camels.

Key Words: racing camels, environmental factors, racing speed

724 Influence of genomic predictors on yearling sales price and total career earnings in Thoroughbred racehorses.

C. R. Davis*[1,2], E. W. Hill[1,2], and A. G. Fahey[1], [1]*School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland,* [2]*Equinome Ltd., NovaUCD, Belfield Innovation Park, Belfield, Dublin 4, Ireland.*

Many factors contribute to the yearling sales price (YSP) and total career earnings (TCE) of Thoroughbred horses. The aim of this study was to identify the most influential factors and determine if the addition of genomic information [e.g., genomic predictors (GP) provided by the Equinome Elite Performance Test; www.equinome.com] improves predictions of TCE. Individual, sire, dam, sale and racing information was collected for 256 Thoroughbreds from 4 countries (Ireland, Great Britain, United States, and France). Correlation and regression analyses were performed on the data. TCE had a correlation of 0.23 with GP and 0.15 with YSP. Linear mixed regression analysis identified the main contributing factors to YSP and TCE; the regression model for YSP obtained an $R^2 = 0.49$ without GP information and an $R^2 = 0.53$ with GP included. The main factors influencing sales price ($P < 0.05$) were identified as GP, year of sale, parity of the dam, number of winning offspring of the dam, number of races won per crop of foals of the sire and stud fee paid for the covering. The regression model for TCE (in the form of Earnings per start) obtained an $R^2 = 0.39$ without GP and an $R^2 = 0.57$ when GP information was included. These data indicate that genomic predictors have a considerable influence on the TCE of a horse. The most influential factors influencing TCE ($P < 0.05$) were GP, month of birth within the year of sale, sex, whether or not the dam was a winner, the number of black type offspring of the dam, parity of the dam and races won per crop of foals of the sire. The results showed GP to have a significant ($P < 0.05$) influence in both models and therefore highlights the contribution that genomic information can have in decision making. This study illustrates that genomic information can enable owners, breeders and trainers to better judge the value of a horse by determining its genetic potential for racing and breeding.

Key Words: genomic, performance, regression

725 Genetic variation study in Pakistani buffalo breeds using microsatellite markers.

T. Hussain*[1,2], M. E. Babar[1], M. Imran[1], A. Nadeem[1], A. Ali[1], R. Saif[1], A. Wajid[1], M. De Donato[2,3], S. O. Peters[2], and I. G. Imumorin[2], [1]*Institute of Biochemistry and Biotechnology, University of Veterinary and Animal Sciences, Lahore, Pakistan,* [2]*Dept. Animal Science, Cornell University, Ithaca, NY,* [3]*IIBCA, Universidad de Oriente, Cumana, Venezuela.*

To assess the status of genetic diversity in Pakistani buffalo, 19 microsatellite loci were genotyped to obtain data on 184 DNA samples from all 5 native buffalo breeds (Nili, Ravi, Nili Ravi, Kundhi and Azakheli). All loci showed polymorphism in each breed. The observed number of alleles ranged from 8 (ETH10, ILSTS049, ETH225, CSSM66) to 24 (TGLA227) with a mean value of 13.368 alleles per locus. The effective number of alleles across all loci was as usual lower than the observed values with a mean value of 3.207 alleles per locus. The average observed and expected heterozygosity values across all polymorphic loci in all studied buffalo breeds were estimated to be 0.283 and 0.648

respectively. The overall value for Polymorphic Information Content (PIC) for all markers was 0.56 suggesting their appropriateness for genetic diversity analysis in buffalo. The mean Fis, Fit, and Fst values were 0.511, 0.570 and 0.120 respectively. The 5 buffalo populations were genetically less diverse as indicated by a small mean Fst value. The average gene flow (Nm) indicative of population migration was calculated as 1.817. The Nei's (1972) original measures of genetic distance (Ds) revealed ancient divergence of Nili-Ravi and Azakheli (Ds = 0.3018) and recent divergence of Nili and Ravi (Ds = 0.0468). These estimates of genetic diversity were seen in coincidence with phenotypic differentiation among the studied buffalo breeds. The present study results can facilitate the future researchers interested in further studies in buffalo as well as other livestock breeds of Pakistan.

Key Words: genetic diversity, microsatellite markers, buffalo breeds

726 Analysis of egg production using a random regression model with genomic relationships in layer chickens. A. Wolc*[1,2], J. Arango[3], P. Settar[3], J. E. Fulton[3], N. P. O'Sullivan[3], R. Preisinger[4], D. Habier[2], R. Fernando[2], D. J. Garrick[2], and J. C. M. Dekkers[2], *[1]Poznan University of Life Sciences, Poznan, Poland, [2]Iowa State University, Ames, [3]Hy-Line International, Dallas Center, IA, [4]Lohmann Tierzucht GmbH, Cuxhaven, Germany.*

Random regression models (RRM) can account for the longitudinal nature of egg production which, together with the use of genomic information, are expected to increase accuracy of selection compared with using only mean production and pedigree information. The objective of this study was to estimate variance components for egg production at various ages in a commercial brown egg layer population using genomic relationship information. A random regression reduced animal model with a marker-based relationship matrix (VanRaden, 2008) was used to estimate genomic breeding values of 3,908 genotyped animals from 6 generations. The first 5 generations were used for training, with predictions validated in generation 6. Daily egg production up to 46 weeks in lay was cumulated into 85,462 bi-weekly records for training, of which 17,570 were recorded on genotyped hens and the remaining on their non-genotyped progeny. The model for bi-weekly records included fifth-order Legendre polynomials nested within hatch-week as fixed effects. Random terms were quadratic polynomials for genetic and permanent environmental components, and residual variances that were uncorrelated and heterogeneous. Models with pedigree based or genomic relationships were used. Estimates of residual variation were very similar for both measures of relationship but the model with genomic relationships estimated a higher proportion of genetic variance. Heritability estimates increased with age up to mid production and decreased thereafter, resulting in average heritability of 0.20 or 0.33 for pedigree or genomic relationships. Predictions of total 46-week egg number and of most biweekly periods were more accurate with genomic than pedigree relationships (correlations with progeny performance of 0.26 vs. 0.16). In conclusion, random regression reduced animal models can be utilized in breeding programs using genomic information, resulting in substantial improvement of accuracy of selection for longitudinal traits. Practical implementation depends on computing and genotyping strategies to minimize costs to make such an approach cost effective.

Key Words: egg production, random regression model, GBLUP

Dairy Foods Symposium: Advances in Yogurt Manufacture and Product Functionalities

727 The impact of biopolymers on yogurt gelation and properties. J. A. Lucey,* *University of Wisconsin-Madison, Madison.*

Most yogurts in the US contain multiple stabilizers (polymers) that are added to try to control texture during storage. The nature of the interactions between these biopolymers and the milk proteins is poorly understood in yogurt systems. Often manufacturers add several different types of stabilizers in the hope of achieving the desired textural properties. Polymers can be added as stabilizers (e.g., pectin) or can be naturally produced in situ by certain bacteria in the form of exopolysaccharides (EPS). Most cultures supplied for commercial yogurt manufacture in the US contain an EPS-producer. Much confusion exists concerning the precise physico-chemical mechanism(s) by which EPS influences yogurt texture. Complicating factors include: variation in fermentation conditions (e.g., rate of acidification) also affect gel formation, it is not easy to accurately estimate the concentration of EPS in a yogurt matrix; it is usually unknown when in the fermentation process that the EPS was produced (before/during/after gelation), and the nature of the EPS (molar mass, degree of branching, etc) may also influence its interaction with the protein matrix. Better control of the interactions that occur between proteins and polymers during the fermentation process would help manufacturers to tailor-make a product with the desired physical and sensory characteristics. Examples of how different types of biopolymers (e.g., pectins, dextran and EPS) influence yogurt texture will be discussed.

Key Words: yogurt, texture, biopolymers

728 Advancements in yoghurt process design and unit operations. L.-E. Nilsson,* *Tetra Pak, Lund, Sweden.*

Yogurt is one of the fastest growing dairy products in many countries and has been so for many years. Yogurt is produced in different forms such as stirred, set, drink, concentrated, and frozen. Within each type there are many variants, including fat-free, low fat, high-fat, probiotic, prebiotic, lactose-free, mineral enriched, fruit added, fiber-added, etc. The quality of yogurt is influenced by several factors in the process line, most important of which are milk standardisation, deaeration, homogenization, heat treatment as well as culture type and overall plant design. Yogurt milk for stirred and set yogurt is most often increased in dry matter to obtain high viscosity and stability. This can be achieved by powder addition, evaporation or membrane filtration, of which each system has advantages and limitations. The most common fortification method today is powder addition. The basis for manufacture of high quality yogurt is predicated already in the milk treatment. Culture type has a large influence on the final yogurt taste and consistency, but also on the design of the yogurt line. Depending on culture activity in the range of pH 4.3, the design of incubation tanks, pipes, pumps, and cooler etc. are optimized. Some cultures are used which are specially adapted to provide improved functionality to the yogurt. Yogurt coagulum is sensitive to mechanical treatment and due to this fact, plant design is of utmost importance. Calculations of pumps, pipe dimensions, cooler configurations, and process layout must be carefully considered to maintain the natural viscosity built up during fermentation. Concentrated yogurts have recently been increasing in popularity. Traditionally the industry has used specialized separators to remove whey from the yogurt coagulum. Membrane filtration is another technique used for this process. This technique can retain more protein into the finished yogurt and achieve higher yields. Shelf life of yogurt, which is judged by microbiology, appearance, texture and flavor, depends on several factors, from milk quality to filling machine and packaging. There are different ways to extend the shelf life dependent on what limits the shelf life today.

Key Words: yogurt, process design

729 Impact of total solids, protein content, and protein source on the functionality of nonfat yogurt. L. E. Metzger* and K. N. Shah, *Midwest Dairy Foods Research center, South Dakota State University, Brookings.*

In the US, NDM is a commonly used ingredient in yogurt formulations. However, in International markets, skim milk powder (SMP) milk protein concentrate (MPC), and de-proteinized whey are also used in yogurt formulations. The total solids, protein content and source of the protein in a yogurt formulation can affect the functionality of the yogurt. Additionally, physicochemical changes during storage of powders can result in variation of the functional properties of powders as well as of the product in which they are used. The objective of this study was to evaluate the effects of storage of various milk powders (SMP, NFDM, MPC 40, MPC 70) on their functional properties and on the functionality of nonfat yogurt formulations at 3 different protein and total solids levels. Three different lots of SMP, NDM, MPC 40 and MPC 70 were collected from US manufacturers and each lot was divided into 3 portions. A portion was analyzed after 3, 9, and 15 mo of storage at 25°C. At each storage time, yogurt formulations with protein (%)/TS (%) ratios (4/12.5, 4.5/13.5 and 5/15.5) were produced from each lot of SMP, NDM, MPC 40, and MPC 70. The data was analyzed by split plot design using PROC Mixed in SAS. Storage time had a significant effect ($P < 0.05$) on solubility and foaming properties where solubility of MPC70 and foam overrun of SMP, MPC40, and MPC70 decreased significantly ($P < 0.05$) with an increase in storage time of the powders. Emulsification properties of MPC70 were significantly higher ($P < 0.05$) than SMP, NDM, and MPC40. Storage time did not have significant effect on the yogurts from NDM, MPC40, and MPC70 at all protein/TS ratio. Viscosity of both MPC40 and MPC70 yogurts was significantly lower ($P < 0.05$) than SMP and NDM yogurts at each protein/TS ratio. The storage of milk powders has an effect on their functional properties but has a minimal influence on the textural properties of nonfat yogurt, whereas the use of MPC had a substantial effect on the functionality of nonfat yogurt.

Key Words: nonfat yogurt, viscosity

730 Advancements in starter technology and functional benefits in yogurt. DA Romero*[1], C. Fremaux[2], P. Fourcassie[2], S. Huppert[3], and P. Steele[1], [1]*DuPont/Danisco, Madison, WI,* [2]*DuPont/Danisco, Dangé-St.Romain, France,* [3]*DuPont/Danisco, Paris, France.*

Yogurt represents one of the oldest forms of biotechnology, employing lactic acid bacteria to ferment milk thus preserving it as a flavorful and healthy food. From the chance contamination of desirable bacteria the industry has progressed to the selection and development of highly specialized strains. Research that began with identifying and characterizing the responsible microbes has progressed to correlating starter metabolism in milk with technological attributes in yogurt. Today we have the complete genomes for traditional starters *Streptococcus thermophilus* and *Lactobacillus bulgaricus* and a host of probiotics cultures with which to map function to specific genes and pathways. Notwithstanding this revolution of genomics and bioinformatics, research has been grounded in a thorough understanding of microbial bioconversions to deliver rapid and reliable acid, flavor and texture development. In parallel to our increased understanding of starter functionality, there are ongoing and ever sophisticated studies focusing on the role of probiotics; in particular strains belonging to *Lactobacillus* and *Bifidobacterium*. As an excellent vehicle to deliver nutrition and health in food, the incorporation of live microbes to yogurt to provide additional nutrition and health attributes has helped drive the market forward in this age of health conscious consumers. Coupled with current studies of the human gut microflora, the role of probiotics in general wellbeing is transforming to more increasing rigorous scientific investigation in expectation of escalating regulatory expectations. We will present selected examples of strain (e.g., bacteriophage resistance, natural texture and flavor, strain safety) and probiotic (e.g., digestive health, gut transit time, immune health) development to highlight recent advancements and the current state of the yogurt culture development. Further, we will discuss how these technological developments positively affect the demands of the yogurt manufacturer and consuming public.

Key Words: yogurt, starter, probiotic

731 Fine tuning the structure of yogurt by changing the milk properties.

M. Corredig,* *University of Guelph, Guelph, Ontario, Canada.*

During fermentation using lactic acid bacteria, as the pH decreases, colloidal calcium phosphate is released from the casein micelles, and the overall charge of the protein is reduced, ultimately causing colloidal destabilization of the protein particles and the formation of a protein network. Although the physico-chemical changes occurring to casein micelles during acidification of skim milk are well understood, the interactions occurring at the molecular level in a yogurt mix are less understood. Such mixes may vary in protein and fat concentrations, contain various stabilizers and different texturizing cultures. This presentation will review the interactions between the important building blocks of structure in acid gels. To better understand these interactions will allow for fine-tuning of the structure. The aggregation of whey protein complexes with caseins and the interactions between caseins and added stabilizers are known to play a major role in texture. The presence polysaccharide produced by lactic acid bacteria also needs to be considered. The interactions between these polysaccharides and milk proteins will vary in the type and extent with time, because of the changes in concentration and environmental conditions, namely pH and ionic strength. Fat globules are also an important building block of the structure and texture of yogurt, and their mode of incorporation in the gel will be modulated by changes to their size and interface. Another important aspect to consider is the pre-concentration of the milk. The processing history of the milk during membrane filtration will affect the gelation behavior of the casein micelles and the interactions between milk proteins. This presentation will provide an overall view of the factors involved in the formation of structure, and identify opportunities to improve or design new processes and product formulations.

Key Words: yogurt, structure, acid gelation

Extension Education Symposium: Does Extension Have a Future in Today's Agriculture?

732 National Science Foundation outreach: A non-traditional model. S. Ellis,* *Clemson University, Clemson, SC.*

Agricultural issues emphasized by extension personnel are obviously well-aligned with the mission of the US Department of Agriculture (USDA). But there are also substantial areas of overlap between missions of the National Science Foundation (NSF) and extension groups. Both groups seek to expand the pool of scientifically literate residents that can apply scientific advances to improve the health, prosperity, welfare, and security of the US. Both groups also support adult learners with interest in science, technology, engineering and mathematics (STEM) topics. So, while the NSF does not have a singular focus on agricultural issues, there are opportunities for Extension personnel to extend, improve, and adapt their practices with NSF support. As an example, a typical extension presentation might be directed toward a crowd of adult learners with common STEM interests (e.g., entomology or economics) but with varied educational backgrounds. Questions related to the effectiveness of curricular design, pedagogy or andragogy approaches, and outcomes assessment that are the mainstay of education researchers are just as valid and important for Extension personnel. The opportunity to involve Extension program participants as study subjects could improve our understanding of adult learning and lead to improvements in Extension service offerings. Another example of the potential to align Extension activities with NSF priority areas is in the Broader Impacts domain. All NSF proposals are rated for 2 merit criteria: intellectual merit and broader impacts. The broader impacts of a NSF research project frequently include public outreach and preparation of educational materials. Extension offerings that include similar activities are already exceptionally well-aligned with the NSF goals for broader impacts. Having access to producers, commodity groups, youth groups, and other interested consumers may thus provide a distinct advantage to Extension personnel who lead or collaborate on NSF research projects in either the physical or social science domains. The challenge is to recognize complementary or synergistic funding opportunities for which Extension personnel and their resources are at a competitive advantage.

Key Words: adult education, broader impacts, STEM learning

Graduate Student Symposium: From Hypothesis to Manuscript: How to Conduct Valuable and Efficient Research

733 Developing the research question, hypothesis, design, and protocol. D. E. Bauman*[1] and R. J. Collier[2], [1]*Cornell University, Ithaca, NY,* [2]*University of Arizona, Tucson.*

The first step in developing a research question is to undertake a thorough examination of the background literature. Review articles are often a good start to gain context, but this review should include specific investigations representing current and historical research. The end result is the investigator is able to identify current issues in this area. Nobel laureate physiologist Albert Szent-Györgyi described this as "seeing what everybody has seen and thinking what nobody has thought." The next step is to identify a researchable question and develop a hypothesis that will provide clarity and structure to the research question as well as a tentative explanation of the research problem and a potential outcome. Identifying a researchable question is one of the most challenging aspects of science. Nobel Prize-winning biologist Peter Medawar referred to science as "the art of the solvable," identifying which questions are solvable through scientific investigations, and then developing hypotheses and designs to address them. The research design needs to be structured to be quantifiable, verifiable, replicable, and defensible. The protocol is a logical outcome of the research design and should include methods for all of the procedures to be utilized. Methodology is a critical component of science; results will be judged on quality of the data, but also on the validity and accuracy of the methods used to derive the data. Likewise, variables being measured need to be thoroughly evaluated to ensure they are appropriate and essential to allow a critical evaluation of the hypothesis. The protocol should also include development of the data collection forms to be used for data entry. Presentations by others will discuss additional critical dimensions including statistical considerations, data collection and publication, but we emphasize that the principle investigator is responsible for the conduct of the study. This includes laboratory determinations and data analyses, summarization and interpretation of the results, and finally publication of the investigation in a peer-reviewed journal. Throughout the presentation, authors will draw on their experience to provide insight and examples.

Key Words: research, scientific method, review

734 Data collection and integrity. G. Hartnell,* *Monsanto Company, St. Louis.*

Accurate data collection is the foundation on which the integrity of research results is based. Procedures should be in place that results in the detection and minimization of errors (systematic and random) and ensures accuracy so results can be repeated with a high level of certainty by others. The protocol should contain sufficient detail so others can accurately repeat the study. Standard operating procedures should be in place to address the question "How do I know?" in regards to data and data collection. For example, how do I know the scale or balance is accurate? How do I know the corn used in feeding the animals was not contaminated with mycotoxins that could influence the outcome of the study? How do I know the animals were deemed healthy before the start of the study? How do I know the diets were mixed properly? How do I know the personnel were properly trained to collect and measure the information on the variables of interest? Good laboratory practice, quality assurance, and quality control are approaches to be considered. Researchers must be vigilant in preventing data integrity issues when selecting, collecting, recording, analyzing, handling, storing, reporting and publishing data. Data integrity must be preserved to ensure the scientific validity of study results and conclusions that in the end reflect on the integrity of the researcher.

Key Words: data collection, data integrity, GLP

735 I'm an animal scientist, why do I need statistics? D. K. Aaron,* *University of Kentucky, Lexington.*

The answer to the question posed in the title of this presentation should be obvious: Scientists conduct research and research is dependent upon statistics. Statistics plays an integral role in experimentation, starting with planning, continuing through execution, data collection and analysis, and ending with interpretation and presentation of results. This is the reason all graduate programs in animal (dairy) sciences require students to take one or more formal courses in statistics. The expectation is that understanding statistical theory and its application to experimental design and analysis makes better researchers. In other words, future researchers will know proper design, good execution strategies and correct data analysis procedures. Is this expectation being met? Are we training better scientists? Yes and no. On the positive side, completion of formal statistics courses results in graduate students who are generally adept in the computational aspects of experimentation; that is, they can "run" SAS (SAS Inst. Inc., Cary, NC). Give them a data set and the light comes on. On the negative side, graduate students often exit formal statistics courses deficient in the non-computational components (e.g., design, implementation, measurement, interpretation) of experimentation. Ask them to design experiments or interpret research results and the light flickers or doesn't come on at all. Whose fault is this? Whose responsibility is it to ensure that future researchers are proficient in both computational and non-computational aspects of experimentation? Is more formal statistical training the answer? Questions such as these will be addressed in this presentation. The importance of statistics will be discussed in a serious, but sometimes light-hearted, way. The result will be a greater appreciation and understanding of the role statistics plays throughout the entire process of research.

Key Words: science, statistics, research

736 It is not a scientific contribution until it is published: Tips from a journal editor. S. A. Zinn,* *University of Connecticut, Storrs.*

Graduate students meticulously plan and implement experiments. Data are generated, carefully analyzed, thoroughly discussed and presented at lab meetings and regional, national and international scientific meetings in a variety of formats. Students spend endless hours writing theses and dissertations to earn, and deservedly so, their advanced degrees in their chosen discipline. But without peer-reviewed publication of their work, a graduate student has little to show for their efforts, especially if they are trying to compete with their peers to be successful in a diminishing market of tenure-track faculty positions and laboratory-based industry positions. The focus of this talk will be on preparation of manuscripts from submission to acceptance in the *Journal of Animal Science*. Differences between thesis and manuscript writing will be covered and details regarding the submission and peer-revision process will be discussed.

Key Words: publication, peer-review, graduate students

Growth and Development Symposium: Participation of Adult Tissue-Restricted Stem Cells in Livestock Growth and Development

737 Regulation of skeletal muscle satellite cell chemotaxis. R. E. Allen* and X. Liu, *University of Arizona, Tucson.*

The objective of this study was to determine the role of the stromal derived factor 1 and its receptor CXCR4 in chemotaxis of skeletal muscle satellite cells. Skeletal muscle satellite cells in postnatal muscle serve as a pool of muscle precursor cells for muscle growth and muscle repair. Over the past 3 decades, a great deal has been learned about the regulation of satellite cell activation, proliferation and differentiation into muscle fibers; these events are associated with muscle fiber growth and hypertrophy. Repair of damaged muscle, however, requires an additional biological response, migration of satellite cells to the site of fiber damage. The response has not been well characterized. Recent experiments have identified the chemokine receptor CXCR4 and its ligand, stromal-derived factor 1 (SDF-1), as potential regulators of satellite cell chemotaxis. In experiments with rat muscle, CXCR4 was upregulated when satellite cells were activated from quiescence and entered the cell cycle. Furthermore, SDF-1 was not expressed in uninjured muscle, but it was found at the site of muscle injury. In vitro experiments demonstrated satellite cell chemotaxis in response to SDF-1. The ability of satellite cells to migrate toward SDF-1 in living muscle was demonstrated in experiments where isolated satellite cells were injected into the proximal end of rat tibialis anterior muscle, and SDF-1 was deposited in the distal end of the muscle in a collagen gel. In these experiments satellite cells were labeled with Quantum Dots in culture, before injection into muscle. Within 3 d labeled cells were found at the injury site. Treatment of rats with the CXCR4 inhibitor, AMD3100, inhibited cell migration to the SDF-1 injection site, and AMD3100 inhibited migration of injected cells to sites of muscle injury. Skeletal muscle sustains minor and even major injury throughout life, and normal muscle function and subsequent meat quality depend on the ability of satellite cells seek out sites of injury and repair the damage. Results from these and additional experiments suggest that CXCR4 and SDF-1 play a role in this process.

Key Words: muscle, satellite cell, chemotaxis

738 Potentials of male germline stem cells to influence the efficiency of beef cattle production. J. M. Oatley,* *College of Veterinary Medicine, Washington State University, Pullman.*

Genetic gain is the increase in performance characteristics from generation to generation and in cattle populations is primarily made through the male germline. Sperm are the vehicle by which male genetic contributions are passed to the next generation and expanded use of these cells from specific sires has a major impact on production characteristics of cattle populations. Artificial insemination technology has been widely used as a reproductive tool in dairy cattle production to exploit this concept; however, utilization in beef cattle production is limited due to intensive management required for effective implementation which is not conducive with current strategies for managing most the world's beef cattle populations. Thus, there is need for alternative reproductive tools that expand availability of sperm from specific sires. The foundation for spermatogenesis is provided by the actions of testicular germline stem cells which possess the capacity for unlimited self-renewal and generation of committed progenitor cells that terminally differentiate into sperm. Research with rodents has shown that these cells can be isolated from testes of a donor male and transplanted into testes of recipient males in which donor-derived spermatogenesis occurs and offspring with donor haplotype produced after natural breeding. Adapting this methodology for cattle could provide an efficient means to expand the use of germlines from specific sires without the requirement for intensive management. Because stem cells are rare, a period of in vitro expansion following isolation from donor testes is required to provide an abundance of cells for efficacious engraftment following transplant. In recent studies, we have developed a multiparameter selection approach for isolating a culture-viable cell fraction from bovine testes that is enriched for germline stem cells. Moreover, we have devised a method for long-term maintenance of these cells in vitro that is xeno-free, thereby meeting a key requirement for practical application. These advances provide crucial building blocks for developing germline stem cell transplantation methodology into a utilizable reproductive tool for modern beef cattle production that will influence genetic gain.

Key Words: germline stem cells, cattle, reproduction

739 Tenocytic potential of equine umbilical cord derived stem cells. S. A. Reed*[1] and S. E. Johnson[2], [1]*University of Connecticut, Storrs,* [2]*University of Florida, Gainesville.*

Mesenchymal stem cells offer promise as therapeutic aids in the repair of tendon, ligament, cartilage, and bone damage in the sport horse. Umbilical cord blood (UCB) contains a population of putative stem cells that may be harnessed to aid in the repair of these injuries. Equine UCB derived stem cells express Oct4, Nanog, and Sox2 in a manner similar to embryonic stem cells and can differentiate into a variety of less naïve cell types including those with osteogenic, chondrogenic, hepatogenic and myogenic properties. The objective of this work was to determine if equine UCB derived stem cells (eUCB-MSC) are capable of differentiation into tenocyte-like cells. Equine UCB stem cells ($n = 3$) were cultured on gelatin or matrigel coated dishes or gelatin coated beads and treated with 10 ng/mL fibroblast growth factor (FGF)-2, - 4, or −5. Expression of *scleraxis* (*scx*), a transcription factor required for tendon development, and *Tenascin-C* (*TnC*), a protein abundant in developing tendons, was measured by real-time PCR (reported as mean ± SEM). Growth kinetics were measured following FGF supplementation. Equine adipose derived stem cells (AdMSC) were used to compare eUCB-MSC to a more adult stem cell population. Both eUCB-MSC and AdMSC express *scx* and *TnC*. When cultured on varying matrices, eUCB-MSC and AdMSC adapted different morphologies. Further, culture in matrigel increased *scx* expression in both cell populations (eUCB-MSC: 6.73 ± 2.1 fold; AdMSC: 39.5 ± 26.6 fold, $P < 0.05$) and increased *TnC* 12.3 ± 1.85 fold in AdMSC ($P < 0.05$). In AdMSC culture in matrigel, supplementation with FGF2 or FGF5 increased *TnC* expression 1.84 ± 0.22 fold and 2.66 ± 0.48 fold, respectively. Fibroblast growth factors affected growth kinetics in AdMSC and eUCB-MSC. In conclusion, both eUCB-MSC and AdMSC express markers of early tenocytes. *Scx* expression is increased when cultured in matrigel, a 3 dimensional matrix. FGF supplementation further increased *TnC* expression in AdMSC. These results demonstrate a potential use for AdMSC and/or eUCB-MSC in future therapies to improve tendon healing.

Key Words: umbilical cord blood, horse, tendon

740 Development, characterization and use of a porcine epiblast-derived liver stem cell line: ARS-PICM-19. T. J. Caperna,* W. M. Garrett, and N. C. Talbot, *USDA/ARS, Beltsville, MD.*

Totipotent embryonic stem cell lines have not been established from ungulates, however, we have developed several somatic cell lines from the in vitro culture of pig epiblast cells. One such cell line, PICM-19, was isolated via colony-cloning and was found to spontaneously differentiate into hepatic parenchymal epithelial cell types, viz., hepatocytes (H) and bile duct cells (BD). Hepatocytes form as monolayers and BD as 3D bile ductules. PICM-19 cells are sensitive to variations in extracellular pH in that low pH induces H differentiation and high pH elicits BD differentiation. Transmission electron microscopy revealed that BD were composed of radially arranged, monociliated cells with their cilia projecting into the ductuleâ€s lumen, whereas H were arranged in monolayers with lateral canalicular structures containing numerous microvilli and connected by tight junctions and desmosomes. Extensive Golgi and rough endoplasmic reticulum networks were also present in H and BD, indicative of active protein synthesis. Analysis of conditioned media by 2D-electrophoresis and mass spectrometry indicated a broad spectrum of serum protein secretion by H. The PICM-19 cell line maintains a range of inducible cytochrome P450 activities, and, most notably, is the only non-transformed cell line that synthesizes urea in response to ammonia challenge. In collaboration with NASA, PICM-19 cells were placed on orbit (Shuttle Mission STS 126) where it was determined that short-term (14 d) microgravity exposure did not affect hepatic cellular differentiation. A PICM-19 subclone which only differentiates into H was isolated. It was evaluated as a platform for toxicity testing and has been utilized in a commercial artificial liver rescue device bioreactor (Hepalife Biosystems). Methods are currently under development to improve the growth of PICM-19 cells without feeder cells. Feeder-cell independent growth will facilitate the study of mesenchymal-parenchymal interactions that influence the divergent differentiation into H or BD, will enhance our ability to genetically modify the cells, and will provide a better model system to investigate porcine hepatic metabolism.

Key Words: liver stem cells, hepatocyte, bile duct

741 Mammary stem cells: Novel markers and novel approaches to increase lactation efficiency. A. V. Capuco*[1], R. K. Choudhary[1,2], C. M. Evock-Clover[1], and K. M. Daniels[3], [1]*Bovine Functional Genomics Lab, USDA-ARS, Beltsville, MD,* [2]*Department of Animal and Food Sciences, University of Kentucky, Lexington,* [3]*Department of Animal Sciences, The Ohio State University, Wooster.*

Mammary stem cells (MaSC) provide for net growth, renewal and turnover of mammary epithelial cells, and are therefore potential targets for strategies to increase production efficiency. Appropriate regulation of MaSC can potentially benefit milk yield, persistency, dry period management and tissue repair. Accordingly, we and others have attempted to characterize and alter the function of bovine MaSC. Approaches used have included flow cytometry and in vitro cultivation to enrich for and characterize these cells. Recent data indicate that MaSC retain labeled DNA for extended periods. Relying on this long-term retention of bromodeoxyuridine-labeled DNA, we identified putative bovine MaSC and hypothesized that the label retaining epithelial cells (LREC) present in the basal layer of the mammary epithelium represent MaSC. As in other species, these cells were present in low abundance within mammary epithelium (<1%) and were estrogen receptor-negative. We recently excised LREC and control cells from the mammary epithelium, using laser microdissection, and characterized their transcriptome by microarray analysis. Molecular profiles were consistent with the concept that LREC represent populations of MaSC and progenitor cells, that basal LREC are enriched for MaSC, and that LREC in suprabasal locations are enriched for committed progenitors. Analysis also provided novel candidate biomarkers for MaSC/progenitors. Potential biomarkers currently under investigation include NR5A2, NUP153, FNDC3B and HNF4A. Cells bearing these biomarkers are present in abundance and localization consistent with their utility as MaSC markers. We have attempted to modulate MaSC number in vivo and in vitro. Infusing a solution of xanthosine through the teat canal and into the mammary ductal network of prepubertal heifers and treatment of bovine mammary epithelial cells in vitro, increased the number of putative MaSC/progenitors. This was evidenced in vivo by an increase in the percentage of LREC and increased telomerase activity and in vitro by increased FNDC3B labeling and telomerase activity. The exciting possibility that stem cell expansion can influence milk production is under investigation.

Key Words: stem cells, progenitor cells, mammary

Lactation Biology Symposium: The Long-Term Impact of Epigenetics and Maternal Influence on the Neonate Through Milk-Borne Factors and Nutrient Status

742 Role of colostrum and colostrum components on glucose metabolism in neonatal calves. H. M. Hammon,* *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Mammalians undergo dramatic organ-specific as well as metabolic and endocrine changes after birth. Nutrient intake shifts from continuous glucose supply via the placenta to discontinuous colostrum and milk intake with lactose and fat as main energy sources. The development of the neonatal calf is influenced by colostrum intake when compared with colostrum replacement diets. Besides establishing a passive immunity, colostrum promotes maturation and function of the neonatal gastrointestinal tract (GIT) in calves. Nutrients and non-nutritive factors, such as hormones and growth factors, which are present in high amounts in colostrum of first milking, affect intestinal growth and function and enhance the absorptive capacity of the GIT. In addition, colostrum feeding improves the glucose status in neonatal calves. Glucose absorption increases and glycogen concentrations in liver rise much higher when colostrum instead of a milk-based colostrum replacer is fed. In contrast, first-pass glucose uptake in the splanchnic tissue is greater in calves fed colostrum replacer without growth promoting substances. The improved energy status in neonatal calves after enhanced colostrum intake leads to accelerated stimulation of anabolic processes indicated by an enhanced maturation of the postnatal somatotropic axis and increased production of endogenous IGF-I in neonatal calves. Besides the somatotropic axis, other endocrine changes such as higher postprandial insulin release, a reduced glucagon to insulin ratio and cortisol level in blood plasma, and an increased plasma leptin concentration after colostrum instead of replacer feeding support the concept of stimulation of anabolic processes. These endocrine changes may favor postnatal organ development and may improve growth and lactation performance in cattle in later life. Therefore, intensive colostrum and subsequent milk feeding by increasing amounts and frequency of colostrum and milk intake may have long-lasting effects on postnatal performances and might be a key factor of successful cattle breeding.

Key Words: neonatal calf, colostrum feeding, glucose metabolism

743 Nutrition of the dam affects mammary gland development and milk production in the offspring. P. Kenyon,* A. Paten, E. Garnett, H. Blair, S. Pain, C. Jenkinson, S. Peterson, and N. Martin, *Massey University, Palmerston North, New Zealand.*

In animal systems, the dam's milk production affects the growth and survival of its offspring. Further in agricultural systems any mechanism that can enhance milk production has the potential to increase financial returns. Our group has previously shown that maternal nutrition during pregnancy in sheep alters fetal mammary gland development and the volume and composition of milk produced by the offspring at their first lactation (fetal programming). Second generation offspring showed no difference in milk yield or composition. In 2009, 382 twin-bearing ewes (G0) were offered 1 of 3 nutritional treatments between d 21 and 50 of pregnancy: sub-maintenance (Sb), maintenance (M) or adlib (A) access to pasture. They were subsequently offered either M or A until d 139 of pregnancy. A sub-set of ewes were euthanized in late pregnancy. During 2010, puberty in ewe offspring (G1) was monitored and in 2011 G1 ewes were mated and a sub-set milked. At d 51 of pregnancy H G0 ewes were heavier than M which in turn were heavier than Sb ewes ($P < 0.05$, 69.5 ± 0.53 vs 65.1 ± 0.53 vs 62.2 ± 0.56kg). At P137, ewes offered H during d 51 to 139 of pregnancy were heavier than those offered M (88.2 ± 0.53 vs 82.6 ± 0.53). Fetal mammary gland weight was affected ($P < 0.05$) by ewe nutrition during d 21 to 50 of pregnancy, but not by nutrition in late pregnancy. Ewe nutrition during d 21 to 50 of pregnancy had no effect ($P > 0.05$) on G1 lamb birth weight, but during late pregnancy it did ($P < 0.05$). Ewe nutrition in either early or late pregnancy had no effect ($P > 0.05$) on puberty attainment in G1 ewes. Initial data analysis indicates G1 ewes born to G0 ewes fed M during d 21 to 50 of pregnancy produced a greater ($P < 0.05$) amount of milk over a 7-week, once-a-week milking period, compared with G1 ewes born to either G0 Sb or G0 H ewes. G0 nutrition in late pregnancy had no effect on G1 milk production. These preliminary results suggest that it is in the early pregnancy period that the fetal mammary gland is susceptible to the affects of dam nutrition. Molecular and physiological mechanisms for these effects are being examined.

Key Words: fetal programming, maternal nutrition, milk supply

744 Lactational programming of infant behavioral and somatic development. K. Hinde*[1,2], A. Foster[2], and J. P. Capitanio[2,3], [1]*Human Evolutionary Biology, Harvard University, Cambridge, MA,* [2]*Brain, Mind, and Behavior Unit, California National Primate Research Center, University of California-Davis,* [3]*Department of Psychology, University of California-Davis, Davis.*

Glucocorticoids in mother's milk have been associated with infant behavioral phenotype in rodents, macaques, and humans presumably by shaping the HPA axis. However, infant behavioral activity budgets are necessarily constrained by available energy. Cortisol, usually thought of only in the context of stress physiology, is actually a metabolic hormone that ties together both of these perspectives. Energy utilization, and the metabolic function of cortisol, becomes particularly critical during challenging conditions e.g., nutritional stress, predator encounters, and social conflicts- the same environmental conditions that have been implicated in the development of behavioral phenotype. We hypothesize that behavioral phenotype is organized in concert with the metabolism by energetic conditions during early development. Here we present data from rhesus macaque mother-infant dyads at the California National Primate Research Center, expanding upon previous findings that milk energy is correlated with milk cortisol and predicts infant behavioral phenotype. Changes in milk cortisol across lactation precipitate changes in infant growth velocity after controlling for maternal and infant covariates and predict infant temperament. In adulthood the HPA axis, metabolism, and behavior do not exist apart from one another. We present a synthesis of emerging evidence that suggests that the organization of these interconnected systems is likely shaped, in part, by mother's milk during ontogeny. Research supported by NSF BCS-0921978 and BCS-0525025 to KH and NIH RR019970 to JPC and NIH RR000169 to the CNPRC.

745 Lactocrine signaling and postnatal developmental programming. F. F. Bartol*[1], D. J. Miller[1], A. A. Wiley[1], J. C. Chen[2], A-L. Frankshun[2], M. E. Camp[2], K. M. Ferio[2], and C. A. Bagnell[2], *[1]Auburn University, Auburn, AL, [2]Rutgers, The State University of New Jersey, New Brunswick, NJ.*

Lactocrine signaling is defined as transmission of bioactive factors from mother to offspring as a consequence of nursing. Transmission of lactocrine-active signaling molecules is likely to be an evolutionarily conserved process through which bioactive factors of maternal origin necessary for support of neonatal development are delivered postnatally. Dependence on maternal resources for development in eutherian mammals extends into neonatal life for at least that period of time when nutrition is obtained solely from first milk (colostrum). Data for the pig (*Sus scrofa domesticus*) provide compelling evidence of lactocrine-mediated effects on development of female reproductive tract and other somatic tissues. Porcine uterine gland development is an estrogen receptor (ESR1)-dependent process that begins within 2 d of birth (postnatal d 0 = PND 0). A lactocrine-driven, ESR1-mediated process was proposed as a component of the regulatory mechanism governing onset of nascent uterine gland development and endometrial maturation in the neonatal pig. Compared with nursed controls, gilts maintained in a lactocrine-null state for 2 d from birth by being fed milk-replacer displayed altered patterns of endometrial gene expression and severely retarded uterine gland development by PND 14. For example, in the absence of lactocrine signaling, inhibition of endometrial ESR1 and vascular endothelial growth factor (VEGF) expression observed on PND 2 persisted to PND 14, even after gilts were returned to nursing on PND 2. Similar effects were observed in cervical and cardiac tissues and in male reproductive tissues at PND 2. Lactocrine induction of neonatal uterine and cervical ESR1 and VEGF expression is related directly to duration of nursing from birth and inversely to age at first colostrum consumption. Single feedings of porcine, equine or bovine colostrum (30mL/kg BW) to newborn gilts induced uterine and cervical ESR1 and VEGF expression. These effects were most pronounced with porcine colostrum. Collectively, data support a role for lactocrine signaling in regulation of critical neonatal developmental events. Maternal lactocrine programming of postnatal development may be essential to ensure healthy developmental outcomes.

Key Words: development, neonate, lactocrine programming

746 The effect of nutrient intake from milk or milk replacer of pre-weaned dairy calves on lactation milk yield as adults. F. Soberon* and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

Pre-weaning nutrition and management of dairy calves has generally focused on rumen development, starter intake and disease management. Recent data have shown that pre-weaning nutrition can have profound effects on development that enhance lifetime productivity. Using a combination of milk yield data from a test day model and a mixed model analyses incorporating pre-weaning nutrient intakes and growth rates of more than 1,800 calves on 2 dairy farms in NY, the relationship among growth and milk yield were evaluated. The relationship between pre-weaning average daily gain (ADG) and milk yield was positive and resulted in 850 and 1,113 kg more milk ($P < 0.01$) during first lactation for every kg of ADG before weaning for each farm, respectively. Further, pre-weaning ADG explained 22% of the variation in first lactation milk yield. In addition, for every megacalorie of intake above maintenance, calves yielded 235 kg more milk during first lactation. In addition, at least 11 studies have been reported describing milk yield of calves that had been fed various levels of pre-weaning nutrients, from both milk and milk replacer, which evaluated the effect of pre-weaning ADG and long-term productivity. A mixed model analysis of these studies was conducted, where study was considered a random effect and the analysis considered the number of animals per treatment in each study. Two models were utilized; the first model considered only treatment, high or low intake levels, and that analysis resulted in a prediction of 506.5 ± 99.1 kg ($P < 0.01$) first lactation milk yield in calves consuming higher levels of milk or milk replacer during the pre-weaning period. In a model that included pre-weaning ADG as a continuous variable with study as a random effect and weighted each study-treatment combination by the number of animals, the resulting equation was: $Y = 8{,}974$ kg + 1,404 ADG kg ($P < 0.001$) indicating that for every kg of ADG, heifers produced 1,404 kg more milk in the first lactation. This data reinforces the observation that early life nutrition of dairy calves positively impacts long-term productivity.

Key Words: pre-weaning nutrition, milk yield, dairy calves

Meat Science and Muscle Biology

747 Impact of stunning and carcass chilling on pork quality and post-mortem proteolysis. G. Petca and G. Bee,* *Agroscope Liebefeld Posieux, Research Station ALP, Posieux, Switzerland.*

The aim of the study was to evaluate the effects of stunning procedures (electrical (ES) vs. CO_2 (CS) stunning) and carcass chilling regimens (conventional [CC; 4°C for 23.5 h] vs. rapid chilling [RC; −30°C for 2.5 h; 4°C for 21 h]) on pork quality traits and post-mortem (pm) proteolysis in the LM. Twenty Swiss Large White × Piétrain crosses were randomly assigned to either ES or CS. Carcasses were then scalded (7 min; 65°C), eviscerated and split. At 45 min pm, the left and right carcasses were subjected to CC and RC, respectively. Compared with ES, the pH of the LM (10th rip) was greater ($P < 0.01$) at 45 min (6.5 vs. 6.0), 3 h (6.3 vs. 5.6) and 24 h (5.5 vs. 5.4) in CS. Stunning procedure affected muscle temperature being lower in CS at 45 min (38.3 vs. 38.8°C) but greater at 3 (18.8 vs. 16.2°C) and 24 h (1.8 vs. 1.5°C) pm. Regardless of the stunning procedure, pH of the LM was slightly greater ($P \leq 0.03$) in RC than CC at both 3 (6.1 vs. 5.9) and 24 h (5.5 vs. 5.4) pm. As expected, RC resulted in lower ($P < 0.01$) LM temperature at 3 h pm (13.7 vs. 21.4°C). Percentage drip loss (48 h) was lower ($P < 0.01$) in loin chops from CS pigs (3.5 vs. 4.5%). Considering the cooling regimen, RC resulted in greater ($P = 0.04$) drip loss than CC (4.3 vs. 3.7%). Maximal shear force was influenced both by stunning procedure ($P < 0.01$) and chilling regimen ($P < 0.01$), with greater values for CS (6.3 vs. 5.3 kg) and RC (6.4 vs. 5.3 kg). Intact desmin abundance determined at both 24 and 72 h pm was not affected by the stunning procedure ($P \geq 0.46$) or by the chilling regimen ($P \geq 0.07$). When CS is followed by CC and when ES is followed by RC, abundance of intact talin in the LM is lower at 24 but not ($P \geq 0.39$) at 72 h (stunning procedure × chilling regimen interaction; $P < 0.01$). Relative abundance of the unautolyzed 80 kDa μ-calpain unit at 24 h pm was influenced by stunning procedure ($P < 0.01$) and cooling regimen ($P < 0.05$), with greater abundance in the LM of CS and RC. By contrast, the relative abundance of the 78 kDa μ-calpain subunit was lower ($P \leq 0.06$) for the CS and RC. The results reveal an overall positive effect of CS, except for shear force values, and CC on LM quality traits.

Key Words: stunning procedure, chilling rate, proteolysis

748 Effects of cannabinoid receptor 1 on muscle fiber types and muscle oxidative metabolism. E. Xu*[1,2], L. N. Zhu[1], T. Wu[1], Y. N. Huang[1], and Y. Z. Wang[1], [1]*Institute of Feed Science, Zhejiang University, The Key Laboratory of Molecular Animal Nutrition, Ministry of Education, Zhejiang Provincial Laboratory of Feed and Animal Nutrition, Hangzhou, Zhejiang, China,* [2]*College of Animal Science, Guiyang, Guizhou, China.*

The cannabinoid receptor type 1 (*CNR1*) is a key component of the endocannabinoid system, which has been reported to play a pivotal role in modulating feeding behavior and energy balance. *CNR1*is expressed in skeletal muscle and has effects on skeletal muscle metabolism. However, how this gene regulates muscle fiber types and muscle oxidative metabolism remains un-elucidated. In this study, 2 different strategies have been carried out: siRNA suppression and overexpression of *CNR1*.Results showed that the *CNR1*-overexpressed L6 cells exhibit higher expression levels of oxidative type muscle gene myosin heavy chain typeIIα (MyHCIIα, $P < 0.01$) and oxidative enzyme succinic dehydrogenase(SDH, $P < 0.05$) compared with the control group. While knockdown the *CNR1* in L6 cells, MyHCIIα expression ($P < 0.01$) was decreased and the expression of glycolytic enzyme lactate dehydrogenase (LDH) was significantly increased ($P < 0.01$). Overexpression of *CNR1* in rat soleus muscle significantly increased MyHCIIα ($P < 0.01$), SDH ($P < 0.01$) and malate dehydrogenase (MDH, $P < 0.05$) mRNA expression. In addition, *CNR1* overexpression in vivo induced SDH ($P < 0.01$) and MDH ($P < 0.05$) enzyme activities and downregulated LDH ($P < 0.05$) enzyme activity. Furthermore, gene expression of extracellular-regulated kinase 1 (ERK1) and proliferator-activated receptor-γ coactivator-1α (PGC-1α) were remarkably increased in both overexpression L6 cells and rat soleus muscle. In contrast, we observed that PGC-1α gene expression was significantly decreased, but extracellular-regulated kinase2 (ERK2) gene expression significantly increased in siRNA cell lines. Based on these results, we conclude that *CNR1*enhance the MyHCIIα and oxidative enzyme MDH and SDH gene expression and activities, inferring that the gene may play an important role in muscle oxidative metabolism. Moreover, *CNR1* may affect muscle fiber types and muscle oxidative metabolism via ERK1/2 and PGC-1α. These results contribute to further understanding the role of *CNR1* in skeletal muscle energy metabolism, and also help to explore the key genes to improve meat quality.

Key Words: cannabinoid receptor type 1, muscle fiber types, oxidative metabolism

749 Fatty acid profile of meat from young bulls fed different levels of crude glycerin. M. M. Ladeira,* J. R. R. Carvalho, M. L. Chizzotti, E. M. Ramos, P. D. Teixeira, M. C. L. Alves, P. E. P. Barros, and O. R. Machado Neto, *Federal University of Lavras, Lavras, MG, Brazil.*

The fatty acid profile in beef has an extreme importance, because many of these fatty acids have beneficial and malefic actions to human health. The objective was to determine the fatty acid (FA) profile of muscle and subcutaneous fat of feedlot young bulls fed different levels of crude glycerin in the diet. The experiment was conducted in a completely randomized design, with 4 treatments and 11 repetitions. Forty-four Red Norte animals were slaughtered at average live weight of 519 ± 15 kg, and the levels of crude glycerin (83% glycerol) in the diet were: 0, 6, 12 and 18% DM. The basal diet consisted of 30% corn silage, 12% soybean meal, 56% corn grain and 2% mineral mixture. Corn was partially replaced by glycerin, and to achieve an isonitrogenous diet, corn gluten meal (21% CP) was used. After slaughter, samples were taken from the *Longissimus dorsi* muscle of the left half carcass, and fatty acids were quantified using gas chromatography (GC-MS Finnigan Focus Gas Chromatograph; Column CP-Sil 88). When there was significant effects ($P < 0.05$), regressions analysis using PROC REG of SAS 9.1.3 were done. There was a linear increase of oleic acid (C18:1 cis-9) content in subcutaneous fat ($P < 0.05$) and muscle ($P < 0.05$), which could be due to an inhibition effect of glycerol on rumen lipolysis and, consequently, on the biohydrogenation, resulting on greater flow of unsaturated fatty acids to small intestine. The octadecenoic acid (C18:1 trans-10, trans-11 and trans-12) content in muscle decreased ($P < 0.05$), and there was a tendency ($P < 0.10$) of reduction on palmitic acid (C16:0) content in the muscle and subcutaneous fat with the increase of crude glycerin in the diet. However, the linoleic acid (C18:2 ω-6), α-linolenic acid (C18:3 ω-3) and CLA (C18:2 cis-9, trans-11) contents were not affected ($P > 0.05$) by the levels of crude glycerin. In the muscle tissue, there was an increase ($P < 0.05$) in concentration of monounsaturated fatty acids, and unsaturated:saturated fatty acids ratio ($P < 0.01$). As a conclusion, the use of crude glycerin in the beef cattle diet improved the fatty acids profile of meat. Funded by Fapemig, CNPq, Capes and INCT-CA.

Key Words: biohydrogenation, CLA, glycerol

750 Effect of vitamin E inclusion on *trans*-18:1 isomers in subcutaneous fat of steers fed a high-barley grain diet.

C. Mapiye*[1], M. E. R. Dugan[1], M. Juárez[1], J. A. Basarab[2], V. S. Baron[1], T. Turner[1], X. Yang[1], N. Aldai[3], and J. L. Aalhus[1], [1]*Agriculture and Agri-Food Canada, Lacombe Research Centre, Lacombe, Alberta, Canada,* [2]*Alberta Agriculture and Rural Development, Lacombe Research Centre, Lacombe, Alberta, Canada,* [3]*University of Basque Country, Vitoria-Gasteiz, Spain.*

Beef from animals fed high-concentrate diets can contain more *trans* (t)10–18:1 than vaccenic acid (t11–18:1) and consumption of t10–18:1 is associated with unhealthy blood lipoprotein profiles in animal models. Vitamin E has been reported to alter the levels of biohydrogenation intermediates in the rumen and consequently the fatty acid composition of tissues. The objective of the current study was to determine the effect of different dietary vitamin E levels on t18:1 isomers in subcutaneous fat from steers fed a high-barley grain diet. Steers were fed 1 of 4 levels of supplementary DL-α-tocopheryl acetate (340, 690, 1040 or 1740 IU/steer/day) in a barley-based finishing diet for 120 d. Two pens of 7 animals were fed per diet. At slaughter, subcutaneous fat was collected from the grade site (12th rib), methylated with sodium methoxide, and analyzed by a combination of GC and Ag+-HPLC. Polynomial contrasts were used to test for linear and quadratic effects of increasing dietary levels of vitamin E on subcutaneous fatty acid composition. Addition of vitamin E led to linear reductions ($P < 0.05$) in t6-/t7-/t8–18:1 and t10–18:1, and linear increases ($P < 0.05$) in t11–18:1 and t11-/t10–18:1 ratio in subcutaneous fat. Although vitamin E led to improvements in the t18:1 profile of beef subcutaneous fat, t10–18:1 remained the predominant t18:1 isomer. Additional testing is, therefore, warranted where a greater range of vitamin E is fed combined with testing for interactions with other biohydrogenation modifiers.

Key Words: subcutaneous fat, *trans* fatty acids, vaccenic acid

751 Influence of gender on meat quality and skatole in the fat of lambs.

N. M. Schreurs,* *Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand.*

Boar taint is a negative attribute of pork that occurs due to hindgut skatole production. The sheep rumen also produces skatole but there is no scientific evidence of ram taint. The objective was to investigate the influence of gender on lamb meat quality and fat skatole concentration. Five-month-old entire (n = 19) and castrated ram-lambs (n = 19) were grazed on autumn ryegrass pasture for 70 d. Live weight was measured at the start and before slaughter. Hot carcass weight was measured and the carcass chilled at 4°C for 24 h. After chilling the left loin was removed, vacuum-packed, chilled for a further 24 h at 4°C then stored at −20°C. Intermuscular fat was collected from the hind legs of the carcass and stored at −20°C. After thawing, muscle lightness and redness was assessed on a fresh slice of the loin after 30 min exposure to air (Minolta CR-200 chromameter calibrated to a white standard). Tenderness was assessed by the peak force required to shear 13 mm-square cores from loin steaks cooked in a water bath at 70°C for 90 min (Warner-Bratzler device, square blade and 30 kg load cell). Skatole concentration in the intermuscular fat was measured by GC-MS. Skatole concentration and peak shear force data required a log-transformation to achieve a normal distribution. Data were analyzed by *t*-test. The ram lambs had a greater pre-slaughter live weight (51.5 vs. 46.6 kg; $P < 0.001$) and carcass weight (22.0 vs. 20.5 kg; $P < 0.01$) due to a greater live weight at the start (40.3 vs. 37.7 kg; $P < 0.05$) and a greater growth rate (160 vs. 127 g/day; $P < 0.01$). Gender did not influence the lightness, redness or peak shear force. The skatole concentration was greater in the fat of the entire ram lambs (0.079 vs. 0.052 μg/g; $P < 0.05$). In production systems, rams are preferred over castrated male lambs due to their greater growth rates and ability to produce a heavier carcass, as observed in this study. The ram lamb was not associated with poorer meat quality in terms of tenderness and color compared with the castrated male. The greater skatole concentration indicates potential flavor issues for meat from ram lambs but the concentration was well below the 0.25 μg/g threshold at which boar taint is detected.

Key Words: lamb, skatole, gender

752 Comparison of skinning versus scalding and singeing: Effect on temperature, pH and meat quality in goats.

A. B. Omojola*[1], E. S. Apata[2], O. O. Olusola[1], and A. B. Omotoso[1], [1]*University of Ibadan, Ibadan, Oyo State, Nigeria,* [2]*Olabisi Onabanjo University, Ago-Iwoye, Ogun, Nigeria.*

The aim of this work was to investigate the effect of temperature and pH changes taking place at the slaughter line due to different post slaughter processing methods (PSPM) on meat of red Sokoto buck goats. A total of 27 good grade red Sokoto buck goats were slaughtered in batches of 3 and assigned randomly to the 3 PSPM of skinning, scalding, and singeing in a completely randomized design. Samples for pH analysis were taken from the Longissimus dorsi while the semi-membranosus muscles were used for evaluating shear force values (Kg/cm3) of the meat. Eating quality was estimated on aged semi-membranosus muscles using a trained taste panel on a 9-point hedonic scale. The internal temperature and pH values were taken at a depth of 2 cm at the Longissimus dorsi immediately after dressing and subsequently at 30 min intervals over a period of 3 h post-mortem. The rib-eye area was measured at the interface of the 12th and 13th rib while meat color was evaluated after freezing and thawing. Water Holding Capacity (WHC), drip loss and cooking loss were also evaluated. The ultimate pH was measured 24 h post-mortem. All data obtained were subjected to ANOVA. At the slaughter line, the skinned carcasses had a lower temperature ($P < 0.05$) compared with scalded and singed carcasses. The rate of pH fall was lowest ($P < 0.05$) in skinned carcasses from exsanguination until 3 h post-mortem while the ultimate pH was lowest ($P < 0.05$) in skinned (5.54) carcasses and highest ($P < 0.05$) in singed carcasses (5.70). Skinned carcasses showed a darker ($P < 0.05$) meat color compared with meat from scalded and singed carcasses. Scalding and singeing led to increased toughness by 26.21 and 50% respectively over meat from skinned carcasses. Drip and cooking losses were higher ($P < 0.05$) in meat from scalded and singed carcasses. WHC increased by 9.67% in meat from scalded carcasses while a decrease of 14.20% was obtained in meat from singed carcasses compared with those from skinned carcasses. The rib-eye area was not affected ($P > 0.05$) by the 3 PSPM. The trained panelist preferred ($P < 0.05$) meat from singed carcasses in terms of color, flavor, and overall acceptability.

Key Words: temperature, pH, postmortem processing

753 Organoleptic and shelf life of displayed Red Sokoto buck meat as influenced by post-slaughter processing methods. A. B. Omojola*[1], E. S. Apata[2], O. O. Olusola[1], and A. B. Omotosho[1], [1]*University of Ibadan, Ibadan, Oyo State, Nigeria,* [2]*Olabisi Onabanjo University, Ago-Iwoye, Ogun, Nigeria.*

While post-slaughter processing methods have the potential to add value, enhance shelf life and eating qualities of animal products, their effects on meat displayed for marketing as practiced in most developing nations needs to be evaluated. An experiment was carried out to investigate the effects of 3 post-slaughter processing methods (PSPM) of scalding, skinning, and singeing on eating and shelf life of displayed Red Sokoto buck meat. Twenty-seven (27) matured Red Sokoto buck goats weighing between 18 and 20 kg were slaughtered in batches of 3 and assigned to the 3 PSPMs. A completely randomized design in a 3 × 4 factorial arrangement was employed. After evisceration, the carcasses were split into symmetric halves and were fabricated into wholesale cuts. Meat from the leg cut (semi-membranosus) of each carcass from each treatment were displayed on a clean and sanitized table to simulate open market retail situations at an ambient temperature of 27°C. Meat samples were removed from the open displayed meat at intervals of 0, 3, 6 and 9 h for measurement of peroxide value, microbial load and organoleptic characteristics. The organoleptic score as measured on a 9-point hedonic scale was highest ($P < 0.05$) at 0 h of display for all parameters while the value reduced as time of open display increased. Irrespective of the time of display, meat from singed carcasses were scored highest ($P < 0.05$) for color (6.24), aroma (6.60), flavor (6.76) and overall acceptability (6.63). Tenderness and juiciness score were rated highest ($P < 0.05$) in meat from scalded carcasses. The peroxide value was least ($P < 0.05$) at 0 h of open display (0.43mEq) and increased as the display time increased. Displayed meat from skinned carcasses elicited the highest ($P < 0.05$) peroxide value (0.52 mEq) followed by meat from scalded carcasses (0.45 mEq). The microbial load of displayed meat from singed carcasses were least ($P < 0.05$) at various time of display while displayed meat from skinned carcasses had the highest microbial load at 0,3 6 and 9 h. Microbial load of all the displayed meat increased as time of display increased. Singeing enhanced shelf life and eating qualities of chevon displayed in open market situation.

Key Words: scalding, skinning, singeing

Nonruminant Nutrition: Feed Additives

754 Effect of different probiotics on diarrhea frequency and body weight of weaned piglets challenged with *Salmonella typhimurium*. L. J. Parazzi,* E. R. Afonso, S. M. M. K. Martins, T. A. Santo, A. F. C. Andrade, J. Diniz-Magalhães, and A. S. Moretti, *USP/FMVZ, Pirassununga, SP, Brazil.*

The aim of study was to test the effect of different probiotics fed to piglets on diarrhea frequency and body weight. The probiotic A (PA) mixture was composed of *B. subtilis, B. bifidum*, *E. faecium*, *L. acidophilus*, *L. casei*, and *L. lactis* and probiotic B (PB) contained *B. subtilis* and *B. toyoi* . A total of 160 crossbred piglets were weaned at 23 d of age, blocked by initial weight, equalized for sex, and distributed to 8 treatments: PA44 (4kg/ton) and PB44 (2kg/ton) fed through 44 d of age; PA65 (4kg/ton to 44 d and 2kg/ton to 65 d) and PB65 (2kg/ton to 44 d and 1kg/ton to 65 d) fed through 65 d of age; PA138 (4kg/ton to 44 d and 2kg/ton to 138 d) and PB138 (2kg/ton to 44 d and 1kg/ton to 138 d) fed through 138 d of age; control (C) without additives, and Antimicrobial (Atb), with antibiotic growth promoter. At 51 d of age, piglets received an oral dose of 1×10^5 UFC/pig of *S. typhimurium* (LSS-SR41). Feces from each experimental unit (4 pigs/pen) were visually examined every day (23 to 79d) to determine the diarrhea frequency using a subjective score on scale ranging from 1 to 3, where 1 = normal; 2 = soft feces; 3 = liquid feces. Piglets receiving Atb showed higher occurrence of normal feces compared with PA ($P = 0.0485$) and similar compared with PB during 23 to 79 d, independent of the administration period both PA and PB. Piglets fed PB138 demonstrated higher frequency of normal feces (32.75% vs 19.56%, respectively) and lower liquid feces (26.54% vs 35.62%, respectively) in relation to PA138. During 23 to 65 d of age, piglets fed Atb showed a higher body weight ($P < 0.05$) compared both PA and PB (25.99, 21.74 and 21.91 kg, respectively), but at slaughter (138 d) body weights were similar between all treatments ($P > 0.05$). In conclusion, the probiotic PA was not effective in reducing the incidence of diarrhea compared with PB and Atb, but the final body weights were similar, suggesting medium- and long-term actions of these probiotics on intestinal health.

Key Words: diarrhea, probiotics, *S. typhimurium*

755 Effect of mannan oligosaccharides on performance of weanling piglets. F. C. Horta, L. J. Parazzi,* S. M. M. K. Martins, O. H. O. Eckhardt, T. A. D. Santo, A. F. C. Andrade, J. Diniz-Magalhães, and A. S. Moretti, *USP/FMVZ, Pirassununga, SP, Brazil.*

The mannan oligosaccharides (MOS) have been used as prebiotics in the diets of pregnant and lactating gilts and weaned piglets. The aim of the study was to evaluate the effect of MOS in the diet on gestation and lactation of gilts and piglets during the weaning period on growth performance in the nursery. In a 2 × 2 factorial arrangement, 17 gilts and 140 weaned piglets (23 d of age) were used. There were 8 replicate pens (4 pigs/pen) per treatment, except CC and MM with 9 and 10, respectively. The compositions of diets for gilts and piglets were based on corn and soybean meal met NRC recommendations (1998). The groups consisted of gilts and piglets either fed with MOS (BioMOS, Alltech, 28% of the glucomannoprotein from *Saccharomyces cerevisiae*) or without it. The treatments were: MM (feeding MOS to gilts and piglets), MC (feeding MOS only to gilts), CM (feeding MOS only to piglets) and CC (control diets to gilts and piglets). The gilts received MOS at late gestation (81 ± 1.36 d) and lactation (0.1% MOS) and the piglets received MOS on the following schedule: 0.4% of the diet beginning on the last week of lactation to 37 d of age, 0.2% from 38 to 51 d of age, and 0.1% from 52 to 65 d of age. At 35 d of age, piglets were challenged orally (1×10^8 cfu/piglets) of *Salmonella* typhimurium. The weaning weight by the 5th week was higher ($P < 0.05$) in MM and MC treatments. Feed intake during first week post-weaning was higher ($P = 0.0449$) in MM and MC than CM and CC. The same result was observed for weight gain of piglets during the 2nd week ($P = 0.002$), but the CM and CC treatments showed a lower ($P = 0.0103$) G:F compared with MM and MC. In the 6th week, MM and MC treatments exhibited a higher feed intake ($P = 0.0007$), however, with no difference in the body weight of piglets. MM and MC piglets maintained highest body weight despite the challenge employed. In conclusion, supplementation with MOS in the diets of gilts increased the body weights of piglets by 5th week, independent the piglet MOS supplementation.

Key Words: mannan oligosaccharides, piglets, *S. typhimurium*

756 Multi-NSP enzymes improved growth performance and gut health in nursery pigs fed corn or rye and barley diets. J. Zhao,* F. Yan, D. L. Lichtenstein, A. Lawhorn, and M. Vazquez-Anon, *Novus International Inc., St Charles, MO.*

This study was conducted to investigate the benefits of an NSP enzyme blend in pigs fed either corn or rye and barley diets. A total of 128 nursery pigs (34 d of age, 9.95 ± 0.28 kg) were randomly assigned to 4 treatments with 8 replicates per treatment and 4 pigs per pen. The trial was a 2*2 factorial arrangement with 2 diet types (corn vs. rye and barley) with and without NSP enzyme for 3 phases (d 0–20, d 21–32, and d 33–55). Rye and barley were added at 30% and 15%, respectively. The enzyme (combination of Cibenza CSM and DE200, Novus International Inc., St. Charles, MO) is a blend of endo-xylanase, β-glucanase, α-galactosidase, and β-mannanase. Feed was withdrawn from all pigs from d 21–23 and d 28–30 to create a minor gut health challenge. Gain:feed was improved with enzyme supplementation in phase I and phase III in both corn (7 and 9%, respectively) and rye and barley diets (9 and 13%, respectively, $P < 0.05$). The presence of enzyme tended to improve daily weight gain (443 vs. 480 g, $P = 0.08$) and body weight in phase I (18.8 vs. 19.6 kg, $P = 0.08$) regardless of diet type. Daily feed intake was significantly decreased with enzyme supplementation in phase III (2.353kg vs. 2.209 kg, $P = 0.03$), perhaps due to improved energy utilization. No differences were observed on cecum viscosity, *E. coli*, *Clostridium*, and coliform counts among treatments ($P > 0.10$). Total aerobic counts were significantly reduced with enzyme supplementation at all 3 time points ($P < 0.02$). On d 55, cecum lactic acid bacteria counts were increased ($P < 0.01$) while pH was decreased (6.21 vs. 5.59, $P < 0.01$) with enzyme supplementation. Decreased intestinal pH is beneficial for controlling pathogenic bacteria in general. No significant effects of diet type or interaction of diet type and enzyme supplementation were observed on either growth performance or gut health measurements. In conclusion, enzyme improved feed utilization and weight gain in both corn and rye and barley diet in pigs. The benefits are partially associated with improved gut health.

Key Words: NSP, enzyme, swine

757 Effect of increasing concentrations of a novel β-glucanase to a constant β-mannanase in corn-soybean meal-corn distillers dried grains with solubles (DDGS) diets on grower pig performance. Z. Rambo[1], J. Ferrel*[2], D. Anderson[2], D. Kelly[1], and B. Richert[1], *[1]Purdue University, West Lafayette, IN, [2]ChemGen, Gaithersburg, MD.*

Two-hundred 52 pigs (initial BW = 26.0 kg ± 0.45) were used to evaluate the effect of adding a β-glucanase (ENz1) to a β-mannanase (ENz2) enzyme, titrated at 5 concentrations, in a corn-soybean meal-DDGS diet on pig growth and feed efficiency during the grower period. Pigs were allocated in a randomized complete block design of mixed sex pens, stratified by sex, litter and initial BW to 6 treatments with 7 pens/treatment. Dietary treatments were: T1-Negative Control (no enzymes), treatments 2–6 had a constant level of Enz2 at 0.16 MU/kg plus increasing levels of ENz1; T2 = 0 MU/kg, T3 = 0.044 MU/kg, T4 = 0.088 MU/kg, T5 = 0.132 MU/kg, and T6 = 0.176 MU/kg of ENz1. Pigs were fed 2 dietary phases (25 and 30% DDGS, respectively), each 3 weeks in duration. Individual BW and pen feed disappearance were recorded weekly. Phase 1 ADG was greater for T5 compared with T1 ($P < 0.05$) with all other treatments being intermediate (743, 768, 780, 768, 782, 772 g/d; T1-T6, respectively). Phase 1 G:F tended to linearly ($P < 0.07$) increase with increasing levels of ENz1 (0.449, 0.449, 0.456, 0.465, 0.473, 0.465, respectively). During phase 2 there were no differences in ADG among treatments; however, G:F linearly ($P < 0.02$) improved with increasing levels of Enz1 (0.372, 0.367, 0.378, 0.371, 0.382, 0.385, respectively). Overall ADG was greater for T3, T5, T6, compared with T1 ($P < 0.05$) with T2 and T4 being intermediate (788, 801, 825, 810, 817, 818 g/d; respectively). Overall G:F linearly ($P < 0.01$) improved with increasing levels of Enz1 (0.400, 0.397, 0.407, 0.405, 0.416, 0.414, respectively). Final BW was greater for T3 compared with T1 with all other treatments being intermediate (59.5, 60.2, 61.2, 60.6, 60.8, 60.8 kg, respectively). Increasing levels of β-glucanase (Enz1) linearly improved feed efficiency (4.8%) during the grower period and numerically improved ADG and final BW with corn-soybean meal diets containing up to 30% DDGS.

Key Words: swine, β-glucanase, β-mannanase

758 Evaluating nutritive value of pepper *Capsicum annuum* and garlic *Allium sativum* on performance, egg trait and serum parameters of old layers.

F. A. Aderemi,* O. M. Alabi, and O. M. Ayoola, *Bowen University, Iwo State, Nigeria.*

This study was conducted to investigate the effects of garlic powder and dried pepper on the performance, egg traits, egg cholesterol and serum parameters of laying chickens. A 10-wk study was carried out using 90 ISA brown layers that have laid eggs for 2 years. The diets were formulated such that diet I with 0% pepper and garlic served as the control, while diets II and III had 4g/kg of dried pepper and powdered garlic, respectively. The layers were divided into 3 groups fed on these diets and replicated thrice. Data were analyzed by ANOVA using a completely randomized design. The results showed that there were no differences ($P > 0.05$) among the dietary treatments in feed consumption and feed efficiency; layers receiving garlic powder had better numerical values as compared with pepper and control. There were improvements ($P < 0.05$) in egg albumen index and Haugh unit of garlic-fed layers. There was also a reduction ($P < 0.05$) in egg yolk cholesterol concentration of layers fed the garlic-supplemented diet compared with the pepper and control diets. Serum total protein of garlic-fed layers increased ($P < 0.05$), while blood glucose and cholesterol levels decreased ($P < 0.05$). We concluded that garlic improved performance characteristics and may increase egg shelf life as indicated by egg quality measurements.

Key Words: garlic powder, dried pepper, layers

759 Defatted algae biomass may replace one-third of soybean meal in diets for laying hens.

X. J. Leng, K. N. Hsu, R. E. Austic, and X. L. Lei,* *Cornell University, Ithaca, NY.*

Although soybean meal is a commonly-used source of feed protein for laying hens and other food-producing animals, it is very expensive and limited in supply. Microalgae have recently been explored as a new exciting source of biofuel, and the residual biomass contains a good amount of protein and other nutrients. The present study was conducted to determine whether defatted algal biomass from biofuel production (Cellana, Kailua-Kona, HI) could replace a portion of soybean meal or a combination of corn and soybean meal in diets for laying hens. A total of 100 ISA Babcock White Leghorn laying hens (47 weeks old, *Gallus gallus domesticus*) were randomly assigned to 4 dietary treatments. There were 5 replicates for each treatment and each replicate consisted of 5 individually caged hens. The 4 experimental diets included a corn-soybean meal basal diet (BD), the BD with 7.5% defatted algae and the 5 most limiting amino acids substituting for 7.5% soybean meal, and the BD with 7.5% or 15% defatted algae substituting for soybean meal and corn. During the 8-week experiment, hens fed 15%, but not 7.5% defatted algae had lower ($P < 0.05$) egg production rate (−12%) and daily feed intake (- 9 g) than those fed the BD. There was no significant difference in egg weight (58–61g), shell strength (33–35 N), and shell specific gravity (1.08) or activities of plasma alanine aminotransferase (24–33 U/L) and alkaline phosphatase (112–155 U/mL) among the 4 dietary treatment groups at wk 4 and(or) wk 8. The inclusion of defatted algae tended to decrease the lightness (L value) and yellowness (b value) of the egg yolk color ($P < 0.05$), but increased the redness (a value; $P < 0.05$). In conclusion, it was feasible to substitute 7.5% defatted algae for soybean meal or for a combination of corn and soybean meal in the diets of laying hens without adverse effects on their health or egg production. Supported in part by a USDA/DOE Biomass R&D Initiative grant.

Key Words: algae, biofuel, laying hens

760 Effects of various replacements of corn and soy by defatted microalgal meal on growth performance and biochemical status of weanling pigs.

K. K. Lum,* K. R. Roneker, and X. G. Lei, *Cornell University, Ithaca, NY.*

Marine microalgae biomass derived from biofuel production has great potential as a nutrient-rich alternative feed protein or energy source. Our objective was to evaluate effects of partial replacements of corn and soybean meal by defatted algal meal in diets for young pigs on their overall growth performance and biochemical status. Weanling pigs (BW = 13.4 ± 1.6 kg; n = 8/treatment) were individually housed and fed for 6 wk with 1 of 4 diets: corn-soybean meal basal diet (BD), BD with 7.5% defatted algal meal (provided by Cellana, Kailua-Kona, HI) in replacing 7.5% soybean meal, and BD with 7.5 and 15% defatted algal meal in replacing 7.5 and 15% corn and soybean meal in combination, respectively. Data were analyzed using one-way ANOVA as complete random design with or without time-repeated measurements. Compared with those fed the BD, pigs fed 15% defatted algal meal had 9% lower final BW ($P < 0.05$) and 12% lower overall ADG ($P < 0.05$). The substitution of 7.5% defatted microalgal meal for the same amount of soybean meal also resulted in 12% lower overall ADG ($P < 0.05$) than the control. However, ADFI, gain/feed efficiency, and the percent body lean yield predicted by ultrasound scans at wk 6 were not significantly affected by the dietary treatments. Likewise, there were no treatment differences in the biweekly analyses of plasma biochemical indicators including urea nitrogen concentration, alanine aminotransferase, and alkaline phosphatase activities, and total triglycerides, cholesterol, and nonesterified fatty acid concentrations. In conclusion, weanling pigs manifested comparable growth performance and plasma biochemical status in responses to the replacement of 7.5% soybean meal and corn by defatted microalgal biomass, but failed to tolerate a higher level (15%) of such replacement, or the sole replacement of 7.5% soybean meal. Supported in part by a USDA/DOE Biomass R&D Initiative grant.

Key Words: microalgae, pigs, nutrition

761 Effects of a blend of essential oils on post-weaning growth performance of piglets.

A. Aufy*[1], T. Steiner[1], and Y. Jung[2], [1]*Biomin Holding GmbH, Herzogenburg, Austria,* [2]*Jung P&C Institute, Yeongdoek-Dong, Giheung-Gu, Yongin-City, Gyeonggi-Do, Korea.*

As a consequence of the ban on antibiotic growth promoters (AGPs) in several countries, piglets have been exposed to different challenges that have resulted in a notable deterioration in productive performance. The aim of this study was to investigate the effects of a phytogenic feed additive (PFA) on piglet performance and to evaluate it as an alternative to AGPs. A total of 360 weanling crossbred (Duroc × Yorkshire × Landrace) pigs with an initial body weight of 6.7 kg, weaned at 23 d of age, were used in 28-d growth feeding experiment. Pigs were randomly allocated to 1 of 3 experimental treatments. Each treatment had 30 pigs per pen and 4 replications (pens). Treatments were negative control (commercial diet based on corn and soybean meal), positive control (commercial basal diet + 100 mg/kg apramycin/ton), and PFA (commercial diet + 125 mg/kg Biomin P.E.P. 125). Two-phase feeding programs were implemented with phase 1 diet fed from 0 to 14 d and phase 2 diet fed from 14 to 28 d post-weaning. All experimental diets were fed in crumbled feed. The data set was analyzed using the GLM procedure of SAS (1998) with pen as experimental unit by adjusting initial body weight. Through the experimental period from d 1 to d 28 post-weaning, performance parameters including body weight, body weight gain, feed intake, feed conversion ratio and mortality were recorded. The results obtained revealed that piglets treated with PFA had 1 to 7% higher body weight than the negative control group and the AGP group respectively. Piglets treated with the PFA showed significantly higher ($P < 0.05$) average daily gain than the AGP group while the difference to the negative control group was numerically higher. At d 28, there were no significant differences in feed intake between the groups. Dietary supplementation with the PFA attained significantly lower ($P < 0.05$) feed conversion ratio values than the AGP supplemented group and insignificant values compared with the negative control group. No mortality was observed in the PFA group while dietary supplementation with AGP insignificantly ($P > 0.05$) reduced mortality by about 32%. The efficacy of any feed additive is judged by its potential to improve mainly feed utilization (feed conversion ratio) and other physiological parameters. The present study showed performance promoting effects in piglets fed the PFA, indicating its potential use as growth enhancer and as successful alternative to AGP piglet rations.

Key Words: phytogenics, growth performance, piglets

762 Effects of a dietary antioxidant blend on growth and plasma markers of oxidative status in pigs fed an oxidative stress diet.

T. Lu*[1], A. F. Harper[1], J. Zhao[2], R. A. Dalloul[1], and M. J. Estienne[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg,* [2]*Novus International Inc., St. Charles, MO.*

Crossbred barrows (n = 100, 10.9 kg BW, 36 ± 2 d of age) were used to assess inclusion of a commercial antioxidant (AOX; Agrado Plus, Novus International, St. Charles, MO) to diets formulated to increase oxidative stress. There were 5 pens of 4 pigs each in 5 treatments that included: 1) a negative control (NC) oxidative stress diet containing oxidized soy oil (5%) and a source of polyunsaturated fatty acids (PUFA, 10%) with no added vitamin E (VE) and no AOX; 2) the NC diet with 11 IU/kg of added VE; 3) the NC diet with AOX providing a proprietary antioxidant blend of ethoxyquin and propyl gallate; 4) the NC diet with AOX and VE; and 5) a standard control diet (SC) with no oxidized soy oil or PUFA source. Growth was assessed and plasma collected at defined time points throughout the 118 d study. No treatment effects were observed in performance by d 25 ($P > 0.33$), but at d 82 BW for pigs fed the NC, VE, AOX, AOX+VE and SC diets were 48.4, 69.5, 82.3, 81.7 and 85.3 kg respectively (NC pigs lower than all others, VE pigs lower than AOX, AOX+VE and SC, $P < 0.05$). At d 82, pigs fed the NC diet were switched to the SC diet due to very poor animal condition resulting in some recovery such that by d 118, BW for the respective treatments were 83.3, 92.9, 127.3, 130.6 and 135.1 kg, for NC/SC, VE, AOX, AOX + VE, and SC, diets respectively (AOX, AOX+VE and SC pigs greater than NC/SC and VE pigs, $P < 0.05$). Plasma concentrations of thiobarbituric acid reactive substances (TBARS) and carbonyl were consistent with growth data, being elevated ($P < 0.05$) in the NC compared with the SC pigs at d 55 but corrected to a level not different from the SC pigs at d 118. At d 118, TBARS (μM/mL) was 2.76, 10.56, 4.21, 4.10 and 2.33 and carbonyl (nmol/mL) was 25.94, 71.53, 24.21, 21.31 and 19.24 for the NC/SC, VE, AOX, AOX+VE and SC fed pigs, respectively, with both markers elevated in the VE pigs compared with all other treatments ($P < 0.05$). In the oxidative stress model used in this study, dietary addition of AOX or AOX plus VE was effective in improving growth and plasma markers of oxidative stress, but VE was not.

Key Words: pigs, oxidative stress, antioxidant

763 Effects of eubiotics (VevoVitall, Crina Piglets, Cylactin ME10) supplementation on growth performance, nutrient digestibility, fecal noxious gas emission, and fecal microbial shedding in weanling pigs.

Z. F. Zhang*[1], S. M. Hong[1], A. V. Rolando[2], D. H. Yoo[3], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea,* [2]*DSM Nutritional Products Philippines Inc., Bonifacio Global City, Taguig, Philippines,* [3]*All The Best Ltd., Seoul, South Korea.*

A total of 150 weanling pigs [(Landrace × Yorkshire) × Duroc, BW = 8.86 ± 0.43 kg] were used in a 42-d trial to evaluate the effects of eubiotics on growth performance, apparent total tract digestibility (ATTD), fecal microbial shedding, and fecal noxious gas emission. Pigs were randomly distributed into 1 of 5 dietary treatments on the basis of BW and litter. Each treatment had 6 replicate pens with 5 pigs per pen. Dietary treatments were as follows: T1, basal diet; T2, T1 + 0.5% VevoVitall + 0.01% Crina Piglets; T3, T1 + 0.5% VevoVitall + 0.007% Cylactin ME10; T4, T1 + 0.3% VevoVitall + 0.01% Crina Piglets; T5, T1 + 0.3% VevoVitall + 0.007% Cylactin ME10. VevoVitall is an ultrapure grade of benzoic acid, Crina Piglets contains around 10% essential oils (thymol, eugenol, and piperine), and Cylactin ME10 contains 1.0 × 10^{10} cfu/g of *Enterococcus faecium* NCIMB 10415. During 8–21 d, ADG and G/f in T2 and T3 treatments were improved ($P < 0.05$) compared with T1 and T5 treatments. Overall, pigs fed the T2 diet had greater ($P < 0.05$) ADG and G/f than those fed the T1 diet. Pigs fed the T2 diet significantly increased ($P < 0.05$) the ATTD of DM compared with those fed the T1 diet at d 21, while the ATTD of N in T2, T3, T4 treatments was increased ($P < 0.05$) compared with T1 treatment. The fecal *Lactobacillus* counts were increased ($P < 0.05$) by T2 treatment compared with other treatments, whereas the fecal *E. coli* population was decreased ($P < 0.05$) in T2 and T3 treatments compared with T1, T4, and T5 treatments. All the diets supplemented with eubiotics decreased ($P < 0.05$) the fecal NH_3, total mercaptans, H_2S emission compared with T1 treatment. Results indicated that 0.5% VevoVitall + 0.01% Crina Piglets could improve the growth performance, increase the fecal *Lactobacillus* population, decrease *E. coli* counts, as well as reduce fecal noxious gas emission in weanling pigs.

Key Words: eubiotics, noxious gas emission, weanling pigs

Physiology and Endocrinology: Nutritional Physiology

764 mRNA expression of a novel adipokine (pigment epithelium-derived factor, PEDF) in various tissues from dairy cows receiving supplements with or without conjugated linoleic acids (CLA). B. Saremi*[1], S. Winand[1], S. Dänicke[2], J. Pappritz[2], D. von Soosten[2], H. Sauerwein[1], and M. Mielenz[1], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

Pigment epithelium-derived factor (PEDF) is a recently discovered adipokine, a secreted glycoprotein belonging to the non-inhibitory serpin group; it is one of the most abundant proteins secreted by human adipocytes and is related to obesity, insulin resistance and inflammatory signaling. To our knowledge, no information is available on bovine PEDF expression and functions. Herein, CLA effects on PEDF mRNA abundance (Ab) were tested in tissues of dairy cows ante and postpartum (a.p., p.p.). In 2 trials, Holstein cows were allocated to a CLA (Lutrell, BASF, Germany) or control (Silafat, BASF) fat supplement at 100 g/day from d 1 to 182 p.p. in trial 1 and d 1 to 105 p.p. in trial 2. Trial 1: 21 multiparous cows at d 21 a.p. and d 1, 21, 70, 105, 182, 196, 224, 252 p.p. were biopsied from tail head adipose tissue (AT) and liver. In trial 2, 25 heifers were slaughtered on d 1 (n = 5; control), 42 and 105 p.p. (n = 5 per each group) and 3 visceral (Vc; mesenterial, omental and retroperitoneal) and 3 subcutaneous (Sc; sternum, withers and tail head) AT, liver, mammary gland, and muscle tissues were sampled. PEDF mRNA was quantified by qPCR. Data were analyzed using mixed model for trial 1 and GLM or nonparametric test for trial 2 (SPSS 17, $P < 0.05$). In trial 2, liver had 34.3, 15.1, 6.8 and 2.9 fold higher PEDF Ab than muscle, mammary gland, VcAT, and ScAT respectively. VcAT had 2.4 fold lower PEDF Ab than ScAT (trial 2). Liver PEDF Ab did not change with time in both trials. In AT, time-dependent changes were solely observed in the control group in which PEDF Ab increased after parturition, decreased until d 200, and increased thereafter (d 231 and 252). CLA effects were limited to trial 1 in which PEDF Ab in ScAT did not show the p.p. and late lactation increases of control cows. In trial 2, time-dependent changes were limited to mesenterial fat and to ScAT from sternum and withers with lowest values each on d 1. Our data confirm expression of PEDF for bovine AT with consistently higher Ab in Sc than in VcAT. Moreover, we identified the liver as a major site of PEDF expression.

Key Words: pigment epithelium-derived factor (PEDF), CLA, liver and fat

765 Effects of long-term hyperketonemia on metabolism and performance in lactating dairy cows. M. Zarrin*[1,2], L. De Matteis[1,3], M. C. M. B. Vernay[1], O. Wellnitz[1], H. A. van Dorland[1], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Department of Animal Science, Yasouj University, Yasouj, Iran, [3]Istituto di Zootecnica, Università Cattolica S, Cuore, Piacenza, Italy.*

Hyperketonemia in dairy cows occurs frequently in early lactation. Previous studies observed that increasing plasma BHBA concentration decreases glucose levels in pigs and ewes through hormonal mechanisms or possible inhibition of gluconeogenesis. In cows, this has not yet been investigated. The objective was to study effects of a BHB infusion for 48 h in mid lactating dairy cows on metabolism and performance. Thirteen mid lactation dairy cows were randomly assigned to one of 2 treatments, including an intravenous infusion with Na-DL-β-OH-butyrate (1.7 mol/L) at a rate of 8.5 ± 0.6μmol/kg BW/min (HyperB, n = 5), or an infusion with a 0.9% saline solution (20 mL/h; NaCl, n = 8). The infusions started from 0900 h and continued to 0900 h 2 d later by use of a permanent catheter in the jugular vein. Blood was sampled before and on an hourly basis during the infusions for metabolite and hormone levels. In liver, mRNA transcripts of pyruvate carboxylase, mitochondrial phosphoenolpyruvate carboxykinase, and glucose-6- phosphatase were measured by real-time RT-PCR. GAPDH and ubiquitin were housekeeping genes. Cows were fed hay and concentrate and were milked twice daily throughout the study. Changes (difference between before and after 48h infusion) in the measured parameters were evaluated by ANOVA with treatment as fixed effect. The plasma BHB concentration reached and maintained during the study period in HyperB cows was 1.7 ± 0.2 mmol/L (mean ± SE) compared with 0.59 ± 0.02 mmol/L for NaCl cows. The change in feed intake, milk and ECM yield was not different between 2 groups. BHB infusion reduced the plasma glucose concentration (3.47 ± 0.11mmol/L) in HyperB compared with NaCl cows (4.11 ± 0.08mmol/L; $P < 0.05$). The other plasma factors were unaffected. In the liver, changes in mRNA abundance for the selected genes were similar between HyperB and NaCl cows. Results demonstrate that intravenous infusion of BHB decreased plasma glucose concentration in dairy cows but this decrease was not explained by alterations in insulin or key enzymes related to hepatic gluconeogenesis at a molecular level.

Key Words: hyperketonemia, metabolism, gluconeogenesis

766 Tissue-dependent expression of G-protein couple receptor (GPR) 40, 41, 43, 109A mRNA in early lactation dairy cows treated with conjugated linoleic acids (CLA) and long-chain fatty acids (LCFA). B. Saremi*[1], H. Sauerwein[1], D. von Soosten[2], S. Dänicke[2], and M. Mielenz[1], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

The receptors GPR40, 41, 43, and 109A are a group of transmembrane receptors related to energy homeostasis through regulation of insulin and glucagon secretion, leptin release, adipogenesis and lipolysis, respectively. LCFA and CLA as ligands of GPR40 are insulinotropic in humans. We investigated GPRs mRNA abundance (Ab) in dairy cows tissues considering effects of CLA. From 25 heifers, 5 were slaughtered on d 1 postpartum (p.p.). Remaining heifers were randomly allocated to a CLA (Lutrell pure, BASF, Germany, n = 10) or a control fat supplement containing LCFA but without CLA (Silafat, BASF, n = 10) each at 100 g/d. Five animals per group were slaughtered at d 42 or 105. Subcutaneous (ScAT; sternum, withers and tail head) and visceral (VcAT; mesenterial, omental and retroperitoneal) adipose tissues, liver, mammary gland, and muscle were sampled. The mRNA was quantified by qPCR. GLM or nonparametric tests were used for statistical analysis (SPSS 17; $P < 0.05$). GPR40 was the only receptor which had a higher Ab in CLA group in liver ($P < 0.065$), omental and retroperitoneal AT. GPR41 and 43 Ab were higher (3.3 and 3.5 fold respectively) in VcAT in comparison to ScAT. GPR109A Ab was 1.4 and 33 fold higher in ScAT vs. VcAT and in AT vs. the mean of liver, muscle and mammary gland. Liver and mammary gland exhibited similar and muscle showed a lower GPR43 Ab in comparison to ScAT. Liver and muscle had the highest and lowest GPR40 Ab respectively, with the exception of equality of liver to ScAT from withers. GPR40 Ab increased from d 1 to d 42 and 105 p.p. in AT and was stably expressed in muscle and liver. GPR41 Ab decreased from d 1 and 42 to d 105 p.p. GPR43 Ab increased from d 1 to d 42 and 105 in ScAT and was consistently expressed in VcAT and non fat tissues. Different behavior of GPR40 Ab between CLA and LCFA in bovine AT and liver raises the differential regulation of the receptor in bovine vs. human. Differential expression of the GPRs in different fat or nonfat tissues might be a hint to their tissue specific roles.

Key Words: GPR40-43 and GPR109A, CLA, dairy cow

767 Is calcitonin involved in hypocalcemia of periparturient cows? E. M. Rodríguez*[1], A. Bach[1,2], M. Devant[1], and A. Arís[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

Evidence for an association of calcitonin (CALC) in hypocalcemia in the cow is inconsistent: whereas some studies point out that this hormone secretion is increased, others state that it is diminished. The objective of this study was to elucidate the involvement of CALC on periparturient hypocalcemia establishing a comparative profile of the changes in calcium-regulating factors under high and normal dietary Ca supplies. Sixteen Holstein multiparous cows (674 ± 22.8 kg of BW and 3.9 ± 0.29 y of age) were distributed into 2 groups: a diet containing 1.64% Ca (HIGH) or a diet containing 0.87% Ca (CTR) during 3 wk before calving. Feed intake was individually recorded and blood samples were obtained daily from −7 to 7 d from parturition. Milk yield was recorded daily during 3 weeks after calving. Calcium was analyzed in plasma using a colorimetric method (SPINLAB 100) and in milk using atomic absorption spectrophotometry. Plasma parathyroid hormone (PTH) and 1,25-dihydroxyvitamin-D (1,25-vitD) were analyzed using ELISA, and plasma CALC was determined by RIA. Data were analyzed with a mixed-effect model with repeated measures. No differences in DMI were observed between groups. During the first 7 d after calving, milk yield tended ($P = 0.06$) to be greater in CTR than in HIGH cows (23.9 vs. 19.4 ± 1.56 L, respectively) and milk Ca concentration tended ($P = 0.08$) to be lower in CTR than in HIGH cows (1482 vs. 1627 ± 57.4 mg/kg, respectively), although total milk Ca production (31.7 ± 2.91g/d) did not differ between treatments. Seventy 5 percent of the cows incurred subclinical hypocalcemia (blood Ca concentrations <8 mg/dL). During hypocalcemia the CALC secretion was not increased and the hormone was maintained under basal concentrations. Blood PTH concentrations increased at d 1 postpartum as a reaction to Ca loss and 1,25-D concentrations increased at d 2. In conclusion, this study shows that CALC secretion is not increased on the hypocalcemic period of cows and as expected, the main Ca reduction was followed by an increase in PTH and 1,25-D secretion.

Key Words: hypocalcemia, calcitonin, parathyroid hormone

768 Reproductive performance of Ossimi rams fed biologically treated rations. E. B. Abdalla*[1], F. R. Abed El-Aziz[2], H. M. Gado[1], A. E. Hassan[2], and M. S. Ziada[3], *[1]Ain Shams University, Cairo, Egypt, [2]Anim. Prod. Res. Inst., Agric. Res. Center, Ministry of Agric., Giza, Egypt, [3]Anim. Reprod. Res. Inst., Agric. Res. Center, Ministry of Agric, Giza, Egypt.*

This experiment was conducted on 20 adult Ossimi rams (1–2 years old and averaged 44–48 kg live body weight) to evaluate the dietary supplementation of ZAD compound (patent product contains cellulases, xylanases, protease and α amylase) to improve overall nutritional status and consequently will improve semen quality characteristics in sheep. Rams were randomly divided into 2 equal groups (10 for each). The first group (G1) served as control and was fed rice straw without supplementation, while the second group (G2) was fed rice straw treated with ZAD compound. All rams received concentrate feed mixture (CFM) to cover 100% of their maintenance energy. Forage and CFM were adjusted biweekly according to live body weight changes and roughage to CFM ratio was 60:40 during the experimental period. The experimental feeding period lasted for 8 mo, the first 2 mo were a preliminary period and the other 6 mo were the main period of semen collection (once a week). General Linear Model (GLM) procedure of SAS, ANOVA and LSD test were used for statistical analysis. Results revealed that overall mean of semen characteristics were 0.54 vs. 1.21 mL, 77.81 vs. 85.18%, 2.15 vs. 2.85 × 10^9/mL, 75.90 vs. 78.05%, 12.10 vs. 9.68% and 5.20 vs. 5.91 for ejaculate volume, advanced motility, sperm cell concentration, live sperm, abnormal sperm and pH value of semen for control and treated group, respectively. Body weight changes were promoted ($P < 0.05$) by treatment as compared with the control group. Blood plasma concentrations of total protein, albumin and globulin were higher ($P < 0.05$) in G2 (8.22, 2.82 and 5.40 g/dL) as compared with those corresponding values in G1 (5.59, 2.18 and 3.41 g/dL, respectively). Blood plasma levels of thyroxine (T4) hormone showed a tendency of increases in G2 than in G1 (5.21 vs. 4.65 ng/dL). Similarly, triiodothyronine (T3) and testosterone concentrations were significantly higher in G2 than in G1 (164.8 vs. 138.3 ng/mL). Results of the present study indicated that feeding rams on ration containing ZAD compound had a beneficial effect on their semen quality characteristics, including sperm motility %, sperm cell concentration (× 10^9/mL), live sperm% and normal sperm % comparing with the control group .

Key Words: ZAD, hormone, semen

769 The effect of yeast cell wall supplementation on the metabolic responses of crossbred heifers to endotoxin challenge. N. C. Burdick*[1], T. R. Young[2], J. A. Carroll[1], J. R. Corley[3], R. J. Rathmann[2], and B. J. Johnson[2], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [3]Lesaffre Feed Additives, Milwaukee, WI.*

This study examined the effect of feeding yeast cell wall (YCW) products on the metabolic responses of newly-received heifers to endotoxin (lipopolysaccharide; LPS) challenge. Heifers (n = 24; 218.9 ± 2.4 kg) were obtained from commercial sale barns and transported to the Texas Tech Univ. Beef Center. Heifers were separated into treatment groups receiving a Control Diet (C; n = 8), YCW A (2.5 g/hd per day; n = 8) or YCW C (2.5 g/hd per day; n = 8) and were fed for 52 d. Heifers were weighed on d 0, 14, 36, 38, and 52. On d36 heifers were fitted with indwelling jugular catheters and moved into a barn with individual stalls. On d37 heifers were challenged i.v. with LPS (0.5 μg/kg BW) and blood samples were collected every 0.5 h from −2 to 8 and again at 24 h relative to LPS challenge (0 h). Serum was isolated and stored at −80°C until analyzed for glucose, insulin, nonesterified fatty acid (NEFA), and blood urea nitrogen (BUN) concentrations. Heifer weight increased from d0–36 and from d38–52 ($P < 0.01$), but was not affected by treatment ($P > 0.32$). Post-LPS YCW A (−6.0 ± 0.9 kg) lost more weight (from d36–38) than C (−2.4 ± 0.9 kg) and YCW C (−4.2 ± 0.9kg; $P = 0.04$). Post-LPS glucose increased ($P < 0.001$) and was less in YCW A (98.5 ± 2.5 mg/dL) than C (105.6 ± 2.4 mg/dL) and YCW C (109.5 ± 2.4 mg/dL; $P < 0.01$). Pre-LPS insulin was greater in YCW A (0.80 ± 0.06 ng/mL) and YCW C (0.087 ± 0.06 ng/mL) than C (0.44 ± 0.06 ng/mL; $P < 0.01$). Post-LPS insulin increased ($P < 0.01$) with YCW C (0.95 ± 0.04 ng/mL) and YCW A (0.71 ± 0.05 ng/mL) having greater insulin than C (0.59 ± 0.04 ng/mL; $P < 0.001$). Pre-LPS NEFA tended ($P = 0.07$) to be less in YCW C (0.14 ± 0.01 mmol/L) than C (0.18 ± 0.01 mmol/L) and YCW A (0.17 ± 0.01 mmol/L). The difference in NEFA was significant post-LPS (0.18 ± 0.01, 0.21 ± 0.01, and 0.21 ± 0.01 mmol/L respectively for YCW C, C, and YCW A). Pre-LPS BUN was greater in YCW A (8.2 ± 0.3 mg/dL) than C (6.9 ± 0.3 mg/dL; $P = 0.03$). Post-LPS BUN was greater in YCW A (8.9 ± 0.2 mg/dL) than C (8.2 ± 0.2 g/dL) and YCW C (8.1 ± 0.2 mg/dL; $P < 0.01$). These data indicate that certain YCW products can enhance the energy metabolism during an immune challenge without causing lipolysis or muscle catabolism.

Key Words: cattle, metabolism, yeast

770 Effect of sward condition on metabolic endocrinology during the early postpartum period in primiparous grazing dairy cows and its association with productive and reproductive performance.

A. Meikle*[1], L. Adrien[1], D. Mattiauda[2], and P. Chilibroste[2], [1]*Faculty of Veterinary, Montevideo, Uruguay,* [2]*Faculty of Agronomy, Montevideo, Uruguay.*

The effect of differential sward herbage allowances and a total mixed ration (TMR) management on milk production, body condition, first postpartum ovulation and endocrine/metabolic parameters were investigated. Primiparous dairy cows (n = 44) were randomly assigned to one of the following grazing treatments (n = 11 each): high (HA, 30 kg DM/cow/d), medium (MA, 15 kg DM/cow/d) and low herbage allowance (LA, 5 kg DM/cow/d), and a TMR group fed ad-lib. Non esterified fatty acids (NEFA), β-hydroxybutyrate (BHB), cholesterol, protein, albumin, urea, insulin, insulin-like growth factor-I (IGF-I) and leptin were determined in plasma every 15 d. Progesterone was determined 2 times per week after parturition to determine first ovulation. TMR group had higher milk production than the HA and MA groups which did not differ, which were in turn greater than LA cows. Overall, the TMR and HA groups had a greater BCS, protein, albumin and urea concentrations than MA and LA groups, suggesting a better energy balance. While metabolic differences were observed among HA cows and MA cows early in the pospartum period (15–30 dpp), differences among HA and LA cows were observed later on (45–60 dpp). While IGF-I concentrations increased after calving in all groups, no increases were found in LA group, probably due to the energy restriction due to the nutrients offered. Greater insulin and IGF-I concentrations were found in the TMR group, which is consistent with the higher nutrient density offered to this group. The probability of cyclicity one month after calving was lower in MA cows than TMR and HA cows, which is consistent with the higher NEFA and lower urea concentrations found in this period. The lowest probability of first ovulation throughout the study was observed in LA cows. This study shows that different nutritional treatments affected several metabolites and hormones that reflect the nutritional partitioning toward milk and reproductive processes.

Key Words: dairy, metabolism, endocrinology

771 Association of biomarkers of stress, inflammation, and negative energy balance with milk yield and reproductive performance in Holstein dairy cows.

J. M. Huzzey*[1], D. V. Nydam[2], R. J. Grant[3], and T. R. Overton[1], [1]*Department of Animal Science, Cornell University, Ithaca, NY,* [2]*Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY,* [3]*W. H. Miner Agricultural Research Institute, Chazy, NY.*

The objectives were to evaluate the association between peripartum concentrations of fecal cortisol metabolites (11,17-dioxoandrostane; 11,17-DOA), plasma haptoglobin (Hp), and nonesterified fatty acids (NEFA), and milk yield and reproductive performance. Blood and fecal samples were collected weekly from 412 Holstein dairy cows from wk −3 through wk +1 relative to calving. Pregnancies by 150 DIM and projected 305ME milk yield based on the 3rd DHI test day (102 DIM) were measured. A range of concentration cutpoints were evaluated for each biomarker; associations of these cutpoints with 305ME or risk of conception were assessed using mixed effects or semiparametric proportional hazards models, respectively. Associations between the biomarkers and reproductive performance were strongest for primiparous (PP) cows during wk −1 or +1 relative to calving. Among multiparous (MP) cows, no biomarker measured during wk −1 or +1 was associated with reproductive performance ($P \geq 0.2$). Primiparous cows with Hp >0.4 g/L, 11–17-DOA >2300 ng/g fecal DM, or NEFA >0.40 mEq/L during wk −1 had a 41%, 42%, or 42% decreased risk of conception, respectively ($P \leq 0.05$), compared with PP cows below these cutpoints. Primiparous cows with Hp >1.3 g/L or NEFA >0.45 mEq/L during wk +1 had a 41% or 39% decreased risk of conception, respectively ($P = 0.02$). Associations between Hp and 11,17-DOA with 305ME milk yield were strongest when these analytes were measured during wk +1; however, wk −1 NEFA concentrations were a better predictor of milk yield than wk +1 NEFA. Postpartum Hp >1.1 g/L was associated with 947 kg lower 305ME milk yield for both PP and MP cows ($P = 0.001$). For MP cows only, 11,17-DOA >400 ng/g fecal DM during wk +1 was associated with a 663 kg lower 305ME milk yield ($P = 0.03$). Primiparous and MP cows with NEFA >0.55 mEq/L during wk −1 had a 1360 kg lower projected 305ME milk yield ($P = 0.002$). Biomarkers of stress, inflammation, and negative energy balance around calving can be used to identifying opportunities to improve milk yield and reproductive performance.

Key Words: biomarkers, milk yield, reproduction

772 Serum amyloid A3 (SAA3) mRNA in liver and adipose tissue of dairy cows supplemented with or without conjugated linoleic acids (CLA): A whole lactation cycle study.

B. Saremi*[1], S. Winand[1], J. Pappritz[2], S. Dänicke[2], M. Mielenz[1], M. M. Rahman[1], and H. Sauerwein[1], [1]*Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany,* [2]*Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

Serum amyloid A3 (SAA3) is an acute phase protein (APP) mainly expressed extrahepatically. Bovine adipose tissues (AT) are immune responsive and express SAA3. In monogastrics, CLA have anti-inflammatory and anti-lipolytic effects. We hypothesized that CLA might exert analogous effects in bovine tissues and be related to AT metabolism. Holstein Frisian cows received a CLA (Lutrell pure, BASF, Germany, n = 11) containing 12% each of the *cis*-9, *trans*-11 and the *trans*-10, *cis*-12 CLA isomers or a non-CLA fat supplement (Silafat, BASF, n = 10) from d 1 to 182 in milk. Biopsies were collected from subcutaneous (Sc) AT from tail head and liver tissue at d 21 ante partum (a.p.) and d 1, 21, 70, 105, 182, 196, 224, 252 postpartum (p.p.). SAA3 mRNA abundance (Ab) was measured by real-time PCR in all biopsies, but in the CLA group only on d 21 a.p. and d 21, 105, 196, 252 p.p. Detection of the SAA protein in AT was done by Western blot. Statistical analyses were done using the mixed model or Pearson correlation (SPSS 17; $P < 0.05$). Typical SAA protein bands were obtained from AT. CLA had no effect on SAA3 Ab in liver and ScAT. Liver SAA3 Ab exhibited a peak at the day of parturition (8 fold higher in comparison to the mean of the other d a.p. and p.p.) but remained stable throughout all other times. In ScAT, the day of parturition was significantly different in comparison to 196 and 252 d p.p. (7.7 fold higher SAA3 Ab). Liver and ScAT SAA3 Ab were positively correlated to haptoglobin plasma concentrations and ScAT and liver haptoglobin mRNA (r ranging from 0.30 to 0.62); ScAT SAA3 Ab was positively correlated to plasma NEFA (r = 0.31) (haptoglobin and NEFA from published data). The correlation of ScAT SAA3 Ab with plasma NEFA might be related to the homeorhetic adaptation regarding to the energy requirement during lactation. The peripartal peak of SAA3 in liver and ScAT is comparable to haptoglobin as another APP. The expression of SAA protein in bovine AT is a novel finding though the relevance of individual SAA isomers remains to be clarified.

Key Words: serum amyloid A3 (SAA3), CLA, cow liver and adipose tissue

773 Responses of mammary gland metabolism to long-term manipulated plasma concentrations of insulin and glucose in lactating dairy cows. J. J. Gross,* M. C. M. B. Vernay, L. Kreipe, O. Wellnitz, H. A. van Dorland, and R. M. Bruckmaier, *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.*

The regulation of genes involved in mammary gland metabolism was investigated during manipulated concentrations of insulin and glucose for 48 h. Six mid-lactating dairy cows each were assigned to a hyperinsulinemic hypoglycemic clamp (HypoG), a hyperinsulinemic euglycemic clamp (EuG) and a control treatment (NaCl). Blood samples were collected before and hourly during the infusions for measurements of glucose and insulin. Mammary gland biopsies were taken immediately before and at 48 h of infusion and mRNA abundance of genes involved in the mammary gland metabolism were measured by RT-qPCR with glycerinaldehyde-3-phosphate-dehydrogenase, ubiquitin and cyclophilin as static expressed housekeeping genes. Changes in the measured parameters, and the area under the curve of plasma parameters from 24 to 48 h of infusion were evaluated by ANOVA with the treatment as fixed effect. For HypoG, insulin infusion rate (IIR) was 0.46 ± 0.02 mU/kg/min from 24 to 48 h whereas IIR for EuG was maintained constant at 0.62 mU/kg/min, and the simultaneous glucose infusion rate in EuG was 2.47 ± 0.05 mmol/kg/min. From 24 to 48 h of infusion, HypoG had a lower glucose concentration (2.25 ± 0.05 mmol/L) in comparison to EuG (3.80 ± 0.16 mmol/L) and NaCl (4.17 ± 0.10 mmol/L; $P < 0.05$); HypoG and EuG had higher insulin concentrations than NaCl (41.9 ± 8.1, 57.8 ± 7.8, and 12.2 ± 2.8 mU/L, resp.; $P < 0.05$). In mammary tissue, the mRNA abundance of glucose transporter (GLUT) 4 was decreased in EuG compared with HypoG, and that of αS1-Casein and insulin receptor was decreased compared with HypoG and NaCl, while mRNA abundance of insulin induced gene 1 and UDP-glucose pyrophosphorylase was upregulated compared with NaCl and HypoG ($P < 0.05$), while mRNA abundance of κ-Casein and acetyl-CoA-carboxylase were increased in EuG by trend ($P = 0.06$). No differences between groups were found for mRNA abundance of GLUT1, E74-like factor 5, α-lactalbumin, sterol response element binding factor 1 and fatty acid synthase. In conclusion, most differences in gene expressions of mammary gland metabolism were found between HypoG and EuG indicating the regulatory role of glucose at simultaneously elevated insulin concentrations during an increased glucose turnover.

Key Words: mammary gland, metabolism, dairy cow

774 Tumor necrosis factor-α (TNF-α) mRNA expression in early lactation in different tissues of dairy cows with a focus on different fat depots. B. Saremi*[1], H. Sauerwein[1], D. von Soosten[2], S. Dänicke[2], and M. Mielenz[1], *[1]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

The pro-inflammatory cytokine TNF-α is expressed in different cell types, mainly in stimulated monocytes and macrophages. In humans, TNF-α is involved in inflammation, apoptosis, insulin sensitivity, and induction of lipolysis. The *trans*-10, *cis*-12 isomer of conjugated linoleic acids (CLA) attenuates the release of TNF-α from bovine immune cells. Therefore, we investigated possible changes of TNF-α mRNA abundance (Ab) in tissues of dairy cows in postpartum (p.p.), considering effects of CLA. From 25 heifers, 5 were slaughtered on d 1 p.p. and remaining heifers were randomly allocated to conjugated linoleic acids (CLA) (Lutrell pure, BASF, Germany, n = 10) or control fat supplementation without CLA (Silafat, BASF, n = 10) each at 100 g/d. Five animals per group were slaughtered at d 42 or 105. Subcutaneous (Sc) (sternum, withers and tail head) and visceral adipose tissue (VcAT: mesenterial, omental and retroperitoneal), liver, mammary gland and muscle tissues were sampled. Quantification of TNF-α was done by qPCR. Fat mass and NEFA were adopted from published data on the same cows. Pearson correlation, GLM or non parametric tests were used for statistical analysis (SPSS 17; $P < 0.05$). From 1 to 105 d p.p. TNF-α Ab increased in ScAT and liver and decreased in mammary gland and retroperitoneal AT (from d 1 and 42 to 105 p.p.). In omental and mesenterial AT as well as in muscle, TNF-α Ab was stably expressed. Abundance of TNF-α mRNA was not affected by CLA except at d 42 in mesenterial AT (lower Ab in the CLA group). Liver, mammary gland and muscle TNF-α Ab was 5.3, 2.5 higher and 4.4 fold lower than that in AT. Within AT, Sc sternum and omental had the highest and mesenterial and retroperitoneal had the lowest TNF-α Ab. In contrast to AT, liver TNF-α Ab was correlated negatively to fat mass and positively to blood NEFA. As in humans, TNF-α in cattle might be linked to fat mobilization. Differential expression of TNF-α throughout lactation could be associated to paracrine mechanisms related to insulin sensitivity in the analyzed tissues.

Key Words: TNF-α, liver and fat tissues, dairy cattle

Production, Management and the Environment: Environmental Quality

775 Evaluation of a feeding strategy to reduce greenhouse gas emissions from milk production: The level of analysis matters. C. E. Van Middelaar*[1], P. B. M. Berentsen[2], J. Dijkstra[3], and I. J. M. De Boer[1], [1]*Animal Production Systems Group, Wageningen University, Wageningen, the Netherlands,* [2]*Business Economics Group, Wageningen University, Wageningen, the Netherlands,* [3]*Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands.*

The dairy sector contributes to climate change through emission of greenhouse gases (GHGs): carbon dioxide (CO2), methane (CH4), and nitrous oxide (N2O). From an animal perspective, a feeding strategy with high potential to reduce enteric CH4 emission is replacing grass silage by corn silage. Increasing corn silage in the ration, however, affects the farm plan (e.g., plowing grassland for corn cropping; type of concentrate), and consequently GHG emissions along the milk production chain. The level of analysis, therefore, can affect results and conclusions. This study evaluated effects of replacing grass silage by corn silage on GHG emissions, at 3 interdependent hierarchical levels; that is, the animal, farm, and chain level. Linear programming (economic optimization), mechanistic modeling of enteric fermentation, and life cycle assessment were combined to define an economically optimal basis farm (based on an average Dutch dairy farm) and to evaluate GHG emissions at animal, farm, and chain level. Subsequently, starting from the optimal ration, corn silage was fixed at a 1 kg dry matter (DM) higher level per dairy cow per day at the expense of grass silage, and the model was used again to determine the new optimal farm plan for the farm with this strategy, and to compare GHGs emitted with the basis farm. The basis farm has 35 ha of land and a fat- and protein corrected milk (FPCM) production of 8425 kg per cow per year. Per ton FPCM, replacing grass silage by corn silage resulted in an annual emission reduction of 11.2 kg CO2-e at animal level, 13.4 kg CO2-e at farm level, and 17.6 kg CO2-e at chain level. At farm and chain level, however, land use change (i.e., plowing grassland for corn cropping) resulted in non-recurrent CO2 and N2O emissions of 845 kg CO2-e per ton FPCM. From an animal perspective, therefore, this feeding strategy offers potential to reduce GHG emissions, whereas from a chain perspective it takes up to 47 years before annual emission reductions compensate for emissions related to land use change.

Key Words: dairy farming, greenhouse gas emission, feeding strategy

776 Are high production, low GHG emission dairy farms in New Zealand possible? R. E. Vibart*[1], T. White[2], D. Smeaton[3], S. Dennis[4], R. Dynes[4], and M. Brown[1], [1]*AgResearch Limited, Grasslands Research Centre, Palmerston North, New Zealand,* [2]*AgResearch Limited, Ruakura Research Centre, Hamilton, New Zealand,* [3]*DairyNZ, Hamilton, New Zealand,* [4]*AgResearch Limited, Lincoln Research Centre, Christchurch, New Zealand.*

Dairy farming in New Zealand (NZ) is under increasing scrutiny due to growing environmental concerns. Considerable investments have been made in the search for sustainable land management options and opportunities for mitigation of greenhouse gas (GHG) emissions and nutrient losses. High production, low emission systems are hard to run, but a small number of farmers are currently doing this. The objective of this study was to identify and examine dairy farms that were highly productive and profitable while maintaining reduced GHG emissions; these systems needed to carry reduced stock numbers (i.e., less than 3.3 cows/ha). Two suitable farms in the Waikato region and 2 in the Southland region were identified. The whole-farm system models FARMAX and OVERSEER were used to examine feed flow and nutrient balances, as well as profitability, of these systems. Although differing in size, all farms tended to be reliant on homegrown feeds for most of their needs; imported feed ranged from 2.2 to 9.7% of feed consumed. Stocking rates ranged from 2.5 to 3.3 cows/ha, annual production ranged from 377 to 464 kg milksolids (MS)/cow, and operating profits ranged from 1600 to 2350 NZD/ha. Wintering policies (i.e., the use of an off-farm block of land for dry cow wintering and young stock) differed between regions; the Waikato farms used these blocks only for young stock whereas the Southland farms used them for young stock and dry cows. Despite these differences, emissions intensity ranged from 8.4 to 9.6 kg CO_2-e/kg MS, thus below the average NZ farm range (11 - 13 kg CO_2-e/kg MS). Lower emissions intensity farms tended to be more profitable and achieve greater feed conversion efficiencies (kg MS/kg DM consumed). Although low stocked dairying often requires a high level of managerial skill to be successful, these systems were associated with low emission levels and highly competitive farm profitability. These farms are commercial working examples of the opportunities for highly profitable, emission efficient farms.

Key Words: dairy, livestock emissions, profitability

777 Impact of animal density on predicted greenhouse gas emission from selected conventional, organic and grazing dairy farms in Wisconsin. M. Dutreuil*[1], V. E. Cabrera[1], R. Gildersleeve[2], C. A. Hardie[1], and M. Wattiaux[1], [1]*University of Wisconsin-Madison, Madison,* [2]*University of Wisconsin Extension, Dodgeville.*

Our objective was to test the effect of animal density (AD) on predicted greenhouse gas emission (PGE) from 3 Wisconsin farms with contrasting management systems. A combination of farm data and model-based predictions, using the Integrated Farm System Model, was used to derive PGE on 1 conventional (C), 1 organic (O) and 1 grazing (G) farm at 2 AD. The farms had a herd size of about 80 cows, 133 ha of forage land, and 0.6 cows/ha. At this low AD (LAD), the PGE were 0.53, 0.70 and 0.77 kg of PGE (CO2eq)/kg of milk for the C, O and G respectively and the main source of PGE was from housing facilities (47, 39, and 31% of total PGE on C, O and G, respectively). The indirect emission sources (manufacture or production of fuel, electricity, machinery, fertilizer, pesticides, and plastic) accounted for 21, 12, and 30% of PGE on C, O and G, respectively. Other important PGE sources at LAD were feed production on C (19%), and grazing on O and G (35 and 14%, respectively). Doubling the AD (HAD, 1.2 cows/ha of forage land) increased PGE by 22.9% on C, mainly due to 48% increase from indirect sources. The emissions from feed production and indirect sources increased by 38 and 29%, respectively on O, but the emission from grazing and housing facilities decreased by 5 and 1.3%, respectively, which led to a 6.4% net increase. Finally, PGE decreased by 3.1% on G as the net result of a decrease in emissions from manure storage and fuel consumption (41 and 20%, respectively) but 8% increase in indirect sources. These results demonstrated that the effect of AD on PGE was different on the 3 selected farms because of different farm management practices such as feeding, manure storage, and housing facilities. Although increasing AD might have a beneficial effect in reducing PGE per unit of milk on the selected G farm, results predicted a slight negative effect in the O farm and a more substantial negative effect on the C farm. Although the scope of the study is limited to the 3 selected farms, combining farm data with model-based predictions may be useful to study the changes in farm-level management practices on PGE.

Key Words: greenhouse gas, Integrated Farm System Model (IFSM), animal density

778 Life-cycle assessment of greenhouse gas emissions from dairy production in eastern Canada: A case study.

E. J. Mc Geough,* S. M. Little, H. H. Janzen, T. A. McAllister, S. M. McGinn, and K. A. Beauchemin, *Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada.*

The objective of this study was to conduct a life-cycle assessment (LCA) of greenhouse gas (GHG) emissions from a typical non-grazing dairy production system in eastern Canada. Additionally, as dairying generates both milk and meat, this study assessed methods of allocating emissions between these co-products. The LCA was conducted over 6 yr for a simulated farm in the province of Quebec. The assessment considered 65 female Holstein calves, of which 60 heifers survived to first calving at 27 mo of age. These animals were subsequently retained for an average of 2.75 lactations. Progeny were also included in the analysis, with bulls and heifers in excess of replacement requirements finished as grain-fed veal (270 kg) at 6.5 mo of age. Cattle were housed indoors, and fed forages and grains produced on the same farm. Pre-farm gate GHG emissions and removals were quantified using Holos, a whole-farm model developed by Agriculture and Agri-Food Canada and based on the IPCC Tier 2 methodologies, with modifications for Canadian conditions. The LCA yielded a GHG intensity of 0.91 kg CO_2e/kg fat and protein corrected milk yield. Methane accounted for 56% of the total emissions, of which 86% originated from enteric fermentation. Nitrous oxide accounted for 40% of total GHG emissions. Lactating cows contributed 64% of the total GHG emissions while cattle under 1 yr contributed 10%, with the veal calves accounting for 3% of this figure. Allocation of GHG emissions between meat and milk were assessed as: a) no allocation, b) economics, c) dairy vs veal animal, and d) International Dairy Federation (IDF) equation using feed energy demand for meat and milk production. Comparing emissions from dairy vs veal calves resulted in 97% of the emissions allocated to milk. The lowest allocation of emissions to milk (78%) was associated with the IDF equation. This LCA showed that the greatest reductions in GHG emissions would be achieved by applying mitigation strategies to the lactating cow, with minimal reductions being achievable in young stock. Choice of co-product allocation method can also significantly impact the relative allocation of GHG emissions to milk and meat.

Key Words: life cycle assessment, dairying, eastern Canada

779 Effects of saponin extracts, in the diet of Holstein steers or added directly to their manure, on gaseous emissions from that manure.

W. Li* and W. Powers, *Michigan State University, East Lansing.*

A series of experiments (Exp) were conducted to investigate the effects of saponin extracts, in the diet of Holstein steers or added directly to their manure, on gaseous emissions from that manure. Saponin extracts added to the feed or manure were from *Quillaja saponaria* (quillaja saponin), *Yucca schidigera* (yucca saponin) and *Camellia sinensis* (tea saponin). During Exp 1, manure from Holstein steers fed corn and corn silage based control diet (C1) was compared with manure from steers fed control diets plus 1.5% quillaja (QS) or 0.64% yucca (YS) saponins. In Exp 2, the effect of direct application of 2% yucca (CYS, wet basis) or quillaja saponin (CQS, wet basis) to manure collected from steers fed corn and corn silage based diet (C2) on manure air emissions was investigated. In Exp 3 the effects of dietary tea saponin supplementation (TS, 0.25% DM) and direct addition (CTS, 2% wet basis) to manure collected from steers fed corn and corn-silage based diet (C3) on manure air emissions were compared in the same experiment. Gaseous emissions methane (CH_4), ammonia (NH_3), hydrogen sulfide (H_2S), nitrous oxide (N_2O) and non-methane total hydrocarbons (NMTHC) were reported. When saponin extracts were fed, daily manure CH_4 emission mass was different among treatments ($P < 0.01$; 40.97, 58.12, and 71.49 mg/d, for YS, C1, and QS, respectively). Feeding YS resulted in less ($P < 0.01$) daily manure NH_3 emission mass than C1 and QS (318.18 vs. 391.62 and 365.54 mg/d, respectively). Daily manure H2S emission mass differed ($P < 0.01$) among dietary treatments (10.63, 15.16 and 21.10 mg/d for YS, C1, and QS respectively). In Exp 2 the addition of saponin extracts directly to manure did not affect any gaseous emissions measured. Average daily emission mass of CH_4, NH_3 and H_2S was 11.92 mg/d, 424.25 mg/d and 19.36 mg/d, respectively. Overall, the results of these experiments indicate that manure-derived gaseous emissions are altered by dietary inclusion of saponins rather than by direct application to manure.

Key Words: saponin extracts, air emissions, manure

780 Effect of manure source on ammonia emission on first day of application.

F. Sun*[1], J. H. Harrison[1], E. Whitefield[1], P. Ndegwa[2], and H. S. Joo[2], [1]*Washington State University, Puyallup,* [2]*Washington State University, Pullman.*

Three sources of manure were evaluated for their effect on ammonia emission on day of application. Dairy slurry (DS) with large particle solids, dairy slurry with large particle solids removed (DSSR: 0.4 cm diameter × 0.7 cm on center screen), and anaerobically digested manure with large particle solids removed (ADSR) were applied to grass plots in 2010 and 2011. The DS and AD manures were applied to 1m x 1 m grass plots in replicate on 5 occasions in 2010 and 2011. The DSSR manure was applied on 4 occasions to 1 m × 1 m plots in 2011. Measurements of ammonia were obtained at hourly intervals from the air space inside a PVC cap dome (10 cm diameter × 10 cm height) to determine relative loss of ammonia from each manure source. Replicate domes were placed on each plot at hourly intervals for 6 to 10 min and then the concentration of ammonia was obtained in real time with a GasAlert hand-held meter with automated air pump. The day of application ammonia concentration for the combined years of 2010 and 2011 were different ($P < 0.05$): DS, 7.3 ppm, and ADSR, 5.4 ppm. Peak ammonia for the combined years of 2010 and 2011 ranged from 16.4 and 16.9 and was not different due to manure source. When DS, DSSR, and ADSR manure sources were compared in 2011, manure source significantly ($P < 0.05$) affected ammonia concentration with concentrations of DS — 11.0 ppm, DSSR, 8.8 ppm, and ADSR, 5.5 ppm, with all means different from each other. Peak ammonia was greatest ($P < 0.05$) for DS (24.9 ppm), with DSSR (19.3 ppm) and ADSR (17.5 ppm) the lowest, and not different from each other. Data indicated that the effect of anaerobic digestion and amount of solids impact the loss of ammonia from manure on the day of application.

Key Words: manure, ammonia

781 Partitioning of solids, nitrogen, and phosphorus in solids and liquid fractions of anaerobically digested dairy effluent.

J. H. Harrison*[1], E. Whitefield[1], and A. Werkhoven[2], [1]*Washington State University, Puyallup,* [2]*Werkhoven Dairy, Monroe, WA.*

Data on the partition of solids, nitrogen, and phosphorus were collected at a commercial dairy that anaerobically digested (AD) manure (70% of

volume) and pre-consumer food wastes (30% of volume). Daily input into the AD averaged ~60,000 g/d as dairy manure and 30,000 g/d as pre-consumer food wastes (ruminant blood, egg waste, whey, fish stick byproduct, paper pulp waste, grease trap waste). The AD was a modified plug-flow design, operating under mesophilic conditions (23.5°C), with a 17 d retention time, and storage capacity of ~6,100,000 l. Data on flow of post AD effluent and solids were obtained by in-line flow meter (Siemens Magflo MAG 5000) and a stationary mixer wagon (NDE vertical feed mixer), respectively. Anaerobically digested effluent was ~3% solids. In 2008, data were collected when an Eys screw press liquid-solids separator was utilized. In 2011, data were collected when a DT 360 (Daritech) liquid-solids separator was utilized. Solids, nitrogen, and phosphorus separation from the effluent into solids was, mean and (standard deviation): Eys — solids 74% (8.5), nitrogen 13% (5.5), and phosphorus 21% (8.0): DT 360 — solids 21% (8.2), nitrogen 1.6% (0.63), and phosphorus 2.4% (0.97). Mean differences were observed for large particle solids removal from the AD dairy effluent. The majority of the nitrogen and phosphorus remained with the AD effluent after liquid-solids separation.

Key Words: anaerobically digested manure, solids, nitrogen

782 Inoculant volume of a mixed culture of rumen microorganisms on rate and extent of methanogenesis from processed dairy excrement for biofuel production by anaerobic digestion.

C. L. Ross,* K. C. Das, and M. A. Froetschel, *University of Georgia, Athens.*

The major limitation with anaerobic digestion of dairy waste is related to its initial rate of microbial activity and its concentration of volatile organic compounds as substrate for methanogenesis. Inoculating batch anaerobic digesters of dairy excrement with a viable mixed culture of rumen fluid at 30% of digester volume resulted in a several fold increase in methane production as compared with a non-viable (heat-killed) control. Practical application requires that a lower volume of inoculant be established. In vitro batch culture fermentations were conducted to test lower volumes of inoculant and different extracts of dairy excrement in a 3-way factorial designed experiment. Batch cultures with water extracts of fresh dairy excrement or liquid from a solid separator as substrate were inoculated with levels A (1%), B (5%), or C (10%) viable rumen fluid (V/V). Fermentations were conducted in duplicate along with representative blanks of each type of waste extraction and inoculation level. Fermentations were maintained for 0, 2, 4, 7, 9, 12, 14, and 16 d periods. Gas production, CO_2 and CH_4 concentrations, pH, free-ammonia, dry matter digestion, volatile fatty acid production, and gross energy digestion were measured. CH_4 volume averaged 11.4mL for B and 10.9mL for C inoculations, an increase of 176% and 175%, respectively, compared with inoculation A ($P < 0.01$). Differences in gas production were observed between the waste substrates as well. Liquid waste from a solid separator had 24% greater concentration of CH_4 than a fresh waste extract ($P < 0.01$), but total gas and CH_4 volume were 180% and 128% higher from fresh waste extract ($P < 0.01$). As the duration of fermentation was extended from 0 to 16 d the CH_4 volume increased by 200% ($P < 0.01$). Lower levels of viable rumen fluid are effective for inoculating dairy waste for bio-fuel production but require a longer fermentation.

Key Words: methane, anaerobic digestion, microbial inoculation

783 Effects of inorganic versus organic copper on nitrous oxide reductase activity in peat soil.

Q. Wang,* M. Burger, A. Castillo, W. Horwath, and F. Mitloehner, *University of California-Davis, Davis.*

Nitrous oxide (N_2O) is a potent greenhouse gas that contributes to global warming and stratospheric ozone destruction. Animal production emits approximately 1.5 Tg of N_2O annually and 51% of these emissions are associated with manure incorporation into soil. Nitrous oxide is mainly produced through the denitrification pathway. Nitrous oxide reductase (N_2OR) is the enzyme responsible for the reduction of N_2O to N_2 during denitrification. Nitrous oxide reductase uses copper (Cu) as its cofactor and its activity is compromised under conditions of Cu deficiency. The present study investigated organic (ORG) versus inorganic (INO) Cu at various concentrations (750, 550, 125, and 60 ug Cu/g soil) applied to soil, respectively, for their efficacy in affecting N_2OR activity. A control treatment (CON) containing soil and water, without added Cu, was also evaluated. The INO and ORG Cu treatments were dissolved in water and added to soil with low existing Cu concentrations in incubation vials. Treatment vials were anaerobically incubated to favor denitrification over a 24 h period. Gas samples were collected from the incubation vials every 8 h and analyzed for N_2O and N_2 concentrations, which were utilized to estimate N_2OR activity. The INO Cu versus CON did not affect N_2OR activity among different concentrations (0.11, 0.10, 0.04, 0.19, and 0.80 ug N_2O/g soil/h for INO 750, 550, 125, 60, and CON treatments, respectively) over sampling time ($P > 0.05$). However, N_2OR activity was higher for all ORG Cu treatments versus CON (11.42, 12.57, 2.67, 2.12, and 0.80 ug N_2O/g soil/h for ORG 750, 550, 125, 60, and CON, respectively) over the sampling time ($P < 0.05$), especially at the increasing Cu concentrations. These results highlight the importance of Cu form and concentration on N_2OR activity. Optimization of N_2OR activity could potentially decrease N_2O emissions associated with manure management in livestock production.

Key Words: organic Cu, inorganic Cu, nitrous oxide reductase

784 Nutrient removal with harvest of soybean forage and soybean seed produced with and without irrigation of dilute swine manure lagoon effluent.

A. F. Harper,* D. L. Holshouser, C. D. Teutsch, and M. J. Estienne, *Virginia Polytechnic Institute and State University, Blacksburg.*

Nutrient management plans dictate the quantity of swine lagoon effluent and other manures applied to agricultural fields. Within a nutrient management plan, nutrient removal through crop harvest affects capacity for subsequent effluent application. A trial was conducted to compare nutrient removal with production of a forage-type soybean cultivar (soyF; Large Lad, Eagle Seed, Weiner, AR) harvested as forage and a standard cultivar (soyS; USG74A91, UniSouth Genetics, Dickson, TN) harvested as seed when produced with or without irrigation using dilute swine lagoon effluent. Twelve plots of 0.072 ha each planted on May 12, 2010, comprised 3 replications of the following treatments: 1) soyF non-irrigated, 2) soyF irrigated, 3) soyS non-irrigated, and 4) soyS irrigated. The irrigated plots received 6 applications of 2.84, 3.10, 2.54, 2.74, 4.52, 2.13 cm of effluent (0.005–0.022% N, 0.01–0.015% P, 0.02–0.03% K) via sprinkler irrigation from June 30 through August 8, when irrigation was terminated due to depleted effluent volume. Applications coincided with a drought season with mean rainfall of 2.11, 2.57 and 5.18 cm for June, July and August, respectively. The soyF plots were harvested with a plot forage harvester on August 12 and the soyS plots with a plot combine on October 19. Individual treatment means ± SEM (kg/ha) were: DM yield 4302, 8581, 1548, 2572 ± 664; N removal 116.9, 252.8, 95.8, 162.0, ± 20.8; P removal 14.2, 35.5, 10.3, 17.9 ± 2.8; K removal 114.8, 314.8, 34.1, 59.9 ± 22.9 for soyF non-irrigated, soyF irrigated, soyS non-irrigated and soyS irrigated treatments, respectively. There were crop-type by irrigation application interactions ($P < 0.05$) for DM yield, P removal and K removal with these responses being more pronounced when irrigation was applied to soyF than when applied to soyS. As expected more nutrients were removed with soyF than with

soyS harvest. However, under the conditions of this trial, crop removal of certain elements that influence nutrient management plans and effluent application rate were more responsive to effluent irrigation in soyF than in soyS production.

Key Words: effluent, soybean, nutrient removal

785 Effect of fibrous diets and inclusion level on the chemical composition and odors from pig slurry.

C. T. Mpendulo* and M. Chimonyo, *Animal and Poultry Science, College of Agriculture, Engineering and Science, University of KwaZulu-Natal, Pietermaritzburg, South Africa.*

Incorporation of high fiber ingredients into pig rations has the potential to reduce pollutants emitted from pig slurry tanks. A study was conducted to test whether diets containing 0, 80 and 160 g/kg of alfalfa hay, sunflower hulls or corn cobs influence the characteristics and odors from pig slurries. A total of 14 pigs weighing an average of 36 kg were kept in individual cages to allow the total collection of feces and urine. All pigs were fed ad libitum. Feces and urine were mixed in a 1:2.3 ratio (wt/wt), stored and fermented for 16 d in a temperature controlled room at 22 to 24 C. The slurry was sampled twice (on d 1 and on d 16) of the fermentation period and analyzed for pH, short chain fatty acids, chemical oxygen demand (COD) and nitrogen on a wet basis. All samples were tested for odor offensiveness using 18 trained panelists from the University of KwaZulu-Natal. A scale of 1 to 5 was used to rank the odor severity, where 1 = not offensive, 2 = mildly offensive, 3 = moderately offensive, 4 = strongly offensive and 5 = extremely offensive. Slurry pH and COD varied with fiber source ($P < 0.05$). After d 16, the COD for alfalfa hay, sunflower hulls and corn cobs were 369, 512 and 425 ± 34.2 mg of oxygen per liter. There was a significant interaction of fiber inclusion level and incubation period on COD and SCFA concentrations. Total SCFA concentration was higher at d 16 than d 1 ($P < 0.05$). Odor offensiveness varied due to fiber source ($P < 0.05$). Sunflower hulls and alfalfa diets were rated as less offensive (mean rank = 2.2) than corn cob diets (mean rank of 4.3). For all fiber sources, no differences ($P > 0.05$) were found between 80 and 160 g/kg. It was concluded that characteristics of pig slurries were influenced by fiber source and inclusion levels. The offensive odor from corn cobs suggests its considerable digestibility. More work still needs to be done to characterize other compounds from a large variety of locally available fiber sources that reduce water and air pollution from pig enterprises.

Key Words: short-chain fatty acids, slurry characteristics, odor offensiveness

Ruminant Nutrition: Beef Co-Products

786 Performance by feedlot cattle fed varying proportions and amounts of lime treated crop residues and distillers grains as substitutes for corn grain. A. L. Shreck*[1], C. J. Schneider[1], B. L. Nuttelman[1], D. B. Burken[1], G. E. Erickson[1], T. J. Klopfenstein[1], and M. J. Cecava[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]Archer Daniels Midland, Decatur, IL.*

The objective of this experiment was to displace graded amounts of dry-rolled corn (DRC) with varying ratios of distillers grains and lime-treated crop residues (DGCR). Linear and quadratic effects of DRC displacement within ratio of DGCR were tested. Sixty individually fed steers (Initial BW: 402 ± 31.3 kg) were assigned randomly to 10 treatments (6 steers/ treatment) and blocked (20 steers/block) based on initial BW. Treatments were 2 ratios of DGCR, 2 types of treated crop residue, and 3 DRC concentrations in the diet (10%, 25%, 40%; DM basis). The DGCR replaced corn and consisted of 2:1 or 3:1 ratios of modified distillers grains plus solubles (MDGS) and treated corn stover or a 3:1 ratio of MDGS and treated wheat straw. The control diet contained 35% MDGS, 5% untreated corn stover, and 56% DRC. All diets contained 4% supplement. Corn stover and wheat straw were ground (76 mm screen) and treated with 5% CaO (DM basis) at 50% DM and stored anaerobically. Increasing DRC quadratically increased ($P = 0.06$) DMI within the 3:1 straw diets. When comparing 3:1 treated stover and straw, DMI tended ($P = 0.10$) to interact across corn amount with DMI decreasing for treated stover and increasing for treated straw with increasing corn level. Carcass adjusted final BW tended ($P = 0.10$) to quadratically increase and G:F ($P = 0.06$) quadratically increased as corn amount increased in 3:1 stover diets. Increasing corn amount increased ($P = 0.07$) G:F in treated stover diets, regardless of ratio. Increasing corn level tended to increase ($P = 0.10$) ADG and increased ($P = 0.01$) 12th rib fat for 3:1 ratios. Cattle fed diets containing at least 25% corn and 3:1 ratios of distillers grains and lime-treated crop residues can achieve similar efficiency and carcass merit compared with cattle fed diets containing 5% roughage and 56% corn.

Key Words: alkaline treatment, corn, grain replacement

787 Comparing wet and dry distillers grains plus solubles for yearling finishing cattle. B. L. Nuttelman,* D. B. Burken, C. J. Schneider, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska-Lincoln, Lincoln.*

A finishing trial was conducted to compare the effects of drying distillers grains plus solubles (DGS) produced from the dry milling process. Yearling, crossbred steers (n = 171; 362 ± 30 kg) were utilized in a randomized complete block design, stratified within block, and then randomly assigned to one of 21 pens (8 or 9 steers/pen). Pens were assigned randomly to one of 3 treatments (7 replications/treatment) that consisted of: 1) corn-based control (CON); 2) wet distillers grains plus solubles (WDGS, 34.6% DM); and dried distillers grains plus solubles (DDGS, 88.2% DM). Distillers grains plus solubles were included at 35% of the diet DM and replaced a 1:1 blend (DM basis) of high-moisture and dry-rolled corn which was the same blend in CON. Grass hay and dry supplement were included at 7.5% and 5.0% of diet (DM), respectively in all diets. Additional fat was not added to CON, and therefore diets including DGS contained more fat than CON. All diets were formulated to contain a minimum of 13% CP. Steers were fed for 148 d. Final BW for WDGS and DDGS (679 and 675 kg, respectively) was greater than CON (646 kg; $P < 0.01$). Daily gain increased 0.23 and 0.20 kg/d for WDGS and DDGS, respectively when compared with CON (2.11, 2.08, and 1.88 kg, respectively; $P < 0.01$). Dry matter intake was not different ($P = 0.33$) between CON, WDGS, and DDGS (12.9, 13.1, and 13.3 kg/d, respectively). Cattle fed WDGS had greater G:F than DDGS and CON steers (0.162, 0.157, and 0.146, respectively; $P < 0.01$), and DDGS steers were more efficient than CON (i > $P < 0.01$). Cattle fed either distillers grains gained more, and thus had heavier HCW ($P < 0.01$). There were no differences for 12th rib fat, marbling score, or LM area ($P > 0.09$). Using G:F values, a 31.3 and 21.5% improvement above CON was calculated for WDGS and DDGS at 35% inclusion, respectively. Using the same calculations, WDGS was determined to have a 9.1% greater feeding value than DDGS. Similar to previous work, feeding DGS improves gain and efficiency compared with corn based diets, and WDGS has greater energy than DDGS.

Key Words: distillers grains, energy value, finishing cattle

788 Performance of cattle fed diets based on blended by-product pellets varying in rumen available energy and protein content. M. G. Zenobi*[1], P. Yu[1], D. A. Christensen[1], P. G. Jefferson[1,2], H. A. Lardner[1,2], and J. J. McKinnon[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Western Beef Development Centre, Humboldt, SK, Canada.*

Two trials were conducted to evaluate the performance of growing cattle fed blended by-product pellets. Pellets were based on by-products from the oilseed and grain sectors and were formulated to be isonitrogenous (17.0% CP) and isocaloric (1.92 and 1.28 Mcal/kg NE_m and NE_g, respectively). In trial 1, 4 pellets were evaluated. The pellets were formulated to be either high starch (HS 45% DM basis) or high fat (HF 8.8% DM basis) and either low or high in soluble protein (LSP 27% of CP; HSP 37% of CP DM basis). In trial 2, only the 2 HF pellets were evaluated. In trial 1, 300 cross-bred steers (320 ± 19.6 kg, mean ± SD) were randomly assigned to one of 25 pens and fed one of 5 diets in a completely randomized block design. The control diet consisted of 46.9% forage and 53.1% barley-based concentrate. The 4 treatment diets consisted of 48.4% forage and 51.6% blended pellets (DM basis). All diets were formulated to 1.63 and 1.02 Mcal/kg NE_m and NE_g, respectively (DM basis). In trial 2, 180 cross-bred steers (326 ± 0.2 kg) were randomly assigned to one of 15 pens with each pen randomly assigned to one of 3 treatments in a completely randomized design. Treatments included a barley-based control and the 2 HF pellets from trial 1. In trial 1, no ($P = 0.36$) effect of treatment was observed on ADG, however, DMI was reduced ($P \leq 0.01$) with the HS LSP treatment and was highest ($P \leq 0.01$) for the HF HSP treatment. Gain:feed (G:F) was poorest ($P \leq 0.01$) for the HF HSP diet. In Trial 2, no effect of treatment was observed on ADG ($P = 0.80$) or DMI ($P = 0.06$), however cattle fed the barley-based control diet had the highest ($P \leq 0.01$) G:F ratio. Relative to the control diet, the calculated NE_g content (Mcal/kg DM) was 8.7% lower ($P \leq 0.01$) for the HF HSP treatment in trial 1 and 6.7% lower ($P \leq 0.01$) for both HF treatments in trial 2. The results indicate that blended by-product pellets can be a viable alternative for supplementing energy and protein in backgrounding diets. Caution needs to be exercised when feeding HF pellets due to poorer G:F ratios and potential negative impacts on cost of gain.

Key Words: blended by-product pellets, fat, growing cattle

789 Replacement of grazed forage and animal performance with distillers grains supplementation in a forage system.

K. L. Gillespie,* T. J. Klopfenstein, B. L. Nuttelman, C. J. Schneider, J. D. Volesky, and G. E. Erickson, *University of Nebraska, Lincoln.*

A beef systems study was conducted to determine optimal time within a forage system to supplement distillers grains, and feedlot performance relationship to supplementation. A completely randomized design with a 2 × 2 factorial arrangement was used. Spayed heifer calves (n = 203, BW = 205 ± 23 kg) grazed corn residue 138 d and bromegrass 29 d (WTR), native Sandhills range 128 d (SMR), and were finished on a common diet. Factorial treatments were 0.91-kg DM wet distillers grains with solubles (WDGS) (LO) or 2.3-kg DM WDGS (HI) supplement on corn residue, and modified distillers grains with solubles (MDGS) fed at 0.6% BW daily (SUP) or no MDGS (NO) during SMR. Available SMR grazing acres for SUP were 17% less than NO based on past research. Winter ADG was greater for HI cattle at 0.62 kg than LO at 0.31 kg ($P < 0.01$). Summer SUP ADG at 0.82 kg was greater than NO at 0.58 kg ($P < 0.01$). System gains included total WTR and SMR gains and were greatest among treatments for HI, SUP at 0.66 kg ($P < 0.01$). HI, NO and LO, SUP had a greater system ADG than LO, NO ($P < 0.01$). There were no differences in system ADG of HI, NO at 0.59 kg and LO, SUP at 0.57 kg ($P = 0.09$). Of all treatments, LO, NO had the lowest system gain at 0.47 kg ($P < 0.01$). There was no system gain interaction between WTR and SMR treatments ($P = 0.14$). Factorial treatments were maintained through finishing with 2 replications per treatment. Cattle were serially slaughtered and performance data adjusted to 1.32 cm BF. With SMR supplementation, feedlot ADG decreased ($P = 0.02$). Feedlot ADG for HI, NO and LO, NO were 1.8 kg and 1.7 kg, respectively, and for HI, SUP and LO, SUP were 1.6 kg and 1.5 kg, respectively. There were no significant DMI treatment differences. Summer SUP decreased G:F ($P = 0.005$) with HI, NO and LO, NO at 0.144 and 0.140, respectively, and HI, SUP and LO, SUP at 0.132 and 0.128, respectively. Higher WTR supplementation positively affected HCW ($P = 0.004$) with HI, NO and HI, SUP at 382.3 kg and 369.0 kg, respectively, and LO, SUP and LO, NO at 355.3 kg and 350.8 kg, respectively. Gains increased with higher WTR WDGS level and SMR MDGS supplementation, due to additional energy or undegradable intake protein supplied. System gains were highest for HI, SUP, intermediate for HI, NO and LO, SUP, and lowest for LO, NO. Winter supplementation increased HCW, and SMR supplementation decreased feedlot ADG and G:F, and no winter by summer treatment interactions were observed.

Key Words: beef cattle, distillers, supplement

790 Flint corn grain processing and increasing levels of citrus pulp in finishing diets for Nellore bulls.

V. N. Gouvea[1], L. J. Chagas[1], J. Souza[1], F. Batistel[1], C. Sitta[1], P. R. B. Campanili[1], D. B. Galvani[2], and F. A. P. Santos*[1], [1]*University of São Paulo, Piracicaba, SP, Brazil,* [2]*EMBRAPA Goats and Sheep, Sobral, CE, Brazil.*

The effects of flint corn processing (steam flaking, 310g/l vs. grinding, 1.3 mm GMD) and the partial replacement of corn with citrus pulp (0, 25, 50 or 75%) in feedlot diets were evaluated. A total of 216 Nellore bulls (IBW 350 kg) were allotted to 40 pens and used in a randomized complete block design with a 2 × 4 factorial arrangement of treatments (SF100:CIT0; SF75:CIT25; SF50:CIT50; SF25:CIT75; GC100:CIT0; GC75:CIT25; GC50:CIT50; GC25:CIT75) for 103 d. The diets contained (% DM) 12% sugar cane bagasse and 88% concentrate. Data were analyzed using mixed procedure of SAS with pens as experimental units. For DMI, ADG, G/F and observed NE_g the effects of grain processing, the effects of citrus pulp inclusion in the diets and interactions were significant ($P < 0.01$). All the diets containing SFC presented less DMI than the GC75:CIT25 and the GC50:CIT50 diets. Citrus pulp had no effect on DMI of the SFC diets, however it increased DMI when it replaced up to 50% of the GC ($P < 0.01$). Inclusion of CIT decreased ADG in the SFC diets (1.80; 1.52; 1.70; 1.58 kg/head) and it increased ADG in the GC diets (1.60; 1.74; 1.85; 1.70 kg/head). The greatest G/F was observed for Nellore cattle fed the SF100:CIT0 diet followed by the SF50:CIT50 diet. Inclusion of citrus pulp decreased G/F of cattle fed SFC (0.222; 0.190; 0.200; 0.184) and had no effect for cattle fed GC diets (0.180; 0.176; 0.180; 0.186). Diet NE_g was greater for SFC diets (1.73; 1.51; 1.56; 1.45 Mcal/kg DM) than for GC diets (1.42; 1.37; 1.39; 1.44 Mcal/kg DM), with a negative effect of CIT in the SFC diets. Fat thickness was greater for GC than for SFC diets (4.4 mm vs. 5.0 mm). When CIT replaced up to 50% of corn in the diets fecal starch was less for SFC diets than for GC diets (2.0% vs. 9.3%). In conclusion, SFC increases diet NE_g for Nellore cattle fed high concentrate diets compared with ground corn. Citrus pulp decreases NE_g in SFC diets and has no negative effects on ground corn diets NE_g for Nellore cattle.

Key Words: citrus pulp, feedlot, grain processing

791 Evaluation of rumen metabolism and digestibility when treated crop residues are fed in cattle finishing diets.

A. L. Shreck*[1], J. L. Harding[1], G. E. Erickson[1], T. J. Klopfenstein[1], and M. J. Cecava[2], [1]*University of Nebraska-Lincoln, Lincoln,* [2]*Archer Daniels Midland, Decatur, IL.*

Five rumen fistulated steers were used in an incomplete 5 × 7 Latin square design. A 2 × 3 + 1 factorial arrangement of treatments was used. One factor was crop residue type (corn cobs, wheat straw, corn stover) and the other factor was degree of processing. For processing, residues were ground but not treated or ground and treated with 5% CaO (lime) at 50% moisture and stored anaerobically. All diets contained 40% wet distillers grains plus solubles and 4% supplement (DM basis). Residues replaced DRC at 25% of the diet (DM basis). The control diet contained 10% roughage (equal cobs, straw, and stover) and 46% DRC. An interaction ($P = 0.06$) was observed for acetate:propionate (C2:C3) ratio. Treatment of cobs (3.1 vs 2.6) and corn stover (2.9 vs 2.6) increased C2:C3 but treatment of wheat straw increased propionate which decreased C2:C3 (2.4 vs 2.6). No difference ($P > 0.10$) was observed for treated straw or stover compared with control (2.6) for C2:C3. An interaction was noted for average ruminal pH because compared with untreated forms, treated cobs (6.52 vs 6.38) and stover (6.23 vs 5.95) had greater pH but treated straw (5.81) had lower ($P = 0.08$) pH compared with untreated (6.05). Greater DM (73.7 vs 66.1%; $P = 0.001$), OM (77.0 vs 68.5%; $P = 0.001$), lipid (89.2 vs 85.2; $P = 0.02$) and NDF (66.8 vs 51.5%; $P < 0.001$) digestibility were noted when diets contained treated compared with untreated residues. However, no difference ($P > 0.10$) was observed between control and treated diets for DM (70.7 vs 73.7%) or OM (72.1 vs 76.9%) digestibility. Similar DMI was noted for treated and untreated ($P = 0.38$) diets but lower ($P = 0.001$) NDF intake was observed for treated diets (3.1 vs 3.5 kg/d), suggesting that CaO treatment partially solubilized NDF thereby decreasing measurable NDF intake. Results suggest that treated crop residues can substitute a portion of grain in feedlot diets and result in similar nutrient supply to the animal. The improvements in digestibility when treated residues are fed compared with untreated residues are related to fiber solubilization and improved fiber digestibility.

Key Words: alkaline treatment, crop residues, grain replacement

792 Effects of alternate feeding of dried distillers grains plus solubles on performance and body composition in gestating forage-fed beef cows.

S. I. Klein,* P. L. Steichen, A. Islas, R. S. Goulart, T. C. Gilbery, and C. R. Dahlen, *Department of Animal Sciences, North Dakota State University, Fargo.*

Forty-six nonlactating, gestating beef cows were used to examine effects of feeding either dried distiller′s grains plus solubles (DG) or grass hay on alternate days during mid-late gestation on intake, BW, ADG, G:F, and ultrasound carcass characteristics. Cows were arranged in a completely randomized design and dietary treatments included: 1) ad libitum hay daily (CON; n = 12); 2) hay and 0.4% BW DG daily (DG7; n = 12); 3) hay daily and 0.93% BW DG on Monday, Wednesday, and Friday (DG3; n = 11); and 4) hay only on Tuesday, Thursday, Saturday, and Sunday and 0.93% BW DG only on Monday, Wednesday, and Friday (DGA; n = 11). Cows were fed diets for 84 d with BW and carcass ultrasound data collected every 28 d. Feed intake was continuously monitored and intake data collected daily using the Insentec B. V. roughage intake control feeding system. Hay intake was greatest ($P < 0.01$) in CON (15.5 ± 1.0 kg/d) and least ($P < 0.01$) in DGA (10.6 ± 1.0 kg/d) with DG7 (13.6 ± 1.0 kg/d) and DG3 (12.7 ± 1.0 kg/d) being intermediate. By design DG intake was similar for DG7 (3.4 ± 0.1 kg/d), DG3 (3.3 ± 0.1 kg/d), and DGA (3.2 ± 0.1 kg/d). Total DMI was less ($P < 0.01$) for DGA compared with all other treatments. Body weight was similar ($P > 0.10$) among treatments at each weigh date, however a decrease ($P < 0.01$) in ADG was observed for CON (0.34 ± 0.06 kg/d) compared with all other treatments (0.73, 0.75, and 0.60 ± 0.06 kg/d for DG7, DG3, and DGA, respectively). Likewise, the G: F ratio was least ($P < 0.01$) for CON compared with all other treatments (0.02 ± 0.003, 0.04 ± 0.003, 0.05 ± 0.003, and 0.04 ± 0.003 kg of gain/kg of feed for CON, DG7, DG3, and DGA, respectively). Change in REA from d 1 to d 84 was greater ($P < 0.05$) in DG7 compared with all other treatments however there were no differences among treatments for intramuscular fat, rib fat, and rump fat throughout the trial. The feeding strategy DGA altered hay intake, total DMI, and REA, but did not alter other performance and carcass characteristics compared with other supplementation methods.

Key Words: beef cows, distillers grains, supplementation frequency

793 Dry-rolled or whole shell corn with or without wet corn gluten feed in receiving diets.

A. V. Siverson*[1], S. P. Montgomery[2,1], B. E. Oleen[1], and D. A. Blasi[1], [1]*Kansas State University, Manhattan,* [2]*Corn Belt Livestock Services, Cedar Rapids, IA.*

With historically high grain and cattle prices, reducing ration costs while maintaining health and performance is important for attaining profitability. Previous research indicates the use of whole shell corn in receiving diets allows for cheaper processing costs and has the added benefit of slowing starch fermentation enough to limit incidence of grain-induced acidosis. Wet corn gluten feed (WCGF) is a byproduct that can aid in controlling bloat by providing energy in the form of fermentable fiber and protein. Our objective was to determine whether corn processing with or without WCGF had any effect on growth and performance. Two hundred 79 crossbred calves (230 kg) were randomly assigned to 24 pens. Pens were randomly allocated to treatment sequence in a 2 × 2 factorial completely randomized design. Treatments were a diet including 47% whole shelled corn (WSC), a diet including 29% whole shelled corn with 30% WCGF (BP WSC), a diet including 47% dry rolled corn (DRC), and a diet with 29% dry rolled corn with 30% WCGF (BP DRC). Diet percentages were recorded on a dry matter basis (DM). Data were analyzed using mixed models including the fixed effects of treatment and lot number while the random effects were lot × treatment, period, pen, and period × pen interaction. The addition of WGCF had a positive effect on ending weight; they were significantly higher than the WSC or DRC diets alone ($P = 0.03$). Daily gains for diets with WCGF were also higher ($P = 0.04$), thus making overall weight gain on the BP WSC and BP DRC significantly better ($P = 0.02$). There were no corn processing effects (all $P \geq 0.34$). There was an apparent interaction between digestive upsets that required treatment and the DRC diet ($P = 0.006$). However, this may be misleading due to the fact only 4 animals were treated for illness over the course of the study. Only one animal was treated for a digestive problem. There was no benefit seen to processing corn, but including WCGF at 30% (DM) increased gains and overall performance.

Key Words: receiving, whole shell corn, wet corn gluten

794 Effect of dried distillers grains with solubles on enteric methane emissions and nitrogen excretion from finishing beef cattle.

M. Hünerberg*[1,2], T. A. McAllister[2], K. A. Beauchemin[2], S. M. McGinn[2], O. M. Harstad[3], and E. K. Okine[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [3]*Norwegian University of Life Sciences, Norway.*

The objectives of this study were to examine the effect of corn- or wheat-based dried distillers grains with solubles (WDDGS, CDDGS) on enteric CH_4 emissions from finishing beef cattle, and to determine if any observed reductions were a result of the fat content of CDDGS. Another objective of this study was to compare the effect of CDDGS or WDDGS on N excretion. The experiment was designed as a replicated 4 × 4 Latin square with 28-d periods using 16 ruminally fistulated crossbreed heifers (529.1 kg ± 41.1). The control diet contained 87% barley grain, 8% barley silage and 5% supplement (DM basis). Treatment diets were formulated by replacing 40% of barley grain DM with CDDGS, WDDGS, or WDDGS+oil. Corn oil was added to WDDGS (3.4% fat DM) to achieve the same level of fat as CDDGS (9.7% DM). All diets were fed as total mixed rations once daily ad libitum. Total collection of urine and feces was conducted between d 18 and 21. Enteric CH_4 was measured between d 25 and 28 using 4 environmental chambers. Feeding WDDGS increased ($P < 0.05$) CH_4 emissions as a percentage of gross energy intake (GEI) from 4.9 to 5.6% compared with the control. Heifers offered CDDGS (3.9% of GEI) or WDDGS+oil (4.2% of GEI) produced less ($P < 0.05$) CH_4 than heifers fed the control diet. Emissions between CDDGS and WDDGS+oil did not differ ($P > 0.15$). Excretion of N (as % of daily N intake) was greater ($P < 0.05$) for CDDGS, WDDGS and WDDGS+oil (82.5, 82.6 and 83.0%) compared with the control diet (73.8%). Results suggest that feeding CDDGS or WDDGS+oil can mitigate enteric CH_4 emissions in finishing beef cattle. However, the potential contribution of increased N excretion to heightened nitrous oxide emissions would have to be considered in a life cycle analysis of greenhouse gases arising from the feedlot.

Key Words: methane, beef cattle, dried distillers grains with solubles

795 Comparing the digestibility of wet and dry distillers grains plus solubles in cattle finishing diets.

B. L. Nuttelman,* A. L. Shreck, J. L. Harding, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska-Lincoln, Lincoln.*

Twelve crossbred steers (525 ± 34 kg) were utilized in a 3-period crossover design to compare the digestion characteristics of wet and dry distillers grains plus solubles (DG) in finishing diets. Diets consisted of 40% of wet distillers grains plus solubles (WDGS, 34.1% DM) or dried distillers grains plus solubles (DDGS, 93.1% DM), or a corn control

(CON) containing no DG. Basal ingredients were dry-rolled corn, 7.5% alfalfa hay, and 5% dry supplement (DM basis) with DG replacing DRC. Molasses was included at 5% in the CON and DDGS diets to prevent sorting. Steers were adapted to diets for 14 d before the 5 d total fecal collection period. During the collection period, steers were individually tethered in stalls lined with rubber mats. Feces were collected and weighed daily at 0800 h and a composite was made by steer within collection period and analyzed to determine total tract nutrient digestibility. A duplicate sample was taken by day and dried for 48 h in a 60°C forced air oven to determine fecal DM output. There were no differences observed for DM or OM intake ($P > 0.15$). The CON and WDGS treatments had greater ($P < 0.03$) OM digestibility than DDGS diets (76.2, 73.0, and 67.3%, respectively), but were similar between CON and WDGS ($P = 0.22$). Diets containing DG had greater NDF intake compared with CON ($P < 0.01$). However, there were no differences for NDF digestibility between CON, WDGS, and DDGS (64.3, 62.0, and 58.4%, respectively; $P = 0.28$). Fat intake was greater for DG diets ($P < 0.01$), but fat digestibility was not different ($P = 0.46$) between treatments. Previous literature suggests animal performance will be improved when WDGS is included up to 40% compared with corn-based diets, and that drying DG negatively affects the feed efficiency relative to WDGS. Results from this study suggest OM digestibility is negatively affected when DG is dried to produce DDGS. However, OM digestibility for WDGS and corn-based diets are similar in this study and do not explain the improved performance in finishing diets containing WDGS.

Key Words: digestibility, dried distillers grains plus solubles, wet distillers grains plus solubles

796 The effects of titrating corn-based dried distillers grains plus solubles with sorghum-based wet distillers grains plus solubles on yearling heifers feedlot performance and carcass characteristics.

B. T. Johnson,* C. L. Maxwell, B. K. Wilson, J. J. Wagner, C. J. Richards, and C. R. Krehbiel, *Oklahoma State University Department of Animal Science, Stillwater.*

This study compared performance and carcass effects of altering corn dried distillers grains plus solubles (DDGS) to sorghum-based wet distillers grains plus solubles (WDGS) ratios in a dry-rolled corn feedlot ration with 30% distillers grains plus solubles (DM basis). Yearling cross-bred heifers (n = 150; initial BW 383 ± 28 kg) were blocked by BW, implanted with Revalor H, stratified by hide color and randomized to treatment, and fed for 125 d. On d 98, 330 mg-hd^{-1}-d^{-1} of ractopamine hydrochloride (Optaflexx) was included into each treatment ration and fed the final 27 d of the finishing period. Combinations of distillers grains evaluated were: 30% DDGS (TRT1); 22.5% DDGS: 7.5% WDGS (TRT2); 15% DDGS:15%WDGS (TRT3); 7.5%DDGS:22.5%WDGS (TRT4); and 30% WDGS (TRT5). There were no differences ($P > 0.54$) among treatments in overall ADG, G:F, and DMI. Between Treatments 1 and 5, DMI increased 3.3% ($P = 0.05$) and G:F decreased 14.6% ($P = 0.03$) from 57 to 84 d. No other differences were detected in HCW, dressing percentage, marbling score, KPH or USDA Yield grade. Data suggest that when fed at 30% of the finishing diet DM, corn DDGS and sorghum WDGS can be blended or exchanged with no effect on finishing performance or carcass characteristics. These data would serve as a useful tool when formulating least cost dry-rolled corn based rations.

Key Words: beef heifers, carcass characteristics, distillers grains

797 Effects of increasing levels of distillers dried grains on intake and digestibility of moderate quality fescue hay.

W. W. Miller,* J. D. Kohler, and M. D. Hudson, *Missouri State University, Springfield.*

Ethanol production in the United States has increased more than 7-fold in the past decade, displacing nearly one-third of corn once used for livestock feed. Producers must find alternative feed sources, such as distillers dried grains plus solubles (DDGS). Including DDGS in dairy and finishing diets has been widely studied, but less information is available regarding the use of DDGS as a supplement for cattle consuming a forage-based diet. The purpose of this study was to determine the differences in voluntary intake and digestibility of moderate quality, long-stem fescue hay (9.5% CP, 72.3% NDF; DM-basis) by steers consuming increasing levels of DDGS (27.7% CP, 35.7% NDF; DM-basis). Four Hereford steers (384 ± 42.8 kg) were housed in individual pens (4 × 4 m) and randomly assigned to treatment blocks in a completely randomized, replicated 4 × 4 Latin square design. Steers were fed daily one of 4 levels of DDGS (0, 0.2, 0.4, or 0.8% of BW; DM-basis), denoted as control (CON), low (LOW), moderate (MOD) and high (HI). Steers were fed DDGS at 0800 and ad-libitum hay was offered at 0830. Steers had access to fresh water and salt at all times. Each pd consisted of a 10-d adaptation and a 7-d collection, during which hay intake, orts, and total fecal output were measured daily, followed by a 10-d washout. Data were analyzed using PROC Mixed, where the model included the fixed effects of treatment and pd and steer was included as a random variable. Period was the repeated measure and included steer nested within pd. Hay intake (kg DM or % of BW) did not differ ($P > 0.47$) between treatments. Total tract DM digestibility did not differ between CON and LOW steers but tended ($P = 0.09$) to be greater for MOD compared with LOW (56.48 vs. 51.11%, respectively). Digestibility did not differ between HI and MOD, but HI steers had greater ($P < 0.05$) DM digestibility (60.54%) compared with LOW and CON steers (51.11 and 51.98%, respectively). Digestibility of NDF did not differ between treatments. Increased DDGS did not affect hay intake; however, total tract digestibility of diet DM was improved as DDGS supplementation increased.

Key Words: DDGS, fescue hay, intake and digestibility

Ruminant Nutrition: Dairy Production IV

798 Sampling behavior of dairy cattle: Effects of spatial variation in feed quality on movements at the feed bunk. J. M. Huzzey,* J. A. Fregonesi, M. A. G. von Keyserlingk, and D. M. Weary, *University of British Columbia, Animal Welfare Program, Vancouver, BC, Canada.*

The factors affecting feed sampling behavior of cattle housed indoors are poorly understood. The objectives of this study were to measure the effects of spatial variation in feed quality on the feeding behavior of Holstein dairy heifers. Thirty-two heifers were housed in 4 groups of 8. Pens had 8 distinct feeding stations (FS). Three TMR qualities were used in the study: low energy (TMR-L), moderate energy (TMR-M), and high energy (TMR-H). During trial 1 (d 1 to 8), heifers were offered a uniform baseline diet (TMR-M to all 8 FS) interspaced with 2 uniform test diets on d 3 and 6 (TMR-L or TMR-H). During trial 2 (d 9 to 17) heifers were offered a non-uniform baseline diet (7 FS: TMR-L, 1 FS: TMR-H) interspaced with 3 uniform test diets on d 11, 14, and 17 (TMR-L, TMR-M, or TMR-H). Heifers were observed in pairs ($n = 16$) continuously for 15 min following fresh feed delivery each morning. Frequency of switches between FS and competitive displacements were recorded. Pair was considered the experimental unit. During trial 1 the average (±SE) number of FS switches per min when fed the uniform baseline diet was 0.68 ± 0.10; this was lower than when fed a TMR-L (1.34 ± 0.10; $P < 0.001$) and tended to be higher than when fed a TMR-H (0.44 ± 0.10; $P = 0.06$). Displacement frequency did not differ between dietary treatments in trial 1 ($P > 0.14$). During trial 2 the number of FS switches per min when fed the non-uniform baseline diet was 0.87 ± 0.09; this was lower than when fed a TMR-L (1.16 ± 0.09; $P = 0.01$) but higher compared with the TMR-M and TMR-H diets (0.56 and 0.38 ± 0.09, respectively; $P \leq 0.007$). Heifers engaged in more displacements per min when fed a non-uniform TMR (0.13 ± 0.03) than when fed TMR-M (0.06 ± 0.03; $P = 0.04$) or the TMR-L and TMR-H diets (0.07 ± 0.03 for both; $P \leq 0.11$). Dairy heifers appear to sample feed quality by changing feeding locations at the feed bunk; this sampling behavior is affected by variability in the energy density of the diet.

Key Words: sampling behavior, diet uniformity, agonistic interactions

799 Effect of precision feeding on performance, nutrient excretion, and feeding behavior of early lactation dairy cows. E. Maltz*[1,2], L. F. Barbosa[1], P. Bueno[1], L. Scagion[1], L. F. Greco[1], K. Kaniyamattam[1], A. de Vries[1], and J. E. P. Santos[1], [1]*University of Florida, Gainesville,* [2]*The Volcani Center, Bet Dagan, Israel.*

Objectives were to evaluate the effects of 2 feeding strategies on performance of early lactation cows. Fifty-eight Holstein cows at 21 DIM were randomly assigned to a control [$n = 29$; 16.2% CP, 1.64 Mcal of NE_L, 22% starch, and 19% forage NDF] or a precision diet [$n = 29$, 16.2% CP, 1.59 to 1.68 Mcal NE_L, 18 to 26% starch, and 16 to 22% forage NDF] that varied in the caloric density based on energy balance (EB) of cows. The TMR of precision cows were adjusted individually once a week according to the EB and DMI of the preceding week. The study lasted 16 wk, and nutrient digestibility, rumen fluid composition, microbial protein synthesis, and feeding behavior were evaluated. Data were analyzed with the GLIMMIX procedure of SAS. The mean diet NE_L was greater ($P < 0.01$) for precision than control cows (1.65 vs. 1.64 Mcal/kg) because of greater ($P < 0.01$) dietary concentrate (55.0 vs. 52.3%). Compared with controls, precision cows had similar DMI (24.3 kg/d), but NE_L intake tended ($P = 0.10$) to be greater (40.6 vs. 39.1 Mcal/d) because of greater caloric intake in the first 6 wk of the study. Yields of milk (45.2 vs. 41.9 kg/d), 3.5% FCM (44.0 vs. 40.8 kg/d) and milk protein (1.33 vs. 1.23 kg/d), and the feed conversion ratio (3.5% FCM/DMI; 1.82 vs. 1.74) were greater ($P < 0.05$) in precision compared with control cows. Precision cows produced more ($P < 0.05$) milk calories per kg of $BW^{0.75}$ (0.227 vs. 0.213 Mcal of NE_L/kg), although the proportion of consumed calories (82.3%) and N (37.4%) partitioned into milk did not differ between treatments. Digestibility of nutrients, composition of rumen fluid, rumen pH and microbial N synthesis remained mostly unaltered by treatments. Meal pattern differed, and precision cows consumed feed more sparsely throughout the day, spent more time ruminating lying, had similar meal length (36.3 min/meal) compared with control cows, but smaller ($P < 0.05$) meal size (3.33 vs. 3.64 kg/meal). Results indicate that allocating dietary resources according to individual needs of cows based on EB improves lactation performance compared with feeding a single TMR despite minor changes in caloric intake.

Key Words: dairy cow, feeding behavior, precision feeding

800 Concentrate levels and supplemental fat for grazing mid lactating cows. F. L. Macedo, S. F. Angolini, W. F. Angolini, C. T. dos Santos Dias, and F. A. P. Santos,* *University of São Paulo, Piracicaba, SP, Brazil.*

A grazing trial was conducted to evaluate the production response of mid lactating dairy cows to concentrate levels and supplemental fat. Twenty-two Holstein x Jersey cows were assigned to randomized blocks according to number of lactation (primiparous or multiparous), DIM (132 ± 60) and milk yield (20.9 kg $d^{-1} \pm 2.22$), in a 2x2 factorial arrangement. Treat ments were: 1) HS: High supplementation (1 kg of concentrate for every 2.5 kg of milk); 2) LS: Low supplementation (1 kg for every 5 kg of milk); 3) HSCS: HS with 2.78% of calcium salt (CS) of soybean oil (Megalac-E®); 4) LSCS:LS with 5.76% CS of soybean oil. Cows grazed fertilized Elephant grass pastures during 90 d. Concentrates were 15.2% CP (HS and HSCS) or 12% CP (LS and LSCS), based on fine ground corn. Data were analyzed using GLM procedure of SAS (1999) and effects were significant at P-value of < 0.05. Hand plucked samples of forage contained 18.6% CP and 54.4% NDF. Feeding HS decreased forage DMI (9.3 vs. 12.2 kg d^{-1}) with no changes in total DMI (16.5 vs. 15.2 kg d^{-1}). Fat supplementation had no effect on forage and total DMI ($P > 0.05$). There was an interaction for concentrate level and fat supplementation for milk yield ($P < 0.05$). Feeding HS increased milk yield (17.6 vs.14.2 kg d^{-1}) compared with LS when fat was not fed, but concentrate level had no effect when fat was fed (15.4 vs. 15.0 kg d^{-1}). Fat supplementation had a negative effect on milk yield when cows were fed with HS (17.6 vs. 15.4 kg d^{-1}) but not with LS (14.2 vs. 15.0 kg d^{-1}). Milk fat content was decreased ($P < 0.05$) by feeding either HS (3.53 vs. 3.60%) or fat (3.76 vs. 3.38%) with no interaction ($P > 0.05$). Content of milk protein, casein and lactose were not affected by treatments ($P > 0.05$) and MUN was decreased by feeding HS ($P < 0.05$). Plasma glucose was not affected ($P > 0.05$) by treatments but feeding HS decreased plasma NEFA ($P < 0.05$).

Key Words: calcium salts of soybean oil, grazing dairy cows, supplementation

801 Dry matter intake and behavior patterns of dairy cows fed diets combining pasture and total mixed ration.

A. Mendoza[1,2], C. Cajarville*[3], R. Colla[1], G. Gaudentti[1], M. E. Martín[1], and J. L. Repetto[1], [1]*Facultad de Veterinaria, Departamento de Bovinos, Montevideo, Uruguay,* [2]*Instituto Nacional de Investigación Agropecuaria, Colonia, Uruguay,* [3]*Facultad de Veterinaria, Departamento de Nutrición Animal, Montevideo, Uruguay.*

Nine Holstein cows (mean BW = 572 kg; SD = 76) fed a total mixed ration (TMR) were assigned to 3 3 × 3 latin squares (each with 10 d of adaptation followed by 10 d of sampling) to evaluate the effect of 0 (TMR0), 4 (TMR4) or 8 (TMR8) hours of daily access to fresh pasture on DMI and behavior patterns. Pasture (*Lolium multiflorum*; 22.1% CP, 24.0% ADF) was daily cut and offered ad libitum from 0800 h in individual stalls and TMR (16.8% CP, 16.4% ADF) was offered ad libitum during the remaining time. Daily DMI was measured for 7 consecutive days by weighing the amount of feed offered and refused. Behaviors (eating (EAT), ruminating (RUM), and others (OTH)) were recorded during one day using instantaneous sampling of each cow using 5 min scan sampling for 12 h after 0800 h. Mixed and general linear models were used to test main effects for traits with or without repeated measurements, respectively. Pasture DMI increased and TMR DMI decreased with time of access to pasture (TMR0 = 0 and 24.5 kg; TMR4 = 2.8 and 22.8 kg; TMR8 = 3.6 and 19.0 kg; SEM = 0.5 and 1.5, respectively) while total DMI intake was higher in TMR4 than TMR8 cows (25.6 vs 22.6 kg), but no differences were detected with TMR0 (24.5 kg; SEM = 1.6). Proportion of cows EAT (0.43; SEM = 0.03), RUM (0.25; SEM = 0.02) or OTH (0.31; SEM = 0.02) were not affected by treatments, but an effect of hour and treatment × hour were detected for these traits ($P < 0.01$). After hour 1, the proportion of cows EAT decreased and RUM and OTH increased in every treatment, but at hour 5 (after TMR4 cows were changed to TMR feeding), the proportion of TMR4 cows EAT was higher than in TMR0 and TMR8 cows (0.81, 0.46, 0.10, respectively) and RUM lower than in TMR0 and TMR8 cows (0.05, 0.20, 0.49, respectively). At hour 9 (after TMR8 cows were changed to TMR feeding) the proportion of TMR8 cows EAT was higher than in TMR0 and TMR4 cows (0.90, 0.42, 0.59, respectively) and RUM lower than in TMR0 and TMR4 cows (0.01, 0.27, 0.19, respectively). Time of access to fresh pasture influenced both DMI and behavior of TMR-fed dairy cows.

Key Words: pasture, total mixed ration

802 Supplemental fat for dairy calves fed accelerated milk replacer during mild cold stress.

N. Litherland*[1], D. Lobao[1], R. LaBerge[1], W. Weich[1], Z. Sawall[1], J. Schefers[1], and A. Kertz[2], [1]*University of Minnesota, St Paul,* [2]*ANDHILL LLC, St, Louis, MO.*

Sixty Holstein and Holstein-cross dairy calves (31 female and 29 male) fed accelerated milk replacer (MR) were used to determine response to increasing amounts of supplemental fat during mild cold stress. Calves (n = 20) were randomly assigned to one of 3 treatments; 1) Low fat (LF) (28:15 MR; 2) Medium fat (MF) (28:15 MR + 113 g/d commercial fat supplement (FAT) (60% fat); 3) High fat (HF); 28:15 MR + 227 g/d FAT. MF and HF calves received FAT d 1–21. All calves were fed LF d 22–49. MR was fed at 1.4% of birth body weight (BBW) d 1–10 and then 1.8% of BBW d 11–42 and 0.9% of BBW d 43–49 Weaned on d 49 and remained in hutches to d 56. MR was reconstituted to 13% solids. Calves were fed ad libitum a commercial starter grain (19.2% CP) and offered 4 L/d warm water. Calves were fed MR twice d at 0630 and 1730 in hutches bedded with straw. Starter intake (SI), MR intake (MRI), and ambient temperature (AT) were measured daily and body weight (BW), hip height (HH), and body length (BL) were measured weekly. Data were analyzed using PROC MIXED in SAS as a randomized design. Calf BBW averaged 42.0 ± 1.0 kg ($P = 0.41$), total serum protein averaged 5.8 ± 0.1 mg/dL, and birth AT averaged 5.0 ± 1.1°C. Average daily gain (ADG) was similar among treatments through 21 d and averaged 0.59, 0.76, and 0.68 ± 0.1 kg/d and through 56 d averaged 0.81, 0.84, 0.83 ± 0.1 kg/d for LF, MF and HF. Through 56 d SI averaged 1.1, 1.0, 0.9 ± 0.1 kg/d for LF, MF and HF and was higher ($P < 0.05$) for LF vs HF. Cumulative starter intake was similar among treatments on d 21, 42, and 56 but was 10.4 kg higher ($P < 0.05$) for LF vs. HF on d 49. Gain of HH on d 56 tended ($P = 0.09$) to be greater and d 49 BL gain tended ($P = 0.06$) to be greater for LF vs. HF. Gain:feed on d 56 ($P = 0.50$) averaged 0.81, 0.84 and 0.83 ± 0.02 for LF, MF and HF. Retrospective analysis showed calves with BBW <40.0 kg fed MF tended ($P = 0.08$) to have higher 21 d BW gain than LF. Calves with BBW >40.0 kg fed HF had greater ($P < 0.05$) 21d BW gain than MF with LF intermediate. Supplementing fat to nursery calves fed accelerated MR decreased SI through d 21 which had carryover effects on SI on d 49 but did not alter ADG, total gain or feed efficiency.

Key Words: accelerated milk replacer, supplemental fat, nursery calf

803 What do preweaned and weaned calves need in the diet: A high fiber content or a forage source?

M. Terré*[1], E. Pedrals[1], and A. Bach[2,1], [1]*Institut de Recerca i Tecnologia Agroalimentàries, Caldes de Montbui, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.*

The objective of this study was to determine whether the improvement of the performance of young calves associated with the supplementation of chopped grass hay is due to an increase of the total NDF content of the consumed diet or to the provision of chopped grass hay. Sixty-three Holstein calves (9 ± 4.4 d old) were randomly distributed in 4 treatments resulting from the combination of 2 levels of NDF content of a pelleted starter and the supply or absence of forage provision: low NDF starter (18%) with or without chopped oat hay, and high NDF starter (27%) with or without chopped oat hay. All animals were fed the same milk replacer (21% CP, 19.2% fat) at the rate of 4 L/d at 15% DM from d 1 to 34, and 2 L/d at 15% DM from d 35 to 42 (weaning). The study finished 2 wk after weaning. Body weight was measured weekly, and individual calf starter and hay intake was recorded daily. On d 50, blood samples were obtained 2 h after the morning concentrate offer to determine serum glucose and insulin concentrations. On d 52, ruminal fluid samples were obtained via an esophageal tube, and pH was measured immediately. Data were analyzed with a mixed-effects model with repeated measures, except for pH values that had no repeated measures. During the preweaning period, starter intake was similar among treatments, but ADG tended ($P = 0.053$) to be greater in low NDF than in high NDF treatments (0.69 vs. 0.63 ± 0.020 kg/d, respectively). However, during the 2 wk after weaning, supplementation of forage improved ($P < 0.05$) concentrate intake and ADG without affecting the gain to feed ratio. Probably, the greater starter intake observed in forage-supplemented calves was mainly due to the greater ruminal pH found in forage-supplemented calves compared with forage-deprived calves (5.81 vs. 5.05 ± 0.063, respectively). On the other hand, the insulin to glucose ratio was greater ($P < 0.05$) in forage-supplemented compared with non-forage calves (6.53 vs. 4.24 ± 0.125 ng/L to mg/dL, respectively). In conclusion, a low NDF starter should be recommended during the preweaning period, and the provision of chopped hay is necessary right after weaning to improve calves performance.

Key Words: forage, NDF content, young calves

804 Fat and fatty acid sources affect growth and health of milk-fed calves.

K. M. Esselburn*[1], K. M. Daniels[1], T. M. Hill[2], H. G. Bateman II[2], J. M. Aldrich[2], and R. L. Schlotterbeck[2], [1]*Department of Animal Sciences, The Ohio State University, Ohio Agricultural Research and Development Center, Wooster,* [2]*Nurture Research Center, Provimi North America, Brookville, OH.*

Fatty acid profiles of milk and milk replacer (MR) differ. Calf MR in the US are made from lard or tallow, which are low in short- and medium-chain fatty acids and linolenic acid. This 56-d trial compared a control MR containing 27% CP and formulated with 3 fat and fatty acid compositions. The 3 MR treatments were A) only lard totaling 17% fat, B) animal fat supplemented with butyrate, medium chain fatty acids, and linolenic acid using a commercial product (1.25% NeoTec4 MR, Provimi North America, Brookville, OH) totaling 17% fat, and C) milk fat totaling 33% fat. Holstein calves (24 female, 24 male; 41 ± 1 kg initial BW; 2 to 3 d of age) from a single farm were fed 660 g of DM from MR for 42 d and weaned. Starter (20% CP) and water were fed ad lib for 56 d. Calves were housed in a naturally ventilated nursery with added heat during the summer of 2011. Calves were in individual pens with straw bedding. Pen was the experimental unit. Data were analyzed as a completely randomized design with a 3 (MR treatment) by 2 (sex) factorial arrangement as a repeated measures mixed model. Pre-planned contrast statements of treatments A vs. B and A vs. C were used to separate means. There were no interactions of MR treatment by sex. Starter intake did not differ. Calf ADG and feed efficiency differed ($P < 0.05$; A < B, A < C). Pre-weaning days with scours differed ($P < 0.05$; A > B). Titers to bovine respiratory parainfluenza-3 and bovine virus diarrhea type 1 (vaccinations to these pathogens were on d 7 and 28) in serum samples taken on d 49, and 56 differed ($P < 0.05$; A < B). Concentrations of urea nitrogen and glucose in serum samples taken on d 7, 21, 28 differed ($P < 0.05$; A > B, A > C). The MR with lard was less optimal than the other 2 MR for baby calf growth and health.

Key Words: fat, fatty acids, dairy calf

805 Fatty acid profile and global gene expression in liver of calves supplemented with linoleic acid.

M. Garcia*[1], L. F. Greco[1], M. B. Rabaglino[1], A. L. Lock[2], W. W. Thatcher[1], J. E. P. Santos[1], and C. R. Staples[1], [1]*University of Florida, Gainesville,* [2]*Michigan State University, East Lansing.*

Aim was to assess the fatty acid (FA) profile and global expression of genes in liver of calves fed increased linoleic acid (LA) during the first 30 d of life. Within 2 h of birth, bull calves (n = 31) were fed 4 L of good quality colostrum and assigned randomly to receive milk replacer (MR) with low (LLA, 0.56% LA) or high concentration of LA (HLA, 1.78% LA, DM basis) twice daily at 6.7 g of fat per kg of metabolic BW. Amounts fed were adjusted weekly. Liver biopsy was performed at 30 d of age. Microarray analysis (n = 9 per MR) was performed using GeneChip Bovine Genome Array from Affymetrix; transcriptome expression was analyzed by one-way ANOVA. The HLA treatment upregulated 236 genes whereas 265 genes were downregulated ($P < 0.05$, fold change ratio ≥1.3). KEGG pathway analyses were employed with WebGelstat database. Main upregulated biological pathways were focal adhesion, metabolic pathway, MAPK pathway, and PPAR α signaling. Some genes involved in these pathways were actinin α 2 (ACTN2), collagen type IV (COL4A4), acyl-CoA synthetase (ACSL6), prostaglandin D2 synthase (PTGDS), cytochrome P450 (CYP2E1), PPAR α (PPARA), filamin C (FLNC), and transforming growth factor B3 (TGFB3). The main downregulated biological pathways were metabolic pathways, T cell receptor signaling, Type II diabetes mellitus, and pentose phosphate pathway. Some genes related with these pathways were pyruvate kinase (PKLR), phospholipase (PLD1), phosphofructokinase (PFKM), 3-hydroxyisobutyate dehydrogenase (HIBADH), phosphoinositide 3-kinase (PIK3R3), and protein kinase C (PRKCQ). Liver FA were analyzed by gas-liquid chromatography. Total FA concentration of liver tissue was 8.5 vs. 7.6 g FA/100 g tissue (DM basis, LLA vs. HLA, $P < 0.02$). Calves fed HLA-MR had greater ($P < 0.01$) liver concentrations (g/100 g FA) of LA (22.1 vs. 15.9), PUFA (43.1 vs. 35.5), and n-3 FA (5.1 vs. 4.2). Calves fed LLA-MR had greater ($P < 0.02$) concentrations (g/100 g FA) of SFA (45.1 vs. 40.0) and MUFA (16.3 vs. 14.3). Supplementing LA increased LA content of liver and altered the expression of key genes involved in different hepatic metabolic processes.

Key Words: calves, linoleic acid, gene expression

806 Use of tail skin temperature as a proxy for core body temperature in neonatal Holstein male calves.

H. G. Bateman II* T. M. Hill, A. B. Chestnut, J. M. Aldrich, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

Our objective was to determine if tail skin temperatures could be used as a proxy for core body temperature in neonatal Holstein male calves to have continuous measurements of body temperature over multiple days. A total of 79 calves were used in 3 measurement periods (7+ d each). Thermocron (Maxim Integrated Products, Inc., Sunnyvale, CA) were attached to the underside of the tail immediately proximal to the observable vein using expandable tape (Vetrap, 3M, St. Paul, MN). These calves were then used to compare core body temperature (as measured via rectal temperature, M700 digital thermometer, GLA Agricultural Electronics, San Luis Obispo, CA) and measured tail skin temperatures. Rectal temperatures were manually measured and recorded along with the clock time and date. These were then matched to the recorded skin temperature closest in time from individual Thermocrons (continuous recording every 10 min) and those data used in mixed model regression analysis. The final data set used 1178 paired observations coded to indicate day of trial, calf, and time of day (AM or PM). The model used had fixed terms for recorded tail temperature and day of trial. Time of day, calf and period were included as random terms. Day of trial was found to be non-significant and removed from the model. All other terms remained significant at $P < 0.05$. The final model adjusted for calf, period, and time of day. Rectal temperature (°C) was best predicted as tail temperature (°C) * 0.4964 ± 0.02551 + 19.9177 ± 0.9869. This equation has an R^2 of 0.6120, variance inflation factor of 2.57, and RMSPE of 0.68°C. Tail skin temperature is related to rectal temperature in neonatal male calves and can be used as a noninvasive proxy for core body temperature.

Key Words: calves, model, temperature

807 Body temperature of neonatal male Holstein calves is partially influenced by ambient temperature in the calf nursery.

H. G. Bateman II* T. M. Hill, A. B. Chestnut, J. M. Aldrich, W. Hu, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

Neonatal mammals have limited ability to regulate their body temperature. This ability improves as the animal ages. However, even adult mammals ability to thermoregulate is known to be influenced by the ambient conditions. An experiment was designed to determine the extent that ambient temperatures influenced body temperature in neonatal male Holstein calves housed in a non-temperature controlled calf nursery. A total of 78 calves were used in 3 measurement periods (7+ d each). Each calf had Thermocron (Maxim Integrated Products, Inc., Sunnyvale, CA) attached to the underside of the tail immediately

proximal to the observable vein using expandable tape (Vetrap, 3M, St. Paul, MN). Calves were initially 2 d old and were monitored for 56 d. Ambient temperature was recorded using a Thermocron suspended inside the calf facility. Temperatures were recorded every 10 min and exhibited a circadian rhythm. All calves were housed in a single naturally ventilated barn with no added heat. Calves were housed in 1.2 × 2.4 m wire mesh stalls and bedded with straw. Calves were fed a common diet of milk replacer and ad libitum starter. Water was available at all times. Mixed model regressions were used to evaluate the relationship between ambient temperature and body temperature. Lag periods of 10 min from 0 to 120 min were calculated and used as potential regressors. Calf and trial were included in the model as random effects. Measurement time was modeled as a repeated term. Fixed terms were sequentially removed from the model until only significant terms remained and the variance inflation factor was less than 10 at which time the model was considered optimally parameterized. The accepted model included random terms of calf and trial in addition it includes terms for intercept, ambient temperature at the time of body temperature recording and ambient temperature 10, 20, 30, 40, 50, 100, and 120 min before body temperature reading. The model has log-likelihood R^2 of 0.32 and a variance inflation factor of 1.46. Body temperature in neonatal calves had a circadian rhythm and was partially related to ambient temperatures indicating that they may have troubles thermoregulating in periods of extreme temperature swings.

Key Words: calf, body temperature, ambient temperature

808 Jersey calf performance in response to high protein, high fat liquid feeds with varied fatty acid profiles.

W. S. Bowen, V. A. Swank,* K. M. O'Diam, M. L. Eastridge, and K. M. Daniels, *Department of Animal Sciences, The Ohio State University, Columbus.*

Most commercially available milk replacers (MR) use edible lard as the main fat source; it contains primarily long-chain fatty acids (LCFA). However, 10.8% of fatty acids (FA) in Jersey whole milk are medium-chain fatty acids (MCFA). Coconut oil (CO) is a rich source of MCFA. The objective was to determine whether altering the FA profile of MR with varying amounts of CO, to more closely match the FA profile typically found in whole milk from Jersey cows, would improve Jersey calf growth. This randomized complete block design trial was conducted at Waterman Dairy (Columbus, OH) from November, 2010 through August, 2011. Male (n = 18) and female (n = 32) Jersey calves were randomly assigned at birth to 1 of 4 liquid diets: pasteurized Jersey saleable whole milk (pSWM; 27.9% CP, 33.5% fat, DM basis); MR containing 100% of fat as edible lard (100:00; 29.3% CP, 29.1% fat); MR containing 20% of fat as CO (80:20; 28.2% CP, 28.0% fat); MR containing 40% of fat as CO (60:40; 28.2% CP, 28.3% fat). Calves were fed 2L of their respective liquid diet twice daily from 2d of age until 7wk of age, and once daily until weaning (8wk of age). Calves had ad libitum access to starter and water. Calf BW was recorded at birth and once weekly for 9 wk. Feed intake and scour days (number of days with fecal score > 2) were recorded daily. Hip height (HH) and wither height (WH) were taken at birth, 4, 7, and 9 wk. Average daily gain, BW, WH, and HH did not differ by treatment. Calves fed pSWM had a higher milk DMI than calves fed 80:20 (0.523 vs. 0.498 kg/d). There was no effect of CO on milk DMI. Grain DMI and total DMI did not differ among treatments. Calves fed pSWM had an increase in days with a fecal score >2 compared with calves fed 80:20 (4.24 vs. 2.00 d). Coconut oil had a quadratic effect on fecal score, with calves fed 100:00, 80:20, and 60:40 scouring 4.00, 2.00, and 3.63 d, respectively. In conclusion, DMI and ADG were similar among treatments. Differences among treatments in fecal scores implicate possible benefits of MCFA inclusion on calf health, presumably due to their known antimicrobial properties.

Key Words: Jersey calf, milk replacer, fatty acids

809 Methods of reducing milk replacer to prepare dairy calves for weaning when large amounts of milk replacer have been fed.

T. M. Hill,* H. G. Bateman II, J. M. Aldrich, and R. L. Schlotterbeck, *Nurture Research Center, Provimi North America, Brookville, OH.*

Numerous trials and labs have reported that calves fed large amounts of milk replacer (MR) and weaned over 7 d (or less) have reduced ADG from depressed starter intake, lessened rumen development, and reduced post-weaning digestion. At least 3 laboratories have implemented 21 to 25 d weaning periods that ameliorated the ADG and intake problems. We compared different gradual weaning programs to have calves fully weaned after 42 d on MR. Measurements were made for 56 d. Calves were 2 to 3 d old Holstein male calves (44 ± 1.2 kg BW) sourced from a single farm and housed in individual 1.2 by 1.4 m pens within a naturally ventilated nursery. A textured 20% CP starter and water were fed free-choice. Trials were completely randomized designs using repeated measures with means separated using pre-planned contrasts. In Trial 1, a 27% CP, 17% fat MR fed at 0.66 kg DM/d for 42 d (LOW) was compared with the same MR fed at 0.88 kg/d for 21 d and reduced to 0.66 kg/d in one step for 21 d (HIGH), or a 22% CP, 27% fat MR fed at 0.79 kg/d for 21 d and changed to the 27% CP, 17% fat MR fed at 0.66 kg/d for 21 d before weaning (HIFAT). Calves fed HIGH had greater ($P < 0.05$) ADG and similar starter intake compared with calves fed LOW, while calves fed HIFAT had lower ($P < 0.05$) starter intake and ADG compared with calves fed LOW. In Trial 2, the same 27% CP, 17% fat MR was fed at 0.66 kg DM/d for 42 d (LOW), fed at 0.96 kg/d for 21 d and reduced to 0.66 kg/d in one step for 21 d (HIGH), or fed at 0.96 kg/d for 28 d and gradually reduced compared with HIGH over 14 d before weaning (HIGRAD). Calves fed both HIGH and HIGRAD had greater ($P < 0.05$) ADG and similar starter intake to calves fed LOW. Weaning calves over 14 to 21 d that had been fed MR at 0.88 kg DM or more did not result in reductions in ADG and starter intake. Treatment HIGH tested in both trials and published previously is relatively simple to implement.

Key Words: feeding rate, milk replacer, weaning

WSASAS Symposium: Ruminant Stress: Implications on Health and Performance of Ruminants

810 Effects of environment on fetal programming in ruminant livestock. S. W. Limesand,* D. T. Yates, A. R. Macko, and X. Chen, *University of Arizona, Tucson.*

Environmental heat stress reduces placental transfer of oxygen and nutrients to the fetus and can influence the set-points of metabolic pathways. Developmental adaptive responses to heat stress-induced placental insufficiency promote thrifty fetal metabolism and are necessary for in utero survival. However, thrifty metabolic programming can be detrimental after birth when sufficient nutrition and oxygen are available. The endocrine pancreas plays an important role in metabolic homeostasis even before birth by secreting insulin from β-cells in response to stimulation by nutrients, thus coordinating fetal growth with nutrient supply. Our goal is to understand the mechanisms by which developmental adaptations in β-cells occur in heat-stressed fetuses and determine how they manifest into less desirable production traits. We induce placental insufficiency and intrauterine growth restriction (IUGR) in fetal sheep by exposing the pregnant ewe to chronic heat stress during mid-gestation. This treatment results in fetal hypoxemia and hypoglycemia that progressively worsens throughout the third trimester. Glucose-stimulated insulin secretion (GSIS) in IUGR fetuses is also reduced by more than 80% compared with controls due to a 78% reduction in β-cell mass and less insulin per β-cell. However, β-cells isolated from IUGR fetuses secrete more insulin relative to total insulin content in vitro, indicating that stimulus-secretion coupling is greater than in control β-cells. In contrast, fetal sheep that are hypoglycemic only (produced by chronic maternal insulin infusion) exhibited a 45% reduction in GSIS in vivo as well as diminished insulin secretion from isolated islets. Together, these data demonstrate that hypoxemia is a major cause of developmental adaptations observed in β-cells after fetal heat stress. We are currently exploring elevated catecholamines as a mediating factor of hypoxemic effects. Plasma norepinephrine concentrations are negatively correlated with blood oxygen content and have been shown to inhibit insulin secretion. We have recently found that fetal islets chronically exposed to elevated norepinephrine in vivo exhibit enhanced insulin secretion after norepinephrine is removed, indicating that adaptive changes persist.

Key Words: intrauterine growth restriction, heat stress, pancreas

811 An evaluation of cold stress on ruminant nutritional requirements. B. Olson,* *Montana State University, Bozeman.*

In northern climates, cold may challenge a cow's ability to meet its energy/nutritional requirements during winter. For this reason, cattle are commonly fed 2 to 3 tons of hay per head, at high cost, to offset this perceived stressor, presumably because cold, often combined with wind, is thought to challenge a cow's thermal balance. At times, feeding hay meets a cow's direct physiological needs. Besides being fed hay during winter, cold temperatures can increase activity level, shivering, or metabolic rate, which require energy, or increase use of energy reserves, which reduces insulation. However, these are not long-term responses to cold stress. Alternatively, cattle in good body condition entering winter adjust behaviorally to maximize energy gain, primarily from the sun, and to minimize energy loss, primarily from wind. They also may reduce activity level under extreme conditions, and lower metabolic rate to conserve energy. Cattle that do not adjust, and subsequently produce a weak calf or do not rebreed are likely to be culled. Several studies indicate that the 1996 NRC model over-estimates maintenance requirements for beef cattle grazing winter range, presumably because the model does not account for the benefits of solar energy to help meet a cow's thermal balance, and their behavioral adjustments to winter conditions.

Key Words: cold, thermal, winter

812 An evaluation of temperament on performance and health of ruminants. R. F. Cooke,* *Oregon State University, EOARC, Burns.*

Temperament is defined as the fear-related behavioral responses of cattle when exposed to human handling. Our group evaluates cattle temperament using: 1) chute score; 1–5 scale that increases according to violent behavior during chute restraining, 2) exit velocity; speed of cattle exiting the chute, 3) exit score; dividing cattle according to exit velocity into quintiles and using a 1–5 scale (slowest to fastest quintiles), and 4) temperament score; average of chute and exit scores. To facilitate interpretation and dissemination of results, our group also assigns a final temperament type to cattle; adequate temperament (ADQ; temperament score ≤3) or aggressive temperament (AGR; temperament score >3). To understand the implications of temperament on beef production, our group recently evaluated the impacts of this trait on cattle productive, reproductive, and health parameters. As expected, AGR cattle had greater plasma cortisol vs. ADQ cattle during handling, independent of breed type (*Bos indicus* × *B. taurus*, $P < 0.01$; *B. taurus*, $P < 0.01$) or age (cows, $P < 0.01$; heifers, $P < 0.01$). In regards to reproduction, AGR females had reduced annual pregnancy rates vs. ADQ cohorts, independent of breed type (*B. indicus* × *B. taurus*, $P = 0.03$; *B. indicus*, $P = 0.05$). Moreover, *B. taurus* AGR cows had decreased pregnancy rate ($P = 0.03$), calving rate ($P = 0.04$), weaning rate ($P = 0.09$), and kg of calf weaned/cow exposed ($P = 0.08$) vs. ADQ cohorts. In regards to feeder cattle, AGR calves had reduced weaning BW ($P = 0.04$), heightened acute-phase protein response upon feedlot entry ($P \leq 0.05$), and reduced carcass weight ($P = 0.07$) vs. ADQ cohorts. Our group also reported that exposing *B. indicus* × *B. taurus* or *B. taurus* heifers to frequent human handling improved temperament ($P \leq 0.02$), reduced plasma cortisol ($P < 0.01$), and hastened puberty ($P \leq 0.02$). Similar benefits, however, were not observed in mature cows or feeder cattle. In conclusion, temperament affects productive, reproductive, and health parameters of beef cattle independent of breed type. Hence, strategies to improve herd temperament are imperative for optimal production efficiency of beef operations worldwide.

Key Words: cattle, production, temperament

813 Impact of weaning, transportation. and vaccination stress on beef cattle performance. J. D. Arthington,* *University of Florida, Range Cattle Research and Education Center, Ona.*

Stress is the result of an external or internal pressure which causes an organism to deviate from homeostasis. Professionals engaged in food animal production systems are certainly aware of the range of stressors affecting their animals; however, the repercussions of these events on nutrition and performance considerations are recently becoming better understood. This presentation will discuss research findings directed toward the acute phase protein (APP) reaction and performance of beef calves. Our research, and the work of others, has identified several instances where BW gain was negatively correlated to blood concentrations of APP. Although other studies have linked APP concentrations to instances of feedlot morbidity and/or disease, our research has focused on response variables collected from overtly healthy cattle being exposed to normal production stressors such as weaning, vaccination, transportation, and castration. Each of these practices will create an inflammatory reaction in cattle, the magnitude of which depends on a variety of factors which are currently not well understood. These can be both deliberate and non-deliberate in nature. Some common deliberate production practices are castration or the inclusion of an adjuvant within a vaccine. Production practices which may induce non-deliberate inflammatory responses include transportation, weaning, and commingling. Typically, deliberate production stressors are associated with some degree of tissue injury, whereas non-deliberate production stressors are linked to a disruption in social order, depression, or anxiety. Despite the source of stress, these inflammatory reactions tend to respond similarly in beef cattle and lead to the initiation of the APP reaction. The APP reaction begins with the production of pro-inflammatory proteins called cytokines (namely interleukin −1, interleukin-6, and tumor necrosis factor α). These cytokines are the initial instigators of the acute phase reaction, which orchestrates the subsequent production of APP and ultimately metabolism alterations affecting feed intake, nutrient utilization, and growth. These cytokines are highly pleiotropic and affect food animal performance both (1) directly, by decreasing circulating concentrations of insulin-like growth factor-1 via a reduction in hepatic cell sensitivity to growth hormone, and (2) indirectly, by stimulating the production of plasma proteins, thus diverting energy and nutrients away from BW gain and toward the production of inflammatory proteins and support of the immune system. In terms of total protein mass, the combination of immunoglobulin and the APP sum the majority of plasma protein mass observed following an acute phase inflammatory reaction. Our research group has specifically targeted 3 APP, including haptoglobin, ceruloplasmin, and fibrinogen. These proteins were selected due to their abundance in the blood of cattle responding to inflammatory signals, their acceptable stability during storage (i.e., freezing, thawing, and refreezing), and their relatively simple and cost-effective measurement in routine assay systems. The collective results of these studies implicate an important relationship between beef calf performance and the APP response to normal production stressors. An overreaching goal of these efforts is to seek modifications to beef production practices that help ameliorate the inflammatory response and thus improve beef cattle performance and well-being.

Key Words: stress, acute phase proteins, cattle

814 Impact of environmental stress on feedlot cattle.

T. L. Mader,* *University of Nebraska, Concord.*

In the Midwest and Plains states, the heat waves of 1995, 1999, 2006, 2009, and 2010 were particularly severe with documented cattle losses approaching 5,000 head each year. However, during the summer of 2011, nearly 15,000 head of cattle perished across 5 states as a result of heat stress. The winters of 1992 to 93, 1996 to 97, 1997 to 98, 2006 to 07, and 2008 to 09 also caused hardship for cattle producers with some feedlots reporting losses in excess of 1,000 head. Up to 50% of the newborn calves were lost in many areas with over 75,000 head of cattle lost in the Northern Plains states during the 1996 to 97 and 2008 to 2009 winters. Late fall and early winter snowstorms in 1992, 1997, and 2006 resulted in the loss of over 25,000 head of feedlot cattle each year in the Central and Southern Plains of the United States. Economic losses from reduced performance of cattle experiencing severe environmental stress likely exceed losses associated from cattle death by 5- to 10-fold. Use of alternative supplementation programs may need to be considered for cattle challenged by adverse environmental conditions. Use of additional water for consumption and cooling, shade, and/or alternative management strategies need to be considered to help cattle cope with heat stress. During the winter, catastrophic losses typically occur during severe snowstorms, however early winter moisture combined with poor drying conditions may result in greater losses in performance and income due to muddy lot conditions and muddy cattle. Strategies need to be employed to minimize effects of mud, which is probably the single largest contributor to poor cattle performance in winter and spring. The above-mentioned weather events suggest that there are ample opportunities for cattle producers to minimize impact of environmental stress. Data will be presented regarding use of environmental models to determine benefits of sprinklers, shade and/or other mitigation techniques, which can reduce animal discomfort and address consumer concerns regarding welfare of animals housed outside. A greater understanding of cattle responses to weather challenges will be conveyed to caretakers to help animals cope with adverse climatic conditions.

Key Words: environmental stress, models, livestock management

Breeding and Genetics: Swine Breeding

815 Estimation of genetic parameters for birth weight, pre-weaning mortality and hot carcass weight in a crossbred population of pigs. M. Dufrasne*[1,2], I. Misztal[3], S. Tsuruta[3], J. Holl[4], K. A. Gray[4], and N. Gengler[1], [1]*Animal Science Unit, Gembloux Agro-Bio Tech, University of Liege, Gembloux, Belgium,* [2]*FRIA, Brussels, Belgium,* [3]*Department of Animal and Dairy Science, University of Georgia, Athens,* [4]*Smithfield Premium Genetics Group, Rose Hill, NC.*

Economically important traits, such as piglet mortality and growth potential, are both associated with birth weight (BRW) and therefore it is possible that BRW could be used as an early indicator for indirect selection for piglet survival and final weight. The aim of this study was to estimate genetic parameters for BRW, weaning mortality and growth traits in a commercial crossbred population of pigs to improve selection in a purebred terminal sire line. The edited data set consisted of 21,618 crossbred pigs from 262 purebred Duroc sires and 1,987 crossbred non-pedigreed Large White x Landrace dams. Traits analyzed were BRW, pre-weaning mortality (PWM) and hot carcass weight (HCW). All pigs had BRW and PWM records and 15,946 of these pigs had records for HCW. A multiple trait model with fixed effects of sex, dam parity and contemporary group, defined as month by year of birth, and random effects of sire, dam, litter and residual was utilized in the analysis. The mean BRW was 1.41 kg, the mean HCW was 93.4 kg and the percentage of PWM was 19.7%. PWM and HCW were nonlinear functions of BRW. PWM (HCW) were 75.51% (88.24 kg) for $BW < 0.7$ kg, 38.76% (91.71 kg) for $BW < 1.2$ kg and 11.75% (94.03 kg) for $BW > 1.4$ kg. The phenotypic correlations between BRW and HCW and between BRW and PWM were 0.11 and −0.28, respectively. Estimates of heritability and common litter effect were 0.19 and 0.11 for BRW, 0.04 and 0.06 for PWM, and 0.05 and 0.09 for HCW, respectively. Estimated genetic correlations were −0.75 between BRW and PWM, 0.49 between BRW and HCW, and −0.33 between PWM and HCW. Selection for increased birth weight in purebred terminal sire line may improve pre-weaning survival and final weight in the crossbred population.

Key Words: birth weight, genetic correlation, growth traits

816 Effect of within-year variation on growth performance and subsequent reproductive performance in gilts. C. R. G. Lewis*[1,2], K. L. Bunter[1], and S. Hermesch[1], [1]*Animal Genetics and Breeding Unit (AGBU), University of New England (UNE), Armidale, NSW, Australia,* [2]*PIC North America, Hendersonville, TN.*

Uniform performance is required for optimal production. This study aimed to examine within-year variation observed on gilts for production traits and their subsequent breeding performance. Data consisted of 5060 gilts from 3 breeds (Large White, Landrace and Duroc) and 3 herds in Australia over 15 years. Production traits were average daily again (ADG $\mu = 662$g/d) and backfat (BF $\mu = 10.9$mm) recorded at a live weight (WT) of 100kg. Reproduction traits were total born (TB $\mu = 10.6$), the number born alive (NBA $\mu = 9.76$), the number of stillbirths (SB $\mu = 0.83$) and farrowing age (FA $\mu = 384$) recorded in the first parity. General linear models were utilized to examine variation associated with month (12 levels, calendar month) at recording. Significant effects for all traits were herd, year, month, breed and the interaction between month and breed, which were fully cross-classified in these data. Farrowing age was fitted as a linear covariate for TB, NBA and SB, and TB was a linear covariate for SB. The production traits were also corrected for dam parity and birth litter size. Models for reproduction traits also included the animal's performance traits fitted within month. Least squares means (LSM) and associated P-values by breed, month and the month*breed interaction were assessed to examine differences in the within-year variation for traits and any possible breed (genetic) differences. The ranges in LSM for the effects of month were ADG = 50g/d, BF = 1.1mm, TB = 0.67, NBA = 0.72, SB = 0.23 and FA = 15.7d (min and max for all traits $P < 0.05$ difference). Growth rate was higher and BF was lower in cooler months. The differences between winter and summer were larger in magnitude for Duroc in comparison to the other 2 breeds. For reproduction traits, less TB were produced in cooler months (mated during the summer) and SB was higher for summer farrowings. Further analyses showed that if variation is generated in growth performance before breeding, then there is a differential effect on variation in the reproductive traits. Linear regressions of FA on ADG nested within month of farrowing resulted in ADG solutions of −0.35d/g in winter and −0.12d/g in summer. Quantifying the different sources of within-year variation and their interactions is of economic importance and could suggest paths for intervention strategies to increase uniformity in performance.

Key Words: gilts, variation, growth

817 Towards robust sows: Heat tolerance expressed in fecundity traits. S. Bloemhof*[1,2], E. Knol[1], E. van der Waaij[2], and I. Misztal[3], [1]*TOPIGS Research, Beuningen, the Netherlands,* [2]*Animal Breeding and Genomics Centre, Wageningen, the Netherlands,* [3]*Department of Animal and Dairy Science, University of Georgia, Athens, Georgia, United States of America.*

Globalization results in increased pork production, especially in warm climates such as Latin America and Asia. This requires a robust sow that is tolerant to environmental perturbations such as disease and heat tolerance, without compromising production. Objective of this study is to evaluate the effect of heat stress during the reproduction cycle of the sow on farrowing rate (FR) and litter size (LS). This as a start for genetic improvement of heat tolerance in sows and genetic selection for robust sows. Data included 22,750 observations on FR (0 or 1) and LS (1–25), on 5,024 sows. Sows of a purebred Yorkshire dam line were located on 16 farms in Spain and Portugal. Outside temperature data were available. Sows are exposed to heat stress when temperature exceeds the upper critical temperature (UCT). In a previous study the UCT for FR was estimated to be 19.2°C and for LS to be 21.7°C. Heat load can be calculated as temperature-UCT. To simplify the analysis, the effect of heat stress was studied as the effect of temperature or heat load per day on FR or LS; analyses included temperatures/heat loads from 28 d before until 75 d after insemination. Correlations were estimated between temperature/heat load and LS and FR for each day. Strongest correlation between temperature and FR was −0.09 on d 22 before insemination; −0.13 on d 16 before insemination in gilts, and −0.09 on d 18 before insemination in sows (parity > 1). Correlations increased marginally when estimated between FR and heat load instead of temperature. Heat load had the largest effect on FR on d 21 before insemination. Strongest correlation between temperature and LS was −0.04 on d 10 after insemination; −0.08 on d 10 after insemination in gilts. Correlations increased when estimated between LS and heat load instead of temperature. Heat load had the largest effect on LS on d 10 after insemination, intriguingly this is 2 d before implantation. In conclusion, gilts are more susceptible for heat stress than older sows. A genetic model for genetic improvement of heat tolerance in sows for LS and FR should include heat load instead of temperature as correlations between LS/FR were strongest with heat load.

Key Words: sows, fecundity, heat stress

818 A comparison of methods for predicting litter size in commercial pig lines. L. Tusell*[1], P. Perez[1], S. Forni[2], X. L. Wu[1], and D. Gianola[1], [1]*Department of Animal Sciences, University of Wisconsin, Madison,* [2]*Genus Plc, Hendersonville, TN.*

Genome-assisted evaluation requires statistical models capable of dealing with high-dimensional genotype data while yielding accurate predictions of merit of selection candidates. Various methods have been proposed for genome-enabled selection. Here, several procedures were compared with regard to their ability to predict phenotypes in 2 purebred pig lines and their cross. Data represented 2,598, 1,604 and 1,879 sows from 2 purebred and one crossbred line, respectively. Phenotype was the average number of piglets born, pre-corrected for systematic environmental effects. Genotypes were obtained using the Illumina PorcineSNP60 BeadChip. SNPs with minor allele frequency <0.05 and call rate >0.95 were excluded, yielding 46,855, 45,597 and 50,151 SNPs for the 2 purebred and crossbred lines, respectively. Missing genotypes were imputed from average allele frequencies at each locus. A 10-fold cross-validation assessed predictive ability of Bayesian Lasso, Bayesian Ridge Regression, Genomic BLUP, Reproducing Kernel Hilbert Spaces with kernel averaging, and a Radial Basis Function Neural Network using either the additive genomic relationship matrix (RBF-G) or principal component scores of the SNP matrix (RBF-UD) as inputs. Within line, methods yielded similar predictive ability, except for RBF models. The average correlation between observed and predicted phenotypes in testing sets (r) was higher in the crossbred line (0.27) than in purebred lines (0.19–0.23). RBF-G had the worst predictive ability in all lines: r = 0.10 and 0.17 in purebreds, and 0.21 in crossbreds. On the other hand, RBF-UD yielded the best predictive ability (r = 0.30) in crossbreds. This suggests that population structure affects predictive ability. When prediction was assessed in a large data set, principal component scores of the SNP matrix led to better predictive results, possibly because these scores are more informative than genomic relationships.

Key Words: genomic selection, neural networks, pigs

SYMPOSIA AND ORAL SESSIONS

Animal Behavior and Well-Being: Pain and Discomfort in Farm Animals

819 Pain and discomfort in farm animals. S. T. Millman,* *Iowa State University, Veterinary Diagnostic and Production Animal Medicine, Ames.*

Animal pain is at the forefront of public concerns about animal welfare. In the field, animal caregivers and veterinarians must recognize species-specific and insult-specific responses to pain for timely diagnosis and treatment of ill and injured animals within the herd or flock. State animal protection laws typically prohibit “unnecessary pain and suffering,” and provide exemptions for customary livestock husbandry practices. However, defining what pain may be deemed “unnecessary” and which routine surgical procedures are “customary” is a contentious debate for the legal system and for livestock producers. Regional differences exist in terms of husbandry practices that are criticized, as well as the manner in which animal pain is addressed by animal producers, veterinarians, and policymakers. Differences in regulations and policies about painful husbandry procedures occur partly due to cultural reasons and public pressure, as well as understanding of animal welfare science, practical and economic constraints for implementation by producers and differences in data requirements for drug approval by regulatory agencies, especially for food producing species. Pain is defined by the International Association for the Study of Pain as “an unpleasant sensory and emotional experience associated with actual or potential tissue damage.” For both humans and animals, affective states such as pain can only be measured indirectly, and hence present challenges when designing experiments to gather empirical data. Whereas verbal self-reporting is the Gold Standard for pain assessment in humans, non-verbal procedures such as operant preference/avoidance tests are needed to enable animals to respond to our questions about their feelings of pain and distress. Interdisciplinary research teams, including animal scientists, biomedical scientists, agricultural engineers and applied ethologists, are developing novel and emerging techniques to facilitate scientific scrutiny of animal pain, to explore endogenous mechanisms of analgesia and to evaluate novel and currently available pain mitigating interventions. Understanding species-specific responses to pain and techniques to measure animal pain and distress in the laboratory or on farm, and efficacy of pain mitigating interventions are essential for development of socially acceptable husbandry guidelines, effective management of convalescent livestock and decision-making about humane endpoints, culling and euthanasia.

Key Words: pain, analgesia, animal welfare

820 The impact of housing and exercise on inflammatory molecules in the joints of open gilts. M. W. Orth,* J. M. Mapes, C. I. Robison, J. E. Link, and G. M. Hill, *Michigan State University, East Lansing.*

Osteoarthritis, a degenerative disease of articular cartilage, can contribute to the incidence of lameness in sows. Housed in gestation crates, sows spend much of their reproductive lives with limited mobility. Joint disuse may exacerbate joint degeneration. Degradation of articular cartilage produces an inflammatory process within the joint. The purpose of these studies was to determine if housing type and exercise affect the production of inflammatory molecules in joints. The objective was to measure concentrations of prostaglandin E2 (PGE2), interleukin-6 (IL-6), and leukotriene B4 (LTB4) in radioulnar joint synovial fluid. In Study 1, 16 Yorkshire × Landrace gilts, with an average BW of 125 kg, were housed in gestation crates (C, n = 8) or pens (P, n = 8) for 8 wk. Crates measured 0.6 m × 2.1 m and pens measured 2.4 × 3.0 m, with 4 animals per pen. In study 2, 18 gilts of the same breed cross (average BW of 114 kg) were housed in crates of the same dimensions. For 8 wk, 9 gilts ran 217 m, 5 d/wk (E), while the other 9 gilts remained in crates without exercise (NE). In both studies at the end of 8 wk sows were harvested and both forelimbs were collected from each gilt and placed on ice. Legs were cleaned of soft tissue while maintaining a closed radioulnar joint. Synovial fluid samples were collected via hypodermic needles, placed in microcentrifuge tubes, and stored at −80°C. Concentrations of PGE2, IL-6, and LTB4 were measured in the synovial fluid. There were no differences in PGE2, IL-6, or LTB4 concentrations between C and P gilts in Study 1. In Study 2 concentrations of IL-6 and LTB4 were not different between E and NE gilts. Non-exercised gilts had higher PGE2 concentrations than E gilts. Prostaglandin E2 is produced by articular cartilage as a result of trauma or degradation and inhibits collagen synthesis and activates matrix metalloproteinases. Therefore, higher concentrations of PGE2 in the joints of NE gilts over a period of time may be problematic. Even a short daily bout of exercise may reduce or prevent the production of inflammatory molecules in sedentary animals.

Key Words: inflammation, housing, exercise

821 Argon versus CO_2 gas induction of unconsciousness in piglets. L. J. Sadler*[1], T. M. Widowski[2], C. Wang[1], A. K. Johnson[1], and S. T. Millman[1], [1]*Iowa State University, Ames,* [2]*University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to compare efficacy of argon and CO_2 gases to induce unconsciousness and effects on piglet distress. Sixty-six 7-d-old piglets (BW 3.27 ± 0.24) from 11 litters were utilized. Three treatments were compared: 100% CO_2, 100% argon (ARG) and a control novel odor (peppermint: ODOR), supplied at 35% chamber volume exchange rate/min. Piglets were tested as pairs utilizing a modified Euthanex AgPro (Value-Added Science and Technology, Mason City, IA). Piglets were placed in the box and exposed to gas treatment until 30 s after loss of posture, at which time they were removed, checked for signs of sensibility (corneal reflex, pupil dilation and nose prick), and then placed in a pen until normal behavior resumed. ODOR piglets remained in the box for 14 min. Digital audio recordings were collected using a Marantz PMD 661 recorder and Crown PZM185 microphone during exposure to gas and analyzed with the STREMODO program for distress vocalizations. Individual piglets were weighed on d0 and d+1 relative to treatment and at weaning. Pupil dilation occurred in more ARG than CO_2 pigs (59% vs. 23%, $P = 0.02$), but there were no differences between gases for other signs of sensibility ($P > 0.1$). Piglets exposed to ARG took longer to lose posture ($P < 0.001$; 70 ± 8 vs. 214 ± 6, s) and to regain sensibility ($P = 0.03$; 371 ± 62 vs. 567 ± 64, s). ARG piglets performed more distress vocalizations while in the box compared with the other 2 treatments (ARG 8.8 ± 0.38, CO_2 0.34 ± 0.88 and ODOR 0.23 ± 0.25, % conscious time in which piglets were emitting a distress calls, $P < 0.001$). There were no ADG or weight differences between treatments. In conclusion, ARG to induce insensibility was more distressing for piglets than CO_2 based on number of distress calls, and increased latencies to loss of posture and return of sensibility.

Key Words: insensibility, distress, argon

822 Return to sensibility: Use of yohimbine (alpha 2-antagonistic reversal agent) for anesthetized sows.

M. D. Pairis*[1], A. K. Johnson[1], S. T. Millman[2], K. J. Stalder[1], and L. A. Karriker[2], [1]*Iowa State University Department of Animal Science, Ames,* [2]*Iowa State University Veterinary Department of Production Animal Medicine, Ames.*

The objective of this study was to evaluate yohimbine efficacy as an anesthetic reversal agent for sows. A total of 12 mixed parity sows (233.6 ± 18.7 kg) were individually housed in pens. Sows were anesthetized using a combination of Xylazine (4.4 mg/kg), Ketamine (2.2 mg/kg), and Telazol (4.4 mg/kg) injected IM. Following a 20-min stabilization period, palpebral reflex was tested to confirm insensibility, and sows were injected with either S (0.1 mg/kg) or Y (0.1mg/kg) IM in the neck. Following anesthetization, 2 anesthesia reversal treatments were compared in a cross over design; TRT 1: sterile saline (S; n = 12) and TRT 2: yohimbine (Y; n = 12). A 3-point scale (0 = alert, 1 = diminished response, 2 = unresponsive) was used to score 5 sensibility responses every 10 min. including; human approach test (HAT), sow posture, palpebral reflex, jaw tone, and nose prick. Data were analyzed using PROC MIXED of SAS. For all sensibility parameters (mean ± SE), sows returned to sensibility faster when treated with Y compared with S; palpebral reflex (45.2 ± 10.7 vs. 115.3 ± 11.2 min) jaw tone (71.3 ± 23.2 vs. 271.8 ± 25.9 min) nose prick (73.9 ± 22.5 vs. 200.8 ± 23.5 min) HAT (187.2 ± 32.6 vs. 413.1 ± 33.8 min, $P < 0.001$), and sow posture (293.54 ± 35.5 vs. 458.3 ± 37.9 min), respectively. In addition, Y reduced overall recovery time by 172 min (289.9 ± 41.0 Y vs. 461.9 ± 42.4 S min, $P < 0.001$). In conclusion, Yohimbine is an effective reversal agent in sows. Yohimbine use reduced overall recovery time and reduced latency to regain sensibility. This drug may be a tool that veterinarians and researchers can use to ensure that sows recover from anesthesia with minimal complications more quickly. Yohimbine should be considered as an adjunct treatment when anesthetizing sows based on welfare benefits associated with faster return to sensibility and reduced recovery time.

Key Words: anesthesia, yohimbine, swine

823 Herd-level risk factors for hock injuries in US freestall herds.

A. K. Barrientos*[1], N. Chapinal[1], D. M. Weary[1], E. Galo[2], and M. A. G. von Keyserlingk[1], [1]*Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada,* [2]*Novus International Inc., St. Louis, MO.*

The aim was to investigate herd-level risk factors associated with the prevalence of hock injuries on Holstein herds in the northeastern United States (NE; n = 38) and California (CA; n = 38). One group of high production multiparous cows was monitored on each farm and data on housing, production, management, lying behavior and the condition of the hocks were collected. Focal cows (38 mean ± 3 SD), randomly selected from the assessment group, were evaluated for hock injuries on a scale of 1 to 5 (1 = healthy and 5 = evident swelling and severe lesion). Outcome variables were the (logit-transformed) proportion of cows having at least a minor hock injury (≥2) or moderate-to-severe injury (≥3). Univariable associations ($P \leq 0.05$) between predictors and outcome variables are presented. Prevalence of overall and moderate-to-severe injuries in the NE averaged (±SD) 80.7 ± 22.6 and 55.4 ± 27.6, respectively. The odds of either injury decreased with access to pasture (OR ≤0.17), deep bedding (OR ≤0.05), sand bedding (OR ≤0.06), bedding dry matter (%; OR ≤0.96), daily lying time (h/d; OR ≤0.51), lying bout duration (min; OR ≤0.93), and bedding hygiene (OR ≤0.25). The odds of these injuries increased with the number of lying bouts (OR ≥1.36), group variation in lying bouts (OR ≥1.80), brisket board height (cm; OR ≥1.09). Prevalence of overall and moderate-to-severe injuries in CA averaged (±SD) 56.7 ± 21.8 and 16.2 ± 17.1, respectively. The odds of overall hock injuries in CA decreased with daily lying time (h/d; OR = 0.52) and increased with stall stocking density (%; OR = 1.04). The odds of moderate-to-severe hock injuries decreased with herd milk production (OR = 0.72 for a 1,000-kg increase). These results suggest that improvement in barn design and management can decrease hock injuries.

Key Words: leg injury, animal welfare, barn design

824 Herd-level risk factors for lameness in US freestall herds.

N. Chapinal*[1], A. K. Barrientos[1], M. A. G. von Keyserlingk[1], E. Galo[2], and D. M. Weary[1], [1]*Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada,* [2]*Novus International Inc., St Louis, MO.*

The objective was to identify herd-level risk factors for lameness in free stall housed Holstein herds in the northeastern United States (NE) and California (CA). Measures of productivity, management, housing, lying behavior and gait scores for the high producing group were collected in 40 farms in NE and 39 in CA. Predictors associated with the (logit-transformed) proportion of lame or severely lame cows at $P < 0.20$ were submitted to a multivariable general linear model and retained if $P < 0.05$. Prevalence of clinical lameness averaged (±SD) 30.8 ± 15.5% in CA and 54.8 ± 16.7% in NE; whereas, severe lameness averaged 3.6 ± 4.2% in CA and 8.2 ± 5.6% in NE. In the NE, clinical lameness decreased with herd size, deep bedding, and access to pasture, and increased with average herd lactation number and sawdust bedding. Severe lameness decreased with herd size, access to pasture, deep bedding, sand bedding, bedding hygiene and raising of heifers on farm. The final model for clinical lameness ($R^2 = 0.55$) included herd size (OR = 0.94, CI = 0.91–0.97, for a 100-cow increase), deep bedding (OR = 0.51, CI = 0.35–0.75) and average herd lactation number (OR = 2.45, CI = 1.49–4.00). The final model for severe lameness ($R^2 = 0.60$) included herd size (OR = 0.93, CI = 0.89–0.96, for a 100-cow increase) and deep bedding (OR = 0.35, CI = 0.23–0.53). In CA, clinical lameness decreased with herd size, water trough space per cow, bedding hygiene, and presence of rubber in the alley to the milking parlor, and increased with the variability of the lying bout duration. Severe lameness decreased with bedding hygiene, frequency of manure removal in the pen, and average frequency of lying bouts, and increased with average lactation number, average lying bout duration and variability of the lying bout duration. The final model for clinical lameness ($R^2 = 0.48$) included variability of the lying bout duration (min; OR = 1.06, CI = 1.03–1.09) and presence of rubber in the alley (OR = 0.54, CI = 0.35–0.81). The model for severe lameness ($R^2 = 0.42$) included variability of the lying bout duration (min; OR = 1.07, CI = 1.02–1.12) and average lactation number (OR = 3.33, CI = 1.58–7.01). In conclusion, changes in management factors may help decrease the prevalence of lameness on dairy farms.

Key Words: cow comfort, barn design, lying behavior

825 Differences in pain thresholds associated with active and healing digital dermatitis lesions in dairy cattle.

J. H. Higginson Cutler*[1], D. F. Kelton[1], G. Cramer[2,1], J. Walter[1], and S. T. Millman[2], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Cramer Mobile Bovine Veterinary Services, Stratford, ON, Canada,* [3]*Iowa State University, Ames.*

Lameness is one of the primary animal welfare concerns in the dairy industry. Digital dermatitis, an infectious cause of lameness, is common in dairy cattle and appears to be painful. The pressure algometer is a tool that reliably quantifies pain responses in cattle and swine. The objective of this study was to determine pain thresholds associated with active and healing digital dermatitis lesions. Two hundred fourteen cases of digital dermatitis were enrolled in this trial, with a convenience sample (n = 129) re-examined either once or twice 3 to 12 d following treatment with tetracycline hydrochloride. Cows were restrained in a hydraulic lift table for hoof exams and lesion identification. Digital dermatitis lesions were classified as active, healing or healed. The 1 cm diameter tip of the pressure algometer was pressed against the lesion until the cow performed a leg withdrawal response, and the corresponding force was recorded in kg. Data were censored at 25kg, the maximum pressure recording limit for the device. Regression analysis of survival data, with robust sandwich variance estimates aggregated over cow, was used to distinguish pain associated with active, healing, or healed cases of digital dermatitis. Pain thresholds were significantly different between lesions that were classified as active, healing, or healed ($P < 0.0001$), with mean force (±SD) of 7.90kg (±9.45), 12.84kg (±10.49) and 25.0kg (±0) for active, healing and healed lesions, respectively. Contrast statements demonstrated that all 3-way comparisons were significantly different ($P < 0.001$). Measurement of pain thresholds using pressure algometry confirmed that digital dermatitis lesions are painful. Although pain is reduced during the healing stage relative to the initial active stages of disease, cattle remain twice as sensitive to pressure during healing versus when lesions are fully healed. These results indicate pain management should be considered when treating digital dermatitis, and pressure algometry could be used in future research to determine efficacy of pain management interventions for lameness in cattle.

Key Words: pain, digital dermatitis, lameness

826 Effects of anti-GnRF vaccine Bopriva and band castration on acute indicators of pain in feedlot beef cattle under North American management practices.

S. Marti*[1], M. Devant[1], S. Amatayakul-Chantler[2], L. A. Jackson[3], E. D. Janzen[4], and K. S. Schwartzkopf-Genswein[5], [1]*IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes de Montbui, Barcelona, Spain,* [2]*Veterinary Medicine R&D, Pfizer Animal Health, Parkville, Victoria, Australia,* [3]*Veterinary Medicine R&D, Pfizer Animal Health, Kalamazoo, MI,* [4]*University of Calgary Veterinary Medicine, Calgary, AB, Canada,* [5]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Angus bulls (n = 60; 257 d of age; initial BW 358.8 ± 3.98 kg) were used to study the effect of an anti-GnRF vaccine and band castration on acute indicators of pain. Cattle were randomly assigned to 1 of 3 treatments: Bulls (C), band-castrated animals without pain mitigation (B), and animals administered an anti-GnRF vaccine Bopriva (I). Animals were randomly assigned to one of 6 pens and were fitted with a radio frequency ear tag so that individual animal feed intake could be recorded daily using an electronic feed bunk monitoring system. Two doses of Bopriva were administrated on d −35 and 0, and band-castration was performed on d 0. Visual analog scores (VAS) indicative of pain or discomfort were used to visually assess the behavioral responses of the bulls to the treatments on d −36, −35, −1, and 0 and salivary cortisol on d −35 and 0 as well as at −30, 0, 30, 60, 120, and 270 min post castration. Blood samples were collected on d 1, 2, 5, and 7 for determination of complete blood count (CBC). Data were analyzed using a mixed-effects model with castration, time and their interactions as main effects. No treatment differences in salivary cortisol or VAS ($P = 0.76$ and $P = 0.33$, respectively) were observed on d −35. However, on d 0, B cattle had greater ($P < 0.05$) salivary cortisol concentrations (4.6 ± 0.45 nmol/L) than C or I cattle (3.1 ± 0.45 and 3.3 ± 0.45 nmol/L, respectively). Also, VAS assessed on d 0, was 78.2 and 78.9% greater in B than C and I cattle, respectively. CBC did not differ ($P > 0.05$) between treatments on d 0, 1, and 2. However, on d 7, platelet concentration was greater ($P < 0.01$) in I than in C and B cattle. There was no indication that vaccination with Bopriva caused physiological or behavioral changes indicative of pain or discomfort. In contrast, band-castration resulted in elevated cortisol and VAS scores indicative of a pain response. Administration of Bopriva may be a welfare-friendly alternative to traditional castration methods for beef cattle.

Key Words: beef welfare, anti-GnRF vaccine, band castration

827 Effect of road transport and lairage on body temperature of feedlot steers.

J. B. Gaughan*[1], S. L. Bonner[2], I. D. Loxton[3], and R. J. Lawrence[4], [1]*The University of Queensland, Gatton, Qld, Australia,* [2]*FSA Consulting, Toowoomba, Qld, Australia,* [3]*Beef Support Services, Yeppoon, Qld, Australia,* [4]*Integrated Animal Production, Toowoomba, Qld, Australia.*

The effects of 6.5 h transport, location within truck trailer, and 16 h in lairage (LAR) following transport on the body temperature (TB) of 60 Angus steers (120 d grain-fed) were studied. Steer TB was obtained at 30 min intervals via transmitters surgically implanted 150 d before transport. Cattle were weighed and randomly allocated to a truck pen (10/pen) on loading. The truck had 3 upper deck (UD) pens (unshaded) and 3 lower deck (LD) pens (shaded). Ambient temperature (TA) and relative humidity (RH) were obtained every 30 min from loggers placed within each truck pen and at 4 lairage locations. During the trip TA was greater (29.7 ± 0.14°C;$P < 0.05$) on the UD compared with 28.5 ± 0.12°C on the LD. RH was lower ($P < 0.05$) on the UD compared with the LD at 31.8 ± 0.48% and 34.4 ± 0.41% respectively. At LAR mean TA and RH were was 24.4 ± 0.16°C and 52.4 ± 0.36% respectively. During loading TB increased from 39.4 ± 0.11°C to 40.2 ± 0.11°C. On commencement of travel TB of UD and LD cattle were 41.0 ± 0.08°C and 40. Nine ± 0.08°C ($P = 0.62$) respectively. Time series analysis was used to determine the effects of travel duration, time in LAR and location within truck on TB. Over the first 3 h of travel TB of LD cattle fell by 1.1 ± 0.7°C ($P < 0.01$) compared with 0.8 ± 0.7°C for UD cattle. Overall UD cattle TB (40.5 ± 0.11 C) were greater ($P < 0.01$) than LD cattle (40.0 ± 0.12°C). When the truck stopped for welfare checks (n = 4) TB of UD cattle increased by 0.5 to 1.1°C and 0.1 to 0.2°C for LD cattle. When travel re-commenced TB returned to the pre-stoppage values. On arrival at LAR the TB of UD and LD cattle were 40.1 ± 0.11 and 39.9 ± 0.11°C respectively ($P = 0.08$). During 16 h in LAR there were no differences between UD and LD cattle (mean TB = 39.3 ± 0.01°C; $P = 0.11$). Minimum TB (38.9 ± 0.11°C) occurred at 0300 h, and then increased gradually (39.4 ± 0.13°C) to 0900 h. The TB increase was likely due to human activity and animal movement within pens. Cattle previously on the UD were exposed to solar radiation and therefore had a greater heat load than those on the LD. However this did not appear to have any carry-over affects while the cattle were in LAR.

Forages and Pastures III

828 An electronic rising plate meter improves ability to accurately determine cool-season annual forage availability: I. Calibration.

C. Moffet,* J. Rogers, and R. Reuter, *The Samuel Roberts Noble Foundation Inc., Agriculture Division.*

A key component of managing grazing enterprises and conducting grazing research is accurate and timely forage availability determination. Hand clipping quadrats is labor intensive, typically resulting in too few samples collected to accurately estimate paddock forage mass. An electronic rising plate meter (Jenquip ECO9, Feilding, New Zealand) can quickly produce immediate, objective estimates of forage availability. Our objective was to develop a set of equations to convert plate height to dry forage mass and determine the accuracy and precision of the plate meter estimated forage mass in cool-season annual forage. The plate meter was calibrated by observing the plate meter reading (settled plate-height, cm) centered on a 1,452 cm^2 quadrat and subsequently hand clipping the forage in the quadrat to ground level. Forage was bagged, weighed wet, dried for 72-h in a forced air oven at 50°C, and reweighed. Twenty such samples were collected on 14 to 28-d intervals (Oct 25, 2011 to Jan 19, 2012) at 2 locations (total data sets = 15, total samples n = 300). The data sets included measurements of wheat and rye, each grazed and ungrazed. Forage dry weight measured on individual quadrats (range 234 to 8,557 kg/ha) was regressed (PROC MIXED) on linear and quadratic centered plate height (plate height range 0 to 43 cm) with data set as a random effect. The analysis revealed that the quadratic term was not significant so it was removed. The random effects of data set tended to cluster into 2 groups that could be associated with time of year. Adding a season fixed effect with 2 levels, fall and spring (defined as before and after Jan 1, respectively) significantly improved the model fit. The equations were fall: 92.07 × plate height (cm) + 352 kg/ha, and spring: 154.82 × plate height (cm) + 699 kg/ha. The model had an r^2 of 81% in a simple linear regression with dummy variables for season. The limit of agreement was 0 ± 1,323 kg/ha at 95% confidence. This indicates that a single plate height is an unbiased estimator of forage mass that will be within 1,323 kg/ha of the clipped forage mass measurement 95% of the time. To reliably estimate mean forage mass in a paddock, several plate height measurements are needed.

Key Words: plate meter, forage mass

829 An electronic rising plate meter improves ability to accurately determine cool-season annual forage availability: II. Application.

R. Reuter,* J. Rogers, and C. Moffet, *The Samuel Roberts Noble Foundation Inc., Agriculture Division.*

A key component of managing grazing enterprises and conducting grazing research is accurate and timely forage availability determination. An electronic rising plate meter (Jenquip ECO9, Feilding, New Zealand) can produce immediate estimates of forage availability quickly and objectively. The plate meter was calibrated (method described in a companion abstract), and the resulting equation had an r^2 of 81% in a simple linear regression. A single plate height forage mass estimate is imprecise but unbiased. Therefore, many plate height samples will improve the precision of the forage mass estimate in a paddock. Further, spatial variation of forage availability is a major component of the error of estimating forage mass. To characterize spatial variation, multiple plate heights were collected from random locations in paddocks in 2 data sets (data set 1: 90 plate heights in each of 10 paddocks of ungrazed wheat; data set 2: 60 plate heights in each of 12 paddocks of grazed rye). Coefficient of variation of plate heights within a paddock ranged from 23% to 45%. Confidence in the paddock estimates was increased by sampling more heights in each paddock and taking the means of forage mass estimates. For example, in an paddock with low estimated forage mass (1,043 kg/ha), collecting 5, 10, 30, or 60 random plate heights per paddock produced estimates of paddock forage mass with 95% confidence limits of 202, 142, 78, and 61 kg/ha, respectively. In an example paddock with high estimated forage mass (4,115 kg/ha), collecting 5, 10, 30, or 60 random plate heights per paddock produced estimates of paddock forage mass with 95% confidence limits of 792, 568, 356, and 226 kg/ha, respectively. Practitioners and researchers can use this relationship to optimize the number of plate height measurements for each enterprise or experiment.

Key Words: plate meter, forage mass

830 Evaluation of forage quality predictors in early- and late-maturing cultivars of annual ryegrass (*Lolium multiflorum* Lam.).

W. B. Smith*[1,2], R. B. Muntifering[1], E. van Santen[2], S. L. Dillard[1], E. A. Guertal[2], and D. M. Ball[2,3], [1]*Dept of Animal Sciences, Auburn University, Auburn, AL,* [2]*Dept of Agronomy & Soils, Auburn University, Auburn, AL,* [3]*Alabama Cooperative Extension System, Auburn.*

Annual ryegrass (*Lolium multiflorum* Lam.) is a commonly utilized cool-season forage in the Southeast. Conventional laboratory predictors of forage quality (FQ) are based in large measure on the inverse relationship between cell wall constituents and digestibility with advancing forage maturity. However, total nonstructural carbohydrates (TNC) could have a more robust statistical relationship with digestibility than does fiber concentration in early-maturing cool-season annuals that exhibit significant growth with decreasing temperature and photoperiod. A field experiment was conducted to determine DM yield and FQ characteristics in an early-maturing Japanese (J) cultivar (Shiwasuaoba) and a conventional cultivar (Marshall; M) as influenced by planting date. Forty-eight plots were established at 2-wk planting-date (PD) intervals (8 plots/date) at the E.V. Smith Research Center in Tallassee, AL, from September through November 2008. The experimental design was a randomized complete block (n = 4) with split-plot restriction in which cultivars were subplots. Plots were harvested when forage canopy height reached 20 cm. Samples harvested from the first and second PD (PD1 and PD2, respectively) were analyzed for IVDMD and concentrations of NDF, ADF and TNC. Standard regression of TNC on IVDMD revealed adjusted r^2 values of 0.55, 0.18, 0.00 and 0.00 for M, and 0.00, 0.89, 0.19, and 0.00 for J from PD1 in successive regrowth harvests. For PD2, values for M were 0.00, 0.13, 0.79, and 0.00, and for J were 0.82, 0.70, 0.73, and 0.00. Standard regression of ADF on IVDMD from the same harvests revealed adjusted r^2 of 0.97, 0.59, 0.00, and 0.62 for M, and 0.00, 0.99, 0.99, and 0.85 for J from PD1. Harvests of M from PD2 had adjusted r^2 values of 0.39, 0.99, 0.80 and 0.76, and J had values of 0.91, 0.99, 0.95, and 0.00. Data are interpreted to mean that concentration of ADF was the superior predictor of forage quality across both cultivars and planting dates, but that concentration of TNC shows promise as a reliable predictor of FQ in early-season harvests of the early-maturing cultivar.

Key Words: annual ryegrass, total nonstructural carbohydrates, forage quality

831 Response of postpartum dairy cows to different grazing strategies: Effect of herbage allowance on milk and solids production. M. Sprunck[1,2], D. A. Mattiauda[1], G. Motta[1], M. Fajardo[1], and P. Chilibroste*[1], *[1]Facultad de Agronomía, Paysandú, Paysandú, Uruguay, [2]Agencia Nacional de Investigación e Innovación, Montevideo, Montevideo, Uruguay.*

The effect of contrasting herbage allowances on animal performance for early lactation Holstein dairy cows was under research. The experiment was carried out in autumn 2010 at the EEMAC, Research Station, Agronomy Faculty, Uruguay (30° S). Dairy cows (n = 36, LW = 572 ± 68 kg) were blocked by parity, expected calving date, LW and BCS, and randomly assigned to one of the following treatments: high (H: 14.5 kg DM day^{-1}/100 kg LW), medium (M: 9.6 kg DM day^{-1}/100 kg LW), and low (L: 8.3 kg DM day^{-1}/100 kg LW) herbage allowances (HA, n = 12 each). Grazed in individual plots of a 2nd year mix pasture (30% *Trifolium repens* and 70% *Festuca arundinacea*) between am and pm milking (7:30 to 14:30 h). After pm milking cows were supplemented with 8.5 kg DM of a TMR diet (CP = 171 ± 10 g/kg DM, NDF = 400 ± 20 g/kg DM). The chemical composition of herbage samples were: HHA (CP = 178 ± 34 g/kg DM, NDF = 449 ± 58 g/kg DM), MHA (CP = 170 ± 30 g/kg DM, NDF = 463 ± 62 g/kg DM) and LHA (CP = 169 ± 29 g/kg DM, NDF = 487 ± 69 g/kg DM). Dry matter intake from pasture was estimated with Diet Check approach (Heard, J. W. et al., 2004). The experimental design was randomized complete block. There were no significant differences in pasture DMI, but increased milk production and milk solids production (protein and fat, kg/cow/day) was observed for HHA and MHA treatment. This could be due to the lower NDF in the diet of these cows since herbage DMI did not differ between treatments. Increased of pasture allowance from low to medium and high herbage allowances per cow, increased milk solids production (protein and fat) resulting from a better quality of herbage intake.

Table 1. Measurements

	Herbage allowance			
Item	Low	Med	High	*P*-value
Milk (L/cow/day)	24.3	27.3	25.9	0.003
% Milk fat	3.74	3.62	3.8	0.137
% Milk protein	3.12	3.19	3.21	0.008
Milk fat (kg/cow/day)	0.902	0.993	0.985	0.039
Milk protein (kg/cow/day)	0.757	0.871	0.829	< 0.001
LW (kg)	551	549	540	0.681
Pasture DMI (kg/DM)	15.6	15.7	15.4	0.275

Key Words: early lactation, grazing, herbage allowance

832 The effects of time of allocation of a ryegrass-based pasture on animal performance, nitrogen utilization and grazing behavior from late-lactation dairy cows. R. E. Vibart,* D. Pacheco, K. Lowe, and B. A. Barrett, *AgResearch Ltd., Grasslands Research Centre, Palmerston North, New Zealand.*

The consumption of a more balanced fermentable carbon to nitrogen (N) ratio from herbage can potentially enhance herbage dry matter intake (HDMI), milk production, and N utilization by dairy cows, particularly those in late lactation. Eighty lactating cows (225 ± 3.3 DIM) were used to examine the effects of allocating a morning (0730 h, AM; 2 herds) vs. an afternoon (1530 h, PM; 2 herds) fresh pasture strip of a ryegrass (*Lolium perenne* L.)-based pasture on milk production, N utilization, and grazing behavior during 4 weeks in autumn (April, 2010). Cows grazed on the same pasture strip for a 24-h period, and were offered similar daily herbage DM allowance. Herbage composition differed among treatments. Herbage from the PM treatment had greater DM (22.7 vs. 19.9%; $P < 0.01$), organic matter (OM; 89.5 vs. 88.9%; $P < 0.01$) and water soluble carbohydrate concentrations (WSC; 10.9 vs. 7.6%; $P < 0.01$), primarily at the expense of crude protein (CP; 20.5 vs. 22.2%; $P < 0.01$) and neutral detergent fiber (NDF; 48.8 vs. 50.4%; $P < 0.05$). Estimates of HDMI did not differ among treatments; mean values (±SE) were 12.8 ± 0.64 kg/d. Although milk yield was similar among treatments, trends toward greater milk fat, milk protein, and milksolids (MS) yields were observed for cows on the PM treatment (684 vs. 627 g milk fat, 545 vs. 505 g milk protein, and 1228 vs. 1132 g MS/cow, respectively; $P < 0.10$). Estimates of urinary N excretion (g/d) did not differ among treatments; mean values (±SE) were 219.6 ± 6.9 g N/d. Initial HM available (kg DM/ha) and instantaneous HM disappearance rates (kg DM/ha and per h) did not differ among treatments, but fractional disappearance rates (0.56 vs. 0.74%/h for AM vs. PM treatments, respectively) differed among treatments ($P < 0.05$). Despite similar partitioning of N toward urine, given similar amounts of herbage allocation, a simple change in management practice such as allocating a fresh strip later in the day resulted in moderate increases in N captured in milk and MS yields in late-lactation dairy cows.

Key Words: grazing, herbage allocation, nitrogen utilization

833 Effect of stocking rate and cow lactation stage on nitrogen balance of grazing dairy cows considering two periods of supplementation at pasture. A. I. Roca-Fernandez,* D. Baez-Bernal, and A. Gonzalez-Rodriguez, *Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain.*

To achieve high levels of efficiency from dairy systems is important to make the best use of nutrients for feeding cows by setting appropriate grazing management strategies on farms. For this, a balance between offer and demand has to be established at cow level. The aim of our study was to investigate the effect of stocking rate (SR), low (L, 3.9 cows/ha) vs. high (H, 5.2 cows/ha), and cow lactation stage (LS), early (E, 30 DIM) vs. middle (M, 135 DIM), on nitrogen (N) balance of grazing dairy cows. Seventy-two Holstein-Friesian cows were randomized in a block design with a 2 × 2 factorial arrangement of 4 treatments (LE, LM, HE, and HM). ΣN inputs (grass, silage, and concentrate) and ΣN outputs (milk and live weight) were evaluated in dairy cows grazing on rotationally perennial ryegrass-white clover swards. Two periods of supplementation at pasture, with (P1, March–April) vs. without (P2, May–August), were considered. Data were analyzed using PROC MIXED in SAS. Pasture and silage intake were higher ($P < 0.001$) in cows at the middle LS (15.9 ± 1.5 and 7.8 ± 0.8 kg of DM/cow per day) than in cows at the early LS (12.6 ± 0.2 and 6.2 ± 0.2 kg DM/cow per day) while concentrate intake was higher ($P < 0.001$) in cows at the early LS (4.1 ± 0.1 kg DM/cow per day) than in cows at the middle LS (1.5 ± 0.2 kg DM/cow per day). ΣN inputs were higher ($P < 0.001$) in cows at the early LS (189 ± 14 g N/cow per day) than in cows at the middle LS (163 ± 2 g N/cow per day). ΣN outputs were higher ($P < 0.001$) in cows at the early LS (121 ± 9 g N/cow per day) than in cows at the middle LS (105 ± 5 g N/cow per day). No differences were found between the 2 LS for N excretion. Supplements intake was higher ($P < 0.05$) in the high SR groups (10.4 ± 0.2 kg DM/cow per day) than in the low SR groups (9.2 ± 0.9 kg DM/cow per day). No differences were found between the 2 SR for ΣN inputs, ΣN outputs and N excretion. ΣN inputs were higher ($P < 0.001$) in the P1 (237 ± 8 g N/cow per day) than in the P2 (114 ± 19 g N/cow per day). ΣN outputs were higher ($P < 0.001$) in the P1 (140 ± 10 g N/cow per day) than in the P2 (86 ± 8 g N/cow per day). N excretion was higher ($P < 0.001$) in the P1 (479 ± 67 g N cow/

ha) than in the P2 (68 ± 24 g N cow ha-1). Increasing supplementation at pasture produced lower efficiency of N utilization by dairy cows.

Key Words: nitrogen efficiency, grazing dairy systems, supplements

834 Milk performance of two dairy cow genotypes (Holstein-Friesian vs. Normande) at two levels of supplementation (low vs. high) in long residence time grazing paddocks. A. I. Roca-Fernandez*[1,2], L. Delaby[3], S. Leurent[4], M. E. Lopez-Mosquera[2], and A. Gonzalez-Rodriguez[1], [1]*Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain,* [2]*University of Santiago de Compostela, Lugo, Galicia, Spain,* [3]*INRA Agro-Campus Ouest UMRPL, Saint Gilles-Rennes, Bretagne, France,* [4]*INRA Experimental Farm Le Pin au Haras, Borculo-Exmes, Normandy, France.*

Grazing long residence time paddocks is a way to reduce management practices, fencing and labor in dairy farm conditions. Milk performance response of 2 dairy cow genotypes, Holstein-Friesian (H) vs. Normande (N), managed at 2 levels of concentrate supplementation at pasture, low (0 kg DM/cow per day) vs. high (4 kg DM/cow per day), was investigated during 9 years (2001–2009) at Le Pin au Haras (Normandy, France) experimental farm using the simplified rotational grazing system. Cows (n = 72) were randomly assigned in a block design with a 2 × 2 factorial arrangement of 4 grazing treatments (H0, H4, N0 and N4). Animals were rotationally grazing on 3 large paddocks (2.3 ha) with a mean residence time per paddock of 10 d. The aim of this research was to study the maximum of milk yield (MY max., at d 4) and the subsequent drop of milk (Dm, at d 10) reached in each long residence time grazing paddocks for both cow genotypes managed at both feeding regimens. Daily milk yield (MY) was recorded and every 10 d the MY max. and Dm were calculated. Data were analyzed using PROC MIXED in SAS. On average, milk production was higher ($P < 0.001$) in the Holstein-Friesian cows than in the Normande cows (7,452 ± 483 over 6,067 ± 358 kg/cow per year). The highest milk performance was reached by the H4 group (8,407 ± 285 kg/cow per year) and the lowest by the N0 group (5,401 ± 587 kg/cow per year) with the other 2 groups (H0, 6,497 ± 680 and N4, 6,733 ± 120 kg/cow per year) in between. Supplemented cows produced more milk ($P < 0.001$) than unsupplemented cows (7,570 ± 207 over 5,949 ± 634 kg/cow per year). The MY max. and Dm were higher ($P < 0.001$) in the Holstein-Friesian cows (25.5 ± 2.3 and −6.2 ± 0.6 kg/cow) than in the Normande cows (21.3 ± 1.6 and −4.7 ± 0.5 kg/cow). The group of cows feeding concentrate at pasture showed higher ($P < 0.001$) MY max. and lower ($P < 0.001$) Dm (25.6 ± 1.6 and −5.3 ± 0.2 kg/cow) than unsupplemented cows (21.2 ± 1.9 and −5.7 ± 0.4 kg/cow). The results indicate the importance of controlling the MY max. and the Dm reached in each long residence time grazing paddocks for both cow genotypes at both levels of supplementation. In each paddock, a cyclic 10 d grazing sequence was observed for MY response without affecting milk performance of cows over the whole lactation.

Key Words: dairy cow breeds, simplified rotational grazing system, milk peaks and drops

835 Effect of daily herbage allowance (low vs. high) and cow lactation stage (early vs. middle) on sward quality and milk performance of grazing dairy cows. A. I. Roca-Fernandez,* A. Gonzalez-Rodriguez, and O. P. Vazquez-Yañez, *Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain.*

Sward structural characteristics have been shown to influence grass nutritive value, sward quality, pasture dry matter (DM) intake and milk performance of cows at different stage of lactation. The aim of this study was to investigate the effect of 2 daily herbage allowances (DHA), low (L, 25 kg DM cow^{-1} day^{-1}) vs. high (H, 30 kg DM cow^{-1} day^{-1}), on sward quality and milk performance of cows at 2 lactation stages (LS), early (E, 30 DIM) vs. middle (M, 135 DIM). Seventy-two Holstein-Friesian cows were randomized in a block design with a 2 × 2 factorial arrangement of 4 treatments (LE, LM, HE and HM). Animals grazed rotationally perennial ryegrass-white clover swards from March to August using variable stocking rates to impose the fixed DHA treatments. Sward quality was determined by NIRS System 6500. Daily milk yield (MY) was recorded by Alprow System and weekly milk composition was measured by MilkoScan FT6000. Data were analyzed using PROC MIXED in SAS. The low DHA treatments had more rotations ($P < 0.05$, +1 rotation), lower rotation length ($P < 0.05$, −3.7 d) and more grazing days ($P < 0.05$, +13 d) in comparison to the high DHA treatments (4 rotations, 31.4 d per rotation and 126 grazing days). The low DHA treatments showed lower pre- and post-grazing sward heights ($P < 0.05$, −2.1 and −1.0 cm) than the high DHA treatments (16.4 and 6.4 cm, respectively). The low DHA treatments presented lower ($P < 0.05$) DM content (18.4%), acid (ADF, 284 g kg^{-1} DM) and neutral detergent fiber (NDF, 509 g kg^{-1} DM) while higher ($P < 0.05$) crude protein (CP, 149 g kg^{-1} DM), water soluble carbohydrates (WSC, 167 g kg^{-1} DM) and digestibility in vitro of organic matter (747 g kg^{-1} DM) in comparison to the high DHA treatments (DM, 20.3%; ADF, 312 g kg^{-1} DM; NDF, 546 g kg^{-1} DM; CP, 131 g kg^{-1} DM; WSC, 149 g kg^{-1} DM; digestibility, 730 g kg^{-1} DM). There were differences on sward quality between rotations for both DHA treatments. The highest ($P < 0.05$) DM (26.2%) and fiber levels (ADF, 369 g kg^{-1} DM and NDF, 626 g kg^{-1} DM) and the lowest ($P < 0.05$) crude potein (CP, 106 g kg^{-1} DM), carbohydrates (WSC, 93 g kg^{-1} DM) and digestibility levels (678 g kg^{-1} DM) were found in the last rotation compared with the first rotation (DM, 16.4%; ADF, 231 g kg^{-1} DM; NDF, 433 g kg^{-1} DM; CP, 160 g kg^{-1} DM; WSC, 226 g kg^{-1} DM; digestibility, 803 g kg^{-1} DM) due to higher sward quality deterioration when grazing season advanced (from rotation 1 to 5) in both DHA treatments. Cows managed at the early LS showed higher ($P < 0.05$) MY (+5.3 kg cow^{-1} day^{-1}), with the lowest ($P < 0.05$) milk protein (−2.4 g kg^{-1}) and fat (−2.2 g kg^{-1}), than cows managed at the middle LS (19.5 kg cow^{-1} day^{-1}), with the highest ($P < 0.05$) milk protein (31.3 g kg^{-1}) and fat (39.1 g kg^{-1}). No differences were found on MY between both DHA treatments (L, 22.4 vs. H, 22.1 kg cow^{-1} day^{-1}), but higher ($P < 0.05$) milk protein (+0.9 g kg^{-1}) and fat (+1.0 g kg^{-1}) were observed in the low DHA treatments compared with the high DHA treatments (milk protein, 29.7 and fat, 37.5 g kg^{-1}). Decreasing DHA resulted in higher sward quality and milk protein and fat without penalizing MY.

Key Words: rotational grazing, grass nutritive value, pasture-based dairy system

836 Rearing of dairy heifers at pasture from temperate regions (Galicia, NW Spain). A. I. Roca-Fernandez,* A. Gonzalez-Rodriguez, and O. P. Vazquez-Yañez, *Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain.*

To reduce rearing costs, some Galician dairy farmers have considered use of pasture as the main source of nutrients for heifers for 8 mo per year (5 mo, spring grazing + 3 mo, autumn grazing) and use of grass and maize silages to supplement heifers the remaining 4 mo. A study was carried at CIAM (NW Spain) experimental farm during 2 consecutive years to evaluate sward and animal responses of dairy heifers within different age and managed at different stocking rate. The aim of this research was to identify appropriate grazing management strategies capable of being implemented on farms for reaching acceptable daily body weight (BW) gains of dairy heifers. The trial involved spring-calving Holstein-Friesian heifers (n = 40) rotationally grazing perennial ryegrass and white clover pastures from March to July and supplemented with mixed silage (grass and maize), when grass production and/or sward quality was not appropriate to achieve desirable daily BW gains at pasture, due to summer drought in August and September and cold winter season in January and February. Sward variables related to grassland management as SR, herbage utilization and grass quality were determined and animal variables related to animal performance as BW, body condition score (BCS), rump height and daily BW gains were weekly controlled in 2 groups of dairy heifers at different age (young, 11 mo vs. old, 13 mo). Data were compared using Tukey′s test. On average SR was of 3.85 animals/ha, herbage utilization of 65%, sward crude protein content of 145 g/kg of DM and digestibility in vitro of organic matter of 783 g/kg of DM. Despite the seasonality observed in Galician grass production and quality across the year (higher grass nutritive value was found in spring grazing than in autumn grazing), daily BW gains in both dairy heifer groups ranged from 0.620 to 0.980 kg/d during the experimental period. Average daily BW gain at pasture was of 0.770 kg/d in both dairy heifer groups, with higher ($P > 0.05$) BW gains observed in young heifers (0.828 kg/d) than in old heifers (0.717 kg/d) due to young heifers were managed at lower SR ($P < 0.05$; 3.17 animals/ha) than old heifers (4.69 animals/ha). Average BCS in both dairy heifer groups was of 2.86 (over 5) reaching 440 kg of BW per animal with a rump height of 137 cm to insemination. Animals in both dairy heifer groups were inseminated within 15 mo of age while on pasture. Average pregnancy rate was of 80% and calving was programmed at 24 mo in both dairy heifer groups. Results from this trial show that rearing of dairy heifers at pasture is influenced by sward (SR) and animal (age) factors. Higher daily BW gains were observed in young heifers than in old heifers due to lower SR was applied in young heifers than in old heifers.

Key Words: dairy replacement, daily body weight gain, grazing system

837 Milk urea concentration test as a quick response of the energy/protein balance in dairy cattle ration. A. I. Roca-Fernandez,* A. Gonzalez-Rodriguez, and O. P. Vazquez-Yañez, *Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain.*

When management decisions need to be taken at farm level, it is important to have an appropriate diagnosis tool as the milk urea concentration (MUC) test to get a quick response of the energy-protein balance in dairy cattle ration under different feeding conditions. The aim of this trial, carried out from March to August in 2007 at CIAM (NW Spain), was to investigate the MUC response on Holstein-Friesian dairy cows (n = 90) under 2 feeding regimens, grazing (G) vs. confinement (C), for milk production. Animals at different lactation stages, early (E) vs. late (L) calving cows, were randomly assigned to 3 treatments (GE, GL, and CE). Daily milk yield (MY) was recorded by Alprow System and weekly milk composition was measured by MilkoScan FT6000. Sward, silage and concentrate chemical composition were determined by NIRS System 6500. Data were analyzed using PROC MIXED in SAS. Silage and concentrate intake were higher ($P < 0.05$) in confined cows (9.3 ± 1.5 and 6.8 ± 1.2 kg DM/cow per day) compared with grazing cows (1.4 ± 1.0 and 2.3 ± 0.7 kg DM/cow per day). There were no differences ($P > 0.05$) between grazing treatments for pasture intake (GE, 13.6 ± 1.0 vs. GL, 13.0 ± 0.9 kg DM/cow per day) and grass crude protein content (GE, 133 ± 10 vs. GL, 146 ± 12 g/kg of DM). MY (25.6 ± 0.4 kg/cow per day) and body weight (644 ± 11 kg) were higher ($P < 0.05$) in confined cows compared with grazing cows with lower MY (GE, 24.3 ± 0.7 and GL, 18.4 ± 1.2 kg/cow per day) and body weight (GE, 569 ± 9 and GL, 601 ± 10 kg). The levels of MUC were higher ($P < 0.05$) in confined cows (CE, 251 ± 10 mg/kg) than in grazing cows (GE, 192 ± 9 and GL, 222 ± 8 mg/kg). Cows at E lactation stage showed the lowest ($P < 0.05$) values of MUC during the first month of lactation (GE, 141 ± 8 and CE, 107 ± 9 mg/kg) due to animals being in a negative energy balance situation attributed to the inability for ingesting sufficient amount of nutrients from grass and/or supplements (silage and concentrate). The highest levels ($P < 0.05$) of MUC in grazing cows were reached at 2 mo after calving (GE, 269 ± 5 and CE, 282 ± 6 mg/kg) when pastures contained highly degradable protein content and had high protein-energy ratio. The MUC test was an effective quick response diagnostic tool for detecting an imbalanced ration and correcting protein-energy levels in dairy cows at different lactation stage and feeding regimens.

Key Words: cow lactation stage, feeding regimens, milk urea content

838 Effect of calving date (spring vs. autumn) and parity (primiparous vs. multiparous) on milk performance of Holstein-Friesian grazing dairy cows from Galician conditions. A. I. Roca-Fernandez,* A. Gonzalez-Rodriguez, and O. P. Vazquez-Yañez, *Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain.*

High inputs systems are currently applied by dairy farmers using higher productivity cows (9–10 t of milk/cow per year), with shorter life persistency (2–3 lactations), higher annual replacement (40–50%) and higher rates of concentrate (3–4 t/cow per year). Nevertheless, increase on inputs costs are now driving Galician farmers to thrust on grazing systems using lower productivity cows (6–7 t of milk/cow per year), with longer life persistency (5–6 lactations), lower annual replacement (20–25%) and lower rates of concentrate (1–2 t/cow per year). Questions about cow efficiency in terms of milk production according to calving date and parity are also in farmers minds when these 2 dairy systems are compared. The aim of our study was to evaluate the effect of calving date, spring (S, 23 ± 5 DIM) vs. autumn (A, 135 ± 7 DIM), and parity, primiparous (P, 1.2 ± 0.2 lactation) vs. multiparous (M, 2.9 ± 0.4), on milk performance response of Holstein-Friesian dairy cows on spring-summer grazing conditions. Animals (n = 72) were randomized in a block design with a 2 × 2 factorial arrangement of 4 treatments (SP, SM, AP and AM) grazing rotationally perennial ryegrass-white clover pastures. Sward chemical composition was measured by NIRS System 6500. Daily milk yield (MY) was recorded by Alprow System and weekly milk composition was determined by MilkoScan FT6000. Data were analyzed using PROC MIXED in SAS. The S groups were supplemented at pasture with 6 kg/cow per day of concentrate while the A groups only received 3 kg/cow per day of concentrate. The grazing season in 2009 was divided into 3 periods according to pasture quality: (1) March–April, (2) May–July, and (3) August–September. The S groups were yielding a 32% and 22% more milk ($P < 0.001$) than the A groups (AM, 24.8 ± 1.2 and AP, 22.3 ± 0.9 kg cow-1). The MY was a 18% and 12% higher ($P < 0.001$) in the M groups than in the P groups (SP, 26.7 ± 1.5 and AP, 21.9 ± 0.7 kg/cow). The highest ($P < 0.001$) milk peak was reached by the S groups (SM, 38.8 ± 2.1 and SP, 24.9 ± 1.7 kg/cow). MY and pasture quality were progressively decreasing accross grazing season advanced. Higher ($P < 0.001$) crude protein content (160 ± 6 g/kg of DM), water soluble carbohydrates (226 ± 8 g/kg of DM) and digestibility (803 ± 18 g/kg of DM) while lower neutral detergent fiber (433 ± 11 g/kg of DM) were observed in the (1) grazing period than in the (2) and (3). The lowest ($P < 0.001$) milk protein and the highest ($P < 0.001$) fat content were reached by the A groups. The results obtained from this trial point that calving date and parity are very important factors on dairy farms conditioning cow needs and milk performance at pasture. The group of spring calving multiparous cows showed the highest milk response on spring-summer grazing while the autumn calving primiparous cows showed the lowest milk response.

Key Words: dairy cattle, stage of lactation, pasture-based milk production systems

839 Effect of oilseed concentrate source (cottonseed vs. linseed) on milk composition and fatty acids profile of dairy cows (grazing vs. silage + grazing) from NW Spain humid region. A. I. Roca-Fernandez*[1], A. Gonzalez-Rodriguez[1], O. P. Vazquez-Yañez[1], and J. A. Fernández-Casado[2], [1]*Agrarian Research Centre of Mabegondo, La Coruna, Galicia, Spain,* [2]*Agrarian and Fitopathologic Laboratory of Galicia, La Coruna, Galicia, Spain.*

Diet of dairy cows influences milk composition and fatty acid (FA) profile. The highest concentrations of conjugated linoleic acid (CLA) and unsaturated fatty acids (UFA) are usually found in pasture-based milk production systems feeding lipid supplements. The objective of this study was to investigate the effect of forage source (G, grazing vs. S, silage+grazing) on milk composition and FA profile of autumn calving Holstein-Friesian cows supplemented with different oilseed concentrates (C, cottonseed vs. L, linseed). Four groups of cows (GC, GL, SC and SL) grazed separately in 4 farmlets at CIAM (NW Spain) from spring to summer in 2008. The G groups (GC, n = 12 and GL, n = 11) were all day grazing while the S groups (SC, n = 14 and SL, n = 13) were grazing half day and received 20 kg/cow per day of grass:maize (50:50) silage (33% DM). Daily milk yield (MY) was recorded by Alprow System and weekly milk composition was measured by MilkoScan FT6000 and FA profile by gas chromatography-mass spectrometry. Short (SCFA), medium (MCFA) and long chain FA (LCFA) were determined. Mono- (MUFA) and polyunsaturated (PUFA) were calculated. Data were analyzed using PROC MIXED in SAS. Average MY was higher ($P < 0.05$) in the G groups (GC, 22.3 and GL, 21.1 kg/cow per day) than in the S groups (SC, 20.9 and SL, 20.6 kg/cow per day). Milk protein was lower ($P < 0.001$) in the G groups (GC, 30.1 and GL, 31.3 g/kg) than in the S groups (SC, 32.3 and SL, 32.0 g/kg). Milk fat was lower ($P < 0.001$) in the G groups (GC, 35.7 and GL, 37.0 g/kg) than in the S groups (SC, 38.6 and SL, 39.9 g/kg). SCFA and MCFA were lower ($P < 0.001$) in the G groups (10.7 and 40.4 g/100 g of FA) than in the S groups (12.1 and 43.4 g/100 g of FA). LCFA were higher ($P < 0.001$) in the G groups (MUFA, 23.8 and PUFA, 3.7 g/100 g of FA) than in the S groups (MUFA, 21.5 and PUFA, 3.2 g/100 g of FA). CLA content was higher ($P < 0.001$) in the G groups (1.1 g/100 g of FA) than in the S groups (0.8 g/100 g of FA). LCFA and MUFA were higher ($P < 0.05$) in the cows feeding cottonseed concentrate (37.1 and 23.4 g/100 g of FA) than in the cows feeding linseed concentrate (35.2 and 21.5 g/100 g of FA). Farmers with high reliance on grazing and cottonseed concentrate would get higher LCFA and MUFA levels in milk fat.

Key Words: grazing dairy cattle, milk fatty acids composition, lipid feed supplements

Physiology and Endocrinology II

840 The physiology of heat stress: A shift in metabolic priorities at the systemic and cellular levels. R. P. Rhoads*[1] and L. H. Baumgard[2], [1]*Virginia Polytechnic Institute and State University, Blacksburg,* [2]*Iowa State University, Ames.*

Environmental heat stress (HS) undermines efficient animal production resulting in a significant financial burden to agricultural producers. The reduction in performance parameters, either lactation or lean tissue accretion, during HS has traditionally thought to result from the typical animal response of reduced nutrient intake during environmentally driven hyperthermia. Recently, this notion has been challenged with observations indicating heat-stressed animals may exploit novel homeorhetic strategies to direct metabolic and fuel selection priorities independently of nutrient intake or energy balance. Alterations in systemic physiology support a shift in metabolism, stemming from coordinated interactions at whole-body and tissue specific levels. Such changes are characterized by increased basal and stimulated circulating insulin concentration in addition to the ostensible lack of basal adipose tissue mobilization coupled with a reduced responsiveness to lipolytic stimuli. Hepatic and skeletal muscle cellular bioenergetics also exhibits clear differences in carbohydrate production and use, respectively due to HS. The apparent dichotomy in intermediary metabolism between the 2 tissue types may stem from factors such as TCA cycle substrate flux and mitochondrial respiration. Thus, the HS response markedly alters post-absorptive carbohydrate, lipid and protein metabolism through coordinated changes in fuel supply and utilization across tissues in a manner that is distinct from commonly recognizable changes that occur in animals on a similar reduced plane of nutrition. Perhaps most intriguing is that the coordinated systemic, cellular and molecular changes appear conserved across physiological states and among different ruminant and monogastric species. Ultimately, these changes result in the reprioritization of fuel selection during HS, which may be important for whole-body metabolism and overall physiological adaptation to hyperthermia.

841 Single and double, fixed-time insemination of postpartum sows given intravaginal triptorelin gel. N. R. Augspurger*[1], M. E. Johnston[1], M. E. Swanson[2], and S. K. Webel[1], [1]*JBS United Inc., Sheridan, IN,* [2]*Pennatek LLC, Radnor, PA.*

The objective was to compare farrowing rates and litter sizes from 1 or 2 fixed-time inseminations of sows treated with 200 μg triptorelin gel (TG: OvuGel) at 96 h post-weaning with those of untreated sows inseminated daily while in estrus. Four hundred 3 weaned sows were blocked by genetic line (Ausgene, PIC), parity (parities 1–7; average parity 3.1), and previous lactation length (range 13 to 25 d; average length 19.4 d), and allocated to one of 4 treatments: 1) Controls (n = 102) inseminated the day they were observed in estrus and at 24 h intervals for the duration of estrus; 2) TG24 sows (n = 100) treated with TG 96 h post-weaning and inseminated once 24 ± 2 h post-TG; 3) TG30 sows (n = 101) treated with TG 96 h post-weaning and inseminated once 30 ± 2 h post-TG; and 4) TG24+30 sows (n = 100) treated with TG 96 h post-weaning and inseminated 24 and 30 h post-TG. The number of inseminations per sow allotted was 1.7, 1.0, 1.0, and 2.0 for treatments 1–4, respectively. Estrus was detected in 89%, 94%, 90%, and 88% of the sows in treatments 1–4, respectively. There was no effect of treatment on farrowing rate ($P = 0.743$). Farrowing rates were 83.3%, 81.0%, 77.2%, and 81.0% for treatments 1–4, respectively. Average number of pigs born alive was 11.1, 10.8, 10.7, and 11.0 for treatments 1–4, respectively ($P = 0.822$). Control sows were inseminated if detected in estrus, whereas sows assigned to TG treatment were inseminated at a fixed-time, regardless of estrus. The number of sows farrowed/number not in estrus was 0/11, 2/6, 5/10, and 4/12 for treatments 1–4, respectively. These data indicate that sows treated with TG 96 h after weaning and inseminated at a fixed-time, independent of estrus status, have farrowing rates and litter sizes comparable to sows inseminated multiple times during behavioral estrus. Furthermore, 2 fixed-time inseminations (24 and 30 h post-TG) did not improve sow performance over a single insemination given at either 24 or 30 h post-TG.

Key Words: sow, reproduction, OvuGel

842 Effects of glucuronic acid and *N*-acetylglucosamine supplementation on the in vitro maturation and fertilization of pig oocytes. A. Mello,* K. Dalton, and B. D. Whitaker, *The University of Findlay, Findlay, OH.*

Increasing the perivitelline space (PVS) surrounding pig oocytes could improve the cortical reaction and decrease the incidence of polyspermic penetration during in vitro fertilization (IVF). Oocytes were supplemented during the last 24 h of maturation with 0.01 mM of PVS components, glucuronic acid or *N*-acetylglucosamine (GlcNAc) and then subject to IVF and subsequent embryonic development. Oocytes (n = 300) were evaluated for zona pellucida and PVS thickness after maturation in addition to the presence of cortical granules using the intensity of fluorescence. Fertilization characteristics were evaluated 12 h after IVF and rates of embryonic cleavage and blastocyst development were observed at 48 h and 144 h after IVF, respectively. There were no significant differences in zona pellucida thicknesses or fluorescent intensities of cortical granules; however, unsupplemented oocytes had a significantly thinner ($P < 0.05$) PVS (10.28 ± 0.86 μm) compared with the glucuronic acid (16.44 ± 0.87 μm) and GlcNAc (15.14 ± 1.20 μm) supplemented oocytes. Oocytes supplemented with glucuronic acid had a significantly less ($P < 0.05$) incidence of polyspermic penetration (15.00 ± 6.88%) compared with unsupplemented (30.00 ± 8.07%) and GlcNAc supplemented oocytes (40.00 ± 7.93). Oocytes supplemented with GlcNAc had significantly less ($P < 0.05$) male pronuclear development (60.00 ± 4.03%) compared with unsupplemented (70.00 ± 4.77%) and glucuronic acid supplemented oocytes (75.00 ± 5.07%). No significant differences in embryo cleavage rates at 48 h after IVF were seen but oocytes supplemented with glucuronic acid had a significantly higher ($P < 0.05$) percentage of blastocysts at 144 h after IVF (40.82 ± 6.29%) compared with the unsupplemented oocytes (21.74 ± 6.49%) and the GlcNAc supplemented oocytes (19.15 ± 6.42%). The results of this study suggest that there are positive effects of 0.01 mM glucuronic acid supplementation during the oocyte maturation on successful IVF and subsequent embryo development in pigs.

Key Words: cortical granule, polyspermy, IVF

843 Litter characteristics and thermoregulatory behavior of first parity sows exposed to a controlled heat stress (HS) during gestation. M. C. Lucy*[1], T. J. Safranski[1], J. N. Rhoades[1], J. W. Ross[2], N. K. Gabler[2], R. P. Rhoads[3], and L. H. Baumgard[2], [1]*University of Missouri, Columbia,* [2]*Iowa State University, Ames,* [3]*Virginia Tech, Blacksburg.*

First parity sows suffer from seasonal infertility that is associated with HS. The objective was to test the effects of HS on thermal regulation during gestation and assess carryover effects after farrowing in first parity sows. Nulliparous gilts (n = 23) were brought into environmental chambers, inseminated and assigned to one of 2 ambient temperature treatments [HS, n = 12 (27 to 37°C; relative humidity, RH 85 to 55%) or TN, n = 11 (15 to 20°C; RH 60 to 50%)] that were applied during gestation. Rectal, ear and shoulder temperatures (RT, ET, and ST) and respiration rate [RR; breaths per minute (BPM)] were collected (0900 and 1500h). Piglets and placentas were weighed after farrowing. There was an effect of treatment ($P < 0.001$) on RT (38.4 ± 0.1 vs 38.1 ± 0.1°C), ET (35.9 ± 0.1 vs 29.6 ± 0.1°C), ST (35.8 ± 0.1 vs 29.1 ± 0.1°C), and RR (58 ± 2 vs 30 ± 2 BPM) in gestation (HS vs TN). Sows were moved to a thermoneutral farrowing room (23°C) during the last wk of gestation. Gestation was shorter ($P < 0.05$) for HS (115.7 ± 0.5 d) compared with TN (117.4 ± 0.5 d). The number of live born (11.5 ± 0.8), still born (0.3 ± 0.1), and mummies (0.4 ± 0.2) per litter were similar for HS and TN. There was an effect of treatment on birth weight ($P < 0.01$) and placental weight ($P < 0.10$) because HS sows had lighter piglets (1180 ± 50 vs 1409 ± 53 g) and lighter placenta (224 ± 12 vs 255 ± 13 g) compared with TN. The piglet weight difference (HS vs TN) was maintained for wk 1 (2171 ± 109 vs 2761 ± 113 g; $P < 0.001$) and wk 2 (3809 ± 205 vs 4488 ± 205 g; $P < 0.05$) but not at weaning (4824 ± 205 vs 5259 ± 214 g; $P > 0.10$). The RT, ET, and ST (respectively) increased ($P < 0.001$; 38.2 ± 0.1 to 39.5 ± 0.1°C, 31.8 ± 0.3 to 35.0 ± 0.3°C, 30.2 ± 0.3 to 33.8 ± 0.3°C; d −5 to d 10) after farrowing (during lactation). There was a carry-over effect of gestational HS on RT in farrowing (non-HS conditions) because HS sows had a greater increase in RT after farrowing (39.8 ± 0.1 vs 39.2 ± 0.1°C on d 2; $P < 0.001$). In summary, gestational HS shortened gestation and reduced piglet birth and placenta weight. There were carry-over effects of gestational HS on sow thermoregulation during lactation. This project was supported by USDA NIFA 2011–67003–30007.

Key Words: sow, heat stress

844 Comparison between conventional sex-sorted semen and a higher dose\ lower concentration sex-sorted semen on conception rates and calf gender ratio.

J. A. Lucena*[1], A. G. Kenyon[1], J. P. Reynolds[2], J. D. Champagne[1], T. L. Lehenbauer[1], and S. S. Aly[1], [1]*Veterinary Medicine Teaching & Research Center, School of Veterinary Medicine, University of California, Davis,* [2]*Western University of Health Sciences, Pomona, CA.*

The objective of this study was to compare conception rates and gender ratios among Jersey heifers and lactating cows inseminated with conventional (Low Dose High Sort [LDHS]) or High Dose Low Sort (HDLS) sex-sorted semen. Study subjects consisted of nulliparous heifers and lactating cows that received their first service after a 50-d voluntary waiting period (VWP). Females were allocated systematically to each treatment group. Subjects that failed to conceive were rebred to the same sire and type of sex-sorted semen for up to 2 additional services. Females that were not pregnant after 3 breeding attempts were censored. A total of 1,879 services were performed on 1,029 eligible females (LDHS; n = 499, HDLS; n = 530). Experiment groups were comparable at enrollment with respect to age at first AI among heifers ($P = 0.45$) and DIM at first AI for multiparous cows ($P = 0.53$). Nulliparous heifers bred to HDLS had a 17% higher risk of conceiving compared with LDHS (HR = 1.17; $P = 0.12$); cows had a 22% higher risk of conception to HDLS (HR = 1.22; $P = 0.05$). Insemination to HDLS resulted in fewer female calves compared with LDHS (77.4% vs. 88.4%, $P < 0.01$). The odds ratio for a female calf born to a dam inseminated to HDLS compared with LDHS was 0.44 ($P < 0.01$). The use of HDLS sex-sorted semen resulted in a minimal improvement in the instantaneous risk for pregnancy. Furthermore, the use of HDLS resulted in 11% less females compared with LDHS which may be explained by the lower gender bias in HDLS compared with LDHS. Nevertheless, the reduction in proportion of pregnancies with female calves may be cost-effective given the simpler processing technique required to sort semen into HDLS compared with LDHS.

Key Words: sex-sorted semen, sperm dose, conception rate

845 Effect of a post-weaning high-energy diet on age at puberty, testicular characteristics, and semen production in Holstein bulls.

B. R. Harstine*[1], M. Maquivar[1], L. A. Helser[2], M. D. Utt[1], C. Premanandan[3], J. M. DeJarnette[2], and M. L. Day[1], [1]*Department of Animal Sciences, The Ohio State University, Columbus,* [2]*Select Sires Inc., Plain City, OH,* [3]*Department of Veterinary Biosciences, The Ohio State University, Columbus.*

We previously reported that feeding Holstein bulls a high energy (HE) diet beginning at 58 d of age increased LH secretion at 125 d, increased testosterone concentration from 181 to 210 d, and increased scrotal circumference (SC) from 147 to 230 d. In the present experiment, the impact of this diet on age at puberty and on testicular measurements, seminiferous tubule diameter, and semen production in mature bulls is reported. From 58 to 230 ± 0.3 d of age, calves received either a high energy diet (HE, n = 8; 2.2 Mcal/kg NEm and 1.37 Mcal/kg NEg, targeted ADG 1.5 kg/d) or a control diet (n = 7; 1.70 Mcal/kg NEm and 1.09 Mcal/kg NEg, targeted ADG 0.75 kg/d). Thereafter, bulls were fed a similar diet. Beginning at 241 ± 5 d of age, semen collection was attempted and continued every 14 d using a teaser animal and artificial vagina until each bull attained puberty. Puberty was defined as the day an ejaculate containing 50×10^6 spermatozoa with 10% motility was obtained. Ages of bulls during these collections ranged from 233 to 396 d. SC was measured on d 262, 305, 332, and 367. To assess mature semen production, semen was collected thrice weekly during the 4 weeks before slaughter at 580 ± 18 d of age. Epididymal and testicular measurements were collected after slaughter, and seminiferous tubule diameter was measured using fixed and stained sections of testes. Age at puberty did not differ between treatments (310 ± 35 d), but SC was greater ($P < 0.05$) in the HE treatment during the puberty assessment period. As mature bulls, sperm production did not differ between treatments in the collections preceding slaughter. However, testis weight (318.0 ± 13.5 vs. 267.5 ± 14.4 g), epididymal weight (31.6 ± 1.1 vs. 28.0 ± 1.2 g), and testis volume (305.0 ± 11.9 vs. 244.9 ± 12.9 cm^3) were all greater ($P < 0.05$) in the HE treatment. Seminiferous tubule diameter did not differ between treatments (252.23 ± 2.44 μm). These data suggest that a HE diet initiated at 2 mo of age increased testis size, but did not accelerate puberty, increase sperm production, or increase seminiferous tubule diameter.

Key Words: bull, diet, testes

846 Oviductal protein and ovarian hormone concentrations during the first five days of the estrous cycle in first and third estrous ewe lambs and mature ewes.

J. G. Berardinelli,* *Montana State University, Bozeman.*

The objectives of this study were to determine if ampullary (AMP) and isthmic (IST) protein concentrations patterns, and progesterone (P4) and estradiol (E2) concentrations patterns differ over the first 5 d of the estrous cycle among first (pubertal; FE) and third estrous (TE) ewe lambs and mature ewes (ME). Crossbred, spring-born ewe lambs (n = 40) and mature (4- to 6-yr-old; n = 20) were assigned randomly at estrus to treatments arranged in a 3 (cycle type; CT) x 5 (day of cycle) factorial (n = 4 ewes per treatment). Observation of estrus occurred twice daily with the aid of mature, epididymectomized rams beginning in October. Each ewe was bi-laterally salpingectomized on either Day 0 (estrus), 1, 2, 3 or 4 after estrus. A jugular blood sample was collected from each ewe immediately before surgery on these days. Right and left AMP and IST segments were flushed with 4 and 2 mL of Delbecco's PBS (pH = 7.2), respectively. PMSF was added to a final concentration of 10 mM to each flushing and flushings were flash frozen in liquid N2. Protein in flushings was assayed using the BCA method (Pierce, Rockford, IL). Serum samples were assayed for P4 and E2 concentrations by RIA. There was an interaction ($P < 0.01$) between CT and day of cycle for AMP and IST protein concentrations. These interactions were caused by greater ($P < 0.05$) protein concentrations in the AMP and IST of ME than in FE ewes on Day 2 and lower ($P < 0.05$) concentrations in ME than in FE ewes on Day 4. There was an interaction ($P < 0.01$) between CT and day of cycle for P4 and E2 concentrations and P4:E2 ratios. P4 increased ($P < 0.05$) more rapidly from D 2 to 4 in ME than in FE and TE ewes. E2 increased ($P < 0.05$) from D 2 to 3 more rapidly in ME than in FE and TE ewes; whereas, E2 deceased ($P < 0.05$) from D 3 to 4 in ME and TE ewes, while E2 increased ($P < 0.05$) from D 2 to 4 in FE ewes. P4:E2 ratios increased ($P < 0.05$) from D 2 to 4 in ME and TE ewes than in FE ewes. In conclusion, concentration patterns of AMP and IST protein and ovarian steroid hormones during the first 5 d of the estrous cycle differ between FE and ME ewes. These results indicate the possibility that reduced fertility in ewe lambs at their first estrus may be caused by an inappropriate protein milieu in the AMP and IST that may be detrimental to normal early embryonic development.

Key Words: oviductal protein, ovarian steroids, ewe lambs

847 Effect of phytoestrogens on basal and GnRH-induced gonadotropin secretion from ovine pituitary cells in culture.

S. A. Arispe,* B. M. Adams, and T. E. Adams, *University of California, Davis.*

The objective of our study was to assess the effect of dietary phytoestrogens (PEs) on basal and stimulated gonadotropin secretion. We used ovine pituitary cells in culture to assess the effect of PEs on basal and GnRH agonist-induced LH and FSH secretion. Pituitary tissue was collected from wether lambs, enzymatically dispersed and aliquots of the resulting cell suspension were used to seed 24 well culture plates. After attachment, media containing vehicle, 50 or 5000 pM estradiol (E2), or increasing concentrations (1, 10, 100, or 1000 nM) of PE (coumestrol [CM] or zearalenone [ZR]) was added to 4 replicate wells. Each experiment was duplicated. Media was collected after treatment with E2 or PE for 48 h and basal FSH secretion was determined by RIA. The effect of estrogen on gonadotrope responsiveness was also assessed by incubating cells with E2 or PE for 12 h followed by addition of a GnRH agonist (Des-Gly^{10}, D-Ala^{6} GnRH ethylamide [GnRH-A] at 0.1, 1, 10, 100, 1000 pM) and incubation for 6 h. Data were analyzed using linear mixed model procedures. For basal secretion, fixed effects were treatment (TRT) and experiment (EXP). Random effect was plate (PL). For GnRH-A induced LH secretion, fixed effects were TRT, GnRH-A, and TRT:GnRH-A. Random effects were EXP, EXP:GnRH-A, PL, and PL:GnRH-A. Our data indicate that 100 nM CM and ZR decreased ($P < 0.001$) basal FSH secretion by 40%. Treatments with 50 pM E2 or 100 nM CM or ZR increased ($P < 0.01$) the sensitivity of the response to GnRH-A by 27-fold. The effects of E2 and PE on basal and agonist-induced gonadotropin secretion were blocked ($P < 0.01$) by the estrogen receptor (ER) antagonist ICI 182,780. To examine the role of specific ER isoforms in the PE-induced effects, we incubated cells with ERα or β agonists (propyl pyrazole triol [PPT] and diarylpropionitrile [DPN], respectively) and assessed basal and GnRH-A induced responses. PPT was 10–100 times more effective than DPN in decreasing basal FSH secretion and increasing GnRH-A induced LH secretion ($P < 0.01$). Overall, these data demonstrate that PEs mimic E2 and affect gonadotrope function in a manner that is likely mediated by ERα.

Key Words: phytoestrogen, gonadotropin, estrogen receptor

848 Effect of acidic pH on uterine response to interferon-τ.

A. Ahmadzadeh,* T. Davis, K. Carnahan, and C. Autran, *University of Idaho, Moscow.*

Low uterine pH associated with high blood urea and dietary protein, can reduce fertility in dairy cows. The objective was to determine the effects of acidic pH on protein expression of the endometrial cells of the bovine uteri in response to interferon-τ (IFN-τ).Using bovine endometrial (BEND) cells as a model, the experiment was designed to determine the effects of acidic pH on the production of 2 IFN tau stimulated proteins, ISG15 and Mx1. Dimethadione (DMD), a weak non-metabolizable acid, was used to decrease culture medium pH. Bovine endometrial cells were cultured in media containing 0 (pH = 7.3 ± 0.05), 10 (pH = 7.2 ± 0.05), 15 (pH = 7.0 ± 0.05), or 20 (pH = 6.8 ± 0.05) mM DMD and subsequently challenged with 0 or 10,000 antiviral units of recombinant IFN-τ and were incubated for 24 h. Once harvested, BEND cells were lysed and the lysate was analyzed for protein content. Protein was separated by SDS-PAGE and subjected to Western blot analysis and immunoblotting to assess the production of Mx1 and ISG15. DMD decreased ($P < 0.01$) the pH of the culture media. Based on optical density, IFN-τ increased ($P < 0.01$) Mx1 and ISG15 production regardless of DMD treatment after 24 h. There was effect of DMD ($P < 0.01$) and DMD by IFN-τ interaction ($P < 0.01$) on both Mx1 and ISG15. The 15 and 20 mM DMD reduced ($P < 0.01$) IFN-τ-induced Mx1 expression, whereas 20 mM DMD reduced ($P < 0.01$) ISG15 expression in response to IFN-τ indicating that acid pH abrogated BEND cell Mx1 and ISG15 production in response to IFN-τ. These results show that acidic pH disrupted IFN-τ-stimulated Mx1 or ISG15 production, and it may indicate that high dietary protein may compromise fertility by inducing lower pH in uterine secretions altering proteins essential for pregnancy.

Key Words: pH, interferon-τ, bovine endometrial cells

Symposium: Reproductive Immune Interactions

849 Maternal immunological adjustments to pregnancy in ruminants and possible implications for postpartum uterine health. P. J. Hansen,* *University of Florida, Gainesville.*

It is an oft-stated maxim that pregnancy represents a natural allograft because the conceptus inherits paternal histocompatibility genes that encode proteins recognized as foreign by the dam. Despite this fact, there is little evidence that immunological rejection or dysregulation is an important cause of pregnancy loss or retarded fetal development in livestock. The one exception may be for conceptuses produced by somatic cell nuclear cloning since increased trophoblast expression of major histocompatibility complex class I proteins and accumulation of CD3+ T lymphocytes in endometrium have been reported for cloned pregnancies. Experiments with rodents and livestock indicate that there are a multitude of mechanisms to prevent immune rejection of the conceptus. Some of these mechanisms are played out at the level of the conceptus (for example, reduced antigenicity of the trophoblast) whereas others involve regulation of maternal immune responses, largely in the endometrium, under the control of maternal or conceptus derived regulatory molecules. There is some evidence in rodents for a temporary maternal anergy toward conceptus antigens. There is also non-specific immunosuppression mediated by regulatory T cells, gamma-delta T cells, M2 macrophages, and the corpus luteum and placenta (via secretion of progesterone). It may be that the prolonged period of local immunosuppression in the endometrium during pregnancy renders the female less able to prevent establishment of microbial infections after parturition. Little is known about the restoration of immunocompetence in the uterus after parturition although some populations of immunoregulatory cells, such as gamma-delta T cells in sheep, are largely cleared in the first week postpartum. Understanding regulation of endometrial immune function during pregnancy and the consequences for postpartum immune function may lead to novel strategies to reduce microbial infections of the uterus during the postpartum period.

Key Words: pregnancy, immunology, postpartum

Ruminant Nutrition: General Ruminant Nutrition

850 Effects of crude glycerol supplementation on in vitro ruminal fermentation and Merino ewes performance. S. J. Meale*[1], S. Ding[1], T. A. McAllister[2], R. D. Bush[1], D. Palmer[1], and A. V. Chaves[1], *[1]Faculty of Veterinary Science, University of Sydney, Sydney, NSW, Australia, [2]Lethbridge Research Center, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

The increasing availability of crude glycerol from the biodiesel industry has led to an interest in its use as an energy source in ruminant diets. However, its effects on ruminal fermentation patterns and CH_4 production are unclear and there are no reports on the effect of its inclusion in the diet on wool production or growth in Merino sheep. Thus, the objectives of this study were to determine the effects of increasing levels of crude glycerol on in vitro ruminal fermentation and CH_4 production and DMI, ADG, wool growth and quality in Merino ewes. Crude glycerol replaced whole wheat (DM basis) in the diet at levels of 0, 6 and 12% DM, in both in vitro and in vivo studies. In exp. 1, diets were dried and ground through a 1-mm screen and incubated twice for 24 h. Buffer and rumen liquor were mixed 3:1 and gas production and CH_4 concentration was measured after 6, 12 and 24 h of incubation with pH and IVDMD measured at 24 h. Data from both the in vivo and in vitro experiments were analyzed using the MIXED procedure of SAS. Cumulative gas (mL/g DM) and CH_4 production (mg/g DM) were similar ($P > 0.05$) among dietary treatments. In vitro DMD (%) increased ($P < 0.01$) and pH showed a tendency ($P = 0.07$) to decline, with increasing concentrations of crude glycerol. In exp. 2, 39 Merino ewes were randomly assigned to the 3 treatments (n = 13 ewes/treatment). Diets were available continuously for a 10 wk period through the use of automatic feeders. Ewes were weighed every 7 d. Wool yield was determined on mid-side patches of 100 cm cm^2 shorn at d 0 and d 70. Dye-bands were used to determine wool growth. Intake, ADG and G:F were similar among treatments ($P > 0.05$). Neither wool yield nor length were affected by diet ($P > 0.05$). Yet, spinning fineness declined ($P < 0.05$) in ewes fed 6% DM crude glycerol and fiber diameter (μm) showed a tendency ($P = 0.06$) to decline following the supplementation of crude glycerol. This indicates the potential for crude glycerol to be included in the diets of Merino sheep at up to 12% DM with the potential to marginally improve wool quality.

Key Words: Merino ewes, methane, wool production

851 Process development and nutritional evaluation of a supplemental byproduct feed for cattle from expired grocery foods. M. A. Froetschel*[1], C. L. Ross[1], and L. E. Brewer[2], *[1]The University of Georgia, Athens, [2]Viridiun LLC, Cumming, GA.*

An ensiling experiment and a feeding/digestibility trial were conducted in response to a commercial effort to recycle outdated vegetable foods from large scale grocery stores into cattle feed. A representative mixture of vegetable, fruit and bakery refuse from several Atlanta grocery stores was processed into a homogeneous slurry. Pre-ensiled grocery byproduct (GBP) was 5.06 pH and contained 20.8% DM, 85% predicted TDN, 53.7% WSC, 23.5% NDF 14.5% ash, 12.3% CP, 11.9% fat and 17.7% lactic and 2.3% acetic acid. GBP was ensiled in 8L lab silos with pre-ensiling treatments to increase its DM content including 0, 8, 16 and 24% additions of citrus pulp and 2 levels of oven drying (5 replications / treatment). After 8 wk of anaerobic storage all GBP mixtures were effectively preserved and stable for 72 h of aerobic exposure. Ensiled GBP (100%) was 3.96 in pH, 20.6% DM,80.1% predicted TDN, 1.7% WSC, 37.6% NDF, 13.8% ash, 14.3% CP, 11.6% fat and 18.6% lactic and 2.7% acetic acid. In the feeding trial, 8 yearling Holstein steers (267 kg BW, SD = 29 kg) were fed increasing dietary concentrations of the GBP (commercially processed as Readi-Blend, Viridiun LLC) in a replicated 4 × 4 Latin Square designed experiment. Steers were fed 0, 18, 36 and 54% ensiled GBP (DM basis) as part of a total mixed ration (TMR) substituted for a control TMR. The control TMR on a DM basis was 68% wheat silage and 32% concentrate (81% soyhulls, 9.5% soybean meal and 9.5% ground corn). The TMR rations averaged 35.9, 30.7, 26.8, and 23.8% DM with increasing supplemental GPB. Steers were fed rations daily to provide 1.2 times their previous day intake with chromic oxide included as a digestibility marker. Individual intakes were measured daily and BW was determined at wk intervals. Overall, steers exhibited 1.25 kg ADG during the 8 wk feeding trial. DM intake of rations, expressed as a percent of BW, was 2.12, 2.31, 2.23 and 2.07 (SE = 0.05) and increased in a quadratic manner ($P < 0.01$), respectively, with incremental levels of GBP. Supplemental GPB appears to be palatable and digestible as it increased DM intake 5 to 9% ($P < 0.01$), when included at 18 to 36% (DM basis) in a TMR that was very high in moisture content. Commercially processed ensiled GBP is an effective concentrate feed supplement for growing cattle.

Key Words: cattle feed, grocery byproduct, nutritive value

852 Biometrics of digestive tube of kids suckled up to 90 days fed different sources of goat milk replacers. L. S. Knupp, M. I. Marcondes,* M. M. S. Santos, N. O. Souza, L. M. Carvalho, M. A. S. Novaes, J. V. F. Souza, and C. M. Veloso, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The organs of animals have different development rates; their maximum rates occur at different ages and body weight. The development rates of each organ can be influenced by plane of nutrition. This work aimed to evaluate the biometrics of the digestive tract of goats suckled up to 90 d with different sources of goat milk replacers. Twenty-four Saanen (12) and Alpine Brown (12) kids were randomly assigned to treatments and were slaughtered at 90 d. The animals were fed with coast-cross hay and starter, both ad libitum, and one liter of milk, or replacer, per day. The treatments were goat milk (GM), cow milk (CM), fermented cow colostrum (FC) and lactal - commercial milk replacer (LAC). The organs were separated and weighed with and without digesta. The parameters analyzed were: Rumen, omasum, abomasum, small and large intestine. Data were analyzed using a complete randomized design, using the initial weight as a covariate. When occurred difference between treatments, the Tukey test was applied to evaluate the least squares means, using a significance level of 5%. The animals treated with CM had greater rumen weight ($P < 0.05$) than the ones fed with GM and FC (0.414 vs. 0.311 and 0.308, respectively), likely due to greater starter and hay intake. Omasum, abomasum and large intestine were not affected by applied diets and their mean weights were 0.026; 0.105 and 0.256, respectively. The small intestine in animals treated with CM, were greater than those fed FC (0.490 vs. 0.334; $P < 0.05$). In conclusion, cow milk and lactal provided the best development of the digestive tract, especially for the rumen. Supported by CNPq/INCT-CA.

Key Words: abomasum, omasum, rumen

853 Evaluation of a prototype galactooligosaccharide supplement in milk replacer for neonatal calves.

J. J. Castro*[1], C. R. Bromfield[1], H. J. Mangian[1], J. R. Loften[2], and J. K. Drackley[1], [1]*University of Illinois, Urbana,* [2]*Milk Specialties Global, Carpentersville, IL.*

Digestive disorders are common during the first few weeks of life of the newborn calf, particularly under non-optimal sanitary conditions and immune status. Strategies to improve gut health and alleviate intestinal upsets during this period are required. Non-digestible oligosaccharides with good fermentation potential may function as prebiotics that modulate growth and activity of beneficial microbial populations, which results in enhanced gut health and function. Galactooligosaccharides (GOS) have demonstrated such prebiotic potential. In this study, the effect of GOS supplementation on intestinal health, development, function, and integrity as well as performance of dairy calves was evaluated under intensified feeding conditions. Eighty purchased male calves were assigned either to a control commercial milk replacer or to the same diet enriched with GOS (ca. 3% of DM). After 2 and 4 wk, 8 calves per treatment were slaughtered. Organ size was determined and samples of rumen, duodenum, jejunum, ileum, and colon were collected for in vitro nutrient transport, permeability, and histology analysis. The remaining 48 calves continued on trial to wk 8. Body growth, nutrient intake, and fecal and respiratory scores were measured throughout the trial. Calves on the control treatment showed significantly greater growth, nutrient intake, lower fecal scores and had fewer days with elevated fecal scores than GOS-supplemented calves. Size of digestive organs, nutrient transport, and epithelial permeability were not affected by treatment. Although digesta VFA concentrations were greater for control, intestinal villi height and width and crypt depth were greater in calves receiving GOS. Although total hydrolyzed monosaccharide content was similar between diets, lactose content of the GOS-supplemented diet was much lower than the control diet (19.7% vs. 43.6%), which may have limited growth. In conclusion, the GOS-supplemented milk replacer had a laxative effect and supported slightly lower performance while promoting greater intestinal epithelial growth.

Key Words: prebiotics, galactooligosaccharides, gut

854 Remote monitoring of individual animal mineral supplement intake by range cattle.

T. Dal Molin*[1], D. Tolleson[1], J. Sprinkle[1], M. Sprinkle[2], D. Schafer[1], and B. McMurry[3], [1]*University of Arizona, Tucson,* [2]*Intel Corporation, Hillsboro, OR,* [3]*Cargill Animal Nutrition, Elk River, MN.*

Individual animal intake and behavior associated with mineral supplementation of cattle on rangelands is largely undocumented. Our objective was to develop instrumentation to remotely obtain such information. We designed and constructed a solar powered high precision load cell and continuous (every 0.25 s) data acquisition system, configured to a standard range mineral feeder. The system was field tested in November 2010 and October 2011 at the V Bar V Ranch in central Arizona. Load cell precision varied with temperature and wind. Wind speed (kph) ranged from 0 to 23 and averaged 14 ± 0.3 in 2010. Corresponding values were 0 to 32 and 11 ± 0.4 respectively, in 2011. Temperature (°C) ranged from −7 to 4 and averaged −2 ± 0.9 in 2010. Corresponding values were −1 to 11 and 2 ± 1.1 respectively, in 2011. In pre-dawn hours when ambient conditions were relatively consistent, baseline variation of the load cells was ± 2 g. This value increased to ± 17 g during mid day. Individual cow identification was accomplished via time-stamped, motion activated digital photography. Feeding bouts were classified by predetermined acute weight change thresholds and matched to a cow by visual inspection of images. Duration of feeding bouts (min) ranged from 1 to 16 and averaged 3 ± 0.4 in 2010, and 1 to 21 and 4 ± 0.4 respectively, in 2011 ($P > 0.1$). Mineral intake (g/feeding bout) ranged from 1 to 679 and averaged 109 ± 16.0 in 2010, and 2 to 1598 and 226 ± 25.4 respectively, in 2011 ($P < 0.05$). Measured total daily intake (g/cow) ranged from 1 to 1009 and averaged 190 ± 26.0 in 2010, and 2 to 1009 and 218 ± 48.6 respectively, in 2011 ($P < 0.05$). Intake rate (g/min) ranged from 1 to 182 and averaged 45 ± 5.2 in 2010, and 1 to 446 and 82 ± 8.0 respectively, in 2011 ($P < 0.05$). Correlation of the classification protocol was tested between 2 independent observers. For discrete (n = 5) bouts, $r^2 = 0.95$, SE = 5.3 ($P < 0.05$), and for multiple animal (n = 7) bouts, $r^2 = 0.75$, SE = 18.0 ($P < 0.05$). This system, as tested, is capable of providing individual animal intake of mineral supplement under rangeland management conditions.

Key Words: individual animal intake, mineral supplement, remote measurement

855 Effect of corn processing on growth performance and fecal nutrient composition in dairy bull calves fed whole or steam-flaked corn diets from pre-weaning to 8 weeks post-weaning.

J. D. Allen*[1], L. W. Hall[1], C. D. Burrows[1], and G. C. Duff[2,1], [1]*University of Arizona, Tucson,* [2]*Montana State University, Bozeman.*

A study was conducted to investigate the effect of corn processing growth performance and fecal nutrient concentrations in dairy bull calves fed from 8 weeks pre-weaning to 8 weeks post-weaning. Sixteen individually housed dairy bull calves (8 Holstein and 8 Jersey; average initial BW = 34.2 ± 8.13 kg) were separated within breed into 1 of 2 treatments: diets (starter and growing) containing either steam-flaked (SF) or whole (WC) corn. Body weights were collected on arrival, at weaning, and at study completion. Feed intakes were recorded daily. Fecal samples were collected every 7 d from 8 weeks before weaning through 8 weeks post-weaning when the first steer reached feedlot weight (125 kg). Samples were dried at 100°C until dry and ground in a Wiley mill to pass through a 1 mm screen. Ground samples were analyzed for all or part of the following: DM, ADF and NDF (Ankom 200 fiber digester, Ankom, Macedon, NY), CP (TC400; Leco Corp., St. Joseph, MI), and starch. Starch analysis was performed using an amyloglucosidase colorimetric assay. Data were analyzed as a complete random design using the mixed procedure of SAS (Cary, NC) with animal as the experiment unit and week from weaning as the repeated measures. Growth performance, including BW (initial, weaning, and final), ADG (pre- and post-wean), pre-wean DMI, and feed efficiency were similar ($P > 0.10$) across treatments, with SF animals tending ($P < 0.10$) to have higher overall DMI and lower post-wean G:F compared with WC animals. Post-weaning DMI was greater ($P < 0.05$) for SF calves versus WC calves. Pre-weaning fecal components were similar for both groups ($P > 0.10$). Fecal NDF and ADF were higher ($P < 0.01$) and starch content was lower ($P < 0.01$) in the SF group post-weaning versus the WC group. We conclude that corn processing does not affect dairy calf performance through 8 weeks post-weaning. However, fecal starch concentrations between whole and steam-flaked corn begins to diverge once the dairy calf has been weaned.

Key Words: corn processing, dairy calf, fecal nutrient

856 Effects of short-term feed restriction on ruminal function.

S. Zhang*[1], D. R. Barreda[2], J. R. Aschenbach[3], and G. B. Penner[1], [1]*University of Saskatchewan, Saskatoon, SK, Canada,* [2]*University of Alberta, Edmonton, AB, Canada,* [3]*Free University of Berlin, Berlin, Germany.*

This study was conducted to evaluate whether the severity of short-term feed restriction (FR) affects ruminal function. Eighteen ruminally cannulated heifers were blocked by BW and randomly assigned to 1 of 3 treatments differing in the severity of FR; 75, 50, or 25% of ad libitum intake relative to the baseline period. Each heifer was exposed to 14 d for adaptation, 5 d for baseline, 5 d of FR, and 3 wk of recovery (R1, R2, and R3). Heifers were fed the same diet (60% forage: 40% concentrate) throughout the study and were fed ad libitum during the baseline and recovery periods. Water was available at all times. Ruminal pH and DMI were measured daily and absorptive function was evaluated using the temporarily isolated and washed reticulo-rumen technique. There was a treatment × period interaction for DMI ($P < 0.01$) with lowest values for 25% (2.65 kg/d), intermediate for 50% (5.3 kg/d), and greatest for 75% (8.2 kg/d) during FR, but differences were not observed among treatments within other periods. Treatment × period interactions were also detected for nadir ($P < 0.01$), mean ($P < 0.01$) and maximum ($P < 0.01$) ruminal pH. Generally, heifers fed 25% increased pH to a greater extent during FR but decreased to a greater extent during R1 when compared with those fed 50 and 75%. The area ($P < 0.01$) that pH <5.5 was smaller during FR (0.4 pH × min/d) and greater during R1 (80.4 pH × min/d) than baseline (24.2 pH × min/d), but R2 and R3 (44.9 and 36.2 pH × min/d, respectively) did not differ from baseline. The absolute rate (mmol/h) for acetate absorption ($P < 0.01$) was greater during baseline (332.1 mmol/h) than FR (253.5 mmol/h) with the rate being faster in R3 relative to FR; however, the rates did not differ between R1 (320.0 mmol/h) and R3 (343.8 mmol/h). Absolute rates for propionate and butyrate absorption (period effect, $P \leq 0.04$) also followed a similar pattern as for acetate, except that baseline and FR values did not differ. The results of this study indicate that 5-d FR increases the risk for ruminal acidosis, regardless of the severity of FR imposed, which may be linked to negative carry-over effects of FR on acetate absorption.

Key Words: feed restriction, ruminal pH, short-chain fatty acid absorption

857 Identifying improbable feed samples using a multivariate procedure.

P. S. Yoder,* N. R. St-Pierre, and W. P. Weiss, *The Ohio State University, Wooster.*

Individual feed analyses can be in error and unrepresentative of a feed population. Erroneous feed samples within a feed summary will decrease the accuracy of summarized nutrient statistics and may reduce ration formulation accuracy. Our objective was to implement a robust multivariate procedure for identification of improbable samples and to create an accurate database summarizing nutrient means, SD, and covariances of feeds. The covariance of nutrients is critical for understanding complex nutrient variation and the NRC (2001) feed library does not provide covariances. The procedure examines 3 statistics; individual nutrient concentrations of a single sample, the covariance of a single sample, and the joint covariance of multiple samples. The SAS (version 9.3) procedures were univariate, principal component analysis (PCA), and two-stage clustering (TSC), respectively. Specific removal criteria were: nutrient concentrations > 3.5 SD from the mean, PCA scores > 3.5 SD from the mean PCA, and concurrent global peaks of pseudo F-statistic and pseudo T-Square. The proposed procedure results in minimal statistic changes (<1%) when applied to a simulated normal population free of outliers. Adding simulated erroneous samples greatly affected the covariance in some situations and application of the procedure removed problematic samples and resulted in similar statistics of interest compared with the normal population. The procedure was applied to 133,677 corn silage samples and 18,237 samples were removed (83% of the removed samples by PCA and TSC). After removal of improbable samples, the ash with lignin correlation decreased from 0.65 to 0.30, SD changes ranged from 0.02 to 1.04 units, and minor changes of the means were observed. Correlations of −0.31 (NDF with lignin), −0.37 (NDF with starch) and −0.29 (NDF with CP) were observed in the removed outlier clusters compared with correlations of 0.70, −0.88, and 0.18 in the proposed corn silage population, respectively. Evaluating multiple nutrients of a feed sample using a multivariate procedure is more robust compared with examining one nutrient and is important for obtaining accurate covariance estimates.

Key Words: covariance, multivariate

858 Application of meta-analysis to build new feed unit systems for ruminants based on absorbed nutrients and animal responses in France.

D. Sauvant*[1], J. L. Peyraud[2], and P. Noziere[3], [1]*AgroParistech-INRA, Paris, France,* [2]*INRA-AgroCampus, Rennes, France,* [3]*INRA UMR Herbivores, Clermont-Ferrand, France.*

A steering group is now working in France to update the Feed energy, protein systems for cattle, sheep and goat by 2013. A major goal of this project is to simply model the main digestive events to predict the absorbed flows of VFA, amino acids, glucose and fatty acids. For cattle, a large database (2156 treatments, 818 experiments) was built from the literature to develop the updated systems. The attention is first focused on the fermentable organic matter (FOM) in the rumen, which is the key to predict productions of microbial protein, volatile fatty acids and gas. FOM (54.4 ± 11.0%dry matter, DM) is predicted from diet digestible OM (DOM = 63.8 ± 8.1%DM) minus the digestible fractions in the intestines of starch, protein, fatty acids and NDF (FOM = DOM –DST –DPR – DFA –DNDF). DOM is corrected for digestive interactions due to levels of dry matter intake, % of concentrate and the rumen protein balance (duodenal CP-ingested CP). Fractions DST (8.2 ± 5.5%DM) and DPR (5.5 ± 1.8%DM) are predicted from in sacco data, DFA (3.4 ± 1.2%DM) and DNDF (3.5 ± 2.3%DM) are predicted from regressions issued from meta-analysis. A second point focusing the interest is the prediction of the microbial growth efficiency (MGE = 25.6 ± 8.6 gNm/kg of TDOMr) which is influenced by the fractional outflow rates of particles (MGE = 21.3 + 1.06 kp%/h, n = 215, nexp = 87, RMSE = 2.2) and liquids (MGE = 22.9 + 0.22 kl%/h, n = 297, nexp = 117, RMSE = 2.3). A third point of interest is the rumen undegradable protein (RUP) which are predicted from the in sacco effective degradability of N (EDN) corrected for actual transit (RUP%DM = CP%DM*(1 - EDN), n = 318, nexp = 124, RMSE = 0.94% DM). Afterward, the major empirical responses of digestion were integrated into a simple mechanistic model of the rumen with an optimization procedure to determine the optimal values of some less known parameters of digestion. The further step of the project is the updating animal requirements and their multiple responses to diet (efficiency, outflows of N, P and CH_4, composition of products…) to absorbed nutrients according to their nutritional and physiological status.

Key Words: feed unit, meta-analysis, ruminants

859 Sampling sites and inserting depth of oral stomach tube affects the fermentation parameters of ruminal fluid collected in dairy cows.

J. S. Shen,* Z. Chai, L. J. Song, J. X. Liu, and Y. M. Wu, *Institute of Dairy Science, MoE Key laboratory of Molecular Animal Nutrition, College of Animal Sciences, Zhejiang University, Hangzhou, China.*

Six rumen-fistulated dairy cows (BW = 604 ± 36 kg; milk yield = 15 ± 2.4 kg) were used in 2 trials to validate the technique for collection of ruminal fluid by a Geishauser oral stomach tube (OST). Trial 1 was conducted to compare the difference of ruminal fermentation parameters among rumen sites (cranial dorsal, cranial ventral, central, ventral, caudal dorsal and caudal ventral). Ruminal fluid was collected at 5 to 6 h after morning feeding for 3 consecutive days through rumen cannula (RC). The samples were analyzed for pH, volatile fatty acids (VFA), ammonia N, sodium, potassium, calcium, chloride, and phosphorus concentrations. Variables of ruminal fluid collected were analyzed using the mixed procedure of SAS. Compared with central or ventral rumen, cranial dorsal rumen had higher pH, ammonia and sodium concentrations, and lower VFA concentrations ($P < 0.05$), indicating that sampling site was one main factor contributing to the difference of ruminal fermentation parameters for samples collected via OST and RC. In trial 2, the fermentation parameters of ruminal fluid collected via OST at 2 inserting depth (180 or 200 cm) were compared with those of ruminal fluid collected via RC (ventral sac). When OST was inserted at a depth of 180 cm, the OST head was located in the cranial dorsal (atrium) of the rumen. Ruminal fluid collected via OST had higher pH and sodium concentration, and lower VFA, potassium, calcium and phosphorus concentrations than that collected via RC ($P < 0.05$). However, when OST was inserted at a depth of 200 cm, OST head could reach to the central rumen through the front rumen pillar. No differences were found in pH, VFA, ammonia, and ion concentrations between samples collected via 2 methods ($P > 0.05$). These results indicated that the OST should be inserted to reach the central rumen to obtain representative rumen fluid samples.

Key Words: oral stomach tube, fermentation parameters, dairy cows

860 Comparison of nutrient composition and in vitro digestion characteristics of spent mushroom soybean (*Pleurotus* spp.) substrate and soybean straw. J. P. Gafigi[1], M. Mutimura[2], and S. Uwituze*[1], [1]*National University of Rwanda, Faculty of Agriculture, Department of Animal Productions, Butare, Rwanda,* [2]*Rwanda Agriculture Board, Kigali, Rwanda.*

Landholdings in Rwanda are small with over 60% of households cultivating less than 0.7 ha. This has resulted in low animal productivity; hence the search for alternative animal feeds is encouraged in Rwanda. A study to compare nutritive values and in vitro digestibility characteristics of spent mushroom soybean substrates (SMS) and soybean straw (SBS) as potential animal feeds was conducted. Samples of SMS and SBS were analyzed for DM, OM, CP, P, Ca, NDF, and ADF. In vitro fermentation medium consisted of 1:2 ruminal fluid: McDougall′s buffer and the experiment was a completely randomized design. Each sample (0.2 g, DM basis) was put in a gas syringe and there were 3 replicates per substrate. Syringes containing samples with 30 mL of fermentation medium and 2 blanks were incubated in a water bath at 39°C for 72 h. Readings of gas volumes were recorded every 2 h. Gas accumulated within 24 h of incubation was used to calculate metabolizable energy (ME), OMD, and digestible crude protein (dCP). Data for in vitro gas production, ME, OMD, and kinetic coefficients of fermentation were statistically analyzed using PROC Nonlinear Model of SAS (9.3. Inc.). Results showed that SMS contained less ($P < 0.05$) OM, NDF, and ADF (91.7, 58.4, and 34.5% DM, respectively) compared with SBS (95.4, 74.2, and 59.79% DM for OM, NDF, and ADF, respectively), but SMS had higher ($P < 0.05$) CP (7.8% DM) than SBS (6.1% DM). SMS had less ($P < 0.05$) gas production than SBS over 72 h of incubation. SMS had less ME ($P < 0.05$) compared with SBS (1.39 vs. 1.53 Mcal/kg of DM), but more dCP ($P < 0.05$) than SBS (40.8 vs. 25.0 g/kg DM). SBS had greater ($P < 0.05$) portions classified as slow degradable, effective degradable and potential degradable than SMS. SBS required more time ($P < 0.05$) to be degraded in vitro than SMS, but both substrates had similar ($P > 0.05$) degradation rates. SMS had a high CP content but had less in vitro gas production. The low gas production might be attributable to *Pleurotus* spp., which contains complex compounds such as polyphenols and flavonides that are hardly degraded by ruminal microbes. Soybean straw is likely a better feedstuff than SMS based on its greater potential degradable portion, which is a good indicator of better quality feeds.

Key Words: digestibility, mushroom byproduct, soybean byproduct

Ruminant Nutrition Symposium: Update on Nutrient Requirements for Ruminants

861 Revising protein requirements of calves and heifers. T. M. Hill*[1], H. G. Bateman II[1], J. M. Aldrich[1], and A. J. Heinrichs[2], *[1]Nurture Research Center, Provimi North America, Brookville, OH, [2]Department of Animal Science, Penn State University, University Park.*

Research published since the dairy NRC (2001) relating to protein needs of calves and heifers was reviewed and compared with requirements from NRC (2001). The experiments used varied intakes or concentrations of CP or varied fraction or fractions of CP in the diet relative to an energy measure. Animal requirements were reviewed in 4 categories to identify advances in understanding of nutritional requirements since publication of NRC (2001). Categories included 1) calves less than 2 mo of age fed milk and starter, 2) calves to approximately 4 mo of age fed starter with limited forage, 3) pre-breeding age heifers, and 4) post-breeding age heifers. For calves in category 1, data estimating optimum ratios of amino acids for the milk-fed calf were identified. For calves in categories 1 and 2, data estimating optimum ratios of CP to ME were identified. For heifers in category 3, optimum diet CP:ME appeared similar to NRC (2001) but other differences existed. No experiments found tested the 70% RDP of CP recommendation for calves in category 3, however, approximately 65% RDP supported more typical dairy heifer ADG than lower amounts. Few differences from NRC (2001) were found for heifers in category 4. Precision or limit-feeding vs. more conventional ad lib fed programs appears to offer utility to save costs and reduce nutrient and fecal outputs with dietary adjustments to maintain protein intake relative to energy and DMI. The presentation will cite the literature since NRC (2001) found in the search. The new literature includes experiments measuring growth, rumen and whole animal metabolism, digestibility, tissue harvest, blood chemistries, and hormones. The focus will be on change in protein fraction consumed relative to growth and metabolism in calves and heifers with differences and similarities to recommendations from NRC (2001) highlighted.

862 Revising energy requirements of dairy breed calves and heifers. M. E. Van Amburgh,* *Cornell University, Ithaca, NY.*

Work conducted over the last 15 years has provided a wealth of data on the maintenance and growth requirements of dairy calves and heifers. The data provide new insights and refines our ability to describe tissue requirements for energy, protein, amino acids, fatty acids and minerals for growth. Re-evaluation of the 2001 Dairy NRC maintenance requirements for calves (Diaz et al., 2001; Tikofsky et al., 2001; Blome et al., 2003) indicated the maintenance requirement is accurate for calves up to approximately 100 kg BW. Data from harvest studies have provided information that allows us to refine the efficiencies of energy and protein utilization for growth before weaning and post-weaning. For example, the 2001 NRC calf model uses an efficiency of metabolizable energy to net energy of 0.69 (Toullec, 1989) whereas a re-evaluation indicates a value of 0.60 for lighter, leaner calves. This partial efficiency is not fixed and is a function of body fat deposited by calves which is dependent on rate of growth, stage of maturity and before weaning, the amount of fat calories consumed above maintenance. Joost et al., (2007) and Tikofsky et al. (2001) directly and indirectly demonstrated that fat deposition does not come from carbohydrates in milk fed calves and Mills et al. (2010) showed that fatty acid profile impacts fat deposition. Tissue samples from various studies were used to update the values for amino acid composition (g/100 g of CP): methionine, 1.79; lysine, 6.26; histidine, 2.41; phenylalanine 3.65; tryptophan, 1.18; threonine, 3.83; leucine, 6.96; isoleucine, 2.94; valine, 4.28; and arginine, 6.75 and provides the opportunity to better formulate pre-weaned calf diets. Data now exist to describe the apparent energy supply to the animal from pre-weaning to full rumen function and this had been lacking from growth models and will be discussed. The study by Meyer (2005) from birth to 350 kg BW provides the ability to assess application of the mature body weight and target growth system implemented by the 2001 NRC. Evaluations of the current net energy equations indicate a 35% bias in energy required when mature body size is not accounted for.

863 Protein and amino acids for growth. E. C. Titgemeyer,* *Kansas State University, Manhattan.*

The Beef NRC (1996) predicts that all AA are used by cattle for growth with equal efficiency and that the efficiency decreases linearly with BW up to 300 kg. More recent data from Holstein steers (BW 132 to 228 kg) indicate that different AA are used for growth with different efficiencies. Efficiency of AA use for whole- body protein deposition (increase in AA deposition divided by the increase in AA supply) averaged 26% for Met (11 trials), 38% for Leu (4 trials), and 64% for His (2 trials). Efficiencies of Met and Leu utilization for growth were less than predicted by NRC. Energy supplementation improves efficiency of AA utilization. Analysis of data from 11 trials demonstrated that efficiency of Met use increases with supplemental energy but decreases with BW [Efficiency = 0.465 + 0.082 supplemental GE (Mcal) - 0.0028 BW (kg)]. Improvements in Leu utilization in response to energy supplementation appear somewhat less than for Met. Improvements in AA use in response to energy supply were similar when energy was provided as glucose, fat, or VFA, so energy source is not as important a factor as energy level. Supplementation of excesses of other AA improved efficiency of use of Met, Leu, and His; this may be due in part to energy provided as AA. Increases in ruminal ammonia absorption did not affect efficiency of Met use, but improved utilization of Leu. Efficiency of Met use was improved when Gly was supplemented, and this may be due to modulation of sulfur-AA metabolism. Despite the over-estimation by NRC of efficiency of AA utilization for growth, predicted total (maintenance plus growth) AA requirements in some situations are reasonable, reflecting that maintenance requirements are less than predicted by NRC or that AA are used for growth at much greater efficiencies when AA supplies are well below the requirement for maximal protein deposition. It is unknown if growth promotants impact efficiency of AA use. NRC (1996) provides a useful framework for estimating AA requirements of growing cattle, but modifications to predicted efficiencies and maintenance requirements areneeded to improve accuracy of the estimates.

Key Words: amino acids, cattle, utilization

864 Update on protein and amino acid requirements for lactating dairy cows. H. Lapierre*[1], L. Doepel[2], and D. R. Ouellet[1], *[1]Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]Faculty of Veterinary Medicine, University of Calgary, Calgary, AB, Canada.*

The Nutrient Requirements of Dairy Cattle (NRC, 2001) states that "current knowledge (on AA) is too limited to put forth a model that

quantifies AA requirements for dairy cattle." A decade later, have we gained enough information to move forward? This presentation assumes that 1) requirements (rqt) should be expressed as metabolizable protein (MP) and not CP; 2) for simplicity, MP rqt cover only maintenance and milk; that is, MP rqt = endogenous urine (EnU) + scurf + metabolic fecal protein (MFP) + milk; 3) duodenal endogenous proteins are not part of rqt (unlike NRC, 2001). To estimate total MP rqt, first the type and amount of proteins exported out of the cow need to be estimated and then divided by an efficiency of utilization of MP supply to synthesize these proteins or end products. From 217 treatments (Doepel et al., 2004 JDS 87:1279), MP rqt for EnU and scurf averaged only 6 and 1% of MP rqt (NRC, 2001): current estimations based on Swanson (1977. JDS 60:1583) can probably be kept. Our efforts focus on the greater contributors to MP rqt: milk and MFP. Milk protein is certainly an easy assessment, acknowledging that true protein needs to be used. Conversely, MFP is a challenging measurement. Estimations from Swanson (1977) are currently used by most models, but with different interpretations (e.g., NRC, 2001 vs. CNCPS v 6.1). Furthermore, this estimation of fecal protein excretion is not divided by an efficiency factor, unlike all the other functions, probably because it includes more than excreted proteins synthesized from AA. We therefore propose to use values of endogenous loss estimated in dairy cows using an isotopic dilution method (e.g., Ouellet et al., 2010 JDS 93:4252). Once the protein rqt is estimated for each function, AA composition for the function is needed to determine AA rqt. An update of milk AA composition, based on true protein output, is proposed. Similarly, estimation of the AA composition of endogenous loss is proposed to replace the currently used composition (whole empty body weight). In addition, based on measurements of liver and mammary AA uptake, it is proposed that the efficiency of utilization 1) varies with AA supply; 2) differs among AA; 3) is the same across the different functions. These refinements should improve estimations of protein rqt for dairy cows.

Teaching/Undergraduate and Graduate Education Symposium: Online Education for a Hands-On Career: The good, the bad and the ugly of online education in animal sciences

865 Making the world your stage through best practices in distance education. E. Sewell[1], B. Parr*[1], and D. Mulvaney[2], *[1]College of Education, Auburn University, Auburn, AL, [2]Animal Sciences, Auburn University, Auburn, AL.*

Opportunities for students to participate in courses via distance education (DE) are becoming increasingly prominent in many tertiary education institutions. Those with enrollment of 10,000 or more students typically offer some distance delivered course work. Online graduate degree programs are slowly emerging in the agriculture sectors. What are some best practices for DE? Through DE classrooms, students can participate in valuable education experiences that fit around their schedule and location. Video cameras and computer technologies are employed to take students out of the normal classroom and put them in places such as active business and industry to give students a first-hand understanding of the concepts being covered. Class videos may be supplemented with PowerPoint presentations through course capture software. For example, Panopto allows instructors to have slides transition while a video is playing enabling students to simultaneously watch video and PowerPoints. Classroom capture can be used both as an off-line recorder for asynchronous videos as well as on-line for streaming classes in real time. Complimentary videos are posted via YouTube that help promote class discussions on web-based learning management systems. Communication can use text messages, social networks and video chat. Platforms are set up to enable communication with students, other instructors, and administrators using methods and tools that are already familiar and effective for them. The secret to simulating the face-to-face experience has been the frequent exposure of students to simply recorded videos of their classmates and the professor via CMS. Discussions through DE can virtually be face-to-face via video chat functions. Typewritten responses to discussion board topics may be completely replaced with the easy video capture available through CMS. Instructional videos in technical subject areas; for example, animal science can be recorded up-close and viewed and reviewed often by students, eliminating the need to "move in close" so everyone can see. Integrating sound teaching practices with technology serves as a foundation for best practices of developing a DE course and program.

866 Real and perceived barriers to distance education in animal sciences and other disciplines. K. Boland*[1], B. Parr[1], and D. Mulvaney[2], *[1]College of Education, Auburn University, Auburn, AL, [2]Animal Sciences, Auburn University, Auburn, AL.*

Providing distance education (DE) courses, while not new, has become an increasingly popular approach to serve diverse populations of learners. Despite the movement toward more DE courses in tertiary institutions, many refrain from developing DE courses due to numerous barriers involved in developing these courses, curricula and programs. We test a hypothesis that DE has not received universal respect in the animal sciences community because of a diverse number and seriousness of perceived problems to be presented here. Using a rank analysis within a multi-component, qualitative/Delphi survey, animal science faculty and administrators were asked to identify which barriers were most likely impediments toward advancement of DE development in the discipline to gain insight into the perception of which barriers are most problematic. Reasons that institutions presently did not offer courses via DE included: time constraints of faculty, costs or lack of funding; equipment and technology limitations, technical knowledge/technical support, demand for distance education, lack of recognition for faculty, pedagogical issues and concerns, administrative issues, lack of adequate compensation/ administrative appreciation for faculty's time and efforts, lack of faculty rewards or incentives, lack of ability to teach skills requiring "hands on" instruction, concerns about faculty workload, lack of time and support from administration to develop course and materials, lack of time and support from administration to learn technologies, lack of personal contact between instructor and student, concerns about course quality, equipment failures/costs of maintaining equipment, lack of faculty commitment to spend time to master the use of technologies, and lack of nonverbal communication between instructor and student. Analysis of the real and perceived barriers for developing DE options in animal sciences should enable faculty and administrators to overcome them and adapt to pedagogies, curricula, and learning systems that meet increasing expectation and demand for dynamic blended, mobile learning environments.

Key Words: distance education, barriers

867 Engaging the new biology: Integrating quantitative genetics and genomics in animal breeding graduate learning. R. M. Lewis* and B. B. Lockee, *Virginia Tech, Blacksburg.*

Over the past 25 years in land-grant institutions, focus on quantitative areas of genetics, particularly animal breeding, has reduced sharply as programs focused new hires in molecular genetics. Many faculty members with expertise in quantitative genetics are in the later stages of their careers. Thus, at a time when integrating genomic information with quantitative genetics is imperative, our capacity to train professionals with such expertise is at risk. One means to redress this situation is through across-institutional collaboration. Beginning in fall 2007, 4 universities joined efforts to develop a multi-state curriculum in animal breeding and quantitative genetics through distance-delivery. Thus far, 147 graduate students from 32 institutions have enrolled in 8 one-credit online courses, completing a total of 444 credit hours. Recently, an expanded consortium of 7 universities has formed to extend that curriculum further. Its aim is to train students with the skills to integrate advances in animal genomics with the agricultural systems emerging from our "New Biology for the 21st Century." Courses are being offered using programmatic tools in distance-delivery complemented by on-site summer short courses. The curriculum will consider 5 areas: core (prerequisite) knowledge, applications, quantitative genetics, statistical methods, and interface with molecular genetics. Educational backgrounds and aims differ among students enrolled. Therefore, the program is designed to be comprehensive, offering both breadth and depth of coverage, and to combine theory with application to solve real-world problems. The curriculum will be integrated into AG*IDEA, a national consortium of universities offering programs and courses in agriculture disciplines online. Beyond providing an infrastructure, that partnership will increase the accessibility of the curriculum nationally. The outcome will be more students pursuing and completing a postsecondary degree in quantitative aspects of genetics, with advanced skills and knowledge directly applicable to the agricultural workplace.

Key Words: distance delivery, genetics, graduate education

868 Service learning: Hands-on opportunities for on-line courses. O. U. Bolden-Tiller*[1], L. G. Martin[2], and I. Everett[1], [1]*Tuskegee University, Tuskegee Institute, AL,* [2]*Auburn University, Auburn, AL.*

Service learning can draw the most disengaged individuals into meaningful school experiences that deepen understanding and nurture practical effectiveness. We hypothesize that students enrolled in courses, including online courses, can gain skills and knowledge by participating in service learning. The objective of the current study was to ascertain knowledge gained through service learning in an introductory course in animal sciences. The service learning project (SLP) consisted of students selecting the animal species of their choice and developing an activity/fact sheet and interactive presentation geared toward 3- to 5-yr-olds. Following their participation in the SLP, 65 students enrolled in an introductory animal science class during fall 2011 completed a survey consisting of quantitative items, primarily on a Likert scale (0 = strongly disagree; 5 = strongly agree), aimed to gauge what and how these students learned, particularly in comparison to other teaching styles, such as lecture. Overall, students enjoyed the assignment, indicating that they learned more than in a lecture setting (3.57/5) and that they learned something new through the service learning project (4.24/5). Participants also indicated that they learned something beyond the assigned topic (3.35/5) and looked forward to participating in additional SLP (4.48/5). Interestingly, there was a significant difference ($P < 0.05$) in "what service learning meant" to each participant, ranging from teaching (43), learning and then teaching about what one has learned (14) and community service (7) to a class requirement (1). Our findings suggest that although students found service learning beneficial, consistent with previous findings, there were mixed results and inconsistent findings of student outcomes that seek to assess what and how service-learning students learned as well as how their learning compared with that within other pedagogical contexts, suggesting that a more rigorous assessment tool should be used to document and assess student learning in service-learning courses.

Key Words: animal sciences, service learning, distance education

869 Student learning in undergraduate animal breeding courses is improved through play of an online genetic simulation game. K. L. Kessler*[1], R. M. Lewis[2], J. P. Cassady[3], and K. M. Cammack[1], [1]*University of Wyoming, Laramie,* [2]*Virginia Polytechnic Institute and State University, Blacksburg,* [3]*North Carolina State University, Raleigh.*

The need to develop genetic simulation tools that provide undergraduate students an opportunity to apply course concepts in practice has long been recognized by educators in animal breeding. CyberSheep is an online genetic simulation tool developed at Virginia Tech, in which students manage a flock of sheep within a cooperative breeding scheme. The aim of CyberSheep is to provide a virtual lab where students can observe the consequences of their culling and breeding decisions in real time, benefiting their understanding of animal breeding concepts. Undergraduate students at the University of Wyoming and North Carolina State University were anonymously evaluated before and after playing CyberSheep to determine its contribution to their learning. Students were asked to evaluate their level of understanding of fundamental concepts used in CyberSheep including inbreeding, estimated breeding values, evaluating genetic merit of breeding stock, management of a lethal recessive allele, and cooperative breeding generally. Survey scores were analyzed using the GLM procedure of SAS. Play of CyberSheep corresponded with clear improvement ($P < 0.05$) in student understanding of cooperative breeding schemes, recessive allele management, and evaluation of genetic merit. Based on a 5-point scale, students rated their initial understanding of these 3 concepts at 3.1, 3.6, and 3.6, respectively, coinciding with a moderate level of understanding. Their scores rose ($P \leq 0.007$) to 3.6, 4.0, and 3.9, respectively, in the final survey indicating an improvement in their understanding of these same concepts with the use of CyberSheep. In general, students were satisfied with what they learned from CyberSheep with a score of 3.8, and found the simulation to be "fun" and a "worthwhile experience" with an average score of 3.5 and 3.6 for each criterion, respectively. It was concluded that the use of CyberSheep benefited animal breeding students in their understanding of fundamental concepts taught in animal breeding courses.
