Journal of Dairy Science (ISSN 0022-0302) is published monthly on behalf of the American Dairy Science Association® by the Federation of Animal Science Societies, Champaign, IL, and Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710. Business and Editorial Office: 1600 John F. Kennedy Blvd., Ste. 1800, Philadelphia, PA 19103-2899. Customer Services Office: 3251 Riverport Lane, Maryland Heights, MO 63043. Periodicals postage paid at New York, NY, and additional mailing offices. The electronic edition of the journal (ISSN 1525-3198) is published online at http://www.journalofdairyscience.org.

JOURNAL OF DAIRY SCIENCE® *SINCE 1917*

1800 S. Oak St., Ste 100, Champaign, IL 61820
Phone 217/356-5146 | Fax 217/378-4083 | adsa@assochq.org | http://www.journalofdairyscience.org

Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $818 for print. For institutions in all other countries (prices include airspeed delivery): $922 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $53 for paper copy in US, and additional $79 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: To advertise a position announcement in the News and Announcements section of the journal, please use the FASS Job Resource Center (http://www.fass.org/job.asp); e-mail jrc@assochq.org if you have questions.

For display advertising orders and inquiries please contact Bill Hipple at 212.592.4467; by fax at 214.975.2933; or by e-mail at b.hipple@elsevier.com. For non-recruitment classified advertising orders and inquiries please contact John Marmero at 212.633.3657; by fax at 212.633.3820; or by e-mail at j.marmero@elsevier.com.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact journals@assochq.org.

Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail jennig@assochq.org; fax 217.378.4083.

Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.462.1935; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Late-Breaking Original Research

LB1 Identification of a genomic region associated with severe combined immunodeficiency in pigs. E. H. Waide*[1], C. K. Tuggle[1], D. M. Thekkoot[1], N. Boddicker[1], R. R. R. Rowland[2], C. R. Wyatt[2], and J. C. M. Dekkers[1], *[1]Iowa State University, Ames, [2]Kansas State University, Manhattan.*

Severe combined immunodeficiency (SCID) is a genetic defect caused by a recessive mutation in one of several genes and has been identified in humans, horses, and dogs, and artificially created in rats and mice. SCID mice have been extensively used to study immune mechanisms, cancer progression and treatment, autoimmune diseases, and vaccination strategies. We recently reported the first discovery of SCID in pigs based on the postmortem examination of 4 related piglets from a selection line of Yorkshire pigs, which showed severely underdeveloped immune systems, later characterized as being devoid of B and T cells. Repeat matings of the 2 sires and 4 dams of these piglets produced 6 additional litters with confirmed SCID piglets in an approximately 20 to 25% frequency. Piglets with SCID appear normal up to weaning but deteriorate quickly after weaning, typically because of respiratory disease. Affected piglets have been shown to sustain human tumor growth, consistent with SCID. To identify the genomic region associated with this defect, 20 affected piglets, 50 unaffected littermates, the 6 parents, and 96 normal ancestors were genotyped using the Illumina Porcine SNP60 Beadchip. The dfam option of PLINK was used to identify a 5.6-Mb region that is associated with the defect ($P = 2.7 \times 10^{-7}$). The region contains a strong candidate gene associated with the immune system. Haplotype phasing analyses using phase (2.1.1) identified 2 distinct haplotypes that are associated with the recessive defect. Single SNP testing in the region confirmed BeadChip data and co-segregation of the region with the SCID phenotype. Sequencing of the region is underway to identify the causative mutation. This novel finding of SCID in pigs and the associated genetic test are important from several perspectives: (1) this defect may be present in commercial populations, as the line that produced the SCID pigs was originally derived from the US Yorkshire population, and (2) SCID pigs will be valuable for infectious disease research in pigs and as a biomedical model for humans. EHW is a Fellow supported by USDA NIFA National Needs grant #2010-38420-20328.

Key Words: pigs, immune system, genetics

LB2 Characterization of genetic variation within the somatotropic axis in DNA pools of beef and dairy cattle divergent for milk production, size, fertility, and immune response. M. P. Mullen*[1,2], C. Creevey[3], D. P. Berry[4], M. S. McCabe[2], D. J. Howard[1], D. A. Magee[5], M. C. Lucy[6], D. E. MacHugh[5,7], and S. M. Waters[2], *[1]Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Teagasc, Athenry, Co. Galway, Ireland, [2]UCD School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland, [3]Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Teagasc, Grange, Co. Meath, Ireland, [4]Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Teagasc, Moorepark, Fermoy, Cork, Ireland, [5]UCD School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, [6]Department of Animal Sciences, University of Missouri, Columbia, [7]UCD Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Belfield, Dublin 4, Ireland.*

The somatotropic axis is well established as a key regulator of postnatal growth and development in mammals with direct effects on agro-economic traits in livestock. The identification of genetic variants affecting performance within this axis is therefore an attractive goal. The aim of this study, using a pooled DNA approach coupled with target enrichment and high-throughput sequencing, was to identify polymorphisms and estimate allele frequencies across 83 candidate genes of the somatotropic axis in (1) dairy bulls of high or low genetic merit for milk protein percent, carcass weight, calving interval, somatic cell count, and tuberculosis susceptibility; and (2) beef bulls representing 6 beef cattle breeds. DNA samples from (1) 750 Holstein-Friesian bulls divided into 10 groups (n = 75) divergent (high and low) for genetic merit for each trait; and (2) 300 beef cattle (n = 50 per breed), were pooled using equimolar quantities from each animal to construct 16 Illumina sequence libraries. A custom Agilent Technologies SureSelect Target Enrichment System was used to selectively capture and enrich approximately 2 Mb of coding, intronic, and regulatory sequences from the 83 targeted genes. These enriched libraries were then sequenced using an Illumina Genome Analyzer II. In total, 7,450 SNPs and 995 indels were identified across all pools. Thirty-five percent (n = 2,637) of SNPs were located within 5′ and 3′ UTRs. Fifty-nine percent (n = 4,351) were intronic and 6% (n = 462) were exonic, including 223 non-synonymous substitutions (NSS) with 11 mutations resulting in a stop codon gain or loss. Significant (≥2-fold; $P < 0.01$) allele frequency differentials between the 5 low and high genetic merit groups were observed for 878 SNPs including 55 NSS (3 stop gain/loss). This study has identified novel variation and allele frequency differentials within key genes involved in growth and development, metabolism and health in cattle, potentially harboring heritable variation in performance and contributing to differences between breeds in somatotropic axis regulation and control.

Key Words: DNA pools

LB3 Imputation of microsatellite alleles from dense SNP genotypes for paternal verification. M. C. McClure[1], T. S. Sonstegard[1], G. R. Wiggans[1], A. Van Eenennaam[2], K. Weber[2], C. Penedo[2], and C. P. Van Tassell*[1], *[1]USDA-ARS, Beltsville, MD, [2]University of California, Davis.*

Microsatellite (MS) markers have recently been used for parental verification and are still the international standard despite higher cost, error rate, and turnaround time compared with single nucleotide polymorphism (SNP)-based assays. Despite domestic and international interest from producers and research communities, no viable means currently exist to verify parentage for an individual unless all familial connections were analyzed using the same DNA marker type (MS or SNP). This requirement is a major limitation for historic animals where a DNA source does not exist due to culling, death, or change in ownership of animals. Moreover, the additional cost of MS genotyping is difficult to justify when increasing numbers of commercial dairy cows are SNP genotyped and nearly every dairy sire is SNP genotyped. A simple and cost-effective method was devised to impute MS alleles from SNP haplotypes within breeds. This approach has been verified

(>98% accurate) for imputing the International Society of Animal Genetics (ISAG) recommended panel of 12 MS for cattle parentage verification across 479 dairy cattle representing 4 dairy breeds (Brown Swiss, Guernsey, Holstein, and Jersey). Some MS-haplotype associations held true across these phylogenetically diverse breeds, implying that some combinations were present before modern breed formations and have been preserved across breeds. Results from the dairy breeds were used to impute MS in 117 beef animals from 7 breeds (Belgian Blue, Devon, Angus, Maine-Anjou, Charolais, Dexter, Texas Longhorn, Ankole). While the beef MS imputation call rate was lower (69%), of those called the imputation was still fairly accurate (78%) although for most loci multiple (2–4) alleles were imputed. MS markers are currently the international standard parentage verification for exported semen; this work represents a tool to quickly migrate toward SNP based verification in 1 generation. Finally, these imputation methods can be implemented in any species with available high-density SNP genotypes flanking MS allele genotype.

Key Words: microsatellite, SNP, impute

LB4 Improvement of feed efficiency through diet and breed-dependent genetic polymorphisms.

N. V. L. Serão,* J. E. Beever, D. B. Faulkner, and S. L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign.*

The consideration of different production systems in genome-wide association studies may provide insights into the effects of markers interacting with other factors. The objective of this study was to identify SNPs with diet and breed-dependent associations for feed efficiency traits in beef cattle. A total of 1,321 steers obtained from 5 ranches (2005 to 2008) were used in this study. Animals from 5 breeds, using Angus (AN) and Simmental (SM; purebred Angus [AN], 3/4AN, 1/2AN:1/2 SM, 3/4 SM and purebred SM) were fed with 5 diets, with different ingredients, and levels of total energy and non-degradable fiber. Traits analyzed were: average daily gain (ADG), dry matter intake (DMI), residual feed intake (RFI), residual average daily gain (RADG) and residual intake and gain (RIG). For RFI, DMI was predicted using ADG, back-fat depth (BF), rib-eye area (REA) and mid-test metabolic weight (MW), whereas for RADG, ADG was predicted using DMI, BF, REA and MW. The sum of RADG and −1*RFI defined RIG. Associations were performed using Qxpak5 v.5, in a model including the fixed effects of individual SNPs, breed, diet, breed/diet by SNP interaction, initial weight (covariate), and the random effects of contemporary group (29 levels), and additive polygenic effect. A total of 33 and 26 SNPs interacting with, respectively, breed and diet, were significantly associated ($P < 0.0001$), in which 10 markers were overrepresented across all traits. In addition, 19 markers are harbored on gene regions. The SIPA1L1 gene showed diet-dependent effect for RFI. Higher efficiency is observed in animals presenting "CC" genotypes when fed diet with medium energy and non-degradable fiber content, compared with those fed a low-energy diet containing stored wet distiller grains. For the PTPRT gene, the additive effect for allele "A" was 0.3143 g higher in 3/4 AN steers compared with SM for RADG. This indicates that 3/4 AN steers present higher gain than SM steers with similar intake. Our results show the importance of identifying diet and breed-dependent genomic markers to be used for selection on different production systems.

Key Words: genome-wide association study, residual feed intake, residual average daily gain

LB5 Mixed rumen microbes respond to excess carbohydrate by synthesizing glycogen and spilling energy.

T. J. Hackmann,* K. L. Backus, and J. L. Firkins, *The Ohio State University, Columbus.*

Some pure cultures of rumen bacteria respond to excess carbohydrate by storing it as glycogen, but others respond by spilling energy. Whereas pure culture studies suggest possible responses of mixed cultures to excess carbohydrate, the response of mixed cultures has not been directly studied. We determined whether mixed rumen microbes direct excess carbohydrate toward glycogen synthesis, energy spilling, or both. Batch cultures of mixed microbes were prepared by centrifuging rumen fluid from 4 dairy cows and washing with N-free buffer. Cultures were maintained under anaerobic conditions (39°C) and contained prokaryotes, protozoa, and fungi. Cultures were dosed with 5 or 20 m*M* glucose. Heat production, free glucose, cell protein, and glycogen were measured using calorimetry, glucose-oxidase peroxidase, bicinchoninic acid, and anthrone. Glycogen was measured enzymatically in preliminary experiments, but these measurements led to lower recovery of cell components than when glycogen was measured using anthrone. Heat production was partitioned across (i) baseline endogenous metabolism (heat production before dosing glucose), (ii) glycogen synthesis (assuming 100 kJ/mol glucose residues accumulated in glycogen), and (iii) energy spilling [total heat production minus (i) and (ii)]. For cultures dosed with 5 m*M* glucose, endogenous metabolism and glycogen synthesis accounted for all (101.4 ± 7.1%) heat production; no spilling occurred ($P \geq 0.152$). For cultures dosed with 20 m*M* glucose, endogenous metabolism and glycogen synthesis accounted completely for heat production, but only initially. Energy spilling became detectable ($P \leq 0.05$) by approximately 30 min, and it eventually accounted for as much as 29.8% of heat production in one culture. After glucose was exhausted, cultures dosed with 20 m*M* glucose degraded glycogen rapidly and continued to spill energy, showing spilling may be mediated by rapid glycogen degradation. As in some pure cultures, mixed cultures can spill some energy. However, mixed cultures respond to excess carbohydrate predominantly by glycogen synthesis, without spilling, when the excess is small.

Key Words: rumen microbes, glycogen, energy spilling

LB6 Fine mapping and discovery of recessive mutations that cause abortions in dairy cattle.

P. M. VanRaden[1], D. J. Null*[1], T. S. Sonstegard[2], H. A. Adams[3], C. P. Van Tassell[2], and K. M. Olson[4], [1]*Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD,* [2]*Bovine Functional Genomics Laboratory, ARS, USDA, Beltsville, MD,* [3]*Institute for Genomic Biology, University of Illinois, Urbana,* [4]*National Association of Animal Breeders, Columbia, MO.*

Five haplotypes that never become homozygous (HH1, HH2, HH3, JH1, and BH1) were previously confirmed to have recessive effects on dairy cow conception rate. Inheritance is now routinely traced and reported. Regions suspected to contain the mutations were narrowed to 3.2 Mb for HH1 and 0.8 Mb for JH1 where source and crossover haplotypes do not become homozygous. Only crossovers between BovineSNP50 (50k) genotyped animals and a 50K parent are used in narrowing the suspect region. Because pedigrees extend many generations, crossovers of crossovers are used both to designate carrier status and in fine mapping. Sequence data then revealed the causative mutation for HH1 in the APAF1 gene on BTA5 and for JH1 in the CWC15 gene on BTA15. These 2 genes are conserved across many species, but a single nucleotide mutation in each stops the translation of DNA to protein and causes

loss of homozygous embryos and fetuses. Frequency of heterozygous animals among those genotyped is 4.5% for HH1 and 23.4% for JH1. Accuracy of detecting the fertility haplotypes using the BovineLD (LD) chip with 6,909 markers was tested by reducing 50K genotypes to LD for 1,000 animals (500 heterozygous and 500 normal) and then imputing back to 50K. Concordance was 100% between status from the LD imputed and the 50K genotypes, but can be poorer if imputation is not done first or if pedigrees are incomplete. To improve accuracy for such animals and to allow laboratories to determine status without imputation, nearby markers were selected that had lowest frequency within breed for alleles that were present in each fertility haplotype. The best 40 markers per haplotype provided high concordance without requiring pedigrees or imputation and were added to the LD chip by GeneSeek in the Genomic Profiler. For animals genotyped with other chips, inheritance of several previously known recessive defects can also be determined with 95 to 100% accuracy and used in selection and mating programs. If sequence data reveals causative mutations for the remaining fertility haplotypes, these can be added to future chips so that the nearby markers are no longer needed.

Key Words: haplotype, crossover, mutation

LB7 Maternal dietary energy source during gestation affects expression of imprinted genes in fetal tissues in sheep. X. Lan, R. Gambra, M. A. Berg, E. J. Cretney, H. Khatib, and A. E. Radunz,* *University of Wisconsin-Madison, Madison.*

Mature pregnant multiparous Polypay ewes (n = 14) were used in a randomized complete block design to evaluate the effects of maternal dietary energy source during mid- to late-gestation on gene expression in maternal placental tissue and fetal tissue. From d 67 ± 3 of gestation until necropsy (d 130 ± 1), ewes were fed 1 of 3 diets formulated to contain 3.52 Mcal ME/d. The primary energy sources were from alfalfa haylage (HL; fiber), corn (CN; starch), or dried corn distillers grains (DG; protein, fat, fiber). At necropsy, cotyledons were removed and a sample was flash-frozen. Fetuses were dissected and samples were collected from the perirenal and subcutaneous adipose depots as well as longissimus dorsi (LD) muscle. Total RNA was extracted from tissues and used to synthesize cDNA. Expression profiles of 9 ovine imprinted genes (H19, IGF2R, GRB10, MEG8, IGF2, PEG1, PEG3, DLK1, and DIO3) were estimated in placental tissue and the fetal LD using qRT-PCR. No significant differences between sex and treatment were detected among the imprinted genes. In fetal LD tissue, expression of DLK1 ($P = 0.03$) and PEG 1 ($P = 0.04$) were greater in fetuses from dams fed CN vs. HL or DG and expression of IGF2R was greater ($P = 0.01$) in fetuses from dams fed HL vs. CN or DG. Expression of DIO3 in fetal LD tissues from dams fed CN tended ($P = 0.09$) to be greater than fetal LD from dams fed HL or DG although it did not reach significance level. The DLK1 and DIO3 genes are found in a cluster of imprinted genes that is highly conserved in mammalian species. Interestingly, this cluster contains the mutation responsible for the callipyge phenotype (muscle hypertrophy) in sheep. To the best of our knowledge, this is the first report of the effects of maternal diet on gene expression in the callipyge region.

Key Words: fetal programming, imprinted genes, sheep

LB8 Potential for post-extraction algal residue to replace cottonseed meal as a protein supplement to grazing cattle. M. L. Drewery,* J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

Algal biomass has been identified as a second-generation biofuel. Significant quantities of the co-product, post-extraction algal residue (PEAR) result from conversion to biofuel. After extraction, PEAR is concentrated in protein, suggesting it may replace cottonseed meal (CSM) as a protein supplement. Our objectives were to determine the optimal level of PEAR supplementation to steers consuming low-quality forage and compare effects of supplementation on N metabolism and forage utilization to a CSM control. Five steers (BW = 198 kg) arranged in a 5 × 5 Latin square had ad libitum access to oat straw (4% CP). Treatments were infused ruminally once daily and included PEAR (18% CP) at 0, 50, 100, and 150 mg of N/kg of BW daily and CSM (43% CP) at 100 mg of N/kg of BW. Increased provision of PEAR stimulated total digestible organic matter intake (TDOMI) quadratically ($P = 0.05$) from 0.9 to 1.6 kg/d for 0 and 100 mg of N/kg of BW of PEAR, respectively. Organic matter digestibility (OMD) increased quadratically ($P < 0.01$) with supplementation, from 47 to 51% for 0 and 100 mg of N/kg of BW PEAR, respectively. At isonitrogenous levels of PEAR and CSM, TDOMI was similar ($P = 0.22$) as was OMD ($P = 0.50$). Negative N balance was observed with all treatments except PEAR provided at 100 or 150 mg of N/kg of BW. Steers consuming straw without supplemental protein lost 13.6 g of N/d. Nitrogen balance was greatest (1.84 g of N/d) when PEAR was provided at 100 mg of N/kg of BW. There were no significant differences between PEAR and CSM supplementation for plasma urea-N, ammonia, or VFA concentrations. Ammonia concentrations increased quadratically ($P = 0.05$) in response to increased supplemental PEAR, from 0.99 to 1.92 m*M* for 0 and 150 mg of N/kg of BW of PEAR. Overall, comparison of PEAR and CSM at isonitrogenous levels suggests there are no significant differences in forage intake, digestion, or N balance, suggesting cattle provided PEAR utilize forage in a similar manner to those supplemented CSM. These observations indicate PEAR may replace CSM as a protein supplement in forage-based cattle operations.

Key Words: post-extraction algal residue, supplementation

SYMPOSIA AND ORAL SESSIONS
ASN-ADSA®-ASAS Preconference: Regulation of Nutritional Intake and Metabolism

1 Role of the central melanocortin system in appetite regulation and nutrient homeostasis. B. L. Panaro and R. D. Cone,* *Department of Molecular Physiology and Biophysics, Vanderbilt University School of Medicine, Nashville, TN.*

The central melanocortin system has long been implicated as a key regulator of energy homeostasis. The melanocortin-4 receptor (MC4R) integrates various homeostatic signals to control body weight through altering food intake and energy expenditure. Inhibition of MC4R signaling causes obesity in all vertebrate species tested, from fish to humans. The most notable differences caused by MC4R deficiency are hyperphagia and decreased energy expenditure, both of which contribute to the obesity observed in humans and mice. There is substantial evidence that MC4R deficient mice overconsume high-fat diets compared with obese controls, in a single food choice model. Previous rodent studies have investigated this feeding behavior in single-diet paradigms without offering another diet choice. Surprisingly, under 2-choice diet paradigms featuring a high-fat or high-sucrose diet paired with standard chow, MC4R deficient mice invariably have a lower preference for palatable high-fat and high-sucrose diets compared with wild-type littermates. Furthermore, while dietary preference for high fat or high sucrose seems to be attenuated in the MC4R deficient mice, the drive for hyperphagia is consistently enhanced by dietary variety, as a result of increased consumption of standard chow. Together, these food preference observations suggest a role for MC4R in the processing of food-directed behaviors, with reduced MC4R signaling leading to hyperphagia in an environment presenting a variety of foods. The mechanisms that guide these behaviors are largely uncharacterized, though we hypothesize that MC4R regulates dietary behaviors through both central and peripheral contributions to gut-brain communication. For example, in additional to hypothalamic sites of action, MC4R may also affect food intake indirectly through effects on gut motility, and even effects on enteroendocrine cell function.

2 The regulation of hepatic glucose uptake in vivo. A. Cherrington,* *Vanderbilt University School of Medicine, Nashville, TN.*

In the postprandial state, the liver takes up and stores glucose to minimize the fluctuation of glycemia. Elevated insulin concentrations, an increase in the load of glucose reaching the liver, and the oral/enteral/portal vein route of glucose delivery (compared with the peripheral intravenous route) are factors that increase the rate of net hepatic glucose uptake (NHGU). The entry of glucose into the portal vein stimulates a "portal glucose signal" that not only enhances NHGU but concomitantly reduces muscle glucose uptake to ensure appropriate partitioning of a glucose load. This coordinated regulation of glucose uptake is likely neurally mediated, at least in part, since it is not observed following total hepatic denervation. Moreover, there is evidence that both the sympathetic and the nitrergic innervation of the liver exert a tonic repression of NHGU that is relieved under feeding conditions. Further, the energy sensor AMPK appears to be involved in regulation of NHGU and glycogen storage. Consumption of a high fat and fructose diet impairs NHGU and glycogen storage, in association with a reduction in glucokinase protein and activity. An understanding of the impact of nutrients themselves and the route of nutrient delivery upon liver carbohydrate metabolism is fundamental to the development of therapies for impaired postprandial glucoregulation.

3 Active and reactive amino acid homeostasis during feeding, lactation, and disease. G. E. Lobley,* *Obesity and Metabolic Health Division, Rowett Institute of Nutrition and Health, University of Aberdeen, Aberdeen, UK.*

Amino acids (AA) are critical responders and regulators during both anabolism and catabolism. In response to either acute or chronic intake AA are partitioned between oxidation and protein gain. Trans-hepatic studies suggest the utilization of ingested AA is driven primarily by the anabolic process while AA oxidation of any excess restores homeostasis. This mechanism provides a simple (and universal) means to regulate inter-tissue metabolism. Feeding exerts 2 aspects on AA metabolism. First, pattern of supply (e.g., meal or continuous) can influence net protein anabolism. In the neonate, intermittent supply gives greater efficiency whereas in the elderly single large meals may be preferred. Second, protein (AA) is the most satiating macronutrient and is used in many weight loss strategies. Satiety may be regulated through release of gut hormones that provide state of "hunger" (e.g., ghrelin) or "fullness" (e.g., PYY) signals. These may be released in response to either protein per se or to free AA. Uptake of AA by specific organs is linked to both direct (e.g., muscle growth, milk protein output) and indirect (e.g., precursors for other AA, gluconeogenesis, energy) needs. Infection increases the demands for specific AA to produce key proteins or peptides. Therefore, AA supply needed during disease differs from requirements for normal physiological processes and the deleterious effects of inflammation may be offset by extra provision of specific AA, such as glutamine, threonine and cysteine. AA or their metabolites can also indicate health status. For example, a key role played by methionine (Met) is to supply C-1 groups that methylate macromolecules involved in metabolic regulation. When either Met or other factors of the methionine cycle are limited, this results in hyperhomocysteinemia, an independent risk factor for several diseases. Kinetic studies in rodents have shown that less than 20% of tissue homocysteine flows through plasma and that uptake by key tissues, including heart, may link to disease progression. AA, both separately and as part of protein, play key roles in maintaining mammalian health and well-being.

4 Adipose and endocrine integration of metabolism. P. E. Scherer,* *UT Southwestern Medical Center, Dallas, TX.*

During the progression from the lean to the obese state, adipose tissue undergoes hyperplasia as well as hypertrophy in an attempt to cope with the increased demand for triglyceride storage. This requires a high degree of plasticity at both the cellular and at the tissue level. Even though adipose tissue as a whole seems to be a relatively static tissue containing many adipocytes that turn over slowly, these cells are embedded in an environment that can rapidly adapt to the needs of expanding and newly differentiating adipocytes. The extracellular matrix of adipose tissue faces unique challenges with respect to adjusting to the need for remodeling and expansion. In parallel, the vasculature has to adapt to altered requirements for nutrient and oxygen exchange. A decrease in the plasticity of these processes leads to metabolic dysfunction. Furthermore, to maintain a healthy, non-inflamed phenotype, complex regulatory mechanisms are in place to ensure adipocytes and stromal vascular cells efficiently crosstalk to allow adipose tissue to expand upon increased demand for storage of triglycerides. Therefore, we propose a model of stepwise adipose tissue dysfunction that is initiated by rapid expansion of existing adipocytes to accommodate triglycerides during excess caloric intake. This leads very quickly to an acute, and eventually chronic, state of hypoxia in adipose tissue. Changes during the expansion process also affect adipocyte-derived secretory factors (adipokines), such as adiponectin. Adiponectin promotes insulin sensitivity, decreases inflammation, and promotes cell survival. Its levels are frequently downregulated in the obese state. We have recently demonstrated that adiponectin potently stimulates a ceramidase activity associated with its 2 receptors, adipoR1 and adipoR2, and enhances ceramide catabolism and formation of its anti-apoptotic metabolite, sphingosine-1-phosphate (S1P). Our observations suggest a novel role of adipocyte-derived factors that have beneficial systemic effects, with sphingolipid metabolism as its core upstream component.

5 Heat stress and post-absorptive metabolic perturbations.

L. H. Baumgard*[1] and R. P. Rhoads[2], [1]*Iowa State University, Ames,* [2]*Virginia Polytechnic Institute and State University, Blacksburg.*

Environmental-induced hyperthermia compromises efficient animal production by marginalizing efforts to reduce food production inputs while negating the contribution of animal genetics toward performance endpoints. Modification of farm infrastructure has yielded modest success in mitigating heat stress-related losses yet heat stress remains arguably the costliest issue facing progressive livestock producers. Reduced output (e.g., milk yield, muscle growth, egg production) during heat stress was traditionally thought to result from decreased nutrient intake (a classic biological response shared by all animals during environmental-induced hyperthermia). Recent observations by our group challenges this belief, indicating heat-stressed animals employ novel homeorhetic strategies to direct metabolic and fuel selection priorities independently of nutrient intake or energy balance. Alterations in systemic physiology support a shift in carbohydrate metabolism, evident by changes such as basal and stimulated circulating insulin levels. Cellular metabolism of the hepatocyte and myocyte also show clear differences in glucose production and use, respectively due to heat stress. The apparent dichotomy in intermediary metabolism between the 2 tissue types may stem from factors such as mitochondrial function and antioxidant capacity. Perhaps most intriguing given the energetic shortfall of the heat stressed animal is the apparent lack of basal adipose tissue mobilization coupled with a reduced responsiveness to lipolytic stimuli. Thus, the heat stress response markedly alters post-absorptive carbohydrate, lipid, and protein metabolism independently of reduced feed intake through coordinated changes in fuel supply and utilization by multiple tissues. Interestingly, the systemic, cellular, and molecular changes appear conserved among different species and physiological states as our work has characterized similar events between growing and lactating ruminants, growing pigs and adult rodents. Ultimately, these changes result in the reprioritization of fuel selection during heat stress, which appears to be primarily responsible for reduced animal productivity during the warm summer months.

6 Linoleic acid and inflammation: Evidence-based research from human clinical studies.

K. L. Fritsche*[1] and G. H. Johnson[2], [1]*University of Missouri, Columbia,* [2]*Johnson Nutrition Solutions, Kalamazoo, MI.*

The authors conducted a systematic review of randomized controlled trials that permitted the assessment of dietary linoleic acid (LA) on biological markers of chronic inflammation among the healthy non-infant population was conducted. A search of the English and non-English literature using MEDLINE, the Cochrane Controlled Trials Register, and EMBASE was conducted to identify relevant articles. Fifteen studies (8 parallel and 7 crossover) met inclusion criteria. None of the studies reported significant findings for a wide variety of inflammatory markers including C-reactive protein, fibrinogen, plasminogen activator inhibitor type 1, cytokines, soluble vascular adhesion molecules or tissue necrosis factor-α. The only significant outcome measures reported for higher LA intakes were greater excretion of prostaglandin E2 and lower excretion of 2,3-dinor-thromboxane B2 in one study 1 and higher excretion of tetranorprostanedioic acid in another. However, both authors observed that these effects were not an indication of increased inflammation. It is concluded that virtually no evidence is available from randomized, controlled intervention studies among healthy, non-infant humans to show that variations in the level of LA in the diet affects in vivo inflammation in healthy humans.

7 Microbial hydrogen metabolism in colonic health and disease.

H. R. Gaskins,* *University of Illinois, Urbana-Champaign.*

In mammals, dietary fiber (polysaccharides, oligosaccharides, lignin and associated plant substances) and other nutritional components not absorbed in the upper digestive tract reach the colon where they are fermented by the cooperative metabolism of a complex microbiota. Fermentation products include short chain fatty acids (SCFAs; acetate, propionate and butyrate) and gases including molecular hydrogen (H_2). Colonic SCFAs, which are present at high concentrations (>100 m*M*), serve as the primary energy source for epithelial cells and modulate cell fate through influences on differentiation, growth arrest, and apoptosis. The H2 produced during fermentation is either excreted or used as a source of electrons by 3 groups of H_2-consuming microorganisms (hydrogenotrophs); the acetogens (generating acetate), methanogens (methane) and sulfate reducing bacteria (SRB; hydrogen sulfide, H_2S). Hydrogenotrophic organisms are present at much lower densities than are fermentative bacteria. However, in the absence of microbial H_2 consumption, the H_2 partial pressure rapidly reaches a level that thermodynamically inhibits further fermentation. Methane and sulfide production have been recognized as major pathways for H_2 disposal in the colon, but various factors such as colonic pH, sulfate availability, transit time, and microbial composition may influence which of these mechanisms predominates. Our research seeks to better understand the nature of the hydrogenotrophic microbiota and the extent to which end products of their metabolism vary among individuals and contribute to chronic inflammation and colorectal cancer. Of particular interest are SRBs and host epithelial responses to their toxic end product H_2S. Host and microbial aspects of our related working hypothesis will be described and data presented from recent studies that demonstrate the prevalence of hydrogenotrophs in the human colonic mucosa and their responsiveness to diet.

8 Characterizing the cellular mechanisms of postprandial thermogenesis in skeletal muscle.

B. A. Henry* and I. J. Clarke, *Department of Physiology, Monash University, Victoria, Australia.*

Thermogenesis is the dissipation of energy through specialized heat production. This process contributes to 10–15% of total energy expenditure in lean individuals. Thermogenesis is well characterized in brown adipose tissue, but whether other tissues are thermogenic is contentious. To characterize this in sheep we developed a model of postprandial thermogenesis, whereby sheep were entrained to a meal-feeding regimen with food restricted to a set meal time. We demonstrate increased skeletal muscle heat production at the onset of feeding and that central infusion of leptin upregulates this. Furthermore, central administration of leptin increases the expression of uncoupling protein (UCP) 2 and 3, but not UCP1 in skeletal muscle. The increase in UCP3 is associated with a switch to uncoupled respiration in isolated mitochondria. Thus, leptin-induced heat production in skeletal muscle is concomitant with the induction of thermogenesis. In addition to mitochondrial function, we examined changes in calcium cycling. Meal-feeding increased heat production as well as the expression of ryanodine receptor 1 (RyR1) mRNA and sarcoplasmic Ca^{2+}-dependent ATPase (SERCA) 2 protein in skeletal muscle. Thermogenesis in muscle, therefore, is facilitated via both mitochondrial uncoupling as well as calcium cycling pathways. Finally, we characterized differences in thermogenesis in animals predisposed to obesity. To do this we utilized two unique models, the genetically lean and obese sheep as well as a model of cortisol responsiveness. We show that animals characterized as high cortisol responders (HR) have greater propensity to obesity when fed a high energy diet compared to low cortisol responders (LR). Resistance to obesity in the LRs is preceded by a higher thermogenic response in muscle. This contrasts the genetically lean and obese animals, where lean animals have increased thermogenesis in adipose tissue, but not muscle. In conclusion, we show that skeletal muscle heat production is associated with altered mitochondrial function and enhanced calcium cycling. Furthermore, innate differences in thermogenesis (either muscle or fat) predispose animals to weight gain and obesity.

Triennial Reproduction Symposium: Impediments to Fertility in Domestic Animals

9 The obstacle course to successful establishment of pregnancy in domestic livestock species. M. D. Utt and M. L. Day,* *Department of Animal Sciences, The Ohio State University, Columbus.*

Research in reproductive biology over the past century has provided valuable knowledge and technologies that have and will be used to increase the likelihood of creating a successful pregnancy in domestic livestock species. However, maximal reproductive efficiency has not been achieved in any of these species. Successful establishment of pregnancy is a complex series of interrelated events that can be impaired at the gamete level through fetal development. The gametes contain genetic information and other factors necessary for creating viable offspring, but genetic and/or developmental deficiencies of gametes and the gonadal environment in which they reside may influence embryonic and fetal development. When sperm are deposited in the female reproductive tract at an appropriate time relative to ovulation, fertilization rate is relatively high, and differences therein are related to compensable and uncompensable sperm traits and/or sperm transport. Following fertilization, developing embryos reside in the oviduct before moving into the uterus. The oviductal and uterine environments are influenced by estrogen and progesterone before and after ovulation, and embryonic development may be affected by fluctuations in concentrations of either or both steroids. Latent effects of estrogen and progesterone on the uterus may impact the lifespan of the corpus luteum (CL) and/or embryonic development through maternal recognition of pregnancy (MRP) and the preimplantation period. Regardless of species, MRP consists of embryonic-derived signals that inhibit destruction of the CL and consequently the conceptus. Defective interactions among the conceptus, uterus, and CL can subsequently lead to failure in MRP. After MRP, embryonic or fetal loss is still possible due to uterine deficiencies, environmental effects, or combinations thereof. Many of the aforementioned obstacles to pregnancy may be exacerbated by production and metabolic stress; therefore, lactating dairy cattle are an appropriate model to study the spectrum of factors that impede attainment of optimal reproductive efficiency.

Key Words: pregnancy, deficiency, embryo

10 Sperm characteristics that limit success of fertilization. W. L. Flowers,* *North Carolina State University, Raleigh.*

The theoretical relationship between male fertility and sperm characteristics resembles a positive, asymptotic equation. When numbers of spermatozoa are low, fertilization rates are low. As the number of sperm cells increase, so does fertility. This response gradually diminishes until a plateau is reached and additional spermatozoa do not affect male fertility. Variation clearly exists among males in how their fertility responds to increasing spermatozoa both in terms of the slope of the positive portion of the curve and the point at which it reaches a plateau. These differences in male fertility patterns often are attributed to differences in the quality of their sperm cells. Sperm characteristics can be qualitative or quantitative and measure individual or functional properties. Qualitative assessments such as motility and morphology deal with population dynamics, and as they increase so does fertilization rate to a point. Hence, qualitative characteristics probably are responsible for variations along the linear portion of male fertility curves. Quantitative evaluations such as amounts of plasma membrane proteins or acrosin activity estimate aspects of all sperm cells produced by males and most likely mainly influence the level at which fertilization rates reach their plateau. Individual and functional characteristics of sperm can be qualitative or quantitative and affect male fertility patterns accordingly. Intuitively, functional traits such as sperm binding should provide a better indication of fertilization than individual ones such as motility. However, correlations of both types with fertility are very similar. Reasons for this may be related to how characteristics of sperm cells are influenced by the female reproductive tract after insemination. For example, capacitation patterns of spermatozoa in some boars are different in vitro than in vivo. If this relationship holds true for other traits, development of tests that account for this variation are necessary to address a critical need for understanding sperm characteristics that limit fertility.

Key Words: livestock, fertility, spermatozoa

11 The ovarian follicular reserve in ruminants: What regulates its formation and size? J. E. Fortune,* M. Y. Yang, and J. J. Allen, *Cornell University, Ithaca, NY.*

Primordial follicles have an oocyte arrested in first prophase of meiosis and a layer of flattened granulosa cells. These nongrowing follicles comprise the follicular reserve, the source of growing follicles until reproductive senescence. Indirect evidence indicates that the size of the follicular reserve in adult women is a measure of their reproductive potential. Therefore, it is of interest to elucidate the mechanisms that regulate follicle formation and factors that may enhance or diminish the size of the primordial pool. In species such as cattle, sheep, and humans, follicle formation and the establishment of the follicular reserve occur during fetal life. We use fetal bovine ovaries as a model to study the regulation of follicle formation and acquisition of the capacity to activate (initiate growth). Our results suggest a critical role for fetal ovarian steroids in the timing of follicle formation and differentiation of newly formed primordial follicles to a stage where meiosis has arrested in prophase I and ability to activate has been acquired. Current studies are focused on the regulation of fetal ovarian steroidogenesis by gonadotropins, steroids, and growth factors. We hypothesize that factors that interfere with production and/or action of fetal steroids may affect the size of the follicular reserve and perhaps the reproductive potential of the ensuing adult. Because domestic animals may be exposed to forage containing estrogenic compounds and to other environmental estrogens, the effects of endocrine disrupting chemicals on follicle formation and capacity to activate are potentially important. Nutrition may be another influence on the size of the follicular reserve. In adult cattle, the number of follicles in follicular waves has been correlated with their fertility and nutritional restriction during the first 110 d of bovine pregnancy was associated with fewer follicles in waves (vs. controls) when daughters reached maturity. Although there is much to be learned about the regulation of follicle formation in cattle and its relationship to fertility, this stage of ovarian development may be very important to adult reproductive potential.

Key Words: ovarian follicle, ovary, cattle

12 Influence of follicle characteristics at ovulation on early embryo survival. T. W. Geary*[1], M. F. Smith[2], M. D. MacNeil[1], M. L. Day[3], G. A. Bridges[4], G. A. Perry[5], F. M. Abreu[3], J. A. Atkins[2], K. G. Pohler[2], E. M. Jinks[3], and C. A. Roberts[1], *[1]USDA-ARS, Fort Keogh, Miles City, MT, [2]Division of Animal Sciences, University of Missouri, Columbia, [3]Department of Animal Science, Ohio State University, Columbus, [4]Department of Animal Science, University of Minnesota, Grand Rapids, [5]Department of Animal and Range Sciences, South Dakota State University, Brookings.*

Reproductive losses are significant in domestic animals and represent huge economic inefficiencies in livestock production. Across livestock species, embryonic mortality is the greatest contributor to reproductive losses. In most livestock species, early pregnancy diagnosis is an impediment to making significant progress to alleviate these losses. Perhaps unfairly, the female of each livestock species receives the blame for the majority of pregnancy failures. Research has focused on production of an optimal follicle that leads to ovulation of a highly fertile oocyte and production of steroids responsible for preparation of the female reproductive tract for pregnancy. Most studies have used hormonal manipulation of the estrous cycle and ovulation to identify factors affecting pregnancy success. Physiological maturity of the ovulatory follicle includes numerous reproductive processes and events obligatory for pregnancy establishment and maintenance. In sows, mares, and beef and dairy cows, oocytes derived from larger follicles were more competent, as assessed by in vitro development, than oocytes from smaller follicles. In cattle, ovulatory follicle size was highly correlated with serum estradiol concentration, and estradiol supplementation at AI improved pregnancy rates of cows ovulating smaller follicles. Greater ovulatory follicle size and more rapidly growing follicles at GnRH-induced ovulation were positively associated with fertilization success; while ovulatory follicle size, but not follicle growth rate, was positively associated with recovery of a viable embryo on d 7 in beef cows. In mares, age related changes in follicular signaling appear to play a large role in oocyte quality and fertility. This presentation focuses on follicular characteristics involved in early embryo survival, including follicle/oocyte maturation as affected by ovulatory follicle age, size, hormonal environment, and so on, and their effects on pregnancy establishment and maintenance. There is a strong relationship between the ovulatory follicle and steroid production related to early embryo development and pregnancy establishment.

Key Words: follicle, fertility, embryo survival

13 Deficiencies in the uterine environment and failure to support embryo development. G. A. Bridges,* *University of Minnesota, Grand Rapids.*

Pregnancy failure in cattle can result from failure to fertilize the oocyte or embryonic loss during gestation. Although fertilization failure occurs, embryonic mortality has a greater contribution to pregnancy failure. A variety of factors contribute to embryonic loss and it may be exacerbated in certain animals including high-producing lactating dairy cows and in some cattle in which estrous synchronization and timed AI was performed. Asynchronous follicular dynamics during timed AI protocols can induce ovulation of immature follicle that produce insufficient estradiol and a corpus luteum that potentially produces reduced progesterone concentrations compared with cows induced to ovulate mature follicles. In lactating dairy cows, circulating concentrations of steroids are reduced due to elevated feed intake causing increased liver blood flow and increased steroid catabolism in the liver. In each of these classes of animals that have decreased steroid concentrations, fertility is reduced compared with females that ovulate mature follicles at timed AI or to nonlactating dairy animals. Recent research in beef cows induced to ovulate immature follicles and lactating dairy cows suggest that deficient uterine function is the primary factor responsible for infertility in these animals. Failing to provide adequate concentrations of estradiol before ovulation results in prolonged effects on expression and localization of uterine genes and proteins that participate in regulating uterine functions during early gestation. Furthermore, progesterone concentrations during early gestation affect embryonic growth, interferon-tau production, and uterine function. Therefore, an inadequate uterine environment induced by insufficient steroid concentrations before and after ovulation could cause early embryonic death either directly by failing to provide an adequate uterine environment for embryo survival, adhesion, and implantation, or indirectly by failing to support appropriate embryonic growth which could lead to decreased conceptus size and malfunction of the process of maternal recognition of pregnancy.

Key Words: fertility, uterus, steroids

14 Interactions of the embryo, uterus and corpus luteum for sustenance of embryos. T. R. Hansen,* A. Q. Antoniazzi, J. J. Romero, R. L. Ashley, and R. C. Bott, *Animal Reproduction and Biotechnology Laboratory, Department of Biomedical Sciences, Colorado State University, Fort Collins.*

Interferon-tau (IFNT) from the ruminant conceptus disrupts oxytocin signaling and pulsatile release of prostaglandin F2α (PGF) in the endometrium through prevention of upregulation of the estradiol receptor, and consequently oxytocin receptor, which occurs during luteolysis. Microarray analysis revealed upregulation of several hundred genes in bovine endometrium and peripheral blood cells, and in ovine corpus luteum (CL) in response to early pregnancy that were mostly interferon-stimulated genes (ISG). For this reason, we hypothesized that IFNT not only protects pregnancy through paracrine action on release of endometrial PGF, but also has endocrine action through induction of resistance of the CL to lytic actions of PGF during early pregnancy. Antiviral activity, an indicator for type I IFN, increased in uterine vein blood on d 15 of pregnancy in sheep and was blocked through preadsorption with anti-IFNT antibody, providing evidence that IFNT was present in uterine vein blood. A specific (no cross-reactivity with other type I or II IFN) and sensitive (100 pg/mL) radioimmunoassay for IFNT was developed and used to detect IFNT in uterine vein blood from d 15–16 pregnant sheep. Global mass spectrometry was used to demonstrate presence of IFNT in uterine vein serum from a d 15 pregnant ewe. The ISG were upregulated in CL by d 14 of pregnancy and were localized primarily to large luteal cells, but also to small luteal cells in ewes. Culture of isolated ovine large and small luteal cells as well as mixed luteal cells with low (100 pg/mL) levels of IFNT caused upregulation of ISG. Endocrine delivery of IFNT (200 µg/d) using miniosmotic pumps into the uterine vein for 7 d (d 10–17 of estrous cycle) caused a delay in return to estrus beyond 32 d. Finally, systemic delivery (subcutaneous or jugular vein) of 20 µg of IFNT/d using miniosmotic pumps starting on d 10 of the estrous cycle, followed 24 h later by a challenge with PGF injection resulted in protection of the CL through d 13 based on serum progesterone profiles. It is inferred from these studies that IFNT protects early pregnancy in ruminants through paracrine action on the endometrium and also through endocrine action on the CL and peripheral blood cells in context of enhancing luteal resistance to PGF and the maternal ability to combat viral infections, respectively. USDA-NIFA-AFRI 2011-67015-20067.

15 Limitations in uterine and conceptus physiology that lead to fetal losses.

J. L. Vallet,* *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Conceptus losses in livestock occur throughout gestation. Clearly, the uterus and embryo/placenta/fetus play interconnected roles in these losses, the details of which depend on the period of gestation and the species. Studies in sheep and pigs have indicated that the uterine glands are essential for full fertility, based on experiments where gland development was reduced through the use of exogenous hormones. In sheep and cattle, normally the uterus is well able to support more than a single fetus, although these species differ in the consequences of multiple births. When 2 conceptuses are present, the placentas of cattle often anastomose, putting one fetus at risk if the other is lost. One likely reason this does not occur in sheep is because sheep embryos undergo intrauterine migration, similar to pigs. In pigs, the equidistant separation of conceptuses is likely to be essential for optimizing conceptus survival, as is the simultaneous and uniform elongation of blastocysts that occurs during the time of maternal recognition of pregnancy. Other studies in pigs have indicated that the size of the uterus influences litter size and therefore fetal losses. In response to crowded intrauterine conditions in the pig, increased conceptus losses begin to occur between d 30 and 40 of pregnancy, and further losses occur sporadically during later gestation. There is evidence that improved fetal erythropoiesis can reduce these losses. Reports also indicated that profound changes in placental development occur under crowded intrauterine conditions that may contribute to losses during late gestation. Reductions in placental stroma formation may compromise the ability of the pig placenta to adapt to reduced uterine space. Consistent with this, both hyaluronan and hyaluronidase activity are decreased in the placentas of small compared with large fetuses. These results suggest that improvements in placental stroma formation could improve placental ability to compensate for reduced intrauterine space, resulting in increased placental function and reduced fetal losses during late gestation. USDA is an equal opportunity provider and employer.

Key Words: placenta, erythropoiesis, hyaluronan

16 The spectrum of factors that impede pregnancy in dairy cows.

R. L. A. Cerri*[1], J. E. P. Santos[2], W. W. Thatcher[2], and J. L. M. Vasconcelos[3], *[1]University of British Columbia, Vancouver, BC, Canada, [2]University of Florida, Gainesville, [3]Sao Paulo State University, Botucatu, SP, Brazil.*

The fertility problem in dairy cows is complex and multifactorial but can be divided into 2 major categories: 1) failure to submit cows for insemination, and 2) extensive embryonic and fetal losses. Numerous factors influence these 2 categories (e.g., heat stress, energy balance, cow comfort, health, ovarian dynamics and uterine environment). In the past 10 yr, however, the trend in daughter pregnancy rate has been positive based on USDA data through 2010. This improvement is likely a direct effect of the intensive use of timed AI (TAI) programs, which improved submission rates and, to some extent, pregnancy per AI because of physiological optimization of the reproductive programs. Recently, the use of activity monitors in North American herds has improved submission rates, thereby reducing pharmacological interventions. Although fertilization rate is relatively high (80%), only around 40% of fertilized embryos result in a pregnancy at 60 d after insemination. Early and late embryonic losses are still an unsolved problem in lactating dairy cows and are partly explained by changes in ovarian and uterine physiology. More time between follicle emergence to ovulation concomitantly with decreased concentrations of circulating progesterone and estradiol, reduce embryo quality and create a suboptimal uterine environment that negatively affects pregnancy. Metabolic and health disorders also play major roles as they affect around 40 to 50% of cows in early lactation. Pregnancy per AI exceeds 50% in cows not affected by any clinical periparturient disorder. A pool of knowledge has been acquired regarding the interactive cellular and molecular mechanisms of the conceptus and endometrium within the periattachment period. However, additional research is needed to unveil the effects of steroid and metabolic hormones, health disorders, and among-cow differences in molecular mechanisms pivotal to successful pregnancy. Genetic selection and applied and basic technologies to improve submission rates and reduce pregnancy losses, without affecting milk production, will likely remain at the forefront to improve reproductive efficiency in modern dairy cows.

M1 Immunological and metabolic responses of Holstein and Jersey cows according to body condition score change prepartum. R. C. Chebel, L. G. D. Mendonça, P. R. B. Silva, and J. G. N. Moraes,* *Department of Veterinary Population Medicine, University of Minnesota, St. Paul.*

Objectives of this experiment were to evaluate the immune and metabolic responses of Holstein (H) and Jersey (J) cows according to body condition score (BCS) change (BCSC) prepartum. Data from 2 experiments were used. Experiment 1 was conducted with Holstein cows (n = 29) and experiment 2 was conducted with Jersey cows (n = 68). Cows received BCS on d −22 ± 7 and 1 ± 1 (calving = d0) and were classified as having lost (L) and as having not lost (NC) BCS prepartum. Blood was sampled on d −7, 0, 7, and 14 for determination of neutrophil phagocytosis (PHAGO) and oxidative burst (OXID) and expression of CD18 and L-selectin and concentrations of NEFA and glucose. Data were analyzed by Chi-squared and ANOVA for repeated measures. Percentages of H (65.5%) and J (51.5%) cows losing BCS prepartum were similar (P = 0.20). The interaction between breed and BCSC was associated with most of the innate immunity parameters evaluated because among J cows BCSC was not associated with innate immunity parameters (P > 0.10). On the other hand, HL cows had reduced PHAGO (57.8 ± 3.6 vs NC = 73.9 ± 4.8%; P < 0.01) and OXID (93.2 ± 0.7 vs 96.0 ± 0.9%; P = 0.02) than HNC cows. The interaction between breed and BCSC tended (P = 0.09) to be associated with intensity of OXID because HL cows had reduced OXID intensity than HNC cows (15857 ± 3052 vs 24770 ± 3782; P = 0.07). There was a tendency for the interaction between breed and BCSC to be associated with percentage of neutrophils positive for CD18 (P = 0.08) because HL cows tended to have reduced percentage of neutrophils expressing CD18 than HNC cows (74.1 ± 2.0 vs NC = 80.2 ± 2.5%; P = 0.06). Concentration of NEFA was associated with BCSC (L = 0.533 ± 0.038, NC = 0.429 ± 0.044mmol/L; P = 0.03) but was not associated with the interaction between breed and BCSC (P = 0.99). On the other hand, glucose concentration was not associated with BCSC (P = 0.50) or with the interaction between breed and BCSC (P = 0.62). Immunological parameters peripartum were differently affected by BCS loss prepartum in Holstein and Jersey cows.

Key Words: peripartum cow, body condition score, immunological parameter

M2 Treatment outcomes for clinical mastitis caused by *E. coli* in a Wisconsin dairy herd. M. J. Fuenzalida*[1], W. Oliveira[1], J. Gaska[2], and P. L. Ruegg[1], [1]*Department of Dairy Science, University of Wisconsin, Madison,* [2]*Gaska Dairy Health Services, Columbus, WI.*

The objective of this study is to describe the effect of intramammary antimicrobial treatment (ceftiofur) on milk yield, and somatic cell (SCC) reduction during a 42-d follow-up period. Clinical mastitis (CM) occurring in a single quarter (n = 133) was diagnosed between May 2011 and January 2012. Average milk yield was 42.3 kg/d, parity was 2.5, logSCC 1.95, and DIM was 162. Explanatory variables considered in the models were DIM, parity, previous cases of CM, previous SCC, and previous milk yield after treatment. Of 133 cases of clinical mastitis caused by *E. coli*, 75 were not treated and 58 received intramammary ceftiofur. PROG GENMOD was used for analyzing the binary outcomes (yes/no for SCC reduction, yes/no for milk yield reduction) and PROC GLM SAS 9.2 was used to analyze the continuous variable milk yield. Milk yield after occurrence of the case was 42.4 and 41.5 for treated and not treated cows, respectively but was not significantly affected by treatment (P = 0.48). One unit increase in logSCC was associated with 2.7 kg/d reduction in milk production. Occurrence of a previous case of CM was associated with about 4 kg/d less milk production. Treatment was not associated with SCC reduction (OR = 1.84, CI 0.32–10.31) or change in milk yield (OR = 0.78, CI 0.27–2.21). In this farm, treatment of CM caused by *E. coli* did not improve milk production or SCC compared with no treatment. Supported by AFRI Competitive Grant no. 2010–85122–20612

Key Words: clinical mastitis, SCC, milk yield

M3 Differential expression of the hepatic and adipose transcriptome in peripartal Friesian cows with endometritis. H. Akbar*[1], J. M. Khan[1], S. Meier[2], C. Burke[2], S. McDougall[3], M. Mitchell[4,5], S. L. Rodriguez-Zas[1], R. E. Everts[1], H. A. Lewin[1], J. R. Roche[2], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*DairyNZ Limited, Hamilton, New Zealand,* [3]*Cognosco, Animal Health, Morrinsville, New Zealand,* [4]*Liggins Institute, University of Auckland, Auckland, New Zealand,* [5]*University of Queensland Centre for Clinical Research, Brisbane, St. Lucia, Australia.*

Inflammation of the endometrial lining of the uterus (endometritis) often develops in dairy cows soon after calving. Afflicted animals can develop chronic infections of the uterus due to pathogenic bacteria. This disease causes poor reproductive performance, decreased energy balance, lower milk yield, and potentially hepatocellular damage. The objective of the current study was to uncover molecular changes induced by endometritis using expression profiling of liver and adipose transcriptomes. Postpartal liver and adipose tissue samples were harvested at slaughter from healthy (NUI; n = 6) cows or cows with endometritis (UIN; n = 6) at 29 d postpartum. Endometritis was defined as > 6% of uterine fluid nucleated cells being polymorphonuclear (PMN) cells; healthy cows had ≤ 1% PMN. Transcriptome expression was performed via bovine microarray (~13,000 oligonucleotides) and RT-PCR. Functional analysis of differentially expressed genes (DEG; P < 0.05, fold-change cut off ≥ or ≤ 1.5 UIN vs. NUI) was carried out using the dynamic impact approach (DIA) with the KEGG pathway database. A total of 97 DEG from liver (35 downregulated, 62 upregulated) and 144 from adipose (82 downregulated, 62 upregulated) were used for functional analysis. In liver, endometritis induced activation of selenoamino acid metabolism, complement and coagulation cascades, glycosphingolipid biosynthesis, and toll-like receptor signaling pathway. Bioinformatics analysis also revealed an inhibition of fatty acid oxidation, PPAR signaling, SNARE interactions in vesicular transport, and N-glycan biosynthesis. Functional analysis of adipose uncovered as the most induced pathways nicotinamide metabolism, glycosaminoglycan biosynthesis, and basal transcription factors. The most-inhibited pathways in adipose were taurine and hypotaurine metabolism, pantothenate and CoA biosynthesis, and TCA cycle. Quantitative PCR of liver tissue further revealed a marked increase in superoxide dismutase-2 (SOD2) and glutathione peroxidase (GPX1) expression in UIN, suggesting a greater state of oxidative stress in those animals. Overall, these preliminary results suggest that uterine infection after calving induces molecular alterations in peripheral tissues.

Key Words: uterine infection, transition cow, genomics

M4 A comparison of two antibiotics on growth performance in beef cattle treated for bovine respiratory disease (BRD). N. O. Minton*[1], L. L. Hawkins[2], and M. S. Kerley[1], [1]*University of Missouri, Columbia,* [2]*Bayer HealthCare, Animal Health, Shawnee Mission, KS.*

Therapy for bovine respiratory disease (BRD) commonly occurs throughout the receiving period. Proper treatment of BRD is critical to cattle performance throughout the feeding phase. We hypothesized differences in growth performance occur among different antibiotics used for treatment of BRD. Naïve crossbred steers (n = 102) were monitored for BRD over a 45-d growth study. Steers were randomly assigned to antibiotic treatments which consisted of either enrofloxacin (ENR; n = 51) (Baytril 100 Bayer HealthCare, Animal Health) or florfenicol + flunixin (F+F; n = 51) (Resflor Gold Merck Animal Health).Within treatment steers were categorized as no treatment (control), single treatment (ST), relapse (RL) or chronic. Steers were randomly assigned to 2 pens with treatment evenly distributed within pen. Two consecutive BW were recorded at treatment initiation, d 28, and d 45. Individual FI using the GrowSafe feed intake system and visual assessment were used to identify cases of BRD. Rectal temperatures of $\geq$40°C were diagnosed with BRD and treated with predetermined antibiotic. Control steers represent non treated steers. Chi-squared distribution determined morbidity and relapse rate were not different among ENR and F+F. ENR had greater percentages of chronics (6.2% vs. 2.1%; $P < 0.001$) with lower mortality rate (2.1% vs. 7.2%; $P < 0.001$) than F+F; respectively. IBW was not different among all categories between both ENR and F+F. ADG, F:G and total BW gain were not different between control steers and ENR ST and RL steers. ENR ST and RL steers tended to be more efficient than either category of F+F steers ($P = 0.11$). ENR ST steers had greater ADG (1.76+0.11 vs. 1.37+0.11; $P < 0.05$), FBW (333.63+6.77 vs. 311.86+6.77; $P < 0.05$) and BW gain (77.5+4.96 vs. 60.30+4.96; $P < 0.05$) than ST F+F steers. DMI as a percent of BW was not different on treatment day as well as 3 d before and after treatment of BRD between ST ENR and F+F steers. We conclude utilizing enrofloxacin for therapy of BRD corresponds to an increase in growth performance and feed efficiency during the receiving period in comparison to florfenicol + flunixin.

Key Words: health, feedlot, beef

M5 Feedback on data entry errors effect on the maintenance of accurate and consistent dairy health records. S. K. Giebel*[1], J. R. Wenz[1], S. A. Poisson[1], C. S. Schneider[2], and D. A. Moore[1], [1]*Department of Veterinary Clinical Sciences, Washington State University, Pullman,* [2]*College of Agricultural and Life Sciences, University of Idaho, Moscow.*

Maintenance of data quality is not a one-time effort; it requires continuous auditing and evaluation to ensure quality. One reason for this is that health data entry is not standardized in dairy management software (DMS), like reproductive records. The purpose of this study was to evaluate the time needed for producers to implement and maintain health data entry protocols. Forty-three dairies enrolled in a demonstration project on consistent and accurate health records, 51% from Eastern Washington (EWA), 26% from Western Washington (WWA), and 23% from Idaho (ID), with an average herd size of 2,683 cows (range 366–9,880). Producers were provided with error reports weekly until the percentage of errors dropped below 5.1% for 2 consecutive reports, at which point the dairy was considered graduated. All dairies continued to receive monthly error reports until January 2012. Reports provided feedback on data entry in comparison to their customized health event data recording protocols. The first report averaged 20.5% errors with a range of 0.0 to 81.3%. It took an average of 9 reports before a dairy graduated to monthly reporting, with a range of 4 to 21. Of those herds that contributed at least 3 mo to the study post graduation, nearly 50% never relapsed (relapse = error rate >5%) but if they did, it most commonly occurred in the first month post graduation. The average months to relapse was one (range 0–6). The error rate on the last report averaged 4.7% with a range of 0.0–16.6%. If the herd was using the Protocol function in Dairy Comp 305 or the Rx-Plus function in DHI-Plus before the start of the project, months to relapse was shorter than those that did not ($P = 0.01$). Median time to relapse was longer for large herds (>1950 cows) compared with smaller herds (4 vs. 2 mo; $P = 0.06$). Median time to relapse was 4 mo for EWA, 2 mo for WWA and 2.5 mo for ID ($P = 0.04$). For those producers less comfortable with computer use, there was a tendency for the rate of relapse to be faster compared with those more comfortable ($P = 0.08$). Dairies can implement and maintain consistent and accurate health records when provided with regular feedback.

Key Words: data recording protocols, dairy management software, dairies

M6 Impact of water and feed deprivation on physiological parameters in steers. J. A. Daniel*[1], P. H. Walz[2], J. A. Carroll[3], T. H. Elsasser[4], and B. K. Whitlock[5], [1]*Berry College, Mount Berry, GA,* [2]*Auburn University, Auburn, AL,* [3]*USDA-ARS Livestock Issues Research Unit, Lubbock, TX,* [4]*USDA-ARS Bovine Functional Genomics Laboratory, Beltsville, MD,* [5]*University of Tennessee, Knoxville.*

A report in rats demonstrated that dehydration as the result of 8 d of water deprivation increased leakage of endotoxin from the intestine (Zurovsky and Barbiro, 2000; Exp. Toxicol. Pathol. 52:37–42). Given the large number of bacteria in the rumen of cattle, a much shorter period of water deprivation may result in increased leakage of endotoxin and subsequent changes in the physiologic parameters. Therefore, the purpose of this study was to determine the effect of water and feed deprivation on physiologic parameters in steers. Holstein steers (n = 4) fitted with indwelling jugular and hepatic vein cannulas received a 72-h period of water and feed deprivation followed by reintroduction of water and feed for a 24-h period (96 h total) or a 96-h period with ad libitum water and hay access (control) in a switch back design with a 3-wk wash-out period between repetitions. Blood samples were collected and rectal temperatures (RT) were recorded every 6 h for a total of 96 h. Body weights were recorded every 12 h. Data were tested for effects of treatment, time, treatment × time interaction and replication using procedures for repeated measures with JMP software (version 7; SAS Institute Inc.). Water and feed deprivation increased packed cell volume at 30, 54, 60, and 66 h relative to control steers ($P < 0.05$). Total protein in the serum was increased at 48, 54, 66, 72, and 78 h in water and feed deprived steers compared with control steers ($P < 0.05$). The average body weight of water and feed deprived steers was less than control steers at 36, 48, 60, and 84 h ($P < 0.05$), and percent of body weight loss was greater in water and feed deprived steers at 24, 36, 48, 60, 72, and 84 h than control steers ($P < 0.05$). Rectal temperature of water and feed deprived steers was lower than control steers at 6, 12, and 66 h, and RT of water and feed deprived steers was higher than control steers at 72 h ($P < 0.05$). These results suggest that water and feed deprivation negatively affect steers before typical indicators of dehydration (packed cell volume and total protein) are altered.

Key Words: steers, water, feed

M7 Implementation of health data entry protocols effect on time for data management.

S. K. Giebel*[1], J. R. Wenz[1], S. A. Poisson[1], C. S. Schneider[2], and D. A. Moore[1], [1]*Department of Veterinary Clinical Sciences, Washington State University, Pullman,* [2]*College of Agricultural and Life Sciences, University of Idaho, Moscow.*

Producers want to be assured that it will not add time to the process of data management when implementing protocols for consistent and accurate dairy health data entry. Research done on data capture and entry into dairy management software (DMS) program is limited and dated. The purpose of this study was to assess the time taken to capture and enter health data before and after implementation and maintenance of data entry protocols. Twenty-three dairies enrolled in the demonstration project were used to evaluate the time taken to capture health data and enter it into their DMS program. Information was collected on the general flow of data from cow to computer during 2 visits, one before implementation of accurate and consistent health records and one 4 mo after maintenance. The difference in time, for data capture and entry, between the first and second visit was categorized as increased, decreased or no change. There were 22 dairies with complete data for the capture of health information. On average, it took dairy personnel 21.8 (range 2.3–65.8) seconds per cow to capture information at the first visit. After data entry protocol maintenance, it took an average of 17.6 (range 1.0–46.6) seconds per cow. Using a sign test, herds were more likely to either take less or the same amount of time for data capture between visits ($P < 0.001$). There were 18 dairies with complete data for entry of health information. On average, it took dairy personnel 4.6 (range 0.6–12.8) seconds per cow to enter data into the computer at the first visit. After protocol maintenance, it took an average of 3.3 (range 0.3–9.7) seconds per cow. Using a sign test, herds were more likely to either take less or the same amount of time for data entry between visits ($P < 0.01$). The only factors that appeared to influence data capture were related to on-farm protocols such as recording all hospital cow numbers in the parlor and the frequency of data capture in the parlor. Implementation of health data entry protocols for more accurate and consistent records did not add time to the process of data management.

Key Words: data capture, data entry, dairy management software

M8 Transcriptome analysis of liver tissue from calves infected with bovine viral diarrhea virus and *Mannheimia haemolytica.*

R. L. Mills*[1,2], L. Carlos-Valdez[2], L. O. Burciaga-Robles[2], D. Stein[2], D. L. Step[2], R. W. Fulton[2], U. DeSilva[2], and C. R. Krehbiel[2], [1]*Austin Peay State University, Clarksville, TN,* [2]*Oklahoma State University, Stillwater.*

Bovine respiratory disease (BRD) negatively affects animal growth and performance, leading to less desirable carcass characteristics. To understand the effects of BRD on liver gene expression, 16 crossbred steers (280.8 ± 32.5 kg) were divided into 2 treatment groups: the control group (CON) received an intratracheal dose of isotonic saline; an infected group (INF) was exposed to a PI-BVDV calf for 72 h followed by intratracheal inoculation with *Mannheimia haemolytica* serotype A (MH). Liver biopsies were taken before exposure to both pathogens (PRE), 12 (12H), and 24 h (24H) following bacterial inoculation. Total RNA was extracted and oligonucleotide microarray hybridization performed on PRE and 24H sampling times ($n = 6$). Significance for the microarray was set at fold change greater than |2| and $P < 0.001$. Quantitative RT-PCR was performed to examine gene expression at the indicated time points with significance set at $P < 0.05$. Pathway analysis was conducted using Ingenuity Pathway Analysis. Microarray analysis found 44 genes were induced and 45 genes were suppressed following 24h of dual infection. Pathway analysis revealed lipid metabolism, molecular transport, cellular assembly and organization, carbohydrate metabolism, and small molecule biochemistry were the molecular and cellular functions most affected. PCR showed that β-site APP-cleaving enzyme 1 (BACE1) was increased 2.3-fold in INF compared with CON ($P < 0.05$). S100 calcium binding protein A8 (S100A8) transcripts increased 28.9-fold in INF versus CON ($P < 0.001$), increased more than 21-fold in 12H and 24H above PRE ($P < 0.01$), and exhibited an infection × time interaction with INF-12H and INF-24H showing mRNA increases of 44- and 42-fold above CON-PRE, respectively ($P < 0.01$). Fatty acid desaturase 2 (FADS2) was suppressed 73.2-fold in INF relative to CON ($P = 0.05$) and tended to be downregulated 29.5- and 95.1-fold at 12H and 24H versus PRE ($P = 0.09$). Gene expression changes in liver are indicative of hepatic inflammation, which may suggest calves with BRD are susceptible to the development of fatty liver.

Key Words: beef cattle, bovine respiratory disease, gene expression

M10 Changes in biomarkers of the nitrooxidative stress response and prolactin signal transduction elements to *E. coli* infection in the mammary gland.

T. H. Elsasser*[1], A. V. Capuco[1], M. Rinaldi[2], and S. Kahl[1], [1]*USDA-ARS, Beltsville, MD,* [2]*Ghent University, Ghent, Belgium.*

Key features of the mammary gland (MG) response to *E. coli* infection (INFec) include (a) the cellular generation of reactive oxynitrogen molecules (Roxn) derived from nitric oxide (NO) and superoxide anion ($O_2^{-\bullet}$) and (b) loss of responsiveness to lactogenic hormone signaling. Of significance to the MG is the damage done to mammary epithelial cells (MEC) by Roxn generated by MEC and neutrophils (PMN). The aim of this study was to determine the time course of production and cellular localization of biomarkers of the Roxn pathway and to quantify changes in PRL receptor (PRLr)-janus kinase-2 (JAK-2) signaling. As applied across the 4 quarters of the MG, 5 multiparous lactating Holstein cows received treatments consisting of PBS or 400 cfu *E. coli* administered 12 or 24 h before euthanasia. MG tissues (lobulo-alveolar) were prepared for immunohistochemical (IHC) localization of biomarker antigens. IHC biomarkers for the Roxn pathway elements consisted of 3′-nitrotyrosine (3-NT, cellular protein nitration) as well as inducible (i) and constitutive (e) isoforms of nitric oxide synthase (NOS, NO generation), and xanthine oxidase (XO, $O_2^{-\bullet}$ generating capacity). Prolactin (PRL) signal transduction elements markers were PRLr, JAK-2, and nitrated JAK-2 (ntJAK, Roxn-inactivated JAK-2). Antigenic markers were quantified by image analysis of digitally captured micrographs. Mean pixel densities of all antigenic determinants were affected by time and/or cell type ($P < 0.02$). Infiltrating PMN were present only at 24 h. The 3-NT increase peaked in MEC (4.6-fold) at 12h and in PMN (3.7-fold) at 24 h. Both iNOS and eNOS increased in MEC at 12 and 24 h but only iNOS was increased in PMN at 24 h. XO increased 118% in MEC at 12 h ($P < 0.04$) but normalized by 24h. PRLr was decreased by 29 ($P < 0.03$) and 54% ($P < 0.01$) in MEC at 12 and 24 h, respectively. JAK-2 was decreased 84% ($P < 0.02$) at 24 h, respectively. ntJAK was increased 22- ($P < 0.005$) and 4-fold ($P < 0.05$) at 12 and 24 h, respectively. The

data indicate that changes in these measured cellular responses to INFec occur in the MG as a function of time and cell type.

Key Words: mammary gland, infection, biomarker

M11 Associations among subclinical hypocalcemia, neutrophil function, and incidence of uterine disease in dairy cows of low or high risk of developing metritis. N. Martinez*[1], F. S. Lima[1], R. S. Bisinotto[1], L. F. Greco[1], E. S. Ribeiro[1], F. Maunsell[2], K. N. Galvão[2], C. A. Risco[2], and J. E. P. Santos[1], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville.*

Objectives were to establish relationships among subclinical hypocalcemia (SCH) and concentrations of energy metabolites, neutrophil (PMN) function and incidence of uterine diseases in dairy cows considered to be of low (LRM; normal calving) or high-risk (HRM; calving problems) of developing metritis. In this prospective cohort study, HRM cows (n = 55) were matched with LRM (n = 55) based on parity and day of calving. Rectal temperature (RT) and vaginal discharge were monitored in the first 12 DIM. Metritis was defined as fetid, watery vaginal discharge, and puerperal metritis (PuMet) was defined as metritis concurrent with RT ≥ 39.5°C. Blood was sampled at 0, 1, 2, 3, 4, 7, and 12 DIM and analyzed for Ca, NEFA and BHBA. Neutrophil function was measured at 0, 1, and 3 DIM. Serum Ca ≤ 8.59 mg/dL in at least one day within the first 3 DIM defined SCH based on receiver operator characteristic analysis (AUC = 0.77; $P < 0.01$). Data were analyzed using PROC GLIMMIX of SAS. Cows with SCH had fewer ($P < 0.01$) circulating blood PMN (3.0 vs. 4.5 $\times 10^3$ PMN/μL) in the first 3 DIM, and reduced ($P < 0.05$) proportion of PMN with oxidative burst (32.4 vs. 42.5%) and phagocytosis (61.3 vs. 73.1%) at 3 DIM compared with normocalcemic (NC) cows. The mean RT of cows increased ($P < 0.01$) when metritis was associated with SCH (39.0°C) compared with cows with metritis and NC (38.7°C). Among HRM cows, those with SCH had greater ($P < 0.05$) incidence of metritis and PuMet [77.8% (35/45) and 53.5% (24/45)] compared with NC cows [(20.0% (2/10) and 10.0% (1/10)]. Among LRM cows, those with SCH had greater ($P < 0.05$) incidence of metritis and PuMet [40.7% (11/27) and 29.6% (8/27)] compared with NC cows [(14.3% (4/28) and 0.0% (0/28)]. Metritis did not influence concentrations of NEFA or BHBA; however, cows with SCH had greater ($P < 0.01$) NEFA (704.6 vs. 426.8 μM) and BHBA (9.9 vs. 7.7 mg/dL) concentrations compared with NC cows. These findings indicate that cows with SCH have impaired innate immunity and increased incidence of uterine diseases compared with NC cows regardless of calving problems.

Key Words: subclinical hypocalcemia, neutrophil function, metritis

M12 Hepatic and peripheral interferon responses to bovine respiratory disease in feedlot steers. J. O. Baggerman,* C. A. Gifford, and C. R. Krehbiel, *Oklahoma State University, Stillwater.*

Bovine respiratory disease (BRD) is the most economically important disease in the feedlot industry. Several pathogens contribute to BRD, yet the mechanism by which these pathogens evade immune response remains unclear. Conflicting evidence suggests that the interferon (IFN) response is impaired by BRD pathogens while others have shown robust IFN response in BRD-infected animals. We hypothesize that the IFN response is muted in cattle that exhibit sustained BRD infection. Liver biopsies were collected and RNA isolated from control calves (CONT, n = 6); calves treated once for BRD (1TRT, n = 6); treated twice for BRD (2TRT, n = 6); or treated 3 times for BRD (3TRT, n = 6). Expression of Interferon Stimulated Gene-15 (*ISG15*) and Myxovirus resistance protein 1 (*MX1*) mRNA levels was quantified. Relative to CONT, *MX1* mRNA levels increased ($P < 0.05$) over 7-fold in liver biopsies from 1TRT, but were similar ($P > 0.10$) to CONT for 2TRT and 3TRT. Likewise, *ISG15* mRNA levels were 40-fold greater ($P < 0.05$) than CONT for 1TRT, but 2TRT and 3TRT were similar to CONT. To determine if the IFN response is impaired with sustained BRD infection as suggested by the changes in gene expression in liver biopies, *MX1* mRNA levels in peripheral blood leukocytes (PBL) was evaluated from chronically infected calves (CHRON, n = 3) and controls (CONT, n = 3). Additionally, peripheral blood mononuclear cells (PBMC) were isolated from CHRON (n = 6) and CONT (n = 6) calves. For each animal, PMBC were isolated and plated into 6 well plates (4 million cells/mL; 4 wells/animal). Two wells served as a control and 2 wells were treated with human interferon-α (Sigma-Aldrich; 2.5 ng/mL) for 8 h before harvest for mRNA extraction. In PBL samples, *MX1* mRNA levels were similar ($P > 0.10$) in CHRON and CONT2 indicating that the type I interferon response was not active. However, in PBMC challenged with IFN, *MX1* mRNA increased approximately 100-fold in both CHRON and CONT2 groups compared with their own non-treated controls. Results demonstrate that the IFN response is reduced in calves treated multiple times for BRD, but the IFN pathway is still responsive to exogenous IFN. Thus, IFN might be a viable treatment alternative in calves that remain sick after 1 to 2 treatments for BRD.

Key Words: bovine respiratory disease, interferon, interferon stimulated genes

M13 Meta-analysis of *Trypanosoma* prevalence in livestock in the Americas. Z. J. Simoni[1], H. E. Rodulfo[1], M. De Donato*[1,2], M. I. Takeet[3], S. O. Peters[2,4], and I. G. Imumorin[2], [1]*IIBCA, Universidad de Oriente, Cumana, Venezuela,* [2]*Dept. Animal Science, Cornell University, Ithaca, NY,* [3]*Dept. Veterinary Microbiology & Parasitology, Federal University of Agriculture, Abeokuta, Nigeria,* [4]*Dept. Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria.*

Cattle tripanosomosis is a hemoparasitic disease caused by species of *Trypanosoma*, transmitted through dipterans of the genus *Tabanus*, in Central and South America. *T. evansi* and *T. vivax* are species that infect horses and cattle, respectively. They have been reported in at least 10 South American countries, including Colombia, Venezuela, Bolivia, Peru, and Brazil. We surveyed data on prevalence and clinical signs reported for *T. vivax* in water buffalo and cattle in these countries. Studies of genetic characterization indicate that the circulating species in South America is very similar to *T. vivax* from West Africa. *T. vivax* has been known to produce economic losses in the livestock industry, causing mortality, poor weight gain, lower fertility, abortion, and low production of milk and colostrums, in addition to costs associated with control (drugs and veterinary fees). *T. evansi* can cause a serious anemic disease in horses, camels, dogs and elephants. In South America, species such as capybara, coati, and wild rats have been found infected by *T. evansi*, without showing clinical alterations, thus, being considered as natural reservoirs. Recent studies have demonstrated that *T. evansi* has an aberrant kADN without maxicircles and the genetic analysis of kADN have shown that strains from equids of Africa, Asia y South America have similar sequences in the minicircles. *T. theileri* has been found in cattle in South and North America, and although this species is considered non-pathogenic, its pathogenicity has been linked to coinfection with other hemoparasites or subjected to severe stress. *T. equiperdum* has been reported in South and Central America in horses, but its form of transmission is by sexual intercourse, associated with important clinical symptoms. The effects of these *Trypanosoma* species on livestock throughout this region especially in isolated rural areas with attendant consequences on the economy of small to medium size producers are highlighted.

Key Words: trypanosomosis, livestock, parasite

M14 Cytokine production of isolated CD4+ T-cells from high and low immune responder dairy cows during the peripartum period. M. A. Paibomesai* and B. Mallard, *University of Guelph, Guelph, Ontario, Canada.*

The peripartum period is one of transition and high stress for dairy cows. It is associated with higher incidents of both metabolic and pathogenic disease. Both antibody (AMIR; IL-4 dominated) and cell mediated (CMIR; IFNγ dominated) immune responses (IR) play a key role in the maintenance of health in cattle protecting against extracellular and intracellular pathogens. These processes are induced and maintained by CD4+ T-helper cells, which undergo specific shifts in population and function in response to parturition effects. The aim of this study was to determine the effects of parturition on cytokine production of CD4+ T-cells isolated from highAMIR/lowCMIR (hiAMIR) and highCMIR/lowAMIR (hiCMIR) cows. Previously IR phenotyped cows were selected based on hiAMIR (n = 12) and hiCMIR (n = 11) responses to test antigens. Isolated CD4+ T-cells collected at 28 d prepartum, 4 d postpartum, and 21 d postpartum from these groups were stimulated with the mitogen, Concanavalin A (ConA) and incubated for 24hrs. Cell culture supernatants were collected and IL4 and IFNγ concentrations were quantified by ELISA and analyzed using ANOVA. There was no difference in IL4 concentration across all time points for hiCMIR cows and an increase of IFNγ ($P = 0.0223$) was observed between 4 d postpartum (3366 pg/mL) and 21 d postpartum (7755 pg/mL). There was a decrease of IL4 ($P = 0.0474$) from 28 d prepartum (496 pg/mL) to 21 d postpartum (212 pg/mL) in hiAMIR cows and no difference observed for IFNγ concentration in this group. There was a difference between hiAMIR and hiCMIR groups at 21 d postpartum with hiCMIR isolated T-cells producing more IL4 than hiAMIR group ($P = 0.0161$) and a tendency to produce more IFNγ ($P = 0.0591$). In conclusion, it is evident that T-helper cells isolated from hiAMIR and hiCMIR show different responses to parturition effects in terms of cytokine production. These differences could be in response to biases in CMIR and AMIR in these 2 groups and was most notable at 21 d from parturition.

Key Words: peripartum period, cytokines, T-helper cells

M15 Space allowance influences Holstein bull calf innate immunity after castration. L. E. Hulbert[1], M. S. Calvo*[1], M. A. Ballou[2], K. C. Klasing[1], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California, Davis,* [2]*Animal and Food Sciences, Texas Tech University, Lubbock.*

Objectives were to determine if space allowance in wooden hutches influences the innate immune responses of Holstein bull calves after castration. Calves were randomly assigned at 4 d of age to either conventional (Cnv; 0.46 m^2 space; n = 18), medium (Med; 0.70 m^2space; n = 17), or large (Lrg; 1.39 m^2 space; n = 18) hutches. Calves were surgically castrated at 24 d. Peripheral whole blood (WB) samples were collected at −1, 1, 5, and 12 d relative to castration. All calves had increased plasma cortisol 1 d after castration ($P \leq 0.01$). Plasma haptoglobin (Hap) increased from pre-castration concentrations 1 d after castration in all calves, but Med-calves had greater Hap 5 d after castration compared with pre-castration ($P \leq 0.05$). Cnv-housed calves had greater Hap concentrations than Med- and Lrg-housed calves, especially at 12 d after castration ($P \leq 0.05$). The day before castration, Cnv-calves had the greatest WB killing (WBK) of *E. coli*, but 1 d after castration, WBK in Cnv-calves decreased to percentages lower than Med- or Lrg-calves ($P \leq 0.05$). Within 12 d after castration, WBK in Cnv-calves returned to similar percentages as pre-castration. The Lrg-calves had the least Tumor Necrosis Factor (TNF)-α concentrations from WB stimulated with endotoxin 1 d after castration ($P \leq 0.05$), but Lrg-calve TNF-α increased at 5 d after castration to concentrations greater than 1 d before castration ($P \leq 0.05$). Percentage of neutrophils undergoing phagocytosis and oxidative burst to *E. coli* tended ($P = 0.06$) to decrease in Lrg-calves following castration, with the least percentage at 12 d after castration. Lrg-calves also had suppressed intensity of neutrophil oxidative burst compared with the other calves ($P \leq 0.01$). Modifying wooden hutches to the maximum space did not seem to positively influence calf innate immune function during castration, when there is a great risk of infection.

Key Words: free-space, inflammation, stress

M16 Effects of *Bacillus cereus* var. *toyoi* (Toyocerin) on the immune system of calves. A. Aris*[1], A. Serrano[1], M. Terré[1], G. Jiménez[3], M. Castillo[3], and A. Bach[1,2], [1]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain,* [3]*Rubinum SA, Rubí, Spain.*

Bacillus cereus var. *toyoi* (Toyocerin) has shown beneficial effects on the immune system of pigs and poultry, but it has not been studied on cattle. The objective of this experiment was to evaluate the effects of Toyocerin on the immune system of calves. Twenty-four Holstein calves (75.2 ± 1.87 kg of BW and 77 ± 0.7 d of age), were randomly distributed according to BW in 2 groups: 12 calves were assigned to a conventional concentrate feed (CTR), and the other 12 calves were fed the same concentrate feed supplemented with 2×10^8cfu *Bacillus cereus var. toyoi*/kg concentrate (TOY). Animals were vaccinated at d 0 with IBRaxion vaccine (Mérial) against infectious bovine rhinotracheitis (IBR) and re-vaccinated at d 20 of the study. On d 0 and 56, blood samples were taken to assess the antibody titer against IBR vaccine. Animals were killed at 60 to 67 d of the study. Before sacrifice, a blood sample was obtained to evaluate the proliferation capacity of peripheral blood mononuclear cells (PBMC). Immediately after sacrifice, animals were abdomen opened, and the whole gastrointestinal tract was removed. Jejunal fragments were sampled to analyze IgA and cytokines expression by qPCR. Data were analyzed by ANOVA using the treatment as the main effect. There were no differences in PBMC proliferation between the 2 treatments. The TOY calves tended ($P = 0.07$) to present a greater antibody response than CTR calves (92.5 ± 1.50% vs. 82.5 ± 3.50%, respectively); whereas no differences in IgA expression were observed at jejune level. Calves in the TOY group showed a clear increase ($P < 0.05$) in the expression level of Th2 cytokines such as IL-10 ($3.12 \times 10^{-3} \pm 0.8x10^{-3}$) in comparison to calves in the CTR group ($1.37 \times 10^{-3} \pm 0.3 \times 10^{-3}$), which would explain the observed improvement in humoral response to vaccination. On the other hand, the levels of Th1 cytokines related to cellular response, such as IL-12 and IL-1β, were numerically lower in TOY group than in CTR group. In conclusion, these preliminary results indicate that Toyocerin exerts a positive effect on the modulation of the immune response in calves.

Key Words: *Bacillus toyoi*, immune response, probiotic

M17 Space allowance influences the innate immune responses of Holstein calves during weaning. L. E. Hulbert*[1], M. S. Calvo[1], M. A. Ballou[2], K. C. Klasing[1], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California, Davis,* [2]*Animal and Food Sciences, Texas Tech University, Lubbock.*

Objectives were to determine if increased space allowance in wooden hutches influences the innate immune responses of Holstein bull calves during weaning. Calves were randomly assigned at 4 d of age to either conventional (Cnv; 0.46 m^2 space; n = 18), medium (Med; 0.70 m^2 space; n = 17), or large (Lrg; 1.39 m^2 space; n = 18) hutches. Calves were fed 227 g as-fed milk replacer (MR) twice daily (am and pm) until weaning and offered a calf starter ad libitum throughout the experiment. Weaning was initiated at age 53 d by removal of the pm MR feeding and was completed at age 64 d by removal of the am MR. Peripheral whole blood (WB) samples were collected before the am MR at age 53, 57, 64, 67 and 71 d. At age 67 and 71 d, all calves had increased circulating cortisol and neutrophil:lymphocyte and decreased Interferon- γ secretion from WB stimulated with phytohemagglutinin, compared with pre-weaning measures ($P \leq 0.01$). Also, at age 67 and 71 d, Med-calves had greater tumor necrosis factor-α secretion from WB stimulated with endotoxin than the other treatments ($P \leq 0.05$). In all calves, plasma urea nitrogen (UN) was increased at age 67 d compared with pre-weaning ($P \leq 0.01$) and was greatest among Cnv-calves ($P \leq 0.05$). Plasma haptoglobin (Hap) increased from pre-weaning in Cnv- and Med-calves ($P \leq 0.01$), but did not change over time among Lrg-calves. In addition, Lrg-calves had the least WB killing of *E. coli* at age 64 d ($P \leq 0.05$) and had less neutrophil phagocytosis and oxidative burst responses to heat-killed *E. coli* at age 53 and 64 d compared with the other calves ($P \leq 0.05$). Weaning was stressful for all calves, especially after the second bottle was removed. However, a moderate increase in space allowance for calves housed in wooden hutches may be beneficial to innate immune responses during weaning, while the largest increase in space allowance may negatively affect innate immunity.

Key Words: free-space, wean, inflammation

M18 Group-housed Holstein bull calves have decreased innate immune responses compared to individually housed calves after surgical castration. L. E. Hulbert[1], M. S. Calvo[1], R. A. Kurzbard*[1], M. A. Ballou[1], K. C. Klasing[1], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California, Davis,* [2]*Animal and Food Sciences, Texas Tech University, Lubbock.*

Objectives were to (1) determine if housing calves in groups of 3 (Group; n = 9 pens) or individually (Indv; n = 18) influences the innate immune responses of Holstein bull calves following surgical castration and (2) determine whether the innate immune responses of grouped calves is influenced by their ADG ranking within a pen (low = 0.80 ± 0.116; mid = 1.27 ± 0.116; or high = 1.68 ± 0.116 kg/d. All calves were surgically castrated at 24 d of age. Peripheral whole blood (WB) samples were collected at −1, 1, 5, and 12 d relative to castration. At 12 d after castration, all calves had greater plasma cortisol than pre-castration measures ($P < 0.01$). In Indv calves, neutrophil:lymphocyte (N:L) did not change after castration ($P > 0.10$), but N:L increased in Group calves 1 d after castration ($P \leq 0.05$). In addition, 12 d after castration, Group calves had greater plasma haptoglobin (Hap) than Indv-calves ($P < 0.01$). In contrast, before castration Indv-calves had greater WB killing (WBK) of *E. coli* than Group calves ($P \leq 0.05$) and the day after castration, WBK decreased in Indv calves to percentages lower than Group-calves ($P \leq 0.05$). Within 12 d after castration the WBK of Indv calves had returned to pre-castration measures ($P \leq 0.05$). At 5 and 12 d after castration, all calves had increased tumor necrosis factor (TNF)-α concentrations in WB stimulated with endotoxin compared with pre-castration ($P < 0.01$). Over the entire study period, neutrophil oxidative burst response to heat-killed *E. coli* was lower in Group calves compared with Indv calves ($P \leq 0.05$). Mid-ranked Group calves had higher interferon-γ secretion from whole blood cultures stimulated with phytohemagglutinin 1 and 12 d after castration than either the high- or low-ranked calves ($P \leq 0.05$). These data suggest that group housing calves in wooden hutches during castration may negatively influence innate immune function. However, group-housing had the least negative effect on immune function in mid-performing calves.

Key Words: bovine, grouping, stress

M19 A transient receptor potential channel 4 (TRPC4) gene to study response to gastrointestinal nematode infection in parasite-resistant goats. M. M. Corley* and J. Ward, *Virginia State University, Petersburg.*

Gut expulsion of a variety of mammalian (human, sheep, and mice) nematodes requires mechanisms that enhance gut contractions and glycoprotein hyper-secretion to allow detachment of the nematode from the gut wall. *Haemonchus contortus*, the blood sucking gastrointestinal nematode (GIN), costs the global livestock industry billions of dollars per year in lost production and anthelmintic drug costs. The transient receptor potential cation channels (TRPC) allows membrane depolarization and entry of calcium into the cell, thereby resulting in smooth muscle contraction. Deletion of TRPC4 in mice greatly reduces intestinal motility and contractility. To date, the relationship between gene expression of TRPC4 and the response to GIN infection has not been assessed in goats or any other species. This study evaluated gene expression of TRPC4 in selected pasture exposed parasite resistant goats. Intestinal tissues were harvested from goats exhibiting susceptibility and resistance to *H. contortus*. Primers were designed from conserved regions of TRPC4 human, bovine, mouse and rat nucleotide sequence alignments. Total RNA was extracted from homogenized goat intestinal tissues and real time RT-PCR (qRT-PCR) was performed to determine TRPC4 gene expression. The qRT-PCR results showed that TRPC4 was upregulated ($P < 0.05$) in goats naturally susceptible to *H. contortus* infection. Breed and gender differences ($P < 0.05$) in TRPC4 expression were observed. Overall, there was a strong positive ($P < 0.05$) correlation between TRPC4 gene expression and FAMACHA eye color chart scores and fecal egg counts, and strong negative correlation ($P < 0.05$) with packed cell volume in goats. These data indicate that TRPC4 may be useful in elucidation of the relationship between gastrointestinal contractility and the response to gastrointestinal nematode infection in goats as well as other species.

Key Words: goat, gastrointestinal nematode, TRPC4

M20 Use of selected blood parameters to identify markers of heat-sensitivity in Angus and Romosinuano heifers. R. Chaffin,* B. A. Scharf, J. S. Johnson, J. Bryant, D. Kishore, P. A. Eichen, and D. E. Spiers, *University of Missouri, Columbia.*

A study was performed to determine blood parameter differences in heat-sensitive Angus (ANG) and heat-tolerant Romosinuano (RO) heifers in response to heat stress. Eighteen month-old ANG (n = 11; 306.7 ± 25.9 Kg BW) and RO (n = 10; 312.9 ± 32.0 kg BW) heifers were maintained in the Brody Environmental Center (University of Missouri-Columbia) at cycling thermoneutral air temperature (TN, 18.5–23.5°C) for 7 d, followed by either continued maintenance at TN or exposure to heat stress (HS, 18.5–38°C) for the remaining 12 d of the study. Heifers received melengestrol acetate (0.5mg/animal/day) to suspend reproductive cycling. Blood samples were obtained via jugular venipuncture at TN (d 5), early HS (EH, d 10), and late HS (LH, d 17), and analyzed for a variety of parameters. Rectal temperature (Tcore) was measured with a thermistor thermometer 6 times daily. On d 5, average Tcore did not differ between breeds ($P = 0.89$). During EH and LH, Tcore was significantly higher in ANG overall ($P = 0.001$), and higher among HS ANG than other groups (~1°C, $P = 0.025$). Though insignificant, Tcore tended to rise continually between EH and LH among HS ANG (~0.4°C) while falling in HS RO (~0.3°C). RO had lower triglycerides (TAG) than ANG on d 5 ($P = 0.028$). On d 10 and 17, RO still exhibited lower TAG than ANG ($P = 0.004$), with no effect of HS on either breed. Cholesterol (CHO) was not different between ANG and RO on d 5 ($P = 0.36$), but ANG showed higher levels of CHO than RO during treatment ($P = 0.04$), with HS exposure causing a further reduction below TN level ($P = 0.02$). On d 5, RO had higher alkaline phosphatase (ALP) than ANG ($P = 0.012$), as well as on d 10 and 17 ($P = 0.004$). In general, HS lowered ALP on d 17 from the pretreatment level ($P = 0.05$). These results suggest that blood TAG and ALP levels may serve as markers for detecting potential heat-sensitivity before stress, while blood CHO and ALP levels may be useful markers for heat-sensitivity in beef heifers during stress.

Key Words: heat stress, Angus, Romosinuano

M21 Variation in innate immune parameters in Holstein calves is influenced by housing environment and physiological period.

M. D. Sellers,* D. L. Hanson, A. R. Pepper-Yowell, C. J. Cobb, and M. A. Ballou, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Objective was to determine if housing environment and physiological state influence the proportion of variation in innate immune parameters due to time, between calves, and within calves during the neonatal, weaning, and commingling periods in Holstein calves. Ninety-nine calves (2 ± 1 d old) were randomly assigned to 5 treatments: 1, 2, or 3 calves/pen indoors (IN1, n = 21; IN2, n = 20; IN3, n = 18), and 1 or 3 calves/pen outdoors (OUT1, n = 21; OUT3, n = 20). Weaning started on d 43 with removal of PM milk, and was completed when starter consumption was 800 g/d. Calves were commingled on d 91 by randomizing all calves into outdoor group hutches (n = 5 calves/hutch). Peripheral blood samples were collected during neonatal (d 3, 10, 21), weaning (d 45, 47, 53), and commingling (d 91, 94, 99) periods and analyzed for neutrophil oxidative burst (OB) capacity when cocultured with an *Escherichia coli*, neutrophil L-selectin expression, whole blood secretion of tumor necrosis factor-α (TNF) when cocultured with lipopolysaccharide, and plasma concentration of haptoglobin. For each treatment within a period, variation was partitioned using Type III sums of squares estimates and reported as eta-squared, or the proportion of variation attributable to a given effect compared with total variation. Sources of variation included: variation due to time (DAY), between-calf (BET) and residual (RES). Values are reported as ranges or means across treatments. During the neonatal period, OUT3 calves had a larger BET proportion than OUT1 calves for neutrophil L-selectin expression (0.44 vs. 0.20) and OB capacity (0.54 vs. 0.29), and plasma haptoglobin (0.25 vs. 0.16). During weaning, OUT1 calves had higher BET proportions than OUT3 calves (0.56 vs. 0.23) for haptoglobin. The BET accounted for more variation across treatments during weaning when compared with the neonatal period for TNF secretion (0.57 vs. 0.40), percent of cells OB positive (0.64 vs. 0.51), and OB capacity (0.66 v 0.43). Proportion of variation due to DAY was lower during weaning than during the neonatal period (0.13 vs. 0.39). The BET variation for percentage of neutrophils positive for OB decreased during commingling compared with weaning (0.45 vs. 0.64). Differences in housing environment and physiological period influence proportion of residual variation, variation between calves, and variation due to time.

Key Words: calf, housing, immune

M22 Intravaginal administration of lactic acid bacteria modulated innate immune responses of periparturient dairy cows.

Q. Deng, J. F. Odhiambo, T. Lam, S. M. Dunn, and B. N. Ametaj,* *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Dairy cows are characterized by a suppressed immunity around parturition, which increases their susceptibility to uterine infections. The goal of this investigation was to evaluate innate immune responses of transition dairy cows administered intravaginally with a mixture of lactic acid bacteria (LAB). In total, 152 pregnant Holstein cows were randomly assigned, based on parity and BCS, into 3 groups 2 wk before the expected day of calving. Cows received intravaginally a mixture of LAB or carrier (sterile skim milk) once per week at −2, −1, and +1 wk relative to the day of calving as following: treatment 1 (TRT1) - 2 consecutive LAB and 1 carrier dose; treatment 2 (TRT2) - 3 consecutive LAB doses; control (CTR) - 3 consecutive carrier doses. LAB were a mixture of *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140 stored in sterilized skim milk. The LAB were infused intravaginally with a sterile insemination pipette at 10^8 to 10^9 cfu per dose. Blood samples were collected from the tail vein before each treatment and once per wk up to +8 wk. A subset of serum samples from 32 cows were used to analyze TNF-α, haptoglobin, and lipopolysaccharide-binding protein (LBP) by ELISA. Results demonstrated that both probiotics and parity had an effect on the concentration of TNF-α in serum. The concentrations of TNF-α were 231, 706, and 326 pg/mL in TRT1, TRT2, and CTR, respectively ($P < 0.05$). Primiparous cows had lower concentrations of TNF-α than multiparous cows (189 vs. 654 pg/mL) ($P < 0.01$). The interaction between TRT and parity showed a tendency to affect the concentration of TNF-α ($P < 0.1$). Concentrations of haptoglobin in serum were 407, 262, and 390 µg/mL in TRT1, TRT2, and CTR, respectively ($P > 0.05$). There was an interaction of TRT and parity on concentrations of haptoglobin ($P < 0.05$) in the serum, although no effect ($P > 0.05$) of treatments was obtained. Concentrations of LBP in the serum were 7,878, 7,500, and 8,337 ng/mL in TRT1, TRT2, and CTR, respectively ($P > 0.05$). Serum concentrations of both haptoglobin and LBP changed with wk ($P < 0.01$). Overall, intravaginal application of LAB modulated innate immune responses in transition dairy cows.

Key Words: dairy cows, lactic acid bacteria, innate immunity

M23 Intravaginal administration of a mixture of lactic acid bacteria lowered the incidence of clinical diseases in transition dairy cows.

Q. Deng, J. F. Odhiambo, T. Lam, S. M. Dunn, and B. N. Ametaj,* *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Infertility is the main cause of culling of dairy cows in Canada causing dairy industry more than $667 million in losses during 2010. More than 35% of the cows in a herd are affected by various forms of reproductive tract infections. Infertility is highly related to bacterial infections of the uterus immediately after calving and uterine infections are highly associated with other periparturient diseases. The objective of this study was to evaluate whether intravaginal infusion of a mixture of lactic acid bacteria (LAB) would affect the incidence of clinical diseases in transition dairy cows. 152 pregnant Holstein cows were assigned randomly to

3 groups 2 wk before the expected day of calving, based on their parity and BCS. Cows received intravaginal LAB around parturition as follows: treatment 1 (TRT1) - 2 consecutive LAB and 1 carrier (1 mL of sterile skim milk) dose; treatment 2 (TRT2) - 3 consecutive LAB doses; control (CTR) - 3 consecutive carrier doses. LAB used were a mixture of 3 lactic acid bacteria including *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140 stored in sterilized skim milk and infused at 10^8 to 10^9 cfu per dose. Cows were checked twice per week after parturition for retained placenta (RP), vaginal purulent discharges, left displaced abomasum (LDA), and lameness. Results indicated an overall incidence rate of vaginal purulent discharges of 25%. Within those cows, 24% were in TRT1, 26% in TRT2, and 50% in CTR ($P = 0.05$). RP had an overall incidence rate of 7.9%. Within the cows with RP, 17% were in TRT1, 33% in TRT2, and 50% in CTR ($P = 0.07$). LDA exhibited an overall incidence rate of 4.0%. Within the cows having LDA, 17% were in TRT1, 50% in TRT2, and 33% in CTR ($P = 0.07$). The overall incidence rate of lameness was 10.5%. Within those lame cows, 31% were in TRT1, 44% in TRT2, and 25% in CTR ($P = 0.02$). It should be pointed out that a major reason for lameness was mechanical injury. In conclusion, intravaginal administration of LAB lowered the incidence of vaginal purulent discharges and RP in periparturient dairy cows.

Key Words: dairy cow, lactic acid bacteria, disease incidence

M24 Acute phase response intensity is related to the metabolic and immunologic statuses of early postpartum dairy cattle.

C. R. Nightingale,* M. D. Sellers, A. R. Pepper-Yowell, D. L. Hanson, C. J. Cobb, B. S. Obeidat, and M. A. Ballou, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Objective was to describe the relationship between the intensity of the acute phase response and the metabolic and immunologic statuses of early postpartum, multiparous cows. Peripheral blood was collected from 240 Holstein cows, 2–8 DIM and 2nd-8th parity from 8 dairies across 5 d (n = 6 cows/dairy/day). Plasma concentrations of haptoglobin were measured colorimetrically and cows were classified as low (1st quartile), moderate (2nd and 3rd quartiles), or high (4th quartile) responders. Metabolic measurements included plasma β-hydroxybutyrate (BHBA) concentrations. Immunologic measurements included total leukocyte counts and differentials, neutrophil L-selectin expression, neutrophil oxidative burst capacity when cocultured with *Escherichia coli*, as well as the secretion of tumor necrosis factor-α and interferon-γ when diluted whole blood was cocultured with lipopolysaccharide and phytohemagglutinin, respectively. All data are reported as Low, Moderate, and High, respectively. Haptoglobin concentrations ranged from 0.42 to 1.04, 1.05–3.50, and 3.51–10.47 adjusted optical density. High cows had greater BHBA concentrations ($P < 0.05$; 509, 548, and 645 ± 57.8 μ*M*), elevated rectal temperatures ($P < 0.01$; 101.3, 101.4, and 101.7 ± 0.14°C), and neutropenia ($P < 0.01$; 3.5, 3.3, and $2.2 \pm 0.34 \times 10^6$ cells/mL). In addition, the innate immune responses of High cows were stimulated as evident by increased secretion of tumor necrosis factor-α ($P < 0.05$; 570, 562, and 732 ± 72.5 pg/mL), expression of L-selectin on neutrophils ($P < 0.01$; 71, 72, and 119 ± 10.0 mean fluorescence intensity), and neutrophil oxidative burst capacity ($P < 0.05$; 117, 123, and 146 ± 11.7 mean fluorescence intensity). In contrast, the secretion of interferon-γ was suppressed in both the Moderate and High cows ($P < 0.01$; 707, 420, and 309 ± 102.8 pg/mL). These data indicate that a stronger acute phase response during the early postpartum period is characterized by increased concentrations of ketone bodies, activated innate immune responses, and a suppressed adaptive immune response.

Key Words: immune, metabolic, transition cow

M25 Isolation and analysis of transient receptor potential channel (TRPC) genes in goats: Implications for study of gastrointestinal nematode infection.

M. M. Corley and J. Ward,* *Virginia State University, Petersburg.*

Transient receptor potential cation channels (TRPC) are involved in several cellular functions. The TRPC channels function as calcium cation channels that cause membrane depolarization and entry of calcium into the cell, thereby resulting in smooth muscle contraction. Specifically, it has been shown that TRPC4 and TRPC6 deletions in mice, impairs intestinal motility and contractility. Goats are plagued with the gastrointestinal nematode *Haemonchus contortus*, that costs the small ruminant industry billions of dollars per annum in livestock loss and drug treatment. The ability of the intestine to expel worms is dependent on many factors, one of which is intestinal contractility. Although the role of TRPC 4 and 6 has been identified as crucial in intestinal contractility in mice, the TRPC 4 and 6 genes have not been isolated in goats, nor evaluated in *H. contortus* infection. Therefore, the objective of this study was to identify and characterize the TRPC4 and TRPC 6 genes of goats. Total RNA was isolated from homogenized intestinal tissue and purified. Reverse transcriptase PCR (RT-PCR) was performed using cross species primers designed from the human, bovine, mouse and rat TRPC4 and 6 gene alignments. The RT-PCR products were visualized via agarose gel electrophoresis. The expected bp RT-PCR products were observed (388 and 350 bp, respectively), indicating successful amplification of the goat TRPC 4 and 6 cDNA. The cDNA PCR products were sequenced. The goat TRPC showed 98, 92, 91, and 90% sequence homology to the bovine, horse, pig, and human TRPC genes, respectively, and 88 and 87% homology to rat and mouse TRPC. Identification and analysis of goat TRPC 4 and 6 genes will help to elucidate the involvement of TRPC genes in the response to *H. contortus* infection in goats.

Key Words: goat, gastrointestinal, TRPC genes

Breeding and Genetics: Fertility and Early-Life Traits

M26 The relationship of herd-average conception rates and calving interval with sire predicted transmitting ability for three fertility traits. E. S. Benner and C. D. Dechow,* *Penn State University, University Park.*

The objective of this study was to determine the relationship of sire predicted transmitting ability (PTA) for fertility with reproductive performance in low and high fertility Holstein herds. First service conception rate (FSC; 42,389 records), services per conception (SPC; 29,924 records), and calving interval (CI; 28,113 records) were the herd fertility traits. Herds with a FSC of $\geq$28.4% and a CI of $\leq$13.8 mo were classified as high fertility, whereas herds with <28.4% FSC and >13.8 mo CI were classified as low fertility. Records were further stratified into high genetic groups of daughter pregnancy rate (DPR) if sire DPR was ≥ -0.6, high cow conception rate (CCR) if sire CCR was ≥ -0.7, and high heifer conception rate (HCR) if sire CCR was ≥ -0.4. Records with from cows with sire PTA below those levels were classified as belonging to the low genetic group for each trait. Fertility traits were evaluated in ASREML and the effect of DPR, CCR, and HCR genetic groups were evaluated separately. The model included fixed effects for lactation number, herd group (high or low fertility), genetic group (high or low sire PTA), and the interaction of herd and genetic groups. Age within lactation number, herd-calving-cluster, and error were the random effects. The effect of herd group was highly significant for all traits. The effect of DPR genetic group, CCR genetic group, and HCR genetic group was also significant for all traits ($P < 0.05$). FSC was 3.9% and 3.1% higher for the high CCR and DPR genetic groups, respectively, than the corresponding low genetic groups. SPC decreased by 0.07 services for the high HCR genetic group, 0.10 services for the high DPR genetic group, and 0.14 services for the high CCR genetic group. CI decreased from 1.6 d (HCR) to 5.1 d (DPR) in the high genetic groups. The interaction of DPR or CCR genetic group with herd fertility group was not significant for any trait. The interaction of HCR genetic group effect and herd fertility was significant for FSC ($P < 0.05$). FSC was 17% for both high and low HCR group in low fertility herds, but increased from 32% for low HCR group to 34% for the high HCR group in high fertility herds. In conclusion, this study provides evidence that selection for high fertility can improve reproductive performance in both favorable and adverse fertility herds.

Key Words: daughter pregnancy rate, conception rate, fertility

M27 Effect of body condition score at open period on reproductive traits of dairy cows in Hokkaido. J. Hirose,* Y. Masuda, and M. Suzuki, *Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Hokkaido, Japan.*

Body condition score (BCS) is a useful indicator for farmers to evaluate negative energy balance (NEB) of dairy cows. During postpartum period, severe NEB in a cow tends to lower reproductive performance. This suggests that if BCS is scored before conception farmers may be able to predict fertility. The objective of this study was to investigate the relationship between BCS at open period and fertility traits. Reproductive and lactation records collected by the Hokkaido Dairy Milk Recording and Testing Association, and type records collected by Holstein Cattle Association of Japan (Hokkaido Branch) were used. From this data set, only primiparous cows recorded between 2007 and 2009 were extracted. The fertility traits used were days open (DO), days from calving to first service (DFS), and number of services (NS). DO and DFS were analyzed using the GLM procedure of SAS and the LOGISTIC procedure of SAS was used for NS analysis. BCS was scored on a scale of 1 to 9, where 1 = thin and 9 = fat. These scores were then divided into 5 classes: 1 to 3, 4, 5, 6, and 7 to 9. The months of calving were divided into 4 seasons: January to March = spring, April to June = summer, July to September = fall and October to December = winter. BCS, dairy milk yield, protein to fat ratio (P/F), the square of P/F, age of calving, and season were included as fixed effects in all models. As a result, individuals in BCS class 1 showed significantly delayed DO (+11.27 d) and DFS (+11.86 d) compared with BCS class 3 ($P < 0.05$). In contrast individuals in BCS class 4 and 5 were estimated to have a fewer NS (0.15 and 0.23 times) than BCS class 3. The optimal P/F range was found and it significantly decreased DO, DFS, and NS, but spring and summer had significantly adverse effects on these traits. Cows with a younger calving age had significantly shorter DO and DFS. The effects of calving seasons and milk production are associated with fertility traits; however, cows with a medium to high BCS also showed the same tendencies. The BCS at the open period may be an important indicator of when to start the reproductive cycle.

Key Words: body condition score, reproductive trait, dairy cows

M28 Cyclicity and fertility of Holstein, Jersey, and crossbred cows in a fall-calving, pasture-based dairy. K. Glosson* and S. Washburn, *North Carolina State University, Raleigh.*

With the decline in fertility in dairy herds over many years, use of crossbreeding is one practice that may improve reproduction. At the Center for Environmental Farming Systems Dairy Unit in Goldsboro, North Carolina, 143 cows were studied in a fall-calving (Oct. to Jan.), pasture-based dairy. The 2010–2011 herd included 15 Jerseys (JJ), 12 Holsteins (HH), 37 crosses of JH or HJ (F1), 39 crosses >50% Jersey (JX), and 40 crosses >50% Holstein (HX). Milk samples collected at 10-d intervals around 30, 60, and 90 d postpartum were tested for progesterone, to determine cyclic status. Any milk sample with progesterone concentration at >1.0 ng/mL or an observed estrus were used to confirm that a cow was cyclic. Cows were observed for estrus and inseminated via AI from Jan 1, 2011 through April 30, 2011. Data for percentages of cows cycling at 30, 60, and 90 d after calving and for those pregnant to first insemination and within the 120-d breeding season are included in the table as raw data means. More JJ, JX, and F1 cows were cyclic at 30 d postpartum compared with HX or HH. Differences in cyclic status were less at 60 d and all cows were cyclic by 90 d postpartum. Conception rates at first service and pregnancy percentages for the 120-d breeding season were generally higher for crossbred cows than for JJ and HH. However, the number of observations was low for both purebred groups. The data in this study are consistent with the potential for improved reproduction for crossbred dairy cows.

Table 1. Cyclicity and fertility of crossbred dairy cows

	Breed types				
Item	JJ	JX	F1	HX	HH
Number	15	39	37	40	12
Cyclic at 30 d (%)	60.0	59.0	62.2	35.0	41.7
Cyclic at 60 d (%)	100	97.4	89.2	72.5	91.6
Cyclic at 90 d (%)	100	100	100	100	100
Pregnant at 1st service (%)	33.3	46.2	56.8	50.0	41.7
Pregnant within 120-d season (%)	46.7	71.8	78.4	70.0	50.0

Key Words: fertility, progesterone, crossbred

M29 Genomic differences between highly fertile and sub-fertile Holstein dairy heifers. A. E. Navarrette*[1], C. A. Gill[1], T. E. Spencer[2], and T. R. Bilby[1,3], [1]*Department of Animal Science, Texas A&M University, College Station,* [2]*Department of Animal Sciences, Washington State University, Pullman,* [3]*Texas Agrilife Research and Extension, Stephenville.*

Reduced fertility in dairy cattle remains a major economic loss to dairy producers. Identifying dairy cattle with superior genetic potential for fertility would increase dairy farm profitability. Blood samples were taken and DNA extracted from dairy heifers (n = 40) on 2 commercial dairies in Texas. Heifers were classified into 2 groups based upon services per conception (SPC); those animals with a single SPC were determined to be highly fertile (n = 20) and heifers with greater than or equal to 4 SPC were classified as sub-fertile (n = 20), representing the 2 tails of the population distribution. Whole genome association analysis was performed utilizing a 777K high-density (HD) single nucleotide polymorphism (SNP) chip. Genomic data were evaluated utilizing a whole genome association analysis toolset (PLINK) and 570,620 SNP were available for analysis with a total of 39 samples being analyzed. Forty-four SNP were determined to be associated with fertility ($P \leq 10^{-5}$) and were located on *Bos taurus* chromosomes (BTA) 2, 4, 9, 19, and 26. The SNP and ranges between SNP were analyzed using BLAST-Like Alignment Tool (BLAT), and SNP were associated with 5 candidate genes for reproduction. The SNP on BTA 2 were located within the region coding for the non-imprinted Prader-Willi/Angelman syndrome 2 (NIPA2) gene and cytoplasmic fragile X mental retardation 1 (FMR1) interaction protein 1 (CYFIP1). In addition, 3 SNP on BTA 9 were located near monofunctional C1-tetrahydrofolate synthase (MTHFD1L). A difference in allele frequency was observed between the 2 groups for SNP located on BTA 19 in proximity to 2 genes, zinc finger 18 (ZNF18) and mitogen activated protein kinase 4 (MAP2K4). The SNP associated with 3 genes and one microRNA, which were significant but had no known role in reproduction, were elaC homolog 2 (ELAC2), vacuolar protein sorting 41 homolog (VPS41), glutaredoxin 3 (GLRX3), and microRNA 744 (MIR744). The NIPA2, CYFIP1, MTHFDIL, ZNF18, and MAP2K4 genes have all been linked to reproduction in various species and may play a role in fertility in dairy cattle. Further studies are needed to ascertain the involvement of these and other genes related to fertility in dairy cattle.

Key Words: dairy, genomics, SNP

M30 The quality and yield of embryos from Holstein dairy cows in relation to inbreeding. J. Bezdicek*[1], A. Makarevich[2], R. Holasek[2], E. Kubovicova[2], Z. Hegedusova[2], and F. Louda[2], [1]*Agroresearch Rapotin, Ltd., Vikyrovice, Czech Republic,* [2]*Research Institute for Cattle Breeding, Ltd., Vikyrovice, Czech Republic.*

The effect of inbreeding depression on reproduction traits in livestock is very important. There are several reproduction traits that reveal inbreeding depression, such as service period and age at first calving. The aim of this study was to evaluate the effect of inbreeding level (F_X) on yield and quality of embryos from Holstein cows. The data involve cows used for embryo transfer in the years 2010–2011 at farms in the Czech Republic. The value of F_X ranged from 3.125 to 6.25%. In total, 648 embryos were recovered from 87 donors by flushing of the uterus with Complete flush solution. Of these donors, 21 were inbred (163 embryos collected) and 66 non-inbred cows (485 embryos collected). The data were analyzed using StatSoft Inc. Statistica 10 with descriptive statistics and *t*-tests. Of 485 embryos flushed from 66 non-inbred cows (4.9 embryos per flushing; $s_X = 4.5$) 322 embryos (66.4%) were transferred to recipients. The number of unfertilized embryos was 114 (23.5%) with average of 1.7 embryos per flushing ($s_X = 2.2$) and 49 embryos (10.1%) were degenerated with average of 0.7 embryos per flushing ($s_X = 1.3$). Of 163 embryos collected form 21 inbred cows 107 embryos were transferable (65.6%) with average of 5.1 embryos per flushing ($s_X = 5.2$), 39 embryos were unfertilized (23.9%) with average of 1.9 embryos per flushing ($s_X = 2.0$) and 17 embryos were degenerated (10.5%) with average of 0.8 embryos per flushing ($s_X = 1.7$). There were no statistically significant differences between the inbred and non-inbred cows (*t*-test), although in some cases the records from inbred cows were poorer (number of transferable embryos, unfertilized embryos, degenerated embryos). The significant (negative) correlation was found only between F_X and the total number of collected embryos ($r = -0.50$; $P < 0.05$). There was also non-significant correlation between F_X and number of embryos suitable for transfer (−0.41). In conclusion, the inbred cows with a lower degree of F_X showed insignificantly slightly poorer yield and quality of embryos.

Key Words: embryo transfer, inbreeding

M31 Antioxidants in bovine semen cryopreservation. M. F. Duarte-Junior, L. K. Hatamoto-Zervoudakis,* J. T. Zervoudakis, P. P. Tsuneda, P. H. D. Gomes, F. M. Wingert, F. A. P. B. Arguello, and W. A. S. Marinho, *Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil.*

The present study aimed to determine if the addition of vitamins E and C to bovine semen extender reduces damage caused by cryopreservation and oxidative stress, and preserves fertility after the freeze-thawing process. We used 16 Nelore bulls (*Bos taurus indicus*) aged between 2 and 3 years, with proven fertility and without pathology in the reproductive tract. Each ejaculate was split into 3 equal groups and diluted in Tris-based extender containing vitamin E (tocopherol acetate, 10 mmol), vitamin C (ascorbic acid, 0.45mg/ml), and no additive (control). Diluted semen was chilled for 4 h to 4°C and placed into 0.5 mL chilled straws at a concentration of 25×10^6 sperm/straw. Straws were cooled for 10 min to −95°C in nitrogen vapor, followed by storage in liquid nitrogen until laboratory analysis. Frozen straws were then thawed individually at 37°C for 20 s in a water bath for the evaluation. Spermatic characteristics (motility, viability, abnormality and acrosomal integrity) and oxidative stress (lipid peroxidation) were assessed for each sample. No significant differences ($P > 0.10$) were observed in sperm motility, viability and abnormality, and oxidative stress among the groups. Addition of vitamin E to extender provided better acrosomal membrane integrity ($P < 0.10$) when compared with controls (94.34% ± 0.57 vs. 92.04% ± 2.69), however the addition of vitamin C (93.04% ± 2.98) did not protect acrosomal membranes as compared with other groups. Extender supplemented with vitamin E protected acrosomal membranes against freeze-thaw-induced damages and improved measures of bovine semen quality. Further studies are required to obtain more concrete results on the determination of lipid peroxidation and antioxidant capacities of vitamin E in cryopreserved bovine semen

Key Words: vitamin E, vitamin C, oxidative stress

M32 Extender supplementation with vitamin E and cryopreservation of bull sperm. P. P. Tsuneda, L. K. Hatamoto-Zervoudakis,* J. T. Zervoudakis, L. C. M. Soares, M. F. Duarte-Junior, P. H. D. Gomes, and F. M. Wingert, *Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil.*

The objective were evaluation of bovine semen extender supplementation with vitamin E improved viability and quality sperm. Were used

5 young Nelore bulls. Each ejaculate retreated 2 aliquots which were subsequently diluted with lactate extender (Lactato-based extender) and another Lactato extender supplemented with 50.0 m*M* of vitamin E in concentration of 100 × 10^6/mL viable spermatozoa. The diluted aliquots were chilled to 5°C for 4 h, then packaged into 0.5-mL straws and maintained for 20 min up to 5 cm in nitrogen vapor and after immersed in liquid nitrogen. Thawing was performed at 36°C for 30 s, immediately after thawing were evaluated sperm motility, sperm viability and oxidative stress (lipid peroxidation). There was no statistical effect in spermatozoa motility and viability ($P = 0.2133$, $P = 0.3696$, respectively). The supplementation of extender with vitamin E increased oxidative stress ($P = 0.0001$) suffered by spermatic cell during the process of freezing and thawing. Spermatozoa cryopreserved in a medium not supplemented showed a less oxidative stress (180.362 ± 64.858 ng/mL) compared with spermatic cells cryopreserved in extender supplemented (736.851 ± 112.662 ng/mL). It is concluded that extender supplementation with 50 mmol of vitamin E was not effective in protecting spermermatic cell against damage caused by freezing and thawing processes.

Key Words: fertility, spermatozoa, antioxidant

M33 Multibreed genetic evaluation of calving ease and birth weight using a threshold-linear model in Brangus.

S. Tsuruta,* A. H. Nelson, J. K. Bertrand, and I. Misztal, *University of Georgia, Athens.*

Multibreed genetic evaluation (MBE) was implemented for calving ease (CE) and birth weight (BW) using a threshold-linear model applied to data from the International Brangus Breeders Association. Data included 60,586 CE records with 2 categories (1: easy; 2: difficult) and 500,278 BW records from 1975 to 2011. The pedigree file contained 735,925 animals. Calving ease priors for heterosis and unknown parent group within breeds (breed effects) were obtained by scaling the BW heterosis and breed effects 2%; however, external EPD for CE were not available. External BW EPD priors from the American Angus Association for Angus sires were fit in the analysis. (Co)variance components and MBE for CE and BW were estimated with a threshold-linear model. The model included fixed effects of contemporary group (age-sex-herd), age of dam and heterosis breed contribution, and direct and maternal genetic random effects. The EPDs were compared with those from the current (C-) MBE for BW in Brangus. Of all CE records, 94.5% indicated easy calving. Direct and maternal heritability estimates were 0.23 and 0.18 for CE and 0.46 and 0.16 for BW, respectively. Genetic correlations between CE and BW were 0.87 for direct effects and 0.45 for maternal effects. Genetic correlations between direct and maternal effects were −0.19 for CE and −0.50 for BW. By setting the oldest age group for Angus breed as the mean base in MBE (87.5% in probability scale), predicted breeding values for CE were converted to a probability scale. The EPD was calculated as a deviation from the mean. For 17,847 sires with at least one progeny for birth weight, the correlation of direct EPD between BW in this study and in the C-MBE was 0.96. The correlation between BW in the C-MBE and CE in this study was −0.85. The correlation between BW and CE in this study was −0.90. For maternal EPD, the correlation between BW in this study and in the C-MBE was 0.87. The correlation between BW in the C-MBE and CE in this study was −0.18. The correlation between BW and CE in this study was −0.08.

Key Words: multibreed evaluation, calving ease, Brangus

M34 Expression profiling of testicular sense and antisense RNA transcripts of Brahman bulls.

K. K. Adams*[1], L. R. Chenault[1], J. Valenta[1], R. N. Vaughn[1], A. K. Torres[1], K. J. Kochan[1], T. H. Welsh Jr.[1], R. D. Randel[2], F. M. Rouquette Jr.[2], A. D. Herring[1], and P. K. Riggs[1], [1]*Texas A&M University, College Station,* [2]*Texas AgriLife Research, Overton.*

This study was designed to identify the extent to which both sense and antisense RNA transcripts were expressed in testis from postpubertal *Bos indicus* bulls as part of a bovine epigenetics project. Concurrent incidences of sense and antisense gene transcription were investigated by microarray analysis. Total RNA was extracted from testicular parenchymal tissue of sixteen 18-mo-old Brahman bulls immediately after slaughter at the departmental abattoir. A random subset of 4 of the 16 RNA samples was used in a microarray experiment. Expression microarrays were designed to assess transcription across the whole bovine genome without emphasis on known gene loci. Therefore, the 60-mer oligo probe-set from a commercial bovine whole-genome comparative genomic hybridization array was printed in expression format (Agilent Technologies, Santa Clara, CA). A total of 171,533 unique probes distributed approximately evenly across the genome were printed on the array (slide A). A second array was designed in which the reverse complement of each of the 171,353 probes was printed (slide B). Cy3-labeled cRNA from each of 4 bulls was hybridized to 4 pairs of microarrays. Expression was detected for 16,738 probes on slide A, and 20,853 probes on slide B. Transcription was detected in both directions for 2,229 unique oligo sequences. To confirm the microarray results for sequences expressed as both sense and antisense transcripts, nested primers were used to directly prime reverse transcription reactions and amplify PCR products so that sense and antisense transcription could be compared for 8 genes by quantitative real-time RT-PCR (qRT-PCR). Gene expression was measured by qRT-PCR of RNA from tissue from all 16 bulls. By relative quantification analysis, similar patterns of expression were observed across animals for a given gene. The relative abundance of sense to antisense transcript quantity was gene dependent, and appeared to be differentially expressed within genes, but not across animals. In summary, we observed that approximately 10% of expressed transcripts in testis are expressed bi-directionally. These data provide a foundation for examining how non-coding transcripts attenuate and regulate gene expression in the bovine testis.

Key Words: antisense RNA, *Bos indicus*, testis

M35 Model comparison for genetic parameter estimation of birth and weaning weight traits in beef cattle.

S. O. Peters*[1,5], K. Kizilkaya[2,3], D. J. Garrick[2], R. L. Fernando[2], E. J. Pollak[4], M. De Donato[1,6], E. Chaffee[1], T. Hussain[7], and I. G. Imumorin[1], [1]*Cornell University, Ithaca, NY,* [2]*Iowa State University, Ames,* [3]*Adnan Menderes University, Aydin, Turkey,* [4]*US Meat Animal Research Center, Clay Center, NE,* [5]*Federal University of Agriculture, Abeokuta, Nigeria,* [6]*Universidad de Oriente, Cumana, Venezuela,* [7]*University of Veterinary and Animal Sciences, Lahore, Pakistan.*

Assumptions of normality in most animal breeding applications may make inferences vulnerable to the presence of outliers. Heavy-tail densities are viable alternatives to normal distribution and provide robustness against unusual or outlying observations when used to model the densities of residual effects. Our objective is to compare estimates of genetic parameters of fitting normal with heavy-tail distributions (Student's *t* and Slash) for residuals in univariate data of birth and weaning traits in beef cattle. A total of 17,019 birth and weaning weight records from 1998 through 2010 at the Rex Ranch were analyzed. Models included fixed effects of contemporary group and sire breed, while animal and maternal effects were random. The posterior mean and median estimates of the 2 heritabilities, and the genetic correlation using the Markov Chain Monte Carlo algorithms were similar to each other across models, implying that the posterior densities were symmetric and unimodal. Results revealed that posterior means for degrees of freedom were 6.78 and 4.89 in Student's t error model and 2.23 and 1.80 in slash error model for birth and weaning weight. Posterior means of direct and maternal heritabilities for birth weight were slightly smaller in Student's t when compared with the Normal model. The smallest values were found in the Slash model. For weaning weight, posterior means of direct and maternal heritabilities were highest in Normal models, followed by Slash and the least values were found in Student's t error model. Evaluation of 95% posterior probability interval showed that the genetic correlation between additive and maternal effects were not significant for birth weight but they were significant for weaning weight.

Key Words: genetic parameters, robust models, heavy-tailed distributions

M36 Genetic parameters of the reproductive traits in Nelore beef cattle. C. C. P. Paz*[1,2], H. L. Moreira[2], M. E. Buzanskas[3], L. El Faro[1], R. B. Lôbo[2,4], and D. P. Munari[3], [1]*SAA/APTA, Ribeirão Preto, SP, Brazil,* [2]*USP/FMRP, Ribeirão Preto, SP, Brazil,* [3]*UNESP/FCAV, Jaboticabal, SP Brazil,* [4]*ANCP, Ribeirão Preto, SP, Brazil.*

The scrotal circumference (SC) and age at first calving (AFC) are traits easily measured and the most important as indicative of precocity in bovine. Genetic parameters for birth weight (BW), age at first calving (AFC), gestation length (GL) and scrotal circumference (SC) were estimated using records of the 109,185 animals of the Nelore breed participating in a cattle breeding program of the Brazil. The gestation length was analyzed as cow trait (GLcow) and as calf trait (GLcalf). Estimation of genetic parameters was performed using the restricted maximum likelihood method (REML) for animal models, using the WOMBAT software. The mixed model used for BW and GLcalf was $y = Xb + Z1a + Z2m + e$, in which y is the vector of the dependent variable; X is the incidence matrix for fixed effects, thereby associating the elements of b and y; b is the fixed-effects vector (contemporary group); Z1 and Z2 is the incidence matrix for direct and maternal random effects, thereby associating the elements of a and y; a is the random-effects vector for direct additive genetic effects; m is the random-effects vector for maternal genetic effect and e is the residual-effects vector. For SC, AFC and GLcow, the maternal genetic effect was not included in the mixed model. For BW and GL, a linear and quadratic effect of the covariate dam age was considered. Heritability estimates were moderate for BW (0.30 + 0.02), AFC (0.20 + 0.02), GLcow (0.20 + 0.01), GLcalf (0.49 + 0.05) and SC (0.41 + 0.02). Genetic correlation estimates between BW and AFC, GLcow, GLcalf, SC were 0.36, 0.31, 0.13, 0.07 respectively, between AFC and GLcow, GLcalf, SC were 0.19, 0.28, −0.40, respectively, between GLcow and SC was 0.02 and between GLcalf and SC was −0.21. These results suggest that selection for AFC and GL could improve female reproductive efficiency. The direct selection for SC and GLcalf could be better than the selection for AFC due to higher heritability estimate. The gestation length analyzed as calf trait (GLcalf) could be included in the selection index of the Nelore Brazil Program.

Key Words: genetic associations, heritability, precocity

M37 Genetic trends for growth-related traits and calving ease of Simmental beef cattle. H. M. Saad*[1], W. Shafer[2], and R. M. Enns[1], [1]*Department of Animal Sciences, Colorado State University, Fort Collins,* [2]*American Simmental Association, Bozeman, MT.*

Genetic change in a trait, over time, is primarily driven by the genetic variability, accuracy of selection, generation interval, and selection intensity and, in multiple trait selection programs, by genetic correlations with other traits of interest. Given modern genetic evaluation tools, and reproductive tools such as artificial insemination, selection intensity is a primary driver of genetic improvement. The main goal of this study was to quantify the selection pressure placed on growth and calving ease in the American Simmental Association (ASA) registry as part of a larger project to evaluate birth weight or calving ease EPD in selection programs. Data consisted of 2,540,928 records, from 1980 to 2011, from ASA. Data included maternal calving ease EPDs (CEM) and direct EPDs and accuracies for birth weight (BW), weaning weight (WW), yearling weight (YW), and calving ease (CED). To compare genetic trends on an equal scale, mean EPDs by year were converted to standard deviation units (sdu). Based on preliminary analysis indicating a change in selection pressure since the importation of Simmental genetics, genetic trend for all studied traits can be divided into 2 parts, that occurring from 1980 to 1991 (period 1) and that from 1992 to 2011 (period 2). Results show that mean EPDs for BW in period 1 increased by 0.017 ± 0.0004 sdu/year, which indicates that breeders put more emphasis on growth and correspondingly experienced increasing birth weight. During this period, mean EPDs for CED showed little change (0.0017 ± 0.0003 sdu/year), while mean EPDs for CEM increased by 0.023 ± 0.001 sdu/year. During period 2, the rate of genetic change of mean EPDs for BW dropped dramatically (−0.024 ± 0.001 sdu/year) while mean EPDs for CED increased by 0.019 ± 0.0007 sdu/year. As result, the rate of increase in mean EPDs for YW slowed (0.007 ± 0.0006 sdu/year) while that for WW did not show any change (0.00016 ± 0.0007 sdu/year). These results suggest selection emphasis differed between periods, with breeders selecting against BW in period 2 which resulted in a slower genetic change in growth-related traits compared with had they selected directly for calving ease.

Key Words: Simmental, genetic trend, calving ease

M38 Estimates of genetic parameters for female fertility traits of Canadian Simmentals. J. Jamrozik*[1], S. McGrath[2], R. A. Kemp[2], B. Holmquist[3], and S. P. Miller[1], [1]*CGIL, Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*RAK Genetic Consulting Ltd., Lethbridge, AB, Canada,* [3]*Canadian Simmental Association, Calgary, AB, Canada.*

Calving to first insemination (CFI) (probability that a cow will successfully produce a calf from her first service) and days to calving (DC; interval between the first exposure to the bull and calving) defined separately for heifers and multi-parity cows were analyzed with a 4-trait linear animal model. The data were 108,206 records on 56,879 Canadian Simmental females with AI and Natural Service breeding records collected from 1974 to 2010. The model included fixed effects of year-season of breeding, age of cow by season of breeding, and age of cow's dam. Random effects were contemporary group, service sire by year of breeding (for CFI only), animal genetic, and cow permanent environmental (PE) effects for repeated records of multi-parity cows.

Bayesian methods were used to estimate posterior distributions of covariance components and genetic parameters. Estimates (SD) of heritability were low, ranging from 1.8% (0.29) for CFI in heifers to 3.7% (0.44) for DC in multi-parity cows. Interval trait (DC) had slightly higher heritabilities compared with CFI; both traits expressed in older cows were more heritable than corresponding traits for heifers. Contemporary group contributed up to 56% of the total variance for DC in heifers. Service sire and the PE were relatively larger (smaller) sources of variation compared with additive genetic (contemporary group) effects. All traits were highly genetically correlated: from 0.68 for CFI in heifers and multi-parity cows to 0.91 for DC in heifers and multi-parity cows. Environmental correlations ranged from −0.72 between CFI and DC in heifers to 0.91 for DC in heifers and multi-parity cows. Correlations smaller than 1 and heterogeneous variances indicated that CFI and DC expressed different aspects of female fertility in beef cattle, and fertility of heifers and multi-parity cows seemed to be different traits genetically. All 4 traits could be used in a form of selection index in Canadian Simmentals to breed for better fertility. Genetic progress, however, would be challenging given low values of heritability, and accurate EPD of bulls would require large numbers of progeny.

Key Words: female fertility, beef cattle, genetic parameters

M39 Polymorphisms in FSH-β ESR and BF genes and their relationship with reproductive traits in Yorkshire pigs. C. Liu[1], J. Shen[1], S. Zhu[1], W. Shi[2], and Y. Yu*[1], *[1]China Agricultural University, Beijing, China, [2]Animal Husbandry and Veterinary Station of Beijing, Beijing, China.*

The objectives were to provide the molecular basic information of sow reproduction traits for a Yorkshire breeding farm in Beijing, China. We investigated 3 SNPs in swine follicle stimulating hormone β (FSH-β; Zhao et al., 1999), estrogen receptor (ESR; Rothschild et al., 1996) and properdin (BF; Chen et al., 2009) genes and analyzed their relationship with reproductive traits in the Yorkshire population. A total of 251 Yorkshire sows were randomly selected from the breeding farm in Beijing suburb, China. High quality genomic DNA were extracted from the hair follicles for each pig. PCR-RFLP procedure was used for genotyping of the 3 genes. Associations of the SNPs with 3 reproductive traits, total number born (TNB), number born alive (NBA), and litter birth weight (LBW), were analyzed with mixed GLM model (SAS 9.1). The effects of parity, season, herd, and genotype were included in the model. The dominant genotype for FSH-β, ESR, and BF in the population were BB, AB and CC, respectively. Parity, season, and genotypes significantly affected the reproductions traits of the sows. At the first parity, the sows with AB genotype in FSH-β gene had significantly higher NBA and LBW than AA ($P < 0.05$), and significantly higher NBA than BB genotype ($P < 0.05$). The sows with CC genotype of BF gene were 1.70 kg higher in LBW than the CT sows ($P < 0.05$). The sows with combined genotype of AB-BB-CC for FSH-β, ESR, and BF genes was found significantly higher TNB, NBA and BLW than the AB-AA-CT sows ($P < 0.01$). As for the multiparity, the sows with AB and BB genotypes of FSH-β gene showed significantly higher LBW than the AA sows ($P < 0.05$). The key reproductive traits of the Yorkshire population were significantly influenced by single gene effect of FSH-β. Combined effects of multigenes should be considered in the association study on pig reproduction traits.

Key Words: BF, ESR and FSH-β, pig reproduction traits

M40 Genetic parameters for lifetime number of piglets born alive and length of productive life using a linear censored model. C. Y. Chen*[1], A. C. Clutter[2], and S. Tsuruta[3], *[1]Newsham Choice Genetics, Chesterfield, MO, [2]Agricultural Research Division, University of Nebraska, Lincoln, [3]Department of Animal and Dairy Science, University of Georgia, Athens.*

The objective of this study was to estimate genetic parameters for lifetime number of piglets born alive (LNBA) and length of productive life (LPL) using a single-trait linear model accounting for censoring. Records of 8,899 Large White females from a single farm collected between 2003 and 2011 were used. LNBA was defined as the number of piglets born alive produced during the lifetime of the sow. LPL was defined as the number of days from first farrowing to last farrowing in natural logarithm scale. Censored records represented 25% of the data. The average number of litters per sow was 5.0. Analyses were carried out with 3 approaches: a linear model excluding censored data (M1), a linear model ignoring censoring (M2), and a linear censored model (M3). Fixed effects included year_quarter based on entry date as contemporary group. Random effects were animal additive genetic effects. The effect of the 3 approaches on EBVs were evaluated for sows with parity < 4 (n = 3,391) and sows with parity > = 4 (n = 5,508). For LNBA, estimates of heritability were 0.13, 0.18, and 0.12 for models 1, 2, and 3. For LPL, estimates of heritability were 0.05, 0.07, and 0.07. Correlations between EBVs for LNBA were 0.97 for M1–2, 0.94 for M1–3, and 0.97 for M2–3 for sows with parity < 4. The same estimates were 0.94, 0.93, and 0.98 for sows with parity > = 4. For LPL, correlations were 0.95, 0.94, and 0.99 for M1–2, M1–3, and M2–3 for sows with parity < 4 and 0.94, 0.94, and 0.99 for sows with parity > = 4. Analysis accounting for censoring has lowest heritability due to increased residual variance and decreased genetic variance for LNBA whereas analysis excluding censored data has lowest estimate of heritability for LPL. Excluding censored data seemed to have larger effects on the estimation of breeding values than ignoring censoring. The effect of model choice on estimation of breeding values for LNBA was larger for sows with larger parity.

Key Words: censored data, genetic parameter, lifetime prolificacy, pigs

M41 Genome-wide association study of age at puberty in swine. J. F. Schneider,* D. J. Nonneman, R. T. Wiedmann, and G. A. Rohrer, *USDA, ARS, U. S. Meat Animal Research Center, Clay Center, NE.*

Age at puberty (AP) is an economically important trait in swine production. Reducing AP provides opportunities to lower the cost of gilt development, reduce age at first farrowing, increase litter size, and improve sow longevity. This analysis was designed to identify quantitative trait loci (QTL) associated with AP. Heat detection with boar contact began at 140 d of age and ended at 230 d of age. Seven hundred 50 7 gilts representing generations 5–8 of a Landrace-Duroc-Yorkshire cross reached puberty during 7 breeding seasons and were genotyped using a 60k chip. SNP were removed that met criteria including minor allele frequency <0.05, call rates <0.95, and unknown location. Five animals were removed with call rates <0.95 or that failed a Mendelian test. Bayesian methods were used to analyze 41,848 SNP. Prior estimates of variances were taken from MTDFREML with heritability = 0.32. The genomic variance priors were estimated by a preliminary run of BayesC using estimates from MTDFREML as priors. A previous estimate of Pi = 0.99 was confirmed by BayesCPi. Final BayesC using a burnin of 1000 iterations and a total chain length of 51,000 produced an estimate of 0.16 for the proportion of phenotypic variances explained by genetic markers (genomic heritability). A total of 94 QTL (5 consecutive SNP) were selected for statistical testing based on QTL variance. Testing identified 72 significant QTL including 25 at $P < 0.001$, 32 at $P < 0.005$, and 15 at the $P < 0.01$ level. QTL were found on all chromosomes analyzed (SSC) except 17. Chromosome 2 (SSC2) contained the most QTL with 9, followed by SSC1, SSC3, and SSC7 with 6, and SSC6, SSC10, SSC12, and SSC15 with 5 QTL each. These regions correspond to previously identified QTL (http://www.animalgenome.org/cgi-bin/QTLdb/SS/index accessed 2/06/2012). The results of this analysis demonstrate that opportunities exist to introduce QTL into genetic improvement programs designed to reduce AP. USDA is an equal opportunity provider and employer.

Key Words: puberty, swine, QTL

M42 Survival in crossbred lambs: Individual, maternal, heterosis, and breed effects.

V. C. Ferreira*[1,2], D. L. Thomas[1], and G. J. M. Rosa[1], [1]*University of Wisconsin-Madison, Madison,* [2]*Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

Early mortality in lambs causes substantial economic loss and animal welfare concerns and it is considered a major production limitation. The present study was a genetic analysis of lamb survival from a crossbred population involving 14 breeds to assess factors affecting death of lambs in 5 different periods of life. Data from 7,990 lambs, defined as a binary trait (dead or alive) in 5 different periods (until 1 d, 2 to 30 d, 2 to 60 d, 2 to 90 d and 2 to 120 d of age) were analyzed with a logistic version of the Dickerson full genetic model. Factors considered in the model predictor included sex of lamb, birth type (1, 2,…, 5), birth month, dam age, individual and maternal breed composition, individual and maternal heterosis (assuming the same magnitude for all pairwise combinations of breeds), and the random individual and maternal additive genetic effects. Results revealed that the effect of F1 individual heterosis resulted in a significant reduction in the probability of death in all 5 periods of life: −3.71% ($P = 0.08$), −6.12% ($P = 0.01$), −7.28% ($P = 0.02$), −8.24% ($P = 0.01$) and −11.26% ($P = 0.002$). These results suggest the importance of using crossbred animals for increased survival. Maternal heterosis did not have a significant effect in survival in most periods (except the 2 to 30 d period), probably because all animals in the study were artificially raised on milk replacer. The East Friesian maternal effect caused a significant increase in the probability of death in all periods from 2 to 120 d of age (ranging from 11.29 to 14.45%). These results highlight the importance of splitting maternal and heterosis effects from the effect of breed itself when analyzing survival data. All individual breeds with a significant effect on survival caused a decrease in the probability of death relative to the Lacaune breed, but the size of this decrease varied greatly among breeds and periods. Heritability for lamb survival tended to be low in all periods ranging from 0.04 to 0.13 and the maternal component was almost null (<0.04).

Key Words: crossbred, lamb, survival

M43 Efficiency of breeding Pantaneiro bulls by libido test.

J. R. B. Sereno*[1], V. G. Ueno[2], C. H. Bucher[3], U. G. P. Abreu[4], R. S. Juliano[4], and J. V. Malaquias[1], [1]*Embrapa Cerrados, Planaltina, DF, Brazil,* [2]*Centro Paula Souza, Adamantina, SP, Brazil,* [3]*Med. Vet. Autônomo, Campo de Goytacazes, RJ, Brazil,* [4]*Embrapa Pantanal, Corumbá, MS, Brazil.*

Pantaneiro cattle have been a genetic resource of the Brazilian Pantanal region for nearly 3 centuries. They are well adapted to the soil and climate of the region, reproducing naturally. However, with the arrival of zebu cattle in the region in the 1930s, breeders began indiscriminately crossbreeding these 2 breeds and attributed the merit only for zebu cattle. Currently, the Pantaneiro population is threatened in the region by substitution from zebu cattle. However, Pantaneiro bulls are well known for high libido, showing optimal reproductive performance in natural mating. This study aimed to evaluate potential breeding efficiency of Pantaneiro bulls using libido tests, to characterize the breed with the hopes of its conservation. We used 6 adult bulls aged 3–8 years, who underwent libido tests lasting 20 min/test, using 3 females in a prostaglandin-induced heat in each test. Each bull was tested 6 to 11 times, totaling 56 libido tests with 18.6 h of observation. During the libido test, all sexual behaviors of interest were noted. Scoring was from 0 to 10 where zero = bull showed no sexual interest in females and 10 = the bull made 2 or more services, followed by sexual interest, including mounts, attempted mounts, and services. The results showed that all 6 bulls evaluated had grade 10. All bulls showed interest in a female within 17 s and the first service occurred within 5 min. During the 20 min test the following behaviors were observed: smelling/licking of the vulva (8×), Flehmen Reflex (3.5×), mounting tentative with hands suspended (7×), active pursuit (7×), complete mount (1.5×), exposure of the penis (9×), and sexual interest in more than one female (6.5×). These were all behaviors associated with full mounting. These bulls were shown to be direct in their approaches to mounting and held 2 mounts (n = 2), 4 mounts (n = 3), or 5 mounts (n = 1) during 20 min of observation. These results suggest that Pantaneiro bulls have a high libido and that breeding efficiency would be high if this excellent performance is also carried out in natural matings in the field during the breeding season.

Key Words: animal conservation, beef cattle, animal genetic resource

Companion Animals

M44 Vitamin E and seminal quality in Rottweiler dogs. L. K. Hatamoto-Zervoudakis*[1], C. A. Baptista-Sobrinho[3], M. Nichi[2], A. K. S. Cavalcante[4], V. H. Barnabé[2], R. C. Barnabé[2], and C. N. M. Cortada[5], *[1]Federal University of Mato Grosso, Cuiabá, Brazil, [2]University of São Paulo, São Paulo, Brazil, [3]Brazilian Army, Osasco, São Paulo, Brazil, [4]Federal University of Bahia Reconcavo, Cruz das Almas, Brazil, [5]Tecpar, Curitiba, Brazil.*

The objective of this study was to evaluate dogs semen quality supplemented with oral vitamin E (DL-α-tocopherol). Eighteen male Rottweiler dogs were randomly divided in 2 groups: group control (without supplementation) and group treatment (with supplementation: 500 mg of DL-α-tocopherol/animal per day). The supplementation period duration was 90 d. Semen was collected by digital manipulation twice per week and ejaculate volume, sperm motility, spermatic concentration, sperm morphology (primary defects, secondary defects, and total defects) were determined. There were not found effects of treatment ($P > 0.05$) on ejaculate volume, sperm motility, semen concentration, and percentage of total defects. Supplemented animals with vitamin E presented reduction of percentage of primary defects (8.35 ± 0.65 vs. 12.29 ± 0.98; $P = 0.0006$) and increase of percentage of secondary defects (9.37 ± 0.61 vs. 7.52 ± 0.51; $P = 0.0241$) when compared with control animals. In conclusion, supplemented animals had alteration in spermatic morphology, reduced primary defects and increased secondary defects; however, supplemented animals showed no alterations in the other evaluated characteristics

Key Words: antioxidant, fertility, tocopherol

M45 Proximate analysis of commercially available whole prey for small captive exotic cats. K. R. Kerr*[1], L. M. Garner[2], and K. S. Swanson[1,2], *[1]Division of Nutritional Sciences, University of Illinois, Urbana, [2]Department of Animal Sciences, University of Illinois, Urbana.*

Small exotic cats are commonly fed whole prey to supplement traditional diets. Data regarding the composition of commercially available prey is lacking. The objective of this study was to evaluate the macronutrient composition of mammalian and avian species of different ages. Species examined included mice (1 to 2 d, 10 to 13 d, 21 to 25 d, 30 to 40 d, and 150 to 180 d); rats (1 to 4 d, 10 to 13 d, 21 to 25 d, 33 to 42 d, and >60 d); rabbits (stillborn, 30 to 45 d, and >65 d); chicken (1 to 3 d); and quail (1 to 3 d, 21 to 24 d, and ~60 d). Differences between classes were examined. Dry matter and CP concentrations were higher ($P < 0.05$) and fat concentrations were lower ($P < 0.05$) in aves versus mammals. Differences between ages were examined within species for rats, mice and quail. For rats, there was a linear increase ($P < 0.05$) in DM concentration and a linear decrease ($P < 0.05$) in CP concentration with age. Additionally, 1 to 4 d rats had higher ($P < 0.05$) fat concentration than all other ages. In mice, DM concentration was higher ($P < 0.05$) in 1 to 2 d mice than all other ages. Ten to 13 d mice were higher ($P < 0.05$) in fat and lower ($P < 0.05$) in CP than all other age groups. In quail, there was a linear increase ($P < 0.05$) in DM concentration with age. Crude protein concentration was higher ($P < 0.05$) in 21 to 24 d quail compared with all other ages. Fat concentration was higher ($P < 0.05$) in 1 to 3 d quail than all other ages, and higher ($P < 0.05$) in ~60 d quail compared with 21 to 24 d quail. Ash concentrations were not affected by age in rats, mice, or quail. Differences in composition due to age and between mammals and aves should be considered when selecting whole prey types. These data indicate that composition changes with age; however, these changes depend on species. Further research is needed to evaluate how whole prey may be used to meet the nutritional needs of small exotic cats, including micronutrient compositional analysis and bioavailability.

Key Words: whole prey, proximate composition, carcass

M46 In vitro digestion characteristics of expanded porkskin- and rawhide-based chews. S. Hooda*[1], L. G. Ferreira[1], L. L. Bauer[1], G. C. Fahey Jr.[1], M. A. Latour[2], and K. S. Swanson[1], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Department of Animal Science, Purdue University, West Lafayette, IN.*

Chews are a major sector of the pet food industry, but their digestion characteristics are virtually unknown. Therefore, the purpose of this study was to investigate the in vitro digestion characteristics of expanded porkskin- and rawhide-based canine chews. An in vitro method that simulated gastric and small intestinal digestion was used. Chews (in triplicate) were incubated with pepsin/HCl for 6, 12, 18, and 24 h to evaluate gastric digestion. To evaluate gastric and small intestinal digestion, chews were incubated with pepsin/HCl for similar periods, followed by incubation with pancreatin for 18 h. Gastric digestibility of expanded porkskin chews was 54.7% at 6 h and 58.6% at 12 h. An increase was observed after 18 h (76.4%) and 24 h (86.4%) of gastric digestion. In contrast, low gastric digestibility was observed for rawhide chews at 6 h (7.6%) and reached a maximum of 41.6% at 18 h. Both gastric and pancreatin digestion results indicated nearly complete disappearance of expanded porkskin chews even after 6 h gastric and 18 h pancreatin digestion. Extended gastric incubations (12, 18, and 24 h) followed by pancreatin digestion (18 h) did not change expanded porkskin chews digestibility. However, rawhide chews were only 70% digested after 6 h gastric and 18 h pancreatin digestion. Gastric digestion at 12 and 18 h did not result in further improvement in rawhide chews digestibility. The 24 h gastric and 18 h pancreatin digestion led to a increase in dry matter digestibility (85%) of rawhide chews. Thus, in vitro dry matter digestibility of whole chews clearly demonstrated that expanded porkskin chews was readily digestible and took a shorter time to be completely digested. In contrast, rawhide chews were not completely digestible, even after 24 h of simulated gastric and 18 h of simulated small intestinal digestion. Sponsored by Scott Pet Inc.

Key Words: in vitro digestibility, porkskin chews, rawhide chews

Dairy Foods

M47 Use of caseinomacropeptide index as indicator of adulteration of milk powder in Brazil. M. O. Leite, M. C. P. P. Oliveira,* L. M. Fonseca, M. M. O. P. Cerqueira, M. R. Souza, C. F. A. M. Penna, and T. Rosa, *Department of Food Technology and Inspection, Veterinary School, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Minas Gerais, Brazil.*

Brazil is one of the largest milk producer in the world, with 16.5% of the world milk powder production. Due to raw milk high prices, adulteration by cheese whey addition is a persistent practice, which has been increasingly targeted worldwide due to the potential of affecting the economical sustainability of the dairy industry, markedly in developing countries. Chromatographic determination of caseinomacropeptide (CMP) in milk is still recognized as the most suitable method to detect this adulteration. The CMP is a soluble polypeptide formed after splitting of kappa-casein by clotting enzymes during cheese making, and it will be partitioned in the whey. This work objective was to classify milk powder according to CMP levels, and evaluate legal requirements compliance. During 2009–2010, 125 samples of milk powder, from several dairies across the country were analyzed by high performance liquid chromatography (HPLC Shimadzu LC-10), and CMP levels were evaluated according to Brazilian legal requirements. The samples presented CMP levels ranging from 0 to 1,150 mg CMP/L (amount equivalent to reconstituted milk). Average concentration of CMP was 34.1 mg CMP/L, with a median of 18.3 mg CMP/L. CMP levels up to 30 mg/L were found in 73.3% of the samples, and milk with this CMP concentration is classified as high quality milk. CMP levels ranging from 30 to 75 mg/L were found in 21.8% of the samples, being suitable for milk derivatives production. However, 4.8% of the samples were found with CMP levels above 75 mg/L, being classified as poor quality milk and suspected of adulteration by cheese whey addition, not being suitable for human consumption. It is concluded that is necessary a more strict control and inspection, because 4.8% of the samples were not compliant with the legal requirements for milk destined to human consumption, due to adulteration and abnormal composition.

Key Words: caseinomacropeptide, HPLC, milk powder

M48 Effects of vacuum-deaeration on reconstituted milk flavor made from whole milk powder. H. J. Kang,* Y. K. Shin, and S. C. Baick, *Institute of Dairy Food Research, Seoul Dairy Cooperative, Ansansi, Kyunggi, South Korea.*

This study was conducted to evaluate the influence of vacuum-deaeration during the manufacturing process on flavors of reconstituted milk made from whole milk powder. As the first sample groups for pre-vacuum treatment before heating, whole milk powder solution (12%, wt/wt) was deaerated with a vacuum pump at 40°C for 10, 20 and 30 min, and then heated. On the other hands, as the second sample groups for post-vacuum treatment after heating, reconstituted milk was heated at 95°C for 10 min, and then deaerated at 40, 50 and 60°C for 10 and 20 min. Volatile sulfur compounds were analyzed with SPME and GC/PFPD, whereas ketones and aldehydes were analyzed with SPME and GC/MSD. Statistical evaluations including ANOVA and Turkey honest significant difference ($P < 0.05$) were conducted using SAS 9.0. When reconstituted milk was deaerated before heating, dimethyl sulfide and carbon disulfide were significantly reduced as compared with untreated reconstituted milk ($P < 0.05$). Dimethyl disulfide was significantly reduced in reconstituted milk deaerated at 40°C for 10 and 20 min ($P < 0.05$). Hexanal and 2-heptanone were significantly reduced in reconstituted milk deaerated at 40°C for 10 min ($P < 0.05$). In post-vacuum treatment test, hydrogen sulfide, methanethiol, and carbon disulfide in the reconstituted milk deaerated at 50°C for 20 min after heat treatment were significantly lower than untreated reconstituted milk ($P < 0.05$), whereas volatile sulfur compounds except for dimethyl disulfide in reconstituted milk deaerated at 60°C for 10 min were significantly decreased ($P < 0.05$). Hexanal and 2-heptanone of reconstituted milk deaerated at 50°C for 10 and 20 min after heat treatment were significantly decreased as compared with untreated reconstituted milk. It was concluded that vacuum-deaeration before or after heat treatment during the manufacturing process could reduce the volatile compounds developing off-flavors of reconstituted milk made with whole milk powder.

Key Words: reconstituted milk, off-flavor, volatile compound

M49 Evaluating the efficacy of a typical CIP protocol for cleaning membrane biofilms under in vitro conditions. D. Singh* and S. Anand, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

This study was carried out to evaluate the effectiveness of different chemicals of an industrial CIP protocol against in vitro biofilms formed on whey RO membranes. Bacterial cells isolated from biofilm consortia of 2- to 14-mo-old membranes included species of *Bacillus, Escherichia*, *Klebsiella*, *Enterococcus*, *Streptococcus*, *Staphylococcus*, *Micrococcus*, *Aeromonas*, *Corynebacterium*, and *Pseudomonas*. The CIP protocol tested against 24-h-old single and mixed species biofilms of above microflora included 6 treatment steps based on alkali, surfactant, acid, enzyme, a second surfactant, and a sanitizer application. Experiments were conducted with individual steps of cleaning, as well as, the sequential CIP protocol under static and dynamic conditions, and the data was statistically analyzed. The results revealed a variation in resistance of single species biofilms against the 6 individual steps of cleaning. Biofilms of *Bacillus* isolates were found to be most resistant, and even the most effective step of the cleaning protocol; acid treatment reduced their counts by only 2.09 and 2.16 logs under static and dynamic conditions, respectively. Biofilms of other isolates followed a similar trend. The sequential CIP protocol using all the 6 steps resulted in a greater reduction as compared with individual steps, but presence of survivors even after sanitizer treatment under static and dynamic conditions concluded the inefficacy of CIP chemicals against *Bacillus* biofilms. Mixed species biofilms developed using 10 mo. consortium of *Bacillus*, *Staphylococcus*, and *Streptococcus* was found to be more resistant than the single species biofilms. Even the acid cleaning step resulted in lower reduction of 1.52 log counts under the dynamic conditions. Overall, the sequential CIP protocol against mixed species biofilms resulted in cumulative reductions of 4.48 and 3.56 log under static and dynamic conditions, respectively. It can be concluded that tested CIP protocol had a limited effectiveness to clean membrane biofilms formed on the whey RO membranes.

Key Words: biofilm, CIP, sequential

M50 Effect of transglutaminase treatment on the functionality of MPC and MCC: Process cheese product slice formulations.

P. Salunke,* C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrate (MPC) is used as an ingredient in process cheese product (PCP) formulations. However, its use can result in texture defects such as soft body and restricted melting characteristics. Use of micellar casein concentrate (MCC), which has a higher level of casein and less whey protein improves the texture of PCP. Further improvement in PCP products may be possible with the use of transglutaminase (TGase), an enzyme that has the ability to crosslink proteins. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC when they are used in a PCP slice formulation. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 U/g of protein, one portion was treated with TGase at 3.0 U/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 10°C and then spray dried. Each MCC and MPC was then used in a PCP slice formulation that was standardized to 20.0% fat, 1.26% salt, 48.0% moisture, 17.5% protein, and 2.0% sodium citrate. In each formulation, the MPC or MCC contributed 15.7% protein to the formulation. Each formulation was manufactured in a Rapid Visco Analyzer (RVA) where it was mixed at 1000 rpm for 2 min at 95°C. Subsequently, the cheese was mixed at 160 rpm for a minute. Functional properties of PCP were analyzed using a penetration test, Dynamic stress rheology (DSR) for transition temperature (TT) and Schreiber melt test. As the TGase addition increased, there was significant ($P \leq 0.05$) increase in TT and a significant ($P \leq 0.05$) decrease in Schreiber melt area. The PCP made from MCC had higher TT and Schreiber melt area values than that made from MPC as an ingredient (TGase or no TGase). It was concluded that TGase treatment modifies the melt characteristics of MCC and MPC in PCP application.

Key Words: transglutaminase, MCC or MPC, process cheese product slice functionality

M51 Radio frequency dielectric heating treatment of NDM affects whey protein nitrogen index and solubility.

M. Michael[1], C. Chen[1], R. Phebus[1], K. Schmidt*[1], H. Thippareddi[2], and J. Subbiah[2], [1]*Kansas State University, Manhattan,* [2]*University of Nebraska, Lincoln.*

Radio frequency dielectric heating (RFDH) provides uniform, rapid heating throughout a medium, including dry powders. Nonfat dry milk (NDM), one of the major dried milk products made in the US, can be consumed directly or used as an ingredient in foods. However, NDM can be contaminated post pasteurization or spray drying with opportunistic pathogens. While RFDH may provide additional food safety effects, it has also been reported to improve functional applications of other dried powders. Thus, the objective of the study was to determine if RFDH affects the whey protein nitrogen index (WPNI) and solubility of NDM. High heat (HH) and low heat (LH) NDM was treated using RFDH at 75, 80, 85, and 90°C and held for a range of time from 0 to 125 min. Treated powders were assessed for WPNI and solubility following standardized methods and compared with a non-treated sample. Three replications were done, ANOVAs were done to determine significant effects ($P \leq 0.05$) and significant means were differentiated by the Dunnett's test. LH-NDM treated at 75°C had similar WPNI and solubilities compared with a non-treated sample, regardless of time. However, at all other temperature/time combinations significant decreases in WPNI and solubility occurred ($P \leq 0.05$). For WPNI, decreases ranged from 10.5 to 18%, whereas for solubility decreases ranged from 3.4 to 5%. Overall, the WPNI of treated HH-NDM was not affected; however, the solubility was ($P \leq 0.05$). Solubility decreases ranged from 1.2 to 3% compared with a non-treated sample and significant decreases were observed in all but one sample. Although, some significant changes were observed in the RFDH-treated NDM, it is concluded that this technology merits further evaluation both as a post-process lethality treatment as well as its effects on other functional properties.

Key Words: nonfat dry milk, radio frequency dielectric heating, whey protein nitrogen index

M52 Effect of transglutaminase treatment on the functionality of MPC and MCC. III. Imitation mozzarella cheese formulations.

P. Salunke,* C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

A critical parameter in dairy based imitation mozzarella cheese (IMC) is the amount of intact casein provided by dairy ingredients in the formulation. Intact casein provides IMC with a firm unmelted texture and a stringy, elastic melted texture. From a functionality perspective, rennet casein is the preferred ingredient to provide intact casein in a formulation and is superior to milk protein concentrate (MPC) and micellar casein concentrate (MCC). The use of a cross-linking enzyme such as transglutaminase (TGase) has the potential to modify the physical properties of MPC or MCC and may improve its functionality in IMCs. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC when they are used in IMCs. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 units/g of protein, one portion was treated with TGase at 3.0 units/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 10°C and then spray dried. Each MCC and MPC was then used in IMC formulation that was standardized to 21.0% fat, 1.0% salt, 48.0% moisture, and 20.0% protein. In each formulation, the MPC or MCC utilized contributed all the protein. Each formulation was manufactured in a Rapid Visco Analyzer (RVA) where it was mixed at 1000 rpm for 2 min at 95°C. Subsequently the cheese was mixed at 160 rpm for a minute. The IMC formulation using either MCC or MPC treated with the highest TGase did not form an emulsion. The RVA end of manufacturing viscosity and transition temperature (TT) was significantly ($P \leq 0.05$) higher and Schreiber melt test area was significantly ($P \leq 0.05$) lower for IMC containing TGase. The IMC made from MCC (with or without TGase) had higher TT values and Schreiber melt test area as compared with that made from MPC. The study demonstrates that TGase treatment modifies the melt characteristics of MCC and MPC in IMC application.

Key Words: transglutaminase, MPC or MCC, imitation mozzarella cheese functionality

M53 Effect of transglutaminase treatment on the functionality of MPC and MCC: Process cheese product loaf formulations.

P. Salunke,* C. Marella, and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Milk protein concentrate (MPC) is used as an ingredient in process cheese product (PCP) formulations. However, its use can result in texture defects such as soft body and restricted melting characteristics. Use of micellar casein concentrate (MCC) which has a higher level of casein and less whey protein improves the texture of PCP. Further improvement in PCP products may be possible with the use of transglutaminase (TGase), an enzyme that has the ability to crosslink proteins. The objective of this study was to determine the effect of TGase treatment of MPC and MCC retentates on the functionality of MPC and MCC when they are used in a PCP loaf formulation. Three lots of MCC and MPC retentate were produced using 3 different lots of pasteurized skim milk. Each replicate of retentate was divided into 3 equal portions. One portion of the retentate was treated with TGase at 0.3 U/g of protein, one portion was treated with TGase at 3.0 U/g of protein and one had no TGase addition. All the retentates were incubated for 25 min at 50°C, heat treated at 72°C for 10 min, cooled to 10°C and then spray dried. Each MCC and MPC was then used in a PCP loaf formulation that was standardized to 18.0% fat, 1.0% salt, 49.0% moisture, 15.0% protein, and 2.5% disodium phosphate. In each formulation the MPC or MCC contributed 12% protein to the formulation. Each formulation was manufactured in a Rapid Visco Analyzer (RVA) where it was mixed at 1000 rpm for 2 min at 95°C. Subsequently the cheese was mixed at 160 rpm for a minute. Functional properties of PCP were analyzed using a penetration test, RVA remelt test and Schreiber melt test. The PCP manufactured from the higher level of TGase had significantly ($P \leq 0.05$) higher RVA apparent viscosity after manufacture, RVA melt viscosity, penetration hardness and had significantly ($P \leq 0.05$) lower Schreiber melt area. The PCP made from MCC and MPC showed no difference in RVA viscosity; however the Schreiber melt area was significantly ($P \leq 0.05$) higher in PCP made from MCC. The study demonstrated that TGase treatment modifies the melt characteristics of the PCP made from either MCC or MPC.

Key Words: transglutaminase, MCC or MPC, process cheese product loaf functionality

M54 Influence of fat replacement by inulin on rheological properties and kinetics of milk coagulation and syneresis of milk gels.

O. Arango, H. M. Taterka,* A. J. Trujillo, B. Guamis, and M. Castillo, *Centre Especial de Recerca Planta de Tecnologia dels Aliments (CERPTA), Departament de Ciència Animal i dels Aliments, Facultat de Veterinària, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

The objective of this study was to evaluate the effect of inulin as a fat replacer on the rheological properties, coagulation kinetics and syneresis of milk gels. A randomized factorial design, replicated 3 times, with 3 inulin concentrations (0, 3, and 6%), 2 levels of fat (<0.2 and 1.5%) and 3 coagulation temperatures (27, 32, and 37°C) was used. The coagulation process was monitored using NIR spectrometry, small amplitude oscillatory rheometry and visual coagulation indexes. The syneresis was evaluated by volumetric methods. Inulin addition significantly ($P < 0.05$) increased the rates of aggregation and curd firming reactions in the casein gels. The observed effect, which was more evident on the aggregation reaction, depended on the concentration of inulin and the coagulation temperature. Addition of 6% inulin reduced the clotting time by ~26% and the time at which the gel reached a storage modulus equal to 30 Pa by ~36%. The optical parameter *R'max* defined as the maximum value of *dR/dt*, was used to calculate an approximation of the temperature coefficients (Q_{10}) for milk coagulation. The apparent Q_{10} values obtained in milk having 0.2% fat were 3.1, 2.8 and 2.4 for samples with 0, 3 and 6% inulin, respectively. These results suggest that inulin addition attenuates the effect of temperature on the coagulation rate. Increasing fat concentration induced a consistent increase in all the optical, rheological, and visual parameters studied, although the observed trend was not statistically significant. The addition of inulin at a level of 6% produced a significant ($P < 0.05$) reduction in syneresis and significantly ($P < 0.05$) increased the curd yield by ~30%. It was concluded that the addition of inulin affects the kinetics of milk coagulation and the cutting time and therefore the use of inline sensors such as NIR may be necessary for an optimal process control.

Key Words: inulin, milk gels, NIR sensor

M55 Effects of season and locality on amino acid composition of raw milk in dairy cows.

J. X. Zhang[1,2], J. Q. Wang*[1], Y. X. Yang[1], D. P. Bu[1], P. Sun[1], L. Y. Zhou[1], Q. J. Luo[2], and J. H. Yang[1], [1]*Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*Xinjiang Agricultural University, Urumqi, China.*

Raw milk is a good source of antioxidants, vitamins (including B^{12}), essential amino acids, and natural protein and fat. Favorite balance of amino acids profile in dairy foods would promote absorption in digestive tract. Amino acids composition in milk is influenced by many factors, such as feed composition and lactation stage. The objective of this study was to investigate the effects of season and locality on raw milk amino acid. Milk samples were collected from 6 cities (Beijing, Chuzhou, Harbin, Hohhot, Urumqi, and Xi'an) in spring (February, March, and April) and summer (July, August, and September), respectively. Amino acids were extracted by hydrolyzed with 7.8 mol/L HCl for 24 h, and concentrations of amino acids were determined by Hitachi L-8900 high speed amino acid analyzer. The experimental data were analyzed by SAS 8.0 with GLM procedure and expressed as absolute concentration (mg/mL). The results showed that significant variation ($P < 0.01$) of Cys, Val, Tyr, Phe were determined between spring (1.83, 206.07, 113.33, 140.98) and summer (13.08, 193.83, 101.38, 148.19). Significant difference ($P < 0.01$) of all amino acids existed among these 6 regions. Raw milk from Hohhot had highest Asp (251.37), Glu (691.21), Gly (67.59), Ala (111.38), Ile (177.40), Leu (315.03), Lys (276.34), and Pro (329.54), while Urumqi samples contained highest Ser (133.11) and Tyr (118.07). It was concluded that amino acids in raw milk were influenced by locality significantly, and some of them were also affected by season.

Key Words: season, locality, amino acid

M56 Qualitative analysis of fatty acids variation in milk of different farms in China.

J. H. Yang, J. Q. Wang,* Y. X. Yang, D. P. Bu, P. Sun, L. Y. Zhou, T. J. Yuan, and J. X. Zhang, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

There are several factors affecting fatty acids (FA) in milk. The variation of milk FA could be defined by a reliable qualitative and quantitative analysis. Principal component analysis (PCA) convert a set of related variables into several new uncorrelated variables called principal components (PCs), using an orthogonal transformation. The number of PCs is less than or equal to the number of original variables. And first few PCs explain the majority of data variation. The objective of this study was to investigate the variation in FA composition of milk from different farms in China using PCA. During April and May, samples were collected from primiparous or multiparous cows (30–90 d in milk) screened from 3 different dairy farms, which were situated in Anhui (n

= 29), Heilongjiang (n = 21) and Xinjiang (n = 27) provinces. Samples were stored at less than −20°C and unfrozen at room temperature. Milk fat was extracted through centrifugation. The FA methyl esters (FAME) were prepared by base-catalyzed trans-esterification and measured using gas chromatography (GC). Data analysis was completed by PCA with cross validation in Unscrambler 9.8 (CAMO, Bangalore, India). The first 4 PCs explained variation of total fatty acids 99.1%. PC1 exhibited heavy loading on C14 (−0.29), C16 (−0.50), C18 (0.46) and c9C18:1 (0.64). PC2 and PC3 had opposite loading values on FA except C18 and c9C18:1. PC4 held a high loading on c9c12C18:2 (0.66) particularly. And the 3D scatter scores of the first, third, and fourth PCs could discern the 3 farms′ FA clearly. The scores and loading plots showed: milk from Anhui had higher C18 and c9C18:1, Xinjiang samples contained more c9c12C18:2, and Heilongjiang milk appeared to have more C16. It was concluded that variation of milk FA profile in these farms is attributed to the difference of some specific individual FA.

Key Words: principal component analysis, milk FA, different farms

M57 Qualitative identification of cow, buffalo, and yak milks using near infrared spectroscopy (NIRS). J. H. Yang, J. Q. Wang,* Y. X. Yang, D. P. Bu, P. Sun, L. Y. Zhou, T. J. Yuan, and J. X. Zhang, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Near infrared spectroscopy (NIRS) has been used in agricultural and food products testing extensively. Compared with many other detection methods, it has better for accuracy, in non-destructive to samples and rapid. The spectrum of dairy milk can predict major components such as protein, fat, and lactose with high precision. The objective of this study was to investigate the variations of milk spectrum between 3 dairy species, which included dairy cows (n = 27), buffaloes (n = 21) and yaks (n = 30). The milk samples were stored at below −70°C. After thawing in 37°C water, samples were shaken lightly for uniformity. Milk raw spectrums were obtained with a DA 7200 diode array Near-IR analyzer (Perten instruments AB, Huddinge, Sweden) in the spectral range 950–1650nm with 100 scans. Operation of the spectrophotometer and collection of spectra were performed using Simplicity software 4.0. Data were processed by multivariate regression software (Unscrambler, version 9.8, CAMO, Bangalore, India). After transformation of MSE/RMSE and elimination of outliers, the PCA analyst with cross validation showed: first 3 principal components (PC) explained the variation of calibration and validation set 98.8 and 98.7%, respectively. PC1 represented the variation of milk spectrum on 1382 nm, PC2 and PC3 described spectrum difference on 1454 and 1404 nm wavelength respectively, although first 3 PCs had same interpretation on 1210 nm. 3D scatter scores image showed PC1, PC2 and PC3 could distinguish between the milk spectra of the 3 species. Milk from buffaloes had its characteristic absorption peaks on 1404 nm wavelengths, while yak samples on 1382 nm, and milk spectrum from cows had a subtle trait on 1518 nm, according to the loading and scores images. It was concluded that the NIRS spectrum was able to distinguish milk from cows, buffaloes, and yaks through multivariable analysis.

Key Words: NIRS, qualitative identification, milk species

M58 Transfer of conjugated linoleic acid from milk to ice cream. G. A. Gagliostro*[1], L. E. Antonacci[1], G. Genero[1], M. R. Williner[2], and C. A. Bernal[2], [1]*INTA, Balcarce, Buenos Aires, Argentina,* [2]*UNL, Sante Fé, Argentina.*

The objective was to test the recovery rate (RR) from milk to ice cream (IC) of cis9 t11C18:2 (RA), t11 C18:1 (VA) and other fatty acids (FA). The experimental dairy cows were treated as 2 group (5 animal each): One Oralac (OR) supplemented group (0.798 kg/d), and one control (C) without supplementation. OR is a lipid supplement, which has 90% DM, 68.6% fat, and contains palmitic (11.25%), stearic (4.65%), oleic (31.7%), linoleic (44.7%), linolenic (2.45%), EPA (0.6%) and DHA (1%). After 21 d of OR feeding milk samples were analyzed for FA (GLC) and used for IC making. Differences between milk and IC FA were tested by the Student *t*-test for paired observations. OR cows produced (kg/d) more milk (32.1 vs. 26.5) and 4%FCM (25.4 vs. 22.9). Milk fat (g/kg) decreased (33.3 in C vs. 25.1 in OR, $P < 0.009$) and milk protein (35.2 vs. 31.9) and lactose (48.7 vs. 47) were not affected. Milk from OR cows showed higher contents (g/100 g) of VA (7.39 vs. 2.75) and RA (2.96 vs. 1.23) and lower C12:0 (2.23 vs. 3.35), C14:0 (8.39 vs. 9.82), and C16:0 (19.45 vs. 23.45). The atherogenicity index (IA) of milk was reduced from 1.92 (C) to 1.37 (OR). IC making showed no differences in FA composition. The RR of FA ranged from 115% for RA (1.23 in milk vs. 1.42g/100g in IC) to 82% for C18:2n-6 (2.84 in milk vs. 2.33g/100g in IC). When the high RA milk was transformed in IC, the RR of VA and RA was 97%. Composition (g/100 g) of C14:0 (8.39 vs. 7.59) and C18:2n-6 (2.25 vs. 1.95) were lower in IC and C16:0 increased (19.45 vs. 23.44). The IC elaborated with the high RA milk (IC-OR) showed a lower ($P < 0.05$) composition (g/100g) of C12:0 (1.95 vs. 3.38) and C14:0 (7.59 vs. 10.00) with a reduction in the AI (1.48 vs. 2.07) compared with the IC-Control. Values (g/100 g) for VA (7.19 vs. 2.96) and RA (2.71 vs. 1.42) resulted higher in IC- OR. Content (g/100 g) of t9 C18:1 was higher ($P < 0.0002$) in IC-OR (0.58) than in IC-Control (0.17) whereas t10 C18:1 did not differ (1.42 vs. 0.86). Saturated FA were lower ($P < 0.02$) in IC-OR (50.5 g/100 g) than IC-Control (57.4 g/100 g). Unsaturated FA (g/100 g) were higher ($P < 0.04$) in OR-IC (37.5) than IC-Control (32.9). Content of C18:2 and C18:3 were not different. It was concluded that no losses in VA or CLA concentrations were detected when milk was transformed into ice cream.

Key Words: conjugated linoleic acid, milk, ice cream

M59 Assessment of adulteration by urea addition to milk by Fourier transform infrared methodology (FTIR). M. C. P. P. Oliveira,* R. S. Conrrado, L. M. Fonseca, M. M. O. P. Cerqueira, and M. O. Leite, *Department of Food Technology and Inspection, School of Veterinary Medicine, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil.*

Urea or milk urea nitrogen (MUN) is a non-protein component of milk. Non-protein nitrogen is composed of 30 to 50% of urea nitrogen, while the remaining is composed of creatinine, uric acid, amino acids, and ammonia, among others. MUN has been used as a tool to assess the herd nutritional status, and the excretion of nitrogen to the environment. Adulteration of milk by urea has been occurring in some developing countries. This fraudulent practice seeks to increase analytical values for solid-not-fat (SNF) or protein content of milk. The objective of this study was to evaluate the CombiScope FTIR, an equipment based on Fourier transform infrared methodology (FTIR) in comparison with ChemSpec 150 Analyzer, a enzymatic method, to quantify adulteration by urea addition to milk, and to investigate its effect on protein levels. Extraneous urea was added to the raw milk, simulating a fraudulent practice, and simultaneously analyzed by CombiScope FTIR, and ChemSpec 150 Analyzer. A total of 60 raw milk samples were split into 3 subsamples each, respectively, without any urea addition, 20 mg, and 40 mg of urea addition for 100 g of milk. FTIR results for MUN in milk samples added with extraneous urea were lower than expected only at levels of 40 mg/100 g ($P < 0.05$). There was no significant difference in the levels of protein readings by FTIR equipment after urea addition to the milk. It was concluded that FTIR equipment failed to detect extraneous urea added to the milk at levels of 40 mg/100 g, and protein levels measured by FTIR were not affected by added urea, as happens with the standard nitrogen analytical methods.

Key Words: milk, FTIR, urea addition to milk

M60 Freezing point of raw milk by Fourier transform infrared methodology (FTIR).

R. S. Conrrado, M. C. P. P. Oliveira,* L. M. Fonseca, L. R. Borges, M. M. O. P. Cerqueira, M. O. Leite, R. Rodrigues, M. R. Souza, and C. F. A. M. Penna, *Department of Food Technology and Inspection, School of Veterinary Medicine, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil.*

Milk adulteration with water addition is a worldwide problem, with prominence in developing countries. Several methods have been developed for its detection. Determination of freezing point of raw milk has been known as one of the best methods in detection of milk adulteration. Classical methods for freezing point determination have high precision and accuracy, but low output. The objective of this study was to evaluate the freezing point of milk analyzed by FTIR equipment, in comparison with a standard method (freezing point determination by thermistor cryoscope). About 220 samples of bulk tank milk were randomly chosen from 220 farms located in Minas Gerais State, Brazil, and simultaneously analyzed by a thermistor cryoscope (Laktron, LK 7000; PZL, Londrina-PR, Brazil) and a FTIR equipment (CombiScope FTIR; Advanced/Delta Instruments, Drachten, Netherlands). The chosen farms are representative of each region of the state, which is responsible for 30% (7 million metric tons) of Brazilian milk production. Each sample was added with bronopol as preservative, and final freezing point results were obtained by subtracting the effect of its soluble components. Average results for milk freezing point was −0.518°C with a standard deviation of 0.0013°C. Values of freezing point for samples obtained from herds predominantly crossbred were significantly lower when compared with pure Holstein herds. Average values for thermistor cryoscope, and FTIR were, respectively −0.520°C, and −0.518°C, with no significant difference between the 2 methods ($P > 0.05$), and Pearson correlation coefficient of 0.87. It is concluded that FTIR equipment presented a good reliability and repeatability over the range of freezing point for normal milk and for abnormal milk; that is, above −0.520°C, being an efficient screening method to detect milk adulteration by water addition to milk samples in dairy herd improvement programs and dairy industry payment systems.

Key Words: freezing point, thermistor cryoscope, FTIR cryoscope

M61 Identification of a high γ-aminobutyric acid-producing *Lactobacillus plantarum* from traditional dairy products in Inner Mongolia of China.

Y. Guo[2], Y. Shan[1], C. Man[1], S. Yang[2], Y. Xue[2], Y. Liu[2], X. Dong[2], J. Wang[2], M. Guo*[3], and Y. Jiang[1,2], [1]*National Dairy Engineering and Technology Research Center, Northeast Agricultural University, Harbin, Heilongjiang, China,* [2]*Department of Food Science, Northeast Agricultural University, Harbin, Heilongjiang, China,* [3]*Department of Nutrition and Food Sciences, The University of Vermont, Burlington.*

γ-Aminobutyric acid (GABA) as a non-protein amino acid, is the major inhibitory neurotransmitter in the sympathetic nervous system and plays a crucial role in cardiovascular function. It is well known that GABA is widely distributed in nature and could be produced by animal brains, plant germs and microorganisms. The objective of this study is to isolate and identify high GABA-producing lactic acid bacteria from traditional dairy products in Inner Mongolia of China. Eighteen strains exhibited different GABA-producing ability in MRS broth by high performance liquid chromatography analysis. Among them the strain NDC 75017 produced the highest amount of GABA, and its yield reached to 138 mg/L. By phenotypic, physiological and biochemical methods, NDC 75017 was characterized as gram-positive, catalase-negative, facultatively anaerobic, non-spore-forming and non-motile rod, which could produce lactate from lactose and did not ferment L-arabinose and D-turanose. In addition PCR amplifications of 16S rDNA and 16S-23S rDNA intergenic spacer region (IGS) were carried out with primers P1 (AGAGTTTGATCCTGGCTCAG), P6 (GGTTACCTTGTTACGACTT) and P2 (CTTGTACACACCGCCCGTC), P7 (GGTACTTAGATGTTTCAGTTC), respectively. Based on 16S rDNA gene sequence, we found that the strain NDC 75017 shared 99.8% similarity with *Lactobacillus plantarum* WCFS1 and *L. plantarum* ST-III. Furthermore, the similarity of 16S-23S rDNA IGS gene sequence between NDC 75017 and above reference strains was 99.5%. Therefore the strain NDC 75017 was identified as *L. plantarum*. Contributed to its high GABA-producing ability, this strain can be used as a potential starter culture to produce GABA-enriched fermented dairy products in future. This work was supported by National Science and Technology Project (2011AA100902), National Natural Science Foundation of China (31171718), Program for Changjiang Scholars and Innovative Research Team in University (IRT-0959–203), and Key Project of Education Department of Heilongjiang Province (12511z005).

M62 Whey protein isolate affects cysteine content and gel quality of yogurt.

S. Bala and K. Schmidt,* *Kansas State University, Manhattan.*

Whey protein isolate (WPI) is an excellent protein source which is used in a variety of processed foods. Some people with diminished γ-cystathinase are prone to develop cataracts due to decreased glutathione in their eye tissues. For this group, dietary cysteine may be beneficial for their health. Yogurt contains a significant quantity of whey proteins, hence if supplemented with WPI, cysteine could be enhanced. The objective of this research was to increase cysteine content in yogurt while maintaining gel quality. All yogurt mixes were formulated to have a total solids of 12.5% - the control mix consisted of nonfat dry milk (NDM) and the experimental formulas contained mixtures of NDM and WPI (2.0, 2.5 and 3.5%). Mixes were heat treated at 90°C for 7 min, cooled to 43°C, inoculated and fermented at 43°C until 4.5- 4.6 pH. Yogurt samples were maintained at 4°C for 24 h and evaluated for total solids, pH, cysteine content and gel quality following published methods. Three replications were performed, and ANOVA and Dunnett's test were done to determine significant differences. All yogurts had similar total solids contents, but the experimental yogurts had significantly greater cysteine contents, which ranged from 2 to 3.8 × when compared with the control (~141 mg/1000mL). The pH of the experimental yogurt with WPI (2.0%) was similar to the control (~4.52) but the other experimental yogurts had a lower pH compared with the control. The experimental yogurts had significantly greater firmness (ranged from ~2.3 to 8.2 ×) and water-holding capacity (ranged from ~2 to 3 ×) compared with the control (~51 g and 21% wt/wt, respectively). The yogurt with WPI (2.0%) had a 2-fold increase in cysteine content but the gel firmness was ~116 g. Supplementing yogurt mixes with WPI increased the cysteine content in the yogurt without adversely affecting the yogurt quality, except for gel firmness; however, other strategies may need to be used to address the gel firmness.

Key Words: yogurt, whey protein isolate, cysteine

Forages and Pastures I

M63 Body growth and first-lactation milk production of pregnant Holstein heifers reared on pasture or conventional diets. R. R. Peters*[1], S. W. Fultz[2], J. W. Semler[3], and R. A. Erdman[1], [1]*University of Maryland, College Park,* [2]*University of Maryland Extension, Frederick,* [3]*University of Maryland Extension, Boonesboro.*

The objective was to compare body growth rates and first lactation milk production of pregnant heifers reared on intensively grazed pasture (P) to those fed conventional (C) diets in a 2-yr replicated study. Pregnant Holstein heifers based on date of pregnancy confirmation were assigned to P (yr 1, n = 15; yr 2, n = 16) or C (yr 1, n = 15; yr 2, n = 16) for study in spring to summer seasons of 2010 and 2011. Heifers fed conventional TMR included corn and rye silage, grass hay, and a monensin-supplemented grain mix. Pastured heifers were fed 0.454 kg /heifer per d of ground shelled corn with minerals and monensin. Pasture consisted primarily of endophyte-infected tall fescue. Pasture-fed heifers were rotated daily to a new paddock of 0.1 to 0.3 ha, based on available DM. Measurements included body weight (BW), wither height (WH), and hip height (HH) taken every 2 wk. Growth rates and projected first lactation 305 d actual milk, fat, protein, calving age, and somatic cell count from DHI records were analyzed using ANOVA using treatment group within year as a replicate. No differences were found in least square treatment means of any variable averaged by year when comparing pasture and conventionally raised heifers. It is concluded that pregnant heifers can be reared on pasture without detrimental effects on skeletal development, milk production, or somatic cell count.

Table 1.

Growth and lactation measure	Pasture	Conventional	SEM	*P*-value

M64 Antioxidant activity and blood parameters in early weaned calves fed yeasts and fermented apple pomace. C. Rodríguez-Muela,* P. Mancillas-Flores, C. Arzola, D. Díaz-Plascencia, O. Viramontes, G. Corral, A. Grado-Ahuir, and A. Ramírez-Godínez, *Universidad Autonoma de Chihuahua, Chihuahua, México.*

The objective was to evaluate the effect of a yeasts inoculate and fermented apple pomace in the diet on the antioxidant activity and blood biometric. Twenty-seven calves (BW = 126.2 kg) were randomly assigned to 3 diets. CD: 1.2 kg oat hay, 1.7 kg corn silage, and 1.2 kg DMI.d^{-1} protein and energy supplement; FD: CD + 12% of fermented apple pomace in the supplement and YD: CD + 2% of yeasts in the supplement. Animals were fed for 98 d including a 14-d adaptation period and were bled every 28 d. The variables evaluated were antioxidant activity (AA), white cells count (WBC), hemoglobin (HM), corpuscular volume (CV), corpuscular hemoglobin (CH) and plaques (PQ). The data were analyzed with PROC MIXED of the SAS program in a completely randomized design. The results are shown in Table 1. AA in the calves of the 3 diets was reduced during the study, however, AA at 84 d as well as WBC were higher ($P < 0.05$) in the calves of FD and YD than those of CD. We concluded that the addition of the fermented apple pomace and yeasts in the diet of early weaned calves increased the antioxidant activity and tended to improve the immune system.

Table 1. Means of the square minimums and standard error of antioxidant activity (AA) and blood parameters (d 56 of test) in early weaned calves

	CD	FD	YD	SE

M65 Use of yeasts and fermented apple pomace in the diet of early weaned calves. P. Mancillas-Flores,* C. Rodríguez-Muela, C. Arzola, D. Díaz-Plascencia, A. Grado-Ahuir, O. Viramontes, A. Flores, and A. Ramírez-Godínez, *Universidad Autonoma de Chihuahua, Chihuahua, México.*

The objective was to evaluate the effect of yeasts inoculate and fermented apple pomace on blood mineral levels of early weaned calves diets. Twenty 7 Angus calves (PV = 126.2 kg) were assigned to CD:oat hay 1.2; corn silage 1.7 and protein and energy supplement 1.2 kg DMI/d^{-1}), FD: CD+12% of fermented apple pomace in the supplement and YD: CD+2% of yeasts inoculate in the supplement. The animals were fed during 98d. The variables evaluated were DMI, ADG and Zinc (Zn), Manganese (Mn) and Copper (Cu) in the blood serum. Data were analyzed with PROC GLM of the SAS program, in a completely randomized design for DMI and AVG and PROC MIXED for minerals concentration. The results are shown in Table 1. DMI of YD calves was greater ($P < 0.05$) than those of CD and FD. There was a reduction ($P < 0.05$) of level of Zn at 84 d in calves of FD. Calves of YD showed a greater concentration of Zn at 84 d of study ($P < 0.05$) than those of CD and FD. We concluded that the yeasts inoculate in early weaned calves diets increased significantly DMI and Cu serum concentration however fermented apple pomace decreased Zn serum concentration.

M66 Performance and carcass traits of steers grazing annual ryegrass supplemented with increasing levels of flaxseed.

N. Fanego[1,2], L. B. Pouzo[2,4], F. J. Santini[1], J. Killefer[5], and E. Pavan*[1], *[1]Unidad Integrada Balcarce (INTA, EEA Balcarce-UNMdP, FCA), Balcarce, Bs. As., Argentina, [2]Comisión Investigaciones Científicas, Buenos Aires, Argentina, [3]Universidad Nacional de La Plata, La Plata, Buenos Aires, Argentina, [4]Consejo Nacional de Investigaciones Científicas y Tecnologícas, Argentina, [5]Oregon State University, Corvallis.*

This study evaluated the effects of increasing flaxseed addition to corn grain supplemented to steers grazing annual ryegrass on performance and carcass traits and whether dietary treatment effects were affected by animal live weight (LW). Forty-eight Angus steers were randomly assigned to 8 treatment combinations: 2 animal weights (LIGHT and HEAVY) and 4 dietary treatments (CNTRL = no supplement; CORN = 0.7% LW of cracked corn; LFLAX and HFLAX = CORN + 0.125% and 0.250% LW of whole flaxseed, respectively). Steers assigned to LIGHT received their dietary treatment when the average LW reached 366 ± 27.3 kg (mid winter) and those assigned to HEAVY, when they reached 458 ± 42.8 kg (mid spring). Steers were managed under a daily rotational system with no forage limitation and individually supplemented with 0.5 kg/d of wheat bran in addition to their dietary treatment. Steers were slaughtered after 70 d on trial. Data were analyzed as a complete randomized design with a 2 × 4 factorial arrangement; preplanned contrasts were used to compare CNTRL vs. supplemented treatments, and linear and quadratic flaxseed effects. No main factor interactions were found ($P > 0.10$). Average daily gain (ADG) was greater ($P < 0.01$; SEM = 0.028) in LIGHT than in HEAVY (1.43 and 0.75 kg). Final LW and HCW were greater ($P < 0.05$) in HEAVY than in LIGHT, but subcutaneous fat thickness (FT), carcass yield and ribeye area did not differ ($P > 0.05$). Supplemented steers tended ($P = 0.06$) to have greater ADG (87 ± 45 g) than CNTRL steers, but no effect was observed ($P > 0.05$) by increasing flaxseed level. Supplementation increased ($P = 0.04$) FT by 1.4 ± 0.68 mm, and each increment of flaxseed increased ($P = 0.03$) FT by 0.9 ± 0.42 mm. No dietary treatment effects ($P > 0.05$) were observed for final LW, HCW, carcass yield, or ribeye area. In conclusion: (a) the different animal weights considered in the present study did not influence supplementation response; (b) with no limiting forage availability, the main effect of energy supplementation was to increase FT; and (c) flaxseed could be supplemented up to 0.25% of LW without negative effects on animal performance or carcass traits.

Key Words: pasture, oil, corn

M67 Evaluating grazing performance and forage quality differences between AC-Saltlander green wheatgrass (*Elymus hoffmannii*) and smooth bromegrass (*Bromus inermis*).

A. D. Iwaasa,* H. Steppuhn, and E. Birkedal, *Semiarid Prairie Agricultural Research Centre, Agriculture and Agri-Food Canada, Swift Current, Saskatchewan, Canada.*

AC-Saltlander (ACS) green wheatgrass (*Elymus hoffmannii*) is a Canadian perennial forage cultivar that has salinity tolerance equaling that of tall wheatgrass. Study objective was to evaluate beef and forage production and forage quality differences between ACS and smooth bromegrass (SB; *Bromus inermis*). Seeding of the 6 paddocks (ea 1.2 ha in size) occurred in 2006 and each pasture treatment was replicated 3 times. Paddocks were grazed by Angus yearling steers (308 ± 10 kg) when the grasses were at the bloom to heading stage at a stocking rate of 2.0 AU ha^{-1}. Forage and gazing data were collected over 4 production years (2008 to 2011). No interactions ($P \geq 0.10$) were observed, thus only significant main effects were presented. Available biomass production at time of grazing and peak biomass production did not differ ($P \geq 0.10$) between pasture treatments. However, peak forage biomass production for ACS was numerically higher than SB in 2008, 2009 and 2010. Percent organic matter digestibility (OMD), NDF, ADF, CP, Ca and P differed ($P \leq 0.01$) among years which was expected due to changing environmental growing conditions. Percent forage OMD values (mean ± SE) were higher ($P \leq 0.01$) for SB versus ACS and were 60.8 versus 57.6 ± 0.48, respectively. Average daily gains, total livestock production and number of grazing days did not differ ($P \geq 0.10$) between ACS versus SB, and the values were 1.32 and 1.14 ± 0.12 kg d^{-1}, 87.9 and 87.8 ± 1.9 kg ha^{-1}, and 53.2 and 46.8 ± 5.8 d ha^{-1}, respectively. Beef cattle grazing performance and forage qualities were generally similar between ACS and SB. Throughout the entire study differences in overall system performance of the 2 grasses were not observed.

Key Words: AC-Saltlander green wheatgrass, smooth bromegrass, grazing

M68 Continuous versus rotational stocking of rye and ryegrass pastures at different stocking rates and forage allowance.

F. Rouquette Jr.,* J. Kerby, G. Nimr, and K. Norman, *Texas AgriLife Research and Extension Center, Overton.*

Stocking strategies are implemented for cool-season annual grass pastures to enhance efficiency of gains per animal and per unit land area. A 7-year stocking study with 482 steers and heifers quantified ADG and gain/ha using stocking methods (MTH) of continuous (CONT) vs. an 8-paddock rotational (ROTN) system on Maton rye (*Secale cereale* L.) plus TAM-90 annual ryegrass (*Lolium multiflorum* Lam.) pastures at different fixed stocking rates (STK). Two replicate pastures of MTH × STK each with 6 to 8 270-kg fall-weaned calves were stocked from late Dec to mid-May each year at the Texas AgriLife Research Center at Overton. The 8-paddock ROTN system consisted of a 2 d graze and 14-d deferment cycle with forage mass measurements pre- and post-graze. The ADG ranged from 1.38 kg/d on low STK to 0.23 kg/d on high STK, and was affected ($P < 0.01$) by year, STK, year × STK, year × MTH, and at $P = 0.07$ for STK × MTH. Only at one STK in each of 3 years and when forage allowance (FORG) was <0.80 kg forage DM per kg body weight was ADG affected ($P < 0.01$) by MTH. At low STK with FORG >1.0, MTH had no affect on ADG. Gain per ha was affected ($P < 0.01$) by year, STK, and year x STK, and ranged from 1206 kg/ha for medium STK to 389 kg/ha for high STK. Gain per ha was maximum at the medium to medium-high STK. With the nutritive value of rye plus ryegrass, there were no biological nor economic advantages to using an 8-paddock ROTN system compared with CONT

stocking. Although forage DM tended to be increased on ROTN pastures due to the 14-d deferment, gains were not enhanced. Stocking rate and resultant decreased forage DM and FORG affected ADG and gain/ha each year, thus, STK should be the primary consideration for stocking strategies and management.

Key Words: stocking rate, rotational stocking, ryegrass

M69 Improving calf performance by extending the grazing season with warm season grasses and brassica forages.

S. J. Filley* and J. Hunter, *Oregon State University, Corvallis.*

The objectives of this experiment were to determine whether grazing cow-calf pairs on warm season grasses and brassica pastures would extend the grazing season by providing high quality forage into the late summer and improve calf weaning weight. Treatments were pasture type; extended season pasture (EXT), a new planting mixture of sorghum × Sudangrass (*Sorghum bicolor* (L.) Moench) and brassica forages (*Brassica* and *Raphanus* species), and control pasture (CON), an existing field of cool season forage (*Festuca* and *Lolium* species plus *Trifolium repens* and *subterraneum*). Thirty cow-calf pairs (cows with 6 mo old steer calves) were stratified by calf weight and assigned to treatments randomly. Each pasture type was divided into 3, 2-ha paddocks (replicates of experimental unit) and grazed with 5 cow-calf pairs until late summer weaning. Data were analyzed by ANOVA as a randomized design. Cool spring weather at planting (May 14, 2010) slowed EXT establishment and growth so that grazing was delayed until mid-August, allowing for only a 14-d grazing period. Prussic acid and nitrate screening tests were conducted, and forages were determined to be safe to graze. Forage yield of EXT tended ($P = 0.06$) to be lower than that of CON (4,972 and 7,642 kg/ha, respectively; SEM ± 746.8). In contrast, CP (10.3% and 6.7%; SEM ± 0.839) and TDN (69% and 56%; SEM ± 2.86) of pasture plants sampled randomly were higher ($P < 0.04$) for EXT compared with CON, respectively. Calf weaning weights (205-d adjusted) were not different ($P = 0.21$) between EXT and CON (288.1 and 305.0 kg, respectively; SEM ± 9.36). In year 2, planting strategy for EXT was adjusted to delay seeding until soil temperature reached 16°C (June 15, 2011). However, growing conditions were again less than optimal, pasture was not sufficient for grazing, and no additional data were obtained. Early establishment of warm season forages in western Oregon can be severely affected by weather, making it difficult to graze cows with February–March born calves for the purpose of improving late summer weaning weights. Strategies that include grazing cow-calf pairs that are to be weaned in the fall may be more advantageous.

Key Words: brassica, sorghum, weaning weight

M70 Beef steer performance when grazing native warm season grasses.

H. T. Boland[1,2], B. J. Rude*[2], J. A. Martin[3], S. K. Riffell[3], and L. W. Burger Jr.[3], [1]*Prairie Research Unit, Mississippi Agricultural and Forestry Experiment Station, Prairie,* [2]*Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State,* [3]*Department of Wildlife, Fisheries and Aquaculture, Mississippi State University, Mississippi State.*

Use of native warm-season grasses (NWSG) in forage systems may maintain, or improve, animal performance while providing vital ecosystem services. The drought tolerance, low fertilizer needs, high production, and nutritive value of NWSG suggest they could provide a valuable forage base for cattle producers in the south. Also, NWSG provide superior wildlife habitat compared with non-native forages such as Bermudagrass (*Cynodon dactylon*). The objective of this study is to evaluate the productivity of forage systems for beef cattle production that integrate NWSG. Three forage treatments were evaluated: Indiangrass (*Sorghastrum nutans*) monocultures (IND); mixed specie pastures of Big Bluestem (*Andropogon gerardii*), Little Bluestem (*Schizachyrium scoparium*), and Indiangrass (MIX); and Common Bermudagrass (BG) which is a typical summer forage of the region. Site preparation began in spring 2008 and forages were planted in spring 2009. Grazing began in May 2011, with 225 British-crossbred beef steers (IBW 237 kg ± 1.5). Nine pastures were used (3 per treatment) ranging in size from 7 to 11 ha. Pastures were stocked at 2.7 steers/ha and continuously grazed. Cattle were weighed every 28 d and remained on pasture for 110 d. Selected cattle wore activity monitors (IceTag, v 2.004) to measure grazing behavior. Data were analyzed using PROC MIXED of SAS (SAS Inst., Cary, NC) and a significance level of $\alpha \leq 0.05$ was used, with trends defined at $0.10 \geq \alpha > 0.05$. Average daily gain (ADG) of steers did not differ between treatments during periods, d 1–28, 56–84, or 84–110. However, during the peak of the season (d 28–56), ADG was greater ($P < 0.02$) in IND (1.1 kg) and MIX (0.9 kg) than BG (0.64 kg). Overall season ADG tended ($P \leq 0.10$) to be greater for IND (0.6 kg) and MIX (0.6 kg) than BG (0.4 kg). Percent of the day that animals spent grazing (IND 45%, MIX 45%, BG 46%), lying down (IND 41%, MIX 40%, BG 38%), or standing still (IND 13%, MIX 13%, BG 14%) did not differ within period or overall during the season. Time spent walking did differ between treatments with IND steers walking less (1.6%, $P < 0.05$) than BG (2.3%) or MIX (2.2%) steers. These NWSG show promise for use in beef grazing systems in Mississippi.

Key Words: native warm season grass, forage systems, grazing behavior

M71 Animal performance on pastures managed at two forage heights to produce grass finished beef.

M. J. Baker*[1], M. L. Thonney[1], L. O. Tedeschi[2], G. Jacimovski[1], and L. M. Furman[1], [1]*Cornell University, Ithaca, NY,* [2]*Texas A&M University, College Station.*

The animal benefits of management intensive grazing (MIG) are well documented but little is known about managing pastures using the tall grass grazing (TGG) principle. The purpose of this experiment was to evaluate animal performance on pastures managed using either MIG or TGG. Sixteen Angus steers (n = 10, BW = 371 ± 15 kg) and heifers (n = 6, BW = 317 ± 15 kg) were assembled from 2 farms (8 per farm). The cattle were blocked by sex and randomly assigned to MIG or TGG (treatments) based on projected adjusted final BW (AFBW) computed from frame score. Land area required was computed based on average BW, 2 d rotation, 60 d rest period, an estimated forage yield of 183 kg/ha/rotation, and a DMI of 2.5% of BW. Before animals were rotated, forage height was measured on both paddocks. Forage was sampled to approximate the plants cattle grazed. Statistical analyses were conducted assuming farm as a random factor; treatment and sex were assumed to be fixed effects. The initial BW was used as covariate. No interactions were significant ($P > 0.10$) and were removed. Cattle were placed on MIG and TG when forage was 4.24 ± 0.08 cm and 7.43 ± 1.95 cm, respectively. There were no treatment effects ($P > 0.05$) for AFBW, initial BW, final BW, 64 d ADG or 64 to 135 d ADG. The ADG was greater ($P = 0.0067$) for MIG compared with TGG from 64 to 135 d (0.90 ± 0.09 vs. 0.54 ± 0.07 kg, respectively). Cumulative ADG (165 d) was greater ($P = 0.0197$) for MIG compared with TGG (0.95 ± 0.08 vs. 0.79 ± 0.07 kg, respectively). Body condition score was higher ($P = 0.0089$) for MIG compared with TG (7.7 ± 0.13 vs. 7.0 ± 0.21, respectively). There were no treatment effects ($P > 0.05$) for forage NDF, CP, ME or forage composition. However MIG tended ($P = 0.0632$) to produce higher proportion of grass (86.0 ± 2.2%) compared with TGG (71.0 ± 7.4%) and a lower ($P = 0.0743$) proportion of weed (8.5 ± 1.7% vs 22.5 ± 7.2%, respectively). It is likely that the MIG cattle consumed more DM compared with TGG, but the residual forage height between MIG and TGG (0.24 ± 0.11 vs. 0.49 ± 0.12 cm, respectively) was not significant ($P = 0.1778$). While TGG forage was of similar quality to MIG animal performance was reduced, perhaps due to reduced DMI.

Key Words: beef, pasture, finishing

M72 Nutritive value of plants and milk production from crossbreed cows grazing Tanzania guinea grass subjected to rotational stocking managements.

M. L. P. Lima*[1], F. F. Simili[1], A. Giacomini[2], C. C. P. Paz[1], L. C. Roma Jr.[1], and E. G. Ribeiro[2], [1]*SAA Agencia Paulista de Tecnologia dos Agronegocios APTA, Ribeirao Preto, Sao Paulo, Brazil,* [2]*Instituto de Zootecnia, Nova Odessa, Sao Paulo, Brazil.*

Managements for grazing strategies can promote change in the sward structure and can affect nutritive value and animal production in grazing system. The objectives were to evaluate the crude protein (CP) and neutral detergent fiber (NDF) and milk yield from crossbred cows grazing Tanzania guinea grass (*Panicum maximum* Jacq. cv. Tanzania) and the stocking rate, subjected to rotational stocking managements. The 2 treatments were grazing when swards height was 70 cm or growing fixed period of 30 d, according to a randomized complete block design. The 16 paddocks with 4,000 m^2 were evaluated during spring, summer and fall (5 grazing cycles). The pre-grazing samples of plants and leaves were analyzed for CP and NDF. Eight cows, per treatments, were used for milk production evaluations, in a randomized complete block design. The concentrate supplementation was 4 kg/cow/day. The data were analyzed using the Proc Mixed Procedure of SAS. Interactions between treatments and grazing cycles for CP in forage mass and leaves ($P < 0.001$) were observed. The average for CP was 12.6% for grazing when swards height was 70 cm. The grazing cycles affected ($P = 0.014$) the CP for the fixed period of 30 d treatment. The average of CP was 8.6% for the 1st cycle and end 9.6% for the last cycle (fall). During the summer, the CP was 13.16% for leaves. NDF of leaves was higher ($P = 0.006$) for growing fixed period of 30 d (75.3%) compared with swards height was 70 cm (72.3%). No effect on milk yield and milk composition was found. The average were 19.83 and 18.56 kg/cow/day for 3.5% fat corrected milk, 3.19 and 3.14% of fat; 3.02 and 2.99% of protein; 4.46 and 4.37% of lactose for grazing when swards height was 70 cm or for fixed period of 30 d, respectively. The stocking rate was higher ($P = 0.0456$) for the fixed period of 30 d treatment (6.18/ha) compared with grazing when swards height was 70 cm (5.76/ha). The management based on growing fixed period of 30 d can affect the nutritive value of pasture and the stocking rate but do not affect the milk production from cows supplemented with concentrate.

Key Words: milk components, *Panicum maximum*, sward height

M73 Sward structural characteristics, herbage accumulation of Tanzania guinea grass subjected to rotational stocking managements.

M. L. P. Lima*[1], F. F. Simili[1], A. Giacomini[2], C. C. P. Paz[1], L. C. Roma Jr[1], and E. G. Ribeiro[2], [1]*SAA Agencia Paulista de Tecnologia dos Agronegocios APTA, Ribeirao Preto, Sao Paulo Brazil,* [2]*Instituto de Zootecnia, Nova Odessa, Sao Paulo, Brazil.*

Managements for grazing strategies promote change in sward structure and can affect herbage accumulation. The objectives of this study were to evaluate the plants structural characteristics, the production and the herbage accumulation in pasture of Tanzania guinea grass (*Panicum maximum* Jacq. cv. Tanzania) subjected to rotational stocking managements. The 2 treatments were grazing when swards height was 70 cm or growing fixed period of 30 d for each grazing cycle, according to a randomized complete block design. The 16 paddocks with 4,000 m2 were evaluated during spring, summer and fall, for 5 grazing cycles. The height of plants was compared. The forage mass was evaluated before and after grazing time and the herbage accumulation. The morphological composition of plant (leaves, stem and dead material), the interception of the incident light (LI) and the leaf area index (LAI) were evaluated in pre-grazing samples. The data were analyzed using the Proc Mixed Procedure of SAS. No influence of treatments was found for post-grazing mass and herbage accumulation. The height of plants was 20% higher ($P = 0.0014$) and the forage mass was higher ($P = 0.0034$) for the fixed growing period of 30 d treatments. In pre-grazing samples, the leaves ($P = 0.00429$), stem ($P = 0.0131$), dead material ($P = 0.0106$), LI ($P = 0.0071$) and LAI ($P = 0.023$) were higher for the fixed growing period of 30 d treatment. The results for forage mass were 2508 and 3317 kg/ha; the leaves mass were 1527 and 1790 kg/ha; the stem mass were 699 and 984 kg/ha; the dead material were 282 and 472 kg/ha; the IL were 97 and 91% and the LAI were 4.5 and 5.2, for grazing when swards height was 70 cm and the growing fixed period of 30 d, respectively. The fixed period of 30 d for each grazing cycle improved the forage production and change characteristics in sward.

Key Words: grazing management, *Panicum maximum*, sward height

M74 Simulation of the effect of stocking rate on forage harvest efficiency under New Zealand intensive grazing systems.

P. Gregorini*[1], A. J. Romera[1], J. R. Galli[2], P. C. Beukes[1], and H. H. Fernandez[3], [1]*DairyNZ, Hamilton, New Zealand,* [2]*Facultad de Ciencias Agrarias, Universidad Nacional de Rosario, Rosario, Santa Fe, Argentina,* [3]*Instituto Nacional de Tecnología Agropecuaria, Balcarce, Buenos Aires, Argentina.*

Long-term experiments comparing the effect of stocking rates (SR) on forage harvest efficiencies (FHE) in dairy grazing systems are costly and time consuming; however, this can be facilitated by the use of simulation models. The objective of this work was to explore the effect of SR on FHE using DairyNZ Whole Farm Model (WFM). The WFM is a farm-scale computer model that includes a mechanistic model of a dairy cow and a climate driven pasture growth model, which interact with a grazing behavior model to mechanistically and dynamically determine FHE (proportion of forage consumed [FC] by cows related to the net forage produced [NFP] by pasture). An average, pasture-based New Zealand farm (forage base: 80% *Lolium perenne* and 20% *Trifolium repens*; cow: Holstein-Friesian crossbreed, 450 kg liveweight and 270 d in milk) was simulated using 7 SR (treatments) and over 3 series of 3 different (e.g., rain, temperature, solar radiation and potential evapotranspiration) climate years (replicates). Resulting variables of the simulation, NFP (ton DM/ha/year) and FC (tonnes DM/ha/year) were analyzed by regression analysis. Then FHE was estimated as FC/NFP. Results of the simulations (Table 1) demonstrated a significantly ($P < 0.001$) positive relationship between SR and the output variables (NFP, FC and FHE), which are concomitant with experimental results (Macdonald et al., 2008 J. Dairy Sci.). Simulation modeling allows examination of costly experimental frameworks and outcomes under pastoral production systems, providing useful information for researchers and farmers in a relatively short period of time and at low cost. This study indicates that under the simulated conditions, increments in SR will lead to greater NFP and FC, and consequently a greater FHE.

Table 1. Effect of stocking rate (SR) on net forage production (NFP), forage consumed (FC), and forage harvest efficiency (FHE)

	NFP (t of DM/ha/yr)		FC (t/ha/yr)		FHE	
SR (cows/ha/yr)	Mean	SD	Mean	SD	Mean	SD

Key Words: modelling, forage produced and consumed, grazing management

M75 Nitrogen fertilizer management to improve forage production in south-central Vietnam. K. C. McRoberts[1], D. Parsons[2], J. H. Cherney[1], Q. M. Ketterings[1], and D. J. R. Cherney*[1], [1]*Cornell University, Ithaca, NY,* [2]*University of Tasmania, Hobart, Tasmania, Australia.*

The objective of this field trial was to assess the effect of nitrogen (N) fertilization from composted cattle manure and urea on forage yield in tropical sandy soils (organic matter < 1%). *Brachiaria* 'Mulato II' was established in summer 2010 on 6 farms in Binh Dinh Province of south-central Vietnam. Experimental design was a randomized complete block with 5 levels of manure N (0, 40, 80, 120, 240 kg N/ha/yr) and 3 levels of urea N (0, 60, and 120 kg N/ha/yr) applied in 6 split applications at 2 mo intervals. Canopy height, maximum height, live tiller count, and dry matter (DM) yield were measured monthly ($n = 830$). DM yield data through January 2012 were log-transformed and analyzed using a linear mixed model (REML) in JMP Pro 9.0.2. Coefficient of determination was 0.78. Fixed effects included urea ($P < 0.0001$), manure ($P = 0.8387$), and their interaction ($P = 0.0994$), as well as additional covariates (pre-experiment soil pH, month, and plant count). Random effects included block (52.4% residual variance) and block x treatment (4.1%). Mean differences were evaluated using Tukey's test. Urea levels 60 (18 mt/ha/yr; 95% CI [11.3, 28.6]) and 120 (18.5; [11.6, 29.4]) were significantly higher than level 0 (14.7; [9.2, 23.4]). In the urea × manure interaction, 120 × 240 (21; [13.2, 33.5]) and 60 × 40 (20.9; [13.1, 33.3]) treatment combinations were significantly higher than 0 × 120 (14.1; [8.8, 22.4]). Urea significantly affects yield. Manure × urea interaction plot suggests positive yield response for urea level 120 at increasing levels of manure. Yield response to urea level 60 across manure levels suggests net N immobilization when the C:N ratio is high. Yield response to manure was absent without urea. Model results for tiller count response were similar to the yield model. Preliminary results suggest that high forage yield requires sufficient inorganic N, and organic matter in composted manure may decrease N available for plant uptake. Future field trial priorities include continued field data collection and assessment of forage nutritive value and soil fertility changes over time. N fertilization recommendations will be developed and disseminated to farmers and educators in the study region.

Key Words: tropical forage yield, nitrogen, manure

M76 Anatomy and histochemistry of lignin in *Festulolium* and its progenitors. J. M. Vargas-Romero[1], H. A. Zavaleta-Mancera[2], S. S. González-Muñoz*[2], J. Burgueño-Ferreira[3], M. Meneses-Mayo[2], and B. Alarcón-Zúñiga[4], [1]*Universidad Autónoma Metropolitana-Iztapalapa, México D.F., México,* [2]*Colegio de Postgraduados, Montecillo, Estado de México, México,* [3]*CIMMYT, Estado de México, México,* [4]*Universidad Autónoma Chapingo, Chapingo, Estado de México, México.*

The objective of this study was to evaluate the lignified tissue distribution in *Festulolium* and its progenitors. *Festuca arundinacea* Schreb, *Lolium perenne* L. and *Festulolium* sp. (*F. arundinacea* × *L. perenne*) were cultivated in a greenhouse. At 22 d after sowing mature leaves from the 3 species were studied for anatomy, lignin histochemistry and NDF and ADF content by light microscopy, scanning electron microscopy, phloroglucinol staining and the Van Soest method. The cross sectional area of protoxylem and metaxylem of the central vein, number of bulliform cells, number and distance between vascular bundles, stomata and epidermal hair density were measured. The relative lignin content (%) was estimated measuring the cross sectional area or the lignified cellular components/total leaf area with the software Motic Images Plus 2.0. The data were statistically analyzed with SAS using the *genmod-zero inflated* Poisson method of the observed and residuals data. The number of vascular bundles did not show differences among species but it related significantly with the epidermal hair density. The adaxial stomata density was related inversely with the metaxylem size; in contrast the abaxial stomata density showed a positive relation with the protoxylem, but there were no differences among species. The distance between veins, associated with the photosynthetic mesophyll, was directly proportional with the NDF and inversely with ADF, behaving differentially among species. There was more lignin in *Festuca* than in the other species, particularly in the abaxial and adaxial epidermis, subepidermal fibers, vascular bundle sheath, marginal fibers, metaxylem vessels and fibers. *Lolium* showed lignin only in the metaxylem of veins. *Festulolium* inherited from *Festuca* large vascular bundles but less lignified, and from *Lolium* the absence of lignin in epidermis, margin and vascular bundle sheath. These characters confer a greater robustness to *Festulolium* in its architecture but with less lignin and greater digestibility.

Key Words: *Festulolium*, anatomy, lignin

M77 The n-alkane technique provides a reliable estimate of fescue and clover composition in mixed forages. N. Vargas Jurado,* A. E. Tanner, S. R. Blevins, H. M. McNair, and R. M. Lewis, *Virginia Polytechnic Institute and State University, Blacksburg.*

N-alkanes are saturated hydrocarbons found in the cuticular wax of plants. Because patterns of n-alkanes differ among plants, they can be used to define the dietary composition of grazing herbivores. N-alkanes are extracted by saponification, with concentrations determined by gas chromatography. Methodological differences, including operator expertise, may contribute to variability in the technique's reliability. Our objectives were to determine: (i) the reliability of estimating the composition of a 2-plant mixture using n-alkanes, and (ii) the extent within and between operator variability affects those estimates. Pure and 2-plant mixtures of red clover and fescue were prepared; the mixtures contained 10 to 90%, at 10% increments of each plant. Two operators, one experienced and one novice, performed 2 extractions of each mixture. For the 4 extractions, concentrations of C_{27}, C_{29}, C_{31} and C_{33}, as plant markers, and C_{22} and C_{34}, as internal standards, were determined. The compositions of the 9 mixtures were estimated using nonnegative least squares. Reliability was assessed by regressing actual on estimated fescue contents, testing the hypothesis that the slope equaled unity. Operator differences were tested with ANOVA.

Across extractions, mean concentrations of C_{27}, C_{29}, C_{31} and C_{33} were 28.0 ± 1.5, 116.8 ± 6.7, 168.5 ± 5.9 and 45.6 ± 1.5 mg/kg for fescue, and 19.6 ± 1.5, 284.6 ± 6.7, 35.6 ± 5.9 and 8.6 ± 1.5 mg/kg for red clover, respectively. The 3 longer chain n-alkanes provided greater discrimination between the plants. Within operator, concentrations of C_{27} and C_{29} differed between extractions ($P < 0.05$). Between operators, only concentrations of internal standards differed (C_{22}, $P = 0.02$; C_{34}, $P = 0.01$), likely due to differences in the standard solutions used. For the experienced operator, the slopes were 0.98 ± 0.03 and 0.98 ± 0.01. For the novice operator, the slopes were 0.83 ± 0.08 and 0.97 ± 0.04. None of the slopes differed from unity, although predictions based on the first extraction of the novice operator were less consistent. Clearly, with training, the n-alkane methodology provides reliable estimates of the composition of plant mixtures.

Key Words: n-alkanes, forage composition, reliable estimate

M78 Assessment of stockpiling methods to increase late summer and early fall forage biomass.

A. L. Hickman,* A. O. Abaye, B. F. Tracy, C. D. Teutsch, and D. A. Fiske, *Virginia Polytechnic Institute and State University, Blacksburg.*

In Virginia, tall fescue can be found on more than 4 million acres as hay and pastureland. Management programs to optimize stockpiled tall fescue can potentially increase livestock productivity in Virginia and throughout the region. Prior to making a decision on stockpiling, the producer needs to consider the need for high quality forage. This includes the time of greater forage needs, number, and production level of animals. The objective of this study was to assess the effect of summer stockpiling endophyte-infected Kentucky 31 tall fescue on biomass and nutritive value of tall fescue forage. The experiment consists of 4 treatments each replicated 6 times in a split plot design. The 4 treatments were 2 nitrogen application timing, legume inclusion, and control. Each of the 4 treatments was divided into a cut and a no cut treatment. The cutting treatment consisted of a single cutting taken in May. Nitrogen in the form of urea was applied in March (before the cutting) to one nitrogen application timing treatment and in May (after the cutting) to the other nitrogen application timing treatment at the rate of 56.04 kg/ha. The extent of clover establishment was dependent on the amount of tall fescue residue present at the time of frost seeding. Yield and nutritive value results were analyzed using the glimmix procedure in SAS statistical analysis software. Significance was determined at a level of $\alpha = 0.05$ and responses for significant effects were separated using the Tukey-Kramer grouping of least squares means. Initial results indicate no biomass yield differences between fertilization treatments ($P = 0.3556$) or cutting treatments ($P = 0.8510$). However, some differences in the nutritive value of the stockpiled fescue were observed between the cut and no cut treatments for acid detergent fiber ($P < 0.0001$), neutral detergent fiber ($P < 0.0001$), and crude protein ($P = 0.0022$). Additionally, effect of fertilization treatment on nutritive value was not evident for acid detergent fiber ($P = 0.1199$), neutral detergent fiber ($P = 0.5637$), or crude protein ($P = 0.1488$). The same experiment will be repeated during the 2012 growing season.

Key Words: tall fescue, summer stockpile, forage

M79 Soil nutrients in tall fescue (*Festuca arundinacea* L.) paddocks managed under different outdoor hog systems.

S. Pietrosemoli*[1] and J. T. Green[2], [1]*Animal Science Department, North Carolina State University, Raleigh,* [2]*Crop Science Department, North Carolina State University, Raleigh.*

To evaluate the effects of outdoor hog management systems (MS) on soil nutrients, nine 0.16-ha tall fescue paddocks were established at the Center for Environmental Farming System (Goldsboro, NC). The 12-wk-long experiment was conducted twice (Dec 2010 - Mar 2011, and May - Aug 2011). The stocking rate was equivalent to 49 wean-finish hogs/ha. Hogs (23.4 ± 0.6 and 84.8 ± 1.12 initial and final weight, respectively) had ad libitum access to shelter, water and a concentrated feed (16% CP). Animals were managed under 3 systems: continuous (C), rotational (R) and strip (S). In C, hogs had access to the whole paddock area. In R, the paddocks were divided into 9 sections and the central section where shelter and water were located considered a heavy use area (HUA); hogs had permanent access to the HUA and were moved weekly to one of the other 8 sections where feed was provided; after the first 8 weeks, animals had access to the HUA + 2 sections. In S, the paddocks were divided into 8 strips and shelter, water and feed were moved with the animals once a week; after the first 8 weeks, animals were moved to 2 strips on a weekly basis. Soil samples were hand probe collected on 2 dates: before (Dec 2010) and after (Aug 2011) hogs, and at 2 depths (0–15 cm; D1) and (15–30 cm; D2). Paddocks were divided into 9 sections, and 12 core samples per depth were randomly collected within each section and composited. A composite sample per paddock was analyzed for nitrate concentration. The experimental design was a randomized complete block with 3 field replicates. Data were analyzed using the PROC MIXED procedure of SAS and included MS and depth as main effects. The MS affected concentrations of P, K, Mn, Zn, Cu ($P < 0.05$) and NO_3 ($P < 0.09$). Higher ($P < 0.05$) concentrations of nutrients were observed in D1. According to the conditions of this experiment, lower soil nutrient contents were observed in the paddocks managed under the rotational compared with the continuous system.

Table 1. Soil nutrients (mg/dm^3) in tall fescue paddocks under 3 outdoor hogs managing systems (C, R, S[1]) and 2 depths (D1 and D2)

	C	R	S	D1	D2
P	49.0 ^{a}	40.2 ^{b}	39.6 ^{b}	50.4^b	35.4^b
K	97.6^a	78.7^b	78.5^b	113.3^a	56.6^b
Ca	643	650.5	655.5	654.5	644.8
Mg	151	155.9	157.9	151.8	158.1
S	14.4	14.4	13.4	15.6	12.5
Mn	47.5^a	41.0^b	46.3^a	46.4	43.5
Zn	4.2^a	3.4^b	3.8^{a,b}	4.6^a	3.0^b
Cu	1.8^a	1.6^b	1.7^{a,b}	2.0^a	1.5^b
Na	23.1	26.1	25.6	26.8^a	23.0^b
NO_3[2]	21.8^c	16.9^d	18.1^{c,d}	25.2^c	12.8^d

Means with different letters differ (a, b: $P < 0.05$; c, d: $P < 0.09$).

Key Words: outdoor swine, soil nutrients, *Festuca arundinacea*

M80 Effect of outdoor swine management systems on tall fescue (*Festuca arundinacea* L.) ground cover and animal performance.

S. Pietrosemoli*[1] and J. T. Green[2], [1]*Animal Science Department, North Carolina State University, Raleigh,* [2]*Crop Science Department, North Carolina State University, Raleigh.*

During 2 seasons (S; December 2010-March 2011 = S1, and May–August 2011 = S2), the ground cover (GC) of tall fescue paddocks (0.16 ha) was recorded weekly for 12 wk at the Center for Environmental Farming Systems (Goldsboro, NC), to evaluate the effects of 3 outdoor hogs management systems (MS). The stocking rate (8 pigs/plot) was equivalent to 49 weaning-finishing hogs/ha. Initial and final (avg 23.3 ± 1 and 84.8 ± 1 kg, respectively) animal weights were recorded and daily weight gain (DWG) was calculated. The MS evaluated were: continuous (hogs had permanent access to the entire paddock [MS1]), rotational (hogs had permanent access to 1/9 of the area considered as a heavy use area, and were rotated to another 1/9 section on a weekly basis (wk 1–8) or to 2/9 sections (wk 8–12) [MS2]) and strip grazing (hogs had access to 1/8 of the paddock (wk 1–8) or to 2/8 sections (wk 8–12) [MS3]). Animals had ad libitum access to shelter, water and feed (16% CP). Intake averaged 1.96 kg/pig/d. A modified step point method was employed to estimate live vegetation (LV), vegetation residue (VR) and bare soil (BS). The GC was defined by GC = LV+VR. The experimental design was a randomized complete block with 3 field replicates (REP). The LV, BS and GC data were log(x+1) transformed whereas the equation $((x+1)/100)^{1/2}$ was used for VR. After pigs removal data (wk 12) were analyzed using PROC MIXED of SAS v 9.2, following a mixed linear model including MS, S and MS*S as fixed effects, and REP and REP*MS as random effects. For DWG, initial weight and sex condition (female or castrate) were used as covariates. Under the conditions of this experiment GC, its components or DWG did not differ ($P > 0.05$) among management systems. Season affected the variables under evaluation with the exception of DWG.

Table 1. Ground cover (%) of tall fescue paddocks and DWG (kg/pig) under 3 outdoor hogs managing systems (MS 1, MS2, MS3) during 2 seasons (S1 and S2)

	MS1	MS2	MS3	SE
LV	62.4	69.8	69.8	3.1
VR	4.6	2.6	4.4	1.1
BS	31.9	28.3	25.8	2.9
GC	67.5	72.4	74.3	2.5
DWG	0.7	0.8	0.7	0.02

	S1	S2	SE
LV	58.8^{b}	76^{a}	3.1
VR	6.7^{a}	1.0^{b}	1.0
BS	33.9^{a}	23.5^{b}	2.4
GC	65.5^{b}	77^{a}	2.5
DWG	0.7	0.8	0.02

Key Words: outdoor swine, ground cover, *Festuca arundinacea*

M81 Effect of outdoor swine management systems on the botanical composition of tall fescue (*Festuca arundinacea*) paddocks.

S. Pietrosemoli*[1], J.-M. Luginbuhl[2], and J. T. Green[2], [1]*Animal Science Department, North Carolina State University, Raleigh,* [2]*Crop Science Department, North Carolina State University, Raleigh.*

An experiment was performed at the Center for Environmental Farming Systems (Goldsboro, NC) to compare the botanical composition (BC) of tall fescue paddocks under 3 outdoor swine management systems. The systems consisted of Continuous (C; hogs had access to the entire paddock during the length of the evaluation), Rotational (R; the paddocks were divided into 9 sections with the central section used as a heavy use area [HUA]); hogs had permanent access to the HUA and were moved weekly to one of the other 8 sections), and strip grazing (S; the paddocks were divided into 8 strips, and the hogs were moved once a week with shelters, feeders and drinkers). Nine 0.16-ha tall fescue paddocks were managed with a stocking rate equivalent of 49 weaning-finishing hogs/ha for 12 weeks during 2 periods: winter 2010–2011 and summer 2011 (S2011). Hogs had ad libitum access to feed (16%CP) and water and free-choice access to shelter. One week after hog removal in S2011, the botanical composition of the paddocks (tall fescue, broadleaf weeds and other grasses) was estimated using the visual estimation (VE) and the dry weight rank (DWR) methods. Paddocks were divided into 9 sections, and 5 quadrats (0.25 m^2) were randomly thrown into each section for the DWR, and the VE of each section was also estimated. The experimental design was a complete randomized block with 3 field replicates. Data were analyzed using Proc Mixed of SAS 9.2 and repetition, treatment × repetition, method × treatment, and method × repetition were included as random effects. No statistical differences ($P > 0.05$) were observed among management systems nor methods of botanical composition estimation. Tall fescue was the main component of the pasture (64.97%), followed by other grasses (29.82%) and broadleaf weeds (4.13%). Crabgrass (*Digitaria sanguinalis*) was the most frequently observed grass, while ragweed (*Ambrosia artemisifolia*) was the most prominent broadleaf weed. The 3 management systems under evaluation had no impact on the botanical composition components of tall fescue paddocks. In addition, similar botanical composition results were obtained using the VE or the DWR methods.

Key Words: outdoor swine, botanical composition, *Festuca arundinacea*

M82 Endophyte-infected fescue seed causes constriction of the palmar and uterine arteries in pregnant mares.

K. J. McDowell,* M. A. Stickney, E. Delaney, and D. A. Hestad, *University of Kentucky, Lexington.*

Pregnant mares grazing endophyte-infected (E+) tall fescue may incur problems in late pregnancy such as extended gestation, thickened placenta, decreased prolactin secretion and agalactia. One hallmark of E+ fescue consumption in cattle is vasoconstriction, and we previously demonstrated that it also caused a marked constriction of the palmar artery in nonpregnant horses. The purpose of this experiment was to determine if consumption of E+ tall fescue seed caused constriction of the palmar and uterine arteries in pregnant mares, and if it altered the combined uterine/placental thickness (CUPT). Pregnant mares (n = 23) at 276 + 4.79 (mean ± SE) days gestation were used in an experiment that was divided into 3 periods (P) of 1-week each. During P1, all mares received E- fescue seed, while during P2, 11 mares received E- seed and 12 mares received E+ seed. During P3, all mares once again received E- seed. Seed, averaging 6.5 ppm ergovaline + ergovalinine, was mixed with the daily grain ration in twice/day feedings such that each day mares received seed at 0.2% body weight. Three times per week during P1 and P2 the left palmar and uterine arteries of each mare were scanned via Doppler ultrasonography, and CUPT near the cervical star was measured. The same measurements were taken again on the last day of P3. Blood samples were taken 3 times per week throughout the study to measure hormone concentrations. When P2 was compared to P1, mares consuming E+ fescue seed, but not E- seed, had reduced diameters of the palmar ($P = 0.0001$) and uterine ($P < 0.0174$) arteries. However, there were no period or treatment differences in the CUPT measurements. Prolactin was lower ($P = 0.0009$) in P2 vs P1 when mares received E+ seed but there were no differences in progesterone or estradiol concentrations. In conclusion, consumption of E+ fescue seed caused constriction of both the palmar and uterine arteries but did not alter CUPT. Constriction of the palmar artery is a sensitive response variable in mares receiving E+ seed, and measuring palmar artery diameter may be a useful tool in monitoring mares' exposure to E+ tall fescue in pastures.

Key Words: horse, fescue, pregnancy

M83 Consumption of endophyte-infected tall fescue seed causes constriction of the palmar artery and vein but does not alter estradiol, progesterone, or estrous cycle length in nonpregnant mares.

D. A. Hestad* and K. J. McDowell, *University of Kentucky, Lexington.*

Endophyte-infected (E+) tall fescue (TF) has deleterious health effects in pregnant mares, however, effects are not well understood in nonpregnant mares. Previously, our lab has demonstrated constriction of the palmar artery of nonpregnant horses consuming E+TF seed (Moore et al., 2008). The purpose of this experiment was to determine if the consumption of E+TF seed by nonpregnant mares alters interovulatory intervals and serum hormone concentrations, and to determine if E+TF causes constriction of the palmar vein as well as the artery. Nonpregnant cycling mares (n = 12) were used in a crossover experiment consisting of 2 periods (P), where each P was the duration of 1 estrous cycle (from ovulation, d 0, to next ovulation). On d 0 of P1 mares were assigned to receive either E+ (at 6.5 ppm ergovalinine + ergovalinine) or endophyte free (E-) TF seed. All mares were placed on E- seed at the end of P1 to allow for a washout period, where Lutalyse (10 mg) was given on Day 6 to cause luteal regression. On d 0 of P2 (day of next ovulation) mares began receiving the treatment alternate from P1. Seed was mixed with the daily grain ration such that each day mares received seed at 0.2% body weight. During P1 and P2, the palmar artery and vein of each mare were scanned via Doppler ultrasonography every 2 to 3 d. Blood samples were taken every other day during P1 and P2, with more frequent ultrasound scanning and blood sampling on days immediately around ovulation. Lengths of estrous cycles and concentrations of progesterone and estrogen were not different between treatments. However, E+ seed caused constriction of the palmar artery ($P < 0.0001$) and vein ($P = 0.014$) compared with the E- seed. Measuring vasoconstriction therefore may be a useful tool in monitoring mares' exposures to E+ TF, and vasoconstriction could affect fertility and embryonic development. Future experiments will assess the effects of E+TF on the vascularity of the uterine endometrium.

Key Words: tall fescue, Doppler ultrasound

M84 Changes in bovine vascular contraction and constriction relative to time off endophyte-infected tall fescue.

J. R. Bussard*[1], G. E. Aiken[3], J. R. Strickland[3], K. R. Brown[3], B. M. Goff[1], A. P. Foote[2], and J. L. Klotz[3], *[1]Department of Plant and Soil Sciences, University of Kentucky, Lexington, [2]Department of Animal and Food Sciences, University of Kentucky, Lexington, [3]USDA-ARS, FAPRU, Lexington, KY.*

Beef cattle grazing endophyte-infected (E+; *Neotyphodium coenophialum*) tall fescue (TF; *Lolium arundinaceum*) are exposed to ergot alkaloids produced by the endophyte. Ergot alkaloids induce constriction in vascular tissue of extremities of animals grazing TF, which leads to an inability to regulate body temperature and an increased susceptibility to heat and cold stresses. To better understand consequences of alkaloid exposure, a study was conducted to evaluate changes in vascular contraction relative to time-off E+ TF pasture after an 88-d grazing period. Lateral saphenous veins were biopsied from 24 predominantly Angus steers (361 ± 4 kg) at 0-, 21-, 42-, and 63-d off of TF pasture (n = 6 per time point) and 6 control steers (370 ± 18 kg) at 0-d and 63-d off bermudagrass (BG) pasture (n = 3 per time point). Off pasture, steers were housed in a dry lot and fed a non-toxic corn silage diet. To evaluate contractile response, biopsied vessels were cleaned, incubated in a multimyograph, and exposed to increasing concentrations (1×10^{-11} to 10^{-4} M) of ergotamine. Myograph data were normalized to a reference edition of 1×10^{-4} M norepinephrine. Cross-sectional ultrasound scans of caudal artery at the fourth coccygeal vertebra were taken on d 0, 8, 15, 21, 29, 36, 42, and 45 using an Aloka 3500 Ultrasound Unit with a UST-5542 (13 MHz) linear array transducer set to 2-cm depth to determine mean artery luminal area to evaluate constriction. Data were analyzed as a CRD using mixed models in SAS with steer as experimental unit. Veins from steers of TF pasture differed over time ($P < 0.05$) and d-0 TF veins had a much lower ($P < 0.05$) contractile response to ergotamine compared with d-0 BG veins. By 63-d myograph contractile responses for TF steers were similar to those of BG steers ($P = 0.29$). Luminal areas of caudal arteries in steers grazed on E+ TF had relaxed and were similar to steers that had grazed BG by 36-d on the non-toxic diet ($P = 0.15$). Measures of contraction indicate that cattle should be removed from E+ TF pastures for a minimum of 4 weeks to obtain vascular responses similar to those of cattle grazed on non-toxic pastures.

Key Words: bovine, ergot alkaloid, tall fescue

M85 Lateral saphenous vein responses to serotonergic and α-adrenergic receptor agonists increase with time off endophyte-infected tall fescue.

J. L. Klotz*[1], J. R. Bussard[2], G. E. Aiken[1], A. P. Foote[3], D. L. Harmon[3], K. R. Brown[1], B. M. Goff[2], and J. R. Strickland[1], *[1]USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY, [2]Department of Plant and Soil Sciences, University of Kentucky, Lexington, [3]Department of Animal and Food Sciences, University of Kentucky, Lexington.*

Previous research has indicated that serotonergic and α-adrenergic receptors in peripheral vasculature are affected by exposure of cattle grazing toxic endophyte-infected (E+) tall fescue (TF; *Lolium arundinaceum*). This study was conducted to investigate changes in vascular contractile response over time relative to removal from an E+ TF pasture after an 88-d grazing period. Lateral saphenous veins were biopsied from 24 Angus-cross steers (361 ± 4 kg) at 0-, 21-, 42-, and 63-d off of TF pasture (n = 6 per time point) and 6 steers (370 ± 18 kg) off of bermudagrass (BG) pasture on d-0 and d-63 (n = 3 per time point). Off pasture, steers were housed in a dry lot and fed a corn silage diet. Biopsied vessels were cleaned and incubated in a multimyograph and exposed to increasing concentrations (5×10^{-8} to 1×10^{-4} M) of TCB-2 (TCB; 5HT$_{2A}$ agonist), guanfacine (GF; α$_{2A}$-adrenergic agonist), and

(R)-(+)-m-nitrobiphenyline oxalate (NBP; α_{2C}-adrenergic agonist). Data were normalized to a reference addition of 1×10^{-4} M norepinephrine and analyzed as a CRD using mixed models of SAS for main effects of d off pasture, agonist concentration, the interaction, and comparison of TF to BG veins at d 0 and d 63 included a pasture effect. Steer was the experimental unit. Increasing concentrations of 3 agonists incubated with TF veins were significant for agonist ($P < 0.01$) and d off pasture ($P < 0.01$), but only TCB was significant for d off pasture × concentration interaction ($P < 0.01$). Vasoactivity to agonists was reduced when steers were initially removed from E+ TF pasture. Contractile response at d 63 was greatest ($P < 0.05$) for GF, NBP, and TCB and d-42 TCB response was greater ($P < 0.05$) than on d 21 or d 0 (which did not differ). Contractile responses to NBP at d 0 were greater in BG veins ($P < 0.01$) than TF and tended to be greater ($P = 0.07$) for GF and TCB, but none were different at d 63. These data demonstrate changes in peripheral vasoactivity occur beyond 1 mo off pasture and $5HT_{2A}$ receptors appear to be more dramatically affected in the lateral saphenous vein by grazing E+ TF pasture than adrenergic receptors.

Key Words: bovine, tall fescue, vasoconstriction

M86 Validation of a housekeeping gene for use in bovine vascular gene expression studies.

J. L. Klotz*[1], K. R. Brown[1], J. C. Matthews[2], J. A. Boling[2], and J. R. Strickland[1], [1]*USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY,* [2]*Department of Animal and Food Sciences, University of Kentucky, Lexington.*

Exposure of ungulate vasculature to ergot alkaloids while grazing endophyte (*Neotyphodium coenophialum*)-infected tall fescue (*Lolium arundinaceum*) affects vasoactivity and causes vasoconstriction. Bovine vascular gene expression as affected by exposure to ergot alkaloids in tall fescue is largely unstudied. The objective of this study was to investigate the suitability of β-actin (ACTB), glyceraldehyde 3-phosphate dehydrogenase (GAPD), hypoxanthine phosphoribosyl-transferase I (HPRT), succinate dehydrogenase flavoprotein subunit A (SDHA), and ubiquitin C (UBC) as potential housekeeping genes for use in bovine vascular gene expression studies that include different levels of exposure to ergot alkaloids. Lateral saphenous (SV) and right ruminal veins (RV) were selected as models for comparison of peripheral and visceral vasculature for future experiments. Veins were collected immediately after slaughter from 19 predominantly Angus steers that had grazed either a low-endophyte-infected tall fescue pasture (LE; 5.7 ha; n = 9; BW = 266 ± 6 kg) or a high-endophyte-infected tall fescue pasture (HE; 5.7 ha; n = 10; BW = 267 ± 6 kg) for 89–105 d. Isolated veins were frozen in liquid N and stored at −80°C until completion of total RNA isolation and 1st strand synthesis of cDNA. Real-time PCR was run using SYBR Green with PCR product verified by dissociation curve analysis. Relative standard curve analysis of each gene was done using separate serial dilutions of composite cDNA (10 ng/μL) from SV and RV. Transcript levels (ng/μL) for each gene were analyzed as CRD factorial for endophyte level and vein with mixed models in SAS. Endophyte level (HE vs. LE) did not affect expression of any gene, nor were any endophyte level × vein interactions detected. There was a main effect of vein for HPRT, GAPD, and SDHA ($P < 0.01$). Expression levels of HPRT, GAPD, and SDHA were all greater ($P < 0.05$) in SV than RV, whereas levels of ACTB and UBC did not differ between veins. Thus, ACTB or UBC mRNA transcripts are appropriate to use as normalizing genes when assessing the effects of grazing endophyte-infected tall fescue on gene expression by bovine RV and SV tissues.

Key Words: bovine, housekeeping gene, vein

M87 Tiller appearance in pastures of Guinea grass ‘Tanzania’ managed with different frequencies and defoliation severities.

D. Nascimento Júnior*[1], A. M. Zanine[2], B. M. L. Sousa[1], and W. L. Silva[3], [1]*Univsersidade Federal de Viçosa, Viçosa, MG, Brazil,* [2]*Universidade Federal do Mato Grosso, Rondonópolis, MT, Brazil,* [3]*Universidade Estadual Paulista, Jaboticabal, SP, Brazil.*

The experiment was conducted from November 2005 to October 2006 in Viçosa, MG, Brazil (20°45′ S; 42°51′ W; 651 m a.s.l.). Tiller appearance was evaluated in Guinea grass ‘Tanzania’ (*Panicum maximum* ‘Tanzania’) subjected to rotational stocking management characterized by 2 post-grazing heights (30 and 50 cm) and grazings carried out at the 90 and 95% canopy light interception condition. The 4 grazing management strategies (90/30, 90/50, 95/30, and 95/50) were allocated to experimental units in a completely randomized block design with 3 replications.Tiller dynamics were assessed in 3 clumps per experimental unit. This assessment made it possible to calculate the tiller appearance rate {[new tillers/total of live tillers in the previous marking) x 100]/regrowth days}. The data were grouped into 4 seasons: end of spring (November and December 2005), summer (January to March 2006), fall (April to June 2006) and winter/beginning of spring (July to October 2006). The data were submitted to variance analysis using the GLM Procedure of SAS (Statistical Analysis System) and compared by the Tukey′s test, with 10% of significance. The tiller appearance rate was influenced by the interaction post-grazing height × light interception × season of the year ($P < 0.10$). In the end of the spring, pastures managed with 90/30 and 90/50 presented higher values ($P < 0.10$) relatively to the ones managed at 95/30 and 95/50 (1.10 and 0.85 versus 0.45 and 0.45 tiller/100.tiller.day, respectively). Swards managed with 90/30 (1.92 and 1.10 tiller/100.tiller.day) and 95/30 (2.33 and 1.30 tiller/100.tiller.day) presented higher values ($P < 0.10$) in comparison to the ones managed at a 90/50 (1.66 and 1.79 tiller/100.tiller.day) and 95/50 (1.40 and 0.70 tiller/100.tiller.day) in the summer and in the fall, respectively. In the winter/beginning of the spring, pastures managed with 95/30 presented lower tiller appearance rate ($P < 0.10$) comparatively to the ones managed at 90/30, 90/50, and 95/50 (0.69 versus 1.21, 1.08 and 0.98 tiller/100.tiller.day, respectively). All the evaluated management strategies were adequate for Guinea grass.

Key Words: ecophysiology, post-grazing height, light interception

M88 Aerial tiller density in pastures *Pennisetum purpureum* submitted to different post-grazing heights.

B. M. L. Sousa, D. Nascimento Júnior*, H. C. F. Monteiro, F. C. Gomes, C. Z. Assis, and C. S. Almeida, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

Elephant grass is a plant that has a high forage yield potential and is widely used in dairy farming under grazing in Brazil. With this type of management, attention should be given to the type of tiller being produced because, under grazing, Elephant grass produces a great quantity of aerial tillers. The experiment was carried out from February to May in 2009 to evaluate the aerial tiller density in Elephant grass ‘Napier’ (*Pennisetum purpureum* Schum.) submitted to different grazing severities. The study was conducted in an area cultivated with Elephant grass ‘Napier’ in Vicosa, MG, Brazil (20°45′ S; 42°51′ W; 651 m a.s.l.). Soil is classified as Inceptic Hapludults, with clay-loam texture. Treatments corresponded to 3 post-grazing conditions (residues of 30, 50 and 70 cm) associated with a pre-grazing condition of 95% sward canopy light interception during regrowth. A complete randomized block design with 3 replications was used. The monitoring of the light interception was done using the canopy analyzer (LAI 2000). The aerial tiller density was evaluated by counting the living tillers within 4 existing metal frames measuring 0.25 m × 1.00 m per experimental unit. The data were grouped by month and subjected to an ANOVA using the Mixed Procedure of SAS (Statistical Analysis System).The means were compared by the Student's *t*-test at a 5% significance level. The aerial tiller density was influenced by the post-grazing height ($P = 0.0017$) and was lower in the pastures that were managed at a post-grazing height of 30 cm (125 tillers/m^2) compared with those that were managed at 50 or 70 cm (211 and 201 tillers/m^2, respectively). These swards had also lower tiller renewal and higher quantity of weeds, suggesting the beginning of degradation process and that this post-grazing height (30 cm) should not be recommended for grazed elephant grass. The aerial tiller density was not affected by the month ($P = 0.5567$), being on average 179 tillers/m^2. The post-grazing height of 30 cm can drastically reduce the pasture accumulation rate.

Key Words: ecophysiology, grassland management, light interception

M89 Tiller density stability of Piatâ palisadegrass swards deferred with different initial heights. B. M. L. Sousa[1], D. Nascimento Júnior*[1], M. E. R. Santos[2], H. H. Vilela[1], M. C. T. Silveira[3], G. O. Rocha[1], B. D. Faria[1], and C. A. S. Freitas[1], [1]*Univsersidade Federal de Viçosa, Viçosa, MG, Brazil,* [2]*Faculdade de Medicina Veterinaria e Zootecnia, Uberlândia, MG, Brazil,* [3]*Empresa Brasileira de Pesquisa Agropecuária - Pecuária Sul, Bagé, RS, Brazil.*

The study was conducted to evaluate the stability index of the tiller density of the Piatâ palisadegrass (*Brachiaria brizantha* 'Piatâ') deferred with 3 initial heights of the sward (20, 30 and 40 cm) and 4 deferring periods (1 to 30, 31 to 60, 61 to 90, and 91 to 120 d). The experiment was carried out in the Federal University of Vicosa, in Viçosa, Minas Gerais, from March 1 to July 7, 2011. The experimental design was a complete randomized block with 3 replications in subdivided plots repeated in time. Tillering was evaluated inside of a 30 cm diameter metal ring in each experimental unit. This evaluation made it possible to calculate the stability index of the tiller density [survival rate × (1 + appearance rate)] for the basal and aerial tillers. Data were analyzed using the SAEG (Statistical Analysis System and Genetics) and the means comparisons were made by the Student-Newman-Keuls′s test at a probability of 5%. In general, the stability index values under 1.0 indicate that the survival and appearance of new tillers are not enough to compensate the death rates, and, thus, the density tends to decrease, while higher values than 1.0 suggest increase, and values near 1.0 indicate a stable tiller density, in which the number of tillers does not practically vary. The stability index of basal ($P = 0.6652$) and aerial ($P = 0.6907$) tillers was not affected by the initial deferring height, presenting, in average, 1.05 and 1.68, respectively. However, the stability index of basal ($P = 0.0007$) and aerial ($P = 0.0003$) tiller density was influenced by the deferring period. The Piatâ palisadegrass deferred from 1 to 30 d (1.62 and 4.11) presented higher value of stability index of basal and aerial tillers in relation to the ones deferred from 31 to 60 (0.89 and 0.90), 61 to 90 (0.83 and 0.94) and 91 to 120 d (0.85 and 0.79), respectively.

Key Words: *Brachiaria brizantha*, grassland management, structural characteristics

M90 Tiller density in Piatâ palisadegrass deferred in different seasons and initial heights. B. M. L. Sousa[1], D. Nascimento Júnior*[1], H. H. Vilela[1], M. E. R. Santos[2], C. Z. Assis[1], G. O. Rocha[1], and B. D. Faria[1], [1]*Univsersidade Federal de Viçosa, Viçosa, MG, Brazil,* [2]*Faculdade de Medicina Veterinaria e Zootecnia, Uberlândia, MG, Brazil.*

Deferring management strategies can affect the number of tillers of the sward, compromising the persistency, the productivity and sustainability of the grassland. Therefore, the study was conducted to evaluate the effect of the seasons and initial deferring heights on the number of tillers of the Piatâ palisadegrass (*Brachiaria brizantha* 'Piatâ'). The experiment was carried out in the Federal University of Viçosa, in Viçosa, Minas Gerais, in 3 areas deferred in March 20, April 10, and May 1, 2010, and with initial heights of 20, 30, and 40 cm. A complete randomized block design with 3 replications in a subdivided plot scheme was used. The area was deferred until 07/01 in 2010, at which time the number of tillers inside 2 square metal frames of 0.4 × 0.4 m was determined. The data were analyzed using the SAEG (Statistical Analysis System and Genetics) and compared by the Tukey test at 5% of significance. The number of tillers was influenced by the interaction between initial height and season ($P = 0.0345$). Higher number of tillers was obtained in the area deferred in May 1 in the initial heights of 20 (1,056 tillers/m^2), 30 (1,158 tillers/m^2), and 40 cm (1,113 tillers/m^2), in April 10 in the heights of 20 (1,069 tillers/m^2) and 30 cm (1,356 tillers/m^2), and in March 20 in the height of 20 cm (1,135 tillers/m^2), in relation to the ones deferred in April 10 in the height of 40 cm (704 tillers/m^2) and in March 20 in the heights of 30 (911 tillers/m^2) and 40 cm (808 tillers/m^2). Long deferring periods associated to the high initial sward heights decreases the number of tillers of deferring Piatâ palisadegrass.

Key Words: *Brachiaria brizantha*, grassland management, structural characteristics

M91 Animal productivity on brachiaria grass deferred at different heights[1]. M. C. T. Silveira[1], D. M. Fonseca[2], D. Nascimento Júnior*[2], M. E. R. Santos[3], V. M. Gomes[2], F. K. Gomes[2], V. L. N. Brandâo[2], G. O. Rocha[2], B. M. L. Sousa[2], A. Deus[2], R. L. Albino[2], L. S. Moura[2], and G. A. Borges[2], [1]*CPPSU-Embrapa Pecuária Sul, Bagé, RS, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, MG, Brazil,* [3]*Faculdade de Medicina Veterinaria e Zootecnia-UFU, Uberlândia, MG, Brazil.*

Pasture deferment consists of postponing the grazing in one area for utilization in the offseason period. Thus, the objective of this study was to evaluate the animal productivity on brachiaria grass pastures deferred at different heights. The experiment was conducted in a field of the Animal Science Department of Universidade Federal de Viçosa, Minas Gerais, Brazil. The experimental area consisted of Brachiaria decumbens Stapf. 'Basilisk' pasture subdivided in 8 paddocks (experimental units), plus a reserve area, totaling approximately 3 ha. The experiment was conducted in randomized block design with 2 replicates and 4 heights at the beginning of deferment (10, 20, 30, and 40 cm). In March 2010, pastures were managed under continuous stocking and variable stocking rate, so that the heights could be established, and the deferment was started. In June 2010, the grazing on deferred pastures began. During 115 d, pastures were managed under continuous stocking, and the initial fixed stocking rate was approximately 3.0 AU/ha. The animals were growing crossbred steers, with an average weight of 190 kg. During the grazing period, cattle consumed, in addition to deferred pasture, mineral salt ad libitum. Average daily weight gain, stocking rate and production per area were measured. Variance and regression analyses at significance level up to 10% of probability were carried out. Stocking rate and animal production per area were not affected by pasture heights ($P > 0.10$), with an average value of 3.78 AU/ha and 0.69 kg/ha.d. This result can be explained by the stocking rate, which was fixed at the beginning of the grazing period. These productivity rates are high for this period, since in Brazil the climatic conditions are not conducive to pasture growth. The average daily gain increased quadratically with pasture height at the beginning of deferment ($P < 0.10$), with maximum value of 0.134 kg/animal.d in the pasture deferred at 20 cm. Therefore, with lowering of brachiaria pastures to 20 cm at the beginning of the deferment period, it is possible to avoid weight loss in cattle kept on pasture, which is common during the fall and winter seasons (June to September).

Key Words: *Brachiaria decumbens* 'Basilisk', grazing management, stocking rate

M92 The effect of cutting at different stages of maturity on yield and quality of nine forage oat varieties in the peace region of Alberta.

T. A. Omokanye*[1] and K. S. Gill[2], [1]*Peace Country Beef and Forage Association, Fairview, Alberta, Canada,* [2]*Smoky Applied Research and Demonstration Association, Falher, Alberta, Canada.*

Beef cattle producers commonly use annual cereals for silage, greenfeed and swath grazing in parts of the Peace Region of Alberta. In Alberta, oats account for more than 40% of total annual greenfeed production. As with most forage crops, there is a yield and quality trade off as small grains mature from boot to dough maturity stages. Timing of the cereal forage harvest is critical to obtain the desired forage quality. The objective of this study was to examine the effects of stage of maturity at cutting on forage yield and feed value of forage oat varieties for greenfeed and swath gazing systems. Nine forage oat varieties were seeded and cut at the late milk and dough stages for yield and feed value in a split-plot experimental design. Forage dry matter (DM) yields of all oat varieties did not show any significant ($P > 0.05$) increase as cutting was delayed from the late milk stage until the dough stage. The mean forage DM yields across the 9 oat varieties ($P > 0.05$) were, respectively, 8,496 and 9,601 kg/ha for late milk and dough stages. When pooled across the 2 stages of maturity at cutting, the average forage DM yield was in the following order ($P > 0.05$): Warden > Foothills > Mustang > SO-I > Murphy > Baler > Morgan > Everleaf > Jordan. When averaged across the 9 oat varieties, mean forage crude protein (CP) was significantly ($P < 0.05$) higher at the late milk stage (9.17%) than at the dough stage (5.66%). For the late milk stage, SO-I oat had the highest CP (10.55%) and Jordan oat had the least CP with 7.24%. When harvesting was delayed till the dough stage, Everleaf significantly ($P < 0.05$) had the most CP (7.20%), while Mustang had the least CP (4.54%). Generally, for each oat variety, cutting at the late milk stage gave slightly lower total digestible nutrients (TDN) (3–8% less energy) than cutting at the dough stage. For all the forage oat varieties examined, the dough stage had significantly ($P < 0.05$) lower ADF and NDF contents than the late milk stage. In summary, the stage of maturity at cutting oat in the present preliminary study did not affect forage DM yield. However, harvesting the forage oat in the late milk stage gave better CP than at the dough stage, but higher energy harvested per acre occurred at the dough stage.

Key Words: Stages of maturity, oats, forage yield and feed value

M93 Structural properties of milk protein concentrate (MPC) dispersions and emulsions as influenced by presence of small molecule components. Y. Liang*[1,2], H. Patel[1], L. Matia-Merino[2], A. Ye[3], and M. Golding[2,3], *[1]Fonterra Research Centre, Palmerston North, New Zealand, [2]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [3]Riddet Institute, Massey University, Palmerston North, New Zealand.*

Heat-stable milk-protein-stabilized emulsions with desirable mouthfeel and shelf-life stability are a challenging system. The compositions (i.e., proteins, sugars, and small molecule surfactants) of various emulsion phases affect the stability and the rheological properties of this type of emulsion. This study investigated and elucidated the potential ingredient interactions (i.e., protein—sugar) in protein-based dispersions and emulsion systems. MPC-I and MPC-II were used as model proteins. They had similar protein contents of ~81% and calcium contents of 2230 and 1140 mg/100 g, respectively. They were reconstituted as 10% w/w dispersions at neutral pH and the pHs were adjusted to 6.2, 6.4, 6.6, 6.8, 7.0, 7.2, and 7.4. Model emulsions with 10% w/w protein and 10% w/w oil were prepared at pH 6.8. Sucrose was added at 0—30% w/w. Oscillatory rheology and heat coagulation time (HCT) were measured twice for each sample, and all samples were prepared in duplicate. The presence of sucrose (5—30% w/w) influenced the aggregation process of 10% w/w MPC-I dispersions during a heating and cooling cycle (25 to 90 to 25°C), as shown by an inhibition of the increase in the complex modulus during cooling. The heat stability, which would be expected to have a marked maximum at pH ~6.5 and a minimum at pH ~6.9, of the MPC dispersions was influenced by protein type, pH, and sucrose concentration. MPC-I exhibited a marked maximum at pH 7.2 in the absence of sucrose, which shifted to pH ~6.8 in the presence of 30% sucrose. The HCT of MPC-I was higher in the presence of up to 15% sucrose than in the absence of sucrose and decreased gradually with increased sucrose (>15%) to less than that in the absence of sucrose. In contrast, MPC-II dispersions exhibited a marked maximum at pH 6.4 regardless of the addition of sucrose. The emulsions stabilized by MPC-I and MPC-II, with and without sucrose, had markedly different stabilities and rheological properties. The aggregation state of casein micelles and sugar-induced calcium activity changes affected the heat stabilities and rheological properties of MPC-based dispersions and emulsions. The results help in our understanding of the behavior of milk proteins in systems with high carbohydrate content.

Key Words: milk protein concentrate, emulsion, rheology

M94 Application of bixin as an alternative colorant for Cheddar cheese. X. Li,* T. J. Smith, and M. A. Drake, *North Carolina State University, Raleigh.*

Colorless whey ingredients are desirable in food applications, therefore bleaching is necessary to remove residual annatto (norbixin) colorant from Cheddar cheese whey. Bleaching negatively affects the flavor of dried whey ingredients and new restrictions on chemical bleaching agents have increased the need for bleach or cheese color alternatives. Bixin is a nonpolar form of annatto and is not currently used in the cheese industry. However, because bixin is nonpolar, it may have an increased retention in the cheese matrix with less carryover into cheese whey. The objective of this study was to determine viability of bixin as an alternative cheese colorant and if less bixin was present in cheese whey compared with norbixin. Preliminary studies established minimal homogenization pressure to stably suspend bixin in milk. A concentration of 60 mL bixin /454 kg milk was selected for comparable concentration to norbixin incorporation concentration. Pasteurized milk was cooled to 55°C, then 60 mL bixin/454 kg milk (3.8% wt/vol bixin) was added and homogenized (single stage) at 80 bar. Milk with no colorant and milk with 15 mL/454 kg milk norbixin (3% wt/vol norbixin) were processed analogously as controls. Mass balance was determined by extraction and quantification of bixin and norbixin in milk, whey, and cheese. The experiment was replicated 3 times. Nine percent norbixin (2.1 ppm) was recovered in the unseparated cheese whey compared with 1.3% bixin (0.3 ppm; $P < 0.05$). The amounts of norbixin and bixin both decreased after fat separation of whey, but the decrease was greater for bixin than for norbixin ($P < 0.05$). Whey from cheese with bixin was visibly lighter in color concurrent with decreased b* values compared with whey from cheese with norbixin ($P < 0.05$). These results confirm that less bixin colorant was present in cheese whey compared with norbixin colorant, thus potentially circumventing the need for whey bleaching. Bixin may be a viable alternative to norbixin in the cheese and whey industry.

Key Words: bleaching, norbixin, bixin

M95 Cold enzymatic bleaching of fluid whey and retentate. R. E. Campbell* and M. A. Drake, *North Carolina State University, Raleigh*

Chemical bleaching of fluid whey and retentate with hydrogen peroxide (HP) requires high concentrations (250 to 500 ppm) and is most effective at temperatures greater than 35°C. Off flavors are generated during HP bleaching. Enzymatic bleaching of fluid whey and retentate with lactoperoxidase or Maxibright at cold temperatures (4°C) may be a viable alternative to chemical bleaching. The objective of this study was to compare enzymatic and traditional chemical HP bleaching of fluid whey and retentate at 4°C. Fluid Cheddar whey was manufactured in triplicate from pasteurized whole milk, and subsequently, 80% whey protein retentate was manufactured from the fluid whey. The optimum concentration of HP for enzymatic bleaching at 4°C (10 ppm for fluid whey and 15 ppm for retentate) was determined. In subsequent experiments, bleaching efficacy, sensory characteristics, and volatile compounds were evaluated after 1 h (retentate) or 24 h (fluid whey) bleaching. Controls with no bleaching and traditional HP bleaching (250 ppm HP) were also evaluated. Bleaching efficacy was determined by measuring norbixin destruction compared with the unbleached control, sensory profiles were evaluated by descriptive analysis, and volatiles were measured by gas chromatography mass spectrometry (GCMS). At 4°C, enzymatic bleaching of fluid whey and retentate resulted in higher bleaching efficacy than chemical bleaching with HP alone ($P < 0.05$). Due to concentrated levels of naturally present lactoperoxidase, retentate bleached to completion (>80% norbixin destruction) in less than 10 min. In fluid whey, the addition of Maxibright increased the rate of enzymatic bleaching ($P < 0.05$), from 6 to 2 h for 80% norbixin destruction. Percent norbixin destruction by HP was 11% (after 24h) and 90% (after 1h) in fluid whey and retentate, respectively. Bleached wheys and retentates had decreased sweet aromatic and cooked/milky flavors compared with unbleached controls. Wheys and retentates bleached chemically by HP displayed sulfur flavors not present in enzymatically bleached samples. Volatile compound results were consistent with sensory analysis. These results suggest that enzymatic bleaching may be a viable and desirable alternative to HP bleaching.

Key Words: bleaching, whey, lactoperoxidase

M96 The effect of milk pasteurization temperature on the bleaching of fluid whey.

E. Kang* and M. A. Drake, *North Carolina State University, Raleigh.*

Chemical bleaching is a commonly applied unit operation in whey protein processing that negatively influences whey protein flavor. Recent studies have shown that native milk lactoperoxidase (LP) is active in cheese whey and can be used to bleach annatto colored fluid whey. A low concentration of hydrogen peroxide (10–50 ppm) is required for LP activity. When excess concentrations of HP (>100 ppm) are applied, LP is inactivated and HP chemical bleaching occurs. Fluid milk can be subjected to a wide range of heat treatment before cheese manufacture and heat treatment may influence subsequent whey bleaching efficacy. The objective of this study was to investigate the effect of milk pasteurization temperature on the bleaching efficacy of fluid whey. Milk was pasteurized at 63°C for 30 min (LHT) or 79°C for 20 s (HHT) and colored Cheddar whey was produced and fat separated. LP activity (LHT) or inactivation (HHT) was determined by a colorimetric assay. Hydrogen peroxide was then added at 250 ppm (chemical bleaching) or 25 ppm (LP bleaching) at 35 or 50°C and aliquots were collected after 10, 20, or 60 min. Unbleached colored wheys was used as a control. Norbixin extraction and quantification as well as b* values were measured to determine bleaching efficacy. The norbixin content of HHT whey was 82% lower than that of LHT ($P < 0.05$), and the protein content was decreased by 22% for HHT whey compared with LHT whey. Whey from LHT had a higher bleaching efficacy ($P < 0.05$) from 25 ppm HP (80% norbixin destruction) than 250 ppm HP (10% norbixin destruction) at 35°C and 50°C, consistent with LP activity. Bleaching of whey from HHT was lower than LHT in all treatments and there were no differences ($P > 0.05$) between 25 and 250 ppm HP (1.2% norbixin destruction). Regardless of milk pasteurization temperature, greater bleaching was observed with increased time. These results demonstrate the influence of milk heat treatment on bleaching efficacy and also suggest differences in norbixin association with whey components with different milk heat treatment.

Key Words: bleaching, lactoperoxidase, pasteurization

M97 The effect of acidification of retentate on the flavor of spray-dried whey protein concentrate.

C. W. Park*[1], E. Bastian[2], B. Farkas[1], and M. A. Drake[1], [1]*North Carolina State University, Raleigh,* [2]*Glanbia Nutritionals, Twin Falls, ID.*

Off-flavors in whey protein negatively influence consumer acceptance of whey ingredient applications. Clear acidic beverages are a common application of whey protein and recent studies have demonstrated that beverage processing steps, including acidification, enhance off flavor production from whey protein. The objective of this study was to determine the effect of pre-acidification of whey protein retentate before spray drying on flavor of dried whey protein concentrate (WPC). Cheddar cheese whey was manufactured, fat-separated, pasteurized, bleached (250 ppm hydrogen peroxide), and ultrafiltered (UF) to 80% protein retentate, 13% solids (wt/wt). The liquid retentate was then acidified using a blend of phosphoric and citric acids to the following pH values: no acidification (pH 6.5), pH 5.5, or pH 3.5. UF permeate was added to pH 5.5 and pH 6.5 retentates to dilute the protein to the same level as the pH 3.5 retentate (74% protein retentate, 13% solids (wt/wt)). The retentates were then spray dried. The experiment was replicated 3 times. Flavor and volatiles of the WPC74 were evaluated by sensory and instrumental analyses, respectively. Each WPC74 ($n = 9$) was rehydrated to 10% solids (wt/vol) and adjusted to each of the pH values (6.5, 5.5, or 3.5). Both main effects (pH 6.5, 5.5, and 3.5 before spray drying) and interactions between treatments and final pH when evaluated were investigated. Pre-acidification to pH 3.5 resulted in decreased cardboard flavor and aroma intensity and an increase in soapy flavor ($P < 0.05$) with decreased concentrations of lipid oxidation products hexanal, nonanal, decanal, as well as the protein degradation products dimethyl disulfide and dimethyl trisulfide ($P < 0.05$). Adjustment to pH 5.5 before spray drying increased cabbage flavor ($P < 0.05$) and increased the concentration of the protein degradation product dimethyl trisulfide ($P < 0.05$). The effects of pre-acidification were consistent regardless of the pH the solutions were adjusted to after spray drying. These results demonstrate that acidification of WPC80 retentate before spray drying decreases off flavors compared with acidification of spray dried WPC.

Key Words: whey protein, flavor, acidification

M98 Sensory properties and composition of permeate and permeate fractions.

K. Frankowski* and M. A. Drake, *North Carolina State University, Raleigh.*

One of the major contributing factors to hypertension in the US is from the amount of sodium in the American diet. Many food companies are trying to limit the amount of sodium in their products. Permeate, the liquid remaining after whey or milk is ultrafiltered, has been suggested as a salt substitute. It has not been established what component(s) of permeates contribute to sodium replacement or if permeates exhibit salty taste. The objective of this study was to determine the sensory properties of permeates and their composition with a specific focus on organic acids and mineral composition. Eighteen milk or whey permeates and permeate fractions were obtained in duplicate from commercial facilities. Proximate analyses and specific mineral contents were determined. Descriptive analysis of permeates, fractions and model solutions was conducted using a trained sensory panel. Organic acids were extracted and separated and quantified by high performance liquid chromatography (HPLC). Milk and whey permeates were characterized by cooked/milky and brothy flavors, sweet taste and low salty taste. Permeates with lactose (DLC) removed were distinctly salty. Sensory tests with sodium chloride solutions confirmed salty taste of DLC and the low salty taste of permeates were not solely due to the sodium concentration present. Lactic and citric acids and minerals were higher in DLC compared with milk or whey permeates, concurrent with increased salty taste. These results demonstrate that organic acids and minerals enhance salty taste in permeates.

Key Words: permeate, lactose, sodium reduction

M99 Effect of SO-TEC clear whey on physico-chemical characteristics of Cheddar cheese and its whey.

A. C. Biswas* and L. E. Metzger, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Annatto is a color extract that is widely used to produce colored cheddar cheeses. Approximately 15 to 20% of the annatto added to the cheese milk partitions into the whey, which gives it an undesirable yellow color that is bleached chemically or enzymatically. However, bleaching can generate off flavors and a reduction in the nutritive and functional value of proteins. Recently, SO-TEC Natural Cheese color NCC22000, a patent-pending proprietary color formulation, was developed. This cheese color is prepared by encapsulating a blend of red and yellow fat-soluble carotenoid colors of paprika and β-carotene. This color is claimed to be selectively entrapped within the cheese curd with none of the color being carried into the whey stream. Consequently, using this color, cheddar cheese can be produced while generating an uncolored whey stream. The objective of this study was to characterize the physicochemical properties of cheddar cheese and its whey manufactured using SO-TEC cheese color. Three replicates of 3 treatments of cheddar cheese were produced in this study. The treatments were: a control with no color addition (NC); annatto color (AC) addition at 0.007% of milk weight; and SO-TEC NCC22000 color (STC) at 0.056% of the milk weight. The whey from each treatment was separated, pasteurized, and analyzed for color and compositional analyses. There were no significant differences ($P > 0.05$) in whey composition (fat, protein, total solids, and ash) or cheese composition (fat, protein, total solid, ash, and salt) among the treatments. The color of the STC cheese and AC cheese were similar. The L*, a*, and b* values were 74.27, 14.92, and 56.05, respectively, for the STC cheese and 74.34, 13.16, and 50.89, respectively, for the AC cheese. There were no significant ($P > 0.05$) differences in the color of the STC whey and the NC whey and both of these treatments had a significantly ($P < 0.05$) higher L* value and a significantly ($P < 0.05$) lower a* and b* value compared with the AC whey. The whey produced from SO-TEC Natural Cheese color NCC22000 has a color identical to uncolored cheese whey and would not need to be bleached to remove undesirable yellow/orange color.

Key Words: cheese color, no-color whey, cheddar cheese

M100 Effectiveness of ultrasonication in inactivating spores of *Bacillus* spp. in skim milk. S. Khanal*[1], S. Anand[1], and K. Muthukumarappan[2], [1]*Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings,* [2]*Agricultural and Biosystems Engineering Department, South Dakota State University, Brookings.*

Bacterial spores are resistant to pasteurization and may affect quality of milk products. They are known to form biofilms within dairy processing environments. Non-thermal processes such as high pressure, and pulse electric field have been tried to inactivate spores but with a limited success. In this investigation, effect of ultrasonication has been studied on spores of 3 *Bacillus* species, commonly isolated from thermally processed dairy products. Spores of *Bacillus coagulans* (ATCC 12245), *B. licheniformis* (ATCC 6634), and *G. stearothermophilus* (ATCC 15952) were produced by 1 to 2 wk of incubation on modified Brain Heart Infusion agar plates. Spores were harvested from plates by washing and centrifugation, followed by heating at 85°C for 10 min to inactivate the vegetative cells. Sterile skim milk samples, spiked with individual spores at an average level of log 5 cfu/mL, were subjected to ultrasonication through a 13 mm probe using a 20 KHz-VC 505 sonicator (Sonics and Material, USA), at 80 and 100% amplitude for 1, 5, and 10 min. Samples were kept in an ice bath during the treatments for temperature control. Ultrasonicated samples were batch pasteurized at 63°C for 30 min to study the combined treatment effect. Experiments with 3 replicates each were repeated twice. Spore counts were compared before and after respective treatments and were found to be significantly different ($P < 0.05$). A maximum of 35, 33, and 49% of *B. coagulans*, *B. licheniformis*, and *G. stearothermophilus* spores were inactivated respectively, by the ultrasonication treatment of 80% amplitude for 10 min. The combined ultrasonication and pasteurization resulted in 50, 40, and 65% reduction of these spores, respectively. No changes were observed in spore morphology or dimensions, as visualized under the scanning electron microscope. From this research, it is evident that the ultrasonication has the limited ability to destroy *Bacillus* spores. The inactivation percentage was increased up to 65 by combining pasteurization with ultrasonication. Among the spores studied, *B. licheniformis* and *G. stearothermophilus* were the most and least resistant, respectively

Key Words: ultrasonication, spores, amplitude

M101 Screening of different enzymes for modification of the enzyme cleaning step of an existing membrane CIP protocol. D. Singh* and S. Anand, *Dairy Science Department, Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Our previous studies revealed that the *Bacillus* species were observed to be most resistant against the cleaning protocol being followed for the entire constitutive microflora isolated from commercial whey concentration membranes. The present investigation was conducted to degrade biofilms by screening of different enzymes (protease, lipase, lactase, α-glucosidase, β-galactosidase) against 24-h-old in vitro biofilms developed by a *Bacillus* isolate using a CDC bioreactor. Data were statistically analyzed using PROC GLM of SAS program with treatment being a fixed effect. The enzyme β-galactosidase was observed to be most effective as it resulted in reductions of 1.71 logs and 0.88 logs under static and dynamic conditions, respectively. Protease and lipase were also found to be effective against embedded cells to some extent. For further evaluations, 3 different approaches were applied to modify the existing CIP protocol. Replacement of existing enzyme cleaning step with only β-galactosidase enzyme (CIP-1) as first modification, against single and mixed species biofilms did not result in any improvement in the effectiveness of the existing CIP protocol. Second approach with modified cleaning conditions (CIP-2) using a narrower range of pH for all the steps, and extended time (60 min) for the enzyme cleaning (step 4) followed by surfactant step (20 min) resulted in greater cleaning efficacy. Third approach (CIP-3) applied a combination of enzymes; protease, lipase, and β-galactosidase to replace the enzyme cleaning step along with modified cleaning conditions as given above. Results revealed increased effectiveness of CIP-3 against *Bacillus* biofilms with cumulative reductions of 3.21 logs as compared with 3.09 logs of existing CIP protocol. Similarly, treatment with CIP-3 against mixed species biofilms resulted in a reduction of 3.86 logs, as compared with the existing CIP reductions of 3.56 logs. Application of CIP-3 on other single and mixed species biofilms also showed a similar trend of effectiveness. It is concluded that the CIP-3 protocol may serve as an effective replacement for the existing CIP protocol.

Key Words: biofilms, CIP, dynamic

M102 Meta-analysis: Impact of corn silage harvest practices on intake, digestion, and milk production by dairy cows. L. F. Ferraretto* and R. D. Shaver, *University of Wisconsin-Madison, Madison.*

A meta-analysis was performed to determine effects of DM content, kernel processing (PROC), and theoretical length of cut (LOC) of whole-plant corn silage (WPCS) on intake, digestion, and lactation performance by dairy cows using a data set composed of 106 treatment means from 24 peer-reviewed journal articles published from 2000 to 2011. Categories for DM content at silo removal and PROC and LOC at harvest were: ≤28% (VLDM), >28% to 32% (LDM), >32% to 36% (MDM), >36% to 40% (HDM), and >40% (VHDM) DM; 1 to 3 or 4 to 8 mm roll clearance or unprocessed; 0.48 to 0.64, 0.93 to 1.11, 1.27 to 1.59, 1.90 to 1.95, 2.54 to 2.86, and ≥3.20 cm LOC. Data were analyzed using Proc Mixed in SAS with WPCS treatments as fixed effects and trial as a random effect. Milk yield was decreased ($P = 0.01$) by 2 kg/d per cow for VHDM. Fat-corrected milk yield decreased ($P = 0.01$) as DM content increased. Total-tract digestibility of dietary starch (TTSD) was reduced ($P = 0.03$) for VHDM compared with HDM and LDM. Processing (1 to 3 mm) increased ($P = 0.001$) TTSD compared with 4 to 8 mm PROC and unprocessed WPCS. Milk yield tended ($P = 0.10$) to be 1.8 kg/cow/d greater, on average, for PROC (1 to 3 mm) and unprocessed WPCS than 4 to 8 mm PROC. An observed interaction ($P = 0.01$) between DM content and kernel processing for TTSD revealed that the mechanical processing of WPCS increased ($P = 0.01$) TTSD for diets containing 32% to 40% DM WPCS but not ($P > 0.10$) VHDM. The LOC of WPCS had minimal effect on any of the parameters evaluated. However, an observed interaction ($P = 0.01$) between LOC and kernel processing for TTSD revealed that kernel processing increased diet TTSD when LOC was 0.93 to 2.86 cm ($P = 0.01$), but not ($P = 0.01$) when ≥3.20 cm LOC. Starch digestibility and lactation performance were reduced for dairy cows fed diets containing WPCS with > 40% DM or WPCS with insufficient kernel processing. Furthermore, kernel processing WPCS to improve starch digestibility is effective across a wide range of DM contents and LOC, but does not overcome adverse effects of very high DM content on TTSD and was ineffective at a very long LOC.

Key Words: corn silage, dairy cow, meta-analysis

M103 Response to different concentrations and sources of dietary protein on blood urea nitrogen concentrations and plasma amino acid utilization for milk production. I. P. Acharya,* D. J. Schingoethe, K. F. Kalscheur, and D. P. Casper, *South Dakota State University, Brookings.*

A trial was conducted to determine the response of feeding 2 different crude protein (CP) concentrations (15% and 17%) and sources [canola meal (CM) and high-protein dried distillers grain (DG)] on blood urea nitrogen (BUN) concentration and plasma amino acid (AA) utilization. Sixteen lactating Holstein cows were used in multiple 4 × 4 Latin squares having a 2 × 2 factorial arrangement of treatments. Each period was 4 wk and blood samples were collected once during wk 4 of each period from tail artery (TA) and mammary vein (MV) 3 h after feeding. Diets were formulated with 15% CP with CM (15CM), 15% CP with DG (15DG), 17% CP with CM (17CM) and 17% CP with DG (17DG). All diets contained 55% forage (50% alfalfa hay and 50% corn silage) and 45% concentrate and approximately 4.1% ether extract. Average DMI (25.2 kg/d) and milk yield (34.2 kg/d) were similar between diets. Concentration of BUN (mg/dL) from TA was higher ($P < 0.01$) for cows fed 17% CP diets than the 15% CP diets (18.1 vs. 14.3), but similar between CM and DG. Concentration of BUN from MV and artery-vein difference (AVD) were different ($P < 0.01$) between CP concentrations but similar between CP sources. Total essential amino acid (EAA) concentrations (μmol/dL) in TA plasma were higher ($P < 0.01$) for cows fed 17% CP diets compared with 15% CP diets (106.1 vs. 91.1), but similar for CM and DG. Branched chain amino acid (BCAA) concentrations (μmol/dL) in TA plasma were higher ($P < 0.01$) for cows fed 17% CP diets compared with 15% CP diets (62.9 vs. 52.0), but similar for CM and DG. Total plasma MV EAA concentrations were higher ($P < 0.01$) for 17% CP diets, but similar between sources. Total EAA AVD (μmol/dL) were higher ($P < 0.05$) for 17% CP diets than for 15% CP diets (33.6 vs. 27.8), but similar between sources. Mammary gland extraction efficiency of EAA indicated that Met was first limiting AA for CM-based diets followed by Lys, Arg, and Phe, while Lys was first limiting for DG-based diets followed by Met, Arg, Glu, and Phe. The order of limiting AA for milk production is altered by protein sources.

Key Words: crude protein, blood urea nitrogen, plasma amino acid

M104 Effects of adjustable and stationary fans with misters on core body temperature and resting behavior of lactating dairy cows in a semi-arid climate. S. D. Anderson*[1], B. J. Bradford[2], J. P. Harner[2], C. B. Tucker[3], J. D. Allen[1], L. W. Hall[1], S. Rungruang[1], E. Rajapaksha[3], R. J. Collier[1], and J. F. Smith[1], [1]*The University of Arizona, Tucson,* [2]*Kansas State University, Manhattan,* [3]*University of California, Davis.*

Cows readily seek shade to reduce solar heat load during high ambient heat. When shade structures are orientated north-south, stationary cooling systems are unable to follow shade as sun angle shifts during the day. The FlipFan Dairy Cooling System (FLFN) employs fans and misters to follow shade by rotating on a horizontal axis and compensates for wind speed. Multiparous, lactating Holstein cows (n = 144) on a commercial dairy in Arizona were cooled by either a system comprised of stationary fans and misters (CTRL) or the adjustable FLFN operated for 16.5 h/d (0830 to 0100 h). Core body temperature (CBT) of 64 cows (4 pens/treatment; 8 cows/pen; 7 d) and resting behavior of 144 cows (4 pens/treatment; 18 cows/pen; 5 d) was collected by intravaginal and leg data loggers, respectively. Cows were allotted to pens based on milk production and DIM. Pen was the experimental unit. Mean temperature-humidity index (THI) during the study was 80.2 (33.0°C and 40.3% relative humidity) and ranged from 76.3 to 84.4. Mean 24-h CBT was lower for cows cooled by FLFN than CTRL (38.9 vs. 39.1 ± 0.04°C; $P < 0.01$). A treatment × time interaction was observed in which CBT of FLFN was 0.4°C lower than CTRL ($P < 0.001$) from 0600 to 0800 h and 1500 to 1600 h. Cows cooled by FLFN spent more time lying down compared with CTRL (9.5 vs. 8.6 ± 0.13 h/d; $P < 0.001$). Cows in the FLFN treatment had more frequent lying bouts than CTRL (12.8 vs. 10.7 ± 0.10; $P < 0.001$). Lower CBT and decreased standing time are consistent with other studies in which ambient heat load was reduced. In a second experiment, isothermal maps representing the shaded area of pens at different times of day were analyzed for differences in THI provided by each cooling treatment. The FLFN provided a lower THI in the morning and evening (5.9 and 1.7%, respectively; $P < 0.001$) and tended to be lower (0.8%) in the afternoon ($P < 0.10$) compared with CTRL. Results suggest that FLFN is more effective than stationary fan systems at decreasing CBT, increasing lying time and bouts, and providing a more desirable microenvironment for cows throughout the day. The FLFN may yield similar results in different housing systems.

Key Words: adjustable fan, body temperature, resting behavior

M105 Evaluation of fc receptor gene variants in cow genomic dna. J. Williams* and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro, North Carolina.*

Genetic differences exist among cows in susceptibility to mastitis. Receptors for the Fc portion of immunoglobulin molecules (FcR) provide an important link between circulating antibody and cellular functions. Cattle possess the 3 classes of immunoglobulin G (IgG) FcR (FcγRI, -II, and -III). Further, activating (CD32a) and inhibitory (CD32b) isoforms of IgG Fcγ receptor (FcγR) II (CD32) have also been identified. Genetic variations in FcR have been identified as risk factors for chronic inflammatory conditions in man. Genetic differences in FcR may affect response to pathogens in cattle. The objective of this study was to detect FcR I, FcR II and their sub isoforms in cows. Blood was collected from 10 lactating cows (8 were 100% Holstein Friesian and 2 Holstein × Jersey). The somatic cell counts (SCC) were recorded. Genomic DNA was isolated from blood stored on FTA cards. Specific primers for FcRI (CD64), FcRII (CD32) and FcRII sub-isoforms were used to amplify Fc receptor genes. A primer for GAPDH was used as a loading control. Amplified products were separated on a 1% agarose gel and observed following staining with ethidium bromide. Genes encoding FcRI and FcRIIc were detected in all cows. The activating (FcRIIa) and inhibitory (FcRIIb) respectively were detected only in Holstein × Jersey crossbred cows regardless of SCC. Further studies are needed to evaluate the effect of FcR gene polymorphism on the cellular response in cattle.

Key Words: fc receptor, crossbreed, genetic variation

M106 Quantitative calcium determination from an ashed feed sample. D. J. LaMay,* J. L. Squire, K. D. Baldock, and D. L. Smith, *Eastern New Mexico University, Portales.*

Advances in technology have continued to improve the speed and quality of feed analyses. This protocol is a quantitative spectrophotometric method of determining calcium in an ashed feed sample. Hydrochloric acid (HCl) aids in the release of calcium bound to other molecules; while O-Cresolphthalein Complexone binds calcium ions in an alkaline medium, and 8-Hyrdroxy-quinoline binds magnesium ions to eliminate their interference. To maintain an alkaline pH, 2-amino, 2-methyl, 1-propranol (AMP) is used as a buffer. From a stock solution of calcium carbonate, dilutions (0.078, 1.56, 3.13, 6.25, 12.5, 25, and 50 mg/dL) are produced. One gram of ashed feed sample is transferred to a 50 mL conical tube. The crucible is rinsed with 10 mL of 0.1N HCl. Add 0.7 mL of 37% HCl to the tube and vortex for 5 s. Pour the solution into an acid rinsed beaker. Rinse the tube with 10 mL of distilled water into the beaker, then add 479.3 mL of distilled water. Vortex each standard for 5 s, and pipette 50 µL of each standard into 4 wells of a 96-well microplate. The 6.25 and 12.5 mg/dL standards are used as controls. Vortex each control and pipette 50 µL of each. Mix the ash solution and pipette 50 µL of the solution. All the standards, controls, and samples are run in quadruplicate. Pipette 180 µL of color reagent and AMP buffer into all wells. Incubate the plate at room temperature for 10 min on a shaker plate at 318 rpm. The test is analyzed at 630 nm with a background subtraction of 490 nm. The curve fit of the standard dilution is linear and the test samples are compared with these values. Results obtained from Cumberland Valley Analytical Services (CVA) were compared with results obtained from our laboratory (OL), replicated 6 times. Results for Feed Sample A were 0.27 versus 0.28% on a dry matter (DM) basis for CVA versus OL, respectively. Results for Feed Sample B were 3.92 versus 3.94% on a DM basis for CVA versus OL, respectively. Results for Feed Sample C were 0.79 versus 0.76% on a DM basis for CVA versus OL, respectively. These results present validation the quantitative spectrophotometric protocol is an effective and inexpensive method of calcium determination.

Key Words: calcium, ashed feed, spectrophotometric

M107 Cow comfort in dry lots: Lameness, leg injuries and lying times on dairy farms in Texas and New Mexico. A. K. Barrientos*[1], D. M. Weary[1], E. Galo[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada, [2]Novus International Inc., St. Louis, MO.*

The aim of the study was to describe the variation in lameness, leg injuries and lying behavior on dry lot dairies in Texas and New Mexico. Data were collected by the same 2 trained individuals from 35 predominantly Holstein herds. Herd size had on average (±SD) 3056 ± 1047 milking cows. One group of high production multiparous cows was monitored on each farm, with pen size averaging (±SD) 286 ± 177 cows. Cows were gait scored using a 5-point Numerical Rating System where 1 and 2 are considered non-lame, ≥ 3 clinically lame, and ≥ 4 severely lame. Prevalence of knee injuries was recorded based on swollen carpal joints (yes/no). Focal cows (n = 40), randomly selected from the assessment group, were evaluated for hock injuries on a scale of 1 to 5 (1 = healthy and 5 = evident swelling and severe lesion). Electronic data loggers recorded lying behavior of the focal cows at 1-min intervals for 3 d. The analysis was descriptive and all results are presented as means ± SD. Prevalence of clinical lameness averaged 31.7 ± 7.7%; severe lameness averaged 2.0 ± 1.6%. Prevalence of swollen knees averaged 16.8 ± 10.2%. The overall prevalence of hock injuries (≥2) was 18.2 ± 11.0%; the prevalence of moderate-to-severe hock injuries (3, 4, and 5) was 4.7 ± 3.7%, with almost no presence of severe injuries (4 and 5). Lying times were similar across farms, averaging 10.2 ± 0.8h/d, but cows within farms varied from 1.9 to 17.9 h/d. To our knowledge this study is the first to describe the variation in lameness, injuries and lying times in dairy cattle housed in dry lot dairies.

Key Words: dry lot, lameness, leg injuries

M108 The effect of temperature on performance of Keto-Test strips. J. Shire*[1], J. L. Gordon[2], and E. L. Karcher[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada.*

Ketosis is estimated to affect 15% of early lactation dairy cows. The Keto-Test (Elanco Animal Health, Greenfield, IN) offers producers an easy test to determine the concentration of β-hydroxybutyrate (BHBA) in milk and track herd incidence of ketosis. The objective of this study was to determine the effect of altering temperature at time of test on the reliability of the Keto-Test. A total of 116 Holstein cows, ranging from 5 to 17 DIM, were selected from a commercial Holstein dairy herd in Michigan. A milk sample was collected from one quarter of each cow during the AM milking. Each sample was tested under 4 temperature treatment conditions, A: Keto-Test strips and milk at room temperature (RT, 24.0°C ± 0.1; control, manufacturer's recommendations); B: cold strips (10.8°C ± 0.9) and milk at RT; C: cold strips and fresh milk; D: strips at RT and fresh milk. Blood samples were collected immediately following milk collection and analyzed for BHBA concentration using a Precision Xtra meter (Abbott Laboratories, Abbott Park, IL). Cows with BHBA of ≥ 1400 μmol/L were considered positive for subclinical ketosis. Accuracy of the Keto-Test strips under the 4 conditions was determined by the kappa coefficient of agreement, using the result of treatment A as the control. Additionally, sensitivity and specificity were calculated using the blood BHBA concentrations and results of the treatment A. Using the Keto-Test 60.2% of cows tested negative for milk BHBA, 24.6% tested weak positive, 14.4% tested positive, and 0.8% tested highly positive. The weighted kappa coefficient of agreement between the control test (A) and tests B, C, D and 95% lower and upper confidence intervals were: test B = 0.71 (0.62, 0.80), test C = 0.69 (0.60, 0.78), and test D = 0.63 (0.54, 0.73). These results indicate good agreement between the outcome of the treatment A and tests B, C, and D. The sensitivities/specificities for A, B, C, and D are as follows: 0.70/0.81, 0.68/0.77, 0.60/0.88, and 0.58/0.87 indicating that the test in all temperature conditions had a strong ability to detect the presence of BHBA in milk. In conclusion, the reliability of the Keto-Test strips was not dependent on the temperature of the milk or the strips.

Key Words: BHBA, ketosis, Keto-Test

M109 Effects of prepartum grouping strategy on immune parameters of peripartum dairy cows.

P. R. B. Silva*[1,2], J. G. N. Moraes[1,2], L. G. D. Mendonça[1], A. A. Scanavez[1], G. Nakagawa[1], M. I. Endres[2], M. A. Ballou[3], and R. C. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [2]Department of Animal Science, University of Minnesota, St. Paul, [3]Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Objectives were to evaluate the effect of an "all-in-all-out" (AIAO) prepartum grouping strategy on immune parameters of Jersey cows. Cows (254 ± 7 d of gestation) were paired by gestation length and assigned randomly to an AIAO or control (CON) treatment. In the AIAO treatment groups of 44 cows were moved into a pen where they remained for 5 wk, whereas in the CON treatment approximately 10 cows were moved into a pen weekly to maintain stocking density (44 cows for 48 headlocks). Pens were identical in size and design and each of the pens received each treatment a total of 3 times, totaling 6 replicates and 259 and 308 cows enrolled in the AIAO and control treatments, respectively. Blood was sampled weekly from d-14 to d 14 from a subgroup of cows (n = 34/treatment) to determine neutrophil phagocytosis (PHAGO), oxidative burst (OXID), and expression of CD18 and L-selectin and for hematology. Data were analyzed by MIXED procedure with the fixed effect of treatment (AIAO vs control) and random effects of pen by replicate and cow by pen by replicate. Among the subgroup of cows evaluated for immune parameters no differences between treatments were observed in percentage of male calves ($P = 0.81$) and twins ($P = 0.57$) or incidence of retained fetal membranes ($P = 0.71$) and metritis ($P = 0.43$). Percentage of neutrophil positive for OXID ($P = 0.91$) and intensity of OXID ($P = 0.94$) were not different between treatments. Similarly, no differences were observed between treatment regarding percentage of neutrophil positive for PHAGO ($P = 0.98$) and intensity of PHAGO ($P = 0.91$). In addition, percentages of neutrophil expressing CD18 ($P = 0.17$) or L-Selectin ($P = 0.83$) were not different between treatments. Number of leukocytes ($P = 0.64$), neutrophils ($P = 0.33$), and lymphocytes ($P = 0.80$) were not affected by treatment. Cows submitted to an AIAO prepartum grouping strategy had similar innate immunity and hematological parameters compared with cows submitted to a conventional prepartum grouping strategy.

Key Words: prepartum dairy cow, grouping strategy, immune parameters

M110 Detection of clinical and subclinical mastitis using reticulorumen temperatures.

A. E. Sterrett,* K. N. Brock, B. I. Kiser, J. D. Clark, D. L. Ray, and J. M. Bewley, *University of Kentucky.*

The objective of this study, conducted at the University of Kentucky Coldstream Dairy from September 15, 2011, to February 1, 2012, was to examine the relationship between changes in reticulorumen temperature (RT) and subclinical and clinical mastitis. The DVM Systems, LLC (Boulder, CO) bolus system monitors RT using a passive RFID transponder (Phase IV Engineering, Inc., Boulder, CO) equipped with a temperature sensor queried twice daily by a panel reader placed in parlor entrances. A composite milk sample was obtained from each cow in the herd every 14 d for SCC analysis (Fossomatic FC somatic cell counter, Foss, Hillerød, Denmark). Subclinical mastitis events were established by SCC >200,000 cells/mL. Milkers recorded clinical mastitis events. Data were analyzed using SAS (Cary, NC). Reticulorumen temperatures <38.9°C were interpreted as erroneous reads, likely from water intake before entering the parlor, and were eliminated from the data set. Reticulorumen temperatures were adjusted for the change in herd RT at each milking to account for the effect of changing ambient conditions and diurnal variation. A 30-d rolling mean baseline RT was calculated along with the number of SD from which each respective RT varied from this baseline. The maximum RT and number of SD among all RT within the previous 10 d were used as a baseline to assess whether a RT alert was observed for mastitis and high SCC events. Using alert levels of >2 SD and >3 SD within 10 d of a mastitis event, alerts occurred for 47% (n = 7) and 33% (n = 5) of clinical mastitis events, respectively (n = 15). Using alert levels of >2 SD and >3 SD within 10 d of a high SCC event, alerts occurred for 23% (n = 10) and 5% (n = 2), respectively. Across all RT (n = 23,298), 11% (n = 2491) were >40°C. Using alert levels of RT >40°C, alerts occurred for 80% (n = 12) and 50% (n = 22) of clinical mastitis and high SCC events, respectively. Reticulorumen temperature may be an indication of subclinical and clinical mastitis, but natural variation may limit the utility of a RT monitoring system.

Key Words: mastitis, reticulorumen, temperature

M404 Effect of precision processing barley grain on dry matter intake, milk production, rumen pH and nutrient digestibility in lactating dairy cows.

N. Schlau*[1], L. Duineveld[1], W. Z. Yang[2], T. A. McAllister[2], and M. Oba[1], *[1]University of Alberta, Edmonton, AB Canada, [2]Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB Canada.*

The objective of this study was to evaluate the effects of precision processing (processing based on kernel size and volume weight) barley grain on rumen fermentation and productivity of lactating dairy cows. Twenty multiparous lactating Holstein cows including 8 ruminally cannulated cows were used in a replicated 4 × 4 Latin square design with 21-d periods. Cows were fed diets containing light barley grain (52.8 kg/hL) processed using a narrow roller setting (LIGHT, processing index (PI) = 80.2); heavy barley grain (68.6 kg/hL) processed using a wide roller setting (HEAVY, PI = 76.4); light and heavy barley grain precision processed and mixed equal proportions (PP, PI = 76.3); or light and heavy barley grain mixed equal parts then processed at a single narrow roller setting (industry standard; CON, PI = 82.9). All diets consisted of 40%

barley grain, 40% barley silage, and 20% of a supplement premix. There were no treatment effects between LIGHT and HEAVY or PP and CON on DMI (24.0 vs. 23.9 kg/d and 24.7 vs. 23.5 kg/d, respectively), rumen pH (6.13 vs. 6.25 and 6.20 vs. 6.07, respectively), rumen metabolites or sorting index. Digestibility of DM, OM, CP, starch, and NDF were unaffected by treatment. Milk yield was not different between LIGHT and HEAVY or PP and CON (28.8 vs. 28.3 kg/d and 28.6 vs. 28.9 kg/d, respectively); nor was milk fat, protein, and lactose. MUN was higher for cows fed the PP diet compared with those fed the CON diet (11.0 vs. 10.4 mg/dL; *P* = 0.02) and for cows fed the LIGHT diet compared with those fed the HEAVY diet (11.6 vs. 10.7 mg/dL; *P* = 0.05), which can be attributed to the differences in starch availability in the rumen and amount of N captured by rumen microbes for protein synthesis. These results suggest that precision processing barley grain may not drastically affect rumen fermentation or productivity in dairy cows. Previous research on beef steers showed that precision processing barley grain improves nutrient digestibility without affecting rumen pH. Different responses between dairy and beef cattle might be explained by the difference in the level of barley grain in the diet.

Key Words: rumen acidosis, precision process, barley grain

Graduate Student Competition: ADSA Production Division Poster Competition, PhD Division

M111 Effects of energy supplementation for pasture forages on in vitro ruminal fermentation in continuous cultures. C. T. Noviandi*[1], M. N. McDonald[1], D. R. ZoBell[1], J.-S. Eun[1], M. D. Peel[2], and B. L. Waldron[2], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Forage and Range Research Laboratory, USDA-ARS, Logan, UT.*

Eight dual-flow continuous culture fermentors (700 mL) were used to assess effects of energy supplementation [no concentrate, 30% ground corn, or 30% dried distilled grains with solubles (DDGS)] with 4 pasture forages [tall fescue (TF) without N fertilizer (TF-NF), TF with N fertilizer (TF+NF), TF-alfalfa mixture, and TF-birdsfoot trefoil mixture (TF+BFT)] on in vitro ruminal fermentation and N utilization. Twelve dietary treatments were tested in a completely randomized design with a 3 (energy supplements) × 4 (pasture forages) factorial arrangement. Each culture fermentor was offered a total of 15 g DM/d. Forages were supplied in 4 equal portions at 0600, 1200, 1800, and 2400 h, while energy supplements were fed in 2 equal portions at 1200 and 2400 h. Three replicated runs lasted 10 d each, with the first 7 d allowed for microbial adaptation to the diets, and 3 d for sampling. Average daily culture pH was affected by energy supplementation ($P < 0.05$), but not by forage, ranging from 5.94 to 6.44. Energy supplementation increased total VFA concentration ($P < 0.01$). Corn supplementation resulted in greater VFA concentration in the TF+NF compared with DDGS supplementation, whereas the DDGS supplementation increased VFA concentration in the TF+BFT compared with corn supplementation ($P < 0.05$), leading to an interaction between energy supplements and pasture forages ($P < 0.01$). However, corn supplementation resulted in greater total VFA concentration than DDGS (43.4 vs. 41.5 m*M*). Decreases in ruminal ammonia-N concentration, methane production, and acetate-to-propionate ratio were observed when corn or DDGS was added into diets ($P < 0.01$). These results indicate that supplementing pasture forages with corn or DDGS enhanced microbial assimilation of ammonia-N and shifted metabolic pathways of microbial fermentation. Supplementation of corn in the TF+BFT elicited a similar ammonia-N concentration as the corn supplemented in the TF+NF. Therefore, grass-legume mixtures would be a sustainable component in grass grazing systems to improve N utilization efficiency with appropriate energy supplementation.

Key Words: continuous cultures, energy supplementation, pasture forage

M112 Evaluation of feed delivery methods for prepubertal dairy heifers during the growing period. T. S. Dennis,* J. E. Tower, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

The objective of this study was to evaluate effects of feed delivery method on growth, dry matter intake (DMI), feed efficiency, and rumen fermentation characteristics of prepubertal dairy heifers during the growing period. Ninety Holstein heifers (179.1 ± 29.9 kg, 171 ± 26 d of age) were randomly assigned to 1 of 15 pens by body weight (BW). Treatment diets contained 56% forage and 44% grain mix (DM basis) and were delivered using a hay feeder and grain bunk (HF), forage and grain fed side-by-side in a bunk (SBS), or a total mixed ration (TMR) for 98 d. Heifers were weighed every 2 wk, and hip and withers heights and heart girth circumference (HGC) were measured monthly. Blood and rumen fluid were collected at the beginning, middle, and end of the study to measure plasma urea N, plasma glucose, and rumen NH_3 and volatile fatty acids (VFA). Data were analyzed as repeated measures using PROC MIXED of SAS with pen as the experimental unit. Feed delivery method affected final BW, as HF heifers were 11.1 kg and 9.7 kg heavier than SBS and TMR heifers ($P < 0.01$ and $P < 0.01$), respectively. Average daily gains were lower for SBS ($P < 0.05$) and tended to be lower for TMR ($P < 0.10$) compared with HF, averaging 0.75, 0.78, and 0.87 kg/d, respectively. Average DMI was greater for HF compared with SBS and TMR (8.2, 7.7, and 7.7 kg/d, respectively; $P < 0.01$), resulting in similar gain:feed between delivery methods overall ($P > 0.10$). Heifers fed using HF had greater HGC than SBS ($P < 0.05$) and tended to have greater HGC than TMR ($P < 0.10$); however, hip and withers heights were not affected by delivery method ($P > 0.10$). Heifers fed using SBS had increased acetate and butyrate concentrations on d 42 ($P < 0.05$), resulting in increased total VFA concentrations on d 42 ($P < 0.05$). Acetate and butyrate concentrations were similar for HF and TMR throughout the study ($P > 0.10$). Blood metabolites, rumen pH, and rumen NH_3 were not affected by delivery method ($P > 0.10$). Results from this study showed that component feeding using a hay feeder increased ADG; however, the manner of feed delivery did not affect feed efficiency or growth in prepubertal dairy heifers.

Key Words: dairy, heifer, feed delivery

M113 Prediction of pregnancy outcome using machine learning algorithms. S. Shahinfar*[1], K. Weigel[1], D. Page[2], J. Gunter[1], V. Cabrera[1], and P. Fricke[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]Department of Biostatistics and Medical Informatics, and Department of Computer Science, University of Wisconsin-Madison, Madison.*

On a daily basis making decisions about whether or not to breed a given cow and knowledge about expected outcome outcome of the breeding would have an economic impact on profitability of breeding program and net income of the farm. The outcome of each breeding can be affected by many management and physiological factors that vary between farms. Machine learning algorithms offer a great opportunity with regard to problems of multi co-linearity, missing values, or complex interactions among variables (Caravielo et al., 2006). The objective of this study was to develop a user friendly and intuitive on-farm tool to help farmers making decisions about breeding cows. To achieve our goal, we applied several different machine learning algorithms to predict the pregnancy status of each cow after breeding based on phenotypic and genotypic data. Data from 26 dairy farms in Alta Genetics Advantage progeny testing program were used, representing a 10-year period from 2000 to 2010. Reproduction, production, health events, and breeding values of cows and sires were extracted from an on-farm dairy management software and USDA-AIPL databases. The edited data set consisted of 195128 breeding records for multiparous lactation dairy cows, and each of record had 38 potential explanatory variables. Naïve Bayes classifier, Bayesian network, and bagging with RepTree were applied to the data. Among all of these methods, bagging had the best performance with 0.697, area under the ROC curve and 0.665 precision. Naïve Bayes and Bayesian network had 0.599 and 0.615 area under ROC curve respectively. An Information base variable selection procedure identified Mean conception rate in last 3 mo in herd, period, DIM at breeding, past times breed, current times breed and calving interval as the most effective explanatory variable in predicting pregnancy outcome.

Key Words: machine learning, bagging, fertility

M114 Genes for lysine catabolism in lactating dairy cows are responsive to postruminal lysine supply.

H. A. Tucker*[1], M. D. Hanigan[2], J. Escobar[3], P. H. Doane[4], and S. S. Donkin[1], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [3]Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg, [4]Archer Daniels Midland Company, Decatur, IL.*

Lysine supply is potentially limiting for milk protein production in dairy cows. The availability of lysine to the mammary gland and other tissues is a function of the quantity of metabolizable lysine and hepatic lysine catabolism. This experiment evaluated the effect of increased postruminal lysine supply on expression of aminoadipate semialdehyde synthase (AASS), a committing step in lysine catabolism in liver, and ornithine transcarbamoylase (OTC) and argininosuccinate synthase (ASS), key urea cycle enzymes. Eight multiparous early lactation Holstein cows were utilized in a replicated 4 × 4 Latin square. Cows were fed a lysine-limited ration and infused post-ruminally with 0, 9, 27 or 63 g/d of lysine. Periods consisted of a 10-d washout phase followed by 10 d of lysine infusion. On the last day of infusion liver samples were collected for mRNA analysis and blood samples were collected for analysis of blood urea nitrogen, amino acids, and α-aminoadipic acid. Milk protein percent was increased ($P < 0.05$) with infusion of lysine (2.53 vs. 2.68 ± 0.05% for 0 and 63g/d lysine). Blood urea nitrogen decreased ($P < 0.05$) with infusion of lysine (11.4 vs. 10.8 ± 0.4 mg/dL for 27 and 63 g/d lysine). Plasma lysine increased ($P < 0.01$) with lysine infusion (39.5, 45.8, 60.7 and 68.7 μM for 0, 9, 27, 63 g/d lysine). Plasma α-aminoadipic acid concentration increased ($P < 0.05$) with lysine infusion (2.9 vs. 4.7 ± 0.4 μM for 27 and 63 g/d lysine). Expression of OTC and ASS did not differ with increased postruminal lysine. Expression of AASS resulted in numeric differences between 0 and 63 g/d lysine (0.50 vs. 1.38 ± 0.44 arbitrary units, respectively), but were not significant ($P > 0.05$). These data indicate responsiveness of milk protein synthesis to lysine and suggests changes in amino acid and nitrogen metabolism in liver in response to postruminal lysine supply in early lactation dairy cows.

Key Words: lysine, gene expression, postruminal infusion

M115 Evaluation of rumen protected lysine supplementation to lactating dairy cows consuming increasing amounts of DDGS.

H. A. Paz*[1], M. de Veth[2], R. Ordway[2], and P. J. Kononoff[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]Balchem Corp., New Hampton, NY.*

Twenty multiparous Holstein cows were used in 4 5 × 5 Latin squares to determine the effects of feeding increasing amounts of dried distillers grains plus solubles (DDGS) in diets with or without the supplementation (60 g/d) of a rumen protected Lys (RPL) product (AminoShure-L; L-Lysine 38%) on milk yield and composition and plasma concentration of AA. Dietary treatments were (1) Control, (2) 10% DDGS (10DDGS), (3) 20% DDGS (20DDGS), (4) 10% DDGS+RPL (10DDGSRPL), and (5) 20% DDGS+RPL (20DDGSRPL). Basal diets were formulated using the CPM Dairy model (v3.0) to provide a predicted decreasing supply of Lys, 117, 99, and 91% of requirement for the Control, 10DDGS, and 20DDGS diet, respectively. Periods lasted 21 d with the last 3 d for data collection. Compared with cows fed the Control diet, cows fed diets with DDGS had a similar DMI (25.2 vs. 25.4 ± 0.04 kg/d; $P = 0.14$), milk yield (30.1 vs. 30.9 ± 0.11 kg/d; $P = 0.11$) and composition except for protein percentage which was higher (3.15 vs. 3.21 ± 0.03%; $P = 0.03$) and resulted in higher (0.94 vs. 1.00 ± 0.05 kg/d; $P = 0.04$) protein yield by cows fed diets with 20% DDGS. Supplementation of basal diets with RPL had no effect on milk production or composition. Compared with an expected DMI of 23.3 kg/d and milk yield of 38.5 kg/d, cows had a greater intake and lower milk production across diets, which resulted in diets that were predicted to supply sufficient amounts of Lys (140, 118, 104% of requirement for the Control, 10DDGS, and 20DDGS diet, respectively). Plasma concentration of Lys decreased (11.8%; $P = 0.01$) as DDGS inclusion increased and supplementation with RPL did not change Lys concentration. For other essential AA, plasma concentrations of cows fed diets with DDGS were lower ($P \leq 0.05$) for His and Val (8.62 ± 0.03 and 40.62 ± 0.01 μg/mL) and greater ($P \leq 0.01$) for Met (4.27 ± <0.01 μg/mL) compared with cows fed the Control diet (9.50 ± 0.03, 44.38 ± 0.01, 3.47 ± <0.01 μg/mL; respectively). Overall, inclusion of DDGS increased the yield of milk protein and when combined with RPL resulted in no response in milk production parameters suggesting that Lys was not the first limiting AA.

Key Words: dairy cow, dried distillers grains plus solubles, rumen-protected Lys

M116 Integrating nutritional and reproductive models to improve reproductive efficiency in dairy cattle.

S. L. Shields*[1], H. Woelders[2], M. Boer[2,3], C. Stötzel[4], S. Röeblitz[4], J. Plöntzke[4], and J. P. McNamara[1], *[1]Department of Animal Sciences, Washington State University, Pullman, [2]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Lelystad, the Netherlands, [3]Adaptation Physiology Group, Department of Animal Sciences, Wageningen University, Wageningen, the Netherlands, [4]Computational Systems Biology Group, Zuse Institute Berlin, Berlin, Germany.*

The objective was to integrate 2 existing mechanistic, dynamic models of nutritional and reproductive processes in the dairy cow. The objective of this research model is to be suitable for evaluation of data, concepts, and hypotheses regarding underlying genetic, nutritional, and physiological control of reproduction. A model of metabolism (Molly, UC Davis); which describes metabolism of glucose, amino acids, and fatty acids in tissues at an aggregated metabolic pathway level was integrated with a model of reproductive processes which describes growth and decay of the follicles and corpus luteum, gonadotropin releasing hormone, follicle stimulating hormone, luteinizing hormone, progesterone, estrogen, oxytocin, and prostaglandin F2α over time. The nutritional and reproductive processes are integrated at specific points: glucose, IGF-I, leptin and growth hormone affect rates of follicle stimulating hormone, luteinizing hormone, and follicular growth. Degradation of estrogen and progesterone is a function of metabolic clearance rate (MCR); (MCR progesterone, ng/μl = 2.6455 - 0.1606(DMI)2 - 0.5896(DMI) $r^2 = 0.9964$). Progesterone affects probability of embryo survival (% survival = 51.74 + 4.18 (ng/ml) $r^2 = 0.9943$). Pulse frequency of LH is a function of leptin (LH pulses/8h = 0.591 + 0.0015 (ng/ml)5 - 0.025(ng/ml)4 + 0.144(ng/ml)3 - 0.319(ng/ml)2 + 0.237(ng/ml) $r^2 = 0.65$). The probability of ovulation is a function of dominant follicle diameter (probability, % = 465.6 - 0.72(diam.)3 + 21.1(diam.)2- 180.0 (diam.); $r^2 = 0.99$). Probability of first service conception is a function of IGF1: (prob., % = 11.36 + 10.42(IGF1 ng/ml) $r^2 = 0.97$). Changing energy intake or milk production causes a pattern and direction of response in reproductive processes consistent with literature values. Increased metabolic rate decreases estrogen and progesterone concentration, reduces the ovulatory surge and decreases embryo survival. This research model should be useful to frame specific hypotheses on control of reproductive processes by genetic and nutritional driven mechanisms.

Key Words: systems biology, reproduction, nutrition

M117 Variation of mucosal innate immune genes expression in the gastrointestinal tract of dairy calves fed with or without calf starter during weaning transition.

N. Malmuthuge,* M. Oba, and L. L. Guan, *University of Alberta, Edmonton, AB, Canada.*

Weaning transition is considered as the most critical period in calf management, which causes significant level of stress in animals, and the dietary changes associated with weaning can cause functional and morphological changes in the gastrointestinal tract (GIT). However, how these drastic changes affect immunity of calves and what immune mechanisms help calves dealing with their stress are not fully understood. This study aimed to investigate the expression of mucosal innate immune genes (toll-like receptors and antimicrobial peptides) in the GIT of calves in weaning transition (8 weeks old). Holstein bull calves were assigned to one of 2 diets 2 weeks of age to 8 weeks of age; milk replacer only (MR, n = 4) or milk replacer plus calf starter (MR+S, n = 4), and mucosal tissue samples were collected from jejunum, ileum, cecum and colon at the end of feeding trial. Gene expression data were analyzed using MIXED procedure in SAS and statistical model includes diet and location as fixed effects. Expression of mucosal innate immune genes displayed distinct patterns between 2 feeding regimens. TLR 9 and 10 were differentially expressed among the GIT locations of claves fed MR ($P < 0.05$) whereas TLR 1, 2, 4, 7, 9 and 10 were differentially expressed among the GIT locations of calves fed MR+S ($P < 0.01$). TLR 2, 3, 5 and 6 showed a significantly higher expression in MR+S group than the calves fed MR. However, TLR 4 and 10 showed a significantly lower expression in MR+S calves. β-defensin and peptidoglycan recognition protein 1(PGLYRP1) expressions were observed in both groups of animals without any regional variation except for significantly higher expression of PGLYRP1 in the jejunum than the other GIT regions of MR+S calves (($P = 0.04$). However, β-defensin expression was lower in MR+S calves than MR calves with a significantly lower expression in the cecum, while PGLYRP1 showed a significantly higher expression in MR+S calves than MR calves in all regions except the ileum. Gene expression differences observed in the present study suggest that the consumption of solid feed may affect immune responses of calves and thus possibly determine the capability of calves to deal with stress associated with weaning.

Key Words: gastrointestinal tract, weaning transition, mucosal immunity

M118 Web forums as a method for engagement on contentious issues in dairying: Should dairy calves be separated from the cow within the first few hours after birth?

B. A. Ventura,* M. A. G. von Keyserlingk, C. A. Schuppli, and D. M. Weary, *Animal Welfare Program, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada.*

Over the past few decades the public has become increasingly interested in the welfare of food animals. However, the food animal industries, including the dairy industry, possess few mechanisms for discussion of contentious practices. Here we present results from a web-based forum designed to promote discussion of controversial issues among stakeholders. In the present application we asked participants to respond to the question, "Should dairy calves be separated from the cow within the first few hours after birth"? A total of 163 people participated in 4 independent web forums; 33% were students/teachers, 13% animal advocates, 23% farmers, veterinarians, and industry professionals, and 31% had no involvement in the dairy industry. Overall there was little participant consensus, with 44% choosing "yes," 48% choosing "no," and 9% neutral. Responses varied with demographics, with opposition to early separation higher among females, advocates, and those with no involvement in the industry. Participants were also able to provide reasons in support of their views, with opponents and supporters often referencing similar issues in their reasoning. Opponents of early separation gave reasons such as: it is unnatural, it compromises calf and/or cow physical health, it is emotionally stressful, and the industry can and should accommodate cow-calf pairs. In contrast, supporters of early separation reasoned that it promotes calf and/or cow physical health and production, emotional distress is best minimized by separating before bonds develop, and the industry is limited in its ability to accommodate cow-calf pairs. These results illustrate the potential of web-based forums to identify areas of shared concern and disagreement among stakeholders, providing a foundation to develop practices that satisfy both producer and consumer expectations. More generally, the results suggest that web-based forums can provide a safe platform for much needed discussion on contentious issues in the dairy industry.

Key Words: public attitudes, animal welfare, maternal filial bond

M119 A cluster analysis to describe profitability on Wisconsin dairy farms.

M. Dutreuil*[1], V. E. Cabrera[1], R. Gildersleeve[2], C. A. Hardie[1], and M. Wattiaux[1], [1]*University of Wisconsin-Madison, Madison,* [2]*University of Wisconsin Extension, Dodgeville.*

A survey was implemented on Wisconsin dairy farms to understand the impact of farm management on profitability. Farms were selected across 3 systems: conventional (C), grazing (G) and organic (O). The objective was to characterize main factors associated with profitability. A cluster analysis using complete linkage was conducted on 20 farms as preliminary analysis: 4 O, 4 G and 12 C. The analysis yielded 3 clusters. Cluster 1 included 1 O, 2 G and 6 C farms; cluster 2 included 4 C and 1 G farms; and cluster 3 included 3 O, 1 G and 2 C farms. Clusters 1 and 3 had the same income over feed cost (IOFC, $5.97 and $5.22/d per cow, respectively) whereas cluster 2 had an IOFC of $8.09/d per cow. Farms in cluster 2 had 71 cows and 95 ha and were managed by the youngest farmers (44 years old). They used a ration with 35% grass silage (GS), 1% hay, 18% corn silage (CS) and 46% concentrate (CC). They had the greatest milk production (10,764 kg/cow per year) and the lowest percentage of milk withheld from sale (0.49%). They produced milk with 3.55% fat, 3.03% protein and 203,000 somatic cells (SCC), but received the lowest milk price (0.348$/kg). Farms in cluster 1 had 72 cows and 115 ha and were managed by 49 years old farmers. They used 20% GS, 32% hay, 12% CS and 36% CC in the ration. They had a lower milk production (7,068 kg/cow per year) and more milk withheld (1.65%) than farms in cluster 2. Their milk had 3.78% fat and 2.99% protein with a price of 0.368$/kg. Farms in cluster 3 were the smallest farms with 48 cows and 54 ha and were managed by 49 year old farmers. They used 17% GS, 54% hay, 5% CS and 24% CC in the ration. They produced the least amount of milk (4,146kg/cow per year) and withheld 3.08% of production. They had the greatest milk fat and protein content (4.36% and 3.25%, respectively), the greatest SCC (317,167) and the greatest milk price (0.480$/kg). The 3 clusters contained farms from different systems indicating that management system was not a major descriptor of IOFC. However, this study suggested that IOFC was associated with quantity and quality of milk, percentage of milk withheld, feeding strategy and age of the farmer.

Key Words: cluster analysis, farm profitability, farm management

Growth and Development I

M120 Effect of protein supplementation in the last trimester of gestation in Nellore cows on subsequent growth of their bull calves submitted or not submitted to creep-feeding.

F. M. da Rocha[3], A. V. Pires[2], R. Sartori[2], D. D. Nepomuceno[2], M. V. Biehl*[3], I. Susin[2], E. M. Ferreira[2], M. V. C. Ferraz Junior[3], J. R. S. Goncalves[4], L. H. Cruppe[1], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]University of Sao Paulo, Pirassununga, SP, Brazil, [4]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, PR, Brazil.*

The objective of this study was to evaluate the effect of supplemental protein to Nellore cows in the last trimester of gestation on subsequent growth of their calves, submitted or not to creep-feeding. Cows (n = 227) were assigned to a randomized complete block design. Blocks were balanced for BW (432 ± 50 kg) and BCS (2.85 ± 0.4; 1 to 5 scale). Treatments were arranged in a 2 × 2 factorial. Cows and bull calves were kept on pasture containing 8% crude protein (CP). The treatments were 1 and 2 - cows (n = 119) supplemented with soybean meal (0.5 kg/cow/d) and bull calves in either a creep (1, n = 114) or non-creep feeding program (2, n = 113) and; 3 and 4 - cows not supplemented (n = 108) and bull calves in either a creep (3) or non-creep (4) feeding program. Chemical composition of the creep diet was 22% CP, and 72% TDN. Data were analyzed using GLM procedure of SAS and differences among means were tested using Student's *t*-test ($P < 0.05$). At weaning time, there were no effects of cows prepartum supplementation on ADG and BW of bull calves (0.789 ± 0.16 vs. 0.777 ± 0.17 kg/d and 189.7 ± 34.0 vs. 191 ± 38.1 kg) for supplemented or not supplemented cows, respectively. Bull calves supplemented with creep feeding had greater ($P < 0.01$) ADG (0.842 ± 0.14 vs. 0.725 ± 0.16 kg/d for creep vs. non-creep feeding program, respectively) and BW at weaning (196.0 ± 30.1 vs. 184.6 ± 40.3 kg for creep vs. non-creep feeding program, respectively). In conclusion, supplementation with 0.5 kg of soybean meal in Nellore cows during the last trimester of gestation did not alter subsequent growth of their bull calves. However, the creep feeding increased ADG and BW at weaning in Nellore bull calves.

Key Words: beef cattle, fetal programming, creep diet

M121 Protein supplementation of Nellore cows in the last trimester of gestation and consequent performance of their heifer calves in creep feeding.

D. D. Nepomuceno[2], A. V. Pires[2], R. Sartori[2], F. M. da Rocha[3], M. V. Biehl*[2], I. Susin[2], E. M. Ferreira[3], M. V. C. Ferraz Junior[3], J. R. S. Goncalves[4], F. M. Abreu[1], L. H. Cruppe[1], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]University of Sao Paulo, Pirassununga, SP, Brazil, [4]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, PR, Brazil.*

The objective of this study was to evaluate the effect of supplemental protein to Nellore cows in the last trimester of gestation on subsequent growth of their heifer calves in creep feeding. Cows and their calves were managed on pasture containing 8% crude protein (CP). The cows were assigned to a complete randomized block design. Blocks were balanced for BW (431 ± 49 kg), age (8.9 ± 2.2 years), and BCS (2.8 ± 0.4; 1 to 5 scale). Treatments were arranged in a 2 × 2 factorial. The treatments were designated: 1 and 2 - cows (n = 106) supplemented with soybean meal (0.5 kg/cow/d) and heifer calves in either a creep (1, n = 106) or non-creep (2, n = 103) feeding program or; 3 and 4 - cows not supplemented (n = 103) and heifer calves in either a creep (3) or non-creep (4) feeding program. Chemical composition of the creep diet was 22% CP, and 72% TDN. Data were analyzed using GLM procedures of SAS and differences among treatments means were tested using Student's *t*-test ($P < 0.05$). At weaning time, there were no effects of cow supplementation on ADG and BW of heifer calves (0.677 ± 0.13 vs. 0.664 ± 0.126 kg/d and 168.2 ± 26.0 vs. 170.5 ± 32.8 kg) for supplemented or non-supplemented cows, respectively). Heifer calves supplemented with creep feeding showed greater ($P = 0.01$) ADG (0.708 ± 0.112 vs. 0.632 ± 0.13 kg/d) and BW at weaning (172.7 ± 26.7 vs. 165.8 ± 31.9 kg) than those not supplemented. In conclusion, supplementing 0.5 kg of soybean meal for Nellore cows in the last trimester of gestation did not alter subsequent growth of their heifer calves but ADG and BW at weaning were increased with creep feeding.

Key Words: beef cattle, growth, production systems

M122 Identification of key amino acids associated with fetal skeletal muscle growth in sheep.

F. A. Sales*[1,4], B. P. Treloar[1], D. Pacheco[1], H. T. Blair[2], P. R. Kenyon[2], G. Nicholas[3], M. Senna-Salerno[3], and S. A. McCoard[1], *[1]Agresearch Grasslands, Palmerston North, New Zealand, [2]Sheep Research Centre, Massey University, Palmerston North, New Zealand, [3]Agresearch Ruakura, Hamilton, New Zealand, [4]Instituto de Investigaciones Agropecuarias, Punta Arenas, Chile.*

The role played by free amino acids (FAA) in the regulation of muscle growth during gestation in ruminants is poorly understood. The objective of this study was to compare maternal and fetal plasma and muscle FAA profiles between single and twins fetuses, and to examine the potential association between these profiles and muscle weight from well-fed late-gestation ewes. Single- (n = 9) and twin-bearing (n = 10) ewes, fed ad libitum on pasture were used. At d 140 of gestation ewes were euthanized, maternal and fetal plasma and fetal semitendinosus muscle (ST) collected and stored at −80°C. Reverse phase HPLC was used for FAA determination in plasma and ST muscle. Analysis of variance was used for comparisons of muscle weight and FAA concentration between single and twins and Pearson correlation analysis to estimate the relationship between ST weight and intracellular FAA. Twin fetuses had lighter ST muscles compared with singles (8.6 ± 0.3 g vs. 11.1 ± 0.9 g, $P = 0.02$). Total maternal plasma FAA was similar between single- and twin-bearing ewes ($P > 0.05$). Total fetal plasma FAA was similar between single and twin fetuses ($P > 0.05$). Twin fetuses had lower plasma concentrations ($P < 0.05$) of aspartate, glutamate, citrulline, and ornithine, and higher ($P < 0.05$) concentrations of glutamine and methionine compared with single fetuses. In muscle, lower concentrations of aspartate and threonine, and higher concentrations of citrulline and methionine were found in twins compared with singles ($P < 0.05$). Significant correlations between ST weight and intracellular arginine concentrations were found in both singles ($r = 0.62$, $P = 0.007$) and twins ($r = 0.67$, $P = 0.03$). These results indicate that restricted growth of twins compared with singles may be associated with altered placental AA transport and/or fetal AA metabolism. Observed differences between singles and twins in plasma AA and muscle FAA profiles indicate possible differences in AA transport and/or utilization in muscle. Arginine was the only FAA correlated with muscle mass in both single and twins, indicating that arginine may play an important role in the regulation of muscle growth in the ovine fetus.

Key Words: skeletal muscle, amino acids, sheep

M123 Is placental functionality different between singletons and twins in sheep? D. S. van der Linden* and S. A. McCoard, *Animal Nutrition Team, AgResearch Grasslands Limited, Palmerston North, New Zealand.*

A greater understanding of the factors that regulate placental nutrient transport will help elucidate mechanisms underlying perturbations in fetal growth. This study investigated the relationship between fetal weight and placentome type and size in placentae of singleton and twin fetuses in late pregnancy. In addition, free amino acid (AA) profiles were measured in fetal, umbilical artery and vein plasma using ion exchange chromatography and used as an indicator of placental nutrient transport. Singleton (n = 9) and twin (n = 10) placentae, from ewes offered ad libitum grazing throughout pregnancy were studied at d 140 of pregnancy. Blood samples from each fetus, umbilical vein and artery were collected before being removed from the placenta. Individual placentae per fetus were dissected and placentomes were classed per type and size and placentome number and individual weight were recorded. Data was analyzed using the PROC MIXED procedure in SAS with the fixed effects of birth rank, plasma pool type, their interactions and the random effect of ewe.Twin fetuses were 16% lighter ($P = 0.01$) than singletons, and had a smaller placenta with 28% decreased placentome weight ($P = 0.03$) and 35% fewer placentomes ($P = 0.001$). However, compared with singletons, twins tended ($P = 0.19$) to have a 17% more efficient placenta than singletons. In addition, twins showed a different distribution of placentome type and size compared with placentae of singletons, such that twins showed a greater proportion of type B and light placentomes compared with singletons. Fetal plasma of twin fetuses had 44% lower arginine ($P = 0.03$), 34% lower histidine ($P = 0.02$) and 20% lower leucine ($P = 0.04$) concentrations than singletons. In twins, fetal plasma had 55% lower asparagine ($P = 0.005$) and 47% ($P = 0.03$) higher glutamine (Glu) ($P = 0.03$) concentrations than umbilical artery plasma. No differences in AA concentrations between fetal, umbilical vein and artery plasma were observed in singletons. Glutamine is a major oxidation-energy source for the placenta and the fetal liver is the net producer of Glu. This may indicate that the functionality of the feto-placental unit is different between singletons and twins. In conclusion, individual placentae of twins may differ in functionality and nutrient transport from singletons and more research is warranted to better understand placental nutrient transport and function.

Key Words: placenta, sheep, amino acid

M124 Placental efficiency at birth has no effects on postnatal muscle development. T. A. Wilmoth*[1], C. S. Perkins[2], Z. E. Kerley[2], Z. D. Callahan[2], M. E. Wilson[1], and B. R. Wiegand[2], *[1]West Virginia University, Morgantown, [2]University of Missouri, Columbia.*

By d100 of gestation the populations of primary and secondary muscle fibers have formed. This number changes little after birth and throughout postnatal growth, however the size of these fibers can change, influencing pork quality. Placental function is an important factor in fetal and muscle development. Placental efficiency (fetal weight divided by placental weight) is often a measure of placental function and may impact muscle development during gestation and assumedly at slaughter. The objective of this work was to determine the relationship of placental efficiency to muscle development of the market weight hog. Placental efficiency was determined for each piglet at birth. At 2 mo of age, barrows (n = 19) were individually housed and fed to a final weight of 121 kg. Following a 24 h chill, a 2.5 cm^2 sample of longissimus dorsi (LD) at the 10th rib and semitendonosus (ST) from the middle of the muscle were collected and frozen. Two sections were taken of each muscle type and 2 images of each section were captured. The number and diameter of primary and secondary fiber types were determined by ATPase assay using acid preincubation. From each image 15 primary fibers and 20 secondary fibers were measured for diameter. The GLM procedures of SAS were used to determine Pearson correlation coefficients between variables. The diameter of primary and secondary muscle fibers in LD were positively related ($P < 0.0001$, r = 0.80). The diameter of primary muscle fibers was negatively correlated to the number of secondary muscle fibers in the LD ($P < 0.05$, r = −0.42). As primary fiber diameter increased in the LD, primary and secondary fiber number also increased in the ST ($P < 0.05$, r = 0.62, r = 0.56, r = 0.49, respectively). The number of secondary muscle fibers in LD were negatively correlated to the diameter of secondary muscle fibers in LD ($P < 0.05$, r = −0.40). In ST, the secondary to primary fiber ratio was found to be positively correlated to the diameter of primary fibers (r = 0.39, $P < 0.05$). Placental efficiency, determined at birth, appears to have to no effects on future muscle development of the animal.

Key Words: fiber number, postnatal growth, placental efficiency

M125 Effects of metabolizable protein supply during late gestation on ovine offspring growth and development. C. A. Schwartz*[1], K. R. Maddock-Carlin[1], C. O. Lemley[1], L. E. Camacho[1], W. L. Keller[1], J. S. Caton[1], R. D. Yunusova[1], C. S. Schauer[2], and K. A. Vonnahme[1], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]Hettinger Research Extension Center, North Dakota State University, Hettinger.*

The objective of this study was to evaluate the effects of maternal metabolizable protein (MP) supply on fetal growth in sheep. Multiparous singleton pregnant ewes (n = 18) were randomized to receive 1 of 3 diets that were isocaloric and formulated to supply 60% (MP60), 100% (MP100), or 140% (MP140) of MP requirements during late (d 100 to 130) gestation. Metabolizable protein requirements were calculated as: MP (g/d) = (CP, g/d x (64 + (0.16 x undegraded intake protein of diet)))/100. Pregnant ewes and fetuses were euthanized and necropsied on d 130 ± 1 of gestation. Data were analyzed using PROC GLM of SAS. There was no effect ($P \geq 0.12$) of maternal MP supplementation during late gestation on fetal BW, empty BW, curved crown rump length, heart girth circumference, or adrenal, brain, heart, kidney, lung, pancreas, large intestine, spleen, and stomach weights when expressed as g or as g/g BW. Fetuses from MP140 ewes (8.8 ± 0.4) had increased ($P \leq 0.05$) small intestinal mass (g/g BW) at d 130 compared with fetuses from MP60 (7.3 ± 0.5) and MP100 (7.0 ± 0.5) and ewes. Fetuses from MP60 (21.4 ± 1.59) ewes had increased ($P \leq 0.05$) perirenal fat mass (g and g/g BW) compared with fetuses from MP100 (15.5 ± 1.5) and MP140 (17.2 ± 1.5) ewes. Although all pregnant ewes were provided adequate energy, restricting levels of maternal MP supply during the defined period of gestation increased fetal perirenal fat whereas high levels of MP supply increased fetal small intestinal mass, all while not altering fetal BW.

Key Words: fetal growth, metabolizable protein, ovine

M126 Vascularization in ovine utero-placental tissues during early pregnancy: Effects of assisted reproductive technology (ART). P. P. Borowicz,* L. P. Reynolds, D. A. Redmer, and A. T. Grazul-Bilska, *Department of Animal Sciences, and Center for Nutrition and Pregnancy, North Dakota State University, Fargo.*

Compromised pregnancies can be caused by genetic, epigenetic, environmental and/or other factors. Assisted reproductive technology (ART) has profound effects on placental and fetal development, leading eventually to compromised pregnancy. Development of an adequate blood supply to the placenta, which is regulated by numerous angiogenic factors, is critical to support normal fetal development. We hypothesized that vascular development, reflected by the number, density and size of capillaries, is altered in utero-placental tissues in compromised pregnancies due to ART. Pregnancies were achieved through natural breeding (NAT, control, n = 3), transfer of embryos generated through natural breeding (NAT-ET, n = 7), in vitro fertilization (IVF, n = 4), or in vitro activation (IVA; parthenogenetic clones, n = 4). On d 22 of pregnancy, cross sections of gravid uteri, containing utero-placenta, were collected and fixed for histochemical (hematoxylin and periodic acid Schiff staining) detection of capillaries followed by image analysis to determine the capillary area density (CAD), capillary surface density (CSD, exchange area), and capillary number density (CND) per unit of maternal placental (caruncular) tissue area, as well as area per capillary (APC; i.e., average capillary size).Data were analyzed using the general linear models (GLM) procedure of SAS with the main effect of pregnancy type. Area per capillary (APC) was less ($P < 0.05$) in IVA and IVF vs. NAT or NAT-ET groups (NAT, 203 ± 32; ET, 177 ± 21; IVF, 110 ± 27; IVA, 117 ± 27; μm^2). Capillary number density (CND), CAD and CSD were similar for all pregnancy types. Thus, in sheep, ART affects specifically capillary size, which may reflect altered vascular growth and function of utero-placental tissues. These data provide a foundation for determining the basis for altered vascularization in placental tissues in compromised pregnancies and may help to identify strategies for rescuing placental development in such pregnancies. Supported by Hatch Project ND01712; USDA 2007–01215 to LPR and ATGB, NIH HL64141 to LPR and DAR, and NSF-MRI-ARRA-0959512 to ATGB.

Key Words: sheep placenta, vascularity, early pregnancy

M127 Influence of *Bos indicus* genetics on pregnancy-associated glycoproteins (PAG) and their association with fetal development.

P. M. Mercadante*[1], K. M. Bischoff[2], V. R. G. Mercadante[2], G. C. Lamb[2], and A. D. Ealy[1], [1]*University of Florida, Gainesville,* [2]*University of Florida, North Florida Research and Education Center, Marianna.*

Cross-breeding *Bos indicus* and *Bos taurus* genotypes improves various production traits for cattle maintained in sub-tropical or tropical climates. Pregnancy-associated glycoprotein (PAG) concentrations are influenced by various factors during gestation and recent evidence indicates that *Bos taurus* subspecies impacts concentrations of PAG and fetal size during early gestation. We determined the correlation between maternal genotype, PAG concentrations, and fetal development during early gestation in cattle with distinct subspecies genotypes. A fixed-time AI estrous synchronization protocol with semen of multiple sires within each breed was used on multiparous Angus (n = 17), Brangus (n = 25) and Braford (n = 9) cows. Transrectal ultrasonography was used to measure fetal size at 35 (crown-rump) and 62 d (nose-crown) of gestation. Blood was harvested to determine plasma concentrations of PAG and progesterone (P4). Orthogonal contrasts were used to compare outcomes for cattle containing *Bos indicus* genetics (Brangus and Braford) from those containing solely *Bos taurus* genetics (Angus). Concentrations of PAG tended to be greater ($P = 0.09$) in Angus (5.0 ± 0.5 ng/mL) than Brangus (4.3 ± 0.5 ng/mL) and Braford (3.4 ± 0.5 ng/mL) at d 35 of gestation. At d 62 of gestation, concentrations of PAG tended ($P = 0.09$) to be lower in Angus (2.0 ± 0.4 ng/mL) than Brangus (2.5 ± 0.4 ng/mL) and Braford (3.3 ± 0.4 ng/mL). Concentrations of P4 were not influenced by cow genotype. Concentrations of PAG were positively correlated ($P = 0.01$) with concentrations of P4 at d 35 but not at d 62 of gestation. Cow breed did not affect fetal size at d 35 of gestation(15.5 ± 0.4, 15.4 ± 0.4 and 14.6 ± 0.4 mm for Angus, Brangus, and Braford, respectively), but at d 62 of gestation Angus cows (29.6 ± 0.3 mm) contained larger fetuses ($P \leq 0.01$) than Brangus (28.0 ± 0.3 mm) and Braford (28.4 ± 0.3 mm) cows. No correlation between PAG and fetal size were observed at 35 or 62 d of gestation. In conclusion, cow genotype influenced fetal size on d 62 and tended to influence concentrations of PAG on d 35 and 62. Plasma PAG concentration had a correlation with cow breed and plasma P4 concentrations, indicating that maternal genotype may influence placental activity and early fetal development.

Key Words: PAG, fetal size, cow genotype

M128 Fetal size and pregnancy-associated glycoprotein concentrations are influenced by *Bos indicus* genetics during early gestation.

C. M. Waits,* P. M. Mercadante, S. E. Johnson, A. D. Ealy, and J. V. Yelich, *University of Florida, Gainesville.*

Several gestational events influence newborn calf size and survivability. Subspecies genotype (*Bos taurus* vs. *Bos taurus* × *Bos indicus*) influences fetal development and uteroplacental activity during late gestation and recent evidence suggests it also may affect events of pregnancy in early gestation. The objective of this study was to examine fetal size and plasma pregnancy-associated glycoprotein (PAG) concentrations between Angus and Brangus cows in early gestation. Primiparous and multiparous Angus (n = 43) and Brangus (n = 33) cows were bred by AI to multiple sires within their respective breeds. Transrectal ultrasonography was completed by the same technician on d 33–34, 40–41, 47–48 and 54–55 post-insemination and crown rump length or nose to crown length (d 54–55 only) was recorded. Blood was collected on each occasion, plasma was harvested, and concentrations of PAGs were determined by enzyme immunoassay. Data were analyzed by ANOVA. Fetuses in Angus cows tended to be smaller at d 33–34 than fetuses in Brangus cows (1.29 vs. 1.37 cm; pooled SE: 0.03, $P = 0.06$). Fetus size was not different between genotypes on d 40–41 and 47–48 but nose to crown size was greater for fetuses in Angus than Brangus cows (2.08 vs. 1.95 cm, pooled SE: 0.03, $P = 0.001$). Breed-dependent changes in the rate of fetal growth were also detected. Specifically, the rate of change in fetus size between d 33–34 and 54–55 was greater for fetuses from Angus than Brangus cows (4.14 vs. 3.67 cm, pooled SE: 0.09, $P = 0.003$). Plasma PAG concentrations were less in Angus than Brangus cows at each time point and after averaging PAG concentrations across time points (4.9 vs. 8.2 ng/ml; pooled SE: 0.9, $P = 0.005$). In conclusion, the *Bos taurus* × *Bos indicus* (Brangus) genotype influences fetal size, rate of fetal development, and placental PAG production in the first 8 weeks of gestation in cattle. Such effects may help explain postnatal growth potential for these animals.

Key Words: fetal size, pregnancy-associated glycoprotein, early gestation

M129 Effects of nutrient restriction in beef cows during early gestation on maternal and fetal small intestinal and hepatic mass and in vitro oxygen (O_2) consumption.

L. D. Prezotto,* L. E. Camacho, C. O. Lemley, J. S. Caton, K. A. Vonnahme, M. Kapphahn, M. Van Emon, R. S. Goulart, R. D. Yunosova, T. J. Swanson, and K. C. Swanson, *Animal Science Department, North Dakota State University, Fargo.*

The objectives were to examine the effects of maternal nutrient restriction during early gestation on maternal and fetal small intestinal and hepatic mass and in vitro O_2 consumption. Pregnant multiparous beef cows at d 30 of gestation were randomly assigned to one of 2 treatment groups: 100% NRC (CON; n = 6) or 60% NRC (RES; n = 6) requirements. At d 85 of gestation, animals were slaughtered and fetuses were immediately removed, weighed, and liver and intestine were collected. Maternal liver and jejunal tissues were also collected, and weighed. After collection, fetal and maternal tissues were transported to the laboratory for O_2 consumption analysis. Tissue weight relative to BW (g/kg) in the cow (liver = 7.58 ± 0.7; jej = 2.4 ± 1.5) and fetus (liver = 37.2 ± 3.4; jej = 18.6 ± 1.9), and tissue weight (g) for maternal liver and jejunum (4148.3 ± 462.7; 1270.5 ± 791.5), and fetal small intestine (2.4 ± 0.4), were not influenced ($P > 0.2$) by nutrient restriction. However, fetal liver weight (CON = 4.29 ± 0.27g; RES = 5.1 ± 0.7g; $P = 0.04$) was greater for the RES group. Oxygen consumption per unit of tissue (maternal liver = 1.62 ± 0.52µl/g/hr; maternal jej = 0.87 ± 0.36µl/g/hr; fetal liver = 2.95 ± 0.85µl/g/hr; fetal jej = 0.9 ± 0.3µl/g/hr), total O_2 consumption per tissue (maternal liver = 6729.4 ± 2325.4µl/tissue/hr; maternal jej = 1098.9 ± 780.5µl/tissue/hr; fetal liver = 14.1 ± 5.4µl/tissue/hr; fetal jej = 2.2 ± 0.8µl/tissue/hr), and O_2 consumption relative to BW (maternal liver = 12.28 ± 4.05µl/BW/hr; maternal jej = 2 ± 1.4µl/BW/hr; fetal liver = 110.1 ± 30.1µl/BW/hr; fetal jej = 17.1 ± 5.7µl/BW/hr) were not influenced ($P > 0.2$) by nutrient restriction in maternal and fetal liver and intestine. These data indicate that nutrient restriction in pregnant cows during early gestation increased fetal liver mass at d 85 but did not alter maternal and fetal O_2 consumption in liver and small intestine.

Key Words: oxygen consumption, gastrointestinal tract, gestational nutrition

M130 The effects of intrauterine growth retardation (IUGR) due to poor maternal nutrition on muscle development in lambs.

M. L. Hoffman,* M. A. Rokosa, S. Neupane, K. K. McFadden, S. M. Tornaquindici, S. A. Zinn, and K. E. Govoni, *Department of Animal Science, University of Connecticut, Storrs.*

Recent research has demonstrated that poor maternal nutrition can cause a decrease in carcass quality as the resulting offspring exhibit a reduction in muscle tissue. We hypothesized that lambs experiencing intrauterine growth retardation (IUGR) due to poor maternal nutrition will have decreased muscle development and reduced expression of key genes involved in myogenesis. Ewes pregnant with twins (n = 24) were fed 100% (CON), 60% (RES) or 120% (OVER) of NRC requirements beginning at d 85 of gestation. The offspring were euthanized within 24 h of birth (d 1; n = 3/treatment) or at 3 mo of age (n = 3 to 5/treatment). Animals maintained until 3 mo of age were removed from the ewe and fed a control diet of milk replacer and 18% creep feed. Quadricep muscle was collected immediately following euthanasia for gene expression analysis using real time-reverse transcriptase (RT)-PCR. Data were analyzed using ANOVA with significance considered as $P \leq 0.05$. As reported, BW were reduced in RES lambs by 16% at d 1 and 3 mo ($P \leq 0.05$) compared with CON. There was a tendency for a 2.9 ± 0.1-fold increase in *IGF-I* mRNA expression in RES animals at d 1 ($P \leq 0.18$) but not at 3 mo ($P \geq 0.90$). A difference in *IGF-I* mRNA expression was not observed in OVER lambs at d 1 or 3 mo ($P \geq 0.76$). We did not observe an effect of poor maternal nutrition on the expression of markers of muscle development, *myogenin, myogenic regulatory factor-5* (*myf-5*) and *paired box protein-7* (*PAX7*), at either time point ($P \geq 0.32$). In addition, we did not observe an effect of treatment on genes affected by glucose availability, *glucose transporter type 4* (*GLUT4*) and *tuberous sclerosis protein 2* (*TSC2*; $P \geq 0.36$), within the muscle. In summary, although we did not observe an effect of IUGR on markers of myogenesis, *IGF-I* gene expression tended to be increased in RES lambs at d 1 but not at 3 mo. Based on the reduced size of the RES lambs and the critical role of IGF-I in muscle growth, these data suggest there may be altered sensitivity to IGF-I in the muscle of lambs suffering from IUGR at birth.

Key Words: intrauterine growth retardation, insulin-like growth factor-I, muscle

M131 Maternal diet interactions with fetal sex in beef cattle.

C. Fitzsimmons*[1,2], K. Wood[3], F. Paradis[1,2], B. McBride[3], S. Miller[3], I. Mandell[3], and K. Swanson[4], *[1]Agriculture and Agri-Food Canada, Edmonton, Alberta, Canada, [2]Dept. of Animal, Food, and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [3]Dept. of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada, [4]Dept. of Animal Sciences, North Dakota State University, Fargo.*

Prenatal nutrition affects postnatal life in many mammals, including cattle. Our aim is to determine which physiological processes are affected, to what degree, and how we can optimize prenatal nutrition to ensure/enhance performance in economically important traits. Multiparious beef cattle (n = 46) were fed a haylage-based TMR containing 20% wheat straw at either 85% (n = 23; LOW) or 140% (n = 23; HIGH) of maintenance energy requirements (NEm). The treatment began mid-way through gestation (~150 ds), and continued for 105 ds. Diet treatment (TRT) had a significant effect upon cow ADG ($P < 0.0001$), and TRT and cow age had significant effects upon cow average end weight (AEWt) (both $P < 0.0001$). Only cow age was significant for average start weight (ASWt) ($P = 0.0001$). Least squares means AEWt for HIGH and LOW cows was 853 and 765 kg resp., therefore dietary treatment performed as expected. Birth weights of calves born from these cows were evaluated using a mixed model which included TRT and sex of calf (plus interaction), and cow age as fixed factors, with pen as random effect. Only TRT*calf sex was significant ($P = 0.038$). Cow weight measurements (ASWt, CowADG, AEWt) were tested separately as covariates in the model for calf birth weight. Both ASWt and AEWt significantly interacted with TRT, and appeared to explain some of the same variation in birth weight as fetal sex. In retrospect we included calf sex in models for ASWt, CowADG, and AEWt. We found that CowADG was significantly affected by both TRT and calf sex ($P < 0.0001$, $P = 0.013$ resp.). Cows carrying bulls as opposed to heifers gained more weight during the trial. By weaning there was no difference in cow weights for any parameters tested except cow age ($P = 0.0019$). Adjusted (205-d) weaning weights of calves, as well as average daily gain from birth to weaning, were not affected by any parameters tested. These results illustrate that maternal diet during the second trimester in beef cattle has sex-specific effects upon birth weight of calves, and that fetal sex interacts with rate of gain in pregnant cows. Translating the maternal-fetal dialog can lead to innovative management practices for the pregnant beef cow.

Key Words: fetal-programming, epigenetics, bovine

M132 Lamb growth in response to the duration of maternal undernutrition during gestation in twin sheep pregnancies.

M. E. Field,* R. V. Anthony, T. E. Engle, S. L. Archibeque, and H. Han, *Colorado State University, Fort Collins.*

The experimental objective was to determine the impact of duration of maternal undernutrition during gestation in twin pregnancies on lamb growth and development. Multiparous western whiteface ewes were randomly assigned to one of 3 treatments and acclimation to individual pens (7d) began at 21 d of gestational age (dGA). Ewes were fed 100%

(Control; n = 8), or 50% of their nutrient requirements from 28 to 78 dGA and readjusted to 100% beginning at 79 dGA (50–100; n = 10), or 50% from 28 to term (50–50; n = 9). Lambs were birthed naturally and harvested at 18 wk of age. Data were analyzed by preplanned orthogonal contrasts: Control vs. 50–100 and 50–50 and 50–100 vs. 50–50. Lambs born to 50–100 ewes were heavier ($P = 0.02$; 5.41 ± 0.28 kg) than 50–50 (4.34 ± 0.29 kg) lambs. Crown-rump length (CRL) tended ($P = 0.09$) to be greater in 50–100 (17.90 ± 0.54 cm) than 50–50 (16.38 ± 0.68 cm) lambs. Body weight of 50–100 lambs was greater ($P < 0.05$) than 50–50 lambs at 2 (8.52 ± 0.51 kg vs. 4.34 ± 0.29 kg) and 3 wk (9.79 ± 0.53 kg vs. 7.94 ± 0.53 kg) and the same trend ($P = 0.07$) was observed at 4 wk (11.63 ± 0.70 kg vs. 9.51 ± 0.81 kg). At 4, 16 and 17 wk body weight tended ($P < 0.10$) to be greater in Control than 50–100 and 50–50 lambs. At 18 wk rear leg length was greater ($P = 0.03$) in 50–100 (63.92 ± 1.30 cm) and 50–50 (61.54 ± 1.26 cm). At 18 wks CRL of 50–100 (114.46 ± 2.82 cm) lambs tended ($P = 0.09$) to be greater than 50–50 (107.30 ± 3.72 cm) lambs. At 18 wk, brain weight was greater ($P = 0.03$) in 50–100 (107.98 ± 2.61 cm) than 50–50 (99.74 ± 2.47 cm) lambs. Elevated body weight and CRL of 50–100 lambs at birth may indicate a shift in fetal metabolism to compensate for nutrient restriction during early gestation. Lactation Biology I

M133 Nursing frequency alters circadian patterns of mammary gene expression in lactating mice. D. L. Hadsell,* W. Olea, and L. W. Rottman, *Baylor College of Medicine, Houston, TX.*

Milking frequency impacts lactation in dairy cattle and in rodent models of lactation. The role of circadian gene expression in this process is unknown. The hypothesis tested was that changing nursing frequency alters the circadian patterns of mammary gene expression. Mid-lactation CD1 mice were studied in 2 groups, for up to 54 h. Ad-libitum (AL) nursed dams were allowed AL access to their litters for the entire study. Variably nursed (VN) dams were placed on a 4-time (4X) per day (d) schedule on d1, and an AL nursing schedule on d 2 of the study. Samples were collected at 6 h intervals (n = 3 dams/ treatment-time combination). Mammary gland (MG) weight was used to indicate the combined effects of secretory activity and suckling-dependent milk removal. Total MG RNA was analyzed by real-time qRT-PCR for the expression of Bmal, Per1, Per2, Lalba, and B4galt1. On d 1, MG weight in the AL dams exhibited circadian oscillations with a peak at Zeitgeber time (ZT) 12 and a trough at ZT0. MG weight was higher ($P < 0.01$) in VN dams for the first 18 h on 4X, but then decreased. Placement of VN dams back onto AL nursing during d 2 of the study decreased ($P < 0.01$) MG weight during the subsequent 18 h. On d 1, both Bmal and Per2 mRNA levels exhibited circadian oscillations with peaks at ZT0 and 18, respectively, and troughs at ZT12 and 6, respectively. In AL dams, both Lalba and B4galt1 mRNAs also oscillated, with troughs at ZT12 and peaks at ZT18. Both Per2 and B4galt1 were affected ($P < 0.05$) by decreased nursing frequency in the VN dams on d 1. For Per2, the response was an increase in amplitude at ZT18 ($P < 0.02$) while B4galt1′s expression pattern was decreased ($P < 0.0001$). These differences resolved during d 2 when VN dams were placed on AL nursing. These results support the conclusion that decreased nursing frequency alters circadian gene expression and could influence lactose synthesis through dampening the expression of B4galt1. This project supported by National Research Initiative Competitive Grant no. 2007–35206–17831 from the USDA Cooperative State Research, Education, and Extension Service and by the USDA/ARS Cooperative Agreement #6250–51000–048.

Key Words: lactation, milking frequency, circadian

M134 Functional analysis of swine mammary gland transcriptome during late gestation using two bioinformatics approaches. W. S. Zhao*[1,2], K. Shahzad[1], D. E. Graugnard[1], J. Luo[2], J. J. Loor[1], and W. L. Hurley[1], [1]*University of Illinois, Urbana,* [2]*Northwest A & F University, YangLing, Shaanxi, China.*

As in other mammals, sow mammary glands are essential to support growth and development of neonatal piglets via the synthesis of milk. We used a newly developed dynamic impact approach (DIA) and the online bioinformatics tool DAVID to perform functional analysis of the sow mammary transcriptome during pregnancy. Mammary tissue was harvested at slaughter on d 80, 100 and 110 of gestation. A swine oligoarray (70 mer) with 13,263 inserts was used for transcriptome profiling. An ANOVA with false discovery rate (FDR < 0.15) correction resulted in 1,539 genes with a significant time effect. Bioinformatics analysis using DIA included the entire data set with Entrez gene ID, FDR, fold-change, and post-hoc P-values between time points ($P < 0.05$; d 110 vs. 80, d 110 vs. 100, d 100 vs. 80). For the DAVID analysis, a cut-off of FDR < 0.15 and P-value <0.05 was used. By implementing a criterion of mean impact +1 SD to the final results, a total of 14 highly impacted KEGG pathways were uncovered during gestation. Within the 'Metabolism' KEGG category, DIA uncovered that 'one carbon pool by folate', 'galactose metabolism', and 'fatty acid biosynthesis' were among the most-impacted pathways on d 100 and 110 vs. d 80; whereas 'linoleic acid metabolism' was inhibited overall on d 100 and 110 vs. d. 80. Within 'Genetic Information Processing' in KEGG, protein export was markedly activated at d 110 compared with d 80 and 100. Within 'Environmental Information Processing' KEGG category, 'ABC transporters' was the most-induced pathway during late gestation, while 'ECM-receptor interaction' was inhibited at d 110 vs. 80. The latter category was markedly activated at d 110 vs. 100. Within the 'Organismal Systems' KEGG category, 'intestinal immune network for IgA production' was markedly induced during d 110 and 100 vs. 80. Similar findings were obtained using DAVID approach. Overall, preliminary results from both bioinformatics approaches indicated that folate-mediated one carbon metabolism may serve an important metabolic role in preparation for copious milk synthesis. In addition, the immune system properties of the mammary gland also seem to play an important role in allowing the organ to recognize potential pathogens. Such response may be a mechanism of the mammary gland to prevent invasion of microbes during late gestation.

M135 Changes in milk composition of Holstein dairy cows within a milking. D. E. Rico,* E. R. Marshall, and K. J. Harvatine, *Penn State University, University Park.*

The variation in milk composition within a milking was studied in high producing cows. Eight multiparous Holstein cows (54.86 ± 6.8 kg milk/d; mean ± SD) fed a 31.5% NDF and 17.0% CP diet were used in the experiment. A milk-sampling device was designed to allow collection of multiple samples during a milking without loss of vacuum or interruption of milk subsampling. The average milk yield of the previous 7 milkings was used to determine 5 equal weight sampling intervals. If milk yield exceed expected by more than 25% of the interval weight a sixth sample was collected. Milk was collected during consecutive morning and afternoon milkings for all cows and was replicated one week later. Each sample representing approximately 20% of the milking was analyzed for fat, true protein, and lactose by infrared spectroscopy. A second subsample was stored at −20°C without preservative for analysis of FA composition. Data were analyzed using the Proc Mixed procedure (SAS institute) as a random regression. The model included the random effect of cow and week and the fixed effect of milking fraction, time of milking (AM vs PM) and the interaction of milking fraction by time of milking. Denominator degrees of freedom were calculated by the Satterthwaite procedure. Milking fraction (MF) was a continuous variable calculated as the midpoint of the sampling interval. There was an effect of milking (AM vs PM) on total milk yield and milk protein, lactose, and fat concentration. There also was an interaction of milking time (AM vs PM) and milking fraction, and a quadratic effect of milking fraction on milk fat, protein and lactose concentration ($P < 0.001$). Milk fat concentration exhibited the most marked change during milking and the best fit predictions for the AM and PM milkings were $1.43 + 1.65 \times MF + 2.71 \times MF^2$ and $1.89 + 1.42 \times MF + 2.7124 \times MF^2$, respectively. Milk fat content increased quadratically over the course of milk let down in high producing dairy cows, while much smaller changes were observed in protein and lactose. This pattern is consistent with previous results in lower producing dairy cows and reflects the dynamic nature of milk fat secretion from the mammary gland.

M136 Osteopontin secretion in milk is correlated to the presence of DNA polymorphisms in the secreted phosphoprotein 1 (*SPP1*) gene.

P.-L. Dudemaine*[2] and N. Bissonnette[1,2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Center, Sherbrooke, QC, Canada,* [2]*Université de Sherbrooke, Sherbrooke, QC, Canada.*

Osteopontin (OPN), encoded by secreted phosphoprotein 1 (SPP1) gene, is a phosphoglycoprotein that is present in various tissues and secreted into body fluids, such as bovine milk. It is recognized as an important pro-inflammatory cytokine which has numerous functions, including its role in early T-cell activation during bacterial infection. The goal of the study was to evaluate the impact of polymorphisms in the *SPP1* gene on OPN secretion in milk. In a previous study, elevated OPN expression in response to mammary gland infection has been characterized. Furthermore, several polymorphisms detected in the 5′ untranslated region of the gene (promoter) have an impact on the estimated breeding value (EBV) for somatic cell score (SCS), an indicator of udder health. Also, haplotypes were defined for low (H1 × H4) and high (H2 × H3) SCS. In dairy cows, OPN is secreted during lactation and could be involved in the mammary gland immunity. In the present study, the main objective was to determine whether polymorphisms in the *SPP1* gene are related to the presence of isoforms or the level of OPN in milk. An antibody panel was used to characterize OPN isoforms by immunoblotting and to measure the amount of OPN secreted in milk. This enabled the selection of the most suitable antibodies to develop an ELISA. The sensitivity of the ELISA was determined at 220 pg/mL with a recovery of 94 ± 5%. Variations in OPN milk concentrations were detected during lactation for cows representing haplotype H1 × H4 (n = 3) and H2 × H3 (n = 3). Elevated concentration in colostrum (678.5 ± 68.7 mg/L) drastically decreased within the first week to reach 19.3 ± 3.7 mg/L of milk, and then remained constant until d 150. From d 150 to 200, cows with haplotypes associated with a low EBV for SCS had increased OPN level in milk ($P < 0.0006$) compared with the cows with haplotype associated with high EBV. This is the first study to demonstrate that a cow′s *SPP1* genetics affects OPN concentration in milk.

Key Words: osteopontin, bovine lactation, genetic variation

M137 Growth hormone influences mTORC1 and IGF-1 signaling in the lactating bovine mammary gland.

S. McCoard,* Q. Sciascia, and D. Pacheco, *Animal Nutrition Team, AgResearch Grasslands Limited, Palmerston North, New Zealand.*

The objective of this study was to determine whether mTOR and IGF-1 signaling mediates the effect of growth hormone (GH) on milk protein synthesis in the bovine mammary gland. Mammary tissue was obtained post-mortem from non-pregnant second parity Jersey cows (178–200 d postpartum) 6 d after a single subcutaneous injection of either a slow-release formulation of commercially available GH (Lactatropin) 500mg; (n = 4) or saline (n = 4). Total DNA, RNA and protein were extracted using TRIzol reagent and relative ratios used to evaluate cell size, number and translational efficiency and capacity. The abundance and phosphorylation status of targets of mechanistic target of rapamycin complex 1 (mTORC1) and insulin-like growth factor-1 (IGF-1) signaling were evaluated using Western blotting. Expression of IGF-1 signaling targets was evaluated using qPCR and the data analyzed using LinRegPCR and REST software. Treatment with GH increased mammary gland weight (33%; $P = 0.03$) and total protein content (34%; $P = 0.05$) and tended ($P < 0.10$) to increase ribosome number (33%) and cell size (30%) and DNA concentration (20%), while protein synthetic efficiency, capacity and cell number were unchanged ($P > 0.10$). These results suggest that GH stimulation of global protein synthesis is mediated by an increase in ribosome number and cell size. Abundance of mTOR and mTOR-Ser2448 (1.5 fold, $P < 0.05$), eIF4E (1.8 fold, $P < 0.05$), eIF4E-Ser209 (2.6 fold, $P < 0.01$), the eIF4E-eIF4G complex (1.8 fold, $P < 0.01$) and eIF4E-4EBP1 complex (1.3 fold, $P < 0.05$), MKNK1 (1.5 fold, $P < 0.05$), phosphor-MKNK1 (2.1 fold, $P < 0.01$), RPS6KA1 (1.7, $P < 0.01$) were increased in response to GH, but 4EBP1, p70S6K1 and p85S6K1 were unchanged. Expression of IGF1BP3 (1.4 fold, $P < 0.01$) and IGF1BP5 (1.6 fold, $P < 0.01$) were increased, IGF-1 receptor (1.3 fold, $P < 0.01$) was decreased, and IGF-1 was unchanged in response to GH. Overall, these results indicate that the mTOR pathway may mediate the effect of GH on ribosome biogenesis and cell size, while GH-activation of global protein synthesis is linked to changes in the abundance, phosphorylation and association state of components of the IGF-1 signaling pathway and downstream targets of translational regulation.

Key Words: mTOR pathway, bovine, mammary gland

M138 First demonstration of decorin, an extracellular matrix molecule, in bovine mammary tissue.

K. M. O’Diam*[1], S. G. Velleman[1], V. A. Swank[1], S. Ellis[2], A. V. Capuco[3], and K. M. Daniels[1], [1]*Department of Animal Sciences, The Ohio State University, OARDC, Wooster,* [2]*Animal and Veterinary Sciences Department, Clemson University, Clemson, SC,* [3]*Bovine Functional Genomics Lab, USDA-ARS, Beltsville, MD.*

In the mammary gland, an extracellular matrix (ECM) is secreted by and surrounds cells located in both mammary parenchyma (PAR) and stroma. Decorin is an ECM proteoglycan with cell growth regulatory effects mediated by its ability to interact with growth factors or upregulation of cyclin-dependent kinases. It also serves a structural role by regulation of collagen crosslinking. Based on these known roles, we undertook a pilot scale study to examine the spatial and temporal localization of decorin in bovine mammary tissue at various physiological stages. Mammary PAR (n = 6) was obtained from female Holsteins (n = 4). Samples represented 3 prepubertal times (d40, 56 and 100 of postnatal life), 2 gestational times (d213 and 248 of gestation) and one lactating time point (d10 post calving). Slides were subjected to immunohistochemical staining for the decorin antigen. A horseradish peroxidase conjugated secondary antibody and diaminobenzidine chromagen were used for detection. The negative control for the assay was incubated with control sera instead of the decorin primary antibody; all other procedures were the same. The negative control was free of chromagen. Our analyses demonstrated that decorin is present in bovine mammary ECM. Furthermore, temporal and spatial localization changed with physiological stage. At all time points observed, except for d56, decorin was not observed immediately surrounding epithelial cells comprising ducts. Across all time points, decorin localization in the intralobular stroma was minimal. Interlobular stroma showed a temporal distribution pattern of decorin staining. At d40, the gestational time points and d10 post calving, decorin localization was intense; at the d56 and d100 prepubertal time points, comparatively less decorin was localized in the interlobular stroma. To the best of our knowledge, this report is the first demonstration of the localization of decorin in bovine mammary PAR. Given our observation that localization appears to vary with physiological state, decorin may be important in the regulation of growth, development and remodeling of bovine mammary gland.

Key Words: decorin, extracellular matrix, mammary gland

M139 MicroRNA expression patterns are affected by stage of lactation in dairy cattle mammary gland. M. Z. Wang*[1,2], S. Moisa[2], D. Bu[1], J. Wang[1], and J. J. Loor[2], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]University of Illinois, Urbana.*

MicroRNA (miRNA) are small non-coding RNA which regulate gene expression post-transcriptionally and play a key role in development and specific biological processes. The human breast-specific signature is characterized by the expression of 23 miRNA and the mouse mammary-specific signature is characterized by the expression of 9 miRNA (let-7a, let-7b, let-7c, miR-26a, miR-26b, miR-24–2, miR-145, miR-30b, and miR-30d). Those data suggest that miRNA could play a role in mammary gland physiology. Knowledge of the expression patterns of miRNA in bovine mammary gland during the transition from pregnancy into lactation might provide insights into their role in regulating aspects of metabolism, differentiation and apoptosis, and immune response. The objective of this work was to determine the expression pattern of selected miRNA involved in cellular proliferation, lipid metabolism, and innate immunity in dairy cow mammary gland tissue at different stages of lactation. Cows from the University of Illinois Dairy Research farm were used in this study. The expression of miR-10a, −15b, −16, −21, −31, −33b, −145, −146b, −155, −181a, −205, −221, and −223 was studied by RT-PCR in tissue ($n = 7$/stage) harvested via repeated biopsy during the dry period (−30 d prepartum), early lactation (7 d postpartum), and peak lactation (30 d postpartum). The results showed that expression of all miRNA, except miR-31, increased markedly between the dry period and early lactation. Among those, the expression of miR-221 increased further by peak lactation potentially suggesting a role in the control of endothelial cell proliferation/angiogenesis; whereas, the expression of miR-223 decreased by peak lactation but to a level that was greater than the dry period suggesting it may play a role in the mammary response to pathogens soon after parturition. The expression of miR-31, a hormonally regulated miRNA that inhibits cyclin gene expression, was greater at peak lactation vs. the dry period. From a metabolic standpoint, the consistent upregulation of miR-33b during early lactation vs. dry period suggests that this miRNA may exert control over lipogenesis in mammary tissue as it does in rodents. Collectively, results indicated that expression of miRNA associated with regulation of transcription of genes across diverse biological functions is altered by stage of lactation. Determining the specific roles of these miRNA during lactation requires further research, including examination of the expression patterns of their target genes.

Key Words: metabolism, genomics, bioinformatics

M140 Proteomic analysis in MAC-T cells reveals proteins involved in *cis*-9, *trans*-11 CLA de novo synthesis. T. Wang,* J. J. Oh, D. C. Piao, J. H. Hwang, Y. C. Jin, S. B. Lee, K. H. Lee, J. N. Lim, H. S. Kang, and H. G. Lee, *Department of Animal Science, Pusan National University, Miryang, Gyeongnam, Korea.*

This study was conducted to explore proteins involved in *cis*-9, *trans*-11 CLA de novo synthesis through proteomic analysis in MAC-T cells. Cells were routinely cultured in DMEM growth medium at 37°C and 5% CO_2. After reaching 100% confluence, the cells underwent differentiation in lactogenic medium for 90 h. Treatments were performed in triplicate with BSA (control) or t11 C18:1 (50 μM in BSA) and samples were collected every half hour for 4 h. Lipids were extracted following the Folch method and the lipid methyl esters were quantified by GC with a SP-2560 fused silica capillary column. The expression of SCD1 protein was detected by Western blotting using a specific mouse monoclonal primary antibody to SCD. On the basis of the SCD1 expression in 2.5 h, the difference of protein expression among control and t11 C18:1 group were compared by 2-DE. The striking differently expressed spots (≥2 or ≤ 0.5) were identified using ESI-Q-TOF and a protein search engine. Results showed that t11 C18:1 continually converted into *cis*-9, *trans*-11 CLA in MAC-T cells and showed a positive correlation ($R^2 = 0.887$) during the test. The SCD1 protein expression increased more than 2-fold at 2 h and 2.5 h whereas it decreased by half at 4 h. One upregulated and 6 downregulated proteins were identified in 2.5 h. The expression pattern of the upregulated protein (RASGRP4) (0–3.5 h) was positively related ($R^2 = 0.466$) to that of SCD1, however 3 of the 6 downregulated proteins (PGAM1, ANXA3, TPMT) were negatively ($R^2 = 0.280$, $R^2 = 0.297$, $R^2 = 0.182$) related to SCD1. Our results suggest that these identified proteins may be involved in the *cis*-9, *trans*-11 CLA de novo synthesis of MAC-T cells.

M141 Potent growth promoting activity of prolactin and estrogen to E-cadherin/β-catenin adhesion molecules in bovine mammary gland: Modulation of Wnt signaling. J.-J. Tong, Q.-Z. Li,* X.-J. Gao, N. Zhang, and Y. Lin, *Key Lab of Dairy Science, Ministry of Education, Northeast Agriculture University, Harbin, Heilongjiang, China.*

The Wnt signaling pathway and subsequent upregulation of β-catenin driven downstream targets (e.g., cyclinD1) are associated with development of mammary gland. E-cadherin is a key molecule component of the cell-cell adhesion junctions, which plays a principal role in maintaining the morphogenesis of numerous organs including mammary gland. Therefore, the objectives of this presentation is that to fully elucidated the molecular mechanisms underlying the effects of prolactin and estrogen on E-cadherin, β-catenin and cyclinD1 in Wnt signaling pathway in bovine mammary epithelial cells (BMECs). The effect of prolactin and estrogen (5 μg/mL) treatment on expression the key elements of Wnt signaling pathway components in BMECs was analyzed at mRNA level and protein level by qRT-PCR, immunofluorescence and Western blotting. Our present findings showed that prolactin and estrogen effectively promoted the expression of E-cadherin and cyclin D1 on mRNA level ($P < 0.05$), as well as protein level ($P < 0.05$), tested by by qRT-PCR, immunofluorescence and Western blotting. The analysis of β-catenin protein showed that prolactin and estrogen can markedly reduce the nuclear β-catenin expression at protein level. Furthermore, we suggest that modulation of Wnt signaling may be one of the mechanisms implicated the effect on cell proliferation in BMECs by prolactin and estrogen. We demonstrated that prolactin and estrogen can activate cell proliferation in BMECs tested by Reagent WST-1 ($P < 0.05$). Prolactin and estrogen enhanced Wnt signaling through increasing E-cadherin on protein level by lowering the levels of intracellular β-catenin and the influence on the important component of Wnt pathway target-cyclinD1. In conclusion, we were first focused on the effect of prolactin and estrogen on modulation of key components of Wnt signaling components in BMECs. Our results also highlighted the importance of Wnt components—E-cadherin, β-catenin, cyclinD1 that may serve as future subjects in the study of development and lactation of the mammary gland in dairy cattle.

Key Words: Wnt pathway, E-cadherin, bovine mamary epithelial cells

Meat Science and Muscle Biology I

M142 Effect of power ultrasound on the physicochemical properties of beef longissimus dorsi muscle.

C. Valenzuela-Gonzalez*[1], A. D. Alarcon-Rojo[1], E. Santellano[1], and A. Quintero-Ramos[2], [1]*Universidad Autonoma de Chihuahua, Facultad de Zootecnia y Ecologia, Chihuahua, Mexico,* [2]*Universidad Autonoma de Chihuahua, Facultad de Ciencias Quimicas, Chihuahua, Mexico.*

High-intensity ultrasound has been used to modify the physical or chemical properties of food. Several areas have investigated the potential future development of this technique in the food industry. To determine the effect of power ultrasound on the physicochemical characteristics of beef, we excised the m. longissimus dorsi muscle from 4 Holstein cows at 48 h postmortem. Any visible fat was trimmed away and the meat was cut into 5 cm slices, before chopping into 4-cm^3 cubes. Half of the cubes from the same slice remained untreated (control samples), whereas the other half were irradiated with power ultrasound for 4 or 8 min. Ultrasound waves were applied at a frequency of 40 kHz using water as the transmission medium. We then evaluated the meat pH, color (L*, a*, and b*), water-holding capacity (WHC), drip loss (DL), and shear force (SF). The adjusted model for statistical analyses included the effects of treatment, sonication time, and the interaction of treatment x sonication time. Data were analyzed using the mixed procedure method in SAS. If the main effects or their interaction were significant ($P \leq 0.05$), the means for a given characteristic were compared among time and treatment groups using the least significant difference method. There was an effect ($P \leq 0.05$) of ultrasound on the a*, b*, pH, WHC, and DL of the meat samples. The ultrasound-treated meat had a lower redness (a*) and yellowness (b*) compared with the control samples for both ultrasound application periods. Ultrasonication of meat for 8 min produced the highest pH value and the lowest DL ($P \leq 0.05$). There was no effect ($P \geq 0.05$) of ultrasound on the L* and SF of meat. It has been reported that ultrasound alone did not change the peak force of pork, and it was only effective when combined with marination. However, the use of power ultrasound may be an alternative method for improving the physicochemical properties of beef.

Table 1. Least squares means ± standard error for physicochemical properties of beef L. dorsi muscle treated with power ultrasound

Sonication time, min	Treatment[1]	Luminosity, L*	Redness, a*	Yellowness, b*	pH	Drip loss, %	Shear force, kg/cm^2

M143 Diffusion of sodium chloride in bovine meat treated with power ultrasound in continuous and pulse modes.

E. B. Ordaz-Portillo, A. D. Alarcon-Rojo, and C. Valenzuela-Gonzalez,* *Universidad Autonoma de Chihuahua, Chihuahua, Mexico.*

To evaluate the effect of power ultrasound on the diffusion of sodium chloride in beef muscles, an experiment with 6 replicates was carried out using the Semitendinosus muscle of adult Holstein cows. Semitendinosus muscle was cut transversally into one -inch -thick slices and placed in an ultrasonic bath containing a salt solution that just covered the slice. The ultrasound was applied in both, pulsed and continuous modes for 6 treatment times (10, 20, 30, 40, 50 and 60 min) and in 2 salt solutions (5% and 10% sodium chloride). To assess the diffusion of salt into meat the concentration of sodium chloride was measured with a digital refractometer in 3 regions of the meat slice (external, middle and inner). The data were analyzed using PROC GLM of SAS and included the ultrasound mode, salt solution concentration, ultrasound application time, slice (external, middle and central) region and their possible interactions as fixed factors. The results showed significant differences ($P \leq 0.05$) in the diffusion of salt which depended on the salt solution concentration. There was also a significant interaction between ultrasound mode and slice region. The highest salt diffusion was observed in the 60 min continuous mode with 10% sodium chloride solution. The application of ultrasound in continuous mode resulted in the highest salt diffusion in all meat slice regions, with the external region having the highest salt concentration. The increase in salt concentration was proportional to the sonication time. It is concluded that power ultrasound may be a potential method for improving sodium chloride transfer during meat processing.

Key Words: salt diffusion, power ultrasound, beef

M144 Meat traits of steers fed with whole cottonseed.

D. P. Borges da Costa*[1], R. de Oliveira Roça[2], Q. P. Borges da Costa[3], L. da Silva Cabral[4], D. P. D. Lanna[5], E. da Silva Lima[3], D. G. Fagundes[1], and N. L. Filho[1], [1]*Instituto Federal de Mato Grosso, Campo Novo do Parecis, Brazil,* [2]*Faculty of Agricultural Sciences, Universidade Estadual Paulista, Botucatu, Brazil,* [3]*Faculty of Veterinary Medicine, Universidade Estadual Paulista, Botucatu, Brazil,* [4]*Universidade Federal de Mato Grosso, Cuiabá, Brazil,* [5]*Escola Superior de Agricultura "Luiz de Queiroz,"Universidade de São Paulo, Piracicaba, Brazil.*

The objective of this study was to determine the effect of inclusion whole cottonseed in the diet on the meat characteristics of Nellore steers. Thirty-six steers (average initial body weight of 333.50 kg and aged 20 mo) were housed during 94 d in pens with 3 animals each. The animals were distributed, equally, among 4 treatments, and these corresponded to diets containing increasing amounts of whole cottonseed: without whole cottonseed, 14.35% of whole cottonseed, 27.51% of whole cottonseed and 34.09% of whole cottonseed in relation to the dry matter of the diet. The animals' final live weight average was 446.64 kg ± 27.96 kg. These animals were slaughtered and was collected from the left half carcass of each animal, it was taken off part of the sirloin steak, in the 12th thoracic vertebra - 3rd lumbar vertebra, individually wrapped in plastic bags, identified and frozen at −18oC and were sent for analysis. A completely randomized design with 4 treatments and 9 replications was used. Treatments' effects if significant ($P < 0.05$) were estimated by regression analysis. MIXED from SAS (2001) for statistical analysis. The protein values, shear force; lipid oxidation, meat and fat color were similar among the treatments. However, the addition of the whole cottonseed levels linearly reduced the intramuscular fat percentage and increased moisture content of meat. Whole cottonseed feeding reduced the fatty acids concentration of C14:1 cis 9, C16:1 cis 9, C17:0, C17:1 and C18:1 cis 9 in the meat. The fatty acids C13:0 ISO,

C13:0 ANTEISO, C14:0 ISO, C15:0 ISO, C15:0 ANTEISO, C17:0 ISO, C18:0 and C18:1 trans 10 - trans 11 content in the meat have increased by the whole cottonseed addition in the diet. Inclusion of 27.51 and 34.09% of whole cottonseed in the diet altered negatively the meat aroma and flavor, respectively. The whole cottonseed diet did not change the concentration of conjugated linoleic acid, saturated fatty acids and the total unsaturated in the meat.

Key Words: flavor, CLA, stearic acid

M145 Lipid peroxidation and color of meat from young bulls fed different levels of crude glycerin.

M. M. Ladeira,* J. R. R. Carvalho, M. L. Chizzotti, E. M. Ramos, P. D. Teixeira, M. C. L. Alves, P. E. P. Barros, and O. R. Machado Neto, *Federal University of Lavras, Lavras, MG, Brazil.*

The use of crude glycerin in ruminant diets has the objective of decrease the operational cost. However, its effects on the meat characteristics should be better studied. The objective was to evaluate lipid peroxidation, using thiobarbituric acid reactive substances (TBARS), and color of meat from young bulls fed different levels of crude glycerin in the diet. Forty-four Red Norte animals were slaughtered at average live weight of 519 ± 15 kg, and the levels of crude glycerin (83% glycerol) were: 0, 6, 12 and 18% DM. The experiment was conducted in a completely randomized design, with 4 treatments and 11 repetitions. The basal diet was consisted of 30% corn silage, 12% soybean meal, 56% of corn grain and 2% mineral mixture. Corn was partially replaced by glycerin, and to achieve an isonitrogenous diet, corn gluten meal (21% CP) was used. After slaughter, samples were taken from the Longissimus dorsi muscle. Then, they were vacuum packed and maintained refrigerating at 4°C for 0, 7, 14 and 21 d post mortem. The color reading was conducted on the surface, using the CIE L*a*b* system. When significant effects ($P < 0.05$), regressions analysis using PROC REG of SAS 9.1.3 were done. There was no effect of storage time on color and lipid peroxidation ($P > 0.05$). The indices of lightness (L*), red (a*), yellow (b*), saturation index (C*) and the index of hue angle (h) showed a quadratic effect ($P < 0.01$) with the inclusion of crude glycerin (Table 1). Therefore, the meat changed from a red-purple color when the animals received 6% of glycerin, for the cherry-red when 18% was used. It was observed a tendency ($P = 0{,}07$) of increase on TBARS in the muscle of animals fed crude glycerin. As a conclusion, the use of a crude glycerin provided meat with better color and better appearance to the consumer. Funded by Fapemig, CNPq, Capes and INCT-CA

M146 The use of visible and near infrared spectroscopy for quality control of organic and conventional beef stored under protective atmospheres.

M. Ólivan[1], V. Sierra[1], G. Fiorentini*[2,4], N. Prado[3], P. González[3], B. Álvarez[3], J. Díaz[3], and K. Osoro[1], [1]*Servicio Regional de Investigación y Desarrollo Agroalimentario (SERIDA), Apdo. 13, 33300 Villaviciosa, Asturias, Spain,* [2]*Universidade Estadual Paulista (UNESP), Jaboticabal, SP, Brazil,* [3]*Asociación de Investigación de Industrias Cárnicas del Principado de Asturias (ASINCAR), Polígono de la Barreda, Noreña, Spain,* [4]*Bolsista Processo nº2469-11-1 - CAPES, Setor Bancário Norte, Brasília, Brazil.*

The objective of this work was to evaluate the potential of Visible (VIS) and Near Infrared Spectroscopy (NIRS) for on-site control of beef shelf life on meat trays stored at display counters. Beef samples (steaks) were obtained from the *Longissimus dorsi* muscle of 12 young bulls managed under organic (pasture or maize silage plus organic concentrate) or conventional (finished at feedlot with concentrate meal and barley straw ad libitum) feeding. These beef samples were packed under 2 different protective atmospheres (vacuum and 80%O_2-20%CO_2) and analyzed after 1, 3, 5, 8, 12 and 15 d of storage, so the global study included a total of 144 samples (12 animals x 2 protective atmospheres x 6 storage time). Meat quality analysis included color (L*, a*, b*), microbiology (mesophilic, anaerobic, enterobacteriaceae), texture (Warner-Bratzler shear force “WBSF”) and oxidative status (TBARS index). VIS/NIRS spectra were obtained by using a portable LabSpec 5000 fitted with a fiber optic probe (ASD Inc., USA) in reflectance mode (350–2500nm). Representative spectra of each beef steak were calculated as the average of 5 scans obtained on the steak surface, with or without film interaction, that is, before and after tray wrap opening. VIS/NIRS calibrations were calculated using the software Unscrambler 9.7. The results of the calibration statistics showed good prediction for beef color (L*, a*, b*) when measured on intact (R^2 of 0.84, 0.88 and 0.73, respectively) or opened (R^2 of 0.90, 0.88 and 0.74, respectively) meat trays. However, poorer predictions were obtained for other shelf life parameters showing high stability along the storage period, like microbial spoilage (R^2 between 0.40 and 0.55), TBARS ($R^2 < 0.40$) and texture ($R^2 < 0.37$). Furthermore, VIS/NIRS spectra showed some potential for classification of beef samples into shelf-life quality grades.

Key Words: beef, NIRS, shelf life

M147 Fatty acid composition of cattle fattened with tropical forage at rainy and drought season.

M. E. E. Rodríguez*[1], G. Corral-Flores[1], B. S. Solorio[2], A. D. R. Alarcón[1], J. A. Grado-Ahuir[1], C. Rodríguez-Muela[1], L. P. Cortés[1], and V. E. B. Segovia[1], [1]*Facultad de Zootecnia y Ecología. UACH, Chihuahua, México,* [2]*Fundación Produce Michoacán A. C., Morelia, México.*

The objective of this study was to quantify intramuscular fat and fatty acid composition of meat from cattle fattened on tropical forages (*L. leucocephala*, *P. maximum* and *C. plectostachyus*) under the intensive Silvopastoril System (SSPi) at 2 seasons (rainy n = 12 and drought n = 10). Intramuscular fat of *L. dorsi* (Ld) and *Semimembranosus* (Sm) muscles was extracted and fatty acids (myristic, mirystoleic, palmitic, palmitoleic, stearic, oleic, linoleic, eicosanoic, arachidonic acid (ARA) and docosahexaenoic (DHA) acids) were quantified. The effect of season was analyzed with a linear model. The intramuscular fat was higher ($P \leq 0.05$) in rainy (3.530 ± 0.22%) vs. drought (2.47 ± 0.21%) season and myristic, mirystoleic, palmitic, palmitoleic and stearic acid were not different ($P \geq 0.05$) between seasons. Oleic acid had higher concentration ($P \leq 0.05$) in the rainy (40.69 ± 3.15%) vs. drought (27.52

± 3.46%), while linoleic, linolenic and eicosanoic acid concentration were lower ($P \leq 0.05$) in rainy season. For the essential fatty acids, ARA concentration was lower ($P \leq 0.05$) in rainy (0.08 ± 0.10%) vs. drought (0.48 ± 0.11%) season and DHA had similar concentration ($P \geq 0.05$) along year seasons. It is concluded that beef fattened with tropical forages yield leaner meat in both seasons and its fatty acid compositions is maintained during the year. The SSPi is another alternative toward more sustainable meat production and promising source of dietary fat for human nutrition.

Table 1. Least squares means ±SE of intramuscular fat composition (% of fatty acids) of cattle fattened with tropical forages at two season

Variable	Rainy	Drought
Total fat	3.53±0.22^{a}	2.47±0.21^{b}
Oleic	40.69.±3.15^{a}	27.52±3.46^{b}
Linoleic	0.11±0.88^{b}	3.11±0.97^{a}
Linolenic	1.67±0.51^{b}	6.10±0.56^{a}
Eicosanoic	0.11±0.18^{b}	0.93±0.20^{a}
Arachidonic acid (ARA)	0.08±0.10^{b}	0.49±0.11^{a}

^{ab}Superscripts different between columns denote significant difference between season ($P \leq 0.05$).

M148 Genetic parameters for fat thickness measured in different anatomical points of *Longissimus* muscle in Nellore cattle. M. N. Bonin*[1], F. J. Novais[1], S. L. Silva[1], R. C. Gomes[2], A. S. Figueiredo[1], P. F. Torralvo[1], L. G. Figueiredo[1], P. A. B. McLean[1], V. N. Barbosa[1], J. H. A. Campo[1], T. V. Solpelsa[1], M. H. A. Santana[1], F. M. Rezende[1], and J. B. S. Ferraz[1], *[1]College of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, Brazil, [2]State University of Londrina, Londrina, Brazil.*

Carcass backfat thickness (FT) is usually measured between the 12th and 13th ribs, however, in Brazil, the forequarter is not separated from the hindquarter at this section to preserve the loin integrity. Therefore, investigating alternative anatomical points to measure carcass traits in the Brazilian industry is needed. The purpose of this work was to evaluate the genetic correlation between fat thickness measured in different anatomical points of the *Longissimus* muscle (LM). Nellore bulls with 30 mo of age were evaluated for fat thickness between the 12th and 13th ribs by ultrasound (FTU, n = 2,028) using an equipment Aloka SSD500 micrus and a linear 17.2 cm probe and directly in the carcass, at the same site, after slaughter (FTC, n = 610). The other anatomical point was the section between the last lumbar and first sacral vertebra, that is the site where the loin is separated from the carcass hindquarter in Brazilian industries (FTLS, n = 1,072). For the estimation of genetic parameters a pedigree matrix with 14,722 animals was used and multi-traits analyses were carried out including the fixed effects of age at ultrasound evaluations and at slaughter, using the software VCE 6.0 (Groeneveld et al., 2008). The range for FT was 0.00 to 9.00 mm for FTU, 0.5 to 13.00 mm for FTC and 0.5 to 6.00 mm to FTLS. The FTU presented high genetic correlation with FTC (0.90 ± 0.05) and FTLS (0.80 ± 0.14). These correlations suggest that ultrasound is a good predictor of FT in the carcass and is highly correlated with the fat deposition in the loin since that the measures were collected in different anatomic points of the LM. FTC presented a moderate genetic correlation with FTLS (0.52 ± 0.14). The traits heritability values were moderate to low, but similar among each other, with values of 0.14 (0.04), 0.17 (0.07) and 0.13 (0.04) for FTU, FTC and FTLS, respectively. These results suggest that there is a genetic control of the FT deposition in the loin of Nellore bulls and that the FTLS may be a useful tool for genetic evaluation programs for carcass traits in Brazilian industries.

Key Words: *Bos indicus*, Brazilian cuts, ultrasound

M149 Comparative effects of two beta adrenergic agonists on Warner-Bratzler and slice shear force of USDA Choice strip steaks from calf-fed Holsteins. A. J. Garmyn*[1], J. N. Martin[1], J. C. Brooks[1], R. J. Rathmann[1], J. M. Hodgen[2], K. D. Pfieffer[2], C. L. Armstrong[2], D. A. Yates[2], J. P. Hutcheson[2], and M. F. Miller[1], *[1]Texas Tech University, Lubbock, [2]Merck Animal Health, DeSoto, KS.*

Our objectives were to determine the effects of zilpaterol hydrochloride (ZH), ractopamine hydrochloride (RH), or no β-adrenergic agonist (β-AA) on Warner-Bratzler shear force (WBSF) and slice shear force (SSF) of USDA Choice strip steaks in response to 2 postmortem aging periods (14 or 21 d). Calf-fed Holstein steers (n = 565) were assigned to one of 3 treatments: ZH (8.3 mg/kg of DM for 20 d; Merck Animal Health, DeSoto, KS), RH (300 mg/kg/d for 28 d; Elanco Animal Health, Greenfield, IN), or no β-AA (CON). Strip loins (n = 315) were obtained and portioned into 2.5-cm steaks using a Marel Portioning Machine (IPM-3, Marel Townsend, Des Moines, IA). Interactions between treatment and aging were not detected ($P > 0.10$) for any response variables. Supplementation with β-AA resulted in greater WBSF and SSF ($P < 0.01$). Control steaks (3.25 kg) had a lower average WBSF value than steaks from steers fed ZH (3.68 kg) and RH (3.67 kg), which did not differ. Similarly, CON steaks (14.13 kg) had a lower average SSF value than steaks from steers fed ZH (16.11 kg) and RH (16.00 kg). Aging for 21 d resulted in lower ($P < 0.01$) WBSF (3.43 vs. 3.64 kg) and SSF (16.36 vs. 14.46 kg) values compared with steaks aged 14 d. The percentage of steaks with WBSF values <4.4 kg were affected ($P < 0.01$) by treatment, but postmortem aging had no effect ($P = 0.13$). Ninety percent of CON steaks would be considered tender (4.4 kg) based on ASTM guidelines, but β-AA supplementation resulted in a lower percentage of tender steaks for ZH (79.2%) and RH (77.3%). Feeding β-AA ($P < 0.01$) and postmortem aging period ($P = 0.02$) affected the percentage of steaks measuring <3.9 kg of shear force. The percentage of very tender steaks was 84.0, 66.5, and 66.8% for CON, ZH, and RH, respectively. In conclusion, feeding β-AA to calf-fed Holsteins increased shear force values of USDA Choice strip steaks, regardless of postmortem aging period. Although, feeding β-AA reduced the percentage of tender steaks, no differences in shear force were observed between ZH and RH at these inclusion levels.

Key Words: beta agonist, dairy beef, shear force

M150 Carcass characteristics of Nellore steers receiving protected linseed oil during different periods of feedlot. T. M. Pivaro*[1], W. Henrique[2], A. A. M. Sampaio[1], J. L. V. Coutinho Filho[2], E. A. Oliveira[1], B. L. Rosa[1], and V. G. Carvalho[1], *[1]FCAV/Unesp, Jaboticabal, SP, Brazil, [2]APTA, São José do Rio Preto, SP, Brazil.*

The objective was to assess the supply of linseed oil or linseed oil protected from ruminal degradation during different periods of feedlot feeding on carcass characteristics of 35 Nellore steers. The animals were housed in individual pens for 105 d at Sao Paulo Agency for Agribusiness Technology, in Sao Jose do Rio Preto, Brazil, and received one of the following diets: control (without oil), with linseed oil during all the confinement (LO), or protected linseed oil during all the feedlot (OLiP 3), in the last 70 d (OLiP 2) or the last 35 d (OLiP 1). The corn silage was used as the exclusive roughage in the proportion of 40% in DM of diet. All diets were isonitrogenous and those with addition of oil were isoenergetic. The experimental design was a randomized block, balanced by animal weight, and the means were compared by Student's *t*-test at 5% probability. After slaughter, weight (HCW), dressing percentage (HCY), length (LC) and depth (DC) of hot carcass were determined. The longissimus muscle area (LMA) and the backfat thickness (BFT) between the 12th and 13th ribs were measured 24h after cooling, and the longissimus muscle area per 100 kg of carcass (LMAC) calculated. There were no differences among the variables assessed in this study (Table 1). Therefore, there was no benefit related to the addition of linseed oil, protected or not, to the diet or to the proposed durations for the supply of protected linseed oil during feedlot feeding over the carcass characteristics of Nellore cattle.

Table 1. Carcass characteristics of Nellore steers, finished in feedlot

Treatment	HCW (kg)	HCY (%)	LC (cm)	DC (cm)	LMA (cm^2)	LMAC (cm^2/100 kg)	BFT (mm)
Control	289.14	55.84	129.85	67.64	75.57	26.11	6.88
OLiP 1	287.78	55.45	129.07	67.21	74.14	25.83	7.56
OLiP 2	293.71	56.76	129.57	67.50	74.57	25.45	5.96
OLiP 3	298.92	56.35	128.28	65.50	80.14	26.85	6.66
LO	295.14	55.77	128.57	65.42	77.28	26.25	7.44
P[1]	0.4983	0.4527	0.8436	0.2754	0.3684	0.8443	0.7726
CV (%)[2]	4.40	2.51	2.29	3.73	10.64	8.96	36.88

[1] P = probability.

[2] CV = coefficient of variation.

Key Words: backfat thickness, longissimus muscle area, weight

M151 Meat fatty acids profile of Nellore steers receiving protected linseed oil during different periods of feedlot.

T. M. Pivaro*[1], W. Henrique[2], E. A. Oliveira[1], A. A. M. Sampaio[1], B. L. Rosa[1], J. L.V. Coutinho Filho[2], and V. G. Carvalho[1], [1]*FCAV/Unesp, Jaboticabal, SP, Brazil,* [2]*APTA, São José do Rio Preto, SP, Brazil.*

The objective was to assess the fatty acid profiles in the meat of 35 Nellore steers fed linseed oil or linseed oil protected from ruminal degradation (OLiP) during different periods of feedlot. The animals were housed in individual pens for 105 d at Sao Paulo Agency for Agribusiness Technology, in Sao Jose do Rio Preto, Brazil. The treatments were: control diet (CD), linseed oil during all the confinement (LO), or OLiP fed during the last 35 d (OLiP 1), last 70 d (OLiP 2) or all the confinement (OLiP 3). Corn silage was the exclusive roughage at the rate of 40% in DM of diet. The experimental design was a randomized block, balanced by animal weight, and means were compared by Student's *t*-test at 5% probability. The animals were slaughtered at an average weight of 522.71 ± 27.99 kg and samples were taken from the Longissimus between the 12th and 13th ribs and lyophilized after 24 h of carcass cooling. The fatty acids were quantified by gas chromatography. The ratio unsaturated:saturated was different among CD, OLiP 2 and OLiP 3 treatments (1.37, 1.16 and 1.16, respectively) while OLiP 1 (1.29) and LO (1.30) did not differ from any of the treatments. A similar result was observed for monounsaturated:saturated. However, OLiP 1 and LO differed in n-3 fatty acids (0.47 and 0.72%, respectively), and both did not differ from the other treatments (0.50% for CD, and 0.64% for OLiP 2 and OLiP 3). No difference was detected in the ratio of n-6:n-3 between treatments OLiP 2 and OLiP 3 (7.32 and 6.52, respectively), but both differed from OLiP 1 (9.12), DC (10.91) and LO (4.77), which differed from each other. Increasing the supply of protected linseed oil provides improvement in the amount of n-3 and, the ratio n-6:n-3 became closer to the ideal for a more balanced diet.

Key Words: Longissimus, meat quality, unsaturated

M152 Meat quality of crossbred cattle finished at feedlot and fed increasing levels of linseed oil.

E. A. Oliveira*[1,3], B. L. Rosa[1], T. M. Pivaro[1], M. B. P. Costa[1], V. G. Carvalho[1], A. T. Andrade[1], W. Henrique[2], and A. A. M. Sampaio[1], [1]*FCAV/Unesp, Jaboticabal, SP, Brazil,* [2]*APTA, São José do Rio Preto, SP, Brazil,* [3]*FAPESP Post-doctorate fellowship, São Paulo, SP, Brazil.*

The aim was to assess the effects of increasing linseed oil supplementations (1, 3.8 and 5.2% in diet DM) and sex on meat quality of crossbred cattle Nellore × Canchim. Fifteen steers (427.80 ± 42.01 kg and 24 ± 2 mo old) and 14 heifers (400.57 ± 33.79 kg and 24 ± 2 mo old) were housed in individual pens and fed diets with 80% concentrate in DM and sugarcane IAC 86–2480 as the exclusive roughage source at Sao Paulo State University in Jaboticabal, Brazil. The experiment was a randomized block design, arranged in a 3 × 2 factorial scheme (oil ratios × sex) and means were compared by Student′s *t*-test at 5% probability. After fattening period, the animals were slaughtered by blocks. After 24 h of cooling carcasses, samples of *Longissimus* muscle between the 12th and 13th ribs were taken and analyses were conducted (meat and fat color characteristics (L*, a*, b*), water holding capacity (WHC), cook loss (CL), shear force (SF) and pH)). Oil levels, sex, and the interaction between these factors did not show differences for meat and fat color characteristics L*, a*, b* (38.63, 7.65 and 18.75; 72.90, 7.65 and 18.75, respectively), WHC (66.93%), SF (5.04 kgF) and pH (5.71). The interaction was significant for the CL variable, and heifers fed 1% oil showed the highest value (37.44%) compared with those fed 3.8 and 5.2% of oil (32.34 and 29.41%, respectively). Thus, higher levels of linseed oil supplementation for heifers decreased CL, which can improve beef organoleptic aspects such as juiciness. Steers showed no difference among oil levels, with an average of 36.14%. Analyzing each linseed oil level, only 5.2% on diet showed higher values for steers compared with heifers (36.26 and 29.41%, respectively). The use of increasing levels of linseed oil in cattle diet, from 1 to 5.2% in DM, did not improve qualitative aspects of the meat, such as tenderness and color (characteristics related to the presentation to the customer). Steers and heifers fed increasing linseed oil supplementations produce meat with similar qualitative characteristics except for CL.

Key Words: cook loss, meat color, shear force

M153 A study of the variance in tenderness and carcass traits of pasture and feedlot finished beef cattle.

L. A. Goonewardene*[1,2], J. A. Basarab[1], Z. Wang[2], R. W. Seneviratne[2], W. N. P. Yalingasinghe[2], P. S. Mir[3], J. L. Aalhus[4], and E. K. Okine[2], [1]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada,* [2]*University of Alberta, Edmonton, Alberta, Canada,* [3]*Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada,* [4]*Agriculture and Agri-Food Canada, Lacombe, Alberta, Canada.*

Tenderness is an important beef quality trait and consumers judge the overall acceptability based primarily on tenderness, flavor, color and texture. The objectives of this study were to compare the variance (based on a variance ratio) in Warner-Bratzler (WB) tenderness and selected carcass traits in pasture (P, n = 47) and feedlot (F, n = 48) finished steers. The 7 dietary treatments making up P and F were: 1) steers on pasture only throughout (n = 12), 2) steers on pasture supplemented with cracked barley grain throughout (n = 12), 3) steers on pasture supplemented with whole sunflower seed (WSS) throughout (n = 23), 4) steers with no supplement on pasture and feedlot (n = 12), 5) steers supplemented with WSS on pasture and no supplement in the feedlot (n = 12), 6) steers with no supplement on pasture but supplemented with WSS in the feedlot (n = 12) and 7) steers supplemented with WSS on pasture and the feedlot (n = 12). Steers in treatments 1–3 were harvested directly off pasture and steers in treatments 4–7 were finished in the feedlot. The variation in WB tenderness in steaks taken from the M. longissimus thoracis from P steers (3.92 kg) was higher ($P < 0.01$) than in F steers (1.89 kg). The highest variance was in P finished steers fed cracked barley supplement (6.33 kg) and this was higher ($P < 0.01$) than steers given no supplement on pasture but supplemented with WSS in the feedlot (1.19 kg) and steers supplemented with WSS on pasture and in the feedlot (1.82 kg). Steaks from pasture finished steers are expected to be more variable in tenderness, less tender and have consistently less trimable subcutaneous fat compared with steaks from feedlot finished steers.

Key Words: toughness, pasture, Warner-Bratzler

M154 Partitioning of Energy into Muscle and Fat in Relation to Beef Composite Type and Age at Harvest. N. P. Y. Welegedara*[1], E. K. Okine[1], J. A. Basarab[2], Z. Wang[1], C. Li[3], H. Bruce[1], S. Markus[2], J. Stewart-Smith[4], and L. A. Goonewardene[1,2], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada,* [3]*Agriculture and Agri-Food Canada, Lacombe Research Centre, Lacombe, Alberta, Canada,* [4]*BeefBooster Inc., Calgary, Alberta, Canada.*

Beef composite types (CT) have combined favorable traits of pure breeds. The objective was to compare energy required to grow muscle (M) and fat (F) in the carcass tissues of 5 BeefBooster composites (M1, M2, M3, M4 and TX) serially slaughtered at 6 harvest ages (HA) from 274 to 456 d in 2 years. The foundation breed for the M1 was Angus, M2 was Hereford, M3 was various small breeds, M4 was Gelbvieh or Limousin and TX was Charolais. The energy requirement for M (EM) and F (EF) deposition, the ratio of EF:EM and the proportion (%) of energy required to produce M and F without accounting for turnover, were analyzed by GLM of SAS with CT, HA, interaction of CT and HA and year as main effects. EM, EF, EF: EM ratio and proportions of energy required to produce M and F were different ($P < 0.01$) for CT and HA. EF was dependent on both CT and HA due to interaction ($P = 0.03$). EF was 1158.7, 1121.6, 1013.3, 1012.3, 1052.5 Mcal, EP was 384.6, 412.7, 330.3, 410.9, 428.9 Mcal and EF: EM was 2.95, 2.61, 2.97, 2.38 and 2.40 for M1, M2, M3, M4 and TX respectively. EF was 423.7, 831.3, 1058.8, 1213.1, 1394.3 and 1508.8 Mcal, EP was 275.1, 362.3, 412.8, 416.4, 441.6 and 453.0 Mcal and EF: EM was 1.54, 2.33, 2.60, 2.95, 3.19 and 3.38 for harvest ages at 274, 347, 372, 399, 427 and 456 d respectively. The proportion of energy required to produce F increased from 60.2% at 274 d to 76.8% at 456 d ($P < 0.01$) and the proportion of energy required to produce M decreased from 39.8% at 274 d to 23.2% at 456 d ($P < 0.01$). Based on energy partitioning and energetic efficiency of producing M and F, M1 and M3 can be harvested before 456 d and TX harvested after 456 d to avoid the production of excessively fat carcasses.

Key Words: energy partitioning, fat, muscle

Nonruminant Nutrition: Amino Acids and Energy

M155 Influence of energy concentration of the diet and terminal sire line on growth performance and carcass and meat quality of pigs slaughtered at 115 kg of BW. G. Coca[1], M. P. Serrano[1], L. Cámara[1], P. Guzmán[1], J. D. Berrocoso[1], J. Coma[2], and G. G. Mateos*[1], *[1]Animal Science Department, Universidad Politécnica de Madrid, Madrid, Spain, [2]Vall Company, Lleida, Spain.*

In total, 480 pigs (48 ± 5.15 kg BW) were used to investigate the effects of net energy (NE) concentration of the diet (2,350, 2,400, 2,450, and 2,500 kcal/kg) and terminal sire line (PIC L62 vs. Pietrain) on growth performance and carcass and meat quality of gilts and boars slaughtered at 115 kg BW. Pigs were fed according to a 2-phase feeding program using diets based on cereals, rapeseed meal, and soybean meal. Within each feeding period the lys:NE (g/Mcal) ratio was the same for all diets (3.8 vs. 3.5 respectively). Cumulatively, feed intake was reduced ($P < 0.001$) and G:F was improved ($P < 0.001$) as the level of NE of the diet increased but ADG and carcass and meat quality traits were not affected by diet. Crossbreds from PIC L62 sire line had higher ADFI and ADG ($P < 0.001$) than crossbreds from Pietrain sire line but G:F was not affected. Carcasses from Pietrain crossbreds were leaner ($P < 0.001$) and tended to have higher shoulder ($P < 0.08$) yield and less intramuscular fat ($P < 0.05$) than carcasses from PIC L62 crossbreds. Fat at m. gluteus medius was higher ($P < 0.001$) for PIC L62 crossbreds than for Pietrain crossbreds. Boars had better ADG ($P < 0.01$) and G:F ($P < 0.001$) and higher shoulder yield ($P < 0.001$) and less carcass yield ($P < 0.001$) and fat at m. gluteus medius ($P < 0.01$) than gilts. Also, boars tended to have less intramuscular fat ($P < 0.08$) in m. longissimus dorsi than gilts. In conclusion, an increase in NE concentration of the diet did not affect ADG or carcass quality of pigs. Therefore, an increase in energy content of the diet might not be justified under most economic circumstances. PIC L62 crossbreds had better growth performance but fatter carcasses than Pietrain crossbreds and gilts had higher carcass yield than boars. Consequently, gilts from PIC L62 crossbreds are preferred when carcasses are destined to the dry-cured industry.

Key Words: carcass quality and growth performance, sex and sire line, net energy concentration

M156 The utilization of energy by pigs differing in estimated growth potential. A. D. Beaulieu*[1], D. A. Gillis[1], J. N. Shea[1], J. P. Marriott[1], and J. F. Patience[2], *[1]Prairie Swine Centre Inc., Saskatoon, SK, Canada, [2]Iowa State University, Ames.*

A significant challenge in pork production is managing the variability within a cohort of pigs. Our objective was to compare the utilization of dietary energy for growth and protein deposition among pigs selected at nursery exit based on growth potential (GP). Treatments, arranged as a 3 × 2 × 2 factorial were 3 GPs, 2 dietary energy concentrations (NE; 2.18 or 2.40 Mcal NE/kg) and 2 intake levels (IN; 100 or 85% of ad libitum). Dietary energy was increased with canola oil and substituting wheat for barley. Each wk for 8 wks, 15 barrows were selected at nursery exit (about 62 d of age, DOA) from 3 litters and divided into a fast (0.46 ± 0.04), average (0.40 ± 0.04) or slow (0.34 ± 0.04 kg/DOA ± SD) GP group. Within GP, pigs were randomly allocated to 1 of the 4 NE by IN treatments or to an initial slaughter group (ISG). Dietary treatments began at 90 kg BW. Pigs were slaughtered at 90 (ISG) or 120 kg BW. Growth rate between 90 and 120 kg BW was unaffected by GP or NE ($P > 0.10$) and decreased by lower IN (0.86 vs. 1.01 kg/d; $P < 0.01$). GP did not affect feed intake ($P > 0.10$) which was increased when pigs were fed 2.18 vs. 2.40 Mcal NE/kg or 100% IN ($P < 0.05$). Feed efficiency was similar among treatments ($P > 0.10$). Efficiency of energy utilized for BW gain (Mcal NE/kg) was unaffected by GP and NE but tended to be higher at the 85 vs. 100% IN ($P = 0.06$). The efficiency of energy utilized for protein deposition (g CP/Mcal NE) was increased or tended to be increased by low NE ($P < 0.05$) or low IN ($P = 0.09$). The rate of protein deposition was increased at low NE (161 vs. 137 g/d; $P < 0.05$), tended to be increased by higher IN ($P = 0.09$) and was unaffected by GP ($P > 0.10$). Pigs fed 100% IN or 2.40 NE had an increased rate of lipid deposition ($P < 0.05$) which was unaffected by GP ($P > 0.10$). The rate and efficiency of protein deposition from 90 to 120 kg BW were increased by a lower NE. Pigs selected for GP at nursery exit, however, were similar during finishing with respect to rate and efficiency of growth and protein deposition. Separating pigs into GP classes at nursery exit will not aid management of variability in the finishing barn.

Key Words: swine, variability, dietary energy

M157 Effect of starch level in pig diets on digestible energy value of crude glycerin using the mobile nylon bag technique. C. A. Ordoñez-Gomez*[1,2], C. Ariza-Nieto[1], and G. Afanador-Tellez[2], *[1]CORPOICA, Bogota, Colombia, [2]Universidad Nacional de Colombia, Bogota, Colombia.*

In recent years, crude glycerin production has increased exponentially, which has led to a reduction of its price, making it possible for this co-product to reduce feed production costs in the pig industry. The aim of this study was to evaluate the effect of starch level on the digestible energy (DE) value of crude glycerin. Eight barrows (46 kg initial body weight and fitted with a duodenal T-cannula) were used to estimate DE of crude glycerin derived from diets containing 2 starch levels (10 and 12%) and 5 crude glycerin levels (0, 2.5, 5.0, 7.5, 10%). Therefore, 10 mixed diets were formulated and evaluated by the mobile nylon bag technique. A total of 320 nylon bags were used for DE value determination (32 per diet). In vitro digestion of the bags was carried out in pepsin-HCl solution with 450 IU pepsin/L at pH 2.0 and 37°C for 4 h. In the in vivo phase, 8 nylon bags were inserted into the duodenal cannula of each pig daily, during feeding times (800, 1030, 1300, and 1530 h). The nylon bags used in the study were excreted within 24 h of insertion and were carefully isolated from feces with a dry paper towel, then were frozen (−20°C) and freeze-dried for gross energy determination. The amount of material remaining in the nylon bag after passage through the digestive tract was used to calculate energy digestibility. The DE value of each bag was corrected for the DE of corn starch. Data were analyzed by a multiple linear regression model using PROC REG of SAS (v9.0). The slope of the regression line indicated the DE for crude glycerin, while the regression intercept indicated the effect of starch level. Results showed no interaction between the level of starch in the basal diet and the digestible energy value of crude glycerin ($P = 0.239$). The apparent DE of crude glycerin fed to pigs was 3251 kcal/kg DM ($R^2 = 0.578$; $P < 0.001$). According to the results of this study, the level of starch in pig diets does not affect the digestible energy value of crude glycerin.

Key Words: digestible energy, crude glycerin, pig

M158 Dynamic changes in blood flow, oxygen consumption and metabolite responses to acute arginine supplementation in growing-finishing pigs. B. E. Tan[1], Y. L. Yin*[1], X. F. Kong[1], and G. Y. Wu[1,2], [1]*Institute of Subtropical Agriculture, The Chinese Academy of Sciences, Chansha, Hunan, China,* [2]*Department of Animal Science, Texas A&M University, College Station.*

Arginine plays an important role in regulating nutrient metabolism. This study was conducted to determine the dynamic changes in blood metabolite responses to acute arginine supplementation in growing-finishing pigs using a blood catheter technique. Eight barrows (Duroc × Large White × Landrace) with an average initial BW of 70 kg were surgically fitted with chronic catheters in the portal vein, ileal vein and carotid artery and were randomly allocated to 2 groups to receive alanine (103 mg/kg body wt, isonitrogenous control) or L-arginine-HCl (61 mg/kg body wt) by the portal vein. Blood flows were measured with infusion of p-aminohippuric acid (PAH) into the ileal vein, and blood samples were obtained every 0.5 h for 4 h to determine oxygen consumption by portal vein-drained organs (PVDO) and concentrations of blood metabolites. Compared with alanine treatment, arginine infusion increased portal vein blood flow at 30, 60 and 90 min after infusion, but decreased ($P < 0.05$) PVDO at 60, 90, 120 and 150 min after infusion. Plasma concentrations of glutamate (at infusion times of 180 and 240 min) and arginine (at infusion times of 60, 120, 180 and 240 min) in arginine-infused pigs were higher ($P < 0.05$) than those of alanine-infused pigs at the same infusion time. However, arginine infusion decreased ($P < 0.05$) plasma cystine concentrations at infusion times of 60, 120, 180 and 240 min and valine at infusion times of 60 and 120 min compared with alanine treatment. Plasma concentrations of insulin and glucagon at infusion times of 30, 60 and 90 min were higher, and free fatty acids at infusion times of 60, 90 and 120 min were lower, compared with pigs both in alanine treatment at the same infusion time and at the pre-infusion (baseline) time ($P < 0.05$). These results suggest that acute arginine supplementation improves blood flow and reduces PVDO oxygen consumption, thereby enhancing amino acid availability for utilization. Insulin and glucagon may also play important roles with arginine infusion by transiently regulating nutrient metabolism.

Key Words: pig, nutrition, amino acids

M159 Dietary valine:lysine ratios of 0.80 and 0.85 did not differ performance of primiparous sow and nursing large litters. S. M. Hong,* P. Y. Zhao, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

An experiment using 18 primiparous sows (Landrace × Yorkshire) to determine the effect of dietary valine:lysine ratios on performance in primiparous sows and litter. Sows were randomly assigned to 1 of 2 experimental diets (9 replicate pens per treatment and 1 sow per pen) containing different valine:lysine ratios of 0.80 or 0.85. Corn-soybean-wheat based diets were formulated to achieve the dietary treatments (0.86% SID lysine, and 0.69% or 0.73% SID valine). All diets were formulated to have 3.45 Mcal ME/kg and contained vitamins and minerals that exceeded NRC (1998) recommendations. The experiment lasted for 21 d. On d 107 of gestation, sows were moved into farrowing crates in an environmentally regulated farrowing house. Farrowing crates (2.1 × 0.6 m) contained an area (2.1 × 0.6 m) for newborn pigs on each side, and the temperature in the farrowing house was maintained at a minimum of 20°C. After farrowing, daily feed allowance increased gradually, and sows had ad libitum access to feed by wk 2. Overall, body weight loss (41.8 vs. 37.7 kg), backfat loss (5.5 vs. 7.9 mm), and ADFI (5.39 vs. 5.72 kg) of sows were not affected ($P > 0.05$) by different dietary valine:lysine ratios. No difference ($P > 0.05$) was noted in estrus interval (5.5 vs. 5.8 d). There was no difference ($P > 0.05$) in average body weight of piglets on the day of birth (1.39 vs. 1.26 kg) and d 21 (7.14 vs. 6.99 kg) between treatments. The numbers of weaned piglets (11.75 vs. 11.67), piglet survival rate (97.03 vs. 98.15%), weaning litter weight (83.60 vs. 81.49 kg), litter weight gain (67.25 vs. 66.76 kg), piglet gain (5.75 vs. 5.73 kg) and piglet daily gain (240 vs. 239 g) were not affected ($P > 0.05$) by dietary treatments. In conclusion, dietary valine:lysine ratios of 0.80 and 0.85 had no effects on lactation performance of primiparous sow and their offspring.

Key Words: lactation performance, primiparous sows, valine:lysine ratio

M160 Sequence of apparent ileal digestible lysine for growing-finishing gilts. G. C. Rocha*[1], F. C. O. Silva[2], R. F. M. Oliveira[1], L. Alebrante[1], A. Saraiva[1], and J. L. Donzele[1], [1]*Federal University of Viçosa, Viçosa, MG, Brazil,* [2]*EPAMIG, Viçosa, MG, Brazil.*

This study was conducted to evaluate sequences of apparent ileal digestible lysine (AIDL) for gilts from 63 to 153 d of age. Eighty gilts (AGPIC 425 x Camborough 25), were used in a randomized complete block design to evaluate 5 AIDL level treatments with 3 phase-feeding per treatments (9–8-7; 10–9-8; 11–10–9; 12–11–10 and 13–12–11 g/kg from 63 to 103, 103 to 133 and 133 to 153 d of age, respectively). Each treatment was replicated with 8 pens (1.87m^2/pig) with 2 pigs each. The basal diet for each phase contained corn, soybean meal and no supplemental industrial amino acids. Four additional diets (each phase) were formulated by adding L-lysine HCl 78% and when necessary DL-methionine 99%, L-threonine 98%, L-tryptophan 98%, L-valine 96.5% and L-isoleucine 99% replacing the starch. At the beginning and the end of each phase, pigs and feeders were weighed to assess ADG, ADFI, final BW and feed to gain ratio (F:G). From 63 to 103 d the AIDL levels (9, 10, 11, 12 and 13 g/kg) influenced linearly ($P<0.05$) the ADG (945, 956, 965, 981 and 1004 g) of the pigs, while the F:G (2.12, 2.00, 2.00, 1.97 and 1.99) was improved ($P<0.05$) quadratically to 1.97 at a level of 11.8 AIDL g/kg, and with no effects ($P>0.05$) on the ADFI and the final BW. There was no effect ($P>0.05$) of the sequences of AIDL on the gilts growth performance between 63 to 133 d, and 63 to 153 d. Sequences of diets containing 9-8-7 of AIDL g/kg fed from 63 to 103, 103 to 133 and 133 to 153 d, respectively, meet the AIDL requirements of growing-finishing gilts from 63 to 153 d of age.

Table 1. Growth performance of gilts from 63 to 153 days

	Apparent ileal digestible lysine, g/kg					
Item	9-8-7	10-9-8	11-10-9	12-11-10	13-12-11	SEM
Initial BW, kg	24.4	24.5	24.2	24.2	24.3	0.54
Final BW, kg	114.1	113.2	112.6	114.4	114.2	1.86
ADFI, g	2311	2267	2279	2322	2331	44.38
ADG, g	996	988	978	1004	997	17.14
F:G, g/g	2.32	2.29	2.33	2.31	2.34	0.02

Key Words: amino acids, performance, requirements

M161 Feed efficiency and carcass grade can be improved in finishing pigs by increasing the standardized ileal digestible lysine to metabolizable energy ratio. J. A. Jendza* and S. K. Baidoo, *University of Minnesota, Waseca.*

Two trials were conducted to evaluate the effect of increased standardized ileal digestible (SID) lysine to ME ratio on growth performance and carcass characteristics in finishing pigs. Trial 1 fed 256 mixed sex pigs with an initial BW of 99.2 kg (SD = 8.9 kg) for 4 wk. Pigs were housed 8 to a pen in a completely randomized design with 8 pens per treatment. Treatments consisted of a 72.8% corn/22% soy basal diet containing 7.5 g SID lysine and 3,401 kcal ME/kg of feed supplemented with 0, 1.2, 2.4, and 3.6 g lysine HCl/kg for treatments 1 to 4, respectively. At the end of 4 wk, pigs were individually identified and carcass characteristics recorded. Carcass grade was a composite measure of hot carcass weight and percent lean. Grading scores ranged from −7.5 to +10, with lighter and fatter pigs receiving lower scores than heavier and leaner pigs. With pen as the experimental unit, dietary treatments had no effect on any measure of growth performance or carcass quality. Trial 2 used 317 pigs, housed by sex 7 or 8 to a pen, with an initial BW of 90.4 kg (SD = 6.5 kg) for 4 wk. Treatments were based on a 72.9% corn/ 22% soy basal diet containing 7.85 g SID lysine and 3,404 kcal/kg of feed. This basal was then supplemented with lysine HCl to achieve SID lysine to ME ratios of 2.3, 2.6, 2.9, and 3.2 g SID lysine/Mcal ME. Crystalline DL-methionine, L-threonine and L-tryptophan were also added to maintain their respective ratios to lysine in the basal diet. Growth performance and carcass characteristics were recorded at the end of 4 wk. Average daily gain and ADFI were not affected by dietary treatment, nor were most carcass characteristics. However, linear improvements were detected in feed efficiency and carcass grade ($P < 0.05$). Feed efficiency increased from a low of 0.313 to a high of 0.329. Carcass grade increased from a low of 6.2 to a high of 6.86. There was also a trend to increase hot carcass weight ($P < 0.10$). In summary, carcass grade and feed efficiency of finishing pigs can be improved by feeding a higher SID lysine to ME ratio as long as care is taken to maintain adequate concentration of the other essential amino acids to lysine.

Key Words: swine, standardized digestible lysine, carcass characteristics

M162 Chemical composition of dietary fat affects fat and energy digestibility when supplemented to lactating sows.

D. S. Rosero*[1], J. Odle[1], R. D. Boyd[2], and E. van Heugten[1], [1]*Department of Animal Sciences, North Carolina State University, Raleigh,* [2]*Hanor Company Inc., Franklin, KY.*

Levels of free fatty acids (FFA) and saturation of supplemental fat affects fat digestibility, which may be particularly important in lactating sows which require high amounts of nutrients. This hypothesis was tested using 85 mature sows assigned randomly to a 4 × 5 factorial arrangement of treatments and a control diet with no added fat. Factors included: 1) FFA level: 0, 18, 36 and 54% and 2) Iodine value (IV): 77, 88, 100, 112 and 124. Diets were corn-soybean meal based, and contained 3.42 g standardized ileal digestible lysine/Mcal ME. Dietary fat was supplemented at 6% and different FFA and IV levels were obtained by blending 4 fat sources: choice white grease (FFA = 0.3%, IV = 74.8, GE = 9469 cal/g), choice white acid grease (FFA = 57.8, IV = 79, GE = 8266), soybean-cotton seed oil (FFA = 0.1, IV = 67.5, GE = 9442) and soybean acid oil (FFA = 67.5, IV = 112.9, GE = 9196). Titanium dioxide was added to diets (0.5%) and used as a marker to determine digestibility of fat and energy. After 6 d of adaptation to treatment diets, fecal grab samples were collected from sows during the following 4 d (d 10 to 13 of lactation), twice per day. Digestibility of fat from ingredients in the control diet was 31.5%. Digestibility of the supplemented fat increased with levels of IV (quadratic, $P < 0.001$; 74.4, 84.5, 85.2, 82.9 and 73.53 for IV of 76, 88, 100, 112 and 124, respectively), and decreased with increasing levels of FFA (linear, $P < 0.001$; 87.4, 81.6, 74.0 and 77.3% for 0, 18, 36 and 54%). Apparent digestible energy content of the diet decreased with higher levels of FFA (quadratic, $P = 0.007$; 88.8, 88.2, 87.4 and 88.6%) and increased with increasing levels of IV (quadratic, $P = 0.017$; 87.6, 87.5, 88.9, 89.2 and 88.2%). Digestibility of supplemental fat was described by: Fat digestibility $= -78.45 - 1.59 \times \text{FFA} + 3.75 \times \text{IV} + 0.007 \times \text{FFA}^2 - 0.02 \times \text{IV}^2 + 0.01 \times \text{FFA} \times \text{IV}$, $r^2 = 0.47$. Digestibility of energy content of the diet was described by: Digestible energy $= 73.48 - 0.12 \times \text{FFA} + 0.31 \times \text{IV} + 0.001 \times \text{FFA}^2 - 0.001 \times \text{IV}^2$, $r^2 = 0.19$. In conclusion, higher levels of FFA negatively affected fat and energy digestibility. Also, saturation of the fat affected digestibility in a quadratic manner when fed to lactating sows.

Key Words: lactating sows, free fatty acids, saturation

M163 Feeding phytonutrients to chickens: The relationship between energy availability and growth performance.

D. Bravo*[1], V. Pirgosliev[2], and S. P. Rose[3], [1]*Pancosma, Geneva, Switzerland,* [2]*Avian Science Research Centre, Scottish Agricultural College, Ayr, UK,* [3]*National Institute of Poultry Husbandry, Harper Adams University College, Newport, UK.*

A total of 400 male day-old Ross 308 chicks were used in a floor pen study to investigate the effects of dietary supplementation of a mixture of carvacrol, cinnamaldehyde and capsaicin (XT, Pancosma S.A.) on dietary apparent metabolizable (AME), dietary net energy for production (NEp), and bird growth performance. Four diets (maize- or wheat-soybean based and with or without XT in a 2 × 2 factorial arrangement) were offered to the birds from 0 to 21 d of age. The diets were formulated to be adequate in protein (215 g/kg diet) but marginal in AME (2890 kcal/kg), and slightly higher in non-starch polysaccharides than recommended in the control diets supplemented with XT (100 g/t). The diets were provided in mash form ad libitum throughout the experiment. The treatments were allocated in a randomized complete block design with each treatment having 10 replicate floor pens with 10 birds per pen. The pens were bedded with used litter. Feeding wheat-based diets resulted in lower AME ($P < 0.05$) but higher NEp ($P < 0.05$), and feed efficiency ($P < 0.05$). Irrespective of cereal type, XT supplementation improved AME, NEp and feed efficiency ($P < 0.05$). There was a lack ($P > 0.05$) of cereal source by XT interaction suggesting that similar responses may be expected when XT is added to both, maize or wheat-based diets. Linear regression analysis was used to assess the relationship between determined dietary energy and bird growth performance. Dietary NEp was more highly correlated with performance criteria than dietary AME and seems to be a more sensitive way to evaluate broiler response to phytonutrients supplementation.

Key Words: phytonutrients, broiler, energy availability

M164 An evaluation of glutamine feed supplementation on the immune response, intestinal morphology, and growth performance of broilers at various stages of development.

S. Khempaka* and W. Molee, *School of Animal Production Technology, Institute of Agricultural Technology, Suranaree University of Technology, Muang, Nakhon Ratchasima, Thailand.*

Banned antibiotic feed additives classed as growth promoters in poultry feed, have resulted in increased incidence of disease and depressed growth performance. Glutamine (Gln) may be an alternative feed additive to resolve these problems, since many beneficial effects of it have been reported in animals. Gln is the principle metabolic fuel for small intestine enterocytes, lymphocytes, macrophages and fibroblasts and is considered an essential amino acid in some species under inflammatory conditions. In a previous study we found that the addition of 1% Gln provided the highest efficacy without any negative effects on dry matter, organic matter and ash digestibility and nitrogen retention. Therefore, the purpose of this study was to evaluate the effect of glutamine supplementation at various stages of development on the immune response, intestinal morphology and growth performance of broilers. Three hundred, day-old male chicks were randomly assigned in a completely randomized design into 5 treatments with 3 replicates of 20 birds per treatment. Dietary treatment groups consisted of a control and the control supplemented 1% Gln that was fed to broilers for 7, 14, 21 or 28 d of age. The birds were raised through 42 d of age. Feed and water were provided ad libitum throughout the experimental period. Significant differences among treatment were assessed by Duncan′s new multiple range-test at $P < 0.05$. Orthogonal contrasts were used to evaluate treatment effects of control vs. mean of glutamine supplementation period. The addition of Gln at a level of 1% provided no significant benefits in most parameters studied, including growth performance, and immunoglobulin measured in serum and small intestinal tissue samples ($P > 0.05$). However, chicks receiving 1% Gln for 7 and 14 d had significantly wider villi in the duodenum compared with chicks fed the control diet ($P < 0.05$). In which the mean value of villus wide in chicks fed Gln for 7 and 14 d of age compared with control were 24 vs 55 and 35 vs 63.5 µm, respectively. Thus, it was concluded that the most advantageous time to add Gln to the diet of newborn chicks is from 0 to 14 d of age, beyond which point 1% added dietary Gln has little to no effect.

Key Words: broiler chicken, glutamine, intestinal morphology

M165 Velocity of L-methionine incorporation into the blood plasma of broiler chickens at the first week of age. A. C. Stradiotti*[1,4], C. Ducatti[2], J. R. Sartori[1], J. A. Bendassolli[3], V. C. Pelícia[1], P. C. Araujo[1], M. K. Maruno[1], L. V. C. Girão[1], F. G. Luiggi[1], R. Fasanaro[1], M. M. P. Sartori[2], J. C. Denadai[2], E. T. Silva[2], C. R. Souza-Kruliski[2], and A. C. Pezzato[1], *[1]São Paulo State University, Faculty of Veterinary Medicine and Animal Science, Botucatu Campus, Botucatu, Brazil, [2]São Paulo State University, Institute of Bioscience, Botucatu Campus, Botucatu, Brazil, [3]University of São Paulo, Center of Nuclear Energy in Agriculture, "Luiz de Queiroz" Campus, Piracicaba, Brazil, and [4]FAPESP.*

Studying the metabolic pathway of methionine using a carbon-13 enrichment protocol to measure kinetics of this amino acid in various tissues of birds may provide a greater understanding of methyl group metabolism. The aim of this study was to use stable isotope methodology to assess the rate of incorporation of labeled methionine in blood plasma of broilers aged 1–7 d old. A total of 51 one-d-old male Cobb chicks were housed (density = 12 birds/m^2) and selected with an initial BW of 45 ± 1.125 g. The diet was formulated based on corn and soybean meal and supplied ad libitum. To promote tissue enrichment, we used a dosage of 29 µmol of L-[$^{13}C_1$]methionine/kg BW/h, administered orally within 6 h (99 atom% ^{13}C; Cambridge Isotope Laboratories, Inc.). At the times 0 (control), 0.5, 1, 2, 3, 4, 5, 6, 8, 10, 12, 16, 20, 24, 48, 72 and 96 h after initial dosing, 3 birds per time point were slaughtered for sampling of blood plasma for carbon isotope ratio analysis using a mass spectrometer. The isotope ratios obtained were analyzed by a first-order exponential equation expressed as: $\delta^{13}C(t) = \delta^{13}C(f) + [\delta^{13}C(i) - \delta^{13}C(f)]\, e^{-kt}$, which enables calculation of the half-life of carbon-13 ($t = \ln 2/k$), obtained using a software package (OriginPro 8 Professional). Maximum enrichment occurred 8 h after oral administration of enriched solution. The results of $\delta^{13}C$ blood plasma to the maximum enrichment resulted in the following equation: $\delta^{13}C = -15.60 - 3.24\, e^{-0.2291t}$, with a carbon half-life calculated as 3.03 h and $R^2 = 0.93$, representing the velocity of incorporation of methionine into embedded tissue. Thus, the time required for 50% of orally-administered methionine to be metabolized is approximately 3 h at this dose and age of bird.

M166 Influence of dietary Quantum phytase on bone strength and bone phosphorus contents of weaned pigs. S. K. Baidoo*[1], Q. Yang[1], G. He[1], T. D. Crenshaw[2], C. L. Wyatt[3], and J. A. Jendza[1], *[1]University of Minnesota, SROC, Waseca, [2]Department of Animal Science, University of Wisconsin, Madison, [3]AB Vista Feed Ingredient, Stillwell, KS.*

A total of 180, 18-d crossbred pigs (GAP English Belle × Duroc) with BW of 7.0 ± 1.1 kg were randomly allotted to 6 treatments with 5 replicate pens/treatment for 3 phases with 11, 11 and 12 d in each feeding phase, respectively. Six corn-soybean meal mash diets were formulated: a positive control (PC) diet (0.32% available P (aP); met NRC, 1998 recommendations), a negative control (NC) diet with approximately 10% reduction of aP (0.28% aP), NC + 200 FTU/kg Quantum (QP: *E. coli* phytase expressed in *Pichia pastoris*), NC + 500 FTU/kg QP, NC + 1,250 FTU/kg QP, and NC + 500 FTU/kg Natuphos (NP; fungal phytase expressed in *Aspergillus niger*). On d 42, 9 pigs from each treatment were randomly selected and euthanized for metatarsal collection to measure breaking strength and to determine ash and P content. Ash and P content of the metatarsal bone was not different among the dietary treatments. However, sex influenced ($P < 0.01$) metatarsal ash, and P content. In general, the average ash and P content of both fresh and dry metatarsal bone in female pigs was higher ($P < 0.05$) than in male pigs. There were no differences ($P > 0.05$) for the P content per unit of ash among the dietary treatments or between sexes. The metatarsal bone breaking strength was reduced ($P < 0.05$) in pigs fed the NC diet compared with pigs fed the PC diet or pigs fed the NC + 1,250 FTU/kg QP or NC + 500 FTU/kg NP. There were no other differences in bone breaking strength between the dietary treatments. In conclusion, Quantum supplementation at 1,250 FTU/kg and Natuphos at 500 FTU/kg improved the bioavailability of P. In addition, metatarsal P content was higher in female pigs than male pigs.

Key Words: piglet, phytase, bone strength

M167 Dietary effects of Quantum phytase on performance and phosphorus utilization of weaned pigs. S. K. Baidoo*[1], Q. Yang[1], G. He[1], C. L. Wyatt[2], and J. A. Jendza[1], *[1]University of Minnesota, SROC, Waseca, [2]AB Vista Feed Ingredients, Stillwell, KS.*

A total of 180, 18-d old crossbred pigs (GAP English belle × Duroc) with BW of 7.0 ± 1.1 kg were divided into 6 treatments with 5 replicates pens/treatment for 3 phases with 11, 11 and 12 d in each phase, respectively. Corn-soybean meal mash diets were formulated with a positive control (PC) diet (NRC, 1998 requirement), a negative control (NC) diet with approximately 10% reduction of available phosphorus (aP), NC + 200 FTU/kg Quantum (QP; *E. coli* phytase expressed in *Pichia pastoris*), NC + 500 FTU/kg QP, NC + 1,250 FTU/kg QP, and NC + 500 FTU/kg Natuphos (NP; *Aspergillus niger* phytase). Growth performance was not influenced ($P > 0.05$) by diet during phase 1 or phase 3. However, in phase 2, ADG of pigs fed the NC diet was reduced ($P < 0.05$) compared with pigs fed the PC, NC + 1,250 FTU/kg QP, or NC + 500 FTU/kg NP. Quantum supplementation to the NC at 200 or 500 FTU/kg improved ADG comparable to the PC diet, but not different than the NC diet. Overall, ADG was reduced ($P < 0.05$) in pigs fed the NC diet compared with pigs fed the NC + 1,250 FTU/kg Quantum. Phosphorus digestibility was reduced ($P < 0.05$) in pigs fed the PC diet compared with all other diets. Quantum supplementation to the NC diet at 1,250 FTU/kg improved ($P < 0.05$) P digestibility compared with pigs fed the PC or NC diet. Crude protein (CP) digestibility was reduced ($P < 0.05$) in pigs fed the PC diet, but this was not different than pigs fed the NC diet. Quantum supplementation to the NC diet at 200 or 500 FTU/kg improved ($P < 0.05$) CP digestibility compared with the PC, but not different than the NC diet. Quantum supplementation at 1,250 FTU/kg or NP at 500 FTU/kg improved ($P < 0.05$) CP digestibility compared with all other diets. In conclusion, phytase supplementation improved ADG and digestibility of P and CP in diets for early-weaned pigs fed reduced P diets.

Key Words: piglet, phytase, phosphorus digestibility

M168 Evaluation of phytase with different calcium and phosphorous density diet on the growth performance, nutrient digestibility, blood characteristics, and fecal noxious gas emission in growing pigs. L. Yan*[1], S. Zhang[1], D. S. Nam[2], and I. H. Kim[1], *[1]Department of Animal Resource and Science, Dankook University, Cheonan, Choongnam, South Korea, [2]Nonghyup Feed Co. Ltd., Seoul, South Korea.*

A 6-week trial with 96 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 22.49 ± 1.38 kg] were conducted to investigate the effects of phytase with different calcium and phosphorous density diet on the growth performance, nutrient digestibility, blood characteristics, and fecal noxious gas emission in growing pigs. Pigs were assigned to 1 of 4 treatments in a randomized complete block design according to their sex and BW. Each treatment contained 6 replication pens with 4 pigs (2 gilts and 2 barrows) per pen. Treatments included: 1) T1, CON, basal diet (0.70% Ca, 0.65% P); 2) T2, CON + 0.01% phytase (0.65% Ca, 0.60% P); 3) T3, CON + 0.015% phytase (0.60% Ca, 0.55% P); 4) T4 + 0.02% phytase (0.55% Ca, 0.50% P). Pigs were housed in an environmentally controlled, slatted-floor facility in 24 adjacent pens and were allowed ad libitum access to feed and water through a self-feeder and nipple drinker throughout the experimental period. No differences were observed in growth performance and nutrient digestibility throughout the experimental period. Pigs fed CON diet had a lower ($P < 0.05$) red blood cell concentration than other treatments. Pigs fed T2 and T4 had an increased ($P < 0.05$) serum calcium concentration compared with those fed T3. Pigs fed T1 had higher ($P < 0.05$) ammonia and acetic acid emissions compared with pigs fed T3 and T4 on d 7. Higher ($P < 0.05$) total mercaptan emission was also observed in the CON group compared with T4 and the other treatments on d1 and d7, respectively. Pigs fed T1 also had higher ($P < 0.05$) H_2S and acetic acid emissions compared with those fed T3 and T4 during 3–5 d of the study. In conclusion, our results indicate that dietary phytase supplementation with lower calcium and phosphorous density could reduce the fecal noxious gas emission without any negative effects on the growth performance and digestibility in growing pigs.

Key Words: growing pigs, phosphorous, phytase

M169 Nutritional balance of broilers at starter and grower phase fed diets containing multienzyme complex and lipid sources.

G. do Valle Polycarpo*[1], V. C. da Cruz[2], J. C. M. Cravo[3], P. de Assunção Pimenta Ribeiro[3], C. C. do Valle Polycarpo[1], and A. C. Pezzato[1], *[1]São Paulo State University, Botucatu, Brazil, [2]São Paulo State University, Dracena, Brazil, [3]University of São Paulo, Pirassununga, Brazil.*

The aim of this paper was to evaluate the nutritional balance of broilers fed diets containing multienzyme complex (MeC) and different lipid sources during starter (16 to 21 d-old) and grower (30 to 35 d-old) phases. A total of 150 1-d-old male Cobb chicks were allotted in a completely randomized design featuring a 2x2+2 factorial arrangement of soybean oil or poultry fat added at 2 or 4% to diets supplemented with MeC. Two control diets without added lipids were without or with added MeC. There were 5 replications with 5 birds per experimental unit. The diets were corn and soybean meal-based and had similar energy and amino acid levels within each phase. The MeC contained enzymatic activities of pectinase, protease, phytase, β-glucanase, xylanase, cellulase and amylase. Water and feed were supplied ad libitum. There was no interaction ($P > 0.05$) between lipid source and inclusion level for the metabolizability coefficient of dry matter (MCDM), nitrogen (MCN), fat (MCF) and energy (MCE). Lipid sources did not influence ($P > 0.05$) the nutritional balance, which can be attributed to the higher ratio of unsaturated and polyunsaturated fatty acids in poultry fat as compared with other animal fat sources, making it a good alternative to soybean oil. In the starter phase, higher levels of lipid reduced the MCDM ($P < 0.01$); however, this seems to be related to the greater amount of content of inert material added to keep diets isocaloric. Birds fed diets containing lipids showed greater MCF ($P < 0.01$) in both periods compared with birds fed lipid-free diets, and this was also observed when comparing the diets with 4% and 2% added lipids ($P < 0.01$). Addition of MeC to diets without lipid resulted in greater MCF ($P < 0.01$) at starter and grower phase. Treatments did not affect MCN and MCE ($P > 0.05$). In conclusion, the increasing levels of lipid in feed increase the MCF in broilers at starter and grower phases, regardless of lipid source. Addition of a multienzyme complex shows better MCF in diets without lipid inclusion in both phases.

Key Words: poultry fat, soybean oil

M170 Performance of 1- to 42-day-old broilers fed diets supplemented with multienzyme complexes.

V. C. da Cruz*[1], G. A. M. Pasquali[1], P. A. B. Aiello[1], G. do Valle Polycarpo[2], R. Crivellari[1], R. F. de Oliveira[1], A. Barbieri[1], L. H. Zanetti[1], and C. C. do Valle Polycarpo[3], *[1]São Paulo State University, Dracena campus, Dracena, Brazil, [2]University of São Paulo, Pirassununga campus, Pirassununga, Brazil, [3]São Paulo State University, São José do Rio Preto campus, São José do Rio Preto, Brazil.*

The aim of this work was to evaluate the effect of 2 multienzyme complexes (MeC) on the performance of broilers from 1 to 42 d old. A total of 868 Cobb chicks were allotted into 7 treatments, distributed in a completely randomized design with 4 replications. Diets and water were provided ad libitum according to the following treatments: T1 = basal diet; T2 = basal diet with MeC-A (SSF Allzyme); T3 = replacement of MeC-A by inert material; T4 = basal diet with MeC-B (Vegpro Allzyme); T5 = replacement MeC-B by inert material; T6 = basal diet with MeC-A and MeC-B; T7 = replacement MeC-A and MeC-B by inert material. MeC inclusions were made considering nutritional value of the enzyme as follows: MeC-A provided in the diet 75 kcal/kg ME, 0.20% CP, 0.029% Lys, 0.02 Met+Cys, 0.014% Thr, 0.004% Trp and 0.1% of P and Ca; MeC-B provided 7 kcal/kg ME, 7% CP and 7% in amino acid values of soybean meal. Treatments T3, T5, and T7 differed from T1 in nutrient content due to substitution of an inert material (kaolin) for the MeCs. The MeCs were composed by pectinase, protease, phytase, β-glucanase, xylanase, cellulase and amylase (MeC-A) and protease and cellulase (MeC-B). All experimental diets were formulated based on corn and soybean meal. The BW and ADG of broilers fed with multienzyme complexes were lower ($P < 0.05$) than those fed basal diets. However, AFI was not affected by the treatments ($P > 0.05$). The G:F ratio was worse in diets with MeC-A and with MeC-A + MeC-B supplementation compared with the basal diet ($P < 0.05$). The comparison between diet with MeC-A supplementation (T2) and diet without MeC-A (T3) indicated that the inclusion of MeC-A is not effective to improve G:F ratio of broilers, except in the diet containing both MeCs (A+B) which presented better results comparing to the T7 ($P < 0.05$). These results suggest that the supplementation with MeCs in diets with reduced nutrients is not effective to improve BW and ADG, and only MeC-B provides the same G:F ratio as basal diets to broilers from 1 to 42 d-old.

Key Words: enzymes, nutritional value, poultry

M171 Effects of Crina Poultry Plus and Ronozyme ProAct supplementation on growth performance, nutrient digestibility, relative organ weight, blood profiles, fecal microflora, and fecal noxious gas emission in broilers.

Z. F. Zhang*[1], B. R. Lee[1], A. V. Rolando[2], D. H. Yoo[3], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea, [2]DSM Nutritional Products Philippines Inc., Bonifacio Global City, Taguig, Philippines, [3]All The Best Ltd., Seoul, South Korea.*

A total of 720 1-d-old male ROSS 308 (BW = 39.8 ± 1.8 g) broilers were randomly allotted to 1 of 8 treatments (15 birds/pen, 6 pens/treatment) to evaluate the effects of Crina Poultry Plus (Crina) and Ronozyme ProAct (Ronozyme) in different nutrient density diets on growth performance, apparent total tract digestibility (ATTD), relative organ weight, blood profiles, fecal microflora, and fecal noxious gas emission. Dietary treatments were: PC, basal diet; PCR, PC + 0.02% Ronozyme; PCC, PC + 0.03% Crina; PCRC, PC + 0.02% Ronozyme + 0.03% Crina; NC, 4% CP and AA lower than PC; NCR, NC + 0.02% Ronozyme; NCC, NC + 0.03% Crina; and NCRC, NC + 0.02% Ronozyme + 0.03% Crina. Crina contains an ultra-pure grade of benzoic acid and essential oils (thymol, eugenol and piperine), and Ronozyme is a preparation of serine protease produced by *Bacillus licheniformis*. During d 8–21, NCC treatment increased ($P < 0.05$) BWG compared with NC treatment. During d 22–35, BWG was higher ($P < 0.05$) in PCRC treatment than that in NC treatment. Overall, chicks in PCR, PCC, PCRC, and NCRC groups had greater BWG ($P < 0.05$) than those in NC group. The ATTD of DM, N, and energy were improved ($P < 0.05$) in PCR, PCC, PCRC, and NCC treatments compared with PC and NC treatments at 5 week. The relative weights of liver and breast muscle were heavier ($P < 0.05$) in PCC treatment than those in PC and NCC treatments. The gizzard relative weight was increased ($P < 0.05$) in PCRC and NCRC groups compared with PC group. NCRC treatment increased ($P < 0.05$) the fecal *Lactobacillus* population compared with NC treatment. Fecal H_2S, NH_3, and total mercaptans emission was decreased ($P < 0.05$) in NCR treatment compared with PC treatment. In conclusion, application of 0.02% Crina + 0.03% Ronozyme in low nutrient density diet could improve growth performance, and increase the fecal *Lactobacillus* population in broilers.

Key Words: Crina Poultry Plus, Ronozyme ProAct, broilers

Nonruminant Nutrition: Weanling Pig

M172 Effects of freeze-dried *Lactobacillus reuteri* on growth performance, serum indices, and intestinal microflora of weaned pigs. D. Y. Zhang, H. F. Ji,* J. Wang, S. X. Wang, H. Liu, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences, Beijing, China.*

The objective of this study was to evaluate the effect of supplementation of freeze-dried *Lactobacillus reuteri* on growth performance, serum indices, and intestinal microflora of weaned piglets compared with antibiotic. The strain was isolated from the cecum mucosa of healthy weanling pigs in our laboratory. Sixty 4 crossbred (Duroc × Landrace × Large White) weaned pigs with (9.02 ± 1.01 kg BW) were randomly distributed to 4 groups comprised of an antibiotic-containing control (Zinc Bacitracin; 1 g/kg) and 3 dietary inclusion levels of *L. reuteri* (5.6×10^6, 2.4×10^7 and 1.5×10^8 cfu/g of diet). The experiment lasted 30 d. Live weight gain and feed consumption of the weaned pigs were recorded weekly. Blood and fecal samples were collected at the end of the experiment. Viable bacterial counts were estimated by a standard plate counting method. *L. reuteri* supplementation had the same effect on ADG, ADFI, and FCR compared with the antibiotic control. Supplementation of *L. reuteri* decreased ($P < 0.05$) the serum urea nitrogen concentration and increased ($P < 0.01$) the IFN-γ concentration compared with the antibiotic control. Overall, supplementation with 2.4×10^7 cfu of *L. reuteri*/g produced the greatest improvements ($P < 0.05$) in serum indices among the 3 different probiotic levels. The number of *Lactobacilli* in the feces was increased ($P < 0.01$) by the supplementation of *L. reuteri* compared with control (2.74×10^8, 3.00×10^8, 5.35×10^8 vs. 1.25×10^8 cfu/g). The 2.4×10^7 and 1.5×10^8 cfu/g *L. reuteri* supplementation showed lower ($P < 0.01$) *Escherichia coli* in the feces compared with control group (4.65×10^6, 6.75×10^6 vs. 4.35×10^7 cfu/g), and 2.4×10^7 cfu/g supplementation had lower ($P < 0.01$) *Escherichia coli* than 1.5×10^8 cfu/g. This experiment indicated that *L. reuteri* at 2.4×10^7 cfu/g may be the most appropriate and feasible level with regard to enhance the growth performance, promote the serum indices, and improve the intestinal bacteria of weaned pigs.

Key Words: *Lactobacillus reuteri*, weaned pigs

M173 Effects of two kinds of lactic acid bacteria on productive performance and intestinal microflora of weaned piglets. H. Liu, H. F. Ji,* S. X. Wang, J. Wang, D. Y. Zhang, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences, Beijing, China.*

The objective of this study was to evaluate the effects of 2 kinds of lactic acid bacteria (*Lactobacillus plantarum* and *Enterococcus faecalis*, isolated from small intestinal mucosa of healthy piglets) on the productive performance and intestinal microflora of weaned piglets. Ninety weaned piglets (Duroc × Large Yorkshire × Landrace) at 35 ± 2 d were randomly assigned to 3 groups and each group had 3 replicates with 10 piglets per replicates on the basis of body weights. Group A was fed basal diet, group B was fed basal diet with *Lactobacillus plantarum* (1.0×10^7 cfu/g diet), and group C was fed basal diet with *Enterococcus faecalis* (3.6×10^6 cfu/g diet). The concentrations of 2 bacterium were based on the previously study in our lab and were the optimal additional level. The experiment lasted 30 d. All piglets were free access to feed and water. The liveweight gains and feed consumption of the piglets were recorded weekly and fecal samples were collected at the end of the experiment. Data were analyzed using the ANOVA procedures of SPSS 18.0. Supplementation of *Lactobacillus plantarum* and *Enterococcus faecalis* significantly improved ADG (by 7.37% and 8.79% respectively; $P < 0.05$) and FCR (by 7.28% and 8.05% respectively; $P < 0.05$) compared with control group. Pigs supplemented with *Lactobacillus plantarum* and *Enterococcus faecalis* had lower diarrhea incidence compared with pigs fed basal diet (1.44%, 1.33%, vs. 2.56%, $P < 0.05$). The result also showed that, compared with basal diet group, there was increase in lactobacillus counts (by 4.18% and 3.96%, $P < 0.05$) and decrease in *E. coli* counts (by 9.31% and 10.08%, $P > 0.05$) in the fecal samples of weaned pigs fed *Lactobacillus plantarum* and *Enterococcus faecalis*. There was no significant difference between group B and C on ADG, FCR, diarrhea incidence, and fecal bacterium. This experiment indicated that supplying 2 kinds of lactic acid bacteria had the same beneficial effect on enhancing growth performance, reducing diarrhea incidence, and improving the intestinal health of weaned piglets.

Key Words: lactic acid bacteria, weaned piglet, intestinal microflora

M174 Assessment of probiotic properties of *Enterococcus faecalis* isolated from gastrointestinal tract of piglet and its effect on growth performance of weaned pigs. J. Wang, H. F. Ji,* F. M. Wang, S. X. Wang, D. Y. Zhang, H. Liu, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences, Beijing, China.*

The objective of this study was to evaluate the probiotic characteristics of *Enterococcus faecalis* isolated from gastrointestinal tract of healthy piglet and its effects on growth performance of weaned pigs. Acid tolerance of *Enterococcus faecalis* was estimated by the survival rate when it cultured in simulated gastric fluid with pH of 2.0 and 3.0 after 2 h. Bile salt resistance of this strain was examined in MRS broth containing pig bile salt concentration from 0.1% to 0.3%. The sizes of the inhibitory zone of *Enterococcus faecalis* against *S.* aureus, *E. coli*, and *S. choleraesuis* were also determined to estimate the inhibition of this strain on pathogenic bacteria. Sixty-four piglets weaned at 28 d of age (8.05 ± 0.47 kg BW), were divided into 4 groups comprising of control with zinc bacitracin at 60 mg/kg, 3 treatments of different *Enterococcus faecalis* concentration (1.8×10^6,6.2×10^7,3.1×10^8 cfu/g diet). The experiment lasted 4 weeks. Data were analyzed using the ANOVA procedures of SAS. The results showed that *Enterococcus faecalis* had high tolerance to simulated gastric fluid at pH 2.0 and 3.0 with survival rates were 86.1% and 91.3%, respectively. The viable count of *Enterococcus faecalis* achieved 10^7 cfu/mL when it cultured in 0.2% pig bile salt medium of MRS 6 h, while the viable count achieved 10^6 cfu/mL cultured in 0.3% medium. Furthermore, *Enterococcus faecalis* performed well in inhibitory activity to 3 selected pathogens. The feeding trial results exhibited that *Enterococcus faecalis* supplementation enhanced average daily gain (490, 508, 471 vs. 466 g/d; $P < 0.05$) and feed conversation ratio (1.59, 1.60, 1,65 vs. 1.76; $P < 0.05$) in weaned pigs compared with control. The incidence of diarrhea was significantly decreased along with the increase of *Enterococcus faecalis* concentration in the diet compared with antibiotic control (13.1, 10.4, 9.0 vs. 15.2). It was also showed that there was increase in *Lactobacillus* counts and a numerical decrease in *E. coli* counts in the fecal samples of weaned pigs fed *Enterococcus faecalis*, especially with 6.2×10^7 cfu/g of feed. It was concluded from this study that the strain *Enterococcus faecalis* could be considered as a potential probiotic for weaned pigs.

Key Words: *Enterococcus faecalis*, probiotic, growth performance

M175 Digestibility of feed containing energy and protein ingredients to substitute dried whey and lactose for weanling pigs. L. V. C. Girão*[1], F. G. Luiggi[1], G. Mello[1], A. C. Stradiotti[1], C. C. E. J. Villela[1], N. B. Athayde[1], V. S. Cantarelli[2], R. Fasanaro[1], and D. A. Berto[1], *[1]São Paulo State University, Faculty of Veterinary Medicine and Animal Science, Botucatu Campus, Botucatu, SP, Brazil, [2]University Federal of Lavras, Lavras, MG, Brazil.*

This experiment was carried out with the aim of evaluating apparent digestibility of pre-initial (PI) and initial (I) diets for weanling pigs containing a combination of energetic and protein ingredients to substitute dried whey and lactose. A total of 108 crossbred pigs (Landrace × Large White) weaned at 21 ± 2 d of age with an average of 6.02 kg BW were used in a 4-wk experiment. Piglets were blocked by weight and distributed in a randomized complete block design of 4 treatments and 3 animals per pen: 1) control with dried whey and lactose; 2) whey protein concentrate, maltodextrin and an energetic blend containing maltodextrin and corn oil; 3) gluten meal 60% CP, maltodextrin and energetic blend containing maltodextrin and corn oil; and 4) protein energetic blend containing maltodextrin, corn steep liquor and corn oil. The blends used were obtained by spray dryer. Two digestibility trials were performed with diets containing 0.1% chromium (III) oxide as a digestibility marker starting on the 7th and 19th day of the experiment. Pooled fecal samples were collected from an experimental unit (3 animals per pen) during the 2 periods (12th to 17th and 24th and 29th day post-weaning), and digestibility parameters evaluated included: dry matter (DCDM), ether extract (DCEE), crude protein (DCCP), and gross energy (DCGE); digestible values for dry matter (DMD), protein (PD), ether extract (EED), and energy (ED). Data was statistically analyzed using the GLM models of SAS. Differences were found just for I diet in DCEE was higher ($P = 0.007$) for piglets fed diets 3) and 4) (71.19 and 69.38%, respectively), PD was higher ($P = 0.002$) for piglets fed diets 1) and 4) (12.35 and 12.03%, respectively), and EED was higher ($P < 0.001$) for piglets fed diet 3) (4.27%). The ingredient blends tested in this experiment, whether associated or not with vegetable or animal protein sources, were feasible substitutes for dried whey and lactose in PI and I diets. They did not interfere in the digestibility coefficient of dry matter, crude protein and gross energy of weanling pigs aged from 21 to 50 d old.

Key Words: blend, maltodextrin, microencapsulated

M176 Dietary clay does not negatively affect growth performance, nitrogen and iron status, or diarrhea score of weanling pigs. M. Song*[1], B. G. Kim[2], O. Osuna[3], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Konkuk University, Seoul, Korea, [3]Milwhite Inc., Brownsville, TX.*

Clay may be included in diets fed to weanling pigs as mycotoxin binders, but it has been speculated that dietary clay may bind nutrients in the intestinal tract of pigs and increase diarrhea among pigs. The objective of this experiment was, therefore, to test the hypothesis that dietary clay does not negatively influence growth performance, serum nitrogen, serum iron parameters, and diarrhea score (DS) of weanling pigs. A total of 256 weanling pigs (initial BW: 6.49 ± 0.97 kg) were randomly allotted to 8 diets, 8 replicate pens per diet, and 4 pigs per pen in a randomized complete block design. A conventional control diet was formulated. Seven additional diets that were similar to the control diet with the exception that 0.3% clay was added to each diet were also formulated. The 7 clay treatments included 0.3% smectite (SM), 0.3% kaolinite (KL), 0.3% zeolite (ZL), 0.15% SM + 0.15% KL, 0.15% SM + 0.15% ZL, 0.15% KL + 0.15% ZL, and 0.10% SM + 0.10% KL + 0.10% ZL. No antibiotics were included in the diets. Pigs were allowed ad libitum intake of the diets throughout the 29 d experiment, and blood was collected from 2 pigs per pen on the last day of the experiment. For the overall experimental period, no differences in ADG, ADFI, or G:F were observed among treatments (Table 1). Serum urea nitrogen (SUN), red blood cells (RBC), hemoglobin (HGB), hematocrit (HCT), and DS were also not different among treatments indicating that dietary clay did not impair N and Fe absorption. In conclusion, dietary clay does not negatively affect growth performance, nitrogen and iron status, serum values measured, or diarrhea score of weanling pigs.

Table 1. Effects of dietary clay on growth performance and N and Fe status of weanling pigs[1]

M177 Effects of dry matter content of milk replacer on intake and growth in suckling pigs. S. M. Mendoza*[1], E. van Heugten[1], P. Hock[2], D. McKilligan[3], and R. D. Boyd[2], *[1]Department of Animal Science, North Carolina State University, Raleigh, [2]Hanor Company Inc., Franklin, KY, [3]TechMix Inc., Stewart, MN.*

This study was designed to determine the effect of dry matter (DM) content of milk replacer (MR) on intake and growth in suckling pigs. Data were collected from one hundred litters in a 2,600-sow commercial research unit. Litters (10 ± 1.0 pigs) were randomly assigned to treatments consisting of a control without MR and supplementation with MR having 15, 20, 25, 30, 35, or 40% DM. Litters were adapted from d 10 to 12 of age to MR with a 20% DM content. At d 13, litters were weighed (43.8 ± 0.8 kg) and fresh MR was provided in enclosed, gravity dispensed containers on a daily basis according to disappearance. Milk consumption was measured daily by the difference of MR addition minus refusal. At weaning (20.3 ± 2.0 d) litter weights (63.8 ± 1.2 kg) were recorded. Milk replacer linearly increased ($P = 0.007$) total litter gain (19.5, 18.5, 20.1, 20.4, 23.7, and 21.9 kg for 15, 20, 25, 30, 35, and 40% DM, respectively) and tended ($P < 0.10$) to increase gain per pig (2.03, 1.81, 1.95, 2.00, 2.16, and 2.08 kg), and ADG (244, 231, 239, 256, 279, and 263 g/d) with increasing DM. Supplementation with MR tended to improve ($P = 0.06$) gain per pig compared with non-supplemented pigs (2.00 vs. 1.86 kg). Litter gain (23.7 vs. 19.6 kg) and gain per pig (2.16 vs. 1.86 kg) were greater for litters receiving MR having 35% DM compared with non-supplemented control pigs. Milk consumption was similar, regardless of DM content (140 g/pig/d; $P = 0.70$). Consequently, DM intake increased linearly ($P < 0.001$) with increasing DM content (20, 30, 34, 49, 46, and 50 g/pig/d). Conversion efficiency of DM (gain:DM intake) improved linearly ($P = 0.009$) with increasing DM (16.4, 10.7, 9.1, 6.9, 8.8, 5.9). These results demonstrate that nutrient intake in nursing pigs can be greatly increased by increasing the DM content of milk above that typical for sow milk, and that litter growth was moderately improved. Additional studies may help us understand how to take advantage of the increase in nutrient intake to promote growth recovery, especially in litters composed of small pigs, the target of this technology.

Key Words: milk replacer, litter, growth

M178 The protein-to-energy ratio is a main driver of growth performance in piglets. S. A. Guzmán-Pino, D. Solà-Oriol, J. Figueroa,* and J. F. Pérez, *Universitat Autònoma de Barcelona, Bellaterra, Spain.*

It is well accepted that there is an optimal dietary protein-to-energy ratio for young pigs. However, there is not a final recommendation and doubts may arise about how to reach this ratio through changes on the dietary levels. The aim of the present study was to determine how a difference in the dietary protein or energy content and their corresponding protein-to-energy ratio affect growth performance in post-weaned piglets. A total of 480 weanling piglets (28d-old, initial BW 7.17 ± 0.01 kg) were distributed according to their BW into 48 pens (10 pigs/pen), and were randomly allotted to 1 of 4 experimental diets formulated to have different protein-to-energy ratios: a high protein (HP, 204 g CP/kg as-fed) and a low protein diet (LP, 142 g CP/kg) with similar DE content (3.60 Mcal/kg), and a low energy (LE, 3.35 Mcal DE/kg) and high energy diet (HE, 3.90 Mcal DE/kg) with similar CP content (190 g/kg). The protein-to-energy ratios were 56.6 and 56.7 g CP/Mcal DE for HP and LE, and 39.4 and 48.7 g CP/Mcal DE for LP and HE. Performance was measured on d 8 and 18 post-weaning. Up to d 8, HP diet promoted a higher ADFI than LP and HE diets ($P < 0.05$), and a higher ADG and BW than LP, HE and LE diets ($P < 0.01$). Feed:gain ratio also was more efficient for HP piglets in this period. On d 18, LE diet promoted the highest ADFI and ADG during period 8–18d ($P < 0.001$). Piglets fed the LE diet had a statistical approach to the highest piglet BW in comparison with piglets fed the HP diet (11.89 vs. 11.42 kg; $P = 0.09$), however, both treatments were higher than piglets fed the HE diet (10.84 ± 0.13 kg) and piglets fed the LP diet (9.16 ± 0.13 kg), that were the lightest ($P < 0.05$). Feed:gain ratio of latter piglets was higher than the rest of the experimental diets for this period. Growth results are in accordance with dietary protein-to-energy ratio offered. It is concluded that independently of the nature of the nutrient promoting imbalance, dietary protein-to-energy ratio may determine post-weaning piglet performance.

Key Words: protein-to-energy ratio, protein, energy

M179 Nucleotides in weanling pig diets. C. Andrade*[1], V. V. Almeida[1], M. Sbardella[1], D. P. Perina[1], F. L. Silva[1], P. L. Y. C. Chang[2], B. Berenchtein[3], L. B. Costa[4], and V. S. Miyada[1], *[1]USP/ESALQ, Piracicaba, SP, Brazil, [2]University of North Carolina, Raleigh, [3]USP/CENA, Piracicaba, SP, Brazil, [4]UESC, Ilhéus, BA, Brazil.*

Nucleotides have been supplemented in weanling pig diets due to their beneficial effects on maintenance of animal health, performance, immune response and on intestinal histology. The purpose of this study was to evaluate the effects of dietary nucleotide levels on performance, diarrhea occurrence, and intestinal histology of weanling pigs fed complex diet based on corn, soybean, dried milk and dried plasma. One hundred and 60 weaned pigs, averaging 6.43 ± 0.71 kg initial BW, were used in a randomized complete block design experiment with 5 treatments, 8 replications per treatment and 4 animals per pen (experimental unit). The treatments were: basal diet with 120 ppm of chloro-hydroxyquinoline (antimicrobial treatment) and basal diet with 0 (control), 100, 150 and 200 ppm of nucleotides. At the end of the experimental period (34th d), an animal per experimental unit was slaughtered for analysis of intestinal histology (villus height and crypt depth) of the duodenum and jejunum. Data were analyzed using the GLM procedure of SAS. For 1–14 d of the experimental period, performance was not affected ($P > 0.05$) by treatments. For the total experimental period (1–34 d), linear effects of dietary levels of nucleotides on final BW ($P = 0.005$; 23.08, 24.13, 24.18 and 24.23 kg) and on ADG ($P = 0.008$; 0.491, 0.520, 0.523 and 0.523 kg) were observed, but not ($P > 0.05$) on ADFI and G:F. Pigs fed nucleotides had higher ($P = 0.0002$) diarrhea occurrence (0.89, 1.78, 1.78, 3.57 and 5.36%) from 1 to 14 d than those of control and antimicrobial treatments. However, for the total experimental period (1–34 d), dietary nucleotide levels did not affect ($P > 0.05$) diarrhea occurrence and intestinal histology. Therefore, added nucleotides up to 200 ppm in weanling pig complex diets showed beneficial effect on growth performance, but not on intestinal histology and diarrhea occurrence.

Key Words: feed additives, growth promoter, swine

M180 Time-related changes of serum amino acids in weanling piglets. Y. Xiao,* T. Wu, A. Chen, L. Yang, and C. Yang, *College of Animal Sciences, Zhejiang University, Hangzhou, Zhejiang, China.*

The time-course of serum amino acids following response to early weaning was investigated over a 30 d period in weanling piglets using amino acid analyzer. Eight healthy piglets were selected from 4 litters (one male and one female per litter). The piglets were weaned at 21 d of age and their blood samples were collected on d 0, 1, 3, 5, 7, 10, 15, and 30 post-weaning. Serum concentrations of arginine and its immediate precursors (citrulline and ornithine) decreased ($P < 0.05$) from d 0 to 5 post-weaning, and increased from d 7 to 30 post-weaning. Serum concentrations of leucine, proline, tyrosine, and taurine decreased ($P < 0.05$) on d 1 and 3 post-weaning, and increased to the level of d 0 post-weaning on d 30. Serum concentrations of isoleucine, lysine, glycine, and serine were lowest on d 5 post-weaning; histidine, phenyalaine, valine, aspartic acid, and serine were lowest on d 10 post-weaning, which then increased thereafter. Methionine concentration changed slightly ($P > 0.05$) from d 0 to 3 post-weaning, while it increased by 43.51% ($P < 0.05$) and 41.11% ($P < 0.05$) on d 5 compared with that on d 1 and 3 post-weaning, and kept constant thereafter. Serum concentration of threonine increased by 31.67% ($P < 0.05$) and 79.06% ($P < 0.05$) on d 3 post-weaning compared with that on d 0 and 1, and then decreased on d 15 and 30 post-weaning. Serum concentration of glutamic acid was relatively higher ($P < 0.05$) from d 3 to 30 than that on d 0 and 1 post-weaning. These findings indicate that the serum levels of amino acids are robustly altered in weanling piglets and the critical phase are from d 3 to 10 post-weaning.

Key Words: amino acids, weaning, piglets

M181 Comparing different copper sources at pharmacological levels in nursery pigs. J. Zhao*[1], G. Allee[2], M. Vazquez-Anon[1], and R. J. Harrell[1], *[1]Novus International Inc., St. Charles, MO, [2]University of Missouri, Columbia.*

Pharmaceutical $CuSO_4$ is widely used in nursery pigs to promote growth when included beyond Cu requirements as defined by NRC (1998). However, high dietary Cu antagonizes other minerals (Zn and Fe) and nutrient utilization in monogastric animals. The objective of this research was to compare different Cu sources at pharmacological levels in nursery pigs. A total of 616 crossbreed piglets (PIC, 20 d of age, 5.0 ± 0.3 kg) were randomly allocated to one of 4 treatments with 7 replicates per treatment and 22 piglets per pen. The treatments included an inorganic negative control ($CuSO_4$) at NRC level (6 mg/kg), and a pharmaceutical level (150 mg/kg) of Cu supplemented using $CuSO_4$, tribasic copper chloride ($Cu_2[OH]_3Cl$), or $Cu(HMTBa)_2$. The $Cu(HMTBa)_2$ (Mintrex, Novus International Inc., St. Charles, MO) is a chelate of one Cu molecule with 2 molecules of 2-hydroxy-4-methylthio butanoic acid (HMTBa). Pigs were fed typical commercial nursery diets for 21 d. At the completion of 21 d, one median pig per pen was harvested for liver mineral analyses. Pigs fed $CuSO_4$ and $Cu(HMTBa)_2$ exhibited 8% and 10% improvements ($P = 0.02$) in feed efficiency, respectively, compared with pigs fed the negative control. Weight gain tended to be improved by both $CuSO_4$ and $Cu(HMTBa)_2$ ($P = 0.07$). Pigs fed $Cu_2[OH]_3Cl$ were intermediate but were not differ from the negative control. No ADFI differences were observed among treatments ($P = 0.75$). For liver mineral concentration (dry weight basis), pigs fed $Cu(HMTBa)_2$ had the highest liver Cu concentration, which was significantly higher than pigs fed ($Cu_2[OH]_3Cl$) and the negative control (71% improvement, $P = 0.02$). Pigs fed $CuSO_4$ were intermediate with 39.8, 48.8, 52.1, and 68.2 mg liver Cu per kg dry weight for the negative control, $Cu_2[OH]_3Cl$, $CuSO_4$, and $Cu(HMTBa)_2$, respectively. No differences were observed for liver Fe, Mn, or Zn concentration ($P > 0.28$). In conclusion, pigs fed $Cu(HMTBa)_2$ at a pharmacological levels performed the best based on feed efficiency and liver copper concentrations, followed by $CuSO_4$. No benefits of $Cu_2[OH]_3Cl$ was observed on performance or liver Cu concentration in this trial.

Key Words: Mintrex, copper, swine

M182 Effects of steam-processed rice, natural vitamin E, and glutamine in diets for weaning piglets. G. J. M. M. Lima*[1], M. Kutschenko[2], and E. T. Nogueira[2], [1]*Embrapa, Concordia, SC, Brazil,* [2]*Ajinomoto, Sao Paulo, SP, Brazil.*

Expanded rice (R) obtained by heat steam processing, glutamine (Gln) and natural vitamin E sources (E) improve performance of young piglets. An experiment was conducted to compare these 3 ingredients using 400 barrows and gilts from the same genotype. Pigs were weaned at 21 d of age (6.90 ± 0.35 kg average initial BW) and allotted to 5 treatments according to a randomized block design, with 8 replicates/treatment and 10 pigs/pen (5 per sex). A 3-phase feeding program was used with free access to feed and water until the end of the trial (63 d of age). Treatments were: T1- control diet (corn, SBM, lactose sources, fish meal, soybean oil, amino acids, minerals, vitamins and a growth promoter); T2 – similar to T1, with the inclusion of 20% ground R in partial replacement of corn; T3 – similar to T1, with the addition of 0.8% and 0.6% of AminoGut (Gln source) in dietary phases 1 and 2, respectively, and no supplementation in phase 3; T4 – similar to T1, with the inclusion of 3% mechanically extracted rice oil (166.79 mg total E/100 g and 37.47 mg α-tocopherol/100 g) in replacement of soybean oil; T5 – similar to T2, with Gln and E addition at the same levels used in T3 and T4. Treatment diets had the same nutrient levels in each phase. Diarrhea occurrence throughout the trial did not differ among treatments (X^2 test, $P > 0.05$). Pigs fed control diet (T1) showed lower average final wt ($P < 0.06$) and daily gain (ADG, $P < 0.05$) compared with all treatments, except T4 ($P = 0.70$). There were no differences in average daily feed consumption ($P = 0.28$) or feed:gain ratio ($P = 0.40$) among treatments. Expanded rice (T2) or Gln (T3) supplementation alone or in combination (T5) improved pig BW gain, but no additive effects were observed. In conclusion, partial replacement of corn by expanded rice and Gln supplementation improved piglet performance in the nursery phase.

Table 1. Effects of expanded rice, glutamine, and natural vitamin E in diets for weaning pigs

Variable	T1	T2	T3	T4	T5	SEM	*P*-value
Final wt, kg	27.60^b	28.51^a	28.80^a	27.77^b	28.76^a	0.39	0.02

Physiology and Endocrinology I

M183 Cortisol levels during roping acclimation in rodeo calves. K. Comeaux, B. Pousson, A. Greathouse, D. Terro, J. Browning, and C. E. Ferguson,* *McNeese State University, Lake Charles, LA.*

Roping calves (n = 10) were evaluated for chute behavior and cortisol concentration for the first 9 weeks of being roped. These calves were between 90 to 120 d of age and weighed between 93 to 120 kg at the beginning of the study. Each Monday (haul), calves were penned via horseback, placed in a chute, and given a chute score from 1 (calm) to 5 (frantic). Calves were then weighed, a jugular blood sample was collected, and they were loaded onto a stock trailer and transported ~10 min to the rodeo area. At the rodeo arena, calves were left in a pen for 3 h. They then received a chute score, second blood sample (collected at arena), and returned to the pen. On Tuesday, calves were roped twice and on Wednesday (rope) received a chute score, and a blood sample was collected twice, once before roping. Within 30 min of second roping, a second chute score was given and blood sample was collected. Following this, calves were returned to the farm for the remainder of the week. This routine was repeated for 9 weeks and at the end of the 9-week period blood samples were analyzed for plasma cortisol via radioimmunoassay. Statistical differences among chute scores and plasma cortisol concentrations (µg/dL) pre-event, post-event, the change in cortisol (post-event – pre-event), and weight gain were analyzed using SAS Proc GLM with repeated measures. The change in cortisol decreased following roping ($P < 0.05$) compared with hauling during wk 3, −1.04 ± 0.50 (rope) vs. 2.40 ± 0.46 (haul) and wk 4, −3.08 ± 0.56 (rope) vs. 0.03 ± 0.77 (haul). There was no difference in the change of cortisol for wk 5 and 6. However, roping during wk 7 differed ($P < 0.05$) from hauling; −4.62 ± 0.92 (rope) vs. −1.54 ± 89 (haul). There was no difference in the chute score for pre-event, but chute score decreased ($P < 0.05$) post-hauling after wk 3 and remained lower compared with wk 1 and 2. The chute score was lower ($P < 0.05$) after roping compared with after hauling during first 3 weeks but did not differ afterward. Additionally, weight gain in calves significantly increased after the third week. From these results it can be concluded that although after 3 weeks calves begin to acclimate to hauling and roping they acclimate more quickly to roping than hauling ~10 min.

Key Words: rodeo, cortisol, roping calf

M184 Improving reproductive performance of Ossimi ewes using hormonal and enzymatic treatments. E. B. Abdalla*[1], A. Q. Al-Momani[2], F. A. Khalil[1], H. M. Gado[1], and F. S. Al-Barakeh[3], *[1]Ain Shams University, Cairo,Egypt, [2]Ministry of Agriculture, Amman, Jordan, [3]National Center for Agricultural Research and Extension, Al-Baq'a, Al-Balqa, Jordan.*

The current experiment was conducted to evaluate the effect of dietary supplementation of melatonin, Zado (patent product contains cellulases, xylanases, protease and α amylase) and their combination on the reproductive performance of Ossimi ewes. Fifty-seven, multiparous, adult Ossimi ewes were randomly assigned to 4 groups, each group was fed ration supplemented with one of the following components: melatonin (G1; n = 14), Zado (G2; n = 14), melatonin and Zado (G3; n = 15) and ration with no additives (G4; control, n = 14). All ewes were fed maintenance ration for one month (during June) followed by flushing ration for 5 weeks (2 weeks before and 3 weeks after ram introduction). Melatonin (3mg/h/d) and Zado (15g/h/d) started to be added with maintenance and flushing rations, respectively. Fertile rams were introduced to ewes for 2 successive estrous cycles. General Linear Model (GLM) procedure of SAS, ANOVA and Duncan's multiple range test were used for statistical analysis. Percentage of ewes expressed estrus was significantly different ($P < 0.05$) among the treated groups. All ewes expressed estrus in G1, while the lowest percentage (71%) was detected in G4. The interval from ram introduction to the onset of estrus differed ($P < 0.01$) among the treated groups. Ewes received melatonin in G1 and G3 expressed estrus earlier than ewes didnâ€t receive melatonin in G2 and G4. Neither body weight nor body condition score was different at the first estrus following ram introduction, while average daily gain was slightly promoted by treatments particularly with melatonin. Melatonin treated groups (G1 and G3) had significantly higher ($P < 0.01$) progesterone concentration than that in G2 and G4. Lambed ewes as percentage of total ewes were similar in G3 and G4 (50%), while they increased in G1 and G2 (57 and 67%, respectively). Prolificacy was greater in G1 and G3 than that in G2 and G4. Maximum prolificacy was detected in G3 while the minimum was observed in G4 ($P < 0.01$). Fecundity was lower ($P < 0.01$) in G4 (control group) than all the treated groups (G1, G2 and G3).Results of the present study indicated that melatonin could increase the estrus expression of ewes and decrease the interval to estrus after ram introduction. Thus, treatment with melatonin alone, or in combination with Zado, may provide a viable means to improve the fecundity and prolificacy of Ossimi ewes.

Key Words: Zado, melatonin, estrus

M185 Prostaglandin-$F_{2\alpha}$ may not be necessary in short-term progesterone-based estrous synchronization protocols in cyclic ewes. K. N. D'Souza,* S. L. Rastle-Simpson, Q. S. Baptiste, and M. Knights, *West Virginia University, Morgantown.*

Two experiments were conducted to determine the requirement for prostaglandin F2α to achieve ample synchrony of fertile estrus in short-term progesterone-based (STPB) estrous synchronization protocols in cyclic ewes. In Exp. 1, ewes (n = 175) were randomly assigned to receive 0, 1 or 2 CIDR inserts for 7 d before introduction of rams. At insert removal, approximately half of the ewes in each group were injected with 20mg lutalyse (dinoprost; PGF) or received no further treatment. In Exp. 2, crossbred Katahdin ewes (n = 83) were randomly assigned to receive a CIDR for 5 or 7 d before the introduction of rams, with or without PGF at insert removal. The effects of treatments on reproductive performance were analyzed using logistic regression and ANOVA for categorical and continuous variables, respectively. In Exp. 1, the use of CIDR inserts tended to increase the proportion of ewes lambing to the first service period ($P = 0.08$) and reduced the mean lambing day ($P = 0.1$) by 13 percentage points and 1.7 d, respectively. Ewes treated with 1 CIDR device were more prolific ($P < 0.001$; 1.7 ± 0.07 vs 1.4 ± 0.07), lambed earlier ($P < 0.05$; 6.4 ± 0.8 vs 9.2 ± 0.8), and a greater portion tended to lamb to the first service period ($P = 0.1$; 88 vs 74%) than ewes treated with 2 CIDR devices. There was no significant effect of PGF on any of the reproductive performance variables. In Exp. 2, neither the length of treatment with CIDR device nor the use of PGF affected estrous response. Ewes treated with CIDR for 5-d tended to have higher conception rates ($P = 0.07$; 81.3%) and pregnancy rates ($P = 0.1$; 66.7%) compared with ewes treated for 7-d (61.8 and 51.2%, respectively). Injection with PGF decreased ($P < 0.01$) both conception and pregnancy rates (53.6 and 42.9% and 84.2 and 71.1%, for PGF and non- PGF treated ewes, respectively). The effect of PGF was not altered by the duration of CIDR treatment. The results of the current study indicate that there are no beneficial effects of increasing the duration of treatment from 5 to 7 d, or using an additional CIDR device when using a STPB estrous synchronization protocol in cyclic ewes. Treatment with a CIDR device for 5-d alone is sufficient to induce fertile estrus and synchronize lambing.

Key Words: fertility, prostaglandin, synchronization

M186 Is a CIDR as effective as a sponge in a novel follicle wave emergence and estrus synchronization protocol in anestrous ewes? M. B. Gordon[1], M. Bidarimath[1], M. Moggy[1], M. Camara[1], J. A. Small[3], P. M. Bartlewski[2], and D. M. W. Barrett*[1], *[1]Department of Plant & Animal Science, Nova Scotia Agricultural College, Truro, NS, Canada, [2]Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [3]Atlantic Food & Horticulture Research Centre, Agriculture & Agri-Food Canada, Truro, NS, Canada.*

The characteristics of ovulating follicles and the timing of ovulation can be very inconsistent when estrus is synchronized in anestrous ewes. Moreover, the well-utilized MAP sponge, containing synthetic progesterone (P_4), was discontinued and replaced by the controlled internal drug releasing device (CIDR), containing natural P_4. The objectives of this study were to compare the patterns of follicular and luteal development of seasonally anestrous ewes treated with CIDR-estradiol-eCG or MAP-estradiol-eCG. During seasonal anestrus, Texel ewes were randomly assigned to receive MAP sponges (60 mg MAP; Veramix; n = 7) or CIDRs (0.33 g P_4; Eazi-Breed CIDR; n = 7) for 12 d. An intramuscular injection of estradiol-17β (350 µg) was given 6 d before intravaginal device removal and an intramuscular injection of eCG (500 IU; Folligon) at intravaginal device removal. Daily ovarian ultrasonography was performed on the day of intravaginal device insertion and continued until ovulation and corpora lutea were confirmed. Blood for P_4 analysis was collected from 5 to 15 d after device removal. To determine the exact timing of ovulation, ovarian ultrasonography was done twice daily from eCG treatment until ovulation was detected. There were no differences in the interval from eCG treatment to ovulation (4.1 ± 0.2 d; $P = 0.67$), number of follicles that ovulated (1.4 ± 0.2; $P = 0.69$), or number of corpora lutea that developed (0.9 ± 0.2; $P = 0.44$) between the sponge and CIDR treatments. There were also no differences between the sponge and CIDR treatments for P_4 concentrations from 5 (0.2 ± 0.06 ng/mL) to 15 (1.2 ± 0.3 ng/mL) d after eCG treatment ($P = 0.92$). This study demonstrates that the CIDR-estradiol-eCG treatment may be as efficacious as the MAP-estradiol-eCG treatment. Further research is required to examine the affects of the CIDR-estradiol-eCG treatment on other critical criteria of ewe reproductive performance, such as pregnancy and lambing rates.

Key Words: anestrous ewes, CIDR, synchronization

M187 Effects of parity and litter size on body reserves dynamics across a complete physiological year in Romane ewes reared under extensive grazing conditions. E. González-García*[1], V. Gozzo de Figuereido[2], D. Foulquie[3], E. Jousserand[3], A. Tessniere[1], F. Bocquier[1], and M. Jouven[1], *[1]INRA UMR868 Systèmes d'Èlevage Méditerranéens et Tropicaux (SELMET), 34060 Montpellier, France, [2]Escola Superior de Agricultura, São Paulo, Brazil, [3]INRA UE0321, Domaine de La Fage, 12250 Roquefort-sur-Soulzon, France.*

How adaptation mechanisms interact across functional levels to control the adaptability of an individual during its own lifetime and also across generations is a core complex question of contemporary research. This work belongs to a series of first efforts in our team looking for gaining insights in identifying and understanding the adaptation mechanisms of ruminants through decrypting functional levels effects in a series of environmental and physiological conditions changes. We consider the evolution of energy body reserves (BR) mobilization or accretion process as an indicator of adaptability while evidencing individual differences responsive of internally or environmentally driven changes in grazing ruminants. Forty-one Romane ewes reared in a natural extensive rangeland of Center France were allocated in homogeneous groups according to body weight (BW) and body condition score (BCS), and distributed by parity [multiparous (MULT), n = 20; primiparous (PRIM), n = 21] and litter size (LSi) [having singletons (SING), n = 21 or TWIN, n = 20]. Feeding was restricted to grazing and other fibrous sources (hay), thus avoiding luxury energy intake and enhancing BR mobilization in function of requirements. Individual BW, BCS (1 to 5 scale), plasma NEFA and glucose (GLU) were monitored across a complete physiological year at –44, 0, 24, 61, 88, 119, 168, 207, 227, 257 and 312 d relatives to lambing (DIM). Blood sampling were performed early morning before the first meal. Data were analyzed by mixed procedure of SAS (2003), considering parity, litter size and its interactions as fixed effects. MULT (59.8 ± 1.21 kg) were systematically heavier ($P < 0.0001$) than PRIM (51.7 ± 1.18 kg). Beginning of lambing, LSi affected ($P < 0.05$) BW in MULT [where ewes with SING (46.5 ± 0.95 kg) were heavier than TWIN (43.3 ± 0.92 kg)] but not in PRIM. BCS was not affected by parity but, from lambing and throughout the experiment, MULT with SING (2.8 ± 0.06) expressed consistent higher ($P < 0.0001$) BCS than those MULT with TWIN (2.5 ± 0.06). NEFA was higher for ewes having more than 1 fetus (TWIN; 0.61 ± 0.040 vs. 0.49 ± 0.041 mmol.L^{-1}) just 1.5 mo before lambing, afterward this difference disappeared probably because of a lack of sensitiveness of this parameter for the fluctuating feeding regimens in extensive grazing conditions. This was coherent with the higher concentration of GLU at lambing in MULT with one fetus (SING; 0.83 ± 0.047 vs. 0.68 ± 0.043 g.L^{-1}, $P < 0.0385$) but not in PRIM. Results indicates that MULT are able to mobilize BR easier than PRIM in situations of negative energy balance (e.g., TWINS vs. SING; peri-lambing days), confirming that flexibility in BR utilization comes with experience, as evidence of an environmentally driven character. Trying to unravel how interactions between heritable and environment-dependent differences between individuals lead to interindividual differences in BR dynamics is our main research goal in the next future.

Key Words: body reserves, extensive grazing, adaptive capacity

M188 Pregnancy per AI (P/AI) after presynchronizing estrous cycles with Presynch-10 or PG-3-G before Ovsynch-56 in four dairy herds. J. S. Stevenson* and S. L. Pulley, *Kansas State University, Manhattan.*

Our objective was to monitor P/AI at first service in 3,005 lactating dairy cows located in 4 herds in northeast Kansas. Cows with eartags ending with odd digits at calving were enrolled in Presynch-10 (Pre-10): 2 25-mg injections of $PGF_{2\alpha}$ (i.e., PG-1 and PG-2) 14 d apart. Cows with eartags ending with even digits were enrolled in PG-3-G: one 25-mg injection of PG (PrePG) 3 d before 100 µg GnRH (Pre-GnRH), with the PrePG injection administered at the same time as PG-2 in the Pre-10 treatment. Cows were enrolled in a timed AI protocol (Ovsynch-56; injection of GnRH 7 d before [GnRH-1] and 56 h after [GnRH-2] PG with AI 16 to 18 h after GnRH-2) 10 d after PG-2 or PrePG injections. Median DIM at scheduled timed AI was 74 d. The study began in September 2009 and was completed in September 2011. Cows detected in estrus before the scheduled timed AI were inseminated (early bred; EB). Pregnancy was diagnosed at d 32–39 and at d 60–67 after timed AI by transrectal ultrasound or palpation. Data were analyzed using procedure GLIMMIX, with herd as a random effect and with fixed effects of treatment (EB, Pre-10, PG-3-G), lactation number (1 vs. 2+), season (hot [June through September] vs. cool-cold [October through May]), DIM, estrus at timed AI (0 vs. 1), and all 2-way interactions with treatment. The P/AI at d 32–39 for EB (n = 472), Pre-10 (n = 1,247), and PG-3-G (n = 1,286) was: 31.4, 35.0, and 41.2% ($P = 0.071$); P/AI at d 60–67 was: 29.8, 32.2, and 37.3% ($P = 0.107$); and pregnancy loss: 5.1, 7.0, and 9.2% ($P = 0.523$), respectively. Season ($P < 0.001$) influenced P/AI at d 32–39 and d 60–67, but a treatment x season interaction was not detected (d 32–39: $P = 0.468$; d 60–67: $P = 0.195$). The P/AI for PG-3-G and Pre-10 treatments did not differ during cool weather (d 32–39: 46.8 vs. 44.3%; d 60–67: 41.6 vs. 41.1%), respectively, but during hot weather, P/AI in PG-3-G was greater than in Pre-10 (d 32–39: 35.9 vs. 26.7% [$P = 0.001$] or d 60–67: 33.2 vs. 24.4% [$P = 0.009$]), respectively. We concluded that presynchronizing estrous cycles with PG-3-G produced more P/AI than Pre-10 during hot weather.

Key Words: Presynch-10, PG-3-G, pregnancy per AI

M189 Effect of bovine somatotropin (bST) injected at fixed-timed insemination of Holstein cows exposed to an ovsynch protocol. A. Reyes-Gomez, C. F. Arechiga,* M. A. Lopez-Carlos, J. I. Aguilera, R. R. Lozano, R. M. Rincon, F. De la Colina, and F. J. Escobar, *Autonomous University of Zacatecas, Zacatecas, Mexico.*

Objective of present work was to determine the effect of growth hormone (GH), or bovine somatotropin (BST; Lactotropin, Elanco, Mexico), injected at fixed-timed insemination in Holstein cows exposed to an Ovsynch protocol. Holstein cows (n = 849) from Las Palomas Dairy at Aguascalientes, Mexico, were included in the study and randomly alloted into 4 experimental groups: Control (n = 244), Ovsynch (n = 225), Ovsynch+CIDR (n = 241) and Ovsynch+BST (n = 139). Cows received 2 prostaglandin injections (i.e., 26–32 d PP and 40–46 d PP, respectively). By 52–58 d PP cows were included into treatment: 1) Control (d 0, PGF2α; d 3–7 estrus detection and insemination). 2) Ovsynch (d 0, GnRH; d 7, PGFα; d 9, GnRH; d 10, Timed A.I.). 3) Ovsynch/CIDR (d 0, GnRH + CIDR; d 7, CIDR removal + PGF2α; d 9, GnRH; d 10, timed A.I.). 4) Ovsynch/BST (d 0, GnRH; d 7, PGF2α; d 9, GnRH; d 10, timed A.I. + BST). Data was analyzed by PROC FREQ of SAS using X-square and Fisher test. Ovsynch with or without CIDR or BST, increased estrus response and estrus detection (i.e., 97% vs. 68%; total average of 89%). BST at fixed-timed insemination (i.e., d 10, of Ovsynch protocol), increased pregnancy rates determined at 62 + 3 d postpartum by rectal palpation). (30.9% Ovsynch + BST vs. 24.4%, without BST), vs. 21.7% with conventional management or 19.1% using Ovsynch + CIDR. There were differences on estrus response ($P < 0.001$), pregnancy rates to first service and/or treatment and by 160 d PP ($P < 0.02$) and differences in PR disappear by 360 d PP ($P > 0.05$). BST administration at fixed- timed insemination during Ovsynch decreased the number of services per conception (NSC = 2.12 vs. 2.44 SC) compared with Ovsynch without BST; or to Control group (2.45). Contrarily, CIDR insertion increased the number of SC (2.58 SC; $P < 0.05$). In conclusion, a BST-injection at the time of insemination increased pregnancy rates and reduced services per conception in cows exposed to ovsynch.

Key Words: dairy cows, somatotropin, fixed-insemination

M190 Effect of adding a GnRH or PGF$_{2\alpha}$ between the Presynch and Ovsynch program for first AI in lactating dairy cows. R. G. S. Bruno*[1,2], A. M. Farias[1], J. A. Hernández-Rivera[1], A. E. Navarrette[1], D. E. Hawkins[2], and T. R. Bilby[1], *[1]Texas A&M University, College Station, [2]West Texas A&M University, Canyon.*

The objective was to evaluate the effect of 3 reproductive programs for first AI on fertility in lactating dairy cows. Lactating cows (n = 1521) from a dairy in Texas were presynchronized (PS) with 2 injections of prostaglandin (PG) given at 36 and 50 ± 3 DIM. At 50 ± 3 DIM, 915 multiparous and 606 primiparous cows were blocked by parity and assigned to 1 of 3 programs: GPG (n = 552) which initiated the Ovsynch protocol 14 d after PS, GGPG (n = 402) in which a GnRH injection was given 7 d after PS followed by the Ovsynch protocol 7 d later and PG7-GPG (n = 567) in which a PG injection was given 7 d after PS followed by the Ovsynch protocol 7 d later. Cows were AI based on signs of estrus (ED) beginning after the PS and, if AI, cows were removed from subsequent injections. Ovaries were examined and blood was sampled for progesterone levels on day of first GnRH and PG of Ovsynch. Pregnancy per AI (P/AI) was diagnosed at 36 and 66 d after AI. Overall 52.3% of cows were AI based on ED with the GGPG program having the least ($P < 0.01$) number of cows being identified in estrus (GGPG = 46.8 vs. GPG = 50.7 and PG7-GPG = 57.7%). Reproductive program did not affect ($P > 0.33$) overall P/AI at 33 and 66 d after AI (36d GPG = 34.1, PG7-GPG = 34.6 and GGPG = 31.3%; 66d GPG = 32.3, PG7-GPG = 31.9 and GGPG = 28.1%) or pregnancy loss ($P = 0.68$) between 36 and 66 d after AI. Cows AI upon ED had higher P/AI than TAI (ED = 37.9 vs. TAI = 28.8%, $P < 0.01$). However, treatment did not affect ($P > 0.61$) P/AI for cows AI upon ED or TAI (36d, GGPG = 34.1, PG7-GPG = 34.6 and GGPG = 31.3%; 66d GPG = 32.3, PG7-GPG = 31.9 and GGPG = 28.1%). Reproductive program affected ($P < 0.01$) the median DIM at first service (PG7-GPG = 59 vs. GPG = 68 and GGPG = 68 d). At beginning of Ovsynch, more GGPG cows had CL (GGPG = 72.7 vs. GPG = 54.4 and PG7-GPG = 46.4%, $P < 0.01$). However, treatment did not affect ($P = 0.26$) ovulation to first GnRH of Ovsynch. In conclusion, adding a GnRH injection 7 d after presynchronization reduced number of cows AI upon ED. Pregnancy per AI was not affected by reproductive program but adding a PG injection 7 d after PS decreased the median DIM at first AI.

Key Words: dairy cows, fertility, synchronization

M191 Application of progesterone insert for the induction of lactation in nonpregnant dairy cows or heifers. F. Rivera-Acuña*[1], R. C. Fierros[1], E. M. Prado[1], P. Luna-Nevarez[1], J. G. Aceves[1], L. R. Avendaño[2], and A. C. Correa[2], *[1]Instituto Tecnológico de Sonora, Ciudad Obregón, México, [2]Universida Autónoma de Baja California, Mexicali, México.*

The induced lactation of cows or heifers can be an alternative to reduce the rate of culling and to increase the economic benefits in a dairy operation. The objective of this study consisted of evaluating the effectiveness of replacing the traditional progesterone (P4) source with injections in programs of induced lactation by means of 2 P4 vaginal inserts containing 0.186 g each. During the study 15 animals, dairy cows and heifers were blocked by days dry and parity and were assigned at random to one of 3 treatments. Natural lactation (LN, n = 5) 2 P4 inserts (CRONI2, n = 5) injections only (INY, n = 5). The LN group initiated their lactation at the time of the calving date and was handled like dairy fresh cows. Treated groups during the first 7 d received P4 of different forms, one by means of daily i.m. injections 0.25 mg/kg/d and another one with 2 P4 vaginal inserts. Additionally blood was sampled during the same period to determine P4 levels. Furthermore during the first 14 d both groups received estradiol-17Î^{2} 0.1 mg/kg/d i.m. In addition 3 bST applications at intervals of 10 or 14 d during the study and lactation respectively and dexamethasone 10 mg/cow i.m. during the d 17, 18 and 19 and the lactation beginning to the 21 d. All the cows were submitted to the Co-Synch timed artificial insemination protocol (TAI) at 60 d in milk (DM) and were inseminated at 70 DM. The data was analyzed in random blocks with replications through the commands Repeated and Random Mixed procedure of SAS. The P4 levels during the first 7 d of treatment had a similar behavior ($P = 0.9$), the milk yield at 112 DM was highly significant ($P = 0.0001$) for LN and INY groups, the milk yield to the tip result ($P = 0.001$) in LN and INY groups. On the other hand there were no differences ($P = 0.59$) between the interval of beginning of the lactation to the tip of lactation either on days of persistence period. Milk yield during the persistence period result significant ($P = 0.0004$) for LN and INY groups. Finally the 305 d adjusted milk yield also were significant ($P = 0.0001$) for LN and INY groups. The BCS at TAI tended ($P = 0.08$) to be better for CRONI2 in relation to the other groups. The pregnancy per AI was better ($P = 0.71$) in the LN group (40%) compared other 2 (20%) each. Change P4 source by means of vaginal inserts during induced lactation programs did not improved lactation performance nevertheless the application of P4 by i.m. injections can show very similar results to natural lactation cows.

Key Words: induced lactation, progesterone, milk yield

M192 Enhancing endogenous progesterone during growth of the ovulatory follicle is positively associated with fertility in dairy cows treated with Presynch-11/Ovsynch, Double Ovsynch, and G6G/Ovsynch. F. Jiminez-Krassel,* J. P. Martins, B. S. Raghavendra, M. Kron, and J. R. Pursley, *Michigan State University, East Lansing.*

Presynchronization strategies that enhance ovulation to first GnRH of Ovsynch have a greater chance of enhancing progesterone during ovulatory follicle growth. The objectives of this study were to 1) determine the effect of 3 presynchronization strategies on pregnancy/AI (PAI) of lactating dairy cows, 2) determine the relationship between P4 at PG of Ovsynch on PAI, and 3) determine if decreasing time from follicular wave induction to luteolysis during Ovsynch enhances fertility. Cows (n = 2453) were assigned to 4 treatments by parity to receive Presynch-11 (P11), G6G/Ovsynch (G6G), and Double Ovsynch 7 or 5 d between G and PG of Ovsynch (DO7, DO5) beginning 39 to 51 DIM. Cows received final GnRH of Ovsynch 72 h after PG and AI 16 h later. Ovulation was diagnosed with ultrasound. Serum was collected at strategic intervals to assay P4. Pregnancy was diagnosed with ultrasound 32 d post-AI. Percent cows with P4 > 1 ng/mL were different between treatments at final PG of the Presynch program (65, 56, 78, 77%; $P < 0.01$, n = 2451), at first GnRH of Ovsynch (67, 76, 87, 87%; $P < 0.001$, n = 2453), and at PG of Ovsynch (84, 86, 93, 93%; $P < 0.001$, n = 2451) for P11, G6G, DO7 and DO5. Ovulation rate in response to the first GnRH of Ovsynch (80, 85, 89, and 86%; $P < 0.05$, n = 1878), percent cows with luteolysis after final PG of Ovsynch (96, 92, 93, and 43%; $P < 0.001$, n = 2223) were different for P11, G6G, DO7 and DO5. PAI in cows (n = 1802) that ovulated to first GnRH of Ovsynch and had P4 > 1ng/mL at PG and decreased to <0.3 ng/mL P4 72h later were 52, 50, 49, and 48% ($P = 0.7$) for P11, G6G, DO7 and DO5. Concentrations of P4 at time of PG injection was positively associated with pregnancy outcome: 33, 43, 44, 50, 51 and 57% PAI for P4 ranges of 1–2 (n = 171), 2–3 (n = 136), 3–4 (n = 201), 4–5 (n = 308), 5–6 (n = 327) and > 6 (n = 659) ng/mL P4 ($P < 0.05$ for P4 < 4ng/mL vs. P4 > 4 ng/mL). Enhancing progesterone during growth of the ovulatory follicle is associated with enhanced PAI of lactating dairy cows. Decreasing time from wave induction to luteolysis did not increase fertility.

Key Words: Ovsynch, progesterone, fertility

M193 Effect of progesterone (P4) supplementation after AI on circulating P4 and development of the corpus luteum (CL) in dairy cattle. P. L. J. Monteiro Jr.*[1], F. L. M. Silva[1], M. Borsato[1], G. P. Nogueira[2], G. B. Mourão[1], L. D. Silva[1], M. C. Wiltbank[1], and R. Sartori[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]São Paulo State University, Araçatuba, SP, Brazil, [3]University of Wisconsin-Madison, Madison, WI.*

Supplementation with P4 at 3 d after AI may improve fertility of lactating dairy cows, however, concerns have been expressed that early P4 supplementation may inhibit normal CL development or lead to early CL regression. The objective of this study was to evaluate CL development, by transrectal ultrasonography, and circulating P4, as measured by radioimmunoassay. Lactating dairy cows were synchronized (2 mg estradiol benzoate + CIDR on d 0 with prostaglandin F2α on d 7 and CIDR removal and 1 mg estradiol cypionate on d 8) and received timed AI (TAI). All cows that demonstrated synchronized ovulation (ovulated 1.5 to 3.5 d after CIDR removal; n = 42) were randomized to 1 of 2 treatments: No treatment (Control; n = 21) or CIDR supplementation starting on d 3 until d 20 after TAI (CIDR-treated; n = 21). Ultrasound was performed 2, 3, and 4 d after CIDR removal to confirm ovulation. Luteal volume was measured on d 4, 7, 11, 14, and 20 after TAI and circulating P4 concentrations on day of TAI and d 3, 4, 7, 11, 14, 17, 20, and 21. The procedure GLIMMIX of SAS was utilized for statistical analysis. The circulating P4 concentration demonstrated a tendency for an effect of P4 supplementation ($P = 0.07$) and an effect of day ($P = 0.001$) and an interaction of day by P4 supplementation ($P = 0.01$). This interaction was related to the largest difference due to CIDR-treatment during the earliest stages of supplementation (d 4: 0.9 ± 0.2 vs 2.2 ± 0.2 ng/mL and d 7: 2.7 ± 0.2 vs 3.6 ± 0.2 ng/mL). In contrast, the CL volume demonstrated an effect of day ($P < 0.001$) but there was no effect of P4 supplementation ($P = 0.921$) and no interaction of P4 supplementation by day ($P = 0.352$). For example, CL volumes on d 7 were 9,030.1 ± 126.4 vs 9,021.4 ± 129.1 mm^{3} for Control and CIDR-supplemented cows, respectively. Thus, P4 supplementation 3 d after TAI induced an early increase in circulating P4, but did not compromise CL development in lactating dairy cows. Acknowledgments: Pfizer, FAPESP and CNPq of Brazil.

Key Words: progesterone supplementation, corpus luteum, dairy cow

M194 Reproductive performance of lactating dairy cows managed for first service using timed artificial insemination with or without detection of estrus using an accelerometer system. P. M. Fricke,* A. Valenza, J. O. Giordano, M. C. Amundson, and G. Lopes Jr., *University of Wisconsin, Madison.*

Lactating dairy cows (n = 564) on a commercial dairy farm were fitted with accelerometers (Heatime, SCR Engineers Ltd., Netanya, Israel) at 21 DIM and were randomly assigned to one of 3 treatments: 1) Heatime + Ovsynch (HOv): cows received AI to detected estrus from the end of the VWP (50 DIM) until initiation of Ovsynch (GnRH-7d-PGF-56h-GnRH; cows initiated Ovsynch at 65 ± 3 DIM if not detected in estrus from 21 to 65 DIM, whereas cows initiated Ovsynch at 79 ± 3 DIM if detected in estrus from 21 to 50 DIM but not from 51 to 79 DIM); 2) Presynch-Ovsynch (PGF-14d-PGF-12d-GnRH-7d-PGF-56h-GnRH) + Heatime (PSOvH): cows received AI to estrus detected after the second PGF injection of Presynch at 50 DIM, and cows not detected in estrus initiated Ovsynch at 65 ± 3 DIM; and 3) Presynch-Ovsynch (PSOv): cows were monitored for estrus after the second PGF injection of Presynch, but all cows received TAI at 75 ± 3 DIM. Pregnancy outcomes were determined by the herd veterinarian using transrectal ultrasonography 39 ± 3 d after AI. Average days to first service (DFS) differed ($P < 0.0001$) among treatments with PSOvH cows having the fewest ($P < 0.0001$) DFS (62.4 ± 8.3 d), followed by HOv cows (67.4 ± 10.7 d) and finally PSOv cows (74.7 ± 2.1 d). Overall, pregnancies per AI (P/AI) did not differ ($P = 0.58$) among treatments for HOv cows (33%; 64/194), PSOvH cows (29%; 57/194), or PSOv cows (34%; 60/176). For HOv cows, 57% were detected in estrus (P/AI = 33%), whereas 43% received TAI (P/AI = 33%). For PSOvH cows, 71% were detected in estrus (P/AI = 26%), whereas 29% received TAI and had P/AI of 36.8% (21/57). For PSOv cows, 76% showed estrus after PGF but completed the protocol and received TAI (P/AI = 35%), whereas 24% did not show estrus and received TAI (P/AI = 30%). Based on these preliminary results, the fewest DFS occurred when cows were submitted to a Presynch-Ovsynch protocol combined with detection of estrus using the Heatime system, whereas no overall differences in P/AI were observed among the 3 management strategies for submitting cows to first service.

Key Words: Heatime, Presynch-Ovsynch, timed AI

M195 Accuracy of pregnancy diagnosis outcomes using transrectal ultrasonography 29 days after artificial insemination in lactating dairy cows.

J. O. Giordano* and P. M. Fricke, *University of Wisconsin-Madison, Madison.*

Our objective was to assess the effect of different criteria to determine pregnancy status on the accuracy of transrectal ultrasound (TU) 29 d after a timed AI in lactating dairy cows in a commercial setting. Pregnancy status was determined 29 d after timed AI (TAI) using transrectal ultrasonography (TU; Easi-scan, BCF Technology Ltd.) based on the following criteria: presence or absence of a corpus luteum (CL), presence, absence, volume and appearance of uterine fluid (UF) typical for a 29 d conceptus, presence or absence of an embryo with a heartbeat. Cows were classified as 1) non-pregnant (NP): presence or absence of a CL, absence of UF, or insufficient UF, and absence of an embryo; 2) pregnant (P): CL present, normal UF, and no embryo; 3) pregnant embryo (PE): CL present, normal UF, and at least one embryo visualized; and 4) questionable pregnant (QP): CL present, and one or more of the following: UF, insufficient UF, and either no embryo or a non-viable embryo. At 39 and 74 d after TAI, pregnancy status was determined using transrectal palpation (TP). Overall, 802 cows were classified as NP 29 d after TAI, whereas 799 cows were classified as NP 39 d after TAI resulting in misdiagnosis rate of 0.5% (4/802) for TU 29 d after TAI. At 29 d after TAI, 1,116 cows were classified as either P (28.9%; n = 322), PE (67.9%; n = 758), or QP (3.2%; n = 36). Among QP cows, 69.4% (25/36) were classified as NP 39 d after TAI, and an additional 45.5% (5/11) of the cows were classified as NP 74 d after TAI. For cows classified as P and PE using TU 29 d after TAI, more ($P < 0.0001$) P (17.7%) than PE (4.0%) cows were classified as NP using TP 39 d after TAI. Similarly, more ($P = 0.0004$) P (12.1%) than PE (5.4%) cows diagnosed at 39 d after TAI using TP were classified as NP 74 d after TAI. From the initial pregnancy exam at 29 d to the last exam at 74 d after TAI, more ($P < 0.0001$) P (27.6%) than PE (9.1%) cows were diagnosed as NP. Cows classified as P using TU 29 d after TAI were 3.8 (95% CI = 2.7 to 5.4) times more likely to be classified as NP than PE cows 74 d after TAI. We conclude that the accuracy of TU outcomes are increased when an embryo is visualized compared with TU outcomes based only on the presence of a CL and the volume of uterine fluid. Supported by Hatch project WIS01171.

Key Words: transrectal ultrasonography, pregnancy diagnosis, dairy cattle

M196 Early detection of pregnancy-specific protein B (PSPB) following conception in Holstein heifers.

J. Howard*[1,2], C. Autran[1], J. Branen[2], G. Sasser[2], and A. Ahmdzadeh[1], [1]*University of Idaho, Moscow,* [2]*BioTracking LLC, Moscow, ID.*

Pregnancy-specific protein B (PSPB) is produced by ruminant placentae during pregnancy, and can be detected in maternal blood by a specific ELISA. The objective of this study was to determine the earliest appearance of PSPB after AI and when it can reliably be utilized to determine pregnancy status in Holstein Heifers as compared with the standard ultrasonography method. One hundred twenty-one Holstein replacement heifers were synchronized and subsequently submitted to timed-AI. Blood samples from all heifers were obtained at initiation of the experiment (at the time of AI, d 0), and again on d 18, d 25 and d 32 after AI for PSPB concentration. Pregnancy status was then determined by ultrasonography on d 32 after AI. The results of the PSPB data were then categorized into non-pregnant and pregnant animals based on ultrasonography results. Data were analyzed using a mixed model ANOVA for repeated measures. There was an effect of pregnancy status and pregnancy status × time ($P < 0.01$) on PSPB. Mean PSPB concentrations, expressed as optical density (OD), did not differ between pregnant and non-pregnant heifers on d 0 or d 18. However, PSPB concentrations increased by 1.7 fold, and were greater ($P < 0.01$) in pregnant compared with non-pregnant heifers on d 25 (0.083 ± 0.002 vs. 0.138 ± 0.003; $P < 0.01$) and d 32 (0.079 ± 0.002 vs. 0.296 ± 0.003; $P < 0.01$). Similarly, PSPB levels expressed as ng/mL did not differ on d 0 or d 18, but were greater ($P < 0.01$) in pregnant compared with non-pregnant heifers on d 25 (0.006 ± 0.031 vs. 0.290 ± 0.038; $P < 0.01$) and d 32 (0.026 ± 0.030 vs. 1.124 ± 0.037; $P < 0.01$). These results indicate that PSPB increases overtime and can be detected as early as d 25 after breeding and potentially used to identify non-pregnant heifers.

Key Words: PSPB, pregancy detection, heifers

M197 Possible associations between ova-embryos characteristics in early lactating cows and subsequent reproductive performance.

R. L. A. Cerri*[1], W. W. Thatcher[2], and J. E. P. Santos[2], [1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Florida, Gainesville.*

Ova-embryos (348) from 321 single ovulating Holstein cows were recovered 6 d after AI. Objectives were to determine if previously collected ova-embryo influences future reproductive outcome. Cows were enrolled in a presynchronized Ovsynch program starting at 30 ± 3 DIM and only cows that responded to the first GnRH of the Ovsynch were included. The BCS was measured at enrollment; cyclicity was monitored by ultrasonography. After ova-embryos collection, cows were subjected to a timed AI protocol. Cows were then re-inseminated if in estrus or resynchronized after diagnosed non-pregnant. Pregnancy at first AI, pregnancy loss at first AI, proportion of pregnant cows at 300 DIM, number of AI and interval to pregnancy were analyzed according to grade of ova-embryos collected from the same cows. Ova-embryos were classified based on fertilization and grade quality (IETS). The following combinations of fertilization and embryo grade quality were used to predict fertility responses of dairy cows: fertilized vs. unfertilized; grade 1 vs. remaining; grades 1 and 2 vs. remaining; grades 1 to 3 vs.

remaining. Data were analyzed using GLM, LOGISTIC, and LIFETEST procedure of SAS. Cows that yielded grades 1–3 embryos had a greater number of AI to become pregnant (3.2 ± 0.2 vs. 2.3 ± 0.3), had more median days open (117 vs. 90 d) compared with other structures, but proportion of cows pregnant at 300 DIM was unaltered (90.4 vs 97.9%). Conversely, cows that yielded fertilized ova compared with unfertilized ones required fewer AI (3.0 ± 0.1 vs. 3.8 ± 0.3) and had fewer median days open (109 vs. 122 d) and greater proportion of pregnant cows at 300 DIM (91.8 vs 81.2%). No other combinations of fertilization and embryo quality were associated with number of AI, days open or conception rate at first AI or at 300 DIM. In conclusion, embryo quality in early lactation does not seem to be related to subsequent reproductive performance, but fertilization was associated with reduced subsequent days open and greater conception rate. The genetic potential to produce fertilized ova, but not necessarily good quality embryos, seems to influence reproductive performance.

Key Words: embryo, fertilization, genetic potential

M198 Effects of induced clinical and subclinical mastitis on oocyte developmental competence in bovine. S. Asaf[1], O. Furman[1], G. Leitner[2], D. Wolfenson[1], and Z. Roth*[1], *[1]The Robert H. Smith Faculty of Agriculture, Food and Environment, the Hebrew University, Rehovot, Israel, [2]The Veterinary Institute, Bet Dagan, Israel.*

Clinical and subclinical mastitis can lead to decreased fertility in cows. We examined the effects of gram-positive exosecretions (G+; *S. aureus* ex.) or gram-negative (G-; *E. coli* LPS) toxin induced mastitis on oocyte developmental competence. Two models were established to simulate short-term, acute, clinical mastitis and long-term, subclinical mastitis. Holstein cows were synchronized with GnRH and $PGF_{2\alpha}$ to induce development of a preovulatory follicle. Follicular fluid (FF) was aspirated by transvaginal probe from (1) uninfected cows, (2) cows with clinical mastitis induced by G+ or G-, and (3) cows with subclinical mastitis induced by G+ or G-. FFs were used as maturation medium for IVF procedures. Oocytes were matured (FF, 22 h, 5% CO_2, 38.5°C), fertilized (18 h, 38.5°C, 5% CO_2), and cultured for 8 d (KSOM, 5% CO_2, 5% O_2, 38.5°C). Cleavage rate and proportion of oocytes developed to the blastocyst stage were recorded 44 h and 7 to 8 d post-fertilization. Apoptotic index for blastocysts was determined by TUNEL assay. Total RNA and poly(A) mRNA were isolated from mature oocytes and 4-cell-stage embryos and subjected to real-time PCR for *COX2*, *POU5F1*, *GLUT1*, *HSF1* and *GDF9* genes. Maturation in FF aspirated from clinical- or subclinical-mastitic cows reduced ($P < 0.05$) the cleavage rate and the proportion of developing embryos and increased ($P < 0.05$) the proportion of apoptotic cells in blastocysts. Alterations in gene expression were evident in embryos developed from oocytes matured in FF obtained from mastitic cows, with the most prominent impairments being in *COX2* expression. While clinical G- mastitis decreased *COX2* expression in MII-stage oocytes ($P < 0.05$), both clinical G- and G+ mastitis and subclinical G- and G+ mastitis increased *COX2* expression in 4-cell-stage embryos ($P < 0.05$). In addition, both clinical G+ and subclinical G+ mastitis reduced *OCT4* expression in 4-cell-stage embryos ($P < 0.05$). The findings indicate a deleterious effect of FF obtained from both clinical- and subclinical-mastitic cows on oocyte developmental competence. The disruptive mechanism seems to be associated with alteration in embryonic gene expression.

Key Words: mastitis, oocyte, developmental competence

M199 Assessing the relationships of prostaglandin E2 in uterine flush fluid, peripheral blood prostaglandin E2 and progesterone with pregnancy outcome in dairy cattle. J. L. Fain*[1], M. W. Overton[2], D. J. Hurley[2], and G. P. Birrenkott[1], *[1]Clemson University, Clemson, SC, [2]University of Georgia, Athens.*

Uterine inflammation can negatively affect animal welfare, milk production and rebreeding capacity in dairy cattle. The objectives of the current work were to investigate the relationship between prostaglandin E2 (PGE) found in uterine flush fluid to that found in peripheral blood and their potential effect on reproductive success in postpartum dairy cows. Animals (n = 34) were enrolled in a presynch program beginning at 35 ± 3 d postpartum with a $PGF_{2\alpha}$ injection followed by a second at d 49. Cows then received the Ovsynch protocol (100µg GnRH d 60, 25mg $PGF_{2\alpha}$ d 67, 100µg GnRH d 69 with TAI 16–18 h later on d 70). Uterine flush samples of both horns were collected from animals before the $PGF_{2\alpha}$ injection of the Ovsynch protocol. All animals received 100µg of GnRH on d 28 post TAI for the resynchronization program. Any animals open to the first TAI as determined by transrectal ultrasonography on d 35 had a second flush sample collected from the uterine body while receiving 25mg $PGF_{2\alpha}$ with an injection 100 µg GnRH following on d 37 and TAI 16–18 h later on d 38. Cows were then monitored for and bred off standing estrus with any animals not seen in estrus having pregnancy confirmed. If open to a third breeding, a third and final flush sample was collected. Blood samples were collected at d 35, 49, 60 and 67 post-parturition and d 14, 18, 22, 25, 28, 32 and 35 post TAI for P4 and PGE analysis. Additional blood samples were collected before each flush for testing by BioPRYN and for PGE. Blood and uterine PGE values shared no relationship with P4 concentrations. Significantly higher P4 values were found on d 18 post TAI in animals that were pregnant ($P < 0.05$). Though numerically there was evidence that reduced PGE value increased the likelihood of pregnancy, neither the PGE values in uterine flush fluid nor blood were significant predictors of pregnancy success at the 1st, 2nd or 3rd breeding or the likelihood of securing pregnancy after 3 breedings ($P > 0.05$). There was a high correlation between uterine PGE values and BioPRYN optical density readings ($P < 0.05$). Though the second flush showed a strong correlation between blood PGE and uterine flush PGE when SCC was added as a covariate ($P < 0.05$), this was not consistent across flushes ($P > 0.05$). Correlation potentials with BioPRYN as well as blood PGE would lend a less complicated method for detection of uterine inflammation as assessed by PGE.

Key Words: prostaglandin E2, dairy, uterine inflammation

M200 Effect of oral or subcutaneous administration of vitamin E and selenium on milk quality and reproductive function of Holstein cows. C. Garcia-Barrios, M. Rodriguez-Loera, C. F. Arechiga, M. A. Lopez-Carlos, J. I. Aguilera, R. M. Rincon, H. Rodriguez-Frausto, D. Rodriguez-Tenorio, and Z. Cortes,* *Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

Aim of this study was to determine factors affecting milk quality and reproductive efficiency of Holstein dairy cows in response to subcutaneous or oral administration of vitamin E and selenium. Cows (n = 159) were randomly allotted into 3 groups: 1) Control cows (n = 53; non-injected or supplemented cows); 2) Cows (n = 53), injected subcutaneously with 10 mL of vitamin E and selenium at days −45, −22, 0, before parturition and d 15 and 30 after parturition, (each injection contained 600 mg of vitamin E and 109.5 mg of selenium (BeefSe, Aranda

Labs., Queretaro,Mexico) 3) Cows (n = 53), were supplemented orally with 20 g of Selenio E (Ripoll, Mexico, D.F.), containing 2,500 mg of vitamin E/cow/d, and 3 mg of selenium/cow/d) from days −45 before parturition through d 30 after parturition. Milk quality and reproductive efficiency of cows was evaluated. Data obtained include determination of fat, protein, lactose, total solids (TS), non-fat solids (NFS) using a Milkoscan equipment (Foss, Hillerød, Denmark). Reproductive data were obtained and analyzed using PROC MIXED of SAS. The model includes the effects of season, lactation, treatment and treatment by season, a REML and PPDIFF methods were utilized considering days as repeated measurements. In conclusion, milk components were reduced during autumn ($P < 0.05$). However, antioxidant administration during the peripartum period, by subcutaneous injection of vitamin E and selenium were effective preventing milk protein reduction during autumn. Moreover, oral supplemented administration of vitamin E and selenium did not prevented seasonal reductions of milk components. Whereas, reproductive function was improved during autumn

Key Words: dairy cow, milk components, reproduction

M201 Effects of supplementation with different PUFA during the postpartum periods of early lactating dairy cows, estradiol concentration and luteal function.

E. Dirandeh[1], A. Towhidi*[1], S. Zeinoaldini[1], M. Ganjkhanlou[1], Z. Ansari Pirsaraei[2], and T. Saberifar[1], [1]*Department of Animal Science, Faculty of Agricultural Science and Engineering, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran,* [2]*Department of Animal Science, Faculty of Animal Science and Fishery, Sari University of Agricultural and Natural Resources, Sari, Mazandaran, Iran.*

Ninety high-yielding multiparous Holstein dairy cows with no over clinical illnesses were blocked according to calving date and parity. Cows were assigned randomly to be fed either 1-soybean whole roast (S, n = 30), or 2-linseed (L, n = 30), or 3-palm oil as a source of saturated fatty acid (C, n = 30) from calving until d 60 postpartum (dpp). There was no difference between groups (mean ± SEM) in parity (3.0 ± 1.90) or BCS at calving (3.2 ± 0.07). Beginning at 30 DIM, cows were induced into a synchronized ovulatory cycle with 2 injections of PGF2α 14 d apart. Blood was collected daily; from the day that second PGF2α inject until the day of next estrous. Ovarian follicular development was monitored daily by transrectal ultrasonography with a real-time linear scanning ultrasound diagnostic system (B mode; Piemedical, Falco 100; 8 MHz transducer). Ultrasonography was performed once daily from the day that second PGF2α inject until the day of next estrous. Data were analyzed with PROC MIXED of SAS. Cows offered diet S and L had a greater size of corpus luteum than cows offered Diet C. There were no significant differences between groups L and S in size of corpus luteum (17.70 ± 0.86 and 18.30 ± 0.86 mm respectively; $P < 0.05$). Although mean serum progesterone concentrations on d 17 of synchronized cycle were higher in cows fed S (8.40 ± 0.10 ng/ml) or L (9.10 ± 0.20 ng/ml) than cows fed palm oil (6.30 ± 0.15 ng/ml, $P < 0.01$), there were no significant differences between groups L and S groups. Mean estradiol concentration was higher at the time of estrus in cows fed S or L compared with those fed palm respectively (12.60 ± 0.016, 13.00 ± 0.08 vs. 10.10 ± 0.09 pg/mL; $P < 0.05$) in the cows.

M202 Hepatic patatin-like phospholipase domain-containing protein 3 mRNA expression is increased during feed restriction and in transition dairy cows.

M. E. Viner*[1], S. S. Donkin[2], and H. M. White[1], [1]*Department of Animal Science, University of Connecticut, Storrs,* [2]*Department of Animal Sciences, Purdue University, West Lafayette, IN.*

Patatin-like phospholipase domain-containing protein 3 (PNPLA3), commonly known as adiponutrin, is part of a novel subfamily of triglyceride lipase enzymes with potential effects on triglyceride metabolism in adipose and hepatic tissues. In rodents and humans, PNPLA3 mRNA expression is suppressed during fasting and is increased by subsequent refeeding. The bovine predicted PNPLA3 sequence has been identified; however, expression of this gene has not yet been examined. The objectives of this study were to verify expression of the bovine predicted PNPLA3 gene and to determine response to whole-animal energy balance. Genomic DNA was isolated from liver biopsy samples collected from cows at +28 d relative to calving (DRTC) and the predicted PNPLA3 region was amplified via PCR and visualized to confirm expression. To determine if energy balance alters expression of PNPLA3, RNA was isolated and quantified in liver samples from mid-lactation cows (n = 5) after a 5-d ad libitum period and after a subsequent 5-d 50% feed restriction period, to determine if energy balance altered expression. Expression of hepatic PNPLA3 was decreased ($P < 0.05$) after a period of feed restriction (8.14 vs. 1.08 ± 2.17, arbitrary units, ad libitum vs. fasted). Dairy cows commonly experience negative energy balance during the transition to lactation; therefore, PNPLA3 expression was also examined in liver biopsy samples cows (n = 16) at −14, +1, +14, and +28 DRTC. Expression was decreased ($P < 0.05$) at +1 and +14 DRTC compared with −14 DRTC (23.35, 7.28, 10.17, and 14.5 ± 4.9, arbitrary units, −14, +1, +14, and +28 DRTC, respectively). The data indicate increased hepatic PNPLA3 expression that is part of the adaptive response to the transition to lactation and suggests a link to negative energy status associated with this interval.

Key Words: patatin-like phospholipase domain-containing 3, adiponutrin, energy balance

M203 Changes of the serum and milk proteome in lactating dairy cows duodenal infused with α-linolenic acid.

J. H. Yang, J. Q. Wang,* T. J. Yuan, D. P. Bu, Y. X. Yang, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study investigated the effect of a duodenal infusion of a C18:3 free fatty acid on the serum and milk proteome of lactating dairy cows. Four primiparous Holstein cows were fitted with duodenal cannulas and received 0, 100, 200, 300, and 400 g/d of α-linolenic acid (LNA) in a 2-treatment crossover design. Blood and milk were collected for determination of protein composition by 2-dimensional gel electrophoresis. Quantitative analysis of protein dyeing density were prosessed by Quantity One 4.6. Alteration of protein spots were detected and identified using matrix-assisted laser desorption/ionization time-of-flight/time-of-flight tandem mass spectrometry (MALDI-TOF-TOF MS). Data were analyzed by SPSS 16.0. Serum haptoglobin levels, and milk β-casein A2, αs1-casein variant, and albumin, did not differ in cows after infusion of 0, 100, 200 and 300 g/d of LNA, but were increased after the cows received duodenal infusion of 400 g/d of LNA. Western blot analysis of haptoglobin expression in the serum confirmed the alterations in protein expression seen using mass spectrometry. This study demonstrated that infusion of high doses of LNA by duodenal cannula can result in metabolic stress to the cows and changes in milk composition.

Key Words: linolenic acid, proteome, dairy cow

M204 Investigation of the relationship between resumption of ovarian cyclicity and plasma nutritional markers in lactating dairy cows.

A. Ahmadzadeh[1], J. Spencer*[1], B. Shafii[1], C. Johnson[1], J. Dalton[2], K. Carnahan[1], and S. Reeds[1], [1]*University of Idaho, Moscow,* [2]*University of Idaho R & E Center, Caldwell.*

Previous reports have shown the association between metabolic hormones, ovulation intervals and reproductive performance. The objective of this study was to investigate the relationship between the resumption of ovarian activity and plasma nutritional markers including glucose, NEFA, plasma urea nitrogen (PUN), cholesterol and β-hydroxybutyrate (BHBA). Forty-three lactating Holstein cows, housed in a free stall barn, were randomly selected from a commercial herd. From wk 2 to wk 7 postpartum, weekly ultrasonography and blood sampling was performed to characterize ovarian status, plasma metabolites, and blood progesterone. The occurrence of the first postpartum ovulation was determined by the analysis of plasma progesterone and confirmation of ovulation using visualization of a corpus luteum by ultrasonography. Based on plasma progesterone concentration and ovarian status, cows were divided into 2 treatment groups, cows that ovulated ≤25 DIM were designated early ovulators (EO) and cows that ovulated >25 DIM were considered late ovulators (LO). Data were analyzed using mixed model ANOVA for repeated measures. The mean interval to 1st ovulation for EO was 16.7 d, and for LO was 34.7d. Mean BCS was greater ($P < 0.05$) for EO than LO and (3.3 ± 0.1 vs 2.9 ± 0.1). There were effects of week ($P < 0.01$) and week by group interaction ($P < 0.05$) on blood cholesterol. Mean blood cholesterol increased over time for both EO and LO, however, mean cholesterol concentrations between wk 2 and 3 were less ($P < 0.05$) for EO compared with LO. Across all weeks, the mean glucose concentrations tended to be greater ($P = 0.06$) in EO than LO. There was no effect of group, week, or their interaction on blood BHBA. Blood NEFA did not differ between EO and LO, however, the mean concentration of NEFA decreased over time ($P < 0.01$) for both groups. Mean PUN was not different between EO and LO throughout the experiment. These results provide evidence that the 1st postpartum ovulation may be associated with blood glucose and cholesterol during the early postpartum period and may be indicative of the resumption of reproductive function in lactating dairy cows.

Key Words: blood metabolites, ovulation, dairy cows

M205 Insulin responses in dairy cows with different fat mobilization during early lactation.

U. Kautzsch[1], B. Kuhla[1], M. Röntgen[1], S. Görs[1], R. M. Bruckmaier[2], C. C. Metges[1], and H. M. Hammon*[1], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*Veterinary Physiology, Vetsuisse Faculty, Bern, Switzerland.*

Dairy cows differ in fat mobilization around calving. Insulin has antilipolytic effects and may antagonize body fat mobilization, but insulin action is probably impaired in cows early postpartum (pp). The objective of the present study was to compare insulin responses ante partum (ap) and pp in cows differing in fat mobilization. German Holstein cows (>10,000 kg milk/305 d; ≥ 2nd lactation) were classified by liver fat concentration (LFC) pp in low (L; < 240 mg total fat/g DM; n = 9) and high (H; > 240 mg total fat/g DM; n = 10). Cows were studied from dry off up to 30 DIM and were fed TMR ad libitum. DMI and milk yield were recorded daily. Liver biopsies were taken on d 3, 18, and 30 pp to measure LFC. Hyperglycemic (HGC) and euglycemic-hyperinsulinemic clamps (EGHIC) were performed in wk 5 ap and wk 3 pp to measure pancreatic and peripheral insulin responses. In HGC glucose was infused to reach plasma concentrations 50% higher than basal glucose concentrations. In EGHIC insulin (6 mU/kg BW × min) was infused for 6 h and plasma glucose was kept constant according to pre-clamp concentrations. Blood samples were taken to measure plasma glucose and insulin and glucose infusion rates (GIR) were determined during steady-state conditions. Before and during the EGHIC pp [U-^{13}C]-glucose (prime: 5.4 μmol/kg BW; infusion: 7.5 μmol/[kg BW × h] for 9 h) was infused to measure of endogenous glucose production (eGP), glucose turnover (GT), and oxidation (GOx). Data were analyzed by Mixed Model of SAS with LFC and time as fixed effects. LFC differed between groups ($P < 0.01$) (H: 306 ± 0.2 mg/g; L: 195 ± 0.1 mg/g). Basal glucose and insulin concentrations were higher ($P < 0.05$) ap than pp. In HGC GIR was higher ($P < 0.001$) and insulin release was lower ($P < 0.01$) pp than ap. In EGHIC GIR tended to be higher ($P < 0.1$) in H than L. During insulin infusion pp eGP decreased to 19% of pre-clamp eGP. GT was higher ($P < 0.05$), but GOx relative to glucose turnover tended to be lower ($P < 0.1$) in H than L. Insulin action was not affected by elevated fat mobilization pp but stimulation of insulin secretion was impaired pp. Supported by DFG, Germany.

Key Words: dairy cow, glucose, insulin response

M206 Effects of heat stress and plane of nutrition on adipose tissue metabolism-related gene expression in lactating Holstein cows.

G. Xie*[1], L. W. Hall[2], M. Nearing[2], L. C. Cole[2], J. Allen[2], L. H. Baumgard[3], D. M. Spurlock[3], and R. P. Rhoads[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg,* [2]*University of Arizona, Tucson,* [3]*Iowa State University, Ames.*

During heat-stress (HS) in lactating dairy cows, adipose tissue appears to become refractory to lipolytic signals whereas pair-fed cows employ mechanisms allowing lipid mobilization to spare glucose utilization in peripheral tissues. Despite this, little is known regarding the effects of HS on metabolic gene expression in adipose tissue. Multiparous cows (n = 12; parity = 2, 305 ± 33 DIM; 665 ± 18 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn and subjected to 2 experimental periods (P): 1) thermoneutral (TN) conditions (18°C, 20% humidity) with ad libitum intake for 9d and 2) either HS conditions (cyclical temperature 31–40°C, 20% humidity: min THI = 73, max THI = 86) fed for ad libitum intake (n = 6), or TN conditions, pair-fed (PF in TN conditions, n = 6) for 9d. Rectal temperature (Tre) and respiration rate (RR) were measured thrice daily at 0600, 1400 and 1800h. To evaluate adipose tissue gene expression, biopsies were obtained from the tail-head region at the end of each period and total RNA isolated for real-time PCR analyses. Data was normalized using β-actin as a control gene and analyzed by the Proc Mixed procedure in SAS. During P2, HS cows had a 1.8°C increase in Tre and a 3-fold increase in RR compared with TN cows ($P < 0.01$). Pair feeding did not alter Tre or RR. Heat stress reduced ($P < 0.01$) DMI by 20% and by design PF cows had similar intake reductions. Milk yield was decreased 12% during HS and 8% in PF cows. Adipose triglyceride lipase (ATGL), lipoprotein lipase (LPL), and pyruvate carboxylase (PC) significantly decreased ($P < 0.05$) during HS compared with TN, but was unaffected by PF. Fatty acid synthase (FAS) mRNA abundance decreased during PF ($P < 0.05$) but was unchanged by HS. In contrast, gene expression of β1 adrenergic receptor (AR) and perilipin (PLIN) tended to increase ($P = 0.10$) while β2 AR and the truncated leptin receptor (ObRa) increased significantly during PF ($P < 0.05$) but not HS. These results indicate that HS directly alters adipose tissue metabolism-related gene expression independently of reduced plane of nutrition. This project was supported by NRI Competitive Grant no. 2008-35206-18817 and AFRI Competitive Grant no. 2010-65206-20644 from the USDA NIFA.

Key Words: heat stress, adipose, metabolism

M207 Relevance of mineralocorticoid receptors in different fat depots of dairy cows supplemented with CLA.

K. Friedauer*[1], S. Dänicke[2], D. von Soosten[2], H. Sauerwein[1], and S. Häussler[1], [1]*University of Bonn, Bonn, NRW, Germany,* [2]*Federal Research Institute, Braunschweig, Lower Saxony, Germany.*

Adipose tissue (AT) consists of different cell types, among those preadipocytes, marked by preadipocyte factor-1 (Pref-1), are crucial for differentiation into mature adipocytes. This process is induced by glucocorticoids mediating their effects through the glucocorticoid (GR) and mineralocorticoid receptor (MR). Whether bovine adipocytes differentiate through GR or MR activation is not known. To investigate the main pathway of adipocyte differentiation, 25 primiparous Holstein cows were divided into control (CON, n = 15) and CLA group (n = 10), slaughtered on 1, 42 and 105 DIM. CLA cows received 100 g/d of a CLA-mixture (Lutrell BASF) from 1 DIM until slaughter. CON cows were fed with 100 g/d of a fatty acid mixture (Silafat BASF) without CLA. Samples from 3 visceral (vc) and 3 subcutaneous (sc) AT depots were obtained. MR and Pref-1 were localized on paraffin embedded sections by immunohistochemistry. Data are given as percentage of positive cells per total cell number (mean ± SEM) and were correlated by Pearson correlation (SPSS 19). Both MR and Pref-1 were detected exclusively in the stromal vascular cell fraction (SVF) of all fat depots, while GR was detected solely in adipocytes. The mean values were 1.05 ± 0.1% and 2.99 ± 0.2% for Pref-1 and MR, respectively. Significant correlation coefficients between MR and Pref-1 are given in the table ($P \leq 0.05$). We assume that bovine adipocyte differentiation is mediated through MR, for MR and Pref-1 are allocated to the SVF. In vc AT lipolysis in early lactation might be compensated by preadipocyte differentiation and seems to vary between different AT depots.

Table 1. Correlation coefficients (r) between mineralocorticoid receptor (MR) and Pref-1 (only significant data are shown; $P \leq 0.05$)

M208 The effects of a soybean and canola diet during pre-pubertal growth on dairy heifer fertility.

M. B. Gordon*[1], E. Thompson[1], T. Gowan[2], D. Mosely[3], J. A. Small[2], and D. M. W. Barrett[1], [1]*Department of Plant & Animal Science, Nova Scotia Agricultural College, Truro, NS, Canada,* [2]*Atlantic Food & Horticulture Research Centre, Agriculture & Agri-Food Canada, Truro, NS, Canada,* [3]*AgraPoint, Bible Hill, NS, Canada.*

Dietary phytoestrogens (such as those in soybean) can have detrimental influences on the rate of sexual maturation and reproductive physiology of animals; however, the precise effect of phytoestrogens on reproductive function in dairy cattle has not been fully elucidated. This study examined the effects of feeding a soybean (SOY) and canola (CAN) calf starter diet during pre-pubertal development on the fertility of Holstein dairy heifers. At 8 wk of age calves (n = 24) were randomly assigned to receive CAN or SOY until 24 wk of age. Calves were fed approximately 1.5 kg/calf/day and ad libitum hay and water. At 24 wk of age heifers were group housed and fed a TMR of grass and corn silage and hay. At approximately 60 wk of age heifers were synchronized for AI using Double Ovsynch (GnRH–$PGF_{2\alpha}$, 7 d–GnRH, 3 d followed 7 d later by GnRH–$PGF_{2\alpha}$, 7 d–GnRH 48 h–AI 16 to 20 h). Blood samples were collected on d −3, 0 (AI), 7, and 14 for progesterone (P_4) analysis. Transrectal ultrasonography was performed twice daily for 3 d, starting 24 h before AI, to determine timing of ovulation and ovulatory follicle size and on d 42 for pregnancy diagnosis. Ovarian and hormone data were analyzed using ANOVA; pregnancy rate (PR) was analyzed using logistic regression. The timing of ovulation following the last GnRH injection was not different (35.9 ± 2.6 h; $P = 0.39$). However, 1 CAN and 2 SOY heifers did not ovulate. The maximum ovulatory follicle diameter was similar (15.3 ± 0.5 mm; $P = 0.58$). The CAN treatment had greater P_4 concentrations than the SOY on d −3 (4.9 ± 0.5 ng/mL vs. 2.7 ± 0.5 ng/mL; $P = 0.003$). There were no differences in P_4 concentrations on d 7 (2.3 ± 0.2 ng/mL $P = 0.42$) or 14 (2.6 ± 0.3 ng/mL; $P = 0.20$). Pregnancy rates were 66.7% vs. 41.7% ($P = 0.62$) for CAN and SOY, respectively. Concentrations of P_4 on d −3 ($P = 0.10$) and 7 ($P = 0.09$) tended to influence PR. In summary, there were no differences between treatments for the timing of ovulation, ovulatory follicle size, and post-AI P_4 concentrations. However, P_4 concentrations on the day of $PGF_{2\alpha}$ treatment of Ovsynch TAI tended to influence PR and on this day CAN treatment had higher P_4 concentrations.

Key Words: phytoestrogens, dairy heifers, fertility

M209 Reproduction in grazing dairy cows treated with 14-d CIDR for presynchronization before a timed AI (TAI) compared with AI after observed estrus.

R. C. Escalante,* S. E. Poock, D. J. Mathew, W. R. Martin, E. M. Newsom, S. A. Hamilton, K. G. Pohler, and M. C. Lucy, *University of Missouri, Columbia.*

Progesterone-releasing devices (CIDR; Pfizer, New York, NY) inserted for 14 d are used to presynchronize the estrous cycle for TAI in beef heifers (14-d CIDR-PG program). The objective was to test a similar program in dairy cows by measuring first service conception rates (FSCR), pregnancy rates, and time to pregnancy compared with a control (AI after observed estrus). Postpartum cows (Holstein, Jersey or crossbred; n = 1363) from 4 grazing dairy farms were assigned to one of 2 programs: 14dCIDR_TAI [TRT; CIDR in, 14 d, CIDR out, 19 d, $PGF_{2\alpha}$ (5 mL Lutalyse, Pfizer), 56 h, GnRH (2 mL Factrel, Pfizer), and then 16 h, TAI; n = 737] or control [AI after observed estrus; reproductive program with $PGF_{2\alpha}$ (cycling cows) and CIDR (non-cycling cows) to synchronize estrus with the start of the breeding season; n = 626]. Body condition (BCS; 1 to 5; thin to fat) was scored at trial start. The interval from the start of breeding to first AI was shorter for TRT vs control (3.0 ± 0.2 vs 5.3 ± 0.2 d; $P < 0.001$) but TRT cows had lesser FSCR than control (48 vs 61%; $P < 0.05$). Farm affected ($P < 0.002$) FSCR (69, 50, 58, and 51% for farms 1 to 4) but there was no treatment by farm interaction ($P > 0.10$). BCS affected FSCR (50, 55, and 62%; 2, 2.5, and 3; $P < 0.05$). Cows that either calved the year before (carry-over) or that calved early in the calving season had greater FSCR than cows that calved later in the calving season (55, 61, and 42%, respectively; $P < 0.001$). The percentage of cows pregnant to AI (6 wk breeding season) was similar for TRT and control (65 vs 70%; $P > 0.10$) but farm (81, 66, 69, and 62; $P < 0.01$) and time of calving (70, 76, and 56%; carry-over, early, and late; $P < 0.001$) affected the percentage. Survival analyses showed an initial advantage for TRT [more cows inseminated ($P < 0.001$) and more pregnancies achieved ($P < 0.07$) early in the breeding season] that was not maintained over time. Conclusions were that the 14dCIDR_TAI program achieved acceptable FSCR (48%) and overall 6 wk pregnancy rates (65%) for a TAI but did not surpass a control program that employed AI after observed estrus (61 and 70%; respectively).

Key Words: dairy, cow, timed AI

M210 Hormonal therapies on repeat breeder cows of a dairy production unit of central Mexico (Aguascalientes State).

F. Lugo-Garcia, C. F. Arechiga,* A. Reyes-Gomez, R. R. Lozano, F. J. Escobar, R. M. Rincon, J. I. Aguilera, and M. A. Lopez-Carlos, *Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

The aim of this study was to determine the factors that influence the reproductive efficiency of Holstein repeat-breeder cows (n = 320) in response to 5 different protocols or treatments used in an intensive dairy production unit at Aguascalientes State. Hormonal therapies were: 1) control; 2) GnRH at d 5 post-AI; 3) hCG at d 5 post-AI; 4) GnRH at d 5 post AI + CIDR; 5) GnRH at d 11 post-AI. Data was recorded from February to September 2011. Information obtained was analyzed by Chi-squared using the SAS statistical package (SAS, 2006). Subsequently, orthogonal contrasts were performed (control vs. hCG vs. GnRH). A high incidence of repeat-breeder cows showed reduced conception rates, which, in turn, compromise general reproductive performance of the herd and it has economic and managemental implications such as the genetc progress and replacement programs of the herd. Only 17% of repeat breeder cows were diagnosed pregnant whereas 83% were non-pregnant. Responses to all 5 hormonal therapies implemented were considerably low. However, a GnRH injection 11 d post-insemination presented higher pregnancy rates compared with the control group (31 vs. 21%), or to other GnRH (15.7%) or hCG treatments (0%). In conclusion, a GnRH injection 11 d post-insemination could be effective increasing fertility of repeat breeder cows.

Key Words: dairy cows, reproduction, repeat breeder

M211 Effects of month of breeding on reproductive efficiency of dairy cows inseminated with sexed or nonsexed semen in a hot arid environment.

E. Sepulveda*[1], O. Angel-Garcia[1], J. M. Guillen[1], C. A. Meza-Herrrera[2], F. G. Veliz[1], and M. Mellado[1], [1]*Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico,* [2]*Universidad Autonoma Chapingo-Unidad Regional Universitaria de Zonas Aridas, Bermejillo, Durango, Mexico.*

The objective of this study was to assess the effect of month of breeding on reproduction performance of Holstein cows treated with rbST throughout lactation and inseminated with sexed or nonsexed semen in a hot arid environment. Pregnancy per artificial insemination (P/AI; 62666 services over a 5-year period) both in nulliparous heifers (n = 20313) and cows (42353) from a large dairy herd in northern Mexico (26° N) were evaluated with respect to month of AI. The GENMOD procedure of SAS was implemented to assess the effect of month of breeding on P/AI. Overall, P/AI with sex-sorted semen was greater ($P < 0.01$) in heifers (41.6%) than cows (17.3%). P/AI for cows serviced with conventional semen was 10 percent points higher ($P < 0.01$) in January and December (31 vs 21) than cows serviced with sex-sorted semen. While there was no difference in P/AI between the sex-sorted sperm, and conventional semen in cows inseminated in June, P/AI plummeted for both groups of cows at this time of the year (16 and 18%, respectively). What was observed in cows, P/AI was not different between heifers serviced with sex-sorted or conventional semen during the hottest months of the year (July to October). However, during the coldest months of the year (January and February), P/AI was 10 percentage points greater ($P < 0.01$) in heifers serviced with conventional semen than heifers serviced with sex-sorted semen. It was concluded that in this hot-arid climate of northern Mexico breeding cows and heifers during summer compromise the breeding success. This data also show that the use of nonsexed semen resulted in meaningful advantages in terms P/AI compared with sexed semen, however, this advantage was reduced during extreme heat loads.

Key Words: nulliparous, sex-sorted, conventional

M212 Effects of follicular wave and progesterone concentration during follicle growth on conceptus global gene expression in dairy cows.

R. S. Bisinotto*[1], E. S. Ribeiro[1], L. F. Greco[1], N. Martinez[1], R. L. A. Cerri[2], W. W. Thatcher[1], and J. E. P. Santos[1], [1]*University of Florida, Gainesville,* [2]*University of British Columbia, Vancouver, BC, Canada.*

Effects of wave of the ovulatory follicle and progesterone (P4) concentration during follicle growth on subsequent conceptus gene expression were evaluated. Nonlactating Holstein cows received a timed artificial insemination (AI) protocol (d-9 GnRH, d-2 and d-1 $PGF_{2\alpha}$, d0 GnRH and AI, d1 AI) initiating either during proestrus or early diestrus. The rationale was to induce ovulation of either a first (FW, n = 13) or second wave follicle (SW, n = 12) at AI, respectively. To evaluate the effects of P4 during follicle development, a third group of cows induced to ovulate first wave follicles received 3 intra-vaginal inserts containing P4 inserted sequentially at 12, 24 and 48 h after the initial GnRH (FWP4, n = 8). All inserts were removed on d-2. Cows were killed on d17 after d0 AI and uteri were flushed with PBS solution. Recovered concepti mRNA was extracted and global gene expression was evaluated using Affymetrix GeneChip Bovine Genome arrays. Data analyzed using the MIXED procedure of JMP-Genomics/SAS. Orthogonal contrasts were performed to determine the effects of P4 (FW vs. FWP4) and follicle wave (FW+FWP4 vs. SW). Differentially expressed genes were selected if $P < 0.05$ and fold-difference >1.5. Analyses identified 155 upregulated and 478 downregulated genes in response to the ovulation of a FW compared with a SW follicle. Upregulated genes were associated with 18 pathways from the Kyoto Encyclopedia of Genes and Genomes (KEGG). Downregulated genes are involved with a greater variety of biological processes (50 pathways), including several of those encompassing the upregulated transcripts. Progesterone supplementation during growth of the FW follicle induced upregulation of 73 genes from 13 pathways, including MAPK (hsa04010) and Wnt signaling pathways (hsa04310), focal adhesion (hsa04510) and regulation of cytoskeleton (hsa04810). Interestingly, P4 induced upregulation of TCF7 and EGFR in concepti. These genes have been associated with endometrial cell proliferation and cancer in humans; therefore, are potential candidates to mediate P4 maternal-conceptus communication.

Key Words: embryo gene expression, progesterone, dairy cow

M213 Expression of CYP11A1, CYP17, and CYP19A1 in granulosa cells, and determination of hormone levels in follicular fluid from dominant follicles and follicular cysts in Holstein cows.

P. Hernández-Briano, J. A. Grado-Ahuir,* E. Burrola-Barraza, R. M. Villaseñor González, L. E. Escobedo-Morales, and S. A. Quintana-Quintana, *Facultad de Zootecnia y Ecología, Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

Follicular cysts are a major cause of infertility in dairy cattle. The objective was to assess the expression of genes coding for CYP11A1, CYP17, and CYP19A1 in granulosa cells, and to measure the level of IGF-1, 17-β estradiol (E_2), and progesterone (P_4) in follicular fluid of dominant follicles and follicular cysts. We analyzed 17 dominant follicles and 16 follicular cysts obtained from dairy cows slaughtered in Chihuahua, México. Gene expression relative to GAPDH was measured by real-time PCR using the comparative threshold cycle method. The concentration of IGF-1, E_2 and P_4 was measured by enzyme immunoassay. The experiment was conducted using a completely randomized design, with the fixed effect of follicle (cystic or dominant). We also studied the correlation among gene expression, follicle diameter and hormone levels. There were no differences ($P > 0.05$) between follicular cysts and dominant follicles for the expression of CYP11A1 (3.51 ± 0.25 vs 3.42 ± 0.26), CYP17 (1.88 ± 0.26 vs 1.84 ± 0.29), CYP19A1 (4.07 ± 0.36 vs 3.37 ± 0.42), and the concentration of E_2 and P_4 (1142.00 ± 1.82 vs 1384.65 ± 1.82, and 23.40 ± 1.45 vs 13.10 ± 1.45 ng/mL, respectively). The concentration of IGF-1 was higher ($P < 0.05$) in follicular cysts compared with dominant follicles (132.78 ± 1.88 vs 78.21 ± 1.88 ng/mL). We found significant correlations ($P < 0.05$) between the expression level of CYP11A1 with CYP17 and CYP19A1 (0.57 and 0.73, respectively) in dominant follicles. There was a negative correlation ($P < 0.05$) between IGF-1 and CYP11A1 expression (−0.69), and CYP11A1 and follicle diameter (−0.60) in follicular cysts. Level of expression for CYP19A1 was positively correlated to E_2 concentration in both follicular cysts and dominant follicles (0.93 and 0.88 respectively). Cystic follicles show greater concentration of IGF-1, which is negatively related to CYP11A1.

Key Words: follicular cyst, gene expression, IGF-1

M214 Comparison of dry matter intake and somatotropic axis components of Holstein and crossbred dairy cows.

L. G. D. Mendonça*[1], N. B. Litherland[2], M. C. Lucy[3], D. H. Keisler[3], and R. C. Chebel[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, Saint Paul,* [2]*Department of Animal Science, University of Minnesota, Saint Paul,* [3]*Division of Animal Sciences, University of Missouri, Columbia.*

Objectives of the study were to compare dry matter intake (DMI), somatotropic axis components, plasma cortisol (COR), and leptin (LEP) concentrations of Holstein (HO) and Montbéliarde sired crossbred (MS) cows. Cows were enrolled in the study 45 d before calving (d −45) and followed until d 90. Daily DMI was measured from d −45 to 45. Liver was biopsied on d −14, 7, 14, and 28 to determine mRNA expression of growth hormone receptor (GHR) 1A, insulin-like growth factor-I (L-IGF1), and insulin receptor b (IRB). Plasma concentrations of growth hormone (GH), insulin-like growth factor-I (IGF1), insulin (INS), and LEP were determined on d −7, 1, 7, 14, 21, 42, and 56 and that of COR was determined on d −14, −7, 1, 7, 14, 21, and 42. Data were analyzed by ANOVA for repeated measures. Breed tended ($P = 0.08$) to be associated with DMI from d −45 to 45 (HO = 16.5 ± 0.7kg/d vs MS = 14.9 ± 0.6kg/d) and DMI expressed as percentage of body weight (DMIBW) tended ($P = 0.10$) to be affected by the interaction between breed and day because among HO cows DMIBW on d −15 and −1 were 1.89 ± 0.12% and 1.43 ± 0.14%, respectively, and among MS cows DMIBW on d −15 and −1 were 1.51 ± 0.10% and 1.41 ± 0.11%, respectively. There were no associations between breed and expression of GHR1A ($P = 0.83$), L-IGF1 ($P = 0.70$), and IRB ($P = 0.68$) mRNA. The interaction between breed and day was ($P = 0.02$) associated with expression of IRB mRNA because among HO cows IRB expression was ($P < 0.05$) greater on d 7 compared with d 28 and on d 14 compared with d −14 and 28 but no changes in IRB expression were observed among MS cows. There were no associations between breed and concentrations of IGF1 (55.4 ± 1.7ng/mL; $P = 0.81$), INS (65.2 ± 0.7ng/mL; $P = 0.69$) and LEP (2.8 ± 0.2ng/mL; $P = 0.30$), but HO cows had ($P < 0.01$) greater concentrations of GH (7.4 ± 0.4 vs 5.1 ± 0.4 ng/mL) and cortisol (9.4 ± 0.8 vs 7.1 ± 0.8ng/mL) than MS cows. The greater decrease in prepartum DMI for HO cows may have caused the increased levels of GH and COR. The similar IGF1 concentration among HO and MS cows, despite HO cows having greater GH concentration and similar expression of GH1RA mRNA to MS cows, may suggest a more pronounced decoupling of the somatotropic axis in purebred HO cows.

Key Words: transition cow, somatotropic axis, crossbreeding

M215 Effect of subclinical mastitis and postpartum uterine disease on expression of estrous behavior in cows.

Y. Lavon[1], M. Kaim[2], G. Leitner[3], H. Voet[4], and D. Wolfenson*[4], [1]*Israel Cattle Breeders Association, Caesarea, Israel,* [2]*Agricultural Research Organization, Bet-Dagan, Israel,* [3]*The Veterinary Institute, Bet Dagan, Israel,* [4]*Faculty of Agriculture, Food and Environment, The Hebrew University, Rehovot, Israel.*

The objective of this study was to determine the effect of mammary and uterine diseases on manifestation of estrus in cows. Cows (n = 1247) from 50 to 130 d of lactation, in the summer and winter, were synchronized with 2 $PGF_{2\alpha}$ injections administered 14 d apart (before 1st AI); 36 h after the 2nd injection, cows were checked for estrus 4 times daily for 6 d. Uterine diseases were recorded during the first week postpartum. Cows were sorted to uninfected control or chronic (most likely subclinical) mastitic cows by somatic cell count in the monthly milk samples taken before and after 2nd $PGF_{2\alpha}$ injection. Body condition score difference (BCS-diff) between calving and 2nd $PGF_{2\alpha}$ injection, and milk yield were recorded. Factors relevant to manifestation of estrus were selected by stepwise logistic regression. As some interactions were detected, separate logistic regressions were performed by season and parity. In the winter, the percentage of cows not expressing estrus increased, compared with controls (26.6 vs. 12.6%; odds ratio [OR] 2.4, $P < 0.002$), in multiparous cows with uterine diseases. Similarly, a high BCS-diff tended to increase the rate of cows not expressing estrus (21.3 vs. 12.1%; OR 1.93, $P < 0.06$). In primiparous cows, subclinical mastitis as well as high milk yield increased the percentage of cows not expressing estrus (34.7 vs.14.3%; OR 3.4, $P < 0.02$, and 24.1 vs. 9.4%; OR 3.2, $P < 0.03$, respectively). In the summer, an increased percentage of cows not expressing estrus (24.2 vs. 16.9%; OR 1.7, $P < 0.05$) was recorded in multiparous cows with high BCS-diff. In primiparous cows, a subclinical mastitis by uterine disease interaction was detected, showing a higher rate of cows not expressing estrus (41.4 vs. 17.2%; OR 3.9, $P < 0.05$). Results indicate a higher risk for not expressing estrus, which is parity- and season-dependent, in cows with subclinical mastitis and postpartum uterine diseases. The above findings could result in increased days open in dairy herds, and could be associated with disease induction of anestrus, or with disruption of the endocrine process associated with expression of estrous behavior.

Key Words: estrus, mastitis, cows

M216 Dietary protein:carbohydrate ratio affects glucose tolerance and oxidation in pregnant gilts. C. C. Metges,* S. Görs, I. Lang, K.-P. Brüssow, C. Rehfeldt, and W. Otten, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Low as well as high dietary protein:carbohydrate ratios during pregnancy cause changes of maternal metabolism and body composition, and intrauterine growth restriction (IUGR) in the pig (Rehfeldt et al., J Anim Sci 2011,189:329–341; Metges et al., PLoS ONE 2012, in press). We performed intravenous glucose tolerance tests (IVGTT) with labeled glucose to further characterize maternal constraints of glucose metabolism in late pregnant gilts. Twenty-seven German Landrace gilts were fed diets with low (6.5%, L), adequate (12%, A), or high (30%, H) protein levels (n = 9/group) made isoenergetic by adjusted carbohydrate content throughout pregnancy. Gilts were fitted with jugular catheters and an IVGTT was performed on d 90 of pregnancy. After overnight fast 0.5 g/kg BW glucose and 0.5 mg/kg U^{13}C-glucose were administered i.v. Blood samples were analyzed for plasma glucose (GLC), insulin (INS), glucagon (GCG) concentrations, and U^{13}C-glucose and blood $^{13}CO_2$ enrichments by mass spectrometry. Areas under curve (AUC) and cumulative $^{13}CO_2$ appearance in blood ($^{13}CO_2$cum) were calculated. Diet effects were evaluated by PROC MIXED of SAS. L gilts had a lower BW as well as a lesser basal INS concentration and INS-AUC than controls, whereas H gilts showed a higher basal GCG level and GLC-AUC (Table 1). In H gilts lower $^{13}CO_2$cum suggested a lower GLC oxidation (Table 1). Apparently higher and lower INS sensitivity in L and H, respectively, might be explained by lower pancreatic INS secretion caused by protein deficiency, and reduced GLC oxidation due to GLC sparing, respectively. Thus, L and H diets might cause altered feto-maternal glucose interaction possibly associated to the observed offspring IUGR in these groups. Supported by Deutsche Forschungsgemeinschaft ME1420/8–1.

Table 1. Body weight and glucose metabolism analyzed by IVGTT in pregnant gilts fed L, A, or H diet throughout pregnancy

	Diet			
Item	L	A	H	*P*-value
BW, kg	174^{a}	196^{b}	197^{b}	0.017
GLC$_{basal}$, mmol/L	5	5	5	0.970
INS$_{basal}$, μU/mL	7^{a}	11^{b}	9^{a,b}	0.077
GCG$_{basal}$, ng/L	44^{a}	46^{a}	65^{b}	0.013

Production, Management and the Environment: Dairy I

M217 Measuring dry matter of corn silage, haylage, and TMR samples with a food dehydrator. R. J. Norell*[1], C. M. Matuk[2], S. Hines[2], M. Chahine[2], M. de Haro Marti[3], and S. C. Parkinson[4], [1]*University of Idaho, Idaho Falls,* [2]*University of Idaho, Twin Falls,* [3]*University of Idaho, Gooding,* [4]*University of Idaho, Preston.*

Quality control procedures for TMR feeding require on-farm measurement of dry matter for ensiled forages and prepared TMRs. Current on-farm tests require operator attentiveness during the drying process and moderate laboratory skills. In this study, we compared dry matter determinations with a food dehydrator (DEHY) against a laboratory oven (OVEN). The dehydrators were 500 Watt, Nesco brand, FD-60 with 4 trays and each tray had a fruit roll-up sheet. Temperature settings were 68 C for DEHY and 55 C for OVEN. In part 1, 4 dehydrators with 4 trays each were utilized. Single corn silage, haylage, and TMR samples were split into 16 subsamples for dry matter determination. Each feedstuff was run separately with 100g of each subsample placed on an individual tray. Tray weights were collected at 0, 2, 4, 6, and 8 h. Sample weights were stabilized at the 4 or 6 h weighing period. Data were analyzed as a randomized block design with repeated measures on the tray position. Dry matter did not differ between tray position for corn silage ($P = 0.15$), haylage ($P = 0.52$), and TMR ($P = 0.07$). In part 2, unique lots of corn silage, haylage, and TMR (12 each) were collected and split into 4 subsamples. Dry matter determinations were made in groups of 4 lots for each feedstuff and each lot was replicated 4 times (once in each dehydrator and once within each tray position). Dehydrator tray weights were collected at 0, 2, 4, 6, and 8 h. Oven dry matter determinations were collected after 24 h. Means were calculated from the 4 replicates and then used to compare OVEN versus DEHY measurements at 8 h with paired *t*-tests. Mean difference (OVEN-DEHY), SE_{diff}, and significance were: +1.11 ± 0.16%, $P < 0.001$; +0.84 ± 0.30%, $P = 0.02$; +0.65 ± 0.16%, $P < 0.001$ for corn silage, haylage, and TMR, respectively. OVEN dry matter contents were slightly higher than DEHY, possibly due to greater volatilization of VFA's or other compounds with the dehydrators. Sample dry matters were mostly stable after a 4 h drying time. We conclude that food dehydrators with fruit roll-up trays are an effective, reliable tool for on-farm determination of dry matter.

Key Words: on-farm testing, food dehydrator, dry matter

M218 Determining surface area of exposed silage on California dairy farms. D. Meyer[1], P. H. Robinson[1], P. L. Price[1], R. Rauch[1], and J. M. Heguy*[2], [1]*University of California, Davis,* [2]*University of California Cooperative Extension, Modesto.*

Ensiled forages (i.e., silage) are a key ingredient in California dairy rations, but they are also emitters of volatile organic compounds (VOC). Our objective was to evaluate silage structures (pile, bunker, drive-over) on California dairy farms to determine the number of structures simultaneously utilized per farm, as well as the exposed silage surface area of each structure. The San Joaquin Valley Air Pollution Control District (SJVAPCD) had proposed a VOC emission mitigation to restrict exposed surface area of silages to 199.7 m^2 if only one structure was open, or 399.5 m^2 if more than one structure was open, per dairy farm. Forages preserved in plastic bags were not examined because they are exempt from the SJVAPCD calculation of surface area exposure. Silage structures on 20 dairy farms were evaluated. Exposed silage surface area was determined by identifying geometric features, making appropriate measurements and calculating surface area. Number of cattle in each age group was obtained for most farms. An animal feed unit equivalent (AFU) calculation assumed coefficients for each animal group as: 1.0, lactating cows; 0.9, dry cows; 0.7, heifers 15 to 24 mo of age; 0.5, heifers 7 to 14 mo of age; and 0.2, heifers 4 to 6 mo of age. The silage structures consisted of winter cereal, corn and alfalfa. The number of structures open per farm was 2.2 (SD = 0.9) with a maximum of 4. All farms with only 1 silage surface exposed (n = 4) met the SJVAPCD surface area requirement, but 5 of 16 farms which had more than one exposed silage surface did not. Exposed silage surface area per farm was 27.7 to 738.2 m^2. Exposed surface area (m^2)/AFU was 0.01 to 0.28 with 4 of 16 farms having values > 0.10. Total AFU and exposed silage surface areas within farm did not correlate with exposed silage surface area ($r^2 = 0.32$), suggesting that AFU is not a substantive factor in the amount of exposed silage surface area needed at silage feedout. The variation in exposed surface area (m^2)/AFU among farms suggests opportunities to develop and implement management practices to reduce exposed silage surface area on commercial California dairy farms.

Key Words: silage, volatile organic compounds , regulations

M219 Comparison of two methods of collecting calf birthweights (BW) in dairy calves. N. M. Long* and J. F. Smith, *Department of Animal Sciences, University of Arizona, Tucson.*

The collection of calf BW in dairies in the US is not a common practice. Calf BW was collected on 3 dairies (2 Holstein and 1 Jersey herd) over a 6 week period. All calves BW were collected less than 2 h after birth. A total of 872 calves were weighed by both a spring scale (SP; Rubbermade Co., Huntersville, NC) and also a hooftape (HT, Calfscale BW Tape, Nasco, Fort Atkinson, WI) with both weights and sex recorded. The Proc GLM (SAS Institute Inc., Cary, NC) was used to estimate LS means for SP BW with sex of calf and also dairy. Calf SP vs HT BW was compared using the Proc Reg of SAS. Calf BW was also broken down into increments and SP vs HT BW were compared utilizing *t*-test. Bull calves had a heavier ($P < 0.001$) BW (kg) compared with heifer calves (36.7 ± 0.4, n = 450 vs 34.6 ± 0.4, n = 422, respectively). Dairy in which calves were born had a significant effect ($P < 0.001$) on calf BW (kg) (Dairy 1: 36.8 ± 0.4, n = 204; Dairy 2: 39.5 ± 0.2, n = 463; Dairy 3: 25.9 ± 0.4, n = 205). When SP calf BW was linearly regressed by HT BW there was a significant relationship ($P < 0.01$) with a R2 value of 0.91. The breakdown of calf BW and comparison of SP and HT BW are shown in Table 1. For calves less than 31.3 kg, the HF overestimated ($P < 0.001$) calf BW compared with SP. However, for calves that weighted between 31.3 to 44.9 kg there was no difference ($P \geq 0.104$) between SP and HT BW. For calves heavier than 44.9 kg, HT underestimated ($P = 0.022$) BW compared with SP. Collection of calf BW by SP or HF appears to be comparable for most calves, since most calves weigh between 31 to 45 kg, but caution should be utilized for light or heavy BW calves.

Table 1. Comparison of spring scale and hoof tape on birthweight determination (mean ± SEM)

BW, kg	n	Scale	Tape	*P*-value
<27.2	148	23.2 ± 0.2	24.6 ± 0.3	<0.001
27.2-31.3	95	28.9 ± 0.2	29.7 ± 0.2	<0.001
31.3-35.8	135	33.8 ± 0.1	34.0 ± 0.1	0.217
35.8-40.4	242	38.0 ± 0.1	37.8 ± 0.1	0.133
40.4-44.9	165	42.4 ± 0.1	42.2 ± 0.2	0.104
> 44.9	87	47.4 ± 0.3	46.5 ± 0.4	0.022

Key Words: dairy calves, birthweight, hoof circumference tape

M220 Assessing among-farm variability in heifer body weights.

G. B. Bond*[1,2], M. A. G. von Keyserlingk[1], N. Chapinal[1], E. A. Pajor[2], and D. M. Weary[1], *[1]University of British Columbia, Vancouver, BC, Canada, [2]University of Calgary, Calgary, AB, Canada.*

Raising healthy young stock to be productive cows is crucial to a dairy farm, but indicators of successful heifer rearing, including weight gains, are rarely measured. Our aim was to describe the variation in growth of Holstein heifers reared on dairy farms in the lower Fraser Valley region of British Columbia. Data were collected by the same individual on 33 farms, all using the Dairy Herd Improvement (DHI) recording system and with a minimum milking herd of 100 cows. Farms were visited between June 2010 and October 2010. Heart girth circumference was measured for all heifers aged 12 to 17 mo (n = 560) and these values were converted to estimate body weight (BW). Birth dates were also recorded. Data were analyzed through a simple linear regression analysis resulting in a line equation of BW (kg) = 112.9 + 5.1* (age in weeks) ($R^2 = 0.35$). Residuals derived from this regression were averaged across heifers within each farm; these farm averages ranged from −53.8 to 71.5 kg. We tested the effects of a range of farm level descriptors (including weaning method, time between weaning and moving to a new pen, size of the heifer group, frequency of regrouping heifers, times per day heifers were provided fresh feed) but only one variable was able to account for among-farm variation in residual weights; average weight gain during the pre-weaning phase (i.e., calves 0 to 2 mo of age; residual gains measured as described above for heifers). Residual weights of heifers increased with gains of the pre-weaned calves (line equation: Residual Heifer BW (kg) = −1.50 + 2.99* Residual Calf BW (kg); $R^2 = 0.39$). These results show considerable among-farm variation in heifer weight gains, indicating that some farms are doing well while others could improve performance. Farms able to rear faster growing heifers were also rearing faster growing calves, suggesting that management of milk-fed calves is especially important.

Key Words: calf growth, milk feeding, welfare

M221 The effects of increased space allowance on dairy calf performance, behavior, and respiratory antibody production.

M. S. Calvo*[1], L. E. Hulbert[1], A. Louie[2], L. J. Gershwin[3], K. E. Pinkerton[4], K. C. Klasing[1], C. B. Tucker[1], and F. M. Mitloehner[1], *[1]Department of Animal Science, University of California, Davis, [2]School of Veterinary Medicine, University of California, Davis, [3]Department of Pathology, Microbiology and Immunology, School of Veterinary Medicine, University of California, Davis, [4]Department of Anatomy, Physiology, and Cell Biology, School of Veterinary Medicine; Center for Health and the Environment; University of California, Davis.*

California dairy calves are typically raised individually in wooden hutches with a space allowance of 1.23 m^2/head. Because management and housing of livestock continues to be an important issue to both consumers and producers, the objective of the following research was to modify current calf housing systems to investigate the possible benefits of increasing space allowance. The 3 housing treatments were: 1) conventional housing (SML; 1.23 m^2/head; n = 18), 2) 1.5 x SML (MED; 1.85 m^2/head; n = 19), or 3) 3 x SML (LRG; 3.71 m^2/head; n = 20). Milk and starter intake were recorded daily and BW were measured on d 0, 20, 45, 73, and 87. Visual health assessment scores were recorded daily and behavior loggers were utilized on 21–31, 46–56, and 74–84 d to assess the effects of treatments on health and resting behavior over the 87 d study period. In a sub-experiment, healthy calves from each treatment (n = 6, SML; n = 8, MED; n = 7, LRG) were sensitized (subQ) and challenged (aerosolized) with Ovalbumin (OVA) at age 76 ± 0.5 d. Broncho-alveolar lavage fluid (BALF) was collected at age 80 ± 0.5 d and was analyzed for OVA-specific IgG, IgG1, IgA, and IgE. Calves in MED and LRG had greater body weights and average daily gains by 45 d of age ($P < 0.05$). A greater percentage of days with clean hide scores were observed in LRG calves ($P < 0.05$). Although there were no differences across treatments in clinical symptoms of respiratory illness, MED calves had less BALF OVA-IgE compared with SML and LRG ($P < 0.05$). As SML and MED calves grew, they spent less time in the standing-position ($P < 0.05$), but LRG calf standing time stayed the same ($P > 0.10$). Early in life (age 21–23 d), all calves spent 16.6 ± 0.31 h/d in resting-position ($P > 0.10$). Calves in SML and MED hutches increased resting time as they aged (47–49, 74–76 d; $P < 0.05$), but LRG calf resting time did not change over time. Although maximizing space allowance in wooden hutches provides more room for calves, a moderate increase in space allowance may be more beneficial to calf performance, resting time, and respiratory antibodies.

Key Words: bovine, performance, behavior

M222 Growth measurements of organically raised dairy steers compared with conventionally raised dairy steers.

E. A. Bjorklund* and B. J. Heins, *University of Minnesota, West Central Research and Outreach Center, Morris*

Bull calves (n = 50) were used to compare growth measurements of conventional and organic dairy steers. Calves were assigned to one of 3 groups at birth: conventional (CONV, n = 16), organic (ORG, n = 17), and organic-grass only (GRASS, n = 17), and were born at the University of Minnesota West Central Research and Outreach Center, Morris from March to May 2011. Breed groups of calves were: Holstein (n = 10), Holsteins (n = 11) maintained at 1964 breed average level, and crossbreds (n = 29) comprised of Holstein, Swedish Red, Montbéliarde, and Jersey. The CONV steers were fed a diet of 80% concentrate and 20% roughage and received steroidal implants. The ORG steers were fed a diet of organic corn, organic corn silage, and at least 30% of their diet consisted of organic pasture during the grazing season. The GRASS steers grazed pasture during the grazing season and were fed high quality hay or hay silage during the non-grazing season. Diets fed were recorded daily with herd management software. Body weight was recorded at birth, weaning, and monthly. Hip height, heart girth and body condition score were measured at weaning and monthly thereafter. Analysis was with PROC GLM of SAS, and independent variables for statistical analysis were the fixed effects of steer group and breed group. For the first 9 mo of age, steer performance was: total gain (kg), CONV (324), ORG (227), GRASS (146), ($P < 0.01$), and average daily gain (kg/d); CONV (1.12), ORG (0.79), and GRASS (0.51), ($P < 0.01$). From weaning (90 d) to 9 mo of age, performance was: total gain (kg) CONV (255), ORG (157), and GRASS (89) ($P < 0.01$), and average daily gain (kg/d), CONV (1.31), ORG (0.81), and GRASS (0.46), ($P < 0.01$). Hip height gain (cm) (CONV, 21.8; ORG, 15.1; GRASS, 6.7) and heart girth gain (cm) (CONV, 39.0; ORG, 21.5; GRASS, 14.2) from weaning was different ($P < 0.01$) for all steer groups. Furthermore, body condition score was different ($P < 0.01$) for all steer groups (CONV, 3.96; ORG, 3.40; GRASS, 3.01). No significant differences were found for breed groups for growth measurements.

Key Words: organic, grass-fed, dairy steers

M223 Associations between herd-level feeding management practices, feed sorting, and milk production in freestall dairy farms. A. D. Sova*[1], S. J. LeBlanc[2], B. W. McBride[3], and T. J. DeVries[1], [1]*Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada,* [2]*Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada,* [3]*Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Challenges associated with group housed dairy cows include within-herd variability in nutrient consumption and milk production, which may be related to feeding management. The objective of this study was to examine the association of herd-level feeding management factors, feed sorting, and milk production. Ten free-stall herds, with average lactating herd size of 106 ± 26 cows, feeding TMR were studied for 7 consecutive days. Milk production parameters, including yield, fat, and protein, were recorded through a DHI test occurring ± 3 d of the study. A survey of feeding management practices and barn characteristics was administered on each farm. Amount of feed offered and refused was recorded and sampled daily to assess DM and particle size distribution. The particle separator had 3 screens (19, 8, 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each particle fraction expressed as a % of its predicted intake. Sorting values > 100% indicate selection for, while values < 100% indicate sorting against. Data were summarized across each 7-d period for each farm and analyzed in multivariable mixed-effect regression models. Categorical variables included in the models were milking frequency (MF; 0 = 2x/d; 1 = 3x/d) and feeding frequency (FF; 0 = 1x/d; 1 = ≥ 2x/d). Greater milk yield was associated ($P < 0.04$) with herds of lower average DIM, which milked 3x/d and fed ≥ 2x/d; milk yield (kg/d) = −0.06(SE = 0.02) × DIM + 3.5(SE = 1.2) × MF + 3.0(SE = 1.1) × FF + 40.8(SE = 3.2). Greater DMI was associated ($P < 0.02$) with herds of greater average parity, which fed ≥ 2x/d; DMI (kg/d) = 6.5(SE = 1.9) × parity + 4.1(SE = 1.1) × FF + 7.4(SE = 4.4). Higher milk fat % and less sorting against long ration particles were associated ($P < 0.03$) with herds of greater average DIM, which fed ≥ 2x/d; milk fat (%) = 0.005(SE = 0.001) × DIM + 0.3(SE = 0.1) × FF + 2.6(SE = 0.3); sorting of long particles (%) = 0.07(SE = 0.02) × DIM + 4.7(SE = 1.3) × FF + 81.0(SE = 3.0). The results suggest that herd-level feeding management practices to promote feed access, such as increased feeding frequency, may be used to improve DMI, reduce sorting, and improve milk yield and fat percentage.

Key Words: feeding management, sorting, milk production

M224 Comparison of the effects of conductive cooling to fan cooling on lactating dairy cattle. R. B. Thornton*[1], W. A. Greene[1], J. Bruer[2], and T. Steele[2], [1]*The Ohio State University, Wooster,* [2]*Conco Technologies, Chandler, AZ.*

The objective of this study was to compare physiological effects of conductive cooling (COND) to fan cooling (FANS) on lactating dairy cattle for 12 wk during the summer (June–August) of 2011 in northwest Ohio. Cows, milked 3x/day, were housed in a sand-bedded 6-row barn configuration with 122 cm fans at 12.2 m intervals over the feed aisle and free-stalls, programmed to operate at temperatures above 15.6°C. Seventy cows were paired for parity, DIM, and milk yield. Thirty-five cattle were housed in one section of the barn where fans were disabled and heat exchangers were buried 30.5 cm below the bed in the 33 freestalls (COND). Well water (12.5 to 18.1°C) was pumped through the heat exchangers. The other (paired) 35 cows were a part of an 114-cow group that had 107 freestalls with operating fans (FANS). Milk weights, milk components, and SCC were recorded for the paired cows. At the start of the trial, COND and FANS cows had similar ($P > 0.05$) least squares means (LSM) for average daily energy-corrected milk (ECM) weights (43.0 ± 1.5 vs. 42.8 ± 1.5 kg) and SCC (28,030 ± 4,416 vs. 23,969 ± 4,485 cells/mL). The percent of cows resting in each group was observed weekly at approximately 1100. Midday rectal temperatures and respiratory rates were randomly measured weekly on 15 cows in each housing group. Hourly ambient temperature and humidity measurements were recorded and thermal-humidity indexes (THI) were calculated throughout the trial. Daily average THI ranged from 62.4 to 81.7. COND and FANS cows had similar ($P > 0.05$) LSM for average daily ECM (37.8 ± 0.8 vs. 37.7 ± 0.8 kg) and SCC (36,626 ± 23,244 vs. 87,772 ± 23,191 cells/mL) during the 12 wk trial, although SCC tended to be higher for the FANS group from wk 8 to 12. There was no difference ($P > 0.05$) in LSM for average percent of cows observed resting between the COND (50.3) and FANS (50.6) groups. COND and FANS cows had similar ($P > 0.05$) LSM for average rectal temperatures (38.7 vs. 38.6°C) and respiratory rates (67.8 vs. 67.6/min). In general, there were no differences observed between the 2 methods of cooling lactating dairy cattle.

Key Words: cow cooling, heat stress

M225 Effect of FlipFan cooling system on lactating dairy cattle performance in an open dry-lot commercial dairy in a sub-tropical environment in central Texas. J. A. Hernandez-Rivera*[2], F. D. Alvarez-Valenzuela[2], U. Macias-Cruz[2], L. Avendano-Reyes[2], and T. R. Bilby[1], [1]*Texas AgriLife Research and Extension Service, Texas A&M System, Stephenville,* [2]*Instituto de Ciencias Agricolas, Universidad Autonoma de Baja California, Ejido Nuevo Leon, Valle de Mexicali, Mexico.*

Heat stress negatively affects dairy cattle performance, thus adequate cooling strategies are needed. Objective of the current study was to evaluate the effect of a new cooling system on production and physiological parameters during a 4 d period in summer. Twenty-four multiparous cows balanced for DIM, parity, and daily milk production were assigned to 1 of 3 treatments: H (control Holstein group with shade only; n = 8); FF-H (Holstein cows cooled with Flip Fan cooling system plus shade; n = 8), and JxH (control Jersey x Holstein crossbred group with shade only; n = 8). All groups were cooled before milking at 1100 and 2300 h with sprinklers and fans in the holding pen. The cooling system (Schaefer FlipFan) was placed on the south edge under the shade approximately 4 m from the ground, and consisted of 33 fans, that could rotate 180° and high pressure misters fixed to the front of the fans which followed the movement of the shade. The FlipFan system ran continuously throughout the duration of the study. Skin temperatures (ST) of the hip region (30.2 vs. 32.0 and 33.1°C), right flank (30.6 vs. 32.6 and 33.1°C), udder (31.3 vs. 32.7 and 33.4°C) and head (28.5 vs. 30.2 and 31.9°C) in the morning were lower ($P < 0.05$) in FF-H versus H and JxH cows, respectively. During the afternoon, ST of the hip, right flank, udder, and head were lower ($P < 0.05$) in FF-H cows (34.9, 34.7, 35.1 and 33.6°C, respectively) compared with H (38.5, 38.3, 38.8 and 39.3°C, respectively) and JxH (37.2, 37.2, 37.9 and 38.2°C, respectively). During the morning and afternoon, the respiration rate per minute (rpm) in H (74 and 111 rpm) and JxH (84 and 112 rpm) groups were greater ($P < 0.05$) than in FF-H (61 and 88 rpm) group. In addition, H group core body temperature peaked at 40.9°C, whereas both JxH and FF-H groups were lower and peaked at 40.5 and 40.0°C, respectively. The FlipFan cooling system reduced heat stress effects by reducing ST, respiration rate and core body temperature in lactating Holstein dairy cattle.

Key Words: dairy cow, heat stress, cooling

M226 Correlation between invasive methods for recording physiological parameters and infrared thermography in calves. P. A. B. Mac-Lean[1], H. Savastano Junior[1], L. C. Roma Junior*[2], S. Correa[1], C. N. Barra[1], C. G. Titto[1], and C. E. L. Oliveira[1], [1]*University of Sao Paulo, Pirassununga, Sao Paulo State, Brazil,* [2]*APTA Centro Leste, Ribeirao Preto, Sao Paulo State, Brazil.*

Evaluation of physiological parameters such as temperature have been used as indicators of heat stress. Human intervention and proper restraint are usually necessary to measure these physiological parameters; therefore, the development of a tool that avoids interference would be desirable. The objective of this study was to compare measurement of physiological parameters (traditional method) with infrared thermography (non-invasive method). Twenty Jersey and crossbred suckling calves were used in the study for a period of 5 d with an interval of 6 h between each measurement, totaling 400 measurements per variable. Variables analyzed were rectal temperature, ear temperature, coat surface temperature, in addition to infrared thermography (IRT) of auricular, dorsal and caudal regions. A randomized block design balanced for sex and breed was used. Data were analyzed using the Proc GLM, Proc Corr and Proc Reg of SAS. The correlations between IRT and coat surface temperature, ear temperature and caudal region temperature were 0.88, 0.86 and 0.75, respectively. Ear temperature by IRT showed the best correlation with traditional method for rectal temperature (0.69; $P < 0.001$). Thus, the regression for other physiological parameters used ear temperature recorded by IRT as the dependent variable. The coefficients of determination provided with regression were 0.53, 0.73, 0.62 and 0.47 for coat surface temperature, ear temperature, caudal region temperature and rectal temperature, respectively. It appears from these results that infrared thermography could be used to estimate physiological indicators of heat stress with minimal interference. Financial support by FAPESP, process 10/07978-8.

Key Words: physiological variables, thermoregulation, thermal imaging

M227 Agreement between reticular and vaginal measurement of core temperature in dairy cattle. J. A. Small[1,2], R. Hayman[2], T. Rudderham[2], A. Fredeen[2], and W. Webster*[3], [1]*Agriculture and Agri-Food Canada, Truro, NS, Canada,* [2]*Nova Scotia Agricultural College, Truro, NS, Canada,* [3]*DVM Systems LLC, Denver, CO.*

Agreement between reticular and vaginal measurements of core temperature (Tc) in dairy cattle was determined using fistulated lactating dairy cattle (n = 4) in good body condition (BCS 2.5 to 3.0) A prototype hand-held reader was used to capture reticulo-rumen temperatures (Trr) from passive transponder boluses containing thermistors that were placed in the reticulum (DVM Systems, LLC, Denver CO). A digital thermometer was used to determine vaginal temperatures (Tv). Cattle were offered 68 L of either warm (39°C) or cold (12°C) fresh drinking water at 0600 and 1700, in a crossover design. Starting at 0420 and 1517, Tc were taken at intervals relative to free water intake (FWI) −105, −90 (before milking) −60, −45 (milking), −30, −15 (after milking), 05, 10 (FWI) and 15, 30, 45, 60, 75, 90 min (post-FWI). Cattle were housed in tie-stalls exposed to barn lights from 0400 to 1800 and natural light, full-fed a total mixed ration (33% dry matter) offered at 0530, 0830, 1030, 1400, and moved to an exercise yard from 0730 to 0830. The barn temperature-humidity index ranged from 45 to 51. To determine agreement between Tv and Trr the average of the 3 previous Tc were deemed the baseline to calculate the deviation of the current value from baseline. Agreement between Trr and Tv was fair overall observations (kappa = 0.23; $P < 0.01$; n = 333), moderate before FWI (kappa = 0.57; $P < 0.01$; n = 96), and substantial when measurements were taken before FWI in the morning (kappa = 0.71; $P < 0.01$ n = 56) and fair (0.37; $P = 0.02$) in the afternoon. The predicted change in Trr at each time after FWI was dependent upon FWI temperature and volume. Predicted Trr decreased −4 to −9°C at 10 min after drinking 2 to 70 L of cold water and regardless of volume remained 3°C below baseline after 60 min. The predicted change in Tv at each time after drinking water was dependent upon the temperature and volume of FWI until 60 min after drinking. However, in contrast to Trr, small volumes of cold water caused a transient decrease in Tv and larger volumes increased Tv 0.2°C. In dairy cattle FWI influenced Trr and Tv, and the most accurate measurements were obtained in the morning before milking and FWI.

Key Words: reticular temperature, drinking water, dairy cattle

M228 Warm drinking water lowers core temperature in dairy cattle. J. A. Small[1,2], T. Rudderham[2], R. Hayman[2], A. Fredeen*[2], and W. Webster[3], [1]*Agriculture and Agri-Food Canada, Truro, NS, Canada,* [2]*Nova Scotia Agricultural College, Truro, NS, Canada,* [3]*DVM Systems LLC, Denver, CO.*

Fistulated lactating dairy cattle (n = 4) in good body condition (BCS 2.5 to 3.0) were used in a crossover design to determine the effects of warm free water intake (FWI) on core temperature. Cattle were offered 68 L of either warm (W; 39°C) or control (C; 12°C) drinking water twice daily at 0600 and 1700. Each period consisted of 7 d adaptation to treatment followed by 2 consecutive days of data collection. A prototype hand-held reader was used to capture reticulo-rumen temperature (Trr) from passive transponder boluses containing thermistors that were placed in the reticulum (DVM Systems LLC, Denver CO). A digital thermometer was used to determine vaginal temperature (Tv). Core temperatures taken at intervals starting at 0420 and 1517 were deemed pre-milking (−105, −90 min); milking (−60 and −45 min), post-milking (−30 and −15 min), FWI (05 and 10 min) and post-FWI (15, 30, 45, 60, 75, 90 min). Cattle were housed in tie-stalls exposed to barn lights from 0400 to 1800 and natural light, full-fed a total mixed ration (33% dry matter) offered at 0530, 0830, 1030, 1400, and moved to an exercise yard from 0730 to 0830. The barn temperature-humidity index ranged from 45 to 51. Data were subjected to Proc Mixed procedures for a cross over design with repeated measures (morning and afternoon). Mean milk yields were greater ($P < 0.05$) and mean FWI were less ($P = 0.10$) for morning than afternoon, and did not differ ($P > 0.20$) between W and C (41.9, 50.0 and 39.5, 48.1 ± 8.4 L FWI, respectively). Pre-milking, morning and afternoon Trr and Tv means for W and C were 38.7, 38.7 and 38.8, 38.9 ± 0.24°C, and 38.5, 38.6 and 38.5, 38.8 ± 0.07°C, respectively. Post-milking, morning and afternoon Trr and Tv means were 0.2, 0.4°C and 0.1, 0.3°C lower ($P < 0.05$) for W than C, respectively. After FWI, morning and afternoon Trr means were higher ($P < 0.05$) and Tv similar ($P > 0.29$) for W than C (38.7, 38.2, and 31.9, 30.6 ± 0.24°C, and 38.5, 38.7 and 38.4, 38.7 ± 0.07°C), and 90 min later were 1.4, 0.9°C and 0.1, 0.3°C higher for W than C, respectively. In conclusion, warm FWI caused a transient increase in core temperature, but had the net effect of lowering basal core temperature especially in the afternoon.

Key Words: reticular temperature, drinking water, dairy cattle

M229 Influence of time of day, breed, and season on reticulorumen temperature in lactating dairy cows. D. Liang,* D. L. Ray, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this research was to characterize the influence of time of day, breed, and season on reticulorumen temperatures in lactating dairy cows. Reticulorumen temperatures (RT) were recorded every 15 min using SmartBolus transponders (TenXsys Inc., Eagle, ID) for 103 cows (68 Holstein, 25 crossbred and 10 Jersey) at the University of Kentucky Coldstream Dairy from November 06, 2009 to July 24, 2011. Air temperatures (AT) were collected every 15 min on location with a SmartBolus transponder. Raw RT (n = 1,646,145) were edited to remove erroneous reads and temperatures potentially influenced by water intake by removing any RT lower than 38.33°C. The mean (±SD) RT among the remaining 927,048 temperatures was 40.16 ± 0.52°C. Peak and nadir mean RT occurred at 23:45 (40.26°C) and 10:00 (39.92°C), respectively. Mean (±SD) AT was 14.75 ± 10.55°C. The MIXED procedure of SAS (Cary, NC) was used to assess the impact of breed and season on RT. The CORR procedure of SAS was used to calculate correlation coefficients between RT and AT. The reticulorumen temperature was lowly correlated with AT ($r = 0.28$, $P < 0.01$). Least squares means (LSM) Holstein RT (40.16 ± 0.01°C) were higher ($P < 0.01$) than crossbred RT (40.07 ± 0.01°C) while Jersey RT (40.09 ± 0.03°C) were not significantly different from Holstein RT or crossbred RT. Summer RT (40.24 ± 0.02°C) were higher than spring RT (40.08 ± 0.01°C), fall RT (40.09 ± 0.03°C) and winter RT (40.03 ± 0.02°C) ($P < 0.01$). In the spring, Holstein RT were higher than Jersey RT ($P < 0.01$) and crossbred RT ($P < 0.01$), with no significant differences observed between Jersey RT and crossbred RT. In the summer, Holstein RT were higher than crossbred RT ($P < 0.01$) and crossbred RT and Holstein RT were higher than Jersey RT ($P < 0.01$). In the fall, crossbred RT were higher than Holstein RT ($P < 0.01$) with no other significant differences among breeds observed. In the winter, Jersey RT were higher than Holstein RT ($P < 0.01$) and crossbred RT ($P = 0.02$) and Holstein RT were higher than crossbred RT ($P = 0.02$). These results may be useful in interpreting differences in RT obtained across varying seasons and breeds.

Key Words: reticulorumen temperature, season, breed

M230 Udder skin temperature of dairy cows under heat stress and physiological parameters tested by infrared thermography in two cooling system conditions.

R. B. Younes[1,3], G. Licitra[2,3], G. Azzaro[2], I. Schadt[2], M. Caccamo*[2], R. Petriglieri[2], and S. Carpino[2], *[1]Institut National Agronomique de Tunisie, Tunis, Tunisia, [2]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [3]DISPA, Catania University, Catania, Italy.*

Obtaining internal temperature is difficult under practical farm management conditions and requires animal restraint. An alternative might be to directly measure animals′ surface temperature. In this study infrared thermography was used to measure udder skin temperature. Thermal stress can adversely affect milk yield and milk composition. Our primary objective was to examine how udder temperature, as a measure of core body temperature, is affected by environmental conditions; moreover we aimed to assess the effects of test day, stage of lactation and 2 different cooling systems, Sprinkler system (SP) and Shower system (SH), on physiological parameters. Twenty Holstein cows were split into 2 treatment groups, SH and SP and within each treatment had additional ventilation. Cows were assigned to 2 treatments of 10 animals with similar average days in milk (DIM), milk production and milk composition. Respiration rates (RR), rectal temperature (RT) and udder skin temperature (UST) were measured, each time, between 3 and 5:30 p.m. Individual milk samples were measured 6 times, with 15-d intervals, beginning at the end of June and analyzed for fat, protein and lactose content. At each test day, ambient temperature, relative humidity and THI were calculated. THI values at test d 1 through 6 were 73.3, 79.7, 77.8, 74.1 and 72.3, respectively. Udder skin temperature was significantly affected by test day ($P \leq 0.001$). Measured RT and RR (LSMeans ± SE) in SH were 39.3 ± 0.1 and 61.2 ± 1.6, respectively and in SP were 38.9 ± 0.1 and 53.9 ± 1.6, respectively. Udder skin temperature, milk yield, fat protein and lactose (%) were not different between treatments ($P \geq 0.05$). These parameters were only affected by test day ($P \leq 0.001$). Relative humidity with SH might be higher compared with SP and might have increased heat stress of dairy cows. In conclusion, RT and RR were more sensitive than the udder skin temperature, measured by infrared, to detect core body temperature during heat stress. More work, on different milk parameters, would be necessary to better understand the infrared application in measuring udder surface temperature.

Key Words: infrared thermography, udder skin, cooling system

M231 Establishing the summer:winter ratio to evaluate the effects of heat stress on conception rates in US commercial dairies.

H. M. Robertson*[1,2] and T. R. Bilby[2], *[1]Department of Animal Science and Wildlife Management, Tarleton State University, Stephenville, TX, [2]Texas AgriLife Research and Extension, Texas A&M System, Stephenville.*

Objective was to utilize conception rates (CR) to establish a summer:winter ratio (S:W) to determine the severity of heat stress on US dairies. Records for 684 dairies totaling 767,768 lactating cows were collected from Dairy Herd Improvement Association and Reproductive Program Management software (Genex Cooperative Inc.). The average CR for 3 summer months (Jul.-Sep. 2010) was divided by the average CR of 3 winter months (Jan.-Mar. 2011) to obtain the S:W ratio. Effects of herd size (small < 500 cows, medium 500–1000 cows, large > 1000 cows), facility type (drylot vs. freestall), US region (north vs. south), and breed (Holstein vs. crossbred and Jersey) on the S:W ratio were analyzed. There was no difference between breeds (Holstein; 0.69 vs. crossbred and Jersey; 0.70). A main effect ($P < 0.05$) of US region (north: 0.89 vs. south: 0.51 ± 0.02), facility (drylot: 0.73 vs. freestall: 0.66 ± 0.25), and dairy size (small: 0.64 vs. medium: 0.71 and large: 0.74 ± 0.03) was observed. However, there was an interaction ($P < 0.01$) between US region and dairy size with small and medium-sized dairies in the north having an increased S:W ratio vs. large dairies (0.88, 0.93 vs. 0.84 ± 0.03), whereas in the south, small and medium-sized dairies had a smaller S:W ratio than larger dairies (0.40, 0.48, vs. 0.64 ± 0.02). Herds were further separated into the top and bottom 10% for S:W ratio by US region. The top herds in the north (n = 42) and south (n = 18) had a S:W ratio of 1.12 and 0.97 ± 0.01, respectively. The bottom herds in the north (n = 42) and south (n = 18) had a S:W ratio of 0.56 and 0.25 ± 0.01, respectively. An interaction ($P < 0.01$) between US region and herd ranking was observed with dairies in the north having smaller difference in S:W ratio between top and bottom herds compared with dairies in the south (1.12, 0.56 vs. 0.97, 0.25 ± 0.01). There was no effect of breed. Our results indicate that facility type, dairy size and US region can affect S:W ratio. In addition, top dairy herds have almost eliminated the summer decline in CR whereas bottom herds have a 44 - 75% reduction in CR due to heat stress.

Key Words: heat stress, dairy, summer:winter ratio

M232 Utilizing production parameters to establish the summer:winter ratio to evaluate the effects of heat stress on commercial dairies in the southwest.

H. M. Robertson*[1,2] and T. R. Bilby[2], *[1]Department of Animal Science and Wildlife Management, Tarleton State University, Stephenville, TX, [2]Texas AgriLife Research and Extension Service, Texas A&M System, Stephenville.*

Objective was to utilize pregnancy rate, conception rate, and standardized 150 d milk production (STMLK) to establish a summer:winter ratio (S:W) for evaluating the severity of heat stress on dairies in the southwest. Records for 124 dairies totaling 192,765 lactating cows were collected from Dairy Herd Improvement Association and Reproductive Program Management software (Genex Cooperative, Inc.). The average conception rate, pregnancy rate and STMLK for 3 summer months (Jul.-Sep. 2010) were divided by the average of 3 winter months (Jan.-Mar. 2011) to obtain a S:W ratio for each. Effects of herd size (small < 700 cows vs. large > 700 cows), facility type (drylot vs. freestall), SW region (central, east, south and west), breed (Holstein vs. crossbred and Jersey) and reproductive management (bull vs. AI) on each S:W ratio were analyzed. There was no effect of any variables analyzed on S:W ratios for STMLK and conception rate. There was an effect of herd size ($P < 0.01$) and region ($P < 0.01$) with small herds having a lower S:W pregnancy rate ratio compared with large herds (0.42 vs. 0.62 ± 0.07) and herds in the west having a greater S:W pregnancy rate ratio compared with central, east and south (1.0 vs. 0.45, 0.42, 0.20 ± 0.1, respectively). Herds were further separated into the top and bottom 20% for both STMLK (1.08 and 0.86 ± 0.01) and pregnancy rate (0.71 and 0.23 ± 0.05) S:W ratio. The top 20% of the herds (n = 19) for STMLK S:W ratio also had a greater S:W pregnancy rate ratio compared with bottom herds (n = 18; 0.68 vs. 0.24 ± 0.08). In addition, the top S:W pregnancy rate ratio herds had an increased ($P < 0.01$) S:W STMLK ratio compared with bottom herds (1.02 vs. 0.96 ± 0.02). In conclusion, STMLK is reduced 22% and pregnancy rate 48% from the top versus bottom ranking herds. Also, herds which maintained an increased STMLK during summer also maintained a greater reproductive performance during summer. The top ranked herds evaluated still lost 29% of their pregnancy rate during summer whereas bottom herds lost 77%.

Key Words: heat stress, dairy, summer:winter ratio

M233 Heat stress effects on milk production and udder health in Holstein and Jersey cows. D. L. Smith, S. H. Ward,* T. Smith, and B. J. Rude, *Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State.*

The objectives of this study were to: 1) investigate effects of heat stress and breed on milk and component yield for Holstein and Jersey cows on the same farm and 2) determine the effects of breed on udder health as measured by somatic cell count during times of heat stress. Data were collected from DHIA records from the Bearden Dairy Research Center at Mississippi State. After the removal of duplicates, 16,429 individual monthly records from 1997 to 2010 pertaining to Holstein and Jersey cows were used. Measures taken from the monthly records were: yield, milk fat percentage, milk protein percentage, and SCC. Milk yield (MY) and milk fat percentage were used to calculate 4% fat corrected milk (FCM). Climatological data were obtained from the National Weather service station located at the Golden Triangle Regional Airport (GTR) and the weather station operated by the Department of Geosciences on the campus of Mississippi State University (MSU). The weather measurements included, maximum and minimum temperature, along with maximum and minimum relative humidity. Any missing weather measurements were obtained from the National Weather Service station located at the Columbus Air Force base near Columbus, Mississippi. Maximum and minimum ambient temperature and relative humidity were determined from hourly data for each 24-h period and were used to calculate THI. Effects of THI, breed, and the interaction were analyzed using PROC MIXED (SAS Institute, 2009). The dependent variables were test day milk yield and milk components, SCC, and FCM. The model included fixed effects for combined THI (t), breed (b), and breed x THI, with DIM (d) as a covariate. All main effects were tested along with all interactions. Milk yield and FCM decreased during heat stress in Holsteins (34.2 vs. 32.9 kg/d, $P < 0.01$) and was not different in Jerseys (24.7 vs. 25.8 kg/d, $P < 0.20$). Heat stress affected somatic cell count although effects varied by intensity of heat stress. Breed did not have an effect on somatic cell count. Milk fat and protein percentages declined for both breeds in heat stress conditions. Milk fat but not milk protein of Jersey cows increased as stress increased from mild to severe. During heat stress and cool conditions Holstein cows had reduced FCM from 35.7 kg to 33.6 kg ($P < 0.05$) while Jersey did not differ. From mild heat stress to moderate Jersey FCM did not differ from 27.1 kg/d to 25.7 kg/d, respectively ($P > 0.05$) but was reduced to 23.7 kg/d when THI exceeded 90. FCM in Holsteins decreased during mild, moderate and severe heat stress from 34.8 kg/d to 32.8 kg/d and 30.9 kg/d, respectively. During heat stress, total MY in Holstein cows remained greater than in Jerseys, however, MY in Jersey cows was not affected by increased THI.

Key Words: dairy cows, heat stress, milk production

M234 Impact of season on the metabolic profile in transition Holstein dairy cows in summer and winter. K. J. Lager*[1,2], E. R. Jordan[1], R. G. S. Bruno[1,2], J. A. H. Rivera[3], R. Sprowls[4], and D. R. Topliff[2], [1]*Texas AgriLife Extension Service, Texas A&M System, College Station,* [2]*West Texas A&M University, Canyon,* [3]*Texas AgriLife Research, Stephenville,* [4]*Texas Veterinary Medical Diagnostic Laboratory, Amarillo.*

The objective of this study was to determine differences on an extensive metabolic profile between seasons of transition Holstein dairy cows with current genetics and dairy management strategies. Blood samples were collected in summer (n = 1787) and winter (n = 1871) from Holstein cows within the transition period via coccygeal vessel venipuncture in nonheparinized vacuum blood tubes at morning feeding on 8 commercial dairies. One day per dairy was utilized to collect blood samples for cows within the transition period and the same dairies were sampled for both time periods. Following centrifugation, samples were stored frozen (−20°C) in duplicate before laboratory analysis for calcium, phosphorus, magnesium, albumin, urea, glucose, cholesterol, sodium, potassium, chloride, and nonesterified fatty acids. Weather data was collected for the 2-week period before sample collection. Herd records were reviewed to identify data points from cows experiencing dystocia, retained placenta, displaced abomasum, twin births, stillbirths and cows being dry <30d or >80d and data were analyzed using multiple regression in SAS. Seasonal effects were shown ($P < 0.05$) for all parameters exclusive of Na. Designating 3 d before 3 d post calving as week zero with 7 d intervals radiating from zero, analysis revealed that week relative to calving had an effect ($P < 0.05$) on serum P, Mg, glucose, cholesterol, NEFA, Na, K, and Cl levels. However, the effects of health parameters were limited to Ca, Cl, and albumin. Dry period length was also shown to affect ($P < 0.05$) profile parameters including P, albumin, glucose, cholesterol, NEFA, and K. Based upon these results reference values utilized for metabolic profile analysis may benefit by taking into account seasonal variation.

Key Words: dairy cow, metabolic profile, transition period

M235 Abundance of antibiotic resistance genes in the gut and feces of ionophore-fed lactating cows. T. Galligan,* P. P. Ray, A. Pruden, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The contribution of dairy cattle to the global pool of antibiotic resistance genes (ARG) is a growing concern. The use of ionophores or subtherapeutic doses of other antimicrobials may select for antibiotic-resistant bacteria, contributing to the ARG reservoir in the cow gut. Improved knowledge of the establishment of ARG in the gut and feces would support assessment of the contribution of dairy cattle to the environmental pool of ARG. The objective was to evaluate the effect of ionophores on the abundance of ARG in ruminal fluid, ileal digesta, and feces of lactating cows. Five lactating dairy cows were examined in a crossover design over 2, 30-d periods. Cows were fed diets with and without the ionophore monensin (320 mg/d). Cows in the study were exposed to oxytetracycline in milk replacer as calves but had no history of exposure to sulfonomides or erythromycin. On d 30 of each period, ruminal, ileal, and fecal samples were collected and subjected to DNA extraction. Six common ARG were subsequently analyzed by quantitative polymerase chain reaction: *tet*W, *tet*G, *tet*X, *tet*O, *sul*1, and *erm*F, encoding resistance to tetracyclines, sulfonomides and erythromycin, respectively. The effects of site (rumen, ileum, feces) and ionophore feeding on absolute and relative abundance of the ARG were analyzed using PROC GLIMMIX procedure in SAS. All 6 ARG were detected in all samples. *Tet*W was the most abundant ARG in all sample types, followed by *tet*O. Absolute abundance (log gene copies/g wet sample) of each ARG was similar in rumen and ileal samples but lower ($P < 0.10$) in fresh feces. Relative abundance (gene copies/16s rRNA) was similar among the rumen, ileum, and feces. Monensin did not affect absolute or relative abundance of any ARG at any sampling site. The ARG were present in the digestive tract before the cows were exposed to monensin, suggesting that monensin is not a driver of the cow gut ARG reservoir. Therefore, simply removing these antibiotics from the diet will not reduce the global ARG pool. Other management strategies must be evaluated to reduce ARG contribution from dairy cattle.

Key Words: antibiotic resistance gene, ionophore, dairy cow

M236 Production and management consequences of abortion in dairy herds of central Mexico.

R. R. Lozano-Dominguez,* C. F. Arechiga, R. M. Rincon, F. J. Escobar, and J. M. Silva, *Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

The objective of this study was to evaluate annual abortion rate and consequences of abortion on dairy management, milk production and herd growth of intensive dairies in central Mexico. Abortions, as well as productive and reproductive events after abortion, were recorded for 2 consecutive years. Records included abortion-conception interval, days in milk, days to culling of cows post-abortion and days of gestation when abortion occurred. Annual rate of abortion, as well as percentage of pregnant cows and percentage of culled cows were calculated. Productive and reproductive events were analyzed using an ANOVA where parity and the reproductive state post-abortion were considered as main effects, and the herd as a block. Proportional variables were analyzed by multiple logistic regressions. Annual rate of abortion was variable between herds with a range of 13.3 to 19.9% ($P < 0.01$). Days of gestation at the time of abortion in multiparous cows with a parity greater than 3 (182.9 ± 3.6 d) was higher ($P < 0.05$) than in primiparous cows (165.7 ± 5.3 d). Stage of gestation (thirds) at the time of abortion and parity were not important on the percentage of pregnant cows after abortion ($P > 0.05$). Days in milk (274 ± 155.2 d) and abortion-conception interval (124.2 ± 96.4 d) were similar for parity ($P > 0.05$). Pregnant cows after abortion had more days in milk (307.6 ± 9.2 d) than non-pregnant cows (175.4 ± 11.7; $P < 0.01$). It was found that 36% of the cows that aborted were eliminated or culled by 223.1 ± 177.4 d post-abortion whereas only 19.5% of cows pregnant were culled ($P < 0.01$). Elevated abortion rates negatively compromised cow replacements, production and management of dairy farms located in central Mexico.

Key Words: dairy cow, abortion, Mexico

M237 Prevalence of dairy cattle diseases and abortion in central Mexico.

C. Murillo, R. R. Lozano, C. F. Arechiga,* M. Rincon, and Z. Cortes, *Autonomous University of Zacatecas, Zacatecas, Mexico.*

Objective of this study was to describe prevalences, risk populations, and in some cases risk factors for diseases such as Leucosis, Paratuberculosis and Brucellosis in dairy cattle of Aguascalientes state in Central Mexico. Serum samples were collected to analyze for Leucosis (n = 340), Paratuberculosis (n = 422), and Brucellosis (n = 445) and it was found that the prevalence for those diseases was 51.6%, 16.3% and 20.3%, respectively. There was an association ($P = 0.01$) between cows having abortion 15 d before the blood sampling and Brucellosis. Abortion prevalence was also evaluated in milking herds at highlands of Central Mexico (Aguascalientes and Jalisco states). Four dairy herds that had similar management (i.e., related to preventive medicine, health and sanitary conditions, production, nutrition, and reproduction) were evaluated. Abortion cases were reported (n = 810), with 183.4 ± 58.0 d of gestation at abortion, average days in milk at abortion of 328.7 ± 130.9 d, interval from abortion to new pregnancy of 355.9 ± 197.7 d, and 73.9% of cows calving after abortion. Culling of cows as a consequence of abortion was reported as 36.0% with an average days in milk of 223.1 ± 177.4 d. It was also observed that 35.3% of cows had abortions during the dry period. This study provided some descriptive information related to disease and abortion prevalences in Central Mexico's dairy herds.

Key Words: dairy cows, brucellosis, Mexico

M238 Analysis of factors affecting heifer fertility traits in Chinese Holstein.

Y. Wang*[1], X. Guo[1], G. Guo[2,4], X. Li[2], L. Liu[3], W. Zheng[3], T. Yang[3], Q. Liu[5], Y. Zhang[1], S. Zhang[1], and Y. Zhang[1], [1]*College of Animal Science and Technology, China Agriculture University, Beijing, China,* [2]*Beijing Sanyuan Lvhe Dairy Cattle Center, Beijing Sanyuan Breeding Technology Co., Beijing, China,* [3]*Beijing Dairy Cattle Center, Beijing, China,* [4]*Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [5]*Beijing Capital Agribusiness Group, Beijing, China.*

The improvement of fertility in heifers plays a key role in improving longevity and lifetime production in dairy farm. However, there were only few studies analyzing fertility traits in Chinese Holstein. The objective of current study was to identify factors affecting fertility traits in heifers and to provide a theoretical basis for improving dairy cattle production efficiency in Chinese Holstein. Data of fertility traits from 22 dairy farms (2000 to 2010) were collected from Beijing Sanyuan Lvhe Dairy Cattle Centre, including interval from first service to conception (FSTC) and conception rate for first insemination (CR) in heifers. The final data set included 23,035 heifers, daughters of 119 bulls. Fixed effects of herd, birth year, birth season, year of first mating, season of first mating, and sire were considered in the model, and SAS 9.1 was used to run the analysis. The simple statistics for FSTC and CR were 13.59 ± 30.82 d and 74.4% ± 43.7%, respectively. All factors studied had significant association with FSTC and CR ($P < 0.05$ or $P < 0.01$) except birth season. For FSTC and CR, the largest differences among farms were 14.28 d and 26.0%, respectively. For heifers born in year 2000, average FSTC and CR were 0.34 d and 99.7%, respectively; thereafter there was a declined trend for reproductive efficiency, e.g., average FSTC increased about 3 d per year while CR decreased 6.0% per year from birth year 2000 to birth year 2006. Birth year 2006 became a turning point, since then both FSTC and CR started to be improved. Year of first mating showed exactly the same trend as birth year did. Therefore further analysis of fertility traits can drop birth season and either of the 2-year factors. The heifers first mated in colder seasons (autumn and winter) had lower CR (2.9%) and longer FSTC (1.29 d) than those mated in warmer seasons (spring and summer). The effect of sire was significant, which means genetic selection could improve heifer fertility performance. In conclusion, heifer reproductive performance was influenced by multiple factors, and could be improved by better on-farm management and selection of a fertile sire.

Key Words: fertility traits, heifer, Chinese Holstein

M239 Characterization of certified organic Wisconsin dairy farms: Management practices, feeding regimens, and milk production. C. A. Hardie*[1], V. E. Cabrera[1], M. Dutreuil[1], R. Gildersleeve[2], and M. Wattiaux[1], *[1]University of Wisconsin-Madison, Madison, [2]University of Wisconsin Extension, Dodgeville.*

The purpose of this project was to characterize certified organic Wisconsin dairy farms and evaluate their feeding regimens during the course of 2010. Farms were identified by cross listing 2 separate directories: the Wisconsin Active Dairy Producers and the Wisconsin Certified Organic Producers. All resulting organic dairy herds from these lists were invited to participate (n = 565) in this study. An on-site survey containing sections on farm demographics; feeding, pasturing, cropping and nutrient management practices; sources of income; and farm satisfaction was conducted on 54 farms throughout the state between March 2011 and January 2012. Forty-six percent of the farms relied entirely on family labor to complete farm chores. Total area operated ranged from 17.8 to 775.6 ha, with a mean (±SD) of 123.4 (±133.4). Hectares of pasture ranged from 6.1 to 145.8, with a mean (±SD) of 40.9 (±30.84). Herd size ranged from 12 to 650 cows, with a mean (±SD) of 71.3 (±92.2). The predominant breed varied on the farms, too, with 51.9, 27.8, 9.3, and 11.1% of the herds having Holstein, crossbred, Jersey, and other, respectively as their major breed. Milk rolling herd averages varied from 2,356 to 10,274 kg/cow per year, with a mean (±SD) of 6,182 (±1,846). Total dry matter intake (DMI) for lactating cows ranged from 11.8 to 25.6 kg/cow per day, with a mean (±SD) of 19.8 (±3.4). Peak pasture intake during the grazing season ranged from 1 to 100 percent of total DMI, with a mean (±SD) of 69.1 (±25.5). The farms' grazing seasons in 2010 ranged from 122 to 244 d, with a mean (±SD) of 182.0 (±28.7). During the grazing season, 79.6, 13.0, and 31.5% of the herds supplemented grain, protein, and corn silage, respectively. As indicated by the ranges and SD presented here, certified organic Wisconsin dairy farms varied widely in farm characteristics, feeding regimens, and animal production. Awareness of these extreme variations should help design extension programs and agricultural publications better suited to meet the educational needs of this growing dairy sector. Supported by AFRI Competitive Grant no. 2010–51300–20534.

Key Words: organic, grazing, supplementation

M240 Impact of dairy herd reproductive performance on predicted economic performance, enteric CH$_4$ emission and excretion of N and P using a Markov-chain model. M. J. Aguerre,* J. O. Giordano, A. S. Kalantari, M. A. Wattiaux, P. M. Fricke, and V. E. Cabrera, *University of Wisconsin-Madison, Madison.*

Our objective was to estimate the effect of reproductive performance on predicted enteric CH$_4$ emission, and N and P excretion of lactating and dry cows in a dairy herd. A Markov chain model was used to simulate herd dynamics based on productive and reproductive input parameters. Different herd structures were obtained after simulation of herds with 12 (Low) vs. 22% (High) 21d-pregnancy rate. Lactation curves from a commercial farm were used to simulate milk production whereas DMI was calculated based on NRC 2001 empirical equation. Diets for cows in early (0 to 150 DIM) or late (>150 DIM) lactation contained 16.7 vs. 15.4% CP, 44.2 vs. 41.4% NFC, 10.4 vs. 11.2% hemicellulose (HC), 16.7 vs. 23.0% cellulose (CEL) and 0.38 vs. 0.34% P, respectively. Dry cows diet was formulated to contain 13.2% CP, 34.8% NFC, 14.3% HC, 24.8% CEL and 0.27% P. Enteric CH$_4$ emission was predicted by an empirical equation (CH$_4$ g/d = [(0.814 + 0.122 x intake NFC kg + 0.415 x intake HC kg + 0.633 x intake CEL kg)/0.05565]. Manure N and P excretion (g/d) was predicted by difference between intake and milk secretion for each element. Net value ($/cow per yr) for High and Low pregnancy rate were calculated by summation of income over feed cost, replacement cost, reproductive program cost, and calf value. Compared with Low, High program resulted in higher milk production per lactating cow (40.3 vs. 41.8 kg/d), lower percentage of lactating cows (90.6 vs. 88.8%), lower average DIM (188 vs. 176), and higher income over feed cost (7.76 vs. 7.84 $/cow per d). In addition, High outperformed Low by $69.4/cow/yr. Predicted CH$_4$ and CH$_4$/milk were 425 g/d and 11.64 g/kg for Low and 419 g/d and 11.37 g/kg for High which represented a 1.4 and 2.3% reduction. Relative to Low, with the High program N and P excretion were reduced by 1.1% (373 vs. 369 g/d) and 1.3% (45.0 vs. 44.4 g/d), respectively. Under the simulation conditions of this study, changes in herd structure associated with improved reproductive performance reduced predicted environmental impact while improving profitability.

Key Words: reproductive performance, methane, nitrogen and phosphorus

M241 Reproductive indicators of dairy enterprises in north and west Mexico. H. Estrella-Quintero,* D. V. Mariscal-Aguayo, R. Núñez-Domínguez, and G. Maldonado-García, *Universidad Autónoma Chapingo, Chapingo, Estado de México, México.*

The purpose of this study was to evaluate the reproductive performance of family-based dairy enterprises in transition and business considering their technological level. Transition enterprises are those moving from subsistence to business, the latter being the ones that market all their products. The information used was registered in the AGROPEC Star software of 12 farms in transition level and 7 in business level located in northern and western Mexico, with a total of 3,935 Holstein cows and for a period from 1996 to 2011. The variables evaluated were: services per conception (SPC), calving interval (CI), calving to first estrus interval (CFEI) and interval from calving to first service (CFSI). A mixed model was used that included fixed effects of technological level, and number, year and season of birth, and significant 2-way interactions between these effects, and as random effects, the enterprise nested in the technological level and cow within enterprise. The technological level had an effect ($P < 0.05$) in SPC and CI; the interaction of technological level by year of birth had an effect ($P < 0.05$) in all the variables. The transition technological level had 1.8 ± 0.05 SPC and 403.4 ± 4.9 d of CI lower ($P < 0.05$) than the business technological level which averaged 2.08 ± 0.09 and 426.7 ± 8.1 d, respectively. No significant differences were found between technological levels for CFEI and CFSI. In conclusion, enterprises in transition had better reproductive performance than business enterprises.

Key Words: enterprises, cows, Holstein

M242 Seasonal variation on milk components and relation to quality payment program. L. C. Roma Junior*[1], A. C. S. Gonçalves[1], and P. F. Machado[2], *[1]APTA Centro Leste, Ribeirao Preto, Sao Paulo State, Brazil, [2]Clínica do Leite, ESALQ/USP, Piracicaba, Sao Paulo State, Brazil.*

The existence of a wide variation in milk quality in subtropical regions due to season of the year has been reported previously. However, participation in a payment program based on milk quality can generate profits or losses to the producer due to this variation. The main objective of this study was to quantify the effect of milk price variation, recognizing significant causes of it and possible parameters that need more attention. For one year, 250 dairy farms in the Southeast region of Brazil were inspected for the following milk parameters: fat, protein, non-fat solids, somatic cell count and total bacterial count. At the same time, monthly climate data were collected in the region to observe climate variability and allow investigation correlating those data with the outcomes. The randomized design was used, with season as a factor (summer, autumn, winter and spring). The means were evaluated using Proc GLM, by Tukey test with a significance level of 5%. It was observed that there was a significant effect between variation on milk quality and final price of the marketed milk. The bonus variation ranged from 2.34% (spring) to 7.87% (autumn), and the only season that showed a significant variation in the milk price was autumn ($P < 0.05$). One of the factors that influenced the bonus the most was somatic cell count, contributing with a year average penalty of 1.89%, followed by bacterial count, with a penalty of 0.24%. On the other hand, milk protein was the component responsible for providing most of the bonus, averaging 3.77%. In conclusion, there was an effect of season on bonus/penalty for the producer; somatic cell count was the variable that penalized price the most. Knowledge on the effect of season in payment amount for quality can inform the producer, who should act to prevent and control quality of milk produced. In some cases, the producer would be able to concentrate milk production increases and calving at a season when best bonuses are offered, aiming to achieve greater production profitability. Financial support by FAPESP, process 05/51369-8.

Key Words: environmental effects, payment for milk quality, seasonability

M243 Effects of temporary calf removal (CR) prior to fixed-time AI (TAI) on pregnancy rates and subsequent calf performance in suckled beef cows.

G. H. L. Marquezini,* F. M. C. Silva, K. M. Bischoff, T. E. Black, V. R. G. Mercadante, N. DiLorenzo, and G. C. Lamb, *North Florida Research and Education Center, University of Florida, Marianna.*

Two experiments were conducted to determine the effect of calf removal (CR) on pregnancy rate and calf performance in suckled beef cows. Cows were synchronized with the 7-d CO-Synch + CIDR protocol (100 µg injection of GnRH at CIDR insertion [d −7] with 25 mg injection of $PGF_{2\alpha}$ at CIDR removal [d 0], followed by injection of GnRH and TAI on d 3). Cows were stratified by d postpartum, BCS, and parity and assigned to one of 2 treatments in Exp. 1: CON (control; n = 156) and CR72 (calves were separated from their dams for 72 h from d 0 and 3; n = 168); and one of 4 treatments in Exp. 2; CON (n = 105), CR72 (n = 107), CR48A (CR for 48 h from d 0 to d 2; n = 99), and CR48B (CR from d 1 to d 3; n = 53). Follicle dynamics and CL development were assessed on d 0, 3, and 10 and pregnancy status determined on d 30. Blood was collected on d −14, −7, 0, 3, and 10 to determine P4 and E2. Overall pregnancy rates did not differ among treatments (Exp. 1, 50.3%, $P = 0.58$; Exp. 2, 49.1%, $P = 0.15$). In Exp.1, CR72 (0.42 ± 0.15 mm/d) had increased follicle growth rate ($P < 0.01$) from d 0 to 3 compared with CON (0.02 ± 0.15 mm/d), but there were no differences in follicle diameter on d 0 or 3 ($P > 0.1$). In Exp. 2, E2 concentrations were greater ($P < 0.01$) in the CR72 treatment at 24 h after $PGF_{2\alpha}$ compared with other treatments (7.4 ± 1.4, 14.6 ± 1.6, 8.4 ± 1.6, and 7.7 ± 1.6 pg/mL for CON, CR72, CR48A, and CR48B, respectively). Young (25 to 59 d of age) and old (>80 d of age) calves lost a greater ($P < 0.05$) percent of body weight (PBW) during CR than medium (60 to 79 d of age) aged calves exposed to CR72 (−4.7 ± 0.4%, −1.9 ± 0.4%, and −2.5 ± 0.5% PBW change for young, medium, and old, respectively) and to CR48 (−4.8 ± 0.5%, −2.1 ± 0.6%, and −2.6 ± 0.8% PBW change for young, medium, and old, respectively), whereas CON calves gained weight during CR (3.7 ± 0.4%, 1.7 ± 0.5%, and 2.1 ± 0.5% PBW change for young, medium, and old, respectively). We conclude that CR was not able to improve pregnancy rates but did increase follicle growth rate before TAI. Subsequent calf performance was affected by 72 or 48 h calf removal.

Key Words: calf removal, artificial insemination, beef cows

M244 Effect of cattle processing and handling on changes in measures of temperament during a 70-d feed efficiency test.

K. M. Bischoff,* T. E. Black, V. R. G. Mercadante, G. H. L. Marquezini, D. Henry, N. DiLorenzo, and G. C. Lamb, *North Florida Research and Education Center, University of Florida, Marianna.*

We determined the effect of animal handling and processing over a 70-d feed efficiency test (FET) on changes in temperament in beef cattle. Over a 3-yr period (2009 to 2011) 8 separate groups of bulls (n = 526), steers (n = 182), and heifers (n = 133) comprising *Bos taurus*, *Bos indicus*, or *Bos taurus* × *Bos indicus* genetics were processed through the University of Florida Feed Efficiency Facility using a GrowSafe feed intake system (GrowSafe Systems Ltd., Alberta, Canada) for a FET. Animal was the experimental unit. Cattle were exposed to a 14 d acclimation period before initiation of a 70 d FET. Cattle were processed every 14 d (d0, d14, d28, d42, d56, and d70) for collection of BW and temperament data. Temperament data consisted of chute score (CS) and exit velocity (EV). Chute score, the subjective measurement of the behavioral response to restraint in the squeeze chute, was assigned on a 1 to 5 scale (1 = calm and docile; 2 = restless; 3 = nervous; 4 = excited and flighty; 5 = aggressive) and EV was the speed (m/s) at which each animal exited the squeeze chute and passed by infrared sensors placed 1.83 m apart. Chute score ($r = -0.199$) and EV ($r = -0.254$) were correlated with BW ($P < 0.001$) and EV was correlated with CS ($P < 0.001$; $r = 0.273$). For repeated measures analysis on CS and EV, BW was used as a covariate and day as the repeated variable. There was no effect of sex ($P = 0.119$) on CS. However, CS was affected by breed ($P = 0.002$) with 50% Angus-50% Brahman (50/50) crossbred cattle having greater CS than Ultra Black (UB; 75% Angus, 25% Brahman) cattle ($P = 0.04$). In addition, Brangus (BN; $P < 0.001$) and Brahman cross (BX; $P = 0.003$) cattle had greater CS than Angus (AN) cattle, with BN having greater CS than UB ($P = 0.02$). For EV, a breed × sex interaction existed ($P = 0.047$) indicating that EV for heifers of BN origin was greater ($P < 0.01$) than for bulls of BN origin. Exit velocity did not differ ($P < 0.01$) between sexes among all other breeds. There was a group × day interaction ($P < 0.001$) for CS and EV, with cattle from differing FET groups having differences in CS and EV as d on test progressed. In conclusion, handling and processing during a FET did not improve animal temperament, and changes in CS and EV during a FET appear to be associated with previous management and herd genetics, as evidenced by the group × day interaction. However, breed influenced CS and EV during a 70-d FET.

Key Words: temperament, beef cattle, animal handling

M245 Culling reasons and the association of herd size and milk yield with culling rates in dairy herds in southern Brazil. R. Almeida*[1], D. F. F. Silva[1], L. Alegransi[1], R. B. Navarro[2], A. A. Valloto[3], and J. A. Horst[3], [1]*Universidade Federal do Paraná, Curitiba, PR, Brazil,* [2]*Capal Cooperativa Agroindustrial, Arapoti, PR, Brazil,* [3]*Associação Paranaense de Criadores de Bovinos da Raça Holandesa, Curitiba, PR, Brazil.*

The objective of this study was to identify reasons for culling lactating dairy cows in herds located in Arapoti county, Paraná State, southern Brazil. In addition, the association of culling rate with milk yield and herd size was also investigated. Statistical analyses were performed using CORR and GLM procedures (SAS), and herd within year was the experimental unit. A multivariate regression model was developed, where culling rate was the dependent variable, and year, herd size, and herd milk yield categories were the independent variables. Data set included 21 herds and data were collected from January 2007 to December 2010. A total of 3,961 cows were culled or died in these herds during the study period. The most important reasons for culling were reproductive disorders (33.5%), clinical mastitis and high somatic cell count (22.2%), and feet and leg problems (18.5%). The first 3 mo of lactation were critical; 28.1% of deaths and culls were observed during this period. Approximately one-fifth (19.8%) of culled cows were first-parity females. Culling rates were lower ($P < 0.05$) in the first 2 years (21.9% in 2007 and 24.2% in 2008) than in the last 2 years (26.2% in 2009 and 26.4% in 2010) of the study. The observed culling rates were lower than the 30% culling rate typically found in confined herds in Brazil, suggesting that the current milk prices encouraged dairy farmers to keep cows in their herds longer. Small herds (less than 150 cows) had lower culling rates ($P < 0.05$) than medium (150 to 250 cows) and large herds (more than 250 cows). The correlation between culling rate and herd size was moderately positive ($r = 0.25$; $P < 0.05$), suggesting that small herds kept cows for more lactations. There was a difference in culling rates between high- and low- milk yield herds and the correlation between these 2 variables was significant ($r = 0.26$; $P < 0.05$). Larger and higher-producing dairy farms had higher culling rates in the subtropical south of Brazil and these farms should carefully investigate culling reasons in their herds to identify areas for improvement.

Key Words: culling rate, reproduction, herd size

M246 Nitrogen utilization efficiency in specialized dairy herds in southern Brazil. D. Jerszurki[1], L. Jerszurki[2], R. B. Navarro[3], A. Ostrensky[4], G. T. Santos[5], and R. Almeida*[1], [1]*Universidade Federal do Paraná, Curitiba, PR, Brazil,* [2]*Universidade Tecnológica Federal do Paraná, Curitiba, PR, Brazil,* [3]*Capal Cooperativa Agroindustrial, Arapoti, PR, Brazil,* [4]*Pontifícia Universidade Católica do Paraná, Curitiba, PR, Brazil,* [5]*Universidade Estadual de Maringá, Maringá, PR, Brazil.*

The objective of this study was to determine current nitrogen utilization efficiency (NUE) of dairy herds in Arapoti county, Paraná State, southern Brazil, as well as to evaluate possible effects of dietary crude protein (CP) levels and milk yield on NUE. Twenty-eight commercial herds mostly containing Holstein cows and producing 29.0 ± 3.9 kg/cow/d were studied in a 5-year period (from January 2007 to December 2011). Each herd was monitored on average 4x per year, totaling 547 visits in the evaluation period. For validation purposes, on-site collection of TMR, milk, feces, and urine samples was conducted in 6 participating herds on February 2011. Freshly deposited feces were sampled just after being excreted by 60 lactating cows, randomly selected within herd. Urine samples from another 60 cows also randomly chosen were collected by a noninvasive method and mixed to make a composite urine sample with H_2SO_4 solution. Daily fecal and urinary volume excretions were estimated by the equations from the American Society of Agricultural and Biological Engineers Standards (ASAE, 2005). Statistical analyses were carried out with GLM procedure of SAS, and each farm visit was considered as an experimental unit. A multivariate regression was developed with NUE as the dependent variable, herd, year, and season as fixed effects, and milk yield as covariate. Estimated variables with their respective means and standard deviations were: 523 ± 49 g/d N intake (15.6 ± 0.7 dietary CP), 143 ± 19 g/d milk N (3.14 ± 0.11 milk protein %), 202 ± 16 g/d fecal N, 194 ± 20 g/d urinary N, and 27.31 ± 2.82% of NUE. N efficiency increased ($P < 0.01$) over the years: 25.2% in 2007, 27.0% in 2008, 27.3% in 2009, 28.0% in 2010, and 28.4% in 2011. Season was a significant effect ($P < 0.01$) only when the model did not include the covariate milk production, indicating that dairy cows had higher N balance in the winter season only because they produce more milk during cooler months. Correlations between NUE and milk yield ($r = 0.64$; $P < 0.01$) and between NUE and dietary CP ($r = -0.27$; $P < 0.01$) indicated that high-producing dairy herds that adopt conservative dietary CP levels had higher N efficiency.

Ruminant Nutrition: Beef I

M247 Carcass primary cuts proportions of Nellore bulls stratified for residual feed intake. F. L. Araujo*[1], R. H. Branco[2], C. D. A. Batalha[1], S. F. M. Bonilha[2], A. C. Queiroz[1], and W. P. Costa[1], *[1]Departmento de Zootecnia, Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho, SP, Brazil.*

The study was conducted to evaluate proportion of primary cuts in carcass of Nellore bulls stratified for residual feed intake (RFI). Thirty animals with 414 ± 35.68 kg BW and 18 ± 1.11 mo of age, were evaluated in 2 experiments. The bulls were stratified in low RFI (<mean - 0.5 SD; n = 14) and high RFI (>mean + 0.5 SD, n = 16), and 2 feeding levels: ad libitum and restricted (65 g DM / kg BW0, 75). After slaughter and carcasses chilling period (24h), the right half-carcasses were divided in hindquarter, forequarter and spare ribs, which were weighed and had their ratio calculated based on cold half-carcass weight. Edible primary cuts were determined based on the relationship between the sum of cuts weights and the respective carcass primary cut weight; bones proportion was determined based on the relationship between the sum of bones weight and the respective primary cuts weight; shavings proportion was determined based on the relationship between the sum of shavings weight and the respective primary cut weight. Statistical analyzes were performed according to a 2x2x2 factorial scheme (2 RFI groups, 2 feeding levels and 2 experiments) in a completely randomized design, assuming $\alpha = 0.05$. There were no effect of different RFI levels in hindquarter weight (60.93 kg and 63.33 kg, respectively for low and high RFI; $P = 0.2549$), forequarter weight (51.39 kg and 54.82 kg, respectively for low and high RFI; $P = 0.1123$), spare ribs weight (17.95 kg and 19.01 kg, respectively low and high RFI; $P = 0.2112$), hindquarter edible portion (71.44% and 71.02%, respectively for low and high RFI; $P = 0.4621$), forequarter edible portion (64.25% and 65.60%, respectively for low and high RFI; $P = 0.1473$), spare ribs edible portion (43.26% and 45.27%, respectively for low and high RFI; $P = 0.3233$), hindquarter bones proportion (20.73% and 20.78%, respectively for low and high RFI; $P = 0.9167$), forequarter bones proportion (22.33% and 21.77%, respectively for low and high RFI; $P = 0.4982$), spare ribs bones proportion (14.37% and 14.91%, respectively for low and high RFI; $P = 0.4240$), hindquarter shavings proportion (10.14% and 10.64%, respectively for low and high RFI; $P = 0.3221$), forequarter shavings proportion (13.19% and 12.58%, respectively for low and high RFI; $P = 0.5399$) and spare ribs shavings proportion (16.64% and 16.21%, respectively for low and high RFI; $P = 0.7414$), showing that more efficient bulls (low RFI) had a lower dry matter intake ($P = 0.0003$) and had similar carcass traits ($P > 0.05$) when compared with less efficient animals (high RFI). RFI can be used to increase efficiency and reduce costs of production systems without resulting in damage to the carcasses of Nellore bulls.

Key Words: edible portion, Nellore, RFI

M248 Creatinine excretion and metabolizable protein requirements for maintenance of Red Norte young bulls. T. R. Amorim, M. M. Ladeira,* M. L. Chizzotti, J. R. R. Carvalho, A. R. V. Lima, N. L. Magalhães, and P. D. Teixeira, *Federal University of Lavras, Lavras, MG, Brazil.*

Protein is an expensive nutrient in beef cattle diets, and its correct balance is important to achieve high performance of the animals. In addition, an excess of dietary protein can increase nitrous oxide emissions. Therefore, the objective of this trial was to investigate the creatinine excretion and metabolizable protein requirements for maintenance of Red Norte young bulls. The experiment was conducted in a completely randomized design, with 5 treatments and 7 repetitions. Thirty-five animals, with an average live weight of 280 ± 4 kg, were allocated to individual pens, and received the following CP levels in the diets: 8, 10, 12, 14 and 16%. After 9 d for diet adaptation, total urine and feces collections were performed for 5 d. Metabolic fecal nitrogen, urinary endogenous losses and total endogenous losses were all estimated by regression approach. Creatinine concentration in urine was analyzed using colorimetric method. Protein levels did not influence ($P > 0.05$) creatinine excretion. The net protein requirements for maintenance were obtained as the intercept of the regression of retained nitrogen on nitrogen intake ($0.441 \times 6.25 = 2.75$ g/EBW$^{0.75}$; $P = 0{,}006$), with a partial efficiency of use of metabolizable protein to net protein for maintenance of 0.68 ($P < 0{,}001$). This efficiency is very similar of the values reported by NRC (1985) and BR-Corte (2010): 0.67, and 0.667, respectively. Using this efficiency and assuming the net protein requirement of 2.75 g of net protein/EBW$^{0.75}$ for maintenance, the daily metabolizable protein requirement was calculated as 4.05 g/EBW$^{0.75}$. According to this result, protein requirements for maintenance of Red Norte young bulls was higher than the value described by the NRC (1996) (3.8 g/EBW$^{0.75}$), and very close to the requirement recommended by BR-Corte (2010) (4.03 g/EBW$^{0.75}$).

Key Words: crude protein, nitrogen, requirement systems

M249 Measurement of purine derivatives and creatinine excretion in steers fed fescue seed. J. H. Eisemann,* G. B. Huntington, and A. E. Lamb, *North Carolina State University, Raleigh.*

The objectives were to measure urinary excretion of purine derivatives (PD) and creatinine (CRT) in steers in response to dietary ergot alkaloids, and to compare total daily and spot collections. Angus steers (n = 8) were fed a concentrate mix: switchgrass hay (40:60) diet containing endophyte-free (E-) or endophyte-infected (E+; 2.7 mg/d total ergot alkaloids, 9.6 ug/kg BW) fescue seed. Steers were housed indoors in individual pens with daily temperature ranging from 23.5 to 32.1°C. The design was a single reversal with 14-d treatment periods and 21 d between periods. Steers were fitted with a harness for total collection of urine on d 12 and 13 of each period. Urine was collected at 6-h intervals beginning at 1200 h on d 13. Aliquots from each interval collection within days were combined to form a daily collection. A spot urine sample was collected at 0800 and 1400 h. Urine PD and CRT were analyzed by HPLC. Data ANOVA included effects of treatment, day, and period. Steers' BW and DMI did not differ ($P = 0.20$) for E- (290 kg, 5.49 kg/d) and E+ (289 kg, 5.38kg/d). In total daily collections, urinary CRT excretion was lesser ($P < 0.05$) for E- than E+. Means were 1.13 and 1.21 mmol CRT per kg BW$^{0.75}$, respectively. The PDC ratio (PD/CRT, 1.21 and 1.08) and PDC index (PDC ratio x BW$^{0.75}$, 85.0 and 75.0) were greater ($P < 0.01$) for E- than E+. Total PD excretion (mmol/d) did not differ ($P < 0.15$) for E- (95.8) and E+ (91.0). Estimated microbial N production was not affected by E+ and was 58.8 and 54.8 g N/d for E- and E+, respectively. In spot collections, PDC (1.21 and 1.10) and PDC index (84.9 and 76.5) were greater ($P < 0.01$) for E- than E+. Calculated PD excretion (mmol/d) from spot collections was greater ($P < 0.01$) for E- (99.3) than E+ (89.5). Treatment responses were similar for PDC and PDC index in total daily and spot collections; however, treatment responses differed for total daily PD excretion and calculated daily PD excretion from spot samples. Treatment responses indicate urinary CRT excretion per kg BW$^{0.75}$ is not a constant for calculating PD excretion and microbial N production.

Key Words: purine derivatives, creatinine, steers

M250 Feedlot performance and carcass characteristics of limit-fed steers. K. Thompson*[1], P. Gunn[2], R. Lemenager[2], M. Claeys[2], T. Nennich[2], and S. Lake[1], [1]*University of Wyoming, Laramie,* [2]*Purdue University, West Lafayette, IN.*

The objectives of this study were to evaluate limit-fed feedlot steers on performance and carcass characteristics. Angus crossed steers (n = 168) were randomly blocked into one of 24 pens (6 pens/treatment; 7 steers/pen) and assigned to one of 4 dietary treatments: 1) 85% ad libitum intake 2) 90% ad libitum intake 3) 95% ad libitum intake; or 4) 100% ad libitum intake. Diets consisted of a corn-based finishing ration and the percentage of intake was calculated from the 100% ad libitum treatment on a weekly basis. All animals were harvested when their respective 12th rib fat depth reached 0.4 tenths. Data were analyzed using the MIXED procedure of SAS with preplanned orthogonal contrasts between the 4 dietary treatments. As expected, steers on the 100% ad libitum diet had greater DMI ($P < 0.001$) compared with all other treatments. Steers on the 95% ad libitum diet had greater DMI ($P < 0.001$) compared with the 85 and 90% ad lib diets, however, there was no difference ($P = 0.26$) between the 85 and 90% ad libitum treatments. Total ADG over the course of the study was greater ($P = 0.002$) for steers on the 100% ad libitum treatment; however, there were no differences ($P \leq 0.36$) between the other treatments. Steers on the 90% ad lib diets had a greater G:F ($P = 0.01$) compared with steers on the 95% ad lib treatment, while the 85 and 100% ad lib treatments were intermediate. Days on feed were greater ($P = 0.003$) for steers on the 85 ad libitum treatment when compared with the 95 and 100% ad libitum intake treatment; however, there was no difference ($P = 0.29$) between the 95 and 100% ad libitum treatments. Total feed costs did not differ ($P = 0.47$) between treatments. Steers on the 85% ad lib treatment group had less ($P = 0.01$) KPH fat compared with all other treatments; however, no differences ($P \geq 0.17$) were detected in HCW, 12th rib fat, REA, yield grade, or quality grade. Limit-feeding steers decreased DMI without sacrificing carcass quality; however, because days on feed were increased, there appears to be no economic advantage to limit-feeding feedlot steers.

Key Words: limit-fed, feedlot, steers

M251 Ergovaline disappearance from a ruminally incubated buffer. A. P. Foote*[1], N. B. Kristensen[2], J. L. Klotz[3], K. R. Brown[3], J. R. Strickland[3], D. H. Kim[1], A. F. Koontz[1], K. R. McLeod[1], L. P. Bush[1], and D. L. Harmon[1], [1]*University of Kentucky, Lexington,* [2]*Syddansk Kvæg, Vojens, Denmark,* [3]*USDA-ARS, FAPRU, Lexington, KY.*

Ergovaline (ERV) is an alkaloid present in endophyte-infected tall fescue (*Lolium arundinaceum*) that contributes to fescue toxicosis in cattle. To determine disappearance of ERV in the washed reticulorumen, steers (n = 8) were pair-fed alfalfa cubes at $1.5 \times NE_m$ and dosed with ground endophyte-infected tall fescue seed (E+) or endophyte-free tall fescue seed (E-) via rumen cannula 2 × daily for 7 d at thermoneutral (TN; 21°C) and heat stress (HS; 32°C) conditions. On d 8, the rumen was emptied and rinsed. Buffer containing VFA was incubated with 0.015 mg ERV/kg BW (1 × EXT) followed by an incubation with 0.045 mg ERV/kg BW (3 × EXT). The ERV in the buffer was supplied as a seed extract. For each buffer treatment there were 2 consecutive 30-min incubations where the first 30 min buffer incubation was not sampled. Following removal of the buffer an identical sampling buffer was incubated with the addition of Cr-EDTA. Buffer was sampled at 5, 15, and 30 min. Analysis of buffer samples for ERV was conducted using an Acquity UPLC with a TQ detector. Disappearance of ERV was calculated by changes in the pool size in the buffer corrected for dilution by physiological water and passage out of the rumen. In this model, ERV disappearance is the sum of absorption into blood, adsorption to the rumen wall or residual digesta particles, and metabolism. Treatment of steers with E+ seed had no effect on ERV disappearance ($P = 0.64$). ERV disappearance rate was higher with the 3 × EXT than 1 × EXT ($P = 0.02$). The interaction of temperature and buffer ($P = 0.08$) indicated that ERV disappearance increased 6.5-fold with increasing ERV during HS, but only increased 2-fold during TN. These data indicates that increasing the ruminal ERV dose increases ERV disappearance in steers at high ambient temperatures which could be caused by increased absorption rate, metabolism, or binding of ERV.

Key Words: washed reticulorumen, fescue toxicosis

M252 Body condition score and heart girth change between 7 and 18 months of age to estimate pregnancy probability of Hereford heifers mated at 18 months of age. J. B. G. Costa Junior*[1], J. O. J. Barcellos[1], J. C. Whittier[2], I. D. P. S. Diaz[3], L. Canellas[1], V. Peripolli[1], J. K. Ahola[2], and R. K. Peel[2], [1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil,* [2]*Colorado State University, Fort Collins,* [3]*Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

Our objective was to use body condition score (BCS) and heart grith (HG) to estimate pregnancy probability (OR, odds ratio) in Hereford heifers at 18 mo of age originated from a commercial cattle herd at a facility in the state of Rio Grande do Sul, Brazil. Heifers were developed at 3 different levels of average daily gain - (ADG) (high - H, moderate - M and low - L) with 3 different combinations (LHM; HLL; MMH). These ADG levels were applied between 7 to 12 mo (P12); 12 to 15 mo (P15) and 15 to 18 mo of age (P18). Used to the LHM, MMH, and HLL treatments 65, 58, and 60 heifers respectively. This was done by OR, being adjusted within a complete model involving the treatment classifing variables and all the continuous variables (body weight - BW, hip's height - HH, heart girth - HG, body weight:height ratio - WH) at the age of 7, 12, 15, and 18 mo. The variables selected for this study were the BCS at 12 mo (BCS12) and HG at 18 mo (HG18), within the effect of treatment ($y = -30.6165 + 1.5294\ BCS12 + 0.1701\ HG11 + Treat$ (HLL = 0.0; LHM = 1.1699 and MMH = 2.2996); H&L = 0.30). The HLL treatment was taken as reference once it was determined to result in the lowest percentage of pregnancy. The heifers receiving the LHM treatment had 3.2 times more chances to conceive, while heifers in the MMH treatment presented a ratio 9.9 times higher than the ones of the HLL treatment. The variable HG18 effect showed higher significance ($P < 0.05$) in the pregnancy probability model than the BCS12. We conclude that high HG18, even when combined with low BCS12, produces high pregnancy probability estimates, however, the opposite does not happen. The measure of heart girth at the beginning of the mating is a good reference for the estimation of the pregnancy rate.

Key Words: average daily gain, body weight, logistic model

M253 Use of body weight gain at different ages to evaluate the pregnancy probability and the change in the pregnancy chance of Hereford heifers mated at 18 months of age. J. B. G. Costa Junior*[1], J. O. J. Barcellos[1], J. C. Whittier[2], I. D. P. S. Diaz[3], L. Canellas[1], V. Peripolli[1], J. K. Ahola[2], and R. K. Peel[2], [1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil,* [2]*Colorado State University, Fort Collins,* [3]*Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

The objective of this study was to evaluate the estimated pregnancy probability and the change in the pregnancy chance (odds, ratio - OR) using variable body weight (BW) in Hereford heifers at 18 mo of age originated from a commercial cattle herd at a facility in the state of Rio Grande do

Sul, Brazil. Three different levels of average daily gain - ADG (high - H, moderate - M and low - L) with 3 different combinations (LHM; HLL; MMH) were considered. These ADG levels were applied between 7 to 12 mo (P12); 12 to 15 mo (P15) and 15 to 18 mo of age (P18). Used to the LHM, MMH, and HLL treatments 65, 58, and 60 heifers respectively. To determine these effect OR was adjusted within a complete model involving the treatment classification variables and all the continuous variables of body weight (BW), hip height (HH), heart girth (HG), body weight:height ratio (WH) at the age of 7, 12, 15, and 18 mo. This study used only the variable BW gain from 7 to 12 mo of age (BWG12), from 12 to 15 (BWG15), and from 15 to 18 mo of age (BWG18), 30 d before and during the mating time. The last 2 variables (30 d before and during the mating time) did not enter into the model and therefore were excluded from further consideration ($P > 0.3$) ($y = -3.6131 + 0.0431\,BWG12 + 0.0432\,BWG15 + 0.0302\,BWG18$; H&L = 0.77). There was a similar change in the OR as to an increase of 10 kg of BW in the P12 and P15 periods. However, at the age of 18 mo, showed a 54% increase in the changing rate. During P18, before the mating time, an increase of 35% in the pregnancy chance for every 10 kg of BW gained was observed. According to the average BW in each treatment at the end of each period, an increase of 10 kg represents 5% of the BW at the age of 12 mo, 3.7% of the BW at the age of 15 mo, and 3.2% of the BW at the age of 18 mo. We conclude that using the pregnancy probability described in this study will provide a useful tool for decisions related to heifer development for heifers mated at 18 mo of age.

Key Words: average daily gain, logistic model, mating time

M254 Use of a fescue seed model to study effects of ergot alkaloids on temperature regulation in steers.

G. B. Huntington* and J. H. Eisemann, *North Carolina State University, Raleigh.*

The objective was to measure changes in surface temperature (ST) of the left ribs, rectal temperature (RT), blood pressure (BP), heart rate (HR), and respiration rate (RR) in steers fed diets containing either endophyte-free (E-) or toxic endophyte-infected (E+) fescue seed under conditions where the temperature was above the thermoneutral zone. Angus steers (n = 8) were housed indoors in individual pens and adapted to a concentrate mix:switchgrass hay (40:60) diet. Seed replaced soy hulls in the basal diet for E- and E+ (2.7 mg/d total ergot alkaloids; 9.6 ug/kg BW). Design was a single reversal with 14-d periods and 21 d between periods. Baseline measurements were taken 2 d before the start of each period. Measurements were taken at 0730, 1230, and 1530 h on d 4, 8, and 14 of each period. Digital infrared thermographic imaging was used to measure ST. Data analysis included effects of treatment, day, and period with baseline data used as covariates. Mean (SD) daily temperature ranged from 23.5°C (1.3) to 32.1°C (1.6). Steers' BW and DMI did not differ ($P = 0.20$) for E- and E+ and were 285 and 288 kg (SE 4.3) and 5.49 and 5.38 kg/d (SE 0.09), respectively. Steers' RT, ST, and RR were greater ($P < 0.05$) with E+ and increased ($P < 0.01$) with time of day. Means for RT (°C) for E- and E+ at 0730, 1230, and 1530 h were 38.1, 38.3, and 38.5; and 38.2, 38.6, and 38.9, respectively. Steers' ST (°C) for E- and E+ at 0730, 1230, and 1530 h was 36.6, 37.9, and 38.4; and 37.1, 38.2, and 38.9, respectively. Steers' RR (breaths/min) for E- and E+ at 0730, 1230, and 1530 h was 27, 33, and 35; and 29, 41, and 44, respectively. Steers' HR decreased ($P < 0.01$) when fed E+ but increased ($P < 0.01$) with time of day. Systolic BP did not respond to E+ but diastolic BP increased ($P < 0.05$) with E+. Means for HR (beats/min) were 62 and 57, and for diastolic BP (mm Hg) were 48 and 51 for E- and E+, respectively. Greater surface temperature in response to E+ was not sufficient to prevent increased rectal temperature. Decreased heart rate in response to E+ may explain the impairment of thermoregulation.

Key Words: steers, tall fescue, thermoregulation

M255 Deposition of muscular and subcutaneous fat tissues of Nellore steers fed pasture with crude glycerin.

E. San Vito,* T. T. Berchielli, J. F. Lage, E. E. Dallantonia, L. M. Delevatti, C. S. R. Junior, R. G. Canesin, M. Machado, A. F. Ribeiro, R. A. Silva, and R. A. Reis, *Universidade Estadual Paulista "Júlio de Mesquita Filho," Jaboticabal, São Paulo, Brazil.*

The aim of this work was to evaluate the deposition of muscular and subcutaneous fat tissues of steers fed crude glycerin (CG) on pasture. The rib eye area (REA), the rib fat thickness between the 12th and 13th ribs (RFT) and the subcutaneous fat thickness in the region P8 (P8) of growing Nellore steers under grazing in the dry season were evaluated, supplemented with different levels of crude glycerin. The CG used was derived from soybean biodiesel production (80% glycerol). Fifty Nellore steers with initial shrunk body weight of 279.52 ± 16.31 kg were used, distributed in 5 treatments in a completely randomized design. The animals were distributed in 10 paddocks, with 1.8 ha each (2 paddocks per treatment), of *Brachiaria brizantha* 'Xaraés'. Treatments were constituted by 5 levels of CG inclusion in the supplement: (0, 7, 14, 21 and 28% of CG based on dry matter) as a substitute to the corn grain. The animals were supplemented daily in a proportion of 0.7% of body weight, and it contained 40% of crude protein based on dry matter. The supplement was constituted of corn grain, soybean meal, urea, gluten meal and mineralized salt. The experiment was executed in 136 d. The measurements were done in the beginning of the experiment and in each 28 d, through the use of ultrasound, to evaluate the deposition of muscular and subcutaneous fat tissues. Data was analyzed using the MIXED procedure of SAS program. There was no statistical significance ($P > 0.05$) among the treatments, and the final observed average values were: 61.5 cm^2 to REA, 2.4 mm to P8 and 2.0 mm to RFT. The gain observed in the variables (initial value – final value) AOL, P8 and SFT were of 18.2 cm^2, 0.57 mm and 0.47 mm, respectively. Crude glycerin can be a substitute to corn grain up to 28% in supplements to growing Nellore steers on pasture, without affecting animals' muscular and subcutaneous fat tissues growth.

Key Words: growth, forage, ultrasound

M256 Differences in residual feed intake are largely associated with changes in body weight gain composition.

M. L. Nascimento*[1], A. R. D. L. Souza[1], R. R. Tullio[2], M. M. Alencar[2], A. N. Rosa[3], and D. P. D. Lanna[1], *[1]University of Sao Paulo, Piracicaba, São Paulo, Brazil, [2]Embrapa Cattle Southeast, São Carlos, São Paulo, Brazil, [3]Embrapa Beef Cattle, Campo Grande, Mato Grosso do Sul, Brazil.*

Residual feed intake (RFI) is defined as the difference between observed and predicted intake (predicted from the average weight and daily gain). RFI has been proposed as an index for genetic selection, however differences in body composition were pointed as a limiting factor in genetic selection based on RFI. The objective of this work was to study the relationship between RFI and gain composition in Nellore steers. Two hundred and 81 Nellore steers, progeny of 30 2 bulls, were individually fed for a minimum period of 70 d. The diet contained 2.8 Mcal ME/kg DM and 13.5% crude protein and was supplied twice a day for ad libitum intake. The animals were classified in low, medium and high RFI (mean ± 0.5SD) and then extreme classes were compared. Results are presented on the table below. The high RFI animals retained 0.7 Mcal/day more energy than the low RFI animals ($P < 0.05$). Therefore the change in estimated body weight composition explained 37.4% of the 1.54 kg/d difference in feed intake between high and low RFI classes. This effect is far greater than the 5% suggested in the literature by different authors based on regression analysis.

Table 1.

	Low RFI	High RFI	Mean ± SD
RFI, kg/d	0.79^{a}	-0.78^{b}	−0.06 ± 0.04
Gain, kg/d	1.35	1.37	1.33 ± 0.02

M257 Effects of trehalose on performance and morbidity of newly received beef steers. E. M. Domby,* C. H. Ponce, J. S. Schutz, and M. L. Galyean, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Trehalose is a disaccharide that has been previously associated with decreased oxidative stress in dairy cattle. The use of trehalose as a dietary supplement for newly received beef steers has not been investigated. Our objective was to evaluate the effects of trehalose concentration in the diet on performance and morbidity from bovine respiratory disease (BRD). One hundred and 24 steers (average initial BW = 182.1 kg ± 3.69 kg) purchased from auction markets in southwest Missouri were received, routinely processed (vaccinations, deworming, and metaphylactic antibiotic treatment), housed in 12 pens (10 to 11 steers/pen), and fed a 65% concentrate, steam-flaked corn-based receiving diet during a 28-d receiving period. Treatments were 0 (Control), 1, or 2% trehalose (% of dietary DM; Cargill Health and Nutrition, Minneapolis, MN). Initial BW did not differ ($P = 0.605$) among treatments. Similarly, final (d 28) BW was not affected by treatments ($P = 0.779$), and there were no differences ($P > 0.420$) among treatments for ADG, DMI, or G:F for d 0 to 14 or for the overall 28-d period. Only 7 steers were treated for BRD (5.6% total morbidity; 2, 1, and 4 steers from the Control, 1, and 2% trehalose treatments, respectively). Because of the low numbers of morbid steers, morbidity data were not analyzed statistically. Results from this experiment suggest neither positive nor negative effects on short-term receiving period performance or BRD morbidity with dietary supplementation of 1 or 2% (DM basis) trehalose in a steam-flaked corn-based receiving diet.

Key Words: newly received beef cattle, trehalose, bovine respiratory disease

M258 Performance of fattening steers on Marandu pasture supplemented with levels of total digestible nutrient in the water season. J. F. W. Koscheck[1],* J. T. Zervoudakis[1], L. K. Hatamoto-Zervoudakis[1], L. S. Cabral[1], A. A. Oliveira[1], J. M. B. Benatti[1], D. M. G. Carvalho[1], and R. P. Silva[1], [1]*Federal University of Mato Grosso, Cuiabá, MT, Brazil.*

This study aimed at evaluating the performance of cattle supplemented with different levels of total digestible nutrients (TDN), fattened on *Brachiaria brizantha* ‘Marandu’ pasture. The experiment lasted 84 d and was conducted in an area with 4 paddocks of 1.45 ha, provided with covered water fountains and feed troughs. Twenty (20) uncastrated male steers with 24 mo of age and initial live weight average of 418.48 ± 6.95 kg were used. Animals were distributed in total randomized design with 4 supplements and 5 replicates. Supplements were composed of mineral mixture, ground grain corn, soybean hulls, roasted soybeans and urea. Supplements to levels of 800, 1600 and 2400 g/animal/day, containing respectively 500, 1000 and 1500g of TDN, called S500, S1000, S1500, were provided to fulfill 300 g of crude protein (CP)/animal/day, besides the control group which received only mineral mixture. Availability of forage mass, dry matter potentially digestible and the CP content of the forage were 5.45, 3.53 t/ha and 10.59%, respectively. For the supplements S1000, S1500, S500 and MM the animal weight gain was respectively 1.071 ± 0.062; 0.960 ± 0.102; 0.914 ± 0.094 and 0.671 ± 0.079 kg/day, statistical difference was verified through orthogonal contrast only between the supplement MM and the other supplements ($P < 0.05$). The increase in the level of supplementation, with consequent increase in the supply of extra TDN, was unable to generate positive response in animal weight gain, between supplemented animals. The common characteristic between the supplements was the amount of CP provided to each animal (300 g), which probably was the key point to get superior performance compared with animals not supplemented. The supply of multiple supplements that provide 300 g of CP/animal/day,for fattening cattle during the summer promotes additional gain of 311 g/animal/day in relation to the supply of mineral mix, which is important to get a short cycle of beef production.

Key Words: beef cattle, supplementation, weight gain

M259 Different supplementation strategies to grazing beef cattle in Brazil. H. O. A. Santana[1], H. J. Fernandes*[1], M. A. Rezende[3,2], G. L. D. Feijó[2], A. Aguiar[4], E. P. Rosa[1], C. N. F. Guaraldo[1], and J. A. da Costa Lima[1], [1]*State University of Mato Grosso do Sul, Aquidauana, MS. Brazil,* [2]*EMBRAPA Beef Cattle Center, Campo Grande, MS. Brazil,* [3]*Federal University of Grande Dourados, Dourados, MS. Brazil,* [4]*University of Florida, Gainesville.*

The objective of this study was to evaluate the effect of different supplementation strategies on the final weight and carcass characteristics of young Nellore bulls grazing *Panicum maximum* ‘Mombaça’ pastures during 426 d. Thirty-two bulls (287 ± 17.8 kg), were randomly distributed in 4 pastures, with 2.5 ha each. Treatments were: mineral supplementation (Control), continuous concentrate supplementation, concentrate supplementation on dry season, and compensatory gain (concentrate supplementation on rainy season). Concentrate supplement contained corn, soybean meal and urea (27.6% of CP and 79.8% of TDN) and was supplied at 0.5% of body weight. Mineral supplement was supplied ad libitum. At the beginning and at the end of the trial, animals were weighted (to calculate the average daily gain, ADG) and, at the end, ultrasound measurements of loin eye areas (LEA), fat thickness at the 12th rib (FTR) and at the P8 rump site (FT8) were taken. The effect of the concentrate supplementation, of the continuous or tactical (just in part of the year) concentrate supplementation, and of the season of the tactical concentrate supplementation were evaluated by the partition of the sum of squares of treatment in orthogonal contrasts. LEA and FTR did not differ (Table 1). Treatments did not affected the initial body weight ($P > 0.10$). Concentrate supplementation and continuous supplementation strategy increased the ADG and the FT8 of the animals. This result pointed to a greater sensitivity of the P8 site to assess the differences in fat deposition in the carcass, or to a difference in the site of fat deposition in animals submitted to different supplementation strategies.

Table 1. Final weight and carcass traits according to the supplementation strategy

		Conc. suppl.				*P*-value		
	Control	Dry season	Compensatory gain	Continuous	CV, %	Conc	Continuous or tactial conc.	Season of tactical suppl.

M260 Determination of net energy requirements of growing Nellore cattle.

S. L. Posada[1], A. L. C. C. Borges*[2], R. R. Noguera[1], N. M. Rodríguez[2], R. R. Silva[2], C. G. Pancoti[2], and H. F. Lage[2], [1]*Universidad de Antioquia, Medellín, Antioquia, Colombia,* [2]*Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

In 1968 Lofgreen and Garrett introduced a net energy (NE) system designed for use in beef cattle, adopted by NRC (1996). Their equations were developed using *Bos Taurus* cattle. The objective of this study was to determine the NE requirements for maintenance and weight gain in growing Nellore cattle by calorimetry. Five Nellore bulls were confined at the Federal University of Minas Gerais (Belo Horizonte, Brazil), receiving *Cynodon* spp. hay, corn and soybean meal, from 200 to 450kg BW. Heat production (HP) was quantified by open circuit indirect calorimetry at 3 feeding levels: ad libitum, restricted and fasting. The Brouwer (1965) equation was used to estimate HP resulting from respiratory exchange and urinary nitrogen excretion: HP (kcal) = $3.866\ O_2 + 1.200\ CO_2 - 0.518\ CH_4 - 1.431\ N$. NE_m requirement was determined by linear regression between the log of HP and the metabolizable energy intake (MEI) for the ad libitum and restricted levels and also by measuring the fasting heat production (FHP) of the animals. The NE_g requirement was calculated by the difference between MEI and HP during ad libitum feeding. Data were analyzed by a repeated-measures design, using the PROC MIXED procedure of SAS (2001). The NE_m and NE_g requirements are shown in Table 1. Lofgreen and Garrett (1968) found 77 kcal/kg $EBW^{0.75}$ for NE_m, which was lower than the values found. NE_m requirements showed a decreasing trend with increasing BW. That could be explained by lower weight proportion of organs and body protein as age increases. Retained energy (ER, NE_g) values (kcal/kg $EBW^{0.75}$) obtained were within the range described by Lofgreen and Garrett (1968).

Table 1. Energy requirements (in kcal/kg EBW0.75) for maintenance (NEm) and gain (NEg) in experimental periods

	Period							
	1		2		3		4	
Item	Mean	SD	Mean	SD	Mean	SD	Mean	SD

M261 Supplementation of fattening steers on Marandu pasture in the summer: intake and digestibility.

J. W. K. Koscheck[1],* J. T. Zervoudakis[1], L. K. Hatamoto-Zervoudakis[1], L. S. Cabral[1], A. A. Oliveira[1], J. M. B. Benatti[1], D. M. G. Carvalho[1], R. P. Silva[1], and R. G. F. Silva[1], *Federal University of Mato Grosso, Cuiabá, MT, Brazil.*

The objective was to evaluate intake and digestibility on fattening cattle on Marandu grass pastures supplemented with different levels of the total digestible nutrients (TDN). Four cattle, with an initial average weight of 512kg, rumen fitted and distributed in 4 paddocks, in 4x4 Latin square design, were used. The supplements were composed of mineral mixture, ground grain corn, soybean hulls, toasted soybean grain, and urea. Supplements to levels of 800, 1600 and 2400 g/animal/day, containing respectively 500, 1000 and 1500g of TDN, called S500, S1000, S1500, were provided to fulfill 300 g of crude protein (CP)/animal/day, besides the control group which received only mineral mixture. Each period lasted 17 d, 5 d for adaptation and forage collecting and 9 d for evaluation of the intake and digestibility. To estimate the intake, chromium oxide was used as external indicator and the indigestible NDF as internal indicator. Collecting of feces was made in 3 d at different collection times. SNK test was used for averages comparison. There was no statistical difference in the total dry matter intake (TDMI) and dry matter intake of pasture; however, there was a numerical increase in the TDMI with a trend to the replacement in the intake of forage for supplement. The intake of ethereal extract (EE) and non-fibrous carbohydrates (NFC) was higher for the animals fed with S1500 ($P < 0.10$), which can be explained by the increased supply of supplement.

Table 1. Intake and digestibility of cattle supplemented with levels of TDN

	Supplements				
	MM	S500	S1000	S1500	CV (%)

M262 Performance, feed efficiency and ultrasound carcass traits of Nellore cattle with different classes of residual gain.

M. H. A. Santana*[1], R. C. Gomes[2], S. L. Silva[1], J. B. S. Ferraz[1], and P. R. Leme[1], [1]*College of Animal Science and Food Engineering, University of São Paulo, Pirassununga, SP, Brazil,* [2]*State University of Londrina, Londrina, PR, Brazil.*

The residual gain (RG) was proposed as a measure that estimates the weight gain according to feed intake and body weight (Koch et al., 1963; J. Anim. Sci., 22:486). With the objective to verify the differences between RG classes in performance, feed efficiency and ultrasound carcass traits in Nellore cattle (bulls n = 141, 21-mo old 385 kg initial BW; steers n = 224, 20-mo old, 350 kg initial BW), we computed the average daily gain (ADG), dry matter intake (DMI), feed conversion ratio (F:G), residual feed intake (RFI) and the gain of ribeye area (GREA), gain of backfat thickness (GBFT) and gain of rumpfat thickness (GRFT) measured by ultrasound. Residual gain was calculated by regression of ADG in DMI, metabolic BW (BW superscript 0.75), contemporary group, and sex. The animals were divided into 2 classes according the standard deviation of RG (high > 0.5 SD and low < 0.5 SD). The RG class effect was analyzed by ANOVA and the means were compared with Tukey test with a 5% probability level. Only the DMI, as expected, did not differ ($P > 0.05$) between the RG classes as well as GREA. The high RG group had ($P < 0.05$) higher ADG, GBFT and GRFT and lower F:G and RFI when compared with low RG group. An improvement in the RG may increase the deposition of fat on the carcass, the weight gain and improving feed efficiency without affecting the feed intake.

Key Words: growth, *Bos indicus*, intake

M263 Effect of diet type on the expression of genes regulating ruminal epithelium function of cattle.

A. K. Kelly*[1], S. M. Waters[2], K. Keogh[1,2], E. O'Shea[1,2], and D. A. Kenny[2], [1]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland,* [2]*Teagasc, Animal Bioscience Department, Dunsany, Co. Meath, Ireland.*

The objective of this study was to investigate the effect of varying dietary concentrate to forage content on the expression of genes encoding for enzymes involved in the absorption and metabolism of VFA, ion transporters and transcription factors in ruminal epithelial tissue of cattle. Forty-eight Holstein-Friesian bull calves were assigned to one of 3 post-weaning dietary regimens; namely, grazed pasture only (n = 17; G); pasture plus 2 kg DM of concentrate (n = 16; GC) or ad-libitum concentrate plus 1 kg of straw (n = 15; C), fed indoors. Animals were slaughtered at 8 mo of age and ruminal epithelial tissue was harvested from the ventral sac of the rumen. Tissue from 10 animals per treatment was then selected for use in the current study. Total RNA was extracted and primers were designed to amplify specific regions of 25 genes involved in ruminal absorptive metabolism. Samples of rumen digesta were also collected at slaughter for VFA analysis, determined using gas chromatography. Ruminal VFA concentration was greatest for C and similar for G and GC. Acetic acid was highest for G and lowest for C (63.1 v 55.3 mol/mol VFA; $P < 0.05$). Conversely, propionic acid concentrations were greatest for C and lowest for G (32.1 v 23,2 mol/mol VFA; $P < 0.05$). The ratio of acetic:propionic was highest for G and lowest for C. There was no difference between dietary treatments ($P > 0.10$) for N-butyric, Iso-valeric or N-valeric acids. mRNA expression for Acetyl-CoA-Synthetase was greatest for C, intermediate for GS and lowest for the G treatments. Differences in expression was also detected between treatments ($P < 0.05$) for key genes involved in the ketogenesis pathway viz. Acetyl-CoA-Trans, HMGL, BDH1 and BDH2. An effect of diet type ($P < 0.05$) was also observed for genes involved in cholesterologenic homeostasis, namely ACAT2, HMGCS2 and ABCA1, with higher expression detected for C compared with GC, which in turn was higher than G. Interestingly, similar dietary effects were also observed for transcription factors PPAR-α and SREBP2 believed to regulate these biochemical events. Moreover, the relative expression values for the ion transporters NHE2, and NHE3 were greatest for C, lowest for G and intermediate for GC. These results suggest that the biochemical pathways involved in ion exchange and VFA metabolism, in particular ketogenesis and associated regulatory transcriptional coordinators were upregulated in rumen epithelial tissue, in a linear fashion, with increased concentrate allowance. This study provides further evidence for the elucidation of the molecular mechanism regulating ruminal absorptive metabolism.

Key Words: VFA metabolism, rumen, nutrient absorption

M264 Correlations between arrival plasma amino acid concentrations and feedlot performance and effects of arrival sex and antibiotic treatments in high-risk calves.

C. L. Maxwell*[1], S. J. Terrill[1], J. W. Dillwith[2], R. D. Madden[2], M. L. May[3], G. K. Kim[3], S. L. Parr[3], C. W. Booker[3], C. R. Krehbiel[1], and L. O. Burciaga-Robles[3], [1]*Department of Animal Science, Oklahoma State University, Stillwater,* [2]*Department of Entomology and Plant Pathology, Oklahoma State University, Stillwater,* [3]*Feedlot Health Management Services Ltd., Okotoks, AB, Canada.*

Data from 2 experiments was pooled and used to determine correlations between arrival plasma AA concentrations and 60 d feedlot performance, and the effects of arrival sex (Bull vs. Steer) and antibiotic treatment (Trt vs. No Trt) on arrival AA concentrations. Beef calves (n = 281; BW = 259 ± 9.5 kg) were processed and administered metaphylactic treatment for control of BRD. Bulls were elastrated and all animals were allocated to individual feed intake systems (40 animals/pen; GrowSafe Systems, Ltd., Airdrie, Canada) and fed for 60 d. Cattle were observed by trained personnel for detection and treatment of disease. Twenty-three calves were administered an antibiotic treatment, and 33 bulls were elastrated. Pearson correlation coefficients were calculated using PROC CORR (SAS 9.3, Cary, NC) examining the relationship between arrival AA concentration and 60 d feedlot performance. The effects of sex and antibiotic treatment on AA concentration were analyzed using PROC GLIMMIX. Animal was the experimental unit, and the model included the fixed effect of treatment and the random effects of pen and sex nested within trial. For all cattle, glutamic acid had a negative correlation to DMI, ADG, and G:F (−0.185, −0.307, −0.272, respectively; $P < 0.05$) for the 60 d period. Serine, alanine, and 4-hydroxyproline had negative correlations ($P < 0.05$), and glycine, leucine, ornithine, and histidine had positive correlations ($P < 0.05$) to d 0–60 G:F. For calves treated, leucine and isoleucine concentrations tended to be increased ($P \leq 0.12$) compared with calves never treated. Calves that arrived as bulls had higher total, gluconeogenic, branched-chain, aromatic, and non-essential AA concentrations ($P < 0.05$) than those that arrived as steers. These data indicate that a relationship exists between arrival AA concentrations and feedlot performance, and AA concentrations are increased in bulls compared with steers. However, there appears to be no relationship between arrival AA concentrations and subsequent antibiotic treatment.

Key Words: amino acid concentration, BRD, feedlot performance

M265 Evaluation of the acid insoluble ash technique as a method for determining apparent diet digestibility in beef cattle.

E. J. Mc Geough*[1,2], D. A. Kenny[2], and P. O'Kiely[1], [1]*Teagasc Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, Ireland,* [2]*School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Dublin, Ireland.*

The objective was to determine if the acid-insoluble ash (AIA) method provided accurate estimates of in vivo apparent diet digestibility compared with the standard total fecal collection (TFC) method. Twelve Holstein-Friesian steers, mean LW 328 (SD 27.3) kg, were assigned to 1 of 3 blocks on a descending LW basis and randomly allocated, from within block, to 1 of 4 diets based on either whole-crop wheat (WCW) or grass silage (GS) in a 4 × 4 Latin square design. The 3 WCW silages were based (DM basis) on ratios of grain to straw plus chaff as follows: 11:89, 26:74 and 47:53. The fourth treatment was GS. Each period within the Latin square was 28 d, with all silages offered for ad libitum consumption for 15 d after which time, the amount of silage offered to each animal was limited to 0.90 of its ad libitum intake. A concentrate supplement (2.60 kg) was offered to each animal in a single feed daily.

For the last 10 d in each period diet digestibility measurements were undertaken. TFC was carried out at 08.00 h, with AIA fecal sampling carried out simultaneously. For the AIA method, fecal grab samples (200 g) were obtained per rectum and pooled for each animal at the end of the measurement period. All feed and fecal samples were assayed for DM, NDF, ADF, CP, and starch. The 2 methods were compared using graphical representation on an agreement plot and by computing a total deviation index ($TDI_{0.9}$) and coverage probability ($CP_{0.06}$). Computation was carried out using the SAS macro of Lin et al. (2002), available at http://www.uic.edu/. The $TDI_{0.9}$, which is an estimate of the deviation that covers 90% of the digestibility measurements, was 0.08 for apparent DM digestibility, with a $CP_{0.06}$ estimate of 0.75, indicating that 75% of the observations fell within the previously specified error limit of 0.06. Upon removal of GS from the analysis, the strength of the agreement between the 2 methods was increased ($TDI_{0.9} = 0.06$ and $CP_{0.06} = 0.89$). Thus, it may be concluded that the AIA method is a useful method to determine diet digestibility given the proportion of measurements that fell within the pre-specified range of acceptability.

Key Words: acid insoluble ash, total fecal collection, beef cattle

M266 Feedlot performance and carcass traits of Nellore cattle as affected by sex condition and frame size.

S. L. Silva*[1], R. C. Gomes[2], M. N. Bonin[1], L. S. Martello[1], P. L. Alvarez[1], L. S. Oliveira[1], M. R. Mazon[1], J. C. M. Nogueira Filho[1], J. B. S. Ferraz[1], and P. R. Leme[1], [1]*Universidade de São Paulo, Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brazil,* [2]*Dep. Zootecnia, Universidade Estadual de Londrina, Londrina, PR, Brazil.*

Use of non-castrated (NC) males for red meat production has been a common practice in Brazil because they grow fast, utilize feed more efficiently and show high-yielding and leaner carcasses when compared with castrated males (CM). The objective of this work was to investigate the effects of sex condition and frame size (FS) on feedlot performance and carcass traits of finishing *Bos indicus* steers and bulls. Nellore bulls (n = 119; 372 ± 32kg LW) and steers (n = 122; 351 ± 36 kg LW) averaging 20-mo old, were tested for feedlot performance, being fed high-grain diets (85% of concentrate) for 56 to 140 d. Individual DMI, ADG and G:F were recorded. At the beginning of each test, animals were weighed (LW) and hip height was measured to calculate FS. In 28-d intervals, animals were weighed and ultrasound scanned for determinations of LM area (LMA) and backfat thickness (BFT) between 12th/13th ribs. At the end of test period, animals were slaughtered and hot carcass weight (HCW) and kidney, pelvic and inguinal fat (KPIF) were registered. Animal FS ranged from 4 to 9. Data was analyzed by ANOVA with year (block), FS and sex as fixed effects and time on feed (test length) as covariate. At the beginning of feedlot period, NC were heavier (369 vs 351 kg), had greater LMA (61.6 vs 59.9 cm^2) and lower BFT (0.5 vs 1.4 mm) than CM ($P < 0.0001$), respectively. Also had higher ADG (1.86 vs 1.58 kg/day), DMI (10.7 vs 10.3 kg/day) and G:F (0.176 vs 0.155 kg ADG/kg DMI) than CM ($P < 0.0001$). Steers had smaller HCW than NC (292.7 vs 320 kg, respectively) but they did not differ in dressing percentage (59.3%). Steers had higher KPIF (3.6 vs 2.8%) and BFT at slaughter (5.6 vs 4.4 mm) than NC, respectively, but they had greater final LMA than CM (79.8 vs 74.1 cm^2, respectively). FS was positively and linearly associated to initial and final LW, G:F and HCW ($P < 0.0001$) but did not affect other traits. Non-castrated and large FS finishing animals may be more profitable due to their greater weight gain and G:F. When fed high concentrate diets, NC Nellore males present carcass with adequate BFT to the meat industry.

Key Words: beef cattle, *Bos indicus*, feedlot

M267 Evaluation of a rapid determination of heat production and respiratory quotient in Holstein steers using the washed rumen technique.

D. H. Kim*[1], K. R. McLeod[1], J. L. Klotz[2], A. F. Koontz[1], A. P. Foote[1], and D. L. Harmon[1], [1]*University of Kentucky, Lexington,* [2]*USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

The objective of this study was to validate use of the washed rumen technique for rapid measurement of fasting heat production (FHP) and respiratory quotient (RQ), and compare this with heart rate (HR) and core temperature (CT). The experiment used 8 Holstein steers (322 ± 30 kg) under controlled temperature (21°C) as follows: 10 d diet adaptation, 1 d measurement of respiratory gases at $1.5 \times NE_m$ (Unwashed rumen), 1 d measurement of respiratory gases at fasting (Washed rumen), and 7 d for re-establishing intake. Steers were offered alfalfa cubes top-dressed with a mineral pre-mix at $1.5 \times NE_m$. At the day of measurement the reticulorumen was washed and refilled with ruminal buffer ($NaCl = 96$; $NaHCO_3 = 24$; $KHCO_3 = 30$; $K_2HPO_4 = 2$; $CaCl_2 = 1.5$; $MgCl_2 = 1.5$ mmol/kg of buffer) that was gassed with a mixture of 75% N_2 and 25% CO_2 before incubation in the rumen. Mean daily CT between unwashed and washed rumen were not different (Table 1). Mean daily HR and HP were lower for washed rumen than for unwashed rumen ($P < 0.001$). RQ was lower for washed rumen and there was an interaction ($P < 0.001$) with sampling hour. To define the plateau of RQ, dependence of RQ rate and hour on unwashed and washed rumen was fitted by a one-phase decay equation. The plateau of RQ values were calculated at 0.87 ± 0.01 and 0.72 ± 0.01 for unwashed and washed rumen, respectively. The RQ decreased to approximately 0.7, by 8 h after washing the rumen. This approach may provide an alternative to the traditional 48 h fasting time, or measurements made during the third and fourth day after starvation. Applying the washed rumen technique may be more rapid and less stressful means to predict energy required for maintenance in cattle.

Table 1. Comparison of washed and unwashed rumen models

				P-value		
Item	Unwashed	Washed	SEM	Treatment (T)	Hour (H)	T × H

M268 Effects of lipid sources on intake and digestibility of beef cattle finished at pasture.

I. P. C. Carvalho*[1,3], T. T. Berchielli[1,2], G. Fiorentini[1,3], J. F. Lage[1,3], Y. T. G. Salcedo[1], H. V. Brandt Filho[1], L. G. Rossi[1], C. S. Ribeiro Junior[1,3], and L. M. Delevatti[1], [1]*Universidade Estadual Paulista Julio de Mesquita Filho, Jaboticabal, Brazil,* [2]*INCT/CA member, Brazil,* [3]*FAPESP Fundação de Amparo a Pesquisa do Estado de São Paulo, São Paulo, Brazil.*

This study was carried out to evaluate the effects of lipid sources in supplements on intake and apparent digestibility of finishing beef steers kept at pasture. Forty-five Nellore steers (initial average body weight of 440kg) were assigned to 5 treatments on a completely randomized design. The animals were divided in to 10 paddocks (2 paddocks per treatment) of *Brachiaria brizantha* 'Xaraés'. Different lipid sources (linseed oil, palm oil, soybean grain and calcium salts; Lactoplus) was added to the supplements (100 g/kg DM) and offered at 1.0% body weight. The control treatment was composed of a corn and soybean meal supplement with no additional fat. All the concentrate contain 200 g/kg crude protein (CP) and 100 g/kg ether extract (EE) (except the control supplement, which contained 30 g/kg EE). External markers were used to estimate fecal excretion (LIPE) and individual supplement intake (titanium dioxide, TiO_2).Calculation of dry matter intake was performed by using indegradable neutral detergent fiber (iNDF) as internal marker. The treatments were compared by analyzing variables using the GLM procedure (SAS 9.1, SAS Institute Inc., Cary, NC). Dry matter intake (DMI), pasture intake (PI) and supplement intake (SI) were not affected by the lipid sources ($P < 0.05$), with average values of 11.87, 6.87 and 4.81 kg/animal per day, respectively. The addition of linseed oil decreased dry matter and organic matter apparent digestibility ($P < 0.05$). This oil also lessen CP apparent digestibility ($P < 0.05$) relative to the other lipid treatments. Palm oil and Linseed oil presented a negative effect on neutral detergent fiber digestibility ($P < 0.05$). These results suggested that the addition of linseed oil on supplements for grazing beef cattle impair nutrient utilization, and the addition of palm oil decrease fiber degradation.

Table 1. Least squares means for apparent digestibility (g/100 g)

	Control	Palm oil	Linseed oil	Calcium salts	Soybean grain	CV (%)	*P*-value
DM	60.79^{a}	59.83^{a}	55.01^{b}	61.13^{a}	61.27^{a}	5.06	0.0007
OM	65.57^{a}	64.27^{a}	60.53^{b}	66.12^{a}	65.89^{a}	3.79	0.0006
NDF	59.23^{a}	46.17^{b}	48.20^{b}	61.87^{a}	62.04^{a}	6.16	<0.0001

M269 Nutrient mass balance and performance of feedlot cattle fed barley segregated by near infrared spectroscopy.

E. M. Hussey, C. F. O'Neill,* R. E. Peterson, L. O. Burciaga-Robles, and M. L. May, *Feedlot Health Management Services Ltd., Okotoks, AB, Canada.*

Crossbred yearling heifers (n = 9,617, 32 pens, 269 ± 6 kg initial BW, days on feed = 229) were assigned randomly at feedlot arrival to one of 2 treatments: LOW or HIGH starch:NDF barley. Barley was determined to be HIGH (starch:NDF >3.25) or LOW (starch:NDF <3.25) at feedlot arrival based on values determined by Near Infrared Spectroscopy. The objective was to evaluate the impact of HIGH or LOW barley on feedlot performance, animal health, carcass characteristics, and N and P mass balance. Data were analyzed using the GLIMMIX procedure of SAS, with fixed effect of treatment and random effect of replicate. Intake was 0.2 kg/d greater ($P < 0.01$) for LOW barley compared with HIGH. Gain and final BW were greater ($P < 0.01$) for LOW on a live and carcass adjusted basis, but G:F was not different ($P \geq 0.30$). Carcass weight, 12th rib fat, and marbling score were greater ($P < 0.01$) for LOW barley compared with HIGH. Percentage of carcasses grading USDA Choice was greater ($P < 0.01$) and percentage grading USDA Standard was lower ($P < 0.01$) for LOW barley compared with high, whereas the percentage of carcasses grading USDA Prime or Select was not different ($P \geq 0.36$). Feeding LOW starch:NDF barley decreased ($P < 0.01$) the percentage of YG 2 carcasses, increased ($P < 0.01$) the percentage of YG 3 carcasses, and tended to increase ($P = 0.07$) the percentage of YG 4 carcasses. No differences ($P \geq 0.19$) in morbidity outcomes were observed. Overall mortality was similar ($P = 0.79$) between the 2 barley treatments, but mortality due to miscellaneous causes was greater ($P = 0.03$) for LOW compared with HIGH. Intake, retention, and excretion of both N and P were greater ($P < 0.01$) for LOW, but removal of N, P, DM removed, as well as N and P lost were not different ($P > 0.60$) between the 2 treatments. Feeding low starch:NDF barley improved feedlot performance and carcass characteristics, had a slight negative impact on animal health, but had no effect on N and P losses.

Key Words: barley, feedlot performance, mass balance

M270 Development of a fecal starch index to predict the feeding value of barley grain for feedlot cattle.

W. Z. Yang* and T. A. McAllister, *Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Fecal starch content is considered to be a good indicator of the utilization of grain by cattle fed high-grain diets. However, an accurate and rapid method for determining the starch content of feces is lacking. The objective of this study was to evaluate the relationship of in vitro gas production (GP) from feces with differing residual starch content to in vivo digestibility in an effort to develop a rapid indirect method to assess the residual starch content. Thirty-two fecal samples were collected from beef cattle in a replicated 4 × 4 Latin square study in which barley grain was processed so as to deliberately introduce variation in ruminal fermentation and total tract digestibility. Fecal samples were used as substrates in vitro. Gas production was recorded at 3, 6, 9, 15, 24, 36, 48 h and DM disappearance (DMD) was measured at 24 and 48 h of incubation. Pearson correlation coefficients of GP with fecal contents (N, NDF and starch) and in vivo feed digestibility were estimated using the CORR procedure of SAS. Ruminal contents (RI) or feces (FI) collected from 2 ruminally cannulated steers were used as inocula. Gas production (ml/g DM) was lower ($P < 0.01$) with FI than RI at 24 h (172 vs. 331) and 48 h (214 vs. 341). Dry matter disappearance was also lower ($P < 0.01$) with FI than with RI at 24 h (23 vs. 24%) and at 48 h (26 vs. 30%). In contrast, starch disappearance was higher ($P < 0.01$) with FI than with RI at 24 h (96 vs. 91%) and 48 h (99 vs. 97%). When using RI, there was no correlation of GP with either fecal starch content or in vivo starch digestibility, but there was a moderate correlation with fecal NDF content ($r = 0.45$; $P < 0.02$). However, when using FI, there was a positive correlation of GP with fecal starch content ($r = 0.5$; $P < 0.02$), and negative correlation with in vivo starch digestibility ($r = -0.48$; $P < 0.01$). The results suggest that GP from feces, using FI as an inoculum may be a good indicator on variation of residual energy value of feces. However, GP alone may not be a reliable indicator for assessing the residual starch content of feces.

Key Words: fecal starch, gas production, in vitro

M271 Effect of direct-fed microbials on utilization of ruminally degradable protein in receiving steers.

N. M. Kenney,* C. A. Schaeffer, E. S. Vanzant, J. W. Lehmkuhler, D. L. Harmon, and K. R. McLeod, *University of Kentucky, Lexington.*

Direct-fed microbials (DFM) have been shown to alter rumen fermentation, thus response to DFM may be influenced by supply of degradable intake protein (DIP). One hundred ninety-two crossbred beef steers (280 ± 25 kg) were used to determine if DIP supply affects response to DFM in receiving cattle. Treatments were arranged in a 5 × 2 factorial, with 5 levels of DIP (80, 90, 100, 110, 120% of DIP requirement) fed with and without DFM (1 billion cfu/hd). DIP requirement was assumed to be 11% of TDN and diets were formulated to be isocaloric and meet or exceed metabolizable protein requirement. Differences in protein degradability were achieved by altering soybean meal:treated soybean meal (Amino Plus) and urea level. DFM consisted of a mixed bacterial culture, primarily *Lactobacillus acidophilus* and *Enterococcus faecium*. BW was recorded weekly and fecal pH was determined by rectal grab on d 7 and 14. There were no DIP or DFM effects on dry matter intake

across the 56 d study. A DFM by DIP interaction ($P = 0.05$) was observed for ADG during the first 28 d of the trial, which resulted in a tendency for an interaction ($P = 0.08$) over the 56 d trial. In the absence of DFM, ADG was similar across level of DIP, whereas in the presence of DFM, ADG increased with increasing level of DIP in a cubic ($P = 0.08$) fashion. Growth efficiency (DFM×DIP, $P > 0.10$) increased linearly ($P < 0.05$) with increasing level of DIP through the first 28 d, however, this difference was not maintained over the entire 56 d ($P > 0.10$). DFM increased growth efficiency ($P = 0.05$) primarily due to increases in efficiency over the first 28 d ($P < 0.05$) of the study. A DFM by time interaction was observed for fecal pH ($P < 0.05$). In the absence of DFM pH decreased from 6.71 to 6.62 on d 7 and 14, respectively. However, in the presence of DFM there was no change in pH over time (6.64). These data show that DFM improved growth efficiency across levels of DIP, however ADG response to DFM was dependent on DIP supply. This suggests that variable responses of cattle to DFM reported in the literature may be partially explained by DIP supply.

Key Words: cattle, direct-fed microbial, rumen degradable protein

Ruminant Nutrition: Dairy I

M272 Utilizing dietary nutrients to predict nitrogen efficiency in lactating dairy cattle. N. Swanepoel* and P. H. Robinson, *University of California, Davis.*

Proactive approaches, such as monitoring dietary nutrient profiles, are methods for dairy farmers to improve efficiency of nitrogen (N) utilization (NEF) of their dairy cows and prevent excretion of excess N which can be environmentally harmful. On farm NEF (i.e., milk N/feed N) are often 20–33%, but could theoretically reach 38–40% with optimal nutrition of the total mixed rations (TMR) fed to the cows. Commercial practice suggests that formulating rations to balance essential amino acids (EAA) in metabolizable protein (MP) may further improve NEF. Our objective was to determine if analyzable dietary nutrients of 'high group' lactation TMR could be used to predict NEF, and if AA profiles of MP as predicted by 2 metabolic models (i.e., 'CPM Dairy' & 'Shield') would improve that predictability. Nutrient profiles of 16 commercial dairy cow rations were determined and then model evaluated to estimate AA profiles of MP. Correlation analysis was used to determine the predictability of NEF from single analyte levels in the TMR. The most predictive TMR nutrients were starch (ST; $P = 0.07$), crude protein (CP; $P = 0.07$) and potentially digestible CP (DCP; $P = 0.08$). Soluble CP, fat and neutral detergent fiber were non-predictive (i.e., $P > 0.35$). Multiple correlation analysis of all TMR nutrients resulted in the best fitting model being: NEF (%) = 65.7 – 1.60*(CP, %DM) – 0.48*(ST, %DM) [$r^2 = 0.49$]. That most of the predictive power from CP appeared to be from DCP suggests that it may be the EAA profile of MP that influences NEF. Thus model predicted EAA/MP ratios were added to CP and ST as potential predictors in a stepwise procedure. The final multiple prediction equations differed by model. For 'CPM Dairy': NEF(%) = 49.84 – 1.91*(CP, %DM) – 0.59*(ST, %DM) – 21.90*(Met, %MP) + 13.24*(Ile, %MP) [$r^2 = 0.65$] while for 'SHIELD' no EAA were added to the analyte based model (above). Group milk yields were a poor predictor (i.e., $r^2 = 0.05$) of NEF. This evaluation of commercial dairy rations suggests that analyzable components of TMR only predict a low amount of the variation in NEF of dairy cows but that, dependent upon model, addition of predicted EAA/MP ratios may improve it.

Key Words: amino acid, metabolic model

M273 Effects of water iron concentration, valence and source on drinking water preference of lactating cows. O. N. Genther* and D. K. Beede, *Michigan State University, East Lansing.*

Drinking water can contain high concentrations of Fe, mainly of the ferrous (Fe^{2+}) valence. Current recommended upper tolerable concentration of Fe in drinking water for cattle (0.3 mg/L) comes from guidelines for human palatability, but cattle may be able to tolerate greater concentrations. Our objective was to determine the effects of varying concentrations of ferrous (Fe^{2+}) or ferric (Fe^{3+}) iron and Fe-salt source on lactating Holstein cows' preferences for drinking water offered as choices ad libitum. In 4 separate experiments, cows were offered pairs of water treatments for 22-h periods and water intake and drinking behavior were recorded. Data were analyzed by ANOVA. In Experiment 1 treatments were: 0, 4, or 8 mg of Fe/L from ferrous lactate [$Fe(C_3H_5O_3)_2$]. Cows exhibited no preference between water with 0 or 4 mg Fe/L, but water intake tended to be less with 8 compared with 0 or 4 mg Fe/L ($P < 0.10$). Also, cows spent less time drinking water containing 8 mg Fe/L ($P = 0.01$). Total drinking duration (r = 0.62) and frequency (r = 0.55) correlated positively with water intake ($P < 0.05$) when pooled across treatments. In Experiment 2, treatments were: 0 or 8 mg Fe/L from either ferrous sulfate ($FeSO_4$) or ferric sulfate [$Fe_2(SO_4)_3$]. Water intake did not differ among treatments. Treatments in Experiment 3 were: 0 or 8 mg Fe/L from either ferrous chloride ($FeCl_2$) or ferric chloride ($FeCl_3$). Again, cows exhibited no preference among the treatments. Treatments in Experiment 4 were: 0 or 8 mg Fe/L from ferrous lactate, sulfate, or chloride. Cows preferred water without added Fe ($P < 0.05$), but did not exhibit a preference among waters containing the Fe sources with different anionic moieties. Total drinking duration and frequency were less ($P < 0.05$) when offered water containing 8 mg of Fe/L from ferrous chloride compared with ferrous lactate or sulfate. Overall, our results indicate that upon first exposure to drinking water, lactating dairy cows tolerate concentrations of Fe up to 4 mg/L without reducing water intake; however, water intake was reduced with 8 mg Fe/L. Preference was not dependent upon Fe valence or Fe source in our studies

Key Words: dairy cattle, drinking water, iron

M274 Effect of cecum starch infusion on hindgut fermentation and inflammatory response in dairy cattle. S. Li,* H. Khazanehei, E. Khafipour, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

To assess the effect of cecum starch infusion (CSI) on hindgut fermentation and inflammatory response, 4 dry Holstein dairy cows (BW = 610.5 ± 42.7kg) were used in a crossover trial with 2 periods. Each period consisted of 23d of adaptation followed by 3 d of CSI. Dietary treatments were: 100% grass hay diet (HF), or 60% grass hay and 40% concentrate diet (CF) that were delivered ad libitum at 0900 h. On the starch infusion days (d 1 to d 3), cows also received a dose of 600g corn starch suspended in 600mL 0.9% saline via the cecal cannula at 0900. On the day before the first starch infusion (d −1) and 3, blood and fecal samples were collected at 0900 and 1500. DMI was monitored daily. Fecal samples were used to measure pH, VFA, ammonia, and lipopolysaccharide (LPS). Inflammatory markers (serum amyloid-A and haptoglobin) concentrations were measured in peripheral blood. DMI was higher in CF than HF animals and tended to be reduced by CSI. Fecal pH was lower in CF than HF group and was reduced by CSI. Total VFA in the feces was higher in CF than HF animals due to greater molar proportion of butyrate but not that of acetate and propionate. Total VFA and molar proportion of propionate increased but acetate decreased on d 1 after CSI but the effects were disappeared by d 3. Ammonia nitrogen concentration in the feces was similar in both CF and HF animals, and only decreased in the CF group due to CSI. Endotoxin concentrations in the fecal water were similar between treatments, and only increased in CF animals following CSI challenge. Inflammatory markers were not affected by treatment and CSI. Results indicate that the increase in the hindgut

LPS concentration following a CSI challenge is greater when the diet contains more concentrate.

Table 1.

	HF diet		CF diet			*P*-value		
Item	Control	CSI	Control	CSI	SEM	CSI	Diet	CSI× Diet

M275 Hepatic triglyceride concentration and fatty acid profile in early lactation Holstein cows fed saturated medium- or long-chain fatty acids.

M. Hollmann*[1], T. H. Herdt[2,3], J. A. Zyskowski[3], and D. K. Beede[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]Department of Large Animal Clinical Sciences, Michigan State University, East Lansing, [3]Diagnostic Center for Population and Animal Health, Michigan State University, East Lansing.*

Partitioning of medium-chain fatty acids (FA) in lactating dairy cows is not well understood. We examined hepatic triglyceride concentration ([TG]) and FA profile of early lactation cows fed 2 sources of saturated FA. Dietary treatments were: no added fat (CTRL); 2.7% of DM as saturated long-chain FA (Energy Booster 100; EB); 2.7% as mostly saturated, medium-chain FA (coconut oil; CNO); or, a 2.7% mixture of EB and CNO (1:1; INT). CNO diet had 47 g C12:0/kg and 30 g C14:0/kg. CTRL diet contained 36% NDF (77% from forage), 41% NFC, and 16.5% CP, DM basis. Multiparous (MP; n = 36) and primiparous (PP; n = 31) Holstein cows 10 to 14 DIM were fed 1 of 4 treatments for 16 wk. Hepatic tissue was biopsied before treatment diets were fed, and then on d 14, 28, and 112. Main effects of treatment, biopsy day (repeated measure), and their interaction were tested separately for MP and PP by least-squares ANOVA. Dietary CNO concentration increased hepatic [TG] linearly (CNO > INT > EB; $P < 0.001$). In MP, [TG] decreased linearly from d 14 to d 28 and 112 ($P < 0.001$). In PP [TG] was similar across time ($P > 0.05$). Increasing hepatic [TG] related positively to concentrations of C14:0, C16:0, C16:1, or C18:1 *cis*-9 in total hepatic FA, but negatively to C18:0, C18:2, or FA longer than 18 C ($P < 0.01$). Cows fed CTRL or EB had less than 0.1% C12:0 of total hepatic FA. In contrast, CNO increased hepatic C12:0 to 0.9% (MP) or 0.5% (PP) regardless of day of experiment. Hepatic C14:0 accumulated over time with CNO. MP cows fed EB or CTRL vs. INT or CNO had greater increase in C16:0, C16:1, and C18:1 cis-9 as hepatic [TG] increased (interaction of [TG] by treatment; $P < 0.02$). In MP, CNO decreased C18:0 concentration ($P < 0.01$). Concentration of C18:2 *trans*-10 *cis*-12 in hepatic FA accumulated in CNO and over time, presumably indicative of ruminal biohydrogenation. Dietary CNO increased hepatic [TG] in early lactation cows. Greater hepatic accumulation of C14:0 vs. C12:0 (opposite of dietary concentrations) indicates different physiological partitioning of these FA.

Key Words: fatty acid oxidation, fatty liver, coconut oil

M276 Production and metabolic response of lactating dairy cows to heat stress while supplemented with a dietary antioxidant.

A. L. Kenny*[1], Y. M. Wang[2], N. M. Barkley[1], R. R. Rodrigues[1], K. A. Davison[1], G. I. Zanton[2], and M. R. Waldron[1], *[1]University of Missouri, Columbia, [2]Novus International Inc., St. Charles, MO.*

The effect of the antioxidant Agrado Ultra [dry blend of ethoxyquin and propyl gallate] on the production and metabolic response of 24 lactating dairy cows to heat stress was investigated. Holstein cows (153 ± 5 d in milk) were blocked by milk production, body condition and lactation and randomly assigned to 1 of 2 treatments: Control (Soy hulls 6.1 g/cow/day; n = 12) or AOX (Agrado Ultra Dry 6.1 g/cow/day; n = 12). Cows were housed in a free stall barn with access to Calan doors from d −2 to 14 of treatment. Cows were then housed in environmentally controlled rooms for 7 d at thermoneutral temperature (d 15 to 21; Constant at 20°C) and then 14 d of programmed 12 h cyclical heat stress (HS; d 22 to 35; Mean THI range of 72.5 ± 0.1 to 81.3 ± 0.5). Cows were returned to free stalls for 7 d of recovery (d 36 to 43). Plasma and milk were sampled 17 times during the experiment. Rectal temperature was measured daily except during HS (3 times/day). Data were analyzed using SAS by mixed model ANOVA with repeated measures. Pretreatment values were used as covariates if found to be significant. Rectal temperature increased ($P < 0.01$) during HS with a tendency for cows fed AOX to have lower rectal temperatures ($P = 0.09$). Plasma glucose concentration was greater ($P = 0.004$) in the AOX group and also responded to HS differently ($P = 0.02$) than controls. Only changes in time, particularly during HS, were observed for BHBA and NEFA ($P < 0.01$). All milk composition variables decreased during HS except for milk urea nitrogen which increased for 4 d of HS before declining to pre-HS levels by the end of study. Control cows had a greater milk fat yield ($P = 0.02$) and AOX cows had a greater percentage of milk protein ($P = 0.001$). Dry matter intake and milk yield decreased ($P < 0.01$) in both groups during HS. Live weight decreased ($P < 0.01$) by 45 ± 5 kg during the time cows were housed in the environmental rooms. Cows fed an antioxidant had a tendency to respond to HS better with lower rectal temperatures and also had greater plasma glucose concentrations and milk protein concentrations.

Key Words: dairy, antioxidant, heat stress

M277 Effect of supplemental fatty acids on production responses and hepatic fatty acid composition and gene expression of dairy cows fed diets containing low concentrations of fatty acids.

L. F. Greco*[1], M. Garcia[1], B. L. Artiaga[1], E. K. Ganda[1], R. S. Bisinotto[1], F. S. Lima[1], N. Martinez[1], E. S. Ribeiro[1], A. L. Lock[2], W. W. Thatcher[1], C. R. Staples[1], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]Michigan State University, East Lansing.*

Objectives were to evaluate the effects of supplementing diets containing low amounts of long chain fatty acids (FA, < 1.8% DM) with either mostly saturated free FA (SFA, 35% C16:0, and 52% C18:0) or with Ca salts enriched with essential FA (EFA, 27% C18:2 n-6 and 3.5% C18:3 n-3 of the FA) on production responses and hepatic FA composition and global gene expression of Holstein cows. In study 1, prepartum cows were allocated randomly to 1 of 3 dietary treatments from 60 d before to 90 d after calving. Supplementation with FA (% dietary DM) consisted of 0% (CTL, n = 26), 1.7% SFA (n = 25, Energy Booster100), and 1.9% as Ca salts of EFA (EFA, n = 25, Megalac-R). On d 14 postpartum, liver was biopsied and analyzed for FA and global gene expression. Feeding supplemental fat did not affect ($P = 0.35$) the FA content of the liver, but increased ($P = 0.02$) the content of n-6 FA (15.4, 19.0 and 19.3 g/100 g FA, respectively for CTL, SFA and EFA). Feeding EFA increased ($P < 0.01$) the content of total conjugated linoleic acid and C18:1 *trans* isomers in liver. Feeding fat upregulated genes related to T cell activation, antigen receptor-mediated signaling pathway and activation of immune response. In study 2, 30 cows at 12 DIM were allocated randomly to the same treatments as in study 1. The DMI, BW, and milk yield and composition were recorded daily for 10 wk. Supplementing the diet of cows with fat increased yields of milk and milk components, and the response was greater for EFA than SFA (Table 1). Milk composition and BW were not influenced by dietary treatment.

Table 1.

	Treatment				P-value[1]			
Item	CTL	SFA	EFA	SE	TRT	TRT*P	Fat	FA
DMI, kg/d	20.2	21.4	21.4	0.6	0.23	0.42	0.09	0.93

M278 Effect of lactation stage on milk production and milk quality in dairy cows in confinement.

J. A. de Freitas*[1], J. C. de Souza[3], R. P. Lana[2], A. F. G. Neto[1], V. L. Souza[1], and A. L. dos Santos[1], *[1]Federal University of Parana, Palotina, Parana, Brazil, [2]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [3]Federal University of South of Mato Grosso, Aquidauana, Mato grosso do Sul, Brazil.*

Milk is a rich food of high biological quality that presents important substances with anti-carcinogenic action. Some factors can affect the qualitative characteristics and milk production like animal breed, age, stage of lactation, milk production at peak lactation, health and previous nutrition. The study of factors affecting the production and milk quality were very important in economic aspect. The aim of this study was to analyze the influence of lactation stage on production, milk quality, milk production on lactation peak and period of occurrence of peak of lactation. It were used 8700 data from a commercial herd using Holstein cows in the state of Parana, Brazil. The animals were kept under confinement (free stall) during the lactation. The total ration contained 17% of crude protein in DM and the concentrate: silage proportion was 1:1 in DM. The animals were fed and milked 3 times daily. The dependent variables used were: fat correct milk (FCM), milk fat, protein, lactose and total solids (expressed in %), somatic cells count (x1000), milk production (kg), peak of production (kg) and peak occurrence (in days). The dependent variables were submitted to ANOVA using the GLM (Generalized Linear Model) procedure of SAS (2009) and means were compared using a Tukey's test at 5% probability, considering the effect of lactation stage. The percentage of protein, lactose, total solids and peak occurrence did not vary ($P > 0.05$) according to stage of lactation. However, the lactation stage on % of fat, somatic cells count, fat corrected milk and peak of milk production vary ($P < 0.05$) with stage of lactation (Table 1).

Table 1. Percentage of fat, protein, somatic cell counting, total solids (TS) and fat-corrected milk (FCM) as a function of number of lactation for Holstein cows

Lactation stage	Fat (%)	Protein (%)	SCC (x1000)	TS (%)	FCM
1	3.74^{a}	3.17^{a}	92.27^{a}	12.51^{a}	8821.08^{a}
2	3.62^{a}	3.27^{a}	135.79^{a}	12.64^{a}	9692.93^{b}
3	3.56^{a}	3.16^{a}	151.60^{a}	12.89^{a}	10603.43^{b}
4	3.82^{b}	3.12^{a}	194.96^{a}	12.13^{a}	8252.35^{a}
5	4.19^{b}	3.08^{a}	232.15^{b}	12.07^{a}	7379.20^{a}

^{ab}Values in the same column followed by same letter do not differ statistically at 5% probability by the F test.

Key Words: dairy cows, lactation number, milk quality

M279 Comparison of growth curves between two genetic compositions of dairy goats using nonlinear mixed models.

J. G. L. Regadas Filho*[1], M. T. Rodrigues[1], R. A. M. Vieira[2], L. F. Brito[1], and T. S. Oliveira[1], *[1]Universidade Federal de Viçosa, MG, Brazil, [2]Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, RJ, Brazil.*

Studies on the growth curves for animals have been used extensively to examine how body mass and others parameters of interest develop over time and in relation to the environment, genotype, diet management and other factors. The goal of this study was to evaluate which nonlinear model normally used in the literature best describes dairy goat growth, and compare the curve parameters obtained for 2 genetic compositions of dairy goats. Data used in this study were collected from the goat flock of the Universidade Federal de Viçosa, MG, Brazil, 12,573 records were used from 2,476 females collected between 1992 and 2010. Two genetic compositions of dairy goats were assessed: predominantly Alpine (+A; n = 1,458; weighings = 7,335) and predominantly Saanen (+S; n = 1,018; weighings = 5,238). The models evaluated were the Brody, Van Bertalanffy, Richards, Logistic, and Gompertz models. Random effects (μ_1, μ_2, and μ_3 were linked to the β_1 (asymptotic value), β_2 (sigmoidal curve shape parameter), and β_3 (rate of maturing) parameters, respectively. We used dummy variables to estimate curve parameters independently for each genetic composition. Residual variance and the Schwartz Information Criteria were used to evaluate the models. After selecting the model that best describes the growth curves and possesses the variance and covariance matrix previously estimated, we were able to test the equality hypotheses all parameters of the growth curve using the Wald statistic. The Brody model (+A: $\beta_1 = 56.54$; $\beta_2 = 0.9324$; $\beta_3 = 0.00258$; and +S: $\beta_1 = 58.84$; $\beta_2 = 0.9383$; $\beta_3 = 0.00244$) with 2 variance component ($\mu_1 = 23.86$ and $\mu_3 = 4.04\text{E-}07$; $P < 0.001$), provided the best fit to the data. A significant difference was detected between the estimated parameters for the 2 genotypes in selected model ($P < 0.001$). Despite the genotypes have the same origin and are often considered similar in terms of productive animals (only visibly different in their coats), differences have been found in their lactation curves, and now, in this study, in their growth parameters. There are differences in the growth patterns between the 2 genetic compositions.

Key Words: Alpine, Saanen, Wald statistic

M280 Nonlinear mixed models fitted to growth curves of dairy goats.

J. G. L. Regadas Filho*[1], M. T. Rodrigues[1], R. A. M. Vieira[2], L. F. Brito[1], and T. S. Oliveira[1], *[1]Universidade Federal de Viçosa, MG, Brazil, [2]Universidade Estadual do Norte Fluminense Darcy Ribeiro, Campos dos Goytacazes, RJ, Brazil.*

Measurements taken on the same experimental unit (animal) are more closely correlated than those taken in other experiment units, as well as measures taken at closer time intervals. These relationships are inherent in animal growth data, which may disrupt the basic assumptions of statistical analysis, such as independence of errors. However, there is still controversy about which growth curve parameters normally used in the literature should be considered as random. This decision should be based on the biological interpretation of the parameters and significance of the estimated variance components. The goal of this study was to evaluate the nonlinear mixed model methodology for fitting the growth curves of dairy goat. Data used in this study were collected from the goat flock of the Universidade Federal de Viçosa, MG, Brazil, were used 12,573 records from 2,476 females. The models evaluated were the Brody, Van Bertalanffy, Richards, Logistic and Gompertz models. Random effects μ_1, μ_2, and μ_3 were linked to the β_1 (asymptotic value), β_2 (sigmoidal curve shape parameter), and β_3 (rate of maturing) parameters, respectively. In addition to the traditional fixed-effects model, we evaluated 4 combinations of random variables: all parameters linked to random effects (μ_1, μ_2, and μ_3), only the β_1 and β_2 parameters (μ_1 and μ_2), only the β_1 and β_3 parameters (μ_1 and μ_3), and only the β_1 parameter (μ_1). Residual variance and the Schwartz Information Criteria were used to evaluate the models. There was reduced residual variance in all scenarios in which random effects were considered. The Brody (μ_1 and μ_3), Van Bertalanffy (μ_1 and μ_3), and Richards (μ_1) models provided the best fit to the data. Interestingly, all 3 models have in common parameters with biologically significance linked to variance component significant ($P \leq 0.01$). A major advantage of using nonlinear mixed model methodology in fitting animal growth curves is the possibility of including population variation measurements in stochastic models to predict animal performance. Growth curves should be fitted using the nonlinear mixed model methodology, linking biologically parameters to random effects.

Key Words: stochastic, parameters, random effect

M281 Increasing doses of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) and changes in milk fat content and secretion of dairy ewes. M. Baldin[1], R. Dresch[1], D. R. M. Alessio[1], J. Souza[2], M. A. S. Gama[3], M. P. Soares[4], and D. E. Oliveira*[1,5], *[1]Centro de Ciências Agroveterinárias, UDESC, Lages, SC, Brazil, [2]Esalq/USP, Piracicaba, SP, Brazil, [3]Embrapa, CNPGL, Juiz de Fora, MG, Brazil, [4]Instituto Federal Catarinense, Araquari, SC, Brazil, [5]Centro de Educação Superior do Oeste, UDESC, Chapecó, SC, Brazil.*

The aim of this study was to examine the relationship between milk fat depression and increasing levels of t10, c12 CLA fed as a rumen unprotected supplement (UnCLA, 29.9% of t10, c12) to dairy ewes. Twenty-three Lacaune ewes, 40 DIM, were used in a completely randomized design. Treatments were fed during a 14-d experimental period: Control (C): 30g of Megalac-E, n = 5; T1: 20g of Megalac-E plus 10g of UnCLA, n = 6; T2: 10g of Megalac-E plus 20g of UnCLA, n = 5 and T3: 30g of UnCLA; n = 7. The treatments provided 0, 2.99, 5.98 and 8.97 g/d of t10, c12 CLA, respectively. Ewes received after a.m. and p.m. milkings an isoproteic concentrate (1.0 kg/ewe/d) in which the fat supplements were added. Ewes were grazing paddocks of a tropical pasture. Milk samples were taken every 2d and on the last day of the experimental period for fat content and FA profile analyses, respectively. The relationships between milk fat and t10, c12 CLA-related variables were tested by linear regression analysis using the REG procedure of SAS, where Y is the variation observed in milk fat content or yield and X is the t10, c12 CLA in the diet or in milk fat. Outliers were removed from the data set. Milk fat content was decreased by 5.2, 14.1 and 26.5% and milk fat yield by 10.9, 17.9 and 26.8% in response to T1, T2 and T3, respectively. Inclusion of CLA linearly increased t10, c12 CLA content (C = 0.03; T1 = 0.10; T2 = 0.19; T3 = 0.30; $r^2 = 0.92$; $P < 0.001$) and t10, c12 CLA secretion (C = 0.03; T1 = 0.06; T2 = 0.12; T3 = 0.15; $r^2 = 0.95$; $P < 0.001$) in milk fat. Overall, estimated regression models (Table 1) show that the magnitude of milk fat depression increased linearly as t10, c12 CLA increased either in the diet or in milk fat.

Table 1. Estimated regression models

Predictors	Change in fat content (%)	Change in fat yield (%)
Dose of t10, c12 CLA (g/d)	y = 6.97 – 2.87x[1]	y = −11.57 – 1.32x
	$r^2 = 0.69$, n = 21	$r^2 = 0.44$, n = 18
Milk t10, c12 CLA (g/100g FA)	y = 7.76 – 80.61x	y = −7.56 – 60.73x
	$r^2 = 0.50$, n = 22	$r^2 = 0.84$, n = 14
Milk t10, c12 CLA (g/d)	y = 7.46 – 143.13x	y = −10.11 – 73.05x
	$r^2 = 0.43$, n = 23	$r^2 = 0.56$, n = 17

[1]All model coefficients were significantly different from zero ($P < 0.001$).

Key Words: CLA, milk fat

M282 Impacts of fat level and source on production of high producing California dairy cows. J. M. Soderstrom*[1], P. H. Robinson[1], and K. Karges[2], *[1]University of California, Davis, [2]POET Nutrition, Sioux Falls, SD.*

Addition of supplemental fat is common in total mixed rations (TMR) fed to high producing dairy cows, but these fats often have different saturations which influences their maximum dietary inclusion level. Unsaturated fats, especially those high in linoleic and linolenic acids, can affect rumen microbial activity leading to altered rumen biohydrogenation intermediates which can inhibit fat synthesis in the mammary gland. Saturated fats are less likely to affect rumen fermentation due to their high rumen stability. We determined if increasing net energy (NE) of a TMR with fat affects productive performance of high producing cows, and if unsaturated fat can be added at the same level as saturated fat without negatively affecting animal performance. The experiment was a 3 × 3 Youden square with 4 28 d periods and it was completed on a dairy farm using 3 high group pens (i.e., cows not yet confirmed pregnant), each with ~340 early lactation multiparity cows. All TMR were formulated with 75% of dry matter (DM) the same, mainly corn grain, wheat and sorghum silages, alfalfa hay, corn grain, canola meal, almond hulls and cottonseed. The other 15% of each TMR was 9% high crude protein (CP) (i.e., fat extracted) distillers dried grains with solubles (HPDDGS) and 6% beet pulp (BP) (diet LOWFAT); 15% DDGS (high fat diet with unsaturated fats: diet UNSAT); 11.1% HPDDGS, 2% BP and 1.9% rumen inert fat (high fat diet with saturated fat: diet RIFAT). The TMR had the same CP (avg. 17.3% DM), but fat levels were 3.8, 4.8, 5.0%. DM intake was highest for UNSAT ($P < 0.05$). Milk, fat and true protein yields, and milk energy output, were higher ($P < 0.01$) for RIFAT vs. UNSAT and LOWFAT. Milk fat % was lowest ($P < 0.01$) for UNSAT, highest for RIFAT and intermediate for LOWFAT. In contrast, true protein % was lowest ($P < 0.01$) for RIFAT. Change in body condition score was lowest for LOWFAT ($P < 0.01$). Whole tract digestibility of neutral detergent fiber did not differ among diets, but CP was higher for UNSAT vs. RIFAT ($P = 0.05$). Production performance and milk fat % were decreased by feeding unsaturated fat to increase diet NE but were increased by feeding rumen stable saturated fat.

Key Words: milk fat, saturated, unsaturated

M283 Meta-analysis: Impact of grain type and corn harvest and processing practices on digestion and lactation performance by dairy cows. L. F. Ferraretto* and R. D. Shaver, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

A meta-analysis was performed to evaluate the effect of cereal grain type and corn grain harvest and processing practices on intake, digestion and milk production by dairy cows using a data set comprised of 414 treatment means from 100 peer-review articles published 2000 - 2011. Categories for cereal grain type, corn processing and mean particle size (MPS) were: barley, corn and wheat; dry ground, cracked or rolled corn (DRY), high-moisture shelled or ear corn (ENS), and steam-flaked or steam-rolled corn (STM); 500–1000, 1000–1500, 1500–2000, 3000–3500 and 3500–4000 µm for DRY and <2000 or ≥2000 µm for ENS. Data were analyzed using Proc Mixed of SAS with treatments as fixed effects and trial as a random effect. Digestibility of dietary starch was lower for corn than barley ruminally, but not ($P = 0.89$) total tract (TT). The TT digestibilities of dietary DM and OM tended ($P = 0.06$ and$P = 0.09$, respectively) to be greater for corn than barley or wheat. Ruminal and TT dietary NDF digestibilities were similar among the grains ($P = 0.92$ and $P = 0.25$, respectively); actual and fat-corrected milk yields and concentrations of milk fat, protein and urea-nitrogen (MUN) did not differ ($P > 0.10$) either. The TT dietary starch digestibility was reduced ($P = 0.01$) and ruminal starch digestibility tended ($P = 0.08$) to be reduced for DRY compared with ENS or STM. Milk yield was 1.0 kg/d greater ($P = 0.01$) and DMI tended to be 1.3 kg/d lower ($P = 0.08$) for ENS than DRY. Milk fat and protein concentrations were greatest ($P = 0.05$) for DRY and STM, respectively. The TT digestibility of dietary DM, OM and starch were reduced ($P = 0.01$) for both DRY and ENS as MPS increased. The MPS, however, did not affect ($P > 0.10$) DMI or actual and fat-corrected milk yields for either DRY or ENS. Milk fat concentration decreased ($P = 0.01$) with decreasing MPS for ENS, but not ($P = 0.28$) DRY. The MUN concentration tended ($P = 0.08$) to increase with increasing MPS for DRY. Corn ensiling and particle size were major factors influencing dietary nutrient digestibilities in lactating dairy cows.

Key Words: dairy cow, meta-analysis, starch

M284 Finding a proxy for the inhibiting effects of polyunsaturated fatty acids on milk fat in dairy cows. G. Maxin*[1], H. Rulquin[1], and F. Glasser[2], *[1]INRA-Agrocampus Ouest, Rennes, France, [2]INRA, Theix, Saint-Gènes-Champanelle, France.*

Diets supplemented with plant lipids, high in polyunsaturated fatty acids (PUFA), often induce milk fat depression (MFD) in dairy cows. Several *trans* FA isomers inhibiting milk fat synthesis have been identified, but cannot fully account for diet-induced MFD. There is still debate on which FA isomers and/or other mechanisms are responsible for diet-induced MFD. The experimental approaches meet several limits (availability of pure FA isomers, simultaneous variations in several FA, and modification of rumen metabolism and other nutrients following dietary lipid supplementation), making it almost impossible to identify the FA that are involved in diet-induced MFD. The aim of this study was to identify, using a modeling approach, a proxy of the inhibiting effects of PUFA on milk fat. A database was compiled from published studies of dietary lipid addition in dairy cow diets. It included 38 responses to lipid addition (differences between a lipid-supplemented diet and a control). From diet composition and intake, using published empirical equations, we predicted the changes in nutrient flows (VFA, glucose and proteins) following lipid addition. Then, the milk fat responses to these changes in nutrient flows were predicted using another set of published empirical equations. We thus got a prediction of the milk fat changes induced by the nutrients other than FA. The prediction bias was computed for each response by difference between this prediction and the response of milk fat reported in the publications, and was assumed to be caused by the inhibiting FA. To identify proxies of the inhibiting effect of PUFA, several variables linked to lipid addition (FA intake, duodenal flows of various FA) were regressed on this bias using GLM model. The 2 best proxies (best regressors on the prediction biases of both milk fat yield and content, based on R^2 and RMSE) were the intake of 18:2+18:3 and the duodenal flow of 18:2. These results have to be confirmed on a larger database, but this modeling approach seems to be a good alternative to complement experimental studies of milk fat inhibition by dietary PUFA, and overcome some of their limits.

Key Words: dairy cow, milk fat, lipids

Ruminant Nutrition: Dairy: Calves and Heifers

M285 Crude glycerin as a replacement for corn in starter concentrate for dairy calves: Ruminal and blood parameters. G. G. O. Napoles[1,2], C. E. Oltramari[1,3], J. T. Silva[1,3], G. B. Mourão[1,3], and C. M. M. Bittar*[1,3], [1]*Escola Superior de Agricultura Luiz de Queiroz, Piracicaba, SP, Brazil,* [2]*Fapesp, São Paulo, SP, Brazil,* [3]*CNPq, Brasília, DF, Brazil.*

The purpose of the study was to evaluate the effects of crude glycerin inclusion in starter concentrate, as a replacement for corn, on dairy calves ruminal and blood parameters. Study was conducted with 24 male Holstein calves allocated into blocks according to age (3–7d of life) and initial weight (36.7kg). Animals were individually housed and fed milk replacer (Servamilk, 22% CP; 18% EE, 4L/d) and starter concentrate (21%CP; 80%TDN) with increasing levels of crude glycerin, replacing corn in the formulation (0, 5, 10%, dry matter basis). Blood samples were collected weekly until 8 weeks of age for glucose, lactate, β-hydroxybutyrate (BHBA) and total protein (TP) determination. In wk 4, 6 and 8 of age, ruminal fluid samples were collected using an oro-ruminal probe and a suction pump for pH, acetate, propionate, butyrate, and total short chain fatty acids (SCFA) determination. Plasma glucose (96.5; 90.7; 94.0 mg/dL for 0%, 5% and 10% glycerin, respectively), lactate (11.66; 11.66; 11.7 mg/dL 0%, 5% and 10% glycerin, respectively), BHBA (0.13; 0.13; 0.12 mmol/L for 0%, 5% and 10% glycerin, respectively) and TP (6.23; 6.40; 6.33 g/dL for 0%, 5% and 10% glycerin, respectively) were not affected ($P > 0.05$) by the replacement of corn by crude glycerin. However, concentrations of BHBA and TP were significantly increased with age ($P < 0.05$). Most of the ruminal parameter were also not affected by the replacement of corn by crude glycerin in the starter concentrate, except for propionic acid which presented lower molar concentrations for the 5% crude glycerin treatment (46.95; 36.03; 44.28 mmol/mL for 0%, 5% and 10% glycerin, respectively). An age effect was observed for pH and propionic acid molar concentration, but there were no significant effects for the interaction of age and treatment for these parameters. Averages were 5.25, 5.11, 5.10 for rumen pH; and 130.46; 107.86; 115.29 mmol/mL for total SCFA, for 0%, 5% and 10% glycerin treatments, respectively. The replacement of corn by crude glycerin does not affect ruminal or blood parameters of calves, being a good alternative for dairy calves solid feed formulation. Support by FAPESP.

Key Words: by-products, volatile fatty acids, solid feed

M286 Effect of feed presentation on pre- and post-weaning performance of dairy calves. E. K. Miller-Cushon[1], R. Bergeron[2], K. E. Leslie[3], G. J. Mason[4], and T. J. DeVries*[1], [1]*Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada,* [2]*Dept. of Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada,* [3]*Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada,* [4]*Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Dairy calves are typically offered feed types separately, despite commonly being fed a total mixed ration (TMR) later in life. The objective of this study was to determine how early feed presentation affects feed intake and performance of dairy calves both before and after weaning and once transitioned to a TMR. Twenty Holstein bull calves were randomly assigned at birth to 1 of 2 feed presentation treatments: they were offered chopped hay (3 - 4 cm) and concentrate at a ratio of 3:7, either as a mixture (MIX) or in separate buckets (COM). All calves received 8L/d of milk replacer for the first 4 wks. The amount of milk fed was reduced incrementally in wks 5–7 to facilitate weaning by the end of wk 7. Calves remained on their respective feed presentation treatments for 8 wks. In wk 9–11, all calves were offered the MIX diet to assess whether early feed presentation affected intake of the mixed feed. In wks 12–13, all calves were offered a novel TMR (containing haylage, corn silage, high moisture corn, and protein supplement) to assess how early feed presentation may impact acceptance of a novel feed type. Calves were weighed 2x/wk and intake was recorded daily. Data were analyzed in a repeated measures general linear mixed model. Calves had similar ADG both pre-weaning (0.75 kg/d, $P = 0.4$) and post-weaning (1.19 kg/d, $P = 0.13$), and similar weights throughout the study ($P = 0.8$). While on their respective treatments, MIX and COM calves had similar total feed intakes (average 0.54 kg/d in wks 2–8, $P = 0.8$). COM calves consumed a greater ratio of hay:concentrate than the offered ratio in wk 3,4, and 5 (7.06:7 vs. 3:7; $P < 0.04$), a similar ratio in wk 6 (3.30:7, $P = 0.3$), and a lower ratio in wks 7 and 8 (1.83:7 vs. 3:7; $P < 0.007$). When all calves were offered the MIX diet in wk 9, intake was similar between treatments (2.67 kg/d, $P = 0.7$), indicating that familiarity with feed presentation did not influence intake. Intake remained similar between treatments upon transition to the novel TMR (average 3.97 kg/d in wks 12–13, $P > 0.6$). These results suggest that dietary selectivity associated with early feed presentation may be transient, without statistically significant effects on longer-term calf intake or growth.

Key Words: dairy calf, feed presentation, growth

M287 Interactive effects of feeding frequency and feed bunk space on the feeding behavior of limit-fed dairy heifers. A. M. Greter[1], T. F. Duffield[2], B. W. McBride[3], T. M. Widowski[3], and T. J. DeVries*[1], [1]*Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada,* [2]*Dept. of Population Medicine, University of Guelph, Guelph, ON, Canada,* [3]*Dept. of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Limit feeding may improve feed efficiency, while reducing feed costs and nutrient excretion, but also poses health and welfare concerns. The objective of this study was to determine the effects of feeding frequency and feed bunk space on the behavior of limit-fed replacement dairy heifers. Sixteen Holstein dairy heifers (183.4 ± 9.1 d of age), divided into groups of 4, were exposed to 4 treatments, using a 2-factor 4 × 4 Latin square design with 21-d periods. The treatments were: 1) feeding 1×/d (at 1200 h) with ample feed bunk space (0.40 m/heifer), 2) feeding 1×/d with reduced feed bunk space (0.34 m/heifer), 3) feeding 2×/d (at 1200 and 1400 h) with ample feed bunk space, and 4) feeding 2×/d with reduced feed bunk space. The ration was formulated to meet nutrient requirements of a dairy heifer growing at 0.8 kg/d and fed at a rate of 2.0% of BW. Feeding and lying behavior were recorded for the last 7 d of each period. Competitive behavior was recorded on d 16, 18, and 20 of each period. DMI was recorded daily and ADG was recorded weekly. Data were analyzed in a general linear mixed model. DMI was similar between treatments (5.5 kg/d). Heifers fed 1×/d spent more time feeding than heifers fed 2×/d, regardless of feed bunk space (70.5 vs. 58.9 min/d; SE = 4.0, $P = 0.001$). Additionally, heifers fed 1×/d displaced each other more often than heifers fed 2×/d (4.8 vs. 2.4 displacements/d; SE = 1.3, $P = 0.008$). Feed bunk space allowance did not affect competition between heifers. Interestingly, regardless of feed bunk space or feeding frequency, all heifers maintained similar ADG

(0.9 kg/d), lying time (835.6 min/d), inactive standing time (539.8 min/d), and unrewarded time (when no feed was present) at the feed bunk (28.9 min/d). No interactions between feed bunk space and feeding frequency were found. Results suggest that feed bunk space does not affect feeding behavior or growth if heifers are allowed sufficient space to feed simultaneously. The lack of interactive effects of feeding frequency and bunk space suggests that behavioral concerns associated with limit feeding may not be addressed by increased feeding frequency when limit-fed dairy heifers are provided with reduced feed bunk space.

Key Words: dairy heifer, feeding behavior, limit feeding

M288 Effect of physical form of forage on performance, feeding behavior, and digestibility of Holstein calves.

C. Montoro[1], E. K. Miller-Cushon*[2], T. J. DeVries[2], and A. Bach[1,3], [1]*Department of Ruminant Production, IRTA, Barcelona, Spain,* [2]*Department of Animal and Poultry Science, University of Guelph, Kemptville, ON, Canada,* [3]*ICREA, Barcelona, Spain.*

The physical form of forage may influence rumen development, and consequently BW gain, DM consumption, digestibility, and welfare of dairy calves. The objective of this study was to determine the effect of different physical forms of forage on performance, apparent digestibility, and feeding behavior of young calves. Twenty Holstein male calves (46.8 ± 1.2 kg) were randomly assigned at birth to 1 of 2 feeding treatments, in which they were exposed to a mixed ration containing (on a DM basis) 90% crumb starter concentrate and either 1) 10% chopped (3–4 cm) grass hay (COARSE; n = 10), or 2) 10% ground (2 mm) grass hay (FINE; n = 10). All calves were offered 8 L/d of milk replacer (MR; 1.2 kg of DM) from birth, which was incrementally reduced after 5 wk to enable weaning by the end of wk 7. The study finished after wk 8. Consumption of mixed ration, MR, and water was recorded daily, and calves were weighed twice weekly. Samples of feed and orts were taken in wk 7 and 8 for nutrient content analysis. Behavioral data of each calf were obtained 2 h per day during wk 6 and 8. Total feces were collected during wk 8 to determine apparent digestibility. Calves exposed to COARSE had a greater ($P < 0.05$) DMI than FINE calves (2.70 vs. 2.45 kg/d, respectively) during the week after weaning (wk 8). Body weight gain was similar between treatments, despite COARSE calves having a numerically greater gain than FINE calves (0.94 vs. 0.89 ± 0.03 kg/d). Interestingly, COARSE calves tended ($P = 0.09$) to have a greater gain to feed ratio than FINE calves (0.68 vs. 0.63 ± 0.02 kg/kg). No differences were observed in CP, soluble protein, and ADF consumption between treatments; however, COARSE calves tended ($P = 0.09$) to consume more NDF than FINE calves during the last week of study (719.2 vs. 610.5 ± 25.84 g/d). Calves receiving COARSE sorted in favor of NDF to a greater extent than FINE calves ($P < 0.05$), whereas FINE calves sorted in favor of CP to a greater extent than COARSE calves ($P < 0.05$). Apparent DM, CP, NDF, and ADF digestibilities were greater ($P < 0.05$) in COARSE than in FINE calves (72.3, 77.4, 40.7, and 42.7% vs. 69.2, 74.5, 34.0, and 35.6%, respectively). Calves fed FINE spent more ($P < 0.05$) time performing non-nutritive oral behaviors than those fed COARSE, and FINE calves tended to spend less time idle (either lying or standing) than COARSE animals. In conclusion, providing chopped hay to young calves improves feed intake, improves DM, CP, NDF, and ADF digestibility after weaning, and reduces non-nutritive oral behaviors.

Key Words: feeding behavior, forage, physical form

M289 Effects of age on gene expression of transport proteins in ruminal epithelia of milk-fed calves.

M. Oba,* T. B. McFadden, and L. L. Guan, *University of Alberta, Edmonton, AB, Canada.*

The objective was to evaluate effects of age of milk-fed calves on expression of genes coding for epithelial transport proteins that facilitate absorption of fermentation acids from the rumen. Eighteen Holstein bull calves were individually housed and fed whole milk twice daily (4L/d) and offered texturized calf starter ad libitum. The calves were harvested at week one (n = 6), 3 (n = 5), or 6 (n = 7) after birth, and ruminal epithelial tissue was harvested; the epithelium was manually peeled off from the muscle layer, rinsed in PBS (pH 7.4), snap-frozen in liquid nitrogen, and kept at −80°C until analysis. Total RNA was extracted, and real-time RT-PCR was performed for monocarboxylate transporter isoform 1 (*MCT-1*; co-transporter exporting protons and dissociated VFA), Na^+/H^+ exchanger (anti-porter importing Na^+ and exporting protons) isoforms 1 (*NHE-1*), 2 (*NHE-2*) and 3 (*NHE-3*), putative anion transporter isoform 1 (*PAT-1*; anti-porter importing dissociated VFA and exporting bicarbonate), and downregulated in adenoma (*DRA*; anti-porter importing dissociated VFA and exporting bicarbonate). The expression of each targeted gene was normalized using 3 internal control genes: ribosomal protein large P0, β-actin, and glyceraldehyde-3-phosphate dehydrogenase. Ruminal epithelia harvested from 3 or 6 wk old calves had higher mRNA abundance of *DRA* (0.44 and 0.39 vs. 0.07 units; $P < 0.05$) and *MCT-1* (1.08 and 0.81 vs. 0.26 units; $P < 0.05$) compared with samples from one-wk old calves. Abundance of *NHE-2* mRNA was greater for 6-wk old calves compared with one-wk old calves (0.72 vs. 0.21 units; $P < 0.05$). However, mRNA abundance of *NHE-1*, *NHE-3*, and *PAT-1* was not affected by age at harvest. Dissociated VFA are transported across apical membrane via *DRA* and basolateral membrane via *MCT-1*, and both *MCT-1* and *NHE-2* regulate intracellular pH by exporting protons generated from absorption of undissociated VFA. These results indicate that ruminal epithelia of calves initiate metabolic adaptations at a molecular level within 3 wk after birth to facilitate absorption of fermentation acids from the rumen.

Key Words: calf, rumen epithelia, transport protein

M290 Ruminal and blood parameters of dairy calves managed on different milk-feeding programs.

M. R. Paula[1,2], G. G. O. Napoles[1,3], M. P. C. Gallo[1,2], M. C. Soares[1,3], and C. M. M. Bittar*[1,2], [1]*Escola Superior de Agricultura, Piracicaba, SP, Brazil,* [2]*CNPq, Brasília, DF, Brazil,* [3]*Fapesp, São Paulo, SP, Brazil.*

The objective was to evaluate the effect of different milk-feeding programs on dairy calves ruminal and blood parameters. After birth, 30 male Holstein calves were utilized in a randomized block design and assigned to 3 milk-feeding programs: 1) Conventional (C): 10% birth weight (BW) (4L/d); 2) Step-down (SD): wk 1: 10% BW (4L/d); wk 2 to 6: 20% BW (8L/d), and wk 7 and 8: 10% BW (4L/d); 3) Intensive (I): 20% BW (8L/d). Animals were individually housed, had water free-choice, starter concentrate fed ad libitum (18% CP; 80% TDN), and milk replacer (MR) (20% CP, 16% EE, 12.5% solids; Sprayfo Violeta, Sloten do Brasil Ltda.) fed according to milk-feeding program. Coast-cross hay was fed after weaning (eighth week). Blood samples were collected weekly until 10 weeks of age for glucose and β-hydroxybutyrate (BHBA) determination. In wk 4, 8 and 10 of age, ruminal fluid samples were collected using an oro-ruminal probe and a suction pump for pH

and short chain fatty acids (SCFA) analysis. Plasma glucose (88.8; 89.8; 92.4 mg/dL for C, SD and I programs, respectively) were not affected ($P > 0.05$) by milk-feeding program, but concentrations decreased as animals aged ($P < 0.0001$). Concentrations of BHBA (0.155; 0.122; 0.101 mmol/L for C, SD and I, respectively) were affected ($P < 0.05$) by milk-feeding program, as well as by age ($P < 0.02$), with similar values up to the 6th week but increasing values thereafter; and by the interaction of age and milk-feeding program ($P < 0.02$). Observed effects for BHBA reflect the observed starter concentrate intake according to milk-feeding programs (722.5; 552.0; 435.7 g/d for C, SD and I, respectively), with higher concentrations of BHBA for treatments with higher starter intake. Average ruminal pH (5.47; 5.51; 5.46 for C, SD and I, respectively), and total SCFA (106.6; 112.5; 105.4 mmol/mL for C, SD and I, respectively) were not affected by milk-feeding program. However, an age effect ($P < 0.001$) was observed for pH, with decreasing values; and for acetate, propionate, butyrate and total SCFA, with increasing concentrations as calves aged. An interaction of age and milk-feeding program effect was observed for propionate ($P < 0.2$), butyrate ($P < 0.6$), and for the total SCFA ($P < 0.05$), with lower concentrations for calves on intensive milk-feeding program at wk 8. Effects of milk-feeding program on starter intake affect rumen and plasma parameters. Support by FAPESP.

Key Words: β-hydroxybutyrate, milk replacer, volatile fatty acids

M291 Effects of kelp meal on performance and structural growth of conventional and organic dairy calves.

G. M. Soule,* A. F. Brito, A. Miranda, L. Chase, N. L. Whitehouse, E. S. Fletcher, and N. T. Antaya, *University of New Hampshire, Durham.*

Kelp meal (KM) is a dried seaweed product used in dairy farms particularly in organic operations. The current study examined the effects of KM (*Ascophyllum nodosum*) on performance and structural growth of 36 heifer calves [18 conventional Holsteins (Trial 1) and 18 organic Jerseys (Trial 2)]. We hypothesized that the high mineral content and salty flavor of KM enhances diet palatability and DMI in calves. Animals were blocked by calving date and, within breed, randomly assigned to 2 treatments: Control (calf starter) or KM (calf starter + 25 g of KM). Approximately 5.7 and 3.8 L of milk were fed daily to Holsteins and Jerseys, respectively. Grass hay was offered ad libitum and orts were collected daily. Body weight and growth were measured twice a week from wk 1–7 and wk 1–8 of age in Holsteins and Jerseys, respectively. Except for whiter height, which was higher ($P = 0.05$) for Holsteins fed the control vs. the KM diet, no other significant treatment differences were observed on Trial 1. However, data from Trial 2 showed that KM significantly increased DMI and ADG compared with the control. No differences ($P > 0.05$) in structural growth were observed for calves fed the control or the KM diet in Trial 2, suggesting that dietary energy was utilized for body fat deposition rather than skeletal growth. A 2-fold difference in ash concentration between the conventional (9.04%) and the organic starter (5.68%) suggests the latter was lacking minerals. Because KM is rich in minerals and adds a salty flavor to the diet, increased DMI in Jerseys may be explained by enhanced diet palatability and/or an animal need to meet mineral requirements. Research is needed to investigate the interaction between KM and the starter nutrient profile on body composition and structural growth of dairy calves.

Table 1. Effects of kelp meal (KM) on performance and growth of dairy calves

	Holsteins (Trial 1)				Jerseys (Trial 2)			
Item	Control	KM	SED	P>F	Control	KM	SED	P>F
DMI, kg/d	1.34	1.39	0.12	0.77	0.93	1.16	0.04	<0.01
ADG, kg/d	0.73	0.76	0.03	0.55	0.49	0.61	0.03	0.01
ADG:DMI	0.50	0.55	0.02	0.11	0.53	0.53	0.03	0.98

M292 Total serum protein in calves is not correlated with future milk performance.

B. Ozer*[1], A. Bach[2,3], and M. Chahine[1], [1]*University of Idaho, Twin Falls,* [2]*IRTA, Caldes de Montbui, Spain,* [3]*ICREA, Barcelona, Spain.*

It is well established that calves with poor passive transfer of immunoglobulins have increased risk of diarrhea, respiratory problems, and mortality. Furthermore, there are some studies that have linked plasma immunoglobulin concentrations or colostrum provision early in life with improvements in future performance. The improvements have been attributed to potential lactocrine mechanisms mediated by hormones present in the colostrum. The objective of this study was to determine whether total serum protein (TSP) in calves was correlated with future milk performance in the first lactation. A total of 6,172 calves born between 2005 and 2009 in the same herd were fed 3 L of colostrum within 1 h after birth followed by 2 additional liters 8 h later, and blood-sampled within 48 h of life to determine TSP. Determinations of TSP were performed by an experienced veterinarian using a refractometer (Jorvet J-351, Jorgensen Laboratories, Inc. CO). Then, total milk produced by the animals in their first lactation was recorded. A categorical variable was constructed including TSP below 5.4 (n = 1,962), between 5.4 and 6.4 (n = 2,324), and above 6.4 mg/dl (n = 1,886). A mixed-effects model that accounted for the random effects of year of birth and sire (father of each heifer considered) plus the fixed effects of the 3 TSP categories and the lactation length as a covariate was run to evaluate any potential relationship between TSP and milk yield in the first lactation. In the first lactation, calves that had TSP below 5.4 mg/d produced 10,551 ± 230 kg, those with TSP between 5.4 and 6.4 mg/dl produced 10,499 ± 229 kg, and those with TSP above 6.4 mg/dl produced 10,445 ± 230 kg. There was no relationship ($P = 0.13$) between TSP and future milk production. These results indicate that either TSP is not a valid proxy to assess the adequacy of colostrum feeding, or that the amount of colostrum offered during the first 2 d of life has no impact on future animal performance.

Key Words: colostrum, metabolic imprinting, performance

M293 Intake and performance of Holstein heifers transitioned to group housing from individual pens using differing grain mixes with or without hay the first two weeks after moving. D. Ziegler*[1], D. Schimek[2], B. Ziegler[2], H. Chester-Jones[1], M. Raeth-Knight[3], and G. Golombeski[4], [1]*University of Minnesota Southern Research and Outreach Center, Waseca,* [2]*Hubbard Feeds Inc., Mankato, MN,* [3]*University of Minnesota, St. Paul,* [4]*Hubbard Feeds Inc., Iowa City, IA.*

One-hundred twelve 57- to 60-d-old Holstein heifers (82.6 ± 1.32 kg) were assigned to 1 of 4 treatments in 4 replicate pens (7 heifers/pen) for 112 d. Treatments were fed d 1–14 and included 1) free choice (FC) 18% CP texturized grain mix without hay (TXT); 2) same as TXT but with FC hay (TXTH); 3) FC 16% crude protein whole corn/pellet grain mix without hay (WCP); 4) same as WCP but with FC hay (WCPH). Then from d 15–112 all heifers were fed a common diet of 16% CP GM (2.73 kg/d d 15–56 and 2.27 kg/d d 57–112) with FC hay. Intakes were taken daily from d 1–28 and then weekly from d 29–112. Daily grain mix dry matter intake and gain/feed did not differ from d 1–14, 2.30 ± 0.05 kg and 0.38 ± 0.006 kg gain/kg feed, respectively. Hay dry matter intake for d 1–14 was 0.06 and 0.11 kg/d for TXTH and WCPH, respectively. There were significant grain mix x hay interactions for ADG ($P < 0.05$) and total dry matter intake ($P = 0.0003$) but no differences in gain to feed from d 1–112 (0.29 ± 0.002 kg gain/kg feed). No differences were observed in body condition score (112 d avg. 3.25) or hip height (112 d avg. 112.2 cm; $P > 0.05$). Under conditions of this study feeding differing grain mixes with or without hay for 14 d in group pens after moving from individual nursery pens had minimal effect on heifer performance.

Key Words: grain mixes, Holstein heifers, performance.

M294 Precision-feeding dairy heifers with different levels of dietary fiber and F:C. Effects on protein utilization, N efficiency, and rumen fermentation. G. J. Lascano*[1] and A. J. Heinrichs[2], [1]*The California Polytechnic State University, San Luis Obispo,* [2]*The Pennsylvania State University, University Park.*

The objective of this experiment was to determine the effects of manipulating dietary fiber level with differing forage to concentrate (F:C) ratios on protein rumen utilization of precision-fed dairy heifers. Six cannulated Holstein heifers (486.98 ± 15.07 kg BW) were randomly assigned to 2 levels of concentrate, HC (45% forage) and LC (90% forage) and to a forage type sequence [33% grass hay and wheat straw HS, 67% corn silage CS (Low fiber); 50% HS, 50% CS (Medium fiber); and 67% HS, 33% CS (High fiber)] within forage level administered according to a split-plot 3 × 3 Latin square design (21-d period). Similar N intake and rumen degradable protein (RDP) were provided (1.20 g N/kg BW 0.75), and casein was added to supply additional N to provide 1.80 g N/kg BW 0.75. Heifers fed HC had greater apparent total tract organic matter (OMD), neutral detergent fiber (NDF), and cellulose apparent digestibility (AD) than those fed LC diets ($P \leq 0.01$). Nitrogen AD was not different between F:C or with increasing levels of HS in diets, but N retention tended to decrease linearly as HS was increased in the diets ($P = 0.09$). Protozoa numbers were not different between F:C treatments, but HS interacted linearly. The HC-fed heifers had a greater VFA concentration ($P \leq 0.05$). Mean pH was not different among F:C rations. Increasing dietary fiber through HS affected RDP utilization and decreased DM, OM, NDF, ADF and cellulose AD linearly ($P \leq 0.05$). Microbial protein synthesis predicted from urinary purine derivatives decreased linearly with HS addition resulting in a linear decrease in N retention with HS addition ($P = 0.03$), which was opposite to rumen NH_3N and BUN, reflecting the inefficiency in N utilization as more HS was added to the diets. Rumen fermentation parameters, DM and fractional passages (solid and liquid) rates support the reduction in protein utilization and retention, microbial protein synthesis and AD observed as more dietary fiber is added to the rations of precision-fed dairy heifers.

Key Words: heifers, fiber, protein degradability

M295 Insulin response is affected by the level of milk replacer offered to young calves. A. Bach*[1,2], Ll. Castells[2], C. Montoro[2], and M. Terre[2], [1]*ICREA, Barcelona, Spain,* [2]*Department of Ruminant Production, IRTA, Barcelona, Spain.*

Eight male Holstein calves (40.6 ± 2.9 kg of BW and 7.8 ± 1.6 d of age) individually housed were allocated to either a LOW milk replacer (MR) allowance of 2 daily doses of 2 L each (478.5 g/d of DM from MR), or to a HIGH allowance of 2 daily doses of 4 L (957.0 g/d of DM from MR). In addition all calves had ad libitum access to the same starter feed and water. At d 7, 30, and 60 of experiment all calves were submitted to a glucose tolerance test (GTT) that consisted on an i.v. infusion of 180 mg/kg of BW of glucose at 4 h after the morning MR offer. Blood was harvested at −15, −5, 0, 4, 8, 12, 25, 35, 45, and 60 min relative to glucose infusions. Blood samples collected at −15 and −5, and 0 relative to glucose infusion were used as baseline concentrations of glucose and insulin. Then, the area under the curve (AUC; concentration/min) for glucose and insulin was calculated as the increase with respect to the baseline. Next, the clearance rates of insulin (CRI, %/min) and glucose (CRG, %/min) were computed. The increase in blood glucose following the GTT (assessed as AUC) was similar in both LOW and HIGH calves, which indicates that all animals were able to control glycemia effectively. Similarly, CRG and CRI were no different between LOW and HIGH calves. However, calves in the HIGH group needed a substantially greater ($P < 0.001$) serum insulin concentration (98.7 ± 13.2 μU/ml) than LOW calves (41.5 ± 13.2 μU/ml) to control glycemia. Furthermore, as age increased, the rise in serum insulin elicited by the GTT continued to increase ($P = 0.01$) in HIGH but not in LOW calves. Insulin to glucose ratio was greater ($P < 0.001$) in HIGH (157.5 ± 7.8 μU/mg) than in LOW (46.7 ± 7.8 μU/mg) calves. This ratio increased with age ($P < 0.01$) and in a more pronounced ($P = 0.03$) fashion in HIGH than in LOW calves. It is concluded that offering 8 L/d of MR in 2 separate doses decreases insulin sensitivity of young calves. Research is needed to assess whether the impaired glucose responsiveness of calves can be minimized by feeding milk more frequently.

Key Words: calf, glucose, metabolism

M296 Optimizing particle size and moisture in diets for dairy heifers. M. A. Khan[1], A. Bach[2,3], Ll. Castells*[3], D. M. Weary[1], and M. A. G. von Keyserlingk[1], [1]*Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada,* [2]*ICREA, Barcelona, Spain,* [3]*Deparment of Ruminant Production, IRTA, Barcelona, Spain.*

Little research to date has addressed diets for growing dairy heifers. In 2 experiments involving 36 replacement heifers (181 ± 7 kg of BW and 175 ± 7 d of age) we tested the effects of forage particle length and DM of a TMR on DMI, feeding rate and feed sorting. Each experiment used a replicated 3 × 3 Latin square design, testing 9 heifers in each of 2 replications for 3 periods of 9 d each. Each group of heifers was housed in a pen with access to 3 electronic feed bins. In Exp. 1, a TMR was formulated using the same ingredients but where the hay component was provided at 3 different lengths resulting in a TMR with 72 (LONG), 64.2 (MEDIUM), or 60% (SHORT) of the particles above 19 mm. In Exp. 2, heifers were provided access to a TMR with different moisture contents (obtained by adding water): LOW (65% DM), MODERATE

(50% DM), and HIGH (35% DM). In both experiments, data from the last 5 d of each period were analyzed using a mixed-effects model accounting for the fixed effects of treatment and period, and the random effects of replication, animal within treatment, and period. In Exp. 1, DMI tended ($P = 0.09$) to increase and time spent feeding decreased ($P = 0.05$) as the particle size of TMR increased. Feeding rate also tended ($P = 0.07$) to increase as particle size of the TMR decreased. Heifers fed the LONG diet selected ($P < 0.05$) in favor of long particles (>19 mm) and against short (1.18–8mm) and fine (<1.18 mm) particles; heifers fed the SHORT diet selected ($P < 0.05$) against long particles and in favor of short and fine particles. In Exp. 2, heifers consuming the LOW moisture diet tended ($P = 0.09$) to have greater DMI than those fed the MODERATE and HIGH diets, with no differences in feeding behavior or sorting activity. We conclude that TMRs with particle sizes similar to the MEDIUM diet minimize sorting. Adding water to achieve moisture contents of a TMR >35% can reduce DMI in heifers.

Key Words: eating rate, feeding behavior, sorting

M297 Replacing processed grains with whole corn in starter diet did not affect the performance of dairy calves.

M. A. Khan*[1], J. H. Kim[2], D. M. Veira[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [2]Agriculture and Agri-Food Canada, Agassiz BC, Canada.*

We compared the effects of replacing processed grains in conventional texturized starter with whole corn on the performance of dairy calves. Individually housed Holstein heifer calves (n = 24) were fed whole milk (8 l/d) for 28 d of age and gradually weaned during d 29 to 39. At 7 d of age, calves were randomly assigned to one of the 2 starter diets i.e., conventional (textured; contain processed grains) starter (n = 12) or whole corn (whole corn replaced the grain component of conventional diet) starter (n = 12). Starter diets were fed ad libitum for 70 d. Daily starter intake in calves fed either conventional or whole corn starter was similar during pre-weaning (0.21 ± 0.02 vs. 0.22 ± 0.02, kg; $P = 0.73$) and post-weaning (2.10 ± 0.07 vs. 1.99 ± 0.10; $P = 0.46$) periods. Overall during the experiment, total (milk solid plus starter) DMI (98.0 ± 3.0 vs. 95.7 ± 3.7, kg; $P = 0.63$), BWG (53.5 ± 2.2 vs. 53.1 ± 2.4, kg; $P = 0.92$) and feed efficiency (0.56 ± 0.01 vs. 0.57 ± 0.02, BWG/DMI; $P = 0.67$) were similar in calves fed either conventional or whole corn starter. Calves fed whole corn starter visit the feeder more frequently (186.5 ± 9.4 vs. 153 ± 15.3, visit/d; $P = 0.02$) than those fed conventional starter. However, daily time spent eating was not affected (3.57 ± 0.17 vs. 3.45 ± 0.19, h/d; $P = 0.18$) by diet. Calves on both treatments did not ($P > 0.05$) preferentially select feed particles (grains or pellets) from the starter diet. Ruminal pH was similar (5.68 ± 0.16 vs. 5.43 ± 0.07, $P = 0.20$) in calves fed whole corn based starter compared with those fed conventional starter. Concentrations of blood glucose and blood BHBA were similar ($P > 0.05$) in calves fed both starter diets. In conclusion, replacing processed grains with whole corn in starter diets did not affect the feed consumption, feed particle sorting, growth and feed efficiency in dairy calves however; it fails to alleviate the severe acidic conditions in the rumen of developing calves. Use of whole corn in starter could potentially lower the rearing cost of heifers by reducing the processing cost of grains.

Key Words: whole corn, starter, rumen development

M298 Performance of dairy calves managed on different milk-feeding programs.

M. R. Paula[1,2], M. P. C. Gallo[1,3], M. C. Soares[1], G. B. Mourão[1,2], and C. M. M. Bittar*[1,2], *[1]Escola Superior de Agricultura Luiz de Queiroz, Piracicaba, SP, Brazil, [2]CNPq, Brasília, DF, Brazil, [3]Fapesp, São Paulo, SP, Brazil.*

The objective was to evaluate the effect of different milk-feeding programs on performance of calves until 10 weeks of age, abruptly weaned at 8 weeks of age. After birth, 30 male Holstein calves were utilized in a randomized block design and assigned to 3 milk-feeding programs: 1) Conventional (C): 10% birth weight (BW) (4L/d); 2) Step-down (SD): wk 1: 10% BW(4L/d); wk 2 to 6: 20% BW (8L/d), and wk 7 and 8: 10% BW (4L/d); 3) Intensive (I): 20% BW (8L/d). Animals were individually housed, had water free-choice, starter concentrate fed ad libitum (18% CP; 80% TDN), and milk replacer (MR) (20% CP, 16% EE, 12.5% solids; Sprayfo Violeta, Sloten do Brasil Ltda.) fed according to milk-feeding program. Coast-cross hay was fed after weaning (eighth week). Fecal scores, starter and milk replacer intake were evaluated daily. Calves were weighted and growth measurements were taken weekly until the tenth week of age. Starter daily intake was affected ($P < 0.05$) by the milk-feeding program with lower intake observed for the intensive fed calves as compare with calves fed by the conventional program, with no difference with the step-down program (722.5; 552.0; 435.7 g/d for C, SD and I, respectively). Measured average MR intake was 3.94; 6.02; 7.30 L/d for C, SD and I programs, respectively. Despite the higher MR intake for the step-down and intensive programs, weight gain (469.1; 455.0; 466.4 g/d for C, SD and I, respectively), average body weight (50.6; 51.6; 52.7 kg for C, SD and I, respectively), and final weight (69.7; 68.6; 69.6 kg for C, SD and I, respectively) were not affected by milk-feeding. Even though average and final body weight were not affected, heart girth was affected ($P < 0.05$) (84.3; 86.2; 87.2 cm for C, SD and I, respectively), suggesting effects on growth other than weight gain. However, other body measurements (hip width: 23.1; 23.4; 23.8 cm and withers height: 82.3; 82.1; 83.0 cm for C, SD and I, respectively), were not affected ($P > 0.05$). Average hay intake was affected ($P < 0.05$) with lowest intake for calves on the step-down program (461.0; 150.5; 307.4 g/week for C, SD and I, respectively). Fecal scores were higher for the step-down and intensive programs (1.44; 2.8; 2.1 for C, SD and I, respectively). Support by FAPESP.

Key Words: milk replacer, liquid feeding, weight gain

M299 Effect of increasing intake of linoleic acid in milk replacer on Holstein calf performance.

M. Garcia,* J. H. Shin, A. Schlaefli, J. E. P. Santos, and C. R. Staples, *University of Florida, Gainesville.*

The aim was to evaluate the linoleic acid (LA) requirement of unweaned Holstein calves from birth to 60 d of age. Within 2 h of birth, calves (n = 88) were fed 4 L of colostrum (>60 g of IgG/L) harvested from cows delivering the experimental calves. Calves were blocked by gender and assigned randomly to 1 of 4 treatments. Soybean and coconut oils were mixed with an emulsifier and added to a basal milk replacer (MR; 7% fat and 28% CP) at the time of feeding (0600 and 1200 h) to supply 0.064, 0.128, 0.256, or 0.512 g of LA/kg of metabolic BW, T1 to T4, respectively. Final MR fed was 15% fat. Amount of MR fed was adjusted based on weekly BW. Blood was collected weekly. A low LA grain mix (18% CP, 2.87 Mcal of ME/kg, and 1.6% fat) was offered starting at 31 d of age. Birth weight and height were covariates for analysis of gain and growth respectively. During the period of feeding MR alone, T2 males gained more BW (5.3 kg) compared with males fed T1, T3, or T4 (2.8, 2.8, and 2.7 kg, respectively, SE = 0.5) whereas BW gain by females did not differ (2.6, 3.1, 3.3, and 3.4 kg; cubic by gender interaction, $P = 0.04$). Increased gain by T2 males was accompanied by increased intake of MR (19.7 vs. 19.2, 19.0, and 19.2 kg, SE = 0.2). Intake of grain mix (480 g/d; SE = 55) and BW gain (21.2 kg, SE = 1.4) between 31 and 60 d of life did not differ among treatments. At 60 d of life, calves fed diets T2 and T3 had greater wither height (82.6, 83.6, 84.0, and 83.2 cm, SE = 0.7, $P = 0.08$) and hip height (87.6, 88.7, 88.9, and 87.9 cm, SE = 0.7; quadratic effect, $P = 0.04$). Mean concentrations of plasma glucose (90.3 mg/dL, SE = 1.5) and insulin (2.2 ng/mL, SE = 0.3) were unaffected by diet. Total cholesterol concentrations in plasma increased linearly ($P = 0.05$) with increasing intake of LA (72.6, 75.2, 79.0, and 80.4 mg/dL, SE = 4.1) whereas plasma concentrations of BHBA tended ($P = 0.10$) to be greater for T1 calves compared with others (0.82 vs. 0.74, 0.72, and 0.76 mg/dL, SE = 0.05). Supplementing LA in MR at >0.064 g/kg of metabolic BW during the first 60 d of life improved growth but not BW of underperforming female Holstein calves.

Key Words: calves, milk replacer, linoleic acid

M300 Effect of feeding increasing amounts of linoleic acid on health and immunity of unweaned Holstein calves. M. Garcia,* J. H. Shin, A. Schlaefli, D. Wang, J. E. P. Santos, and C. R. Staples, *University of Florida, Gainesville.*

The aim was to evaluate the effect of increasing intake of linoleic acid (LA) on measures of health and immunity of Holstein calves from birth to 60 d of age. Within 2 h of birth, calves (n = 88) were fed 4 L of thawed colostrum (minimum of 60 g of total IgG/L) harvested from cows delivering the experimental calves. Calves were blocked by gender and assigned randomly to 1 of 4 treatments. Soybean and coconut oils were mixed with an emulsifier and added to a basal milk replacer (MR; 7% fat and 28% CP) at the time of feeding (0600 and 1200 h) to supply 0.064, 0.128, 0.256, or 0.512 g of LA/kg of metabolic BW, T1 to T4, respectively. Final MR fed was 15% fat. A grain mix of low LA concentration (18% CP, 2.87 Mcal of ME/kg, and 1.6% fat) was offered starting at 31 d of age. Blood was sampled weekly. Serum IgG (g/L) on the day after birth was used as a covariate for health measures. As LA intake increased, fecal firmness tended ($P = 0.07$) to increase linearly as well as age at first day of diarrhea (7.0, 7.3, 7.5, and 7.5 d, SE = 0.3). The % of days with fever (>39.5°C) during the first 14 d of age did not differ (5.7%, SE = 2.3) nor did % of days (4.5%, SE = 1.0) with severe diarrhea throughout the 60-d study. Mean plasma concentration of acid soluble protein tended ($P = 0.06$) to decrease linearly (102.0, 96.5, 91.7, and 92.6 mg/L) with increasing LA intake. Mean plasma concentration of haptoglobin decreased (treatment by age, $P = 0.04$) to a greater extent at first evidence of diarrhea for T1 calves. Mean concentration of TNFα in mitogen-stimulated blood did not differ among treatments (375 pg/mL, SE = 64), but that of IFNγ tended to be greater in T2 and T3 calves (258, 342, 319, and 238 pg/mL, SE = 67; quadratic effect, $P = 0.09$). A similar quadratic response to LA supplementation was detected for % of blood neutrophils undergoing phagocytosis (62.1, 66.6, 64.1, and 62.8%, SE = 2.3; $P = 0.07$) and oxidative burst (51.5, 55.8, 53.6, and 50.4%, SE = 2.5; $P = 0.04$). Feeding LA in MR between 0.128 and 0.256 g/kg of metabolic BW appeared to increase several markers of pro-inflammatory response in unweaned Holstein calves.

Key Words: calves, linoleic acid, immunity

M301 Jersey calf blood metabolites in response to liquid feeds with varied fatty acid profiles. V. A. Swank,* W. S. Bowen, K. M. O'Diam, M. L. Eastridge, and K. M. Daniels, *Department of Animal Sciences, The Ohio State University, Columbus.*

Most commercially available Jersey calf milk replacers (MR) use edible lard as the primary fat source. Edible lard lacks medium chain fatty acids (MCFA) whereas pasteurized saleable whole milk (pSWM) from Jersey cows contains many MCFA. The objective was to determine whether altering the FA profile of MR with the inclusion of coconut oil (CO), rich in MCFA, would alter blood metabolite profiles in Jersey calves over time. This trial was conducted as a randomized complete block design. Male (n = 18) and female (n = 32) Jersey calves were randomly assigned at birth to 1 of 4 liquid diets: pasteurized Jersey saleable whole milk (pSWM; 27.9% CP, 33.5% fat, DM basis); MR containing 100% of fat as edible lard (100:00; 29.3% CP, 29.1% fat); MR containing 20% of fat as CO (80:20; 28.2% CP, 28.0% fat); MR containing 40% of fat as CO (60:40; 28.2% CP, 28.3% fat). Calves were fed 2L of their respective liquid diet twice daily (0600h and 1800h) from 2d of age until 7wk of age, and once daily until weaning (8wk of age). Once a week, a subset of calves (n = 34) were fasted overnight for 12h and jugular blood samples were taken; immediately before morning feeding which occurred at 0600h, 0800h, 1200h, and immediately before the evening feeding at1800h. These samples were collected at 1wk, 3wk, and 6wk of age. Blood samples were used to determine concentrations of triglycerides (TG), glucose, plasma urea nitrogen (PUN), and total protein (TP). Data were analyzed using the mixed procedure of SAS. TP was not different throughout the trial. The interaction of diet and week was significant for TG and glucose concentrations; both variables changed over time in a complex pattern for animals on a given treatment (significant linear and quadratic contrast effects). Treatment, week, and time of collection had a significant effect on intensive PUN concentrations, with all 3 having a linear effect. Moreover, pSWM was significantly different than 80:20, with 6.17mg/dl and 5.76mg/dl, respectively ($P = 0.036$). Given that calves on this trial grew the same (companion abstract) our results here measuring concentrations of blood metabolites are as expected.

Key Words: fatty acids, Jersey calf, milk replacer

M302 Ponderal development of dairy heifers fed sugarcane and increasing crude protein levels. M. F. S. Queiroz*[1], T. T. Berchielli[2], R. D. Signoretti[3], and J. A. S. Morais[4], *[1]Universidade Federal da Paraíba, CCHSA/UFPB, Bananeiras, Paraíba, Brazil, [2]Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal, São Paulo, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brasil, [4]Universidade Federal de Sergipe (UFS), São Cristovão, Sergipe, Brazil.*

Twenty-four Holstein × Zebu crossbred heifers with average age of 19 months and 250 kg fed sugarcane and four different protein levels diets were used. The sugarcane (IAC 862480) was evaluated during August to November (winter/spring) and the diets concentrate was compound by corn meal, soybean meal, urea, ammonia sulfate and mineral mix, in different proportions, to obtain the protein levels (13, 15, 19 and 22% of crude protein) in 70:30 relation forage and concentrate. The animals were maintained in an individual stall and ad libitum fed twice a day (8 and 16 h) during the adaptation and experimental period, 15 and 62 days, respectively. The experimental design was completely randomized blocks, consisting of 3 blocks and 4 treatments. The heifers were weighed and their thoracic perimeter; withers and hip height, and body score were determined at the beginning and at the end of the experimental period, at every 21 days. There was no diet effect ($P > 0.05$) on ponderal development and body score. The heifers had an average growth of 0.05 cm/day withers height and 0.04 cm/day hip height and 0.17 cm/day of heart girth during the experimental period.

Table 1. Means of crossbred dairy heifers ponderal development

	Diet CP level (%)					P-value[1]	
Item	13	15	19	22	CV	LE	QE

M303 Pre- and postweaning performance and health of dairy calves when sodium butyrate is fed in milk replacer and/or calf starter during the summer months.

H. Chester-Jones*[1], S. Moreland[2], D. Ziegler[1], M. Raeth-Knight[3], and J. van Eys[2], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]Nutriad Inc., Elgin, IL, [3]University of Minnesota, St. Paul.*

One-hundred eight (2–4 d old) individually fed Holstein heifer calves (39.3 ± 0.64 kg) were randomly assigned to 1 of 4 treatments to evaluate pre- (d 1–42) and post weaning (d 43–56) calf performance and health when fed sodium butyrate in milk replacer and/or calf starter. All calves were fed a non-medicated 20% fat:20% protein milk replacer (MR) at 0.284 kg in 1.99 L water (12.5% solids) 2X daily for the first 35 d and 1X daily from d 36 to weaning at 42 d. Calf starter (CS; 18% CP) and water were fed free choice d 1 to 56. Day 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Treatments (Trt) were 1), Control MR and CS with rumensin (R; 33 mg/kg); 2), MR with 0.3% sodium butyrate (NaB; Adimix-Pro) and CS with R; 3), Control MR and CS with 0.33% NaB (Adimix-30C); and 4), MR with 0.3% NaB and CS with 0.33% NaB. Ambient temperatures averaged a high of 27.2°C (range 18.9 to 38.3°C) and a low of 16.9°C (range 10.6 to 26.1°C) during the study (June, July, August, 2011). Calves fed MR with NaB (Trt 2,4) had greater pre-weaning ADG ($P = 0.02$) and gain/feed ($P = 0.001$) than those fed MR without NaB (Trt 1,3). Similar trends ($P = 0.09$) were observed for d 1–56 ADG. Calves fed Trt 1 had reduced gain/feed and tended to have lower pre-weaning and overall ADG ($P = 0.07$) vs. Trt 2, 3, and 4. The addition of NaB or R to starter did not affect starter intake pre- or post-weaning. There were also no differences in total DMI between treatments averaging 0.78 kg/d and 1.76 kg/d during the pre- and post-weaning periods, respectively. There were no pre- or post weaning scouring days and treatment cost differences due to treatments. Under the conditions of this study there were benefits to calf performance of adding NaB to non-medicated MR during the summer months. Using NaB in CS appeared to be an acceptable alternative to R.

Key Words: Holstein calves, performance, sodium butyrate

M304 Limiting amino acids for pregnant heifers fed corn silage-based diet.

D. Wang, J. Q. Wang,* S. C. Li, D. P. Bu, Y. D. Zhang, P. Sun, and L. Y. Zhou, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Two experiments were conducted to determine limiting amino acids (AA) for pregnant heifers fed corn silage-based diet. In experiment 1, four 21-mo-old Holstein Heifers (BW = 450 ± 20kg) fitted with ruminal, proximal duodenal and terminal ileal cannula were used to determine flows of AA into the duodenum and apparent intestinal AA digestibilities. These data were used to calculate amounts of total essential amino acids (TEAA) that should be infused into the duodenum to match the requirements of AA of growing and pregnant heifers according to calculations, which suggested that 8, 15, 20, 5, 15, 15, 20, 5, 10 and 5 g/d of methionine, histine, lysine, arginine, threonine, valine, leucine, isoleucine, phenylalanine and tryptophane were required, respectively, to be supplemented to the duodenum. In experiment 2, three 23-mo-old Holstein Heifer (BW = 470 ± 25kg) fitted with ruminal, proximal duodenal and terminal ileal cannula were used in a duplicate 3 × 3 Latin square design experiment, and the 3 treatments were continuously duodenal infusion of a mixture of methionine, Histine, lysine, arginine, threonine, valine, leucine, isoleucine, phenylalanine and tryptophane at 8, 15, 20, 5, 15, 15, 20, 5, 10 and 5 g/d, respectively (TEAA, from experiment 1), or replacement of histine (−15 g histine) or lysine (−20 g lysine) respectively from the TEAA mixture. Data were analyzed using MIXED procedures. When cows were fed corn silage diet, there was no significant effect ($P > 0.05$) of amino acids infusion on nitrogen retention plasma amino acid and plasma urea nitrogen. Replacement of lysine reduced lysine concentrations in plasma ($P < 0.01$). Replacement of histine reduced histine concentrations in plasma ($P = 0.07$). Replacement of lysine increased phenylalanine and valine concentrations in plasma ($P < 0.05$). Collectively, these data suggest that for pregnant heifers fed corn silage-based diet, lysine was likely the first limiting amino acid, followed by histine.

Key Words: limiting amino acid, lysine, plasma amino acids

Ruminant Nutrition: Dairy: Feed Additives I

M305 Effect of live yeast on milk yield and related responses in a commercial dairy herd. G. E. Higginbotham*[1], A. R. Castillo[2], J. M. Heguy[3], and H. A. Rossow[4], *[1]University of California Cooperative Extension, Madera, [2]University of California Cooperative Extension, Merced, [3]University of California Cooperative Extension, Modesto, [4]University of California School of Veterinary Medicine, Tulare.*

Two pens with approximately 220 early lactating Holstein cows (averaging 70 DIM) were used to investigate the effect of supplementing their diets with a live *Saccharomyces cerevisiae* yeast (Yeast) versus no yeast supplementation (Control). Both treatment pens were fed a TMR 2x daily composed of 2.3% wheat hay, 4.0% alfalfa silage, 16.0% alfalfa hay, 26.2% corn silage, 16.0% earlage, 8.4% wet distillers grains, 4.0% whey, 4.8% rolled corn, 18.3% concentrate mix composed of 56.5% canola meal, 21.7% whole cottonseed, 2.2% EnergII, 8.7% high-fat product and 10.9% mineral mix. Total DM offered per cow was 28.5 kg/d. The yeast supplement was fed at the rate of 4.0g/cow/day in the TMR. Cows were milked 2 times daily and housed in freestalls with access to an open dry-lot. Milk yield and composition were recorded by weekly milk weights during the 8-wk trial. Only cows that were in the experimental pens during the complete duration of the trial were used for data analysis (n = 154-control; n = 149-yeast). Milk production of cows before entering treatment pens were used as a covariant. Adjusted mean milk and FCM production was significantly higher ($P < 0.01$) for Yeast versus Control cows, 45.5 vs. 43.3 kg/d (milk) and 43.8 vs. 42.7 kg/d (3.5% FCM). No differences in milk fat (mean 3.28%) or MUN (mean 11.8 mg/dL) were shown. Ruminal fluid pH, total VFA concentration and blood urea N (BUN) were measured twice at one-week intervals from 10 cows per treatment. BUN concentrations were significantly ($P < 0.001$) higher for yeast fed cows, 14.5 vs. 13.7 mg/100mL. Rumen acetic acid was significantly higher ($P < 0.01$) for control, 67.3 vs. 58.5 Mmol/l. Rumen NH3 was significantly ($P < 0.01$) higher for Control versus Yeast fed cows, 16.1 vs. 11.5 mg/100mL. Under the conditions of this field trial, live yeast increased milk production and other parameters (rumen and blood) were affected.

Key Words: milk production, rumen fermentation, yeast

M306 Effects of corn shredlage on lactation performance by dairy cows. L. F. Ferraretto* and R. D. Shaver, *University of Wisconsin-Madison, Madison.*

The objective of this trial was to determine the effects of feeding a TMR containing corn shredlage (SHRD) or processed corn silage (KP) on lactation performance by dairy cows. The KP was harvested using conventional rolls at 3 mm roll gap and the chopper set at 19 mm of theoretical length of cut (LOC). The SHRD was harvested using novel cross-grooved rolls at 2.5 mm roll gap and the chopper set at 30 mm LOC. The SHRD and KP were harvested from one field on 2 consecutive d and stored in separate silo bags for 30 d before the feeding trial. The DM of SHRD and KP during feed-out averaged 35%. One hundred and 12 cows (116 ± 36 DIM and 700 ± 20 kg of BW at trial initiation) were stratified by breed and parity and randomly assigned to 14 pens each with 8 cows. Pens were randomly assigned to the 2 treatment TMR in a completely-randomized design. A 2-wk covariate adjustment period with cows fed a 50:50 mixture of the treatment diets was followed by an 8-wk treatment period with cows fed their assigned treatment diet. The TMR contained (DM basis) KP or SHRD (50%), alfalfa silage (10%), concentrate mixture (40%). Data were analyzed using Proc Mixed in SAS with covariate, treatment, wk, and treatment x wk interaction as Fixed effects and pen within treatment as a Random effect. Cows fed SHRD tended ($P < 0.08$) to consume 0.7 kg/d more DM than KP. Milk yield (43.2 kg/d) did not differ ($P > 0.10$) between treatments. Fat- and energy-corrected milk (FCM, ECM) yields tended ($P < 0.07$ and $P < 0.10$, respectively) to be 1.0 kg/day greater for cows fed SHRD. A treatment by wk interaction ($P < 0.04$) was detected for both FCM and ECM yields; similar ($P > 0.10$) during wk 2, a tendency ($P < 0.10$) for SHRD to be greater during wk 4 and 6, and greater ($P < 0.05$) for SHRD at wk 8. Milk composition did not differ ($P > 0.10$) between treatments. The TMR particle size (15.6+2.9% vs. 3.5+1.4% of particles retained on a 19 mm screen) was greater for SHRD than KP, and feed sorting was minimal and did not differ ($P > 0.10$) between treatments. Feeding corn shredlage tended to increase dry matter intake and fat- and energy-corrected milk yields compared with processed corn silage.

Key Words: corn silage, dairy cow, shredlage

M307 Could live yeast supplement improve milk composition of mid lactating Holstein cows during heat stress? M. Dehghan-Banadaky*[1], R. Motameni[2], and M. Ebrahimi[1], *[1]University of Tehran, Karaj, Tehran, Iran, [2]Islamic Azad University, Tehran, Iran.*

Fifty-six Holstein cows with averaged 145 d postpartum, were used to investigate the effects of live yeast supplement (4 g/cow daily of Probio-Sacc with 15×10^9 cfu) on productivity during hot summer conditions (average thermo humidity index, THI = 78.07). Cows were fed in pens a control diet without or with 4 g of live yeast/cow daily for 4 weeks. The diet as a total mixed ration on dry matter (DM) basis included: corn silage (18.4%), alfalfa hay (21.6%), and a concentrate mix (60%). Live yeast added to the total mixed ration at the time of feeding. Milk production (35.56 and 35.67 kg/d, for control and live yeast treatment, respectively), 3.5% fat-corrected milk (32.20 and 32.96 kg/d), DM intake (22.84 and 22.52 kg/d) were similar for cows fed control and live yeast diets ($P > 0.05$). Greater milk fat percentage (3.02 vs. 3.18) was observed for cows fed live yeast compared with control group ($P < 0.05$). Also milk urea nitrogen (MUN) concentration in cows fed live yeast were lower compared with control group (16.67 vs. 18.75 mg/dl). Other milk components were similar in both groups. Body weights and body condition score changes were similar in both groups. The results suggested that the live yeast cannot improve productivity of heat stressed dairy cows in mid lactation but improved milk fat percentage and decreased MUN.

Key Words: heat stress, lactating cows, live yeast

M308 Investigation of live yeast supplement on blood metabolites and nutrient digestibility in mid lactating Holstein cows. M. Dehghan-Banadaky*[1], R. Motameni[2], and M. Ebrahimi[1], *[1]University of Tehran, Karaj, Tehran, Iran, [2]Islamic Azad University, Tehran, Iran.*

Present study conducted to investigate the effects of live yeast (4 g/cow daily of Probio-Sacc with 15×10^9 cfu) on dietary nutrient digestibility and blood metabolites of mid lactating Holstein cows during hot summer conditions (average thermo humidity index, THI = 78.07). Fifty-six Holstein cows with averaged 145 d in milk, were used in a complete random design with 2 treatments and 28 replicates for 35 d. Cows were fed in pens a control diet without or with 4 g of live yeast/

cow daily. The diets as TMR in dry matter (DM) basis included: corn silage (18.4%), alfalfa hay (21.6%), and a concentrate mix (60%). The live yeast supplement added to the total mixed ration at time of feeding. Blood samples were taken in 2 subsequent days in last week. Feed, ort and fecal samples were taken during 3 subsequent days in last week for nutrient digestibility assay. Acid insoluble ash used as an internal marker. Cows fed live yeast had higher blood glucose (76.60 vs. 66.50 mg/dL, $P < 0.05$) and numerically higher total protein concentration (10.69 vs. 9.73 g/d, $P = 0.07$) compared with control. Blood urea nitrogen was lower for cows fed live yeast compared with control ($P < 0.05$). Nonesterified fatty acids, β-hydroxybutyrate (BHBA), triglyceride, and total cholesterol were similar for both groups. The apparent digestibility of NDF was higher for cows fed live yeast compared with control (53.50 vs. 49.30%, $P < 0.05$) but, the apparent digestibility of DM, OM, CP, and ADF were similar for both diets. Results suggested that live yeast supplement can improve nutrient digestibility and blood metabolites of heat stressed dairy cows in mid lactation.

Key Words: blood metabolites, heat stress, live yeast

M309 Influence of *Salix babylonica* extract on daily milk production and composition as well as in vitro gas production in dairy cows. A. Z. M. Salem*[1], R. Rojo[2], M. Ronquillo[1], H. Gado[3], N. Pescador[1], and F. Peralta[2], [1]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado de Mexico, Mexico,* [2]*Centro Universitario UAEM Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México,* [3]*Department of Animal Production, Faculty of Agriculture, Ain Shams University, Cairo, Egypt.*

A 3 × 3 Latin square design was used to evaluate the effect of 0, 150, and 300 mL of *Salix babylonica* extract on daily milk production and composition in dairy cows. Cows (3 cows for each treatment, 390 ± 10 kg) were fed on 5 kg of commercial concentrate (14% CP and 33% NDF- to meet 70% of their daily metabolizable energy) and oat hay ad libitum. Experiment was carried out in 3 experimental periods of 21 d (14 d of adaptation and 7 d for samples collection). Extract doses were mixed daily morning with a small amount of concentrate (approximately 1 kg) and fed to cows. Daily feed intake, water consumption, milk production and composition (solids not fat, fat, protein and lactose) were determined. In vitro gas production of the diet fed to cows (40: 60, concentrate: Oat hay) was recorded after 2, 4, 6, 8, 10, 12, 24, 48, 72 and 96 h of incubation with 0, 06, 1.2 and 1.8 mL extract/g DM. Rumen liquor was collected from 2 Brown Swiss cows (450 kg BW) and fitted with permanent cannulas. Milk production was increased ($P < 0.05$) with the extract addition at 150 or 300 mL/d while all the milk composition parameters were not affected by the extract addition. Milk energy output (Mcal/d) and milk density were also increased ($P < 0.05$) with extract addition at the 2 doses. Milk efficiency (kg DM/kg of milk) was improved ($P < 0.05$) with the extract doses versus control (1.59, 1.56 and 1.35, for 150, 300 and 0 mL extract/d, respectively). In vitro gas production of the diet fed to cows was increased ($P < 0.05$) dramatically with the 2 levels of extract with a short lag time and high rate of gas production per hour versus control (i.e., 0 mL). Addition of *Salix babylonica* extract improved milk production by 12%, without effect on milk composition in dairy cows probably due to its positive impact of ruminal microorganism's activities.

Key Words: cow, milk production, *Salix babylonica*

M310 A novel approach to measure the bioavailability of rumen protected l-lysine. K. B. Cunningham*[1], J. A. Davidson[1], S. E. Boucher[2], and B. L. Miller[1], [1]*LongView Animal Nutrition Center, Land O' Lakes Purina Feed, Gray Summit, MO,* [2]*Kemin AgriFoods North America, Des Moines, IA.*

This experiment includes 2 studies to determine bioavailability of a rumen protected L-lysine (Lys) product, USA Lysine (Kemin Industries Inc., Des Moines, IA), in cattle through the use of plasma lysine concentrations [p-Lys] affected by L-lysine (i-Lys) infused in the small intestine and fed as USA Lysine. Study 1 was a 4 × 4 Latin square design with 7 d periods. Four, duodenally cannulated steers (290 ± 18 kg) were fed a TMR twice daily (14.9% CP, 2.75 Mcal/kg ME) ad libitum with 60% of the TMR offered at 0800 h and remainder 12 h later. One of 4 Lys levels, 0, 30, 60 or 90 g, was infused daily into the duodenum of each steer for 22 h. On the 7th day, plasma was collected through jugular veinipuncture at 0, 2, 4, 6 and 8 h post-feeding. Each plasma sample was analyzed for L-lysine content. SAS linear regression analysis was applied to [p-Lys] versus g/d of i-Lys. Regression utilizing natural log-transformation of [p-Lys] as a percent of baseline values yields a predication equation of $[\text{p-Lys}] = 0.01146 *(\text{i-Lys}) + 4.60958$, $r^2 = 0.602$. This relationship between [p-Lys] and supplemented Lys infused to the small intestine is useful to predict bioavailability of USA Lysine in study 2. Study 2 was a replicated 4 × 4 Latin square design using 8 steers (276 ± 24 kg) fed the basal diet of study 1 and followed a similar feeding regimen, sampling and analyses. Dietary Lys treatments were offered as USA Lysine and supplied as 3 types of incorporations into the grain mix: hand mixed (50 and 100 g; H50 and H100), mechanical mixed (100 g; M100) and pellet (100 g; P100). Results of H50 did not increase [p-Lys] over the basal diet. Plasma Lys concentrations of H100, M100 and P100 were different from the basal diet ($P < 0.0001$). Mechanical mixing and pelleting of USA Lysine in the top-dress did not affect [p-Lys] compared with hand mixed. Regardless of dietary incorporation method, the regression equation applied to the [p-Lys] of steers fed 100 g of USA Lysine, predicts at least 50% bioavailability of Lys from USA Lysine.

Key Words: bioavailability, cattle, lysine

M311 Determining the bioavailability of lysine in AjiPro-L using the plasma free amino acid dose response method. N. L. Whitehouse*[1], E. S. Fletcher[1], A. F. Brito[1], C. G. Schwab[2], and I. Shinzato[3], [1]*University of New Hampshire, Durham,* [2]*Schwab Consulting LLC, Boscobe,* [3]*Ajinomoto Heartland Inc., Chicago, IL.*

Six multiparous ruminally cannulated Holstein cows averaging 108 d in milk were used in a 6 × 6 Latin square study with 7-d periods. Samples were collected during the last 3 d. The 6 treatments were: 1) control (0 g/d L-Lys), 2) 30 g/d of abomasally infused Lys, 3) 60 g/d of abomasally infused Lys, 4) 30 g/d of feed supplemented Lys, 5) 45 g/d of feed supplemented Lys, and 6) 60 g/d of feed supplemented Lys. An L-Lys HCl product containing 80% Lys and assumed to be 100% bioavailable was used for the infusions. The AjiPro-L (Ajinomoto Co. Inc., Tokyo), which contains 40% Lys (as fed basis) was mixed with 454 g of concentrate and offered to the cows 1 h before each of the 3 daily feedings. The basal diet was formulated to meet the Lys requirements and contained 36% corn silage, 14% grass silage, 3% alfalfa hay and 47% concentrate. Four blood samples were collected from the tail vein at 2-h intervals starting at 0700 h; samples were centrifuged, deproteinized, and composited by cow/day with plasma stored at −80°C for AA analysis. Data were analyzed using the MIXED and PROC REG procedures of SAS. Milk yield and composition, and DMI were not different among treatments. Lysine was the only plasma AA that increased linearly (*P*

≤ 0.05) in response to infused or feed supplemented Lys. The slopes for the infused and feed supplemented Lys were 0.0224 ($r^2 = 0.98$) and 0.0078 ($r^2 = 0.94$), respectively, when the concentration unity μg/mL was used for expressing the concentration of plasma Lys relative to that of total AA. When the concentration unity μM was chosen to express plasma Lys as a proportion of total AA, the slopes were slightly lower for the infused (0.0183; $r^2 = 0.97$) and feed supplemented (0.0068; $r^2 = 0.93$) treatments. The calculated bioavailabilities for AjiPro-L using the 2 different sets of slopes (0.0224 and 0.0078 μg/mL vs. 0.0183 and 0.0068 μM) were relatively similar averaging 35% (0.0078/0.0224 × 100) and 37% (0.0068/0.0183 × 100), thus indicating marginal impact of concentration unity (μg/mL vs. μM) on the outcome of Lys bioavailability values using the in vivo plasma response method.

Key Words: amino acids, lysine, bioavailability

M312 Microencapsulated sodium selenite supplementation in dairy cows: Effects on selenium status. E. Grilli*[1], P. Fantinati[2], M. Morlacchini[3], and A. Piva[1], [1]*DISMVET, Facoltà di Medicina Veterinaria, Ozzano Emilia, Italy,* [2]*Vetagro SpA, Reggio Emilia, Italy,* [3]*Centro Ricerche per la Zootecnia e l' Ambiente, San Bonico, Italy.*

The objective of the study was to assess the selenium status of dairy cows fed with 3 different sources of selenium; that is, free or microencapsulated sodium selenite and yeast selenium. Thirty dairy cows were divided in 5 groups and fed the same total mixed ration with 5 different supplementations of selenium: the control group (CTR) received sodium selenite at 0.3 mg/kg DM; M1 and M2 group received lipid microencapsulated sodium selenite at 0.3 mg/kg, and 0.5 mg/kg DM, respectively; Y1 and Y2 group received selenized yeast providing selenium at 0.3 mg/kg and 0.5 mg/kg, respectively. Cows were fed the supplements for 56 d during which milk, blood, and fecal samples were collected weekly to perform selenium content analysis and glutathione peroxidase 1 (GPx-1) activity. Data measured over time were subjected to ANOVA using the repeated measures in the mixed procedure of SAS in a complete randomized design. The statistical model included the fixed effect of treatment, time of measurement and (treatment x time) interaction. The random variable was the cow within treatment. Pre-experimental variables were subjected to analysis of covariance for adjustments. Cows fed with 0.3 mg/kg of microencapsulated selenium had 6.6% and 5.7% higher total plasma selenium concentration than CTR and Y1 group, respectively. Also, milk selenium concentration was higher in M1 group compared with CTR and Y1 group (+38.2% and 13.1%, respectively; source effect). The increment was more pronounced at the highest inclusion rate (0.5 mg/kg, M2 group). Despite the higher selenium content in body fluids observed in animals fed the microencapsulated form, GPx-1 activity was not significantly affected by treatments. The results showed that lipid microencapsulation is a suitable technique to protect nutrients from ruminal reduction of bioavailability and that microencapsulated sodium selenite is absorbed and incorporated in tissues (plasma and milk) in a more efficient way than in the free form. Microencapsulated sodium selenite resulted also comparable to Se-yeast in terms of availability and incorporation in milk when fed at 0.3 mg/kg DM, whereas the inclusion in the diet at 0.5 mg/kg DM resulted more advantageous for the microencapsulated form.

Key Words: dairy cow, microencapsulation, selenium

M313 Effects of dietary amylase and sucrose on productivity of cows fed low-starch diets. C. F. Vargas*[1], M. Engstrom[2], and B. J. Bradford[1], [1]*Kansas State University, Manhattan,* [2]*DSM Nutritional Products, Parsippany, NJ.*

Recent studies have observed positive effects of both sucrose and exogenous amylase on fiber digestion and productivity of dairy cattle. Our objective was to evaluate direct effects and interactions of amylase and sucrose on DMI, milk production, and milk components. Forty-eight multiparous Holstein cows between 70 and 130 DIM were randomly assigned to each of 4 pens (12 cows/pen). Pens were randomly assigned to treatment sequence in a 4 × 4 Latin square design balanced for carryover effects. The treatments were a control diet (36% NDF, 21% starch), the control diet with amylase (0.5 g/kg DM; Rumistar, DSM), a diet with sucrose replacing corn grain at 2% of DM, and the sucrose diet with amylase (0.5 g/kg DM). All data were analyzed with mixed models including the fixed effect of treatment and the random effects of period and pen. Milk data included the random effects of cow nested within pen and pen × period to provide the error term for the pen-level analysis. DMI was not affected by treatments. Milk yield and milk composition were not altered by the inclusion of sucrose or amylase; however, a tendency for an amylase by sucrose interaction was observed for milk protein content ($P = 0.06$), reflecting slightly lower milk protein concentrations for amylase and sucrose treatments (3.00 and 2.99 ± 0.03%) compared with control and amylase + sucrose treatments (3.02 and 3.03 ± 0.03%). Solids-corrected and fat-corrected milk yield variables were not significantly altered by treatment, although the direct effect of amylase approached significance for both variables (both $P = 0.13$), suggesting possible small increases with amylase supplementation (~0.5 kg/d). Feed efficiency (ECM/DMI) numerically increased with either amylase (1.57 ± 0.12) or sucrose (1.60 ± 0.12) treatment, but the combination of the 2 (interaction $P = 0.19$) resulted in feed efficiency similar to the control treatment (both 1.50 ± 0.12). The inclusion of amylase or sucrose did not significantly affect DMI, productivity, or feed efficiency in mid-lactation cows fed low-starch, high-fiber diets.

Key Words: sugar, enzyme, lactation

M314 The effect of essential oil/botanical product on performance and health of calves. B. L. Miller, T. J. Earleywine,* and T. E. Johnson, *Land O' Lakes Inc., Webster City, IA.*

One hundred seven (107) 3- to 10-d-old Holstein bull calves with an average initial weight of 47.3 kg (SD = 3.44 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility. Calves were randomly assigned according to BW and blood gamma globulin to either a control or experimental milk replacer (MR) diet offered in a 15% solids solution. Both diets utilized a 22% all milk protein/20% fat non-medicated MR powder. The experimental diet was the same as the control with an essential oil/botanical product (Digestarom, Micro-Plus Konzentrate; Stadtoldendorf, Germany) included at 0.05% active ingredient. Calves were fed to provide 681 g DM feeding rate daily in 2 feedings at 0700 and 1615 h. Calves were offered 340.5 g in one feeding at 0700 h during the last week. Calf starter (18% crude protein, as fed basis) was fed ad libitum throughout this 42 d trial. Data were analyzed by Mixed procedures of SAS. Calves offered no essential oil/botanical product were inferior ($P = 0.10$) in total weight gain, MR intake ($P = 0.07$), feed efficiency ($P < 0.05$), scour scores ($P < 0.01$) and scour days ($P < 0.01$) when compared with calves receiving essential oil/botanical product. Essential oil/botanical product improved calf performance and health.

Table 1. Performance of calves offered MR without (Diet 1) or with (Diet 2) essential oils/botanical product

Item	Diet 1	Diet 2	*P*-value	SE
BW gain, kg	20.6	22.8	0.10	0.914
MR (DM), kg	24.1	25.0	0.07	0.342
Starter (DM), kg	20.2	20.9	0.66	1.070
Feed/Gain	2.28	2.10	0.04	0.060
Scour score,[1] 2 wk avg	1.35	1.22	0.01	0.030
Scour days, 2 wk	4.53	3.03	0.01	0.388

[1]Scour score = 1 to 4 scale; 1 = normal to 4 = watery with dehydration.

Key Words: calves, milk replacer, essential oils/botanical

M315 Effects of two sources of rumen-protected fat associated or not with conjugated linoleic acid (CLA) on milk fatty acid profile in dairy ewes. E. Ticiani[1], J. De Souza[2], F. Batistel[2], M. Baldin[3], R. Dresch[3], M. A. S. Gama[4], F. C. F. Lopes[4], and D. E. Oliveira*[1,3], *[1]Universidade do Estado de Santa Catarina, CEO, Chapecó, Santa Catarina, Brazil, [2]Universidade de São Paulo, ESALQ, Piracicaba, São Paulo, Brazil, [3]Universidade do Esatado de Santa Catarina, CAV, Lages, Santa Catarina, Brazil, [4]Embrapa Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

The aim of this study was to evaluate the associative effects of 2 sources of calcium salts of fatty acids (Agelac 84 or Megalac E) and an unprotected CLA (UnCLA) supplement (Luta-CLA60) on milk fatty acid profile in dairy ewes. Thirty-nine Lacaune and 36 East Friesian ewes in mid lactation (70 ± 7 DIM) received for 53 d one of the following dietary treatments in a 2 × 2 factorial design:1) 27g of Agelac 84; 2) 30g of Megalac E; 3) 27g of Agelac 84 + 20g of UnCLA; and 4) 30g of Megalac E + 20g of UnCLA. The UnCLA supplement contained 29.9% of trans-10, cis-12 and 29.8% of cis-9, trans-11. Ewes grazed Panicum maximum Jacq. cv. Aruana grass and were fed an isoproteic concentrate (1 kg DM/d) in which the fat supplements were added. Milk samples were collected on the 14th day of the experimental period and analyzed for fatty acid profile by gas chromatography. Data were analyzed using the PROC MIXED of SAS. There was no interaction between treatments and breed. The concentration of fatty acids < 16C in milk fat was reduced by CLA and Megalac E (Table 1). Milk fat trans-10, cis-12 CLA was increased by 861% in ewes fed CLA (0.026 vs 0.224 g/100g of FA, $P < 0.001$) with no fat and fat x CLA effects. Milk fat cis-9, trans-11 was increased 18% (0.99 vs 0.84 g/100g of FA) and 0.7% (0.84 vs 0.83 g/100g of FA) by CLA and Megalac E ($P < 0.01$), respectively and there was an interaction between CLA x fat (Megalac E +UnCLA = 1.09 vs Agelac 84 +UnCLA = 0.89 g/100g of FA, $P < 0.02$). All desaturase indexes were reduced by CLA, and Megalac E reduced C16:1/C16:0 and CLA/trans-11 C18:1 ratios. The milk fatty acid profile of ewes was altered by dietary supplementation with UnCLA and different sources of rumen-protected fat.

Table 1. Milk fatty acid profile of dairy ewes fed two sources of rumen-protected fat (Agelac 84 or Megalac E) associated or not with UnCLA

M316 Feeding protected lysine to lactating dairy cows improved milk protein yield. J. A. Davidson*[1], S. E. Boucher[2], and B. L. Miller[1], *[1]LongView Animal Nutrition Center, Land O' Lakes Purina Feed, Gray Summit, MO, [2]Kemin AgriFoods North America, Des Moines, IA.*

The objective was to determine if increasing metabolizable Lys with either blood meal (BM) or a rumen protected lysine source, USALysine (Kemin Industries, Des Moines, IA), improved milk yield and milk protein yield of dairy cows. Twenty-four cows averaging 90 DIM (blocked by parity, milk yield, and DIM) were assigned to one of 3 treatments varying in metabolizable Lys supply (g/d): Control (Ctrl, 180 g/d), BM (200 g/d), or USALysine (204 g/d). All diets were formulated with Dynamic Nutrition System model of Land O' Lakes Purina Feed with a minimum of 0.14 kg/h/d of BM and 22 g/h/d of Smartamine M (Adisseo, Antony, France) to provide 60 g/d of metabolizable Met. To increase Lys, the BM treatment included an additional 0.27 kg/h/d of BM. Smartamine M was added to diets to maintain a 3:1 ratio of Lys:Met. Cows were individually fed with Calan door system for 28 d. Data from d 5 to 28 were analyzed with repeated measures procedure of SAS. No differences were detected for main effect of day or interactions with day, thus data were pooled across day. Dry matter intake was 22.1 for cows fed additional BM and 23.1 and 23.8 kg/d for Ctrl and USALysine, SE 0.58, $P = 0.13$). Adjusting for actual DMI, cows consumed 165, 177, and 184 g/d of metabolizable Lys and 56, 52 and 54 g/d of metabolizable Met for Ctrl, BM and USALysine, respectively. Cows fed USALysine had greater milk protein concentration (2.92%) and yield (1.30 kg/d) than Ctrl (2.77% and 1.22 kg/d) and BM (2.75% and 1.19 kg/d) fed cows (SE 0.04 and 0.03, respectively, $P < 0.05$). Energy-corrected milk yield tended to be greater for USALysine cows (42.1 kg/d, SE 0.88, $P = 0.07$) compared with the other groups (40.6 and 39.3 kg/d for Ctrl and BM). However, daily milk yield was not statistically different (41.9, 42.0, and 44.1 kg/d for Ctrl, BM, and USALysine, respectively, SE 1.51). Increasing metabolizable Lys with BM numerically decreased DMI, thus no improvements in milk or milk protein yield were observed. Utilizing USALysine to deliver additional metabolizable Lys increased milk protein concentration and yield. USALysine is a protected source of Lys that can be used to improve lactation performance when Lys supply is limiting.

Key Words: dairy cows, milk protein, protected lysine

M317 The effect of treating corn stover silage with cellulase and *Lactobacillus* on nutritive value of silage in dairy cows. H. Ma, J. Q. Wang,* D. P. Bu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences,, Beijing, China.*

Corn stover silage is a major forage source for dairy cows during the winter season in the northern China due to its low cost and high content of carbohydrates. But its crude protein concentration and digestibility are low. The aim of this study was to determine if the nutritive content and digestibility in the total gastrointestinal tract of corn stover silage could be improved by addition of cellulase and *Lactobacillus* preparations at ensiling. Corn stover after harvest was ensiled with untreated or treated with commercial cellulase (1.0 g/kg of fresh forage) and *Lactobacillus* (1 × 100,000 cfu/g of fresh forage) in laboratory silos. Three ruminally cannulated Holstein dairy cows were used in a 3 × 3 Latin square design of three 21-d periods. The data were analyzed using the GLM procedure of SAS 9.1. Duncan's multiple range tests were used to detect statistical significance between treatment groups. Treatment with cellulase and *Lactobacillus* increased CP concentrations of corn stover silages ($P < 0.05$), and decreased neutral detergent fiber (NDF) and acid detergent fiber (ADF) concentrations of silages ($P < 0.05$) compared with the untreated group. In addition, silages treated with cellulase had lower concentrations of NDF and ADF compared with silages treated with *Lactobacillus* ($P < 0.05$). In situ ruminal DM, CP, NDF and ADF degradability of silages were improved by treated with cellulase and *Lactobacillus* ($P < 0.05$). Similarly, digestibility of DM, CP, NDF and ADF in the total tract were also improved by treated with cellulase and *Lactobacillus* ($P < 0.05$). Moreover, ruminal degradability and digestibility in the total tract of DM and NDF were higher in silages treated with cellulase than in untreated and treated with *Lactobacillus* group ($P < 0.05$). The results indicate that when applied at ensiling, cellulase and *Lactobacillus* can improve the degradability and digestibility of corn stover silages in dairy cows. In the experimental conditions of the current trial, nutritive value of corn stover silage treated with cellulase was superior to treatment with *Lactobacillus*.

Key Words: corn stover silage, dairy cow, nutritive value

M318 Degradation of L-arginine and N-carbomyl glutamate and their effect on rumen fermentation in vitro. B. Chacher,* D. M. Wang, H. Y. Liu, and J. X. Liu, *Institute of Dairy Science, MoE Key laboratory of Molecular Animal Nutrition, College of Animal Sciences, Zhejiang University, Hangzhou, China.*

Arginine is a versatile amino acid and plays an important role in urea cycle and protein synthesis, but the high cost limits its use in dairy production. *N*-carbomyl glutamate (NCG) is a metabolically stable analog of *N*-acetyl glutamate, which is an essential allosteric activator of carbamoyl phosphate synthase-I, and may be substituted for endogenous synthesis of arginine. The objective of this experiment was to determine the degradation rates of L-arginine (L-arg) and NCG and to examine their effects on rumen fermentation. The in vitro gas test based on syringes was employed and rumen liquor were collected from 3 rumen-fistulated dairy cows that were fed 55% roughage and 45% concentrate mixture, plus premix (minerals and vitamin). Syringes were filled with 30 mL of medium (10 mL rumen liquor and 20 mL buffer solution) and then aerobically incubated in 3 replicates with 1 mmol/L of L-arg, NCG or control (without L-arg and NCG) at 39°C. At incubation for 0, 2, 4, 6, 12 and 24 h, gas production and pH value were recorded and rumen fluid samples were collected in separate tubes to determine the contents of L-arg and NCG. At 24 h, concentrations of ammonia N, volatile fatty acids and microbial protein were measured. Degradation rates of L-Arg were 0, 32.0, 47.1, 52.8, 99.3 and 100%, while NCG degradation in rumen fluid was 0, 7.8, 12.8, 13.3, 14.2 and 17.8% during 0, 2, 4, 6, 12 and 24 h, respectively. Gas production and ratio of acetate to propionate were higher in groups treated with L-arg and NCG than that in the control ($P < 0.01$). Ammonia N concentration was higher ($P < 0.01$) in group added with L-arg than that in NCG and control group. Microbial protein concentration diminished in groups treated with L-arg and NCG, compared with the control ($P < 0.01$). In summary, the effects of L-arg and NCG on rumen fermentation were numerically relatively similar. Rapid degradation of L-arg in rumen indicates nutritionally wasteful process, and it should be protected from rumen degradation, while NCG can be fed to ruminants with no need for coating.

Key Words: L-arginine, N-carbomyl glutamate, rumen fermentation

M319 Folic acid and vitamin B12 supplement enhances energy metabolism of dairy cows in early lactation. M. Duplessis*[1,2], C. L. Girard[2], D. E. Santschi[3], D. M. Lefebvre[3], and D. Pellerin[1], [1]*Université Laval, Département des sciences animales, Québec, Qc, Canada,* [2]*Agriculture and Agri-Food Canada, Sherbrooke, Qc, Canada,* [3]*Valacta, Ste-Anne-de-Bellevue, Qc, Canada.*

The purpose of this study was to measure the effects of folic acid and vitamin B12 supplement on milk production and components, and indicators of energy balance of dairy cows from 3 wk before expected calving date until 8 wk after parturition. Commercial dairy herds (n = 15) were involved in this project. From February to December 2010, every 2 mo and within each herd, cows (n = 805) were randomly assigned, according to parity, predicted 305d milk production, and calving interval to receive weekly intramuscular injections (5 mL) of 1) saline 0.9% NaCl (C) or 2) 10 mg of vitamin B12 + 320 mg of folic acid (V). Milk production and components were obtained from the DHI agency (Valacta, Ste-Anne-de-Bellevue, Qc, Canada). Only milk production and components data for the first 60 DIM are presented. Cows with less than 2 tests were not included in the analysis. Body weight (BW) was measured by chest girth 3 wk before calving, and 1 and 8 wk after parturition. Body condition score (BCS) was evaluated on a 1 to 5 scale by the same individual every 2 wk until 100 DIM. Data were analyzed using the MIXED and GLIMMIX procedures of SAS. The 305d milk production before the study was similar between treatments (9663 ± 114 kg; $P = 0.97$). Average milk production for C and V was 36.9 ± 0.4 kg/d ($P = 0.99$). Milk fat concentration was 4.19 and 4.03 ± 0.04% for C and V, respectively ($P = 0.007$). Milk protein concentration was 3.09 and 3.15 ± 0.02% for C and V, respectively ($P = 0.02$). The vitamin supplement increased by 8.3% the number of cows with a protein:fat ratio greater than 0.75 ($P = 0.009$). From 1 to 8 wk after parturition, V cows lost 7.4 ± 2.6 kg BW less than C cows ($P = 0.007$). There was no treatment effect ($P = 0.45$) on BCS before calving (3.45 ± 0.04) but after parturition, the vitamin supplement tended to reduce BCS loss (treatment x time, $P < 0.07$). The observed reduction in BW and BCS losses and milk fat secretion without effect on milk production suggest that supplementary folic acid and vitamin B12 lessened the negative energy balance in early lactation. This effect was possibly due to an improved efficiency of energy metabolism.

Key Words: folic acid, vitamin B12, dairy cow

M320 The potential benefits of supplementing corn-based dairy diets with Zado or yeast for milk yield and production efficiency in dairy cows. H. Gado*[1], B. E. Borhami[2], and A. Z. M. Salem[3,2], [1]*Ain Shams University, Cairo, Egypt,* [2]*Alexandria University, Alexandria, Egypt,* [3]*Universidad Autónoma del Estado de México, Estado de México, México.*

The objective of this study was to verify the potential benefits of supplementing corn-based dairy diets (T0, control diet without any supplementation) with Zado (T1, contains 2.32 U/g Xylanase, 61.5 U/g α-Amylase, 7.05 U/g cellulase and 29.2 U/g protease) or yeast (T2) for milk yield and production efficiency in dairy cows. Sixty lactating Holstein dairy cows were randomly assigned to the 3 treatments and housed in pens (20 cows for each). All cows were fed the control diet for 4 weeks, followed by 8-weeks period on their assigned diets. The control diet consisted of 25% corn silage, 25% alfalfa silage, 6% alfalfa hay, and 44% of a ground corn-based concentrate (DM basis). Zado was added to concentrates to provide 40 g/head/day for (T1). Active dry yeast was added to the concentrate to provide 0.5 g Levucell/d per animal (T2). There was no difference in final BW (600 ± 22 vs. 610 ± 25 and 608 ± 20 kg; $P = 0.85$) for T0 vs T1 and T2, respectively. Meanwhile, there were differences for net energy (NE) output (34.1 ± 0.05 vs. 37.5 ± 0.07 and 35.3 ± 0.08 Mcal/d; $P < 0.05$), or efficiency of NE output (1.61 ± 0.03 vs. 1.42 ± 0.07 and 1.63 ± 0.04 Mcal/kg DMI; $P = 0.04$) for cows on T0 vs T1 and T2, respectively. There were differences in dry matter intake (21.3 ± 0.12 vs. 24.7 ± 0.14 and 21.0 + 0.18 kg/d; $P < 0.07$), 3.5% FCM (31.2 ± 0.41 vs. 36.6 ± 0.46 and 31.4 ± 0.38 kg/d; $P < 0.08$), and efficiency of fat corrected milk (FCM) production (1.63 ± 0.12 vs. 1.44 ± 0.24 and 1.68 ± 0.18 kg FCM/kg DMI; $P < 0.06$) for cows fed on T0 vs T1 and T2. In conclusion, cows fed on diet supplemented with Zado increased milk production in comparison to control or YEAST supplemented diets.

Key Words: milk production, yeast, Zado

M321 The effect of carnitine on growth and performance of calves fed milk replacer. B. L. Miller,* T. J. Earleywine, and T. E. Johnson, *Land O' Lakes Inc., Webster City, IA.*

Fifty-eight (58) 3–10 d old Holstein bull calves with an average initial weight of 45.7 kg (SD = 2.14 kg) were shipped from Wisconsin to the Land O' Lakes Research Facility. Calves were randomly assigned according to BW and blood gamma globulin to either a control or experimental milk replacer (MR) diet offered in a 17.6% solids solution. Both diets utilized a 28% all milk protein/20% fat non-medicated MR powder. The experimental diet was the same as the control with added carnitine, (International Animal Technologies, Marion, TX). Calves were fed to provide 1135 g DM feeding rate daily in 2 feedings at 0700 and 1615 h. Calves were offered 567.5 g in one feeding at 0700 h during the last week. Calf starter (22% crude protein, as fed basis) was fed ad libitum throughout this 49 d trial. Data were analyzed by Mixed procedures of SAS. Calves offered no Carnitine were inferior ($P < 0.05$) in total weight gain, starter feed intake ($P < 0.05$) and feed efficiency ($P = 0.11$) when compared with calves receiving carnitine. Carnitine improved calf growth and performance.

Table 1. Performance of calves offered MR without (Diet 1) or with (Diet 2) carnitine

Item	Diet 1	Diet 2	*P*-value	SE
BW gain, kg	30.9	34.9	0.02	1.11
MR (DM), kg	44.7	45.4	0.43	0.61
Starter (DM), kg	10.6	13.8	0.02	0.94
Feed/Gain	1.81	1.73	0.11	0.04

Key Words: calves, carnitine, milk replacer

M322 Effects of a solid oil supplement (Oralac) on milk fatty acid composition of grazing dairy cows. G. A. Gagliostro*[1], L. E. Antonacci[1], J. Ballistreri[2], E. Bonina[2], M. R. Williner[3], and C. A. Bernal[3], [1]*Instituto Nacional de Tecnología Agropecuaria, INTA, Balcarce, Buenos Aires, Argentina,* [2]*Tecnuar SRL, Rosario, Santa Fé, Argentina,* [3]*Universidad Nacional del Litoral, Santa Fé, Santa Fé, Argentina.*

Oralac (OR) is a lipid supplement (90% DM, 68.6% fat) for ruminants containing vegetable and marine oils. The fatty acid (FA) composition of OR is palmitic (11.25%), stearic (4.65%), oleic (31.7%), linoleic (44.7%), linolenic (2.45%), EPA (0.6%) and DHA (1%). The effect of OR on milk FA composition was tested on 20 multiparous Holstein cows in mid lactation. Cows consumed pasture (70% of total DM intake) and were offered concentrates (7.2 kg DM/cow) with increased OR content: OR-0, OR-8.75, OR-11.25 and OR-15%. Intake of OR was 0.666; 0.798 and 0.826 owing to concentrate refuse in OR-11.25 (6.9%) and OR-15 (27%). Intake of C18:2 was 0.13, 0.15 and 0.16 kg/cow/day in OR-8.75, OR-11.25 and OR-15. Fat intake was 1.75% of total DMI in OR-8.75 and 2.40% in the other 2 treatments. Milk yield was lower in OR-0 (27.4 kg/cow/d) than the average yield of 30.6 kg in OR supplemented cows ($P < 0.55$). Milk fat content (g/kg) was 33.5 in OR-0 and 30.2 in OR treatments ($P < 0.44$). Milk protein averaged 35.2 g/kg in all treatments. Milk concentration (g/100g) of C12:0 decreased (−32%) after OR feeding from 3.35 in OR-0 to 2.23 and 2.34 in OR-11.25 and OR-15 ($P < 0.03$) respectively. Basal (OR-0) concentration (g/100g) of C14:0 (9.82) decreased (−13%) in OR-11.25 and OR-15 (8.51) ($P < 0.21$). Basal C16:0 concentration (23.45 g/100g) decreased (−14%, $P < 0.02$) in OR-8.75 and OR-11.25. The atherogenicity index of milk in OR-11.25 and OR-15 (1.47) tended ($P < 0.09$) to be lower (−23%) than in OR-0 (1,92). Basal concentration (g/100g) of vaccenic acid (2.75) increased ($P < 0.0002$) after OR feeding (6.75). Concentration (g/100g) of rumenic acid was 1.23 in OR-0 increasing up to 2.75 in OR treatments (+124% over basal). The highest values were observed in OR-8.75 (3.01) and in OR-11.25 (2.96). Concentration of trans-10C18:1 in OR-0 (0.77 g/100g) remained low after OR feeding (1.88 g/100g) ($P < 0.58$). Basal concentration of trans-9 C18:1 averaged 0.23 g/100 g and was not affected by OR feeding ($P < 0.17$). The n-6/n-3 ratio was 3.5 in OR-0 ranging from 3.12 to 2.78 in OR treatments ($P < 0.58$). Basal OR-0 saturated/unsaturated FA ratio (1.62) was reduced ($P < 0.04$) in OR-8.75 (1.14) and OR-11.25 (1.28). Results suggested a positive effect of OR at very low doses of total oil intake on milk yield, FA composition and functional-healthy value of milk.

Key Words: grazing dairy cows, functional milk, conjugated linoleic acid

M323 Combination of bacterial and yeast probiotics: A step forward to unravel their mode of action. J. Chiquette*[1], J. Lagrost[2], C. L. Girard[1], S. Li[3], J. C. Plaizier[3], and G. Talbot[1], [1]*Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada,* [2]*Institut Supérieur d'Agriculture Rhône-Alpes, Lyon, Rhône-Alpes, France,* [3]*University of Manitoba, Winnipeg, Manitoba, Canada.*

Four ruminally fistulated Holstein dairy cows averaging 616 ± 38 kg body weight and 81 ± 5 d in milk were assigned to the following experimental treatments in a 4 × 4 Latin square design: 1) *Enterococcus faecium* (2.5×10^9 cfu/g; EF); 2) EF + *Saccharomyces cerevisiae* (1×10^9 cfu/g; EFSC; Probio Precise, Chr. Hansen, Milwaukee, WI); 3) EF + *Lactococcus lactis* O 224 (2.8×10^9 cfu/g; EFO); 4) No probiotics (C). Probiotics were given at the rate of 80 mg/ kg DM intake, twice a day before each meal. They were introduced directly into the rumen through the fistula. Each experimental period consisted of 18 d of adaptation, 3 d of subacute rumen lactic acidosis (SARA) challenge and 7 d of rest during which they received the same TMR than during adaptation but without probiotic. Our previous research has shown that EFSC could stabilize rumen pH when dairy cows were submitted to a SARA challenge. The objectives of this study were to: 1) compare EFSC with the bacteria EF alone or with EF and *L. lactis* O 224 as a replacement for the yeast, on rumen pH regulation during SARA; 2) examine the effect of yeast probiotic on redox potential and 3) as vitamin B12 is produced only by bacteria, detect if ruminal concentration of this vitamin could be affected during SARA. Each treatment was compared with EFSC. Milk yield drop during SARA was lower with EFSC (- 0.8 kg/d), compared with C (-7.5 kg /d; $P = 0.03$) and similar to that of EF or EFO (-0.9 kg/d). During SARA, mean pH was greater with EFSC (5.55) than with C (5.43; $P = 0.03$) and tended to be lower than with EFO (5.66; $P = 0.07$). Time with pH <6.0 tended to be lower with EFSC (13.3 h) than with EF (15.4 h; $P = 0.08$) and greater than with EFO (11.1 h; $P = 0.07$). During adaptation, time with pH <5.5 was lower with EFSC (0.2 h) than with EF (5 h; $P = 0.02$) or EFO and C (3 h) ($P = 0.08$ and 0.09, respectively). Redox potential was greater during SARA (−150 mV) than adaptation (−180 mV; $P < 0.001$) or rest (−176 mV; $P = 0.04$). During SARA, EFSC maintained the rumen concentration of vitamin B-12 in the rumen whereas it decreased with other treatments. In conclusion, both EFSC and EFO provided pH regulation during SARA but only EFSC prevented the drop of vitamin B12. Probiotics decreased milk drop during SARA.

Key Words: *Enterococcus faecium* and *Saccharomyces cerevisiae*, *Lactococcus lactis* O224, subacute ruminal acidosis

M324 Effect of live yeast supplementation on milk yield, milk components, and rumen pH in dairy cows. M. B. de Ondarza[1], A. Hall[2], J. Sullivan[2], and E. Chevaux*[2], [1]*Paradox Nutrition LLC, West Chazy, NY,* [2]*Lallemand Animal Nutrition, Milwaukee, WI.*

The trial objective was to determine the effect of supplemental live yeast (LY; 0.5 $g \cdot cow^{-1} \cdot d^{-1}$; *Saccharomyces cerevisiae* CNCM I-1077) vs. sodium bicarbonate (BC; 170 $g \cdot cow^{-1} \cdot d^{-1}$) on milk yield, milk components, and rumen pH in high-producing, multiparous cows. Half of the cows (n = 57) received LY and half (n = 54) received BC. The study was 11 wk in length with 6 wk of diet adaptation and 5 wk of data collection. Treatment groups were housed in separate pens with ad libitum access to TMR. Cow groups were balanced pre-trial for parity, DIM, and pre-trial 14-d average milk yield. Daily milk yield of individual cows was recorded. Milk was sampled on wk 8, 9, and 10 and analyzed for components. The statistical model included treatment, DIM category, and lactation category as fixed effects with cow as the random effect. Pre-trial production data were included as covariates. There was a trend ($P = 0.09$) for higher milk yield with LY treatment (41.9 and 39.8 kg/d for LY and BC, respectively (SE = 0.86)). Percent milk fat, milk fat yield, 3.5% FCM, and energy-corrected milk were not affected ($P > 0.10$) by treatment. Percent milk true protein and milk urea nitrogen (mg/dl) were not affected ($P > 0.10$) by treatment but milk true protein yield tended ($P = 0.09$) to be higher for cows fed LY (1.24 vs. 1.18 kg/d for LY vs. BC, respectively (SE = 0.02)). Somatic cell count (SCC x 1000) was lower ($P < 0.05$) for cows supplemented with LY (80.09) (SE = 49) than for cows supplemented with BC (245.48) (SE = 49). Four cows per treatment were used to measure rumen pH every 5 min using rumen bolus probes. Live yeast significantly increased ($P < 0.0001$) mean daily pH (6.22 vs. 6.03 for LY vs. BC, respectively; SE = 0.01), minimum daily pH (5.54 vs. 5.34 for LY vs. BC, respectively; SE = 0.01), and maximum daily pH (6.98 vs. 6.81 for LY vs. BC, respectively; SE = 0.02). The area under the pH 5.8 curve (pH x min/d) was less ($P < 0.0001$) for cows fed LY (19.5 vs. 80.1 for LY vs. BC, respectively; SE = 4.3). Live yeast reduced the risk of rumen acidosis and tended to increase milk yield.

Key Words: live yeast, rumen pH, sodium bicarbonate

***M325 Enterococcus faecium* as a probiotic for lactating ruminants.** I. K. Hindrichsen,* M. Raun, N. L. Milora, B. Struer-Lauridsen, M. M. Jensen, and E. Upton Augustsson, *Chr. Hansen A/S, Hørsholm, Denmark.*

High-yielding dairy cows often suffer from sub-acute diseases triggered by typical dairy cow diets. These results in ill-thrift and production losses. Sub-acute hindgut acidosis was recently shown to significantly affect the health of dairy cattle. Supplementing high-yielding dairy cows with the probiotic *Enterococcus faecium* has in several studies resulted in improved production and/ or well being parameters. In the current study, the aim was to unravel some of the possible mode of action of *E. faecium* has on dairy cows, using genome sequencing and in vitro assays. First, the survival of 3 *E. faecium* strains under digestion challenges were tested, including high volatile fatty acid, pH and challenge with bile. Optical density (OD) test showed that all 3 *E. faecium* strains survived in a pH range between 2 and 7. At pH 2 the lag time increased, however after 24 h the max OD was the same as for pH 7. *E. faecium* could be shown to withstand up to 9.5% bile concentration with a reduced growth. It was further illustrated that all tested *E. faecium* showed active bile salt hydrolase activity, indicating that *E. faecium* can utilize bile as a substrate in the lower tract. The genome sequencing revealed that all tested *E. faecium* had genes associated with adhesion ability, while only one strain showed genes for producing the 2 bacteriocins enterocin A and enterocin B. The bacteriocin producing strain was superior in inhibiting *S. bovis*, as well as other pathogens such as *C. perfringens*, *S. aureus* and *L. monocytogenes* compared with the none-bacteriocin producing E. faecium. It has been shown that these 2 bacteriocins have synergistic effect in reducing pathogens. It is hypothesized that the positive effect of *E. faecium* on production parameters of dairy cows may be due to the reduction of *S. bovis* in the rumen, the possibility of surviving digestive challenges and passing down to the lower tract where it actively inhibits certain pathogens. These features can significantly affect the occurrence of subacute hindgut acidosis.

Key Words: dairy cows, *Enterococcus faecium*, pathogen

M326 Effect of oral calcium bolus supplementation on early lactation health and milk yield in commercial dairy herds.

G. R. Oetzel*[1] and B. E. Miller[2], [1]*University of Wisconsin-Madison, Madison,* [2]*Boehringer Ingelheim Vetmedica Inc., St. Joseph, MO.*

The objective of this study was to evaluate the effect of supplementation with oral calcium (Ca) boluses after calving on early lactation health and milk yield. Second lactation or greater cows (n = 927) from 2 large dairies in Wisconsin were enrolled during the summer of 2010. Both herds fed supplemental anions during the pre-fresh period and treated less than 1% of fresh cows for clinical signs of hypocalcemia. Prior to calving, cows were scored for lameness and body condition, then randomly assigned to either control or oral Ca bolus supplemented groups. Control cows received no oral Ca boluses around calving. Cows in the oral Ca bolus group received 2 oral Ca boluses (Bovikalc, Boehringer Ingelheim, St. Joseph, MO) - one bolus 0 to 2 h after calving and the second 8 to 35 h after calving. The oral Ca bolus administration schedule was designed to be feasible for large commercial dairies and did not require that cows be locked up more than once daily. Early lactation health events were recorded and summed for each cow. There were only 6 cases (0.6% of calvings) of clinical milk fever during the trial, and only 14% of cows tested were hypocalcemic (ionized Ca less than 1.0 mmol/L) at 8 to 35 h after calving. Subgroups of cows with significant responses to oral Ca bolus supplementation were identified based on significant interactions between oral Ca bolus supplementation and covariates in mixed multiple regression models. Lame cows supplemented with oral Ca boluses had 0.34 fewer health events in the first 30 d in milk compared with control cows. Cows with a higher previous lactation milk yield (greater than 105% of herd rank) produced 2.9 kg more milk when supplemented with oral Ca boluses. Results of this study indicate that lame and higher producing cows respond favorably to supplementation with oral Ca boluses using a protocol that is practical to implement in large commercial dairies, and that oral Ca bolus supplementation to targeted groups of cows is beneficial even for dairies with a very low incidence of hypocalcemia.

Key Words: oral calcium boluses, milk fever, hypocalcemia

M327 Effect of dietary buffers and magnesium oxide on intake, milk yield and composition, and blood metabolites of lactating dairy cows.

J. K. Bernard,* J. W. West, and N. A. Mullis, *University of Georgia, Tifton.*

Forty-eight lactating Holstein cows were used to determine the effect of feeding different buffers on nutrient intake, milk yield and composition, and select metabolic indices of health of early lactation Holstein cows. Treatments included a negative control (NEG), positive control supplemented with sodium bicarbonate (POS), acid buffer (AC, CalMin, Celtic Sea Minerals, Cork, Ireland) or acid buffer plus MgO from seawater (ACM, CalMin16, Celtic Sea Minerals). A basal diet provided similar concentrations of energy and protein and treatments added at feeding provided varying concentrations of Ca, Cl, Na, and DCAD. Beginning at approximately 21 ± 4 DIM cows were fed the NEG diet for 14 d and cows were assigned randomly to one of 4 treatments for the following 10 wk. Contrast statements compared 1) NEG with all other diets, 2) POS with AC and ACM, and 3) AC with ACM. The DMI tended to be higher ($P = 0.07$) for POS compared with AC and ACM. No differences ($P > 0.10$) were observed for milk yield, concentration or yield of milk fat, protein, lactose, or SNF. Concentrations of MUN were lower ($P = 0.01$) for NEG compared with the other treatments and ACM compared with AC ($P = 0.005$). Serum concentrations of total protein ($P = 0.04$), globulin ($P = 0.03$), glucose ($P = 0.0004$), and creatinine kinase ($P = 0.06$) were highest for NEG compared with other treatments. No ($P > 0.10$) differences were observed in serum concentrations of Ca, P, Mg, K, Na, Cl, or bicarbonate. No deleterious effects were observed for cows fed NEG, but cows were not exposed to heat stress during the trial. The POS diet had lower concentrations of dietary Cl (0.52% of DM) compared with the other treatments (0.63% of DM) which could explain the trend for higher DMI. Overall the acid buffers supported similar performance as sodium bicarbonate.

Table 1. Intake, milk yield, composition, and select blood metabolites

Item	NEG	POS	AC	ACM	SE

Ruminant Nutrition: General I

M328 Milk fatty acids composition responses to dietary short-medium chain fatty acids and long chain fatty acids in lactating dairy cows. Y. Sun, D. P. Bu, J. Q. Wang,* H. Cui, X. W. Zhao, X. Y. Xu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

De novo synthesis of short-medium chain fatty acids (SMCFA), which inhibited by the exogenous long chain fatty acids (LCFA), might be promoted by dietary addition of SMCFA. Our objective was to evaluate the effects of different ratios of SMCFA to LCFA on milk fatty acids (FA) composition in dairy cows. The experiment lasted for 9 wks. Thirty-six lactating Holstein dairy cows (183 ± 46 DIM) were blocked base on average daily milk yield, DIM and parity, and were randomly assigned to 1 of 3 treatments. Cows were fed total mixed ration with 1 of 3 fat supplements: 80 g/d SMCFA and 320 g/d LCFA (20S80L); 400 g/d of butterfat (40S60L); 240 g/d SMCFA and 160 g/d LCFA (60S40L), and the ratios of SMCFA to LCFA were 20:80, 40:60, and 60:40 respectively. The FA compositions of the SMCFA mixture (a blend of 6% caproic acid, 4% caprylic acid, 9% capric acid, 10% lauric acid, 32% myristic acid and 39% palmitic acid) and the LCFA mixture (a blend of 59% cocoa butter, 16% olive oil, and 25% palm oil) were identical to those found in milk fat. Analysis of data was conducted using the MIXED procedures of SAS 9.0. As the ratios of SMCFA to LCFA in the supplements increased, concentrations of C < 16:0 (25.39, 27.58, and 27.39%; $P = 0.08$) tended to increase linearly ($P = 0.06$), C14:0 percentage (10.39, 11.18, and 11.90%; $P < 0.05$) increased linearly ($P < 0.05$), and polyunsaturated FA percentage (4.12, 4.68, and 4.31%; $P < 0.05$) was increased quadratically ($P < 0.05$). However, concentration of C16:0 (32.16, 32.01, and 31.91%; $P > 0.05$), C > 16:0 (42.08, 39.78, and 40.28%; $P > 0.05$), saturated FA (68.26, 69.81, and 69.10%; $P > 0.05$), and monounsaturated FA (27.64, 25.51, and 26.59%; $P > 0.05$) were not affected. In conclusion, dietary supplementing different ratios of SMCFA to LCFA influenced milk FA synthesis and caused the alteration of milk FA composition.

Key Words: long chain fatty acids, milk fatty acids composition, short-medium chain fatty acids

M329 Effect of sorghum grain supplementation levels on ruminal volatile fatty acids: Comparison between cattle and sheep. M. Aguerre*[1], C. Cajarville[2], L. Assandri[2], A. Gonzalez[1], and J. L. Repetto[1], [1]*Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay,* [2]*Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

Crossbreed heifers (n = 16; 210 ± 42.5 kg), and lambs (n = 16; 45.6 ± 6.2 kg), were used to compare the response on ruminal VFA concentration and profile to increased levels of sorghum grain supplementation (0, 0.5, 1.0 and 1.5% BW). Heifers and lambs were fed ad libitum fresh *Lotus corniculatus* (31.8% DM, 12.6% CP, 41.8% NDF). After 30d, ruminal liquor samples were taken every 1h from 0 to 6h post-supplementation, to determine acetate, propionate and butyrate concentrations by HPLC, while total VFA (TVFA) were determined as the sum of the above VFA. Mean values and linear regressions were compared between species with the MIXED procedure (SAS). Mean TVFA was lower in cattle than in sheep (94.4 vs. 112 ± 6.81 mMol/L; $P = 0.008$). Increasing supplementation levels similarly increased TVFA in both species (Table 1). Proportion in TVFA of acetate was higher (70.7 vs. 63.7 ± 0.70 mMol/100mMol; $P < 0.001$), while propionate and butyrate were lower in cattle than in sheep (15.8 vs. 20.6 ± 0.83 mMol/100mMol and 13.5 vs. 15.9 ± 0.62 mMol/100mMol; $P < 0.001$, propionate and butyrate respectively). Increasing supplementation levels affected differently acetate and butyrate proportion in TVFA in both species (P<0.001; Table 1), leading to more pronounced changes in acetate and butyrate proportions in sheep than in heifers. However, propionate proportion in TVFA was not affected. In conclusion, increasing levels of sorghum supplementation determined a similar rose in TVFA in cattle and in sheep. However, sheep showed more drastic changes in VFA profile than heifers.

Table 1.

Item	Cattle	Sheep	*P*-value[1]
Total VFA (mmol/L)	$y = 77.6 + 23.0x$; $R^2 = 0.12$, $P < 0.001$	$y = 108 + 30.7x$; $R^2 = 0.21$, $P < 0.001$	0.355
VFA, mmol/100 mmol			
Acetate	$y = 72.7 - 2.49x$; $R^2 = 0.13$, $P < 0.001$	$y = 68.8 - 6.48x$; $R^2 = 0.40$, $P < 0.001$	<0.001
Butyrate	$y = 12.1 + 1.92x$; $R^2 = 0.09$, $P = 0.003$	$y = 10.9 + 6.72x$; $R^2 = 0.53$, $P < 0.001$	<0.001

M330 Effects of different ratios of short-medium chain fatty acids to long chain fatty acids on milk composition in dairy cows. Y. Sun, D. P. Bu, J. Q. Wang,* H. Cui, X. W. Zhao, X. Y. Xu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Dietary addition of long chain fatty acids (LCFA) inhibits milk fat de novo synthesis in dairy cows, whereas short-medium chain fatty acids (SMCFA) may promote this process. This study evaluated the effects of supplementation of different ratios of SMCFA to LCFA on milk composition in dairy cows. Thirty-six lactating Holstein cows (183 ± 46 DIM) blocked by average daily milk yield, DIM and parity, were randomly assigned to 1 of 3 treatments. During the 9 wks experimental period, cows were fed total mixed ration 3 times daily, and supplemented with 1 of 3 supplements: 80 g/d SMCFA and 320 g/d LCFA (20SM80L); 400 g/d of butterfat (40SM60L); and 240 g/d SMCFA and 160 g/d LCFA (60SM40L). The ratios of SMCFA to LCFA in the supplements were 20:80, 40:60, and 60:40 respectively. The FA composition of the SMCFA mixture (a blend of 6% caproic acid, 4% caprylic acid, 9% capric acid, 10% lauric acid, 32% myristic acid and 39% palmitic acid) and of the LCFA mixture (a blend of 59% cocoa butter, 16% olive oil, and 25% palm oil) were representative of those found in milk fat. Data was analyzed by MIXED procedures of SAS 9.0. Dry matter intake (16.3, 16.1, and 16.0 kg/d; $P > 0.05$), milk yield (23.5, 23.9, and 21.8 kg/d; $P > 0.05$), 3.5% fat corrected milk (25.9, 26.8, and 25.4 kg/d; $P > 0.05$), milk protein percentage (3.46, 3.43, and 3.48%; $P > 0.05$) and yield (0.83, 0.82, and 0.76 kg/d; $P > 0.05$) were not affected among the treatments. As the ratios of SMCFA to LCFA increased in the supplements, milk fat percentage (4.01, 4.20, and 4.41%, $P = 0.06$) tended increase in a linear fashion ($P < 0.05$) and milk total solids proportion (13.09%, 13.26%, and 13.55%; $P < 0.05$) increased linearly ($P < 0.05$), while milk fat yield (0.97, 0.99, and 0.97 kg/d; $P > 0.05$) was not different. In conclusion, dietary supplementing SMCFA might compensate the inhibitory effects of LCFA on milk fat synthesis.

Key Words: short-medium chain fatty acids, long chain fatty acids, milk composition

M331 Effects of different fatty acid mixtures on milk fatty acid composition and oxidative stability of milk fat. X. W. Zhao, J. Q. Wang,* D. P. Bu, Y. Sun, H. Cui, X. Y. Xu, L. Y. Zhou, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Unsaturated fatty acids (UFA) as the main function components in milk fat, have beneficial effects on health maintenance and disease prevention. More and more people are concerning to improve UFA content in milk. However, the rich content of UFA, especially polyunsaturated fatty acids (PUFA) in milk fat will increase the risk for developing spontaneous oxidized off-flavor (SOF). The experiment was carried out to determine the effects of different fatty acids mixture on milk fatty acids composition and milk fat oxidation changes. Thirty 6 dairy cows were used in a completed design experiment for 8 wk. Cows supplement 3 types of dietary fatty acids mixture: 1) short- and medium-chain fatty acids (SMCFA), 2) butterfat, and 3) long-chain fatty acids (LCFA). Data were analyzed using the MIXED procedure of SAS. Relative to SMCFA, the C12:0, C14:0 and C16:0 concentration in milk fat from cows on butterfat and LCFA were significantly decreased ($P < 0.05$). The proportions of *cis*-C18:1, *trans*-C18:1 and *cis*-C18:2 were increased by 16.0, 45.6, and 8.8% ($P < 0.05$) in milk fat from cows on LCFA compared with cows on SMCFA. Similar increases in *trans*-C18:1, *cis*-C18:2 and C18:3 were 31.6, 11.9 and 13.6% ($P < 0.05$) in butterfat treatments, respectively. Furthermore, the activities of superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GSH-Px) tended to decrease when increased long-chain FA in cow′ diet, while the concentration of malondialdehyde (MDA) tended to increase in bovine milk. Our results indicated that long-chain FA tended to exhibit positive effects on milk fatty composition, but may decrease the oxidative stability of milk fat.

Key Words: milk fatty acids composition, oxidation changes, milk fat

M332 Endogenous contribution and urinary recovery of purine derivatives in Nellore cattle. A. M. Barbosa*[1], R. F. D. Valadares[2], S. de C. V. Filho[2], D. do Santos Pina[3], and M. A. Fonseca[2,4], *[1]Universidade Federal da Bahia, Salvador, Bahia, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal do Mato Grosso, Sinop, Mato Grosso, Brazil, [4]Texas A&M University, College Station.*

This study was conducted with the objective to evaluate the endogenous contribution of purine derivatives (PD) urinary excretion in Nellore cattle, fed in a single diet with different levels of DM. The trial was performed using 8 cannulated (rumen and abomasum; moreover 4 of those had ileum cannula) heifers with average BW of 258 ± 20 kg. The animals were allocated on individual stalls and fed twice a day. The statistical analyses were performed using 2 balanced Latin square designs (4 × 4). Treatments were constituted of 4 DM offer levels: 1.2, 1.6, 2.0 and 2.4% of BW. The endogenous losses of PD and the purine bases recovery as PD were estimated by the regression between the daily excretion of PD (dePD) in urine, and purine bases in the abomasum (X), expressed as mmol/kg$^{0.75}$. The endogenous contribution and the purine recovery of PD are represented by the coefficient of the regression and the intercept, respectively. Additionally, the endogenous losses were evaluated by the regression between excretion of PD, in mmol/kg$^{0.75}$, and DMI, in g/kg$^{0.75}$. The equation obtained ($P < 0.001$) was: dePD = 0.0196 X + 0.2421. Daily excretion of PD, mmol/kg$^{0.75}$, as a function of RNA flux into the abomasum, mmol/kg$^{0.75}$, was adjusted ($P < 0.001$) to the regression, dePD = 0.8601 X + 0.4603 ($r^2 = 0.661$) where 0.86 represents the recovery of DP in urine, and 0.4603 represents the endogenous contribution. The conclusion was for the different methods utilized was found the estimatives of 0.46 mmol/kg$^{0.75}$ and 0.24 mmol/kg$^{0.75}$ for endogenous excretion of PD in Nellore cattle; the true digestibility of RNA in small intestine was 0.93, which is higher than the classic value adopted in the literature for microbial production calculation.

Key Words: flux RNA abomasum, level of intake, ruminant nutrition

M333 Effects of dietary inclusion of tannin and polyethylene glycol supplementation on nitrogen metabolism in Saanen dairy goats. A. Rahimi[1], A. A. Naserian[1], R. Valizadeh[1], A. Tahmasbi[1], B. Saremi*[2], and A. R. Shahdadi[3], *[1]Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran, [2]Institute of Animal Science, Physiology & Hygiene Unit, University of Bonn, Germany, [3]Agricultural Sciences & Natural Resources, University of Gorgan, Gorgan, Golestan, Iran.*

Tannins reduce the protein degradation in the rumen, shift the site of N metabolism from rumen to the lower digestive tract and large intestine. Shifting excretion pattern of nitrogen from urine to faces and formation of tannin–protein complex are beneficial environmentally. High levels of tannins in the diet may have negative effects on feed intake and digestibility of nutrients and polyethylene glycol (PEG) could eliminate it. We aimed to evaluate the effects of feeding pistachio hull (PH, source of tannin) and PEG on nitrogen metabolism in Saanen dairy goats. Nine animals were used in a 3 × 3 Latin square design. Treatments were: T1) Control, without PH, T2) 30% PH (DM basis) that provided 18.1 g condense tannin per kg DM of diet, and T3) 30% PH + 1% PEG (DM basis). In T2 and T3, PH replaced alfalfa hay. Statistical analysis was performed using the MIXED procedure of SAS ($P < 0.05$). Addition of PH in T2 and T3 (despite of addition PEG) reduced the nitrogen intake. In addition, urinary nitrogen excretion was significantly decreased and fecal nitrogen excretion was increased by addition of PH in T2 and PEG supplementation in T3 increased or decreased them respectively but not to the similar values like control group. Milk nitrogen excretion was not affected by experimental diets. Nitrogen digested was significantly decreased by substitution of PH in diet in T2 and T3 (despite of addition PEG). Nitrogen retained was not affected by experimental diets. To sum up, using of high levels tannin in the diet could alter protein metabolism positively from an environmental aspect and supplementation with PEG could reduce possible negative effectsof tannin on performance.

Table 1.

Nitrogen metabolism	Alfalfa	30% PH	30% PH+PEG	SEM	*P*-value
Nitrogen Intake (g/d)	54.47^{a}	53.01^{b}	53.96^{b}	0.360	0.050
Nitrogen excretion from urine (g/d)	12.42^{a}	9.90^{b}	11.52^{ab}	0.553	0.049
Nitrogen excretion from fecal (g/d)	14.46^{b}	15.43^{a}	15.00^{ab}	0.135	0.011
Nitrogen excretion from milk (g/d)	7.21	6.63	7.18	0.427	0.102
Nitrogen digested (g/d)	38.52^{a}	35.51^{b}	36.73^{b}	0.448	0.013
Nitrogen retained (g/d)	20.36	21.03	20.25	0.794	0.820

M334 Intake and apparent total tract digestibility of dry matter and nutrients in Nellore steers fed with whole raw soybean.

N. R. B. Cônsolo*[1], A. S. C. Pereira[1], J. R. Gandra[1], F. P. Rennó[1], R. Gardinal[1], J. E. Freitas Junior[2], C. S. Takiya[1], and R. D. Mingoti[1], [1]*Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo (FMVZ-USP), Pirassununga, SP, Brazil,* [2]*Universidade Estadual Paulista (UNESP), Jaboticabal, SP, Brazil.*

This study was conducted to evaluate the effects of whole raw soybean on intake and apparent total tract digestibility of dry matter and nutrients in Nellore steers. Twelve steers were assigned to 3 Latin squares in individual pens. Based on dry matter the diets were: T0 with 0% of soybean, T8 with 8% of soybean, T16 with 16% of soybean and T24 with 24% of soybean. Fourteen days were necessary for adaptation and 4 d for evaluation. The individual intake was evaluated by weighing the leftovers of the previous day. Leftovers and feces were collected in the d 14 to 16 to determine the intake and the apparent total tract digestibility of dry matter and nutrients. This material was dried and sampled for posteriori analysis on dry and mineral matter, ether extract, neutral detergent fiber, acid detergent fiber, crude protein and lignin. The total amount of excreted fecal dry matter was estimated by the method of acid detergent fiber indigestible (FDAi). Samples of feces, food and leftovers were placed and subsequently incubated in 3 cannulated Nellore for 312 h. Treatment effects were evaluated by Proc Mixed SAS software. The inclusion of whole raw soybean provided linear effect ($P < 0.05$) for intake of dry matter, organic matter, non-fibrous carbohydrates and total carbohydrates. There was a quadratic effect on crude protein ($P < 0.05$) and the lowest value on the diet with 16% soybean differing from the one with 24% and total control. There was a linear increase ($P < 0.001$) for ether extract intake and all treatments differed. There was no effect ($P > 0.05$) on apparent total tract digestibility of dry matter, organic matter, crude protein, neutral detergent fiber and non-fibrous carbohydrates. However, there was a quadratic effect of soybean on the total apparent digestibility in ether extract with highest digestibility for the 24% soybean. There was a linear decrease ($P < 0.05$) of total carbohydrate in apparent digestibility. Changes in the dry matter and nutrient intake in digestibility were noticed according to the levels of inclusion of whole raw soybean but these effects were not negative to the animals.

Key Words: digestibility, protein source, ruminant

M335 Evaluation of published models for predicting dry matter intake of lactating dairy cows.

J. Lee* and S. Seo, *Chungnam National University, Daejeon, Republic of Korea.*

Accurate prediction of dry matter intake (DMI) is pre-requisite for ration formulation software and a precision feeding program. The equations commonly used for predicting DMI are empirical models, developed on the basis of experimental data obtained more than a decade ago. Considering increases in genetic potential of dairy cows and dairy management, there is an interest in evaluating the model using recent data to see if the published models are still applicable to the field. The objective of this study was thus to evaluate 6 published empirical equations widely used for predicting DMI of lactating dairy cows using recently published experimental observations. A literature database based on the research articles published in the *Journal of Dairy Science* from January 2006 until June 2011 (volumes 89 through 94) was constructed. The database is composed of a total of 525 treatment means from 143 studies, and contains wide ranges of DMI, milk yield and week of lactation. Six published models include NRC (NRC, 2001), Brown (Brown et al., 1977), Chase (Chase and Sniffen, 1985), Rayburn (Rayburn and Fox, 1993), Roseler (Roseler et al., 1997) and Fuentes-Pila (Fuentes-Pila et al., 2003), and they were statistically evaluated using the constructed database. The coefficient of determination and root mean square prediction error (RMSPE) were used to examine precision and accuracy of the model, respectively. Residual analysis was also conducted to assess the mean and slope bias of a model. The NRC, Brown, Chase, Rayburn, Roseler and Fuentes-Pila models explained 49, 39, 48, 41, 51 and 41% of the variations in the evaluation data set, and the RMSPE were 2.59, 2.97, 2.75, 2.08, 3.44 and 3.61 kg, respectively. All of the models showed significant mean bias ($P < 0.01$): the highest absolute mean bias was observed with the Roseler equation (2.336) while the lowest value with the NRC equation (0.450). Among the equations, only the Roseler and the NRC predicted the observed DMI without slope bias ($P > 0.05$). The NRC model was highly ranked among the tested models in all of the evaluation criteria. The accuracy of the NRC model prediction, however, may be reduced with recent observations.

Key Words: dairy cows, dry matter intake, evaluation

M336 Effects of roughage source and dietary level of inclusion on total tract apparent digestibility in Nellore cattle.

R. S. Goulart*[1,2], L. G. Nussio[1], R. A. M. Vieira[3], J. L. P. Daniel[1], R. C. Amaral[1], V. P. Santos[1], and A. V. Pires[1], [1]*University of Sao Paulo, ESALQ, Piracicaba, SP, Brazil,* [2]*Department of Animal Sciences, North Dakota State University, Fargo,* [3]*Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, RJ, Brazil.*

Six ruminally cannulated Nellore steers were allotted in a 6 × 6 Latin square to investigate the effects of roughage source and dietary inclusion on nutrient digestion. The 6 diets were composed of fiber sources: negative control (NC) with 10% NDF from corn silage (50.2% NDF, DM basis), positive control (PC) with 20% NDF from corn silage and 4 diets containing 10% NDF from corn silage and 10% NDF from: sugarcane (SC; 46.8% NDF); sugarcane bagasse (SCB; 81.0% NDF); soybean hulls (SH; 75.1% NDF) and low oil cottonseed meal (LOCM; 49.2% NDF). Total fecal collections, during 4 d consecutively in each period, were used to determine total tract apparent digestibility coefficients (TTAD) of DM, CP, NDF, ADF. Lower inclusion of forage fiber (CN) in the diet presented higher digestion coefficients of DM ($P \leq 0.05$) in comparison with diets containing double amount of fiber sources (20% of NDF). When fiber sources with low amount of CP (SC and SCB) were included in the diets, TTAD of CP were 12.32% lower than diets containing corn silage, SH or LOCM. Fiber digestibility was influenced ($P \leq 0.05$) by roughage sources and inclusion level on TTAD. Although similar DMI ($P \leq 0.05$) was observed between treatments CP, SC, SH e HOCM, differences among TTAD values can be explained either by differences in solid passage rate, ruminal retention time or chemical composition of fiber when different roughage sources replaced each other. In spite of the lower TTAD values of NDF of NC in comparison to PC (6 percentage units), the higher inclusion of concentrate (NC) improved the DM digestibility by 8.3 percentage units.

Table 1. Effects of roughage source and level on total-tract apparent digestibility in Nellore cattle

Total-tract apparent digestibility, %	Diet[1]						
	NC	PC	SCB	SC	SH	LOCM	SE

Key Words: digestibility, forage, Nellore

M337 Intake and digestibility of diets with different levels of concentrates in cattle feedlot Nellore. C. S. Ribeiro Junior,* Y. T. G. Salcedo, R. C. Canesin, T. T. Berchielli, M. Machado, L. M. Delevatti, E. San Vito, I. P. C. de Carvalho, J. F. Lage, and G. Fiorentini, *São Paulo State University, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil.*

The increased meat demand in the world market amplified the production system. For that reason, the use of confinement systems is an option and the inclusion of grains in the diet is essential. Based on these assumptions, this study aimed is to evaluate the intake and digestibility of diets with different forage: concentrate. We used 8 Nellore, male, castrated, with an average weight of 320 ± 44 kg. The animals were divided into 2 latin square 4x4, with 4 treatments and 4 replications. The treatments consisted of 4 diets with different forage: concentrate (70:30, 60:40, 40:60, 20:80), balanced to maximize microbial protein synthesis and increase the use of urea. The forage used was fresh chopped sugar cane and the concentrates consisting of corn bran, soybean meal, urea and mineral salt. The experiment was divided into 4 periods of 22 d each: the first 15 d for the diet adaptation of animal and the other days for data collection. Data were analyzed statistically by SAEG statistical program (Statistical Analysis System), using the Tukey test at 5% probability in comparison of means. The dry matter intake as a function of body weight was greater in relations 60:40 (1.9%) and 40:60 (1.8%), differing significantly ($P < 0.05$) dry matter intake in relations 70:30 (1.6%) and 20:80 (1.7%). The organic matter intake was higher in the 60:40 ratio (6.3 kg/d), differing from the others ($P < 0.05$). As for the digestibility of dry matter and organic matter the highest values were observed in the 40:60 ratio, and the smaller the ratio 20:80. It is concluded that the forage: concentrate ratio 40:60 had a better digestibility of dry matter and organic matter and a higher dry matter intake, with high nutritional value. In this experiment 40:60 ratio is more suitable for feeding beef cattle.

Key Words: digestibility, sugar cane, nutritive value

M338 Voluntary intake, apparent digestibility and blood urea levels in hair sheep fed *Cynodon nlemfuensis* grass mixed with *Leucaena leucocephala* and supplemented with rumen fermentable energy. V. A. Arjona-Alcocer, A. Ruiz-Gonzalez, E. Briceño-Poot, A. J. Ayala-Burgos, N. Ruz-Ruiz, and J. C. Ku-Vera,* *FMVZ-Universidad Autonoma de Yucatan, Merida, Yucatan, Mexico.*

Tropical grasses supply insufficient amounts of energy and protein for grazing sheep, resulting in low productive performance. Silvopastoral systems supply good quality forages (CP, fermentable energy) to grazing sheep. However, in silvopastoral systems there may be an imbalance among energy and nitrogen availability in the rumen leading to the loss of nitrogen from this organ. Four hair lambs housed in metabolic crates were used in a 4 × 4 Latin square design. Sheep were fed *Cynodon nlemfuensis* grass and foliage of the legume *Leucaena* leucocephala mixed in a ratio 50:50 on a dry matter basis. Increasing levels of cane molasses were supplied: 0, 0.24, 0.72 and 1.2 Mcal per lamb daily. The ration was served twice daily at 10:00 and 15:00 h divided in 2 halves. Response variables were DM intake, DM digestibility and concentration of urea in blood and excretion of urea in urine. The experiment lasted for 48 d with 4 periods of 12 d, 7 d for adaptation and 5 d for sampling. Results were analyzed with the statistical package SAS. DM intake was increased by energy supplementation, although DM digestibility was unaffected by treatment (Table 1). There was a trend for energy supplementation to decrease urea concentration in blood and urinary excretion of urea in sheep.

Table 1. DM intake, apparent digestibility of DM and levels of urea in blood and urine of lambs fed a mixture of C. nlemfuensis and L. leucocephala and supplemented with three levels of energy

	ME (Mcal/d) supplied as molasses			
Item	0	0.24	0.72	1.2
DMI, g/head/d	1047.91^{c}	1184.13^{b}	1268.46^{ab}	1316.17^{a}
DMI, g/kg$^{0.75}$/d	93.14^{c}	103.66^{b}	109.72^{ab}	115.43^{a}

Key Words: hair sheep, energy, supplementation

M339 Rumen ammoniacal nitrogen and pH from cattle supplemented with levels of replacement of soybean meal by sunflower cake. R. G. F. Silva,* J. T. Zervoudakis, L. S. Cabral, D. P. Sousa, L. K. H. Zervoudakis, M. F. Costa Filho, R. S. Gomes, F. M. Negrão, and J. F. W. Koscheck, *Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil.*

This study aimed at evaluating the replacement levels of the protein from soybean meal by the protein from sunflower cake in multiple supplements on the rumen ammoniacal nitrogen (RAN) and rumen pH of beef cattle. The experiment was conducted during the Brazilian rainy season. Five Nelore breed animals, uncannulated, submitted to grazing *Brachiaria brizantha* 'Marandu' were used, they were divided into individual paddocks of 0.24 ha. The average initial age and weight were 15 mo and 257 kg, respectively. The treatments were: 0% of replacement (0%SC), 25% of replacement (25%SC), 50% of replacement (50%SC), 75% of replacement (75%SC) of the protein from soybean meal by the protein from the sunflower cake, isoprotein with 30% crude protein and one more control treatment of commercial mineral mixture (MM). One kg of fresh matter/animal/day was provided for the supplemented treatments and the control treatment was provided ad libitum. A Latin square design 5x5 was used. Rumen fluid was collected and the pH was measured right before the supplementation (0 h) and 4 h after the supplementation. The availability of forage in the dry matter ranged on average from 5678 kg in the 1st period to 9743 kg in the 5th period. There was no effect of the treatments on rumen pH ($P > 0.05$), however there was a time effect on rumen pH ($P < 0.05$), in which at time 0 the average was 6.75 and 6.50 at time 4, both within the levels considered physiologically normal. For RAN, there was effect of treatment and time ($P < 0.05$), in the study within the time the RAN concentrations were 5.42 and 12.22 mg/dL for the time 0 and 4 respectively. In the study within the treatments the RAN concentrations were 9.38; 9.89; 9.25; 9.98 and 5.61 mg/dL, respectively, for the treatments 0% SC, 25% SC, 50% SC, 75% SC and MM. Therefore, it is concluded that the inclusion of sunflower cake for beef cattle grazing in the rainy season can be carried out without affecting the activity of rumen microbiota. Furthermore, fermentation quality improves when supplemented, as compared with the control treatment.

Key Words: grazing, forage, supplementation

M340 Comparison of three different methods in determination of accurate soluble fraction in feeds for CPM Dairy formulation to improve efficiency and milk prediction accuracy. P. Yu, B. Liu,* Z. Niu, and D. A. Christensen, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The CPM dairy software is the major software used in Saskatchewan for milk production prediction and diet formulation for dairy producers and for researchers. However, the key information that we need to accurately predict the milk production is lacking, which is the soluble protein fraction. Without accurate feed soluble fractions in the CPM model, we get the poor milk predictions because we only estimate soluble fractions in Saskatchewan feeds. The objectives of this study were to compare 3 available methods to determinate accurate soluble fractions in dairy feed and diet for the CPM dairy formulation to improve feed utilization efficiency and prediction accuracy of milk production. The 3 methods that were accessed to determine protein soluble fractions in Saskatchewan feeds included (1) CNCPS V6.1 method; (2) Dutch 2007 DVE method; (3) In situ Method. The 14 different types of feeds were used in this study. The data normality, correlation, CRD and paired-*t*-test were analyzed using SAS. The results showed that the CNCPS method and In situ method produced similar soluble protein fractions, both methods produced higher soluble fractions than the Dutch-2007 DVE method (35.6 vs. 34.2 vs. 18.0% of CP, $P < 0.05$). Paired-*t*-test between any 2 methods also showed significant differences ($P < 0.01$) between the CNCPS and Dutch-2007 DVE method and between the In situ method and Dutch-2007 DVE method, but showed no difference between the CNCPS and In situ Methods. Although there were significant differences between the methods, the correlation analysis showed significant correlated between any methods with correlation coefficients r = 0.82 (between the CNCPS and in situ methods), 0.81 (between the CNCPS and Dutch-2007 DVE methods) and 0.59 (between the Dutch-2007 DVE method and in situ method).

Key Words: solubility methods, soluble protein fractions of Saskatchewan feeds, dairy cows

M341 Economic analysis of the inclusion of macauba pie of dietary lactating dairy cows.

C. S. Ribeiro Junior*[2], R. A. de Azevedo[1], A. C. R. dos Santos[1], L. C. Gerassev[1], R. N. Bahiense[1], L. Araújo[1], and A. R. C. Lima[2], [1]*Federal University of Minas Gerais, Montes Claros, Minas Gerais, Brazil,* [2]*São Paulo State University, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to analyze the economic feasibility of substitution of corn meal for macauba pie (MP) in the total diet of lactating dairy cows. We used 8 animals with a live weight of 480 kg and average production of 25 kg of milk per day. The animals were divided into 2 4x4 Latin square with 4 treatments with 4 levels of inclusion of in dry matter (0, 10, 20 and 30%) and 4 periods of 21 d, 14 adaptation and 7 d of evaluation. The animals were kept in tie stall and fed ad libitum corn silage and concentrate, the concentrate was composed of corn, soybeans, cottonseed, and increasing levels of macauba pie. Intake of total dry matter (DMI), milk yield (MY), the daily cost of each diet and economic return of the diets. Data were analyzed statistically by SAEG statistical program (Statistical Analysis System), using the tukey test at 5% probability in comparison of means. The dry matter intake as a function of body weight was higher with 0% (4.07%), decreasing significantly in the treatment 30% (3.46%) ($P < 0.05$), the same was observed in the production of milk, where the animals who received treatment 0% produced 26.20 kg of milk per day, against 18.36 kg of milk per day treatment in 30% ($P < 0.05$). The reduction of DMI decreased cost of maintenance, however, this result was not sufficient to compensate the decline shown in milk production, resulting in reduced net margin per kg of milk and less profit for the inclusion in diets for MP dairy cows. For the production of milk, it is necessary that the price adopted per kg dry matter MP is 68.35% of corn.

Key Words: dairy cattle, economic analysis, macauba pie

M342 Survey of nutritional recommendations used by feedlot nutritionists in Brazil in 2011.

C. A. Oliveira[2], M. D. B. Arrigoni[1], J. T. Vasconcelos[3], R. D. L. Pacheco[1], T. V. B. Carrara[2], L. L. Cursino[2], A. L. N. Rigueiro[2], and D. D. Millen*[2], [1]*São Paulo State University (UNESP), Botucatu, São Paulo, Brazil,* [2]*São Paulo State University (UNESP), Dracena, São Paulo, Brazil,* [3]*Elanco Animal Health, Greenfield, IN.*

This survey was designed to describe nutritional and management recommendations of Brazilian feedlot nutritionists in 2011. Thirty-three feedlot nutritionists, responsible for about 2,658,000 animals, completed the survey within 1-mo, which was available on line (www.surveymonkey.com) and consisted of 81 questions. The mean inclusion of roughage and inclusion in finishing diets by nutritionists was 21.0 ± 10.2% and 79.0 ± 19.4%, respectively. The level of grains included in the finishing diets recommended by 12 nutritionists (36.4%) ranged between 51% and 60%, but 11 (33.3%) nutritionists recommended diets with 61% to 80%, and 10 (30.3%) used less than 51% grains. Corn was the primary source of grain used in feedlot diets (n = 29; 87.9%), followed by sorghum (n = 4; 23.1%). Most of the corn fed in Brazilian feedlots was of the flint type (n = 28; 96.5%). The primary grain processing method adopted was coarsely grinding and fine grinding, which were used by 19 (57.6%) and 12 (36.4%) nutritionists, respectively. Whole cottonseed was the primary co-product included in finishing diets, being used by 17 (41.5%) of the nutritionists. Use of soybean hulls was reported by 8 (24.2%) nutritionists, whereas citrus pulp pellets was reported by 7 (21.2%), and soybean residues were used by 1 (3%) of the participants. Corn silage was the primary roughage source, being used by 9 (27.3%) of the respondents, followed by sorghum silage, which was used by 8 (24.2%) of the nutritionists, and sugarcane bagasse by 7 (21.2%), fresh chopped sugarcane by 5 (15.2%), and grass silage by 4 (12.1%) of the nutritionists. In addition, average recommended concentrations of NDF for finishing diets in Brazil were 21.1 ± 12.3%. The average CP, urea and true protein concentrations (DM basis) recommended for finishing diets in Brazil was 13.4 ± 2.5%, 1.4 ± 0.3% and 8.1 ± 1.7%, respectively. The primary source of plant-based protein used by the nutritionists was cottonseed meal (n = 19; 57.6%). The present survey provides an overview of nutritional recommendations currently applied by feedlot nutritionists from all regions in Brazil. These data may facilitate the design of industry-oriented research.

Key Words: Brazil, feedlot, survey

M343 Effects of different ratios of short-medium chain fatty acids to long chain fatty acids on plasma fatty acids profiles in lactating dairy cows.

Y. Sun, D. P. Bu, J. Q. Wang,* X. W. Zhao, H. Cui, X. Y. Xu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this current study was to evaluate the response of plasma fatty acids (FA) profiles to different ratios of short-medium chain fatty acids (SMCFA) to long chain fatty acids (LCFA) in lactating dairy cows. Thirty-six lactating Holstein dairy cows (183 ± 46 DIM), blocked by average daily milk yield, DIM and parity, were randomly assigned to 1 of 3 treatments and fed total mixed ration, which supplemented with 1 of 3 lipids supplements. The supplements were: 80 g/d SMCFA and 320 g/d LCFA (20S80L; the ratio of SMCFA to LCFA is 20:80); 400 g/d of butterfat (40S60L; the ratio of SMCFA to LCFA is 40:60); 240 g/d SMCFA and 160 g/d LCFA (60S40L; the ratio of SMCFA to LCFA is 60:40). The FA compositions of SMCFA mixture (a blend of 6% caproic acid, 4% caprylic acid, 9% capric acid, 10% lauric acid, 32% myristic acid and 39% palmitic acid) and LCFA mixture (a blend of 59% cocoa butter, 16% olive oil, and 25% palm oil) were identical to those found in milk fat. Blood samples were collected from the coccygeal vein at 3 h after the morning feeding. Data was analyzed as a randomized block design with repeated measures using MIXED procedure in SAS 9.0. As the ratios of SMCFA to LCFA in the supplements increased, percentages of $C > 16:0$ (85.66, 86.75, and 85.75%; $P < 0.05$), saturated FA (27.68, 25.55, and 27.85%; $P < 0.05$), and polyunsaturated FA (62.31, 66.05, and 62.49%; $P < 0.05$) increased quadratically ($P < 0.05$). Concentrations of $C < 16:0$ (2.81, 2.21, and 2.69%; $P > 0.05$) and monounsaturated FA (10.00, 8.40, and 9.66%; $P > 0.05$) were not different among the treatments. The results suggested that changes of blood FA composition, which induced by lipid supplements, might be one of the reasons for milk FA profile alternation.

Key Words: long chain fatty acids, plasma fatty acids profiles, short-medium chain fatty acids

M344 Effects of total solids in drinking water and milk yield per cow on milk mineral concentrations from California dairy farms.

A. R. Castillo*[1], N. S. del Rio[2], N. R. St-Pierre[3], and W. P. Weiss[3], [1]*University of California, Cooperative Extension, Merced,* [2]*University of California, Cooperative Extension, Tulare,* [3]*The Ohio State University, Department of Animal Science, Columbus.*

Knowing the quantity of specific minerals secreted in milk by dairy cows is important to comply with Nutrient Management Plans. Forty dairies in Merced, California (mean 787 ± 592 lactating cows/farm) were selected to study the effect of drinking water total solids (TS) contents and milk yield per cow (MY) on milk mineral content. Data was analyzed as 2 × 2 factorial with high TS (HTS; average 809 mg/L) and low TS (LTS; average 307 mg/L), and high MY (HMY; average 36 kg/d) and low MY (LMY; average 27.6 kg/d) as main factors. Milk yield was estimated from DHIA records. Dairy farm water troughs and am-pm bulk tank milk samples were taken by duplicate on 2 non-consecutive days and assayed for TS (water) and concentrations of Ca, P, Mg, Cl, K, Na, S, Cu, Fe, Mn, Se, and Zn (milk). Average milk mineral composition (mg/L) and standard deviation was: Ca 1008 ± 34.8; P 906 ± 34.4; Mg 100 ± 5.4; K 1534 ± 50.1; Na 397 ± 28.1; Cl 1045 ± 79.7; S 308 ± 11.3; Cu 0.036 ± 0.010; Fe 0.159 ± 0.020; Mn 0.016 ± 0.003; Zn 3.28 ± 0.208; Se 33.4 ± 7.54. No interactions between water TS and MY were observed. Milk from dairies with HTS water had lower ($P < 0.1$) concentrations of K (−2%), S (−2%), and Mn (−15%). In dairies with HMY, milk had significantly lower concentrations of Ca (−2.3%), P (−3.1%), Na (−5%), S (−3%), and Cu (−14%). The MY response was likely associated with dilution. More research is needed to evaluate water TS effects. Our results indicate that milk mineral contents might be affected by drinking water TS contents and MY.

Key Words: milk mineral contents, milk yield, drinking water

M345 Effects of supplementing different sources of fatty acids on lipid metabolism and endocrine responses in mid-lactation dairy cows.

X. Y. Xu, J. Q. Wang,* D. P. Bu, H. Cui, X. W. Zhao, Y. Sun, L. Y. Zhou, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to evaluate the effects of supplementing different sources of fatty acids on lipid metabolism and endocrine responses in mid-lactation dairy cows. Thirty-six Chinese Holstein cows were blocked based on milk yield, DIM and parity and randomly assigned in 3 groups. The animals were fed with diets containing 0 or 400g/d short and medium chain fatty acids(SMCFA, containing 6.0% C6:0, 4.0% C8:0, 9.0% C10:0, 10.0% C12:0, 32% C14:0 and 39% C16:0) and 400g/d long chain fatty acids (LCFA, containing 59% cocoa butter, 16% olive oil, and 25% palm oil) for group1(control), group2 and group3, respectively. The experiment lasted 8 weeks and at the last day of the experiment, blood samples were collected from tail vein of the cows. The results showed that serum triglyceride, high-density lipoprotein, low-density lipoprotein, growth hormone and insulin were not affected by supplementing different fatty acids ($P > 0.05$). The concentration of cholesterol increased by supplementing fatty acids, but no differences were observed among all the groups ($P > 0.05$). In group 3, the concentration of non- esterified fatty acid was significantly higher than that in group1 ($P < 0.05$). Compared with the control and group3, supplementing SMCFA significantly decreased the concentration of insulin-like growth factor by 16.9% ($P < 0.05$) and 9% ($P > 0.05$). In conclusion, supplementing SMCFA significantly decreased insulin-like growth factor, which may suggest SMCFA may have some negative effects on lipid metabolism.

Key Words: endocrine, fatty acids, metabolism

M346 Effect of replacing legume/grass silage with corn silage in dairy cow diets on enteric methane production.

F. Hassanat*[1], R. Gervais[2], P. Y. Chouinard[2], C. Julien[3], F. Tremblay[1], D. I. Massé[1], and C. Benchaar[1], [1]*Dairy and Swine Research and Development Centre-Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [2]*Département des Sciences Animales, Université Laval, Québec, QC, Canada,* [3]*INRA-Université de Toulouse, Castanet-Tolosan, France.*

The objective of this study was to determine the effect of replacing legume/grass silage with corn silage in the TMR of dairy cows on enteric CH_4 emissions. Nine lactating cows (DIM = 75 ± 19; BW = 688 ± 66 kg) used in a triplicated 3 × 3 Latin square (31-d periods, 14-d adaptation) were fed (ad libitum) TMR (60:40, forage:concentrate ratio) with the forage portion being either legume/grass silage (0% CS), corn silage (100% CS) or a 50:50 mixture (50% CS). Diets were formulated to be isonitrogenous (CP = 16.4%) and isocaloric ($NE_L = 1.62$ Mcal/kg). Production of CH_4 was determined (3 consecutive days) using respiration chambers. Digestibility and milk performance were determined over 6 consecutive days. Linear (L) and quadratic (Q) contrasts (Proc MIXED; SAS) were used to determine the effects of treatments. Significance was declared at $P \leq 0.05$. Dry matter (DM) intake (21.7, 23.0, and 22.8 kg/d) and DM digestibility (69.7, 70.6 and 71.3% for 0, 50 and 100% CS, respectively) increased linearly as the proportion of CS in the diet increased while a quadratic effect ($P_Q < 0.01$) was observed for milk yield (32.3, 35.3, and 34.3 kg/d for 0, 50 and 100% CS, respectively). Milk protein yield increased ($P_L < 0.01$) and milk fat yield decreased ($P_L < 0.01$) as the proportion of CS increased in the diet. Fat corrected milk (FCM) yield was not affected by treatments and averaged 31.3 kg/d. Methane emissions were lower ($P_Q < 0.01$) in cows fed 0% CS (440 g/d) and 100% CS (434 g/d) than in cows fed 50% CS (483 g/d). When adjusted for DM intake, CH_4 production was lowest ($P_Q < 0.01$) with 100% CS than with the 2 other treatments (20.3, 20.7, and 17.7 g/kg for 0, 50 and 100% CS, respectively). When expressed relative to FCM, CH_4 production was lower ($P_Q = 0.01$) in cows fed 0% CS (14.3 g/kg) and 100% CS (14.6 g/kg) compared with cows fed 50% CS (15.3 g/kg). Results from this study suggest that using corn silage as the sole forage source in dairy cow diets offers a means to decrease (−13%) enteric CH_4 emissions (g/kg DM intake) compared with using legume/grass silage or 50:50 mixture of both forages.

Key Words: corn silage, legume/grass silage, methane

M347 Effects of supplementing different ratios of short-medium chain fatty acids to long-chain fatty acids on the immune function in mid-lactating dairy cows.

X. Y. Xu, J. Q. Wang,* D. P. Bu, H. Cui, X. W. Zhao, Y. Sun, L. Y. Zhou, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

It is well known that fatty acids as the composition of immune cell membrane can modulate immune functions. The objective of this study was to investigate the effects of supplementing different ratios of short-medium chain fatty acids (SMCFA) to long-chain fatty acids (LCFA) on the immune function in mid-lactating dairy cows. Seventy-two Chinese Holstein cows were blocked based on milk yield, DIM and parity and randomly assigned in 6 groups. The animals were fed 0g/d, 400g/d LCFA, 80g/d SMCFA and 320g/d LCFA, 400g/d butter fat, 240g/d SMCFA and 160g/d LCFA and 400g/d SMCFA respectively on the basis of ordinary diets for group1 (control), group2 and group3, group4, group 5 and group 6. The supplementing mixtures consisted of different ratios of fatty acids: 1) SMCFA (C6:0–6.0%, C8:0- 4.0%, C10:0- 9.0%, C12:0- 10.0%, C14:0- 32%, and C16:0- 39%), 2) butter fat (amount to 40% SMCFA plus 60% LCFA), and 3) LCFA (59% cocoa butter, 16% olive oil and 25% palm oil). The experiment lasted 8 weeks and on the last day, blood samples were collected to determine the concentrations of serum immunoglobulin (Ig) A, IgG, IgM, prostaglandin (PG) E2 and cytokines. The results showed that the concentrations of IgA in group 2 and group 5 were higher than that in group 6; but no differences were observed with the control ($P > 0.05$). Among all the groups, IgM and PGE2 were not affected by supplementing fatty acids ($P > 0.05$). Compared with the control, the concentrations of IgG, interleukin 4 and 10 increased after supplementing fatty acids, especially in group 5. In conclusion, supplementing fatty acids which consisted of 240g/d SMCFA and 160g/d LCFA can improve the immune functions in mid-lactating dairy cows well.

Key Words: fatty acids, Holstein cows, immune function

M348 Effects of supplemental extruded full-fat soybean (ESB) on ruminal fermentation, nutrient digestion, blood parameters and productive performance of early lactation dairy cows.

H. Su*[1], F. Wang[1], Y. Zou[1], Z. Cao[1,2], M. Ma[1,2], and S. Li[1,2], [1]*State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China,* [2]*Sino-US Dairy Research and Development Center, Beijing, China.*

Four ruminally cannulated early lactation Holstein dairy cows, with similar days in milk (DIM, 23.6 ± 4.4), body weight (BW, 587 ± 46 kg) and body condition score (BCS, 2.95 ± 0.08), were used a in 4 × 4 Latin square design to determine the effects of supplemental ESB [0 kg/d (control), 1.0 kg/d, 2.0 kg/d or 3.0 kg/d] on ruminal fermentation, nutrient digestion, blood parameters and productive performance. The basal TMR diet was formulated to meet or exceed the predicted requirements (NRC, 2001), contained (DM basis) 13.6% alfalfa hay, 22.8% corn silage, 13.7% Chinese wildrye, and 49.9% concentrate mainly from corn, bran, rapeseed meal, cottonseed meal, soybean meal and DDGS. Extruded full-fat soybean contained 91.0%DM, 38.7% crude protein (CP), 20.6% ether extract (EE), 23.6% neutral detergent fiber (NDF), 12.4% acid detergent fiber (ADF) and 6.20%Ash. Each experimental period was 21-d, including 10-d adaptation period and 7-d sampling period. With the increase of the supplemental ESB, ruminal pH tended to decrease ($P = 0.062$), but ruminal NH3-N, propionate, valerate and isovalerate concentrations increased significantly ($P < 0.05$). Compared with control, test group′s dietary apparent digestibility of CP and EE increased ($P < 0.001$), and that of DM tended to increase ($P = 0.061$), N retention increased significantly ($P < 0.01$). Milk yield tended to increase after ESB supplementing ($P < 0.10$), while milk solids-not-fat (SNF) percentage and milk urea nitrogen (MUN) concentration increased significantly ($P < 0.05$), but milk fat content tended to decrease ($P = 0.081$). Test group′s plasma urea nitrogen (PUN) concentration increased significantly ($P = 0.002$), and the 2.0 kg/d group plasma total bilirubin concentration tended to decrease ($P = 0.072$), indicated that cows′ liver injury was alleviated. Under the conditions of this trial, supplementing ESB during early lactation could improve cows′ productive performance and healthy condition, and 2.0 kg/d amount might be appropriate choice.

Key Words: early lactation, extruded full-fat soybean

M349 Intake and digestibility by lactating cows fed different levels of palm kernel cake.

R. L. Oliveira*[1], R. L. N. V. Silva[2], A. C. Ferreira[1], A. G. Leão[1], M. C. A. Santana[1], A. A. Pinheiro[1], G. G. P. Carvalho[1], and L. F. B. Pinto[1], [1]*Universidade Federal da Bahia, Salvador, BA, Brazil,* [2]*Instituto Federal Baiano, Catu, BA, Brazil.*

Sixteen multiparous dairy cows of the Holstein × Gir crossbreed, with an average weight of 436.6 kg (±59.7), were tested to determine the most appropriate amount of palm kernel cake in a dietary supplement for lactating cows at pasture. The experiment was conducted at the Experimental Farm of the Federal University of Bahia, Brazil, during August to October 2009. A Latin square design was utilized, with the cows distributed in 4 Latin squares (4 × 4 simultaneous; 4 treatments × 4 periods × 4 animals in each treatment). Intake and digestibility were analyzed for cattle with a dietary supplement containing 0, 25, 50, and 75% palm kernel cake, and grazing Massai grass (*Panicum maximum* ‘Massai’). Indigestible neutral detergent fiber (iNDF) was used as an internal indicator of the measure of intake. Intake of DM, CP, ether extract, NDF, NFC, total carbohydrates, and total digestible nutrients within the supplement, as well as the intake of total crude protein, total ether extract, and total NFC, were negatively influenced by level of palm kernel cake supplementation. The forage mass during the experiment was, on average, 8.72 kg DM/ha, with an average supply of 8.32% of live BW in forage DM. The digestibility of DM, OM, CP, NFC, and total carbohydrates was significantly reduced with an increased percentage of palm kernel cake in the supplement. A decrease in the digestibility of CP and NFC indicates that palm kernel cake is not an adequate ingredient in nutritional supplements for dairy cows at pasture. Thus, one should be cautious in using supplements with palm kernel cake and its use must to be very careful. The high fiber content (NDF, 71.13%) and the expressive content of lignin (17.03%), that together comprise a difficult material degradation, associated with the low NFC (12.10%) of palm kernel cake, create the need for a greater period of residence in the rumen to provide a greater degree of breakdown. Therefore, lower percentages of palm kernel cake in the supplement result in a greater availability of nutrients.

Key Words: Massai grass, nutrients, pasture

Ruminant Nutrition: Rumen Function and Digestion

M350 Comparison of three marker systems and three sites of digesta sampling to estimate the rumen outflow in bulls fed with corn silage or sugar cane. P. P. Rotta,* S. de C. V. Filho, L. F. C. Silva, F. A. C. Villadiego, and E. M. Galindo, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The aim of this study was to evaluate the rumen outflow and the rumen and intestinal digestibility of dry matter and digesta components in crossbred bulls by use of sampling in 3 places (abomasum, omasum or reticulum) evaluating 3 marker systems (single, double or triple) with bulls feeding corn silage or sugar cane in different ratios. Eight crossbred bulls fitted with ruminal and abomasal cannulas and with 24 mo, weighting 353 ± 36.94 kg were separated in 2 4 × 4 Latin squares design. The experimental diets were: 1) 60% of corn silage + 40% of concentrate; 2) 40% of corn silage and 60% of concentrate; 3) 60% of sugar cane + 40% of concentrate; 4) 40% of sugar cane + 60% of concentrate. Eight digesta samples were collected in each experimental period with intervals of 9 h. At the end of each experimental period the samples were pooled and they were appointed to the 3 marker systems (single system: sample without separation; double system: filtered sample; and triple system: filtered and centrifuged sample). The whole reticular digesta composition was different ($P < 0.0001$) in comparison with the others to ether extract (EE), neutral detergent fiber (NDF) and indigestible NDF. The digesta sampled at the abomasum and omasum presented similar ($P > 0.05$) values to rumen outflow to dry matter (DM), organic matter (OM) and NDF. Similarly, the abomasal and omasal digesta were similar ($P > 0.05$) to estimate of ruminal digestibility of DM, OM, crude protein (CP) and NDF. Digesta sampled at abomasum and omasum presented similar ($P > 0.05$) values to estimations of intestinal digestibility of OM, CP and NDF. The omasal sampling is recommended as an alternative to abomasal sampling. Due to no difference among the marker systems to ruminal and intestinal digestion for NDF and intestinal digestion for CP, any marker systems can be used. Whereas that there are few differences to rumen outflow and digestions by estimating with double and triple marker systems, it is recommended the use of double marker system (indigestible NDF and Co-EDTA), that can be accessible to any research center.

Key Words: abomasal digesta, ruminal digestibility, omasal digesta

M351 Comparison of in situ nylon bag protocols for analysing ruminal degradation of dry matter and crude protein in forages. H. van Laar*[1], J. Doorenbos[1], J. D. Steckley[2], and J. A. Metcalf[2], *[1]Nutreco R&D, Boxmeer, the Netherlands, [2]Nutreco Canada Agresearch, Guelph, ON, Canada.*

This experiment compared degradation of forages between different in situ nylon bag protocols in 2 laboratories. In laboratory 1 fresh forages were cut to <2cm, 5g DM was weighed into nylon bags and incubated by time point in the rumen of 3 fistulated cows for 0, 3, 8, 16, 32, 56, 96 and 336 h in a net bag with a 1.5kg weight. In laboratory 2 forages were dried and ground over a 2 mm sieve, 5g DM was weighed into polyester bags and incubated in the rumen of 4 fistulated cows for 0, 1, 2, 4, 8, 16, 24 and 72 h attached to a 5 foot long nylon belt with a 1kg weight at the end. Forages were 5 grass silages, 5 grass hays, 5 haylages, 5 mixed hays (both a mix of alfalfa and grass) and 10 corn silages. After incubation samples were pooled by time point within cow and analyzed for dry matter and crude protein content. Degradation characteristics, Washable (W), Degradable (D), Undegradable (U) and degradation rate (K_d) were estimated with PROC NLIN of SAS. Effective degradability (ED) was calculated assuming a passage rate of 0.045/h. Differences between laboratories were analyzed by a paired *t*-test. PROC REG of SAS was used to estimate linear regression coefficients and r-square. For DM and CP (all forages combined), U and residues at 0, 8 and 16 h were lower (all $P < 0.02$) whereas W and ED were higher (all $P < 0.0001$) for laboratory 2. D fractions for DM and CP did not differ whereas K_d for DM was higher ($P < 0.05$) in laboratory 2. The r^2 of the comparison between laboratories for U, D, W, K_d and ED was 0.29, 0.07, 0.74, 0.23, and 0.87 for DM and 0.73, 0.09, 0.53, 0.41, and 0.59 for CP. When analyzed by forage type, correlation for ED of DM and CP between laboratories was good ($r^2 > 0.5$) only for grass hay (0.99, 0.96), haylage (0.92, 0.88) and mixed hays (0.94, 0.55), whereas correlations were poor ($r^2 < 0.5$) for grass and corn silages. The different in situ procedures result in a higher ED for laboratory 2, with acceptable correlation between degradation parameters taking all forages together; however, correlation between laboratories is not acceptable for all individual forage types.

Key Words: in situ, forage, rumen degradation

M352 Methane emissions and diet digestibility for sheep offered diets varying in fat content and forage quality. E. J. Mc Geough,* Y.-H. Chung, K. A. Beauchemin, S. M. McGinn, and T. A. McAllister, *Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada.*

The objective of this study was to determine DMI, diet DM digestibility (DMD) and methane (CH_4) emissions for sheep offered diets varying in fat content and forage quality. The study was a replicated (4 square) Latin Square design with 4 experimental treatments based on 2 levels of fat inclusion (low fat = 21.5, high fat = 59.6 g/kg DM) and 2 basal forages varying in nutritive quality. Fat was derived from the inclusion of canola meals and oil. To achieve variability in diet quality, oat hulls (LQ) and beet pulp (HQ) were chosen as the basal forages, accounting for 400 and 500 g/kg of diet DM, respectively. Twenty 4 Canadian Arcott sheep (16 male and 8 female), initial BW 60.4 (SD 4.80) kg, were assigned to 1 of the 4 treatments. Within treatment, sheep were assigned to 1 of 2 groups based on LW and sex to facilitate measurements in climate-controlled open circuit respiration chambers over 2 subsequent 4 d periods within each period of the Latin square. Each period consisted of 17 d of dietary adaptation followed by 4 d to measure CH_4 production and DMD. Three sheep were assigned to each chamber and housed individually in metabolism crates. Apparent total tract digestibility was determined by collecting total feces and urine for 4 d from group 1. Data were analyzed using PROC MIXED of SAS. Improving forage quality reduced DMI, on average 16.2%, ($P < 0.05$) for both low and high fat diets, but addition of fat did not affect DMI ($P = 0.17$) within forage type. Dry matter digestibility was also higher ($P = 0.001$) for HQ than LQ forage (on average 19.7%) regardless of dietary fat level. Increasing the fat content of LQ diets increased ($P < 0.05$) DMD, however DMD of the HQ diet was not affected ($P = 0.64$) by fat content. Improving the quality of forage in the diet increased ($P < 0.001$) CH_4 emissions (per kg DMI) from both low fat (13.1–15.0 g/CH_4) and high (14.0–16.5 g/CH_4) fat diets. Fat content did not affect CH_4 output ($P = 0.17$) for LQ diets, however CH_4 emissions from HQ diets were increased (9.2%; $P < 0.05$) with the higher level of fat inclusion.

Thus, dietary supplementation of fats may not be an effective means to mitigate CH_4 emissions in high quality forage diets.

Key Words: fat, forage quality, methane

M353 Leucaena diets with or without polyethylene glycol affecting rumen fermentation and methane emission in sheep. Y. Soltan*[1,2], A. Morsy[1,3], R. Lucas[1], S. Sallam[2], H. Louvandini[1], and A. Abdalla[1], [1]*Centre for Nuclear Energy in Agriculture, University of Sao Paulo, Piracicaba,Sao Paulo, Brazil,* [2]*University of Alexandria, Alexandria, Egypt,* [3]*Animal Production Research Institute, Cairo, Egypt.*

This study evaluated the effect of leucaena (*Leucaena leucocephala*) diet with or without polyethylene glycol (PEG) on rumen fermentation and methane (CH4) emission in vivo. Six adult rumen cannulated Santa Inês sheep (70 ± 2.5 kg of BW) divided in to 3 experimental diets completing a double Latin square design [3 treatments, 3 periods (17 d each), 6 animals] as follow: control (CNTRL- 70% Tifton hay (*Cynodon* spp.) + 21% ground corn, 9% soybean meal); leucaena diet that consisted of the control diet replaced by 0.50 of Tifton hay with leucaena (LEUC −123 and 8.8 g/kg DM of total tannins and condensed tannins respectively) and leucaena diet plus 20 g/day/animal of PEG (LPEG). Leucaena diets (LEUC and LPEG) decreased ($P < 0.0001$) the CH4 emission per kg digested organic matter by 0.14 and 0.11, respectively as well as decreased ($P < 0.0001$) the rumen acetate:propionate ratio compared with CNTRL, however LPEG increased butyrate ($P = 0.0034$) when compared with the LEUC. No differences ($P > 0.05$) were detected for rumen pH or protozoa count for all the experimental diets while LEUC showed the lowest ($P < 0.0001$) rumen ammonia concentrations (20.4, 19.6 and 24.3 (SEM = 1.350) mg/100 mL respectively for CNTRL, LEUC and LPEG). These results showed that leucaena diets either with or without PEG addition reduced methane emission by manipulating rumen fermentation.

Key Words: tannins, polyethylene glycol, methane

M354 Biometrics digestive tube of kids suckled up to 60 days fed different goat milk replacers. L. S. Knupp, M. I. Marcondes,* C. S. Cunha, T. S. Oliveira, J. G. L. Regadas Filho, J. C. M. Lima, L. C. Lacerda, and C. M. Veloso, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

There are few studies on the development of the digestive tract of goats. The study of non-carcass parts is important, because they tend to vary with diet, directly affecting carcass yield and weight gain. This work aimed to evaluate the biometrics of the digestive tract of goats suckled up to 60 d fed different goat milk replacers. Twenty-four Saanen (12) and Alpine Brown (12) kids were randomly assigned to treatments and were slaughtered at 60 d. They were offered coast-cross hay, starter ad libitum, and one liter of milk, or replacer, per day. The treatments were: goat milk (GM), cow milk (CM), fermented cow colostrum (FC) and lactal - commercial milk replacer (LAC).The organs were separated and weighed without digesta. The parameters analyzed were: Rumen, omasum, abomasum, small and large intestine. Data were analyzed using a complete randomized design, using the initial weight as a covariate. When a treatment effect was observed, the Tukey test was applied to evaluate the least squares means, using a significance level of 5%. The treatments did not affect any of the evaluated parameters ($P > 0.05$). The averages of rumen weight for kids who received CM, LAC, GM, and FC, respectively, were: 0.231, 0.185, 0.207, 0.163 kg; the average omasum weights were: 0.019, 0.012, 0.015, 0.009 kg; the average abomasum weights were: 0.090, 0.077, 0.085, 0.082 kg; the average small intestine weights were: 0.358, 0.296, 0.297, 0.262 kg; and the average large intestine weights were: 0.179, 0.263, 0.157, 0.129 kg. We concluded that all evaluated goat milk replacers can be used for feeding goats up to 60 d without affecting the development of their digestive tract. Supported by CNPq/INCT-CA.

Key Words: abomasum, omasum, rumen

M355 Comparative influence of solvent extracted-peanut meal and soybean meal on apparent digestibility of diets for finishing lambs. L. R. Flores*[1], A. Camacho[1], N. E. Villalba[2], J. J. Lomelí[1], and R. Barajas[1], [1]*FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Agricola Ganadera Mojolo, Culiacán, Sinaloa, México.*

Four hair lambs 22.3 ± SE 0.5 kg were used to compare influence of solvent extracted-peanut meal and soybean meal on apparent digestibility of diets for finishing lambs. In an experiment with a Crossover design, lambs were assigned to consume one of 2 diets in that consisted the treatments: 1) Diet containing 19.6% CP, integrated (DM basis) with soybean meal 27%, corn 57%, corn straw 8.3%, sugar cane molasses 5.0%, and 2.7 of mineral premix (SBM); or 2) Diet containing 21.4% CP, where SBM was completely substituted by solvent extracted peanut meal (SEPM). The crude protein content of SEPM was 52.3% and its ether extract value was 2.2%. Each 11-d experimental period was integrated for 7 d adaptation phase and 4 d total feces collection phase. Lambs were fed 95% of appetite to prevent refusals. Dry matter intake, crude protein intake, dry matter excreted in feces, and crude protein excreted in feces were similar between treatments ($P > 0.30$). Apparent digestibility of dry matter was no affected by treatments ($P = 0.78$) with mean values of 82.2 and 82.7% for SBM and SEPM, respectively. Crude protein apparent digestibility was similar in both protein-meal sources ($P = 0.80$), with means values of 83.3 and 83.9% for soybean meal-diet and peanut meal-diet, respectively. Digestible energy of diets was unaffected by treatments ($P = 0.78$). Using substitution method and soybean meal as ingredient of reference, true CP-digestibility of peanut meal was calculated in 95% and its digestible energy content in 3.8 Mcal/kg of DM. It is concluded, that peanut meal can substitute soybean meal completely in finishing lambs diets without altering nutritional value of the diet. The true CP-digestibility of peanut meal is 95% and its digestible energy content is 3.8 Mcal/kg of DM.

Key Words: digestibility, lambs, peanut meal

M356 Development of a new marker for utilization in digestibility studies. C. C. C. Couto Filho[1], E. O. S. Saliba*[1], M. N. Pereira[2], N. M. Rodriguez[1], and N. N. Morais Júnior[3], [1]*Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil,* [2]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [3]*Instituto Federal de Educação Ciência e Tecnologia do Espírito Santo, Colatina, ES, Brazil.*

A new marker using nanoparticles was developed by a research group at the Federal University of Minas Gerais. This trial was conducted to evaluate the estimates of fecal output and digestibility in dairy cattle with this new marker. Ten Holstein cows were used in the trial, which had consisted of 14 d for adaptation to the diet, 10 d of adaptation to chromic oxide and 2 d to nanomarker. The markers were also provided during the collection period. The markers were administered separately in capsules containing 500 mg of nanomarker and 10 g of chromic oxide. The fecal output and the digestibility were determined by total collection and by different markers, by sampling at intervals for 6 h, directly from the rectum of each animal, between fifteenth and nineteenth days.

Feces for the analysis of the nanomarker were collected during 24 h, starting on the sixteenth day. The dry matter content (AOAC, 1995), chromic oxide (Williams et al., 1962) and the nanomarker (near infrared reflectance spectroscopy - NIRS) in feces was determined. The statistical design was randomized blocks, with the animals being the blocks. The chromic oxide overestimated fecal output and consequently underestimated digestibility, fact which can be evidenced by the incomplete recovery of this marker in the feces (Table 1). In contrast, the results obtained with the nanomarker does not differ from the total collection method, showing complete fecal recovery (Table 1). The highest velocity dispersion of nanoparticles in the gastrointestinal tract provided a better homogenization of the material in the digesta, allowing a steady state faster. Thus, the nanomarker can be used as an marker in digestibility trials to replace the total collection.

Table 1. Fecal output, fecal recovery and digestibility by different techniques

Technique	Fecal output (kg)	Fecal recovery (%)	Digestibility (%)
Total collection	6.6[a]	100.0[a]	72.1[a]
Nanomarker	6.5[a]	100.8[a]	71.9[a]
Chromic oxide	9.0[b]	139.3[b]	62.2`
SEM	0.17	2.88	0.93
P value	<0.001	<0.001	<0.001

[a,b]Means followed by different letters in the same column differ (P < 0.05) by Tukey test.

Key Words: fecal output, markers, nanotechnology

M357 Effects of vitamin B_{12} on in vitro rumen fermentation and microbial enzyme activity.

Y. X. Li, J. K. Wang, Y. M. Wu, and J. X. Liu,* *Institute of Dairy Science, MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

This study was conducted to investigate the effects of vitamin B_{12} (VB_{12}) on rumen fermentation and microbial enzyme activity in an in vitro study with a 3 × 3 factorial arrangement of treatments. Substrates were designed with 3 ratios of forage and concentrate (C/F, 35:65, 50:50 and 65:35) and 3 doses of VB_{12} (0, 40 and 90 ng/mL). Rumen fluid was collected from 3 rumen cannulated Hu sheep fed a diet consisting of Chinese wildrye hay and concentrate mixture (60:40) twice daily. Cobalt was not added into the incubation medium (mixture of rumen fluid and buffer solution) so that it did not interfere in the effect of vitamin B_{12}. Gas pressure measurements were recorded at 2, 4, 6, 9, 12 and 24 h of incubation and then converted to gas volume. Ammonia N, pH, volatile fatty acids, microbial protein, and activities of carboxymethylcellulase, xylanase and amylase were determined at 24 h incubation. Data were analyzed using the GLM procedure of SAS. Terminal pH varied within normal range (6.52 to 6.65) regardless of treatment or substrate. With the increasing C/F ratio and additional doses of VB_{12}, gas production at 24 h incubation was enhanced ($P < 0.01$) and VB12 had a linear effect. Addition of VB_{12} to the substrate at C/F ratio of 35:65 did not have effects on all the rumen fermentation parameters ($P > 0.05$), while ammonia-N, volatile fatty acids, and microbial protein increased ($P < 0.05$) at 40 and 90 ng/mL VB_{12} when the C/F ratio was at 50:50 and 65:35. Activities of carboxymethylcellulase, xylanase and amylase increased ($P < 0.05$) at 40 and 90 ng/mL VB_{12} for the C/F ratio of 35:65 and 50:50, and at 90 ng/mL VB_{12} for C/F ratio of 65:35. Although the C/F ratio and VB_{12} dose had varying effects on in vitro rumen fermentation, the results of this study indicate that addition of VB_{12} can improve rumen fermentation through enhancing microbial enzyme activity with pronounced effect at higher C/F ratio.

Key Words: microbial enzyme activity, rumen fermentation, vitamin B_{12}

M358 Urinary recovery of purine derivatives and microbial production in Nellore cattle.

A. M. Barbosa*[1], R. F. D. Valadares[2], S. de C. V. Filho[2], D. do S. Pina[3], and M. A. Fonseca[2,4], [1]*Universidade Federal da Bahia, Salvador, Bahia, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil,* [3]*Universidade Federal do Mato Grosso, Sinop, Mato Grosso, Brazil,* [4]*Texas A&M University, College Station.*

The objectives of this study were to estimate the abomasum proportion of purines recovered as purine derivatives (PD) in urine, and verify the effect of intake level on microbial production (Nmic) in Nellore cattle. The animals were fed with one diet with different levels of DM offer. The trial was performed using 8 cannulated (rumen and abomasum; moreover 4 of those with ileum cannula) heifers with average BW of 258±20 kg. The animals were allocated on individual stalls and fed twice a day. The statistical analyses were performed using 2 balanced Latin square designs (4 x 4). Treatments were constituted of four levels of DM offer: 1.2, 1.6, 2.0 and 2.4% of BW. The average of RNA apparent digestibility coefficient obtained was 75.63%, but it was not affected ($P>0.05$) by the levels of DM offered in diet. The daily flux of RNA, and the Nmic into the abomasum as a function of DM offered in the diet presented quadratic behavior. Estimates were maximum of 1.50 mmol/kg$^{0.75}$ and 55.20 g Nmic for the DMI of 2.43 and 2.45% of BW. Daily urinary excretion of PD, in mmol/kg$^{0.75}$, increased linearly ($P>0.05$) with the level of DM offered in diet. When the excretion of PD, expressed in mmol/day basis, was related with TDN intake, kg/day, was observed ($P>0.0001$) an excretion of 32.15 mmol for each kg of TDN consumed. Microbial production estimated by PD in urine as a function of the level of DM offered in the diet, presented linear behavior ($P>0.05$). The recovery of the absorbed PD in urine was 0.86.

Key Words: level of intake, RNA, ruminant nutrition

M359 Methane emission potential, chemical composition and degradability of banana crop wastes for ruminants.

L. N. Oliveira*[1], S. L. S. Cabral Filho[1], and L. C. Geraseev[2], [1]*University of Brasília, Brasília, Federal District, Brazil,* [2]*Federal University of Minas Gerais, Montes Claros, Minas Gerais, Brazil.*

Five substrates, consisting of banana leaves hay, banana pseudostem hay, coastcross hay and 50% substitution levels of coast-cross hay to leaves or pseudostem banana hay were evaluated for the chemical composition, cumulative gas production, methane emission potential and degradability. The semi-automated in vitro gas production technique was employed to determine the cumulative gas production with 2, 4, 6, 8, 12, 16, 20, 24, 30, 36, 48, 72 and 96 h after incubation in ruminal fluid of sheep and cattle. Each sample included 3 repetitions per inoculum, with 6 replicates to evaluate the dry matter degradability in 2, 6, 12, 24, 48 and 96 h. After 24 and 48 h the gas was storage to evaluate the methane concentration using gas chromatograph. The experimental design was completely randomized in 5 × 2 factorial, with substrates and inoculum factors. Data for cumulative gas production, degradability and volume of methane were subjected to variance analysis and the means compared by Tukey test (5%). The fermentation kinetics parameters was estimated using the France model. The banana leaves hay had the highest crude protein content (13.8%), while in pseudostem hay this nutrient level was lower (3.5%). This last substrate had small values of neutral detergent fiber (64.6%) and acid detergent fiber (36.2%) and high proportion of non-fibrous carbohydrates (28.4%), when compared with the coastcross hay. After 24 h fermentation, the pseudostem hay had cumulative gas production higher than others substrates ($P < 0.05$), reflecting their greater effective degradability (76.3%). The lowest rate of effective degradability was observed for the coastcross hay (46.3%), resulting in low gas production. The 50% addition level of leaves or pseudostem banana hay to the coastcross hay improved the fermentative quality of the substrate, being observed increase in effective degradability, up 10.6%, and in maximum potential gas production, up 14.7 mL/g of dry matter. The methane emission was lower ($P < 0.05$) for banana leaves and coastcross hay, both not differing from each other ($P > 0.05$).

Key Words: alternative forages, methane, ruminant nutrition

M360 Corn grain or citrus pulp associated with glycerin in Nellore feedlot steers: intake and ruminal fermentation. V. R. Fávaro,* J. M. B. Ezequiel, J. R. Paschoaloto, M. T. C. Almeida, A. P. D'Áurea, A. C. Homem Junior, and V. C. Santos, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

In most studies glycerin has been evaluated as an energy source replacing the corn of the diet. In Brazil, citrus pulp represents an interesting alternative for feedlot cattle, due to its nutritional characteristics, good availability and lower price when compared with corn. The objective of this research was to evaluate the association of corn grain or citrus pulp with glycerin in diets for Nellore feedlot steers on dry matter intake, rumen pH and rumen ammonia concentration. Five rumen cannulated Nellore steers (420 ± 20 kg BW) were used in a 5x5 Latin square design. Experimental diets consisted of 30% corn silage and 70% concentrate (corn grain, citrus pulp, soybean hulls, urea and glycerin) and were labeled as (DM basis): diet with no added glycerin (CON), 30% of corn grain with 10% of glycerin (CG10), 25% of corn grain with 15% of glycerin (CG15), 25% citrus pulp with 10% of glycerin (CP10), 20% of citrus pulp with 15% of glycerin (CP15). To determine pH and ammonia concentration, rumen fluid samples were taken through the rumen cannula at the time of feeding and, 1, 2, 4, 6 and 8 h after feeding. Statistical analysis was performed using the MIXED procedure of SAS. Orthogonal contrasts were used to determine the effect of 0% glycerin vs glycerin treatment, CG10 vs CG15, CP10 vs CP15 and corn grain vs citrus pulp treatments. For pH, and ammonia data the time of harvest was included as a repeated measure. The rumen pH and ammonia concentrations were not influenced ($P > 0.05$) by the treatments. The mean values of pH and ammonia concentration were respectively 6.38 and 17.99 mg/dL. DM intake decrease ($P < 0.009$) when corn grain treatments was compared with citrus pulp treatments, the mean values were 7.27, 7.55, 7.24, 5.50 and 6.56 kg/day respectively for CON, CG10, CG15, CP10 and CP15. These data suggest that the use of glycerin at 10 or 15% with corn or citrus pulp does not affect the rumen pH neither ammonia concentration but, diets with more citrus pulp proportion causes decrease in dry matter intake.

Key Words: biodiesel, byproducts, feedlot cattle

M361 Assessment of the in vitro fermentation pattern of native forage from the Brazilian semiarid region. D. K. A. Silva*[1,2], L. O. Tedeschi[2], M. A. Fonseca[3,2], N. F. De Paula[3,2], K. P. Pereira[1], G. R. Medeiros[4], J. C. B. Dubeux Junior[1], and D. P. V. Silva[1], *[1]Federal Rural University of Pernambuco, Academic Unit of Garanhuns, Garanhuns, Pernambuco, [2]Texas A&M University, Department of Animal Science, College Station, [3]Federal University of Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [4]National Institute of Semiarid, Campina Grande, Paraíba.*

This work was aimed to evaluate the in vitro gas production (IVGP) and the fermentation kinetic parameters of 6 Brazilian native forages from the semiarid region in 2 seasons (PY) of the year: rainy (RS) and dry (DS) seasons. The forages analyzed were *Calotropis procera* (AS), *Croton sonderiamus* Müll Arg (M), *Caesalpinia pyramidalis* Tul. (CA), *Macroptilium martii* Benth. (OO), *Ipomoea glabra* Choisy (JIT), and *Herissantia crispa* (L.) (MB). The statistical analyses were performed using a random coefficient model assuming PY as a random variable and forage as a fixed variable. The IVGP technique was used to determine the total gas production (TGP). The results indicated that only PY affected TGP ($P < 0.05$) (Table 1). JIT had a greater value during the RS than DS season. During the RS period, AS and CA had the greatest and M had the lowest TGP values. During the DS period, AS and OO presented the greatest while JIT and M had the lowest TGP values. The greatest fractional rate of fermentation (kf h^{-1}) was observed for AS, which also had the greatest lag time (1,351 ± 0,24), suggesting that microbes needed more time to start the fermentation of AS but they were able to ferment it quickly. This is likely because either AS had greater amounts of nonfiber carbohydrates or a specific group of secondary compounds that interfered on the in vitro fermentation. These results indicated that these forages, except for JIT, have the potential to be used as alternative feed sources with no disadvantage in the ruminal fermentative aspects throughout the year under the Brazilian semiarid region.

Table 1. In vitro gas production and fermentation parameters of Brazilians semiarid native forages

	Forages					
PY	AS	CA	JIT	OO	MB	M
Rainy season IVGP (mL/100 g DM)	26.83 ±1.09^{A,a}	25.31 ±1.08^{A,b}	24.65 ±0.92^{A,ab}	23.05 ±0.99^{A,b}	24.07 ±1.08^{A,b}	17.25 ±0.99^{A,c}
Dry season IVGP (mL/100 g DM)	26.60 ±0.99^{A,a}	22.91 ±0.99^{A,b}	19.18 ±0.92^{B,c}	24.24 ±0.92^{A,ab}	22.73 ±0.92^{A,b}	19.87 ±1.22^{A,c}
kf (h^{-1})[1]	0.165 ±0.01^{a}	0.099 ±0.01^{cd}	0.106 ±0.01^{cd}	0.106 ±0.01^{c}	0.133 ±0.01^{b}	0.086 ±0.01^{b}

$^{a\text{–}d}$Values within rows with same lowercase letters do not differ (P > 0.05).

^{A,B}Values in columns (for IVGP) with same uppercase letters do not differ (P > 0.05).

M362 An in vitro evaluation of rumen fluid type on hydrogen sulfide production of common beef cattle feedstuffs. K. L. Neuhold*[1], J. J. Wagner[2], K. S. Sellins[1], and T. E. Engle[1], *[1]Colorado State University, Fort Collins, [2]Southeast Colorado Research Center, CSU, Lamar, CO.*

Rumen fluid from fistulated steers receiving a high roughage (ROU; 50% alfalfa hay, 50% corn silage) or a high concentrate-based diet (CON; 70% rolled corn, and 30% corn silage) was utilized to examine in vitro hydrogen sulfide (H_2S) production of common beef cattle feedstuffs. Rumen fluid was collected and combined in equal amounts from 2 rumen fistulated steers that had ad libitum access to ROU and mixed at a 3 to 1 ratio of artificial saliva to rumen fluid. Fermentation substrates included: corn, alfalfa, consolidated corn distillers soluble, dried distillers grains (DDG), and wet distiller's grain (WDG). Individual substrates (700mg) were added to separate 125 mL glass serum bottles (in triplicate) with 50 mL of rumen fluid-artificial saliva mixture. Fermentation bottles were capped with an air tight rubber stopper and incubated in a water bath for 24 h at 39°C. After 24 h of incubation, the total volume of gas produced was measured and a 5-mL gas sample was obtained. Gas samples were then analyzed for H_2S concentration, after gas sampling, pH and dry matter disappearance (DMD) were determined. This experiment was then repeated using rumen fluid from steers fed CON. A feedstuff by rumen fluid type (ROU vs. CON) interaction ($P < 0.001$) was detected for μmol of H_2S produced per mg of DMD. Consolidated corn distillers soluble substrate produced less H_2S per mg of DMD when incubated with CON compared with ROU rumen fluid while corn, alfalfa, DDG and WDG produce greater μmol of H_2S per DMD when incubated in CON compared with ROU rumen fluid. Across diets (ROU vs. CON) fermentation of corn produced the lowest pH and fermentation of alfalfa produced the highest pH and across feedstuff ROU had a higher pH when compared with the CON rumen fluid. These data suggest that type of rumen fluid (ROU vs. CON) and feedstuff can influence the production of H_2S. Understanding factors that influence H_2S production within the rumen may be useful when formulating beef cattle diets.

Key Words: hydrogen sulfide, in vitro, sulfur

M363 In vitro methane production and dry matter degradability of citral.

T. S. Canaes,* I. C. S. Bueno, F. G. Vilela, A. P. C. Araújo, M. C. B. Santos, B. C. Venturelli, S. N. Macedo, J. E. Freitas Junior, and F. P. Rennó, *Sao Paulo University, Sao Paulo, Sao Paulo, Brazil.*

Citral, a major component of lemongrass oil has several applications in industry and also antibacterial, antifungal, and anticarcinogenic effects. The aim of this study was to determine the in vitro effect of different concentrations of citral from 2 different industries (sources S_1 and S_2) on methane production and ruminal degradability of a ruminant diet using a semi-automatic gas production technique. A total mixed ration (50% maize silage and 50% concentrate) was incubated with buffered rumen fluid and different levels of citral (0, 15, 30, 45 and 60μL/mL) at 39°C for 72h. Gas production was measured at 4, 8, 12, 16, 24, 30, 36, 48, 60 and 72h of incubation and the dry matter disappearance at 12, 24, 48 and 72h. Data were analyzed using PROC MIXED of SAS 9.1. Differences were observed for sources ($P = 0.017$) and doses ($P = 0.001$). The inclusion of citral increased dry matter degradability (DMD) for $S_1(\text{DMD} = -0.0006S_1^2+0.0921S_1+21.611;\ R^2 = 0.58)$ and for $S_2(\text{DMD} = -0.0076S_2^2+0.5949S_2+20.968;\ R^2 = 0.99)$, but the S_2 was more efficient. Unlike what has been expected, the citral, regardless of source, increased production of methane. There was quadratic effect in the methane production to $S_1(CH_4 = 3.186+2.077S_1\text{-}0.021S_1^2;\ R^2 = 0.91;\ P = 0.001)$, 4.69; 23.61; 55.09; 47.73; 52.49 mL/g DMD and S_2 ($CH_4 = 4.228+2.603S_2\text{-}0.032S_2^2;\ R^2 = 0.83;\ P = 0.001$), 4.71; 30.96; 64.63; 43.67; 45.37 mL/g DMD, respectively to doses 0, 15, 30, 45, 60, and the interaction of citral doses and sources was significant ($P \leq 0.001$). Ammonia-N concentration was not altered with inclusion of citral at different doses. There was significant effect of citral on the methane production and dose containing 45 and 60 μL/mL decreased significantly ($P \leq 0.05$) the production. The effects of citral would not be nutritionally beneficial to the ruminal energetic metabolism. Fapesp project number 2011/06260-9.

Key Words: degradation, gas production, lemongrass

M364 Estimated microbial production, efficiency and nitrogen balance in sheep fed high concentrate varying amounts of glycerin from soybean biodiesel.

R. L. Galati,* R. S. Gomes, P. G. Paiva, L. S. Cabral, J. T. Zervoudakis, J. G. Abreu, L. R. Rebelo, and M. Zanchetin, *Universidade Federal do Mato Grosso, FAMEV/UFMT, Cuiabá, Brazil.*

The objectives of this study were to evaluate the effect of glycerin from soybean biodiesel in high-concentrate diets on ammonia concentrations, nitrogen balance, excretion of purine derivatives, and microbial production (Pmic) and efficiency (Efmic). Animals were housed in individual pens, randomly allocated in a 5 × 5 Latin square design, and the dietary treatments were: 0, 5, 10, 15 and 20% of glycerin on diet DM. The glycerin used was derived from soybean biodiesel production (98% glycerol, 19.2% fat, 0.98% methanol, 0.18% ethanol, 101 mg KOH/g). Five male sheep, castrated and cannulated in the rumen, with initial body weight of 56.0 ± 9.02 kg were used in this study, and fed isoproteic diets (12.5% CP), containing 25% corn silage and 75% concentrate, on DM basis. For each 50 mL of ruminal fluid collected, 1 mL of 50% sulfuric acid was added to preserve samples during freeze. Feed, refusal, total fecal and urinary output was collected on 16 d through 20 d of each period. Feces were collected with canvas bag and the urine was collected into plastic vessels containing 50 mL of 20% v/v sulfuric acid for each 450 mL of urine to perform the nitrogen (N) balance, estimates of Pmic and Efmic from the total excretion of purine derivatives in urine. Ammonia concentrations were no effect by glycerin ($P > 0.11$), with an average of 17.24 mg/dL. There was a quadratic effect ($P < 0.11$) on nitrogen (N) intake and absorption, with maximum values of 9.32 and 9.67% glycerin, respectively, but without influence ($P > 0.11$) on N retention (10.28 g/d), which corresponded to 56,35% of the absorbed. Fecal and urinary excretion of N were not affected ($P > 0.11$), with average values of 4.73 and 7.37 g N/d, in the same order. Allantoin, uric acid, xanthine + hypoxanthine excretions ($P > 0.11$) were 7.68, 0.50 and 0.29 mmol/d, respectively, which corresponded to 89.25, 6.35 and 4.39% of total purines. Purine derivatives excretion (8.48 mmol/d) were not affected ($P > 0.11$) resulting in a Pmic of 46.03 g/d and Efmic of 45.45 g CP/kg TDN. Inclusions up to 20% glycerin could be recommended without compromising nitrogen balance, microbial production and efficiency in high-concentrate diets to sheep.

Key Words: ammonia concentrations, glycerol, purine derivative

M365 Microbial kinetics, fermentative and chemical characteristics in solid-state fermentation of apple bagasse.

O. Ruiz[1], Y. Castillo[2,1], C. Angulo[1], C. Rodriguez[1], O. Enriquez*[1], and C. Arzola[1], [1]*Facultad de Zootecnia y Ecología de la Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México,* [2]*División multidiciplinaria de Nuevo Casas Grandes de la Universidad Autónoma de Ciudad Juarez Chihuahua, Nuevo Casas Grandes, Chihuahua, México.*

Nutritional characteristics of solid wastes, and its further utilization as an animal feed, can be improved by solid-state fermentation (SSF). This technology is an efficient way to improve degradation of lignocellulosic compounds and enhance the amount and quality of protein fraction. The aim of this trial was to evaluate the effect of incubation time on the fermentative profile and chemical content of fermented apple residues collected after industrial processing for juice extraction. Apple waste was ground and mixed with (as % fed basis) 1.5 urea, 0.2 of ammonium sulfate, 0.9 calcium carbonate and 0.5 of a mineral salt mixture. Calcium carbonate was added to promote a slight alkaline substrate. These ingredients were mixed and then 340g (as fed basis) as substrate were distributed to separate sterile 500mL flasks plugged with cotton and incubated under static conditions at 32°C for 0, 12, 24, 36, 48 and 72h. A completely randomized design was used with 4 replications at each incubation time and data was analyzed with the GLM procedure of SAS. The pH values decreased ($P < 0.0001$) progressively over time and lactic acid increased ($P < 0.0001$) through time of incubation. Yeast cell counts (expressed in log10) also increased in the first 48h and decreased subsequently ($P \leq 0.0001$; 7.02, 7.19, 7.64, 7.78 and 7.26 cfu/mL).Lactobacilli colonies increased to the 36h and then decreased ($P \leq 0.0001$; 7.86, 8.71, 9.80, 9.69 and 9.54 cfu/mL). Dry matter content (%) was increased in the first

12h ($P < 0.001$; 18.98, 20.28, 20.08, 20.51, 20.33 and 20.53). Crude and true protein content (%) increased ($P \leq 0.0001$) also over time (31.7, 33.9, 33.8, 34.9, 35.0 and 35.2; 15.8, 18.8, 21.1, 19.2, 22.6 and 23.9 respectively). Neutral detergent fiber (%) was not affected in the first 12 h ($P \geq 0.05$), but diminished from 12 to 36 h ($P < 0.002$). According to these results it can be concluded that a 48-h time of fermentation was enough to accomplish an adequate yeast cell growth and obtain an improvement of the protein fraction of fermented residues of the apple industry.

Key Words: apple bagasse, nutritional, solid-state fermentation

M366 Evaluation external and internal markers for digestibility studies.

T. T. Berchielli[1], R. C. Canesin[1], D. A. Mota[2], I. M. Cezinbra[3], and G. Fiorentini*[1], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]Federal University of Amazonas, Parintins, Amazonas, Brazil, [3]Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.*

The objective of this experiment was to evaluate complexed chromium (Cr-EDTA) and ytterbium chloride ($YbCl_3$) as external markers, and indigestible neutral detergent fiber (INDF) such internal marker digestibility in comparison with total fecal collection (TC). Eight crossbred heifers (Holstein/Zebu) with 202.12 kg ± 11.54 of BW, were used. The experimental design was a replicated 4 × 4 Latin square. The diets were isonitrogenous (13% CP), and were composed by different protein sources: soybean meal (60% sugar cane, 15% soybean meal, 23.5% corn grain, 1% mineral and 0.5% urea); cottonseed meal (60% sugar cane, 14.2% cottonseed meal, 23.8% corn grain, 1% mineral and 1% urea); peanut meal (60% sugar cane, 13% peanut meal, 25.3% corn grain, 1% mineral and 0.7% urea); and sunflower meal (60% sugar cane, 16.2% peanut meal, 21.75% corn grain, 1% mineral and 0.85% urea). Each period consisted of 7 d of adaptation and 21 d of sample collections. Total feces were collected for 5 consecutive days during each period. Composite diet and fecal samples were analyzed for nutrients (chemical composition), and concentration of chromium and ytterbium was obtained in atomic absorption spectrophotometer and INDF in 11 d ruminal incubation (non-woven textile bags, 20 mg DM/cm^2). Apparent total digestibilities of all nutrients were lower for INDF compared with Cr-EDTA, $YbCl_3$ and TC. Digestibility estimated using Cr-EDTA, $YbCl_3$ or TC were not different (Table 1). In conclusion, using INDF as a digestibility marker yielded greater fecal output estimates and consequently lower apparent digestibility values for all dietary nutrients compared with TC or Cr-EDTA, $YbCl_3$. In the conditions of this experiment, Cr-EDTA and $YbCl_3$ was a more appropriate digestibility marker than INDF.

Table 1. Comparisons of methods for determining total tract apparent digestibility

	Method					
Item	TC	Cr-EDTA	$YbCl_3$	INDF	*P*-value	SEM
DM	67.62^a	66.86^a	67.01^a	63.62^b	<0.001	4.61
OM	65.23^a	64.80^a	65.54^a	61.30^b	<0.001	6.68
CP	67.20^a	65.11^a	66.29^a	62.57^b	<0.001	8.24

M367 Addition of fumarate reducing bacteria on in vitro fermentation.

L. Mamuad, S. Kim, C. Jeong, and S. Lee,* *Sunchon National University, Suncheon, Republic of Korea.*

Fumarate reducing bacteria utilized hydrogen which is one of the main substrate in methanogenesis. This study was conducted to determine if addition of these bacteria on in vitro fermentation can reduce methane, increase volatile fatty acids (VFA) production, and effect on its microbial diversity. The ruminal samples were collected from Holstein cows, mixed with a basal medium (1:3), transferred into 50-mL serum vials containing rice straw and filled under a stream of O_2-free N_2 gas. *Mitsuokella jalaludinii* and *Veillonella parvula* were added to the serum vials and incubated. After incubation, pH, total gas production, VFA, and methane emission were measured. Moreover, diversity of microorganism was determined by DGGE using universal and specific primer. All data were analyzed using SAS (2003). *M. jalaludinii* significantly reduces methane at 48 h of incubation. In addition, *M. jalaludinii* significantly increases succinate at 12, 24 and 48 h of incubation followed by *V. parvula* and then control. Furthermore, total volatile fatty acid was significantly higher in *V. parvula* at 24 h of incubation. These results suggest that addition of fumarate reducing bacteria to ruminal fermentation reduces methane, increases succinate and total volatile fatty acid, and changes the rumen microbial diversity.

Key Words: fumarate reducing bacteria, in vitro, DGGE

M368 Rumen wall morphology of lambs fed high concentrate diets.

L. S. Oliveira*[1], P. R. Leme[1], M. R. Mazon[1], D. M. C. Pesce[2], S. da Luz e Silva[1], C. A. Zotti[1], R. F. Carvalho[2], and A. P. dos Santos Silva[1], *[1]Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, São Paulo, Brasil, [2]Pontifícia Univerdidade Católica, Poços de Caldas, Minas Gerais, Brasil.*

High concentrate diets results in high rumen fatty acids concentrations which stimulates epithelium proliferation of papillae causing parakeratosis and increased occurrence of injury and inflammation. To evaluate different forms of corn grain processing on the rumen wall and papillae morphology 23 Santa Inês × Dorper male lambs with mean BW of 28 kg and 90 d old were fed a high concentrate diet (75% corn, 20% protein and mineral mix and 5% coast cross hay), with whole corn grain (WCG), high moisture corn (HMC) or ground corn grain (GCG). After 65 d of feeding animals were slaughtered and the rumen content (RC) was weighed and its pH measured. The incidence of ruminitis (IR) was classified according to a 0 to 10 scale. Fragments of 3cm^2were taken from the cranial sac of the rumen and kept in buffer for macroscopic measurements of papillae number (PN), papillary area (PA) and absorption surface (AS). PN was measured by 3 evaluators and PA and AS were measured on scanned images of the papillae and parietal surface fragments using the UTHSCA Image Tool free software. The average BW at slaughter was 47 ± 1.44kg. There were no significant differences among treatments for ADG (mean = 0.32 kg). The RC was higher for WCG (4.5 kg; $P = 0.02$) when compared with GCG (3.5 kg) and HMC (3.4 kg) with no differences between GCG and HMC. The rumen pH was smaller ($P < 0.0001$) for WCG (5.4) when compared with GCG (6.5) and HMC (6.6) with no differences between the last 2 treatments. There was no difference among treatments in IR (mean = 0.48%) and PN (mean = 43 papilla/cm^2). The treatment WCG, expressed as a percentage of rumen wall surface, had greater PA (95%; $P = 0.04$) then HMC (93%) but was similar to GCG (94%) with no differences between GCG and HMC. The AS was greater for treatment WGC (19cm^2) than for HMC (14cm^2; $P = 0.05$) with no difference between GCG (17cm^2) and HMC treatments. Although WCG may be interesting because the grain needs no processing and has a small effect on rumen wall morphology, it may result in an unfavorable rumen environment.

Key Words: feedlot, ruminant, sheep

M369 Growth rate of mixed ruminal bacteria as a function of energetic substrate concentration in bath culture.

T. S. de Oliveira,* R. de Paula Lana, V. S. de Oliveira, T. M. de Oliveira Alves, and G. L. R. Filho, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brasil.*

The objective of this study was to evaluate levels of sucrose on microbial growth. Roll tubes were filled with 15.6 mL of buffer Chen, 1 mL of inocula (rumen fluid from fistulated steer at pasture), 1 mL of Trypticase or hydrolyzed casein (1 g/L as final concentration) and 2.4 mL of sucrose solutions (0.00, 0.37, 0.75, 1.5, 3.0, 6.0, 12.0, and 24.0 g/L), in triplicate. The pH was 5.56 at 0 h and 4.6 after 6 h, and 5.83 in 0 g/L and 4.18 above 1.5 g/L of sucrose. The optical density (OD-600 nm) and microbial protein (MP-595 nm) tended to stabilize after 12 h and 6 g/L of sucrose, with no interaction between them. The OD (6 h to 24 h mean values) was curvilinear (hyperbolic), as a function of sucrose concentration, followed the saturation kinetics of Michaelis-Menten, which is typical of enzymes systems, and was described by the following Lineweaver-Burk equation: $1/OD = 0.508*(1/sucrose) + 1.15$, $R^2 = 0.99$. The theoretical maximum microbial growth (1/a = kmax) was 0.87 OD and the concentration of sucrose to reach half of kmax (b/a = Ks) was 0.44 g/L of sucrose. The microbial growth was affected by incubation time, substrate concentration, and culture medium acidification.

Key Words: Lineweaver-Burk, Michaelis-Menten, saturation kinetics

M370 Nutrient digestibility of pregnant WAD ewe fed Mexican sunflower leaf meal (MSLM) based diets.

A. H. Ekeocha,* *University of Ibadan, Ibadan, Oyo, Nigeria.*

Fifteen days before parturition, studies was conducted using 16 West African Dwarf (WAD) ewes weighing between 22.8 and 26.0kg on a basal diet of *Panicum maximum* were allotted into 4 treatment groups A, B, C and D of 4 replicates each. The Mexican sunflower leaf meal (MSLM) replaced wheat bran (WB) gravimetrically at 0, 15, 30 and 45%. Treatment A served as control, while animals in treatments B, C and D received MSLM at 15, 30 and 45% respectively. The experiment lasted for one week. Digestibility was determined using a 6-d total fecal collection. Ewes were given ad libitum access to feed and water and routine vaccination and medication followed standard procedures. The 16 ewes were previously brought to heat (estrus) by synchronization and served by 2 rams (1:8). Parameters measured were voluntary dry matter intake (VDMI), which comprised concentrate dry matter intake (CDMI) and grass dry matter intake (GDMI), apparent digestibility coefficients of dry matter(DM), crude protein(CP), ether extract (EE), nitrogen-free extract (NDF), acid detergent fiber (ADF), acid detergent lignin (ADL), organic matter (OM), energy and feed conversion ratio (FCR). Data were analyzed using descriptive statistics and ANOVA .The VDMI (g/d) varied from 392.3 - 695.0 for ewes during digestibility. CDMI (g/d) varied from 191.4 – 565.0 and GDMI (g/d) varied from 137.5 – 227.3 for ewes and this was significant ($P < 0.05$) with animals on treatment B having the highest CDMI while animals on treatment C having the highest GDMI respectively. Apparent digestibility coefficients of EE, NDF, ADF, ADL, OM, energy and FCR were similar. Approximately 75.5 ± 1.1% of the VDMI came from the supplement. Diets containing 15% MSLM was superior to others for CDMI (191.4 – 565.0 g/d), C P absorbed (42.1 – 99.5 g/d), CP apparent digestibility (86.5 – 91.5%), digestible DMI (52.3 – 85.2 g/d/kg$W^{0.75}$) and digestible CPI (14.3 – 28.4 g/d/kg$W^{0.75}$) while GDMI (137.5 – 227.3 g/d) for diets containing 30% and 45% MSLM were significant ($P < 0.05$). Therefore, MSLM could suitably replace wheat bran in the diets of pregnant ewe up to 30% level of inclusion without eliciting any adverse effect.

Key Words: Mexican sunflower, nutrient digestibility, pregnant West African dwarf ewe

M371 Rumen bacteria growth and pH of culture medium on different substrate concentrations.

C. P. Ghedini[1], R. P. Lana[1], A. S. Oliveira[2], D. C. Abreu*[1], R. M. Paula[1], G. A. Freitas[1], and M. G. Camilo[3], [1]*Universidade Federal de Viçosa, Viçosa, MG, Brazil,* [2]*Universidade Federal do Mato Grosso, Sinop, MT, Brazil,* [3]*Instituto Federal do Sudeste de Minas Gerais, Rio Pomba, MG, Brazil.*

The objective was to evaluate the response on rumen bacteria growth rate as a function of increasing substrate. Incubations were performed in glass jars saturated with carbon dioxide gas and hermetically sealed, containing 6 mL of rumen liquid, 24 mL of artificial saliva, and substrate weights of 1.2; 0.6; 0.3; 0.1; 0.05 and 0 g, being half of each weight corresponding to sucrose and half soybean meal. The tubes were incubated in triplicate for 72 h at 39°C and the pH and optical density were evaluated at 0, 6, 12, 18, 24, 42 and 72 h of incubation. The experiment was analyzed as completely randomized design as a function of substrate concentration, time of incubation and the respective interaction. Bacterial growth reached high values after 6 h ($P < 0.01$), but with strong depression at 48 and 72 h, associated with the low pH of culture medium and microbial lyses. It was observed increase in microbial growth ($P < 0.01$) with increase in the level of substrate. There was substrate * time interaction in microbial growth ($P < 0.01$), in which there was decrease in microbial growth with increase in time in low substrate levels, due to microbial lyses. Linear regression analyses of the reciprocal of the rate of microbial growth versus reciprocal supply of nutrients were made for the 48 times and 72 h of incubation, which had already reached the maximum growth, technique called Lineweaver-Burk equation. The theoretical maximum growth rate was 1.08 and substrate concentration required to achieve half of the maximum response was 0.128 g. The low observed K_s shows that bacteria affinity for sucrose is high, leading to rapid fermentation of substrate, lowering the pH values below the level tolerable by the predominant microbial population in rumen. This effect takes, consequently the microbial lyses and reduction of optical density. In this experiment it was found that the curvilinear response of saturation kinetics is due to first order kinetics in low levels of nutrients (excess enzymes and/or low substrate) and because of the zero order kinetics in high levels of nutrients (saturated microbial enzyme activity by fermentation products). Supported by FAPEMIG (Fundação de Amparo à Pesquisa do Estado de Minas Gerais).

Key Words: growth rate, saturation kinetics, sucrose

Small Ruminant: Nutrition

M372 Effect of breed and sex on fatty acid composition of fat-tailed and tailed lambs. A. Yousefi,* H. Kohram, A. Z. Shahneh, M. Sadeghi, and M. Poorhamdollah, *University of Tehran, Karaj, Tehran, Iran.*

The objective of this study was to compare fatty acid profile of longissimus dorsi (LD) between fat-tailed Chall (14 male and 15 female) and tailed Zel lambs (15 male and 15 female). All of lambs were pastured with average age of 10–12 mo and BW of 36.5 ± 1.6 (Kg). LD muscles were dissected 24h after slaughtering to evaluation fatty acid composition. Data of fatty acid profile and intramuscular fat of LD muscle were analyzed by SAS 9.2 software and GLM procedure where HCW was used as covariate and breed and sex were used as fixed effect. Results showed (Table 1) that Zel and female stored more intramuscular fat than Chall ($P < 0.001$) and male lambs ($P < 0.0001$), respectively. Oleic (C18:1) acid was lower ($P < 0.001$) and linolenic acid (C18:3n-3) was higher ($P < 0.01$) in Chall compared with Zel lambs. Although percentage of linoleic acid (C18:2n-6) and SFA were not significant ($P > 0.05$) between breeds, LD muscle of Chall contained more percentage of PUFA and PUFA/SFA ratio ($P < 0.05$) rather than Zel lambs. LD muscle of male lambs showed higher percentage of PUFA ($P < 0.05$) and lower proportion of n-6/n-3PUFA ($P < 0.001$). Considering n-6/n-3PUFA, LD muscle of Chall lambs showed lower ratio ($P < 0.01$) than Zel lambs whereas sex did not show significant difference ($P > 0.05$). In conclusion, results indicated that meat produced by Fat-tiled and male lambs was more close to recommended nutritional quality for human.

Table 1. Mean ± SE fatty acid and chemical components analysis

M373 The energetic efficiency of growing lambs fed high-concentrate diets with different roughages. D. B. Galvani[1], A. V. Pires*[2], I. Susin[2], V. N. Gouvea[2], A. Berndt[3], L. J. Chagas[2], J. R. R. Dórea[2], A. L. Abdalla[4], and L. O. Tedeschi[5], [1]*EMBRAPA Goats and Sheep, Sobral, CE, Brazil,* [2]*University of São Paulo, "Luiz de Queiroz" College of Agriculture, Piracicaba, SP, Brazil,* [3]*EMBRAPA Southeast Livestock, São Carlos, SP, Brazil,* [4]*University of São Paulo, Center for Nuclear Energy in Agriculture, Piracicaba, SP, Brazil,* [5]*Texas A&M University, Department of Animal Science, College Station.*

Poor quality roughages have been widely used as fiber source in high-concentrate diets for ruminants. Because roughage quality is associated with the efficiency of energy use in high-forage diets, the objective of this study was to determine whether using roughages with different quality in high-concentrate diets could change the energy requirements of growing lambs. Eighty-two Dorper × Santa Ines ram lambs (18.0 ± 3.3 kg BW) were individually penned and divided into 2 groups according to the diet roughage quality: low quality (sugarcane bagasse; SCB) or good quality [coastcross hay (*Cynodon* sp.)]. Diets were formulated to be isonitrogenous (2.6% N) and to meet the minimum requirement of physically effective NDF (peNDF = 20%). After a 10-d ad libitum adaptation period, 7 animals from each group were randomly selected and slaughtered (baseline). Twenty one animals in each group were fed ad libitum and slaughtered at 25, 35, or 45 kg BW. The remaining 28 lambs were submitted to one of 2 levels of feed restriction: 70 or 50% of the ad libitum intake. Retentions of body fat, N, and energy were determined. Additionally, 6 ram lambs (52.3 ± 6.9 kg BW) were kept in cages to estimate diet ME content. There was no effect of intake level on diet ME content, but it was greater in the SCB diet than in the hay diet (3.18 vs. 2.94 Mcal/kg, respectively; $P < 0.01$). Animals fed the SCB diet had greater body fat and energy concentrations as a response of a larger visceral fat deposition ($P < 0.05$). Using poor quality roughage in high-concentrate diet for growing lambs did not change NE_m and the efficiency of ME use for maintenance, which averaged 72.9 kcal/kg$^{0.75}$ BW and 0.64, respectively. On the other hand, the greater ME content of the SCB diet resulted in a 17% better efficiency of ME use for gain (k_g = 0.41 vs. 0.35; $P < 0.05$), which was associated with a greater partial efficiency of ME retention as fat (k_f = 0.73 vs. 0.58; $P < 0.01$). In a meat production scenario, however, this increased nutritional efficiency should be viewed with caution because it is related to visceral fat deposition, a non edible tissue.

Key Words: efficiency of gain, energy retention, visceral fat

M374 Intake and feeding behavior of Morada Nova lambs fed different energy levels. D. A. Camilo[1], E. S. Pereira*[1], P. G. Pimentel[1], M. S. S. Carneiro[1], I. Y. Mizubuti[2], M. R. G. F. Costa[1], G. M. B. Moreno[1], and J. N. Rocha Junior[1], [1]*Federal University of Ceara, Fortaleza, Ceara, Brazil,* [2]*State University of Londrina, Londrina, Parana, Brazil.*

The eating behavior of ruminants, such as feed intake, ruminating time and number of chews, varies by feed type and physical characteristics and has an important effect on the digestive physiology of the ruminant. The objectives of this study were to evaluate the effects of ME levels on nutrient intake and ingestive behavior of Morada Nova lambs. Forty Morada Nova lambs were used with an initial BW of 12.2 ± 2.05 kg. Five treatments were defined according to the ME levels (0.96, 1.28, 1.72, 2.18 and 2.62 Mcal/kg DM). Diets were composed of Tifton 85 hay as roughage and concentrates based on corn grain, soybean meal, urea, sodium chloride, calcium carbonate, dicalcium phosphate and mineral premix and offered as a total mixed ration. The experimental model was a randomized block design. Regression equation was adjusted when 0.05 significance was observed, using PROC REG SAS (9.0).Linear effect ($P < 0.0001$) of ME levels was determined for DMI, OM, CP, total carbohydrates (TC), non-fibrous carbohydrates (NFC) and TDN in g/day. Quadratic effect was determined for neutral NDF ($P < 0.017$) and non fibrous carbohydrate intake ($P < 0.003$). Eating, ruminating and total chewing times, expressed in h/d, decreased linearly ($P < 0.0001$) with the energy levels of experimental diets. Idle time increased linearly ($P < 0.0001$) with the increase of energy levels of the rations. Feeding and rumination efficiencies were influenced by the energy levels (($P < 0.0001$) when expressed in g of DM/h. The number of ruminal boluses, number of chews and chews per ruminal bolus were not affected by the levels of ME. However, the time spent chewing per ruminal bolus was influenced ($P < 0.0014$). Increase in ME levels of diets influences nutrient intake and feeding behavior of Morada Nova lambs during the growing period.

Key Words: eating time, feeding level, rumination time

M375 Different supplement treatments for lactating meat goat does grazing grass/forb pastures.

A. L. Goetsch,* G. D. Detweiler, Z. Wang, J. Hayes, K. Tesfai, and T. A. Gipson, *Langston University, Langston, OK.*

Lactating meat goats grazing 0.4-ha grass/forb pastures were used to determine effects on performance of different supplement treatments. Boer does (32) with 1 or 2 kids were used in a study with 4 4-wk periods (PR) starting 22 ± 2.0 d after birth. Two groups were subjected to treatments of no supplementation (CO), access to a 20% CP supplement block (SB), and placement in a supplement pasture with mimosa (*Albizia julibrissin*) trees for 6 h 1 d/wk (1×) or twice weekly for 3 h/d (2×). All groups received access to the same mineral-vitamin supplement. Available forage DM in non-supplement pastures averaged 3,477, 3,448, 3,353, 2,802, and 2,423 kg/ha initially and after PR 1, 2, 3, and 4, respectively; hand-plucked forage samples averaged 15 and 67% CP and NDF, respectively. Treatment did not affect doe ADG (−23, −42, −23, and −15 g; SE = 11.5), FAMACHA score, or fecal egg count, although kid ADG in the first 3 PR differed ($P < 0.05$) between type of supplement and frequency of supplement pasture access (121, 111, 120, and 134 g for CO, SB, 1×, and 2×, respectively; SE = 3.3). Spanish does (32) nursing 2 kids were used in a study with three 4-wk PR starting 66 ± 0.8 d after kidding. The same CO and SB treatments were employed, but access to supplement pastures was for 24 h 1 d/wk (1×) or 2 d for 6 h/d (2×). Forage DM averaged 1,530, 842, 791, and 750 kg/ha initially and after PR 1, 2, and 3, respectively), and 0.6 kg/d (as fed) per doe of grass hay (7 and 67% CP and NDF, respectively) was fed after PR 1. Hand-plucked forage samples averaged 14 and 64% CP and NDF, respectively. Treatment did not affect doe or kid FAMACHA score. Kid ADG in PR 1 and 2 was not affected by treatment. Doe ADG was affected by supplementation ($P < 0.05$) and supplement type ($P < 0.09$; −44, −33, −23, and −12 g; SE = 5.5), which resulted from effects ($P < 0.05$) in PR 3 after weaning (−87, −69, −16, and −2 g for CO, SB, 1×, and 2×, respectively; SE = 14.3). In conclusion, use of the SB was not beneficial, and infrequent access to supplement pastures had relatively small effects on ADG perhaps because forage availability and nutritive value were not severely limiting.

Key Words: goats, grazing, supplementation

M376 Effects of level and length of supplementation on BW and harvest characteristics of yearling Boer and Spanish wethers.

R. C. Merkel, T. A. Gipson,* Z. Wang, and A. L. Goetsch, *Langston University, Langston, OK.*

Spanish (S; 28 - 40 wk of age) and Boer (B; 33 - 46 wk) wethers were used to determine effects of level (SL) and length of supplementation on BW and harvest characteristics. The experiment started in January, with wethers residing in 4 pastures primarily with warm season grasses. Alfalfa hay was given free-choice, and a pelleted diet (16% CP and 60% TDN) was group supplemented at 0.5 or 1.5% BW (DM basis; L and H, respectively). Five S and 6 B were harvested initially, and 12 per breed (BR) and SL were harvested after 110 and 218 d (PR 1 and 2, respectively). Data were analyzed by GLM procedures. There were BR differences ($P \leq 0.06$) in initial BW (33.3 and 23.7 kg), carcass weight (15.4 and 10.9 kg), and mass of noncarcass components (NCC; 11.7 and 9.2 kg for B and S, respectively) but not in mass of NCC relative to empty BW (EBW). The ADG was greatest ($P < 0.05$) among PR-BR treatments for PR 1-B (139, 74, 63, and 56 g for PR 1-B, PR 1-S, PR 2-B, and PR 2-S, respectively; SEM = 5.23). The BW was affected ($P < 0.05$) by SL (48.2 and 43.1 kg for H and L), BR (53.1 and 38.2 kg for B and S), and PR (41.8 and 49.3 kg in 1 and 2, respectively). There were corresponding differences ($P < 0.05$) in weight of the carcass (23.6 and 20.4 kg for H and L; 25.5 and 18.5 kg for B and S; 20.3 and 23.8 kg for PR 1 and 2, respectively) and NCC (16.9 and 15.0 kg for H and L; 18.4 and 13.5 kg for B and S; 15.1 and 16.8 kg for PR 1 and 2, respectively). Digestive tract mass was similar between BR and lowest ($P < 0.05$) among SL-PR treatments for PR 2-H (7.21, 7.19, 6.31, and 7.51% EBW for PR 1-H, PR 1-L, PR 2-H, and PR 2-L, respectively). Liver mass was similar between BR and less ($P < 0.05$) for H than for L (2.15 and 2.30% EBW) and for PR 2 vs. 1 (2.11 and 2.34% EBW). Mass of internal fat was greatest ($P < 0.05$) among SL-PR treatments for PR 2-H (6.72, 6.36, 8.61, and 5.95% EBW for PR 1-H, PR 1-L, PR 2-H, and PR 2-L, respectively). In summary, advantages of B in BW and carcass weight were similar after PR 1 and 2, BR had little effect on NCC mass relative to EBW, and H increased mass of internal fat after PR 2 but not PR 1.

Key Words: meat goat, breed, supplement

M377 Energy requirements for growth of male and female Saanen goat kids.

M. H. M. R. Fernandes,* O. Boaventura Neto, A. N. Mendonca, S. F. Souza, D. Oliveira, T. F. V. Bompadre, T. R. Delphino, K. T. Resende, and I. A. M. A. Teixeira, *UNESP/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

Nutritional requirements could be affected by several factors, including sex. However, studies evaluating the effect of sex on body composition and nutritional requirements in goats are scarce. The aim of this study was to evaluate the effect of sex on energy requirement for maintenance and gain of Saanen goat kids, using comparative slaughter technique. A total of 66 animals (24 non-castrated males, 18 castrated males and 24 females) with initial BW of 4.93 ± 0.1 kg were used. Six non-castrated males and 6 females were slaughtered at beginning of the experiment (baseline animals) and 18 randomly selected kids (6 of each sex) were slaughtered when they reached 10 kg BW (intermediate slaughter). The reminder was randomly allocated into 12 groups (blocks) of 3 animals of the same sex, subjected to 0, 25 and 50% of feed restriction. A group was slaughtered when the animal set in the 0% restriction reached 15 kg BW. Initial body composition was determined using equations developed from the energy composition of the baseline kids. The energy maintenance requirement was estimated using the animals subjected to feed restriction (0, 25, and 50% of feed restriction). Animals fed ad libitum (baseline, intermediate and 0% of feed restriction) were used to estimate body composition and requirements for gain. There was no effect of sex on the energy requirements for maintenance and gain. The overall NE_m calculated was 56.3 kcal/kg$^{0.75}$ EBW (47.3 kcal/kg$^{0.75}$ BW). The overall ME_m for maintenance (88.05 kcal/kg $^{0.75}$ EBW) was calculated by iteration assuming heat produced is equal to ME intake at maintenance. Therefore, the partial efficiency of use of ME to NE for maintenance was 0.64. Net energy (NE_g) requirements for gain ranged from 2.07 to 2.30 Mcal/kg empty weight gain (EWG) for kids weighting 5 and 15 kg BW, respectively. These findings suggested that sex did not influence energy requirements of Saanen goat kids at early growth stages.(FAPESP project number 2008/58351–5)

Key Words: gain, sex, maintenance

M378 Influence of reducing starch and increasing digestible fiber on glucose tolerance test of lactating ewes. R. S. Gentil*[1], I. Susin[1], A. V. Pires[1], E. M. Ferreira[1], A. Cannas[2], D. Eysink[1], M. V. Biehl[1], and C. P. Nolli[1], *[1]Universidade de São Paulo/ESALQ, Piracicaba, São Paulo, Brazil, [2]Università degli Studi di Sassari, Sassari, Sardegna, Italy.*

Thirty-three lactating Santa Ines ewes (68 ± 3 initial BW and 13.2 ± 3 DIM; mean ± SD), assigned to a randomized complete block design, were used to define an optimal combination between carbohydrates sources (starch and high digestible fiber) that can favor energy partitioning toward milk production at different lactation stages. Ewes were housed individually for a period of 10 wks from the second wk of lactation. Animals were fed a 60:40 (concentrate:roughage ratio). Soybean hull (SH) replaced corn by 0, 20 or 40% (DM basis). At the end of the lactation trial, 9 ewes (3 animals/treatment) were used for the glucose tolerance test (GTT). Prior to GTT, ewes were removed from feed and weighed 24 h before glucose infusion (0.25 g of glucose/kg of BW, delivered in a 50% dextrose solution). Fasting values of glucose and insulin were determined at 0 min before administration of the glucose bolus. Additional blood samples were collected at 5, 10, 20, 40 and 80 min after the glucose infusion. A colorimetric assay was used to determine plasma glucose concentrations. Plasma insulin concentrations were measured using RIA. Glucose disappearance rate was calculated by regression of glucose concentration over time from 5 to 80 min post glucose infusion. Incremental area under the curve (AUC) for glucose (transformed logarithmically, Ln) was determined using a trapezoidal summation method. Data were analyzed by the PROC MIXED (SAS, 2002). Both, insulin and glucose concentrations showed effect ($P < 0.01$) on the time post glucose infusion. Fasting glucose (53.2; 57.7; 60.4 mg/dL) and insulin (1.4; 3.0; 5.3 μIU/mL) concentrations and peak insulin increased (22.4; 25.9; 35.1 μIU/mL) ($P < 0.05$) with inclusion of the SH. Additionally, peak glucose (247.5; 236.3; 184.7 mg/dL) and glucose clearance rate (2.04; 1.44; 1.11 mg/dL.min) decreased ($P < 0.05$) in the animals fed more SH. Glucose tolerance (measured as glucose AUC) was not affected ($P > 0.05$) by replacing corn by SH. Sheep fed more corn demonstrated greater ability to decrease the concentration of glucose.

Key Words: insulin, ovine, soybean hulls

M379 Soybean meal supplementation of lambs grazing native pastures in the summer-fall season. L. Piaggio[1], M. L. delPino[1], H. Deschenaux[1], and M. de J. Marichal*[2], *[1]Secretariado Uruguayo de la Lana, Montevideo, Uruguay, [2]Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay.*

The objective of this study was to evaluate the effect of soybean meal (SBM) supplementation on growth rate of lambs grazing natural pastures in the summer-fall season. The experiment was conducted at Research Center (S 33° 52’, W 55° 34’) of the Secretariado Uruguayo de la Lana from January 17 to April 27 (15 d of adaptation period plus 85 d of measurements). Thirty-six 3-mo-old weaned Corriedale lambs were divided into 12 homogenous groups according to sex and live weight. Animals were allocated in one paddock of natural pastures (10 lambs ha^{-1},1864 kg of initial available DM ha^{-1}; 8.8 and 70.4% CP and NDF, respectively) and assigned (3 groups of lambs/treatment) to one of the following treatments: continuous grazing (T0), Control + SBM (150 g $lamb^{-1}d^{-1}$; 46.7 and 20.9% CP and NDF, respectively; T1), Control + SBM (250 g $lamb^{-1}d^{-1}$; T2), Control + SBM (350g $lamb^{-1}d^{-1}$; T3). Lambs were weighed at the beginning of the experiment (average 17.8 ± 2 kg), and at every 15 d thereafter. Initial and final BW, and ADG, were analyzed (PROC GLM, SAS) in a completely randomized design (Tukey test), considering the group of lambs by replicate as the experimental unit. Treatment effects ($P = 0.02$) were registered in final weights (FW). Greater ($P = 0.04$) FW was registered in T3 than T0 (22.7 and 28.6 kg, respectively), presenting T1 and T2 intermediate and with similar ($P = 0.19$) values (24.5 and 26.4 kg, respectively). No differences ($P = 0.14$) among treatments were observed for the ADG of lambs at d 14 after the beginning of the measurement period (56, 65, 71 and 109 g $lamb^{-1}d^{-1}$ for T0, T1, T2 and T3, respectively). Differences ($P = 025$) in ADG were first registered on d 28, presenting lambs in T3 greater ($P = 0.004$) in ADG than T0 (126 and 57 g d^{-1}, respectively), and T2 and T3 having similar ($P = 0.16$) values (78 and 101gd^{-1}, for T1 and T2, respectively). These differences were maintained from this point forward. In the overall measurement period, ADG were 56, 78, 101, and 127 g $lamb^{-1}d^{-1}$, for T0, T1, T2 and T3 ($P < 0.05$). Soybean meal supplementation appeared as an effective supplement to improve growth in lambs grazing natural pastures.

Key Words: lambs, soybean meal supplementation, grazing

M380 Nutritional quality, intake, and apparent digestibility of mulberry (*Morus alba*) and star grass (*Cynodon nlemfuensis*) in goats. J. A. Elizondo-Salazar* and J. Rodríguez-Zamora, *Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, Costa Rica.*

The objective of the study was to evaluate the quality, intake, and apparent digestibility of mulberry and star grass offered to goats in fresh or partially dehydrated form. The experiment was carried out at the "Alfredo Volio Mata" Experiment Station of the University of Costa Rica. Forage was fed to 12 Saanen, Toggenburg, and Lamancha nonlactating and non-pregnant goats with an average live weight of 37 ± 5 kg. A 2x2 factorial design was used with 2 forage species (star grass and mulberry) and 2 moisture levels (fresh and partially dehydrated). Thus, treatments were fresh star grass, partially dehydrated star grass, fresh mulberry, and partially dehydrated mulberry. Forage was offered chopped to the animals. The GLM procedure of SAS was used to analyze the data. There were some nutritional differences among treatments. Dry matter content was different ($P < 0.05$) between treatments (28.2, 37.5, 36.7, and 43.1%, respectively). Mulberry had the lowest NDF content (65.7%) but also had the highest lignin concentration (13.0%). Daily DMI was not different when considering water concentration within forages but it was different ($P < 0.05$) for forage type. The levels of intake were 0.93, 0.76, 1.17, and 1.12 kg/animal for fresh star grass, partially dehydrated star grass, fresh mulberry, and partially dehydrated mulberry, respectively. This represented 2.62, 2.09, 3.17, and 3.13% of BW. Crude protein intake was lower for partially dehydrated star grass and greater for fresh mulberry (75.2 vs. 135.4 g/d). Apparent digestibility was not different between treatments and averaged 49.2% for DM, 59.8% for CP, 57.8% for NDF, and 55.3% for ADF. This study demonstrated that forage species significantly affected voluntary DMI in goats; however, DM content of the forages used in this study did not affect DM intake.

Key Words: intake, dry matter, digestibility

M381 Effect of dietary supplementation of ferrous sulfate on performance and carcass characteristics of meat sheep. G. Abdelrahim*[1], J. Khatiwada[2], and A. Gueyec[3], *[1]Alabama A&M University, Huntsville, [2]North Carolina A&T State University, Greensboro, [3]Mount Ida College, Newton, MA.*

The overall objective of this study was to gain a thorough understanding of the impact of increasing the concentration of $FeSO_4$ in meat sheep diets. The specific objective was to investigate the effects of elevated levels of $FeSO_4$ inclusion on DMI, growth, and carcass characteristics of meat sheep. Twenty-four Gulf Coast wether lambs (26.3 ± 3.63 kg initial BW, and 8 to 9 mo of age) were blocked by BW and were randomly assigned within block to 1 of the 3 dietary treatments, giving 8 lambs per treatment. Animals were grouped in 2 pens (replicates) per treatment (4 lambs/pen) with pen serving as the experimental unit. Lambs were fed dietary treatments containing 0, 75, or 150 mg/kg of DM (as-fed basis) supplemental FeSO4. Control diets contained dry-rolled corn, SBM, and fescue/bermudagrass hay. The concentrate mixes were formulated to be isonitrogenous and isocaloric and to meet or exceed the NRC requirements of a finishing lamb. Lambs were slaughtered, and data were collected after a 48-h chill. Both growth and carcass quality data were analyzed using the GLM procedures of SAS. Dry matter intake, final BW, and ADG were not different among treatments ($P = 0.5$, 0.9, and 0.7, respectively). Also, no differences were observed in HCW ($P = 0.9$), cold carcass weight ($P = 0.8$), body wall fat ($P = 0.6$), 12th rib fat ($P = 0.9$), K&P fat ($P = 0.9$) and REA ($P = 0.7$) among treatments. These results support our hypothesis that the addition of 75 or 150 mg $FeSO_4$/kg in finishing lamb diets do not affect DMI, growth rate, and carcass characteristics of meat sheep.

Key Words: iron, meat sheep, growth

M382 Effects of diets with different qualities of roughage on fatty acids metabolism in mammary glands of lactating dairy goats.

L. W. Song[1], C. J. Ao*[1], K. Khas-Erdene[1], H. Zhang[1], Y. X. Wu[2], and S. W. Liu[1], *[1]Department of Animal Science, Inner Mongolia Agricultural University, Huhhot, Inner Mongolia, China, [2]Key Laboratory of Grass and Herbivores of Chongqing, College of Animal Science and Technology, Southwest University, ChongQing, China.*

The objectives of this study were to determine the effects of diets with different qualities of roughage on milk-fat percentage, daily yield of milk fat and fatty acids metabolism in mammary gland. Eight multiparous lactating GuanZhong dairy goats (BW = 45.6 ± 2.5 kg, DIM = 90 ± 12 d) fitted with external pudendal artery (EPA) and subskin abdominal vein (SAV) intubation were assigned to 2 treatments in a crossover design. Animals received same concentrate and different roughage, concentrate-roughage ratio was 40:60. Treatments were: 1) hay (30%), corn silage (20%) and alfalfa (10%) (HCA; CP: 10.6%, NDF: 50.4% and ME: 2.24 Mcal/kg); 2) hay (30%), corn straw (30%) (HCS; CP: 14.2%, NDF: 39.7% and ME: 2.39 Mcal/kg)(DM basis). Each period lasted for 3-wk. At the last 3 d of each period, milk and blood samples from EPA and SAV were collected for FA analysis. Data were analyzed by the PROC MIXED procedure of SAS 9.0. The milk fat percentage of HCA was greater than HCS (3.04 vs. 2.84%; $P = 0.01$), while daily yields of milk fat were not affected (15.3 vs. 14.5 g/d). Compared with HCS, HCA tended to increase total percentage of long-chain FA (>16c) which known as major precursor of de novo milk fat synthesis in mammary gland (35.0 vs. 33.0%, $P = 0.16$); the concentration and profile of FAs in the blood of EPA, SAV and milk were not affected. However, percentage of total milk SFA by HCA was statistically lower than HCS (71.7% vs. 73.4, $P = 0.15$); percentage of milk UFA by HCA was higher than HCS (28.29 vs. 26.59%, $P = 0.15$). Compared with HCS, HCA tended to increase EPA plasma concentration of total FA (0.73 vs. 0.57, $P = 0.32$), and increased SAV plasma concentration of total FA (0.62 vs. 0.44, $P = 0.02$), especially the concentration of C18:0 and C18:2c6 (0.1 vs. 0.08, $P = 0.12$; 0.12 vs. 0.09, $P = 0.11$). No differences were found on the extraction rate of specific FA in 2 groups. Compared with HCS, HCA increased plasma concentration of long-chain FA in EPA and SAV, which might result in higher milk fat percentage.

Key Words: milk fat concentration, FA composition, dairy goat

M383 Effects of diets with different forage profiles on the gene expression of enzymes related to fatty acid synthesis in the mammary gland of lactating dairy goats.

H. Zhang, C. J. Ao,* K. Khas-Erdene, L. W. Song, and X. F. Zhang, *Department of Animal Science, Inner Mongolia Agricultural University, Huhhot, Inner Mongolia, China.*

The objective was to determine the effects of 2 diets with different forage profiles on the key gene expression of enzymes related to fatty acid synthesis in the mammary gland of GuanZhong dairy goats. Analysis of mRNA expression for acetyl-coenzyme A carboxylase- α (ACACA), fatty acid synthesis (FASN), stearoyl coA desaturase (SCD), and lipoprotein lipase (LPL) were performed. Eight multiparous lactating goats (BW = 45.6 ± 2.5 kg, DIM = 90 ± 12 d) were assigned to 2 treatments in a crossover design. Animals were fed diets with different forage profiles, the concentrate-roughage ratio in the treatments were 40:60. Diets were: 1) hay (30%), corn silage (20%) and alfalfa (10%) with additional 40% of concentrate (HCA; CP: 10.6%, NDF: 50.4% and ME: 2.24Mcal/kg); 2) hay (30%), corn straw (30%) with additional 40% of concentrate (HCS; CP: 14.2%, NDF: 39.7% and ME: 2.39Mcal/kg), on DM base. Mammary gland biopsies were performed after milking on the last day of each period. The mammary tissue biopsy (50 mg/animal) was immediately frozen in liquid nitrogen and stored at-80°C until RNA isolation. Samples of total RNA were reverse transcribed to cDNA to determine the expression of key genes for fatty acid synthesis by the method of RT-PCR. Statistical analysis was performed using a paired *t*-test on the difference between treatments. Compared with HCS, in HCA animals mammary mRNA abundance of LPL, which is involved in fatty acid uptake was increased by 39% ($P < 0.01$); ACACA and FASN, which are involved in de novo fatty acid synthesis were increased by 18, and 20%, respectively ($P < 0.01$); SCD, which is involved in fatty acid desaturation was increased by 50% ($P < 0.01$). The data demonstrated that diet with high quality roughage (HCA) can increase the gene expression of enzymes that are related to milk fat synthesis in the mammary gland of dairy goats.

Key Words: mammary gland, milk fatty acid, dairy goat

M384 Performance of Ile de France lambs fed with diets containing different percentages of mulberry hay.

L. G. A. Cirne,* A. G. Silva Sobrinho, V. T. Santana, R. Takahashi, N. M. B. L. Zeola, F. A. Almeida, G. M. Manzi, and F. U. Silva, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Among the concentrated feeds most used in ruminant feeding, stand out the corn and the soybean meal, and the high cost of this feeds limit their use. Efforts have been made in the search for alternative feeds among them the mulberry hay, being fundamental to evaluate the performance of lamb fed with such feeds. The objective of this study was to evaluate the performance of lambs fed with diets containing different percentages of mulberry hay. A total of 20 4 lambs, Ile de France breed, with 25 kg of BW, 3 mo old were used and kept in individual stalls, in a completely randomized design, with 3 treatments and 8 repetitions, in which the data were analyzed using SISVAR statistical software, and when statistical differences were observed, a mean comparison was done using the Tukey test. The treatments were: T1: sugarcane + concentrate with 0% mulberry hay; T2: sugarcane + concentrate with 25% mulberry hay; T3: sugarcane + concentrate with 50% mulberry hay. The sugarcane used was the forage variety IAC 86–2480, and the total diet had forage:concentrate ratio of 50:50 given ad libitum. The remains of the diets were collected, weighed and subtracted from the total provided to quantify the feed consumed by the animals individually. The ADG (0.26 kg/d), DMI (0.82 kg/d), feed conversion (3.21 kg

DM/kg BW), feed efficiency (0.31 kg BW/kg DM) and feedlot period (66 d) were not affected ($P > 0.05$) by different percentages of mulberry hay in the concentrate. The use of mulberry hay partially substituting the concentrate did not affect the performance of feedlot lambs. This research is in progress (Fapesp process number 2011/18362–0).

Table 1. Initial body weight (IBW), final body weight (FBW), daily weight gain (DWG), dry matter intake (DMI), feed conversion (FC), feed efficiency (FE) and days of feedlot (DF) of lambs fed with diets containing different percentages of mulberry hay

Item	T1	T2	T3	CV (%)
IBW (kg)	15.5	15.5	15.5	0.50
FBW (kg)	32.1	32.1	32.3	1.69
DWG (kg/day)	0.26	0.25	0.25	6.53
DMI (kg/day)	0.83	0.80	0.82	9.88
FC (kg DM/kg BW)	3.21	3.21	3.22	7.99
FE (kg BW/kg DM)	0.31	0.31	0.31	7.22
DF	64.8	66.8	66.4	7.14

Key Words: feedlot, feed conversion, weight gain

M385 Effect of metabolizable protein supplementation to ewes during late gestation on wether offspring feedlot performance, carcass characteristics, and nitrogen balance.

M. L. Van Emon*[1,2], K. A. Vonnahme[2], P. T. Berg[2], K. R. Maddock Carlin[2], and C. S. Schauer[1], [1]*Hettinger Research Extension Center, North Dakota State University, Hettinger,* [2]*Department of Animal Sciences, North Dakota State University, Fargo.*

Our objective was to determine the effect of metabolizable protein (MP) supplementation to ewes during late gestation on wether offspring nitrogen (N) balance, feedlot performance, and carcass characteristics. Maternal dietary treatments were isocaloric and contained 60% (60), 100% (100), and 140% (140) of MP requirements for ewes bearing twins during the last 50 d of gestation. Feedlot (28 ± 7 kg) and N balance wethers (29 ± 3 kg) were fed a common feedlot ration (84.7% whole corn, 15.3% commercial market lamb pellet). The N balance trial was 21 d in length and consisted of an adaptation period on d 1 through 14 and on d 15 through 21 feed, orts, urine, feces, and blood samples were collected and composited by lamb. Statistical analysis was accomplished utilizing the MIXED procedures of SAS. Maternal dietary treatment did not affect ($P \geq 0.36$) initial and final BW, ADG or G:F of wether offspring. Hot carcass weight, dressing percentage, longissimus muscle area, 12th rib fat depth, body wall thickness, leg score, conformation score, flank streaking, USDA quality grade, yield grade, and percent boneless, closely trimmed retail cuts were not different ($P \geq 0.40$) due to maternal dietary treatment. For the N balance trial, daily DMI, daily NDF intake, daily N intake, total tract digestibility of DM, NDF, and N, daily N excretion in the feces and urine, daily N balance, daily digested N retained, and serum urea-N concentrations were not different ($P \geq 0.46$) due to maternal dietary treatment. There was a day effect ($P = 0.02$) for serum urea-N concentrations. Days 15 and 17 of the collection period had increased serum urea-N concentrations compared with d 20 ($P = 0.001$ and $P = 0.02$, respectively) and 21 ($P = 0.004$ and $P = 0.04$, respectively); and d 15 also had increased ($P = 0.04$) concentrations compared with d 18. Maternal MP restriction or excess during late gestation did not affect wether offspring performance in the feedlot, carcass characteristics, or N retention.

Key Words: metabolizable protein, performance, wethers

M386 Effects of sources of oil on intake, performance and carcass characteristics of feedlot sheep.

F. B. O. Scarpino*[1,2], J. M. B. Ezequiel[1], E. H. C. B. van Cleef[1,3], A. P. D′Aurea[1,3], M. T. C. Almeida[1], and H. L. Perez[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*CNPq,* [3]*FAPESP.*

Crossbred uncastrated male lambs (Santa Inês × Dorper, n = 24, 24.9 ± 2.4 kg BW) were used to evaluate intake, feedlot performance and carcass characteristics when fed diets containing supplementary oil sources. Treatments (3 diets) consisted of a control diet containing 40% corn silage, 10.8% corn grain, 9.8% soybean hulls, 37.45% sunflower meal, 0.55% urea, 0.4% limestone, and 1% supplement, and 2 diets containing additional 6% soybean oil or 6% residual soybean frying oil (DM basis). Lambs were vaccinated against common viral and clostridial diseases, weighed and assigned randomly to 24 individual feedlot pens (8/treatment). Over a period of 21 d, lambs were transitioned from diets containing 20% concentrate to their respective 60% concentrate finishing diets, using 3 step-up diets that contained, progressively, greater proportions of concentrate. Final diets provided 18.5% CP, 2.6 kcal ME/kg, 0.85% Ca, and 0.60% P, and the animals were harvested when reached 35 kg BW. Data analysis were performed as a completely randomized block design (initial BW as block), using GLM procedure of SAS, and the contrasts control vs. oil treatments and soybean oil vs. frying oil were evaluated. Adding oil sources decreased DMI ($P \leq 0.01$), and the decrease were more severe in animals fed frying oil ($P = 0.02$). This oil source also promoted lower ADG ($P \leq 0.01$) and increased days on feed ($P = 0.05$), compared with other treatments. However, the addition of both sources of oil increased G:F ($P = 0.02$). Carcass weight were unaffected ($P > 0.05$) by diets, but dressing percentage were lower in treatment with soybean oil ($P \leq 0.01$). LM area and BF thickness were not affected by oil addition ($P > 0.05$). Including supplementary oil to sheep diets decreased DMI and improved feed efficiency but when the source of oil is residual frying oil, it decreased performance, by increasing days on feed.

Key Words: by-products, lambs, frying oil

M387 Lipid sources in diets for feedlot sheep: Blood parameters.

F. B. O. Scarpino*[1,2], J. M. B. Ezequiel[1], D. A. V. Silva[1,3], and E. H. C. B. van Cleef[1,3], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*CNPq,* [3]*FAPESP.*

Twenty-four crossbred uncastrated male lambs (Santa Inês × Dorper, 24.9 ± 2.4 kg BW), were used to evaluate the effects of adding lipid sources (soybean oil or residual frying soybean oil) on blood parameters. Lambs were vaccinated against common viral and clostridial diseases, weighed and assigned randomly to 24 individual feedlot pens (8/treatment). Over a period of 21 d, lambs were transitioned from diets containing 20% concentrate to their respective 60% concentrate finishing diets, using 3 step-up diets that contained, progressively, greater proportions of concentrate. Corn silage was the roughage, and concentrate was composed of corn grain, soybean hulls, sunflower meal, urea, mineral supplement, antioxidant, soybean oil or residual frying oil and diets provided 18.5% CP, 2.6 Mcal ME/kg, 0.85% Ca, and 0.60% P. Treatments were labeled as 1 - Control, without added oil, 2 - Soybean, with 6% added soybean oil, and 3 - Frying, with 6% added used frying oil. The animals were kept in a feedlot barn, equipped with individual pens for up to 105 d. Blood sampling was performed with jugular vein puncture on d 59 and serum glucose, triglycerides, cholesterol, total protein, and liver enzymes AST (aspartate aminotransferase), GGT (gamma glutamyltransferase) and ALP (alkaline phosphatase) were determined. Data analysis were performed as a completely randomized block design (initial BW as block), using GLM procedure of SAS, and

the contrasts control vs. oil treatments and soybean oil vs. frying oil were evaluated. The addition of oil increased cholesterol ($P \leq 0.01$) and AST ($P \leq 0.01$). When the residual frying oil was used it was observed a tendency to increase ALP ($P = 0.06$). Serum glucose, triglycerides and total protein were unaffected by the diets ($P > 0.05$). Addition of 6% soybean oil or residual frying oil in feedlot sheep diet increases concentrations of serum liver enzymes, suggesting over activity of the organ. However, such changes, observed to this feedlot period, are not sufficient to cause damage to animal health.

Key Words: frying oil, lambs, liver enzymes

M388 Relationship between phosphorus fluids concentration and phosphorus flows in growing ruminants. R. M. Patiño*[1], T. Soares da Silva[3], J. C. da Silva Filho[2], D. M. S. S. Vitti[3], J. A. Moreira[4], and E. H. van Cleef[5], *[1]University of Sucre, Sincelejo, Colombia, [2]Federal University of Lavras, Lavras, MG, Brazil, [3]Nuclear Energy Center for Agriculture, Piracicaba, SP, Brazil, [4]Federal University of Rio Grande do Norte, Natal, RN, Brazil, [5]State University of São Paulo, Jaboticabal, SP, Brazil.*

The objective of this work was to study the relationship between phosphorus (P) concentration in body fluids and the flows between plasma and organs, and P concentration in liver and bone, in growing sheep fed diets with increasing levels of P. An experiment was carried out using 24 male sheep, initial BW of 33.6 ± 1.6 kg, assigned to 4 treatments (0, 2, 4 and 6 g/d of supplementary P). The animals were injected with 7.4 MBq of ^{32}P and slaughtered 168 h later. The flows were quantified using isotopic dilution technique and applied a compartmental model, to define the flows between the digestive tract and plasma (F_{21}), plasma and digestive tract (F_{12}), plasma and bone (F_{42}), bone and plasma (F_{24}), plasma and soft tissues (F_{32}) and soft tissue and plasma (F_{23}). P concentration in plasma, saliva, ruminal fluid, feces, urine, liver, and bone were determined. Principal components and regression analysis were used. In all cases the first component explained more than 80% of the variation, indicating the effect of P intake on P concentration in fluids and P kinetics, principally when P supplementation exceeded 4 g. F_{12} and F_{21} flows were correlated ($P = 0.002$), as well as the flows F_{23}, F_{32}, F_{24} and F_{42} ($P < 0.05$), however, no correlation was observed ($P > 0.05$) between the 2 groups of variables. The concentration of P in plasma, saliva and urine was related to the flows between compartments, with the exception of F_{21} and F_{12}, however, P concentration in urine (PU) was the better predictor ($P < 0.003$) [F_{23} (g/d) = 5.75 + 0.31 × PU (mg/100 mL) ($R^2 = 0.42$); F_{32} (g/d) = 5.65 + 0.28 × PU (mg/100 mL) ($R^2 = 0.34$); F_{42} (g/d) = 1.58 + 0.06 × PU (mg/100 mL) ($R^2 = 0.47$) and F_{24} (g/d) = 0.79 + 0.05 × PU (mg/100 mL) ($R^2 = 0.44$)]. The equation, P liver (% DM) = 9.87 + 3.36 × P saliva (mg/100 mL) ($R^2 = 0.26$; $P = 0.01$), explained the relation between P concentration in urine and liver. It is concluded that the increase in P intake affects P kinetics in growing sheep. P concentration in plasma, saliva, and urine predicts the flows between organs, principally urine, with the exception of flows between plasma and digestive tract, and vice versa.

Key Words: metabolism, mineral, lamb

M389 Mineral requirements for gain in Saanen goats of different sexes. A. N. Mendonca,* C. J. Härter, I. A. M. A. Teixeira, O. Boaventura Neto, S. F. Souza, and D. Oliveira, *UNESP/Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

There is evidence that sex plays an important role on body composition and requirements of animals; however, there are few studies evaluating the effect of sex on the mineral requirements of goats, thus the objective of this study was to estimate the net calcium (Ca), phosphorus (P) and magnesium (Mg) requirements for growth of Saanen goat kids, using the comparative slaughter technique. A total of 48 Saanen animals, 18 females, 18 males, and 12 castrated males with BW ranging from 5 to 15 kg were used. At the beginning of the experiment 6 intact males and 6 females with approximately 5 kg BW were slaughtered. No castrated males were slaughtered with 5 kg BW, because castration occurred when they were about 15 d old, then the males slaughtered at 5 kg BW were considered for the construction of the equations of both, castrated and intact males. The remainder of the kids, from each sex, were randomly assigned to 2 treatment groups (slaughter weight; 10 and 15 kg BW). The experiment was conducted in a completely randomized design in a factorial scheme (3 × 2). Body composition was estimated using the logarithmized allometric equation (Log y = a + b log x). The equations ($P < 0.0001$) for estimating Ca and Mg body composition were different for males and females (Table 1). There was no sex effect on P body composition (Table 1). The net Ca and Mg requirements for weight gain were influenced by the sex of goats in the early growth phase. On the other hand, kids of different sex had similar net P requirement. FAPESP project number 2011/05176-4.

Table 1. Allometric equations to estimate Ca, Mg, and P body composition of female, intact, and castrated male goat kids

	5 kg	10 kg	15 kg	Equation	RMSE
Ca (g/kg)					
Males	1.74	2.07	2.27	log Ca = 0.99+1.19 log EBW	0.071
Females	1.83	2.06	2.20	log Ca = 1.31+0.83 log EBW	0.071
Castrated	1.74	2.08	2.29	log Ca = 0.94+1.26 log EBW	0.071
Mg (g/kg)					
Males	0.28	0.64	0.86	log Mg = -0.53+1.29 log EBW	0.057
Females	0.36	0.62	0.78	log Mg = -0.24+0.95 log EBW	0.057
Castrated	0.27	0.65	0.87	log Mg = -0.58+1.35 log EBW	0.057
P (g/kg)	1.64	1.95	2.15	log P = 0.91+1.15 log EBW	0.051

M390 Effect of chromium supplementation on ruminal parameters of Mahabadi goat kids. A. Emami, A. Zali, M. Ganjkhanlou,* A. Hojabri, and A. Akbari, *University of Tehran, Tehran, Iran.*

The objective of this study was to evaluate the possible effects of supplementing chromium-methionine (Cr-Met) on different ruminal parameters in growing kids. Thirty-two male kids (BW = 22 ± 2 kg, 4mo) were used in a completely randomized design to one of 4 treatments: 1) control (without Cr), 2) 0.5, 3) 1.0 and 4) 1.5 mg Cr as Cr-Met/animal/d. Diets were formulated for NRC requirements with forage (alfalfa and corn silage):concentrate ratio of 30:70 in TMR form. Diets were the same, except for top-dress addition of Cr-Met fed in 2 equal meals (0800 and 1600 h). Animals were kept in individual pens with self-mangers for 90 d. Ruminal fluid samples were taken from the rumen at 3 h after the morning meal the last day of the experiment to determine rumen concentration of ammonia nitrogen (NH3-N) and VFA. Rumen contents were sampled 5 times during the trial to measure ruminal protozoa and pH. Protozoa counts were determined using light microscopic numeration with a hematocytometer. Protozoa and pH data were analyzed by MIXED MODEL procedure and rumen NH3-N and VFA with GLM MODEL procedure and adjusted Tukey-Kramer (SAS 9.1). Cr supplementation increased rumen pH ($P = 0.03$). Treatment failed to have statistically significant effects on rumen NH3-N and VFA ($P > 0.05$), but there was a higher butyrate concentration in kids receiving 1 mg Cr as Cr-Met/animal/d compared with other groups ($P = 0.009$). There was a negative relationship between Cr supplementation and protozoa count ($P = 0.0079$). These results indicate that supplementation of goat kid diets with chromium-methionine decreased protozoa, and increased pH and butyrate concentration without altering other VFAs.

Table 1. Characteristics of ruminal parameter in kid fed chromium-methionine

	Treatment, mg of Cr				
Trait	Control (0.0)	0.5	1.0	1.5	SEM
pH	6.23^{b}	6.16^{b}	6.45^{a}	6.22^{b}	0.07
Total VFA, mmol/L	48.3	39.7	48.1	60.0	6.25
Acetate, mmol/L	25.7	19.4	24.4	32.1	4.68
Propionate+Isobutyrate, mmol/L	15.0	14.4	12.5	15.3	2.81
Butyrate, mmol/L	5.77^{b}	4.76^{b}	8.77^{a}	4.72^{b}	0.76

Key Words: goat kids, chromium-methionine, ruminal VFA

M391 Effect of feeding tannin-containing pine bark on performance, parasite load and blood metabolites in goats.

E. A. Wilson*[1], S. Solaiman[1], B. R. Min[1], N. Gurung[1], W. McElhenny[1], and J. Miller[2], *[1]Tuskegee University, Tuskegee Institute, AL, [2]Louisiana State University, Baton Rouge.*

The objective of this study was to assess animal performance, parasite load and blood parameters of goats fed condensed tannin (CT)-containing pine bark (PB) diet. Pine bark is one of the abundant forest by-products in Southern US and contains 11–13% CT on a DM basis. Thirty-two Kiko-cross meat goats (*Capra hircus*; BW = 28.0 ± 1.0 kg) were randomly assigned to 2 experimental diets: 1) 0% PB and 30% wheat straw (WS) and 2) 30% PB and 0% WS. Grain mixes were fed at 85% with the remaining 15% provided as bermudagrass hay. Animals were strategically dewormed and one half of each diet group was inoculated with 5000 infective stage (L3) *Haemonchus contortus* larvae (n = 8). Feed intake, refusals, and performance were monitored for 87 d. Blood samples were taken twice, once at the beginning and once at the end of the experiment. Fecal egg counts (FEC) were determined approximately every 2 wk. At the end of the experimental period, goats were slaughtered and carcass characteristics were determined. Total stomach worms were identified and counted. Overall, there were no differences ($P > 0.10$) in DMI, animal performance and carcass characteristics among diet groups or inoculation groups, but ADG (76.8 vs. 97 g/d), G:F (0.05 vs. 0.07), HCW (14.2 vs. 15.8 kg), and cold carcass weight (13.3 vs. 14.8 kg) tended to increase ($P = 0.15$ to 0.18) with PB supplementation compared with WS diet within artificially inoculated groups, respectively. The LM area was lower ($P = 0.02$) for inoculated groups. Goats fed PB had greater ($P = 0.001$) blood urea nitrogen and lower serum triglyceride and cholesterol ($P = 0.03$). Mean red blood cells, hemoglobin, and hematocrit (packed cell volume) were greater ($P = 0.03$) for goats fed PB diets. Mean FEC, coccidia counts, and total worm counts were lower ($P < 0.05$) for goats that were fed PB diet. The results indicated that ground PB as a feed ingredient has the potential to decrease internal parasite infection, and worm burdens while improving animal performance by altering feed efficiency, especially in parasitized goats.

Key Words: goats, internal parasites, pine bark

M392 Lamb performance feeding diets with different crude protein level.

P. Meda Alducin, J. Maldonado Jaquez, I. Tovar Luna,* and J. Jaimes Jaimes, *Universidad Autonoma Chapingo, URUZA, Bermejillo, Mexico.*

Thirty 6-mo old Dorset × Ramboullet lambs with 21.3 ± 4.48 kg BW were used to study the effect of CP level in the diet on feed intake, DM digestibility, ADG, feed efficiency, and water intake during a 50 d feeding period. Lambs were stratified by BW and randomly assigned to one of 3 levels of CP in the diet (12, 14 or 16% with 2.59 Mcal ME/kg DM). After the 50 d feeding period, digestibility of DM was determined with 5 lambs per treatment in metabolic cages. An economic balance was performed including only the feed cost of the total diet consumed. Data was analyzed as a completely randomized design of treatments using the GLM procedure of SAS. No significant differences were detected in DM intake among treatments neither during the pen feeding phase (3.8, 4.2, and 4.2%; 88, 98, and 96 g/kg metabolic BW, respectively), nor when fed in cages (3.1, 3.0, and 3.3%; 75, 76, and 82 g/kg metabolic BW, respectively). Water intake was not affected ($P > 0.05$) by CP level in both phases (pen: 3.21, 3.10, and 3.16 g water/g DM; metabolic cages: 3.22, 3.80, and 3.47 g water/g DM, respectively). Dry matter digestibility was similar among CP levels (74, 72, and 74%, respectively). Feed conversion (6.83, 6.67, and 5.33) and ADG (214, 291, and 276 g/anim/d) were not significantly different among CP levels. Results of this study indicated that even though lambs fed the diets with 14 and 16% CP had numerically higher ADG, there were no differences among CP levels for the variables studied. The economic balance showed that lambs fed the 14% CP diet had the greatest return.

Key Words: lambs, crude protein

M393 Effect of copper and zinc on nutrient digestibility and growth performance in goats.

R. R. Rojo,* A. Z. M. Salem, J. F. Vázquez, and B. Albarrán, *Centro Universitario UAEM Temascaltepec, Temascaltepec, Estado de México, México.*

Copper (Cu) and zinc (Zn) are elements that have specific health functions in animal production; they play an indispensable role in physiological processes. In this study, a growth assay was conducted to evaluate the addition of copper and zinc to a total mixed ration (TMR) for improving of nutrient digestibility and performance of goat. Sixteen Boer crossbred male goats were randomly assigned to the following treatments (mg/kg DM): Cu-Zn (860.7–224.1); Cu (860.7); Zn (224.1) and control (no added trace minerals). Data were analyzed as a completely randomized design. Cu and Zn improved ($P < 0.01$) DM, OM, CP and ADF digestibility. DMI (g/d) was not affected ($P = 0.216$) by the micro-minerals addition. Animals on Cu-Zn treatment presented the highest ($P < 0.01$) ADG (g/d), Cu and Zn, with intermediate values while the control group had the lowest response. Feed conversion ratio was greater ($P = 0.023$) in the diet where Cu-Zn were added. Ruminal pH was not affected by treatments ($P = 0.435$). Copper and Zinc addition improved the nutrient digestibility and performance of growing male goats.

Table 1. Nutrients digestibility (g/kg DM) and growth performance of male goats consumed a total mixed ration supplemented with copper and zinc

Item	Cu + Zn	Cu	Zn	Control	SEM	*P*-value
Digestibility

M394 Growth and carcass characteristics of lambs fed high-concentrate diets containing increasing levels of crude glycerin. D. M. Polizel,* R. S. Gentil, E. M. Ferreira, M. O. Maia, C. P. Nolli, D. Eysink, A. V. Pires, and I. Susin, *Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/University of São Paulo (USP), Piracicaba, São Paulo, Brazil.*

Crude glycerin is a co-product of biodiesel production with a high concentration of glycerol. Due to the high production of biodiesel, there is a wide availability of crude glycerin and it is becoming an interesting ingredient in animal nutrition. The objectives of this trial were to determine the effects of partial replacement of corn by crude glycerin on growth and carcass characteristics of lambs fed high-concentrate diets. Forty Santa Inês ram lambs (initial BW 24.1 ± 0.6 kg and 97 ± 2 d old) were used in a randomized complete block design according to initial BW and age. Lambs were penned individually during 56 d and fed an isonitrogenous (15% CP, DM basis) total mixed ration composed of 90% concentrate and 10% coastcross hay. Levels of crude glycerin (89.7% glycerol, DM basis) were 0, 5, 10, or 15% in experimental diets G0, G5, G10 and G15, respectively. There was a quadratic response for DMI, ($P < 0.04$) and ADG, ($P < 0.06$) with no effect on G:F. Dry matter intake was 1.03, 1.18, 1.12 and 1.09 kg/d while ADG was 250, 293, 294 and 272 g for G0, G5, G10 and G15, respectively. Carcass characteristics (dressing percentage, LM area, backfat thickness and body wall thickness) were unaffected by experimental diets. Dietary crude glycerin up to 10% increases DMI and ADG in feedlot lambs.

Key Words: co-product, glycerol, sheep

M395 Ruminal fermentation, kinetics and digestibility of hair lambs supplemented with cull pinto bean. F. Castillo, G. Villalobos,* D. Domínguez, J. A. Ortega, and L. Cortés, *Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México.*

Cull pinto bean (*Phaseolus vulgaris*) is an ingredient used in ovine feeding in northern Mexico. The objective was to evaluate the effect of 3 levels of cull pinto bean (CPB) on feed intake, ruminal fermentation, kinetics, and nutrient digestibility of hair lambs. Six crossbred (Dorper × Pelibuey and Charolais × Pelibuey) rumen fistulated lambs averaging 56.6 ± 3.8 kg were used. Lambs were randomly assigned to 1 of 3 treatments. Treatments were (DM basis): 1) 0% of CPB of the supplement (CON); 2) 25% of CPB of the supplement (F25); and 40% of CPB of the supplement (F40). Dry matter intake, ruminal pH, ruminal NH_3 and VFA, methane production, Kp, MRT, DMD, CPD, and NDFD were evaluated. Data were analyzed with the MIXED procedure of SAS in a Latin square design 3 × 3 repeated in line. Estimates used for Kp, and MRT were obtained by a non linear regression model (PROC NLIN, SAS). There was a difference in DMI (kg; $P \leq 0.05$) among treatments, F25 (1.62 ± 0.08) and F40 (1.62 ± 0.08) were lower probably due to anti-nutritional factors in CPB. Ruminal pH and NH_3 (mg/100 mL of ruminal fluid) were not different ($P \geq 0.05$) among treatments. Differences were found ($P \leq 0.03$) for ruminal VFA (mM) concentration (CON: 60.4 ± 2.1; F25: 68.4 ± 2.1; F40: 64.2 ± 2.1). Higher DMI of CON did not affect total VFA. The higher value in F40 could be due to its greater oligosaccharide content. Acetate: propionate ratio was greater ($P \leq 0.0001$) for F40 (CON: 2.34 ± 0.073; F25: 2.2 ± 0.07; F40: 2.9 ± 0.07). CH_4 production (mM/ml) was different ($P \leq 0.03$) among treatments (CON: 29.1 ± 0.75; F25: 27.6 ± 0.75; F40: 32.9 ± 0.75). Kp (%/h) (CON: 3.6 ± 1.9; F25: 2.9 ± 1.9; F40: 5.9 ± 1.9%) and MRT (h) (CON: 36.3 ± 13.7; F25: 57.7 ± 13.7; F40: 36.2 ± 13.7 h) were similar ($P \geq 0.42$) among treatments. Digestibility of DM, CP, and NDF was similar ($P \geq 0.26$) among treatments. Cull pinto bean reduced DMI, although it did not affect ruminal pH and NH_3 production. The inclusion of 25% of CPB in the diet of hair lambs allowed having an appropriate nutrient digestibility without affecting Kp and MRT, and this increased the molar proportion of VFA without increasing methane production maintaining acetate:propionate ratio.

Key Words: cull pinto bean, hair lamb, ruminal fermentation and kinetics

M396 Effect of clinoptilolite (zeolite) substituting for soybean meal on apparent digestibility and energy concentration of feed in growing Pelibuey sheep. A. Estrada-Angulo,* S. A. Serrano-Cebreros, V. Martinez-Cruz, J. Cazarez-Rocha, A. Rubio-Angulo, B. I. Castro-Perez, H. Davila-Ramos, J. C. Robles, and F. G. Ríos, *FMVZ-UAS, Culiacan, Sinaloa, Mexico.*

To determine the effect of clinoptilolite (zeolite) substituting for soybean meal on apparent digestibility and energy concentration of feed in growing Pelibuey sheep, 6 male Pelibuey sheep (BW = 25.0 ± 1.1kg) were used in a Cross Over design with the following diets: 1) 3 animals received control treatment (without zeolite) 18.0% CP and 3.68 Mcal DE/kg, and contained 10.0% sudan hay, 49.0% cracked corn grain, 14.0% soybean meal, 14% DDGS, 8.0% sugarcane molasses, 2.5% animal fat, and 2.5% mineral premix; 2) like control, 3 animals received diet with zeolite, had 17.2% CP and 3.60 Mcal of DE/kg, but contained 1.5% zeolite and 12.5% soybean meal. Dry matter intake was adjusted at 1000 g/day/head (500 g am and 500 g pm). Total collection of feces was used in 2 periods under crossover experimental design. Data were analyzed with ANOVA. The OM excreted in feces was greater ($P <$ 0.05) in control treatments (86.4 vs. 83.1%) in comparison with zeolite treatment. The apparent digestibility of OM for control and zeolite treatments was similar ($P > 0.05$) with 85.5 and 84.0%, respectively. Ashes excreted in feces were greater ($P < 0.05$) in sheep with zeolite treatment in respect to control (16.9 vs. 13.6%, respectively). N excreted in feces was minor 12.7% in zeolite treatment. There was no difference in DE concentration of diet ($P > 0.05$) between treatments (3.5 vs. 3.4 Mcal/kg of DM) for control and zeolite treatment, respectively. The observed/expected DE ratio was similar for treatments (0.95 and 0.94 for control and zeolite treatments, respectively). It is concluded that clinoptilolite (zeolite) can substitute soybean meal at 1.5% of the diet increasing the apparent digestibility of OM and without effect on energy concentration in diets for growing Pelibuey sheep. Further, zeolite can diminish the N excreted in feces when it is included in diets for growing hair sheep.

Key Words: clinoptilolite, apparent digestibility, pelibuey sheep

M397 Influence of level of protein and energy on growth performance and tissue composition of feedlot hair lambs. F. G. Rios[1], H. Davila-Ramos*[1], A. Estrada-Angulo[1], A. Plascencia[2], J. J. Portillo[1], and J. C. Robles[1], [1]*FMVZ-UAS, Culiacan, Sinaloa, Mexico,* [2]*IICV-UABC, Mexicali, BC, Mexico.*

Forty-eight Pelibuey × Katahdin (23.9 ± 2.84 kg) crossbred male lambs were used in a 84-d feeding trial (6 pens per treatment in a randomized complete block design) to evaluate the influence of protein and energy supplementation level on growth performance and tissue composition. Lambs were fed with cracked corn-based finishing diet. Treatments were HPHE: 18% CP/2.99 Mcal ME/kg DM; HPLE: 18% CP/2.79 Mcal ME/kg DM; LPHE: 15% CP/2.99 Mcal ME/kg DM, and LPLE: 15% PC/2.79 Mcal ME/kg DM. Final live weight (FLW), DMI, ADG, G:F, slaughter weight (SW), HCW, dressing percentage (DP), LM area, Fat thickness (FT), kidney-pelvic fat (KPF), primal performance and carcass tissue composition were determined. The values were analyzed by ANOVA for a complete block design with 2 × 2 factorial arrangement; for carcass traits, slaughter live weight was used as a covariate. The means were compared using Tukey-Kramer test. FLW was greater ($P < 0.05$) in HPLE by the effect of protein level (49.8 vs. 48.0 kg), DMI was lower ($P < 0.05$) in HPHE and LPHE by the effect of energy level (1.15 vs. 1.27 kg); ADG (0.29 kg/d) and (G:F) (4.27) was not affected ($P > 0.05$) by treatments. SW was greater ($P < 0.04$) in HPHE (46.6 vs. 45.1) due to the protein level, KPF was higher ($P < 0.05$) for HPHE by the effect of energy level (1.03 vs. 0.79 kg). Carcass tissue composition was not modified by the effect of protein and energy level, nor by the factor's interaction. The results of this experiment suggested that 15% protein in the diet is sufficient to optimize the carcass traits of the finishing lambs with high energy diets, on the other hand providing higher levels of protein, does not improve carcass dressing percentage and carcass traits.

Key Words: protein level, hair lambs, carcass composition

Swine Species I

M398 Neutral semi-purified glycerin in starting pigs feeding in Brazil.

I. Moreira*[1], A. G. Gallego[1,2], P. C. Pozza[1], P. L. O. Carvalho[1], L. M. Peñuela-Sierra[1,3], and L. M. Huepa[1,2], [1]*Universidade Estadual de Maringá, Maringá, Paraná, Brazil,* [2]*Universidad del Tolima, Ibagué, Tolima, Colombia,* [3]*Universidad Cooperativa de Colombia, Ibagué, Tolima, Colombia.*

Two experiments were carried out to investigate the use of neutral semi-purified glycerin - NSPG (obtained from soybean oil), in starting piglet diets. Chemical composition (as-fed-basis) of NSPG: DM = 88.11%; glycerol = 80.2%; CP = 0.90%; GE = 3,535 kcal/kg; Methanol = 0.01%; NaCl = 5.86% and Ash = 6.18%. A digestibility trial (Experiment I) was conducted using 30 crossbred barrows with an initial BW of 42.91 ± 1.58 kg. The digestible (DE) and metabolizable energy (ME) values of glycerin were estimated by regression of DE and ME intake vs. glycerol intake (Adeola, 2001). For concentrations (4%, 8%, 12% and 16%) of NSPG in a corn + soybean meal (CSM) basal diet were fed. The values (as-fed basis) of DE and ME (kcal/kg) obtained were 3,298 and 2,531, respectively. The results indicate that the glycerin is a highly available energy source for feeding starting pigs. In the performance trial (experiment II), 100 piglets (BW = 15.14 ± 0.06 to 30.28 ± 0.70 kg) were allotted in a completely randomized block design, with increasing levels (0, 3.5, 7.0, 10.5, and 14.0%) of NSPG in a CSM diet. There were 10 pens per diet with 2 pigs per pen. Experimental diets were formulated according to NRC (1998). No effects ($P \geq 0.05$) of NSPG inclusion on piglet performance (Table 1) were observed by regression analysis. It can be concluded that using up to 14% of NSPG (2,531 kcal of ME/kg) in diets for starting piglet is feasible, without impairing performance.

Table 1. Piglet performance fed on neutral semi-purified glycerin (NSPG)

	Inclusion of NSPG ,%							*P*-value

M399 Brazilian neutral semi-purified glycerin on growing and finishing pigs feeding.

I. Moreira*[1], A. G. Gallego[1,2], P. L. O. Carvalho[1], C. C. Filho[1], T. J. Pasquetti[1], and D. Perondi[1], [1]*Universidade Estadual de Maringá, Maringá, Paraná, Brazil,* [2]*Universidad del Tolima, Ibagué, Tolima, Colombia.*

This study was carried out to evaluate the use of Brazilian Neutral Semi-purified Glycerin - NSPG, on growing and finishing pigs performance. The chemical composition (as-fed-basis) of the NSPG was: DM = 88.11%; Glycerol = 80.2%; CP = 0.90%; GE = 3,535 kcal/kg; Methanol = 0.01%; NaCl = 5.86% and ash = 6.18%. Eighty growing (BW = 30.31 ± 0.47 to 60.41 ± 0.87 kg) and finishing (BW = 60.41 ± 0.87 to 90.99 ± 0.87 kg) pigs were used in the performance trial. Pigs (one per pen) were allotted in a completely randomized block design, with increasing levels (3.5, 7.0, 10.5, and 14%) of NSPG in a corn-soybean meal diet, resulting in 16 replicates per treatment. Additionally a control diet was formulated containing no glycerin (0%). Experimental diets were formulated according to NRC (1998). The regression analysis indicates no effects ($P \geq 0.05$) of NSPG inclusion on pigs performance and carcass traits (backfat thickness and loin depth) (Table 1). It can be concluded that using up to 14% of NSPG (2,531 kcal of ME/kg) on growing and finishing pig diet is feasible, without impairing performance and carcass traits.

M400 Performance and carcass traits of finishing pigs fed on crude glycerin in Brazil.

I. Moreira*[1], P. L. O. Carvalho[1], L. M. Piano[1], J. B. Toledo[1], A. G. Gallego[1,2], and L. M. Peñuela-Sierra[1,3], [1]*Universidade Estadual de Maringá, Maringá, Paraná, Brazil,* [2]*Universidad del Tolima, Ibagué, Tolima, Colombia,* [3]*Universidad Cooperativa de Colombia, Ibagué, Tolima, Colombia.*

This experiment was carried out to investigate 2 types of crude glycerin which were obtained from soybean oil (CGS) and animal fat + soybean oil (CGA) on finishing pigs performance. Chemical composition (as-fed-basis): CGS (DM = 97.46%; Glycerol = 55.95%; CP = 0.06%; GE = 5,247 kcal/kg;Fatty acid = 23.3%; Methanol = 10.96% and Ash = 4.45%); NaCl = 3.52 and CGA (DM = 94.55%; Glycerol = 55.45%; CP = 0.05%; GE = 5,242 kcal/kg; Fatty acid = 21.5%; Methanol = 5.05%; NaCl = 3.01 and Ash = 4.26%). In the performance trial, 63 pigs (BW = 60.35 ± 2.25 to 89.91 ± 5.23 kg) were allotted (one per pen) in a completely randomized design in 2 × 4 factorial scheme, with increasing levels (3, 6, 9, and 12%) of 2 types of crude glycerin (CGS and CGA) in the diet. Additionally a control diet was formulated containing no glycerin (0%). Experimental diets were formulated according to NRC (1998). The regression analysis indicates no effects ($P \geq 0.05$) of CGS and CGA inclusion on pigs performance and carcass traits (Table 1). It can be concluded that using up to 12% of CGS and CGA (4.480 and 4.707 kcal of ME/kg, respectively) on finishing pigs diet is feasible, without impairing performance and carcass traits.

Table 1. Pig performance and carcass traits fed on crude glycerin (CGS and CGA)

	Inclusion of crude glycerin, %								
	CGS					CGA

M401 Determination of optimal dose and time of administration of intravaginal triptorelin gel for synchronizing ovulation in weaned sows.

R. Knox[1], S. Breen[1], J. Taibl[1], M. Swanson[2], and S. Webel*[3], *[1]University of Illinois, Urbana, [2]Pennatek LLC, Radnor, PA, [3]JBS United Inc., Sheridan, IN.*

The effect of dose and time of administration of intravaginal triptorelin gel (TG) on synchronization of ovulation in weaned sows was evaluated in 3 experiments. Sows were weaned and treated intravaginally with TG. Estrus was detected twice daily and ultrasound performed to assess ovulation at 8-h intervals. Sows were inseminated each day during estrus. In expt. 1, sows (n = 131) received 0 (control), 25, 100, or 200 μg of TG at 96 h after weaning. Wean to estrus and duration of estrus were correlated ($P < 0.0001$) and wean to estrus was shorter and duration was longer in TG ($P < 0.05$) compared with controls. More sows ovulated ($P < 0.05$) by 48 h post-treatment with 200 (91%), 100 (70%) and 25 μg (68%) of TG compared with controls (35%). Farrowing rate and total born did not differ. In expt. 2, sows (n = 126) received 200 μg of TG at 72, 84, or 96 h after weaning or served as untreated controls. Wean to estrus and duration of estrus did not differ from controls but wean to ovulation interval was shortened ($P < 0.05$) by TG at 72 and 84 h compared with 96 h and controls. More sows ovulated by 48 h after treatment ($P < 0.05$) with TG at 96 h (73.1%) compared with 72 (32%) and 84 h (43%) while tending ($P = 0.10$) to differ from controls (50%). Farrowing rate was lower ($P < 0.05$) for sows assigned to TG at 72 and 84 h compared with 96 h and Controls, while liveborn did not differ. In expt.3, sows (n = 113) were assigned to OvuGel (200 μg TG given intravaginally at 96 h after weaning), no treatment (Controls) or placebo (Placebo). Wean to estrus did not differ but duration of estrus tended to be shorter following OvuGel compared with other treatments ($P < 0.10$). More sows ovulated ($P < 0.001$) by 48 h following OvuGel (80%) compared with Control (46%) and Placebo (37%). Farrowing rate and liveborn did not differ among treatments. The results of these studies indicate that 200 μg of TG given intravaginally at 96 h after weaning (OvuGel) synchronizes ovulation and results in fertility similar to controls. This methodology will aid in development of single and timed AI procedures for use in swine.

Key Words: OvuGel, sows, ovulation

M402 The effects of arginine supplementation of weanling pig diets on growth performance and IGF expression.

W. C. Wang*[1,3], R. J. Chen[1,2], J. Pan[4], T. J. Li[1], and Y. L. Yin[1], *[1]Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, China, [2]Rice Research Institute of Sichuan Agricultural University, Chengdu, Sichuan, China, [3]Guelph Food Research Center, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [4]Department of Animal Science, Hunan Agricultural University, Changsha, Hunan, China.*

Young piglets have a high requirement of arginine for growth and metabolic function, but the sow milk or endogenous synthesis cannot provide enough arginine for maximal growth. Dietary arginine supplementation can improve the immunity of early-weaned piglets and enhance the skeletal muscle synthesis for growth. The insulin-like growth factor (IGF) signaling pathway is an important regulatory factor in regulating fetal and placental growth, proliferation, differentiation, migration and aggregation, and inhibits apoptosis of mammalian cells. However, the role of arginine in altering IGF expression in newly weaned pigs is not clear. This study was conducted to investigate the effect of dietary arginine supplementation in modulation of the IGF system of weanling piglets. Twelve, 21-d-old healthy piglets (Landrace × Yorkshire) with a mean body weight (BW) were assigned randomly to 2 treatments representing diets supplemented with 0.6% L-arginine or 1.23% L-alanine (isonitrogenous control). At 28 d of age, 12 piglets were killed and samples were collected. In arginine group, ADG was increased significantly, and Gain: Feed obviously decreased compared with control group ($P < 0.05$). However, ADFI were not different ($P > 0.05$). The liver, kidney, heart, spleen and lung weight relative to body weight were lower in arginine group than in control, but not significant ($P > 0.05$). The weight of small intestine in arginine group was 33.4% heavier than that in control ($P < 0.001$).Components of IGF signaling pathway (IGF1, IGF1R, IGF2, IGF2R and IGFBP5) mRNA expression were examined in 3 tissues by RT- PCR method. IGF1 was increased in muscle, liver and kidney tissues of arginine group ($P < 0.05$). IGF2 was significantly increased in muscle of arginine group ($P < 0.01$). Both muscle and liver had a higher concentration of IGFBP5 with arginine supplementation ($P < 0.05$). These data suggest an important role of arginine in modulating the IGF signal pathway and the involvement in improving growth performance.

Table 1. Performance of weanling piglets fed diets containing 0.6% l-arginine or 1.23% l-alanine (control)[1]

Item	Control	l-Arginine
Initial weight(g)	5370 ± 53	5230 ± 203
Finish weight (g)	5870 ± 210	6503 ± 208*
ADG (g/d)	70 ± 23	167 ± 31*
ADFI (g/d)	183 ± 12	187 ± 21
Gain: Feed	2.61 ± 0.47	1.07 ± 0.18*

Key Words: arginine, early-weaned piglets, IGF

M403 Assessment of zero-tannin faba bean and co-fermented corn and wheat DDGS in diets of growing-finishing pigs.

C. Furedi*[1], P. Lopez[1], M. Licayu[1], D. Gurney[1], E. Kiarie[2], and C. M. Nyachoti[2], *[1]The Puratone Corporation, Niverville, MB, Canada, [2]University of Manitoba, Winnipeg, MB, Canada.*

A grow-finish feed trial was conducted to determine the impact on growth performance and carcass characteristics of feeding diets containing co-fermented corn and wheat DDGS (cwDDGS) from and zero-tannin fava beans (ZTFB) as substitutes for corn DDGS (cDDGS) and some soybean meal. A total of 16 diets were tested containing one of 2 DDGS Sources (cDDGS or cwDDGS) at 2 levels (10% or 30%) of inclusion, with either 0% or 15% ZTFB and with 0 ppm or 62.5 p.m. of yucca extract (YE) in a full factorial design. Feed was delivered 3 times daily to 120 pens of 21 pigs to provide ad libitum feeding by robotic feeders (FeedLogic Corporation; Willmar, MN, USA). Diets, formulated to meet NRC (1998) recommendations, were provided in 5 phases and were not split-sex fed. Pigs were tagged, weighed individually on wk 1, 4, 8, 12, 14 and 16 and were shipped to Maple Leaf Foods (Brandon, MB, Canada) at 123–129 kg BW. Slaughtered pigs were tattooed by pen and data for carcass weight, fat and loin thickness, carcass index, and lean yield was recorded and used to calculate carcass value. There was an interaction effect between DDGS source and DDGS level on days to market (DTM) ($P < 0.05$), standardized feed cost per kg BW gain (SFC/kg) ($P < 0.05$), carcass weight ($P < 0.05$) and a trend for carcass value ($P < 0.10$). The DDGS level only affected responses in cwDDGS and not cDDGS in which case 30% cwDDGS resulted in 3 more DTM, $0.036 lower SFC/kg, 2.15 kg lower carcass weight and $3/hog reduced carcass value. Pigs fed diets containing 15% ZTFB had ($P < 0.05$) lower ADG, and higher FCR, SFC and DTM than pigs fed diets without ZTFB. However, when 62.5ppm of YE was added to the diet, performance was similar to pigs fed diets without ZTFB. These results suggest that ZTFB can be used in grow-finishing swine diets as long as YE is also included and that cwDDGS, when compared with cDDGS, has a negative effect on growth when used at 30% inclusion.

Key Words: zero-tannin faba beans, grow-finish pigs, DDGS

17 Effect of supplementing activated charcoal on intake of honey mesquite leaves by lambs. P. Mayagoitia*[1], D. Bailey[1], and R. Estell[2], [1]*New Mexico State University, Las Cruces,* [2]*USDA-ARS Jornada Experimental Range, Las Cruces, NM.*

A study was conducted to determine if intake of honey mesquite (*Prosopis glandulosa* Torr.) leaves by sheep could be increased by supplementing activated charcoal at 0.0, 0.33, 0.67 or 1.00 g / kg of body weight. Twenty wether lambs (36.6 ± 0.6 kg) were randomly assigned to the 4 treatment levels. Lambs were fed low-quality Sudan-grass hay at 2% of BW plus 80 g/d of molasses for 7 d, and Sudan-grass hay at 1.9% of BW plus 80 g/d of molasses mixed with the assigned level of activated charcoal for 16 d (d 8 to 23). On d 8 to 23, lambs were also given ad libitum access to honey mesquite leaves that had been previously harvested, frozen, and thawed immediately before feeding. Repeated measures analyses were used to determine if level of activated charcoal fed to lambs affected daily intake of mesquite leaves. No differences ($P = 0.52$) in intake of mesquite leaves were detected. Mean intake of mesquite leaves was 20.7 ± 3.7, 23.8 ± 3.8, 20.2 ± 3.7, and 27.3 ± 3.7 g/d for 0.0, 0.33, 0.67 and 1.0 treatment levels, respectively. Consumption of mesquite leaves varied greatly among lambs, ranging from 1.4 to 7.4% of their diet during the last 8 d of the study. No differences in hay intake ($P = 0.23$) or lamb weight gain ($P = 0.58$) were detected among supplemental charcoal treatments. Future studies examining the consumption of honey mesquite leaves by sheep should consider the potential variability in intake among individual animals.

Key Words: sheep, rangeland, secondary compounds

18 Pre-breeding β-hydroxybutyrate concentration influences conception date in young postpartum range beef cows. J. T. Mulliniks*[1], M. E. Kemp[1], R. L. Endecott[2], S. H. Cox[1], E. J. Scholljegerdes[1], T. W. Geary[3], and M. K. Petersen[3], [1]*New Mexico State University, Las Cruces,* [2]*Montana State University, Miles City,* [3]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

Cows in negative energy balance after calving often have reduced reproductive performance, which is suggested to be mediated by metabolic signals. The objective of this 3-yr study was to determine the association of serum metabolites, resumption of estrus, milk production, cow BW change, BCS, and calf performance on conception date in 2- and 3-yr-old beef cows (n = 131) grazing native range at the Corona Range and Livestock Research Center. Cows were classified by conception date in a 60-d breeding season as early conception (EC; conceived in the first 15 d of breeding) or late conception (LC; conceived during the last 45 d of breeding). Date of conception was calculated from the subsequent calving date. Beginning on d 30 postpartum, blood samples were collected twice/wk for serum metabolite analysis and progesterone analysis to estimate days to resumption of estrous cycles. As a chute-side measure of nutrient status and glucose sufficiency, whole-blood β-hydroxybutyrate (BHB) concentrations were measured 2 wk before breeding. A random subsample of cows from groups was mechanically milked approximately 57 d postpartum. Whole-blood BHB and serum glucose concentrations were lower ($P \leq 0.04$) in EC cows than LC cows. Serum insulin concentrations were greater ($P = 0.03$) in EC cows relative to LC cows. Serum NEFA and urea N concentrations were not different ($P \geq 0.32$) between EC and LC cows. Initial calving date during the year of the study was not different ($P = 0.19$) between EC and LC cows. The postpartum anestrous interval was shorter ($P = 0.04$) in EC cows, indicating that the earlier conception was due partially to an earlier return to cyclicity. Milk production was not different ($P = 0.28$) between EC and LC cows. Cow BW and BCS and were not different ($P \geq 0.12$) at any period between EC and LC cows. Calf weaning (205-d) BW was not different ($P = 0.67$) between EC and LC cows. This study indicates that blood BHB concentrations before breeding may provide a sensitive indicator of energy status for rebreeding success in young beef cows as measured by interval to conception.

Key Words: beef cows, conception date, β-hydroxybutyrate

19 Effects of algal meal supplementation to finishing wethers on performance and carcass characteristics. M. G. Dib,* T. E. Engle, H. Han, I. N. Roman-Muniz, and S. L. Archibeque, *Colorado State University, Fort Collins.*

Crossbred wethers (n = 40; initial BW = 45.3 kg + 3.5) were used in a randomized complete block design to evaluate the effects of titrated concentrations of algal meal as a protein supplement on live performance, live health status and carcass characteristics. Wethers were blocked by time and randomly assigned to one of the 5 treatments. Treatments included (1) soybean meal and rice meal as protein supplementation sources (CON); (2) 5% of algae meal on a DM basis as a protein replacement (5%A); (3) 10% of algae meal on a DM basis as a protein replacement (10%A); (4) 15% of algae meal on a DM basis as a protein replacement (15%A); and (5) 20% of algae meal on a DM as a protein replacement (20%A). All diets were isocaloric and isoproteic. All wethers were fed a high concentrate finishing diet once daily in individual stalls. Wethers were individually weighed on d −1, 0, 21, and 28. On d 21, wethers were transported to metabolic crates for determination of nutrient digestibility and retention. On d 28, animals were transported to a commercial abattoir for harvest. Initial (45.4 kg) and final (44.5 kg) BW, ADG for feedlot period (0.24 kg/d), ADG for metabolism period (−0.84 kg/d), DMI (1.38 kg/d), and G:F (0.187) were similar ($P > 0.05$) across treatments. Furthermore, hot carcass weight, subcutaneous adipose depth, Longissimus muscle area, calculated YG, marbling score, dressing percentage, muscle percentage, body wall thickness, Leg score, Leg circumference, flank streaking, quality grade, carcass conformation and carcass length were also similar ($P > 0.05$) across treatments. Research results suggest that feeding up to 20% of algae co-product meal as a replacement protein source to finishing wethers is feasible with limited impact on performance and carcass characteristics as compared with the standard protein sources that have been used by the industry. Further research may be necessary to determine the response of different levels of supplementation of algal meal for sheep, effects on animals in a different physiological stage or effects on other ruminants in the finishing diet on performance and carcass merit.

Key Words: algae, protein, co-product

20 Influence of the level of dried distillers grains with solubles on feedlot performance, carcass characteristics, serum testosterone concentrations, and semen quality of growing rams. M. L. Van Emon*[1,2], K. A. Vonnahme[2], P. T. Berg[2], R. R. Redden[2], M. M. Thompson[1], J. D. Kirsch[2], and C. S. Schauer[1], *[1]Hettinger Research Extension Center, North Dakota State University, Hettinger, [2]Department of Animal Sciences, North Dakota State University, Fargo.*

The objective of this study was to evaluate the effects of dried distillers grains with solubles (DDGS) on ram lamb feedlot performance, carcass characteristics, serum testosterone concentration, and semen quality. One hundred 20 ram lambs (40.4 ± 9.1 kg; western whiteface × Suffolk) were used in a completely randomized design to determine the effects of DDGS on feedlot performance and carcass characteristics. Rams were allotted into one of 4 dietary treatments (n = 4 pens/treatment; 10 rams/pen): 1) 0DDGS: 85% corn and 15% commercial market lamb pellet; 2) 15DDGS: 15% DDGS substituted for corn on a % DM basis, 70% corn, and 15% commercial market lamb pellet; and 3) 30DDGS: 30% DDGS substituted for corn on a % DM basis, 55% corn, and 15% commercial market lamb pellet. Rams were weighed on consecutive days at the beginning (d 0, 1) and end (d 96, 97 and d 116, 117) of the trial. Scrotal circumference was measured on all rams on d 84, 96, and 116. Semen and blood samples were collected on a subset of 48 rams (4 rams/pen; 16 rams/treatment; n = 4). Blood samples were collected every 14 d throughout the study. Semen samples were collected on d 84, 98, and 112. Rams were fed to market weight, shipped to a commercial abattoir, and harvested for carcass data collection. Initial BW, final BW, change in scrotal circumference, days on feed, carcass characteristics, serum testosterone concentrations, and semen score were not different ($P \geq 0.11$) due to dietary treatment. However, DMI increased linearly ($P < 0.001$) as DDGS increased in the ration, resulting in a linear increase ($P = 0.02$) in ADG. Additionally, sperm count decreased linearly ($P = 0.05$) as DDGS concentration increased in the ration. Increasing DDGS in the diet did not have a negative effect on ram feedlot performance or carcass characteristics; however, in this preliminary study, sperm production may have been negatively affected, necessitating the need for additional research on the effect of distillers grains on ram development.

Key Words: dried distillers grains with solubles, rams, semen quality

21 Effect of weaning method on welfare and performance of beef calves during receiving. E. A. Bailey*[1], J. R. Jaeger[2], J. W. Waggoner[2], L. W. Murray[3], G. W. Preedy[1], L. A. Pacheco[1], D. L. Davis[1], and K. C. Olson[1], *[1]Department of Animal Sciences & Industry, Kansas State University, Manhattan, [2]Western Kansas Agricultural Research Center, Kansas State University, Hays, [3]Department of Statistics, Kansas State University, Manhattan.*

We evaluated receiving performance and welfare of beef calves that had been subject previously to 1 of 3 ranch-of-origin weaning methods 28 d in duration: drylot weaning + dam separation (D), pasture weaning + fence-line contact with dams (PF), and pasture weaning + fence-line contact with dams + supplemental feed delivered in a bunk (P+S). Calves assigned to D were fed a diet designed to promote a 1 kg ADG at a DMI of 2.5% of BW (17.7% CP, 0.92 Mcal NE_g/kg); PF calves had access to native forage only (6.8% CP, 43% ADF); and P+S calves had access to native forage and received a ration of the diet fed to D at a rate of 1% of BW 3 × weekly. Weaning-phase ADG tended ($P = 0.10$) to be greater for D than for PF or P+S; however, incidence of undifferentiated fever during weaning was similar ($P = 0.22$) between treatments. At the end of the weaning phase, all calves were transported 4 h to a feedlot, were penned according to treatment (n = 8 pens/treatment), and were fed a receiving diet (14.9% CP, 0.93 Mcal NE_g/kg) ad libitum. Feed intake, growth, and health were monitored during a 60-d receiving period. Observations of calf behavior were made 3 × daily for the first 7-d of receiving; the proportion of calves in each pen that were eating, resting, or pacing was recorded by 2 trained observers and reported as a pen average. During the first 30 d of receiving, ADG was less ($P < 0.01$) for PF than for D and P+S; however, ADG of D was greater ($P < 0.01$) than that of PF and P+S during the entire 60-d receiving phase. Diet DMI and G:F were greater ($P \leq 0.01$) also for D than for PF or P+S during receiving. Fewer (treatment × day - $P < 0.01$) PF calves were observed at the bunk during the first 4 d of receiving than D or P+S calves; however, the proportions of calves observed at the bunk were similar (treatment × day - $P = 0.64$) between treatments by d 6. Incidence of undifferentiated fever was similar ($P = 0.50$) between treatments during receiving. We interpreted these data to suggest that animal performance and welfare during the receiving period were not improved by pasture weaning + fence-line contact with dams compared with drylot weaning + dam separation. Best-management practices for animal welfare may involve initiating diet transitions from forage to grain at the ranch of origin.

Key Words: animal welfare, preconditioning, weaning

22 Effects of timing of vaccination (day 0 versus day 14 of a receiving period) with a modified-live respiratory viral vaccine on performance, feed intake and febrile response of beef heifers. K. P. Sharon*[1], G. C. Duff[1], M. M. Harbac[1], J. A. Paterson[1], J. A. Carroll[2], and J. W. Dailey[2], *[1]Department of Animal and Range Sciences, Montana State University, Bozeman, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to evaluate the effects of timing of administration of a modified-live respiratory viral vaccine (IBR-PI_3-BRSV-BVD) on d 0 or on d 14 of a receiving period on performance, feed intake and febrile response in beef heifers. Our hypothesis was vaccine timing will alter febrile response and feed intake of feeder cattle. Thirty-six heifers (Angus and Angus crosses; initial BW = 265 ± 20 kg) were ranked by BW and assigned to treatment pens (9 pens total) in a completely randomized design. Treatments (3 pens/treatment with 4 heifers/pen) included no vaccine (CON), vaccination on d 0 (DO), and a delayed vaccination on d 14 (D14) of the receiving period. Heifers were fed in 6 × 12 m pens with GrowSafe feeding systems. Daily intakes were recorded and BW measured on d −1, 0, 14, 27, and 28. Temperature probes were attached to controlled intrauterine drug release devices (CIDR; active compound was removed) and vaginal temperatures were recorded every 5 min for the experiment; vaginal temperatures were then averaged for every h before data analysis. All data were analyzed using pen as the experimental unit. No differences ($P > 0.10$) among treatments were observed for initial BW, final BW, ADG for d 0 to end, or overall G:F. A treatment x d interaction ($P < 0.05$) was observed for feed intake. Daily intake was decreased for D14 versus D0 on d 14 ($P < 0.01$) and 15 ($P < 0.10$) and decreased ($P < 0.05$) on d 15 for the average of vaccinated calves versus CON. Eating rate (grams consumed/eating duration) was decreased ($P < 0.05$) on d 14 for D14 versus D0. A treatment x d interaction ($P < 0.01$) was observed for vaginal temperature. Vaginal temperature was increased ($P < 0.10$) on d 1 for D0 versus D14 heifers and increased for D14 versus D0 on d 14 ($P < 0.01$), 15 ($P < 0.05$) and 16 ($P < 0.05$). Our results suggest that time of administration of a modified-live respiratory viral vaccine can alter feed intake and vaginal temperature in feeder heifers.

Key Words: beef heifers, respiratory vaccines, feed intake

23 Assessment of chestnut tannin extract supplementation on animal performance and ruminal fermentation profiles in feedlot finishing diets. J. M. Sieg*[1], J.-S. Eun[1], D. R. ZoBell[1], and B. R. Min[2], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan,* [2]*Department of Agricultural and Environmental Sciences, Tuskegee University, Tuskegee, AL.*

The objective of this study was to assess animal performance and ruminal fermentation when feedlot finishing beef steers were fed with supplementation of chestnut tannin extract (CTE). Eight Charolais-cross steers (average BW = 495 kg) were used in a duplicated 4 × 4 Latin square experiment with a 2 × 2 factorial arrangement of treatments. The 4 animals in one of 2 squares were surgically fitted with a ruminal cannula. Within squares, animals were randomly assigned to a sequence of 4 diets during each of the 4 21-d periods (14 d of treatment adaptation and 7 d of data collection and sampling); CTE supplementation (without vs. with CTE) and ionophore (ION; monensin administered as a Rumensin) supplementation (without vs. with ION). Animals were fed a finishing diet consisting of 8.0% alfalfa hay, 7.0% corn silage, 77.0% rolled barley grain, 3.0% CTE or wheat straw, and 5.0% feedlot supplement without or with ION. Intake of DM/d was not affected by CTE supplementation or ION, whereas DMI/kg BW tended to increase ($P = 0.08$) by CTE supplementation. Supplementation of CTE increased ADG ($P = 0.01$), but ION did not influence ADG. Total VFA concentration did not differ in response to supplementing CTE or ION. Additionally, molar proportions of acetate and propionate were similar between dietary treatments. Molar proportion of butyrate tended to increase ($P = 0.10$) by CTE supplementation, but not by ION. Mean ruminal pH measured for 48 h averaged 6.39 across dietary treatments, but was not influenced by dietary treatments. In contrast, daily episodes with ruminal pH <5.80 tended to increase ($P = 0.10$) by CTE supplementation, while ION increased the daily episodes only with CTE supplementation, resulting in an interaction between CTE and ION ($P = 0.03$). Supplementation of CTE had minor impacts on ruminal fermentation, except that CTE affected total buffering capacity of finishing beef steers. Further research is needed to investigate positive effects on animal performance by CTE supplementation in feedlot finishing diets.

Key Words: chestnut tannin extract, beef finishing steers, ruminal fermentation profiles

24 Evaluation of the incidence, causes, and potential solutions for the occurrence of disabled or non-ambulatory cattle within the California beef and dairy industries. M. V. Sis*[1], J. K. Ahola[1], H. A. Foster[2], D. L. VanOverbeke[3], and D. A. Daley[4], [1]*Colorado State University, Fort Collins,* [2]*California Beef Council, Sacramento,* [3]*Oklahoma State University, Stillwater,* [4]*California State University-Chico, Chico.*

A survey was conducted to evaluate how California beef and dairy operations sell market cows and bulls and identify key contributors to these animals becoming disabled or non-ambulatory (NA). Surveys were mailed to 9,778 California beef and dairy producers using the California Beef Council mailing list. Twenty-nine questions were included to evaluate beef and dairy producer demographics, the incidence of NA cattle on-farm or on-ranch, management and marketing practices utilized for market cows and bulls, and reasons animals become NA. Response rate for the mailed portion of the survey was 3.9%. Completed surveys were received from 446 producers (n = 403 beef, n = 43 dairy). The mean age (±SD) for survey respondents was 62 ± 12.3 yr for beef producers and 55 ± 13.1 yr for dairy producers. Survey responses clearly indicated that most beef (77.5%) and dairy producers (62.5%) market their animals at a livestock auction market, which was more ($P < 0.05$) than any other option. The direct sale of market cows and bulls to a beef packer was ($P < 0.05$) the next most common outlet among both beef (11.7%) and dairy (22.9%) respondents. Rates of culling, euthanasia, and death loss among cows were 10.8, 1.2, and 1.3%, respectively, for beef respondents, and 33.1, 2.1, and 3.3%, respectively, for dairy respondents. However, 35.6% of beef and 95.2% of dairy respondents indicated they had at least 1 non-ambulatory cow in the previous 12 mo. The majority ($P < 0.05$) of beef and dairy survey respondents indicated they would consider on-farm euthanasia (92.1 and 88.1%, respectively), and gunshot was identified as the primary method ($P < 0.05$) of euthanasia among beef (76.2%) and dairy (78.0%) producers. Dystocia was reported to be the primary cause ($P < 0.05$) of NA status in cows among beef (46.5%) and dairy (79.1%) respondents. These data suggest that management of potential causes of NA status continues to be a challenge among beef and dairy cattle producers and solutions to reduce NA incidence are needed.

Key Words: beef cattle, dairy cattle, non-ambulatory

25 Effect of two, four, and six-hour intervals between two prostaglandin $F_{2\alpha}$ injections administered with five-day CO-Synch + CIDR protocol on pregnancy rate in beef cows. C. J. Berrett*[1], J. L. Seabrook[1], G. E. Seidel Jr[1], J. C. Whittier[1], J. K. Ahola[1], R. K. Peel[1], and A. V. Grove[2], [1]*Colorado State University, Fort Collins,* [2]*AG Research LLC, White Sulphur Springs, MT.*

At the time this study was conducted, it was recommended when using the 5-d Co-Synch protocol that two 25 mg PG injections at 12-h intervals be given because it was assumed that an immature 5-d CL would not be successfully regressed by a single 25 mg PG injection. Therefore, the objective of this study was to compare fixed-time AI (TAI) pregnancy rates resulting from intervals of 2-, 4-, or 6-h between two 25 mg prostaglandin (PG) $F_{2\alpha}$ injections administered following CIDR removal in the 5-d CO-Synch + controlled internal drug-release device (CIDR) estrous synchronization protocol. Angus and Angus-crossbred cows (n = 901) maintained on native pasture at 3 locations were randomly assigned to one of 3 experimental treatments after blocking for BCS and postpartum interval (PPI). All cows received gonadotropin-releasing hormone (GnRH) and CIDR on d −5, PG with CIDR removal and 25 mg PG on d 0, and GnRH with TAI 72 h after the initial PG injection. Cows also received a second 25 mg injection of PG either 2-, 4- or 6-h after the first injection of PG. Timed AI pregnancy rates were determined by ultrasonography 40 ± 2 d following TAI. Fixed-time AI pregnancy rate was lower ($P \leq 0.05$) in cows receiving 2 PG injections separated by 2- (50.6%) and 4-h (51.4%) intervals, compared with cows receiving 2 PG injections separated by a 6-h (59.7%). Reducing the interval between PG injections from 6 to 2 h resulted in a 9-percentage point (15%) reduction in TAI pregnancy rates for cows synchronized with a 5-d CO-Synch + CIDR protocol. Based on these data the interval between PG injections should be a minimum of 6-h to maintain acceptable pregnancy rates in beef cows when using the 5-d CO Synch + CIDR protocol.

Key Words: beef cow, CIDR, fixed-time AI

26 Effects of pain mitigation and method of castration on behavior and feedlot performance in cull beef bulls. P. E. Repenning*[1], J. K. Ahola[1], R. J. Callan[2], J. T. French[1], R. L. Giles[1], R. K. Peel[1], J. C. Whittier[1], J. T. Fox[3], and T. E. Engle[1], [1]*Department of Animal Sciences, Colorado State University, Fort Collins,* [2]*Department of Clinical Sciences, Colorado State University, Fort Collins,* [3]*JBS Five Rivers Cattle Feeding LLC, Greeley, CO.*

The objectives of this study were to evaluate the effects of castration method (band vs. surgical) and use of analgesia on behavior and feedlot performance in cull bulls. Angus, Hereford, and Angus crossbred bulls (n = 20; initial BW 384 ± 59.3 kg; 336 ± 20.0 d old) were housed in feedlot pens equipped with the ability to measure individual daily feed intake. A balanced randomized block design using a 2 × 2 factorial arrangement of treatments was utilized. Factors included: 1) castration method, and 2) analgesia presence. A multimodal analgesia protocol (MMA) was used and consisted of subcutaneous ketamine-stun containing butorphanol (0.01 mg/kg), xylazine (0.02 mg/kg), ketamine (0.04 mg/kg), and a local 2% lidocaine hydrochloride anesthetic block of the spermatic cords (10 mL per cord) and scrotum (10 mL) on d 0. Flunixin meglumine (1.2 mg/kg) intravenously (iv) on d 0, 1, 2 and 3. Cattle were stratified to treatments based on breed, BW, age and a temperament score. Treatments included: 1) band castration without analgesia (BAND), 2) band castration with analgesia (BAND-MMA), 3) surgical castration without analgesia (SURG), and 4) surgical castration with analgesia (SURG-MMA). Chute exit velocity (EV) and time in chute (TIC) were collected on d −9, 0, 1, 2 and 13. Willingness-to-enter-chute (WTE) score, rectal temperature (TEMP), heart rate (HR), and respiration (RESP) were collected on d 0, 1, 2, 3 and 13. Cattle were weighed on d −9 and 13 while feeding behaviors were collected continuously for 57 d pre-castration and 28 d post-castration. There was a tendency ($P < 0.09$) for ADG to be greater in cattle receiving analgesia. Both SURG treatments exhibited greater ($P < 0.001$) TEMP on d 1 and on d 2 ($P < 0.05$) when compared with BAND treatments. Mean DMI was greater ($P = 0.02$) in MMA treatments when compared with non-medicated treatments. The SURG treatment, when compared with SURG-MMA and BAND, exhibiting greater ($P = 0.04$, $P = 0.04$, respectively) meal size. Results suggest that pain mitigation reduces the impact of castration on ADG and DMI.

Key Words: bulls, castration, ketamine-stun

27 Fetal and maternal induction of angiogenic factors during early pregnancy.

K. E. Quinn*[1], J. D. Lindsey[1], S. M. Stanbrough[1], A. K. Ashley[2], and R. L. Ashley[1], *[1]Department of Animal and Range Sciences, New Mexico State University, Las Cruces, [2]Center for Animal Health, Food Safety, and Bio-Security, New Mexico State University, Las Cruces.*

Early pregnancy, when most embryonic losses occur, is a critical period in which vital placental vascularization is established. Adequate vascular development supports embryonic survival and subsequent fetal growth. Vascular endothelial growth factor (VEGF) is the most potent inducer of angiogenesis, and factors regulating VEGF may ultimately affect vascularization. Activation of chemokine receptor 4 (CXCR4) by CXCL12 increases VEGF synthesis and secretion, which in turn stimulates CXCL12 and CXCR4 production. This synergistic regulation may drive placental vascularization. Our laboratory reported elevated CXCR4 in endometrium during early pregnancy in sheep, but the relationship between the CXCL12/CXCR4 signaling pathway and angiogenic factors such as VEGF, Fibroblast growth factor (FGF2), and Angiopoietin 1 (ANG1) is lacking in ruminants. We hypothesized CXCL12, CXCR4, and select angiogenic factors and their receptors would increase in placental tissue during early pregnancy. To test this hypothesis, caruncle and fetal extraembryonic membrane tissues were collected on d 20, 25 and 30 of pregnancy, with d10 of the estrous cycle as a control. Real time PCR was used to assess relative mRNA levels. Expression levels were normalized by standard methods, and subjected to ANOVA with Newman-Keuls post hoc test to determine significant differences ($P < 0.05$). In caruncles, CXCL12 and CXCR4 increased on d20 in pregnant ewes. FGF2 increased during early to mid-placentation in caruncle tissue. In fetal extraembryonic membranes, CXCL12, CXCR4, ANG1 and VEGF were induced with advancing pregnancy, whereas FGF2 and VEGFR2 peaked on d25. The increase of angiogenic factors in fetal placenta during implantation and placentation highlights the concept that the fetus regulates its vascularization in synergy with the maternal placenta. The relationship between VEGF and CXCL12/CXCR4 underscores the potential role for this chemokine system in placentation. These results provide strong support for enhanced signaling between chemokines and angiogenic factors within the fetal-maternal interface.

Key Words: chemokine, vascularization, pregnancy

28 Effect of swath grazing on forage intake and wastage by ewes.

E. E. Nix,* D. L. Ragen, J. G. P. Bowman, R. W. Kott, and P. G. Hatfield, *Montana State University, Bozeman.*

Sixty non-pregnant and nonlactating mature white faced ewes (Targhee 65.4 ± 5.84 kg BW in 2010 and Rambouillet 61.9 ± 6.28 kg BW in 2011) were used in a 2 yr study to evaluate intake, wastage, and nutrient composition of a pea/barley forage fed either as baled hay in confinement (CONFINEMENT) or swathed and left to graze (GRAZE). Forage intake was estimated using IVDMD and chromic oxide as a marker for estimating fecal output. Forage wastage was estimated by sampling and weighing the initial swath, standing, and baled forage, and weighing the forage again after a 7-d collection period, and subtracting the estimated forage DMI. Baled, swathed, and any standing forage was sampled once per month from the date the forage was swathed (early August) until October. Samples were analyzed for DM, OM, CP, NDF, ADF, and in situ dry matter digestibility (ISDMD). There was no main effect of treatment or year ($P \geq 0.23$) for DMI ($kg \cdot ewe^{-1} \cdot d^{-1}$); however, there was a treatment x year interaction ($P < 0.04$). In 2010, DMI ($kg \cdot ewe^{-1} \cdot d^{-1}$) was greater ($P < 0.10$) by CONFINEMENT compared with GRAZE (2.4 vs 1.7 kg/d). Forage wasted as a percent of beginning available forage did not differ ($P \geq 0.28$) between GRAZE and CONFINEMENT within both years. In 2010, OM was greatest ($P < 0.10$) in baled forage, intermediate in standing forage, and lowest in swathed forage. In 2011, OM did not differ ($P = 0.99$) for baled and swathed forage, but both were greater ($P < 0.10$) compared with standing forage. In 2010, CP was greatest ($P < 0.10$) in swathed forage (12.0%), intermediate in baled forage (10.3%), and lowest in standing forage (8.2%). In 2011, CP was greater ($P \leq 0.05$) in baled forage compared with swathed and standing forage. In both years, NDF and ADF were lower ($P < 0.10$) in baled forage compared with swathed and standing forage. In 2010, ISDMD was greater ($P < 0.10$) for swathed forage compared with baled forage. In 2011, percent ISDMD was greater ($P < 0.10$) in baled forage compared with swathed or standing forage. Forage intake and percent wastage were not affected by treatment, but forage quality was lower in the GRAZE treatment compared with the CONFINEMENT treatment.

Key Words: confinement, ewes, swath

29 Maternal diet restriction in beef cows alters fetal cardiovascular hemodynamics and fetal and placental development during early pregnancy.

L. E. Camacho,* C. O. Lemley, K. C. Swanson, and K. A. Vonnahme, *Department of Animal Sciences, North Dakota State University, Fargo.*

Objectives were to examine the effects of maternal nutrient restriction on fetal cardiovascular hemodynamics, and fetal and placental development during early gestation. On d 30 of pregnancy, multiparous beef cows were randomly assigned to dietary treatments of 100% (CON; n = 6) or 60% of NRC recomendations (RES; n = 6). Cows were individually-fed once daily using Calan gates at 1000 h. On d 85 of gestation, fetal blood flow was determined via Doppler ultrasonography followed by cow slaughter. Ultrasound measurements included fetal heart rate (HR), umbilical blood flow (uBF), pulsatility index (PI), and resistance index (RI). Fetal PI and RI were not affected ($P \geq 0.19$) by maternal restriction, while fetal HR was decreased ($P = 0.006$) in RES vs. CON fetuses. Umbilical BF, uBF relative to placental weight, and uBF relative to cotyledon weight were not affected by maternal nutrient restriction, while uBF relative to fetal weight was decreased ($P = 0.03$) in RES vs. CON. Fetal weight tended to be greater ($P = 0.07$) in RES vs. CON fetuses. Total placentome weight was greater ($P = 0.002$) in RES vs. CON cows; however, cotyledon weight, caruncle weight, fetal membranes, and chorioallantoic/amniotic fluid volume were not different ($P > 0.27$) between treatments. Placental efficiency (fetal weight: placentome weight ratio) tended to be greater ($P = 0.10$) in CON vs. RES cows. Heart girth and ponderal index were increased ($P = 0.004$) in RES vs. CON fetuses, while biparietal distance and crown rump length were not different ($P \geq 0.28$) between treatments. Maternal nutrient restriction during early gestation increased fetal growth and placentome weight, while uBF was decreased relative to fetal weight. Therefore, it would appear that maternal nutrient restriction leads to compensatory fetal and placental development during early gestation.

Key Words: maternal restriction, pregnancy, umbilical blood flow

30 Serum exosome profile as related to early pregnancy status in the mare.

J. R. Hergenreder,* J. C. da Silveira, A. D. Belk, D. N. R. Veeramachaneni, J. G. Bouma, and J. E. Bruemmer, *Colorado State University, Fort Collins.*

During early pregnancy the conceptus and mare must communicate to establish and maintain pregnancy. This is most pronounced between d 12 and 16 post-ovulation. The mechanism behind successful establishment of pregnancy in the mare is unknown. Recently, cell-secreted vesicles, called exosomes, were detected in high amounts in serum of pregnant women. Exosomes are 50–100 nm vesicles containing bioactive materials such as mRNA, miRNA, and protein that can mediate immune-responses through membrane protein interaction and delivery of products into cells. Exosomes have been described in body fluids, including urine, milk, and serum. We hypothesized that exosomes are present in mare serum and that their amount differs with pregnancy status. To test this, we determined the presence and relative amount of exosomes in serum of pregnant and non-pregnant mares. Serum samples were obtained from mares in a crossover design, with each mare serving as a pregnant treatment and non-mated control (n = 3/d). Blood samples were obtained on d 12, 14, 16, and 18 post-ovulation. Serum was removed and stored at −80°C. Exosome isolation, for flow-cytometry and transmission electron microscopy (TEM), was performed using ExoQuick (System Biosciences, Inc.), a precipitation solution designed to isolate exosomes. Samples were analyzed using flow cytometry with 100 nm sized beads as a size control and a counting bead standard for relative amount determination. Flow cytometry analysis revealed exosomes in both pregnant and non-pregnant mares and the presence of 2 distinct size populations, one of exosomes smaller (<100 nm) than previously described, which were more abundant in mare serum from d 12 of pregnancy, and the second of the expected 100 nm size at each day examined. TEM analysis validated the results from the flow cytometry as each population was characterized visually. Along with the 100 nm and slightly smaller sized vesicles, TEM also revealed the presence of vesicles slightly larger than 100 nm, with small amounts of vesicles ~200 nm in size, indicating the presence of microvesicles as well. We conclude that exosomes are present in mare serum and further characterization of such populations can provide clues about the intercellular mode of communication in early pregnancy.

Key Words: mare, pregnancy, exosome

31 Effects of natural service and artificial insemination breeding systems on pregnancy rates and days to conception.

P. L. Steichen*[1], S. I. Klein[1], Q. P. Larson[1], K. M. Bischoff[2], V. G. R. Mercadante[2], G. C. Lamb[2], C. S. Schauer[3], B. W. Neville[4], and C. R. Dahlen[1], [1]*Department of Animal Sciences, North Dakota State University, Fargo,* [2]*North Florida Research and Education Center, University of Florida, Marianna,* [3]*Hettinger Research Extension Center, North Dakota State University, Hettinger,* [4]*Central Grasslands Research Extension Center, Streeter, ND.*

Four hundred 80 crossbred beef cows and 86 crossbred beef heifers were used to compare the effects of 2 breeding systems on pregnancy rates and days to conception. Cattle were stratified by age and BCS, and assigned randomly to 1 of 2 treatments: 1) Females exposed to natural service bulls for the duration of the breeding season (NS; n = 284), or 2) females exposed to estrous synchronization and a fixed-timed AI (d 0; 7-d Co-Synch + CIDR), followed by exposure to natural service bulls for the duration of the breeding season (AI, n = 282). Bulls were introduced on d 1 and both treatments were managed as a cohort in the same pastures. Blood samples were collected on d −20 and −10 to determine cyclic status. On d 49 and again at least 40 d after bull removal from pastures, transrectal ultrasonography was used to determine pregnancy status and fetal age. Overall, 42.8% of cattle were cyclic at the beginning of the breeding season. Treatment × cyclic status interactions ($P < 0.01$) were present for the proportion of cows detected pregnant on d 49, the proportion of cows pregnant at the end of the breeding season, and days from the beginning of the breeding season to conception. A greater proportion ($P < 0.05$) of cyclic cattle in the AI treatment (88%, 104 of 118) had a viable fetus detected on d 49 of the breeding season compared with cyclic cattle in the NS treatment (74%, 88 of 119) and non-cyclic cattle in the AI (75%, 122 of 163) and NS treatments (77%, 120 of 156). A greater percentage ($P < 0.05$) of cyclic cattle in the AI treatment (94%, 111 of 118) were pregnant at the end of the breeding season compared with non-cyclic cattle in the AI treatment (84%, 136 of 162) whereas cyclic (88%, 105 of 119) and non-cyclic (89%, 140 of 157) cattle in the NS treatment were intermediate. Both cyclic (11.6 ± 1.4 d) and non-cyclic (14.5 ± 1.4 d) cattle in the AI treatment became pregnant earlier in the breeding season ($P < 0.05$) compared with cyclic (19.9 ± 1.4 d) and non-cyclic (17.9 ± 1.4 d) cattle in the NS treatment. Breeding systems for beef cattle that incorporated AI altered pregnancy rates and days to conception compared with natural service breeding systems.

Key Words: artificial insemination, estrous synchronization, natural service

32 Evaluation of the ability of grain distillers dried yeast to replace fish meal in the diets of juvenile rainbow trout *Oncorhynchus mykiss*.

B. S. Hauptman*[1], F. T. Barrows[3], S. Block[4], T. G. Gaylord[2], W. M. Sealey[2], and J. A. Paterson[1], [1]*Montana State University, Bozeman,* [2]*USFWS, Bozeman Fish Technology Center, Bozeman, MT,* [3]*USDA, Agriculture Research Service, Bozeman, MT,* [4]*Archer Daniels Midland Company, Decatur, IL.*

Grain distillers dried yeast (GDDY) is a single-cell protein obtained as a co-product during the production of fuel ethanol and may have potential as an alternative protein source for rainbow trout. The objective of the current study was to determine if GDDY could replace fish meal (FM) without negatively affecting growth performance and proximate composition of juvenile rainbow trout. A 2-phase approach was employed where a digestibility trial was first conducted to determine GDDY apparent digestibility coefficients (ADCs) for protein, lipid, energy, DM, and apparent availability coefficients (AACs) for P and amino acids. The second phase was to conduct a feeding trial where a control diet (42% digestible protein and 20% crude lipid with 25% FM) was compared with diets where FM digestible protein was replaced by GDDY at 7 different levels (25, 37.5, 50, 62.5, 75, 87.5, and 100%). All diets were formulated to provide equal amounts of available lysine, methionine, threonine and total P. Diets were fed twice daily to rainbow trout (initial weight 22.1g + 0.26) to apparent satiation in a 15°C recirculating system. There were 4 replicate tanks per diet (30 fish/tank) and diets were fed for 9 weeks. Bulk tank weights and feed intake (FI) were determined every 3 weeks. At conclusion of the feeding trial, 3 fish per tank were sampled for condition indices and proximate composition analyses. Grain distillers dried yeast ADCs for protein, DM, lipid, energy and AAC for P were quantified at 98, 65, 100, 70 and 81%, respectively. Feeding trial results showed that fish performance was not significantly different from the control diet at the 25% and 37.5% replacement levels. However, reduced growth ($P < 0.001$) and poorer feed conversion ($P < 0.001$) were observed when GDDY replaced more than 37.5% of dietary FM (11.2% GDDY inclusion). Feed intake, proximate composition and protein retention efficiency were not significantly affected by GDDY inclusion level. Apparent digestibility coefficients suggested that GDDY nutrients were highly digestible and FI measurements suggest no palatability issues; however, growth was reduced after extended feeding at higher inclusion levels.

Key Words: grain distillers dried yeast, alternative protein, rainbow trout

33 Differences in allele frequency distribution of bovine high-density genotyping platforms in Holsteins and Jerseys. K. L. Weber*[1], G. Rincon[1], A. L. Van Eenennaam[1], B. L. Golden[2], and J. F. Medrano[1], [1]*Department of Animal Science, University of California, Davis,* [2]*Dairy Science Department, California Polytechnic State University, San Luis Obispo.*

Two single nucleotide polymorphism (SNP) genotyping arrays, the Illumina High-Density Bovine BeadChip Array (BovineHD; 777,962 SNP) and the Affymetrix Axiom Genome-Wide BOS 1 Array (BOS1; 648,874 SNP), are available for bovine genomics analyses, such as quantitative trait loci (QTL) fine mapping and genomic selection. These genotyping arrays are of interest to researchers for their high marker density relative to other genotyping platforms. Differences in allele frequency distribution between arrays contributes to their efficacy for association studies as QTL may have rare alleles (low minor allele frequency, MAF), limiting the extent of linkage disequilibrium (LD) possible with intermediate MAF SNP. To evaluate MAF distribution differences between arrays in Holstein (HO) and Jersey (JE) breeds, we genotyped 16 DNA samples (10 HO, 6 JE) from UC Davis cows and their sires with both BovineHD and BOS1, and MAF distribution was determined within breed. A greater proportion of SNP had MAF equal to zero in BOS1 relative to BovineHD (HO: BOS1 45% vs. BovineHD 28%; JE: BOS1 55% vs. BovineHD 39%), which given the fewer number of total SNP in BOS1 resulted in fewer BOS1 SNP for all MAF. However, of polymorphic SNP, low to intermediate MAF SNP (MAF ≤ 0.20) were proportionally more highly represented in BOS1 (HO 45%; JE 42%) relative to BovineHD (HO 38%; JE 39%). An important issue in genotyping arrays is marker redundancy. SNP in complete LD have collinear effects, reducing the accuracy and stability of marker effect estimates when jointly analyzed. To evaluate if removal of redundant SNP altered the MAF distribution in BovineHD and BOS1, LD pruning was performed using SVS7. Using the LD threshold $r^2 \geq 0.99$, a greater proportion of polymorphic SNP were removed from BovineHD relative to BOS1 (HO: BovineHD 75% vs. BOS1 57%; JE: BovineHD 86% vs. BOS1 79%), yielding more informative SNP at nearly all MAF in BOS1 for HO (+18,775 SNP). The proportion of low MAF SNP in BOS1 (HO 37%; JE 32%) became similar to BovineHD (HO 34%; JE 31%), and the correlation between BovineHD and BOS1 MAF distributions rose in HO (0.58 to 0.95) but did not change in JE.

Key Words: genotyping, SNP, cattle

34 Comparing the lifetime productivity of beef females initially conceiving to, or sired by, artificial insemination or natural service. B. J. Bigler,* J. T. French, J. K. Ahola, J. C. Whittier, W. M. Frasier, G. E. Seidel, R. M. Enns, and R. K. Peel, *Colorado State University, Fort Collins.*

Artificial insemination and estrous synchronization can be valuable tools for the beef cattle industry due to the ability to increase productivity and reproductive efficiency. Therefore, the objectives of this study were to: 1) compare lifetime productivity between heifers that conceived to AI with those that conceived to natural service (NS) as a yearling, and 2) compare lifetime productivity between females that were the result of an AI mating with those that were the result of an NS mating. Calving and breeding records (n = 6,693) were utilized from 1,173 Angus females collected at 1 location from 1991 to 2010. The first objective classified heifers into 2 groups: conceived by AI or NS. The second objective categorized females into 4 dam groups, depending on whether they were conceived by an AI bred heifer (H-AI), an NS bred heifer (H-NS), an AI bred cow (C-AI), or an NS bred cow (C-NS). Cutoff dates were formulated to distinguish between AI and NS born calves by documenting the AI date and summing a 290-d gestation length. Economic significance was analyzed using weaning weights from all calves produced by each female while in the herd, along with price data collected from the nearest marketing center. Yearling heifers that conceived to AI were older and heavier ($P = 0.02$) at breeding than heifers that conceived by NS. When compared with heifers that were conceived by NS, females that conceived through AI had a greater ($P < 0.001$) average weaning weight, weaned more ($P < 0.001$) weight, and produced more ($P < 0.001$) total calves. Consequently, females that conceived to AI as yearlings yielded greater ($P < 0.001$) revenue throughout their lifetime in the cow herd than heifers that conceived to NS. There was a positive correlation between heifer age at breeding and lifetime productivity. These data suggest that if the majority of a beef cow herd calves within the first 30 d of the breeding season, producers can maximize the productivity and efficiency of each female, and as a result, increase total revenue per cow.

Key Words: artificial insemination, lifetime productivity, natural service

35 Identification of single nucleotide polymorphisms associated with feed efficiency in rams. R. R. Cockrum*[1], N. K. Pickering[2], R. M. Anderson[2], D. L. Hyndman[2], M. J. Bixley[2], K. G. Dodds[2], R. H. Stobart[1], J. C. McEwan[2], and K. M. Cammack[1], [1]*University of Wyoming, Laramie,* [2]*AgResearch Limited, Mosgiel, New Zealand.*

Residual feed intake (RFI) is a measure of efficiency that is time consuming, expensive, and labor intensive to obtain, making it an ideal trait for marker-assisted selection. The objectives of this research were to 1) identify single nucleotide polymorphisms (SNPs) and heritability associated with feed efficiency in sheep and 2) trace identified SNPs to the corresponding gene or genomic region. We hypothesized that regions of the genome corresponding to feed efficiency could be identified using the Ovine SNP50 BeadChip. Individual intake measurements were collected on rams from 2 separate ram tests (Dual Purpose Ram Test and Blackface Ram Test) at the University of Wyoming Ram Test (n = 328) from 2009 to 2011 using the GrowSafe System. Individual RFI (actual feed intake – predicted feed intake) values were generated. Blood was collected via the jugular and DNA was isolated. Single nucleotide polymorphisms in ram DNA were genotyped using the Ovine SNP50 BeadChip on the Illumina Infinium HD BeadChip Assay. Percentage loci scored per animal and locus, Hardy Weinberg deviations, animal information comparison, replicate sample reproducibility, and unusual allelic ratio analyses were conducted through Genome Studio and R for quality control analysis resulting in 50,896 SNPs used in the analysis. A genome wide association study (GWAS) analysis was conducted in R using the GenABEL package to identify SNPs using a polygenic model, $Y = \mu + G + e$, where μ is the intercept, G is the polygene, and e is the random residual, and estimate heritability. The SNP associated with *RXFP2* was used to confirm the accuracy of the polygenic model resulting in a high association ($P = 9.283^{-04}$) with the horn phenotype. Heritability for RFI was estimated as 0.14, which is similar to reports in cattle. Genome wide threshold ($P \leq 0.00025$) was obtained for 4 SNPs. Corresponding genes to identified SNPs were determined using the UCSC Genome Browser. Corresponding genes included zinc finger 1 (*Glis1*), interleukin 1 receptor accessory protein-like 1 (*IL1RAPL1*), and sex-determining region y – box 5 and 6 (*SOX5* and *SOX6*). Though 4 potential markers for RFI were identified, sample size must increase and markers must be validated for marker-assisted selection use.

Key Words: residual feed intake, sheep, single nucleotide polymorphism

36 Out-of-season reproductive performance of ewes synchronized to estrus with various 5-d protocols. C. G. Jackson*[1], T. L. Neville[1], V. R. G. Mercadante[2], K. M. Bischoff[2], G. C. Lamb[2], C. R. Dahlen[1], and R. R. Redden[1], *[1]North Dakota State University, Fargo, [2]North Florida Research and Education Center, University of Florida, Marianna.*

The objective of this experiment was to evaluate the reproductive performance of ewes after synchronization to estrus with progesterone (P_4) impregnated controlled internal drug release (CIDR) inserts in combination with GnRH and PG. Dorset and Katahdin ewes (n = 61 and 17; respectively) were assigned randomly during the anestrous period (April) to 1 of 4 treatments: 1) Untreated (U; n = 16); 2) CIDR (0.3 g P_4) inserts for 5 d (C; n = 21); 3) CIDR insert for 5 d and PG (dinoprost, 10 mg i.m.) at CIDR removal (P; n = 20); and 4) GnRH (gonadorelin, 0.02 mg i.m.) at CIDR insertion and PG at CIDR removal (G; n = 21). Rams equipped with marking harnesses were introduced at CIDR removal (d 0) and ewes were checked at 0800 h and 1700 h daily for breeding marks. Blood samples were collected via jugular venipuncture on d −12, −5, 0, 1, 2, 3, 4, 5, 8, 11, 14, 17, and 20 relative to CIDR removal and analyzed for serum concentrations of P_4 via RIA. Reproductive performance data were collected which included: days to estrus, days to lambing, percentage of ewes exhibiting estrus, pregnancy rate, lambing rate, and prolificacy. There was a treatment × time interaction ($P \leq 0.05$) for concentrations of P_4. Concentrations of P_4 were decreased ($P \leq 0.04$) in G compared with U on d 2. On d 14, C and P had greater ($P \leq 0.03$) concentrations of P_4 and G tended ($P = 0.06$) to have greater P_4 concentrations compared with U. In contrast, concentrations of P_4 on d 20 were greater ($P \leq 0.03$) in U compared with C. Days to estrus after CIDR removal, as indicated by breeding marks, were greater ($P \leq 0.02$) in U (6.5 ± 1.05) and P (5.90 ± 0.88) compared with G (2.98 ± 0.88). Pregnancy rate within 7 d post CIDR removal were similar ($P = 0.57$) for U, C, P, and G (30 ± 12.27, 30 ± 11.12, 35 ± 10.96, and 51 ± 10.78%; respectively). Similarly, no differences ($P \geq 0.32$) were detected for all remaining reproductive performance data. It appeared the 5 d CIDR coupled with GnRH and PG improved estrus synchronization; however, reproductive performance was not clearly improved by either of the 5 d CIDR protocols. These results warrant further research to determine the efficacy of industry-wide application of the 5 d CIDR in anestrous ewes.

Key Words: CIDR, ewe, synchronization

37 Effects of maternal fluoxetine dosage on lamb serum hormone concentrations and reproductive traits. P. L. Black,* D. M. Hallford, and T. T. Ross, *New Mexico State University, Las Cruces.*

Fluoxetine (human anti-depressant; selective serotonin reuptake inhibitor; FLX) depresses lactation in women and research has been conducted to evaluate sheep as a human lactation model. Fluoxetine has been shown to appear in the milk, yet little is known on how this drug will influence progeny. Our objective was to evaluate the effect of maternal FLX exposure on lamb growth and development. We utilized a completely randomized design with 18 mature Suffolk ewes (BW = 91 ± 12 kg; BCS = 2.0 ± 0.5). Treatments consisted of 0 (control) and 80 mg FLX; ewes were individually fed FLX using ground corn as the carrier at 0700 beginning on approximately d 126 of gestation and continued until 3 wk postpartum. The resulting 31 Suffolk-cross lambs were weighed at birth (birth weight = 4.6 ± 1.0 kg) and weaning (BW = 24.0 ± 3.2 kg; approximately 9 wk of age) and ADG was calculated. Blood samples were taken from lambs on d 1, 3, 5, 7, 14, 21, 28, 42, 56, and 66 and serum was analyzed for serum prolactin (PRL), IGF-I, and triiodothyronine (T_3) concentrations. Following weaning, ewe lambs were kept for subsequent evaluation. A total of 21 Suffolk-cross ewe lambs (BW = 44.7 ± 4.3 kg) were evaluated for age at puberty and pregnancy rate. No additional treatment was administered, as we only wanted to evaluate the effect of maternal FLX. Average daily gain from birth to weaning was similar ($P = 0.42$) between control and FLX-exposed lambs. Lambs exposed to maternal FLX had depressed PRL ($P = 0.01$), IGF-I ($P < 0.0001$), and T3 ($P = 0.04$) compared with controls. Age at first cycle was similar ($P = 0.53$) between FLX-exposed and control ewe lambs. Similarly, pregnancy rates were comparable ($P = 0.37$) between both control and FLX-exposed ewe lambs. Maternal supplementation of FLX reduced PRL, IGF-I, and T_3 serum concentrations in lambs, however this did not appear to have a negative effect on growth or reproductive performance.

Key Words: fluoxetine, growth, sheep

38 Digestibility of algal biofuel co-product in a forage diet. M. K. Beckman,* L. N. Tracey, N. Miller, K. Norman, K. Marchetti, E. J. Scholljegerdes, S. A. Soto-Navarro, C. L. Löest, and S. L. Lodge-Ivey, *New Mexico State University, Las Cruces.*

Co-product produced from extraction of oil from microalgae grown for biofuel production represents a novel feedstuff for ruminants. The objective of this study was to determine the influence of lipid extracted algae (LEA) on feed intake and diet digestibility when included in a forage diet. We hypothesized that an isonitrogenous addition of LEA to a forage diet would yield results similar to soybean meal (SBM). Fifteen crossbred wethers (43 ± 1.4 kg BW) fitted with ruminal and duodenal cannulas were used in a completely randomized design. Lambs were fed twice per day at 110% of previous 3 d DMI. Experimental diets included: 1) sorghum-sudan hay (CP 8.3%; NDF 52.79%, DM basis; HAY), 2) sorghum-sudan hay plus LEA (CP 13.6%; NDF 44.19% DM basis; ALGAE), and 3) sorghum-sudan hay plus SBM (CP 10.6%; NDF 51.24%, DM basis; SOY). Animals were adapted to treatments for 10 d followed by 5 d sample collection. Treatment did not influence OM intake ($P = 0.99$) or total tract OM and NDF digestibility ($P > 0.10$). Total tract CP digestibility was lowest for ALGAE while SOY and HAY did not differ (75.86 vs 84.88 and 82.12 ± 1.177%, respectively; $P < 0.01$). Ruminal pH, liquid dilution rate, and volume did not differ ($P > 0.10$) by treatment. Soybean meal increased ($P < 0.01$) ruminal ammonia by 57.4% and 56.0% compared with ALGAE and HAY, respectively. Total VFA production and molar proportion of butyrate did not differ ($P > 0.14$) by treatment. Acetate was highest for HAY, lowest for SOY, and ALGAE did not differ from HAY and SOY (74.11, 71.57, and 69.07 ± 1.245 mol/100 mol for HAY, ALGAE, and SOY, respectively; $P = 0.04$). Propionate was greatest for ALGAE which differed from HAY, while SOY was similar to ALGAE and HAY (14.80, 19.89, and 17.85 ± 1.233 mol/100 mol HAY, ALGAE, and SOY, respectively; $P = 0.04$). Acetate:propionate ratio was lowest ($P = 0.03$) for ALGAE. Adding ALGAE to a forage diet resulted in increases in propionate production while OM and NDF digestibility was comparable to SOY. However, ALGAE resulted in the lowest ruminal ammonia and total tract CP digestibility. These data imply that CP in LEA may not be as soluble as CP in SBM, therefore we reject our hypothesis.

Key Words: biofuels, sheep, digestibility

39 Effects of preovulatory estradiol concentration on embryo survival and pregnancy establishment in beef cows.

C. A. Roberts*[1,3], G. A. Perry[3], M. D. MacNeil[1], M. A. Minten[2], and T. W. Geary[1], *[1]USDA-ARS Fort Keogh, Miles City, MT, [2]Washington State University, Pullman, [3]South Dakota State University, Brookings.*

The role of estradiol during the preovulatory period on embryo survival and pregnancy establishment has not been characterized in beef cows. We hypothesized that preovulatory estradiol is important for embryo survival and pregnancy establishment. To establish the importance of estradiol during the preovulatory period on embryo survival, ovariectomized multiparous cows (n = 26) received estradiol cypionate (ECP), estradiol benzoate (EB) or no treatment (CON) to mimic a preovulatory period. Prior to treatment, all cows received a progesterone-releasing device (CIDR) for 7 d, 25 mg injection of prostaglandin-F2α (PGF) at CIDR removal (d −2), and an injection of GnRH (100 µg; d 0) 2 d later to mimic the follicular phase. Utilizing a 3 × 3 Latin Square design, cows received either ECP 36 h before GnRH injection, EB 12 h before GnRH injection, or no estradiol (CON). Luteal phase progesterone was mimicked with 2× daily increasing progesterone injections from d 3 to 6 and use of CIDRs from d 7 to 29. On d 7 after GnRH injection, each cow received one embryo and a CIDR. Another CIDR was added 24 h following embryo transfer and every 6 d, the older of the 2 CIDRs was replaced with a new CIDR. Blood was collected every 4 h between d −2 and d 0 for characterization of serum estradiol profiles. Blood was collected on d −2, −1, 0, 3 to 7, 13, and 17 to 29 to characterize progesterone profiles. Serum estradiol profiles were different ($P < 0.001$) between treatments. Mean serum progesterone concentrations were decreased ($P = 0.05$) for EB and ECP treated cows compared with CON. Transrectal ultrasonography on d 29 indicated that 4% of CON, 29% of EB, and 21% of ECP treated cows were pregnant. Expression of interferon stimulated genes ISG15, Mx2, and Oas1 on d 19 indicated 66.0% of CON, 69.3% of EB, and 71.0% of ECP treated cows were pregnant. Thus, 62, 39.7, and 50% of pregnancies in CON, EB, and ECP treated cows, respectively were lost from d 19 to 29. Overall, results indicate greater embryonic survival and pregnancy establishment in cows exposed to estradiol in the preovulatory period.

Key Words: estradiol, embryo survival, pregnancy establishment

40 Individual mineral supplement intake by ewes swath grazing or confinement fed pea-barley forage.

D. L. Ragen*[1], E. E. Nix[1], P. G. Hatfield[1], R. L. Endecott[2], and J. G. P. Bowman[1], *[1]Montana State University, Bozeman, [2]Montana State University, Miles City.*

Sixty mature ewes (non-pregnant, nonlactating) were used in a completely randomized design to determine if feeding method of pea-barley forage (swath grazing or hay in confinement) had an effect on individual ewe mineral consumption. Thirty ewes were randomly allocated to 3 confinement pens and 30 ewes were randomly allocated to 3 grazing plots. Targhee ewes (65.4 ± 5.84 kg BW) were used in 2010. Rambouillet ewes (61.9 ± 6.28 kg BW) were used in 2011. The study was conducted during September 25-October 15, 2010 and September 6–19, 2011. Ewes had ad libitum access to food, water, and a mineral supplement containing 11–12.5% salt with 2% TiO_2 added as an external marker to estimate individual mineral intake. On d 1 of the data collection period, mineral/TiO_2 was weighed and placed in feeders in confinement pens and grazing plots. At the end of the collection period, remaining mineral was weighed and consumed mineral was recorded to provide an estimate of total mineral intake via disappearance. Forage intake was calculated using estimates of fecal output obtained by dosing gelatin capsules containing 2 g Cr_2O_3 every day for 14 d, and in vitro 48 h DM digestibility. Fecal grab samples were collected from each individual ewe for a period of 7 d and composited. Forage and mineral intakes were analyzed using individual ewe as the experimental unit. A year x treatment interaction ($P < 0.001$) existed for forage DMI and mineral DMI. Ewes in confinement consumed more forage than grazing ewes in 2010 (2.60 vs. 1.86 kg/d, respectively), but less than grazing ewes in 2011 (1.99 vs. 2.49 kg/d, respectively). Mean mineral intake was highest ($P < 0.001$) by grazing ewes in 2011 and 2010 (average 69 g/d), intermediate by ewes in confinement in 2010 (57 g/d), and lowest by ewes in confinement in 2011 (31 g/d). In this study, swath grazing ewes consumed more mineral than ewes in confinement, indicating that producers may want to provide a larger quantity of mineral to ewes swath grazing.

Key Words: mineral, confinement, swath

41 Effects of weaning age and winter development environment on heifer grazing distribution.

N. L. Hojer*[1], M. B. Hubert[2], P. S. Johnson[2], M. H. Price[3], and K. C. Olson[2], *[1]South Dakota State University, Brookings, [2]South Dakota State University, Rapid City, [3]South Dakota School of Mines & Technology, Rapid City.*

The objective of this experiment was to determine if early weaning (approximately 125 d) vs. normal weaning (approximately 250 d) and wintering replacement heifers in drylot vs. rangeland affected heifer grazing distribution during the subsequent summer. Heifer calves from the 2009 and 2010 calf crop (n = 104 and 73, respectively) were allocated to the 2 weaning treatments and then stratified by age into the 2 winter development treatments. During the summer of yr 1 heifers were allocated to 2 pastures by winter treatment, and in yr 2 all 4 treatment combinations were allocated to separate pastures. A subset of heifers from each group were selected to wear global positioning system (GPS) collars (n = 2 and 5 in yr 1 and 2, respectively). Readings were taken from the GPS every 15 min in yr 1 and every 65 s in yr 2. The GPS coordinates were then analyzed relative to ecological sites,

water locations, fence locations, and temperature using Arc GIS (Esri, Redlands, CA). Winter treatment affected ($P < 0.05$) mean distance from fence lines, preference index (PI) for claypan and loamy sites in 2010, and distance from water in 2011. Day of sampling affected ($P < 0.05$) claypan and loamy site PI in 2010 and thin claypan site PI in 2011. Day of sampling interacted with winter treatment ($P < 0.05$) for distance from water in 2010, sand and thin claypan site PI in 2010 and thin claypan site PI in 2011, while day of sampling interacted with weaning treatment for distance from water in 2011. A winter by weaning treatment interaction affected ($P < 0.05$) thin claypan site PI in 2011. There was a 3-way interaction ($P < 0.05$) between weaning treatment, winter treatment and ambient temperate on the distance from water in both years and between weaning treatment, winter treatment and day of sampling on claypan and sand site PI in 2011. In conclusion, winter development influenced patterns of range utilization. Day-of-sampling interactions indicated that range heifers did not adjust preferences and thus were already adapted to the range environment, whereas drylot heifers adjusted preferences over time suggesting they re-learned how to utilize the range environment.

Key Words: heifer development, grazing distribution, weaning

42 Effects of distillers dried grains with solubles supplementation on grazing and subsequent feedlot performance of heifers grazing northern Great Plains rangelands.

Q. P. Larson*[1], R. J. Maddock[1], P. L. Steichen[1], K. K. Karges[2], and B. W. Neville[3], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]Dakota Gold Research Association, Sioux Falls, SD, [3]Central Grassland Research Extension Center, Streeter, ND.*

The objectives of this study were to evaluate the effects of distillers dried grains with solubles (DDGS) supplementation on animal performance while grazing northern Great Plains rangeland, as well as the effects of supplementation on subsequent feedlot performance and carcass characteristics. Eighty-two yearling heifers (319.5 ± 4.0 kg) were utilized in a completely random design to examine the outlined objectives. Heifers were stratified by BW and randomly assigned to 1 of 6 groups, with each group randomly assigned to 1 of 2 treatments: 1) no supplement and 2) DDGS supplemented at 0.6% BW. Stocking rates were 1AU/1.6 ha. Distillers dried grains with solubles were delivered daily and placed in plastic lined feed bunks. This study consisted of 2 portions a 74 d grazing phase and a 109 d finishing phase. Feedlot pens coincided with grazing pastures. All heifers received a common corn-based finishing ration for the duration of the 109 d finishing study. At the start of the grazing portion, initial BW was not different ($P > 0.09$). Final BW and ADG were greater for heifers supplemented DDGS ($P \leq 0.03$) during the grazing portion of this project. Heifers supplemented DDGS gained an additional 0.21 kg/d and came off pasture 11.21 kg heavier than heifers not receiving DDGS. No differences in animal performance were observed ($P \geq 0.13$) during the finishing phase. No differences in carcass characteristics were observed ($P \geq 0.23$). Although not statistically different, heifers receiving DDGS had greater marbling scores (Modest-514) compared with unsupplemented heifers (Small-470). Producers could benefit from this small increase in marbling scores; allowing the carcasses to qualify for certified programs possibly resulting in premium returns. Distillers dried grains with solubles improved average daily gain of yearling heifers grazing northern Great Plains rangeland with no adverse effects on feedlot performance or carcass characteristics.

Key Words: distillers dried grains with solubles, feedlot performance, yearling cattle

43 Effects of post-AI nutrition on reproductive and growth performance of yearling beef heifers.

R. P. Arias*[1], P. J. Gunn[2], R. P. Lemenager[2], G. A. Bridges[3], and S. L. Lake[1], *[1]University of Wyoming, Laramie, [2]Purdue University, West Lafayette, IN, [3]University of Minnesota, St. Paul.*

The objective of this study was to determine the effects of a change in nutritional plane during the 21 d immediately following artificial insemination, on growth performance and conception rates of yearling Angus heifers. This experiment was conducted at the University of Wyoming (Loc. 1) and Purdue University, IN (Loc. 2) using a total of 151 animals (n = 98 and 53 respectively). Prior to initiation, heifers were fed 0.68 kg/d between weaning (~7 mo of age) and breeding (~14 mo of age) to obtain a BW of approximately 65% of their mature weight by the beginning of the breeding season. Immediately following routine estrous synchronization and AI, heifers (BW = 931 ± 643.7 kg) were randomly assigned to 1 of 3 nutritional treatments for a 21 d nutritional study: 1) formulated to meet NRC (2000) requirements for heifers to gain approximately 0.68 kg/d (GAIN); 2) formulated to meet NRC (2000) nutrient requirements for maintenance only (MAINTAIN), and 3) formulated to provide 80% of the NRC, 2000 energy requirement for maintenance (LOSS). Two linear pre-planned orthogonal contrasts (Proc GLM; SAS Inst. Inc., Cary, NC) were used to compare effects of GAIN vs. others and MAINTAIN vs. LOSS. No treatment*location interaction ($P = 0.73$) was detected. Heifers fed the GAIN treatment had greater ($P = 0.04$) first-service conception rates (76.5%) when compared with the other 2 treatments (58.5%) overall. No differences were detected between MAINTAIN (56.2%) and LOSS (60.8%). As expected, ADG were greater ($P < 0.01$) for heifers fed the GAIN diet (0.78 kg/d) and greater ($P < 0.01$) for heifers on the MAINTAIN (0.06 kg/d) diet compared with heifers on LOSS treatment (−0.35 kg/d). These results suggest that even small changes in nutrition during the 21 d immediately after breeding can reduce conception rates. Data suggests that keeping heifers on a similar plane of nutrition before breeding and maintaining it through the first 21 d post-AI is beneficial.

Key Words: heifers, reproduction, nutrition

44 Dietary intake in a group of old mares.

S. Otabachian* and T. Hess, *Colorado State University, Fort Collins.*

Dietary intake for 32 old (21.9 ± 0.65), non-pregnant, idle mares was tracked between February to July and was compared with the 2007 National Research Council predicted values for idle maintenance horses. Mares were maintained in stalls with access to ad libitum water and a salt block. Dietary intake was assessed weekly and changes were averaged. A mix diet of alfalfa and grass hay with commercial grain concentrates were weighed, fed twice a day, and any refusals were recorded. Caloric intake per kilogram of body weight was calculated by dividing the total calorie intake by the body weight (kg). Hay was analyzed for DE, CP, ADF, NDF, lignin, ethanol soluble carbohydrates (ESC), water soluble carbohydrates (WSC), starch, crude fat (CF), and minerals. Nutrient intake was analyzed by ANOVA and significant differences among months compared by least squares means analysis. Regressions were calculated between predicted and actual nutrient intake including BCS in the regression if significant. Overall, actual caloric intake was 13.8% higher than predicted caloric intake ($P < 0.0001$); more specifically, in the month of June, actual was higher than predicted by 21.6%. In addition, actual intake of CP, Ca, P, Mg, Zn, and Cu was higher in June than predicted intake of those same nutrients ($P < 0.0001$) in all other months. WSC and CF intake increased ($P = 0.03$; $P = 0.02$) from May (WSC = 6.7%; CF = 0.49%) to July (WSC = 7.6%; CF = 0.59%), occurred with the increase in DMI from May to June. Dietary caloric intake increased

by an average of 20% from May to July and BCS increased ($P < 0.05$) from 5.8 to 6.4; yet NCS ($P = 0.71$) and BW ($P = 0.99$) did not vary even though most of the time the mares were fed on average, 13.8% above DE requirements. No variation was found in CP, Ca, P, K, S, Zn, and Se ($P > 0.15$) intake. When BCS was included in regression between predicted and actual BW adjusted caloric intake, results were significant, but weak ($P < 0.001$; $r^2 = 0.17$). Regression between predicted and actual CP, Ca, P, were significant but weak and intake above required levels. Although previous research has indicated that nutrient intake is similar between old and young horses, in the current study, mares did not increase in BW or BCS when fed 10% above DE requirements.

Key Words: body condition score, water soluble carbohydrates, old horse

Animal Health I

45 Histological examination of the organs of the rats administered varying levels of *Vernonia amygdalina* leaves. A. H. Ekeocha,* P. C. Ekeocha, and T. Fasola, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Histology of the liver, kidney and pancreas of rats administered with *Vernonia amygdalina* was examined. Thirty male Albino rats were divided into 6 groups of 5 rats each. Four groups with basal blood glucose levels of 88.0 ± 0.16, 89.2 ± 0.23, 85.2 ± 0.27, and 85.8 ± 0.25 mg/dL were injected with 10% alloxan in saline to make them diabetic (277.6 ± 6.55, 284.8 ± 3.80, 256.4 ± 1.39 and 265.6 ± 4.41 mg/dL fasting blood glucose (FBG) respectively). The 4 diabetic groups were then treated with different doses (g/kg of BW) of an aqueous extract of dried *Vernonia amygdalina* Leaves herein referred to as VaL. A fifth group (nondiabetic) was treated with 400mg VaL /kg BW. VaL was administered twice daily for 2wks using an oral canula. The sixth group (nondiabetic) received no VaL as a positive control. Blood was collected from the tail to determine blood glucose level on a glucometer. The FBG levels of the 6 albino rat groups were recorded every 2 d for 2 wk. At the end of wk 2, the rats were slaughtered and their liver, kidney and pancreas were examined histologically to ascertain if VaL was toxic to the organs or not. Data were analyzed using ANOVA (SAS, 1999). The plant extract was observed to have hypo-glycaemic effect on each group of diabetic rats as it reduces their fasting blood glucose (FBG) levels from 277.6 mg/dL to 142.2mg/dL (Group 1) 284.8 mg/dL to 102.0 mg/dL (Group 2), 256.4 mg/dL to 86.3 mg/dL (Group 3) and 265.6mg/dl to 82.1 mg/dL (Group 4) over a period of 2 wk. The fifth group consisting of noninduced rats was administered with 400 mg/kg of *Vernonia amygdalina* leaves for a period of 2 wk and the FBG level (91.4 to 81.6 mg/dL) was compared with that of the control group (87.1 to 86.9 mg/dL). The last group i.e the sixth group of rats used as control were only fed with feeds and given clean water only. Their FBG (86.9 mg/dL) were also checked every 2 d and compared with the FBG of the other groups from groups 1–5 (142.2, 102.0, 86.3, 82.1 and 81.6 mg/dL). The rats were sacrificed and their organs (liver, kidney and pancreas) of the experimental animals were examined histologically to ascertain if 400 mg/kg of the plant extract was toxic to the organs. The results show that the plant extract had no adverse effect when administered on normal rats except for a marked congestion of the mesenteric blood vessel. The extract reduced the level of damage to the kidney, liver and pancreas when administered on diabetic rats, which is an indication that the plant extracts of *Vernonia amygdalina* leaves has antidiabetic properties that slowly heals partly damaged organs but not packed up organs.

Table 1. Fasting blood sugar (mg/dL) of normal and induced-diabetic albino rats administered with varying doses of Vernonia amygdalina leaf extracts

Day	G1	G2	G3	G4	G5	G6	SEM
2	277.6^{a}	284.8^{a}	256.4^{b}	265.6^{b}	91.4^{c}	87.1^{c}	8

46 Toxicological properties of liquid dishwashing detergent in Swiss albino mice. M. S. Gulay,* O. Yildiz Gulay, A. Ata, A. Demirtas, and S. Gungor, *Mehmet Akif Ersoy University, Faculty of Veterinary Medicine, Burdur, Turkiye.*

Detergent exposure can pose serious health risks to humans and animals. However, the effect of detergent exposure on animal health is yet to be studied. Thus, the aim of the current study was to investigate the toxicity of liquid dishwashing detergent on blood parameters and organ weights of male Swiss Albino mice. Fourty healthy male Swiss albino mice were randomly assigned to 5 groups of 8 animals each. Animals in TR1 served as control and received tap water while TR2, TR3, TR4 and TR5 received 0.1, 0.5, 1 and 5% v/v of the liquid detergent in tap water, respectively, as the only source of water. All treatments started right after weaning (3 wk of age) and continued for 60 d. Mice were kept in plastic cages under standard laboratory conditions. Food and water were provided ad libitum. At the end of the experiment, mice were kept under Sevorane anesthesia and blood samples were collected into Na-heparinized capillary tubes from the beating hearth. After blood collection, animals were sacrificed and internal organs were removed. Data were analyzed by one way ANOVA. Results of the current study indicate that water consumption among the groups did not differ ($P > 0.1$). There was no treatment effect on hematocrit, RBC, WBC, MCV, MCH, MCHC, total lymphocytes, monocytes, or basophils ($P > 0.1$). No effect of detergent treatment was detected on the weights of liver, kidney, spleen, lung, testis or brain ($P > 0.1$). However, total hemoglobin (TR1 = 15.2 ± 0.39, TR2 = 14.7 ± 0.35, TR3 = 14.4 ± 0.56, TR4 = 12.7 ± 0.54 and TR5 = 13.1 ± 0.40 g/dL; $P < 0.01$), plasma protein (TR1 = 6.88 ± 0.26, TR2 = 6.52 ± 0.13, TR3 = 6.71 ± 0.27, TR4 = 5.98 ± 0.11 and TR5 = 6.08 ± 0.31; g/dL $P < 0.05$), total neutrophils (TR1 = 0.83 ± 0.08, TR2 = 0.78 ± 0.13, TR3 = 0.91 ± 0.05, TR4 = 1.04 ± 0.10 and TR5 = 1.68 ± 0.41 x10^{3}; $P < 0.03$) and total eosinophils (TR1 = 0.071 ± 0.012, TR2 = 0.096 ± 0.024, TR3 = 0.082 ± 0.025, TR4 = 0.272 ± 0.092 and TR5 = 0.263 ± 0.083x10^{3}; $P < 0.03$) were affected adversely due to detergent treatment. In addition, serum alkaline phosphatase and aspartate aminotransferase levels were significantly elevated in TR4 and TR5 ($P < 0.05$). Thus, our results suggest that especially the higher doses used in the current study could be toxic and cause health risks to Swiss albino mice.

Key Words: detergent, toxicity, hematology

47 Isolation of lactobacillus strains with high adhesive ability to the intestinal epithelial cells. W. M. Zhang*[1], H. F. Wang[1,2], and J. X. Liu[1], [1]*Institute of Dairy Science, MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China,* [2]*Department of Animal Science, College of Forestry and Biotechnology, Zhejiang A & F University, Hangzhou, China.*

This study was conducted to investigate the adhesive ability of lactobacillus and how the surface proteins of lactobacillus play a vital role in its adhering to the intestinal epithelia. Intestinal mucus and chyme were collected from a 20-d-old piglet. They were spread on de Man, Rogosa, Sharpe (MRS) agar plates for the selective culture. Agar plate was incubated at 37°C under anaerobic condition for 48 h, and the visible colonies were identified using microscope after stained by methylene blue. The selected colonies of lactobacillus were cultured anaerobically in MRS broth at 37°C. The partial 16s rRNA gene fragment of lactobacillus were then PCR amplified. The 16s rRNA sequences were deposited in GenBank, aligned with Clustal W. Phylogenetic analysis of these strains was performed using MEGA 3.0. The S-layer proteins were isolated with 5 M LiCl, and then analyzed by SDS-PAGE. Eighty-five strains of lactobacillus were obtained and classified into 1 *Lactobacillus johnsonii*, 54 *L. salivarius*, and 30 *L. reuteri* strains. Depending on the phylogenetic analysis of the pictures of the colonies, 40 strains were selected to adhere to caco-2 cells as model of intestinal epithelial cells. Five of 40 strains were found to have higher adhesive ability (4.9–15.9 cfu/cell) than the others ($P < 0.05$), including 4 *L. reuteri* strains and 1 *L. salivarius* strain. They were named as *L. reuteri* ZJ616 (accession number JN981858), *L. reuteri* ZJ617 (JN981859), *L. reuteri* ZJ621 (JN981863), *L. reuteri* ZJ623 (JN981865) and *L. salivarius* ZJ614 (JN981856), respectively. These 5 strains ($P < 0.05$) inhibited the *Escherichia coli* K88 and *Salmonella enteritidis* 50335, with *L. reuteri* ZJ621 indicating the higher inhibition to *S. enteritidis* 50335 than the others ($P < 0.05$). The molecular masses of s-layer proteins from these strains ranged from 34 to 75 kDa and differed from each other ($P < 0.05$). The ability for the strains without s-layer protein to inhibit the *S. enteritidis* 50335 was reduced, indicating that the S-layer protein plays an important role in inhibiting pathogens.

Key Words: *Lactobacillus*, adhesive ability, surface proteins

48 Effect of mycotoxins on the intestine: Analysis of the interaction between fusariotoxins.

B. Grenier*[1,3], A. P. Loureiro-Bracarense[2], G. D. Pacheco[1,2], J. Lucioli[2], A. M. Cossalter[1], W. D. Moll[3], G. Schatzmayr[3], and I. P. Oswald[1], *[1]Institut National de la Recherche Agronomique-ToxAlim, Immuno-Mycotoxicology, Toulouse, France, [2]Universidade Estadual de Londrina, Lab Patologia Animal, Londrina, Brazil, [3]Biomin Research Center, Tulln, Austria.*

Most fungi are able to produce several mycotoxins simultaneously in separate feedstuffs, and considering it is a common practice to use multiple grain sources in animal diets, the risk to be exposed to several mycotoxins at the same time increases. Interactions between concomitantly occurring mycotoxins can be antagonistic, additive, or synergistic. The data on the in vivo combined toxic effects of mycotoxins are somewhat limited. Similarly, data with regard to the impact of these metabolites on intestinal functions and integrity have only gained significant interest over the last decade. Intestinal cells are the first cells to be exposed to mycotoxins, and mycotoxins specifically target high proteins turnover- and activated-cells, which are predominant in gut epithelium. We thus investigated the effect of Fusarium toxins in the gastrointestinal tract of piglets fed deoxynivalenol (DON) and fumonisins (FUMO), alone or in combination at low doses. Piglets received separate diets for 5 weeks: a control diet; a diet contaminated with either DON (3 mg/kg) or FUMO (6 mg/kg); or both toxins. Chronic ingestion of these contaminated diets induced morphological and histological changes, as shown by the atrophy and fusion of villi, the decreased villi height and cell proliferation, and by the reduced number of immune cells. Cytokines analysis (TNF-α, IL-1β, IFN-γ, IL-6, and IL-10) revealed an upregulation of their expression. In addition, ingestion of contaminated diets reduced the expression of the adherent and tight junction proteins, E-cadherin and occludin, respectively. Regarding the association of both mycotoxins, several types of interactions were observed depending on the parameters and intestinal segments assessed. In conclusion, further investigations are required to evaluate the impact of mycotoxins in intestine, especially for the multi-contamination. So far, our findings along with the current data reveal that mycotoxins may affect nutrient absorption, increase the nutrient requirement, predispose animals to infections by enteric pathogens, and lead to chronic intestinal inflammations.

Key Words: mycotoxin, intestine, co-contamination

49 Dietary supplementation of young broiler chickens with capsicum and turmeric oleoresin increases resistance to necrotic enteritis.

S.-H. Lee*[1], H. Lillehoj[1], S.-I. Jang[1], D.-K. Kim[1], M.-S. Park[1], E. Lillehoj[2], and D. Bravo[3], *[1]Animal and Natural Resources Institute, ARS-USDA, Beltsville, MD, [2]University of Maryland, School of Medicine, Baltimore, [3]Pancosma S.A., Geneva, Switzerland.*

The *Clostridium*-related poultry disease necrotic enteritis (NE) causes substantial economic losses on a global scale. In this study, a mixture of 2 plant-derived phytonutrients, capsicum oleoresin and turmeric oleoresin (XT), was evaluated for its effects on local and systemic immune responses using a co-infection model of experimental NE. Chickens were fed from hatch with a diet supplemented with XT, or with a non-supplemented control diet, and orally challenged with virulent *Eimeria maxima* oocyts at 18 d and *Clostridium perfringens* at 20 d of age. Parameters of protective immunity were (a) body weight gain, (b) gut lesions, (c) serum levels of *C. perfringens* α-toxin and NetB toxin, and (d) intestinal levels of proinflammatory cytokine/chemokine gene transcripts. Chickens fed the XT-supplemented diet had increased body weight gains and reduced gut lesion scores compared with birds given the non-supplemented diet. The XT-fed group also displayed decreased serum α-toxin and NetB toxin levels and reduced intestinal IL-8 and LITAF mRNA levels, but increased TNFSF15 mRNA levels, compared with non-supplemented controls. In conclusion, this study documents the molecular and cellular immune changes following phytonutrient dietary supplementation that are relevant to protective immunity against avian NE.

Key Words: phytonutrients, necrotic enteritis, protective immunity

50 The identification of candidate genes for BSE and the application to chronic wasting disease in mule deer.

J. Thomson*[1], V. Bowles[1], U. Basu[1], Y. Meng[1], P. Stothard[1], and S. Moore[2], *[1]University of Alberta, Edmonton, AB, Canada, [2]University of Queensland, Brisbane, Qld, Australia.*

Previous work in our lab identified 64 regions throughout the bovine genome associated ($P < 0.05$) with classical BSE in European cattle. Bioinformatic analysis identified 89 candidate genes within the regions. Data from 10 different tissue mRNA sequence libraries and 2 whole genome sequences, created using next generation sequencing technology, was interrogated to identify structural variation in these candidate genes. Single nucleotide polymorphisms were identified in 87 of the 89 candidate genes and the identified polymorphisms were tested in 729 animals from 2 populations (193 controls and 225 case samples from paternal half sib families, and 14 control and 397 case samples from a second population). There were 31 markers identified as associated with BSE susceptibility ($P < 0.05$ and MAF >0.01) including 7 marker clusters on chromosomes 2, 10, 14, 17, and 20. The functions of the genes associated with significant markers include prion protein binding and proteasome structure and function as well as neurodegenerative disease in humans. A de novo assembly of the mule deer genome has been constructed and the candidate genes are being annotated to provide research targets in the gene pathways underlying prion disease progression, which will enhance our understanding of the disease.

Key Words: bovine spongiform, chronic wasting disease, genomics

51 Phosphorus utilization in broilers fed soybean and benniseed-based diets with and without microbial phytase supplementation. O. Adebiyi, A. Ologhobo, A. Omojola, O. Olusola, W. Muhammed, and M. Olumide*, *University of Ibadan, Ibadan, Nigeria.*

The effects of microbial phytase (Natuphos 500) supplementation of corn- soybean meal and benniseed meal based diets were studied with One hundred and sixty-eight (168) day- old Arbor Acre broiler chicken on the parameters of growth performance, hematology, carcass characteristics and phosphorus and calcium retention in tibia bone for 8 week. The chickens were within a weight range of 40–43 g at day old and allotted in a completely randomized design (CRD) to 6 dietary treatments with 7 broiler chickens per replicate having 4 replicates per treatment. Three levels of phytase (0, 300 and 600 FTU/kg diet) were added to the diets based on soybean meal and benniseed meal respectively. The diets contained 2972.00/ 3299.90 ME kcal/kg DM energy, 23.26/23.10% protein, 1.67/1.72% calcium and 0.85/ 0.87% phosphorus in the soybean meal and benniseed meal based diets respectively at the starter phase. At the finisher phase, the diets contained 3061.20/ 3363.44 ME kcal/kg DM energy, 21.02/ 21.09% protein, 1.52/ 1.57% calcium and 0.75/ 0.77% phosphorus in the soybean meal and benniseed meal based diets respectively. Body weight gains of 48.60 g/day and feed intake of 101.98 g/day were significantly ($P < 0.05$) increased by 300 FTU/kg phytase supplementation in benniseed meal diets when compared with the group without phytase supplementation (control group). Significant ($P < 0.05$) increases were also obtained for percentage retentions of nitrogen (N) 67.22, phosphorus (P) 45.58, ash 74.85, ether extract (EE) 65.43 and crude fiber (CF) 22 in the benniseed diet supplemented with 300FTU phytase. Phosphorus and calcium retentions in the tibia bone were not significantly ($P < 0.05$) affected by supplementation of soybean meal and benniseed meal based diets with microbial phytase supplementation. Likewise, the treatments also failed to induce any statistical effects on hematological parameters of broilers including the PCV, WBC, Hb and RBC respectively. There were however, significant ($P < 0.05$) differences in the magnitude of response of birds to the diets supplemented with phytase. Birds fed benniseed meal with 300 FTU/kg microbial phytase supplementation had the highest feed intake g/day (101.98), weight gain g/day (48.60) and phosphorus retention in tibia bone (24.29).

Key Words: phytase, phosphorus, tibia bone

52 Effects of tropical legume supplementation on parasite burden and health parameters in goats. M. A. Zarate*[1], J. C. Hamie[1], J. J. Romero[1], E. N. Muniz[2], Y. J. Jang[3], K. G. Arriola[1], O. C. Queiroz[1], and A. T. Adesogan[1], *[1]University of Florida, Gainesville, [2]Empresa Brasileira de Pesquisa Agropecuária, EMBRAPA, Aracajú, Sergipe, Brazil, [3]Gyeongsang National University, Jinju, South Korea.*

The objective of the experiment was to evaluate the effects of supplementing bahiagrass hay (BG; *Paspalum notatum*) with perennial peanut (PP; *Arachis glabrata*), soybean (SB; *Glycine max*), cowpea (CP; *Vigna unguiculata*) and lespedeza (LES; *Lespedeza cuneata*) on infection by *Haemonchus contortus* and *Eimeria* sp. in goats. Forty naturally infected male Kiko × Spanish, 8 mo old, kids (23.8 ± 5.2 kg) were blocked by weight, placed in 3 pens per treatment (each with 2 or 3 kids), and fed diets containing BG hay alone or BG hay supplemented with PP, SB, CP and LES at 50% of the diet. Body weight (BW) was measured on 2 consecutive days at the beginning and end of the 4 wk trial. On d 0 and every 7 d thereafter, blood packed cell volume (PCV), fecal egg counts (FEC) and BW were recorded. Data was analyzed as a randomized block design. The model included the effects of treatment, week and their interaction. The PDIFF statement of SAS with Tukey adjustment was used to evaluate means. Feeding PP, SB or LES hay ($P < 0.05$) reduced gastrointestinal nematode FEC compared with BG alone, but LES had the least values ($P < 0.01$). Goats fed LES had lower ($P < 0.01$) Eimeria FEC compared with BG alone and similar tendencies were evident for goats fed PP and SB ($P = 0.08$, $P = 0.06$). Legume supplementation increased PCV ($P < 0.05$) compared with feeding BG alone. Treatments did not affect BW or ADG. We conclude that feeding LES resulted in the greatest reduction in total FEC and it also increased PCV. Feeding PP and SB reduced total FEC to a lesser extent and also increased PCV but feeding cowpea only increased PCV.

Table 1. Effects of legume supplementation on gastrointestinal nematode and Eimeria fecal egg counts (NFEC, EFEC), Hematocrit (HEM), initial and final body weight (IBW, FBW), and average daily gain (ADG)

	Bahiagrass	Peanut	Soybean	Cowpea	Lespedeza	SEM
NFEC, epg	2773^{a}	2072^{bc}	1914^{b}	2641^{ac}	1147^{d}	161

53 Carboxymethylation and antioxidant activity of exopolysaccharides. M. Huang,* T. F. Zhu, Z. Q. Lu, G. X. Wu, and Y. Z. Wang, *National Engineering Laboratory of Bio-Feed Safety and Pollution Prevention and Key Laboratory of Animal Nutrition and Feed Science of Ministry of Agriculture, Institute of Feed Science, Zhejiang University, Hangzhou, Zhejiang, China.*

Polysaccharides have been demonstrated to play an important antioxidant role as free radical scavengers, and chemical modification is one of the methods to improve their bioactivities. In our previous study, exopolysaccharides (EPS) produced by *Enterobacter cloacae* Z0206 were able to improve antioxidant function in rats, tilapia and Broilers. However, modification of EPS is necessary to improve their bioactivities. Therefore, to validate the possibility of enhancing the antioxidant activities of EPS through the carboxymethylated modification and screen out the optimum reaction conditions, carboxymethylated derivatives were prepared in aqueous alkaline medium using monochloroacetic acid (MCA) as etherifying agent according to the orthogonal test. Nine modification conditions were designed to study the effect of 3 parameters such as the reaction time, reaction temperature and ratio of NaOH to MCA on reaction yield and degree of substitution (DS), 9 carboxymethylated derivatives with different DS were obtained. The data were analyzed by general linear model ANOVA, differences between groups were considered statistically significant at the 5% ($P < 0.05$) level.The antioxidant activities were evaluated in vitro, by scavenging abilities on superoxide radical and hydroxyl radical. The results indicated that the extent of the impact of variables on DS followed the order: molar ratio of NaOH to MCA > reaction time > reaction temperature. With the increase of the reaction time and reaction temperature from 50°C to 60°C, DS of derivatives increased gradually. However, the DS decreased when the temperature up to 70°C. The carboxymethylated derivatives showed noticeable antioxidant activities compared with EPS, and carboxymethylated derivative with DS of 0.86 showed highest antioxidant activities. The optimum carboxymethylated conditions of EPS were the reaction time of 4 h, the reaction temperature of 60°C and the ratio of

NaOH to MCA of 2:1. This study provided a theoretical basis for the exploration of a potential antioxidant in feed additives or food industry.

Key Words: polysaccharides, carboxymethylation, antioxidant activity

54 Risk factors for switch in status from *Mycobacterium avium* ssp. *paratuberculosis* test positive to negative; data from the national Johne's disease control demonstration program. A. Kenyon*[1], S. Aly[1], and I. Gardner[2], [1]*Veterinary Medicine Teaching and Research Center, School of Veterinary Medicine, University of California-Davis, Tulare,* [2]*Department of Medicine and Epidemiology, School of Veterinary Medicine, University of California-Davis, Davis.*

The objective of this study was to identify the risk of a switch in status of cows tested by *Mycobacterium avium* ssp. *paratuberculosis* (MAP) antigen-based tests (Agtest) and antibody-based tests (Abtest). A switch in status was recorded when a cow that previously tested positive subsequently tests negative. Data from 65 demonstration herds nationwide were used to study the rate of switch in status from a positive to a negative test result. Study herds' dairy herd improvement records for the respective testing period was downloaded and verified for correctness before importing into the relational database. The data set was comprised of 144,150 dairy herd information association (DHIA) records and 245,063 Agtest and Abtest results including Biocor, Kinetics ELISA, HerdChek (Idexx), liquid culture Trek ESP, Bactec, culture on Herrold's egg yolk medium, MGIT and PCR. Matched DHIA records and results yielded 194,535 records that represent longitudinal data for all the cows tested as part of the national Johne's disease demonstration program and their DHIA records over spanning the time period from 1999 to 2010. In 11 years, a total of 48,434 cows were tested for MAP using at least a single test and a total of 4839 (10%) cows switched status at least once in their lifetime using any of the study tests. In comparison to first parity, as a cow's parity increased to 2, 3, and 4, its odds of switching serostatus using increased by 60, 30 and 50% (P value < 0.01). For every 100 d in milk increase in a cow's lactation, its odds of switching serostatus increased by 7% (P value 0.01). Cows were more likely to switch in status as they aged which could also be explained by repeated testing. In addition, cows were also more likely to switch in status as they progressed in their lactation regardless of parity.

Key Words: switch test results, Johne's, risk

55 Expressing an antimicrobial peptide cathelicidin-BF by fusion with SUMO in *Bacillus subtilis*. C. Luan,* Y. G. Xie, H. W. Zhang, and Y. Z. Wang, *Institute of Feed Science, Zhejiang University, National Engineering Laboratory of Biological Feed Safety and Pollution Prevention and Control, Key Laboratory of Animal Nutrition & Feed Science, Ministry of Agriculture, Hangzhou, Zhejiang Province, People's Republic of China.*

Cathelicidin-BF, an antimicrobial peptide purified from the snake venoms of *Bungarus fasciatus*, is an excellent alternative tool for clinical or agricultural antibiotics. The cathelicidin-BF efficiently killed bacteria and some fungal species, especially active against gram-negative bacteria. No hemolytic and cytotoxic activity was observed at the dose of up to 256 μg/mL. Most antimicrobial peptides were expressed in *Escherichia coli*. In this work, we developed a highly efficient expression system in *Bacillus subtilis* to allow for potential application of cathelicidin-BF. The cathelicidin-BF gene was fused with a small ubiquitin-like modifier (SUMO) gene and ligated into a *Escherichia coli*/*Bacillus subtilis* shuttle vector pHT43, generating pHT43-SUMO-CBF, which was subsequently transformed into *B. subtilis* strain WB800N. The fusion protein SUMO-CBF was secreted into the culture medium, and 60mg of recombinant fusion protein was purified from 1 L of culture supernatant by Ni-NTA chromatography. After the SUMO-CBF fusion protein was cleaved by the SUMO protease 1 at 4°C overnight, the cleaved sample was reapplied to a Ni-NTA resin. Finally, peptide yields of 8mg/l recombinant cathelicidin-BF were achieved. The recombinant cathelicidin-BF had similar antimicrobial activity to the synthetic cathelicidin-BF. These results may lead to a cost-effective way for the mass production of cathelicidin-BF in *B. subtilis*.

Breeding and Genetics Symposium: Systems Biology in Animal Breeding: Identifying relationships among markers, genes, and phenotypes

56 Building SNP-derived regulatory networks. A. Reverter,* *CSIRO Livestock Industries, Brisbane, Queensland, Australia.*

The advent of cheaply available high-throughput genetic and genomic techniques has equipped animal geneticists with an unprecedented ability to generate massive amounts of molecular data. As a result, large lists of genes differentially expressed in many experimental conditions of interests have been reported and, likewise, the association of an ever-growing number of DNA variants with phenotypes of importance is now a routine endeavor. While these studies have greatly improved our understanding of the genetic basis of complex phenotypes, they have also revealed the difficulty in explaining more than a fraction of the genetic variance. Inspired by this data rich - knowledge poor dichotomy, systems biology aims at the formal integration of seemingly disparate data sets allowing for a holistic view of the system and where the key properties emerge in a natural fashion. Herein, I present 2 examples of rigorous ways of integrating molecular data anchored in the power of gene network inference. The first example in concerned with the onset of puberty in cows bred in tropical regions of Australia. Using the results from genome-wide association studies across a range of phenotypes, we developed what we termed an association weight matrix to generate a gene network underlying cattle puberty. The network was mined for the minimal set of transcription factor genes whose predicted target spanned the majority of the topology of the entire network. The second example deals with piebald, a pigmentation phenotype in Merino sheep. Two networks were developed: a regulatory network and an epistatic one. The former is inferred based on promoter sequence analysis of differentially expressed genes. The epistatic network is build from 2-locus models among all pair wise associated polymorphisms. At the intersection between these 2 networks, we revealed a set of genes and gene-gene interactions of validated and de novo predicted relevance to the piebald phenotype. These new approaches render attractive a search for genetic mechanisms underlying phenotypes of importance in livestock species.

Key Words: systems biology, gene network

57 Networks and pathways to guide genomic selection. W. M. Snelling*[1], R. A. Cushman[1], J. W. Keele[1], C. Maltecca[2], M. G. Thomas[3], M. R. S. Fortes[4,5], and A. Reverter[4], *[1]USDA, ARS, US Meat Animal Research Center, Clay Center, NE, [2]Animal Science, North Carolina State University, Raleigh, [3]Animal Sciences, Colorado State University, Fort Collins, [4]Cooperative Research Center for Beef Genetic Technologies, CSIRO Livestock Industries, Brisbane, QLD, Australia, [5]The University of Queensland, School of Veterinary Medicine, Gatton, QLD, Australia.*

Many traits affecting profitability and sustainability of meat, milk and fiber production are polygenic, with no single gene having an overwhelming influence on observed variation. No knowledge of the specific genes controlling these traits has been needed to make dramatic improvement through selection. Gains have been made through phenotypic selection, enhanced by pedigree relationships and continually improved statistical methodology. Genomic selection, recently enabled by assays for dense SNP located throughout the genome, promises to increase selection accuracy and accelerate genetic improvement by emphasizing the SNP most strongly correlated to phenotype, although the genes and sequence variants affecting phenotype remain largely unknown. These genomic predictions theoretically rely on linkage disequilibrium (LD) between genotyped SNP and unknown functional variants, but familial linkage may increase effectiveness for predicting individuals related to those in the training data. Genomic selection with biologically relevant SNP genotypes should be less reliant on LD patterns shared by training and target populations, possibly allowing robust prediction across unrelated populations. While the specific variants causing polygenic variation may never be known with certainty, several tools and resources can be employed to identify those most likely to affect phenotype. Dense SNP associated with phenotype provide a one-dimensional approach to identify genes affecting specific traits, while associations with multiple traits allow defining networks of genes interacting to affect correlated traits. Such networks are especially compelling when corroborated by existing functional annotation and established molecular pathways. The SNP occurring within network genes, mined from public databases or derived from genome and transcriptome sequences, may be classified according to expected effects on gene products. Coupling evidence from livestock genotypes, phenotypes, gene expression and genomic variants with existing knowledge of gene functions and interactions may provide greater insight into the genes and genomic mechanisms affecting polygenic traits, and enable functional genomic selection for economically important traits. USDA is an equal opportunity provider and employer.

Key Words: genomic prediction, functional genomics, gene network

58 Causal graphical models in quantitative genetics and genomics settings. G. J. M. Rosa* and B. D. Valente, *University of Wisconsin, Madison.*

Phenotypic traits may relate to each other through complex causal relationship networks, which may transcend across transcriptome, proteome, metabolome, and endpoint phenotypes, such as economically important traits in livestock. Moreover, such systems of phenotypic interrelationships are often modulated by the joint action of genetic and environmental effects. For example, transcriptional levels may be affected by reproductive status or developmental stage, which in turn may be mediated by other physiological variables, with genetic polymorphisms and environmental components contributing to animal-to-animal variation. A probabilistic representation of such biological systems can be accomplished through causal graphical models, which allow expressing complex relationships between variables. Applying such models, however, involves a central task of inferring the causal structure underlying phenotypic networks, i.e., determining the subset of traits that directly affects each trait of interest. This challenge may be tackled by using algorithms that perform a data driven search for plausible causal network structures, based on some specific assumptions such as the causal sufficiency. In this context, quantitative genetics and genomics have been utilized either to relax the causal sufficiency assumption from removing polygenic pleiotropic effects or by using QTL information to aid in causal structure search and edge orienting. In this presentation we will discuss such applications to phenotype network studies, focusing on the use of genomic information to aid inferences. Additionally, we will provide examples of application of such methods, and discuss their potential benefits in animal sciences, such as optimal management decision and improvement of multiple traits in livestock.

Key Words: graphical models, causal inference, quantitative genetics

59 A systems biology definition for semen quality.

D. Froman*[1], D. Rhoads[2], and S. Burgess[3], [1]*Oregon State University, Corvallis,* [2]*University of Arkansas, Fayetteville,* [3]*University of Arizona, Tucson.*

We have shown that semen quality can be defined as the number of mobile sperm produced per male per day. Moreover, semen quality is subject to genetic selection when so defined. Sperm mobility is a quantitative trait in poultry, and male fertility is a function of sperm mobility phenotype. The term sperm mobility denotes sperm that move against resistance at body temperature. In other words, all mobile sperm are motile but not all motile sperm are mobile. Immobile sperm contain dysfunctional mitochondria. Such mitochondria are damaged before ejaculation. The ratio of mobile to immobile sperm within an ejaculate varies among roosters and is independent of age. We hypothesized that premature mitochondrial failure was due to sperm cell and reproductive tract attributes that interact to affect sperm in a stochastic manner. Our current work tested this hypothesis in terms of (1) reproductive tract throughput, as defined by the number of mobile sperm produced per gram testis per day, and (2) the testis transcriptome. Test subjects were roosters from 2 experimental lines of chickens developed at Oregon State University. Distinct sperm mobility phenotypes have been maintained between lines for more than a decade without inbreeding. Our experimental outcomes demonstrated that deferent duct transit time does indeed differ between lines. In this regard, it is noteworthy that this duct contains the bulk of a rooster's extragonadal sperm reserve. Whereas differential gene expression was first observed in terms of sperm cell glycolytic enzymes (downregulated in sperm from low line males), we have now observed differential gene expression between lines at the level of the testis transcriptome. Analyses based upon reads per kilobase of mRNA per million reads identified 3000 transcripts that were differentially expressed at 1.5-fold or more up or down ($P < 0.01$). Those genes were mapped to the original GWAS data to identify SNPs in mRNAs differentially expressed between lines. Three genes are now under investigation: ATP5a1, CKMT2, and ARMC2. We have 2 long-term goals: (1) to predict adult reproductive potential using DNA obtained from chicks, and (2) to improve fertility within pedigree lines of chickens through SNPlotype-based selection.

Key Words: fertility, sperm, transcriptome

60 A systems-genetics analysis of bovine skeletal muscle iron content.

J. E. Koltes*[1], R. G. Tait Jr.[1], E. R. Fritz[1], B. P. Mishra[1,2], A. L. Van Eenennaam[3], R. G. Mateescu[4], D. L. Van Overbeke[4], A. J. Garmyn[4], Q. Liu[1], G. Duan[1], D. Nettleton[5], D. Beitz[1], D. Garrick[1], and J. M. Reecy[1], [1]*Department of Animal Science, Iowa State University, Ames,* [2]*National Bureau of Animal Genetic Resources, Karnal, India,* [3]*Department of Animal Science, University of California, Davis,* [4]*Department of Animal Science, Oklahoma State University, Stillwater,* [5]*Department of Statistics, Iowa State University, Ames.*

Regulation of cellular iron is critical in immune, mitochondrial, and erythrocyte function. Improper iron homeostasis results in disease both in the case of excessive iron (hemochromatosis) and when iron is deficient (anemia). Therefore, genetic regulation of iron is important to both human and animal health. Since beef is an excellent source of dietary iron, our objective was to investigate the genetic mechanisms responsible for variation in skeletal muscle iron content. To determine the genetic architecture of skeletal muscle iron content, we analyzed Illumina 54k bovine SNP genotypes ($n = 2259$) using a Bayes C genomic selection model in GenSel software. To investigate the transcriptional control of skeletal muscle iron content, we used RNA-seq to contrast mRNA levels in 5 high and 5 low ($n = 10$) total iron content Longissimus dorsi samples. Sequence tags were aligned to the UMD3 genome build using Cufflinks software and analyzed in R assuming a Poisson distribution accounting for fixed effects of iron, sex, age and contemporary group. False discovery rate was controlled using qvalues. GWAS results indicated that markers with the largest effect were located on chromosomes1, 7, 15, and 17. Markers on chromosomes 7 and 17 were near GDF15 and SMAD1 genes with known roles in human hemochromatosis. RNA-seq identified 3010 differentially expressed genes ($q < 0.05$). Pathway studio software was used to identify pathways including known regulators of iron homeostasis: BMP6 ($P < 6.38\text{E}^{-8}$), and STAT1 ($P < 1.3\ \text{E}^{-27}$). The SMAD3 pathway was identified as a potential novel regulator of iron homeostasis ($P < 3.07\text{E}^{-33}$). Additional pathway analyses and genome-wide re-sequencing are underway to identify novel iron regulatory mechanisms. Interestingly, our initial results indicate that many of the same genes involved in human hemochromatosis may also regulate bovine skeletal muscle total iron content.

Key Words: bovine skeletal muscle, genome-wide association study (GWAS), iron homeostasis

Companion Animals Symposium: Nutrition Special Needs—The relationship between novel ingredients, environment and gene expression

61 Alternative ingredients: Which have scientific merit? G. Aldrich,* *Pet Food & Ingredient Technology Inc., Topeka, KS.*

As pet foods continue to address market and health concerns, and as the volume of pet food around the world continues to grow, pressure to develop alternative ingredients and to expand existing ingredient reservoirs escalates. Alternative ingredients are considered for several reasons. These include perceived biomedical value to support the expanding need for novel proteins and starches for so-called hypoallergenic or elimination diets. Regulatory limitations on claims regarding food benefits beyond simple sustenance leaves marketing little latitude short of drawing attention to ingredients as primary points of competitive differentiation. Finally, as consumer perception of certain traditional ingredients becomes less accepting there is an increased demand for more unique, humanized, and less chemical or agricultural sounding elements. Regardless of rationale, utilization of non-traditional, novel, or experimental ingredients as alternatives necessitates the exploration of safety, efficacy and utility for pet diets. Some of this work has been accomplished for the targeted species (dogs and cats) and in some cases validation with model species such as rats and mice is available. However, many of these alternative ingredients are being utilized with little animal or food quality evaluations. Some of these alternative ingredients can be quite exotic, but most are more mainstream alternative ingredients being used with enough frequency that a closer look is warranted. This list includes such items as rabbit and duck meals for lamb and chicken meal, potato and pea protein concentrates for soybean and corn gluten meal, pea fiber for beet pulp, chia for flax, sweet potato and tapioca for grains, algal oil for fish oil, olive oil and coconut oil for soybean or canola oils, cod liver oil for vitamins A and D, and chicken cartilage for glucosamine to name a few. This presentation will review the relevant published information for the more popular alternative ingredients and identify which have scientific merit.

Key Words: petfood, dog, cat

62 Benefits of probiotic supplementation in stressful situations in companion animals. M. R. Lappin,* *Department of Clinical Sciences, Colorado State University, Fort Collins.*

There are many products in the veterinary market purported to contain probiotics that exert a beneficial effect on dogs or cats. In humans, results of studies vary dramatically which emphasizes that biological effects of individual probiotics will vary and that each probiotic should be rigorously evaluated in a controlled fashion to define the potential for clinical utility. In addition, the source of the probiotic should also be considered as the majority of veterinary products claiming to contain probiotics generally do not meet the label claim. It is known that many probiotics in the lactic acid bacteria group help balance the endogenous gastrointestinal microbiota and some can inhibit replication of pathogenic bacteria. It is also now known that some probiotics can beneficially influence innate and acquired immunity systemically by a variety of proposed mechanisms including inducing cytokine production, natural killer cell activity, and both specific and non-specific immunoglobulin production. Recently, our laboratory completed 2 studies showing the beneficial effect of a probiotic (FortiFlora; Nestlé Purina PetCare) on animals in stressful situations. Feline herpesvirus 1 (FHV-1) infection of cats causes chronic respiratory and ocular infections that can be reactivated by stress in a similar fashion to human herpesvirus associated cold sores. It was shown that cats supplemented daily with the probiotic developed less severe signs of FHV-1 associated illness during periods of stress when compared with the control group. Stress associated diarrhea is common in companion animals and is thought to result from changes in the gastrointestinal microbiota. When one cat room of an animal shelter was supplemented with the probiotic and the other room fed a placebo, it was shown that the proportions of housed cats with diarrhea of 2 d or greater was significantly lower in the treated group (20.7% versus 7.7%). In both of these stressful situations, it appears the use of the probiotic improved the health and wellbeing of the treated animals.

63 Dietary and environmental management of feline lower urinary tract disease (FLUTD). K. R. Kerr,* *University of Illinois, Urbana.*

Feline lower urinary tract disease (FLUTD) is a grouping of symptoms that affect the cat's lower urinary tract system and bladder; however, the clinical signs are rarely indicative of a particular disease. There are many conditions that can result in signs of FLUTD, including urolithiasis, cystitis, and urethral obstruction, but the vast majority of cases are idiopathic. Feline idiopathic cystitis (FIC) is seen in 50 to 65% of FLUTD cases. While cases of non-obstructive FLUTD are usually self-limiting, most cats have recurrence of clinical signs. Treatment is recommended to reduce recurrence because FIC is painful and distressing to the cat, can result in self-traumatization and behavioral changes. In cases that progress to obstructive disease, it could be fatal. The etiopathogenesis of FLUTD likely involves combinations of factors: locally present external factors within the urine, such as urine supersaturation, abnormalities in protective factors, or the presence of toxins and microorganisms; intrinsic abnormalities in the glycosaminoglycan (GAG) layer, the urothelium, or other urogenital morphology; and increased sensitivity or abnormal response to external or internal stimuli. Dietary impact and recommendations for decreasing recurrence of the most common types of urolithiasis based FLUTD have been available for many years. More recently, treatments that address additional contributing factors have arisen. The primary recommendations for FLUTD in general are to alleviate stress, and increase water intake. Multimodal environmental modification is one approach to alleviating stress that has been examined in regards to FLUTD. Supplemental GAGs are sometimes provided to potentially ameliorate abnormalities in the GAG layer. Until definitive cause for a FLUTD case can be identified and eliminated (if possible), environmental and dietary modifications will play a significant role in decreasing recurrence events.

Key Words: feline lower urinary tract disease (FLUTD)

64 Functional nutrition: Novel ingredients and new findings. I. S. Middelbos,* *Novus International Inc., St. Charles, MO.*

Human functional foods and beverages currently represent a multi-billion dollar market that is growing rapidly. These functional foods aim to deliver specific benefits beyond standard nutrition, based on the functional ingredients they contain. The continued premiumization of pet food, combined with the humanization of companion animals creates a strong drive to bring functional ingredients from the human market to pets. Indeed, many functional ingredients used in humans have application in companion animals. Two leading categories of functional ingredients for both humans and companion animals relate to joint health and digestive health. In many instances, manifestations of joint or digestive conditions include pain and below-normal functionality of the joint or the digestive tract. When joints are affected, often this leads to decreased mobility and reduced motivation for physical activity, which may in turn contribute to other conditions (e.g., obesity). Currently, several ingredients are under investigation for their potential to support healthy joints. Many of these are food ingredients or co-products that were not previously considered to have specific functionality. Examples include green-lipped mussel and hydrolyzed eggshell membrane and chicken collagen. Digestive conditions may be uncomfortable for the pet as well as the pet owner, because of the resulting symptoms (e.g., diarrhea and flatulence). Whereas dietary fiber has been a mainstay to support a healthy digestive tract, the science is currently evolving to help us understand how specific fiber fractions and structures may affect certain digestive health conditions. Moreover, the field of probiotics continues to evolve with ever more targeted strains to address conditions along the entire digestive tract. The common thread among all these conditions is the immunological component involved. The most successful ingredients appear to be those that are able to negotiate some moderation in immune response. The field of functional ingredients is growing rapidly and has much potential to improve functional nutrition of both man and companion animal, provided the regulatory frameworks allow for this potential to come to fruition.

Key Words: companion animals, functional ingredients, functional foods

65 Nutrigenomics: Using gene expression data to understand and manage pet obesity.

K. S. Swanson,* *University of Illinois, Urbana.*

Pet obesity is a major health problem, with an estimated 30 to 40% of dogs and cats considered as overweight or obese in the United States. Obesity is pleiotropic, resulting in altered adipose, liver, and skeletal muscle tissue function. These changes in tissue functionality lead to metabolic alterations (e.g., insulin resistance, hyperlipidemia), increase risk of chronic diseases, and decrease life span. Although obesity is well accepted as being unhealthy, the mechanisms by which the obese state leads to chronic disease are poorly understood. The use of transcriptomics, particularly whole genome microarrays and quantitative RT-PCR, has increased understanding of tissue biology and has begun to link mRNA changes to the physiological state. Companion animal biologists have applied these technologies to study adipose, skeletal muscle, and hepatic tissues of dogs and cats in many ways. Research has focused on lean vs. obese pets, pets rapidly gaining weight following spay/neuter or ad libitum feeding, pets undergoing weight loss, and obese pets fed specific dietary ingredients to improve metabolism or insulin sensitivity. The results of these studies and application to pet nutrition and management will be reviewed.

Key Words: pet obesity, transcriptomics, nutrition

Dairy Foods: Cheese and Products Processing

66 Influence of proteolysis and amino acid release on bitterness and texture of reduced-fat Cheddar cheese. M. W. Børsting[1], K. B. Qvist*[1], J. Vindeløv[1], F. K. Vogensen[2], and Y. Ardö[2], [1]*Chr. Hansen A/S, Hørsholm, Denmark,* [2]*Department of Food Science, Faculty of Life Sciences, University of Copenhagen, Copenhagen, Denmark.*

In spite of much research, it remains difficult to produce high quality reduced-fat Cheddar cheese. The objective of this study was to investigate the effects of 2 rennets, bovine (BC) and camel chymosin (CC), with different proteolytic activity, and 2 starter cultures with different ability to release amino acids on texture and flavor development. One starter (O) contained strains of *Streptococcus lactis* and *cremoris*; the other (OLb) additionally contained a proteolytic *Lactobacillus delbrueckii* strain. Cheeses with all 4 combinations of coagulants and cultures were produced in 4 replicates. During manufacture essentially identical acidification profiles were obtained, and cheeses were analyzed during 28 wk for composition of casein, peptides and free amino acids by capillary electrophoresis, LC-MS and HPLC, and for textural properties by uniaxial compression. Sensory evaluation of the ripened cheeses was made as well. BC cheeses showed more extensive hydrolysis of α_{S1}-CN, and of peptides derived from it than CC cheeses. BC cheeses also contained higher levels of the bitter peptide β-CN (f193–209) and obtained higher bitterness scores. In OLb cheeses, peptide degradation was extensive, and peptide profiles of BC and CC cheeses were similar after 28 wk, except for α_{s1}-CN (f1–9) and β-CN (f193–209). OLb increased the content of free amino acids ca. 3-fold over that obtained with O. After 28 wk CC cheeses had higher sensory hardness, stress at fracture and modulus of deformability than BC cheeses. OLb cheeses had higher stress but lower strain at fracture, and higher modulus of deformability than O cheeses. Overall, CC reduced problems with bitterness in reduced-fat Cheddar, compared with BC, but the associated increase in hardness was not compensated for by the addition of a proteolytic *Lactobacillus* strain.

Key Words: reduced-fat Cheddar, camel chymosin, *Lactobacillus*

67 Impact of sodium, potassium, magnesium, and calcium salt cations on pH, proteolysis and microbial populations during storage of Cheddar cheese. D. J. McMahon*[1], N. Farkye[2], L. V. Moyes[3], and C. J. Oberg[1,3], [1]*Western Dairy Center, Utah State University, Logan,* [2]*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo,* [3]*Department of Microbiology, Weber State University, Ogden, UT.*

Sodium reduction in cheese can assist in reducing overall dietary Na intake, yet saltiness is an important aspect of cheese flavor. Our objective was to evaluate the effect of partial Na substitution on survival of lactic acid bacteria (LAB) and nonstarter LAB (NSLAB), pH and extent of proteolysis in full fat Cheddar cheese. Seven full fat Cheddar cheeses with molar salt contents equivalent to 1.7% (wt/wt) NaCl but with different ratios of Na, K, Ca and Mg cations were manufactured. Cheese made using 1.7% NaCl (C) served as a positive control while cheese made using 0.7% NaCl served as a negative control (LC). Cheeses were aged at 6°C for 9 mo. Total LAB, starter lactococci, and NSLAB were enumerated using selective media and varied incubation conditions. Proteolysis was monitored by gel electrophoresis and measuring water-soluble N (WSN). Cheese C had a mean composition of 35.0% moisture, 50.2% FDB, 26.0% protein, and 1.74% (±0.05%) salt. Other full salt cheeses had a similar composition, while the LC cheese had higher moisture, 37.3%, and a salt content of 0.68% (±0.04%). Mean water activity of full salt cheeses at 28 d was 0.956 while the LC cheese was 0.975. After salting there was a faster initial drop in cheese pH with K substitution and throughout storage the pH of cheese with 75% K substitution was lower than cheese C. There was no difference in residual casein levels or %WSN levels in the cheeses based on salt content with all cheeses increasing from ~5% WSN at d 1 to ~20% after 6 mo. Cheese C (~4.7% salt-in moisture) exhibited expected changes in bacteria microflora during storage with lactococci gradually decreasing from ~10^7 cfu/g after pressing to ~10^4 cfu/g after 4 mo, while the NSLAB gradually increased from < 10^3 cfu/g to ~10^5 cfu/g to become the dominant portion of total LAB after 4 mo. In cheese LC (~1.8% salt-in-moisture), the lactococci stayed at ~10^6 cfu/g through 6 mo of storage and remained the dominant LAB with NSLAB at ~10^5 cfu/g. With K substitution for Na, there was a trend for lactococci to remain dominant or be at similar levels as the NSLAB, especially when salt substitution also included 10% Mg or Ca.

Key Words: cheese, sodium, potassium

68 Impact of different types of emulsifiers on the reformability of grated cheese. C. Akbulut* and J. A. Lucey, *University of Wisconsin-Madison, Madison.*

Reforming the cheese has found several applications in dairy industry. Our objective was to determine the effect of different types of emulsifiers (EM) on the texture and rheological properties of low-fat and full-fat Cheddar cheese after reforming. Cheeses were ground using food processor and then pressed into plastic molds for 1 h using Carver food press. Eight different types of EM at 4% (w/w) level were added to grated cheeses before reforming. These types included anionic: citric acid esters of monoglycerides (CITREM), diacetyl tartaric acid esters of monoglycerides (DATEM), sodium stearoyl lactylate (SSL), zwitterionic: lecithin and non-ionic: distilled monoglycerides (DM), lactic acid esters of monoglycerides (LACTEM), acetic acid esters of monoglycerides (ACETEM) and sorbitan tristearate (STS). Control reformed cheeses were prepared for both low-fat and full-fat cheese made without any EM. Analyses were performed on cheese bases and reformed cheeses that had been stored for 2 wk at 4°C. Rheological properties of cheese were measured using small amplitude oscillatory test during heating from 5 to 85°C. Textural properties were tested with Texture Analyzer. Melt properties were tested using the UW-Melt-profiler. Use of SSL reduced the hardness of low-fat cheese and made it very sticky and soft. The use of CITREM, DATEM and STS resulted in firmer cheese texture. DATEM and SSL exhibited significantly lower loss tangent maximum during heating (less melt) as compared with control cheese. At low measurement temperatures, except for STS, non-ionic EM did not significantly alter the texture of full-fat cheese; however at high temperatures cheese with non-ionic EM differed from control and they had improved meltability. Use of non-ionic EM seemed to make the low-fat cheese more prone to fracture during compression except for the use of STS. It was concluded that the textural properties of the reformed cheese can be modified with the use of different types of EM. The texture and melting characteristics of the reformed cheese were dependent on charge, hydrophilic-lipophilic balance and molecular characteristics of the EM.

Key Words: cheese reforming, texture, emulsifiers

69 Phenotypic factors affecting cheese yield and whey losses from individual cows. C. Cipolat Gotet,* M. Penasa, A. Cecchinato, M. De Marchi, and G. Bittante, *Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), University of Padova, Legnaro, Padova, Italy.*

The aims of this study were to assess sources of variation of several individual cheese yields obtained by using a micro-cheese making method. Traits were: [1] weight (g) of fresh curd (CY_{curd}) or curd total solids (CY_{solids}) or curd water (CY_{water}) divided by weight (g) of milk processed; [2] weight (g) of total solids (REC_{solids}) or fat (REC_{fat}) or protein ($REC_{protein}$) recovered in curd divided by weight (g) of constituent in milk. A total of 1,271 Brown Swiss cows from 85 herds were sampled. The cheese making procedure consisted of the heating of raw milk (1.5L), the acidification by the inoculation of a direct-to-vat starter of selected strains of *S. thermophilus*, the addition of calf rennet, the detection of coagulation time, 2 subsequent cuts of the curd, the rest of the curd, the pressing and the brining. Then, curd was weighed to calculate the aforementioned traits. Means (SD) for CY_{curd}, CY_{solids}, CY_{water}, REC_{solids}, REC_{fat} and $REC_{protein}$ were 0.150 (0.019), 0.072 (0.009), 0.078 (0.013), 0.521 (0.036), 0.899 (0.036) and 0.781 (0.024), respectively. The linear model considered effects of herd, vat, parity, days in milk and milk yield. The effect of days in milk was relevant for all traits: CY_{curd}, CY_{solids}, CY_{water} and REC_{solids} showed a decrease after parturition and an increase thereafter; REC_{fat} showed a decrease till mid lactation and a slow increase afterward, whereas an opposite trend was detected for $REC_{protein}$. Increasing parity decreased CY_{curd}, despite the inclusion of milk yield in the model, mainly because of a decrease of CY_{water} rather than as a consequence of the variation of CY_{solids}. The effect of milk yield was negative on CY_{curd} because of a decrease of CY_{solids}, and not of CY_{water}. Large differences were detected among herds suggesting differences in dairy management practices. The micro-cheese making method can be used to investigate variation in individual cheese yield and milk components recovery and for genetic purposes.

Key Words: individual cheese yield, whey losses, micro-cheese making

70 Sensory selection of an antimicrobial for use in string cheese. A. Lammert*[1], L. Collinsworth[1], N. Farkye[1], M. Arnold[1], A. Lathrop[2], and T. Taylor[2], [1]*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo,* [2]*Department of Food Science and Nutrition, California Polytechnic State University, San Luis Obispo.*

Sodium has a significant role in the string cheese matrix such as flavor enhancement and inhibition of microbial growth. Recently, there have been government and industry initiatives to reduce the sodium content in a wide variety of foods by 25% within the next 5–10 years. String cheese, often marketed as a healthy snack, has 8% DV of sodium per stick. A lower sodium alternative would need to be safe to eat and taste good; therefore, the antimicrobial used to partially replace the role of salt should be effective against pathogens and have acceptable sensory qualities. The objective of this work was to find an antimicrobial, with demonstrated pathogen protection properties, that is sensory transparent. Three sensory tests were completed using 4 antimicrobials, with confirmed pathogen protection measured using a 5 pathogen cocktail and cheese agar, applied to commercial, unbrined string cheese: 1) A balanced reference duo-trio test was used to determine a difference with and without antimicrobial application (n = 38), 2) Twenty-two cheese consumers used a balanced, 9 point hedonic test to evaluate the overall acceptability, aroma, flavor, and after taste, and 3) A 2^2 design was used to determine the interaction of antimicrobial contact time (30 s and 3 min) and concentration (recommended concentration ± 50%). Differences were evaluated using a duplicated, balanced reference duo-trio test (n = 15). The results showed: 1) 3 potential antimicrobials could be sensory transparent and protect unbrined string cheese from potential pathogens, 2) consumers found no significant difference ($\alpha > 0.05$) for any of the antimicrobials tested for overall acceptability, flavor, or after taste; however, the aroma of 2 antimicrobials were found to be significantly different ($\alpha < 0.05$), and 3) the 3 min contact time and concentration + 50% was found to be significantly different($\alpha < 0.05$) than the rest of the combinations tested. The outcomes indicate that the perceived sensory aspects of unbrined string cheese may change based on the type or method used to apply the antimicrobial.

Key Words: lower sodium, antimicrobials, consumer testing

71 Microfiltration of skim milk and modified skim milk using a 0.1-μm ceramic uniform transmembrane pressure system at 50, 55, 60, and 65°C. E. E. Hurt,* M. Adams, and D. M. Barbano, *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objective was to determine the effect of operating a microfiltration (MF) unit at temperatures up to 65°C on serum protein (SP) removal from skim milk (SM), with and without prior removal of low molecular weight (MW) soluble SM components by ultrafiltration (UF). SM was pasteurized (72°C, 16s) and split into 2 batches. The first batch was ultrafiltered to remove about 90% of the low MW soluble SM components. After UF, the UF retentate was diluted back to the protein concentration of SM. The diluted UF retentate (DUR) and unaltered SM were then microfiltered. The MF system was operated at a concentration factor of 3X and a flux of 54 kg/m^2 per h. After flushing the system with SM or DUR to remove water, the MF retentate and permeate were recycled to the feed tank. The MF system was run in recycle mode at 50, 55, 60 and 65°C for 1h at each temperature. Samples were taken of the retentate and permeate after each hour. The experiment was repeated 3 times. As temperature increased from 50 to 65°C the retentate recirculation pump frequency required to maintain a flow of 648L/min decreased from 59.0 to 57.7Hz ($P < 0.05$) for SM and from 58.6 to 57.3Hz ($P < 0.05$)for DUR indicating reduced pump energy requirements. No permeate pressure decreases indicative of fouling were seen, suggesting an increase in flux may be possible. Between 50 and 65°C there was a decrease in SP removal from 66.39 to 57.76% ($P < 0.05$) for SM and from 67.47 to 54.84%($P < 0.05$) for DUR. The decrease in SP removal was likely caused by heat denaturation of SP and interaction with casein. SP removal did not vary significantly between SM and DUR ($P > 0.05$). It may be possible to operate a MF system to remove SP from SM at temperatures above 50°C. The decrease in pumping costs and possible increase in flux has to be balanced with a decrease in SP removal as temperature increases. It does not appear that low MW soluble materials in SM such as lactose, NPN or calcium caused fouling that reduced SP removal at temperatures up to 65°C.

Key Words: microfiltration, serum protein removal, processing temperature

72 Leveraging existing processing lines for yogurt product innovation through the use of advanced texturizing systems. M. E. Yildiz,* S. Mutz-Darwell, M. Yurgec, A. Perez, and H. Simpson, *National Starch, Bridgewater, NJ.*

The objective of the current work was to test new ingredients to show that using ingredients with different functionalities, it is possible to formulate texturally very different products such as blended yogurt, Greek yogurt

and European set dessert using a common stirred yogurt lines. This will leverage existing capabilities, avoid investment in costly specialized equipment and capabilities and help dairy manufacturers produce variety of new products. In this study several texturally different products were made using Microthermix. Liquid ingredients were added to the Likwifier. Dry ingredients were slowly added while mixing at 500 rpm and hydrated for 30 min before processing in Microthermics. Preheating temperature range of between 140 to 150F and homogenizer pressure range between 50 to 250 bars were studied to find optimal conditions. Final heat and hold time was constant at 208F/6 min. Products made under optimal processing conditions were characterized using rheological and sensory analysis. Rheological methods included dynamic and steady tests whereas descriptive sensory analysis included characterization of several key fundamental texture attributes. In this presentation case studies on developing consumer preferred blended yogurts, producing Greek style yogurts without straining will be presented. For blended preferred yogurts, benchmark texture was quantified to have an elastic modulus (G') of 163 Pa and shear viscosity (Eta) of 6.6 Pa.s. Formulated yogurts had elastic modulus of 218 and shear Eta of 5.5. However, sensory analysis revealed that key attributes such as spoon indentation meltaway, thickness in the mouth and residual mouthcoating there were very similar. For Greek yogurt, commercial strained benchmark had G' of 2220 Pa and Eta of 13 Pa.s while formulated Greek yogurts had elastic modulus of 1535 Pa and Eta of 9.51 Pa.s. However, sensory analysis revealed that key attributes such as spoon indentation meltaway, thickness in the mouth and residual mouthcoating there were very similar. We conclude that it is possible to leverage existing stirred yogurt lines by only changing the key parameters for dairy unit operations to develop texturally very different products some of which are traditionally made with specialized equipment.

Key Words: dairy, processing, texturizers

73 Gravity separation of fat, somatic cells, and bacteria in raw and pasteurized milks.

Z. Caplin, C. Melilli, and D. M. Barbano,* *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

The objective of experiment 1 was to determine if the extent of gravity separation of milk fat, bacteria, and somatic cells is influenced by time and temperature of gravity separation or the level of contaminating bacteria present in the raw milk. The objective of experiment 2 was to determine if there was an effect of different temperatures of milk heat treatment on the gravity separation of milk fat, bacteria, and somatic cells. In raw milk, fat, bacteria, and somatic cells rose to the top of columns during gravity separation. About 50 to 80% of the fat and bacteria were present in the top 8% of the milk after gravity separation of raw milk. Gravity separation for 7 h at 12°C produced equivalent separation of fat, bacteria, and somatic cells as did separation for 22 h at 4°C. The completeness of gravity separation of fat was influenced by the level of bacteria in the milk before separation. Milk with high bacteria count had less (about 50 to 55%) gravity separation of fat than milk with low bacteria count (about 80%) in 22 h at 4°C. Gravity separation caused fat, bacteria, and somatic cells to rise to the top of columns for raw whole milk and HTST pasteurized (72.6°C, 25 s) whole milk. Pasteurization at >76.9°C for 25 s prevented all 3 components from rising, possibly due to denaturation of native bovine immunoglobulins that normally associate with fat, bacteria, and somatic cells during gravity separation. Gravity separation can be used to produce reduced fat milk with low bacteria and somatic cell counts, and may be a critical factor in the history of safe and unique traditional Italian hard cheeses produced from gravity separated raw milk. A better understanding of the mechanism of this natural process could lead to the development of new nonthermal thermal technologies to remove bacteria and spores from milk or other liquids.

Key Words: gravity separation, bacterial removal, somatic cell removal

74 Effect of PEF and UV and their combination on selected microorganisms and physico-chemical properties in whey.

A. Dave*[1], M. Walkling-Ribeiro[1], O. Rodríguez-González[2], M. W. Griffiths[1], and M. Corredig[1], [1]*Canadian Research Institute for Food Safety, Department of Food Science, University of Guelph, Guelph, ON, Canada,* [2]*Rodríguez-González Services, Toronto, ON, Canada.*

Pulsed electric field (PEF) and UV irradiation (UV) are emerging food processing technologies that could represent an alternative to conventional high-temperature short-time pasteurization (HTST) for whey preservation. This study looked into effects of both PEF and UV individually and combined for inactivation of *Listeria innocua* and *Zygosaccharomyces bailii* compared with HTST and change in whey qualitative aspects (pH, electrical conductivity, and color) was also investigated. Inoculated whey was PEF-processed at electric field strengths of up to 40 kV/cm, using treatment times up to 4937 µs, and resulting in energy densities up to 173 kJ/L, while UV was applied for treatment times of up to 7.7 s and dosages up to 229 mJ/mL. Thermal controls were obtained by pasteurizing whey at 72 and 90°C for respective holding times of 15 (HTST72) and 30 s (HTST90). *L. innocua* and *Z. bailii* loads in whey were reduced by up to 3.1 and 3.0 $\log_{10}$ cfu/mL, respectively, with PEF, whereas, UV inactivated up to 6.0 and 5.9 $\log_{10}$ cfu/mL, respectively ($P < 0.05$). With HTST higher *L. innocua* and Z. bailii inactivation of ≥ 8.9 and ≥ 7.8 $\log_{10}$ cfu/mL ($P < 0.05$) was obtained, correspondingly, at 72 and 90°C. However, PEF/UV proved to be comparably effective for bacteria and yeast inactivation of ≥ 8.8 and ≥ 7.9 $\log_{10}$ cfu/mL ($P \geq 0.05$) in whey, while lower reductions of up to 6.9 and 7.1 $\log_{10}$ cfu/mL of *L. innocua* and *Z. bailii* were obtained after UV/PEF ($P < 0.05$). For physico-chemical analysis whey was PEF/UV-treated at 2 selected processing intensity levels, low (PEF/UVL) and high (PEF/UVH), used during the microbial analysis. No significant differences were found in pH ($P \geq 0.05$) while colorimetry indicated HTST72 < PEF/UVH < PEF/UVL < HTST90 ($P < 0.05$). No significant differences in conductivity were obtained between HTST72 and PEF/UVL ($P < 0.05$) in contrast to HTST90 and PEF/UVH ($P \geq 0.05$). Findings showed comparable treatment efficacy with UV- and PEF-based hurdle technologies and HTST for contaminated whey. Overall similar or better product quality was obtained with PEF/UV compared with HTST, thus, indicating PEF/UV as effective non-thermal processing strategy for acid whey.

Key Words: UV irradiation, pulsed electric field (PEF), HTST

Forages and Pastures Symposium: Impact of Fungal-Endophytes on Pasture and Environmental Sustainability

75 Fungal endophytes: Forage friend or foe? C. Young,* *Noble Foundation, Ardmore, OK.*

The epichloae (sexual *Epichloë* and asexual *Neotyphodium* species) are endophytic fungi that systemically infect many cool season grasses, including the common forage grasses tall fescue and perennial ryegrass. The success of endophytes, such as *N. coenophialum* (tall fescue endophyte) and *N. lolii* (perennial ryegrass endophyte), within the host is due to a lifestyle strategy where the fungus systemically infects the aerial parts of the plant without causing disease and is subsequently transmitted in the seed where this association is maintained over successive generations. In modern monoculture-based agriculture, the presence of asexual *Neotyphodium* species has been shown to enhance persistence of the host plant by providing protection from biotic and abiotic stresses. Some known host fitness attributes provided by the endophyte arise from the production of bioactive alkaloids. Lolines and peramine provide beneficial anti-insect properties, while the ergot alkaloids and lolitrem B cause toxicity to grazing livestock that result in production losses. It is well documented that ergot alkaloids produced by the endophyte are the causative agent of fescue toxicosis that presents with numerous detrimental effects such as fescue foot, reproductive disorders, and reduced milk production and weight gains. Similarly, lolitrem B produced by some *N. lolii*-infected perennial ryegrass was found to cause ryegrass staggers. The genes required for the biosynthesis of each alkaloid have been cloned and characterized and this information can now be used to understand alkaloid diversity across the epichloae. To overcome endophyte-related toxicity problems, endophyte-free cultivars were established but despite the improvement in animal quality and production, pasture persistence significantly decreased. Inclusion of “livestock-friendly” endophytes in forage grasses is now considered important in forage grass breeding due to the beneficial properties they impart on the host. Cultivars with endophytes that ameliorate detrimental livestock effects yet retain host fitness benefits are now in use to overcome the problems of livestock toxicity.

Key Words: fescue toxicosis, endophyte, alkaloids

76 Impact of tall fescue—Fungal endophyte associations on sustainability of pastures under current and future environmental conditions. R. McCulley,* J. Iqbal, J. Siegrist, G. Brosi, and J. Nelson, *University of Kentucky, Lexington.*

Tall fescue (*Schedonorus arundinaceous*) is often infected with a fungal endophyte (*Neotyphodium coenophialum*) that, depending on the strain, is capable of producing alkaloids that can affect grazing animal health and pasture ecosystem structure and function. While the above-ground ecological effects of fescue symbiosis with the common toxic form of the endophyte have been well-documented, less is known about below-ground responses or effects of fescue symbiosis with other “novel” strains of *Neotyphodium*. Given that endophyte symbiosis confers abiotic stress tolerance to tall fescue and that the climate and atmosphere are changing, there is a need to understand how tall fescue, the endophyte symbiosis, and the production of toxic alkaloids will be affected by future climatic conditions. Here, we summarize results from 4 studies that explore these topics. Across a range of sites in the southeastern US, tall fescue stands infected with the common toxic strain of the endophyte consistently had greater soil organic carbon and nitrogen than adjacent endophyte-free stands, suggesting that endophyte infection has the potential to increase carbon sequestration in pastures of this region. In central Kentucky, stands of tall fescue infected with the novel endophyte ‘AR-542’ had higher soil-to-atmosphere fluxes of CO_2 and N_2O than adjacent stands of endophyte-free fescue or fescue infected with the common toxic or other novel endophyte ‘AR-584,’ illustrating that root and rhizosphere processes were influenced by endophyte genotype. In Tennessee, we found that 5 years of exposure to elevated atmospheric CO_2 concentrations promoted endophyte-infected tall fescue, but contrary to expectations, endophyte infection frequency did not change under drought conditions or with warming. In Kentucky, warming increased mortality of endophyte-infected vs. –free tillers, and in both experiments, warming significantly increased alkaloid concentrations in infected fescue. These studies demonstrate that endophyte infection is likely important for the sustainability of southeastern US tall fescue pastures both now and in the future.

Key Words: *Neotyphodium*, pasture ecosystems, biogeochemistry

77 Lessons from “down-under” in New Zealand and Australia: The critical role of endophyte in pasture quality and production. D. E. Hume,* *AgResearch, Palmerston North, New Zealand.*

The *Neotyphodium* fungal endophytes of ryegrass and tall fescue are essential for the survival and productivity of these grasses in a large proportion of the pastures in the moderate to high rainfall temperate zones of New Zealand and Australia. This is primarily due to the insect protection these endophytes impart to the grass plant through alkaloid production. This is most evident in New Zealand, with some endophyte strains protecting the grass plant from up to 5 different insect species. The most widespread strains of endophyte are toxic to grazing livestock, resulting in a dilemma for livestock farmers as to whether to choose endophyte-free or endophyte-infected grass seeds. This is of greatest concern for perennial and hybrid ryegrasses, as the market size for tall fescue is relatively small and the majority of tall fescue cultivars over the last century have been sold as endophyte-free. The main disadvantage for farmers is the animal toxic endophyte strains result in ill health of grazing livestock, primarily heat stress, ryegrass staggers (ryegrass only) and fescue foot (tall fescue only). While these symptoms are visually apparent, research has shown there are also reductions in liveweight gains, milk production, reproductive performance and immune function, and in sheep fecal soiling in the breach area resulting in increased fly strike. There are several options for dealing with advantages and disadvantages of endophyte in ryegrass. The most effective solution is the use of selected novel endophytes to manage pasture pests and animal productivity. Industry uptake of this technology has been rapid for the endophytes AR1 and AR37, with AR1 now the industry standard, with other strains also providing options. Greater use of the MaxP/MaxQ novel endophyte in tall fescue is likely to increase the use of this grass species as this endophyte is safe for sheep and cattle and improves grass production and persistence. Further novel endophyte developments are likely to present even more options for the farmer in the future.

Key Words: endophyte, quality, production

78 Phases of physiological adaptation to heat stress and fescue toxicosis.

D. E. Spiers,* B. A. Scharf, J. S. Johnson, and P. A. Eichen, *University of Missouri, Columbia.*

Consequences of consuming tall fescue (*Lolium arundinaceum*) infected with the endophyte *Neotyphodium coenophialum* are well known, along with the fact that simultaneous exposure to heat stress (HS) enhances the negative effect. Less information is available about adaptation to these stressors. Studies were performed using cattle in field and chamber environments to identify the components of physiological adaptation to HS and fescue toxicosis. Exposure of Angus cattle to HS in environmental chambers results in an increase in respiration rate (RR) that remains elevated and unchanged for up to 2 weeks of HS. In contrast, rectal temperature (Tre) exhibits a biphasic response, with an initial increase followed after a few days by a greater rise under constant cycling HS. Over the same period, the initial heat-induced rise in sweat rate decreases. Acclimation to HS over a month on pasture decreases both RR and core temperature responses to heat. In a separate study, Angus cattle were maintained on endophyte-infected (E+) and uninfected (E-) tall fescue pastures for 2 mo into mid-summer, then tested in environmental chambers, followed by return to identical pastures for another 2 mo (late-summer) and retesting after this time. Feed intake (FI) and sweat rate were depressed in E+ treated cattle exposed to HS in the chambers with no change from mid- to late-summer periods showing no signs of adaptation. In contrast, Tre of E+ animals exhibited a progressively greater HS response from mid- to late-summer periods with no biphasic pattern as in controls. However, this hyperthermia merged with controls after a few days of HS. Likewise, E+ animals displayed an increase in RR, which quickly returned to control level after several days of HS to suggest adaptation. Despite evidence of thermoregulatory adjustment to these stressors, some thermal responses characteristic of fescue toxicosis (i.e., skin temperature) still show increased sensitivity to a change in air temperature. These results demonstrate that thermoregulatory and non-thermoregulatory responses to the combined stressors of heat stress and fescue toxicosis exhibit different long-term patterns of change.

Key Words: bovine, acclimation, thermoregulation

79 Managing the fungal endophyte/forage symbiosis for optimum forage-animal production.

G. Aiken,* *USDA-ARS, FAPRU.*

Tall fescue (*Lolium arundinaceum* L.) is widely utilized for grazing in the eastern half of the USA. The grass is productive and persistent under low management, which is attributed to alkaloids produced by a fungal endophyte (*Neotyphodium coenophialum*) that infects most tall fescue plants. Unfortunately, the endophyte also produces ergot alkaloids that can induce fescue toxicosis in cattle. Symptoms of the malady include rough hair coat during the summer, elevated body temperature, labored respiration, and decreased serum prolactin. Ergot alkaloids bind biogenic amine receptors in peripheral vasculature that can reduce the animal's ability to dissipate body heat and make them vulnerable to severe heat stress at onset of high ambient temperature. Calf weight gain can be very low on toxic tall fescue, particularly in warm environments, which has limited the use of fescue for stocker production. Although the grass is primarily used for cow-calf production, calving percentages, milk yields, and weaning weights can be reduced on toxic endophyte-infected tall fescue. Further, there is concern of carry-over effects of ergot alkaloids on performance of calves consuming finishing rations in the feedyard. Management technologies have been developed that demonstrate potential in alleviating or mitigating the adverse effects of fescue toxicosis on cattle performance, physiology, and well being. Evaluations of these technologies will be reviewed and the advantages and disadvantages of each will be presented.

Key Words: tall fescue, ergot alkaloids, fescue toxicosis

Graduate Student Competition: ADSA Dairy Foods Division Oral Competition

80 Norbixin partitioning in full-fat and fat-free Cheddar cheese. T. J. Smith* and M. A. Drake, *North Carolina State University, Raleigh.*

Whey protein is an important commercial product for the dairy industry, and a large portion of it is manufactured from colored Cheddar cheese whey. The Cheddar cheese colorant, annatto, is also present in whey and must be removed by bleaching. A better understanding of the primary colorant in annatto, norbixin, is crucial to produce effective methods for its removal from liquid whey. The objective of this study was to determine norbixin partitioning in cheese and whey from full-fat and fat-free Cheddar cheese. Full-fat and fat-free Cheddar cheeses and wheys were manufactured from colored pasteurized milk in quadruplicate. Three different norbixin levels (7.5, 15, and 30 mL annatto/454 kg milk milk) were used for full-fat Cheddar cheese manufacture and one norbixin level was evaluated in fat-free Cheddar cheese (15 mL annatto/454 kg milk). Norbixin extractions were performed on the milk, the unseparated cheese whey, and the pressed cheese. Norbixin was extracted by solvent extraction and column purification and quantified by high performance liquid chromatography. An average of 9.0% of the norbixin added to the full-fat cheese milk was recovered in the whey and 80.3% was recovered in the cheese. In contrast, 1.2% of the norbixin added to skim milk was recovered in the skim milk cheese whey and 85.2% was recovered in the fat-free cheeses. Level of norbixin addition to cheese milk had no effect on norbixin recovery in cheese or whey ($P > 0.05$) but decreased fat content in cheese milk decreased norbixin content of cheese whey and increased norbixin concentration in the cheese ($P < 0.05$). These results suggest that either norbixin is able to more closely associate with casein when fat is not present or that casein matrix formation and final conformation of fat-free cheese differs from that of full-fat cheese such that a higher percentage of norbixin is entrapped.

Key Words: Cheddar cheese, annatto, norbixin

81 The effect of glucose and citric acid concentration on polymerization of lactose by twin-screw extrusion. A. J. Tremaine* and T. C. Schoenfuss, *University of Minnesota.*

The creation of value-added uses for lactose would benefit dairy processors and enhance whey utilization. Polymerization of lactose to produce oligosaccharides is a promising application. Sugars can be polymerized in the presence of heat and acid, and twin-screw extrusion is a process that could provide a continuous production method. The objective of this study was to investigate the effect of glucose seeding and citric acid levels on the yield of oligosaccharides from lactose. Formulas were blended with a ribbon blender and processed on a Buhler 44-mm twin-screw extruder without a die plate. A high shear profile screw was designed in pretrial experiments, and a feed rate of 15 kg/h and 4 barrel section temperatures of 230°C, 238°C, 238°C, and off, from inlet to outlet were chosen. Treatments included 3 glucose concentrations (0%, 10%, 20%) and 2 citric acid concentrations (1% and 2%), with the remainder of the formula consisting of lactose. Process (die temperature, motor torque and specific mechanical energy) and product responses (color, degree of polymerization (DP), soluble fiber) were measured. DP determined by HPLC indicated profiles were similar between treatments and ranged from DP 1 to DP 15 or higher. Quantification of fiber indicated 26–58% by weight of sample was low and high molecular weight soluble fiber. Citric acid positively affected oligosaccharide yield. These results indicate that oligosaccharides can be created with a continuous process. Further characterization of this product, as well as the development of clean up and concentration methods to remove mono- and disaccharides could lead to the production of a high-value soluble fiber from lactose.

Key Words: extrusion, lactose, oligosaccharides

82 Impact of bleaching on flavor and functional properties of 80% serum protein concentrate. R. E. Campbell*[1], M. Adams[2], D. M. Barbano[2], and M. A. Drake[1], [1]*North Carolina State University, Raleigh,* [2]*Cornell University, Ithaca, NY.*

Whey proteins that have been removed before the cheese making process are referred to as “native” whey proteins or milk serum proteins. Chemical bleaching of residual annatto has a detrimental effect on whey protein flavor and functional properties. Serum protein allows direct investigation of these effects without the confounding influence of cheesemaking parameters. The objective of this study was to characterize and compare the sensory and functional properties of 80% milk serum protein concentrate (SPC80) produced from bleached and unbleached microfiltered (MF) skim milk permeate with and without added annatto color. Colored and uncolored MF permeates were bleached with benzoyl peroxide (BP) or hydrogen peroxide (HP), ultrafiltered, diafiltered and spray-dried. SPC80 from unbleached colored and uncolored MF permeates were manufactured as controls. All treatments were manufactured in triplicate. Flavor and functional properties of SPC80 were evaluated by sensory and instrumental analyses. The HP bleached SPC80 was higher in lipid oxidation compounds than other bleached or unbleached SPC80, specifically hexanal, heptanal, nonanal, decanal, and 2,3 octadienone($P < 0.05$). Consistent with instrumental results, HP SPC80 were also higher in aroma intensity, cardboard and fatty flavors compared with other SPC80 ($P < 0.05$). The BP SPC80 had lower norbixin concentrations compared with SPC80 bleached with HP ($P < 0.05$). Functionality tests demonstrated that HP SPC80 had more soluble protein after 10 min of heating at 90°C at pH 4.6 and pH 7 than the no bleach and BP treatments regardless of additional color. SPC80 foams generated from bleached samples were more stable than those from unbleached samples ($P < 0.05$). SPC80 bleached with HP were lower in yield stress than other samples ($P < 0.05$). HP bleaching caused more lipid oxidation products and subsequent off flavors than BP bleaching. Bleaching also altered heat and foam stability and this effect was more pronounced with HP compared with BP. These results demonstrate that chemical bleaching alters flavor and functional properties of milk serum proteins. Optimized bleach concentrations and conditions should be determined for whey or chemical bleaching alternatives established.

Key Words: serum proteins, bleaching, functionality

83 Study of the heat-induced interaction pathway between whey protein and buttermilk components. M. Saffon*[1], R. Jiménez-Flores[2], M. Britten[3], and Y. Pouliot[1], [1]*STELA Dairy Research Center, Institute of Nutraceuticals and Functional Foods (INAF), Université Laval, Quebec City, QC, Canada,* [2]*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo,* [3]*Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada, St-Hyacinthe, QC, Canada.*

Previous work showed that it was possible to form mixed aggregates by heating whey protein in the presence of buttermilk components. It was hypothesized that caseins and milk fat globule membrane proteins act as a nucleus in the process of whey protein aggregation. Buttermilk powders were obtained by spray drying after ultrafiltration (UF) and diafiltration (DF) of regular buttermilk and whey buttermilk. A portion of these powders was treated by supercritical fluid extraction (SFE) to remove non-polar lipids. Powders were mixed with UF/DF concentrated whey, and the mixtures were heated to 90°C for 5 min at pH 4.6. The dispersions were heated with or without thiol blocking N-ethylmaleimide (5 mM). The liberation of free –SH and the protein profiles were determined every 5 min respectively with the Ellman's reagent and one dimensional PAGE technique (SDS-PAGE) under non-reducing and reducing conditions. 3D images were taken at 100× with a confocal laser-scanning microscope. All experiments were performed in triplicate and the concentrations of free –SH in the mixtures were compared with control (whey) using T tests. Addition of buttermilk significantly decreased the liberation of free –SH during heating. SDS-PAGE gels under non-reducing conditions showed a decrease in native whey and buttermilk proteins during heating, and large aggregates were evident. These large aggregates were also found under reducing conditions and in the presence of N-Ethylmaleimide (NEM). Three-dimensional (3D) images confirmed the interaction between protein and fat globule membrane even in presence of NEM. Overall, our results suggest that the MFGM (either protein or phoshpolipids) could act as an initiator during the formation of mixed aggregates with whey proteins.

Key Words: heat-induced interaction, milk fat globule membrane, whey protein

84 Effect of milk processing on the anticarcinogenic capacity of the milk fat globule membrane.

R. Zanabria*[1], A. Tellez[2,1], M. Griffiths[2,1], and M. Corredig[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Canadian Research Institute for Food Safety (CRIFS), Guelph, ON, Canada.*

The milk fat globule membrane (MFGM), the surface-active material surrounding fat globules in milk, has been shown to have potential anticarcinogenic properties by inhibiting the proliferation of cancer cells through cytotoxic and apoptotic effects. Though the effect of milk processing on the MFGM functional properties is known, the effects over its bioactivity are still lacking. Objective of this work was to determine if processing (i.e., heat treatment) has an effect over the MFGM bioactivity. Two representative colon cancer cell models (HT-29 and Caco-2) were used to test the antiproliferative capacity of MFGM isolates obtained from raw and heat-treated milk. Raw MFGM material was obtained by washing the cream twice with endotoxin free water, subsequent freeze-thawing and ultracentrifugation. Bacterial contamination and lipopolysaccharide (LPS) presence was quantified and kept at minimum by collecting the milk with a catheter and working under sterile conditions. For the heat treated samples, raw milk was batch-treated at 80°C for 10 min (HT80), 74°C for 3 min (HT74) or 63°C for 30 min (HT63) and then the MFGM was extracted. Cell proliferation was studied by the BrdU colorimetric test. Results showed a similar dose-dependent DNA synthesis decrease in both cell lines exposed to 6.25–200 µg protein raw MFGM/mL, although Caco-2 cells seemed to be more resistant. The EC50 values were 111 and 88 µg protein MFGM/mL for Caco-2 and HT-29 cells, respectively. Ceramide (20 µM) used as positive control showed a similar effect, supporting the hypothesis of the sphingolipids as one of the possible compounds responsible for the bioactivity. When the heat treated samples where used, this bioactivity was significantly affected. The HT80 highest dose only produced a 10% reduction in cell proliferation while the lowest concentrations caused the opposite effect by incrementing cell DNA synthesis up to 35%. Similar trends, yet improved, were observed with the HT74 and HT63 fractions: 100 µg protein MFGM/mL caused a cell division decrease of 30 and 40% respectively. These results will be discussed in light of the physico-chemical changes occurring to the MFGM during heating, and they raise new questions related to which active components play a role in the antiproliferative effect observed with the colon cancer cell lines.

Key Words: MFGM, bioactivity, anticarcinogenic

85 Heat stability of micellar casein concentrate (MCC) as affected by temperature and pH.

A. Sauer* and C. I. Moraru, *Cornell University, Ithaca, NY.*

The increasing interest in using MCC obtained by membrane separation in manufacturing shelf-stable high protein products creates a need to understand the effect of sterilization treatments on the stability of this ingredient. The goals of this work were to: 1) elucidate the effects of pH and sterilization temperatures on the mineral distribution and dissociation of caseins; and 2) use the generated knowledge to develop solutions for stabilizing the MCC during sterilization treatments. MCC powders were reconstituted with water at 8% concentration, and the resulting dispersions were adjusted to pH values of 6.5–7.3. Subsequently, the 8% MCC samples were heated in an oilbath to 110°C to 150°C, in 10°C increments. The come-up time was identical for all heat treatments. The treated samples were evaluated for particle size, soluble minerals and casein dissociation. Measurement of soluble minerals and casein dissociation (by LC-MS/MS) were performed on supernatants obtained after ultracentrifuging the samples for 60 min at 100,000 × *g*. The study was conducted in triplicate and the data analyzed statistically. At pH 6.5 and 6.7, all heat treated samples were visibly aggregated or coagulated. At pH 6.9, higher temperatures lead to increased particle size, while at pH > 6.9 little or no changes were observed after heat treatment. Casein dissociation increased with increasing pH for all 4 caseins, at all temperatures, with dissociation of κ-CN and β-CN being most significant ($P \leq 0.05$). At higher pH, the levels of dissociated αs-CN decreased after heat treatment, suggesting aggregation of αs-CN due to the presence of calcium and lost protection by κ-CN. It was concluded that increased stability of MCC requires increasing the pH and lowering the processing temperature. MCCs were then submitted to sterilization after targeted modifications: increased pH and lower processing temperature, at equivalent lethality. A significant reduction ($P \leq 0.05$) in particle size was obtained and no coagulation or aggregation occurred after retorting or UHT. The generated knowledge will allow the effective stabilization of MCC in practical applications, such as the production of novel, shelf-stable protein beverages.

Key Words: micellar casein concentrate (MCC), sterilization, stability

86 Development of a model system to understand the mechanisms of instability and to predict the shelf-life of oil-in-water emulsions.

Y. Liang*[1,2], H. Patel[1], L. Matia-Merino[2], A. Ye[3], and M. Golding[2,3], *[1]Fonterra Research Centre, Palmerston North, New Zealand, [2]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [3]Riddet Institute, Massey University, Palmerston North, New Zealand.*

Emulsion systems are generally very complex depending on the type and the amount of protein or surfactant present in the various emulsion phases; it is difficult to understand the mechanism of instability. The objective of this study was to design a simple model system to characterize the role of the proteins and surfactants present in the various phases of an emulsion and to probe the exact mechanisms of instability. Four possible oil-in-water model emulsion systems (pH 6.8 to 7.0) that represented potential interactions between protein-coated or surfactant-coated emulsion droplets and non-adsorbed proteins present in the continuous phase were designed. The model emulsions were prepared by 2 different methods: (a) by mixing stock emulsions [20% w/w oil-in-water emulsions stabilized by 1.0% w/w sodium caseinate (Na-CN) or Tween-20] with solutions of milk protein concentrate (MPC), whey protein concentrate (WPC) and hydrolyzate (WPH) to yield emulsions with a range of protein concentration and (b) by using Na-CN, WPC, and MPC as the sole source of emulsifier for a comparison study. Model emulsions were characterized for particle size, creaming stability, microstructure, rheology, and PAGE (PAGE). Depletion flocculation was observed in emulsions prepared with MPC when the protein concentration in the continuous phase was above 3% w/w and the oil droplets were stabilized primarily by either Na-CN or Tween-20. The state of aggregation and the polydispersity of non-adsorbed casein micelles in the continuous phase determined the extent of depletion flocculation and the shear flow behavior. The caseinate-stabilized droplets were incorporated in the heat-induced protein gel network in model emulsions containing excess non-adsorbed WPC, but Tween-20 stabilized droplets were repelled from the gel. PAGE analysis of various emulsion phases and the addition of EDTA to the systems confirmed competitive adsorption and surface displacement of caseins by whey proteins. The unique model systems approach improved our understanding of the influence of heat-induced ingredient interactions in the system and was success in describing the potential interparticle interactions, which can be used to improve the stability of protein-stabilized emulsions.

Key Words: milk protein, oil-in-water emulsion, instability

87 Shear stabilized micro-phase-separated dairy gels containing significant concentrations of β-glucan. N. Sharafbafi*[1], S. M. Tosh[2], and M. Corredig[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Agriculture and Agri-Food Canada, Guelph Food Research Center, Guelph, Ontario Canada.*

Incorporation of nutritionally significant concentrations of soluble fiber (β-glucan) into dairy food products is challenged by thermodynamic incompatibility between polysaccharide molecules and milk proteins. It was hypothesized that gelation of milk proteins under shear would increase the connectivity between the β-glucan phase separated domains, and result in dairy matrices for the delivery of nutritionally significant concentrations of dietary fiber. Rennet induced gelation was the method of choice as it possesses minimal effect on ionic condition of mixed systems. Different shear rates (50 and 100 s^{-1}), shearing times (17, 20, 25 min), and different concentrations of milk proteins (2.78, 5.57, and 8.36%, wt/wt) and β-glucan (0.2 and 0.4%, wt/wt) were tested, to evaluate possible differences in structure of the gels formed. The mixtures were continuously sheared (using rheometer) until approximately 80% of the caseino-macro-peptide was released. Shearing for a longer time resulted in an increase in the viscosity of the mixtures and breakage of the bonds formed between renneted casein micelles. At a constant shear rate and β-glucan concentration, increase in protein concentration significantly increased the stiffness of the gel. At constant protein concentration and low concentrations of β-glucan ($\leq$0.4%), an increase in shear rate reduced the time of gelation and the stiffness of the gel, while it resulted in a faster gelation time and higher gel modulus at higher concentrations of β-glucan ($\geq$0.4%; $P \leq 0.5$). Micro-structural analysis of gels after 2 h of renneting revealed high connectivity between the phase separated domains at high concentrations of milk proteins and β-glucan. At these concentrations, due to formation of bi-continuous structures upon mixing, increase in shear rate resulted in lower viscosity and formation of droplet like domains, which may have resulted in self supporting gels. It was concluded that controlling shear during gelation of milk proteins mixed with β-glucan makes it possible to create novel microstructures in dairy products that provide nutritionally significant ($\geq$0.3%, wt/wt) concentrations of soluble fiber.

Key Words: phase separation, shear, gelation

88 Streamlining the product development process: Use of the preferred attribute elicitation technique to extract key texture attributes influencing consumer liking of dairy yogurts. A. Grygorczyk*[1], M. Corredig[1], I. Lesschaeve[2], and L. Duizer[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Vineland Research and Innovation Centre, Vineland Station, ON, Canada.*

Understanding the key attributes affecting consumer liking is very important for guiding the product development process. While conventional profiling methods employing trained panelists provide a detailed description of products, they cannot generate insight into importance of attributes as they do not engage consumers. The method examined in this study is a novel method, which we will refer to as preferred attribute elicitation (PAE). The method derives important attributes by asking a panel of consumers to agree to a set of attributes which stand out most to them, to rank them according to importance and then to rate the products based on those attributes. As this a novel technique there is a need to examine the method further to understand its strengths and weaknesses, as well as its place among sensory methodologies. The principal components plots generated by the PAE approach and conventional profiling were compared using multiple factor analysis and the RV coefficient. The results for texture characterization of yogurts were found to be highly correlated between the 2 methods (RV coefficient = 0.877). The PAE method was repeated in 4 sessions and a comparison of sessions employing the same set of products generated significant RV coefficients, indicating that the approach generated reproducible data for this set of products. The results confirmed the importance of texture to consumer liking and found that runny texture and gritty mouthfeel detracted from liking. Nearly all attributes generated by consumers explained a significant portion of the variability in the study, indicating that consumers were capable of characterizing products in a meaningful way. It is expected that the method would be most useful in the early stages of product development when only a general product characterization is required and a detailed description may generate confusion.

89 Hyperprolactinemia during late gestation increases milk yield from primiparous gilts and piglet growth. M. K. VanKlompenberg,* R. Manjarin, H. F. McMicking, and R. C. Hovey, *University of California, Davis.*

A major limitation for piglet growth and survival is maternal milk yield that is dependent on maximal mammary growth and optimal lactogenesis. Several lines of evidence point to prolactin (PRL) as being crucial for these processes in pigs, where a critical period during late gestation has been defined as being PRL-dependent. We hypothesized that administering a dopamine antagonist to induce hyperprolactinemia in primiparous gilts during late gestation would increase mammary growth, subsequent milk yield and piglet growth. A total of 19 Yorkshire/Hampshire gilts were assigned to receive either vehicle (VEH, n = 9) or domperidone (DOM, n = 10) twice daily from gestation (G) d90 to 110. Serial blood sampling during the treatment period and lactation, and subsequent radioimmunoassay confirmed that serum PRL levels were increased in treated animals at G91 ($P < 0.001$). Data were analyzed using a linear mixed model and *t*-test comparisons. Mammary gland biopsies were performed on d90, 100 and 110 of gestation and d 2 and 21 of lactation (L) to analyze various aspects of mammary gland growth. Piglets raised by DOM dams were 21% heavier than controls (4279 ± 341.0 g and 3533 ± 348.1 g, respectively; $P < 0.05$) at weaning (L21), having significantly greater average daily gains between L8 to 14 (234.7 ± 18.7 g/d, 195.0 ± 19.1 g/d; $P < 0.05$), and L15 to 21 (258.7 ± 18.7 g/d, 206.3 ± 19.1 g/d; $P < 0.01$). Milk production was measured using the weigh-suckle-weigh method on L2, 7, 14 and 21. Similar to piglet gain, milk production rate by DOM dams compared with controls was greater on L14 (30.7 ± 3.3 mL/h, 24.9 ± 3.3 mL/h; $P < 0.05$), and L21 (35.3 ± 3.3 mL/h, 26.9 ± 3.3 mL/h; $P < 0.01$). Taken together, these data indicate that pharmacologically induced hyperprolactinemia in primiparous gilts during late gestation leads to increased milk yield during established lactation that enhances piglet growth.

Key Words: mammary gland, milk production, prolactin

90 Photoperiod treatment during lactation alters organ weights but does not affect litter weight gain in mice. P. A. Bentley* and T. B. McFadden, *University of Alberta, Edmonton, Alberta, Canada.*

Manipulation of photoperiod is a well established method of enhancing milk production in dairy cows. Cows exposed to either short day photoperiod during the dry period or to long day photoperiod during lactation produce more milk. Photoperiod treatment is known to alter hormonal signaling and affect systemic immunity, both of which could be related to the milk yield response; however, definitive understanding of the underlying physiological mechanisms is lacking. The objectives were to determine the effects of different photoperiods on milk yield and weights of organs related to metabolic support of lactation or immune function in mice. Mice (n = 6 for each trt × time) were exposed to normal day length (12L:12D) during gestation and were then randomly allocated to long day (16L:8D), short day (8L:16D), or normal day length treatments from parturition through 15 d of lactation. Milk yield was estimated from litter weight gain and organs were weighed immediately after mice were euthanized. Data were analyzed using Proc GLM to test significance of main effects and interaction of photoperiod and time. Photoperiod had no effect on litter weight or litter weight gain/d. The main effect of photoperiod on dam weight was significant ($P < 0.03$), and dams on long day photoperiod weighed more ($P < 0.001$) on d 5 of lactation than those on short days. There was also an overall effect of photoperiod treatment on weight of dam's liver, normalized to body weight ($P < 0.01$), and d 15 liver weight was greater for dams on long days than on normal or short days ($P < 0.01$). Spleen weight was affected ($P < 0.02$) by photoperiod treatment, being greater in mice exposed to long days ($P < 0.01$). These data demonstrate that exposure of lactating mice to different photoperiods elicited physiological changes but did not affect milk yield. Increased weight of body, liver, and spleen of dams suggests that photoperiod may affect metabolic and immune function in mice, perhaps through mechanisms similar to those affecting mammary and immune function in dairy cows. Understanding of responses to photoperiod treatment in mice may help identify mechanisms of action in dairy cows.

Key Words: photoperiod, lactation, immune

91 Serotonin (5-HT) affects glucose metabolism in transition rats. J. Laporta,* T. L. Peters, K. E. Merriman, and L. L. Hernandez, *University of Wisconsin, Madison.*

The role of 5-HT in regulating processes such as milk synthesis and secretion have been defined. 5-HT has also been implicated in liver glucose homeostasis. 5-HT is synthesized in a 2-step reaction from the amino acid L-tryptophan (L-TRP). The rate-limiting step is catalyzed by tryptophan hydroxylase (TPH1) isoform to form 5-hydroxytryptophan (5-HTP), the immediate precursor to 5-HT. To explore 5-HT's role in glucose homeostasis during the transition period (9 d pre and postpartum) we fed 45 rats (n = 15 per-treatment) 3 diets: control (CON), 5HTP (0.2% total diet) and L-TRP (1.35% total diet) to increase endogenous 5-HT production. We measured daily milk yield (MY) and collected milk samples on d 1, 5 and 9 of lactation to measure lactose concentrations. We collected serum and plasma on d 20 of gestation and d 9 of lactation to measure circulating 5-HT and glucose levels. Total RNA was isolated from liver and mammary gland tissue and mRNAs for growth hormone receptor (GHR), pyruvate carboxylase (PC), phosphoenol pyruvate carboxykinase-1 (PEPCK1) in liver, and for glucose transporter-1 (GLUT1), PC and GHR in mammary gland were quantified by quantitative real time PCR. The 5-HTP and L-TRP treatments effectively increased serum 5-HT over time ($P < 0.001$), with a greater increase seen in the 5-HTP cohort. MY was the same among all cohorts, until d 8 and 9, in which it increased in L-TRP animals ($P < 0.05$). There were no significant differences in milk lactose levels between treatments ($P > 0.05$). Plasma glucose concentrations decreased from d 20 of gestation to d 9 of lactation in all cohorts, but more markedly in the L-TRP ($P < 0.001$). Liver GHR mRNA expression was decreased in both treatment cohorts ($P < 0.05$) while PC mRNA was increased only in the 5-HTP cohort ($P < 0.01$), however there were no significant changes in the mammary gland. Liver PEPCK1 was not affected while GLUT1 mRNA was greater in the mammary gland of both treatment groups when compared with CON group ($P < 0.05$). Feeding 5-HTP during the transition period increases 5-HT synthesis and appears to affect glucose homeostasis, and negatively affects GH's effects in the liver.

Key Words: 5-HT, liver, glucose

92 Inflammatory pathways contribute to the metabolic adaptations to lactation in dairy cattle.

J. K. Farney*[1], L. K. Mamedova[1], J. F. Coetzee[2], B. KuKanich[1], L. M. Sordillo[3], J. E. Minton[1], L. C. Hollis[1], and B. J. Bradford[1], [1]*Kansas State University, Manhattan,* [2]*Iowa State University, Ames,* [3]*Michigan State University, East Lansing.*

Inflammation has been proposed as a contributor to metabolic disorders in transition dairy cows. The purpose of this experiment was to determine if a non-steroidal anti-inflammatory drug, sodium salicylate (SS), alters metabolism of transition dairy cows. At calving, 78 cows (n = 39 primiparous [1P]; n = 24 2nd lactation [2P]; n = 15 ≥ 3 lactations [3P]) were alternately assigned to either control (CON) or SS treatment for 7 d and remained on study until 21 d postpartum. SS treatment was administered via individual water bowls at a concentration of 1.68 g/L, delivering a mean of 123.3 ± 5.5 g SS/d during the 7 d of treatment. Blood samples were collected weekly and liver biopsies were collected on d 4 and 21 postpartum. Data were analyzed using mixed models with repeated measures over time and significance was declared at $P < 0.05$ and interactions were investigated at $P < 0.15$. There were no overall treatment effects on daily intake of water or DM, and SS treatment resulted in plasma salicylate concentrations of 34.4 ± 15.0 μg/mL on d 7. Liver TNFα mRNA abundance was decreased by SS on d 4 (28% reduction). Plasma glucose concentration was decreased by SS on d 7, especially in 2P and 3P cows (51.7 vs. 40.7 ± 3.1 mg/dL); 3P cows treated with SS had a 49% reduction in glucose-6-phosphatase mRNA on d 4 and a 81% reduction (d 21) in mRNA abundance of CREBH, a positive regulator of gluconeogenesis induced by inflammatory pathways. Plasma BHBA concentration was elevated in SS cows on d 14 and 21 (977 vs. 749 ± 56 μM), and plasma NEFA was elevated in SS cows on d 21 (525 vs. 377 ± 36 μM). SS treatment significantly increased liver triglyceride content on d 4 (29% increase) but by d 21 concentrations were similar across treatments. Because the most dramatic responses were observed in 3P cows, plasma samples from this block were analyzed for 14 eicosanoids. An index comprised of 11 pro-inflammatory eicosanoids showed no differences on d 7, but were significantly elevated for SS on d 14 (150% increase). Therefore, responses to SS after d 7 may have been due to altered metabolic programming or to post-SS increases in inflammatory signals. In summary, SS suppressed liver inflammation but decreased plasma glucose, increased plasma ketones, and contributed to liver triglyceride accumulation. These findings suggest that interrupting inflammation during the first week after parturition alters the metabolic adaptations to lactation.

Key Words: transition, inflammation, liver metabolism

93 Metabolism of butyrate infused in the rumen or abomasum of lactating dairy cows.

K. J. Herrick*[1], A. R. Hippen[1], K. F. Kalscheur[1], D. J. Schingoethe[1], D. P. Casper[1], S. C. Moreland[2], and J. E. van Eys[2], [1]*South Dakota State University, Brookings,* [2]*Nutriad Inc., Elgin, IL.*

This research was to investigate the effects on plasma metabolites and rumen measures when butyrate was infused into the rumen or abomasum of lactating cows. Jugular catheters were inserted into 5 ruminally fistulated Holstein cows (94.2 ± 23.3 DIM; 717 ± 45 kg BW) in a 5 × 5 Latin square with 3-d periods. Cows were infused for 24 h with one of 5 treatments: water (CON), 1 g/kg BW of butyrate infused into either the abomasum (A1) or rumen (R1), or 2 g/kg BW of butyrate infused into either the abomasum (A2) or rumen (R2). Sodium butyrate was the source of butyrate and NaCl was added to the CON, A1, and R1 treatments to provide equal amounts of sodium as the 2 g treatments. Flanges were inserted into the abomasum to allow infusion to the abomasum and peristaltic pumps provided continuous infusion of all treatments. Serial blood samples were collected at −2, −1, 0, 0.5, 1, 2, 3, 4, 6, 8, 12, 18, and 24 h relative to starting dosing. Rumen fluid samples were collected at −2, −1, 0, 1, 2, 4, 6, 8, 12, 18, and 24 h relative to starting dosing. Area under the curve (AUC) was calculated using the pre-dosing values as a baseline. Average DMI and average production measures were not affected by treatment ($P < 0.05$). Plasma glucose (73.0, 67.2, 65.3, 69.6, and 62.1 mg/dl), plasma β-OHB (β-hydroxybutyrate) (615, 965, 1454, 676, and 1235 mM), and plasma butyrate (0.08, 0.09, 0.11, 0.10, and 0.15 mM) for the CON, R1, R2, A1 and A2 treatments were affected by butyrate addition and treatment dose ($P < 0.05$). The site of dosing affected ($P < 0.05$) plasma butyrate. Rumen butyrate (9.0, 15.3, 22.1, 9.4, and 9.7 mM) for the CON, R1, R2, A1 and A2 treatments respectively were affected by treatment, dosage, site of infusion, and interaction of site and dosage ($P < 0.05$). The AUC (44, −105, −342, −119, and −338 mg/dL • h) and the height of the largest peak for plasma glucose (−7.3, −12.2, −24.4, −12.8, and −25.6 mg/dL) and the AUC for rumen pH (−12.22, −8.15, −4.95, −10.60, and −6.58 pH • h) for CON, R1, R2, A1, and A2 were affected ($P < 0.05$) by butyrate addition and dose. Results demonstrate that butyrate infused into the rumen or abomasum decreases plasma glucose and increases plasma β-OHB.

Key Words: butyrate, infusion, ketone

94 Effect of breed on the metabolic profile in transition Holstein and Jersey dairy cows.

K. J. Lager*[1,2], E. R. Jordan[1], R. G. S. Bruno[1,2], J. A. H. Rivera[3], A. M. Farias[3], R. Sprowls[4], and D. R. Topliff[2], [1]*Texas AgriLife Extension Service, Texas A&M System, College Station,* [2]*West Texas A&M University, Canyon,* [3]*Texas AgriLife Research, Stephenville,* [4]*Texas Veterinary Medical Diagnostic Laboratory, Amarillo.*

Significant advances in productivity have resulted due to genetic selection of Holstein and Jersey dairy cattle, as well as enhanced nutritional management. The objective of this study was to determine whether differences exist between the metabolic profile of Holstein and Jersey cows during the periparturient or transition period. Blood samples were collected from Holstein (n = 3658) and Jersey (n = 1699) cows within the transition period via coccygeal vessel venipuncture in nonheparinized vacuum tubes at morning feeding on 8 commercial dairies of each breed. Following centrifugation, samples were stored frozen (−20°C) in duplicate before laboratory analysis for calcium (Ca), phosphorus (P), magnesium (Mg), albumin, urea, glucose, cholesterol, sodium (Na), potassium (K), chloride (Cl), and nonesterified fatty acids (NEFA). Feed samples were collected on the day of sampling. Herd records were reviewed to identify data points from cows experiencing dystocia, retained placenta, displaced abomasum, twin births, stillbirths and cows being dry <30d or >80d and data were analyzed using multiple regression. The effect of breed was significant ($P < 0.001$) for all measured parameters exclusive of Na and cholesterol. Further, sampling week relative to calving was shown ($P < 0.001$) to affect P, Mg, Na, K, Cl, NEFA, glucose, and cholesterol, while number of lactations affected ($P < 0.05$) Ca, P, albumin, urea, glucose, cholesterol, and NEFA levels. Animal health is a factor in profile levels as animals experiencing one or more of the previously stated health incidences displayed differences ($P < 0.05$) in Ca, Mg, albumin, urea, cholesterol, K, and Cl but no difference in NEFA or glucose levels. These results suggest greater focus is necessary for the individual breeds if utilizing the metabolic profile as a diagnostic tool.

Key Words: dairy cow, metabolic profile, transition period

95 Effects of corn silage hybrids and quality of alfalfa hay on nitrogen metabolism and ruminal fermentation of early lactating dairy cows.

M. S. Holt*[1], A. J. Young[1], J.-S. Eun[1], and K. E. Nestor[2], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan,* [2]*Mycogen Seeds, Indianapolis, IN.*

This experiment was conducted to determine the effects of corn silage (CS) hybrids and quality of alfalfa hay (AH) in high forage dairy diets on N metabolism and ruminal fermentation by early lactating dairy cows. Eight multiparous Holstein cows were used in a duplicated 4 × 4 Latin square experiment with a 2 × 2 factorial arrangement of treatments. The 8 cows (average days in milk = 23 ± 11.2) were surgically fitted with ruminal cannula, and the 2 squares were conducted simultaneously. Within square, cows were randomly assigned to a sequence of 4 diets during each of the 4 21-d periods (14 d of treatment adaptation and 7 d of data collection and sampling); conventional CS (CCS) or brown midrib CS (BMRCS) was combined with low quality AH (LQAH: 46.4% NDF and 18.7% CP) or high quality AH (HQAH: 37.4% NDF and 21.8% CP) to form 4 treatments: CCS with LQAH, CCS with HQAH, BMRCS with LQAH, and BMRCS with HQAH. Diets were isonitrogenous across treatments averaging 15.8% CP. Intake of DM did not differ because of CS hybrids and AH quality. While feeding BMRCS-based diets decreased urinary N output by 32% ($P < 0.01$), it did not affect fecal N output. Feeding HQAH decreased urinary N output by 18% ($P = 0.01$), but increased fecal N output by 14.5% ($P = 0.01$). Nitrogen efficiency (milk N (g/d)/intake N (g/d)) was similar across treatments. Ruminal ammonia-N concentration was lower for cows fed BMRCS-based diets than those fed CCS-based diets ($P = 0.02$), but was not affected by quality of AH. Feeding BMRCS-based diets decreased MUN concentration and yield by 23% ($P < 0.01$), whereas feeding HQAH decreased MUN concentration and yield by 15% ($P < 0.02$). Total VFA concentration increased with HQAH ($P = 0.02$), but was not influenced by CS hybrids. Milk yield did not differ due to CS hybrids, but it tended to decrease ($P = 0.08$) by feeding HQAH. Significantly decreased MUN by feeding BMRCS or HQAH suggests improved whole-body N utilization efficiency.

Key Words: brown midrib corn silage, alfalfa hay, nitrogen efficiency

96 Effects of partial replacement of dietary starch from barley or corn with lactose on the performance of dairy cows.

G. E. Chibisa*[1], G. B. Penner[1], P. Gorka[1], R. Berthiaume[2], and T. Mutsvangwa[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada.*

Sugars are more rapidly fermented in the rumen than starch, and replacing dietary starch with sucrose in corn/alfalfa silage-based diets has been reported to improve milk production in dairy cows. Few studies have used lactose as a partial replacement of starch from barley or corn, which differ in their rates and extents of ruminal fermentation. The objective of this study was to determine the effects of replacing barley or corn starch with lactose (as dried whey permeate; DWP) on DMI, milk yield and composition, ruminal pH, and blood metabolites. Eight lactating dairy cows were used in a replicated 4 × 4 Latin square design with 28-d periods (18 d of dietary adaptation and 10 d of measurements) and a 2 × 2 factorial arrangement of dietary treatments. Four cows in one Latin square were ruminally-cannulated for the measurement of ruminal fermentation characteristics. The treatment factors were source of starch (barley vs. corn) and dietary inclusion level of DWP (0 vs. 6%, DM basis) as a partial replacement for starch. Diets were isonitrogenous (18% CP) and contained 3% (low) or 8% (high) sugar. The starch content of the low sugar diets was 24% compared with 20% for the high sugar diets. Dry matter intake, milk composition, milk and milk component yields, and blood glucose and β-hydroxybutyrate concentrations did not differ ($P > 0.05$) with diet. The daily mean and maximum pH were similar ($P > 0.05$) across diets. However, minimum pH tended to be lower ($P = 0.07$) when feeding barley compared with corn. The duration (h/d) that ruminal pH was below pH 5.8 also tended to be shorter ($P = 0.06$) whereas the area (pH × min/d) that pH was below pH 5.8 was smaller ($P = 0.04$) on the corn diet compared with the barley diet (47 vs. 111). Cows fed 6% DWP had lower ruminal ammonia ($P = 0.04$; 11.2 vs. 14.0 mg/dL) and milk urea nitrogen concentrations ($P < 0.01$; 16.5 vs. 17.8 mg/dL) and tended to have lower blood urea nitrogen ($P = 0.07$) compared with those fed 0% DWP. In conclusion, partially replacing corn or barley starch with DWP improved N efficiency, but had no effect on production and ruminal pH in dairy cows.

Key Words: lactation performance, lactose, starch

97 In search of privacy: Dairy cow preference for an isolated calving area.

K. L. Proudfoot,* D. M. Weary, and M. A. G. von Keyserlingk, *University of British Columbia, Vancouver, British Columbia, Canada.*

When dairy cows are housed in semi-natural environments, they distance themselves from the herd to calve. Indoor-housed cows have limited ability to isolate from the herd, as many are housed in group pens or in individual pens located in high traffic areas. The aim of this study was to assess whether indoor-housed cows would seek isolation to calve if given a choice, and if this choice was influenced by the time of day and the number of cows in the pen. Seventy-two Holstein dairy cows (50 multiparous; 22 primiparous) were paired by calving date. At 6.6 ± 3.0d before calving, each pair entered one of 4 maternity pens. Each pen included an “open” sawdust pack (2.4 × 7.3m) and an “enclosed” sawdust pack (2.4 × 6m); the enclosed pack was surrounded by 2.4m high plywood walls on 3 sides, the fourth side had a 2.4m opening that allowed cows to freely enter or exit the enclosure. Once the first cow of a pair calved she was removed; the second cow remained single-housed in the pen until she calved. We used video to assess the time and area where calving took place. The probability that pair- and single-housed cows would calve in the open or enclosed pack, and during the ‘day’ (08:00 to 21:00 h) or ‘night’ (21:00 to 08:00 h), was assessed using Chi-Square tests. We noted no differences between primiparous and multiparous cows, so tests were done using a combined data set. Pair-housed cows were more likely to calve in the open pack, whereas single-housed cows were more likely to calve in the enclosed pack (Chi-Square = 4.5; $P = 0.03$). Choice of calving area was contingent on the time of day for single-housed cows (Chi-Square = 7.5; $P = 0.01$) but not for pair-housed (Chi-Square = 0.2; $P = 0.67$). Single-housed cows that calved at night were more likely to calve in the open, but cows that calved during the day were more likely to be in the enclosed area. Results suggest that isolation-seeking at calving is contingent on time of day and the number of cows in the pen.

Key Words: transition, housing, maternity

98 II. Identifying within-herd risk factors affecting reproductive performance of lactating dairy cows under field conditions. S. Bas*[1], R. L. Nebel[2], and G. M. Schuenemann[1], *[1]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [2]Select Sires Inc., Plain City, OH.*

Many factors influence the reproductive performance of dairy herds, thus, profitability. Successful identification of factors affecting pregnancy rate (PR) at herd level can be challenging due to their multi-factorial nature. The objective was to assess the effectiveness of an interactive dairy herd index (DI) to aid in decision making about reproductive management of dairy cows. Data from one dairy herd, previously assisted to improve PR, was used to validate the DI. Risk factors [stillbirth, retained fetal membranes (RFM), metritis, mastitis, lameness, body condition score (BCS), estrus detection (ED), conception risk (CR), labor-cow ratio, and stocking density] were assessed according to their contribution weights (CW) on PR. Data from previous studies were used to estimate the CW using linear regression. Additionally, risk factors (one yr before and after intervention) were compared with desired reference values to obtain the relative difference for individual DI by components and ranking of risk factors. According to the DI, stocking density, metritis, lameness, and stillbirth were the top 4 risk factors explaining PR before intervention. These risk factors were in agreement with findings collected during the herd walk-through. Recommendations were close-up pen for dry cows; 85% stocking density for close-up and fresh cows; comprehensive training (calving management and hoof trimming) to dairy personnel; and no changes were made on nutrition and reproductive management. After intervention, the relative difference (change of risk factor values) was improved for stillbirth (45%), lameness (46%), metritis (33%), stocking density (13%), and mastitis (13%). No changes were observed for RFM (0%), BCS (0%), and labor-cow ratio (0%) while the relative differences for ED (3%) and CR (6%) were decreased after intervention. Dairymen, consultants, and veterinarians often trouble-shoot poor PR in dairy herds and this process requires constant monitoring and comprehensive assessment of several events. Risk factors affecting PR varies from farm-to-farm and blanket recommendations often fail when applied to many herds. This DI may assist decision makers to focus on real within-herd risk factors accounting for the effect of management.

Key Words: index, pregnancy, dairy cow

99 Efficacy of a combination butaphosphan and cyanocobalamin product and insulin for ketosis treatment. J. L. Gordon*[1], S. J. LeBlanc[1], L. Neuder[2], T. H. Herdt[2], D. F. Kelton[1], and T. F. Duffield[1], *[1]University of Guelph, Guelph, ON, Canada, [2]Michigan State University, East Lansing.*

Ketosis is a common transition disease in dairy cattle and can be challenging to treat. The objective of this study was to determine the efficacy of a combination butaphosphan and cyanocobalamin product (B+C; Catosal, Bayer) and insulin on ketosis cure rates and β-hydroxybutyrate (BHBA) concentrations. A double blind randomized clinical trial was performed in 16 herds in Ontario and 1 herd in Michigan from May to September 2011. All cows were tested for BHBA twice, at 3–9 and 10–16 d in milk (DIM) using the Precision Xtra meter (Abbott Laboratories). Cows that tested ≥ 1.2 mmol/L were considered to have ketosis. A total of 629 animals were enrolled and all received 300 g propylene glycol orally for 3 d. Animals were randomly allocated to receive additional treatment in a 2 × 2 factorial design with 199 cows receiving 200 IU (2 mL) insulin glargine (IG; Lantus, Sanofi-Aventis,) and 25 mL saline subcutaneously (SQ), 115 cows receiving 25 mL B+C and 2 mL saline SQ, 108 cows receiving 25 mL B+C and 200 IU IG, and 207 cows receiving both placebos. B+C or corresponding placebo was given for 3 d total. BHBA was measured at 7 and 14 d after treatment. An animal was categorized as a cure if d 7 BHBA was < 1.2 mmol/L. Logistic regression was used to determine the effect of treatment on cure rates and linear regression was used to examine the effect on d 7 post-treatment BHBA controlling for farm, lactation, and enrollment BHBA. Due a temporarily unavailability of B+C, only the 371 cows from Michigan were used for this analysis. All cows were used to analyze the effects of insulin. B+C tended to increase cure rates (OR = 1.5, 95% CI: 0.99–2.29, $P = 0.08$) and decrease d 7 post-treatment BHBA (−0.19 mmol/L, $P = 0.07$). Insulin was not significantly associated with cure (OR = 0.98, $P = 0.93$) or 7-d post-treatment BHBA (−0.07 mmol/L, $P = 0.91$). There was no interaction between B+C and IG. These results suggest that B+C treatment given with oral PG may improve ketosis cure rates, while IG is not helpful.

Key Words: ketosis treatment, insulin, cyanocobalamin

100 Ecology of subclinical ketosis in transition dairy cattle. J. A. A. McArt*[1], D. V. Nydam[1], and G. R. Oetzel[2], *[1]Cornell University, Department of Population Medicine and Diagnostic Science, Ithaca, NY, [2]School of Veterinary Medicine, University of Wisconsin, Madison.*

The purpose was to describe the ecology of subclinical ketosis (SCK) in dairy cows in early lactation and to determine the effect of: 1) presence of SCK, 2) d in milk (DIM) at onset of SCK, and 3) blood β-hydroxybutyrate (BHBA) concentration at onset of SCK on development of displaced abomasum (DA) and removal from herd in the first 30 DIM, conception to first service, d to conception within 150 DIM, and early lactation milk yield. Cows from 4 free-stall dairy herds were each tested 6 times for SCK from 3 to 16 DIM using the Precision Xtra meter. SCK was defined as a BHBA concentration of 1.2 to 2.9 mmol/L. Mixed effects multivariable Poisson regression was used to assess DA, removal from herd, and conception to first service. Semiparametric proportional hazards models were used to evaluate d to conception, and repeated measures ANOVA was used to evaluate milk yield in the first 30 DIM. A total of 741 of 1,717 (43.2%) eligible cows had a least one BHBA test of 1.2 to 2.9 mmol/L. Peak incidence of SCK occurred at 5 DIM when 22.3% of cows had their first SCK positive test. Peak prevalence of SCK occurred at 5 DIM when 28.9% of cows had a SCK positive test. Median time from first positive SCK test until BHBA test <1.2 mmol/L was 5 d. Cows first testing SCK positive from 3 to 5 DIM were 6.1 times more likely (95% confidence interval (CI) = 2.3 to 16.0) to develop a DA than cows first testing SCK positive at 6 DIM or later. Cows first testing SCK positive from 3 to 7 DIM were 4.5 times more likely (95% CI = 1.7 to 11.7) to be removed from the herd, 0.7 times as likely (95% CI = 0.6 to 0.8) to conceive to first service, and made 2.2 kg less milk per day for the first 30 DIM than cows first testing SCK positive at 8 DIM or later. Each 0.1 mmol/L increase in BHBA at first SCK positive test raised the risk of developing a DA by a factor of 1.1 (95% CI = 1.0 to 1.2), raised the risk of removal from herd by a factor of 1.4 (95% CI = 1.1 to 1.8), and was associated with a decrease in milk production by 0.5 kg per day for the first 30 DIM. These results show that time of onset and BHBA concentration of first SCK positive test are important indicators of individual cow performance.

Key Words: ketosis, incidence, prevalence

Graduate Student Competition: ADSA/ASAS Northeast Graduate Paper Competition

101 Metabolomic profiling of the liver in developing chicken embryos and post-hatch chicks reveals unique metabolic differences. Q. Hu,* U. Agarwal, and B. J. Bequette, *University of Maryland, College Park.*

The emerging new field of metabolomics aides in the identification and characterization of global metabolite patterns of organs and tissues. In this study, a metabolomic profiling approach was employed to investigate differences in metabolism in the liver of chicken embryos from 2 egg sizes and from broiler breeders of different maternal ages. Whole livers were collected on embryonic (e) d 17 and 20, and on post-hatch d 1 (n = 9–10) from embryos and chicks derived from broiler breeders of different ages (32 wk vs 51 wk, 63.2 ± 1.2 g) and from 2 sizes of eggs laid by 45 wk old breeders (55.8 ± 1.2 g vs 67.7 ± 1.1 g). Livers were lyophilized to dryness and freezer-milled, and the metabolites were extracted before chemical derivatization. Metabolites were separated by gas chromatography and under full scan mode complete ion spectra were recorded by mass spectrometry. Data files were converted using Agilent data analysis software and processed with the XCMS online server. Compound identification was determined by searching against the NIST 2008 library. Principal component analysis was employed to visualize the metabolite differences between 2 groups at 3 developmental stages. The results showed that embryos on both e17 and e20 from 32 wk old breeders clustered separately from 51 wk old breeders. However, this was not observed for embryos from small vs large eggs at these developmental stages. Concentrations of 6 metabolites from e17 livers differed ($P < 0.05$) between 32 wk and 51 wk old breeder eggs, 13 metabolites differed on e20 and 5 metabolites differed on post-hatch d 1. Metabolite categories included amino acids, carbohydrates, fatty acids and cholesterol esters. Comparison of small and large egg sizes revealed that 14 metabolites differed ($P < 0.05$) on e17, 13 metabolites differed on e20 and 6 metabolites differed on post-hatch d 1. In conclusion, these results reflect that the liver metabolisms of embryos during later development are distinct due to breeder age and egg size. Together, this study is the first assessment of global metabolism of developing embryo livers and our data provides the framework for further metabolic pathway analysis.

Key Words: chicken embryo, liver, metabolomic profiling

102 Effect of resveratrol supplementation on glycemic response in moderately exercised geldings. J. L. Zambito*[1], H. S. Spooner[1], and R. Hoffman[2], [1]*West Virginia University, Morgantown,* [2]*Middle Tennessee State University, Murfreesboro.*

Resveratrol is known to exert numerous health benefits including improved glycemic response. Resveratrol is present in equine supplements, yet no research exists in an athletic horse model. This study tested the hypothesis that resveratrol supplementation would improve glucose tolerance and insulin sensitivity in the athletic horse. Six mature geldings were assigned to 3 groups in a Latin Square design. Horses either received no supplementation (control, C) or one of 2 doses of trans-resveratrol (Equithrive, Lawless, KY); low (L, 2.5g) or high (H, 5g) daily for 14-d. Horses were exercised 3x weekly for 60 min. Body weight (BW) was collected on d0 and d14 of each period. A frequently sampled intravenous glucose tolerance test (FSIGT) was conducted on d10. Samples were analyzed for plasma insulin (INS) and glucose (GLU). Area under the curve (AUC) for INS and GLU was calculated via the trapezoidal method. Glucose effectiveness (Sg), insulin sensitivity (Si), acute insulin response to glucose (AIRg) and disposition index (DI) were calculated using minimal model software. Data were analyzed using ProcGLM in SAS 9.1, and further separated by Tukey's test. Contrasts were conducted to examine differences between C and treatment (T, both low and high). Minimal model analysis of FSIGT, along with AUC INS and GLU showed no effect of resveratrol supplementation (Table 1). In conclusion, resveratrol supplementation in the moderately exercised horse did not improve glycemic response, which may already be optimized in this model. These findings indicate a need to further evaluate resveratrol in other equine models, including a more in-depth assessment in the athletic horse.

Table 1. Glucose and insulin parameters in exercising horses supplemented with resveratrol

	Treatment			*P*-value	
	Control	Low	High	Treatment	Control
Sg (min^{-1})	0.030 ± 0.003	0.032 ± 0.004	0.035 ± 0.003	0.56	0.43
Si (L*mU^{-1} *min^{-1} *10^{-4})	5.93 ± 1.77	7.83 ± 2.33	8.70 ± 1.77	0.59	0.38
AIRg (mU* min*L^{-1})	304 ± 21	333 ± 28	272 ± 21	0.34	0.96
DI	2092 ± 647	2204 ± 857	2440 ± 648	0.93	0.80
AUC GLU (mg/dL*min)	20433 ± 1241	19302 ± 1241	19506 ± 1241	0.80	0.54
AUC INS (mIU/L*min)	7057 ± 992	6666 ± 992	6213 ± 992	0.84	0.64

Key Words: horse, exercise, resveratrol

103 Effects of intrauterine growth retardation due to poor maternal nutrition on bone formation in sheep. S. Neupane*[1], M. L. Hoffman[1], M. A. Rokosa[1], E. R. Ackell[1], D. M. Kaelin[1], S. A. Zinn[1], T. D. Crenshaw[2], and K. E. Govoni[1], [1]*Department of Animal Science, University of Connecticut, Storrs,* [2]*Department of Animal Science, University of Wisconsin, Madison.*

Intrauterine growth retardation (IUGR), often due to poor maternal nutrition, leads to either slow growth or reduced fetal size. Specifically, IUGR impairs muscle and bone development, and leads to increased adipose tissue development. We hypothesized that poor maternal nutrition would impair bone formation in offspring by reducing the differentiation of bone marrow stromal cells (BMSC) into osteoblasts. A total of 24 ewes were fed a diet of 60% (R; n = 8), 100% (C; n = 8), or 120% (O; n = 8) of NRC requirements beginning at d 85 of gestation. Lambs were euthanized at birth (n = 3/treatment) and 3 mo of age (n = 3 to 5/treatment). Femurs (F) and tibia (T) were collected at birth and 3 mo and BMSC were collected at birth. Bone mineral content (BMC) and bone mineral density (BMD) were measured on excised bones by dual-energy x-ray absorptiometry. To determine if IUGR affects ability of BMSC to differentiate into osteoblasts, BMSC were cultured in differentiation media (α-MEM plus β-glycerophosphate, dexamethasone and ascorbic acid) for 21 d and stained with alizarin red to determine mineralization. As reported, BW were reduced in R lambs by 16% at birth and 3 mo ($P \leq 0.05$) compared with C. At birth, maternal diets tended ($P = 0.19$) to affect bone area (22.6 ± 2.7, 20.6 ± 3.4, and 26.0 ± 1.3 cm^2; C, R and O, respectively); however, significant treatment effects were not observed for F BMC or BMD ($P \geq 0.29$). An effect of treatment was not observed for T variables at birth ($P \geq 0.29$). At 3 mo, bone area of the T tended ($P = 0.10$) to be reduced in R and O groups compared with C (53.8 ± 0.7, 50.8 ± 1.5, 50.7 ± 0.6 cm^2; C, R, and O, respectively). Compared with C, significant differences in BMC and BMD were not detected for F or T at 3 mo ($P \geq 0.51$). Cell culture experiments did not demonstrate a significant difference in alizarin red staining between treatment groups ($P \geq 0.6$). In conclusion, poor maternal nutrition reduces bone area in offspring with effects persisting during early postnatal development.

Key Words: bone, bone marrow stromal cells, intrauterine growth retardation

104 Hypoxia stimulates GLUT1 expression in bovine mammary epithelial cells.

Y. Shao*[1], K. M. Lounsbury[2], T. L. Wellman[2], and F.-Q. Zhao[1], [1]*Laboratory of Lactation Physiology, Department of Animal Science, University of Vermont, Burlington,* [2]*Department of Pharmacology, University of Vermont, Burlington.*

Expression of glucose transporters in bovine mammary gland increases a few to several hundred-fold from late pregnancy to early lactation and this increase is not mediated by lactogenic hormones. Hypoxia has been shown to increase glucose transporter 1 (GLUT1) expression in many cell types. Deletion of hypoxia-inducible factor HIF-1α, a key signaling factor which mediates hypoxia effects, in mouse mammary gland results in impaired mammary differentiation and failure in lactation. Therefore, we hypothesized that hypoxia mediates the upregulation of GLUT expression in bovine mammary gland during the transition period. To test our hypothesis, Mac-T bovine mammary epithelial cells and bovine primary mammary epithelial cells were treated with 2% of O_2. GLUT1 mRNA increased 2.2-, 2.8-, and 2.9-fold in Mac-T cells and 5.1-, 8.3-, and 4.2-fold in primary cells after 3, 12, and 24 h hypoxia treatment, respectively ($P < 0.01$). However, GLUT8 mRNA decreased by 42% and 30% in Mac-T cells and 50% and 51% in primary cells after 12 and 24 h hypoxia treatment ($P < 0.01$). Then Mac-T cells were treated with 2, 5, and 10% of O_2 for 12h. GLUT1 mRNA increased 2.4- and 1.8-fold ($P < 0.05$) in cells treated with 2% and 5% of O_2 respectively, and 10% O_2 had no effect. In addition, Mac-T cells and primary cells were treated with 2% of O_2 for 24 h and then incubated with 200 µM of 2-NBDG, a glucose analog with fluorescent group, for 15 min. Glucose uptake was measured by flow cytometry and results showed that hypoxia increased glucose uptake 2.1 fold in Mac-T cells and 2.8 fold in primary cells ($P < 0.05$). Furthermore, when Mac-T cells were transfected with HIF-1α siRNA for 6 h and then treated with 2% of O_2 for 12 h, the upregulation of GLUT1 by hypoxia was abolished, indicating that hypoxia regulates GLUT1 expression through HIF-1α in bovine mammary epithelial cells. Our studies suggest that hypoxia, associated with high levels of oxygen consumption in mammary development and lactogenesis, may be at least partially responsible for increasing GLUT1 expression and glucose uptake through transcription factor HIF-1α in bovine mammary epithelial cells during the transition period.

Key Words: hypoxia, glucose transporter, mammary gland

105 Poor maternal nutrition reduced body weights and circulating concentrations of IGF-I and IGFBP-3 in lambs.

M. A. Rokosa,* M. L. Hoffman, S. Neupane, K. E. Govoni, A. M. Bush, T. A. Hoagland, and S. A. Zinn, *Department of Animal Science, University of Connecticut, Storrs.*

Intrauterine growth retardation (IUGR) may be the result of poor maternal nutrition, and can influence the somatotropic axis and the growth potential of offspring. To determine the effects of nutritional status during gestation on growth and serum concentrations of IGF-I and IGFBP-3 in lambs, 24 (21 Dorsets, 3 Shropshires) ewes were assigned (balanced for breed, parity and age) to 1 of 3 diets; control (C; 100% NRC, n = 8), restricted (R; 60% NRC, n = 8), or overfed (O; 120% NRC, n = 8). Treatment started at d 85 ± 5 of gestation. Nine lambs (3/treatment) were slaughter within 24 h of birth (d 1) and 15 lambs (3 to 5/treatment) were fed a control diet consisting of milk replacer (fed at 1.7%/BW), creep feed and hay for 3 mo and then euthanized. Body weights were taken on d 1 and every 2 to 4 d until slaughter. Crown rump (CRL) measurements were taken weekly, and heart girth (HG) measurements were taken at d 1 and slaughter. Blood samples (10 mL) were collected on d 1 and every 7 d until slaughter. Concentrations of IGF-I and IGFBP were determined by RIA and ligand blot, respectively. At birth, lambs from R ewes (4.15 ± 0.3 kg) were lighter than C (5.3 ± 0.3 kg) and O (5.1 ± 0.3 kg) lambs ($P = 0.01$). At 3 mo, lambs from R ewes (31.0 ± 1.3 kg) tended to be lighter ($P = 0.06$) than C (35.2 ± 1.3 kg) and O (33.5 ± 1.7 kg) lambs. However, we did not observe an effect of maternal diet on CRL at birth ($P = 0.67$) or 3 mo of age ($P = 0.29$). At birth, heart weight ($P = 0.06$) and HG ($P < 0.01$) were less in R (30.2 ± 3.2 g and 36.9 ± 0.8 cm, respectively) than C (36.3 ± 3.2 g and 40.7 ± 0.8 cm, respectively) and O (43.8 ± 3.2 g and 40.4 ± 0.8 cm, respectively) lambs, but not at 3 mo of age ($P = 0.60$, $P = 0.17$). Average serum IGF-I was decreased ($P = 0.04$) in R (158 ± 36 ng/mL) compared with C (308 ± 37 ng/mL) and O (227 ± 40 ng/mL) lambs. Average concentrations of IGFBP-3 were decreased ($P = 0.05$) in R (1,032 ± 135 AU) and O (1,014 ± 148 AU) compared with C (1,438 ± 135 AU). We did not observe a treatment effect on circulating IGFBP-2 ($P = 0.63$). In conclusion, poor maternal nutrition may inhibit fetal growth by reducing circulating concentrations of IGF-I and IGFBP-3.

Key Words: intrauterine growth retardation, IGF, IGFBP

106 Effect of rumen-protected amino acid supplementation of a protein-deficient diet on performance of lactating dairy cows.

C. Lee*[1], A. N. Hristov[1], T. Cassidy[1], K. Heyler[1], H. Lapierre[2], G. A. Varga[1], M. J. de Veth[3], A. Patton[4], and C. Parys[5], [1]*The Pennsylvania State University, University Park,* [2]*Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [3]*Balchem Corporation, New Hampton, NY,* [4]*Nittany Dairy Nutrition Inc., Mifflinburg, PA,* [5]*Evonik Industries AG, Hanau, Germany.*

The objective of this experiment was to evaluate the effect of supplementing a metabolizable protein (MP)-deficient diet with rumen-protected (RP) Lys, Met, and specifically His on dairy cow performance. The experiment was conducted for 12 wk with 48 Holstein cows (75 ± 5.6 DIM). Following a 2-wk covariate period, cows were blocked by DIM and milk yield and randomly assigned to one of 4 diets, based on corn silage and alfalfa haylage: control, MP-adequate diet (AP; MP balance: +9 g/d); MP-deficient diet (DP; MP balance: −317 g/d); DP supplemented with RPLys (AminoShure-L) and RPMet (Mepron; DP-LM); and DP-LM supplemented with RPHis (DP-LMH). Analyzed CP content of the AP and DP diets was 15.7 and 13.6%. Apparent total tract digestibility of all nutrients, plasma urea-N, and urinary-N excretion were decreased ($P < 0.001$) by the DP diets compared with AP. Milk N secretion as a proportion of N intake was greater (34.6 vs. 29.4%, $P = 0.001$) for the DP diets compared with AP. Compared with AP, DMI tended to be lower ($P = 0.06$) for DP, but was similar for DP-LM and DP-LMH (24.5, 23.0, 23.7, and 24.3 kg/d, respectively). Milk yield was decreased ($P = 0.004$) by DP (35.2 kg/d), but was similar to AP (38.8 kg/d) for the DP-LM and DP-LMH diets (36.9 and 38.5 kg/d, respectively), following the trend in DMI. Milk fat and true protein

content did not differ among treatments. Milk protein yield followed the trend in milk yield response ($P = 0.002$; 1.13, 1.01, 1.10, and 1.14 kg/d, respectively). Plasma essential AA, Lys, and His were lower ($P < 0.03$) for DP compared with AP. Compared with AP, plasma Met concentration was higher ($P < 0.001$) for DP-LM and DP-LMH and that of His was similar for DP-LMH. In conclusion, MP-deficiency, approximately 15% below NRC (2001) requirements, decreased DMI and milk yield in dairy cows. Supplementation of the DP diet with RPLys and RPMet diminished the difference in milk yield compared with AP and addition of RPHis eliminated it. This study suggests that His is likely a limiting AA in dairy cows fed MP-deficient diets.

Key Words: metabolizable protein, rumen-protected histidine, dairy cow

107 Effects of lasalocid and pulse-dosed chlortetracycline on health, growth, and thyroxine concentrations of prepubertal dairy heifers.

R. Cabral*[1], P. Erickson[1], N. Guindon[1], E. Kent[1], C. Chapman[1], K. Aragona[1], M. Cabral[1], E. Massa[1], and M. Branine[2], [1]*University of New Hampshire, Durham,* [2]*Pfizer Animal Health, Canon City, CO.*

The effects of feeding chlortetracycline (CTC) and lasalocid (L) and the combination were studied using 40, 12 wk old Holstein heifers (108 ± 12 kg) in a randomized complete block design utilizing a 2 × 2 factorial arrangement of treatments. Heifers were blocked by birth date to 1 of 4 treatments: 1) carrier (30 g; C); 2) L + carrier (1 mg/kg BW; L); 3) CTC+ carrier (22 mg/kg BW; CTC); 4) L + CTC + carrier (CTCL). Heifers on CTC/CTCL were given their respective treatment during wk 1–4, 6, and 10 and within these weeks given treatment Monday— Friday and carrier only on weekends. Heifers were individually fed a total mixed ration (TMR) with treatments top-dressed at 1200 h daily. Heifer DMI was monitored and adjusted according to individual intakes. Skeletal measurements were taken weekly and blood samples obtained every Monday, Wednesday, and Friday. Blood samples were analyzed for thyroxine concentration via radial immunoassay. Heifers supplemented with L (L, CTCL) had lower DMI ($P = 0.05$), ADG ($P = 0.02$), overall BW gain ($P = 0.03$), overall wither gain ($P = 0.04$), and overall girth gain ($P = 0.09$) compared with heifers not fed L (C, CTC). Overall BW ($P = 0.04$) and body length ($P = 0.02$) gains and ADG ($P = 0.10$) were greater in CTC heifers (CTC, CTCL). Interactions occurred for: feed efficiency ($P = 0.03$), overall hip height ($P = 0.03$), and wither height ($P < 0.01$) gains and daily hip height gains ($P = 0.08$) were greater in C and CTCL heifers compared with CTC and L heifers. There was no effect on serum thyroxine concentrations. Supplementation with L did not increase growth. Supplementation with CTC improved growth for some skeletal measurements. The combination of CTC and L was more effective than either L or CTC fed individually. Supplementing CTC and L to growing heifers under conditions of stress may be of benefit.

Key Words: heifer, lasalocid, chlortetracycline

108 Effect of post-ruminal supplementation of phytonutrients on immune response, blood cell counts, and blood chemistry in lactating dairy cows.

J. Oh*[1], A. N. Hristov[1], C. Lee[1], K. Heyler[1], T. Cassidy[1], J. Pate[1], S. Walusimbi[1], E. Brzezicka[1], K. Toyokawa[1], J. Werner[1], and D. Bravo[2], [1]*The Pennsylvania State University, University Park,* [2]*Pancosma, Geneva, Switzerland.*

The objective of this experiment was to investigate the effects of post-ruminal supplementation of phytonutrients on immune response, blood cell counts and blood chemistry in lactating dairy cows. Eight ruminally-cannulated Holstein cows (232 ± 34.1 d in milk) were used in a replicated 4 × 4 Latin square design trial with 23-d periods. Treatments were: (1) control (CON), (2) 2 g/d curcuma oleoresin (CU), (3) 2 g/d garlic extract (GE), and (4) 2 g/d capsicum oleoresin (CA). The phytonutrients were dissolved in ethanol solution and pulse-dosed into the abomasum of the cows once daily, 2 h after feeding for 9 d during each experimental period. Control cows received ethanol solution only. Compared with CON, CU, GE, and CA increased ($P = 0.01$) concentration of cluster of differentiation-antigen-4-positive cells ($CD4^+$; 11.9 vs. 20.3, 18.4, and 17.8%, respectively). Treatments had no effect on $\gamma\delta^+$ and $CD8^+$ cells, interleukin-6, tumor necrosis factor-α and interferon-γ cytokines, and T-cell proliferation ($P = 0.34$ to 1.00). Monocyte counts were lowered ($P = 0.04$) by CU and GE compared with CON (0.26, 0.26 and 0.33 × 10^3/μL, respectively). Relative to CON, CA increased ($P = 0.04$) lymphocytes as proportion of the total white blood cells (WBC; 39.3 and 41.8%, respectively). Lymphocyte counts tended to be decreased ($P = 0.10$) by GE compared with CON (3.43 and 3.77 × 10^3/μL, respectively). Cows treated with GE and CA had lower ($P = 0.03$) mean platelet volume than CON cows (6.51, 6.56, and 6.91 fL, respectively). Blood glucose, BUN, and creatinine concentrations were not different among treatments ($P = 0.39$ to 0.47). In conclusion, post-ruminal supplementation of phytonutrients had no effect on $\gamma\delta^+$ cells, $CD8^+$ cells, cytokine concentrations, T-cell proliferation, and blood chemistry, but all treatments significantly enhanced $CD4^+$ cells, CU and GE reduced monocytes, and CA increased lymphocyte proportion of WBC in dairy cows.

Key Words: phytonutrients, immune response, dairy cow

Growth and Development

109 Zfp423 promotes adipogenic differentiation of bovine stromal vascular cells. Y. Huang*[1], A. Das[1,2], Q. Yang[1,2], M.-J. Zhu[1,2], and M. Du[1,2], *[1]Department of Animal Science, University of Wyoming, Laramie, [2]Department of Animal Sciences, Washington State University, Pullman.*

Intramuscular fat or marbling is critical for the palatability of beef. Intramuscular fat mainly locates inside perimysial connective tissue. In mice, very recent studies show that adipocytes and fibroblasts share a common pool of progenitor cells, with Zinc finger protein 423 (Zfp423) as a key initiator of adipogenic differentiation, while fibrogenesis is promoted by transforming growth factor-β (TGF-β) signaling pathway. To evaluate the role of Zfp423 in intramuscular adipogenesis and marbling in beef cattle, we sampled Sternocleidomastoid muscle for separation of stromal vascular cells (SVC). These cells were immortalized with pCI neo-hEST2 which carries a telomerase and individual clones were selected by G418, an aminoglycoside antibiotic. A total of 288 clones (3 X 96 well plates) were isolated and induced adipogenic differentiation, and their adipogenic potential was assessed by the formation of adipocytes with Oil-Red-O staining. Three clones with the highest and lowest adipogenic potential were selected for further analyses. The expression of Zfp423 was much higher (307.4 ± 61.9%, $P < 0.01$) in high adipogenic cells, while TGF-β was higher (156.1 ± 48.7%, $P < 0.05$) in low adipogenic cells. Following adipogenic differentiation, the expression of peroxisome proliferator-activated receptor γ (PPARγ) and CCAAT/Enhancer Binding Protein α (C/EBPα) were higher (239.4 ± 84.1% and 310.7 ± 138.4%, respectively, $P < 0.05$) in high adipogenic cells. Transfecting a plasmid overexpressing Zfp423 in both stromal vascular cells and cloned low adipogenic cells dramatically increased their adipogenic differentiation, accompanied with the inhibition of TGF-β expression. In conclusion, data show that Zfp423 is a critical regulator of adipogenesis in stromal vascular cells, and Zfp423 may provide a molecular target for enhancing intramuscular adipogenesis and marbling in beef cattle.

Key Words: adipogenesis, muscle, beef cattle

110 Agouti signaling protein abundance in cattle—Relationship with fat deposition. E. Albrecht*[1], K. Komolka[1], H. Sauerwein[2], T. Gotoh[3], and S. Maak[1], *[1]Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany, [2]University Bonn, Bonn, Germany, [3]Kyushu University, Kuju-cho, Oita, Japan.*

The agouti signaling protein (ASIP), originally known for its role in melanogenesis, has been related to obesity in mice and humans. The potentially crucial role in adipocyte development, elucidated in cell culture models, makes it a tempting candidate for economically relevant, fat related traits in farm animals. The objective of our study was to characterize the protein abundance of ASIP in different adipose tissues, in skeletal muscle, and in blood of cattle differing in fat deposition. Japanese Black (JB; n = 6) and Holstein (HS; n = 5) steers were fed a high energy diet to maximize intramuscular fat (IMF) deposition, resulting in 34.3% (±1.7) and 20.4% (±2.5) IMF content in longissimus muscle (LM) for JB and HS, respectively, when harvested at 26 mo of age. Protein extract from subcutaneous, visceral, perirenal, intra- and intermuscular fat, and LM were investigated by Western blotting with a bovine-specific ASIP antibody. Blood plasma samples were also investigated by Western blotting after albumin removal. By immunohistochemistry, ASIP was localized in different cell types of adipose tissues, including adipocytes, and also in skeletal muscle tissue, but never in muscle fibers. In addition to the expected cytosolic signal, a putative nuclear localization of ASIP was observed. The protein abundance was highly variable among animals, and did not show a clear relationship with fat related traits like depot weights or fat cell size. Between breeds, the protein was similarly abundant within fat depots and did not reflect the earlier described ASIP mRNA overexpression in JB compared with HS. However, we detected higher ($P < 0.05$) ASIP levels in blood plasma of JB (normalized to albumin) than in HS (1.13 ± 0.08 vs. 0.89 ± 0.09, respectively), which were paralleled by higher ($P < 0.05$) leptin concentrations in JB (18.9 ng/ml ± 3.1) vs. HS (12.6 ng/ml ± 4.1). Our results provide evidence for a widespread expression of ASIP in bovine adipose tissues at the protein level and for the first time for the secretion and circulation of this protein in the blood of cattle, suggesting a potential endocrine function.

Key Words: ASIP, adipose tissue, blood

111 Blood glucose and acylated ghrelin in response to duration of maternal undernutrition during gestation in twin sheep pregnancies. M. E. Field,* R. V. Anthony, M. D. Vetters, C. Flörcke, T. E. Engle, S. L. Archibeque, and H. Han, *Colorado State University, Fort Collins.*

The experimental objective was to determine the effect of duration of maternal undernutrition during gestation in twin pregnancies on maternal and lamb blood parameters. Multiparous Western white face ewes were fed 100% (Control; n = 8), or 50% of their nutrient requirements from 28 to 78 d gestational age (dGA) and readjusted to 100% beginning at 79 dGA (50–100; n = 10), or 50% from 28 to term (50–50; n = 9). Lambs were birthed naturally, weaned at 10 wk postpartum (wPP) and harvested at 18 wPP. Data were analyzed by preplanned orthogonal contrasts: Control vs. 50–100 and 50–50 and 50–100 vs. 50–50. At 49 and 77 dGA GLU was greater ($P < 0.05$) in Control vs. 50–100 and 50–50 ewes; the same trend ($P < 0.10$) occurred at 63 dGA. At 105, 112, 126, and 147 dGA GLU was greater ($P < 0.05$) in 50–100 vs. 50–50 ewes. At 2 wPP ewe GLU was greater ($P = 0.03$) in 50–100 (3.60 ± 0.17 mM) and 50–50 (3.29 ± 0.17mM) than Control (2.99 ± 0.16 mM). Ewe aGRL was greater ($P = 0.02$) in 50–100 (237 ± 32 pg/mL) and 50–50 (239 ± 38 pg/mL) vs. Control (136 ± 32 pg/mL) at 140 dGA and at 4 wPP the same pattern was observed (50–100, 388 ± 38 pg/mL; 50–50, 326 ± 45 pg/mL; Control, 184 ± 38 pg/mL). Lamb GLU was reduced ($P = 0.02$) in 50–100 (4.12 ± 0.09 mM) vs. 50–50 (4.52 ± 0.09 mM) at 14 wPP. Lamb aGRL was greater ($P = 0.06$) in 50–100 (141 ± 47 pg/ml) and 50–50 (184 ± 48 pg/ml) vs. Control (59 ± 37 pg/ml) at 2 wPP, but did not differ at 16 wPP. Elevated post-weaning glucose in 50–50 lambs may indicate increased insulin resistance in these lambs. Early nutrient restriction resulted in elevated aGRL, even following realimentation, which persisted into the postpartum period, suggesting potential long-lasting programming of maternal appetite control during early- to mid-gestation as a result of dietary restriction. This project was supported by National Research Initiative Competitive Grant no. 2009-35206-05273 from the USDA National Institute of Food and Agriculture.

Key Words: maternal undernutrition, ghrelin, sheep

112 Delaying a bovine viral diarrhea vaccine and growth implant with metaphylaxis affects performance, but not health of feedlot heifers.

M. R. McDaniel*[1], M. E. Hubbert[2], and C. A. Loest[1], [1]*Department of Animal and Range Sciences, New Mexico State University, Las Cruces,* [2]*Clayton Livestock Research Center, New Mexico State University, Clayton.*

Stress and low nutrient intake of newly received feedlot calves may limit efficacy of both a bovine viral diarrhea (BVD) vaccine and growth implant at initial processing. Use of chlortetracycline (CTC) when delaying an initial vaccine and implant may be beneficial. This 56-d study evaluated effects of timing (TIME) of a BVD vaccine and growth implant with or without CTC on health and performance of 312 heifers (184 ± 0.7 kg BW). Initial processing of heifers included treatment with tulathromycin and vaccination for bovine respiratory disease. Heifers were sorted into 24 pens, which were randomly assigned to 4 treatments. Treatments (2 × 2 factorial) were growth implant (Synovex-C; Fort Dodge Animal Health) and BVD vaccination (Bovi-Shield Gold BVD; Pfizer Animal Health) of calves on d 1 (INITIAL) or d 28 (DELAYED) after arrival with (+CTC) or without (-CTC) 3 5-d pulse-doses of CTC (Aureomycin; Alpharma Animal Health) in their diets. Diets were based on a complete feed (RAMP; Cargill) and ground corn delivered twice daily. Performance and health were analyzed using MIXED and GLIMMIX procedures of SAS, respectively. A TIME × CTC interaction ($P = 0.06$) occurred for DMI; DMI was lower for DELAYED than INITIAL when heifers received -CTC, but DMI was not different between DELAYED and INITIAL when heifers received +CTC. No TIME × CTC interactions ($P \geq 0.21$) occurred for BW, ADG, or G:F. Timing of BVD vaccine and implant did not affect ($P = 0.18$) BW of heifers on d 28, but BW were lower ($P = 0.04$) for DELAYED than INITIAL heifers on d 56. From d 29 to 56, ADG was lower ($P = 0.02$) and G:F tended to be lower ($P = 0.07$) for DELAYED than INITIAL heifers. Delaying the BVD vaccine and implant also tended to lower ($P = 0.09$) ADG from d 0 to 56, but did not affect ($P = 0.27$) G:F. On d 28, BW of +CTC heifers tended to be lower ($P = 0.06$) than -CTC heifers, but CTC did not affect ($P \geq 0.21$) d-56 BW, ADG, or G:F. Morbidity and mortality during the 56 d were not affected ($P \geq 0.17$) by treatments. Delaying the initial BVD vaccine and growth implant with or without CTC may not improve animal health, and may have negative implications on performance of newly received feedlot heifers.

Key Words: vaccine, implant, heifer

113 The effects of intrauterine growth retardation (IUGR) due to poor maternal nutrition on adipose tissue development and metabolic status in sheep.

M. L. Hoffman*[1], M. A. Rokosa[1], S. Neupane[1], S. M. Spignesi[1], J. Lee[2], S. A. Zinn[1], and K. E. Govoni[1], [1]*Department of Animal Science, University of Connecticut, Storrs,* [2]*Department of Nutritional Sciences, University of Connecticut, Storrs.*

Poor maternal nutrition negatively affects growth and development of the fetus as well as postnatal metabolism. We hypothesized that intrauterine growth retardation (IUGR) due to poor maternal nutrition would increase adiposity and negatively affect metabolism. Ewes pregnant with twins (n = 24) were fed 100% (CON), 60% (RES) or 120% (OVER) of NRC requirements beginning at d 85 of gestation. Offspring were euthanized within 24 h of birth (d 1; n = 3/treatment) or at 3 mo of age (n = 3 to 5/treatment) at which point blood samples and renal adipose tissues were collected. Animals maintained until 3 mo were removed from the ewe and fed a control diet of milk replacer and 18% creep feed. Circulating concentrations of leptin, insulin and glucose were determined by quantitative ELISA. Total cholesterol (TC) and triglycerides (TG) were determined by enzymatic analysis. Gene expression was determined by real time-reverse transcriptase (RT)-PCR. Data were analyzed using ANOVA with significance considered as $P \leq 0.05$. As reported, BW were reduced by 16% in RES lambs at d 1 and 3 mo ($P \leq 0.05$) compared with CON. A significant effect of treatment was not observed for concentrations of insulin or glucose ($P \geq 0.30$) or mRNA expression of markers for adipogenesis, *PPARγ* and *C/EBPα*, at d 1 or 3 mo ($P \geq 0.60$). However, at d 1, concentrations of leptin tended to be 34% and 61% greater in RES and OVER, respectively (1.28 ± 0.16, 1.72 ± 0.12, 2.07 ± 0.40 mg/dL; CON, RES, OVER, respectively; $P \leq 0.12$). At 3 mo, concentrations of leptin tended to be 25% and 31% greater in RES and OVER, respectively (0.91 ± 0.16, 1.14 ± 0.11, 1.27 ± 0.08; CON, RES, OVER, respectively; $P \leq 0.13$). A similar trend was observed in *leptin* mRNA expression with a 2.60 ± 0.70-fold increase in OVER at 3 mo ($P \leq 0.13$). At d 1, we did not observe a significant effect of treatment on TC (39.52 ± 3.09, 47.3 ± 4.27, 46.70 ± 2.44; CON, RES, OVER respectively; $P \leq 0.22$). At 3 mo, TG were 45% greater in OVER compared with CON ($P = 0.07$). In conclusion, these data suggest that poor maternal nutrition during gestation alters markers of adipogenesis and metabolism of lipids during early postnatal growth.

Key Words: intrauterine growth retardation, adipose tissue, leptin

114 Maternal nutrition of beef cattle on pasture mediates long-term consequences for offspring primarily through effects on growth early in life.

P. L. Greenwood,* L. M. Cafe, and D. L. Robinson, *Australian Cooperative Research Centre for Beef Genetic Technologies and NSW Department of Primary Industries, Armidale, NSW, Australia.*

Long-term consequences of dam nutrition on offspring, beyond those due to variation in early-life growth, were studied. Hereford cows were mated in consecutive years to Piedmontese or Wagyu sires. When confirmed pregnant, treatments (low or high pasture quality and availability) were applied to cows (n = 513) until parturition and(or) weaning. At weaning (7mo), 4 early-life growth groups (gestation-preweaning: Low-Low, Low-High, High-Low and High-High) of offspring (n = 240) were selected within steer and heifer cohorts for further study, resulting in multi-modal distributions of offspring growth to birth and weaning. A stage stepwise regression procedure (final exclusion parameter, $P > 0.05$) examined covariates including birth (BW) and weaning (WW) weight, age at measurement (A), and effects of nutrition during pregnancy (P) and lactation (L), calf sex (S), year (Y), sire breed (G), and first order interactions of factors and with covariates. BW was affected by P; WW by L and P, over and above differences due to BW. For feedlot entry (26mo), exit (30mo) and carcass (CW) weights, there were significant linear effects of BW and WW plus effects of G, S and Y, but no effects of P or L beyond those due to differences in BW and WW. Average differences of 6kg in BW of calves due to P and 55kg in WW due to L both translated into differences of ~20kg in CW, 11–12kg in retail yield and 6kg of fat trim at 30mo, but did not affect beef tenderness or marbling. When adjusted to a constant CW, heavier WW cattle had more fat trim and less retail yield. There were few interactions, however at the same CW there was a significant G x P interaction for rib eye area: Piedmontese-sired, Low 95.7 vs. High 88.4cm^2; Wagyu-sired, both groups 85.7cm^2. Feedlot feed intake (n = 142) was affected by BW and WW but not when corrected for weight at start of the intake test. FCR was affected by WW and L, and whether dams were lactating in early pregnancy. Maternal nutrition did not affect RFI. Overall, there were few long-term influences of maternal nutrition on offspring beyond those related to early-life growth within our pasture-based system. Optimal maternal nutrition that maximizes capacity to re-breed has greater economic effect than longer-term consequences of maternal nutrition on offspring.

115 Lean tissue accretion and the efficiency of energy and protein retention are enhanced by intermittent bolus compared to continuous feeding.

S. W. El-Kadi,* C. Boutry, M. C. Gazzaneo, A. Suryawan, R. A. Orellana, N. Srivastava, H. V. Nguyen, M. L. Fiorotto, and T. A. Davis, *USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

Feed remains the largest non-fixed input cost in animal production systems, and dietary interventions aimed at enhancing the efficiency of nutrient utilization may provide new avenues for improving profitability. To determine the effect of feeding modality on growth and lean tissue accretion, neonatal pigs (n = 6/treatment, 6-d-old) were fed the same diet in equivalent amounts continuously (CON) or intermittently (INT; meal every 4 h) for 21 d. Body composition was measured by dual x-ray absorptiometry (DXA) before and 18 d following the initiation of feeding, and fractional rate of protein synthesis was measured using the flooding dose method. Fractional protein synthesis rates, and plasma glucose and insulin were determined on the last day of feeding. Weight gain was greater ($P < 0.05$) for INT than for CON pigs and resulted in heavier body weights from 9 d of feeding onwards . Total lean tissue mass and spine length were greater ($P < 0.05$) in INT than CON pigs. Glucose and arterial insulin levels were greater ($P < 0.05$) for INT pigs after the meal than for CON pigs. Compared with the CON group, muscle protein synthesis was 40% higher in longissimus dorsi, and 34% higher in gastrocnemius and soleus ($P < 0.05$) of INT pigs. Longissimus dorsi and soleus muscles were 56 and 35% heavier ($P < 0.05$) in INT than CON pigs. Protein synthesis was 22 and 48% higher ($P < 0.05$) in liver and ileum of INT compared with CON pigs. Liver, jejunum and ileum weights were 72, 40, and 35% higher ($P < 0.05$) in pigs receiving the INT compared with the CON treatment. Intermittent feeding resulted in improved ($P < 0.05$) feed conversion efficiency (5.1 vs. 7.2 kg milk/kg body weight gain) compared with continuous feeding. In addition, the efficiency of protein and energy retentions were both enhanced ($P < 0.05$) by 30 and 44% with intermittent compared with continuous feeding. These results indicate that intermittent feeding, as compared with continuous feeding, upregulates protein synthesis resulting in an improved efficiency of protein and energy retention, greater lean tissue accretion, and enhanced growth in the neonate. Supported by NIH AR444474 and USDA/ARS 6250-51000-055.

Key Words: protein synthesis, body composition, insulin

116 Tripalmitolein infusion in finished lambs.

T. A. Burns,* M. C. Miller, A. K. G. Kadegowda, H. M. Stowe, S. M. Calcatera, and S. K. Duckett, *Clemson University, Clemson, SC.*

Palmitoleic acid (C16:1 *cis*-9) has been proposed to function as a lipokine, regulating lipogenesis and desaturation in murine liver. Previously, our bovine adipocyte cultures provide evidence that palmitoleic acid decreases lipogenesis and desaturation. Our objective was to determine if palmitoleic acid functions similarly in ruminant animals where the primary site of lipogenesis is adipose tissue. Eight Southdown lambs approximately 13 mo of age were assigned to 1 of 2 treatment groups [tripalmitin (control) or tripalmitolein (lipokine)] in a completely randomized design. Both jugular veins were cannulated; one was used to infuse 4 μM triglyceride treatment at 9 μmol*kg BW^{-1} per d over a 4 d period and the other was used to sample blood throughout the study and every 30 min for 9.5 h before slaughter. On the last day of infusion, 0.7 mmol 1-^{13}C18:0 was administered 8 h before slaughter. Lambs were sacrificed 96 h after infusion began. Serum was analyzed for fatty acid composition and enrichment. Dorsal and sternal subcutaneous adipose tissues and liver were flash frozen for gene expression and fatty acid analysis. Lipogenic genes of interest were *fatty acid synthase* (*FASN*) and *stearoyl-CoA desaturase* (*SCD1*). There was a main effect of depot on fatty acid composition and gene expression. In the liver, C16:0, C16:1 *cis*-9, C18:1 *cis*-9, were decreased ($P < 0.05$) and C18:2 n-6 was increased ($P < 0.05$) compared with adipose tissue depots. The desaturation ratios (C16:1/C16:0 and C18:1 *cis*-9/C18:0) were highest in sternal adipose tissue compared with dorsal and liver tissues. Expression of *FASN* and *SCD1* was reduced ($P < 0.05$ and $P = 0.07$, respectively) in sternal adipose tissue compared with dorsal subcutaneous fat. In addition, FASN was downregulated ($P < 0.05$) in lipokine compared with control lambs. Enrichment of serum C18:0 and C18:1 *cis*-9, detectable at 90 min following stable isotope injection, indicates a reduction in desaturase activity. The fractional synthetic rate and tracer:tracee ratio of C18:1 *cis*-9 from C18:0 was greater over time ($P < 0.05$) in control compared with lipokine lambs. Therefore, intravenous tripalmitolein infusion alters on fatty acid biosynthesis in lambs.

Key Words: palmitoleic acid, lamb, desaturation

117 Nutritional milieu of preadipocytes determines the differentiating capabilities of bovine primary stromal vascular cultures.

A. K. G. Kadegowda,* M. C. Miller, T. A. Burns, A. Wright, and S. K. Duckett, *Clemson University, Clemson, SC.*

Objectives were to determine the effect of nutritional milieu of preadipocytes on adipogenesis and adipose lipid metabolism in bovine adipocytes. Bovine primary stromal vascular cultures were isolated from intermuscular fat of Angus x Hereford steers (508 kg BW,n = 3 per treatment) fed alfalfa/soybeans with (LC) or without (L) corn grain supplementation (0.75% BW) for 105 d. Preadipocytes were differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μ*M* DEX, 1 μ*M* rosiglitazone, 0.5 m*M* IBMX, and 10 m*M* acetate] for 2 d and from D2 to D12 without DEX and IBMX. From D2 to D12, cells were treated with (0 or 100 μ*M*) of linoleic acid (C18:2). Cells were harvested on D-2, D0, D2, D4, D6 and D12 for gene expression by RT-qPCR and on D6 for fatty acid (FA) analysis by GLC. Cell viability of pre-differentiated cells was assayed using Cell Counting Kit-8. The adipocyte cell sizing was done using Cell Scepter. Glycerol-3-phosphate dehydrogenase (GPDH) activity was assayed to determine adipocyte differentiation. The treatment effects were analyzed by Proc Mixed of SAS 9.2 with steer as experimental unit. The average diameter of preadipocytes and differentiated adipocytes ($P < 0.05$) were larger in LC (16.25 ± 0.48 μm and 18.08 ± 0.37 μm) compared with those of L (15.58 ± 0.43 μm and 16.95 ± 0.32 μm). However, the preadipocytes from L proliferated faster ($P < 0.05$) than those from LC . The GPDH activity (nmol/mg protein per min), an indicator of adipocyte differentiation was higher ($P < 0.01$) in adipocytes from L (4.32 ± 0.50) compared with LC (0.51 ± 0.5). Also, the expression of genes associated with adipocyte differentiation: *fatty acid binding protein 4*, *GPDH*, *peroxisome proliferator-activated receptor gamma*, *CCAAT/enhancer binding protein α* (*C/EBPα*), and *stearoyl-CoA desaturase 1*, were higher ($P < 0.05$) in L compared with LC . Whereas the total FA content or the FA composition (except C18:1c9, $P < 0.05$) did not differ between un-supplemented L and LC, C18:2 supplementation showed higher ($P < 0.05$) content of total FA, C16:0, C16:1, C18:0, C18:1 and C18:2 in L compared with LC. The results showed that the nutritional milieu determines the differentiating capabilities of bovine primary stromal vascular cultures.

Key Words: adipocytes, fatty acids, adipogenesis

118 Effects of feeding different forage sources on rumen fermentation and gastrointestinal tract development in young calves.

Ll. Castells*[1], A. Bach[1,2], and M. Terré[1], [1]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [2]*ICREA, Barcelona, Spain.*

It has been previously demonstrated that offering chopped forage to young calves increases ADG and feed intake. However, the mechanism involved in improving calf performance is not clear. Fifteen Holstein calves (BW = 43.6 ± 4.37 kg) were randomly assigned to one of the 3 dietary treatments (n = 5) to determine the effects of feeding different forages sources on rumen fermentation and gastrointestinal tract (GIT) development. Treatments consisted on a pelleted starter concentrate (20% CP, 21% NDF) offered alone (CTR), with alfalfa hay (ALF), or with oats hay (OAT) in separate buckets. Calves received 2 L of milk replacer (MR) at 12.5% DM twice daily until 49 d of age. From 50 to 56 d of age, calves received 2 L/d of MR at 12.5% and were weaned at 57 d of age. Starter, forage, and MR intake were recorded daily and BW weekly. A rumen sample was taken by an oral tube weekly to determine rumen pH and VFA concentrations. Three weeks after weaning, animals were harvested and each anatomical part of the GIT was dissected and weighed. Data were analyzed with a mixed-effects model with repeated measures, except for harvest data that had no repeated measures. Animals in OAT treatment tended ($P = 0.10$) to eat more starter concentrate than the other treatments after weaning (2612 vs 1990 ± 270.8 g/d, respectively), and ALF animals ate more ($P = 0.05$) forage than OAT animals (147 vs 47 ± 31.0 g/d, respectively). Rumen pH was lower ($P < 0.01$) in CTR compared with OAT and ALF calves (5.5 vs 6.2 ± 0.16, respectively). Furthermore, acetate proportion in the rumen tended to be greater ($P = 0.10$) in ALF than in CTR and OAT treatments (51.8 vs 46.4 ± 1.91% respectively), and butyrate proportion was numerically ($P = 0.12$) lower in ALF compared with the others 2 treatments (9.9 vs 14.7 ± 1.77%, respectively). Total GIT weight expressed as a percentage of BW tended ($P = 0.07$) to be greater in ALF compared with the other 2 treatments (22.4 vs 20.1 ± 0.75%, respectively). In conclusion, feeding forages to young calves increases rumen pH, although the rumen fermentation profile differs depending on the forage source.

Key Words: calves, forage, gastrointestinal development

International Animal Agriculture Symposium: Increasing Undergraduate and Graduate Student Training in International Animal Agriculture

119 What type of employee will international agribusiness companies be seeking? K. A. Jacques* and K. A. Dawson, *Alltech Center for Animal Nutrigenomics & Applied Animal Nutrition, Nicholasville, KY.*

The globalization of agricultural markets and resources has driven up the importance of having a broad-based understanding of the rate-limiting steps that govern food production. Employers look to hire people who command an overall knowledge of an increasingly complex food chain, from production to consumption. The market importance of consumer demands has risen in response to the growth of living standards in emerging nations and worldwide food safety concerns. These considerations are re-shaping the industry and mandate that the ag industry employees of the future be capable of presenting their message across cultures. Moreover, with the rapid emergence of industry-changing biotechnologies, such as nutrigenomics, it is increasingly essential that prospective employees have the communication skills to enable them to explain sophisticated science to a diverse audience. These job demands have important implications for undergraduate and graduate programs in agriculture. Course plans must encourage students to build a wide knowledge base of the economic and cultural, as well as the scientific factors, that drive the industry's future. Today's animal science graduate, for example, comes best equipped with cross training beyond the traditional single species/sector focus and an understanding of the issues that affect the value chain at each stage between farm and consumer. The ability to look beyond a regional or species-based focus is of special value to international companies that typically work in multiple aspects of grain and animal protein production. Partnerships between industry and academia that provide students internship experience will be of increasing value to both employers and students.

Key Words: globalization, education, agribusiness

120 The role of animal scientists in assuring food security in developing countries. J. Turk,* *U.S. Agency for International Development, Washington, DC.*

The objectives of this presentation are to 1) highlight the values of livestock in economic growth and human nutritional security in developing countries; 2) relate how animal scientists are important to this security; 3) describe what skills are required to work in the field; and 4) introduce the international donor livestock community, i.e., the multilateral institutions, bilateral organizations, government agencies such as the European Union and BRIC governments, private foundations (e.g., Rockefeller Foundation, Bill and Melinda Gates Foundation), and non-government organizations (NGOs). The global livestock sector employs 1.3 billion people directly or indirectly. Approximately 70% of households living on less than US$1 per day are fully or partially dependent on livestock for their livelihoods. The largest single sector of agricultural economies, it accounts for up to 50% of agricultural GDPs in most developing and transition countries. As a repository for rural capital livestock provide often more than 10%. For poor households, livestock are key to managing risk, protecting savings, and offering insurance against drought or crop failure. Livestock represent diversified values—social, environmental, economic and nutritional—but not all can be measured in hard numbers or equated across cultures and ecosystems. Although livestock′s economic value is usually regarded as the primary benefit, nutritional value of animal source foods is one of the most difficult to assess. Traditional diets often lack critical micronutrients essential for children′s physical and cognitive development. Improving livestock production and health throughout the value chain requires the knowledge to address major challenges. These include: low animal productivity; disease transmission; weak or non-existent national policies regarding disease control; weak service delivery caused by lack of trained providers; lack of inputs and supplies; inability of producers to pay for services; lack of production, health and market information; and impacts of climate change on all production systems. This paper relates how animal scientists are important to the international livestock community and food security.

Key Words: livestock production, food security, developing countries

121 Implementing new technologies in developing countries: Intellectual property, patent laws, and technology transfer agreements. K. Krafka,* *Kemin Industries Inc., Des Moines, IA.*

As new graduates seek and secure employment in animal agriculture and work in a more global economy, there is an emerging need for today′s scientific professionals to become more familiar with a basic recognition of intellectual property. Those professionals who are proficient in operating with knowledge of intellectual property issues will become more poised to contribute to new product development. The objective of this abstract is to increase both awareness and understanding of intellectual property, including trade secrets, patents, patent laws, registrations and technology transfer agreements, as they may relate to the use of innovative technology on a more global basis. Intellectual property is often misunderstood and consequently overlooked as part of technology transfers from one geography to another. Certain rights are inferred with patents, and those may or may not be applicable across different geographies. Patent terms or lengths may also vary among world geographies. A case study will be presented using an example novel product developed in one geography that is desired for transfer and use in a secondary geography. Intellectual property rights, freedom to operate strategies and licensing options will be discussed. The use of patents as a core strategy and revenue stream for both universities and industry will be explained. The case study will demonstrate how a successful technology transfer can be approached and properly executed on a timely basis. In conclusion, careful management of roles and responsibilities as they relate to intellectual property may result in an increased ability to conduct business in multiple geographies, enhanced research and manufacturing partnerships and most importantly, full utilization of cutting-edge technologies to further improvements and maximize value in livestock and poultry production globally.

Key Words: intellectual property, patents, technology transfer

122 A theme-based approach in smallholder dairy training through a partnership between Malawi and Scotland. M. G. G. Chagunda*[1], T. N. Gondwe[2], and D. J. Roberts[1], *[1]Scottish Agricultural College, Edinburgh, UK, [2]Bunda College of Agriculture, Lilongwe, Malawi.*

Over the past decade the Malawian agrarian policy has been shifting from what was predominantly tobacco based industry into other enterprises. The Department of Animal Health and Livestock Development

(DAHLD) has identified dairy farming as its flagship due to its potential to substantially contribute to sustainable household income, food and nutritional security. However, acute staff shortages and inadequate expertise within DAHLD and other non-governmental organizations has been a major challenge (Mtukuso, 2006, CISANET, 2006). Capacity building and skill development are needed for adequate human capital to complement technical interventions (World Bank, 2009). The national livestock policy and DAHLD strategic plan (DAHLD 2004, 2006) identified the following 6 specific issues in the area of dairy in Malawi. These are, a) inadequate availability of improved breeding stock and inefficient insemination program b) high cost of veterinary drugs and health care c) feed and nutritional problems d) low levels of husbandry e) inadequate production and marketing infrastructure and f) milk keeping quality. Since 2008, Scottish Agricultural College and Bunda College of the University of Malawi have been working on a theme-based program for smallholder dairy training with the 6 specific issues turned into training themes. Each theme is dealt with at different levels reflecting the trainees' prior knowledge, function and commonality of practice. Each training session is delivered by the appropriate resource person, for example, trainers, facilitators and innovators depending on need. Scientists and development workers are sent on either top-up courses or graduate programs and hence integrate training into the sustainable smallholder dairy development initiative. Courses are obtained either locally in Malawi or through sandwich programs in Scotland. Currently, 586 farmers, 28 lead farmers, 43 extension workers, 6 postgraduates, and 16 senior staff have been trained. Through this initiative, a practical diploma course in dairy science has been established in Malawi. A hop-on hop-off program for life-long learning is envisaged in the future.

Key Words: training, partnership, smallholder dairy

123 Preparing students for a changing world: Employer prioritized attributes from international engagement. L. J. Unruh Snyder,* J. M. Fernandez, and M. A. Russell, *Purdue University, West Lafayette, IN.*

As educators, we want to brace students for a changing world to address the needs for our global society. As agriculture students complete their baccalaureate degrees to enter the workforce, we anticipate they will embrace this with a skill set to overcome challenges and to be successful with their new careers. In 2009, the NRC highlighted the need for a new focus in the undergraduate agricultural education experience, and Purdue's College of Agriculture's strategic goal stated that every undergraduate student graduating will participate in at least one transformational learning experience—study abroad, undergraduate research, or internship, etc. Studies have shown that through international engagement students have a deeper understanding and respect of global issues, cultures, stronger intercultural communication skills, increased ability to problem solve more effectively (Table 1). These set of transformational skills are highly prized by future employees. In 2011, APLU and UIC reported that international experiences consistently rank the lowest for preparing students to enter the workforce; however, study abroad literature demonstrates positive effect on learning. The disconnect needs to be brought to the attention of the educators and students on how to articulate these experiences to gain the employers attention. Thus, there is a need to help students report self-efficacy based on these experiences affecting their career development. Preparing students for leadership in animal sciences through exemplary teaching, and learning experiences helps to set the stage for their career advancement.

Table 1. A three-year study comparison of cultural awareness in Costa Rica (Pre-Test N = 43; Post-Test N = 43; Six-Month N =25)

Statement	Pre-test (M, SD)	Post-test (M, SD)	Six month (M, SD)
As a student studying agriculture, it is important for me to understand issues related to international agriculture	4.79 (0.47)	4.60 (0.70)	4.40 (0.96)
Participating in this program will/has enhance(d) my cultural awareness	4.65 (0.53)	4.42 (0.82)	4.12 (1.01)

Note: * < 0.05 and denotes a significant difference between the signified mean and that on the pre-test.

124 In-country partnering needed for successful international service learning. P. Ebner*[1], H. Oliver[2], and M. Russell[1], [1]*Department of Animal Sciences, Purdue University,* [2]*Department of Food Science, Purdue University.*

Service learning is a form of experiential learning that integrates community service by the students with the skill development and learning of course content through that service. Purdue Animal Sciences now offers an "Animals & Food Security" undergraduate-level service learning course that take place each year in 2 international settings (Romania and Haiti). In each course, students are introduced to Extension methodologies, communication strategies and resource management by working directly with food animal producers in the respective countries. Integral to service learning is the identification and development of community partners. An ideal community partner relationship is cooperative, producing equitable benefits for both parties. The success of both service learning courses offered by Purdue Animal Sciences has relied heavily on fostering close and functional relationships with their community partners and similar models are used by each course to identify such partners. A total of 72 Purdue students and 28 host-university students have participated in this community- and student-development course. In each case, Purdue partners with a host-country university (Banat University of Veterinary Medicine and Agricultural Sciences in Romania and the University of Antenor Firmin in Haiti). Working directly with host country universities offers connections to students, shared educational and human capital development, and the capacity to incorporate research components into the service learning courses. Likewise, each course partners with Heifer International, a non-governmental organization devoted to global hunger and food security issues. These partnerships offer connections to local farmers and farmer groups and the ability to integrate into a successful development model and use it as an educational tool. Taken together, these partnerships ensure not only the successes and sustainability of the actual working projects, but the continued functionality of courses themselves. We will elaborate on the values and challenges of working with local partners to make the experience educational for the students and of definite benefit to the host community.

Key Words: international, service-learning, extension

Lactation Biology I

125 Serotonin (5-HT) regulates calcium mobilization at the onset of lactation in rats. J. LaPorta, T. L. Peters, K. E. Merriman, and L. L. Hernandez,* *University of Wisconsin, Madison.*

Serotonin is a known homeostastic regulator of lactation and was recently demonstrated to be a regulator of bone turnover. Circulating calcium (Ca^{2+}) is known to decrease at the onset of lactation, and often results in milk fever in dairy cattle. Serotonin is synthesized in a 2-step reaction from the amino acid L-tryptophan (L-TRP). The rate-limiting step is catalyzed by tryptophan hydroxylase (TPH1) isoform to form 5-hydroxytryptophan (5-HTP). To explore 5-HT's role on Ca^{2+} homeostasis in the transition period (10 d pre and postpartum) rats were fed 3 diets (n = 15 per treatment): control (CON), 5-HTP (0.2% total diet) and L-TRP (1.35% total diet) to increase endogenous 5-HT production. Milk samples were collected on d 1, 5 and 9 of lactation to measure Ca^{2+} concentrations. Serum and plasma samples were obtained on d 20 of gestation and d 9 of lactation to measure circulating 5-HT, Ca^{2+} and parathyroid hormone-related protein (PTHrP) levels. Total mRNA was isolated from mammary gland tissue from d 9 lactating animals and analyzed for PTHrP, TPH1, plasma membrane Ca^{2+} ATPases 1 and 2 (PMCA1, 2), sodium- Ca^{2+} exchanger 1 (NCX1), secretory Ca^{2+} ATPase 1 and 2 (SPCA1, 2), and sarco(endo)plasmic reticulum Ca^{2+} ATPase 2 (SERCA2). The 5-HTP and L-TRP treatments effectively increased serum 5-HT over time ($P < 0.001$), with a greater increase seen in the 5-HTP cohort. Plasma PTHrP was significantly increased ($P < 0.05$) on d 9 of lactation in the 5-HTP cohort. There was a significant increase of milk Ca^{2+} in the 5-HTP and L-TRP cohorts ($P < 0.05$), and decreased serum Ca^{2+} on d 9 lactation in the L-TRP group ($P < 0.05$). The mRNAs for PTHrP, TPH1, NCX1, PMCA2, SPCA2, and SERCA2 were increased in the mammary glands of the 5-HTP cohort ($P < 0.05$) and in the L-TRP cohort, except for PMCA2 and PTHrP ($P < 0.05$). The SPCA1 mRNA was decreased in both the 5-HTP and L-TRP cohorts ($P < 0.05$). These results suggest that feeding 5-HTP increases PTHrP induction in the plasma and mammary glands of transition rats, and increases Ca^{2+} transport within the mammary gland. It is possible that the L-TRP cohort could be working through a different mechanism to increase Ca^{2+} transport.

Key Words: 5-hydroxytryptophan (5-HT), Ca^{2+}, parathyroid hormone-related protein (PTHrP)

126 Genes and functions associated with photoperiodic effects on the mammary gland. T. B. McFadden*[1] and E. H. Wall[2], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada,* [2]*Department of Medicine, University of Vermont, Burlington.*

Pubertal heifers exposed to short day photoperiod during induction of lactation produced more milk in the ensuing lactation than heifers exposed to long day photoperiod, but the mechanisms behind this effect are unknown. To gain insight into potential mechanisms, we used microarray analysis to identify genes differentially expressed in mammary gland of heifers hormonally induced into lactation while exposed to different photoperiods. Holstein heifers (n = 6/treatment; 14 mo old) were assigned to long day (LD; 16 h light:8 h dark), or short day (SD; 8 h light:16 h dark) photoperiod and fed melengesterol acetate for 14 d to synchronize estrous. Heifers were then treated with estrogen and progesterone (E + P; 0.1 and 0.25 mg/kg per d) for 7 d to induce lactation. Mammary tissue was obtained by biopsy at 0, 5, and 10 d relative to initial E+P injections, and Affymetrix GeneChip Bovine Arrays were used to measure gene expression. Ingenuity Pathway Analysis was used to determine functions enriched by differentially expressed genes. Mammary expression of 187 genes was influenced by photoperiod ($P < 0.05$). Enriched functions included cellular assembly and organization, cell morphology, and molecular transport. Those functions are consistent with differences in mammary gland differentiation and activity, which could support the higher milk yield of heifers exposed to SD. Hormonal induction of lactation elicited differential expression over time of 4540 genes ($P < 0.05$), assigned to functional categories including cell cycle, cell death, and protein synthesis, which correspond with the marked development and activation of the mammary gland in preparation for lactation. There was a significant treatment by time interaction such that the temporal pattern of expression of 598 genes differed between LD and SD heifers ($P < 0.05$). Similar to the main effects, enriched functions included cellular development, organ morphology, and lipid metabolism. We conclude that exposure to SD during hormonal induction of lactation markedly influences gene expression in the mammary gland. The genes and functions identified represent potential mechanisms by which photoperiod alters mammary function.

Key Words: gene expression, mammary gland, photoperiod

127 Effect of ovariectomy on milk yield and mammary gland activity in lactating cow. L. Yart*[1,2], F. Dessauge[1,2], L. Finot[1,2], S. Wiart[1,2], A. Mottin[1,2], A. Eveno[1,2], P. G. Marnet[2,1], and V. Lollivier[2,1], [1]*INRA, UMR1348 Pegase, Saint-Gilles, France,* [2]*Agrocampus Ouest, UMR1348 Pegase, Rennes, France.*

Milk yield (MY) in dairy cows is highly dependent on both mammary tissue remodeling and mammary epithelial cell activity during lactation. Previous studies on lactating cows suggested that ovarian steroids (estradiol and progesterone) have a negative effect on MY after the peak of lactation. However, little is known about the effects of ovarian steroids on mammary tissue. The aims of this study were to investigate the effect of ovariectomy on MY and on mammary gland remodeling and molecular activity in lactating cows. Fourteen multiparous Holstein cows were either ovariectomized (Ovx, n = 7) or sham-operated (Sham, n = 7) around 60 d in milk. Cows were milked twice daily during 12 mo; MY was recorded daily throughout the study and milk samples were harvested weekly to follow the milk composition. Mammary tissue samples were collected at 1.5 mo in milk (2 weeks before ovariectomy) and at 4, 8 and 12 mo of lactation to perform molecular analysis on the mammary tissue. Ovariectomy at the time of lactation peak improved MY in the end of lactation (+ 17.1% on mo 8 ($P < 0.1$) and + 60.8% on mo 12 of lactation ($P < 0.1$) for Ovx cows in comparison with Sham cows) without significantly modifying milk composition. Ovariectomy also reduced somatic cell release in milk as of mo 8 of lactation. Moreover, zymography performed on milk samples revealed that mammary tissue remodeling (MMP2 activity) was reduced in Ovx cows. Molecular analysis performed on mammary tissue samples showed that mammary cell apoptosis (Bax transcript level) was reduced by 22.2% ($P < 0.05$) in the Ovx group in an advanced stage of lactation. The Western blot quantification of lactoferrin protein showed that lactoferrin increased over time in both Ovx and Sham cows, but it was reduced by ovariectomy on mo 8 (- 27.4%, $P < 0.1$) and 12 (- 53.3%, $P < 0.1$) of lactation. Taken together these suggest that ovariectomy could delay mammary gland involution.

Key Words: ovariectomy, mammary gland, involution

128 Effect of cooling during the dry period on neutrophil gene expression after *Streptococcus uberis* infection. I. M. Thompson,* S. Tao, K. C. Jeong, W. W. Thatcher, and G. E. Dahl, *University of Florida.*

Heat stress in the dry period affects immune status of dairy cows in lactation. We hypothesized that cooling during the dry period improves immune response to postpartum intramammary infection (IMI) to environmental pathogens such as *Streptococcus uberis*. Cows were dried off 46 d before expected calving and assigned to cooling (CL, n = 15) or heat stress (HT, n = 15). CL cows were housed with sprinklers, fans and shade, whereas the HT group had only shade. All cows were cooled postpartum. Rectal temperature (RT) and respiration rate (RR) were recorded during the dry period. From −46 to 42 d relative to calving, DMI, milk yield and composition were recorded daily, and both BW and BCS weekly. *S. uberis* IMI was induced at 5 d postpartum in a subset of cows (CL, n = 5; HT, n = 5). Blood was collected at 0, 12, 18, 24 and 36 h after IMI. Hematology was performed, and neutrophils isolated for RNA extraction. Neutrophil genes (*TLR2*, *IL1-β*, *IL6*, *IL8*, *IL10*, and *TNFα*) were assessed by real time RT-PCR. Relative to HT, CL cows had lower RT and RR ($P < 0.01$). CL cows also consumed more feed ($P < 0.01$) prepartum but not postpartum, gained more ($P < 0.01$) BW prepartum but lost more ($P = 0.05$) BW in lactation, had higher ($P = 0.01$) BCS score prepartum and a lower ($P < 0.10$) BCS postpartum. During 15 wks of lactation, CL produced more milk (38.8 > 33.6 kg/d; $P < 0.07$) but did not affect milk composition. CL cows had greater ($P = 0.05$) white blood cell count and more ($P = 0.09$) neutrophils than HT during IMI. From 0 to 36 h post IMI, *TNFα* mRNA expression decreased ($P = 0.02$) while *IL6* ($P = 0.02$) and *IL8* ($P < 0.01$) mRNA expression increased in both treatments. Additionally, CL cows had lower ($P = 0.04$) *IL10* mRNA expression at 18 h post IMI. *TLR2* mRNA expression decreased ($P = 0.05$) over time in both treatments. However, CL cows had greater ($P = 0.02$) overall *TLR2* mRNA expression than HT. No differences were detected for mRNA expression of *IL1-β*, *IL6*, *IL8*, and *TNFα*. Cooling cows during the dry period alters immune function and neutrophil response to IMI.

Key Words: heat stress, neutrophils gene expression, intramammary infection

129 Short-term increases in milking frequency and a higher plane of nutrition did not increase total milk production in pasture-based dairy cows during an extended lactation. A. G. Rius,* C. V. C. Phyn, J. K. Kay, and J. R. Roche, *DairyNZ, Hamilton, New Zealand.*

Extended lactations (EL) of > 600 DIM could benefit seasonal, pasture-based dairy systems by improving animal welfare and reducing breeding-related costs; however, lower milk yields on an annualized basis limits farmer adoption. This study determined if temporary increases in milking frequency (MF) and nutrition increased milk production during an EL. Non-pregnant, multiparous Holstein-Friesian cows (333 DIM, n = 120) were randomly allocated to one of 4 treatments (n = 30 cows) for 68 d in a 2 × 2 factorial arrangement which included 2 MF and 2 diets. Treatments were cows i) milked twice daily (2×) and fed pasture only (PAS), ii) milked 2× and fed pasture plus 6 kg DM/d of concentrate (CON), iii) milked thrice daily (3×) and fed PAS, and iv) milked 3× and fed CON. Cows were offered a generous pasture allowance (23 kg DM/d) throughout and milked 2× post-treatment. Statistical analyses were conducted on milk production and body weight (BW) during treatments and an 84-d carry-over period. There were no interactions between MF and diet for each trait in either period and treatments did not affect lactation length (DIM = 570). During treatment, cows milked 3× had increased yields of milk (13.3 vs. 12.0 kg/d; $P < 0.003$) and lactose (0.602 vs. 0.565 kg/d; $P < 0.05$), but not energy-corrected milk (14.7 vs. 14.1 kg/d; $P > 0.18$), relative to 2×. Cows fed CON increased yields of milk (13.1 vs. 12.1 kg/d; $P < 0.01$), protein (0.545 vs. 0.503 kg/d; $P < 0.02$), and lactose (0.612 vs. 0.554 kg/d; $P < 0.002$), and tended to increase energy-corrected milk (14.8 vs. 14.0 kg/d; $P = 0.08$), relative to PAS. Diet and MF did not affect production during the carry-over period or cumulative production from d 1 of treatment to dry-off. Cows fed CON gained more BW (544 vs. 523 kg; $P < 0.001$) and the difference remained for 5 weeks post-treatment. In conclusion, short-term 3× milking and CON increased milk production but these responses did not carry-over to improve total EL yields. Imposing treatments longer than 68 d could increase subsequent production responses but this remains to be tested.

Key Words: extended lactation, dairy cows

130 Transcriptome analysis of blood in heat-stressed dairy goats. A. A. K. Salama*[1], S. Hamzaoui[1], B. Badaoui[2], A. Zidi[3], and G. Caja[1], *[1]Grup de Recerca en Remugants (G2R), Universitat AutÃ³noma de Barcelona, Bellaterra, Barcelona, Spain, [2]Integrative Biology Group, Parco Tecnologico Padano-CERSA, Lodi, Italy, [3]Centre de Recerca en Agrigenomica (CRAG), Bellaterra, Barcelona, Spain.*

With the aim of studying the effects of environmental heat stress on global gene expression, 8 Murciano-Granadina dairy goats (43.3 ± 1.6 kg BW; 81 ± 3 DIM), kept in metabolic cages and allocated in 2 balanced groups, were randomly assigned to 2 climatic treatments according to a crossover design (35-d periods). Treatments were (temperature, °C; humidity, %; THI, Thorn heat index):1) thermal neutral (TN, 15 to 20°C and 35 to 45%; THI = 59 to 64), and 2) heat stress (HS, 12 h/d at 37°C and 45%, and 12 h/d at 30°C and 45%, THI = 86 and 77, respectively). Feed intake and milk yield were recorded daily. Blood samples were collected at d 35 of the second period for microarray analysis (n = 3/treatment). Blood RNA was extracted immediately after collection using RiboPure-Blood Kit (Ambion, Life Technologies, Madrid, Spain). The extracted RNA had an integrity number = 8.6 ± 0.2. Affymetrix GeneChip Bovine Genome designed to monitor expression of approximately 23,000 transcripts was used. The signal intensity of globin genes was low and did not affect the detection of gene expression. The arrays were normalized using the robust multi-array average method. After filtration and normalization, 4,259 genes were included in the analysis. We used the Ingenuity Pathways Analysis (IPA) software to examine biological changes related to heat stress. Feed intake (1.75 vs. 2.47 kg DM/d) and milk yield (1.53 vs. 1.68 L/d) were lower ($P < 0.01$) in HS than in TN goats. We identified 39 and 74 genes whose expression was up- and downregulated, respectively, by HS ($P < 0.05$). These genes were mainly related to biological processes and, to a lower extent, to molecular functions and cellular components. Moreover, IPA analysis detected important pathways related to cell proliferation and death, free radical scavenging, inflammatory response, lipid metabolism, and glycolysis/gluconeogenesis. Transcription regulators affected by HS were: SATB1 (global chromatin organizer) and PPARD (might be related to insulin resistance). In conclusion, chronic HS produced a stress response that was detectable in blood. The HS elicited changes in gene expression related to transcriptional regulation and metabolic processes.

Key Words: heat stress, gene expression, microarray

131 Effects of high feeding level on caprine mammary gland development and milk yield potential. J. M. Aubry[1,2], L. Finot[1,2], L. Yart[1,2], S. Wiart[1,2], E. Siroux[1], M. Chorho[1], J. Lassalas[1], and F. Dessauge*[1,2], [1]*INRA, UMR1348 Pegase, Saint-Gilles, France,* [2]*Agrocampus Ouest, UMR1348 Pegase, Rennes, France.*

The correlation between growth rate during rearing and the subsequent milk yield potential has been extensively studied in dairy cattle and sheep. Many studies highlighted that high feeding level before puberty negatively affected mammary development, but such results are scarce in dairy goats. Present study aimed then to investigate the effect of high feeding level from rearing to kidding on caprine mammary gland development and milk yield potential. A total of 52 Alpine dairy goats were submitted to 2 feeding levels ($n = 26$ per treatment). From weaning (17 kg, 60 d of age) to kidding (50 kg, 12 mo of age), they received either a controlled standard diet according to commercial recommendations (BD, 92 UFL - 17 MAT) or an ad libitum diet (HD, 85 UFL - 17 MAT). Goats weighed twice monthly and were milked twice daily. Milk yield (MY) and composition were recorded twice a week. At mid-gestation, 6 goats of each group were slaughtered and mammary glands were collected. Mammary glands were weighed and dissected for molecular analysis. DNA mammary concentration analysis was measured and used to estimate the total number of mammary cells. Expression of proteins involved in mammogenesis was evaluated on mammary tissue by real-time qPCR, Western Blotting and immunohistochemical staining (ER α, PCNA, MMPs). Before weaning, average daily gain (ADG) were similar between the 2 groups of animals (230 g/d). From weaning to 4 mo of age and from 4 mo of age to conception, HD goats grew faster than BD goats: 180 and 154 g/d vs. 128 and 127 g/d, respectively. At mid-gestation, HD goats had a well developed mammary gland. At slaughter, mammary glands from HD goats already presented a well organized mammary ductal network with the presence of milk. During lactation one, they had a higher milk yield than BD goats (2.92 kg/d vs. 2.73 kg/d on average, $P < 0.05$) during first 2 mo of lactation. Reproduction performance was not affected. In conclusion, high feeding level from weaning to first kidding does not affect mammogenesis and milk yield potential in dairy goats.

Key Words: mammary gland, feeding level, goats

Nonruminant Nutrition: Minerals and Vitamins

132 Determination of endogenous intestinal losses of Ca and digestibility of Ca in canola meal fed to growing pigs. J. C. Gonzalez-Vega*[1], C. L. Walk[2], and H. H. Stein[1], [1]*University of Illinois, Urbana,* [2]*AB Vista, Marlborough, UK.*

An experiment was conducted to test the hypothesis that endogenous Ca is lost from the gastrointestinal tract of growing pigs. The objective was to determine the apparent total tract digestibility (ATTD) and the true total tract digestibility (TTTD) of Ca in canola meal without and with added microbial phytase. Retention of Ca from canola meal was also determined. Forty 8 growing barrows (average initial BW: 16.72 ± 2.52 kg) were allotted to a randomized design with 8 dietary treatments and 6 pigs per treatment. Diets were based on sucrose, cornstarch, potato protein isolate, corn gluten meal, and canola meal. Diets were formulated to contain 0.08, 0.16, 0.24, or 0.32% Ca from canola meal, respectively. All diets were formulated with 0 or 1,500 units per kilogram of microbial phytase (Quantum, AB Vista, Marlborough, UK) and contained 0.32% digestible P. Feces and urine samples were collected from d 6 to d 11. Results indicate that feed intake, Ca intake, P intake, and P excretion increased ($P < 0.05$) by increasing the level of Ca in the diets. The ATTD of Ca and Ca retention increased ($P < 0.05$) if dietary Ca increased and also if phytase was added to the diets. The TTTD of Ca increased ($P < 0.01$) if phytase was used, but was not affected by the level of Ca in the diets. Total endogenous losses of Ca were determined using the regression procedure. Regression analyses indicated that apparent total tract digested Ca increased (linear, $P < 0.05$) as dietary Ca intake increased. The estimated total endogenous loss of Ca was 0.160 and 0.189 mg/kg DMI for canola meal without and with microbial phytase, respectively, and these values were not different. In conclusion, endogenous Ca is lost from the gastrointestinal tract of growing pigs, and values for TTTD of Ca are, therefore, different from values for ATTD of Ca. Values for ATTD of Ca are influenced by the level of dietary Ca, but that is not the case for values for TTTD of Ca. Microbial phytase increases the digestibility of Ca in canola meal, but does not influence the endogenous loses of Ca.

Key Words: calcium, endogenous losses, pigs

133 The effect of supplemental vitamin D_3 as an oral dose or in early nursery pig diets on pig growth performance and serum $25(OH)D_3$ concentrations. J. R. Flohr*[1], M. D. Tokach[1], S. S. Dritz[1], S. C. Henry[2], M. L. Potter[2], N. S. Shelton[1], L. L. Greiner[3], J. Connor[3], R. D. Goodband[1], J. L. Nelssen[1], and J. M. DeRouchey[1], [1]*Kansas State University, Manhattan,* [2]*Abilene Animal Hospital, Abilene, KS,* [3]*Innovative Swine Solutions, Carthage, IL.*

A total of 400 barrows from 80 litters (PIC 1050, initially 7 d of age) were used in a 38 d study in a 2 × 2 factorial to determine the effects of vitamin D_3 supplementation from either a single oral dose or from high levels of vitamin D_3 in early nursery diets on pig performance and serum $25(OH)D_3$. On d 7 after birth, matched pairs of pigs within litters were randomly allotted to 1 of 2 oral dosages (none or 40,000 IU vitamin D_3) in a RCBD. Pigs were weighed at d 7 and weaning (d 21). Following weaning, a subset of 300 barrows were used from d 21 to 45 to determine the effects of the previously administered oral vitamin D_3 and 2 levels of dietary vitamin D_3 (1,378 or 13,780 IU/kg; 0.80% Ca and 0.63% available P) from weaning to d 31 on pig growth and serum $25(OH)D_3$. A common diet containing 1,378 IU/kg of vitamin D_3 (0.70% Ca and 0.47% available P) was fed from 31 to 45 d of age. Barrows were allotted to pens based on their respective vitamin D_3 dose with pens randomly allotted to dietary treatments. There were no dose × diet interactions ($P > 0.09$). Serum $25(OH)D_3$ was increased ($P < 0.01$) on d 21 and tended to be increased on d 31 by dosing pigs with vitamin D_3 before weaning. On d 31, serum concentrations increased with increasing dietary vitamin D_3 levels ($P < 0.01$). Weaning weight was not influenced ($P > 0.17$; dosed 5.26 kg vs. undosed 5.18 kg) by the oral dose of vitamin D_3. Supplementing vitamin D_3 by either dose or diet did not influence ($P > 0.23$) nursery performance. In conclusion, supplementing vitamin D_3 either orally or in the nursery diet increased serum $25(OH)D_3$, but did not influence nursery pig growth performance.

Table 1.

Dosage:	No vitamin D_3		40,000 IU D_3			*P*-value		
Phase 1 Diet:	1,378 IU	13,780 IU	1,378 IU	13,780 IU	SEM	Dose × diet Interaction	Dosage Effect	Diet Effect

134 Carbohydrase and phytase complex improves performance and bone mineralization of pigs fed wheat-soybean base diet. P. Cozannet[1], R. Gerritsen[2], R. Maillard[1], E. Devillard*[1], and A. Preynat[1], [1]*Adisseo France SAS, CERN, Malicorne, France,* [2]*Schothorst Feed Research, Lelystad, Netherlands.*

The trial was carried out to investigate the effects of a multi-enzyme (enz) complex containing carbohydrases (from *Penicillium funiculosum*) and 6-phytase (from *Schizosaccharomyces pombe*) on performance and bone mineralization of growing-finishing pigs fed a wheat-soybean meal diet. Gilts [360; Talent × (GYz × Finnish Landrace)]; 7 wk; 25 kg BW) were assigned to 1 of 3 treatments according a randomized block design with 12 replicates (10 gilts/pen) for 100 d. The positive control (PC) diet was a standard diet, formulated to meet the requirement of all nutrients during growing and finishing period (NE = 8.92/8.95 MJ/kg and lys dig = 0.98/0.56 g/MJ NE, respectively), while the negative control (NC) diet was formulated with reductions in energy (0.42 MJ NE/kg), available phosphorus (av P; 0.10%) and calcium (Ca; 0.08%). NC diet was supplemented or not with Rovabio Max (1,100 endo-β-1,4-xylanase visco units, 100 endo-1,3(4)-β-glucanase units and 500 Phytase units /kg of feed; 50 g/ton of feed). Animal feed intake and BW were recorded at the end of each period. Front left meta-carpi of one pig per pen were collected for bone ash percentage (BAP) measurement at the end of the experiment. Results were analyzed in Genstat (ANOVA) and means compared using LSD test. During the 5 weeks growing period, no treatment effect was observed. During finishing period, ADFI was not affected by treatments ($P = 0.29$).Gilts had higher ADG (887 vs. 818

g/day; $P < 0.05$) when they received PC compared with NC whereas enz addition in NC diet partly restored ADG to PC level (857 vs. 887 g/day; $P < 0.05$). FCR was similar for PC and NC + enz with values lower than NC (2.45 vs. 2.58; $P = 0.01$). Considering overall period, pig fed NC diet were 2.6 ($P < 0.05$) and 4.6 ($P < 0.005$) kg lighter than pig fed NC + enz and PC diet, respectively. Moreover, as expected, BAP was negatively affected by mineral depletion (53 vs. 56%; $P < 0.05$) and fully compensated by enz addition as suggested by no difference between PC and NC + enz ($P > 0.05$). These results demonstrate the efficiency of enz complex to balance av P, Ca and NE depletion on wheat-based diet.

Key Words: pig, carbohydrase, phytase

135 Modulation of phosphorus digestive utilization in weanling pigs: influence of dietary calcium and phytase on gastro-intestinal digesta pH and mineral solubility. A. Narcy[1], M. P. Létourneau-Montminy*[2], E. Bouzouagh[1], N. Même[1], M. Magnin[3], and J. Y. Dourmad[4], *[1]INRA, UR83 Recherches Avicoles, Nouzilly, France, [2]Agriculture et Agroalimentaire Canada, Sherbrooke, QC, Canada, [3]BNA-NA, Chateau-Gontier, France, [4]INRA-Agrocampus Ouest, UMR 1348, Saint Gilles, France.*

The study was conducted to evaluate the impact of dietary calcium (Ca) concentration, added in the form of calcium carbonate (CaCO3), on phosphorus (P) digestibility and gastro-intestinal digesta pH and soluble mineral concentration in weanling pigs fed diets with or without microbial phytase. A 3 × 2 factorial arrangement was used with maize-soybean meal based diets formulated to contain combinations of 3 concentrations of Ca: 0.50, 0.75 and 1.00% with or without the addition of 1000 FTU of microbial phytase/kg. After a 5-d adaptation period under a standard diet, 40 male weanling pigs were blocked by weight and allotted to one of the 6 dietary treatments in a 29 d experiment. The addition of microbial phytase improved ($P < 0.001$, +20.1 points) P digestibility regardless of dietary Ca concentration. In addition, P digestibility was linearly decreased ($P < 0.001$, −4.30 points) when increasing dietary Ca. Dietary Ca concentration and microbial phytase did not affect the pH of the different digestive compartments. Nevertheless, the pH of the different segments followed an increasing proximo-distal gradient (segment, $P < 0.001$): 4.69, 5.62, 6.66 and 7.10 pH units respectively for the stomach, the duodenum, the jejunum and the ileum. A negative quadratic relation was observed between the gastric pH and the proportion of soluble inorganic P (iP) and Ca. In the same segment, phytase improved the solubility of iP depending on dietary Ca concentration (Ca x phytase, $P < 0{,}001$). Indeed, the addition of microbial phytase increased the proportion of soluble iP (% total P) by 20.2, 9.30 and 8.90 points in diets containing 0.50, 0.75 and 1.00% of dietary Ca respectively. The present results suggest that the increase of dietary Ca concentration may affect the solubility of phytates in the stomach reducing in this way their hydrolysis by phytase. Nevertheless, this step did not appear to be limiting regarding the enzyme efficacy in ameliorating P digestibility.

Key Words: phosphorus, calcium, pig

136 Phosphorus utilization in finishing broiler chickens: Effect of dietary calcium and microbial phytase. X. Rousseau*[1,2], M. P. Letourneau-Montminy[3], M. Magnin[1], N. Même[2], Y. Nys[2], and A. Narcy[2], *[1]BNA NA, Château-Gontier, France, [2]INRA UR83 Recherches avicoles, Nouzilly, France, [3]Agriculture and Agri-Food Canada, Lennoxville, Québec, Canada.*

The optimization of phosphorus (P) utilization is crucial to ensure poultry production sustainability. This is particularly the case in finishing broilers (21 to 38 d of age) considering that about 70% of the overall feed intake occurs during the last phase, which also leads to high P excretion, approximately 50% of the P intake being lost in the environment. Response to dietary P in broilers chickens were shown to be dependent on a balance between dietary Ca and P including also P released by microbial phytase. This experiment was carried out to evaluate the response of 144 finishing broilers, reared in individual cages, to 12 dietary treatments differing in dietary Ca (0.37; 0.57; 0.77%), non-Phytate P (nPP; 0.18 or 0.32%) and microbial phytase (0 or 500 FTU/kg). Growth performances, P and Ca retention and bone mineralization were determined. Dietary treatments had no significant effect on ADG, ADFI and FCR. Tibia ash deposition decreased with reduction in dietary Ca at the highest nPP, but improved with reduction in dietary Ca at the lowest nPP (Ca × nPP; $P = 0.035$). Birds fed P-deficient diets used P more efficiently for tibia ash deposition if dietary Ca was sufficient (Ca × nPP; $P < 0.001$). Birds response to microbial phytase was greater with lower level of nPP in terms of P retention and tibia ash content (nPP × phytase; $P = 0.009$ and $P = 0.021$ respectively). Birds could have developed regulative process to cope with P and/or Ca deficiency. Nevertheless, a balanced supply between Ca and P must be considered to ensure optimal utilization of these minerals especially for bone mineralization.

Key Words: phosphorus, calcium, finishing broiler

137 The effect of dietary levels of copper and zinc on rate and efficiency of growth by rainbow trout. E. S. Read*[1], W. M. Sealey[2], F. T. Barrows[3], M. K. Petersen[4], and J. A. Paterson[1], *[1]Montana State University, Bozeman, [2]US Fish and Wildlife Service, Bozeman, MT, [3]US Department of Agriculture, Agriculture Research Service, Bozeman, MT, [4]US Department of Agriculture, Agriculture Research Service, Miles City, MT.*

The objectives of this factorial experiment were to determine if interactions existed between dietary Cu and Zn levels on rate and efficiency of growth and whole body element retention in growing trout. After 6 wk of feeding a diet deficient in Cu (9.4 ppm) and Zn (37.7 ppm), 600 fish (avg wt of 40 g) were randomly assigned to diets with supplementary $CuSO_4$ or $ZnSO_4$ added to provide diets with 0 or 10 ppm added Cu and 0, 30, 300 or 1500 ppm added Zn. There were 25 fish per tank with 3 replications per diet. Diets were formulated to contain 40% CP from soybean meal and corn protein concentrate and 20% crude lipid. Fish were fed experimental diets for 12 wk. The main effects of dietary Cu level, Zn level and the potential interaction on growth and mineral retention were tested. After 6 and 12 wk, 3–5 fish from each tank were sacrificed to determine liver and whole body concentrations of Cu and Zn. Cataracts were observed at 12 wks in 69% of fish fed the Cu and Zn deficient diet compared with an average of 0.01% for all other treatments. Dietary Zn ($P = 0.002$) but not dietary Cu ($P = 0.263$) increased 12 wk weight gain. An interaction ($P = 0.008$) between dietary Cu and Zn was observed for 12 wk weight gain. Slowest gains (19 g/d) were for the Cu and Zn deficient diet and fastest gains (45 g/d) were in the 10 ppm Cu and 1500 ppm Zn diet. Dietary Zn ($P = 0.001$) but not dietary Cu ($P = 0.996$) increased 12 wk whole body Zn levels. Dietary Cu ($P = 0.094$) or Zn ($P = 0.095$) did not alter whole body Cu levels and no interactions were observed ($P = 0.806$). Results of this study indicate rainbow trout fed plant-based diets require Zn supplementation to obtain sufficient growth. Level of supplemented Cu did not improve weight gain. However, the level of Zn did improve weight gain, at the higher levels (300 and 1500 ppm) of Zn. The highest levels of Zn supplementation did not impair Cu uptake in rainbow trout. Diets without additional

Cu or Zn caused increased incidence of cataracts compared with diets with added Cu and Zn.

Key Words: copper, zinc, rainbow trout

138 Varied sources of conjugated linoleic acid (CLA) does not alter bone mineral density (BMD), bone mineral content (BMC), or body fat content in postmenopausal ovariectomized rats. K. M. Kanosky,* Z. D. Callahan, M. A. Brown, C. S. Perkins, E. A. Benavides, D. H. Keisler, and B. R. Wiegand, *University of Missouri, Columbia.*

Altering dietary fat source has been shown to change the fatty acid profile in non-ruminant animals; subsequently changing downstream metabolic events such as bone remodeling, which is influenced by inflammatory prostaglandin E2 (PGE2). Excess production of PGE2 is linked to osteoporosis and associated with postmenopausal bone loss. One potential anti-inflammatory agent is conjugated linoleic acid (CLA). Previous studies have reported that CLA feeding in rats resulted in decreased PGE2 production, thus improving bone mineral density (BMD). The objective of this study was to determine if body fat content, specific organ weights, bone mineral content (BMC) and BMD were altered if aged, ovariectomized female rats were fed varied sources of CLA. All procedures were performed according to University of Missouri Animal Care and Use Committee Approved Protocol. Retired breeder (365 ± 28 d of age and 4.5 ± 0.5 parity), Sprague Dawley, female rats (n = 86) were randomly assigned to ovariectomy (OVX) or sham (SHAM) surgeries. Rats were fed 4% soy oil (CON) for 14 d. For an additional 70 d, within surgery groups, rats were randomly allotted to dietary treatments: CON, 0.6% CLA + 3% soy oil (CLA), 0.6% CLA from cheddar cheese powder + 3% soy oil (CC), or 0.3% CLA + 0.3% CLA from cheddar cheese powder + 3% soy oil (CCCLA). Feed intake and body weight were measured weekly. Dual-energy x-ray absorptiometry (DEXA) scans were performed to measure body fat content and bone composition before dietary treatments and post-mortem. At the end of the feeding period rats were sacrificed, blood was collected, and livers, thigh muscles, peritoneal fat, femurs, and tibias were removed and weighed. There were no significant effects of treatment on bone mineral content (BMC, g), bone mineral density (BMD, g/cm^2), or body fat content (%). Compared with SHAM, rats that were OVX had lower BMD ($P < 0.01$) and femur weights ($P < 0.01$), therefore resulting in less dense bones. However, fat content ($P < 0.001$), ADG ($P < 0.0001$), and ADFI ($P < 0.05$) increased in OVX rats. Unlike growing finishing pigs, 0.6% CLA inclusion in rat diets may not be enough CLA for this enhanced anti-inflammatory response. In conclusion, we were able to make an appropriate postmenopausal rat model that exhibited a decrease in BMD, which may be beneficial in future osteoporosis research.

Key Words: linoleic acid, rats, bone

139 Effects of selenium-enriched exopolysaccharide produced by *Enterobacter cloacae* Z0206 on growth performance, immunity and antioxidant activities in broiler chickens. Z. Q. Lu,* Y. M. Wang, M. Huang, and Y. Z. Wang, *Institute of Feed Science, Zhejiang University, National Engineering Laboratory of Bio-feed Safety and Pollution Prevention, Key Laboratory of Animal Nutrition and Feed science of Ministry of Agriculture, Hangzhou, Zhejiang Province, China.*

Enterobacter cloacae Z0206 (*E. cloacae* Z0206), a recently discovered bacterial strain, could produce huge amount of exopolysaccharides. Our previous studies found that *E. cloacae* Z0206 could accumulate selenium (Se) in the form of Se-enriched exopolysaccharide (Se-ECZ-EPS) efficiently in medium enriched with selenium. Se-ECZ-EPS contained 535.7 mg/kg Se and has been proven to possess immunostimulatory function in mice. However, little was known about the bioactive activities of Se-ECZ-EPS in chickens. Thus the present study was conducted to investigate the effects of Se-ECZ-EPS on growth performance, serum cytokine concentrations and antioxidant enzyme activities in broiler chickens. Two hundred forty Avian broiler chickens were allocated randomly into 5 groups with 4 replicates in each group and 12 chickens in each replicate. Control group was fed with basal diet containing 0.15 mg/kg Se (Na_2SeO_3), and the another 4 groups were fed with diets supplemented with Se-ECZ-EPS at the level of 280 mg/kg (0.15 mg/kg Se), 560 mg/kg (0.30 mg/kg Se), 840 mg/kg (0.45 mg/kg Se) and 1120 mg/kg (0.60 mg/kg Se), respectively. The results showed that average daily gain and feed conversion ratio in 840 and 1120 mg/kg groups were significantly enhanced from 0 to 42 d compared with the control group ($P < 0.05$). And the serum concentrations of TNF-α, IFN-γ, IL-2 and IL-6 showed positive responses in 1120 mg/kg group ($P < 0.05$). Furthermore, administration of Se-ECZ-EPS at the level of 560, 840 and 1120 mg/kg significantly increased activities of glutathione peroxidase and superoxide dismutase, and decreased malondialdehyde production ($P < 0.05$). These results implicated that Se-ECZ-EPS can improve the growth performance, and enhance immune and antioxidant functions by stimulating secretion of cytokine and improving antioxidant enzyme activities in broilers.

140 Effects of metabolic imprinting on growth performance and gene expression of early-weaned beef heifers.

P. Moriel*[1], V. Mercadante[2], A. D. Aguiar[1], S. E. Johnson[2], M. J. Hersom[2], J. M. B. Vendramini[1], and J. D. Arthington[1], [1]*Range Cattle Research and Education Center, University of Florida, Ona, FL,* [2]*University of Florida, Gainesville.*

The study evaluated the effects of calf management system after early-weaning (EW) on performance and liver gene expression of beef heifers. On d 0, Brahman × British heifers (n = 40; BW = 83 ± 10 kg; age = 69 ± 9 d) were stratified by age and BW, and randomly assigned to a control treatment that was normally weaned (NW) on d 177, or 1 of 3 EW treatments, (1) EW and grazed on ryegrass pastures for 67 d then on bahiagrass pastures until NW (Ryegrass), (2) EW and fed a high-concentrate diet in drylot until NW (Drylot), or (3) EW and metabolically imprinted by feeding a high-concentrate diet for 94 d then grazed on bahiagrass pastures until NW (MI). Heifers were assigned to 1 of 2 pens per treatment. On d 177, heifers were grouped by treatment and grazed on bahiagrass pastures until the start of breeding season (d 335). Heifers on pastures were supplemented at 1.0% BW until NW and 1.5% BW from NW to d 335. On d 177 and 335, Ryegrass heifers were lightest ($P < 0.01$) and Drytlot heifers heaviest ($P < 0.001$) compared with all other treatments and Control and MI heifer BW did not differ ($P \geq 0.64$; BW = 212 and 300, 178 and 264, 216 and 302, and 261 and 333 for Control, Ryegrass, MI, and Drylot on d 177 and 335, respectively; SEM = 7.8). On d 94, liver GHR-1A mRNA was greatest ($P < 0.01$) for Control, but similar ($P = 0.64$) among the other treatments, whereas liver IGF-1 mRNA was least ($P = 0.004$) for Ryegrass, but similar ($P > 0.90$) among the other treatments. On d 177, liver GHR-1A was greater for Control and Drylot ($P < 0.03$) than Ryegrass and MI, whereas liver IGF-1 mRNA was greatest for Drylot than all other treatments and greater ($P < 0.07$) for Control than Ryegrass and MI. On d 260, liver GHR-1A mRNA was least ($P < 0.08$) for Ryegrass, whereas liver IGF-1 was greater ($P < 0.04$) for Drylot compared with Ryegrass. Thus, heifer management systems following EW result in significant differences on BW at NW and at the start of breeding season. These impacts appear to affect liver gene mRNA expression, which may persist despite placing heifers on a same plane of nutrition.

Key Words: beef steers, high-concentrate, metabolic imprinting

141 Effects of metabolic imprinting on growth performance of early-weaned beef steers.

P. Moriel*[1], V. Mercadante[2], A. D. Aguiar[1], S. E. Johnson[2], M. J. Hersom[2], J. M. B. Vendramini[1], and J. D. Arthington[1], [1]*Range Cattle Research and Education Center, University of Florida, Ona,* [2]*University of Florida, Gainesville.*

This study evaluated the effects of calf management system after early weaning (EW) on performance of beef steers. On d 0, Brahman × British steers (n = 40; BW = 90 ± 12 kg; age = 72 ± 14 d) were stratified by age and BW, and randomly assigned to a normally-weaned treatment (NW; d 177) or 1 of 3 EW treatments, (1) EW and grazed on ryegrass pastures for 67 d then on bahiagrass pastures until feedlot entry (d 260; Ryegrass), (2) EW and fed a high-concentrate diet in drylot until d 260 (Drylot), or (3) EW and metabolically imprinted by feeding a high-concentrate diet for 94 d then grazed on bahiagrass pastures until d 260 (MI). Within each treatment, steers were assigned to 1 of 2 pens. Concentrate was limit fed at 1% of BW from d 177 to 260, 7 to 260 and 94 to 260 for NW, Ryegrass and MI steers, respectively. Shrunk BW was measured at normal weaning and feedlot entry. Carcass ultrasound was measured on d 260. At normal weaning, Drylot steers were heavier ($P = 0.006$; SEM = 16) than all other treatments, and Control and Ryegrass steers had similar BW (215 and 196 kg, respectively; $P = 0.14$; SEM = 13), but were lighter ($P < 0.04$) than MI steers (243 ± 13 kg). Similarly, at the time of feedlot entry (d 260), Drylot steers were heavier (359 ± 16 kg; $P = 0.0002$) than all other treatments, and Control and Ryegrass steers had similar BW (228 and 230 kg, respectively; $P = 0.94$; SEM = 16), but were lighter ($P < 0.01$) than MI steers (277 ± 16 kg). On d 260, back fat thickness was similar ($P > 0.35$; largest SEM = 0.01) among Control, Ryegrass and MI steers (0.14, 0.14 and 0.15 cm, respectively), but was less ($P < 0.0001$) than Drylot steers (0.18 cm). Area of LM was least (30.4 cm^2; $P < 0.09$; largest SEM = 1.33) for Ryegrass steers, similar ($P = 0.20$) between MI (32.0 cm^2) and Control (30.4 cm^2) steers, and the greatest ($P < 0.001$) for Drylot steers (41.6 cm^2). Thus, feeding a high-concentrate diet to EW steers for at least 94 d (Drylot and MI) increased BW at the time of NW and at feedlot entry compared with calves weaned at a normal age or early-weaned and grazed on pasture with 1% concentrate supplement.

Key Words: beef steers, high-concentrate, metabolic imprinting

142 Correlation of feed intake and efficiency with small intestinal angiogenic factor and receptor expression in finishing cattle born to dams fed varying levels of nutrients during early to mid-gestation.

A. M. Meyer*[1], K. M. Cammack[1], K. J. Austin[1], J. M. Kern[1], M. Du[1], J. S. Caton[2], and B. W. Hess[1], [1]*Department of Animal Science, University of Wyoming, Laramie,* [2]*Department of Animal Sciences, North Dakota State University, Fargo.*

We hypothesized that gestational nutrition would affect calf feed intake and efficiency as well as small intestinal development, and that feed intake and efficiency would be correlated with small intestinal measures. Multiparous beef cows (n = 36) were fed 1 of 3 diets from d 45 to 185 of gestation: a control (CON) diet of grass hay and supplement to meet NRC recommendations, a nutrient restricted (NR) diet providing 70% of CON NE_m, or an NR diet with a ruminally undegradable protein (NRP) supplement to provide similar essential AA as CON. Individual feed intake of calves was measured with the GrowSafe System during finishing. At slaughter (552 ± 10.2 kg BW), the jejunum was sampled for real time RT-PCR analysis of angiogenic factors (vascular endothelial growth factor [*VEGF*], VEGF receptor-1 [*FLT1*], VEGF receptor-2 [*KDR*], endothelial nitric oxide synthase 3 [*NOS3*] and soluble guanylate cyclase [*GUCY1B3*; nitric oxide receptor]). Data were analyzed as a mixed model with calf sex as block. It was previously reported that maternal nutrition affected calf small intestinal length, but not other measures of intestinal growth, intake, or feed efficiency. Jejunal *GUCY1B3* mRNA expression was affected by maternal nutrition ($P = 0.03$), where calves born to NRP dams had greater ($P < 0.03$) *GUCY1B3* than CON and NR (4.59 vs. 2.85 and 2.56 ± 0.54 relative mRNA expression). There was no effect ($P \geq 0.34$) of maternal nutrition on *VEGF*, *FLT1*, *KDR*, or *NOS3* expression. Feed intake was positively correlated with jejunal mRNA expression of *KDR* ($r = 0.37$; $P = 0.05$) and *NOS3* ($r = 0.35$; $P = 0.06$) and tended to be negatively correlated with *VEGF* ($r = -0.30$; $P = 0.11$). Residual feed intake and G:F were not correlated ($P \geq 0.20$) with angiogenic factor mRNA expression. Results indicate that offspring intestinal gene expression may be affected by gestational nutrition even when apparent tissue growth is unchanged. Additionally, changes in intestinal expression of *VEGF* and *NOS3* systems are associated with feed intake and may alter intestinal vasculature.

Key Words: feed efficiency, gestation, small intestine

143 Reproductive and productive responses to suckling-restriction treatments and flushing in primiparous grazing beef cows.

P. Soca*[1], M. Carriquiry[1], D. Keisler[2], M. Claramunt[1], M. Do Carmo[1], J. Olivera- Muzante[1], M. Rodriguez[1], and A. Meikle[1], *[1]University of Uruguay, Paysandu, Uruguay, [2]University of Missouri, Columbia.*

The objectives of this experiment were to analyze the reproductive and productive responses to suckling management treatments and flushing in primiparous grazing beef cows. During 3 years, 153 primiparous anestrous cows were assigned randomly to 4 treatments in a 2 × 2 factorial arrangement of suckling management treatments and flushing. Suckling management treatments started at 61 ± 10 d postpartum and consisted of applying nose plates to calves for 12 d (i.e., TS treatment) or 5 d of isolation of the cow-calf pair followed by applying nose plates to calves for 7 d as calves were reunited with their mothers (i.e., IS treatment). Nutritional treatments (flushing vs. control) started at the beginning of the breeding season immediately after the suckling management treatments were finished (73 ± 10 d postpartum) with cows being offered or no 2 kg/day of whole-rice middling for 22 d. Weather, pasture quantity and quality, calving date, and cow body condition score BCS were recorded every 20 d from calving until definitive weaning (140 ± 10 d postpartum). Calf weight was recorded at birth, at 73 d of age, and at definitive weaning. Duration of postpartum anestrus (PPA) and probability of cyclicity were estimated by plasma progesterone concentrations analyzed in weekly samples. Pregnant cows were determined by ultrasound at 45 d after bull introduction (early pregnancy; EP) and at the end of the breeding period (total pregnancy; TP). The year affected BCS at calving and changes in BCS (ΔBCS), which were indicative of forage availability and weather conditions. Increased cow BCS at calving decreased PPA (b = −41 d; $P < 0.0001$) and in interaction with ΔBCS increased EP ($P < 0.008$) and TP ($P < 0.003$). No interaction was found between suckling and flushing. Isolated suckling (IS) reduced PPA by 11 d when compared with TS ($P < 0.004$). Flushing increased EP by 40%, which was also affected by BCS at calving and was greater in cows that gained, than maintained or lost BCS. We conclude that flushing was a low cost and environmentally tool that was useful in improving pregnancy rates of primiparous beef cows with “suboptimal” body condition (lower than 4.5) at calving and grazing native pasture.

Key Words: body condition score, primiparous beef cows, suckling and flushing

144 Use of an injectable mineral in beef cattle: Mineral status.

O. N. Genther* and S. L. Hansen, *Iowa State University, Ames.*

The objective of this study was to examine the effect of trace mineral (TM) status and response to mineral injection in beef cattle. Forty steers were stratified by weight (323 ± 14.8 kg) and assigned to treatments for an 84 d depletion period: 1) a corn silage-based diet supplemented with Cu, Mn, Se and Zn at NRC recommendations (CON), or 2) CON diet without supplemental Cu, Mn, Se or Zn, plus Fe and Mo as dietary TM antagonists (DEF). Liver Cu and Se concentrations in DEF steers were lower than CON steers before injection ($P < 0.05$) indicating mild deficiencies of these TM. To mimic shipping stress steers were shipped for 20 h on d −3 and received back on d −1. On d 0 an equal number of steers from both dietary treatments were injected with sterilized saline (SAL) or Multimin®90 (MM; containing 15, 40, 10 and 5 mg/mL of Cu, Zn, Mn and Se, respectively) at a dose of 1 mL/68 kg BW. Steers were fed a common finishing diet supplemented with Cu, Mn, Se and Zn at NRC recommendations for the 90 d repletion period. Blood samples were taken on d 0, 1, and blood and liver biopsy samples were collected on d 8, 15, 29, 57, and 85 post-injection. Data were analyzed as repeated measures. Red blood cell lysate (RBCL) Mn superoxide dismutase activity was higher in MM steers ($P = 0.02$), suggesting incorporation of injectable TM into a biological process. Diet or injection did not affect RBCL glutathione peroxidase activity ($P > 0.20$), but plasma Se in MM steers was elevated through d 15 ($P < 0.05$). For liver Se there was an interaction between diet, injection and day where the magnitude of the increase was greater in CON vs. DEF ($P = 0.02$), suggesting that TM from injection were utilized rather than stored in DEF steers. Liver Se and Cu ($P < 0.05$) were elevated through at least d 30 by TM injection. Liver Zn was slightly higher in DEF steers vs. CON ($P < 0.01$) and TM injection tended ($P < 0.10$) to increase Zn liver concentration on d 8 and 15 regardless of previous diet. Interestingly, by d 57 liver TM were higher in DEF steers ($P < 0.05$) suggesting differential TM utilization between CON and DEF steers. Overall, TM from an injectable mineral were utilized differently between TM adequate and mildly deficient steers.

Key Words: cattle, trace minerals

145 Use of an injectable mineral in beef cattle: Growth and carcass characteristics.

O. N. Genther* and S. L. Hansen, *Iowa State University, Ames.*

Trace minerals (TM) are vital for growth in cattle. To examine the effect of TM status and mineral injection on performance in beef cattle, 40 steers were used in a growing and finishing study. Steers were stratified by weight (323 ± 14.8 kg) and assigned to one of 2 treatments for an 84 d depletion period: 1) a corn silage-based diet supplemented with Cu, Mn, Se and Zn at NRC recommendations (CON), or 2) CON diet without supplemental Cu, Mn, Se or Zn, and supplemented with Fe and Mo as dietary TM antagonists (DEF) to induce mild deficiencies. To mimic shipping stress steers were shipped for 20 h on d 88 and were received back on d 89. On d 91 an equal number of steers from both dietary treatments were injected with sterilized saline (SAL) or Multimin 90 (MM; containing 15, 40, 10 and 5 mg/mL of Cu, Zn, Mn and Se, respectively) at a dose of 1 mL/68 kg BW. Steers were fed a common finishing diet supplemented with Cu, Mn, Se and Zn at NRC recommendations for the 90 d repletion period. Steers were harvested 94 d post-injection and carcass data were collected. During the depletion period diet did not affect ADG ($P = 0.72$). During shipping, DEF steers tended to lose more weight per day than CON steers ($P = 0.06$) and had lower DMI after shipping ($P < 0.05$), suggesting that TM status is important in the stress response. During the repletion period ADG of DEF-MM steers was greater ($P = 0.02$) compared with DEF-SAL, and was not different ($P = 0.91$) among CON-MM and CON-SAL steers. There was no effect of diet or injection on HCW or dressing percentage ($P > 0.20$). Within the CON group TM injection decreased yield grade ($P = 0.03$) but did not affect yield grade of DEF steers ($P > 0.20$). MM steers had larger rib eye area ($P = 0.04$) regardless of previous diet. Interestingly, both diet and injection affected marbling scores (MS), where CON steers had greater MS than DEF steers ($P = 0.01$), and MM steers had greater MS than SAL steers ($P = 0.04$). These results indicate that TM are essential for marbling development, during both the growing and finishing phases. Overall, an injectable mineral improved rib eye area and MS regardless of TM status, and improved growth of mildly TM deficient steers.

Key Words: cattle, trace minerals

146 Effects of restricted versus conventional dietary adaptation over periods of 9 and 14 days on feedlot performance and carcass traits of Nellore cattle. R. S. Barducci[1], M. D. B. Arrigoni[1], C. L. Martins[1], D. D. Millen*[2], L. M. N. Sarti[1], M. C. S. Franzói[1], L. C. Vieira Júnior[1], T. L. de Jesus[1], T. C. Putarov[1], M. T. Cesar[1], A. S. Pereira[1], E. T. Macedo[1], A. Perdigão[1], F. A. Ribeiro[1], A. L. N. Rigueiro[2], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine effects of restricting intake of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of 9-d and 14-d on overall feedlot performance and carcass traits. The experiment was designed as a completely randomized block with a 2 × 2 factorial arrangement, replicated 6 times (5 bullocks/pen), in which 120 22-mo-old yearling Nellore bulls (361.3 ± 30.2 kg) were fed in 24 pens for 84-d according to the treatments: STEP for 9-d and 14-d, REST for 9-d and 14-d. The STEP program consisted of ad libitum feeding of 3 adaptation diets over periods of 9-d or 14-d with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted intake of the final diet (85% concentrate) with programmed increases in feed offered until yearling bulls reached ad libitum access over periods of 9-d or 14-d. No significant ($P > 0.05$) days main effect was observed for any of feedlot performance and carcass characteristics variables evaluated. No significant ($P > 0.05$) protocol main effect was observed for final BW, ADG in kg (STEP = 1.71, REST = 1.73; 9-d = 1.74, 14-d = 1.70) and total weight gain (STEP = 143.29, REST = 145.79; 9-d = 146.04, 14-d = 143.05) from 0-d to 84-d. However, significant ($P < 0.05$) protocol main effect was observed for DMI in kg from 0-d to 28-d (STEP = 9.67, REST = 9.01); DMI in % of BW from 0-d to 28-d (STEP = 2.52, REST = 2.36), and from 0-d to 56-d (STEP = 2.58, REST = 2.47); G:F ratio from 0-d to 84-d (STEP = 0.157, REST = 0.165); and cost to gain 1 kg of BW from 0-d to 84-d (STEP = $3.77, REST = $3.59). With respect to carcass traits, no significant ($P > 0.05$) protocols and days main effects were observed for kidney-pelvic fat in kg, HCW, and dressing %. Animals in REST protocol were more efficient than those in STEP protocol. The adaptation in 9-d did not negatively impact the overall feedlot performance and carcass traits of Nellore cattle. Grant provided by São Paulo Research Foundation (FAPESP), São Paulo, Brazil.

Key Words: adaptation, feedlot, Nellore

147 Effect of dietary energy density and control of meal size on growth performance, eating pattern, and carcass and meat quality in Holstein steers fed high-concentrate rations. S. Marti*[1], M. Pérez-Juan[2], A. Aris[1], A. Bach[3,1], and M. Devant[1], *[1]IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Torre Marimon, Caldes de Montbui, Barcelona, Spain, [2]IRTA-Monells, Girona, Spain, [3]ICREA, Barcelona, Spain.*

A total of 121 steers (116 ± 3.7 kg of BW and 97 ± 2.4 d of age) were used to study the effect of dietary energy density and meal size limitation on intake and growth, hormones associated with the regulation of nutrient intake, and carcass and meat quality. Steers were randomly allocated to 3 treatments: a concentrate of moderate energy density (CTR, 3.16 Mcal of ME/kg, 6.1% EE) fed ad libitum with no control on meal size, a concentrate of high energy density (HE, 3.36 Mcal of ME/kg, 8.3% EE) fed ad libitum with no control on meal size, and a HE concentrate offered ad libitum but limited to a maximum meal size of 0.7 kg (HELM), with no total daily concentrate intake limit. Live BW was recorded every 14 d and concentrate consumption and eating pattern were recorded daily with a computerized concentrate feeder. At d 163, blood samples were collected to determine leptin, ghrelin, GLP-1, CCK, glucose and insulin serum concentrations After slaughter, the 9-10-11th rib section was removed to estimate separable bone, lean and fat. Muscle pH and color, WBSF and i.m. fat were analyzed in the LM. Data were analyzed using a mixed-effects model including diet as a main effect. Steers in the HELM had a less ($P < 0.01$) final BW and ADG than CTR and HE steers. Concentrate intake was greater ($P < 0.001$) in CTR steers (6.6 ± 0.1 kg/d) than in HE steers(5.7 ± 0.1 kg/d), and HELM (5.1 ± 0.1 kg/d) ate less than in CTR and HE steers. However HE and HELM steers were more efficient ($P < 0.01$) than CTR steers. Mean daily meals and eating rate were less ($P < 0.05$) in HE and HELM than in CTR steers. Serum concentrations of GLP-1, CCK and insulin were lower ($P = 0.05$) in HELM than CTR and HE steers; also leptin and glucose concentration tended to be less ($P = 0.10$ and $P = 0.08$, respectively) in HELM steers, indicating different satiety levels among treatments. Carcass conformation and HCW were less ($P < 0.05$) in HELM steers than in CTR. No differences were observed in carcass fat cover and i.m. content among treatments. In conclusion, HELM steers reduced total energy intake and performance, however, fat deposition was not affected.

Key Words: beef, hormones, meal size

148 Dataset-specific dry matter intake prediction equation determination for growing calves. M. F. Wilken,* L. L. Berger, G. E. Erickson, M. K. Nielsen, M. L. Spangler, and S. D. Kachman, *University of Nebraska-Lincoln, Lincoln.*

Four years of data collected at the University of Illinois-Urbana were utilized to create a data set-specific model for dry matter intake (OBSm). Previous analysis (Wilken et al., 2011) showed significant inaccuracies between observed intakes and that of 3 intake prediction equations (NRC, 1996; Galyean et al., 2009; Owens et al., 2002) leading to the objective of effectively determining a data set-specific intake prediction model. Individual intakes of calf-fed steers were measured over the feeding period by use of GrowSafe feeding system (GrowSafe Systems Ltd.). While 13 diets were fed over the 4 yr collected, varying in diet NE_m (dNE_m) values, only 3 diets (n = 481) were utilized in the analysis to add minimal dNE_m variation and greater statistical power without being statistically different in energy composition. Treatments were 1) 75% corn and 15% corn silage; 2) 50% corn, 25% dry distillers grains plus solubles, and 15% corn silage; and 3) 40% modified corn distillers grains plus solubles, 35% soyhulls, and 15% corn silage. All diets contained a 10% fine ground corn-based supplement. Because the NRC model for intake {NRCm; $\text{DMI} = \text{SBW}^{0.75} \times [0.1493\ (\text{dNE}_\text{m}) - 0.0460\ (\text{dNE}_\text{m}^2) - 0.0196]$} is the most widely used and verified prediction equation, the current analysis utilized metabolic body weight and dNE_m as parameters for analysis also. Feedstuff NE_m values were obtained from the NRC (1996) and used to calculate dNE_m for analysis in both the NRCm and OBSm. After fitting different models, OBSm was determined to be $\text{DMI} = \text{SBW}^{0.75} \times [23.3078\ (\text{dNE}_\text{m}) - 5.6287\ (\text{dNE}_\text{m}^2) - 24.0203]$. With OBSm defined, this data set-specific model was then compared with that of NRCm. Difference between OBSm and NRCm were significant ($P < 0.01$). The NRCm was determined to overestimate intake which coincides with previous research. These findings allow us to conclude that, while the NRCm is currently the standard equation for dry matter intake prediction, more accurate prediction equations are warranted and can be developed.

Key Words: dry matter intake, feedlot cattle, prediction equation

149 The use of biometric measures to assess body fat composition of F1 Nellore × Angus bulls and steers. M. A. Fonseca*[1,2], L. O. Tedeschi[2], S. C. Valadares Filho[1], H. J. Fernandes[3], N. F. De Paula[1,2], M. G. Machado[1], F. A. C. Villadiego[1], and J. M. Silva Junior[4], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Texas A&M University, College Station, Texas, United States, [3]Universidade Estadual do Mato Grosso do Sul, Aquidauana, Mato Grosso do Sul, Brazil, [4]Universidade Federal Rural de Pernambuco, Garanhuns, Pernambuco, Brazil.*

This study was conducted to assess the body fat composition using biometric measures (BM) and postmortem measurements of 40 F1 Nellore x Angus bulls (B) and steers (S). The animals were 12.5 ± 0.51 mo old, with a shrunk BW (SBW) of 233.03 ± 23.47 and 238 ± 24.58 kg for B and S, respectively. Animals were fed 60% corn silage and 40% concentrate. The trial was design with at 2 × 3 factorial arrangement of treatments (2 genders and 3 slaughter weights). The Animals were slaughtered at the beginning of the trial (4B and 4S), and when the group reached an average BW of 380 (6B and 5S), 440 (6B and 5S), and 500 kg (5B and 5S). Before the slaughter, each animal was lead through a squeeze chute where BM were taken, including hook bone width (HBW), pin bone width (PBW), abdomen width (AW), body length (BL), rump height (RH), height at withers (HW), pelvic girdle length (PGL), rib depth (RD), girth circumference (GC), rump depth (RuD), body diagonal length (BDL), and thorax width (TW). Additionally, the postmortem measurements were collected, including subcutaneous fat (SF), internal fat (InF), intermuscular fat (ImF), carcass physical fat (CF), empty body physical fat (EBF), fat thickness at the 12th rib (FT), and 9 – 11th rib section fat (HHF). The equations were developed using a stepwise procedure to select the variables with the best goodness-of-fit and the least root mean square error (RMSE). Due to differences ($P < 0.05$) in gender the following equations were developed: EBF (kg) = 0.2769 × SBW - 1.0138 × RD ($r^2 = 0.994$ and RMSE = 3.93) for steers, EBF (kg) = −55.0900 + 0.0873 × SBW + 0.0446 × PBW −1.1608 × PGL + 0.3524 × TW + 0.4296 × BDL ($r^2 = 0.992$ and RMSE = 1.28) for bulls, CF (kg) = - 19.2136 - 0.1027 × SBW ($r^2 = 0.924$ and RMSE = 3.09 kg) for steers, and CF (kg) = 26.7893 + 0.1232 × SBW - 1.3067 × PGL ($r^2 = 0.921$ and RMSE = 2.37) for bulls. The main BM observed which affected the CF and EBF in this database were RD for S, and PBW, GC, TW, BDL and PGL for B.

Key Words: carcass fat estimation, empty body fat estimation, modeling

150 Evaluation of volatile fatty acid stoichiometries and methane predictions for high grain fed beef cattle within a mechanistic digestion model. J. L. Ellis*[1,2], J. Dijkstra[2], A. Bannink[3], E. Kebreab[4], S. Archibeque[5], and J. France[1], *[1]Centre for Nutrition Modelling, Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [3]Wageningen UR Livestock Research, Lelystad, the Netherlands, [4]Department of Animal Science, University of California-Davis, Davis, [5]Animal Sciences, Colorado State University, Fort Collins.*

Mechanistic modeling can provide insight into dietary strategies aimed at reducing CH_4 emissions from ruminants, but requires appropriate representation of aspects of underlying rumen fermentation and digestion. Proper prediction of the production of volatile fatty acids (VFA) is central to accurate CH_4 prediction within these models. Previous analysis showed the Dijkstra model to perform poorly in terms of CH_4 predictions on beef cattle data, while it performed well on dairy cow data. The purpose of this study was therefore to evaluate prediction of CH4 emissions from high grain fed beef cattle data using the Dijkstra model with pH-independent and pH-dependent VFA stoichometries, as well as with a new VFA stoichiometry which adjusts for the use of monensin, to see if prediction improvements could be made. Also, several improvements were made to the model to adapt it for typical high-grain beef cattle and their diets. Adaptations included new equations to predict fluid volume and fractional rate of passage of fluid and solids in the rumen and the hindgut, as adjustment to the kinetics of fiber fermentation in the hindgut and changes to the recycling of urea to the rumen. The evaluation database consisted of 98 individual datapoints from 6 studies of high grain fed beef cattle where the average CH_4 (MJ/d) was 5.6 ± 2.19, bodyweight was 425 ± 68.7 kg, DMI was 7.8 ± 1.93 kg/d and roughage % was 11.8 ± 5.62. Root mean square prediction error for CH_4 (MJ/d) prediction was reduced from 49.3% for the pH-independent stoichiometry to 47.2% with the pH-dependent stoichiometry, and was further reduced to 44.0% when monensin stoichiometry was included. While the majority of error was from random sources, all VFA stoichiometries tended to over-predict low observed CH_4 (MJ/d) values for the beef cattle database. Results indicate that progress to-date has made incremental improvements in predictions, but that further work is still required.

Key Words: feedlot beef, modelling, methane

151 Supplemental vitamin C alleviates negative effects of high sulfur diets on beef quality. D. J. Pogge,* S. M. Lonergan, and S. L. Hansen, *Iowa State University, Ames.*

High S (HS) diets may contribute to antemortem oxidative stress in cattle, hindering live performance and expressing residual effects on meat quality. The objective of this study was to examine the effects of a supplemental rumen-protected vitamin C (VC) on meat quality of cattle receiving varying concentrations of dietary S. Angus type steers (n = 120) were blocked by initial BW (355 ± 23 kg) and assigned to treatments including: 1) low S corn diet (LS; 0.18% S), 2) LS + VC, 3) medium S (MS), 40% DDGS diet (0.32% S), 4) MS + VC, 5) HS (0.56% S), MS + sodium sulfate, and 6) HS + VC. An average of 10.3 g supplemental VC$\cdot h^{-1} \cdot d^{-1}$ was consumed. A rib steak, collected from each carcass after a 24 h chill, was stored at −20°C and homogenized before analysis. Data were analyzed on a pen mean basis (n = 5 pens per treatment). By design, increasing dietary S linearly increased ($P < 0.01$) g of S consumed. Increasing dietary S resulted in steaks with a lesser ($P < 0.01$) percent lipid. The proportion of the catalytic subunit of μ-calpain present as the unautolyzed 80 kDa band was increased ($P < 0.05$) as dietary S increased. The abundance of the unautolyzed μ-calpain band tended to decrease ($P < 0.10$) in the HS + VC treatment compared with HS. Addition of VC, regardless of dietary S, tended to increase ($P < 0.10$) the proportion of the catalytic subunit present as the 76 kDa autolysis product of the protease μ-calpain, but was specifically increased ($P < 0.05$) in the MS + VC and HS + VC treatments. This suggests that VC provided a reducing environment that allowed activation of the calpains. Increasing dietary S decreased ($P < 0.05$) troponin-T degradation and protein carbonylation ($P < 0.01$), while added VC, regardless of dietary S, decreased ($P < 0.05$) protein carbonylation. TBARS values were greater ($P < 0.05$) in VC treatments, which may relate to a tendency ($P < 0.10$) for increased Fe content in steaks from VC cattle. In conclusion, supplemental VC appears to negate the negative effects of HS on oxidation of the protease μ-calpain and muscle protein degradation. This may translate to an enhancement in meat quality and potential increases in tenderness of the final meat product.

Key Words: cattle, meat quality, vitamin C

Ruminant Nutrition: Dairy Production I

152 Liver gene expression patterns can explain accumulation of lipid in the liver during the transition period. H. R. Khazanehei,* P. Eck, A. Regassa, D. O. Krause, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

The effects of 2 dry-period managements of dairy cows on the expression of genes related to lipid metabolism in the liver were compared. Twenty-four multiparous cows were paired based on expected calving date, and randomly assigned to treatment within each pair. Treatments were a 60-d dry period (60 d) with separate far-off and close-up diets and a 40-d dry period (40 d) with only close-up diet. The 60-d dry period was divided into a 39-d far-off and a 21-d close-up period. The far-off diet contained 1.28 Mcal/kg net energy for lactation (NEL), 14.7% of crude protein (CP), and 50% of neutral detergent fiber (NDF) on a DM basis. The close-up diet contained 1.43 Mcal/kg NEL, 14.6% of CP, and 38% of NDF. A common diet was fed to all cows after calving, which contained 1.69 Mcal/kg, 17.6% of CP, and 31% of NDF. Liver biopsies were obtained at wk −3, 1 and 4 relative to parturition. Differential gene expression was assessed by Affymetrix microarray analysis and data were normalized through RMA algorithm and then statistically analyzed using FlexArray 1.6.1. An FDR-adjusted P-value lower than or equal to 0.1 and a fold-change greater than 2 were considered as a cut-off point to indicate significant up- or downregulation of genes. Gene networks were assembled using Ingenuity Pathway Analysis. A parallel study showed that lipid accumulation in the liver was greater at wk 1 than and wk −3 and wk 4, and at wk 1, this accumulation was greater for the 40 d than for the 60 d treatment. There was no difference in gene expression between the treaments across the sampling days. Genes involved in lipid accumulation and triacylglycerol synthesis in the liver were upregulated at wk 1. Also mitochondrial fatty acids transporters aiding β-oxidation were upregulated, and genes involved in hydroxylation of fatty acids aiding β-oxidation were downregulated at wk 1. Gene expression at wk 4 was similar as at wk −3. The changes in lipid deposition during the transition period are reflected in changes in the expression of genes related to lipid metabolism in the liver, but the difference between the 40 d and 60 d treatments is not.

Table 1. Comparison of expression of genes involved in liver lipid metabolism between week 3 before and week 1 after calving

153 Effects of nutrition, ketosis, and inflammation on hepatokine and nuclear receptor expression in liver of peripartal Holstein dairy cows. H. Akbar,* J. M. Khan, D. B. Carlson, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

In rodents, fibroblast growth factors 21 (FGF21) has emerged as a metabolic regulator produced by liver in response to different physiological conditions that regulate glucose and lipid metabolism. Its upregulation induces glucose uptake in adipose tissue and skeletal muscle; whereas in liver it increases hepatic fatty acid oxidation, reduces triacylglycerol accumulation, and stimulates ketogenesis. The regulatory mechanism and action of FGF21 in ruminants remain unclear. We sought to investigate the mRNA expression of FGF21, FGF receptors, the hepatokine ANGPTL4, and genes involved in regulation of fatty acid oxidation (CPT1A, PPARA) under different nutritional conditions including early postpartal ketosis (KET), peripartal dietary L-carnitine supplementation (CAR), and prepartal level of dietary energy. We also examined hepatic FGF21 in response to intramammary lipopolysaccharide (LPS) challenge at 7 d postpartum. In CAR liver biopsies were harvested at d 2 and d 10 postpartum in cows assigned to control (n = 5), 100 g CAR/d (C100, n = 5), and 200 g CAR/d (C200, n = 4). In KET, liver biopsies were obtained at d 14 postpartum from control (n = 7) and feed-restricted induced ketotic (n = 7) cows. In the LPS study, cows (n = 6/treatment) were fed during the dry period either moderate-energy (M) or control energy (S) and received 0 (M:N, S:N) or 200 Î1/4g LPS (M:Y, S:Y) at 7 d postpartum. Liver biopsies were harvested at d 7 and d 14 postpartum. Expression of FGF21 was analyzed via RT-PCR. There was an interaction effect ($P < 0.05$) of CAR for FGF21 expression due primarily to lower expression at d 10 with C100 and C200 vs. control. The opposite effect was observed for ANGPTL4 expression (a hepatokine) at d 2 which was greater with C100 and C200 vs. control. Subsequently, a marked decrease by d 10 was observed with C200 at which point ANGPTL4 was lower than C100 and controls. The significant interaction ($P < 0.05$) for PPARA expression was due to a marked increase at d 10 with C100. A similar response to C100 was observed for CPT1A and KLB expression. Ketosis induced the expression of FGF21 ($P < 0.05$), KLB ($P < 0.05$) and FGFR1 ($P = 0.08$); whereas, no effect was observed for the expression of FGFR2 and KL. In the LPS study, expression of FGF21 was induced ($P < 0.05$) with both M:Y and S:Y at d 7 but the response was more marked with S. By 14 d expression decreased markedly with S:N but remained nearly unchanged with other treatments. Prepartal M led to greater ($P = 0.06$) overall ANGPTL4 postpartum. Overall, results indicate that in transition cows both L-carnitine and inflammatory challenge regulate FGF21 expression likely through their effects on fatty acid oxidation and ketogenesis, i.e., L-carnitine enhances and inflammation inhibits both processes. Ketosis could upregulate the expression of FGF21 likely via incoming nonesterified fatty acids and potentially via PPARα. However, the role of PPAR α on FGF21 activation remains unclear because of the inverse response observed with C100.

Key Words: metabolism, transition cow

154 Effects of a moderate-energy diet during the close-up dry period on immunometabolic indices in peripartal dairy cows. J. S. Osorio*[1], E. Trevisi[2], P. Ji[1], J. K. Drackley[1], G. Bertoni[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Universita Cattolica del Sacro Cuore, Piacenza, Italy.*

The peripartal period is characterized by marked changes in hormonal, metabolic, and immune/stress-like conditions all of which may contribute to regulating dry matter intake (DMI) and the supply of nutrients to mammary gland. Twenty 3 multiparous Holstein cows were fed a control diet (CE, n = 10; 1.24 Mcal/kg DM; high-straw) during the entire dry period (ca. 50 d) or were switched to a moderate-energy (ME, n = 13; 1.47 Mcal/kg DM) diet during the last 21 d prepartum through calving. All cows were fed a common lactation diet (1.67 Mcal/kg DM postpartum). Blood samples were collected at −21, −10, 7, 14, and 21 DIM for profiling of 21 markers of liver function, metabolism, oxidative stress, and inflammation. Concentration of cholesterol (CHOL) and the negative acute-phase protein albumin (ALB) decreased (time $P < 0.05$) through calving but CHOL increased markedly between 7 and 21 DIM regardless of treatment. Paraoxonase concentration through calving followed a similar pattern (time $P < 0.01$) as CHOL and ALB; however, concentration remained unchanged from 7 to 21 DIM. Glutamic-oxaloacetic transaminase (GOT) and bilirubin (BIL) concentration increased (time $P < 0.01$) from −21 to 7 DIM regardless of treatment after which it decreased. Concentration of gamma-glutamyl transpeptidase (GGT) tended (treatment × time $P = 0.11$) to differ due to greater concentration with ME after 7 DIM. The concentration of haptoglobin, an inflammation marker, increased (time $P < 0.01$) between −21 and −10 DIM after which it remained stable through 7 DIM and decreased gradually by 21 DIM regardless of treatment. In contrast, concentration of ceruloplasmin, another inflammatory marker, increased (time $P < 0.01$) linearly between −21 and 14 DIM regardless of treatment. The concentration of reactive-oxygen metabolites (ROM; diet $P = 0.08$) and urea (diet $P = 0.07$) was greater overall with CE. For ROM, differences between diets were evident at 7 and 14 DIM. The marked increase in haptoglobin at 7 DIM with CE agrees with that of ROM and ceruloplasmin. Overall, preliminary data provide some evidence that plane of dietary energy during the close-up dry period alters immunometabolism.

Key Words: inflammation, nutrition, metabolism

155 Integrating control by gene expression in adipose tissue into a mechanistic, dynamic model of metabolism to investigate the biological basis for variation in genetics of feed conversion efficiency in lactating dairy cattle. S. Shields* and J. McNamara, *Washington State University, Pullman.*

Variation in efficiency of feed is a multiple function of metabolic flux in visceral, muscle, and adipose tissues. These processes are affected by genotype, phenotype, and intake, and are under control of hormonal and neural systems. To help identify the patterns of metabolic flux in the most efficient dairy cattle, an existing mechanistic metabolic model (Molly, UC Davis) was used, which explicitly includes elements of genetics, including metabolic interactions in the viscera and body. Our present objective was to integrate changes in gene transcription in adipose tissue into control elements in the model. Data were collected from 2nd to 4th parity cows (n = 120) in the first 4 mo postpartum, from studies that measured nutrient intake, milk component output, changes in adipose tissue lipid, visceral and body protein and lipid, and metabolism rates and gene expression in adipose tissue. Explicit inputs into the model included nutrient intake, initial body fat and protein, milk production, fat, and protein output. Visceral energy use averaged 37% of intake energy (range 33 to 46%) and 68% of maintenance energy (range 63 to 73%). The variation in maintenance energy accounted for 37.6% of the variation in milk energy efficiency (milk energy/absorbed energy). Visceral and lean body energy use were the 2 major contributors ($P < 0.05$) to variation in milk production efficiency. Expression of several genes coding for metabolic enzymes in adipose tissue measured by transcriptomic arrays were related to efficiency of milk production. The amount of gene transcripts that control lipolysis including the ADRB2 and LIPE, accounted for 10 to 15% of variation in efficiency ($P < 0.02$). Transcripts of genes controlling lipogenesis, including SREBP, TSHSP14, LPL, and ACACA accounted for 15 to 18% of the variation in efficiency ($P < 0.05$). These results confirm some key metabolic control points that can be targeted for further research to define the genotypic and phenotypic control of metabolic efficiency in dairy animals.

Key Words: systems biology, transcriptomics, metabolic model

156 Dietary manipulation of crude protein and starch content affects energy balance in early lactation dairy cows. S. J. Whelan*[1,3], F. J. Mulligan[2], V. Gath[2], B. Flynn[3], and K. M. Pierce[1], *[1]School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, [2]School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland, [3]University College Dublin Lyons Research Farm, Newcastle, Dublin, Ireland.*

During early lactation, high levels of milk production and low dry matter intake result in a state of negative energy balance (NEB) and a metabolic status that can be detrimental to the health and longevity of the dairy cow. Reducing dietary CP and providing glucogenic nutrients have been shown to alter energy balance (EB) and metabolic status when employed as separate dietary strategies. However, simultaneous employment of these strategies has yet to be reported. This experiment investigated whether or not offering diets low in CP and high in starch (LP-HS) can reduce NEB and improve the metabolic status of the early lactation dairy cow compared with a higher CP low starch diet (HP-LS). Ten Holstein Friesian dairy cows were assigned to each dietary treatment in a randomized block design. Diets were isoenergetic (1.79 Mcal NE/ kg DM) and formulated to contain 119 and 275 g/kg DM of CP and starch respectively (LP-HS); or 146 and 57 g/kg DM of CP and starch respectively (HP-LS). The experiment was conducted from d 0 to 63 of lactation. Energy balance was calculated daily and blood samples harvested weekly for metabolite analyses; data were then analyzed using Proc Mixed of SAS. Intake of DM (17.4 ± 0.5 kg/ d, $P = 0.25$) and energy (31.6 ± 1.02 Mcal NE/ d, $P = 0.22$) were not affected by diet. The HP-LS group had a higher milk yield (31.6 vs. 29.2 ± 0.6 kg/ d, $P < 0.01$) versus the LP-HS group. However, the LP-HS group had a more positive EB (2.2 vs. −0.7 ± 1.02 Mcal NE/ d, $P = 0.02$) when compared with the HP-LS group. Blood glucose (3.2 ± 0.1 mmol/ L, $P = 0.36$) was not affected by diet. However, blood urea N (3.5 vs. 1.8 ± 0.2 mmol/ L, $P < 0.01$) was higher, while β hydroxy butyric acid (0.7 vs. 0.8 ± 0.1 mmol/ L, $P = 0.03$) was lower for the HP-LS group compared with the LP-HS group. These data suggest that limiting milk production through offering a low CP, high starch diet reduces both the degree of and length of NEB in early lactation dairy cows. Such strategies may be useful in reducing production diseases associated with severe NEB on dairy farms.

Key Words: dairy cows, early lactation, energy balance

157 Colostrum yield by multiparous cows is positively correlated with prepartum body fat mobilization. N. Litherland,* W. Weich, D. Lobao, and Z. Sawall, *University of Minnesota, St. Paul.*

One hundred and 20 Holstein and Holstein-cross multiparous dairy cows from 2 studies in 2010 and 2011 were used in a correlation analysis to determine if prepartum nutrition, metabolism, and management factors affect colostrum yield (CY). Cows were fed moderate-energy high-forage diets containing corn silage, wheat straw, alfalfa hay, ground corn, and molasses and protein supplements. Prepartum diets averaged 14.5% CP, 40.5% NDF, 1.5 Mcal NEL/kg DM, 16.8% starch, 6.0% sugar, 2.0% fat. Cows averaged 42.7 ± 8.1 d dry, 13.6 ± 0.9 kg DMI/d, 3.1 ± 1.1 lactations and postpartum 305ME = 10,516 ± 2,203 kg. All cows were from the St Paul Dairy Research Unit and were managed similarly. Colostrum yield was not significantly affected by treatment or by study. Samples were collected and analyzed using the same techniques for both studies. Data were pooled and subjected to Pearson Correlation analysis in SAS. Correlation coefficients and P-values were calculated among CY, parity, days dry, calf birth weight, average prepartum DMI, crude protein intake (CPI), neutral detergent fiber intake (NDFI), sugar intake (SI), starch intake (STI), mature equivalent 305 milk yield (305 ME), pre- and postpartum serum NEFA concentration, and pre- and postpartum liver triglyceride concentration. Colostrum yield averaged 7.9 ± 4.2 kg with a minimum yield of 0.91 kg and maximum yield of 21.6 kg. Twenty-six percent of cows produced <5.0 kg colostrum. Colostrum yield tended to be correlated ($r = 0.19$; $P = 0.06$) with calf birth weight. Colostrum yield was positively correlated with serum NEFA 7 d prepartum ($r = 0.40$; $P < 0.05$), serum NEFA 1 d postpartum ($r = 0.53$; $P < 0.05$), serum NEFA 7 d postpartum ($r = 0.29$; $P < 0.05$), serum NEFA 14 d postpartum ($r = 0.19$; $P < 0.05$). Colostrum yield was positively correlated with liver triglyceride concentration 7 d postpartum ($r = 0.28$; $P < 0.05$) and 14 d postpartum ($r = 0.24$; $P < 0.05$). Prepartum nutrient intake; DMI, CPI, NDFI, SI, and STI were not significantly correlated with CY. Colostrum yield was not significantly correlated with 305ME ($r = 0.07$; $P = 0.6$).

Key Words: colostrum yield, NEFA, transition cow

158 A starch-binding agent decreases the in vitro rate of fermentation of wheat.

F. R. Dunshea*[1], V. M. Russo[1], I. Sawyer[2], and B. J. Leury[1], *[1]Melbourne School of Land and Environment, The University of Melbourne, Parkville, Victoria, Australia, [2]Feedworks Pty Ltd., Lancefield, Victoria, Australia.*

The rapid rumen fermentation of the starch in wheat can result in sub acute ruminal acidosis (SARA) with resultant inhibition of rumen function and loss of milk production in dairy cattle. The aim of the present study was to investigate the effect of a starch binding agent (Bioprotect, RealisticAgri, Ironbridge, UK) on the rate of in vitro gas production. The active ingredient in Bioprotect is a stable non-volatile organic salt that complexes with the hydroxyl groups of starch at neutral or slightly acidic conditions (pH 6 to 7), as observed in the rumen. These complexes decompose under more acidic (pH 2 to 3) conditions as in the abomasum and duodenum, making the starch available for enzymatic digestion. Wheat and maize were ground and passed through a 1 mm sieve. A subsample of the ground wheat was treated with Bioprotect (8 mL/kg). Samples (1.0 g) of the grain ($n = 6$ for each grain) were added to serum flasks containing buffered rumen fluid obtained from lactating dairy cows. The flasks were purged with carbon dioxide and maintained in a shaking water bath at 39°C. Gas production was monitored every 5 min for 48 h using the ANKOM wireless in vitro gas production system. Gas production was modeled using a Gompetz equation to determine the rate and maximum amount of gas production (Rmax) and the rate constant (β). The Rmax was slightly higher for the control wheat than the treated wheat and the maize (134 vs 129 and 130 mL/g for wheat, treated wheat and maize, $P = 0.05$). The β was greater for the control wheat than the treated wheat, which in turn was greater than for maize (0.267 vs 0.207 and 0.173 min^{-1}, $P < 0.001$). These data demonstrate that wheat is fermented faster than maize and that Bioprotect can slow the fermentation of wheat. If more starch can pass through the rumen without being fermented it may reduce the incidence of SARA and allow for greater post-ruminal enzymatic digestion of starch.

Key Words: wheat, fermentation, starch

159 Effects of intrajugular glucose infusion and dietary protein concentration on feed intake, milk yield and metabolic responses of postpartum cows.

W. E. Brown* and M. S. Allen, *Michigan State University, East Lansing.*

Effects of glucose infusion on feed intake, milk production, and metabolic responses of postpartum cows fed a low or high protein diet were evaluated utilizing a randomized complete block design with a 2 × 2 factorial arrangement of treatments. Twenty-four multiparous Holstein cows were blocked by BCS and 305-ME milk production, and randomly assigned at calving to one of 4 treatments. Treatments were continuous intrajugular infusion of glucose (GLU, 1 kg/d as 4 L/d of 25% w/v dextrose) or isotonic saline (SAL, 4 L of 0.9% sodium chloride), and diets containing 13.9% (LP) or 18.4% (HP) crude protein. Treatments were initiated at the first scheduled feeding following parturition and lasted 12 d. Data for DMI was collected daily, blood was collected every 2 d, milk yield was collected at each milking, and milk samples were obtained on d 4, 8, and 12. Data were analyzed by ANOVA, with repeated measures when applicable. The GLU infusion reduced cumulative DMI for HP (164.0 vs. 196.5 kg) but not LP (194.2 vs. 189.7 kg) compared with SAL (interaction $P = 0.04$) and tended (interaction $P = 0.12$) to reduce daily DMI for HP (13.6 vs. 16.4 kg/d) but not LP (16.4 vs. 15.9 kg/d). The GLU infusion did not affect cumulative milk yield for HP (441.6 vs. 437.8 kg) but increased milk yield for LP (469.1 vs. 395.0 kg) compared with SAL (interaction $P = 0.02$). The HP treatment tended to increase loss of body condition from 0.65 to 0.82 BCS units/12 d ($P = 0.06$) compared with LP. Consistent with this, HP increased plasma concentrations of NEFA (1184 vs. 895 μEq/L, $P = 0.01$) and BHBA (13.0 vs. 9.5 mg/dL, $P = 0.03$), milk fat concentration (5.71 vs. 4.72%, $P < 0.01$) and yield (2.14 vs. 1.78 kg/d, $P < 0.01$) and 3.5% fat-corrected milk (50.9 vs. 45.1 kg, $P = 0.02$) compared with LP. Greater dietary protein concentration increased milk fat concentration and yield by mobilization of lipid reserves resulting in greater FCM yield. Furthermore, dietary protein concentration interacted with glucose supply to affect feed intake, milk yield and metabolic responses of postpartum cows.

Key Words: transition cow, glucose infusion, dietary protein

160 Effects of feeding moderate-energy high-forage diets with reduced DCAD for 21 or 42 days prepartum on mineral homeostasis and postpartum performance by multiparous dairy cows.

W. D. Weich*[1], E. Block[2], and N. B. Litherland[1], *[1]University of Minnesota Department of Animal Science, St. Paul, [2]Church and Dwight Co. Inc., Arm and Hammer Animal Nutrition, Princeton, NJ.*

Objectives were to determine 1) if lowing DCAD is beneficial for cows fed moderate-energy high-fiber (MEHF) diets, 2) if feeding a low DCAD MEHF diet for 21 or 42d prepartum affects postpartum performance and mineral homeostasis differentially. Holstein and Holstein-cross cows were randomly assigned to one of 3 treatments ($n = 20$) 42d before expected calving date. Treatments included: 1) CON, DCAD = +12 mEq/ 100 g DM, 2) 21-ND, DCAD = +12/-16 mEq/ 100 g DM, 3) 42-ND, DCAD = −16 mEq/ 100 g DM, with treatments containing 38.6% corn silage, 22.8% wheat straw, 17.6% protein mix, 12.1% alfalfa, 6.0% molasses supplement and 2.9% ground corn on a DM basis. Prepartum diets were similar in nutrient composition, averaging 17.0% CP, 42.0% NDF and 1.5 Mcal/kg DM. High and low DCAD diets were created using 2 isonitrogenous protein mixes: 1) 97.5% soybean meal and 2) 52.8% Bio-Chlor®, 45.8% soybean meal. CON was fed high DCAD prepartum for 42d. 21-ND received high DCAD for the first 21d of the dry period, then switched to low DCAD until calving. 42-ND received low DCAD for 42d prepartum. After calving cows received a common lactation diet (16.6% CP, 31.6% NDF, 1.7 Mcal/kg DM). Urine pH for 21-ND and 42-ND were lower ($P < 0.01$) compared with CON, demonstrating effectiveness of low DCAD.

Pre- and postpartum data were analyzed separately using Mixed models in SAS with repeated measures. Pre- and postpartum DMI was similar among treatments. Milk yield by 21-ND and 42-ND were higher ($P < 0.05$) than CON on wk 2 and 3 and tended ($P < 0.10$) to be greater on wk 1. Serum ionized Ca was similar among treatments. 21-ND and 42-ND had higher ($P < 0.05$) total serum Ca compared with CON at 72h postpartum, and tended ($P < 0.10$) to be higher at 12h postpartum. Biopsies of liver on d −14, 7 and 14 relative to calving had similar contents of triglyceride and glycogen among treatments. Serum concentration of NEFA increased after calving but were similar among treatments. These data suggest low DCAD in MEHF diets during a 21 or 42d transition period had positive effects on postpartum total Ca and milk yield.

Key Words: blood Ca, negative DCAD, transition cow

161 Comparison of methane prediction for pasture fed dairy cows using a simulation model (Molly) incorporating revised VFA stoichiometry and microbial pools. J. McNamara*[1], P. Buekes[2], P. Gregorini[2], M. Hanigan[3], and G. Waghorn[2], *[1]Washington State University, Pullman, [2]Dairy New Zealand, Hamilton, New Zealand, [3]Virginia Tech University, Blacksburg.*

This study compared the outcomes of 3 versions of DairyNZ's metabolic model, Molly, with 2 different VFA stoichiometry constructs, to describe ruminal VFA pattern and methane (CH4) production (g/d). The models outputs were validated using 30 observations from 30 dairy cattle (82 DIM, 17 kg milk/d) fed fresh cut ryegrass (DMI 12.3 kg DM) in respiration chambers. The model versions were DairyNZ Molly4 (similar to Baldwin, 1995); Molly84, which includes updated ruminal fiber digestive parameters and animal hormonal parameters (Hanigan et al., J. Dairy Sci.); and Molly85, a revised version of Molly84 with new digestive and rumen parameters. The original forage diet VFA construct was compared with a new VFA stoichiometry based on a more recent and larger set of data, including lactate and valerate production and, amylytic, cellulytic bacteria, as well as protozoal pools. Average observed CH4 production was 266 (SD 30) (g/d). Mean predicted values for CH4 production were 287 and 258 (g/d) for Molly4 without and with the new VFA construct, respectively. Molly84 predicted 295 and 288 (g CH4/d) with and without the new VFA construct ($P > 0.5$) respectively. Molly85 predicted the same CH4 production (276 g CH4 /d) with or without the new VFA construct. The incorporation of the new VFA construct did not consistently reduce the mean relative prediction error (RPE %) across the versions of Molly evaluated in the present study. The improvements in the Molly versions from 4, 84 to 85 resulted in a decrease in RPE from 8.6, 8.3 to 4.3%, ($P < 0.05$) respectively. The majority of the root mean square prediction error was apportioned to random bias, e.g., 43, 71 and 70% in Molly4, 84 and 85, respectively. The slope bias was 2% in all cases. It is concluded that DairyNZ present version (Molly85) has the capability to predict CH4 production of pasture fed dairy cows with acceptable accuracy.

Key Words: metabolic cow model, methane prediction, VFA

162 Effects of dry period management and time relative to calving on the expression of genes involved in carbohydrate metabolism in the liver. H. R. Khazanehei,* P. Eck, A. Regassa, D. O. Krause, and J. C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

The effects of a 60-d dry period with far-off and close-up diets and a 40-d dry period during which only a close-up diet was fed on the expression of genes involved in carbohydrate metabolism were compared. Twenty-four multiparous cows were paired based on expected calving date, and randomly assigned to treatment within each pair. Treatments were a 60-d dry period (60 d) with separate far-off and close-up diets and a 40-d dry period (40 d) with only close-up diet. The 60-d dry period was divided into a 39-d far-off and a 21-d close-up period. The far-off diet contained 1.28 Mcal/kg net energy for lactation (NEL), 14.7% of crude protein (CP), and 50% of neutral detergent fiber (NDF) on a DM basis. The close-up diet contained 1.43 Mcal/kg NEL, 14.6% of CP, and 38% of NDF. A common diet was fed to all cows after calving, which contained 1.69 Mcal/kg, 17.6% of CP, and 31% of NDF. Liver biopsies were obtained at wk −3, 1 and 4 relative to parturition. Differential gene expression was assessed by affymetrix microarray analysis and data was normalized through RMA algorithm and then statistically analyzed by EB (Wright; Simon) method using FlexArray 1.6.1. An FDR-adjusted P-value lower than or equal to 0.1 and a fold-change greater than 2 were considered as a cut-off point to indicate significant up- or downregulation of genes. Gene networks were assembled using Ingenuity Pathway Analysis. The results showed that in both treatments at wk +1 compared with wk −3, relative to parturition, genes that are involved in glycogenesis downregulated and genes that were involved in gluconeogenesis upregulated. Glucose-6-phosphatase, catalytic subunit, expressed only in 40-d treatment and serine dehydratase expressed only in 60-d treatment. In the 40-d treatment, at wk 4 compared with wk 1, pyruvate carboxylase, which is involved in gluconeogenesis, was downregulated and the PPP1R3C transcript, encoding protein phosphatase 1 regulatory subunit 3C, which is involved in glycogenesis, was upregulated. However, there was no change in gene expression between wk 1 and wk 4 in the 60-d treatment. In conclusion, at the first week after parturition gene expression shows that gluconeogenesis was greater than glycogenesis in both treatments. However, after 4 weeks, cows on the 40 d treatment showed signs of enhanced recovery to normal carbohydrate metabolism in the liver compared with cows on the 60 d treatment.

Table 1. Effects of dry period length on liver gene expression in regard to carbohydrate metabolism

		Fold-change wk +1/-3		Fold-change wk +4/+1	
Genes	Name	40-day trt	60-day trt	40-day trt	60-day trt

Ruminant Nutrition I

163 Silage process affects chemical composition and digestion site in high moisture sorghum grain. M. Torterolo[1], A. Curbelo[2], C. Cajarville[2], J. L. Repetto[1], and M. Aguerre*[1], *[1]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

The aim of this work was to evaluate the effect of silage process on chemical composition and DM digestion site in high moisture sorghum grain. Commercial paddocks of sorghum grain ($n = 25$) were harvested as high moisture grain. A sample was immediately frozen and another sample was ensiled in 1 L drums. For silage production, sorghum grain was compacted with a manual press, and the drum was hermetically sealed. After 60 d silages drums were opened. Chemical composition, rumen and intestinal DM digestibility and in vitro digestibility were determined. For rumen and intestinal digestibility, 3 Holstein steers equipped with ruminal and duodenal cannulas and fed a diet composed by 2 parts of forage and one part of sorghum grain were used. In vitro digestibility was determined after 48 h of incubation in a DAISY fermenter. The effect of silage process on the variables studied was analyzed with the mixed procedure of SAS. While crude protein and condensed tannins contents decreased 4 and 35%, respectively, by silage process ($P \leq 0.028$), in vitro digestibility tended to increase by silage process ($P = 0.062$) (Table 1). Although silage process did not affect total digestibility, it improved rumen degradability by 14% ($P < 0.001$) and reduced intestine digestibility by 20% ($P < 0.001$; Table 1). In conclusion, silage process produced decreases in CP and condensed tannins contents and improved in vitro digestibility. Although total digestibility was not affected, silage process produced changes in the site of digestion.

Table 1. Chemical composition, in vitro digestibility, rumen degradability, intestine and total digestibility of high moisture sorghum before (no silage) and after (silage) silage

	No Silage	Silage	SEM	*P*-value
Moisture (%)	26.2	26.5	1.92	0.298
Composition (% of DM)				
OM	98.9	98.9	0.07	0.947
Ash	1.02	1.03	0.07	0.947
NDF	9.76	9.53	0.33	0.461
CP	7.87	7.56	0.22	0.028
Condensed Tannins	0.66	0.43	0.08	0.004
In vitro rumen digestibility (%)	93.7	94.6	0.56	0.062

164 Effect of corn residue removal on cattle performance and subsequent grain yield. A. L. McGee,* J. L. Harding, T. J. Klopfenstein, S. J. van Donk, and L. A. Stalker, *University of Nebraska, Lincoln.*

A 53 ha, center pivot irrigated, corn field near Brule, Nebraska, was utilized to evaluate the effects of residue removal by grazing and baling on subsequent residue quality, grain yield, and cow performance. The field was divided into 8, 6.6 ha paddocks with 4 treatments that have been maintained for 4 yr: heavy stocking (0.8 AUM/ha), light stocking (0.4 AUM/ha), baled, and no residue removal. Pre-grazing residue was collected from 10 randomly located 0.5 X 0.5 M quadrats in each paddock and sorted into 7 plant part categories. Cattle were weighed and body condition scored before and after grazing each year. There was 16.4 kg (DM) of residue per 21.8 kg (DM) grain yield of which 5.8 kg was the bottom 2/3 of the stem, 3.4 kg was leaf, 2.7 kg was cob, 2.2 kg was leaf sheath, 1.4 kg was husk, 0.6 kg was top 1/3 of the stem, and 0.3 kg was shank which did not differ among treatments ($P \geq 0.23$). Assuming cattle eat only the leaf, leaf sheath, husk and shank, there was 7.2 kg of forage /21.8 kg grain yield after harvest. In vitro organic matter disappearance was similar among treatments ($P \geq 0.37$) and ranged from 67.6% in the husk to 36.8% in the bottom 2/3 of the stem; with the top 1/3 of the stem (43.9%), leaf (51.1%), leaf sheath (50.3%), cob (46.2%), and shank (42.9%) intermediate. Corn yields reflecting the effect of multiple years of treatment application are not different (10.7, 10.0, 10.4, 10.4 Mg/ha for high stocking, low stocking, baling and control, respectively; $P = 0.31$). Final BW was 33 kg greater ($P = 0.005$) and final BCS was 0.3 greater ($P = 0.003$) for cows assigned to the light stocking rate treatment compared with cows assigned to the heavy stocking rate treatment. Stocking rate affected cow performance but residue removal has not affected corn grain yield after 3 yr of data collection.

Key Words: corn residue quality, grazing corn residue, beef cattle

165 Effects of restricted versus conventional dietary adaptation over periods of 9 and 14 days on rumen papillae of feedlot Nellore cattle. T. V. B. Carrara[2], D. D. Millen*[2], M. D. B. Arrigoni[1], C. L. Martins[1], R. S. Barducci[1], F. T. V. Pereira[2], L. M. N. Sarti[1], M. C. S. Franzói[1], D. D. Estevam[2], L. L. Cursino[2], P. L. P. Fontes[1], R. D. L. Pacheco[1], R. A. Rizzieri[1], C. F. da Costa[1], L. D. F. Miranda[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil.*

This study was designed to determine effects of restricting DMI of the final finishing diet (REST) as a means of dietary adaptation compared with diets increasing in concentrate (STEP) over periods of 14-d and 21-d on rumen wall absorptive surface area (RASA) of feedlot Nellore cattle. The experiment was designed as a completely randomized block with a 2 × 2 factorial arrangement with repeated measures over time, replicated 6 times (5 bullocks/pen), in which 120 22-mo-old yearling Nellore bulls (361.3 ± 30.2 kg) were fed in 24 pens for 84-d according to the treatments: STEP for 14-d and 21-d, REST for 14-d and 21-d. The STEP program consisted of ad libitum feeding of 3 adaptation diets over periods of 14-d or 21-d with concentrate level increasing from 55% to 85% of diet DM. The REST program consisted of restricted DMI of the final diet with programmed increases in feed offered until animals reached ad libitum access over periods of 14-d or 21-d. After adaptation one animal per pen was slaughtered for rumen papillae evaluations. The remaining 96 animals were harvested when achieved about 490 kg of BW. At harvest a 1-cm^2 fragment of each rumen was collected from cranial sac. Manually, the number of papillae per cm^2 of rumen wall (NOP) was determined and 12 papillae were randomly collected from each fragment; scanned, and mean papillae area (MPA) in cm^2 was measured. RASA in cm^2 was calculated as follows: $1 + (NOP*MPA) - (NOP*0.002)$. Animals in REST protocol had larger ($P < 0.05$) MPA (0.59 vs. 0.52) than those in STEP protocol. Significant (P

< 0.05) interactions were observed between days and harvesting dates, and protocols and harvesting dates. Animals adapted for 9-d had reduced RASA after adaptation than: 1) after finishing (19.5 vs. 33.2), and 2) animals adapted for 14-d after adaptation (19.5 vs. 26.4). Animals in STEP protocol had reduced RASA after adaptation (20.8 vs. 25.1), but no differences were detected after finishing when compared with animals in REST protocol (33.6 vs. 31.8). The REST protocol and 14-d of adaptation led to greater RASA than STEP protocol and 9-d, respectively, which could indicate lesser extent of rumen lesions. Grant provided by São Paulo Research Foundation (FAPESP), São Paulo, Brazil.

166 Fatty acid composition of backfat, intermuscular, KPH and tail fat depot sites of Angus cross steers finished on grass or high grain diets. G. Acetoze*[1] and H. A. Rossow[2], [1]*Department of Animal Science, University of California, Davis,* [2]*Veterinary Medicine Teaching and Research Center, School of Veterinary Medicine, University of California- Davis, Tulare.*

Fatty acid profiles of backfat, intermuscular fat, KPH and tail fat depots from 15-mo old steers (n = 18) finished on a grass diet at Yolo Land and Livestock Cattle Company were compared with those finished on a grain diet at UC Davis feedlot (n = 14). Grass finished steers grazed on average 10-mo on ryegrass and white clover irrigated pasture (CP = 15.1% and ME = 2.58 Mcal/kg DM). Grain finished steers were fed an 80% corn diet (DM basis) (CP = 11.5% and ME = 2.83 Mcal/kg DM), for 4-mo. Grass finished fat depots contained higher percentages of C6:0, C12:0, C14:0, C16:0 and C20:0 while grain finished had higher percentages of C18:0 and C18:3 ($P < 0.01$) (Table 1). Percentages of C18:1 *trans*9, C18:2 *cis*9 *cis*12 and C18:2 *trans*9 *trans*12 were higher in grass finished steers than grain ($P < 0.01$) (Table 1). C18:0 content was higher in the KPH region (20.7%) compared with outer fat depots such as backfat, intermuscular and tail (16.5%, 19.7% and 14.8%, respectively, ($P < 0.05$) while C18:1 *cis*9 content was lower in the KPH region (29.8%) as compared with outer fat depots such as backfat, intermuscular and tail (46.5%, 39.9% and 48.7%, respectively, ($P < 0.05$). In conclusion, percent inner fat depots were higher in saturated fatty acids compared with outer fat depots. No interaction was found between diet and fat depots. Finishing cattle on grass provided fat with higher percentages of conjugated linoleic acid (CLA).

Table 1. Percentages of fatty acids (FA, g FA/100g FA) of grain and grass finished steers

Fatty Acid	Grain ± SE	Grass ± SE	*P*-value

167 Replacing corn and soybean meal in lactating dairy cow diets with field peas (*pisum sativum*) on milk production and nitrogen utilization. J. J. Albrecht,* K. F. Kalscheur, A. R. Hippen, D. J. Schingoethe, and D. P. Casper, *South Dakota State University, Brookings.*

Sixteen lactating Holstein cows were used in a multiple 4 × 4 Latin square design with 28 d periods to evaluate replacing corn and soybean meal (SBM) with field peas (FP) on milk production and N utilization. Cows were 122 ± 47 DIM, producing 35.4 ± 6.7 kg of milk, and weighed 645 ± 82 kg at the start of the study. All diets contained 37.5% corn silage, 12.5% alfalfa hay, and a 50% concentrate mix. Diets were formulated to replace corn and SBM with FP at 0 (FP0), 12 (FP12), 24 (FP24) and 36% (FP36) (DM basis) of the diet. Milk and DMI data were collected the last 2 wk of each period and milk composition samples were collected on d 17, 18, 24 and 25. No changes in body weight or BCS were observed. With increasing inclusion rate of FP in the diet DMI, milk yield, protein %, fat yield, protein yield, and ECM all linearly ($P \leq 0.03$) decreased while MUN linearly ($P < 0.01$) increased (Table 1). Feed efficiency (ECM/DMI) responded quadratically ($P < 0.01$) to increased inclusion of FP. In the milk, total antioxidant capacity (TAC; 238, 240, 263, and 252 µmol/L FeSO47H2O) tended ($P = 0.10$) and NPN (0.166, 0.168, 0.170, and 0.175%) linearly increased ($P = 0.03$) with the inclusion of FP. True protein (2.91, 2.85, 2.74, and 2.68%), casein (2.33, 2.29, 2.17, and 2.15%), and whey protein (0.57, 0.55, 0.56, and 0.53%) decreased linearly ($P \leq 0.01$) with the inclusion of FP. These results show that replacing corn and SBM with FP at 24% of the diet or greater negatively affects the percentage and yield of milk protein. A deficiency of methionine could have possibly occurred due to the low Met content of FP.

Table 1.

Item	FP0	FP12	FP24	FP36	SEM	*P*-value[1]
DMI, kg/d	24.2a	24.6a	23.5a	21.8b	0.75	L
Milk, kg/d	37.0a	35.4ab	33.8b	33.0b	1.00	L

168 Milk production response to increasing net energy intake in dairy cows. A meta-analysis. C. Jensen*[1,2], M. R. Weisbjerg[1], and S. Østergaard[1], [1]*Department of Animal Science, Aarhus University, Denmark,* [2]*Knowledge Centre of Agriculture, Skejby, Denmark.*

The objective of the study was to estimate the effect of increasing net energy intake (NEL) on milk production in dairy cows in early lactation. A new model for economical optimization of the feeding level of dairy cows is to be developed. Previous models are outdated due to higher yield capacity of cows and a new Nordic feed evaluation system, NorFor. This requires development of production functions on milk responses to increased NEL. A data set from recent feeding trials in Norway, Sweden and Denmark were gathered. Prerequisites of data

were that cows were fed ad libitum, planned ration energy density was independent of recorded milk yield, and different energy levels were planned within trials. The data set included treatment means from 66 primiparous groups (primi) and 68 multiparous groups (multi). Cows averaged 69 DIM during trials. Average milk yield was 27 kg ECM for primi and 33 kg ECM for multi. Range of NEL in data set was from 75 to 154 MJ/day for primi and from 95 to 169 MJ/day for multi. Data were analyzed using nlme of R. A mixed effects model regression analysis with random regression of trials was used to model milk production (kg ECM/day). The preliminary models included independent variables for NEL, NEL^2, NDF per NEL, amino acids absorbed in small intestine per NEL and breed. All analyzed ration characteristics were estimated by NorFor. For multiparous cows a significant decreasing marginal milk response (kg ECM per MJ NEL) ($P < 0.001$) was estimated as: 0.919 - 0.00502 × NEL. In the data set the marginal ECM response to NEL for multi decreases from 0.442 to 0.071 with mean at 0.236. For primiparous cows a decreasing marginal milk response to NEL (kg ECM per MJ NEL) was estimated as: 0.454 - 0.00204 × NEL, however the decrease was not significant ($P = 0.1$). In the data set the marginal ECM response to NEL for primi decreases from 0.301 to 0.140 with mean at 0.218. In either of the models there were no interactions between the independent variables. The significant diminishing return of ECM to increasing NEL found in this meta-analysis emphasizes the importance of economic optimization of the energy level for high producing dairy cows.

Key Words: dairy cows, modelling, production response

ADSA-SAD Undergraduate Competition: Dairy Foods

169 Nutritive value of bovine milk as compared with alternative dairy-free beverages. S. M. Smith* and J. M. Bewley, *University of Kentucky, Lexington.*

In recent years, many dairy-free alternative beverages have been developed and marketed to replace traditional bovine milk. Consumers now have a large variety of alternative dairy-free beverages substitutes to choose from in the grocery store. This emerging market represents a considerable and formidable competitive threat to the dairy industry. With many of these alternative beverages branded as "milk," confusion and frustration prevails in the dairy industry and among consumers. The dairy industry must grapple with questions as to why consumers are choosing these alternative beverages. Per-capita consumption of bovine milk decreased from 24.3 gallons per person in 1994 to 20.8 gallons in 2008. Meanwhile, the alternative beverage industry is growing at a fast pace, with almond beverage sales increasing by 79% in 2011 alone. Bovine milk contains essential nutrients in suitable quantities for human consumption and milk promotes growth and bone strength in children. Bovine milk is a wonderful source of protein, calcium, fat, carbohydrates, as well as sodium and potassium. Some consumers have a negative opinion of bovine milk without any clinical or epidemiological evidence. These negative claims include that saturated milk fat is unhealthy and that bovine milk causes cancer. Moral or ethical controversies about milk also exist with regard to animal care and well-being. Health food beverage alternatives available on the market today include coconut, rice, and soy, each of which have different nutritive properties (i.e., vitamin D, Ccalcium, carbohydrates, and potassium). Nutritional deficiencies have been documented in toddlers as a result of being fed these alternative beverages instead of bovine milk. The parents of children most often are well-educated and conscientious, while providing regular medical care. Growing children who avoided bovine milk had smaller stature and poor bone health. Some of these children even developed diseases such as rickets or kwashiorkor. Additional education and research is needed to reflect the importance of bovine milk in human diets.

Key Words: human nutrition, alternative dairy beverages

170 Milk and cognitive abilities: Can dairy products work to improve your memory? N. L. Leckie* and C. L. Widener, *Clemson University, Clemson, SC.*

With an aging population it becomes important to research and discover possible preventative measures for geriatric diseases, such as the loss in cognitive function. This loss in function affects not only the elderly, but their family and caregivers as well. It is a frustrating and progressive disease that has a negative effect on the individual's quality of life along with an increase in their health care costs. The disease of dementia, particularly of Alzheimer's, is not well understood and the physical, physiological and psychological changes that are caused by these diseases are still being researched. Recent research has shown a surprising and encouraging correlation between daily consumption of dairy products and scoring on a cognitive test, with the highest dairy consumers having the highest scores. Even on the low-end of the consumption spectrum, consumers who ate or drank a dairy product 2 to 4 times per week performed better than those who only ate a dairy product once a week. Taking it a step further, those who drank skim or low-fat milk performed better than those who drank whole milk. Now this correlation between dairy consumption and cognitive function can partially be attributed to the fact that the most frequent dairy consumers also indicated that they ate the most healthfully overall. However even after factoring out risk factors for cardiovascular disease, sex, demographic, lifestyle and dietary factors the relationship between cognitive function and dairy intake remained, suggesting that some factors specific to milk must directly correlate to brain function. Obviously more research needs to be conducted to determine the specific link between dairy and cognitive function, however this new information is promising for both the consumers and the dairy industry.

Key Words: memory, dairy foods, cognition

171 Milk production and pasteurization: Two opposing viewpoints. M. Sprague* and E. L. Karcher, *Department of Animal Science, Michigan State University, East Lansing.*

In the early 1900s a case was made for enforced sanitation of milk and milk products. Diseases, such as typhoid fever, tuberculosis, scarlet fever, and diphtheria, were widespread, and out of these issues, 2 schools of thought emerged. One advocated for the pasteurization of milk, while another for ensuring the cleanliness of the product throughout the whole process as a way to prevent contamination, resulting in a "Certified Milk" product. Because of costs associated, the Certified Milk movement eventually disintegrated. Today a similar type of debate continues between the proponents of pasteurized milk and those of raw milk. Although there are states where the sale of raw milk on farm or in retail stores is legal, there are many states that allow raw milk sales under some circumstances. Several states ban the sale of raw milk, but have legalized "herd shares" or have no laws prohibiting the sale of "herd shares," which allows consumers to pay to own a portion of an animal. The FDA states that raw milk is not a safe product for consumption. However, several unsupported claims have been made stating that raw milk prevents disease, is more nutritious, and better tasting. Research has shown that raw milk does not have any significant nutritional advantages, so the question remains, why risk public health? Enforcing standards on raw milk, like the certified program, would not guarantee the health of consumers. Whether at a state or a national level, the best approach for the entire population should be taken into account. Pathogens, such as *Salmonella*, *Escherichia coli*, and *Listeria*, make drinking raw milk, especially among at risk populations, a dangerous and unnecessary risk. Due to these safety issues of consuming raw milk, bans should be put into place on the retail or on-site sale of raw milk. Alternative options for those who wish to consume raw milk may be pasteurization but not homogenization of milk products. In addition more emphasis on consumer education about the pasteurization process is crucial if these types of raw milk bans were put in place.

Key Words: raw milk, pasteurization

172 The effects of flavored milk in the cafeteria. S. M. Vignes* and C. C. Williams, *Louisiana State University, Baton Rouge.*

In the United States obesity has drastically increased over the past several years. The 2007–2008 National Health and Examination Survey (NHANES) states about one-third of adults are obese. Also, about 17% of children between the ages of 2 and 19 are obese. These staggering statistics have left people searching for answers to improve the weight of Americans. One proposed answer affects the dairy foods industry because the USDA is putting forth a new rule regarding milk requirements in the school cafeteria. The new rule requires schools to serve 8 ounces of milk with lunch and breakfast. The stipulation though is that it must be low-fat or fat-free white milk or fat-free flavored milk. This rule has led some schools to consider pulling flavored milk from the menu entirely. Requiring the flavored milk to be fat free will deter some because the product will not be as satiable. The business from the chocolate milk (the most popular flavored milk) will in turn be shifted to alternative drinks such as juices or soft drinks which have more sugar and less health benefits. The fear that flavored milk is contributing to childhood obesity is misguided though. Chocolate milk contains 2–4 teaspoons of sugar which is about half of drinks that would essentially replace it. Also the benefits of flavored milk greatly outweigh the bad. Milk provides essential nutrients for a healthy body such as: calcium, phosphorous, proteins, and vitamins. A little extra sugar and fat is completely overshadowed by the benefits of continuing to serve flavored milk in the cafeteria due to the beneficial constituents of milk.

Key Words: flavored milk, school lunches, obesity

173 Importance of texturants in dairy products.

H. R. Wentworth* and D. R. Olver, *The Pennsylvania State University.*

Although most consumers recognize the importance of flavor, many do not realize the important role texture plays in determining food preferences. Poor texture can be a deal breaker, no matter how good the flavor. Different ingredients can have a significant effect on a product's texture. Texturants have a variety of functions and play an important role in the formation of dairy foods. They can assist with stability, nutritional value, and provide lower cost ingredients. Texturants function by interacting with proteins, fats, and carbohydrates. They set up a stable structure within the product to allow for easier processing and more consistency over the product's life. Commercially available texturants come in a variety of forms with specific applications, usage level and functionality. They can work together or independently to change the properties of a specific item. For example, gelatin ingredients have many functions in manufacturing dairy products. They help with the freeze-thaw stability of ice cream by changing the nature of ice crystals and also offer stability to casein in yogurt and cheeses. Acacia gum assists in mouthfeel, stability, and added fiber. Guar gum is a hydrocolloid that can influence viscosity and enhance creamy textures in ice cream and other dairy foods. Inulin and some citrus based texturants can help reduce fat in many products without adversely affecting their sensory appeal. Processors will continue to develop products where texturants will replace more expensive and high calorie ingredients while maintaining flavor. Food scientists will discover new synergies among existing ingredients and develop additional texturants. These will provide the framework for healthier products and will allow companies to expand their market share while maintaining cost effectiveness. The continued evolution of texturant technology will benefit consumers and manufacturers through improved dairy products in the marketplace.

Key Words: texturants, dairy product texture

174 Production of functional probiotic and prebiotic dairy foods.

L. Hetrick,* D. Winston, and B. Corl, *Virginia Tech, Blacksburg.*

As people strive to lead healthy lives, more emphasis is being placed on the link between consumption of food and potential health benefits. The addition of live microorganisms to select dairy products is one way to meet this demand. Probiotics are live microorganisms that may provide health benefits when consumed including inhibition of bacterial pathogens and anti-carcinogenic effects. A symbiotic relationship with prebiotics exists; prebiotics are non-digestible food ingredients that stimulate the growth of the probiotic. In order for beneficial effects to be realized, consumption must be around 10^6 to 10^9 viable cells per day. Viability of the probiotic is affected by storage of the fortified product. These products are typically stored in plastic containers, which are highly oxygen permeable. Probiotics require low oxygen levels, creating storage challenges. The use of oxygen-removing steps or addition of oxygen-absorbing compounds are alternatives under consideration. Another factor for consideration is the appeal of the product to the consumer. Studies conducted with the addition of *Lactobacillus casei* and inulin, serving as probiotics and prebiotics, respectively, at levels of 3% inulin, found that health benefits were ensured and sensory characteristics were not altered. Consuming dairy products fortified with probiotics and prebiotics can lead to beneficial effects on intestinal microorganisms and overall health benefits.

Key Words: probiotics, prebiotics

Physiology and Endocrinology: Estrous Cycle Manipulation–Dairy

175 Ovulatory responses to withdrawal of progesterone feedback during the early and late luteal phase. G. E. Mann*[1] and R. S. Robinson[2], *[1]University of Nottingham, School of Biosciences, Division of Animal Sciences, Sutton Bonington Campus, Loughborough, UK, [2]University of Nottingham, School of Veterinary Medecine and Science, Sutton Bonington Campus, Loughborough, UK.*

Synchronization protocols aim to optimize timing of ovulation following removal of the inhibitory action of progesterone on the final stages of ovulatory follicle development. This study investigated the effects of blocking progesterone action during different stages of the luteal phase on endocrine and ovulatory responses in cyclic ewes. Ewes (n = 4 per group) were treated during the Early (d 3–5) or Late (d 12–14) luteal phase with progesterone antagonist (100 mg i.m. 2 × daily; onapristone ZK98299, Schering AG) or Control vehicle and slaughtered on d 17 to determine ovarian morphology. Hormone changes were analyzed by ANOVA for repeated measured and ovulation rate by ANOVA. Early treatment resulted in increased ($P < 0.01$) plasma LH within 6h (Control 1.8 ± 0.3; Treated 5.7 ± 0.3 ng/mL), with LH then rising to surge like levels within 25.5 ± 5.1 h (range 12–36 h). Following Late treatment, an initial modest ($P < 0.1$) increase in LH (Control 0.9 ± 0.1; Treated 2.0 ± 0.4 ng/mL) was followed by surge-like levels 51.0 ± 3.9 h after the start of treatment (range 42–60 h). During Late treatment plasma estradiol (Treated 2.0 ± 0.1, Control 1.2 ± 0.1 pg/mL; $P < 0.001$) and progesterone (Treated 3.3 ± 0.2, Control 2.1 ± 0.2 ng/mL; $P < 0.01$) were elevated. In contrast, Early treatment was not associated with any increase in either hormone. In Control ewes ovulation rate was 2.0 ± 0.0. In the Late group there were 2.0 ± 0.0 mature corpora lutea and 1.5 ± 0.3 accessory corpora lutea (total 3.5 ± 0.3) per ewe. In the Early group it was not possible to clearly differentiate between the original and accessory corpora lutea but the total number (5.3 ± 0.5) was higher ($P < 0.05$) than that seen in the Late group. Blocking progesterone feedback during the early luteal phase resulted in a more rapid induction of an LH surge and higher rate of accessory ovulation than treatment later in the luteal phase. This differential response of the endogenous reproductive architecture, presumably reflecting differences in both follicle populations and hypothalamic-pituitary responsiveness at the time of treatment, is often overlooked in the development of ovulatory synchronization programs.

Key Words: progesterone, ovulation, LH surge

176 Estrus behavior and fertility responses in lactating grazing dairy cows after a timed AI program using estradiol cypionate. M. N. Correa*[1], M. E. Lima[1], C. C. Brauner[1], A. R. T. Krause[1], E. G. Xavier[2], E. Schmitt[1], A. Schneider[1], and F. A. B. Del Pino[1], *[1]Universidade Federal de Pelotas, NUPEEC, Pelotas, RS, Brazil, [2]Granjas 4 Irmaos S/A, Rio Grande, RS, Brazil.*

The objective of this study was to determine the estrus behavior influence during an estrus synchronization program (Heatsynch) on fertility responses in lactating grazing dairy cows. Four hundred and 70 primiparous (n = 229) and multiparous (n = 241) Holstein cows were enrolled in a artificial synchronization program consisting of a controlled internal drug-releasing (CIDR) containing 1.9 g of progesterone, either a new one or previously used once (7 d), plus 25 µg i.m. injection on d 0 (85 + 6 DIM) and all cows were given 25 mg $PGF_{2\alpha}$ i.m. upon CIDR removal 7 d later (d 7) followed by an injection of 1 mg of estradiol cypionate (ECP) i.m. at d 8. Cows were then observed for signs of estrus for at least 2 h (twice daily at 7:00 and 18:00) for 3 d following CIDR removal. Those cows detected in estrus were inseminated 12 h later. Based on the detection of estrus, cows were divided into 3 groups: estrus behavior before TAI (Estrus AI) and inseminated 48–60 h after CIDR insert removal (n = 143); estrus behavior at the TAI (Estrus TAI) (n = 127); and no estrus detection and timed inseminated (TAI) 72 h after CIDR removal (n = 200). A single technician was responsible for the estrus detection and inseminations. Pregnancy status was determined by ultrasonography at 30 to 35 d and 60 to 65 d after AI. Data were analyzed by the LOGISTIC procedure of SAS. Estrus behavior had effect on fertility responses ($P < 0.01$), where both groups that showed estrus (Estrus AI and Estrus TAI) had greater pregnancy rates than the TAI group at 30–35 d (45.5 vs 46.5 vs 28.5), and 60–65 d (36.4 vs 35.4 vs 15.5). Pregnancy losses also were affected ($P < 0.01$) by the estrus behavior (20.0 vs 23.7 vs 45.6), respectively for Estrus AI, Estrus TAI and TAI groups. There was a correlation ($P = 0.02$) among fertility responses and parity, where primiparous cows had better results than multiparous cows. Estrus behavior was similar ($P > 0.05$) among primiparous and multiparous cows. Estrus behavior during a Heatsynch program is beneficial to improve reproductive performance in lactating grazing dairy cows.

Key Words: estradiol cypionate (ECP), timed AI, pregnancy

177 Effect of reusing CIDRs on estrus behavior and fertility responses in a Heatsynch protocol of grazing dairy cows. C. C. Brauner*[1], M. E. Lima[1], A. R. T. Krause[1], E. G. Xavier[2], A. Schneider[1], E. Schmitt[1], F. A. B. Del Pino[1], and M. N. Correa[1], *[1]Universidade Federal de Pelotas, NUPEEC, Pelotas, RS, Brazil, [2]Granjas 4 Irmaos S/A, Rio Grande, RS, Brazil.*

The objective of this study was to determine the effect of reusing intravaginal progesterone inserts (CIDR) on estrus behavior and fertility responses of grazing dairy cows in a Heatsynch protocol. Three hundred and 90 5 primiparous (n = 183) and multiparous (n = 212) Holstein cows were enrolled in a Heatsynch program consisting of a CIDR containing 1.9 g of progesterone, either a new one or previously used once (7d use), plus 25 µg GnRH i.m. injection on d 0 (82 + 6 DIM) and all cows were given 25 mg $PGF_{2\alpha}$ Â ± i.m. upon CIDR removal 7 d later (d 7) followed by an injection of 1 mg of estradiol cypionate (ECP) i.m. at d 8. Used CIDRs had been thoroughly rinsed with a mild disinfectant solution, air-dried, and stored in a dry, enclosed container after first use. Cows were then observed for signs of estrus (twice daily at 7:00 and 18:00) for 3 d following CIDR removal. Cows observed in estrus were inseminated 12 h later. Based on the detection of estrus, cows were divided into 3 groups: estrus behavior before TAI (Estrus AI) and inseminated 48–60 h after CIDR insert removal (n = 115); estrus at the TAI (Estrus TAI) (n = 98); and no estrus detection and timed inseminated (TAI) 72 h after CIDR removal (n = 152). A single technician was responsible for the estrus detection and inseminations. Pregnancy status was determined by ultrasonography at 30 to 35 d and 60 to 65 d after AI. Data were analyzed by the LOGISTIC procedure of SAS. There were no difference ($P > 0.05$) among CIDR uses on pregnancy at 30–35 d (38.6% vs 40.1%); and 60–65 d (24.7% vs 30.0%) and pregnancy losses (36.1% vs 25.3%), respectively for CIDR use 1 and 2. We could not find any difference ($P > 0.05$) of estrus behavior and CIDR uses, as well as across cows parity. However, percentage of pregnancy losses in the primiparous group was great ($P = 0.04$) for the first CIDR use than the second one (42.3 vs 21.1). In conclusion, estrus behavior and fertility responses in a heatsynch protocol of grazing dairy cows are not affected by CIDR uses. Primiparous cows seems to have greater pregnancy losses (up to 65 d) when first CIDR was used.

Key Words: estradiol cypionate (ECP), timed AI, reproduction

178 Effect of intrauterine administration of GnRH on LH secretion in lactating dairy cows.

S. Bas*[1], M. L. Day[2], and G. M. Schuenemann[1], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Department of Animal Sciences, The Ohio State University, Columbus.*

The objective of this study was to evaluate the release of LH following the intrauterine (i.u.) administration of GnRH (Gonadorelin) in lactating dairy cattle. Cows (n = 22) were presynchronized with 2 injections of PGF2α given 14 d apart (starting at 26 ± 3 DIM) followed by Ovsynch [OV; d −9 GnRH, d −2 PGF2α, d 0 GnRH (h 0)] 12 d later. Ovarian structures were recorded and blood samples were collected on d −9 and d −2. Only cows presenting a CL ≥ 15 mm and at least one follicle ≥ 10 mm in diameter at the initial GnRH were used in the study (n = 13). At the time of the second GnRH of OV (h 0), cows were blocked by parity and randomly assigned to 1 of 3 groups: 1) control group (CON; n = 4) received 2 mL i.m. of sterile water, 2) intramuscular group (IM; n = 4) received 100 µg i.m. of GnRH, and 3) intrauterine group (IU; n = 5) received 200 µg i.u. of GnRH with the addition of glycerol (7% v/v). Blood samples for determination of LH serum concentrations were collected at h −0.5, 0, 0.5, 1, 1.5, 2, 3, 4 and 5. Ovulation was determined 48 h after the second GnRH of OV (d 0) by transrectal ultrasonography. Progesterone and LH data were analyzed using mixed procedures of SAS. Serum progesterone concentrations at h 0 did not differ ($P > 0.05$) between groups. The area under the curve for LH was greater for ($P < 0.05$) IM cows compared with IU or CON cows. Most of the cows ovulated by 48 h relative to d 0 in IM (4/4) and IU (3/5) groups compared with CON cows (0/4). Although IU administration of GnRH resulted in lower serum concentrations of LH than IM group, more IU cows ovulated by h 48 compared with CON. These findings support our previous findings, and further, suggests that i.u. administration may be an alternative route of delivery for GnRH to synchronize ovulation in estrous synchronization programs.

Key Words: intrauterine GnRH, LH, dairy cow

Graduate Student Competition: ADSA Southern Section (Graduate)

179 Volatile fatty acids and biohydrogenation intermediates in continuous cultures are returned to normal by addition of potassium carbonate but not by potassium chloride. P. H. Morris*[1], J. G. Andrae[1], J. K. Bernard[2], E. Block[3], and T. C. Jenkins[1], [1]*Clemson University, Clemson, SC,* [2]*University of Georgia, Tifton,* [3]*Arm & Hammer Animal Nutrition, Princeton, NJ.*

In previous work, an increase in milk fat percentage has been reported when lactating cattle were fed $K_2CO_3 \cdot 1.5\ H_2O$, and addition of K_2CO_3 to continuous cultures of ruminal microorganisms partially or totally returned volatile fatty acid (VFA) and biohydrogenation patterns back to normal. The objective of this study was to determine if shifts in conjugated linoleic acids (CLA) and VFA observed previously with K_2CO_3 were also caused by addition of KCl. Six dual-flow continuous fermenters were fed 60 g/d of 1:1 forage (dehydrated alfalfa pellets) to concentrate mix in 2 equal portions at 0800 and 1600 h. The study was conducted as a randomized complete block design consisting of 4 blocks (4 10d periods) and 6 treatments. Treatments consisted of the following additions to the control diet; 1) 0% fat and 0% K 2) 0% fat and 3% K from K_2CO_3 3) 0% fat and 3% K from KCl 4) 3% soybean oil and 0% K 5) 3% soybean oil and 3% K from K_2CO_3, and 6) 3% soybean oil and 3% K from KCl. Addition of K_2CO_3 but not KCl increased ($P < 0.05$) pH, although average daily pH values for all treatments were maintained between 6.1 and 6.5. Supplemental fat increased ($P < 0.05$) production rates (mg/d) of trans-10 18:1 and *trans*-10, *cis*-12 CLA, and decreased ($P < 0.05$) acetate:propionate. Addition of K_2CO_3 increased ($P < 0.05$) cis-9, trans-11 CLA outflow from 7.3 to 16.0 mg/d and increased ($P < 0.05$) *trans*-11 C18:1 outflow from 130.8 to 272.3 mg/d, but *trans*-10 C18:1 decreased ($P < 0.05$) from 221.2 to 143.6 mg/d. No effect on CLA or trans monene outflows were observed with the addition of KCl. *Trans*-10, *cis*-12 CLA outflow was not affected by addition of either K2CO3 or KCL. The addition of K_2CO_3 increased ($P < 0.05$) acetate:propionate at 4 h after feeding from 1.77 to 2.06 in the 0% fat diets and from 1.54 to 1.86 in the 3% fat diets. No changes in VFA were seen when KCl was added. The results of this experiment show that disturbances of VFA and biohydrogenation patterns induced by high fat were alleviated by addition of 3% K as K_2CO_3 as previously observed, but were not alleviated by the same dose of K from KCl.

Key Words: conjugated linoleic acid, biohydrogenation, potassium

180 Dietary L-arginine supplementation effects on growth and health parameters in neonatal Holstein bull calves. A. N. Vanderlick*[1], G. A. Holub[1], and W. T. Bissett[2], [1]*AgriLife Research Texas A&M University, College Station,* [2]*College of Veterinary Medicine, Texas A&M University, College Station.*

The purpose of this study was to determine if calves fed 4 L of arginine supplemented milk replacer daily differed in growth and health parameters as compared with calves supplemented with alanine in heat stress conditions. Previous studies performed in piglets and calves showed increased body weight gains when supplementation of arginine was provided. Calves were supplemented with 0.484 g/d of arginine or 0.818 g/d of alanine (isonitrogenous control). Holstein bull calves (n = 30) < 2 d of age were assigned to a trial based on initial body weight, physical health score, and total serum protein levels. The study was conducted for 56 d from July 24 to September 17, 2011. Fecal scores (FS) of 1 to 4 (1 = hard, firm, 2 = soft, firm, 3 = no form, and 4 = watery) were recorded daily to monitor scouring. Calves with a FS of 4 were considered to have diarrhea requiring treatment. Respiration rates and rectal temperatures (RT) were recorded at 0600 and 1800 to monitor respiratory challenges while rectal temperatures were used to monitor febrile events. If RT was greater than 39.17°C calves were treated for fever. Calves provided arginine supplementation had a higher frequency of treatments for fever (0.957 treatments/d vs 0.03133 treatments/d, $P = < 0.0007$) than calves given alanine for the duration of the study; however, rectal temperatures in the AM or PM did not differ significantly for the 2 treatments. All growth parameters including body weight, hip height, hip width, wither height, heart girth, and cannon bone length were not significantly different for treatment by week, nor for the duration of the trial. Other health parameters including AM and PM respiration rates, fecal score, respiratory treatment, or scour treatment did not differ significantly for treatment by week, nor for the duration of the trial.

Key Words: arginine, calves, health

181 Changes in cortisol levels with alternating access to rotating cow brushes. R. A. Black*[1], M. R. P. Elmore[2], D. L. Ray[1], A. B. Klingenfus[3], B. L. Klingenfus[3], J. D. Clark[1], and J. M. Bewley[1], [1]*University of Kentucky, Lexington,* [2]*University of Illinois, Urbana,* [3]*Harvest Home Dairy, Crestwood, KY.*

Rotating cow brushes are an environmental enrichment device for dairy cows that may satisfy grooming behavior needs. The objective of this study was to quantify changes in cortisol with alternating access to rotating cow brushes. Twenty lactating (2 groups of 10) Holstein cows were provided alternating access to a rotating cow brush (Lely Luna, Maasluis, the Netherlands) in a crossover experiment at the University of Kentucky Coldstream Dairy. Addition or removal of the brush occurred on d 0, 10, 20, 30, 40, and 50. Blood samples were collected on study days −1, 1, 5, 9, 11, 15, 19, 21, 25, 29, 31, 35, 39, 41, 45, 49, 51, 55, and 59 to establish an immediate change, short-term change, and a baseline for the alternating brush access. Samples were collected between 0800 and 0900h in the freestall, feedbunk, or holding pen with minimal added stress. Locomotion scores (Sprecher, 1997; 1 = normal, 5 = severely lame) were evaluated by the lead author. The MIXED procedure of SAS (Cary, NC) was used to assess the effect of sample day, brush access (with or without), group (1 or 2), locomotion score, and their interactions on cortisol level. Cortisol levels were normalized using a natural log-transformation. All interactions were tested using backward elimination ($P < 0.05$). No difference ($P > 0.05$) in cortisol between group 1 (0.32 ± 0.10 μg/mL) and group 2 (0.40 ± 0.10 μg/mL) was observed. Cortisol was not altered by changing brush access (0.40 ± 0.10 vs. 0.32 ± 0.09 μg/mL with and without brush access, respectively, $P > 0.05$). Cortisol was lower in group 1 (0.24 ± 0.13 μg/mL) than in group 2 (0.43 ± 0.13 μg/mL) when access to the brush was restricted; however, no difference in cortisol was observed when brush access was permitted (0.44 ± 0.14 μg/mL vs. 0.37 ± 0.14 μg/mL, $P > 0.05$). A brush access × group interaction was observed ($P < 0.05$) with higher cortisol for group 1 (0.24 ± 0.13 μg/mL) than group 2 (0.43 ± 0.13 μg/mL) when brush use was restricted and no differences in cortisol when brush use was permitted (0.44 ± 0.14 and 0.37 ± 0.13 μg/mL for groups 1 and 2, respectively). Other behavioral and physiological effects of rotating cow brush use should be examined.

Key Words: rotating cow brush, cortisol, stress

182 Glucose transporter and hypoxia-associated gene expression in the mammary gland of transition dairy cattle. C. N. Niewiadomski,* S. A. Mattmiller, and E. L. Karcher, *Michigan State University, East Lansing.*

Glucose is an important energy substrate needed by transition dairy cows postpartum to support the onset of lactation. The prioritization and regulation of glucose uptake is accomplished in part by shifts in cellular glucose transport molecules (GLUTs) within the mammary gland (Zhao and Keating, 2007). These shifts have been demonstrated in rat (Abdul et. al., 1996), mouse, bovine mammary epithelial cells (Zhao and Keating, 2007), and in bovine mammary endothelial cells (BMECs), which are responsible for transport of glucose from the blood. Additionally, increased metabolic activity of the lactating mammary gland causes a decrease in oxygen, a physiologic state referred to as hypoxia, which can also affect the mammary vasculature and potentially glucose utilization. While Zhao et al. (1996) described GLUT expression on epithelial cells, Mattmiller et al. (2010) evaluated for the first time, expression, localization, and functionality of GLUTs and hypoxic associated-genes over the transition period in bovine mammary endothelium. Significant shifts were observed in gene expression of the GLUTs and some of the hypoxia-associated genes evaluated. GLUT1, 3 and 4 were detected on cultured BMECs and shown to be functional. A better understanding of glucose uptake at the endothelial level could prove to be critical to improve glucose absorption and utilization in the mammary gland.

Key Words: GLUT, hypoxia, endothelium

183 Challenges and inconsistencies associated with goat somatic cell counts. K. M. Wolf* and J. M. Bewley, *University of Kentucky, Lexington.*

Goat somatic cell counts (SCC) are considerably higher than cow SCC, which presents a troubling issue for dairy goat producers. Most states have adjusted SCC regulations for goats to allow for this discrepancy. However, because high SCC are typically an indication of an intramammary infection caused by bacteria, elevated goat SCC still present challenges. An increased understanding of the factors affecting SCC and physiological differences between does and cows is needed. Nonpathogenic factors known to contribute to SCC in both species include stage of lactation, animal age, and milking frequency. Goats have several unique characteristics that contribute to elevated SCC. First, unlike cows, most does are seasonal breeders, with estrus occurring only a few months each year. Second, over 65% of the goat population produces antibodies for the caprine arthritis encephalitis (CAE) virus. A primary symptom of CAE is the presence of interstitial mastitis. Additionally, production of antibodies may be correlated with higher SCC, regardless of the presence of an actual infection. A 1997 study involving 1,799 goats from 66 herds demonstrated that first-lactation CAE-negative does had higher SCC than first-lactation CAE-positive does. SCC for CAE-positive does increased significantly through subsequent lactations, and SCC for CAE-negative does did not increase. Another significant difference between goats and cows is in the actual mammary gland physiology. In goats, milk is produced via apocrine secretion. In this type of secretion, a cytoplasmic fragment of the secreting cell is released with the milk fat. Each cell fragment may contribute to a higher SCC with certain cell counting methods. To contrast this, cow milk production occurs by alveolar merocrine secretion, which does not contribute to SCC. Thus, increased goat SCC is caused by goat-specific characteristics not necessarily associated with intramammary infections caused by bacteria. While goat dairy operators should still try to minimize SCC and clinical mastitis, physiological differences may necessitate different standards for goat SCC.

Key Words: goat, somatic cell counts

184 On-farm culturing as a new management practice. A. Patch,* D. Winston, I. Mullarky, and C. Petersson-Wolfe, *Virginia Tech, Blacksburg.*

On-farm culturing (OFC) of milk, an increasingly popular management technology, uses microbiological cultures to identify mastitis-causing pathogens present in a dairy herd. Pathogen identification is usually completed within 24 to 28 h of sampling. Researchers evaluated 2 types of OFC, the University of Minnesota Tri-plate and the 3M Petrifilm; the practicality of materials needed, as well as sensitivity, specificity, and ability to interpret results was examined. This experiment evaluated the ability of 3M petrifilm to correctly identify *Staphylococcus aureus*, with the addition of the Staph express disk (STX disk) to verify the presence of the pathogen. The University of Minnesota Tri-plate was used to identify *Streptococcus* spp. and *S. aureus*. The sensitivity and specificity of the Tri-plate for the classification of *S. aureus* were 97.9% and 81.8%, respectively. The classification of *Streptococcus* spp. using the Tri-plate yielded a sensitivity and specificity of 92.6% and 89.5%, respectively. The addition of the STX disk on the Petrifilm improved the specificity of *S. aureus* detection from 76.1% to 93.1%. In contrast the sensitivity was 97.4% without the use of the STX disk and 92.1% with the addition of the STX disk. Based on the high sensitivity and specificity values of the Petrifilm system with the STX disk and the Tri-plate system to identify *S. aureus* and the Tri-plate system to identify *Streptococcus* spp. both systems are appropriate tools to identify common gram-positive mastitis-causing pathogens in milk. Using OFC to identify cows with mastitis caused by *S. aureus* and *Streptococcus* spp. may lead to decreased use of antibiotics.

Key Words: culturing, mastitis, pathogen

185 New approaches to combat milk fat depression. J. M. Risser* and D. R. Olver, *Pennsylvania State University, University Park.*

Diet-induced milk fat depression (MFD) has been observed for well over a century. MFD is characterized by a drastic decrease in milk fat yield with little to no change in milk production or other milk components. MFD often results from diets supplemented with high levels of oil, especially those derived from plants or fish, or those containing highly fermentable feeds. According to a study at Michigan State University, highly fermentable diets may decrease intake and fiber digestibility and lead to synthesis of bioactive trans fatty acids in the rumen that are known to reduce milk fat synthesis. However, highly fermentable diets are important to maximize energy intake and milk production. With rising input costs, dairy producers require new ways to maximize milk production while ensuring high yield of components. Recent developments have pointed to modifiers of the rumen environment to combat MFD even when feeding rapidly fermentable and high concentrate diets. One example of a rumen modifying additive is yeast culture. Michigan

State researchers found that yeast culture supplementation may assist in the prevention of MFD when transitioning to a diet containing highly fermentable starch. Yeast cultures are responsible for stabilizing rumen fermentation during diet shifts by increasing the population of lactate-utilizing microorganisms, thus maintaining an environment for normal fermentation. In addition to yeast culture supplementation, dietary molasses also has a role as a rumen modifier. Through research at Kansas State, molasses has been shown to change fatty acid biohydrogenation pathways in the rumen, and reduce the synthesis of bioactive fatty acids that cause MFD. These additives, among other rumen modifiers, can lead to more efficient dairy cows by stabilizing rumen fermentation while simultaneously increasing profit for the producer.

Key Words: milk fat depression, rumen modifiers

186 Monitoring the composition of waste milk fed to dairy calves. E. L. Stayduhar,* K. D. Stevens, M. L. Eastridge, and K. M. Daniels, *The Ohio State University, Columbus.*

Profitability of dairy farms is influenced by several characteristics, one of which is calf management. The growth and health of replacement animals influences their future milk yield. With the increasing size of dairy farms and the aim to reduce costs of raising heifers, many farms are opting to pasteurize waste milk for feeding to calves. With this shift from feeding milk replacer to pasteurized waste milk, the cost of pasteurizers has decreased. However, when using this feeding practice, the producer needs to know the composition of the milk being fed. The proportion of milk from fresh cows and cows treated for mastitis (often lower in solids than from healthy cows) will affect the composition of the waste milk. Adequate concentrations of fat and protein (or total solids) in the milk is vital for sound health and expected growth rates for the calves. Simple tests, such as pH and ethanol coagulation, can be easily used, but they only indicate whether or not the waste milk has spoiled. Other on-farm measurements are needed that are more reflective of milk composition. Total solids in milk can be determined using a Brix refractometer, with the Brix readings being converted to total solids using reported equations. In addition, these refractometers are inexpensive and the readings are very rapid. On-farm analytical instruments are available today for measuring the fat, protein, and other solids in milk (e.g., LactiCheck; Page and Pedersen International Ltd., Hopkinton, MA). These instruments require routine calibration, but standards for the calibration are readily available and the calibration steps are simple. Although these instruments are much more expensive than refractometers, they provide more information than just total solids and they can be used to monitor the composition of milk from individual cows (e.g., milk fat concentration for ketosis risk) and the bulk tank. Using the methods described to measure total solids or fat and protein concentrations allows the producer to fortify waste milk with the appropriate amount of milk replacer to increase total solids to the desired level. Continued improvement in on-farm measurement of the composition of waste milk fed to calves will improve calf performance and increase farm profitability.

Key Words: waste milk, calves, milk composition

187 Early pregnancy detection methods in reproductive management. C. E. Burke* and C. C. Williams, *Louisiana State University, Baton Rouge.*

In the cattle industry, pregnancy diagnosis is an important tool in measuring the success of reproductive management. A cow that remains open longer than desired will ultimately cost the producer, whether it is money spent on synchronization and breeding materials or simply the cost to keep her in the herd. To reduce economic losses, producers rely on early pregnancy detection to better manage the reproductive efficiency of the herd. Today many producers use synchronization programs to aid in the breeding process. The hormone prostaglandin is given to an animal to regress its corpus luteum (CL) and cause her to cycle, setting her up for breeding. When a cow is pregnant her CL will remain throughout her pregnancy, preventing her from cycling. One of the many disadvantages of not knowing pregnancy status is mistakenly causing the cow to abort by treating her with prostaglandins as if she were open. The 2 most common methods of pregnancy detection are rectal palpation and ultrasonography, both of which are very invasive procedures. Although these methods are used extensively throughout the industry, there is a new method providing a friendly, cost effective way to detect early pregnancy. Blood pregnancy tests such as BioPRYN simply test for pregnancy specific protein B in the blood rather than relying on invasive practices. BioPRYN uses ELISA technology that requires only a sample of blood from the cow under question. At a price of less than $3 per test, BioPRYN is a cost effective alternative that does not require a trained technician. With labs throughout the United States and internationally, a producer can send in samples and have their results within 27 h of assay setup. Cows must be 90 d postpartum and 30 d post breeding to get an accurate reading. BioPRYN offers up to 95% specificity on pregnant cows and 99% sensitivity on open cows. Blood testing for pregnancy is the next step in improving the reproductive management systems in cattle herds. The earlier a pregnant or open status can be confirmed, the sooner the producer can take the necessary steps to safely and properly manage his herd.

Key Words: pregnancy detection, reproductive management, blood test

188 Anaerobic digestion and the benefits to dairy farmers. S. K. Luther,* A. C. Wilkie, and M. E. Sowerby, *University of Florida, Gainesville.*

Anaerobic digestion has the potential to be a large part of the solution for shrinking our fossil fuel consumption. Anaerobic digestion is a biological process that turns waste into fuel and resources. It is essentially the breakdown of organic materials using a mixed consortium of bacteria in the absence of oxygen. Anaerobic digestion is a full circle process that captures the remaining energy in feedstocks that are currently considered waste and gives back usable goods. On the farm, anaerobic digestion has the ability to produce combustible methane gas and efficient fertilizer. The methane produced is collected and when used eliminates the carbon dioxide that would have been released from the fossil fuels that the methane can replace. With all the hype over going "green," farmers need to be doing all they can to improve their public image and conserve the environment for future growers. As businessmen, dairy farmers can turn their digester output into renewable biofuel, carbon credits, and fertilizer. Anaerobic digestion is a very effective waste management practice on farms that already have manure collection systems in place. It helps to reduce odors normally associated with spray fields and lower pathogen levels in the animal manure that is digested. Anaerobic digestion inactivates "weed" seeds and conserves nutrients, making the liquid effluent a valuable biofertilizer. Dairy farmers must consider herd size, current waste management methods, and possible farm expansion when choosing and sizing a digester. There are 4 main types of digesters, which are each suitable for different manure management methods. For example, one type of digester was specifically designed for the flushing systems used in dairy freestall barns. Anaerobic digestion is a technology that will further contribute to our sustainability efforts while improving the relationship between agriculturalists and consumers. The process captures the energy in feedstocks that are currently considered waste and delivers usable goods.

Key Words: anaerobic digestion, manure management, digester designs

189 Supplemental melatonin: A potential strategy for maintaining mammary health in dairy cattle.

M. M. Palmer,* D. N. Williams, and J. L. Fain, *Clemson University, Clemson, SC.*

Increased somatic cell count (SCC), associated with mastitic infections in dairy cattle can have detrimental effects on animal welfare, reproduction, milk quality and overall milk production. Novel investigations have established melatonin as a potential potent regulator of SCC in dairy cattle. Seasonal response patterns in estrous cycles of small ruminants led to the increased use of melatonin implants to regulate incidences of anestrus during periods of increased day length. Consequently, producers noticed a reduction in SCC in both sheep and goats. Previous work indicates that melatonin acts to protect cells and tissues against damage caused by oxidation. During the inflammatory reaction associated with mastitis, there is damage that occurs to the mammary epithelium. The somatic cell composition changes from a majority macrophage concentration to increasing levels of polymorphonuclear neutrophils (PMN) moving from the blood stream to congregate in the mammary gland during times of infection. These PMNs then engulf the invading pathogen through phagocytosis. During this process, the neutrophils release reactive oxygen species (ROS) which defend against invading pathogens but also trigger epithelial cell damage. Melatonin has demonstrated abilities to scavenge hydroxyl radical, a noted ROS. Serving in an antioxidant capacity, melatonin may be used to supplement the animal's endogenous mechanisms, allowing for faster rate of recovery with reduced total tissue damage. With potential decrease in legal limit SCC, faster recovery rates from mastitis could decrease bulk tank SCC. An even larger impact may be the potential for melatonin to abrogate decreased milk production associated with increased SCC through reduction in tissue damage. Continuous investigation of melatonin and other antioxidents may allow for more insight into their role in maintaining mammary health.

Key Words: melatonin, mastitis, dairy

ADSA Southern Section Symposium: Meeting the Nutrient Requirements of Dairy Cattle During Heat Stress

190 Heat stress in young dairy calves. C. C. Williams,* *Louisiana State University AgCenter, Baton Rouge.*

The initial 2 mo of a calf's life directly influence the quality and condition of its future growth and development. During this period, stress is detrimental to the proper growth of the calf. One common type of stress of particular concern to southern dairy producers is heat stress. Heat stress occurs when any combination of environmental factors causes the relative temperature of the environment to be greater than the calf's thermoneutral zone. In the southern United States, heat stress is particularly common due to uncontrollable environmental factors such as the temperature-humidity index (THI). As a result of an elevated THI, the calf's respiration, internal temperature, and water intake will increase, and dry matter intake, average daily gain, fecal score, and feed efficiency will decrease. These homeostatic alterations disrupt calf development and prohibit the achievement of full production potential. In addition, heat stress can cause a variety of problems on a molecular level. Heat stress causes the adrenal gland to produce the steroid cortisol; in high enough quantities, cortisol can render a calf incapable of absorbing important immunoglobulins through its cellular membranes. Heat stress can also lead to dehydration, which can cause blood urea nitrogen levels to rise. This is a direct result of poor renal function. Dehydration and poor renal function, left uncorrected, are associated with a high mortality rate among calves less than 2 mo old. Limited research has been conducted to determine the effect of heat stress in neonatal calf health and performance. However, studies that been conducted indicate that providing supplemental shade to calves housed in hutches can reduce the severity of heat stress.

Key Words: heat stress, dairy calves

191 Managing heat stress in dairy heifers. R. E. James* and S. Neal, *Department of Dairy Science, Virginia Tech, Blacksburg.*

Limited research indicates that heat stress affects dairy heifers through depressions in ration dry matter intake, nutrient utilization, reproductive function and colostrum production although not to the same degree as milking animals. Given this relationship, the recently weaned heifer, the breeding age heifer and close springing heifer will benefit most from reductions in heat stress. Weaned heifers are especially susceptible to reduced intake as they are adjusting to dry feed and group housing systems. Italian workers found that exposure of 10-mo-old heifers to a THI of > 84 resulted in depressed intake and increased water intake and rectal temperature. However, they also noted that heifers adjusted to longer term heat stress. Virginia Tech researchers found that the influence of temperature on intake was relatively minor as heifers delayed consumption of the diet until the cooler hours of the evening. The breeding age heifer expresses impaired growth and function of the dominant follicle when exposed to 33°C at 50% relative humidity as compared with 21°C at 60% relative humidity. Smaller follicles were associated with decreased serum estradiol concentrations, delayed luteolysis and impaired reproductive success. During the prepartum period, exposure of gravid heifers to a THI of 82 as compared with one of 65 resulted in lower concentrations of IgG, IgA, total protein, lactalbumin, fat and lactose in the colostrum. Management should focus on the critical ages noted. First priority should be given to provision of adequate supplies of water. Water intake is highly correlated with feed intake and is especially important during heat stress. Research is not available to estimate the economic return from use of cooling fans and sprinkler systems. Given the critical influence of reproductive function on timely calving and the production of IgG rich colostrum, facilities featuring use of fans, high and open side walls and open ridge vents will facilitate animal cooling for these animals. Finally, it is apparent that increasing nutrient density of the ration will maintain nutrient intake during heat stress.

Key Words: heifers, heat, stress

192 Impact of management on feeding dairy cows in heat stress. G. Bethard,* *Dairy Records Management Systems, Raleigh, NC.*

Most modern and productive dairy cows experience heat stress of some kind throughout the year. Heat stress degrades short-term financial performance, largely through the direct loss of milk production and milk components. Milk volume declines are obvious and noticeable; less noticeable and potentially more costly are milk component and quality premium losses. Other short-term losses include herd health issues and associated herd losses. Long-term costs are escalated by poor reproductive performance. Much of the economic cost is directly related to the decline in dry matter intake and change in feeding behavior. Lower dry matter intake can lead to lower milk production and body condition loss; altered feeding behavior can lead to slug feeding and perceived rumen health issues. Much is known about the physiological consequences of heat stress. Much less is known about nutritional approaches to alleviate these consequences. Nutritional strategies implemented in the field include altering mineral levels, cation-anion balance, buffering capacity, or fiber digestibility. None are widely accepted in the field, and implementation of strategies differs by region. Management at the dairy typically provides the best opportunity to prevent the decline in dry matter intake. Heat abatement strategies are obvious and recognized widely in the dairy industry. Cow comfort, over-crowding, and cow resting time also have an effect and heightened during periods of heat stress. Preserving and managing forages to extend bunk life and managing feedbunks is crucial to minimizing the declines in dry matter intake.

Key Words: heat stress, dairy, feeding

193 Lactating cows and changes in dry matter intake during heat stress. J. W. West,* *University of Georgia, Tifton.*

Exposure of high yielding dairy cows to elevated ambient temperature and relative humidity impairs the cow's ability to dissipate body heat, leading to increased internal heat load. The mechanisms to dissipate excess body heat (conduction, convection, radiation, and evaporation) are compromised by hot, humid conditions, leading to physiologic and metabolic responses that reduce DMI and milk yield. Declining DMI during thermal stress may be a protective mechanism to limit metabolic heat and is credited with a concomitant reduction in milk yield. Work indicates that reduced DM and nutrient intake is only partially responsible for declining milk yield and that hormonal shifts alter energy metabolism, further reducing yield. Slower rate of passage in the digestive tract occurs in hot weather and can limit intake, though nutrient digestibility may improve. Subclinical acidosis often limits DMI because of very high energy diets fed in an attempt to maintain energy intake at a time when blood buffering is reduced by hyperventilation. The reduced DMI that occurs during heat stress is a complex response to environmental stressors and the steps to ameliorate the impact are multifaceted. Most important is to reduce exposure to radiant energy by shading and to enhance body heat transfer to the environment via cooling. Greater air movement with fans and addition of water in the form of sprinklers or misters are keys to enhancing evaporative cooling for the cow. Once environmental modifications are in place, dietary adjustments to enhance DM or nutrient intake can be implemented. Dietary buffers and rumen modifiers including yeast culture and fungal additives stabilize the rumen environment and may reduce body temperature. Attention to forage quality and particle size is crucial during hot weather and caution should be used when dietary fiber is reduced in the pursuit of greater dietary nutrient density. Continued genetic selection for greater DMI and milk yield presents challenges for the manager who must balance the exceptional metabolic potential of the modern dairy cow with the need to eliminate excess metabolic heat produced in a challenging climatic environment.

Key Words: dairy, heat stress, DMI

194 Use of fat and other feed additives in heat-stressed cattle.

L. H. Baumgard*[1], A. Nayeri[1], M. V. Sanz-Fernandez[1], J. S. Johnson[1], D. B. Snider[1], D. P. Bu[2], and R. P. Rhoads[3], [1]*Iowa State University, Ames,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agriculture Sciences, Beijing, China,* [3]*Virginia Polytechnic Institute and State University, Blacksburg.*

Heat stress (HS) negatively affects parameters associated with profitable milk production. Implementing HS-abatement strategies (barn construction, fans, evaporative cooling, etc.) is crucial to minimize fiscal losses and quantitatively more important at maintaining milk production than potential nutritional changes. However, the effects of nutritional management are not trivial and are key components to efficient production and optimal cow-health during the summer months. Obviously the most vital nutrient to consider is water (water intake can more than double during HS) and ensuring adequate access to clean, fresh water is critical. HS reduces rumen pH and thus nutritional approaches aimed at maintaining rumen health are important. Potassium requirements increase during HS as ruminants utilize potassium to sweat, therefore a dietary potassium based rumen buffer may have dual benefits. A widely held dogma is that supplementing dietary fat is an effective tactic during HS stemming from theoretical calculations indicating that the heat increment of feeding is much lower for lipids (especially compared with roughages). HS markedly alters post-absorptive metabolism and this is, in part, characterized by increased systemic glucose utilization so dietary strategies aimed at safely increasing gluconeogenic precursors (i.e., monensin) are suggested. HS causes “leaky gut” in a variety of species and although not described in ruminants, we suspect it plays a key role in the etiology of HS-induced poor performance and mortality in dairy cows. Consequently, dietary strategies aimed at strengthening intestinal integrity (rehydration therapies, betaine, zinc, etc.) show promise and need to be thoroughly evaluated. It is unknown whether protein or energy requirements (and this is especially true for maintenance costs) increase or decrease during HS, but this is of practical and economic importance to the dairy industry. Surprisingly, our understanding of nutrient requirements during HS is woefully insufficient, and this makes formulating nutritional strategies to mitigate summer-induced low production difficult.

Key Words: heat stress, nutrition, dietary fat

195 Feeding dairy cattle in a grazing system during heat stress.

J. K. Bernard,* *University of Georgia, Tifton.*

Dairy cattle in a grazing system are negatively affected by heat stress resulting in decreased DMI and milk yield and elevated core body temperature. The physiological and metabolic responses to heat stress that contribute to reduced DMI and milk yield will be discussed by others in this symposium. For grazing dairy cattle, heat stress alters grazing behavior as cows seek shade during the day and tend to graze more at night and early morning, reducing nutrient intake. Forage quality also tends to decline in response to heat stress, resulting in higher NDF concentrations and lower digestibility further reducing energy intake. Concurrently, maintenance requirements increase during heat stress because of panting and greater time standing as cows attempt to reduce body temperature. Diets must be adjusted to compensate for reduced DMI to meet higher maintenance requirements and maintain milk yield. Effective strategies include feeding additional energy concentrates, high quality forage, or a partial TMR to maintain DMI and nutrient intake. Provision of shade and soaking plus supplemental high quality forage are reported to maintain milk yield through improved DMI while reducing core body temperature. Supplemental energy may be provided by concentrates or fat. The quantity of starch should be limited to avoid subclinical acidosis and the quantity of supplemental fat should be limited to avoid decreased fiber digestibility or reduced DMI. Dietary buffers to provide additional Na, K, and Mg should be increased to replenish losses incurred through increased panting and sweating and provide additional buffering capacity in the rumen. In addition to dietary changes, water consumption increases in response to heat stress and provisions must be made to provide adequate water.

Key Words: heat stress, grazing, feeding

ADSA-SAD Undergraduate Competition: Original Research

196 Monitoring the incidence of ketosis in fresh cows using milk composition, urine ketones, and milk ketones. K. D. Stevens,* E. L. Stayduhar, M. L. Eastridge, and K. M. Daniels, *The Ohio State University, Columbus.*

Fresh cows have a high risk for ketosis within the first 30 DIM due to low DM intake and the rapid mobilization of fat after parturition. Early detection of ketosis, including subclinical ketosis, can allow for earlier intervention and minimize the loss of milk production. Detection of ketosis is commonly done in the field with measuring ketones in urine or milk, but concentration of fat in milk also may be useful for detection of ketosis. A 700-cow Holstein farm in Ohio was used for collecting samples at 7 and 14 DIM (n = 204 cows). Composite milk samples were collected using a BouMatic (Madison, WI) in-line sampler and right-front (RF) quarter strip samples were collected. Both samples were analyzed for milk components at the farm using a LactiCheck (LIC; Page and Pedersen International Ltd., Hopkinton, MA), with weekly calibration using samples from Eastern Laboratory Services (Medina, OH). Composite milk samples also were sent to DHI Cooperative, Inc. (Columbus, OH) for analysis of milk components. Keto-Test strips (Elanco, Greenfield, IN) were used to measure ketones (β-hydroxybutyrate) in milk stripped from the RF quarter, and urine ketones (acetoacetate) were measured with KetoStix (Bayer Healthcare LLC, Monheim, Germany). The average fat concentration from LIC composite samples was 5.36 ± 2.05% and 5.15 ± 1.90% from DHI, with the RF strippings having a lower milk fat (3.17 ± 1.88%). Average milk ketone concentration was 0.55 ± 0.98 mg/dL, and urine ketone concentration was 4.41 ± 15.4 mg/dL; however, the incidence of clinical ketosis was relatively low in the herd (3.4% based on urine ketones ≥40 mg/dl or 6.9% based on milk ketones ≥2.0 mg/dL). The correlation coefficient for LIC and DHI composites was 0.70 ($P < 0.0001$), and the correlations between the composites and the RF samples were similar for both methods of analysis (0.30; $P < 0.0001$). The correlation of the RF milk fat percentage and the milk and urine ketones also was similar (0.22; $P < 0.001$). The changes in milk fat concentrations from 7 to 14 DIM were similar for LIC and DHI composites and the RF samples (−0.63, −0.88, and −0.77, respectively). Monitoring milk fat concentration of individual cows holds promise for the diagnosis of ketosis, and it appears that either composite samples or strippings can be used to establish a baseline from which to identify cows with elevated milk fat concentrations.

Key Words: ketosis, urine ketones, milk ketones

197 Effect of a liquid acid footbath solution containing a cationic surfactant on digital dermatitis in dairy cattle. T. A. Reiter*[1], B. A. Beavers[2], F. R. Moreira[3], K. J. McQueery[1], C. L. Wood[1], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Beavers Hoofcare Service LLC, Lebanon, KY, [3]GEA Farm Technologies, Naperville, IL.*

Dairy producers use many different footbath solutions for control of digital dermatitis (DD); however, many of these compounds have adverse effects on cows, handlers, or the environment. The objective of this research, consisting of 3 studies, was to examine the effects of a liquid acid footbath solution containing a cationic surfactant (PediCuRx Prevent A (PED), GEA Farm Technologies, Naperville, IL) on digital dermatitis size (DDS) and pain (DDP). For each study, treatment cows were exposed to a 2% PED solution 3X per wk. The same observer evaluated DDS and DDP scores using 0 to 3 scales with 0 assigned to hooves with no DD. For DDS, scores were assigned as follows: 0 = no DD; 1 = <20 mm DD; 2 = ~20 mm DD; and 3 = >20 mm DD. The pain caused by wart presence was determined by the cow's reaction to either water or finger pressure on the hoof. For DDP, scores were assigned as follows: 0 = no pain; 1 = minimal pain; 2 = moderate pain; and 3 = severe pain. Study 1 included 53 cows in a commercial dairy that were exposed to PED in a footbath for 4 mo. Study 2 included 250 cows in 2 commercial dairy farms in a 4-mo experiment comparing PED to a 10% copper sulfate (CS) solution. Study 3 was conducted at the University of Kentucky Coldstream Dairy with 53 cows assigned for 4 mo to either a PED treatment or a 5% CS control. The MIXED procedure of SAS® (Cary, NC) was used to assess factors affecting DDS and DDP. In study 1, mean responses for DDS and DDP were higher ($P < 0.05$) before starting the study (0.37 and 0.39 for DDS and DDP, respectively) than for the 3 test months after the study started (December: 0.12 and 0.10; January: 0.09 and 0.08; February: 0.00 and 0.00 for DDS and DDP, respectively). In study 2, mean responses for DDS and DDP were not different ($P < 0.05$) during PED periods and CS periods (PED: 0.42 and 0.40; CS: 0.40 and 0.39 for DDS and DDP, respectively). In study 3, mean responses for DDS and DDP were not different ($P < 0.05$) between treatments (PED: 0.28 and 0.28; CS: 0.21 and 0.25 for DDS and DDP, respectively). Control of DD was similar for PED and CS footbath solutions.

Key Words: digital dermatitis, footbath

198 Establishment of antibiotic resistance genes in the gut of pre-weaned dairy calves. L. Woloohojian,* E. Hurley, P. Ray, B. Willing, H. Littier, A. Pruden, and K. Knowlton, *Virginia Tech, Blacksburg.*

Antibiotic resistance genes (ARG) are caused by mutations found on specific genes that enable bacteria to survive exposure to antibiotics. ARG are readily transferred horizontally and longitudinally. While ARG have been found in the gut and feces of pre-weaned calves little data are available on the succession of ARG in the early weeks. The objective was to observe the establishment of ARG in fecal bacteria of dairy calves from birth to weaning. Six heifer calves were fed a medicated milk replacer (28% CP, 20% fat, containing neomycin sulfate and oxytetracycline hydrochloride each fed at 10 mg/calf/d) and free choice water and calf starter (22% CP) until weaning at d 42. Fecal grab samples were collected using sterile gloves on d 1, 3, 5, 7, 14, 21, 28, 35 and 42 of age. Colostrum, drinking water, milk replacer, and grain samples were collected to assess possible sources of inoculation with ARG-carrying bacteria. All samples were immediately frozen (−20°C) until DNA extraction. Quantitative polymerase chain reaction was performed to quantify 16S rRNA genes and *tet*W and *sul*1 ARG encoding resistance to tetracyclines and sulfonamides, respectively. Changes in absolute and relative abundance of the ARG over time were analyzed using PROC GLIMMIX procedure in SAS. Both genes were present in the feces of 1-d old calves and the abundance of 16S rRNA (log gene copies/g wet feces) did not change during the 42 d of the study. Similarly, relative abundance of *tet*W and *sul*1 (gene copies/16S rRNA) remained constant over the study period. This study provides new insight into the colonization of calf gut flora with ARGs in the early weeks.

Key Words: antibiotic resistance gene, feces, dairy calf

199 Effects of supplementing propionibacteria in lactation dairy diets on ruminal fermentation in continuous cultures. K. A. Dolecheck*[1], J. M. Vera[1], A. J. Young[1], A. H. Smith[2], V. Fellner[3], and J.-S. Eun[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan,* [2]*Danisco USA Inc., Waukesha, WI,* [3]*Department of Animal Science, North Carolina State University, Raleigh.*

The aim of the present study was to assess characteristics of in vitro ruminal fermentation when mixed cultures were offered lactation dairy diets supplemented with the direct-fed microorganism, *Propionibacterium* P63 in continuous cultures. The design of the experiment was a 2 × 2 factorial with 4 replications. Diets based on corn silage and alfalfa hay as the forage sources were formulated; high forage (HF) or low forage (LF) diet with a forage-to-concentrate ratio of 60:40 or 40:60 (DM basis), respectively, was combined without or with P63 to form 4 treatments: HF without P63, HF with P63, LF without P63, and LF with P63. Approximately 700 mL of the strained ruminal fluid obtained from 2 lactating dairy cows was inoculated into each of 4 fermentors with a continuous dual-flow system. The cultures were allowed 6 d of adaptation to the treatments followed by 3 d of sampling and data collection. Feed totaling 40.0 g of DM was added to each fermentor daily in equal portions delivered at 0700 and 1900 h. The P63 treatments received 7×10^8 cfu of P63/fermentor/feeding. Data were analyzed with a model that included the effects of level of forage in the diet (high vs. low forage), P63 (without vs. with P63), and the interaction between level of forage and P63. Supplementing P63 decreased culture pH ($P = 0.05$) in the LF diet, but not in the HF diet. Feeding the LF diet increased total VFA concentration compared with the HF diet ($P = 0.01$), and supplementing P63 increased total VFA concentration regardless of level of forage in the diet ($P < 0.01$). Molar concentrations and proportions of acetate and propionate did not differ in response to supplementing P63 in the HF and the LF diet. However, molar concentration and proportion of butyrate increased due to P63 supplementation ($P < 0.05$) only in the LF diet, resulting in interactions between level of forage and P63 supplementation ($P < 0.08$). Overall results in this in vitro study indicate that P63 supplementation enhanced ruminal fermentation by increasing VFA production, but its effects on continuous culture fermentation differed between the HF and the LF diet.

Key Words: propionibacteria, ruminal fermentation, continuous cultures

200 Effect of calf starter form and milk source on growth and intake of dairy calves. S. A. McCullough,* T. S. Dennis, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

A combination of texturized calf starter and milk replacer are commonly used feeds for dairy calves, but alternative feeds may offer improved growth and development. The objective of this study was to determine the effects of different forms of calf starter and sources of milk on growth, dry matter intake, and feed efficiency of dairy calves on a commercial dairy. In this randomized complete block design with a 2 × 2 factorial arrangement of treatments, 120 Holstein heifers (BW = 39.6 ± 5.4 kg) were blocked in groups of 4 by hutch type and birth date. Heifers were assigned to either pasteurized whole milk (WM) or milk replacer (MR) and either texturized (T) or pelleted (P) starter. The MR fed was 24% CP and 18% fat. Samples of WM were collected at each feeding and analyzed for total solids, protein and fat. Calves were allowed ad libitum access to starter and received 3.8 L/d of milk for 14 d, 6.7 L/d from d 15 to 21, and 7.6 L/d from d 22 to 56. Calves were weaned on d 63. Calves were weighed at birth and measured every 2 wk for BW, hip and withers height, body length, and heart girth circumference (HGC) for 10 wk. Feed and refusal samples were collected weekly and starter intake was measured every 2 wk. Data were analyzed as repeated measures using the Proc Mixed procedure of SAS. Heifers fed WM were 4.3 kg heavier at wk 10 than heifers fed MR ($P < 0.01$). Heifers fed WM also had greater ADG than heifers fed MR (0.76 and 0.70 kg/d, respectively; $P < 0.01$). Additionally, heifers fed WM and T or MR and T had greater ADG than heifers fed MR and P (0.76, 0.72, and 0.68 kg/d, respectively; $P < 0.01$). Dry matter intake of starter did not differ between milk or starter source, resulting in heifers fed WM having improved feed:gain compared with heifers fed MR (0.65 and 0.78 kg/kg, respectively; $P < 0.05$). Heifers fed WM and P were taller at the hip than heifers fed MR and P ($P < 0.05$). Withers height and HGC were greater ($P < 0.04$) and hip height tended ($P < 0.09$) to be greater for heifers fed WM compared with MR. However, skeletal measurements were similar between starter sources. Feeding heifers WM as compared with MR resulted in improved body weight and ADG.

Key Words: calf starter, dairy calf, milk

201 Effect of a mannanoligosaccharide (Bio-Mos) on health and growth of Holstein and Jersey calves. L. R. Such,* G. D. Hobgood, B. A. Hopkins, and S. Davidson, *North Carolina State University, Raleigh.*

Forty-two neonatal Holstein (n = 24) and Jersey (n = 18) calves were used to examine the effects of adding Bio-Mos, a mannanoligosaccharide, to the milk, on health and growth. Calves were assigned at birth to treatments in a completely randomized block design: 1). Seven grams of Bio-Mos or 2). 0 g of Bio-Mos (control) added to the whole milk diet. Calves were fed colostrum after birth and housed in individual calf hutches through 63 d. Starter mix was fed from d 1 through 56. Data that included repeated measures were analyzed using the mixed procedure (PROC MIXED) of SAS, and data that included one value per calf, such as ADG and feed efficiency (FE), were analyzed using the general linear models procedure (PROC GLM) of SAS. There were no differences in body weight, average daily gain, starter DMI, hip height, hip width, wither height or FE between calves fed Bio-Mos and control calves ($P > 0.05$). Preweaned Holstein calves had greater ADG (0.71 kg/d) and starter DMI (0.67 kg/d) than Jersey calves (0.46 kg/d and 0.41 kg/d, respectively), but there were no differences ($P = 0.26$) in FE between the breeds (1.2 kg/kg in Holstein vs. 1.5 kg/kg in Jersey). Feeding 7 g/d Bio-Mos in the milk did not improve growth or health of pre-weaned Holstein and Jersey calves.

Key Words: calf, Holstein, Jersey

202 Predicting early life illness in Holstein heifer calves. C. A. Bellmund,* K. C. McRoberts, and D. J. R. Cherney, *Cornell University, Ithaca, NY.*

Practical technological tools such as infrared surface temperature and calf feeder intake reports may predict early life health problems in Holstein heifer calves. Early prediction of illnesses including bovine virus diarrhea virus (BVDV) and bovine respiratory disease can allow effective treatment and preventative individual isolation. Calves (n = 50) born between April and July 2011 were selected at birth from the dairy herd at Cornell University's Teaching and Research Dairy Unit, and tracked the first 30 d. Non-invasive infrared surface temperatures were recorded daily using a Fluke 561 hand-held infrared thermometer at 3 locations: cheek, ribs, and rump. Hair color was also noted at these locations. Core temperatures were measured weekly using a digital rectal thermometer. Drinking speed and intake rate of milk replacer were recorded using an automatic feeder. Daily air temperature and relative humidity readings were taken at calf housing locations. Calf illness was assessed based on observation of either BVDV or bovine respiratory disease and coded into multiple parameters including daily calf illness and severity. Nominal logistic model development was undertaken using JMP Pro 9.0.2. Parameters significantly predicting daily illness status included: observation date, core temperature, cheek surface temperature, and intake rate, Coefficient of determination was low (<0.15) for all models and goodness of fit was poor. Hair color recorded at surface temperature locations appeared to be higher for black-haired calves than white-haired calves, especially under sunny, high air temperature conditions. Infrared thermometry, core temperature and intake rate can be used to predict calf illness status; however, efficacy of prediction is poor and its utility as a management tool is minimal. Additional environmental and epidemiological factors not considered in this study are likely contributing more to calf disease status than those recorded. Calves observed in this study will continue to be tracked for age at first calving, milk yield, and lifetime productivity, which could be influenced by early life health status.

Key Words: calf health, illness prediction, bovine virus diarrhea virus

203 Who's listening? The preferred means of communication for Tennessee dairy producers.

M. E. Conley,* G. M. Pighetti, and P. D. Krawczel, *University of Tennessee, Knoxville.*

The dairy industry encompasses a wide range of individuals, from those involved with on-farm production to allied professionals in diverse settings, and requires efficient and effective communication to disseminate information. The objective of this study was to investigate how Tennessee dairy producers currently receive information, how they prefer to receive new knowledge, and how they communicate with their employees. To address this objective, 452 written surveys (with an online option) consisting of 28 questions were mailed to dairy farms with a current grade A milk permit as of September 2011. Survey responses were quantified using the FREQ procedure in SAS. Unanswered questions were treated as missing data. There was a 30% response rate, with 130 responses returned by mail and 4 responses online. Tennessee dairy producers primarily use non-electronic forms of communication, indicating they sometimes or often rely on personal experience (97%), veterinarians (97%), and magazines (94%) to acquire new information. The internet was the least utilized with only 56% of respondents using this resource sometimes or often versus 44% that never use it. This trend was continued in their preferred means of acquiring information. Eighty percent of TN dairies had 1–4 employees. Most communicated with their employees by casual discussion (81%) or when they observed a problem (64%), whereas only 14% had formal meetings. For independent learning, 59% provided their employees with magazines, 37% would be willing to send their employees for training (with 13% unsure), and 29% would be willing to host on-farm training (with 10% unsure). The results indicate that producers use and prefer non-electronic forms of communication when acquiring new information, thus electronic mediums are not the most effective way to communicate with the majority of Tennessee producers. Communicating new information within a farm may not be efficient as it relies more on casual discussion and troubleshooting rather than structured meetings and/or trainings. This study will aid in better designing and implementing communication strategies with dairy producers, their employees, and affiliated professionals.

204 Key Words: producer, communication Incorporation of palmitic and stearic acids into plasma lipid fractions of lactating dairy cows.

S. Schmidt,* C. L. Preseault, J. E. Rico, M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing.*

Transport of fatty acids (FA) in the bloodstream is complex and involves various plasma lipid fractions including phospholipids (PL), cholesterol esters (CE), triglycerides (TG), and NEFA. Effects of dietary FA on plasma lipid fractions have not been well characterized in lactating dairy cows. The mammary gland preferentially utilizes FA from plasma TG and NEFA for milk fat synthesis, thus changes in the profile and concentration of these fractions may impact milk fat synthesis. Effects of dietary palmitic and stearic acids on the concentration and profile of plasma lipid fractions were evaluated in an experiment with a crossover arrangement of treatments. Sixteen Holstein cows (143 ± 50 DIM) were assigned to a treatment sequence; treatments were diets supplemented (2% of diet DM) with palmitic acid (PA; 99% C16:0) or stearic acid (SA; 98% C18:0). Treatment periods were 21 d with plasma samples collected every 15 h between d 17 and d 21 of each period and composited. The statistical model included the random effect of cow and the fixed effects of period, treatment, lipid fraction, and the interaction of treatment and lipid fraction. PA treatment increased MF yield by 6.2% compared with SA treatment ($P < 0.01$). The proportion of total plasma FA in each lipid fraction was not affected by treatment and averaged 50.4, 46.5, 2.3, and 0.83% for PL, CE, TG, and NEFA, respectively (all $P > 0.14$). The PA and SA treatments increased the concentration of C16:0 and C18:0 respectively in TG; for C16:0, values were 29.7 vs. 18.2, and for C18:0 they were 29.5 vs. 36.4 g/100 g FA (PA vs. SA treatment, both $P < 0.0001$). PA treatment also increased C16:0 in NEFA and PL fractions ($P < 0.0001$), but not in CE ($P = 0.24$). Likewise, the SA treatment increased C18:0 in NEFA and PL fractions ($P < 0.01$), but not in CE ($P = 0.9$). The majority of C16:0 and C18:0 were transported in PL with 73.6 vs. 71.4% of total plasma C16:0 (PA vs. SA treatment, $P = 0.08$) and 90.5 vs. 88.3% of total plasma C18:0 (PA vs. SA treatment, $P = 0.006$) within the PL fraction. Results demonstrate that the PA and SA treatments increased the concentration of C16:0 and C18:0, respectively, across plasma TG, PL, and NEFA. Treatment did not however, alter proportions of total FA across lipid fractions. Further work is required to determine if the observed increase in milk fat yield with the PA treatment was due to the increase in C16:0 in TG.

Key Words: plasma lipids, palmitic acid, stearic acid

205 Effect of temperature during drying and mechanical extrusion on soybean meal protein in situ degradability and in vitro digestibility.

B. J. Isenberg*[1], A. N. Hristov[1], D. M. Kniffen[1], C. Lee[1], K. S. Heyler[1], T. W. Cassidy[1], and R. A. Fabin[2], [1]*The Pennsylvania State University, University Park,* [2]*Fabin Bros. Farms, Indiana, PA.*

The objective of this study was to investigate the effect of drying and extruding temperature on ruminal degradability and intestinal digestibility of mechanically-extracted soybean meal (M-SBM) crude protein (CP). Whole soybeans were processed at a commercial extrusion facility with the following treatments: drying at 49°C and extruding at 149°C (HD-LE); drying at 49°C and extruding at 160°C (HD-ME); drying at 49°C and extruding at 171°C (HD-HE); drying at 27°C and extruding at 149°C (LDLE); and drying at 27°C and extruding at 160°C (LD-ME). Control was solvent-extracted SBM (S-SBM). Ruminal protein degradability was determined by incubating samples in situ for up to 24 h in the rumen of 3 lactating dairy cows. Following the in situ incubation, a portion of the undegraded meal residues were further processed to estimate intestinal CP digestibility in vitro using incubation in pepsin-hydrochloric acid solution for 48 h. Ruminally degradable (RDP) and undegradable (RUP) protein in samples were estimated based on NRC (2001) and ruminal passage rates calculated from actual intake and body weight of the cows. All M-SBM had higher RUP ($P < 0.001$) content compared with S-SBM (33% RUP), which could be partially explained by the slightly larger geometric mean diameter of the former meals (769 vs. 759 µm, $P = 0.01$). Increasing the extruder temperature

increased ($P < 0.001$) RUP content of the HD (43, 50, and 55%, for HD-LE, HD-ME, and HD-HE, respectively) or LD (43 vs. 49%, LD-LE and LD-ME, respectively) meals. Drying temperature had no effect on M-SBM RUP. Intestinal digestibility of the undegraded in situ CP was similar among treatments ($P = 0.24$), although digestibility of M-SBM was numerically lower than S-SBM CP (65 vs. 71%, respectively). Lys content of in vitro residues was similar among treatments. Meal output was decreased by about 13% by increasing extrusion temperature. In the specific conditions of this study, increasing extruder temperature from 149°C to 171°C (300 to 340°F) increased RUP content of M-SBM by 28% but decreased meal output.

Key Words: soybean meal, processing, ruminal degradability

Animal Behavior and Well-Being: Use of Animal Behavior to Assess Animal Welfare

206 Use of animal behavior to assess animal welfare. E. A. Pajor,* *Faculty of Veterinary Medicine, University of Calgary, Calgary, AB, Canada.*

The science of animal behavior (ethology) has been closely linked to the study of animal welfare. A major advantage of behavior as a welfare indicator is that it can be measured non-invasively. As a starting point, a species' natural behavior is often compared with its behavior in confinement. Although this approach provides some general information about the range and variation in behavior, it does little to indicate anything about animal welfare. A more rewarding approach currently used by many scientists is to try to determine how particular behaviors develop, understand their function and what motivates them to occur. For many animal welfare scientists an animal's subjective stat is an important, if not the most important aspect of animal welfare. Feelings are not directly observable, but have measurable correlates or consequences. They can be assessed either by giving animals some control over their environments and observing the choices and decisions they make, using preference and motivation tests or by looking for signs of deprivation, frustration or distress when the animal is confined in an environment or subjected to a treatment without any means of control. Although preference and motivation tests are techniques under development, if carefully interpreted they can constitute a powerful tool for the assessment of welfare. Another important research area is the study of the causes and prevention of abnormal behaviors such as stereotypies or injurious behaviors. These behaviors have often been interpreted as indicators of poor animal welfare but recent studies suggest that such interpretations are too simplistic. Another promising approach to evaluating animal welfare is through the study of cognition, learning and memory. The focus of scientific inquiry and policy development is shifting to include the study of positive welfare states. Additional research in understanding and quantifying such states is a significant challenge.

Key Words: behavior, welfare, assessment

207 Prevalence of hock, knee and neck injuries, stall dimensions and lying time on Canadian free-stall dairy farms. J. C. Zaffino*[1], C. G. R. Nash[1], T. J. DeVries[2], S. J. LeBlanc[1], D. F. Kelton[1], J. Gibbons[3], E. Vasseur[3,5], A. M. de Passillé[3], J. Rushen[3], K. Orsel[4], H. W. Barkema[4], L. Solano[4], G. B. Bond[4], and D. B. Haley[1], *[1]University of Guelph, Department of Population Medicine, Guelph, ON, Canada, [2]University of Guelph, Department of Animal and Poultry Science, Guelph, ON, Canada, [3]Agriculture and Agri-Food Canada, Agassiz, BC, Canada, [4]University of Calgary, Department of Production Animal Health, Calgary, AB, Canada, [5]Organic Dairy Research Centre, University of Guelph Alfred Campus, Alfred, ON, Canada.*

Hock, knee and neck injuries on dairy cows are important indicators of welfare, management, and inadequate stall design. We investigated the relationship between injuries, lying time and stall dimensions on 90 free-stall dairy farms in Ontario (n = 40) and Alberta (n = 50). We sampled 40 Holstein cows per farm, scoring injury severity on a 4-point (hocks, knees) or 3-point scale (neck). Higher scores indicated greater severity. The same cows were used to calculate farm average lying time by recording their activity over 4, 24-h periods using electronic data loggers. Bed lengths (brisket board to rear curb) and stall widths were recorded on every farm. The association of stall dimensions with herd prevalence of injuries was analyzed in a mixed logistic regression model. The mean herd prevalence (and range) of hock, knee and neck injuries (score > 1) was 33% (0 - 82%), 17% (0 - 81%) and 8% (0 - 65%), respectively. The median farm average lying time was 10.5 h/d (interquartile range: 10.2 - 11.3 h/d). Mean bed length was 178 cm (range: 151 - 226 cm). Mean stall width was 115 cm (range: 104 - 131 cm). Hock injuries were not associated with bed length ($P = 0.82$) or stall width ($P = 0.98$). Knee injuries were less prevalent on farms with wider stalls (odds ratio = 0.3 per 10 cm increase in stall width; $P = 0.002$) and may be attributed to increased lateral lunge space. Neck injuries were more prevalent on farms with longer stalls (odds ratio = 1.4 per 10 cm increase in bed length; $P = 0.04$) and may be related to the placement of the neck rail on these stalls, yet to be analyzed. This is the first study to examine the prevalence of injuries on Canadian free-stall dairy farms. The finding that injuries are common on some farms is concerning, yet the variation between farms demonstrates that a low level of injuries is attainable. Refinement of stall designs may contribute to a reduction of injuries.

Key Words: injury, stall dimensions, animal welfare

208 Gradual cessation of milking reduces milk leakage and anticipatory behavior in dairy cows at dry-off. G. Zobel*[1], D. M. Weary[1], K. Leslie[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [2]Population Medicine, University of Guelph, Guelph, ON, Canada.*

The welfare effects of abrupt cessation of milking at dry-off are not well understood, but the pain-minimizing effects of gradually reducing milk production are frequently discussed in human work. This study aimed to assess the effect of abrupt vs. gradual cessation of milking on dairy cow behavior, milk leakage and somatic cell score (SCS). Eighteen cows (with a mean milk production of 24 ± 5 kg/d) were randomly assigned to either abrupt milk cessation (i.e., dry-off on d0) or gradual milk cessation (i.e., skipped milkings beginning on d0; dry-off on d5) in 3 replicates. Dry cow antibiotic and teat sealant therapy was administered at dry-off. Measurements were taken d-3 to d8. Three periods were identified for behavior data: P0 (baseline; d-3 to d-1), P1 (abrupt cows dry, gradual cows milking; d0 to d4) and P2 (all cows dry; d5 to d8). Lying and feeding behavior did not differ in P1 and P2 so these periods were combined for these measures. Lying time was recorded using data loggers and 5-min video scan samples were used to measure feeding time and anticipatory behavior (i.e., waiting at the pen's exit gate). Milk leakage was monitored every 20 min for 2 h following the times when cows would have been milked before dry-off (0500 and 1500). Leakage was assessed using the periods after full dry-off (P1 for abrupt vs. P2 for gradual). Composite milk samples were taken before dry-off and after calving to determine SCS. Regardless of treatment, dry-off resulted in reduced lying time (877 vs. 799 ± 9 min/d), reduced lying bouts (11.1 vs. 8.6 ± 0.3 bouts/d) and increased feeding time (285 vs. 350 min/d; SE = 8). Compared with P0, abrupt cows showed a greater increase in anticipatory behavior (P1: OR = 6.0; 95% CI: 2.7 – 13.5 and P2: OR = 8.1; 95% CI: 3.1 – 20.8) than gradual cows (P2: OR = 2.7; 95% 1 – 6.9). Frequency of leakage was greater in abrupt vs. gradual cows (89 vs. 22%, Fisher's exact test). SCS increased at calving regardless of treatment (2.6 vs. 4.5 SCS; SED = 0.4) but returned to P0 levels by d6. Gradually reduced milking frequency results in reduced milk leakage and reduced time spent anticipating milking following dry-off.

Key Words: welfare, milking frequency, SCS

209 Physiological and behavioral responses to bovine respiratory disease. R. Toaff-Rosenstein*[1], L. Gershwin[2], A. J. Zanella[3], and C. Tucker[1], *[1]Department of Animal Science, University of California-Davis, Davis, [2]Department of Pathology, Microbiology and Immunology, School of Veterinary Medicine, University of California-Davis, Davis, [3]Chair, Animal Health and Welfare, Scottish Agricultural College, Edinburgh, UK.*

Bovine respiratory disease (BRD) is the most widespread disease in US beef cattle, affecting 14.4% of feedlot animals, yet early detection is relatively poor. An improved understanding of the coordinated sickness response, including behavioral and physiological changes, can help improve disease detection. BRD was predicted to cause fever accompanied by lower feed intake and average daily gain (ADG). It was also expected to decrease grooming and increase lying time, as non-essential behaviors are reduced and those associated with fever maintenance increased with illness. Healthy beef steers (300 kg) were challenged with bovine respiratory syncytial virus on d0 and *Histophilus somni* on d5 (BRD, $n = 10$) or sterile solution (healthy, $n = 10$). Days −2 to 7 from initial viral challenge, unless stated otherwise, and treatment were analyzed using a mixed model. To assess grooming (d −1, 4, 6, 7) a brush was provided 20 min/d and self-licking was recorded simultaneously. Body temperature (d 3 to 7) and lying behavior were measured 24h/d with a data logger. BRD steers had higher body temperature d3 to d6, with the greatest difference on d5 (42.1 ± 0.16 vs. 39.9 ± 0.16°C, $P < 0.001$). Feed intake declined in BRD steers starting d2 and remained significantly lower on all subsequent days (peak difference on d5, 2.4 ± 0.12 vs. 0.3 ± 0.16% body weight, $P < 0.001$). This was accompanied by decreased overall ADG in BRD steers (−2.4 ± 0.36 vs. 1.6 ± 0.36 kg/d, $P < 0.001$). BRD steers spent more time lying down on d3 and 4 (peak difference on d3, 16.1 ± 0.38 vs. 14.1 ± 0.43 h/d, $P < 0.001$). BRD steers explored the brush less overall (8.4 ± 0.17 vs. 15.2 ± 0.17% of observed intervals, $P = 0.029$) and performed less self-licking on d4 (0.3 ± 0.24 vs. 8.9 ± 0.24% of observed intervals, $P < 0.001$) but there was no effect of BRD on brush-grooming ($P = 0.209$), possibly due to insufficient sampling. These results indicate that the BRD sickness response occurs as early as d2 after viral challenge as indicated by decreased feed intake. Behavioral changes can be used detect BRD, but adequate sampling is required for accurate disease recognition. Automated monitoring of behavioral changes may be a promising way forward for improved, early BRD diagnosis.

Key Words: sickness response, bovine respiratory disease

210 Effect of prepartum grouping strategy on agonistic behavior of dairy cows. K. M. Lobeck,* M. I. Endres, P. R. B. Silva, and R. Chebel, *University of Minnesota, St. Paul.*

The objective of this study was to investigate the effect of 2 prepartum grouping strategies on agonistic behavior of dairy cows measured by displacements from the feed bunk. Treatments were 1) All-In All-Out (AIAO) - cows assigned to a pen as a group and no new cows added during a 5-wk close-up period and 2) control (CON) - weekly entrance of new cows to maintain a pen density of 44 cows. The study was conducted in a freestall sand-bedded dairy farm in south-central Minnesota. Eighty-eight AIOA and 138 CON Jersey cows were enrolled in the study over 2 repetitions. Cows were randomly assigned to one of the treatments 5 wk before expected calving date. Cows were balanced for body condition score and those cows with locomotion score >2 were not included in the study. Displacements from the feed bunk were measured during 3 h on the day of move-in (d0) at 13:00 ± 1:00 and following fresh feed delivery (05:00 ± 1:00) on d 1, 2, 3 and 7 of each wk. Displacement rate was calculated as daily displacements divided by the number of cows in the pen to account for stocking density. Data were analyzed by Proc Mixed with day (week) as repeated measures. CON had greater number of displacements than AIAO (22.0 vs. 10.4; SE = 1.0; $P < 0.01$). Displacements during wk 1–5 were 12.7, 13.4, 13.4, 9.5 and 2.7 in AIAO and 32.3, 20.9, 23.1, 14.1 and 19.3 in CON, respectively (SE = 1.7; $P < 0.01$). There was a treatment by week interaction (SE = 2.3; $P < 0.01$). During wk 1, 2, 3 and 5 numbers of displacements were greater in CON than AIAO. Within AIAO, there were fewer displacements during wk 5 than wk 1–4. Within CON, wk 1 had greater displacements than wk 2–5. Displacement rate was greater in CON than AIAO (0.54 vs. 0.31; SE = 0.03; $P < 0.001$). Displacement rates in wk 1–5 were 0.29, 0.36, 0.37, 0.31 and 0.20 in AIAO and 0.78, 0.53, 0.58, 0.34, and 0.49 in CON, respectively (SE = 0.04; $P < 0.01$). There was a treatment by wk interaction (SE = 0.06; $P = 0.01$). During wk 1, 3 and 5, the CON treatment had greater displacement rate than AIAO in corresponding wk. Within AIAO, wk 5 tended to have a lower displacement rate than wk 2 ($P = 0.06$) and wk 3 ($P = 0.05$). In conclusion, AIAO resulted in fewer displacements and reduced displacement rate than CON.

Key Words: dairy behavior, dry cow, displacements

211 Individual differences in calf defense pattern in Red Angus beef cows. C. Flörcke,* T. E. Engle, T. Grandin, and M. J. Deesing, *Colorado State University, Fort Collins.*

Predation on livestock has increased causing difficulties in management of extensive beef systems. This study evaluates different calf defense patterns and maternal protectiveness within the first 24h past parturition. A total of 341 cow-calf pairs (95% Red Angus and 5% Angus x Hereford commercial crossbreds) were approached with an unfamiliar vehicle that performed circling movements, gradually decreased the distance between the vehicle and the cow-calf pair. Approach -, protective-, vocalization - and closest distance were collected with a digital range finder. Yes/No-classifications were made on calf defense patterns: protective behavior toward the calf (99.1% protective), aggressiveness of the cow toward the vehicle (13.2% aggressive), vocalization toward the calf (78% called calf) and flight behavior of cow and calf (no flight, walk and trot). Hair whorl pattern (HW) on the forehead of the animal was used as a measure of individual differences in temperament. HW pattern and age were collected when the animal was in a squeeze chute during routine handling. HW pattern was classified into: high, middle, low, abnormal, multiple HWs and no HW. Data analyses via ANOVA with Post-hoc Fisher's LSD Test showed a trend for the approach distance ($P = 0.057$). Post-hoc tests revealed that cows with a high HW ($P < 0.05$) or multiple HWs ($P < 0.05$) noticed the presence of the car at a further distance. Post-hoc tests for vocalization distance showed that cows with a high HW vocalized earlier (i. e. at a further distance; $P < 0.05$). The age of cows (3–6yrs) influenced protective behavior. Younger cows could be approached closer than older cows (3yrs vs. 5yrs of age: $P < 0.05$). When only high, middle and low HW pattern were analyzed approximately 50% of cows that trotted away performed aggressive movements (Chi^2 = 18.3, $P < 0.001$). Results suggest that individual differences in maternal protectiveness may be associated with HW pattern. The more vigilant a cow is toward her surrounding the more likely she will be able to detect danger for herself and her offspring.

Key Words: calf defense patterns, maternal protective behavior, temperament

212 Physiologic and behavioral responses of horses to shaded or unshaded pens in a hot, sunny environment. K. E. Holcomb*[1], C. L. Stull[1], and C. B. Tucker[2], [1]*University of California at Davis, School of Veterinary Medicine, Population Health & Reproduction, Davis,* [2]*University of California at Davis, Department of Animal Science, Davis.*

Housing recommendations for horses invariably include providing access to shade on hot, sunny days. The documented benefits of shade to livestock are assumed to apply to horses as well. However, this assumption has not been directly addressed and some owners do not believe horses require shade. This study measured physiologic and behavioral responses of individually-housed horses confined to completely shaded (S) or completely unshaded (NSh) dry-lot pens during the summer in Davis, CA. Twelve healthy adult horses in a crossover design experienced both treatments for 5 d each. The mean ambient temperature during observations (1200–1800 h) was 31.2°C in S and 31.9°C in NSh; relative humidity was 37.7% in S, 37.5% in NSh; black globe temperature was 33.4°C in S, 41.2°C in NSh; soil surface temperature was 30.6°C in S, 55.4°C in NSh. Rectal temperature (RT), respiration rate (RR) and skin temperatures (SK) were recorded hourly from 1230 to 1730 daily. RR was measured by observing flank movement. Behavior observations were recorded at 5-min intervals from 1200 to 1800 h daily to evaluate time spent walking, foraging, and standing near or away from water. Behavior and weather parameter data were averaged per hour for analysis. Data were analyzed using the Proc Mixed model in SAS, with horse as a random variable and ambient temperature as covariate, controlling for time of day. Results showed that RT was greater for NSh than for S (mean 37.8°C and 37.6°C respectively, SE 0.05, $P < 0.01$) as was true for RR (25.4 and 20.5 breaths per minute, SE 1.2, $P < 0.01$), and SK (35.7°C and 34.6°C, SE 0.1, $P < 0.01$). Horses in NSh spent more time than S standing near their water source (35.5% of observations versus 18.8%, SE 0.3, $P < 0.01$). There were treatment-by-time effects with larger treatment differences in RT and RR in mid-afternoon. Although RT and RR were within normal reference ranges, horses without access to shade showed significant physiologic and behavioral responses, suggesting the need to mitigate effects of the hot sun. These results can be used in developing and assessing standards of care for horses.

Key Words: horse, shade, welfare

213 Effect of a magnesium rich marine extract on behavior, salivary cortisol levels and skin lesions in growing pigs in response to mixing and an out of feed event. K. K. M. O'Driscoll*[1], D. Lemos Teixeira[3], D. O'Gorman[2], S. Taylor[2], and L. Boyle[3], [1]*Teagasc, Animal and Bioscience Research Department, Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, Ireland,* [2]*Celtic Sea Minerals, Currabinny, Carrigaline, Co. Cork, Ireland,* [3]*Teagasc, Pig Development Unit, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork, Ireland.*

The aim was to investigate if a magnesium rich marine extract (Acid-Buf) would improve pig welfare in response to mixing and an out-of-feed event. 448 weaned (d 28) piglets were assigned to Control (CL; Mg 0.16%) or Acid-Buf (AB; Mg 0.18%) diets in single sex groups of 14. Seven pigs/pen were mixed with 7 of the same sex and diet from another pen: CL male, AB male, CL female and AB female (n = 4 of each) at d 56. At mixing, aggressive behavior and no. pigs involved per bout was recorded for 3 h from video. Postural behavior was recorded at 10-min intervals. At d 112 feed was removed for 21 h. After re-introduction of the feed pens were observed continuously for 8 × 2-min periods and aggressive behavior was recorded. Skin lesions of 4 focal pigs/pen were scored on the day before, and after, mixing and the out of feed event. Saliva samples were collected on d 56 and d 113 (1 h before and 1, 3 and 8 h after mixing/feed delivery post deprivation) and at 10:00 on d 55, d 57 d 58, d 112 and d 114 by allowing the 4 focal pigs to chew on a cotton bud for 1 min. Cortisol was analyzed by ELISA. Data were analyzed in SAS (Proc Mixed). At mixing, aggressive interactions lasted longer in males than in females (16:55 vs. 34:27 mm:ss, SE 03:38; $P < 0.01$) and more CL than AB pigs were involved/bout (2.13 ± 0.39 vs. 2.08 ± 0.34; $P < 0.05$). There was no effect of diet or sex on skin lesion scores, but AB females had lower cortisol concentrations than CL (1.51 ± 0.12 vs. 1.91 ± 0.13 ng/mL; $P < 0.05$). During the out-of-feed event, neither sex nor diet affected salivary cortisol levels, but males were more aggressive than females (0.182 vs. 0.122 aggressive interactions/pig/min; SE 0.019; $P < 0.05$), and CL pigs had higher skin lesion scores than AB pigs (13.2 ± 1.1 vs. 10.0 ± 1.0; $P < 0.05$). Supplementation with magnesium had some beneficial effects on pig welfare.

Key Words: welfare, magnesium, behavior

214 Neophobic reactions to a new flavored feed are overriden by social learning in pigs. J. Figueroa,* D. Solà-Oriol, J. F. Pérez, and X. Manteca, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Social interactions help animals learn new features of their environment without a trial and error process. This could help to override aversion or neophobia of a particular ingredient or flavor after interacting with a conspecific that has just eaten these components. The aim of this experiment was to evaluate if observer piglets are able to prefer a flavored feed over their common (unflavored) feed by the effect of previous social interactions with models or demonstrators conspecifics. A total of 128 (49d old) weaned pigs, allocated in 16 pens (8 pig/pen), were used in this experiment. Half of animals (8 pens; G1) were exposed to a social learning process and the rest (8 pens; G2) acted as a negative control. In G1, 4 pigs/pen were randomly selected as observers and the rest acted as demonstrators. Demonstrator groups were temporarily moved to an empty pen where a flavored feed (anis (A) or garlic (G); 0.075%) were offered for 30 min. After that, demonstrator piglets were mixed again with the observer animals during 30 min. Flavors were counterbalanced across pens to act as the social flavor. After the interaction time, a double choice test between the flavored feed previously eaten by demonstrators (G1) and a control feed (known unflavored starter diet) was performed with the observer animals (G1) and with 4 animals from each control group. Feed intake was measured after 30 min. Data were analyzed using the GLM procedure of SAS®. Pigs showed higher intakes of the flavored feed in the social learning group (SLG) that in the control group (389 vs. 283g; $P < 0.05$). Higher intakes of socially learned flavored feed compared with the control feed (389 vs. 264g; $P < 0.01$) were observed in the SLG animals (G1). No feed intake differences were observed in the control group between the 2 feeds (283 vs. 325g for flavored and control feed). Social interactions with a conspecific animal that had a recent experience with a flavored feed enhanced the preference for that feed and could even override neophobia to new feed components.

Key Words: neophobia, social-learning, pigs

Animal Health II

215 The effect of yeast cell wall supplementation on the physiological and acute phase responses of crossbred heifers to endotoxin challenge. N. C. Burdick*[1], T. R. Young[2], J. A. Carroll[1], J. R. Corley[3], R. J. Rathmann[2], and B. J. Johnson[2], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [3]Lesaffre Feed Additives, Milwaukee, WI.*

This study examined the effect of feeding yeast cell wall (YCW) products on the physiological and acute phase responses (APR) of crossbred newly-received heifers to endotoxin (lipopolysaccharide; LPS) challenge. Heifers (n = 24; 219 ± 2 kg) were obtained from commercial sale barns and transported to the Texas Tech University Beef Center in New Deal, Texas. Heifers were separated into treatment groups receiving a Control Diet (C; n = 8), YCW A (2.5 $g{\cdot}hd^{-1}{\cdot}d^{-1}$; n = 8) or YCW C (2.5 $g{\cdot}hd^{-1}{\cdot}d^{-1}$; n = 8) and were group fed for 52d. On d36 heifers were fitted with vaginal temperature (VT) recording devices and jugular catheters and moved into a barn with individual stalls during which they were individually fed. On d37 heifers were challenged i.v. with LPS (0.5 μg/kg BW) and blood samples were collected every 0.5h from −2 to 8h and again at 24h relative to LPS challenge (0h). Sickness behavior scores (SBS) were assigned following collection of each blood sample. Serum was isolated and stored at −80°C until analyzed for cortisol, interleukin-6 (IL-6), interferon-γ (IFN-γ), and tumor necrosis factor-α (TNF-α). Data were analyzed using the Mixed procedure of SAS specific for repeated measures. There was an increase in VT in all treatments post-LPS ($P < 0.001$), with YCW C (38.90 ± 0.03°C) maintaining lower VT post-LPS than C (39.00 ± 0.3°C) and YCW A heifers (38.99 ± 0.03°C; $P < 0.01$). Post-LPS SBS increased but were not affected by treatment ($P = 0.54$). Cortisol was greatest in C (39.7 ± 1.5 ng/mL) heifers post-LPS than YCW A (31.3 ± 1.7 ng/mL) or YCW C heifers (32.0 ± 1.7 ng/mL; $P < 0.001$). Concentrations of IFN-γ and TNF-α increased post-LPS ($P < 0.001$) but were not affected by treatment ($P = 0.50$ and 0.35, respectively). Serum IL-6 increased post-LPS ($P < 0.001$) and were greater in C (351.5 ± 36.0 pg/mL) than YCW A (85.8 ± 42.9 pg/mL) and YCW C (136.2 ± 36.0 pg/mL; $P < 0.001$) heifers. These data indicate that YCW supplementation can decrease the physiological and APR of newly-received heifers to endotoxin challenge. Therefore, YCW supplementation may be a viable feed supplement for newly received heifers to reduce the negative effects of illness.

Key Words: cattle, immune, yeast

216 OmniGen-AF supplementation modulates the physiological and acute phase responses of Brahman heifers to an endotoxin challenge. N. C. Burdick*[1], J. A. Carroll[1], J. D. Chapman[2], T. H. Welsh Jr.[3], R. C. Vann[4], and R. D. Randel[5], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Prince Agri Products, Inc, Quincy, IL, [3]Texas AgriLife Research, Texas A&M System, College Station, [4]MAFES, Mississippi State University, Raymond, [5]Texas AgriLife Research, Texas A&M System, Overton.*

This study examined the effect of feeding OmniGen-AF (OG; Prince Agri Products) on the physiological and acute phase responses (APR) of heifers to an endotoxin (lipopolysaccharide; LPS) challenge. Brahman heifers (n = 24; 183 ± 5 kg) from the Texas AgriLife Research Center in Overton, TX were separated into 2 groups at weaning: 1) Control (C; n = 12) and 2) OG (n = 12; fed at 4 g per 45.4 kg BW) and fed for 69d. On d35 heifers were fitted with vaginal temperature (VT) monitoring devices, and were transported from Overton to New Deal, TX on d39. On d40, heifers were fitted with jugular catheters and moved into a barn with individual stalls. On d41 heifers were challenged with LPS (0.25 μg/kg BW i.v.) and blood samples were collected at 0.5h intervals from −2 to 8 h and again at 24h relative to LPS challenge (0h). Additional blood samples were collected every 2h and analyzed for white blood cell (WBC) counts. Sickness behavior scores (SBS) were assigned following collection of each sample. Serum was isolated and analyzed for cortisol, interleukin-6 (IL6), interferon-γ (IFNγ), and tumor necrosis factor-α (TNFα). Heifers were transported back to Overton on d43. Data were analyzed using the Mixed procedure of SAS specific for repeated measures. Post-LPS VT increased ($P < 0.01$) in all heifers, and was lower in OG (38.97 ± 0.01°C) than C heifers (39.03 ± 0.00°C; $P < 0.01$). Post-LPS SBS increased ($P < 0.01$) and were greater in OG (2.34 ± 0.02) than C heifers (2.16 ± 0.02; $P < 0.01$). Cortisol increased post LPS ($P < 0.01$) and were greater in OG (54.8 ± 1.1 ng/mL) than C heifers (48.4 ± 1.1 ng/mL; $P < 0.01$). Pre- and post-LPS WBC and lymphocytes (L) were greater in OG (WBC: 147 ± 4 and 82 ± 2 cells/μL; L: 90 ± 3 and 42 ± 2 cells/μL) than C heifers (WBC: 110 ± 4 and 63 ± 2 cells/μL; L: 68 ± 3 and 35 ± 1 cells/μL; $P < 0.01$). Total WBC, L, and neutrophils decreased 1 h post LPS ($P < 0.01$). Although post-LPS IFNγ, TNFα and IL6 increased ($P < 0.01$), there was no treatment effect ($P > 0.51$). These data suggest that OG-supplemented heifers were primed to produce a quicker APR to LPS challenge (lower VT, greater WBC counts), allowing for the heifers to recover quicker than C heifers.

Key Words: cattle, immune, OmniGen-AF

217 Yeast cell wall supplementation alters the performance and physiological response of beef heifers following an immune challenge. T. R. Young*[1], N. C. Burdick[2], J. A. Carroll[2], M. A. Jennings[1], J. T. Cribbs[1], R. J. Rathmann[1], J. R. Corley[3], and B. J. Johnson[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Lesaffre Feed Additives, Milwaukee, WI.*

A study was designed to determine the effect of feeding yeast cell wall (YCW) products on the performance and vaginal temperature response of crossbred heifers following a subcutaneous endotoxin (lipopolysaccharide; LPS) challenge. Heifers (n = 83; 225 ± 9.4 kg) were obtained from commercial sale barns and transported to the Texas Tech University Beef Center in New Deal, Texas, sorted by source (n = 2), and arranged in a completely randomized block design (21 pens; 7 pens/treatment; 4 heifers/pen). Heifers were separated into treatment groups receiving a Control Diet (CON; n = 28), YCW A (2.5 $g{\cdot}hd^{-1}{\cdot}d^{-1}$; n = 28), or YCW C (2.5 $g{\cdot}hd^{-1}{\cdot}d^{-1}$; n = 27). On d 56 heifers were fitted with indwelling vaginal temperature (VT) recording devices. Heifers were then challenged subcutaneously with LPS (0.5 μg/kg BW) on d 63. Daily DMI was recorded and individual BW was collected on d 63 and d 77. In Source 1, YCW C exhibited greater ADG ($P < 0.01$) and G:F ($P = 0.01$) compared with CON. There was an increase in VT in all treatments post-LPS ($P < 0.01$), with YCW C (39.14 ± 0.01°C) maintaining greater VT post-LPS than CON (38.89 ± 0.01°C) and YCW A (38.92 ± 0.01°C; $P < 0.05$). In Source 2, no significant differences in performance were observed. There was an increase in VT in all treatments post-LPS ($P < 0.01$), with YCW C (38.91 ± 0.02°C) maintaining greater VT post-LPS than CON (38.83 ± 0.02°C) and YCW A (38.83 ± 0.02°C; $P < 0.05$). Ambient temperature was extremely high during this study (greater than 45°C at certain times), indicating a period of high heat stress. Collectively these data suggest that YCW supplementation can affect the physiological response to a mild endotoxin challenge during high heat stress and thereby alter feedlot performance of newly received beef heifers.

Key Words: cattle, immune, yeast

218 A description of dairy heifer raising operations in the United States.

J. E. Lombard,* C. A. Kopral, J. M. Rodriguez, B. A. Wagner, and G. W. Hill, *USDA-APHIS-VS-CEAH, National Animal Health Monitoring System, Fort Collins, CO.*

The National Animal Health Monitoring System conducted the first national study of dairy heifer raising operations in 2011. Twenty-one states participated in the study. Operations were identified via multiple methods including previous interaction with state or federal animal health officials, Dairy Calf and Heifer Association membership list, and via word of mouth. Operations had to raise at least 20 dairy heifer calves in 2010 for at least one operation other than their own to be eligible for the study. The response rate was 60% with 228 operations completing the questionnaire. Operations were classified as small (20–99 heifers), medium (100–999 heifers), and large (1000 or more heifers). One objective of this study was to describe management practices on these specialized operations. Approximately 85% of operations sourced dairy heifers directly from other dairy operations and the median number of sources was 2. One third of operations (34.2%) reported obtaining primarily preweaned heifers while almost 2-thirds obtained primarily weaned heifers (60.1%) and 5.7% obtained primarily pregnant heifers. The majority of heifers left the heifer-raising operation as pregnant heifers (78.5%) while 21.5% left the operation as weaned heifers. The majority of operations raising preweaned heifers fed only medicated milk replacer (59.2%) while 32.1% fed only milk. Almost 80% of operations housing preweaned heifers reported cleaning and disinfecting or rinsing feeding equipment with water between every feeding. For operations housing weaned and pregnant heifers, more than 70% fed ionophores in the feed. A higher percentage of larger operations used consultants to the operation such as veterinarians, nutritionists, university/extension personnel and state or federal animal health officials. More than twice as many large and medium operations as small operations reported keeping written or computerized records of dairy heifer growth and/or health information (86.6, 73.1 and 32.1% respectively). Heifer raising operation practices are important in understanding the overall impact of this segment of the dairy industry.

Key Words: heifer-raising, milk replacer, record-keeping

219 Biosecurity practices on dairy heifer raising operations in the United States.

J. E. Lombard,* C. A. Kopral, J. M. Rodriguez, B. A. Wagner, and G. W. Hill, *USDA-APHIS-VS-CEAH, National Animal Health Monitoring System, Fort Collins, CO.*

The National Animal Health Monitoring System conducted the first national study of dairy heifer raising operations in 2011. Twenty-one states participated in the study. Operations were identified via multiple methods including previous interaction with state or federal animal health officials, Dairy Calf and Heifer Association membership list, and via word of mouth. Operations had to raise at least 20 dairy heifer calves in 2010 for at least one operation other than their own to be eligible for the study. The response rate was 60% with 228 operations completing the questionnaire. Operations were classified as small (20–99 heifers), medium (100–999 heifers), and large (1000 or more heifers). One objective of this study was to describe biosecurity practices with special emphasis on the potential transmission of *Mycobacterium bovis* (bovine TB) on these operations. More than 75% of operations obtained dairy heifers from more than one source. Although dairy operations were the primary source of heifers (84.2% of operations), between 10 and 20% of operations obtained heifers from auction markets/salebarns, other heifer raising operations, or from private sales (cattle dealers). A lower percentage of small operations reported testing for any disease (22.8%) and specifically for TB (16.1%) before or at arrival at the raising operations compared with large operations (68.7 and 42.4%, respectively). Almost 70% of operations allowed heifers contact with cattle from other operations. Almost 30% of operations housed dairy-beef or beef cattle in addition to dairy heifers during 2010. No Small operations pasteurized milk fed to heifers, however the primary source of milk was from a single operation. Large operations primarily fed pooled milk from multiple sources but the majority fed pasteurized milk thus reducing the risk associated with feeding pooled milk. Almost 20% of operations reported not vaccinating for any disease in 2010. Heifer raising operations are a potential source for disease transmission due to the commingling of cattle from multiple sources, including beef cattle and the feeding of pooled milk.

Key Words: heifer-raising, biosecurity

220 Pre- and postpartum immunomodulatory effects of a dietary supplement on the immune system of dairy heifers.

V. J. Eubanks*[1], D. J. Hurley[1], L. O. Ely[1], F. M. Kautz[1], S. C. Nickerson[1], N. E. Forsberg[2], Y. Q. Wang[2], K. P. Zanzalari[3], and J. D. Chapman[3], [1]*University of Georgia, Athens,* [2]*OmniGen Research LLC, Corvallis, OR,* [3]*Prince Agri Products Inc., Quincy, IL.*

The purpose of this study was to evaluate the effect of a dietary supplement (OmniGen-AF) on amplifying heifers' immune response to *Staphylococcus aureus* vaccination. Treated heifers (n = 40) receiving the supplement and unsupplemented controls (n = 43) in 8 age groups were monitored during gestation and into early lactation. For the prepartum parameters measured, there were no differences in body weight, hip height, prevalence of IMI, SCC, or differential mammary secretion leukocyte counts between treated and control heifers. Overall prevalence of IMI was 86% of heifers, with *S. aureus* as the most prevalent pathogen (62.1% of heifers, 25.3% of quarters). Front mammary quarters were 4.5 times more likely ($P \leq 0.001$) to be infected with *S. aureus* than rear quarters. Mean SCC of quarters with *S. aureus* IMI was $3,337 \times 10^3$/mL, while SCC in uninfected quarters averaged $1,846 \times 10^3$/mL. Regardless of infection status, macrophages predominated in mammary secretions followed by neutrophils and lymphocytes. L-selectin mRNA expression of blood leukocytes from group 1 treated heifers was greater ($P \leq 0.04$) than controls, indicating greater leukocyte activity. Additionally, L-selectin mRNA expression in group 2 treated heifers was greater ($P \leq 0.001$) than controls. Interleukin-8 receptor mRNA expression was generally higher in groups 1 and 2 treated heifers but not significantly different from controls. For the postpartum parameters measured, results showed that treated animals exhibited lower SCC than controls (180 vs. 711×10^3/mL) and lower prevalence of mastitis (4% vs. 13%). At 14 d postpartum, treated animals produced a mean of 25.9 kg/d compared with controls producing 21.8 kg/d. Overall, results demonstrated that dietary supplementation with OmniGen-AF improved udder health and milk quality postpartum, resulting in greater milk yield in early lactation.

Key Words: mammary immunity, mastitis, *Staphylococcus aureus*

221 Indoor group housing does not influence performance or measures of innate immune activity of Holstein calves during the neonatal, weaning, and commingling periods. C. J. Cobb,* D. L. Hanson, M. D. Sellers, A. R. Pepper-Yowell, B. S. Obeidat, and M. A. Ballou, *Texas Tech University, Lubbock.*

Objective was to determine if group housing of Holstein calves in indoor pens affects metabolic and innate immunological responses when compared with individually housed calves. Seventy-two calves (2 ± 1 d old) were randomly assigned to 3 treatments: individually housed (G1, n = 29), 2 calves/pen (G2, n = 22), or 3 calves/pen (G3, n = 21). Space allowances per calf were 2.5 m^2. All calves received an identical high plane of milk replacer nutrition. Weaning was initiated during the 7th week by removing the PM feeding and calves were completely weaned when they consumed 800 g dry matter (DM) calf starter after d 53. At d 91, calves were randomly commingled in groups of 5 calves outdoors. Peripheral blood was collected during the neonatal (3, 10, 21 d), weaning (45, 47, 53 d), and commingling periods (91, 94, 99 d) and was analyzed for neutrophil oxidative burst (OB) capacity when cocultured with an *Escherichia coli*, neutrophil L-selectin expression, whole blood secretion of tumor necrosis factor-α (TNF) when cocultured with lipopolysaccharide. Total DM intake was greater ($P < 0.05$) for G2 and G3 during wk 8 and 9 and also at wk 11 for G3 compared with G1. There were no treatment or treatment x time interactions in average daily gain (ADG; $P = 0.589$). Additionally, there were no treatment or treatment x time effects ($P > 0.185$) on any immunological or biochemical variable throughout the entire study. However, during the neonatal period, there were time effects with an increase ($P < 0.05$) in both TNF and neutrophil L-selectin expression with a concomitant decrease ($P < 0.05$) in OB intensity. During weaning, both neutrophil L-selectin expression and OB intensity increased ($P < 0.05$) on d 47 and returned to baseline or below by d 53 ($P > 0.232$). In contrast, commingling decreased ($P < 0.05$) both neutrophil L-selectin expression and OB intensity on d 94. Although group housing increased post-weaning DM intake, it did not influence ADG or any biochemical or immunological measurement throughout neonatal, weaning, or commingling periods.

Key Words: calf, housing, immune

222 Feed intake, rectal temperature and weight gain in *Bos indicus* crossbred steers challenged with bovine viral diarrhea virus. C. A. Runyan*[1], X. Fang[1], E. Downey[1], T. B. Hairgrove[3], J. E. Sawyer[2], J. C. Bailey[1], J. F. Ridpath[4], and A. D. Herring[1], *[1]Texas A&M University, College Station, [2]Texas Agrilife Research, College Station, [3]Texas Agrilife Extension, College Station, [4]USDA-ARS, Ames, IA.*

Yearling, Angus-Nelore half-blood steers (n = 104) born in the spring of 2010 were evaluated for rectal temperature, feed intake and weight gain following vaccination for Bovine Respiratory Disease (BRD) and intranasal challenge with Bovine Viral Diarrhea Virus (BVDV). Steers were tested to be free of BVD persistent infection and stratified by sire across 3 vaccine treatments: killed vaccine (KV; n = 34), modified live vaccine (MLV; n = 35), non-vaccinated group (NON; n = 35). KV steers were administered vaccine at d −49 and d −25. MLV steers received a single vaccine injection at d −25. At d 0, all steers were challenged intranasally with BVDV Type 1b strain CA0401186a. Animals were monitored daily for clinical symptoms of BRD/BVD; weights and rectal temperatures were collected at d 0, 3, 7, 10, 14, 28, and 42. Daily feed intake (DFI) was collected via a 4-pen Growsafe system. A threshold rectal temperature over 40°C was used to classify animals for temperature status during 14 d post-challenge. Mixed model, repeated measures procedures to analyze DFI included models with fixed effects of vaccine treatment (VAC), pen, day, sire, rectal temperature status (RTEMP), and 2-factor interactions. ADG was calculated for the 3–14 d periods following challenge with similar fixed effects plus d-0 weight as a covariate. No steers exhibited visual symptoms that would have led to a morbid classification; however, many had RTEMP over 40°C on evaluation days, including d 0 before challenge and on d 28 and 42; as a result RTEMP alone is likely not an ideal indicator of health status in these data. Also pen and several 2-factor interactions involving pen were important ($P < 0.05$) sources of variation. There was an interaction of RTEMP status and d ($P < 0.01$) where in general, steers exhibiting over 40°C during d 3 to 14 had DFI depressed 0.2 to 0.6 kg/d from d 3 to 10 but appeared to compensate after d 14. A pattern existed in DFI where NON steers consistently ranked lower than KV and MLV steers for d 6–11. No differences in ADG were attributed to VAC or RTEMP status.

Key Words: BVD, feed intake, *Bos indicus* crosses

223 Correlations of temperament with titer and hematological responses of crossbred steers challenged with bovine viral diarrhea virus. X. Fang*[1], E. Downey[1], C. A. Runyan[1], J. E. Sawyer[4], T.B. Hairgrove[2], J. F. Ridpath[3], C. A. Gill[1], W. Mwangi[1], and A. D. Herring[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Extension, College Station, [3]USDA-ARS, Ames, IA, [4]Texas AgriLife Research, College Station.*

Angus-Nelore F_2 and F_3 yearling steers born in 2009 (n = 78) and 2010 (n = 104) were administered bovine respiratory disease vaccine treatments of killed (2009 n = 28, 2010 n = 32), modified live (MLV) (2009 n = 25, 2010 n = 36) or no (NON) vaccine (2009 n = 25, 2010 n = 36) and stratified by breed composition and sire across vaccine treatment. Temperament scores of steers were evaluated shortly after weaning (8 mo age) on a 1–9 scale by 4 evaluators. After vaccination (25 to 35 d), steers were challenged intranasally with a Type 1b bovine viral diarrhea virus (BVDV). Serum samples for antibody titer of BVDV (Types 1a, 1b and 2) were collected on vaccination days, BVDV challenge day (d 0), and 14, 28, and 42 d after challenge. Whole-blood samples for hematological counts were collected on d 0, 14, 28, and 42. Pearson correlations of temperament score and titer and hematological measures were evaluated. Mean temperament scores were 4.2 in 2009-born steers and 5.9 in 2010-born steers. Several correlations ($P < 0.05$) between temperament score and the titer of BVDV (type 1a, b and 2), lymphocyte (LYM), neutrophil (NEU) and platelet (PLT) counts were found. On d 0 temperament had correlation from −0.20 to −0.24 with BVDV titers. On d 14, these values were reduced (r of −0.15 to −0.20), and became non-significant at d 28 and 42. LYM, NEU and PLT counts at d 0 were not correlated to temperament. Correlation of temperament and LYM at d 14 was similar to correlation of temperament and BVDV titers at d 14. NEU counts were not related to temperament except at d 28 and 42 (r of −0.19 and −0.20, respectively); PLT counts had similar magnitude of relationship with temperament ($P < 0.05$) for d 14, 28 and 42, but were positive (r of 0.17 to 0.20). When mixed model analyses of titer and hematological measures incorporated the regression on weaning temperament score, it became non-significant as the large individual variability overshadowed the temperament influence. The relationships involving animal temperament and immune response warrant further investigation, particularly in *Bos indicus* crosses.

Key Words: BVDV, temperament, immune response

224 *Cis*-9, *trans*-11 conjugated linoleic acid and NF-κB inhibitor pyrrolidine dithiocarbamate decrease prostaglandin production by bovine endometrial cells treated with lipopolysaccharide.

L. Badinga,* M. S. Gulay, and A. D. Ealy, *University of Florida, Gainesville.*

Uterine bacterial infection or bacterial products suppress pituitary luteinizing hormone (LH) secretion, and are associated with inhibition of folliculogenesis, decreased ovarian steroidogenesis and abnormal luteal phase. To evaluate whether supplemental fatty acids (FA) may attenuate some of the deleterious effects of lipopolysaccharide (LPS) in cattle, we examined the effects of conjugated linoleic acid isomers (100 µM of cis-9, trans-11 and trans-10, cis-12 CLA) on in vitro prostaglandin E2 (PGE2) and F2α (PGF2α) production by bovine endometrial (BEND) cells treated with LPS. The specificity of CLA effects on endometrial PG production was evaluated by using linoleic acid (LA; C18:2) as the control FA. LPS stimulated both PGE2 and PGF2α productions in a dose and time-dependent manner. At 24 h, the concentration of PGE2 in the incubation medium was much higher than that of PGF2α (average ratio of PGE2 / PGF2α = 16.5; $P < 0.01$). The concentration of PGE2 in cell-conditioned media increased ($P < 0.01$) from 2.5 ± 2.0 to 17.4 ± 2.0 ng/mL as the concentration of LPS in the culture medium increased from 0 to 10 µg / mL. Similarly, PGF2α response to LPS increased from 0.2 ± 0.1 to 2.3 ± 0.1 ng / mL as the amount of LPS in the culture medium was raised from 0 to 10 µg / mL. With regard to time effects, the concentration of PGE2 in the culture medium increased ($P < 0.01$) from 0.4 ± 0.2 ng / mL at 3 h to 5.0 ± 0.2 ng / mL at 24 h. Corresponding values for PGF2α were 0.2 ± 0.05 ng / mL at 3 h and 1.0 ± 0.05 ng / mL at 24 h. Addition of FA to the incubation medium decreased ($P < 0.01$) PGE2 response to LPS by 75.6%. The cis-9, trans-11 (c-9, t-11) CLA isomer was more effective (85.1% reduction) than t-10, c-12 CLA (63% reduction) and LA (78% reduction) at decreasing PGE2 concentration. The c-9, t-11 CLA, t-10, c-12 CLA and LA decreased ($P < 0.01$) PGF2α response to LPS by 80%, 40%, and 10%, respectively. Co-incubation with the c-9, t-11 CLA and NF-κB inhibitor pyrrolidine dithiocarbamate decreased PGE2 response to a greater extent than did the CLA or NF-κB inhibitor alone. Results indicate that selective FA and the NF-κB inhibitor are potent inhibitors of LPS effects on endometrial PG secretion. If repeated in vivo, strategic supplementation of CLA may constitute a producer-friendly means of attenuating deleterious effects of the *E. coli* endotoxin in cattle.

Key Words: CLA, prostaglandin, cattle

225 Peripartum metabolic, immune, and hematological parameters of Jersey cows diagnosed with periparturient diseases.

P. R. B. Silva*[1,2], J. G. N. Moraes[1,2], L. G. D. Mendonça[1], G. Nakagawa[1], and R. C. Chebel[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, St Paul,* [2]*Department of Animal Science, University of Minnesota, St Paul.*

Objectives were to evaluate the metabolic, immune, and hematological parameters of Jersey cows diagnosed with postpartum diseases. Blood was sampled weekly from d −21 to 21 (calving = d0) for NEFA concentration (n = 567) and weekly from d −14 to 14 from a subgroup of cows (n = 68) for neutrophil phagocytosis (PHAGO), oxidative burst (OXID), and expression of CD18 and L-selectin, hemogram, and glucose concentration. Cows were examined on d1 for retained fetal membranes (RFM) and on d4, 7, 10, and 14 for metritis (METR) and were observed daily for displacement of abomasum (DA). Data were analyzed by MIXED procedure with disease as the fixed effect (yes vs no) and cow as the random effect. Receiver operator characteristics analyses were used to determine NEFA concentrations that most accurately predicted disease. Interaction of RFM by day and METR by day were ($P < 0.05$) associated with OXID and PHAGO because RFM cows and METR cows had reduced OXID and PHAGO on d0 than normal cows. Interaction of RFM by day tended ($P = 0.08$) to be associated with CD18 expression intensity as RFM cows had higher intensity on d14 than normal cows. Greater percentage of neutrophils from RFM ($P = 0.03$) and METR ($P < 0.01$) cows expressed L-selectin than normal cows. Interaction of RFM by day and METR by day were ($P < 0.04$) associated with leukocyte count because leukocyte count was highest on d0 in normal cows but leukocyte count was highest from d-14 to 0 in RFM and METR cows. Interaction of METR by day tended ($P = 0.08$) to be associated with neutrophil count because only normal cows had increase neutrophil on d0. Interaction of RFM by day was ($P < 0.01$) associated with glucose because on d-7 and 7 RFM cows had greater glucose than normal cows. Interaction METR by day was associated with glucose ($P = 0.02$) and NEFA ($P < 0.01$) concentration because METR cows had greater glucose pre and postpartum and greater NEFA on d −14, 0, and 7 than normal cows. Interaction of DA and day was ($P = 0.03$) associated with NEFA because DA cows had greater NEFA on d −7, 0, 7, and 21 than normal cows. NEFA >0.18 mmol/l on d-7 predicted DA with 66.7% sensitivity and 76.4% specificity and NEFA >0.43 mmol/l on d0 predicted metritis with 46.2% sensitivity and 74.1% specificity. Immune, metabolic, and hematological alterations peripartum were associated with postpartum diseases.

Key Words: prepartum dairy cow, immune parameter, metabolic parameter

Breeding and Genetics: Dairy Cattle Breeding I: Genetic Improvement of Animal Health

226 Genomics of functional traits in dairy cattle. N. Vukasinovic*[1], Y. Li[2], J. D. Nkrumah[1], P. Boddhireddy[1], J. Osterstock[1], F. A. Di Croce[1], M. Kelly[2], M. Hvinden[1], D. J. Weigel[3], and S. K. DeNise[1], *[1]Pfizer Animal Genetics, Kalamazoo, MI, [2]Pfizer Animal Genetics, Brisbane, Australia, [3]Pfizer Animal Health, Kalamazoo, MI.*

Functional traits in dairy cows include fertility, health, longevity, and other traits that affect efficiency of dairy operations by decreasing input rather than increasing output. Genetic improvement of functional traits is challenging because of low heritabilities and difficulties related to phenotype recording. Application of genomics-assisted selection seems to be promising for functional traits. In the scope of this study, genomic predictions for several traits describing various aspects of mastitis, reproduction, and postpartum metabolic disorders were developed using a 50K SNP panel. The reference population included over 4,500 Holstein cows sampled from 9 large commercial herds located in 5 different states in the US. The animals had complete pedigree and extensive phenotype information for the traits of interest. The validation population included about 1,200 Holstein cows from an independent herd. The phenotypes of all animals, along with the pedigree consisting of 14,685 individuals, were used to obtain estimated breeding values (EBVs) for the traits of interest. The EBVs of the reference animals, weighted by their accuracies, were used in the genomic analyses to derive marker effects. The estimated marker effects were then used to obtain direct genomic values (DGVs) for the validation animals. The accuracy of DGVs was assessed by calculating correlations between originally estimated EBVs and DGVs. Preliminary results show that genomic information can be used to predict genetic potential of animals for functional traits.

Key Words: dairy cows, functional traits, genomics

227 Genomic selection for enhanced immune response to improve dairy health. K. Thompson-Crispi*[1], R. Ventura[2,3], F. Schenkel[2], F. Miglior[4,5], and B. Mallard[1], *[1]Department of Pathobiology, Ontario Veterinary College, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [3]Beef Improvement Opportunities, Guelph, ON, Canada, [4]Guelph Food Research Center, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [5]Canadian Dairy Network, Guelph, ON, Canada.*

Infectious diseases contribute to substantial economic loss in the dairy industry with human and animal health implications. The immune system is a tightly genetically regulated system that largely controls response to infectious disease. Including immune response (IR) traits in a selection index has the potential to improve inherent animal health. Previously, cows classified as High Immune Responders in dairy herds across Canada and one herd in the US were found to have improved response to commercial vaccination, increased milk and colostrum quality and decreased incidence of diseases including mastitis, metritis, ketosis and retained placenta. The objective of this research was to perform a genome-wide association study to determine genetic profiles associated with antibody-mediated immune responses (AMIR). In collaboration with the Canadian Bovine Mastitis Research Network, 680 Holstein cows from 58 herds across Canada were immunized to measure serum antibody to a putative type 2 test antigen. Cows were classified as High, Average and Low immune responders based on EBV for AMIR. A total of 163 cows (81 High IR and 82 Low IR) were genotyped using the Illumina Bovine SNP50 BeadChip. A generalized quasi-likelihood score method was used to determine SNPs significantly associated with AMIR. Preliminary results show 484 SNPs significantly (comparison-wise $P < 0.001$) associated with AMIR. The majority of the SNPs are on chromosome 23 (98/484) followed by chromosome 9 (32/484), 1 (31/484) and 11 (30/484). Determining potential genes and biological pathways associated with these SNPs is currently underway. Results of this study will help to determine if AMIR could potentially be included in genomic selection indices to decrease the incidence and severity of disease in the dairy industry.

Key Words: dairy cattle, genomic selection, immune response

228 Telomere length assessment of Holstein cows in 10 Pennsylvania dairy herds. D. E. Brown,* C. D. Dechow, W. S. Liu, and K. J. Harvatine, *The Pennsylvania State University, University Park.*

Telomeres are known to shorten in humans with increasing age due to the inability of cells to completely replicate chromosomal DNA. Additionally, stress factors in humans are generally associated with a decrease in telomere length. The objective of this study was to assess telomere length variation in dairy cattle using a quantitative PCR (QPCR) procedure and determine if telomere length varied among herds and with age. DNA samples were obtained from purebred Holstein dairy cows from 10 dairy herds. A monochrome multiplex QPCR method was used to quantify relative telomere length for each cow. Primers were designed to create a 79 base pair telomere product and a 144 base pair standard reference gene product with each amplicon having different melting temperatures. Both primer sets were used in the same QPCR reaction well. This allowed independent measurement of amplification, while decreasing variation due to pipetting error and minimized experimental costs. QPCR results for 201 cows, which were run in triplicate, were analyzed using ASREML. Fixed effects of the model included gene, plate, cow, age, herd, the interaction of gene and plate, the interaction of age and gene, and the interaction of gene and herd. Random effects included the interaction of cow and gene, interaction of cow and plate, and the 3-way interaction of cow, plate, and gene. The effect of herd was significant for telomere length ($P < 0.001$). The effect of cow age was significant ($P < 0.05$), with telomere length decreasing as age increased. Least squares means for herd telomere length were positively correlated with rolling herd average milk production ($P < 0.05$). Herd environment appeared to be associated with a physiological response in the telomere length of dairy cattle. However, higher milk production did not appear to elicit a negative effect on telomere length. Telomere assessment may provide a quantifiable measure for future cattle welfare studies.

Key Words: telomere, telomere length, stress

229 Incidence validation and causal relationship analysis of producer-recorded health event data from on-farm computer systems in the United States. K. L. Parker Gaddis*[1], J. P. Cassady[1], J. B. Cole[2], and C. Maltecca[1], *[1]North Carolina State University, Raleigh, [2]Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

Substantial progress has been made in the genetic improvement of production traits in dairy cattle. Due to a negative correlation between production and fitness traits, the health and fitness of dairy cattle have declined as yields have increased. Health and fitness traits are generally difficult and/or expensive to measure, but health event data collected from on-farm computer management systems may provide an effective and low-cost source of health event information. The principle objective of this study was to analyze the reliability of health event data recorded with on-farm recording systems throughout the United States. To validate editing methods, incidence rates of on-farm recorded health event data were compared with incidence rates reported in the literature. A second aim of this study was to examine putative causal relationships among common health events using data recorded in on-farm computer systems. Calculated incidence rates ranged from 1.4% for respiratory problems to 8% for clinical mastitis. Most health events reported had incidence rates lower than the average incidence rate found in literature. This may represent under-reporting by dairy farmers who record disease events only when a treatment or other intervention is required. Logistic regression was used to examine putative causal relationships among health events within a lactation for 3 timeframes: 0 to 60 d in milk (DIM), 61 to 90 DIM, and 91 to 150 DIM. Herd, season, parity, breed, and year were included in each model as fixed effects. Health events occurring on average before the health event of interest were included in the model as predictors when significant ($P < 0.05$). Path diagrams developed using odds ratios calculated from logistic regression models for each of 13 common health events allowed putative relationships to be examined. The greatest odds ratios were estimated to be the influence of ketosis on displaced abomasum (15.5) and the influence of retained placenta on metritis (8.37), and were consistent with earlier reports. The results of this analysis provide evidence for the usefulness of on-farm recorded health information.

Key Words: dairy, health, path analysis

230 Genetic relationships of mastitis, cystic ovaries and lameness with milk yield and somatic cell score in first-lactation Canadian Holstein cows.

A. Koeck*[1], F. Miglior[2,3], S. Loker[1], D. F. Kelton[4], A. Sewalem[2,3], and F. S. Schenkel[1], *[1]Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada, [2]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [3]Canadian Dairy Network, Guelph, ON, Canada, [4]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to investigate the genetic relationships of the 3 most frequent dairy cattle diseases (mastitis, cystic ovaries and lameness) with test-day milk yield (MY) and somatic cell score (SCS) in first lactation Canadian Holstein cows using random regression models. Health data recorded by producers were available from the National Dairy Cattle Health System in Canada. Disease traits were defined as binary traits (1 = affected, 0 = unaffected) based on whether or not the cow had at least one disease case recorded within 305 d after calving. Random regressions on second order Legendre polynomials were used to model the daily genetic and permanent environmental variances of test-day MY and SCS, while only the intercept term was fitted for disease traits. Genetic correlations between MY and diseases were unfavorable with estimates ranging from 0.21 to 0.42 between MY and mastitis, from −0.05 to 0.29 between MY and cystic ovaries, and from 0.23 to 0.36 between MY and lameness. In contrast, favorable associations were found between SCS and diseases. Genetic correlations varied from 0.64 to 0.71 between SCS and mastitis, from 0.10 to 0.22 between SCS and cystic ovaries, and from 0.19 to 0.29 between SCS and lameness. Unfavorable associations between MY and diseases imply that production and health traits should be considered simultaneously in genetic selection.

Key Words: genetic correlation, disease, milk yield and somatic cell score

231 Genetic relationships among health related fatty acids in milk of Canadian Holsteins.

G. Bilal,* R. I. Cue, A. F. Mustafa, and J. F. Hayes, *McGill University, Macdonald Campus, Ste-Anne de Bellevue, Quebec, Canada.*

The objective of the present study was to estimate heritabilities of and genetic correlations among fatty acids in milk of Canadian Holsteins. The fatty acids studied were chosen because they are important in human health. One morning milk sample was collected from 3185 dairy cows between February and June 2010 from 52 commercial herds enrolled in Dairy Production Centre of Expertise, Valacta. Individual fatty acid percentages (g/100g of total fatty acids) were determined for each sample by gas chromatography. Edits were applied to the database on registration status of the cow, breed, country, cow and sire and dam identifications, age at calving and stage of lactation. Cows were sampled between 3 to 450 d in milk and were in either parity 1, 2 or 3. Herd-year-season of calving classes were formed considering 2 season effects in a year; that is, March 1 to August 31 and September 1 to February 28/29. Each herd-year-season of calving class was required to have 5 or more observations. Editing reduced the data set to 2573 cows representing 46 herds. Ten fatty acids were studied and included 3 omega-3 fatty acids (C18–3n3ALA, C20:5n3, C22:5n3), 2 conjugated linoleic acids (CLA-9c11t, CLA-10t12c), 2 omega-6 fatty acids (C20:3n6, C20:4n6), C22:0, C23:0 and C24:0. Genetic parameters were estimated using a 10-trait animal model fitted under REML using Wombat software. The model included fixed effects of age at calving and stage of lactation nested within parity; random effects of herd-year-season of calving, animal and residual. The pedigree of animals with data was traced back 5 generations on both the male and female side to account for relationships among animals. The estimates of heritability ranged from 0.01 to 0.21 with standard errors ranging from 0.01 to 0.04. Genetic correlations among fatty acids ranged from 0.74 to −0.72 with standard errors ranging from 0.1 to 0.5. Improvement of the fatty acid proportions in milk through genetic selection is possible as individual fatty acids can respond differently.

Key Words: cow milk fatty acids, health, genetic parameters

232 Crossbreds of Holstein with Jersey and Montbéliarde compared to pure Holsteins for 305-d production and mastitis in a pasture production system.

B. J. Heins,* L. B. Hansen, A. R. Hazel, J. C. Becker, and E. A. Bjorklund, *University of Minnesota, St. Paul.*

Montbéliarde × Holstein crossbred cows (MH, n = 30); Montbéliarde × Jersey × Holstein crossbred cows (MJH, n = 49); Jersey × Montbéliarde × Holstein crossbred cows (JMH, n = 32); Holstein × Montbéliarde × Jersey × Holstein cows (HMJH, n = 47); and Holstein × Jersey × Montbéliarde × Holstein crossbred cows (HJMH, n = 10) were compared with pure Holstein cows (HO; n = 114) for 305-d milk, fat, and protein production; SCS; and mastitis incidence during their first 3 lactations. Cows were housed at the University of Minnesota West Central Research and Outreach Center, Morris, Minnesota, a grazing herd, and calved from March 2006 to June 2011. Best Prediction was used to calculate actual production (milk, fat, protein, and SCS) for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. Incidence of clinical mastitis was recorded in a binary manner as treated (1) or not treated (0) during a lactation. Independent variables for statistical analysis were the fixed effects of year-season of calving (6-mo seasons), crossbred group (2-breed, 3-breed, or 4th generation crossbred), breed group nested within crossbred group, parity nested within breed group and crossbred group, and random cow within breed group. Across the first 3 lactations, pure HO cows had significantly ($P < 0.01$) higher milk (7,766 kg) production than JMH (6,790 kg) cows, but were not significantly ($P > 0.05$) different than MH (8,054 kg), MJH (7,562 kg), HMJH (8,041 kg) and HJMH (7,230 kg) cows for milk production. The MH (520 kg), MJH (511 kg), JMH (476 kg), and HJMH (499 kg) cows were not significantly ($P > 0.05$) different from pure HO (499 kg) cows for fat plus protein production during the first 3 lactations; however, the HMJH (526) cows had significantly ($P < 0.05$) greater fat plus protein production than pure HO cows. The crossbred cows were not significantly ($P > 0.05$) different from pure HO cows for SCS during the first 3 lactations. The MH (37.9%), MJH (26.3%), and HJMH (23.7%) cows had significantly ($P < 0.05$) less clinical mastitis than pure HO (56.4%) cows during the first 3 lactations.

Key Words: crossbreeding, mastitis, pasture

233 An update: Responses of production and mastitis to selection for milk yield with a control population in a pasture production system.

B. J. Heins,* *University of Minnesota, West Central Research and Outreach Center, Morris.*

The University of Minnesota initiated a designed study of yield selection in 1964 that included an unselected control group of cows. The study continues at the West Central Research and Outreach Center (WCROC), Morris, Minnesota, and is currently part of the low-input sustainable and organic grazing dairy project. At time of dispersal from the Southern Research and Outreach Center, Waseca, in 2003, rolling herd averages were control line (5,964 kg milk, 221 kg fat, 179 kg protein, 3.3 SCS) and selection line (10,099 kg milk, 384 kg fat, 303 kg protein, 2.0 SCS). The control line of cows has not been evaluated in a pasture-based dairy production system. Therefore, control Holstein cows (n = 118) were compared with contemporary Holstein cows (n = 267) for 305-d milk, fat, and protein production; SCS; and mastitis incidence during their first 5 lactations. Cows were housed at the WCROC, a grazing herd, and calved from January 2003 to May 2011. Best Prediction was used to calculate actual production (milk, fat, protein, and SCS) for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. Incidence of clinical mastitis was recorded in a binary manner as treated (1) or not treated (0) during a lactation. Independent variables for statistical analysis were the fixed effects of year-season of calving (6-mo seasons), genetic line, parity nested within genetic line, and random cow within genetic line. Across the 5 lactations, control Holstein cows had significantly ($P < 0.01$) less milk (6,034 versus 8,234 kg), fat (205 versus 271 kg), protein (188 versus 254 kg), and fat plus protein (393 versus 525 kg) production compared with contemporary Holstein cows. The control Holstein cows were not significantly ($P > 0.05$) different from contemporary Holstein cows (3.49 versus 3.42, respectively) for SCS during the first 5 lactations. However, the control line cows (31.9%) had significantly ($P < 0.01$) less clinical mastitis than contemporary Holstein cows (47.1%) during the first 5 lactations.

Key Words: genetic selection, mastitis, pasture

234 Genetic analysis of leukosis incidence in a US Holstein cattle population.

E. Abdalla*[1], G. J. M. Rosa[1], K. A. Weigel[2], and T. Byrem[2], [1]*Department of Animal Sciences, University of Wisconsin-Madison, Madison,* [2]*Department of Dairy Science, University of Wisconsin-Madison, Madison,* [3]*Antel BioSystems Inc., Lansing, MI.*

Bovine leukosis (BL) is a retroviral disease caused by the bovine leukosis virus (BLV) that affects only cattle. It is associated with decreased milk production in addition to death losses. On average, a BLV negative cow has a longer life span, produces 3.5% more milk per lactation, and has 48 fewer days open than does a BLV positive cow. The virus also affects the immune system. Infected cows display a muted response to immunization with J5 bacterin. The aim of this study was to estimate the heritability for BL incidence and the genetic merit of sires for leukosis resistance in the US Holstein population. Continuous and binary data of milk ELISA score for 14,120 cows from 114 dairy herds across 16 US states were considered. Data were obtained from commercial testing records at Antel BioSystems located in Lansing, Michigan. Data used for analysis were limited to animals with a minimum of 3 test results. Out of the 14,120 animals tested, 38% were infected with the disease. Linear and threshold animal models were used to analyze the continuous and binary data, respectively. Variance components and breeding values for animals were estimated using the 2 models and the agreement between the estimated breeding values from each model was assessed. Estimates of heritability obtained with the 2 approaches were very similar and around 7%, indicating that there is a considerable genetic component underlying BL disease incidence. The correlation between the estimated breeding values from the 2 methods was 0.797, and the lists of top 10% bulls selected from each model had a 65.3% overlap. In summary, results indicate that the simple linear model approach using the continuous ELISA scores as response variable is a reasonable approach for the genetic analysis of BL incidence in cattle. In addition, the levels of heritability found indicate that selection could also be used to improve resistance to BL in Holstein populations.

Key Words: bovine leukosis, heritability, threshold model

235 Production traits, somatic cell score, and days open of crossbred cows versus pure Holsteins during their first lactation in Italian commercial dairy herds.

F. Malchiodi,* M. Penasa, and G. Bittante, *Department of Agronomy, Food, Natural Resources, Animals and Environment, University of Padova, Legnaro, Padova, Italy.*

The objective of this study was to compare Swedish Red (SR) × Holstein (HO) crossbred cows (n = 385), Montbéliarde (MO) × HO crossbred cows (n = 71), and Brown Swiss (BS) × HO crossbred cows (n = 52) with pure HO cows (n = 1,583) for production traits. A total of 563,158 test-day information for milk yield and 15,348 for fat and protein, and somatic cell score were recorded on first parity cows milked in 4 herds of northern Italy. Production traits were analyzed through a mixed linear model that included effects of herd-test-day, days in milk based on the Wilmink function, breed group, days open, and the random effects of cow nested within breed group and residual. Days open were grouped into classes of 60 d each, except for the first, which was a class of non-pregnant cows and the last, which was an open class (>240 d). The Wilmink model was used to investigate differences in the shape of lactation curves of milk yield among breed groups. Parameters were estimated for each cow and then used as response variables in linear models including the effects of breed group, herd, and classes of days open. HO produced more milk than SR × HO and MO × HO crossbreds (+2.86 and +2.34 kg/d, respectively) and protein (+0.04 and +0.03 kg/d, respectively), but lower protein percentage (−0.14 and −0.08%, respectively). SR × HO and MO × HO cows became pregnant about 20 d earlier than HO cows. BS × HO produced less milk (−1.47 kg/d) than pure HO cows, but higher (+0.11%) protein percentage. BS × HO and SR × HO had also significantly lower SCS (−0.42 and −0.37, respectively) than HO cows. According to previous results, the Wilmink function showed that milk production was lower for crossbreds compared with pure HO cows, which highlighted stronger increase toward the peak then SR × HO and MO × HO. Breed groups did not differ for the parameter describing the decreasing part of the lactation curve, which was affected by days open. Results indicate that SR and MO are candidate breeds for crossbreeding with HO to maintain good levels of production and improve fertility of dairy herds.

Key Words: crossbreeding, milk traits, days open

236 Birth weight, gestation length, calving-ease and mortality in Holstein, Jersey, and crossbred cows in a pasture-based dairy herd.

K. Dhakal,* J. Cassady, C. Maltecca, and S. Washburn, *North Carolina State University, Raleigh.*

Holstein (H) and Jersey (J) cows were mated to H or J bulls to form purebreds, reciprocal crosses, and backcrosses in a criss-cross mating system in the herd located at the Center for Environmental Farming Systems in Goldsboro, North Carolina. Data for birth weight (BW = 31.1 ± 5.9 kg), calving ease (CE = 0 for unassisted, n = 1106, and 1 for assisted, n = 74), and mortality (0 for alive, n = 1150, and 1 for abortions recorded after mid-gestation, stillborn, and dead within 48 h, n = 30) of calves (n = 1231) were recorded over 9 calving seasons from 2003 through 2011. Gestation lengths (GL = 276.7 ± 5.9 d) were determined from insemination and subsequent calving dates. Linear mixed models for BW and GL included fixed effects of sex, parity (first vs. later parities), twin status, and genetic groups [purebred Holsteins (HH), purebred Jerseys (JJ), reciprocal F1 crosses (HJ, JH), crosses > 50% Holsteins (HX) and crosses > 50% Jerseys (JX)]. The BW model also included GL as covariate. Logistic regression for CE and mortality included fixed effects of sex, parity, and genetic groups. Genetic groups were replaced by linear regression using percentage H genes as coefficients on above models and included as covariates to determine the type of genetic control. Heifer calves, twins and calves born at first parity had lower BW. Differences in genetic groups were observed for BW ($P < 0.01$). Percentage H genes in the calf (direct genetic effects) and percentage H genes in the dams (maternal genetic effects) increased BW ($P < 0.01$). Shorter GL were observed for twin births and for first parity. Direct genetic effects shortened GL ($P < 0.01$), whereas maternal genetic effects increased GL ($P < 0.01$). First parity cows had more assisted births than older cows ($P < 0.01$). Female calves had lower odds ratio (0.27, CI = 0.11, 0.67) for mortality than male calves. Higher percentages of heterosis in the dams (maternal heterosis) reduced calf mortality ($P = 0.015$).

Key Words: crossbreeding, genetic groups, percentage Holsteins

237 Genetic parameters associated with feedlot bovine respiratory disease complex morbidity and mortality.

B. W. Brigham*[1], C. M. McAllister[1], R. K. Peel[1], R. L. Weaber[2], H. VanCampin[1], G. H. Loneragan[3], J. L. Salak-Johnson[4], C. C. L. Chase[5], J. J. Wagner[1], and R. M. Enns[1], [1]*Colorado State University, Fort Collins,* [2]*Kansas State University, Manhattan,* [3]*Texas Tech University, Lubbock,* [4]*University of Illinois, Urbana,* [5]*South Dakota State University, Brookings.*

Bovine respiratory disease complex (BRDC) is a broad term associated with host of infectious agents that occur in cattle. Morbidity and mortality caused by BRDC in the feedlot is associated with annual costs estimated in excess of a billion dollars. Indirect effects of BRDC include depressed performance and carcass quality. Therefore, the objective of this study was to quantify the genetic control of feedlot morbidity and mortality associated with BRDC. Crossbred steers from a single source were shipped from western Nebraska to southeast Colorado over a 2 year period (year 1 n = 1,551, year 2 n = 1,319). Steers were processed the day following arrival and placed in feedlot pens where they remained unless identified as sick and in need of health treatment by feedlot staff. If an animal was pulled as sick it was treated according to defined protocols and housed separately with other sick animals until recovered. Processing and treatment protocols were nearly identical across the 2 years of the study. In the event of mortality, field necropsies were conducted and biological samples were taken to ascertain the cause of death. Treatment and mortality rates attributed to BRDC varied greatly of the 2 years of the study, in year one morbidity and mortality rates were 45% and 6% compared with year 2 8% and 2% respectively. A probit threshold link function in ASReml was used to convert binary observations for both morbidity and mortality to the underlying scale. Variance components were estimated through univariate sire models using the 2,870 total observations and 3,255 pedigree relationships. Fixed effects included contemporary group (ranch unit and feedlot pen) and year. Heritability and standard errors for feedlot morbidity or feedlot mortality were, 0.17 (0.06) and 0.08 (0.16) respectively. These results suggest some amount of genetic control in the susceptibility to BRDC and the inability to recover from an infection. The ability to select for animals with greater disease tolerance or immune function could result in increased performance and decreased input requirements in the feedlot.

Key Words: feedlot, morbidity, mortality

238 Performance of a German Holstein cattle population under stressful conditions near Benghazi, Libya.

R. S. Gargoum*[1], S. A. M. Bozrayda[1], and E. Abdalla[2], [1]*Department of Animal Production, University of Benghazi, Benghazi, Libya,* [2]*Department of Animal Sciences, University of Wisconsin-Madison, Madison.*

The aim of this study was to evaluate productive and reproductive performance of German Holstein Friesian dairy cows and subsequent generations that were born in Libya. Animals were managed by a Dutch company from 1986 to 1990, and Libyan managers were used after 1990. The number of cows that had the first lactation record included in the study was 2094. Data were analyzed using REML to estimate factors affecting milk yield and reproductive traits. The model included month, year of calving, management, generation, origin of sire as fixed effects. In addition, age at first calving and lactation period included for milk yield traits as covariates. Total milk yield was generally high (8409 Liters) and achieved with reproductive efficiency (110 d open) during Dutch management, and at the expense of the reproductive traits (161 d open) during Libyan management. Management, calving year, calving month, age at first calving and lactation period had a significant effect on both milk yield and reproductive traits. In addition, milk yield and days open were affected by the temperature-humidity index (THI). Different trends of milk yield and days open were found during cold and hot seasons. However, Days open were more affected by the increasing in THI than does milk yield. Reasons of culling were mainly due to low fertility (37%), mastitis and udder injuries (15%) and accidental defects (16%). Management plays important role to maintain high productivity with reproductive efficiency under heat stress conditions.

Key Words: milk yield, reproductive traits, THI

Companion Animals Symposium: Companion Animal Reproduction: To breed or not to breed?

239 Canine and feline reproductive biology 101. M. Kutzler,* *Oregon State University, Corvallis.*

This lecture is designed to provide a primer on canine and feline reproduction for scientists unfamiliar with this topic as well as lay people. Domestic bitches are nonseasonally monoestrous. As a result of this unique reproductive physiology, bitches spontaneously ovulate only once or twice per year and ovulation can occur at any time of the year. Queens are induced ovulators, requiring external stimulation (such as natural breeding) to stimulate the ovulation of mature follicles. During the breeding season, queens exhibit estrous behavior every 2–3 wks unless ovulation occurs. However, the occurrence of estrus and ovulation are not repetitive, cyclic or predictable. In bitches, ovulation of primary oocytes occurs 36–50 h after the onset of the surge in luteinizing hormone (LH). Oocyte maturation (extrusion of the first polar body) is complete 2–3 d post-ovulation and sperm can penetrate the zona pellucida before extrusion of the first polar body. Queens ovulate secondary (mature) oocytes capable of fertilization immediately following ovulation. Fertilization (extrusion of the second polar body) occurs in the uterine tube. Embryos are present within the uterine tube 7 d past the onset of the LH surge and late morulas and early blastocysts enter the uterus 10 d past the onset of the LH surge. Prior to implantation, embryos float freely within the uterine lumen, nourished by "uterine milk" (histotroph). Embryo migration between uterine horns does occur and blastocysts space themselves out evenly between horns until 16 d after the onset of the LH surge. Embryonic implantation occurs 22 d after the onset of the LH surge. Implantation sites can be observed ultrasonographically at this time. The bitch and queen have an endotheliochorial, zonary (circumferential), modified deciduate placenta. The continuous availability of ovarian progesterone is required for the initiation and maintenance of pregnancy in both species, such that ovariectomy at any time will result in resorption or abortion. No placental or embryonic luteotrophic secretions that have been demonstrated in the bitch or the queen. However, relaxin is only detectable during pregnancy and is the only specific pregnancy-associated protein in dogs and cats.

Key Words: ovulation, pregnancy, placentation

240 Companion animal reproduction and nutrition 101. D. Greco,* *Nestle Purina Petcare.*

This review covers the use of common nutritional supplements for the bitch and puppies. Basic nutrients such as fat, protein, minerals, vitamins, and essential fatty acid supplementation will be discussed. Newer supplements such as probiotics for stimulation of the immune system of the bitch and puppy and use for the non-pharmaceutical treatment of weaning diarrhea will also be outlined.

241 Companion animal population control: Past, present and future. S. Zawistowski,* *The American Society for the Prevention of Cruelty to Animals, New York, NY.*

The euthanasia of pets in US animal shelters likely peaked at an estimated 20 million per year around 1970. It was then that the first major programs appeared to promote and subsidize sterilization of dogs and cats. The relentless efforts of shelter groups in the past 40 years have helped to reduce the euthanasia figure to about 4 million pets per year. This progress has been the result of broad based public education programs and substantial advances in the methods of surgical sterilization. Maintaining this success, and making further progress will likely require the development of non-surgical contraceptives and sterilants that do not call for the substantial infrastructure investments needed for high volume, high quality spay/neuter programs. Current research on non-surgical approaches employ cutting edge approaches in cell, molecular and neuroendocrine biology.

Key Words: companion animal population, spay/neuter, non-surgical sterilization

242 The role of the domestic cat in endangered species conservation. J. Herrick,* *National Foundation for Fertility Research, Lone Tree, CO.*

Domestic cats are highly prolific breeders, so there has been little demand to study reproduction or develop assisted reproductive technologies (ARTs) in this species. As a result, surprisingly little is known about feline reproduction, despite the widespread popularity of cats as pets. However, most of the other 36 species of cats in the world are threatened with extinction. An improved understanding of feline reproduction would greatly benefit conservation efforts and population management for these endangered species. Since nondomestic cats are poor research subjects due to their limited availability and dangerous nature, the domestic cat has become an important model species for reproductive studies. Research in domestic cats has led to the development of techniques for noninvasive hormone monitoring and electroejaculation that have facilitated studies of estrous cycle dynamics and sperm physiology in nondomestic cats. Similarly, protocols for artificial insemination, in vitro fertilization, and embryo transfer developed in domestic cats have been used successfully in some nondomestic cat species. These ARTs could play a valuable role in conservation programs, but current protocols are inefficient and successful offspring production is sporadic. One of the many areas in need of additional research is the culture environment used for feline embryos following in vitro fertilization. During the first few days after fertilization, the embryo is extremely sensitive to its environment (the fluids of the reproductive tract or synthetic culture media). Even brief exposure to sub-optimal conditions during this time can have dramatic effects on embryonic and fetal viability. By developing a culture medium specific to the needs of the feline embryo, we have been able to greatly improve the success of in vitro fertilization in domestic cats, as well as several species of nondomestic cats. However, embryonic development in vitro is still compromised compared with development in vivo. Specifically, the feline embryo undergoes rapid cell division and appears to have unique nutritional requirements to support this growth that are not being met with current media formulations. Research to develop more appropriate culture media and increase the viability of cultured embryos will continue to rely heavily on the domestic cat, as will all research to improve the efficiency of ARTs. The future existence of endangered cats could very well depend on a better understanding of reproductive physiology in their domestic cousin.

Key Words: feline, assisted reproductive technologies, conservation

243 Population control in wildlife: Lessons learned. J. F. Kirkpatrick,* *Science and Conservation Center, Billings, MT.*

The management of certain wildlife populations by means of fertility control has become widely accepted and is now commonly used in species such as wild horses, urban deer, African elephants, bison, and >85 species of captive exotic animals in zoos, worldwide. The most commonly used contraceptive agent is a porcine zona pellucida vaccine (PZP), which operates entirely outside the cascade of reproductive endocrine events. The characteristics of this vaccine come closer to the ideal for use in wildlife than any other form of contraception and include (1) efficacy of at least 90%, (2) remote delivery, (3) reversibility, (4) safe for use in pregnant animals, (5) minimal effects on behavior, (6) no debilitating side effects, (7) inability to pass through the food chain, and (8) low cost. Despite major scientific strides in achieving these goals and demonstrating success in the field, significant opposition remains. This opposition exists in the form of cultural and social biases, economic concerns, agency inertia and political pandering. Regardless of whether the development of this technology is aimed at wildlife or companion animals, involved scientists must understand that unless they are willing to address the points of opposition, as well as regulatory hurdles, much of their work and the resources expended can come to naught.

Key Words: population control, companion animals, wildlife

244 Obesity is associated with adverse cardiovascular outcomes and insulin resistance in dogs. J. L. Adolphe,* T. I. Silver, M. D. Drew, and L. P. Weber, *University of Saskatchewan, Saskatoon, SK, Canada.*

Obesity and cardiovascular disease are strongly linked in humans, but this association is less clear in dogs. The purpose of this study was to evaluate the effects of obesity on cardiac structure and function as well as insulin resistance in dogs. Cardiovascular variables were measured and oral glucose tolerance tests were performed before and after weight gain in 9 beagles. At baseline, dogs were fed a commercial diet in measured amounts to maintain an ideal body weight. Subsequently, for 12 weeks the dogs were allowed free access to the diet to allow weight gain. Echocardiography was used to analyze left ventricular function. Blood pressure was measured by high-definition oscillometry. Serum glucose and insulin were measured before and at specific time points after an oral glucose challenge to determine glucose tolerance and insulin sensitivity. CT (CT) was used to quantify total and visceral fat accumulation in the dogs in the obese state. Body weight increased from 9.8 ± 0.6 kg at baseline to 12.1 ± 0.7 kg (123 ± 3% of ideal body weight) after ad libitum feeding. Systolic left ventricular free wall thickness, heart rate, area under the glucose response curve and peak glucose significantly increased in the obese state compared with the lean state ($P < 0.05$). Systolic free wall thickness was positively correlated with total fat ($r = 0.7$, $P = 0.02$) and visceral fat ($r = 0.7$, $P = 0.03$). Area under the insulin response curve was associated with visceral fat ($r = 0.8$, $P = 0.03$). Increased systolic free wall thickness, coupled with elevated heart rate, in dogs likely reflects hyperdynamic cardiac function which may have negative long-term cardiovascular consequences. Thus, this study supports the hypothesis that visceral fat is linked to detrimental changes in cardiac function and insulin sensitivity in obesity. These results are particularly remarkable considering that the dogs were obese for only 12 weeks.

Key Words: obesity, dogs, insulin resistance

Dairy Foods Symposium: Maximizing Value of Milk Proteins: Manufacture, applications and market opportunities for milk protein concentrate

245 Market trends and opportunities for milk protein concentrates. V. Lagrange,* *US Dairy Export Council, Arlington, VA.*

The US market for milk protein concentrates (MPC42–70) is estimated at 80–85,000 mt, and is complemented by a milk protein isolate (>85% protein) market estimated at 15–20,000 mt. MPC and MPIs range in protein content from approximately 42% to over 90%. Over 60% of the low-protein MPC (MPC 40–59) are used worldwide in dairy products (other than processed cheese). In Europe, yogurt and dairy desserts are an application where MPC's functional properties–improved viscosity, mouthfeel, emulsification, water binding–a favorable nutritional profile and the marketing appeal of a "clean label" increases their appeal. In the United States use in soups and sauces has increased significantly. Processed cheese dominates applications, although in the United States, volume used in this segment has decreased from 60% in 2007 to less than 40% in 2011. Almost all MPC purchases for use in specialty nutrition (sports, medical and clinical nutrition, geriatric nutrition) are high-protein concentration (80 percent or greater) products. The world market for milk protein isolates is estimated at 40,000 mt. These ingredients are highly valued in lactose free formulations and, increasingly, in medical nutrition product where they offer a milk dairy flavor and a desirable blend of "slow" and "fast" proteins. Clinical trials are underway in several locations to measure their effectiveness in the treatment of sarcopenia, the loss of muscle associated with aging.

Key Words: milk protein, milk protein concentrate, milk protein isolate

246 Impact of processing and storage on milk protein concentrate functionality. J. A. Lucey,* *University of Wisconsin-Madison, Madison.*

Milk protein concentrate (MPC) powder is basically skim milk powder with a reduced lactose (higher protein) content. Ultrafiltration (UF) is used to remove some lactose before drying, and UF processing may be adjusted to give MPCs that span a wide range of protein concentrations, for example, 40–85% protein in dry matter. High protein (>70%) MPCs can be slow to dissolve during rehydration and poor rehydration properties negatively affect the use of MPC in many applications. Another serious concern is that high protein MPCs can also exhibit a decrease in solubility during storage especially at storage temperatures > 20°C. Reports have indicated that some commercial MPC samples were prone to a large decrease in solubility during storage while other samples maintained good solubility. Differences in the mineral composition have been suggested as a possible explanation for variations in solubility behavior. High protein MPC requires extensive diafiltration to reduce the lactose content but this procedure also reduces the concentration of soluble salts. We have explored the impact of washing on protein solubility where washing was done with lactose solutions to remove soluble salts but not change the protein content. At least in our low protein MPC experiments, multiple diafiltration steps did not result in a disruption of the casein micelles or poor solubility during powder storage (although there was a loss of insoluble calcium from micelles). There are commercial MPC products that have been depleted of calcium, which presumably alters the micelle structure and casein-casein interactions that can occur during powder storage. High inlet air temperatures during MPC processing have also been suggested to impair solubility. Possible reasons include greater protein denaturation or enhanced Maillard cross-linking of proteins with lactose. A greater understanding is needed of the processing factors that determine MPC solubility.

Key Words: milk protein concentrate, solubility, functionality

247 Advances in processing and development of new milk protein products. H. Singh,* *Riddet Institute, Massey University, Palmerston North, New Zealand.*

The global demand for milk protein has increased significantly in recent years due to better understanding of its nutritional value, physiological and bioactive properties, and newly developed functional uses. In particular, consumer awareness of the benefits of protein in sports performance, weight management, lean muscle mass retention, satiety and general wellbeing has improved considerably over the last decade. Consequently, the demand for milk protein-enriched food and beverage products has moved into the mainstream as they appear to deliver these benefits more readily than other food proteins. The dairy industry produces a vast range of milk protein products, specifically designed for particular applications. These products include the traditional milk protein products, such as skim milk powder and whey powders, and higher protein products, such as caseins and caseinates, whey protein concentrates and isolates and milk protein concentrates and isolates. Among the higher protein products, milk protein concentrates (MPCs) and whey protein isolates (WPIs) have become very important for the dairy industry, as they provide several processing and functional/nutritional advantages over traditional milk powders. MPCs are now commonly added to milk or cheese formulations to enhance the protein content and to improve texture of yogurts. The use of MPCs in nutritional products is growing. In this application, MPC provides both casein and whey proteins in the same ratio as in milk, but without the high lactose content. However, several functionality problems are associated with high protein MPCs, including cold water solubility. Various patented processes have been developed for manufacturing MPC powders with improved functional characteristics, involving alterations in mineral balances and/or the state of aggregation of whey proteins. Development of high protein foods poses several functionality challenges, such as self-association/aggregation and high viscosity of proteins. New types of protein products and associated processes are being developed to overcome some of these technical challenges.

Key Words: milk protein, processing, functionality

248 Manufacture and application of micellar casein concentrates. D. M. Barbano,* *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Micellar casein concentrate (MCC) is currently produced by removal of intact casein micelles from skim milk by microfiltration. The casein micelles may be further concentrated by ultrafiltration or evaporation. Liquid MCC may be used directly as a fresh ingredient, concentrated and stored as a long shelf-life refrigerated ingredient, or dried and stored for later use as a powdered ingredient. The MCC are different from caseinates, and acid and rennet caseins because the casein in MCC still retains its micelle structure and bound calcium. Casein in MCC is in the same form as casein in NDM powder and milk protein concentrates (MPC) produced by ultrafiltration. The difference between MCC and

NDM or MPC, is the presence of other dairy solids that will cause differences in functionality among these 3 products. The MCC can be produced in a range of purities. The key compounds being removed by microfiltration in the manufacture of MCC are milk serum proteins, lactose, soluble calcium phosphate, monovalent ions, and nonprotein nitrogen compounds. A technically feasible microfiltration process could continuously discharge a high-purity liquid MCC which has been 95% reduced in serum protein and soluble NPN compound contents at 9% true protein and < 0.2% lactose (both on wet bases). This liquid MCC could be further concentrated or dried. The liquid protein concentrate is bland in flavor, white, and viscous. Highly concentrated liquids have some unique properties. The MCC has excellent heat stability; when used as an ingredient in retorted beverage production, there is minimal browning and cooked flavor formation during sterilization. While MCC could be used as an ingredient in making nonstandardized cheeses in the US, the higher value uses for MCC may be as an ingredient in retorted, shelf-stable, high protein beverages and as an ingredient in low-fat natural cheese manufacture.

249 Performance of spiral wound microfiltration membranes during production of micellular casein concentrate. L. E. Metzger,* C. Marella, and P. Salunke, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Micellar casein concentrate can be manufactured from skim milk by microfiltration that utilizes membranes with an average pore size of 0.1 - 0.2µm. The microfiltration process concentrates micellar casein by selectively permeating whey proteins, lactose, and soluble minerals. In contrast to other processes for isolating casein (isoelectric precipitation or rennet induced coagulation), microfiltration has the advantage of concentrating micellar casein in its native state. The most common types of membranes used to microfilter milk are ceramic or spiral wound. In general ceramic membranes have an advantage in terms of performance whereas spiral wound membranes have an advantage in terms of cost. The data related to microfiltration of milk using spiral wound membranes has been collected using small scale manufacturing systems and short processing runs. This is an issue for manufacturers that attempt to scale up and commercialize microfiltration since the performance characteristics of spiral would microfiltration membranes are influenced by a variety of operating conditions and the selectivity of the membrane can vary substantially during a production run. In this study the performance of a 4 stage microfiltration system during a 15–20 h production run at 2 serum protein removal levels (40% and 85%) was determined. Relative to small scale systems, the continuous, single pass 4 stage process resulted in improved whey protein removal over the processing run. However, data on flux rates and selective passage of the major whey proteins showed that even though flux rates remained fairly constant, the membrane selectivity varied during the process run. This flux rate and selectivity data can be utilized by manufacturers to design a spiral wound microfiltration process to achieve their desired whey protein removal targets.

250 Neutrophil function in the transition period and reproductive tract health in dairy cows. J. A. M. Wittrock,* T. F. Duffield, D. Bienzle, and S. J. LeBlanc, *University of Guelph, Guelph, ON, Canada.*

The study objective was to evaluate the relationship between neutrophil function during the transition period and reproductive tract disease in dairy cows. Phagocytic and killing ability of polymorphonuclear neutrophilic leukocytes (PMNL) are commonly reduced around calving. Cows (n = 81) were followed for 8 wk through the transition period. At −2, −1, 1, 2, 3, and 5 wk relative to calving, PMNL were isolated from the blood and phagocytosis and oxidative burst function were evaluated by flow cytometry, and serum glucose, NEFA, BHB, haptoglobin, insulin, and IGF-1 were measured. Endometritis and cervicitis were diagnosed at 5 wk postpartum by cytobrush cytology, with a positive diagnosis based on >5% PMNL. There were 27 cows (34%) with endometritis, and 22 (27%) with cervicitis. There was no difference in PMNL phagocytosis between cows with or without endometritis ($P = 0.2$). Cows with endometritis at wk 5 had 21% lower PMNL oxidative burst function at 2 wk after calving than unaffected cows ($P = 0.01$). Oxidative burst function of PMNL in cows with cervicitis was not different from healthy animals ($P = 0.2$). Cows with cervicitis had 28% lower PMNL phagocytosis than healthy cows 2 wk before calving ($P = 0.03$). Compromised phagocytosis and killing ability of PMNL may precede and contribute to cervicitis and endometritis after calving.

Key Words: transition cow, neutrophil, reproductive health

251 Effects of intrauterine infusion with *E. coli* lipopolysaccharide on systemic and local inflammatory and immune response. J. G. N. Moraes*[1], P. R. B. Silva[1], L. G. D. Mendonça[1], J. Silva[1], M. A. Ballou[2], K. N. Galvão[3], and R. C. Chebel[1], [1]*Department of Veterinary Population Medicine, University of Minnesota, St. Paul,* [2]*Department of Animal and Food Sciences, Texas Tech University, Lubbock,* [3]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville.*

Objectives were to evaluate the effects intrauterine infusion with *E. coli* lipopolysaccharide (LPS) on periperal neutrophil function, hematology, intrauterine cell population, and expression of endometrial interleukin-1 (IL-1). Cows (31 ± 3 d postpartum) diagnosed with endometritis by Metricheck were assigned to receive 0 (NC, n = 31), 150 (150LPS, n = 33), or 300 (300LPS, n = 34) μg of *E. coli* LPS. A sub-sample of cows (n = 25/treatment) had blood sampled on the day of infusion (d0) before treatment and at 2 and 6 h after treatment for determination of neutrophil phagocytosis (PHAGO) and oxidative burst (OXID) and expression of CD18 and L-selectin. All cows had blood sampled at 0, 2, 6, 24, 48 h after infusion for hemogram and were examined for endometritis using Metricheck on d 1, 2, 7, and 28 and for sub-clinical endometritis using cytrobush on d 0 (before infusion), 1, 2, and 7. Data was analyzed by ANOVA for repeated measures or by chi-squared using MIXED and FREQ procedures, respectively. Percentage of neutrophils positive for PHAGO was ($P = 0.02$) greater for 300LPS (66.8 ± 1.5%) compared with NC (61.7 ± 1.5%) and 150LPS (61.9 ± 1.5%), but the intensity of PHAGO was not different ($P = 0.36$). Treatment did not affect percentages of neutrophils positive for OXID ($P = 0.49$) and for expression of CD18 ($P = 0.76$) and L-selectin ($P = 0.80$). Intensity of OXID tended ($P = 0.08$) be affected by treatment. Treatment had no effect on hematological parameters. Percentage of cows with endometritis 7 (59%; $P = 0.47$) and 28 (16.7%; $P = 0.92$) d after treatment was not affected by treatment. No differences in percentage of polymorphonuclear cells in uterine cytology were observed on d0 ($P = 0.35$) or thereafter ($P = 0.55$). Percentage of cows with >10% of PMNC in uterine cytology was not different among treatments on d 0 (48.5%;$P = 0.27$) and d 1 (85.3%;$P = 0.27$), but on d 7 150LPS (51.7%) and 300LPS (50%) cows tended ($P = 0.08$) to be less likely to have >10% of PMNC in uterine cytology than NC (75.9%) cows. Intrauterine infusion with 300μg of LPS resulted in slight increase in percentage of neutrophils positive for PHAGO.

Key Words: lipopolysaccharide, uterus

252 Effects of fresh-cow diseases on reproduction in a large commercial dairy herd. R. P. Tollefsrud*[1], R. L. Larson[1], H. M. Scott[1], G. A. Hanzlicek[1], and D. E. Little[2], [1]*Kansas State University, Manhattan,* [2]*DairyNet Incorporated, Brookings, SD.*

The 2007 NAHMS (National Animal Health Monitoring System) survey indicated that early lactation health issues are major factors influencing reproduction and culling on US dairy herds. The objective of this study was to evaluate fresh-cow health during the first 30 d in milk, and its association with days to pregnancy in the concurrent lactation. Data were collected on cattle that calved over a 2-mo period (July and August 2009) on a dairy farm located in the Upper Midwest region of the US Health and production data were collected daily for each cow from the beginning of lactation until the majority of the study population was confirmed pregnant. Both a competing risk analysis and a semi-parametric Cox proportional hazard regression model were completed, and the association between specific health-related events and days to pregnancy was investigated and compared between the models. These analyses showed metritis and dystocia in the first 30 d of lactation were associated with greater days to pregnancy. No difference was noted between parities, except lactation-5 and greater cows were significantly associated with greater days to pregnancy. These 2 analyses showed conflicting significance of association between retained placenta, ketosis, twinning, lameness, and other non-specific illnesses with days to pregnancy. This study found that a competing risk analysis and a semi-parametric regression model were appropriate methods to analyze time sensitive data such as reproductive efficiency. This study supports the evidence that parity, metritis, retained placenta, ketosis, dystocia, twinning, lameness, and other non-specific illnesses can affect reproductive inefficiencies.

Key Words: reproduction, animal health, dairy

253 Using temperature-sensing reticular boluses to aid in the detection of disease in dairy cows. A. E. Adams,* F. J. Olea-Popelka, and I. N. Roman-Muniz, *Colorado State University, Fort Collins.*

The objective of this study was to examine the feasibility of using a temperature-sensing reticular bolus (TSRB) to aid in the early detection of common dairy cow diseases. Approximately 2175 primiparous and multiparous Holstein dairy cows were utilized in this study. Each cow received an orally administered TSRB after parturition. Reticular temperature (RT) measurements were obtained for approximately 350 d, as cows equipped with a TSRB passed the reading panels located at the exit lanes of the milking parlor. Over the 350 d study period, health data were collected for all cows diagnosed by dairy personnel with the following production disorders: mastitis, metritis, lameness, or pneumonia. A retrospective analysis of all health and RT temperature data was conducted. For analysis of RT data, a cow was determined to have a fever if RT exceeded baseline temperature by 0.8°C during the 4 d before diagnosis, determined by a logarithm in the TempTrack software (DVM Systems LLC, Greeley, CO). The health and RT data were combined and analyzed to examine the relationship between fever and disease. A logistical regression model was used to determine the likelihood of a cow with a fever (as defined by TSRB data) being diagnosed with one of the listed diseases by dairy personnel. A total of 218 health events were included in this data set. Odds ratio analysis indicate that a cow presenting a fever is 6.73 times as likely to be diagnosed with mastitis ($P < 0.0001$) and 7.50 times as likely to be diagnosed with pneumonia ($P = 0.0183$), as one that did not present a RT change. No difference in RT was found between cows diagnosed as being lame or with metritis when compared with the "healthy" controls. These data suggest that RT monitoring coupled with routine observation and the prompt assessment of cows has the potential to aid in the early detection of mastitis and pneumonia in dairy cows.

Key Words: reticular temperature, dairy cow, disease

254 Optimization of methods for the detection of *Mycobacterium avium* ssp. *paratuberculosis* in milk and colostrum of naturally infected dairy cows with Johne's disease.

L. Bradner*[1], S. Robbe-Austerman[2], D. Beitz[1], and J. Stabel[3], [1]*Iowa State University, Ames,* [2]*USDA-APHIS, National Veterinary Services Laboratory, Ames, IA,* [3]*USDA-ARS, National Animal Disease Center, Ames, IA.*

Mycobacterium avium ssp. *paratuberculosis* (MAP) is the causative agent of Johne′s Disease (JD), a chronic enteritis that occurs in dairy cattle and other ruminants. A 2007 NAHMS Dairy Study demonstrated that over 68% of dairy herds are infected with JD so the risk of exposure within a herd is high. MAP is primarily shed in the feces but it is also shed into the milk and colostrum of infected cows. Because of this, there exists concern about transfer of the organism from dam to calf and the prevalence of MAP in the milk supply. The amount of MAP shed into milk is not well defined because the complexity of the milk matrix and presence of confounding microorganisms makes it difficult to recover MAP via culture methods. The objective of this study is to optimize the decontamination of whole raw milk for the isolation of viable MAP and compare recovery rates in liquid culture mediums. The efficacy of 2 liquid culture mediums, TREK-ESP and BD Bactec 12B were compared for recovery speed and thresholds, incidence of contamination, and reproducibility of results. Milk collected from a non-infected cow was spiked with known concentrations of MAP (10^2 to 10^8 cfu/mL). Two chemical decontaminates were investigated, hexadecylpyridinium chloride (HPC) and N-acetyl-L-cysteine-sodium hydroxide (NALC-NaOH). It was found that NALC-NaOH was the superior chemical for decontamination ($P < 0.01$) and that MAP recovery from milk was highest and contamination was lowest when decontaminated with 1.5% NaOH for a 15-min exposure time. In comparing the 2 liquid culture mediums, Bactec 12B was superior in recovery especially at low spiking levels ($P < 0.01$) with a detection threshold of less than 10^2 cfu/ml and superior in speed of recovery of viable MAP. TREK-ESP culture demonstrated an increased incidence in false positive and false-negative results that were not observed in Bactec 12B medium. Optimized methods will be used to assess the frequency and level of MAP shed into milk during a complete lactation period of naturally infected dams.

Key Words: Johne's disease, milk, cattle

255 Effects of transient silage DM concentration variation on dairy cows.

L. R. McBeth*[1], W. P. Weiss[1], N. R. St-Pierre[1], and D. E. Shoemaker[2], [1]*The Ohio State University, Wooster,* [2]*Ohio State University Extension, Wooster.*

Transient changes in silage DM concentration, if unaccounted for, will cause a diet to become unbalanced. We hypothesized that a transient decrease in silage DM% would have a negative effect on DMI and milk yield and composition. Holstein cows (24) at 116 DIM were used in 8 replicated 3 × 3 Latin squares with 21-d periods. The treatments were 1) Control (CON), 2) Unbalanced (UNB), and 3) Balanced (BAL). The CON diet was formulated to have a consistent silage DM% and forage:concentrate (F:C) of 55:45 throughout the period. Forage consisted of 67% alfalfa silage (53%DM) and 33% corn silage (36%DM). The UNB and BAL diets were the same as the CON for most of the period except during 2 3-d bouts when water was added to the silage (simulating a rain event) to cause a 10%-unit decrease in silage DM%. During the bouts, the UNB diet was the same as CON on an as-fed basis, but the F:C changed to 49:51 (DM basis), changing diet DM (67.2 vs 64.0%), NDF (32.0 vs 30.7%), and starch (29.8 vs 31.5%). The BAL treatment corrected for the change in silage DM concentration by an increase in silage inclusion to rebalance the F:C to 55:45. Daily DMI and milk yield were measured and milk composition was measured 3 times during the bouts and 3 times during the normal time. A mixed model including parity, cows within parity, period, bout, and treatment with repeated measures (i.e., bout (wet and dry) within period) was used. Over the 21-d period, treatment did not affect DMI (24.0, 24.1 and 23.8 kg/d for CON, UNB and BAL), milk yield (39.4, 39.9 and 39.6 kg/d), milk fat (3.41, 3.42 and 3.33%), and milk protein (2.78, 2.80 and 2.79%). No differences were observed between wet and dry bouts within each treatment for DMI and milk yield; but for UNB, milk fat (3.48 vs 3.35%) increased and milk protein (2.78% vs 2.82%) decreased during wet bouts. A significant decrease in milk yield between wet bouts occurred within the UNB treatment (40.3 vs 39.4 kg/d). Overall, a large decrease in silage DM% (10%-unit) over short-term bouts (with or without TMR adjustment) had only minor effects on DMI, milk yield and composition. Therefore, with drier silages adjusting for short-term, transient changes in silage DM was not necessary.

Key Words: silage variability, precision feeding, DM change

256 Development of a merit-based genetic selection index for dairy grazing systems.

K. D. Gay,* N. J. Olynk, T. D. Nennich, A. P. Schinckel, and M. M. Schutz, *Purdue University, West Lafayette, IN.*

Pasture-based dairy producers face different costs, revenues and management challenges from those with conventional production systems. These differences have led many graziers to question whether the US Lifetime Net Merit (NM$) index is appropriate to achieve maximum economic gain when selecting dairy cows and bulls for their breeding programs. A Grazing Merit index (GM$) parallel to the US NM$ index was constructed using costs, revenues, and management characteristics representative of grazing systems. Inputs were obtained from surveys, literature, and farm financial record summaries. Derived weights for GM$ were then multiplied by Predicted Transmitting Abilities of 584 active Artificial Insemination Holstein bulls to compare with NM$. Spearman rank correlation between GM$ and NM$ was 0.93 ($P < 0.0001$). Traits included in GM$ (and their percentage of weight) include: milk volume (24%), fat yield (16%), protein yield (4%), productive life (7%), somatic cell count (−8%), Feet and Leg Composite (4%), Body Size Composite (−3%), Udder Composite (7%), daughter pregnancy rate (18%), calving ability (3%), and dairy form (6%). Weights in NM$ were 0, 19, 16, 22, 10, 4, 6, 7, 11, 5, and 0% for the same traits, respectively. Dairy form was added to GM$ to offset the decrease in strength that arises from selection to reduce stature by selecting against Body Size Composite. Relative importance of milk volume was greater due in part to a difference in the milk prices used and the increased marginal value of milk yield when production is less in grazing systems. There is a large decrease in the emphasis placed on productive life probably because grazing cattle tend to remain in the herd longer; therefore, the marginal value of increasing length of productive life is decreased. This trend is reflected in the relative weight for productive life in GM$ (18%) vs NM$ (22%). It appears that NM$ may provide guidance for pasture-based dairy producers, however a GM$ index based upon appropriate costs and revenues, is more beneficial.

Key Words: grazing, Holstein, selection index

257 Effects of stocking rate, supplement strategy and breed in a pasture-based automatic milking system.

C. Nieman,* S. Utsumi, D. K. Beede, and J. Rowntree, *Michigan State University, East Lansing.*

The influence of 2 grazing and supplementation strategies on the performance of 14 United States Holstein (564 ± 38 kg BW; mean ± SD) and 14 New Zealand Friesian (393 ± 27 kg BW) cows in a pasture-based automatic milking system (AMS) was investigated. The study was a 2 × 2 factorial of the 2 breeds and 2 stocking rate treatments lasting 56 d. The low stocking rate (1.92 cows/ha) treatment was offered pasture plus concentrate (PC), whereas the high stocking rate (2.81 cows/ha) treatment was offered PC plus a partial totally mixed ration (pTMR; 60% forage). Amount of pTMR fed was adjusted weekly and used to supplement deficits in pasture allowances and growth rate. Each stocking rate treatment had voluntary access to a single stall AMS where cows were offered 1 kg of concentrate per 6 kg of milk. Voluntary access to pastures was controlled via automated gates. Fresh pasture allocations were opened daily at 0500 h. Targeted pre- and post-grazing pasture biomass was 2,400 kg/ha and 1,600 ± 200 kg/ha, respectively. Pre- and post- grazing biomass was recorded daily with a rising plate meter. Milk yield (MY), daily milking frequency (MF), Milk fat and Milk protein were analyzed with a repeated measures mixed model for a completely randomized design ($P < 0.05$). There was a week by treatment interaction for MF, likely influenced by weekly MF increases for pTMR. The MY followed a similar week by treatment interaction trend ($P = 0.08$), likely explained by MY increases for pTMR during the final weeks of the study. No treatment by breed or week by breed interaction was detected, but significant differences in milk production and composition were detected between the 2 breeds (Table 1). Results suggest a higher milk productivity for the high stocking rate and pTMR supplemented system and superior milk production for United States Holstein cows.

Table 1. Milk production and composition by breed

Variable	New Zealand Friesian	United States Holstein
Milk yield, kg/d	15.3^{b}	27.9^{a}
Milking frequency,/d	2.2^{b}	2.5^{a}
Milk fat %	4.2^{a}	3.6^{b}
Milk protein %	3.3^{a}	3.1^{b}

^{a,b}Means within a row with different superscripts differ ($P < 0.05$).

Physiology and Endocrinology: Estrous Cycle Manipulation–Beef

258 Mean and basal LH concentrations increased in peri-puberal beef heifers during early exposure to androgenized steers. C. Fiol*[1], N. Curbelo[2], G. Larraz[2], L. de Melo Menezes[3], and R. Ungerfeld[2], *[1]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [2]Departamento de Fisiología, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay, [3]Universidad de Pelotas, Rio Grande del Sur, Brazil.*

The aim of the experiment was to characterize the LH secretion pattern in peri-puberal beef heifers exposed to androgenized steers (AS) during 80 d. Thirty anestrous Hereford heifers (24-mo-old, 257.5 ± 32.5 kg) and 3 AS were used. Since D0, 15 heifers were exposed to AS during 80 d (group EH), remaining 15 heifers isolated from AS or any other male (group IH). Both groups grazed low quality native pastures in 2 paddocks separated by 600 m. From D-10 to D30, daily ovarian ultrasonographic evaluations were done in all the heifers to determine the presence of corpus luteum and the onset of cyclic activity. Thereafter, ovarian ultrasonographic determinations were done every week (D32 to D60) and every 10d (D60 to D80) to determine the presence of corpus luteum. At 10 d intervals (D-10 to 30), 8 heifers per treatment were housed in individual cages and blood samples were collected at 15-min intervals for 6h. Concentrations of LH were determined by RIA, and compared with repeated measures ANOVA; cyclic activity was compared with chi-squared test. Cumulative proportion of cyclic heifers was greater for EH than IH on D60 (33.3 vs 0%, $P = 0.01$), 70 (47 vs 0%, $P < 0.005$) and 80 (53 vs 0%, $P < 0.001$). On D10 of the exposure period, mean and basal concentrations of LH were greater in EH than IH (Table 1). The frequency of LH pulses was greater in D10 compared with D0 and 20, and tended to be greater to D30 (Table 1). In conclusion, exposure to AS stimulated LH secretion pattern during the first days of the exposure period.

Table 1.

	Mean LH, ng/mL		Basal LH, ng/mL		LH pulse frequency, pulses/6h
Day	EH	IH	EH	IH	
−10	1.18 ± 0.09	1.27 ± 0.09	1.05 ± 0.08	1.12 ± 0.08	3.12 ± 0.25
0	1.08 ± 0.09	1.19 ± 0.09	0.96 ± 0.08	1.02 ± 0.08	2.81 ± 0.25^{y}
10	1.68 ± 0.09^{a}	0.88 ± 0.09^{b}	1.53 ± 0.08^{a}	0.75 ± 0.08^{b}	3.68 ± 0.25^{x}
20	1.83 ± 0.09	1.82 ± 0.09	1.66 ± 0.08	1.63 ± 0.08	2.68 ± 0.25^{y}
30	1.45 ± 0.09	1.94 ± 0.09	1.26 ± 0.09	1.77 ± 0.08	2.96 ± 0.26

Different superscripts indicate significant differences between treatments (in the same row; a vs b) and days (in the same column; x vs y). a vs b, x vs y: $P < 0.05$.

Key Words: LH profiles, male effect, puberty

259 Plasma progesterone concentration in beef heifers receiving exogenous glucose, insulin, or bovine somatotropin. B. I. Cappellozza*[1], R. F. Cooke[1], M. M. Reis[2], F. N. T. Cooke[1], D. W. Bohnert[1], and J. L. M. Vasconcelos[2], *[1]Oregon State University - EOARC, Burns, [2]UNESP - FMVZ/DPA, Botucatu, SP, Brazil.*

Three experiments evaluated plasma concentrations of glucose, insulin, IGF-I, and progesterone (P4) in pubertal beef heifers receiving exogenous glucose, insulin, or sometribove zinc. All heifers utilized had no luteal P4 synthesis but received a controlled internal drug releasing device containing 1.38 g of P4 to estimate treatment effects on hepatic P4 degradation. In Exp. 1, 8 nulliparous Angus × Hereford heifers (initial BW = 442 ± 14 kg; initial age = 656 ± 7 d) were randomly assigned to receive, in a crossover design containing 2 periods of 10 h: 1) intravenous (i.v.) insulin infusion (1 µg/kg of BW; INS) or 2) i.v. saline infusion (0.9%; SAL). Treatments were administered via jugular venipuncture in 7 applications (0.15 µg of insulin/kg of BW per application) 45 min apart (from 0 to 270 min). Blood samples were collected immediately before each infusion, as well as at −120, −60, 330, 390, and 450 min relative to the first infusion. Heifers receiving INS had greater ($P < 0.01$) plasma insulin, reduced ($P \leq 0.04$) plasma glucose and IGF-I, but similar ($P = 0.62$) plasma P4 concentrations compared with SAL heifers. In Exp. 2, the same heifers were assigned to receive, in a similar experimental design as Exp. 1: 1) i.v. infusion containing insulin (1 µg/kg of BW) and glucose (0.5 g/kg of BW; INS+G) or 2) SAL. Heifers receiving INS+G had greater ($P \leq 0.02$) plasma insulin, glucose, and P4, but reduced ($P = 0.01$) plasma IGF-I concentrations compared with SAL heifers. In Exp. 3, the same heifers were assigned to receive, in a crossover design containing 2 periods of 14 d: 1) subcutaneous injection containing 250 mg of sometribove zinc (BST), or 2) SAL. Blood samples were collected 3 h apart (from 0900 to 1800 h) on d 6, 8, and 10 relative to treatment administration (d 1). Heifers receiving BST had greater ($P < 0.01$) plasma glucose and IGF-I, and similar ($P \leq 0.67$) plasma insulin and P4 concentrations compared with SAL heifers. Results from this series of experiments suggest that concurrent increases in glucose and insulin are required to reduce hepatic catabolism and increase plasma concentrations of P4 in bovine females.

Key Words: heifer, insulin, progesterone

260 Prediction of estrus in beef cows using ruminal temperature. B. H. Boehmer* and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater.*

Core body temperature increases at estrus in beef cows. Monitoring ruminal temperature (RuT), a measure of core body temperature, may be useful for the prediction of estrus. The objective of this experiment was to evaluate the use of RuT in beef cows for the prediction of estrus. Hourly reporting temperature boluses (SmartStock, LLC) were administered to Angus cows (n = 60) with a balling gun. Estrus was synchronized with $PGF_{2\alpha}$ at 66 ± 2 d postpartum. The onset of estrus was determined as a 0.7°C increase in mean RuT of a cow for any 9 h period compared with the mean RuT 12 to 84 h before the 9 h identification period. The onset of estrus was determined by HeatWatch (CowChips, LLC). Ambient temperature (Tamb; www.mesonet.org) and RuT were analyzed using the UNIVARIATE and MIXED procedures (SAS). Mean Tamb for the experimental period was 19.1 ± 0.1°C (range: 16 to 32°C). Maximal daily Tamb (Tmax) was ≥32°C in only one of the 13 d. Mean RuT for all cows was 37.96 ± 0.01°C. The beginning of the 9 h mean increase of 0.7°C in RuT occurred 8.4 ± 6.1 h before the onset of estrus, as determined by HeatWatch. During the 9 h after the onset of estrus (HeatWatch), RuT was greater ($P = 0.001$, 38.54 ± 0.09°C) compared with 16 to 24 h before (37.92 ± 0.09°C) and 24 to 32 h after (37.98 ± 0.09°C) onset of estrus. Ruminal temperature correctly identified estrus in 79% of cows and identified a non estrus cow as estrus in 40% of cows. Diurnal variation in RuT was maximal at 2300 h (38.22 ± 0.03°C) and had a nadir at 1200 (37.70 ± 0.04°C). The magnitude of the increase in

RuT at estrus (9 h period compared with the previous 12 to 84 h) was greater when estrus occurred from 1700 to 0000 h compared with 0100 to 0800 h ($P = 0.009$; 0.98 ± 0.15°C vs. 0.49 ± 0.09°C, respectively). The magnitude of increase in RuT at estrus tended to be greater when estrus occurred from 1700 to 0000 h compared with 0900 to 1600 h ($P = 0.079$). These results indicate that RuT can be used for the prediction of estrus in beef cows. Diurnal variation in RuT should be incorporated in a model that utilizes RuT to predict estrus in beef cows.

Key Words: beef cow, ruminal temperature, estrus

261 Comparison of three CIDR-based fixed-time AI protocols for beef heifers.

G. A. Perry*[1], J. K. Grant[1], J. A. Walker[1], G. A. Bridges[2], S. G. Kruse[2], S. Bird[2], K. Heaton[3], R. Arias[4], and S. L. Lake[4], *[1]Department of Animal Science, South Dakota State University, Brookings, [2]North Central Research and Outreach Center, University of Minnesota, Grand Rapids, [3]Utah State University, Logan, [4]Department of Animal Science, University of Wyoming, Laramie.*

Several effective fixed-time AI (FTAI) protocols have been developed to facilitate AI while eliminating the need for estrus detection. Among these are the 5-d CO-Synch+CIDR (5d), PG 6-d CIDR (PG-CIDR), and 14-d CIDR-PG (CIDR-PG) protocols. While each of these protocols vary in duration and approach to synchronizing estrus and ovulation, each has been reported as an effective method to facilitate FTAI in beef heifers. Therefore, the objective of this study was to compare FTAI pregnancy rates in beef heifers synchronized with these 3 CIDR based protocols. Virgin beef heifers (n = 801) at 4 locations were synchronized with one of 3 protocols: 1) (5d) an injection of GnRH (100 µg; i.m.) and insertion of a CIDR on d −5, PG (25 mg; i.m.) and CIDR removal on d 0 and a second injection of PG (>4 h after CIDR removal) on d 0 and FTAI at 72 h after CIDR removal, 2) (PG-CIDR) PG (25 mg; i.m.) on d −9, GnRH (100 µg; i.m.) and insertion of a CIDR on d −6, PG and CIDR removal on d 0, and FTAI at 66 h after CIDR removal, or 3) (CIDR-PG) a CIDR insert from d 0 to 14 and PG (25 mg; i.m.) on d 30 and FTAI at 66 h after PG. All heifers received an injection of GnRH (100 µg; i.m.) concurrent with FTAI. Timing of treatment initiation was offset to allow all heifers to receive FTAI concomitantly and at random. Pregnancy success was determined between 35 and 40 d after FTAI by transrectal ultrasonography. Blood samples were collected approximately 12 d before the beginning of each protocol and at the initiation of each protocol to determine estrous cycling status (77%). Data were analyzed using the GLIMMIX procedures of SAS. Fixed-time AI pregnancy success did not differ between treatments ($P = 0.13$; 62.5%, 56.9%, and 53.3%, for 5-d, PG-CIDR, and CIDR-PG; respectively) or location ($P = 0.16$; 51.5%, 62.7%, 56.1%, and 58.6% for location 1, 2, 3, and 4; respectively). However, heifers that had reached puberty had greater ($P < 0.01$) pregnancy success compared with heifers that were prepubertal (60.7% and 47.3%; respectively). In summary, all 3 protocols had similar FTAI pregnancy success, and puberty status had the greatest impact on pregnancy success.

Key Words: fixed-time AI, beef heifer, pregnancy

262 Ovarian dynamics and AI pregnancy rates with PGF2α administration 2 d prior to the onset of a 5-d CO-Synch + CIDR program in beef cattle.

L. H. Cruppe*[1], G. A. Bridges[2], M. V. Biehl[3], F. M. Abreu[1], A. D. P. Rodrigues[4], S. G. Kruse[2], M. Maquivar[1], J. L. M. Vasconcelos[4], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]University of Minnesota, Grand Rapids, [3]University of Sao Paulo, Piracicaba, SP, Brazil, [4]Sao Paulo State University, Botucatu, SP, Brazil.*

The 5-d CO-Synch + CIDR program was used in heifers and postpartum beef cows across 2 studies to compare ovarian dynamics and AI pregnancy rates when animals received PGF 2 d before onset of the program. In all animals in both studies; blood samples were collected on d −17 and −7 of the expt. to assess reproductive status based on plasma progesterone (P4) concentration, 100 µg GnRH (GnRH-1; Cystorelin) was given at CIDR insertion on d −5, CIDR was removed on d 0 coincident with PGF injection (heifers, 25 mg; cows, 50 mg; Lutalyse). In Expt 1, prepubertal heifers (n = 35) and anestrous cows (n = 50) were randomized by age and body weight, and age and days postpartum (DPP), respectively, to receive or not, 25 mg of PGF on d −7. On d 3, all females received 100 µg GnRH (GnRH-2).Ovarian ultrasonography was conducted on d −7, −5 and −3 to determine ovulatory response to GnRH-1, d 0 to 3 to evaluate ovarian follicular dynamics during synchronization, and on d 3, 5, and 9, concurrent with blood samples to evaluate P4, size of ovulatory follicle (OF) at GnRH-2, and the proportion of females induced to ovulate and develop a functional CL following GnRH-2. In Expt 2, postpartum beef cows (n = 410) in 3 locations were randomized by DPP and age to receive or not the PGF treatment on d – 7. Estrus was detected for 60 h after PGF and AI according to the AM/PM rule. Cows not bred at estrus were timed AI on d 3 following GnRH-2. In Expt 1, ovulation response to GnRH-1, ovarian follicular development during the program, size of the OF and ovulation response to GnRH-2, size of the CL and P4 on d 9 did not differ between treatments within animal class. In Expt 2, synchronized AI pregnancy rate did not differ between cows that did and did not receive PGF on d −7 (47.3% and 50.7%, respectively). Interactions of treatment with reproductive status, estrus detection, location, AI technician and sire for AI pregnancy rate were not detected. In conclusion, PGF administration 2 d before the onset of the 5-d program did not influence ovarian dynamics in anestrous females or synchronized pregnancy rate in postpartum cows.

Key Words: beef cattle, PGF, AI

263 Efficacy of a new, once-used, or twice-used CIDR in a 5-day CO-Synch + CIDR estrous synchronization protocol in suckled beef cows.

P. J. Gunn*[1], R. P. Lemenager[1], L. A. Horstman[2], and G. A. Bridges[3], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]Department of Veterinary Clinical Sciences, Purdue University, West Lafayette, IN, [3]North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

The objective of this experiment was to compare timed-AI (TAI) pregnancy rates (PR) in suckled beef cows treated with either a new, once-used, or twice-used CIDR within the 5-d CO-Synch + CIDR protocol. Angus-cross beef cows (n = 307) from 2 locations were stratified by estrous cycling status as determined by identification of a corpus luteum (CL) via transrectal ultrasonography on d −11 and −1 (d 0 = CIDR insertion, d 8 = TAI), age (2 yr old; n = 68 vs. ≥ 3 yr [mature]; n = 239), and BCS and randomly allotted to 1 of 3 treatments. Cows were enrolled in the 5-d CO-Synch + CIDR protocol that included either: 1) a new CIDR (NEW); 2) a CIDR previously used once in a 5-d estrous synchronization protocol (1X); or 3) a CIDR previously used in 2, 5-d estrous synchronization protocols (2X). Blood samples were collected

at d −11, d −1 and d 15 for analysis of progesterone (P4) to confirm ultrasound findings for cycling status and to assess the proportion of previously anestrous cows that ovulated and developed a functional CL following TAI. Determination of pregnancy was performed by transrectal ultrasonography 31 d after TAI. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. The proportion of cows cyclic by d −1 (75.8%) did not differ between treatments. TAI PR did not differ ($P = 0.40$) among NEW (55.7%), 1X (57.8%), and 2X (49.5%) treatments. However, there was a treatment × age interaction ($P < 0.001$). In 2 yr olds, the 2X (78.3%) treatment had greater ($P = 0.003$) TAI PR than the NEW (34.7%) treatment, with 1X treatment being intermediate (59.1%). In mature cows, the NEW (61.7%) and 1X (57.5%) treatments had greater ($P \leq 0.02$) TAI PR than the 2X (41.0%) treatment. In addition, TAI PR was greater ($P = 0.008$) in cyclic (56%) than non-cyclic (50%) cows. On d 15, the proportion of previously anestrous cows that had greater than 1 ng/mL of P4 (94.7%) and mean P4 concentrations (4.37 ± 0.20 ng/mL) did not differ among treatments. In summary, cow age affects the number of times a CIDR can be effectively used in the 5-d CO-Synch + CIDR protocol.

Key Words: beef cow, CIDR, timed AI

264 Fixed-time AI in lactating beef cows after GnRH on day 9 of a 14-d CIDR.

R. L. Giles*[1], R. K. Peel[1], J. T. French[1], P. E. Repenning[1], J. K. Ahola[1], J. C. Whittier[1], and G. E. Seidel Jr.[2], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]Department of Biomedical Sciences, Colorado State University, Fort Collins.*

Most progestin-based estrous synchronization protocols focus on inducing a new follicular wave before progestin removal by administering GnRH at the initiation of the protocol. However, lack of response to GnRH due to stage of the estrous cycle when given and incomplete corpus luteum regression upon progestin removal contribute to failure to conceive to timed-AI (TAI). Our objectives were (1) to determine the effectiveness of an extended controlled internal drug release (CIDR) protocol with 2 induced follicular waves, and (2) determine the efficacy of initiating the 14-d CIDR treatment with GnRH analog (Factrel) or prostaglandin F$_{2\alpha}$ (PG) injections. Lactating beef cows at 4 locations (n = 264, location 1; n = 94, location 2; n = 139, location 3; n = 128, location 4) were randomly assigned to 3 treatments. Cows in the 14-d GnRH group received a CIDR (1.38 g progesterone) and 100 µg GnRH im on d 0, 100 µg GnRH im on d 9, CIDR removal with 50 mg PG im on d 14, and 100 µg GnRH im with TAI 72 ± 3 h after CIDR removal. Cows in the 14-d PG group were assigned the same protocol as 14-d GnRH cows except that 25 mg PG im was given at CIDR insertion instead of GnRH. Cows in the control treatment, 5-d CO-Synch + CIDR (5-d CO-Synch), received a CIDR and 100 µg GnRH im on d 9, CIDR removal and 25 mg PG im on d 14, 25 mg PG im 6 ± 1 h later, and 100 µg GnRH im with TAI 72 ± 3 h after CIDR removal. Body condition scores for the 14-d GnRH, 14-d PG, and 5-d CO-Synch treatments averaged (±SD) 4.8 ± 0.82, 4.9 ± 0.85, and 4.8 ± 0.82, and postpartum intervals at TAI were 75 ± 17.2, 76 ± 17.0, and 78 ± 16.7 d, respectively. Pregnancy status to TAI was determined 40 ± 2 d after TAI by ultrasonography. With no treatment x location interaction ($P > 0.05$), combined pregnancy rates to TAI were higher ($P < 0.05$) in 14-d PG cows (70.4%, 2 = 205) than 14-d GnRH (54.4%, n = 214) and 5-d CO-Synch cows (53.5%, n = 206). There was no increase in pregnancy rate to TAI with inclusion of 2 GnRH injections within a 14-d CIDR, however replacement of GnRH with PG at the initiation of the 14-d PG treatment improved TAI pregnancy rates compared with the 5-d CO-Synch treatment.

Key Words: CIDR, estrous synchronization, PGF$_{2\alpha}$

265 Comparison of long-term CIDR-based protocols to synchronize estrus and ovulation prior to fixed-time artificial insemination in postpartum beef cows.

N. T. Martin,* J. M. Thomas, J. M. Nash, D. A. Mallory, M. R. Ellersieck, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment compared 2 long-term CIDR-based protocols to synchronize estrus and ovulation before fixed-time AI (FTAI) in postpartum beef cows. Cows were assigned to treatments by age, body condition score (BCS), and days postpartum (DPP). Cows in treatment one [T1 (n = 92)] received CIDR inserts (1.38 g progesterone) from d 0 to d 14, and PGF$_{2\alpha}$ (PG; 25 mg i.m.) 19 d after CIDR removal on d 33. Cows in treatment 2 [T2 (n = 90)] received CIDR inserts from d 3 to d 17, and PG 16 d after CIDR removal on d 33. Cows in both treatments were inseminated 72 h after PG with GnRH (100 µg i.m.) at FTAI. Blood samples for progesterone were collected at d −10 and d 0 to determine pretreatment estrous cyclicity status, and again at PG. HeatWatch estrus detection transmitters were applied at CIDR removal and replaced at PG to determine onset of estrus following CIDR removal and PG. Dominant follicle diameter was determined via transrectal ultrasonagraphy at PG and FTAI. Pregnancy diagnosis was performed via transrectal ultrasonagraphy 70 d after FTAI and confirmed at 180 d gestation. Age, BCS, DPP, P4 concentrations, and follicle diameters were analyzed by PROC TTEST. Pregnancy rates for FTAI and final pregnancy were analyzed by PROC GLIMMIX. There were no differences between treatments for cow age, BCS, or DPP. Progesterone concentrations at PG were higher ($P = 0.04$) for cows assigned to T2 than T1 (2.4 versus 1.9 ng/mL, respectively). Estrous response after PG and before FTAI was higher ($P = 0.05$) for cows assigned to T1 (45%) compared with T2 (31%). There were no differences between treatments in mean diameter of dominant follicles at PG or FTAI. Despite differences in estrous response between treatments after PG, there was no difference between treatments for FTAI pregnancy rate ($P = 0.23$; T1 52/92 = 57%; T2 42/90 = 47%) or final pregnancy rate ($P = 1.00$; T1 76/91 = 84%; 76/90 = 84%). In summary, both protocols worked effectively to synchronize estrus and ovulation before FTAI in postpartum beef cows, suggesting that a range in interval from CIDR removal to PG may be feasible when using long-term CIDR-based protocols.

Key Words: fixed-time AI, CIDR, beef cow

266 Determination of concentrations of anti-Müllerian hormone at estrus during a synchronized and a natural bovine estrous cycle.

K. Pfeiffer,* L. Jury, and J. Larson, *Mississippi State University, Mississippi State.*

Concentrations of anti-Müllerian hormone (AMH) have been correlated to antral follicle counts, which are indicators of fertility. The effects of exogenous hormones on AMH have not been evaluated. Therefore, the objective of this experiment was to determine if concentrations of AMH at estrus differ in a synchronized compared with a natural estrous cycle. Nulliparous heifers (11 to 15 mo; n = 68) consisting of Angus (n = 19), Charolais (n = 5), Holstein (n = 34) and Jersey (n = 10) breeds were synchronized using the Select Synch + CIDR protocol (GnRH^{+}CIDR-7 d-CIDR removal+PGF$_{2\alpha}$). Heifers were observed for expression of synchronized estrus every 6 h until 84 h after the injection of PGF$_{2\alpha}$. Ovarian structures were evaluated by transrectal ultrasonography performed on heifers detected in standing estrus or with an activated heatmount detector and secondary signs of estrus. Blood samples were collected at estrus via venipuncture of the coccygeal vein of the tail for analysis of concentrations of AMH during the synchronized and natural estrous cycles. Visual detection of the subsequent estrus, considered natural estrus, occurred every 6 h from d 16 to 24 after synchronized estrus. The number of days between synchronized and natural estrus was 20.05 ± 1.60 (mean ± SD). Concentrations of AMH were determined using the Beckman-Coulter AMH Gen II ELISA kit. The GLM, CORR and REG procedures of SAS were used to analyze data. Concentrations of AMH between natural and synchronized estrus were highly correlated ($r = 0.67$, $P < 0.001$). A 0.100 ng/mL increase in the concentration of AMH in a natural estrous cycle was associated with a 0.077 ng/mL increase in the concentration of AMH in a synchronized estrous cycle ($P < 0.001$). The mean concentration of AMH did not differ ($P > 0.05$) between the natural (0.0543 ± 0.008 ng/mL) or synchronized (0.0428 ± 0.008 ng/mL) estrous cycles. In conclusion, concentrations of AMH were similar between a natural and a synchronized estrous cycle.

Key Words: anti-Müllerian hormone, bovine, estrus synchronization

267 Effect of time of insemination relative to ovulation on pregnancy rate of Nelore cows submitted to TAI protocols. M. Maturana Filho, R. Germano de Rezende, J. R. Naves,* G. A. Fonseca, T. K. Nishimura, V. B. Nunes, and E. H. Madureira, *FMVZ/USP, Pirassununga, SP, Brazil.*

The economic efficiency of cattle is related to the production of calves. The time of insemination relative to ovulation is an important factor in conception rate due to 2 physiological factors, time required for sperm capacitation in the female genital tract and survival of both gametes (spermatozoa and oocyte). The present study aimed to evaluate the influence of time of artificial insemination (AI) on pregnancy rate. The experiment was conducted on the campus of University of São Paulo (USP) Pirassununga, College of Veterinary Medicine and Animal Science (FMVZ). We used 665 Nelore cows submitted to timed artificial insemination protocol. The TAI protocol consisted of d 0 — insertion of an intravaginal progesterone-releasing device on a random stage of estrous cycle, and an injection of 2.0 mg of estradiol benzoate (EB). On d 8, the implants were removed and the cows received an injection of 0.150 mg of PGF2α and 300 IU of equine chorionic gonadotropin (eCG). On d 9, they received an injection of 1.0 mg of EB. AI was performed at 10 d and expected to ovulation time was 1900 h. The cows were randomly divided into 3 experimental groups, according to the time of insemination, being performed using semen of 2 Nelore bulls: Group 1 (G1) inseminated between 1330 and 1450 h, Group 2 (G2) between 1451 and 1610 h and Group 3 (G3) between 1611 and 1730 h. Pregnancy rate was obtained after 30 d using ultrasound Aloka SSD 500, using linear probe. The pregnancy rate obtained in G1, G2 and G3 were 63.8, 75.4 and 54.7% respectively. The semen of 2 bulls used to AI, was distributed in a balanced form among the groups, however, there was no difference in pregnancy among them. The time of AI influenced ($P < 0.05$) fertility, was observed that the best time to perform the AI is between 6 and 4 h before the expected ovulation.

Key Words: Nelore cows, ovulation, protocols

268 Substituting ground redberry juniper leaves and stems for oat hay in lamb feedlot diets: Growth performance, serum urea nitrogen, serum insulin-like growth factor-1, and wool characteristics. T. R. Whitney*[1], C. D. Swening[1], J. P. Muir[2], C. J. Lupton[1], and W. C. Stewart[1], [1]*Texas AgriLife Research, San Angelo,* [2]*Texas AgriLife Research, Stephenville.*

The abundance of redberry juniper throughout southwest rangelands presents rangeland management challenges, yet presents opportunity as an untapped feed resource. Drought and rising feed costs also make ground redberry juniper forage a cost-effective alternative roughage. Rambouillet lambs (n = 45) were used to evaluate effects of substituting redberry juniper for oat hay on feedlot performance, serum urea nitrogen (SUN), IGF-1 concentrations and wool characteristics. In a completely randomized design study with 2 feeding periods (Period 1 = 64% concentrate diet, 35 d; Period 2 = 85% concentrate diet, 61 d), lambs were individually fed ad libitum diets containing 40% dried distillers grains with solubles (DDGS) and ground juniper leaves and stems that replaced 0%, 33%, 66%, or 100% of the ground oat hay. In Period 1, a positive quadratic effect was observed in lamb ADG and DMI as juniper replaced 0% to 100% of oat hay ($P < 0.003$). In Period 2, a linear response occurred in lamb ADG as juniper replaced up to 100% of oat hay ($P = 0.007$), whereas DMI was unaffected ($P > 0.10$) after d 49. Overall, final BW of each period quadratically increased ($P < 0.04$) and there was no effect ($P > 0.32$) of treatment on G:F. During Period 2, a positive quadratic effect on SUN ($P = 0.002$) and a linear effect on fecal N ($P = 0.001$) were observed, due in part, to a combined effect of DMI and dietary urea concentrations. No differences ($P > 0.18$) were observed in serum IGF-1, Ca, P, or fecal P. Wool characteristics were unaffected by treatments with the exception of a negative quadratic effect in grams of wool produced/kg of BW. From these findings we can conclude that redberry juniper stems and leaves can effectively replace oat hay in lamb feedlot diets and is a viable alternative roughage source for lamb diets.

Key Words: lamb, feedlot, juniperus

269 Dietary betaine improves physiological responses in sheep under chronic heat load in a dose dependent manner. K. DiGiacomo,* S. Simpson, B. J. Leury, and F. R. Dunshea, *Melbourne School of Land and Environment, The University of Melbourne, Parkville, Vic, Australia.*

Heat stress (HS) results in decreased production, health issues and economic losses in ruminants. Dietary betaine is an organic osmolyte implicated in maintaining cellular osmotic balance and reducing energy expenditure and may help to maintain thermal tolerance. Thirty-six Merino ewe's (40 kg, n = 6 per group) were housed in climate chambers maintained at either thermoneutral (TN) (n = 18, 21°C) or cyclical HS (n = 18, 18–43°C) conditions for 21 d, and supplemented with either 0, 2 or 4 g betaine/d. Animals had ad libitum access to water and were pair fed such that TN intake matched that of HS animals who were fed ad libitum. Water and feed intake was measured twice daily, and plasma samples were obtained at 1500h 3 times per week. Heart rate (HR), respiration rate (RR), skin temperature (T_S) and rectal temperature (T_R) were measured at 0900, 1300 and 1700 h daily. Betaine supplementation did not alter feed intake ($P = 0.66$). All physiological measures differed with time of day ($P < 0.001$) and average daily T_R was increased by HS (39.4 to 40.1°C, $P < 0.001$) and altered by betaine supplementation (39.7, 39.6 and 39.8°C for 0, 2 and 4 g betaine respectively, $P < 0.001$). Heat increased T_S (38.0 to 39.1°C, $P = 0.002$), while betaine did not affect T_S ($P = 0.48$). Heat increased RR by 47 breaths min^{-1} ($P < 0.001$) and 2 g betaine decreased RR (113, 102 and 116 breaths min^{-1} for 0, 2 and 4 g betaine respectively, $P < 0.001$). Heat increased HR by 8 beats min^{-1} ($P < 0.001$), while 2 g betaine decreased HR (95, 88 and 99 beats min^{-1} for 0, 2 and 4 g betaine respectively, $P < 0.001$). Heat stress did not alter plasma glucose and NEFA concentrations ($P > 0.50$), while betaine supplementation decreased plasma NEFA concentrations (80, 55 and 54mM for 0, 2 and 4 g betaine respectively, $P = 0.05$). These data suggest that dietary betaine supplementation in sheep has dose dependent responses, with the 2 g betaine dose able to decrease heat load in sheep.

Key Words: betaine, heat stress, ruminants

270 Evaluation of body temperature and sweating rate of Senepol and crossbred heifers in the tropics. R. W. Godfrey*[1], A. J. Weis[1], P. E. Hillman[2], K. G. Gebremedhin[2], C. N. Lee[3], and R. J. Collier[4], [1]*University of the Virgin Islands, St Croix, VI,* [2]*Cornell University, Ithaca, NY,* [3]*University of Hawaii, Manoa,* [4]*University of Arizona, Tucson.*

Heat stress is a common problem in livestock production throughout the tropics. Senepol (SEN) cattle are well adapted to the tropical environment but other *Bos taurus* breeds are not as well suited for the climate. The objective of this study was to compare the body temperature and sweating rate of SEN (n = 6) and Charolais × Angus × SEN (XBRED; n = 4) heifers. All heifers were nulliparous and 1.3 y of age. Temperature data loggers, programmed to record vaginal temperature (VT) at 10-min intervals, were inserted into the vagina of each heifer and removed after 72 h. Rectal temperature measured using a digital veterinary thermometer (RT), eye temperature measured using infrared images of the left eye (IREYE), surface temperature over the rump measured using a hand-held infrared thermometer (IRR), respiration rate measured as breaths per minute (bpm) using visual observation (RR) and sweating rate (SWR) measured at a site on the rump of each heifer using a hand-held closed-chamber VapoMeter were collected between 1200 and 1430 h. Heifers were evaluated in the shade on d 1 and d 3 and in the sun on d 2 and d 4. Data were analyzed using GLM procedures of SAS with breed, sun exposure and the interaction in the model. Serial VT measurements were analyzed using time and breed in the model. Mean temperature, relative humidity and THI during the data collection were 28.3°C, 83.7% and 80.6, respectively. There was no difference between SEN and XBRED heifers in IREYE or RR ($P > 0.10$). The SEN heifers had lower ($P < 0.05$) VT and RT than XBRED heifers (38.87 ± 0.11 vs. 39.22 ± 0.13°C and 39.14 ± 0.07 vs. 39.36 ± 0.09°C, respectively). There was no difference ($P > 0.10$) in RT or VT between heifers in the sun or shade within breed. The VT of SEN heifers in the shade was lower ($P < 0.06$) than VT of XBRED heifers in sun or shade (38.75 ± 0.15 vs. 39.22 ± 0.18°C, respectively). The IRR of SEN heifers was lower ($P < 0.008$) than that of XBRED heifers (37.39 ± 0.21 vs. 38.38 ± 0.28°C, respectively) and IRR was higher ($P < 0.0001$) in the sun than in the shade (40.60 ± 0.26 vs. 35.16 ± 0.24°C, respectively). The SWR of SEN heifers was higher ($P < 0.001$) than that of XBRED heifers (23.96 ± 0.71 vs. 19.75 ± 0.93 g/m^2, respectively). The SWR of SEN heifers in the sun was higher ($P < 0.03$) than SWR of SEN heifers in shade or XBRED heifers in sun or shade (27.37 ± 1.08 vs. 20.54 ± 0.93 vs. 20.48 ± 1.32 vs. 19.03 ± 1.32 g/m^2, respectively). The higher SWR of SEN heifers may play a role in their lower RT and VT and their adaptation to the tropical climate.

Key Words: heat stress, sweating rate, Senepol

271 Evaluation of body temperature and sweating rate of Senepol cows in the tropics. R. W. Godfrey*[1], A. J. Weis[1], P. E. Hillman[2], K. G. Gebremedhin[2], C. N. Lee[3], and R. J. Collier[4], *[1]University of the Virgin Islands, St Croix, VI, [2]Cornell University, Ithaca, NY, [3]University of Hawaii, Manoa, [4]University of Arizona, Tucson.*

Senepol cattle are well adapted to the tropical environment and there is interest in determining what physiological traits contribute to their adaptation. The objective of this study was to evaluate the body temperature and sweating rate of Senepol cows in the tropics. Primiparous (n = 3) and multiparous (n = 7) cows were evaluated in July (2.3 to 11.4 y of age). Three cows were pregnant (6 mo of gestation) at the time of data collection. Temperature data loggers, programmed to record vaginal temperature (VT) at 10-min intervals, were inserted into the vagina of each cow and removed after 72 h. Rectal temperature measured using a digital veterinary thermometer (RT), eye temperature measured using infrared images of the left eye (IREYE), surface temperature over the rump measured using a hand-held infrared thermometer (IRR), respiration rate measured as breaths per minute (bpm) using visual observation (RR) and sweating rate (SWR) measured at a site on the rump of each cow using a hand-held closed-chamber VapoMeter were collected. Evaporative heat loss (EVHL) was calculated from measured air properties passing over a sample area of the cows' body by a Bovine Evaporation Meter. Cows were evaluated over 3 d in the shade and in the sun after a 20 min acclimation to each condition on each day. Data were analyzed using GLM procedures of SAS with sun exposure and time of day as the main effects in the model. Serial VT measurements were analyzed using time and pregnancy status in the model. Mean temperature, relative humidity and THI during the data collection were 28.3°C, 83.7% and 80.6, respectively. There was no difference ($P > 0.10$) in SWR or VT between the sun and shade (20.95 ± 2.6 vs. 22.98 ± 2.9 g/m^2 and 38.86 ± 0.22 vs. 38.41 ± 0.23°C, respectively). The IREYE, IRR, RT, RR and EVHL were higher ($P < 0.02$) in the sun than in the shade (38.87 ± 0.14 vs. 38.19 ± 0.19°C, 40.16 ± 0.25 vs. 34.64 ± 0.27°C, 39.15 ± 0.06 vs. 38.93 ± 0.06°C, 72.4 ± 0.9 vs. 68.1 ± 1.0 bpm and 344.8 ± 13.7 vs. 179.5 ± 14.9 $g{\cdot}m^{-2}{\cdot}h^{-1}$, respectively). Pregnant cows had a lower ($P < 0.01$) RT than open cows (38.88 ± 0.07 vs. 39.12 ± 0.05°C, respectively). Pregnant cows had higher ($P < 0.0001$) VT than open cows at all times of the day except during the morning (0600 to 1200 h). These data provide more information on the heat tolerance traits of Senepol cattle.

Key Words: heat stress, sweating rate, Senepol

272 Variation in skin surface temperature in different body parts of pigs in response to varying air temperatures. A. Sapkota* and J. J. McGlone, *Pork Industry Institute, Texas Tech University, Lubbock.*

Surface skin temperature may vary with the environmental temperature in mammals and may be a non-invasive method to evaluate the welfare of pigs. Surface skin temperatures may vary with body regions. The objective of this study was to evaluate how surface skin temperature of pigs varied with changes in external environmental temperature (both warm and cold) and over time. An infrared thermometer was used to record surface skin temperature every minute on body parts: rooting disc, bridge, ear, neck, throat, thorax, loin, abdomen, front leg, hind leg and ham of market size pigs. Data were recorded in the home pen (HOME), hallway (HALL), outside the building (OUT), back again in hallway (HALL2) and in home pen (HOME2) during cold (n = 24) or warm (n = 24) weather. Statistical models included the effects of air temperature and time (per min for 5 min; linear and quadratic effects). During winter, pigs in HOME (avg temp = 17.8 C) showed no time effects. When pigs were moved to the HALL (avg temp = 16.4 C), there was a quadratic effect ($P < 0.05$) for bridge, thorax, loin, abdomen, front leg, hind leg and ham. When pigs were moved to OUT (avg temp = 6.3 C), the disc and bridge regions showed a quadratic change over time ($P < 0.05$). When again moved to HALL2 (avg temp = 9.6 C), the quadratic effect over time ($P < 0.05$) was seen in all body parts except ear and thorax. Finally, when pigs were moved to HOME2 (avg temp = 16.4 C), the quadratic change over time was observed for all body parts except bridge, ear and thorax ($P < 0.05$). During summer, pigs in HOME (avg temp = 31.8 C) showed no time effects. When pigs were moved to HALL (avg temp = 32.4 C), there was quadratic time effect ($P < 0.05$) only for ham. When pigs were moved to OUT (avg temp = 35.6 C) and HALL2 (avg temp = 33.9 C), the quadratic time effect was observed in all body parts except disc ($P < 0.05$). Finally, when pigs were moved to HOME2 (avg temp = 32.3 C), there were no time effects. When body parts were compared, the rooting disc was the coolest body part in summer. However, during the winter, body regions had more uniform surface temperatures. Only some of the pigs' body regions (esp. rooting disc) were responsive to warm air temperature. More data are needed to model surface temperature effects on core body temperature and behavior.

Key Words: surface temperature, pigs, welfare

273 Routine exercise of feedlot cattle: Implications for stress response, productivity, and beef quality. N. Miller,* B. Gerlach, H. Glynn, K. Miller, C. van Bibber, L. Edwards-Calloway, J. Drouillard, and T. Houser, *Kansas State University, Manhattan.*

Feedlot cattle normally are limited in the amount of physical activity in which they regularly participate. The objectives were to determine if cattle become conditioned to handling with routine exercise during the finishing period, and to determine if routine exercise affects behavioral and physiological changes, growth performance, and carcass characteristics. Steers (n = 419) were stratified by weight and randomly assigned within strata to one of 4 treatments: 1) exercised 3 times/wk for the entire finishing period (ALL); 2) exercised 3 times/wk for the first 10 wk (E); 3) exercised 3 times/wk for the last 7 wk (L); and 4) no exercise during the 116-d finishing period (CON). Cattle were exercised by animal handlers for a minimum of 20 min at a trotting pace. Temperament scores (TS) and BW were obtained from all cattle on d 0, 72 and 116. Blood was obtained from 3 cattle randomly selected from each pen (n = 84) on these days and at exsanguination for analysis of serum concentrations of cortisol, insulin, glucose, and lactate, and plasma concentrations of epinephrine, norepinephrine, and β-endorphins. Data were analyzed as a mixed model, with fixed effect of treatment and random effect of pen. Date was included as a fixed effect for analyses of blood constituents and TS. There were no treatment x date interactions for blood constituents ($P > 0.10$) or TS. Exercise influenced pre-harvest insulin ($P < 0.01$; 0.75, 0.47, 0.60 and 0.78 ng/mL for ALL, E, L, and CON, respectively), but had no impact on other pre-harvest or post-harvest blood measurements ($P > 0.10$). TS were similar across treatments ($P > 0.10$), indicating no adaptation due to routine exercise or handling. Treatments did not differ with respect to ADG ($P > 0.8$). DMI were 10.29, 10.44, 10.26, and 10.58 kg/d ($P = 0.10$); G:F were 0.197, 0.197, 0.176, and 0.189 ($P = 0.28$); and HCW ($P = 0.77$) were 390, 391, 393, and 389 kg for ALL, E, L, and CON, respectively. Other carcass characteristics were unaffected by exercise regimen ($P > 0.10$). In summary, routine exercise had little impact on blood parameters, feedlot performance, or carcass traits of finishing steers.

Key Words: exercise, cattle, stress

274 Effects of different implant management options on performance of pre and post weaned calves.

H. B. Jones*[1], J. D. Rivera[1], and R. C. Vann[2], [1]*MAFES South Mississippi Branch Experiment Station, Poplarville,* [2]*MAFES Brown Loam Branch Experiment Station, Raymond, MS.*

Fifty-one head of crossbred (primarily *Bos taurus*) beef steers (BW = 166 kg) were used in year one of a multi-year study to evaluate effects of growth implants on performance, in a randomized complete block. Calves were implanted either at calfhood vaccination (approximately 3.5 mo old) with 100 mg of progesterone and 10 mg estradiol benzoate (CALF); at calfhood and again at weaning with 40 mg of trenbolone acetate and 8 mg of estradiol (WEAN); or not implanted (NONE). Cattle were weighed at weaning, and subsequently on d 28, 45, and 80 post weaning. On d 80, all steers were ultrasounded to measure longissimus area (LMA), intramuscular fat (IMF), and fat thickness. Data were analyzed using PROC GLM of SAS, steer was the experimental unit. At weaning, steers implanted at calfhood, had greater pre-weaning ADG compared with non-implanted steers (1.12 vs 1.0 kg, respectively; $P = 0.04$). At 28 d post weaning, no differences were detected among groups regarding ADG. Additionally, at 45 d post weaning, no differences were noted for BW; however, a difference was noted in ADG from weaning to d 45 between CALF and NONE (0.61 vs. 0.48 kg, respectively; $P < 0.10$). Surprisingly, no difference was detected in ADG between NONE and WEAN (0.48 vs 0.52 kg, respectively). Moreover, a tendency was noted in ADG ($P = 0.14$) between NONE and both implanted groups for the period between weaning and d 80 (0.82, 0.90, and 0.90 kg, respectively). Overall ADG was greater ($P < 0.10$) for cattle that were implanted compared with untreated controls (0.88, 0.98 and 0.92 for NONE, CALF and WEAN, respectively). Ultrasound measurements noted a tendency for increased LMA in CALF group ($P = 0.12$), and a tendency for decreased IMF for the CALF and WEAN compared with controls ($P = 0.12$). Results suggest that use of growth promoting implants may be of benefit to cattle producers; however, longer retention periods post weaning may be needed to realize full benefit of implanting.

Key Words: beef cattle, growth, implants

275 Comparison of chelated versus inorganic trace minerals on rate and efficiency of gain and pregnancy rates in beef heifers.

W. A. Whitehurst*[1], J. A. Paterson[1], M. M. Harbac[1], M. K. Petersen[2], G. C. Duff[2], and T. W. Geary[2], [1]*Montana State University Bozeman, Bozeman,* [2]*USDA-ARS Fort Keogh, Miles City, MT.*

Objectives of this experiment were to compare rate and efficiency of gain, and conception rates of yearling heifers supplemented with Cu, Zn and Mn as either metal methionine hydroxy analog chelated trace mineral (CTM; provided as Mintrex) or the same trace minerals in an inorganic SO_4 form. The experimental design utilized 3 ranches, each having 2 replications per treatment with pen as the experimental unit for ADG, DMI and G:F. Individual heifer was the experimental unit for pregnancy rates. Ranch A contained 498 Angus cross heifers, ranch B, 236 Red Angus cross heifers, and ranch C, 1,742 Angus cross heifers. All heifers were fed silage based diets that contained approximately 13.5% CP, 64% TDN (DM basis) and had no significant levels of SO_4, Mo, or Fe in feed or H_2O. Diets contained an average of 24 ppm Cu, 70 ppm Zn and 64 ppm Mn. Supplements were fed for 181 d (Ranch A), 149 d (Ranch B) and 151 d (Ranch C) before breeding. Heifers were weighed once at trial initiation (initial BW 270 kg ± 2.8), end of drylot feeding, at breeding and at pregnancy diagnosis. Ranch A heifers were bred by AI followed by natural service (45 d breeding), Ranch B heifers were bred by natural service (50 d breeding) and Ranch C heifers were bred by AI once. Pregnancy was determined via ultrasound using trained technicians. Ranch effects were significant ($P < 0.001$) for gain, ADG, G:F and overall pregnancy rate, but not for conception in the first 21 d. No ranch x treatment interactions were detected for any measurements ($P \geq 0.47$) and no differences ($P \geq 0.46$) were detected between treatments for total gain, ADG, G:F or the number of heifers that conceived during the first 21 d on Ranches A or B. Conception rate increased ($P = 0.03$) for CTM heifers from ranch C with one AI breeding. Across ranches, conception rates during the first 21 d of breeding did not differ ($P = 0.12$) between treatments but overall pregnancy rate was greater ($P = 0.05$) for heifers supplemented with CTM. Under the conditions of this experiment results suggest that supplementation with CTM contributed to higher pregnancy rates in heifers.

Key Words: chelated minerals, mineral nutrition, fertility

276 Relationships between postweaning residual feed intake in heifers and efficiency, digestibility, and productivity of Bonsmara cows.

A. N. Hafla*[1], G. E. Carstens[1], T. D. A. Forbes[2], J. C. Bailey[1], J. T. Walter[1], J. G. Moreno[1], and J. R. Johnson[1], [1]*Texas A&M University, College Station,* [2]*Texas AgriLife Research, Uvalde.*

The objective of this study was to examine phenotypic relationships between heifer postweaning residual feed intake (RFI), and performance, efficiency, digestibility and productivity of mid-gestation cows. RFI_h was measured in growing Bonsmara heifers (n = 115) during 2 yr. Dry matter digestibility (DMD) was measured in 38 heifers with divergent RFI. Low RFI_h heifers consumed 20% less feed ($P < 0.05$) compared with those with high RFI_h heifers, but had similar BW, ADG and backfat depth. DMD was not affected by RFI group. Heifers with the lowest (n = 12/yr) and highest (n = 12/yr) RFI_h were retained for breeding and use in the cow feeding trial. Subsequently, the midgestation females (19 s-parity cows, 23 primiparous heifers) were fed chopped hay (ME = 2.11 Mcal/kg DM) in pens equipped with GrowSafe bunks to measure individual intake. BW were measured at 7-d intervals and BCS and ultrasound measurements of rump fat thickness obtained on d 0 and 77 of trial. DMD was measured on 32 of the pregnant females. Mixed model included fixed effect of RFI_h class, age and 2 way interaction. Low RFI_hfemales had lower ($P < 0.01$) DMI (9.00 vs 11.6 ± 0.54 kg/d) compared with females with high RFI_h, but initial BW, ADG, BCS and rump fat thickness were similar. Age at calving was not affected by RFI_h classification. An interaction ($P < 0.05$) between RFI_h classification and female age group was found for calf birth weight. Calves from primiparous heifers with low RFI_h were lighter at birth (27 vs 32 ± 1.2 kg; $P < 0.05$) compared with high-RFI_h females, but RFI classification did not affect BW of calves born to second-parity cows. RFI for pregnant cows (RFI_c) was calculated as the residual from the linear regression of DMI on conceptus-adjusted ADG and mid-test $BW^{0.75}$. RFI_c was highly correlated with DMI (0.79), but not BW, ADG, backfat depth or BCS. Moreover, RFI_c was moderately correlated to RFI_h (0.50). DMD tended ($P < 0.08$) to be greater (58 vs 54 ± 1.6%) for cows classified as having high RFI_h. Heifers classified as having low RFI continued to consume 22% less feed during mid-gestation with similar BW and BCS compared with heifers classified as having high RFI. While some reranking of animals occurred between RFI in heifers and mid-gestation females, differences in intake were still evident. Between-animal variation in digestibility and body composition did not contribute to variance in RFI in this study.

Ruminant Nutrition: Beef

277 Effect of yeast β-glucan and antibiotics on growth and gastrointestinal development in pre-ruminant calves. Y. Zhou, Y. Tu,* Q.-Y. Diao, Q. Yun, X.-H. Gao, and L.-H. Zhao, *Feed Research Institute of Chinese Academy of Agricultural Sciences, Beijing, China.*

This experiment was conducted to investigate the effect of yeast β-glucan and bacitracin zinc on growth performance and gastrointestinal morphological development of pre-ruminant calves. Twenty healthy Holstein male neonatal calves were randomly allotted to 4 treatments with 5 replicates each. The calves were fed diets supplemented with 0 (Treatment A), 75 mg yeast β-glucan/kg (Treatment B and C), 60 mg bacitracin zinc /kg (Treatment D). The experiment lasted for 28 d. Feed intake (FI) was recorded daily, body weight was measured every 2 weeks, and average daily gain (ADG) was calculated every 2 weeks. On d 21, the calves of Treatments A,B and D were challenged orally with *Escherichia coli* (O141:K99), with Treatment C fed normally. The rectal content was collected after challenged and diluted for microorganism counts. On d 28, calves were slaughtered and tissues from saccus cranialis, duodenum, jejunum and ileum were obtained and used in tissue slice. Data were analyzed using the GLM procedure of SAS software. The results showed as following: Comparing with Treatment A, the ADG of calves in Treatment B increased by 26.17% and 24.93% in the 2 phases before the *E. coli* challenged ($P < 0.05$), the ADG of calves in Treatment B and D increased by 30.38% and 30.81% after the *E. coli* challenged ($P < 0.05$). As for the F/G, which in Treatment B and D were significantly lower than that in Treatment A ($P < 0.05$). Compared with Treatment A, the amount of *E. coli* in rectum at 12h and 24h in Treatment B and D were significantly decreased ($P < 0.05$), and the amount of *Lactobacillus* was significantly decreased in the Treatment D ($P < 0.05$). Compared with the control treatment, the rumen papilla height and width of yeast β-glucan were significant higher than the control treatment ($P < 0.05$). The crypt depth of duodenum in treatment C and D were significant lower than the control treatment and the treatment D ($P < 0.05$), the ratio of villous height to crypt depth (V/C) in treatment B, C and D were higher than the control treatment ($P < 0.05$). It could be concluded that yeast β-glucan at the dosage of 75 mg/kg could erase the decrease of growth performance of pre-ruminant calves, improve the gastrointestinal morphological development and protect pre-ruminant calves, which challenged with *E. coli* K99, thus using β-glucan in calves feed may decreased the usage of antibiotics.

Key Words: calves, intestinal microflora, yeast β-glucan

278 Effect incremental levels of exogenous enzyme preparation on extent of ruminal fermentation, nutrient digestibilties and average daily gain in steers. H. Gado*[1], A. Z. M. Salem[2], and B. E. Borhami[3], [1]*Department of Animal Production, Faculty of Agriculture, Ain Shams University, Cairo, Egypt,* [2]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca Estado de México, México,* [3]*Department of Animal Production, Faculty of Agriculture (El-Shatby), Alexandria University, Alexandria, Egypt.*

The aim of this experiment was to investigate the effect of the gradual increasing levels of an exogenous enzymes preparation (mixture of cellulase, xylanase, α-amylase and proteases enzymes) in the diet on ruminal fermentations activates, nutrients digestibility and animal performance in steers. Forty 8 steers (Baladi × Friesian, 151 ± 0.95 kg BW) were randomly allocated in 3 experimental groups of the following treatments (12 steers for each): 0 (control, ENZ0), 40 (ENZ40) and 60 (ENZ60) g of ENZ/head/d. A complete randomize block design was set up and a repeated measurement in time model used to analyze the data. The ENZ doses were mixed daily with a part of their daily ration. Steers were fed a total mixed ration (TMR) contained: 11% cracked corn, 8.5% agwa (minced date), 26.5% biscuits (bakery waste), 10% sugar cane molasses, 19% sesame cake, 2% soybean meal, 6% beans, 14.2% rihan straw, 1% salt, 1% limestone and, 0.3 mixture of mineral and vitamins. Steers were fed the TMR for 206 d as experimental period. Feed and orts samples were collected twice weekly to calculate dry matter intake and animals were weighted each 2 weeks during the experiment. At the end of experiment, rumen liquor of 3 animals of each treatment (fitted with permanent rumen fistulated) was collected to determine the concentrations of volatile fatty acids (by gas liquid chromatography) and NH3-N. Nutrients digestibility were determined during the last week of the experiment, using chromium, as a marker, in fecal samples by atomic absorption spectrophotometry. Total digestibility of nutrients, was increased ($P < 0.01$) by addition of ENZ (ENZ40 and ENZ60) vs control (DM, 65.1 and 69.8 vs 61.7%; CP, 66.1 and 68.9 vs 60.3%; NDF, 50.8 and 54.7 vs 41.7%; ADF, 40.8 and 43.5 vs 32.2%, respectively). Average daily gain also improved by the addition of the 2 doses of ENZ (1.45 and 1.58 vs 1.25 kg/d, respectively- $P < 0.05$). Ruminal fermentation activities were improved by the addition of the 2 ENZ doses, however, VFA were higher ($P < 0.05$) in ENZ40 and ENZ60 compared with ENZ0 (120 and 128 vs 100 mM/100mL), respectively), and NH3-N were higher ($P < 0.05$) in the same treatments vs control (ENZ0) (65 and 63 vs 54 mg/L, respectively). Supplementing steers with ENZ could enhance animal performance, ruminal activities and nutrient digestibility in fattening steers.

Key Words: beef production, exogenous enzyme, steers

279 Effect of a blend of castor oil and cashew nut shell liquid on performance, eating pattern, rumen health and carcass quality in Holstein bulls fed high-concentrate rations. M. Devant*[1], A. Aris[1], A. Bach[2,1], and J. Torrent[3], [1]*IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Torre Marimon, Caldes de Montbui, Barcelona, Spain,* [2]*ICREA, Barcelona, Spain,* [3]*Oligo Basics USA LLC, Excelsior, MN.*

This study evaluated the effects of a blend of castor oil and cashew nut shell liquid (Essential, Oligo Basics, Brazil) on the performance, eating pattern, rumen health and carcass characteristics of Holstein bulls. A total of 120 bulls (295 ± 2.5 kg of BW and 214 ± 1.1 d of age) were divided into 2 treatments: 1) control and 2) supplemented with Essential (0.5 g/kg of concentrate as fed). Individual concentrate intake and eating pattern were recorded daily with a computerized concentrate feeder, and BW was recorded every 14 d. Rumen fluid was collected through rumenocentesis for pH and VFA analysis at d 114 of study. Animals were slaughtered after 124 d and HCW, rumen wall ulcers, papillae clumpings, parakeratosis and color, as well as liver abscesses were evaluated. Data were analyzed using a mixed-effects model with repeated measures that included initial BW, Essential supplementation, time, and the interactions among these factors, as fixed effects, and animal as a random effect. The statistical model for rumen pH included previous meal size, total daily concentrate intake and time since last meal as covariates. Essential supplementation improved ($P < 0.001$) ADG (1.6 and 1.4 ± 0.07 kg/d, respectively), and decreased ($P < 0.001$) the CV of daily concentrate intake (14.3 and 20.4% ± 0.96, respectively) during the first 2 wk of the trial, but these differences in both parameters were not observed thereafter. Ruminal pH, VFA, HCW and carcass characteristics were unaffected by dietary treatments. Control bulls tended ($P = 0.08$) to have darker rumen walls (3.4% and 0% black, for control and Essential, respectively), more ($P = 0.09$) papillae clumpings (3.5% and 0% clumping, for control and Essential, respectively), and greater ($P = 0.10$) presence of liver abscesses than supplemented bulls (31.1 and 13.3%, for control and Essential, respectively). Essential® improves intake and growth during the first 2 wk of supplementation, but no further effects are observed thereafter. However, Essential tends to improve rumen wall integrity and decrease liver abscesses.

Key Words: beef, eating pattern, functional oil

280 Yeast cell wall supplementation alters the performance of beef heifers during the receiving period. T. R. Young*[1], N. C. Burdick[2], J. A. Carroll[2], M. A. Jennings[1], J. T. Cribbs[1], R. J. Rathmann[1], J. R. Corley[3], and B. J. Johnson[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Lesaffre Feed Additives, Milwaukee, WI.*

A study was designed to determine the effect of feeding yeast cell wall (YCW) products on feedlot performance of newly-received crossbred heifers. Heifers (n = 140; 225 ± 9.4 kg) were obtained from commercial sale barns and transported to the Texas Tech University Beef Center in New Deal, Texas. Heifers were sorted by source (n = 2) upon arrival and arranged in a completely randomized block design (35 pens; 7 pens/treatment; 4 heifers/pen). Heifers were separated into treatment groups receiving a Control Diet (CON; n = 28), YCW A (2.5 $g \cdot hd^{-1} \cdot d^{-1}$; n = 28), YCW AA (5.0 $g \cdot hd^{-1} \cdot d^{-1}$; n = 28), YCW B (2.5 $g \cdot hd^{-1} \cdot d^{-1}$; n = 28), or YCW C (2.5 $g \cdot hd^{-1} \cdot d^{-1}$; n = 28) and were fed for 56 d. Daily DMI was recorded and individual BW was collected every 14 d. A significant source by treatment interaction was detected, and data were analyzed accordingly. In Source 1, YCW A (278 ± 8.0 kg) and YCW C (285 ± 8.1 kg) showed a greater increase in 28 d BW compared with CON (272 ± 8.0 kg; $P = 0.03$). YCW C exhibited a higher 42 d BW compared with all other treatments ($P = 0.02$). From d 0 to 28, YCW A (1.87 ± 0.09 kg) and YCW C (2.10 ± 0.10 kg) had higher ADG compared with CON (1.65 ± 0.09 kg; $P = 0.03$). YCW C showed improved ADG from d 0 to 42 compared with all other treatments ($P < 0.01$). DMI was improved for YCW AA (7.27 ± 0.20 kg) and YCW C (7.92 ± 0.23 kg) compared with CON (6.75 ± 0.20 kg; $P = 0.04$) for d 0 to 42. YCW C had higher DMI vs. CON from d 14 to 28 and d 28 to 42 ($P = 0.05$ and 0.02, respectively). Cumulative F:G was lower for YCW B compared with all other treatments ($P = 0.03$). In Source 2, a linear effect for YCW A was detected from d 0 to 14 in BW, ADG, and G:F ($P = 0.01$, 0.02, and 0.03, respectively). Collectively these data suggest that YCW supplementation can offer advantages in performance of newly received beef heifers.

Key Words: cattle, performance, yeast

281 Feedlot performance of Nellore young bulls fed biodiesel coproduct. R. L. Oliveira*[1], C. H. da Cruz[1], N. B. de Santana Filho[2], W. G. Cerutti[3], C. A. dos Santos Dias[2], E. I. de Souza Costa[1], O. L. Ribeiro[1], A. G. Leão[1], M. C. A. Santana[1], and A. A. Pinheiro[1], *[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Universidade Federal do Recôncavo Baiano, Cruz Das Almas, Brazil, [3]Universidade Federal de Santa Maria, Santa Maria, Brazil.*

Feedlot performance of Nellore young bulls fed diets with different levels of palm kernel cake (PKC) was evaluated by analysis of average daily weight (ADW), dry matter intake (DMI) and feed conversion ratio (FCR). Thirty-two Nellore breed young bulls (420 ± 2.0 kg) were used in a completely randomized experimental design and allocated into 4 treatments: 0, 7, 14 and 21% PKC inclusion on DM basis. Diets consisted of forage (Tifton-85 hay, as 35% of diet), concentrate (corn and soybean meal and palm kernel cake) and mineral salt. The animals were fed during 92 d and weighted at the beginning of the experiment and every 28 d, after fasting for 16 h. Feeding level was adjusted according to individual intake to remain between 10 and 20% of orts. FCR was obtained using the ratio between DMI and ADW. Data were submitted to regression and variance analysis using a significance level of 5%. The bulls' DMI and ADW average were, respectively, 10.16 and 1.15 kg per day. There were no effects of PKC level ($P > 0.05$) on the animal's ADW (SE = 0.06) and FCR (SE = 0.85) The DMI ($P = 0.037$, SE = 0.32) linearly decreased ($\hat{Y} = 11.235 – 0.1021X$) as PKC was included to the diet. PKC addition to a diet of Nellore young bulls did not compromise feedlot performance on despite of the decreasing on DMI.

Key Words: beef cattle, palm kernel cake, performance

282 Effect of corn oil or corn protein supplementation on performance and rumen fermentation characteristics of feedlot lambs consuming a 90% concentrate diet containing 30% DDGS. C. L. Shelley,* M. Pimienta, J. Caballero, J. Browne-Silva, S. L. Lodge-Ivey, and S. A. Soto-Navarro, *New Mexico State University.*

Feeding values of corn dried distillers grains with solubles (DDGS) are best when included in concentrate diets at 20 to 30% of the diet. When DDGS are included at levels greater than 30%, high EE or CP content may cause a decrease of feeding value. This study evaluated effects of corn oil and corn protein supplementation on feedlot diets containing dry rolled corn (DRC) and DDGS. Twenty-one Suffolk cross wethers (average BW = 41.8 ± 1.95 kg) were randomly assigned to 1 of 4 treatments and were individually fed once daily. Experimental diets were DRC based containing 10% alfalfa (DM basis). Treatments included: 1) DDGS at 30% of the diet (30%), 2) DDGS at 60% of the diet (60%), 3) DDGS at 30% of the diet containing similar EE to the 60% diet supplied by corn oil (OIL), and 4) DDGS at 30% of the diet containing similar CP to the 60% diet with protein supplied by corn gluten meal (PROTEIN). Animals were weighed on d 1 and d 56 of the 56 d experiment. Ruminal fluid samples collected on d 48 via oral lavage 4 h post feeding were analyzed for pH, VFA, ammonia, and bacterial populations. Final BW and DMI were not affected ($P \geq 0.13$) by treatments. Average daily gain and G:F were 69% higher ($P = 0.01$) for 30% than OIL. Ruminal pH tended to be lower for 30% than for 60% or OIL ($P \geq 0.06$). Ammonia concentrations increased 47% when 60% was fed compared with 30% ($P = 0.01$). Total VFA production was not affected ($P > 0.20$) by treatment. Bacterial populations were analyzed using PCR-denaturing gradient gel electrophoresis (DGGE) using the 16S rDNA gene. Bacterial presence or absence was analyzed using Richness index and was not affected ($P = 0.89$) by treatment. Overall, all samples were 60.21% similar in DGGE banding pattern. Animals fed OIL had the least similar DGGE banding pattern (57.73%) when compared with all other treatments. In conclusion, adding enough corn oil to match the EE of 60% DDGS decreased animal performance and resulted in shifts in bacterial populations.

Key Words: sheep, distillers byproducts, rumen bacteria

283 Prospects of raising Sahiwal cow calves for veal production under tropical environment. S. A. Bhatti*[1], K. Nazir[1], M. J. Basra[2], M. S. Khan[3], M. Sarwar[1], and M. A. I. Mughal[2], [1]*Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Punjab, Pakistan,* [2]*Livestock and Dairy Development Department, Punjab, Lahore, Pakistan,* [3]*Department of Animal Breeding and Genetics, University of Agriculture, Faisalabad, Punjab, Pakistan.*

Sahiwal is a tropical dairy cattle breed of Pakistan known for its heat tolerance and tick resistance. Potential of Sahiwal calves for veal production has not been explored. The objective of present study was to evaluate the growth potential of Sahiwal calves for veal production on whole milk or a combination of whole milk and milk replacer in a ratio of 50:50. For this purpose, 48 Sahiwal calves (both male and female) were assigned to 4 dietary treatments having 12 animals/treatment. Calves in the first 2 treatments were fed milk 15 or 20% of their body weight (BW) upto d 84 adjusted on weekly basis. The calves in remaining 2 treatments received the same amount of milk as in the other 2 treatments till d 21; after which 50% of the milk offered was replaced with a blend of chickpea *(Cicer arietinum)* flour and vegetable (corn) oil mixed in water (MR) till d 84.The constituted MR had 3.1, 2.8 and 14.3%, CP, EE and DM, respectively. The growth and intake data were analyzed using repeated measures analysis, with MIXED Procedures of SAS in 2 × 2 factorial arrangements. The 2 factors were feeding level and feeding source. Calves offered whole milk grew faster ($P < 0.05$) and had greater weaning weights ($P < 0.05$) than those offered milk + MR (606.4 ± 18.1 vs 331.3 ± 18.1 g/d and 70.4 ± 1.5 vs 47.8 ± 1.5 kg, respectively). Greatest daily BW gain (656 ± 26 g/day) and weaning weight (74.6 ± 2.1 kg) were observed in calves offered milk 20% of body weight. Numbers of scour days were higher in calves fed milk + MR than those offered milk. Calves offered milk 15% of their body weight had the lowest production cost per kg of daily BW gain (≈US$3.5 ± 0.1). Replacement of 50% milk with a blend of chickpea flour and vegetable oil was neither able to support growth equivalent to whole milk nor was effective for reducing feeding cost during weaning period. Greatest average daily BW gain of Sahiwal calves during 12 weeks period was 650 g/d. However, daily BW gain of calves from 5 to 8 and 9–12 weeks was 717 and 837 g/d, respectively. Sahiwal calves have a promise for being raised for veal production under tropical environments.

Key Words: calf nutrition, Sahiwal calves, veal

Ruminant Nutrition: Dairy Production II

284 Effect of diet composition and incubation time on feed indigestible NDF concentration in dairy cows. S. J. Krizsan* and P. Huhtanen, *Swedish University of Agricultural Sciences, Department of Agricultural Research for Northern Sweden, Umeå, Sweden.*

Indigestible NDF (iNDF) predicts forage OM digestibility accurately and precisely when determined by a 288-h ruminal in situ incubation, and it is an important parameter in mechanistic rumen models. The long incubation time required is a disadvantage. Further, intrinsic cell wall characteristics of feeds should be determined in ideal conditions for fiber digestion. The objective with this study was to determine effects of diet composition and rumen incubation time on iNDF over a wide range of feeds in dairy cows. In this study concentrations of iNDF were evaluated using 18 feeds and 4 cows in a split-split plot design. Ten feeds were concentrates and 8 were classified as forages. Treatments were in a 3 × 3 factorial arrangement, consisting of different diets and incubation times. Diet composition was primarily varied by changing concentrate inclusion between 17 (low), 42 (medium) and 62% (high) of diet DM. Grass silage was used as basal forage to all cows during the incubations. The feeds were incubated for 144, 216 and 288 h. Indigestible NDF was determined from 2 g sample weighed to polyester bags of Saatifil PES (Saatitech S.p.A., Veniano, Como, Italy) with pore size of 12 µm and a pore area equal to 6% of the total surface, providing a sample size to surface ratio of 10 mg/cm^2. Across all feeds concentration of iNDF ranged from 6 to 515 g/kg of DM. Feed iNDF concentration was not affected by cow ($P = 0.14$). The effect of diet composition on feed iNDF concentration was significant ($P < 0.01$). Concentrations of iNDF across feeds were 178, 186 and 197 g/kg of DM when cows were fed the low, medium and high diet, respectively. The effect of incubation time on feed iNDF concentration was significant ($P < 0.01$). Concentrations of iNDF across feeds were 199, 185 and 177 g/kg of DM for 144, 216 and 288 h, respectively. There were also significant ($P < 0.01$) interactions between incubation time and diet, incubation time and feed, and diet and feed. Indigestible NDF should preferentially be determined from 288-h ruminal in situ incubations in cows fed diets with low concentrate inclusion to be representative of the feed fraction that is unavailable to the animal.

Key Words: dairy cow, digestibility, fiber

285 Effect of corn snaplage on lactation performance of Holstein dairy cows. M. S. Akins*[1], M. Digman[2], and R. D. Shaver[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison,* [2]*U.S. Dairy Forage Research Center, Madison, WI.*

The objective of this study was to compare the effects of feeding TMR containing either corn snaplage (SNAP), corn snaplage with dry ground shelled corn (SPDC; 70% SNAP and 30% dry corn on DM basis), or high moisture shelled corn (HMSC) on lactation performance. Corn snaplage (67.6% DM; 61.0% starch DM basis) and HMSC (74.4% DM; 71.2% starch DM basis) were harvested from the same field of corn and stored in separate silo bags. Mean particle size of the SNAP, HMSC, and dry ground corn were 1764, 1335, and 825 microns, respectively. Sixty Holstein cows (30 primiparous and 30 multiparous) at 100 ± 23 DIM were housed in a pen with 30 electronic feeding gates to deliver the TMR teatments and measure DMI. Cows were blocked by parity (primiparous and multiparous), stratified by DIM, and randomly assigned to gates. Gates were randomly assigned to treatments with 10 for each treatment and 5 each for primiparous and multiparous cows. Primiparous or multiparous cows on each treatment could access all 5 gates. A 2-wk covariate adjustment period with all cows fed a 50:50 mix of the SNAP and SPDC treatments was followed by an 8-wk treatment period with cows fed there assigned treatment TMR. The TMR nutrient content (DM basis) for SNAP, SPDC, and HMC were 26.3, 27.5, and 23.9% starch, respectively and 22% NDF from forages for all treatments. Cows fed HMSC had greater ($P < 0.01$) DMI than SNAP and SPDC. Milk yield and fat corrected milk (FCM) yield were similar ($P > 0.10$) across treatments. Milk production efficiency was lower ($P < 0.01$) for cows fed HMSC than SNAP and SPDC, and cows fed SPDC tended ($P = 0.06$) to have greater efficiency than SNAP. Cows fed HMSC also had lower ($P = 0.01$) FCM/DMI than SNAP and SPDC. Milk fat percentage was greater ($P = 0.02$) for cows fed HMSC than SNAP with SPDC intermediate, however milk fat yield was not different ($P = 0.15$) across treatments. Milk protein percentage and yield were similar ($P > 0.10$) across treatments. Milk urea nitrogen was greater ($P < 0.01$) for cows fed SNAP than HMSC, and greater ($P < 0.01$) for HMSC than SPDC. Overall, cows fed SPDC had better lactation performance than SNAP or HMSC.

Key Words: corn snaplage, dairy cow, high moisture corn

286 Dry heat popping of sorghum grain to increase ruminal starch digestion in dairy cattle. A. R. Anstis[1], D. G. Barber[1], E. Raffrenato*[2,3], and D. P. Poppi[2], [1]*Agri-Science Queensland, Department of Employment, Economic Development and Innovation, Lawes, Queensland, Australia,* [2]*School of Agriculture and Food Sciences, The University of Queensland, Gatton, Queensland, Australia,* [3]*Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, Gauteng, South Africa.*

Sorghum grain is commonly fed to dairy cattle across Australia. However, starch digestibility of sorghum within the rumen is limited by its structure and the protein matrix surrounding the starch granules. Steam-flaking consistently improves digestibility. Dry popping using heat could also increase digestibility through gelatinization of the starch molecule and increased surface area for microbial digestion. The aim was to increase the rate and extent of ruminal starch digestion with dry popping compared with other processing methods. Sorghum grain was sourced from a local feed mill in Queensland, Australia, and the following treatments were imposed: disc-milled (DM), hammer-milled (HM), rolled (R), steam-rolled (SR), popped (P), popped and hammer-milled (PHM), popped and disc-milled (PDM), semi-popped and disc-milled (SPDM). The HM and DM treatments had a particle size of 2 and 1.2 mm, respectively. All other treatments were ground to 4 mm. The grain was fermented in vitro using rumen fluid from 2 fistulated steers that were fed 3 kg of rolled sorghum per day while grazing kikuyu pasture ad libitum. Data used for rate estimations were in vitro starch fermentation residues, fermented for 0, 3, 7, 12, 18, 24, 36 and 48 h. A first-order decay model was run to estimate rates of digestion, assuming no lag or indigestible starch present. Digestion rates were also derived using the 7 h starch digestibilities according to Roe (1994) and pair-compared with the rates estimated using the non-linear model. The non-linear model resulted in R^2 between 0.92 and 0.99 and rates of starch degradation between 0.0451 and 0.1157 h^{-1}. The PDM and PHM sorghums resulted in the highest rates ($P < 0.05$), followed by the SPDM, SR and P treatments. Similar results ($P = 0.65$) were obtained using the 7 h values, except for DM and HM, which were underestimated compared with the non-linear procedure. Across all intermediate time points, the PDM and

PHM sorghum resulted in the highest starch digestibilities. Dry popping of sorghum grain has a greater potential than steam rolling to increase ruminal starch degradability when the grain is disc or hammer-milled after being popped.

Key Words: sorghum, starch digestibility

287 Daily methane emission profile in Holstein heifers fed rice straw. G. D. Cruz*[1], P. H. Hai[2], S. Polyorach[3], N. Anantassok[3], P. Beelen[4], H. D. Rosa[5], and E. Kebreab[1], [1]*University of California, Davis,* [2]*Institute of Agricultural Science for Southern Vietnam, Hochiminh City, Vietnam,* [3]*Khon Kaen University, Khon Kaen, Thailand,* [4]*Federal University of Alagoas, Rio Largo, Brazil,* [5]*Sao Paulo State University, Botucatu, Brazil.*

In South East Asia, rice straw is the principal crop residue fed to livestock; it is estimated that 40% of total rice straw produced goes to animal feed. Rice straw is a high lignin, high silica and low digestibility feedstuff, therefore a method to increase its nutritional quality would benefit animal production. The objectives of the study were to 1) improve the utilization of rice straw by increasing dietary nitrogen or energy availability and consequently reduce methane emissions, 2) analyze the daily profile of methane measured in ventilated hood chambers (VHC) and 3) investigate intake variability of heifers in VHC compared with group pen. Nine Holsteins heifers were fed in a 3 × 3 Latin square design, with 3 dietary treatments and 3 periods. Animals were fed twice daily at 0900 and 1700 h. Treatments were: control (14.3 CP% and 2.35 Mcal ME/kg DM), high energy (14.2 CP% and 2.45 Mcal ME/kg DM) and high protein (16.5 CP% and 2.36 Mcal ME/kg DM). Each period consisted of 14 d of adaptation and 1 d in the VHC. During the adaptation period heifers were kept in a group pen equipped with Calan gate system to measure individual feed intake. Feed offered and refused in the VHC was weighted individually. Dry matter intake (DMI) of the day that animals were in the VHC was used as a covariate to analyze the total methane emitted. Increase in nitrogen or in energy in the diet did not have an effect on daily methane emission ($P \geq 0.35$), with heifers in control, higher energy and high protein treatments emitting a daily average of 396, 393 and 414 g/d, respectively. A 37% decrease in DMI between heifers in VHC and previous day in group pen was observed (6.4 vs. 10.2 kg/d, $P < 0.001$, respectively). Methane emission peaks occurred between 1 to 1.5 h after feeding, the morning peak averaged 20 g/h and the afternoon 24 g/h. Daily lowest values were observed early morning, 1 to 2 h before feeding with average values of 10g/h. Even though heifers were provided with the best management conditions during the VHC day, DMI was drastically reduced, which may have affected methane productions. Caution needs to be taken when making inference in methane production data when using VHC method and when few hours of observation are extrapolated to daily emission.

Key Words: dairy heifers, methane emission, rice straw

288 The effects of a two ration feeding regimen on intake, milk production, and rumen fermentation in dairy cows. L. W. Rottman, Y. Ying, P. A. Bartell, and K. J. Harvatine,* *Penn State University, University Park.*

In the dairy cow there is a circadian pattern of feed intake and milk synthesis, consequently a single total mixed ration fed once a day may not stabilize rumen fermentation and synchronize nutrient absorption and milk synthesis. The object of this study was to determine if feeding multiple TMRs that complement the pattern of feed intake over one day would stabilize ruminal fermentation and increase milk synthesis. Nine ruminally cannulated cows were arranged in a replicated 3 × 3 Latin square design with 23 d periods. Diets were control (33.2% NDF), a low forage diet (L; 29.5% NDF), and a high fiber diet (H; 34.8% NDF). The L and H diets were balanced to provide the same composition as the control diet when combined in a 3:7 ratio of L:H. The control (Con) treatment was fed control diet at 0900 h, the high/low treatment (HL) was fed H at 70% of total daily offering at 0900 h and L at 30% of total daily offering at 2200 h, and the low/high (LH) treatment was fed L at 30% of total daily offering at 0900 h and fed H at 70% of daily offering at 1300 h. All treatments were fed at 110% of daily intake. Data were analyzed with mixed model procedures using repeated measures for time course data. Preplanned contrasts compared Con to HL and HL to LH. DMI and digestible DMI were decreased by 1.9 and 0.8 kg/d by HL compared with Con ($P < 0.01$ and $P < 0.05$). Total tract DM and OM digestibility did not differ between Con and HL. Intake and total tract digestibility did not differ between HL and LH. There was no difference between Con and HL for milk yield and composition, but LH tended to reduce milk fat yield compared with HL ($P = 0.06$). There was no effect of treatment on milk *trans*-10 C18:1, *trans*-11 C18:1, and fatty acids less than 16 carbons. There also was no main effect of treatment on empty body weight gain, plasma insulin, glucose, and NEFA, and rumen VFA concentration. There was a significant effect of time on plasma insulin, glucose, and NEFA and rumen VFA concentration ($P < 0.001$), suggesting a circadian rhythm also regulates these variables. Feeding multiple rations over the day decreased intake without decreasing milk or body weight gain. Feeding multiple rations over the day reduced intake with no impact on milk yield or body weight gain, but had little impact on other production and rumen parameters.

Key Words: circadian, rumen fermentation, TMR

289 Validation of an acidosis model. H. M. Golder*[1,2], W. J. Wales[3], M. J. Auldist[3], A. R. Rabiee[1,2], E. Bramley[4], P. Celi[1], R. King[5], and L. J. Lean[1,2], [1]*University of Sydney, Camden, New South Wales, Australia,* [2]*SBScibus, Camden, New South Wales, Australia,* [3]*Future Farming Systems Research Division, Department of Primary Industries, Ellinbank, Victoria, Australia,* [4]*Murdoch University, School of Veterinary and Biomedical Sciences, Murdoch, Western Australia, Australia,* [5]*Dairy Australia, Southbank, Victoria, Australia.*

Twenty 4 rumen fistulated lactating Holstein cows were fed 8, 10, 12, 14 and 16 kg/hd/d of concentrate with either a control diet or partial mixed ration (PMR). These were used to validate an existing acidosis model based on ruminal pH, volatile fatty acid (VFA), ammonia and lactate measures. Controls were fed rolled wheat grain twice a day at milking, and had access to pasture and silage in the paddock. The PMR diet, containing the same amount of grain and silage as controls, was fed twice daily on a feedpad immediately after milking. The target grazed pasture intake for both groups was 8 kg DM/cow/d. Cows were adapted to the diets for 14 d before rumen sampling. Rumen fluid samples were collected 10 times over a 24 h period and rumen pH was immediately measured. Rumen samples were analyzed for VFA, ammonia and lactate concentrations. Milk and milk composition data were collected. The acidosis model was used to assign one of 3 acidosis categories to each rumen sample: acidotic, suboptimum rumen function or normal. Further, the eigenvector values from discriminant analysis were used to estimate the degree of acidosis for each sample on a 0 to 1 scale, with 1 being highly acidotic and 0 not acidotic. A repeated measures ANOVA was used for the analysis of eigenvector data (Table 1). The degree of acidosis linearly increased with increasing the amount of concentrate, and PMR feeding reduced acidosis. Control cattle fed 14 and 16 kg of concentrate were the most acidotic as indicated by the higher eigenvector values. These results validate the ability of the model to predict ruminal acidosis from rumen fermentation measures. The model may be used as an acidosis diagnostic tool and PMR feeding may reduce risk of acidosis.

290 Evaluation of two versions of a mechanistic, metabolic model including bacterial pools, to describe FA flux, pH and milk fat in cattle on various pasture supplementation feeding strategies.

J. McNamara*[1], W. Wales[2], and M. Auldist[2], [1]*Washington State University, Pullman,* [2]*DPI Ellinbank, Ellinbank, Victoria, Australia.*

The objectives were to analyze data from a series of experiments with different proportions of grazed pasture and supplements using 2 versions of a mechanistic, metabolic model and to challenge the ability of the models to describe ruminal VFA flux, pH and resultant production variables, including milk fat production. The model was Molly (UC Davis, Baldwin) and an updated version of the Molly model with new VFA stoichiometry and bacterial pools to describe ruminal processes. Holstein dairy cattle were fed a range (approx. Sixteen to 21 kg DM/d) of grazed pasture plus wheat and silage supplementation (6 to 12 kg DM/d total supplement). Cows averaged 22.2 kg (SD 4.3) of ECM for 283 d Molly) is a mechanistic, dynamic model describing ruminal and body processes at an aggregated pathway level. An updated set of VFA stoichiometry, including lactate and valerate based on pools of amylytic and cellulytic bacteria, and protozoa, which all produced VFA from substrates differently, was integrated into Molly. The observed intake and chemical composition were direct inputs, and VFA production, ruminal pH, milk and milk composition were outputs. Inclusion of the bacterial pools allowed for the estimation of lactate and valerate production. Lactate uptake was highly correlated with lower milk fat (RSQ = −0.96, $P < 0.01$); a finding which although has been known for some time, we have not yet had a model which could predict it. Both versions of the model described VFA production, ruminal pH, milk and milk composition within 1 SD of the observed means; for example, rumen pH in a short-term, within day feeding trial was predicted with a root mean square prediction error of 3.7%, primarily composed of random error and a slight (30% of RMSPE) mean error, slope error was not different from zero and RMSPE was 32% of the SD. The newest version of the Molly model opens a new ability to ask more specific, complex research questions into the efficiency of dairy cattle in various situations.

Key Words: acidosis, metabolic model, milk fat

291 Multi-component versus one-component analysis: A different way of assessing the effect of TMR chemical composition on milk, fat, and protein yield individual lactation curves.

M. Caccamo*[1], R. F. Veerkamp[2], G. Licitra[1,3], R. Petriglieri[1], F. La Terra[1], A. Pozzebon[1], and J. D. Ferguson[4], [1]*1CoRFiLaC, Regione Siciliana, Ragusa, Italy,* [2]*WageningenUR Livestock Research, Animal Breeding and Genomics Centre, Lelystad, the Netherlands,* [3]*Catania University, DISPA, Catania, Italy,* [4]*University of Pennsylvania, PA.*

The objective of this study was to examine the effect of chemical composition of TMRs tested quarterly from March 2006 through December 2008 on milk, fat, and protein yield curves for 27 herds in Ragusa, Sicily. Prior to this study, standard yield curves were generated on data from 241,153 test day records of 9,809 animals from 42 herds in Ragusa province collected from 1995 to 2008. A random regression sire-maternal grandsire model was used to develop variance components for yields. The model included parity, age at calving, year at calving, and stage of pregnancy as fixed effects. Random effects were herd × test date, sire and maternal grandsire additive genetic effect, and permanent environmental effect modeled using 3-order Legendre polynomials. Model fitting was carried out using ASREML. Subsequently, the model with fixed variance components was used to examine the influence of TMR CP, soluble nitrogen (Soluble N), acid detergent lignin (ADL), NDF, acid detergent fiber (ADF), starch, and ash on milk, fat, and protein yield curves. The data set contained 46,531 test-day milk yield records from 3,554 cows in the 27 herds recorded during the study period. Initially, an analysis was performed using one-dietary component (one-component) within each model as fixed effects associated with the test day record closest to month the TMR was sampled within each herd. An interaction was included with the nutrient component and DIM. The effect of the TMR chemical component(s) was modeled using a 9-order Legendre polynomial. Conditional Wald F statistic on fixed effects revealed significant effects ($P < 0.001$) for ADF, NDF, CP, and starch, and their interactions with DIM on milk, fat and protein yield. Based on these results, a multi-component analysis was performed where CP, NDF, and starch were simultaneously included in the model with DIM interactions. Although both analyses revealed diet composition influenced production responses depending on lactation stage, the multi-component analysis showed more pronounced effects of starch and NDF relative to CP for all traits throughout lactation.

Key Words: lactation curve, TMR, test day model

292 Intestinal digestibility of long chain fatty acids in lactating dairy cattle: A meta-analysis.

J. C. Ploetz* and A. L. Lock, *Michigan State University, East Lansing.*

This analysis was performed to examine the intestinal digestibility of individual long chain fatty acids (FA) in lactating dairy cows. Available data were collated from 15 publications containing 61 treatments, which reported total and individual FA duodenal flows and calculations of intestinal digestibility. All studies involved lactating dairy cows and estimates of digestibility were based on measurements either between the duodenum and ileum or between the duodenum and feces. Analysis was performed using Comprehensive Meta Analysis v2 software that calculated the effect size using a random effects model. FA digestibility was calculated for C16:0, C18:0, C18:1 (*cis* and *trans* isomers), C18:2, and C18:3. Initially, intestinal FA digestibility was determined by pooling data regardless of site of collection. Percent digestibility (mean ± SE) were 75.9 ± 1.4, 73.3 ± 1.4, 80.7 ± 1.5, 77.9 ± 1.4, and 76.9 ± 1.6 for C16:0, C18:0, C18:1, C18:2, and C18:3, respectively. Digestibility of C18:0 was lower than for C18:1 ($P < 0.05$). Digestibility estimates for 18-carbon FA were subsequently separated according to site of collection (ileal vs. fecal). Ileal vs. fecal digestibility for C18:0 was 74.3 ± 2.0 vs. 68.7 ± 4.2. Digestibility of C18:1 was 80.1 ± 1.6 vs. 81.8 ± 0.6 for ileal vs. fecal. Comparing results for C18:0 and C18:1 calculated at the ileum indicate that the digestibility of these FA was not different ($P > 0.05$). Site of collection altered digestibility estimates for C18:2

(70.3 ± 2.8 vs. 79.7 ± 1.3; ileal vs. fecal, $P < 0.05$) and C18:3 (66.9 ± 4.5 vs. 79.4 ± 0.6, ileal vs. fecal, $P < 0.05$). In summary, digestibility estimates differed based on collection site (ileal vs. fecal) and degree of unsaturation of FA. These results suggest that unsaturated FA are biohydrogenated in the large intestine which would result in an over-prediction of unsaturated FA digestibility and an under-prediction of saturated FA digestibility when calculated from fecal collection. Since the amount of unsaturated FA reaching the large intestines is small, differences associated with digestibility estimates for unsaturated FA due to site of collection can be large. Relative differences in the digestibility of individual FA are minimal in lactating dairy cattle.

Key Words: fatty acid, digestibility, meta-analysis

293 Effect of replacing dietary soybean meal with canola meal on production of lactating dairy cows. G. A. Broderick*[1], A. P. Faciola[2], L. Nernberg[3], and D. Hickling[3], *[1]U.S. Dairy Forage Research Center, Madison, WI, [2]University of Wisconsin, Madison, [3]Canola Council of Canada, Winnipeg, MB, Canada.*

Previous research suggested that CP from canola meal (CM) was used more efficiently than CP from solvent soybean meal (SBM) by lactating dairy cows. We compared supplementation of either CM or SBM on both low CP (14.9% CP) and high CP (16.8% CP) diets and tested whether feeding rumen-protein Met plus Lys (RPML) was advantageous. Fifty lactating Holstein cows were blocked by DIM and parity into 10 squares in a replicated 5 × 5 Latin square trial. Five squares were fed: 1) low CP with SBM, 2) low CP with CM, 3) low CP with SBM + CM, 4) high CP with SBM, and 5) high CP with CM; the other 5 squares were fed the same diets except with added RPML (20 g/d of Met and 69 g/d of Lys). Diets contained (DM basis): 40% corn silage, 26% alfalfa silage, 13–23% corn grain, 2.4% mineral-vitamin premix and 31–33% NDF. Periods were 3-wk (total 15 wk); data from the last wk were analyzed using the Mixed procedure of SAS. LS-means and contrasts are reported in the table. There were no significant effects of RPML in this trial ($P \geq 0.11$). Increased CP (diets 4 and 5 vs. 1 and 2) increased fat yield and greatly elevated MUN. Relative to SBM, feeding CM increased DMI, and yield of milk and protein, and depressed MUN. At 14.9% CP, there was similar response in DMI and weight gain on CM and SBM + CM vs. SBM. In this trial, replacing SBM with CM resulted in improved production and N-efficiency at both 14.9 and 16.8% CP.

Table 1.

294 Milk yield and composition of dairy cows fed diets combining pasture and total mixed ration. A. Mendoza[1,2], C. Cajarville[3], E. de la Quintana[1], M. E. Garmendia[1], E. Mutuberría[1], E. de Torres[4], and J. L. Repetto*[1], *[1]Facultad de Veterinaria, Departamento de Bovinos, Montevideo, Uruguay, [2]Instituto Nacional de Investigación Agropecuaria, Programa de Producción de Leche, Colonia, Uruguay, [3]Facultad de Veterinaria, Departamento de Nutrición Animal, Montevideo, Uruguay, [4]Facultad de Veterinaria, Campo Experimental N°2, Libertad, Uruguay.*

To establish the effects of time of access to fresh pasture on milk yield and composition of cows fed a total mixed ration (TMR), 9 Holstein cows (mean BW = 572 kg; SD = 76) fed a TMR were assigned to three 3 × 3 Latin squares, with 20-d periods and sampling on the last 10 d of each period. Treatments evaluated were: 0 (TMR0), 4 (TMR4) or 8 (TMR8) hours of daily access to fresh pasture. Pasture (*Lolium multiflorum*; 22.1% CP, 24.0% ADF) was daily cut and offered ad libitum from 0800 h in individual stalls and TMR (16.8% CP, 16.4% ADF) was offered ad libitum during the remaining time. Cows were milked twice daily. Milk yield was measured during 5 consecutive days and individual milk samples were taken during 4 consecutive milkings of each period and analyzed for milk composition. Data were analyzed with a general linear model. There were no differences between TMR0 and TMR4 for any trait. However, compared with TMR0, an allowance of 8 h per day of access to fresh pasture decreased ($P < 0.05$) milk yield (32.7 vs. 34.4 kg/day; SEM = 1.5), 4% solids-corrected (32.5 vs. 34.8 kg/day; SEM = 1.0), protein (1.06 vs. 1.13 kg/day; SEM = 0.04) and total casein yield (0.80 vs. 0.86 kg/day; SEM = 0.03), and tended to decrease ($P < 0.10$) milk fat (1.29 vs. 1.40 kg/day; SEM = 0.05) and lactose yield (1.62 vs. 1.70 kg/day; SEM = 0.08). Milk fat (4.01%; SEM = 0.22), protein (3.31%; SEM = 0.13), total casein (2.50%; SEM = 0.11), lactose (4.94%; SEM = 0.06) percentage, total casein / protein ratio (0.756; SEM = 0.005) and MUN (19.9 mg/dl; SEM = 0.97) were not affected by treatments. It was concluded that time of access to fresh pasture influenced both milk and solids yield but not composition of TMR-fed dairy cows.

Key Words: milk composition, pasture, total mixed ration

295 Effects of dietary fiber source on lactation performance, nutrient digestion, and rumen microbial protein synthesis in early-lactating dairy cows. W. Zhu,* Y. Fu, B. Wang, Y. M. Wu, and J. X. Liu, *Institute of Dairy Science, MoE Key Laboratory of Molecular Animal Nutrition, College of Animal Sciences, Zhejiang University, Hangzhou, China.*

The objective of this study was to evaluate the effects of fiber source on lactating performance, rumen fermentation, nutrient digestion, and microbial protein synthesis in early-lactating dairy cows. Three multiparous (BW = 608 ± 20.0 kg, parity = 2 to 4) and 12 primiparous (BW = 552 ± 16.0 kg) Chinese Holstein cows at 45 (±6.0) d in milk were used in a multiple 3 × 3 Latin square involving 3 dietary treatments. All diets were isonitrogenous and isocaloric with ratio of forage to concentrate at 45: 55 (DM basis), and contained nearly the same concentrate mixture, but different forage source (%): corn silage 21, corn stover 19, and alfalfa hay 5 (CS); corn silage 19, Chinese wild rye hay 21, and alfalfa hay 5 (CW); and corn silage 19, Chinese wild rye hay 9, and alfalfa hay 17 (AH). Each period lasted for 21 d with the first 14 d for adaptation. Neither dry matter intake nor milk yield was significantly affected by the source of fiber. However, an increased trend occurred in milk yield for diet AH. Percent of milk protein was higher ($P < 0.05$) in cows on diet AH than that on CW (3.00 ± 0.104 vs. 2.91 ± 0.192%), with an intermediate value (2.94 ± 0.200%) for diet CS, but milk fat, milk lactose, and total solid content were not affected across the treatments. Milk efficiency (milk yield / DM intake) was higher for diet AH than for CS (1.55 ± 0.032 vs. 1.42 ± 0.032, $P < 0.05$) with medium value for diet CW (1.49 ± 0.039). Rumen fluid pH was not affected, but ammonia-nitrogen concentration was higher ($P < 0.05$) for diet CS than for CW or AH. Volatile fatty acid concentrations were higher ($P < 0.05$) in cows consuming diet AH than those on CS (113 vs. 103 mmol/L), with no difference between diets CW and AH or CS. Apparent total tract digestibility of DM was higher ($P < 0.05$) for diet AH than for CS or CW (70.2 vs. 63.7 or 64.5%), while the digestibility of NDF (61.8 vs. 57.2 or 56.9%) and ADF (58.8 vs. 53.2 or 52.5) was higher ($P < 0.05$) for diet CS than for CW or AH. Excretion of purine derivatives (374 vs. 323 or 338 mmol/d) was higher for diet AH than for CS or CW but with no difference between diets CS and CW, and microbial N flow to the duodenum (215 vs. 186 or 195 g/d) was higher in cows on diet AH than in those on CS with no difference between diets CW and AH or CS. These results indicated that corn stover could replace Chinese wild rye grass in the diets for lactating cows, and that high proportion of alfalfa hay in the diet is beneficial for milk protein production.

Key Words: dietary fiber source, microbial protein, lactation performance

WSASAS Symposium-Beef: Beef Production in Arid Environments

296 Significant research accomplishments applicable to arid environments. J. Paterson,* *Montana State University-Bozeman, Bozeman*

The improvement in the production and sustainability of beef cattle in the US has been remarkable over the past 50 yrs. Research has been responsible for producing beef cattle which require 10% less feed energy, 30% less land, 14% less water and produce 18% less greenhouse gases. Beef produced per cow has more than doubled during the past 50 yr (91 vs. 227 kg/cow/yr) and yet we have the lowest cow inventory since 1952. Thirty years ago it required approximately 600 d to grow calves from birth to slaughter; today its 480 d. Research has shown the benefits of crossbreeding, and its effects on weaning weights (25% improvement), genetic correlations, survivability, stayability, performance testing, accurate selection decisions based on EPDs and evaluation of sires based on residual feed intake (RFI). Selection of animals for low RFI can result in 10% lower feed intakes and a 25% reduction in methane production; clearly desirable under drought conditions. Using DNA from a Line 1 Hereford was the basis of a bacterial artificial chromosome library and the bovine genome sequence. Sixty years ago, ranchers did not have ready access to frozen semen, estrus synchronization, prostaglandins, ultrasound, freezing of embryos or vaccines for reproductive diseases. One of the most widely adapted management strategies has been the use of body condition scoring and its relationship with return to estrus, conception rates, and feeding strategies. Research have shown the consequences of protein restriction of the cow on the depression in the productivity of her calves (fetal programming). To improve nutrient utilization, routine usage of ionophores ($250 million dollar savings in feed), implants, grain byproducts and non-protein nitrogen usage have been widely adopted. Sixty years ago, one of the major accomplishments was the benefits of supplementation with P and protein to increase forage intake, growth and reproductive efficiency. Laboratories that routinely provide nutrient analyses are based on forage and grain chemistry research and confirmatory trials conducted during the 1970s and 1980s. Consumer concerns over animal care has resulted in implementation of beef quality assurance programs. Beef cattle production in the western US will depend on the utilization of high forage diets for the cowherd. Challenges for the future will include high input costs, consumer perception about beef safety, animal welfare, carbon footprint and end product quality. Research will be judged as to whether the outcomes are sustainable in terms of economic, social and environmental acceptance.

Key Words: beef research, arid environment

297 Cows that fit arid environments. B. H. Dunn,* *South Dakota State University, Brookings.*

For any cow, the challenge to be both biologically and economically efficient in the production system they are in is the basic measure of fitness. The ability of a cow to annually reproduce within its given feed environment over a relatively long period is the most important factor in the determination of fitness. For cows in production systems located in arid environments, this basic production phenomenon becomes even more critical, as the feed environment, when compared with that found in more temperate environments, is not only regularly restricted by drought, but subject to greater levels of change, and the importation of supplements expensive. Climate change could also be altering the boundaries associated with historic climatic regions, and exasperate the average, as well as the range, associated with annual precipitation within regions. It follows then, that a functional understanding of how a cow partitions feed energy first to maintenance, second to growth, then to lactation, and lastly to reproduction, is critical in determining cows that fit arid environments versus those that do not. Also, it is important to understand the limitation of using genetic selection as a tool for improving fitness to arid environments because of the low level of hereditability for reproductive traits when compared with other economically important traits. As breed differences for economically important traits continue to moderate, using mating systems to breed cattle that have the genetic potential to thrive in arid environments becomes more challenging. In the future, masking problems associated with raising cattle in arid environments that do not fit, by supplementing them with imported feed resources could be increasingly problematic, as transportation costs, as well as opportunity costs for alternative uses, price supplements beyond economic reason.

Key Words: beef cattle, cow size, cow efficiency

298 Supplementation strategies in arid environments. D. W. Bohnert,* *Eastern Oregon Agricultural Research Center, Oregon State University, Burns.*

The principle goal of most supplementation programs designed for beef cattle is to improve performance by providing the limiting nutrient(s) for the specific production scenario; however, in arid environments most supplementation strategies routinely have this and one other equally important goal: modifying grazing behavior. When this is taken into consideration, along with extensive pastures, variable topography, limited water availability, herd sizes, and inconsistent forage production common to the arid regions of the western US, developing effective supplementation strategies can be a challenge. Also, many of the arid regions grazed by beef cattle in the western US contain sensitive resource areas, such as riparian zones, critical wildlife habitat, and recently burned areas, which should be considered when developing a supplementation program. This is further complicated with the management challenges often faced by producers that utilize public lands in their grazing programs. Areas of research that I will discuss include grouping animals into contemporary groups, infrequent supplementation, variation in supplement intake due to form of supplement, and supplement placement as a tool to modify grazing behavior. This presentation will provide information that can be used in developing supplementation strategies that decrease the costs associated with supplementation while meeting acceptable levels of production. In addition, concepts that can be used to develop supplementation strategies that attract cattle away from critical areas and lure them into underutilized areas while maintaining or improving performance, thereby meeting production and conservation goals, will be provided.

Key Words: behavior, cattle, supplementation

299 Restocking the cow herd. D. Peel,* *Oklahoma State University, Stillwater.*

The US beef cow herd has decreased 14 of the last 16 years. On January 1, 2012, the beef cow inventory was 29.88 million head, the lowest beef cow inventory since 1962. The drought in 2011 pushed cow inventories lower despite growing market incentives for herd expansion. At the same time, high concentrate feed prices are affecting forage values with implications for all sectors of the cattle industry. Record high feeder prices increases profit potential for cow-calf production but rising and volatile input prices makes cost of production uncertain. Rebuilding the cow herd will be a slow and difficult process due to the critically low numbers and the record high prices for breeding animals. This symposium presentation will cover factors that have contributed to the continued decline in cow inventories; the implications of the current herd size; and the challenges of rebuilding the herd in coming years.

Key Words: beef cow inventory, herd expansion

300 A systems approach to ranching in arid environments. C. P. Mathis,* K. C. McCuistion, and R. D. Rhoades, *King Ranch Institute for Ranch Management, Texas A&M University-Kingsville, Kingsville.*

Ranches are complex systems driven by internal and external forces. All ranches are different, but are still affected by the laws of systems. The laws of "unintended consequences," "worse before better," and "compensating feedback" are all real in ranching or any other business organization. It may not be obvious, but success in ranching is affected by how well managers understand the reality of these laws as they make decisions affecting complex ranching systems. In arid environments where variable precipitation and low forage production associated with drought is generally the greatest risk to a sustainable ranching operation, often the most important decision a manager makes is the selection of enterprises in which the ranch engages. The thoughtful mix of cow-calf, stocker, and other livestock enterprise, especially when complemented with wildlife enterprises, helps create income diversification and the flexibility in stocking rate needed to cope with drought or capitalize on excess forage availability. The external forces of nature and commodity prices cannot be controlled; however, adaptability and diversification can help mitigate those risks. In arid environments in North America, cow-calf enterprises are generally the core of the ranching operation. Management decisions relating to the cow-calf enterprise should also incorporate consideration of the effect of those decisions on the ranch as a whole. According to standardized performance analysis (SPA) data from the Southwestern US, labor, depreciation, and purchased feed comprise the majority of costs to a cow-calf enterprise. These categories are also generally the top 3 expenses to arid land ranching operations as a whole. Further, SPA data reveals that ranches in the top net income quartile not only raise the highest value calves at weaning, but they also have the lowest cost of production compared with the less profitable quartiles. Understanding individual drivers of profitability is important; however, managers are encouraged to look past simply optimizing the pieces of the ranch operations. To develop a highly successful and sustainable ranching business, the relationship among the enterprises on the ranch must be maximized.

Key Words: systems, ranching, drought

POSTER PRESENTATIONS
Animal Behavior and Well-Being: Physiology Emphasis

T1 Stress affects plasma serotonin, but not tryptophan, in Holstein steer calves. A. L. Adams,* T. H. Friend, G. A. Holub, L. R. Berghman, P. K. Riggs, S. M. Garey, C. L. Terrill, and M. J. Carter, *Texas A&M University, College Station.*

Cortisol is a well-known indicator of stress, but little is known about the effects of stress on serotonin and tryptophan in livestock. Previous studies in humans have shown that the brain uses serotonin, derived from tryptophan in the bloodstream, to cope with stress. As serotonin production in the brain increases, plasma tryptophan concentrations are expected to decrease. Furthermore, previous studies in humans have also shown that 90% of serotonin is located in the intestines and released into the bloodstream as an individual experiences stress. The objective of this study was to determine how stress affected plasma serotonin and tryptophan concentrations in calves during handling and transport. Thirty-six 4-mo-old Holstein steer calves were housed in groups of 6 with each group randomly assigned to either transport or control treatments. Transported calves were hauled for 6 h in their groups in a 7.3 m × 2.4 m goose-neck trailer divided into 3 compartments, at an average density of 0.87 m^2/calf, every 7 d for 5 consecutive wk. Location of groups within the trailer rotated. Simultaneous blood samples were obtained in the trailer or home pen via jugular venipuncture before loading (pre), and after 2, 4, and 6 h of transport. Plasma samples with the highest cortisol concentrations from each treatment (transport: n = 11, control: n = 8) and sampling period (pre: n = 6, 2 h: n = 3, 4 h: n = 6, 6 h: n = 4) were analyzed for concentrations of serotonin and tryptophan. Pearson correlation coefficients were used to determine associations and mixed model ANOVA determined treatment and sampling period effects on serotonin and tryptophan. Serotonin was not correlated with cortisol ($P = 0.54$) or tryptophan ($P = 0.45$), but tryptophan and cortisol were correlated (r = - 0.52, $P = 0.02$). Treatment did not affect serotonin ($P = 0.79$) or tryptophan ($P = 0.15$). Serotonin was highest (148 ± 16 ng/mL) after 4 h and lowest (46 ± 21 ng/mL) after 6 h ($P = 0.0004$), but tryptophan was not affected by sampling period ($P = 0.64$). These results suggest that stress (handling and/or transport) may cause an intestinal response that releases additional serotonin into the bloodstream.

Key Words: serotonin, stress, tryptophan

T2 Development of a novel method for measuring stress in beef cattle. D. Moya*[1], K. S. Schwartzkopf-Genswein[1], and D. Veira[2], [1]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*Agriculture and Agri-Food Canada, Agassiz, BC, Canada.*

A study was conducted to a) determine if bovine hair contains cortisol at measurable levels, and b) identify the effect of hair location and collection method on hair cortisol levels. Hair samples (0.5 g) from the head, neck, shoulder, hip, and switch were collected from 12 Angus crossed bulls (313.1 ± 14.7 kg BW) using 2 sampling methods: plucking, to ensure collection of the hair follicles; and clipping, using an electric razor to ensure collection of the hair as close as possible to the skin. After a wash with isopropanol, hair samples were ground with a ball mill for 5 min at 22 rps, sonicated with methanol for 30 min, and incubated on a shaker for 18 h, at 50°C and 100 rpm. The supernatant was pipetted off and evaporated in a block heater, at 45°C under a stream of nitrogen. Samples were reconstituted with phosphate buffered saline before quantification of cortisol with a competitive immunoassay. Data were analyzed with a factorial design, considering hair location and collection method as main factors, using the mixed procedure of SAS. Differences were declared at $P < 0.05$. The described method was successful in detecting cortisol in 87.8% of the hair samples, with concentrations ranging from 0.07 to 6.62 pg/mg. A value of zero was used for samples in which no cortisol was detected. The intra-assay coefficient of variation (CV) ranged from 5.91 to 9.96%, while the inter-assay CV ranged from 5.04 to 10.48%. Hair from the switch had the greatest cortisol concentration (3.32 ± 0.20 pg/mg) compared with all other sampling locations, while hair from the head and the neck (2.14 and 1.86 ± 0.20 pg/mg, respectively) had greater cortisol concentrations than from the shoulder and hip (0.83 and 0.62 ± 0.20 pg/mg, respectively). Cortisol was greater in hair samples collected by clipping than by plucking. Results indicate that hair can be used to measure cortisol levels in beef cattle. Future studies will assess hair cortisol concentration as a biomarker of stress and animal welfare under chronic stress conditions, as well as its relationship with other physiological and behavioral measures of animal welfare.

Key Words: hair cortisol, biomarker, welfare

T3 Body temperature and panting in feedlot cattle. J. B. Gaughan*[1] and T. L. Mader[2], [1]*The University of Queensland, Gatton, Qld, Australia,* [2]*University of Nebraska, Concord.*

Assessment of thermal status during periods of high heat load is essential for the maintenance of cattle wellbeing. Respiration rate (RR) and body temperature (BT) are routinely used as indicators of thermal status. However, they are difficult to obtain under commercial conditions. The panting score (PS) system was designed as a visual assessment of the thermal status of cattle. The PS system uses a 7 point score (0, 1, 2, 2.5, 3, 3.5 and 4) where PS0 indicates no elevation in RR (no thermal stress) and a PS4 indicates severe thermal stress (open mouth, tongue fully extended, head drooped, rapid labored breathing). A PS2 (closed mouth, drooling, elevated RR) indicates that the animal is under moderate heat load. A PS3 (open mouth, tongue extended, drooling, further elevation of RR) is an indicator of high heat load. In this study BT and PS data were obtained from 48 Angus steers over 120 d. Steers were implanted with a BT transmitter on d −31, and BT data were obtained at 30 min intervals. The cattle were housed in 2.43 m × 7.4 m pens (8 steers/pen: 3 transmitter steers/pen), and were fed a finisher diet (NEg = 1.44 Mcal/kg). The PS of the steers was obtained daily (±15 min) at 0600 h (AM), 1200 h (MD) and 1600 h (PM). At the same times, climate variables were obtained from an on-site weather station. Observations were made from outside the pens so as not to influence cattle responses. The 2 closest BT values to the time when PS was obtained were retrospectively downloaded from a logger and averaged. A total of 15,361 observations were used and 2nd order polynomial response curves generated: (AM) $y = 39.28 – 0.295x + 0.125x^2$ ($R^2 = 0.99$); (MD) $y = 38.27 + 0.853x – 0.0554x^2$ ($R^2 = 0.99$); (PM) $y = 38.68 + 0.869x – 0.071x^2$ ($R^2 = 0.99$), where y = BT (°C) and x = PS. These data suggest that PS is a good indicator of BT. The BT at MD corresponded to slightly lower PS compared with PM, e.g., for PS1; BT at MD = 39.6°C and

40.1°C at PM. However during AM, BT was lower at PS1, 2 and 2.5 (highest AM value) compared with MD and PM, e.g., for PS2.5; BT at AM = 40.2°C, MD = 40.8°C and PM = 41.1°C. The AM response curve suggests an attempt to increase heat dissipation during the cooler AM period relative to MD and PM.

Key Words: panting, body temperature, heat stress

T4 Use of artificial shade during grazing and its effects on body weight at the end of gestation in red deer (*Cervus elaphus*).

N. G. Mejía, A. Sánchez, A. Paez, and L. Alvarez,* *Facultad de Medicina Veterinaria y Zootecnia, UNAM, México DF, México.*

In grazing animals, solar radiation and high temperatures can seriously compromise the performance and welfare if they lack the necessary protection. The aim of this study was to determine whether the resource shade affects the body weight and behavior of female red deer during the last 2.5 mo of pregnancy. Two groups (n = 23 each) of pregnant does were grazed in different pens of similar botanical composition and size. In the shaded group, a mesh shade (>80% protection, 60m2) was placed. A behavioral scan sampling (10 min) was used to determine the location of animals and their behavior inside the paddock. Ambient and black globe temperature were also measured. All females were weighed at the beginning of the experiment and immediately before delivery. Data was arcsin transformed to be analyzed using a repeated measures ANOVA, correlation and linear regression. Percentage of animals using the shade during daytime was highly correlated with ambient [$R^2 = 0.7$, $P < 0.05$, $y = (2.45x) + (-6.91)$] and black globe temperature [$R^2 = 0.9$, $P < 0.05$, $y = (2.40x) + (-49.24)$]. There were no differences in the percentage of animals grazing during the day ($P > 0.05$). More animals were seen drinking water, and more thermoregulatory behaviors (to get muddy, to introduce forelegs in troughs) were recorded in the unshaded animals (11.1 ± 1 versus 6.3 ± 1 and 10 ± 1.4 versus 3.3 ± 1.4 respectively, $P < 0.05$). The average daily gain of weight was higher in the shaded group (215 ± 24.1 versus 127.1 ± 23.6, g ± SE, $P < 0.05$). It is concluded that artificial shade during the last 2.5 mo of gestation reduces the thermoregulatory behaviors and improves the average daily gain of weight. PAPIIT IN205810, UNAM.

Key Words: animal welfare, body weight, solar radiation

T5 Evaluation of on-farm methods assessing locomotor disorders of individual or group housed sows.

S. Conte*[1], J. Grégoire[1], R. Bergeron[2], S. D'Allaire[3], M.-C. Meunier-Salaün[4], and N. Devillers[1], [1]*Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Sherbrooke QC, Canada,* [2]*University of Guelph, Alfred Campus, Alfred, ON, Canada,* [3]*Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, QC, Canada,* [4]*Institut National de la Recherche Agronomique, UMR1348 Pegase, Saint-Gilles, France.*

The aim was to evaluate methods for on-farm assessment of locomotor disorders in gestating sows, and the influence of housing system on the prevalence of locomotor disorders. Of the 311 sows studied across 10 farms, 120 sows were housed in groups of 4–8 sows per pen and 191 sows were housed in individual stalls. Data recorded were: 3-point gait score, walking speed (≤0.8, ≤1.25, >1.25 m/s), stride length (<83, <100, ≥100 cm), number of steps during 30s at feeding (<3, <6, ≥6), latency to lie down after feeding (≤30, ≤60, >60 min), ability to stand up after being stimulated ("stand-up test": moving freely, hesitancy, refusal), number of feet with uneven toe size and bursitis (0, 1, >1), and presence of cracks (>1 cm) on the side wall. The percentage of sows in each category was calculated. Cochran-Mantel-Haenszel and Chi-squared tests were used to determine the association between variables and housing systems. Following gait scoring, 49% of sows were sound (score 0), 35.5% walked stiffly (score 1) and 15.5% were visibly lame (score 2). There were no differences between housing systems in the percentage of sows within each gait score ($P > 0.05$). The percentage of sows having feet with uneven toe size, bursitis or cracks on the side wall was higher in stalls than in pens ($P < 0.05$). No associations were found between the 3-point gait score and the number of steps during 30s, the stand-up test score or the latency to lie down after feeding ($P > 0.05$). The percentage of sows having reduced walking speed and stride length was higher for sows scored 2 than for sows scored 0, in stalls only ($P < 0.05$). Results indicated no differences in the prevalence of locomotor disorders between housing systems based on the gait score, but highlighted more foot problems in stalls than in pens. New quantitative indicators such as stride length and walking speed seem to be good indicators of locomotor disorders for sows housed in stalls but not in pens. This suggests that methods used to detect lameness are not always applicable from one housing system to another. Other factors associated with the housing system such as the possibility to exercise may interfere with the assessment.

Key Words: gestating sow, locomotor disorders, housing system

T6 Effectiveness of a non-penetrating captive bolt for the euthanasia of nursing and weaned piglets from 3 to 9 kg.

T. M. Casey-Trott*[1], S. G. Nykamp[1], P. V. Turner[1], S. T. Millman[2], and T. M. Widowski[1], [1]*University of Guelph, Guelph, Ontario, Canada,* [2]*Iowa State University, Ames.*

A non-penetrating captive bolt (NPCB) has been shown to be highly effective for euthanasia in neonatal piglets. The objective of this study was to determine the effectiveness of the NPCB for euthanasia of nursing and weaned piglets from 3 to 9kg (5–49 d of age). The NPCB was used by 15 stock people from 6 farms to euthanize 150 compromised piglets (3 kg: 55 piglets, 5 kg: 45 piglets, 7 kg: 25 piglets, 9 kg: 25 piglets). The NPCB was placed on the frontal bone and fired twice in rapid succession. Piglets were monitored for signs of sensibility using brainstem and spinal reflexes. Duration of neuromuscular leg spasms and time to cardiac arrest were also recorded. CT scans and macroscopic scoring were completed post mortem to quantify the degree of skull fracture and brain hemorrhage. Data were analyzed in SAS 9.2 using proc mixed with an age, weight interaction. The NPCB caused immediate and sustained insensibility until death in 98.6% of piglets. Leg spasms ceased in <5 min in 97.3% of the piglets and cardiac arrest was achieved by 98% in <10 min. Stock person variation was significant for duration of leg spasms ($P = 0.0443$), but not time to cardiac arrest ($P = 0.2022$). There were no significant differences among weight groups for either the duration of leg spasms ($P = 0.7338$) or time to cardiac arrest ($P = 0.6585$). However, age significantly affected the duration of leg spasms ($P = 0.0417$) with younger piglets (≤21 d) having a shorter duration than older piglets (≥22 d). Average fracture displacement was 8.3 mm (±1.0SE). Two piglets from the 9kg category had fractures present but no displacement. Moderate to severe subdural-dorsal (SDD) hemorrhage was reported in at least 85% of piglets in each weight category. Moderate to severe subdural-ventral (SDV) hemorrhage was reported in at least 60% of piglets from weight categories 3, 5, and 7kg; whereas the SDV hemorrhage for the 9kg category was predominantly minimal to mild (56%). The NPCB was highly effective for the euthanasia of piglets up to 9kg (49 d) based on immediate insensibility until death. However, age affects should be further studied to ensure the technique remains effective if it is used on piglets beyond this range.

Key Words: euthanasia, piglet, captive bolt

T7 Trailer compartment and trip duration affect stress of pigs transported under Canadian conditions. Y. M. Seddon*[1], J. Brown[1], T. Crowe[2], R. Bergeron[3], T. Widowski[3], L. Faucitano[4], and H. Gonyou[1,2], [1]*Prairie Swine Centre, Saskatoon, SK, Canada,* [2]*University of Saskatchewan, Saskatoon, SK, Canada,* [3]*University of Guelph, Guelph, ON, Canada,* [4]*Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

Long transport times and trailer designs in use in western Canada have raised concerns regarding the welfare of pigs transported to market. Objectives of this study were to assess the effects of the internal trailer compartments (C) and trip duration on measures of stress in pigs transported in western Canada. Over 4 weeks in winter (W) and 4 weeks in summer (S), pigs from one farm (121 ± 0.35 kg) were monitored during transport to market. Each week, market pigs were weighed, identified and loaded onto 3 pot-belly trailers at a density of 0.38 m^2/pig. Trailers were loaded at 6-h (h) intervals to complete journey times of 6, 12 and 18 h, arriving at the abattoir at the same time. The study focused on pigs located in 4 C, namely C1 and C4 (front and rear of the upper deck), C5 (front of the middle deck) and C10 (rear of the bottom deck). At the abattoir, pigs were rested for 1.5 h before slaughter. Blood was collected from 4 pigs per C at exsanguination (total n = 384), and analyzed for packed cell volume (PCV), creatine phosphokinase (CPK), cortisol and lactate. Statistical analysis using the PROC mixed procedure in SAS determined the effects of season, week, travel duration and C on the stress measures. CPK levels were affected by trip duration (6 h: 4172, 12 h: 6552, 18 h: 9697 ± 1659 IU/L; $P < 0.05$) and C (C1: 3834, C4: 8676, C5: 5754, C10: 8968 ± 1455 IU/L; $P < 0.0001$). Despite longer trip durations, CPK levels did not alter in C1, but rose in C4, C5, and C10 (12 h), with C4 and C10 showing the highest levels following 18 h transport ($P < 0.05$). Cortisol was higher ($P < 0.05$) in S than W. C and season affected lactate, with lactate levels being significantly higher ($P < 0.05$) in pigs transported in C1 and C4 than in the other C in W. Data suggest longer trip durations caused increased stress, and seasons present challenging conditions, yet the compartment location can either mitigate or aggravate the stress response. Therefore, determining conditions within the C, such as temperature and humidity extremes, vibrations and G-forces would help to understand these negative effects and assist in the development of targeted improvements to trailer design.

Key Words: transport, stress, pig

T8 Effect of commercial transport by road on prevalence of bruises and meat pH of beef cattle in Brazil. M. H. Romero*[1], M. J. R. Paranhos da Costa[2], L. F. Uribe[1], J. Braga[2], and A. Riobueno[2], [1]*Universidad de Caldas, Manizales, Caldas, Colombia,* [2]*La Universidad Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

Cattle are exposed to various handling and transport conditions during marketing and previous to slaughter. Brazil is the principal meat producer in South America. Commercial crossbreds of Zebu cattle (n = 1841) were evaluated to determine prevalence and risk factors for carcasses with bruises in a slaughterhouse that had modern facilities and had implemented animal welfare practices and driver training. Measurement of pH was performed in the *Longissimus thoracis* muscle at the level of the 5th and 6th rib, approximately 24 h after slaughter in refrigerated carcasses. A logistic regression analysis was done. Bruise prevalence was 59%. A total of 2041 bruises were found (mean 1.1 bruises/carcass). Bruises in subcutaneous tissue (939, 76%) were more frequent than bruises in muscle tissue (24%). The mean time transport was 4.51 ± 1.21 h, and distance ranged between 65 Km and 334 Km. The fat cover was associated with the presence of bruises. Thin animals bruised more easily than fat animals due to a lack of fat cover ($P \leq 0.01$). Average incidences of meat pH greater than 5.8 and 6.0 were 24.6% and 0.3% respectively. Time of transport and distance were related with high pH ($P \leq 0.01$). Prevalence of bruises was not significantly associated ($P \geq 0.01$) with increased carcass pH values, transport time and type of truck. The results suggest that transport time and distance can affect meat quality.

Key Words: bruises, slaughter, well-being

T9 The effect of water sprinkling on behavior and core body temperature of market hogs transported during summer. J. Fox*[1], T. Widowski[1], S. Torrey[2], E. Nannoni[4], R. Bergeron[5], HW Gonyou[6], JA Brown[6], T. Crowe[7], and L. Faucitano[3], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Agriculture and Agri-Food Canada, Guelph, ON, Canada,* [3]*Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [4]*University of Bologna, Bologna, Italy,* [5]*University of Guelph, Alfred, ON, Canada,* [6]*Prairie Swine Centre, Saskatoon, SK, Canada,* [7]*University of Saskatchewan, Saskatoon, SK, Canada.*

Hogs are often transported to slaughter under conditions exceeding their thermo-neutral zones, which can lead to reduced welfare and increased in-transit loss. Water sprinkling during lairage decreases micro-climate and hog body temperatures and improves welfare, but there is no clear evidence of these effects during transport. The aim of this study was to observe if sprinkling hogs in stationary trailers before and after transport decreased signs of heat stress. In each of 12 weeks from May to September 2011, 2 pot-belly trailers with 208 hogs per trailer were transported 2h to slaughter. One was outfitted with a custom made sprinkler system that ran for 5min (~125 L) immediately before departure from the farm and immediately before unloading at the plant. In each trailer, 4 test compartments (1 on the top deck, 2 on the middle deck, and 1 on the bottom deck) were outfitted with cameras, and the core body temperature (CBT) of 4 randomly chosen hogs (n = 384) in each were recorded using orally administered iButtons. Trailer and deck loading order were randomized. Behaviors during transport, unloading and during lairage were recorded from video or live observations. Data were analyzed through ANOVA with ambient temperature external to the truck (AmbT) as a co-variant. AmbT averaged 19.5°C ± 3.8°C (range: 14–26°C). At AmbT > 23°C, there was no effect of sprinkling on behavior on-truck (standing, sitting or lying), but at AmbT < 23°C, more hogs stood on sprinkled trucks ($P < 0.05$). Sprinkling did not affect slips or falls during unloading. In lairage, latency to lie was shorter when AmbT exceeded 23°C ($P < 0.05$) and sprinkled hogs spent more time lying and less time sitting ($P < 0.05$) and had fewer drinking bouts than controls ($P < 0.0001$) regardless of AmbT. CBT increased between loading and departure and decreased while in transit for all hogs ($P < 0.0001$) and sprinkling further reduced CBT at arrival at AmbT > 23°C ($P < 0.05$). Therefore, sprinkling hogs when ambient temperature exceeds 23°C can help to alleviate transport-related heat stress without detrimental effects on unloading.

Key Words: pigs, transport, heat stress

T10 Characteristics of bruises in carcasses of commercial zebu cattle in Colombia. M. H. Romero,* L. F Uribe, J. A. Sánchez, and H. Mesa, *Universidad de Caldas, Manizales, Caldas, Colombia.*

Bruises detected on carcasses at the abattoir, may provide information about the traumatic situations the animal endure during the pre-slaughter period. The objective of this study was to describe the gross characteristics of bruises in commercial zebu cattle of different methods of selling and management. The number of bruises and their distribution on the carcass, as well as their severity, shape and size were assessed

post mortem in a slaughterhouse in Colombia. A descriptive statistical analysis was done. A total of 1195 bruises were found on 453 (38.3%) of the carcasses evaluated (n = 1177). Females (n = 453) had 649 bruises (mean 3.2 bruises/carcass) whereas males (n = 250) had 530 bruises (mean 2.1 bruises/carcass). Cattle transported from livestock market had 3 times more bruises than cattle transported directly from the farm (35% and 59%, respectively). The pin (*tuber isquiadicum*), the hip (*tuber coxae*) and the loin were the more frequently observed bruises (32.9, 25 and 21.3%, respectively). Bruises with muscle tissue affected (grade 2) were more prevalent (80%); however, the bruises were small (≥2 and ≤ 8 cm). Circular shaped bruises were most frequent (71%, n = 850), followed by irregular, linear, speckled and tramline shaped bruises (21, 3.6, 3.4 and 1.0%, respectively). speckled shaped bruises were located predominantly in the loin, and can be caused by electric prod or pointed sticks. The model of logistic regression showed that sex and time of transport were associated with the presence of bruising ($P \leq 0.01$). Lairage time was not considered a risk factor for the presence and severity of bruises ($P \geq 0.1$). The presence of bruises located more frequently in the pin and the hip suggest that bruises are inflicted by rude handling and inadequate design of the trucks and facilities. Cattle transport infrastructure must be improved in the area being studied, as must driver training; animal welfare practice must be promoted in all links of the meat chain and research developed in this particular area.

Key Words: bruises, cattle, welfare

Animal Health II

T11 Intravaginal administration of lactic acid bacteria modulated selected plasma metabolites in transition dairy cows. Q. Deng, J. F. Odhiambo, T. Lam, S. M. Dunn, and B. N. Ametaj,* *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Transition dairy cows experience dietary changes, negative energy balance, and suppressed immunity after parturition, which enhances their susceptibility to uterine infections. The objective of this study was to evaluate blood metabolite responses of periparturient cows administered intravaginally a mixture of lactic acid bacteria (LAB) around calving. One hundred fifty-two pregnant Holstein cows were randomly (based on parity and BCS) assigned to 3 groups 2 wk before the expected day of parturition. Cows received intravaginal LAB or carrier (sterile skim milk) once a wk at −2, −1 and +1 wk relative to calving as following: treatment 1 (TRT1) - 2 consecutive LAB and 1 carrier dose; treatment 2 (TRT2) - 3 consecutive LAB doses; control (CTR) - 3 consecutive carrier doses. Probiotics were a mixture of 3 LAB including *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140, which were infused at 10^8-10^9 cfu per dose. Blood samples were collected from the tail vein once per wk, before treatment, from −2 to +8 wk. A subset of serum samples from 32 cows were used to evaluate concentrations of glucose, cholesterol, nonesterified fatty acid (NEFA), β-hydroxy butyric acid (BHBA), and lactate. Results showed that concentrations of glucose were 60.8 ± 1.1, 65.2 ± 1.1, and 59.3 ± 0.9 mg/dL ($P < 0.01$) in TRT1, TRT2, and CTR, respectively. Serum cholesterol was 121.5 ± 2.3, 113.8 ± 2.1, and 106.2 ± 1.9 mg/dL ($P < 0.001$) in TRT1, TRT2, and CTR, respectively. Furthermore, concentrations of BHBA in the serum were at 738 ± 39, 555 ± 37, and 623 ± 33 µmol/L ($P < 0.01$) in TRT1, TRT2, and CTR, respectively. Treatments had no effect on serum concentrations of NEFA and lactate ($P > 0.05$). Serum glucose, cholesterol, NEFA, BHBA, and lactate were greater ($P < 0.05$) and glucose was lower ($P < 0.001$) in multiparous cows than those in primiparous cows. The concentrations of all metabolites measured changed in relation to wk ($P < 0.05$). In conclusion, data indicated that administration of LAB in the vaginal tract of periparturient dairy cows affected serum concentrations of selected metabolites related to carbohydrate and lipid metabolism and showed differences between multiparous and primiparous cows.

Key Words: dairy cow, lactic acid bacteria, serum metabolites

T12 Indoor versus outdoor housing during the neonatal, weaning, and commingling periods influences innate immune responses in single-housed Holstein calves. M. D. Sellers,* C. J. Cobb, D. L. Hanson, A. R. Pepper-Yowell, and B. S. Obeidat, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Objective was to determine if housing environment (indoor vs. outdoor) influences metabolic and innate immune responses during the neonatal, weaning, and commingling periods in single-housed Holstein calves. Forty-three Holstein calves (2 ± 1 d old) were housed either in indoor pens (n = 21) or outdoor hutches (n = 22). Weaning started during the wk 7 by removing the PM milk feeding and calves were fully weaned after d 53 when daily starter consumption was 800 g dry matter. Calves were randomly commingled in outdoor group hutches (n = 5/pen) on d 91. Peripheral blood samples were collected during the neonatal (3, 10, 21 d), weaning (45, 47, 53 d), and commingling periods (91, 94, 99 d) and analyzed for neutrophil oxidative burst (OB) capacity when cocultured with an *Escherichia coli*, neutrophil L-selectin expression, whole blood secretion of tumor necrosis factor-α (TNF) when cocultured with lipopolysaccharide, as well as plasma concentrations of haptoglobin, glucose, and urea nitrogen. The study concluded on d 99. Data within each period were analyzed by ANOVA with repeated measures. Within the neonatal period, Indoor calves had more neutrophils producing an OB on d 10 and 21 ($P < 0.05$), as well as a more intense OB response on d 3, 10, and 21 ($P < 0.05$). In addition, Indoor calf neutrophils expressed higher L-selectin on d 21 ($P < 0.05$) and had greater TNF secretion on d 10 ($P < 0.05$). During weaning, Indoor calves had greater OB capacity on d 45, 47 and 53 ($P < 0.05$), and lower haptoglobin concentration on d 47 ($P < 0.05$). Urea nitrogen and glucose decreased ($P < 0.05$) over time across both treatments during the weaning period. During commingling, Indoor calves had a lower ($P < 0.05$) percentage of neutrophils positive for OB on d 94 relative to d 91 when compared with Outdoor calves. Indoor housed calves had heightened innate immune responses during both the neonatal and weaning periods compared with Outdoor calves. In contrast, when calves were commingled, Indoor calves had decreased innate immune responses, which could be due to Indoor calves being moved outside during commingling.

Key Words: calf, housing, immune

T13 Prevalence of nematodes eggs of the genera *Cooperia*, *Ostertagia*, and *Haemonchus*, before and after treatment of dairy heifers with commercial anthelmintics in commercial dairy farms in Puerto Rico. L. López-Soberal,* A. Ruíz-Lugo, Á. González-Sanabria, M. Pagán, and G. Ortiz-Colón, *University of Puerto Rico, Mayagüez Campus.*

A total of 316 dairy heifers, between 3 and 12 mo of age, were evaluated in 18 commercial dairy farms in Puerto Rico to determine the prevalence of gastrointestinal nematodes eggs before and after anthelmintic treatment. Three grams (3g) of feces were collected directly from the rectum of each heifer in 2 different visits (d0) and (d7). After feces collection on d 7, treatments: Ivomec (ivermectin) (n = 111), Dectomax (doramectin) (n = 98), and Valbazen (benzimidazole) (n = 107) were randomly administered to heifers according to manufacturers' instructions. Fourteen (14) days after treatment, 3 g of feces was collected again and the number of parasite eggs per gram of feces was counted using the Modified McMaster Technique. A total of 1,230 eggs were counted before treatment. Nematode genera were identified by a combination of microscopic egg visual evaluation (20×), and egg measurements. Before treatments, the prevalence of nematode eggs were *Cooperia* (19%), *Ostertagia* (62%), *Haemonchus* (13%); *Strongyloides* (5%) and *Trichuris* (1%). Overall, 489 parasite eggs were counted after the administration of anthelmintics. After treatments, the prevalence of nematode eggs were *Cooperia* (6%), *Ostertagia* (76%), *Haemonchus* (14%), *Strongyloides* (2%) and *Trichuris* (2%). The number of *Cooperia* eggs before treatments was 109.2 ± 21 eggs/gram feces (EGF), and it was reduced in all treatments to 20.8 ± 28 EGF ($P < 0.03$). *Ostertagia* averaged 166 ± 23 EGF before treatments, and the EGF was reduced by Dectomax and Valbazen treatment to 87 ± 19.3 and 32.4 ± 18.2 EGF respectively ($P < 0.03$). Conversely, Ivomec treatment did not affect the number of *Ostertagia* eggs ($P = 0.63$). *Haemonchus* averaged 76.5 ± 27.7 EGF before treatments, and the egg count was reduced by Dectomax and Valbazen treatment to 30.7 ± 8.7 and 32.4 ± 11.7 EGF respectively ($P < 0.001$). Ivomec treatment did not affect the number of *Haemonchus* eggs ($P = 0.63$). These data suggest that *Ostertagia* and *Haemonchus* populations have developed resistance to ivermectin in Puerto Rico.

Key Words: ivermectin, doramectin, benzimidazole

T14 Eicosapentaenoic acid and NF-κB inhibitor pyrrolidine dithiocarbamate attenuate prostaglandin production by bovine endometrial cells treated with lipopolysaccharide.

L. Badinga,* M. S. Gulay, and A. D. Ealy, *University of Florida, Gainesville.*

The recognition that n-3 polyunsaturated fatty acids (n-3 PUFA) possess anti-inflammatory properties has prompted a series of studies investigating their efficacy in animal and human models of inflammatory disease. Although their action in antagonizing arachidonic acid metabolism is a key anti-inflammatory effect of n-3 PUFAs, these FA have several other anti-inflammatory effects which might occur downstream of altered eicosanoid production or might be independent of this activity. The objective of this study was to examine the effects of α linolenic (ALA, C18:3; 100 μM), eicosapentaenoic (EPA, C20:5n-3; 100 μM) and docosahexaenoic (DHA, C22:6n-3; 100 μM) acids on prostaglandin E2 (PGE2) and F2α (PGF2α) production by bovine endometrial (BEND) cells treated with lipopolysaccharide (LPS, 10 μg / mL). Concentrations of PGE2 and PGF2α in the culture medium increased ($P < 0.01$) in a dose and time-dependent manner following treatment with LPS. Addition of omega-3 PUFAs to the incubation medium decreased ($P < 0.01$) PGE2 response to LPS by 70.2%. Alpha linolenic acid and EPA were equipotent in reducing PGE2 response to LPS (89% reduction). A smaller but statistically significant reduction of PGE2 production was detected ($P < 0.01$) when BEND cells were co-treated with LPS and DHA. ALA and EPA decreased ($P < 0.01$) PGF2α response to LPS by 63 and 79%, respectively. In contrast, DHA increased ($P < 0.01$) PGF2α response to LPS by 42%. Addition of an NF-κB inhibitor (50 μM pyrrolidine dithiocarbamate) to the culture medium decreased ($P < 0.01$) PGE2 response to LPS to a greater extent than did EPA. Results indicate that omega-3 FA and the NF-κB inhibitor attenuate LPS effects on endometrial PG secretion and that these molecules may act trough distinct signaling pathways. Additional studies are needed to fully characterize the mechanism by which omega-3 FA modulate pro-inflammatory eicosanoid biosynthesis in the bovine endometrium

Key Words: eicosapentaenoic acid, prostaglandin, cattle

T15 Plane of milk replacer nutrition influences the acute phase response of weaned Jersey calves to an oral *Salmonella typhimurium* challenge.

D. L. Hanson*[1], M. D. Sellers[1], C. J. Cobb[1], T. J. Earleywine[2], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Lubbock, TX,* [2]*Land O'Lakes, Animal Milk Products Co., Shoreview, MN.*

Objective was to determine if previous plane of milk replacer nutrition influences the acute phase response to an oral *Salmonella typhimurium* (ATCC14028) challenge in weaned Jersey calves. Twenty Jersey bull calves (77 ± 1 d old) that were previously fed either a Low Plane (LP; 409 g/d of a 20/20 milk replacer) or a High Plane (HP; 610 and 735 g/d of a 28/25 milk replacer for wk 1 and wks 2–6, respectively) of milk replacer were enrolled in the study. All calves were offered ad libitum access to calf starter after the 1st wk of life. Calves began weaning by removing the PM feeding during wk 7 and were completely weaned when they consumed 600 g of calf starter / d after the 7th wk. Calves were orally challenged with 1.5×10^7 colony forming units of *Salmonella typhimurium*. Indwelling rectal temperature probes collected a measurement every 5 min. from −16 h to the conclusion of the study at 236 h post-challenge. Peripheral blood samples were collected daily at 0800 throughout the study and analyzed for oxidative burst capacity when cocultured with an *Escherichia coli*, whole blood secretion of tumor necrosis factor-α when cocultured with lipopolysaccharide, as well as plasma concentrations of haptoglobin, glucose, and urea nitrogen. The percentage of neutrophils producing an oxidative burst was greater ($P < 0.05$) among HP calves from d 1— 5 after the challenge. Similarly, the intensity of the oxidative burst tended to be greater ($P < 0.10$) among HP calves on d 2 and 3 after the challenge. In addition, the secretion of tumor necrosis factor-α tended ($P < 0.10$) to be greater on d 1 and was greater ($P < 0.05$) on d 5 and 6 after the challenge among HP calves. Median ranks of haptoglobin concentrations were lower ($P < 0.05$) among HP calves throughout the study; however, there was no difference in rectal temperature ($P = 0.99$) between LP and HP calves. Data was analyzed using ANOVA with repeated measures. These data support that calves fed a HP of milk replacer nutrition have a more aggressive innate immune response to an oral *Salmonella typhimurium* challenge, which may improve resistance to disease.

Key Words: calf, immune, nutrition

T16 Intravaginal probiotics expedited uterine involution in postpartum dairy cows.

Q. Deng, J. F. Odhiambo, T. Lam, S. M. Dunn, and B. N. Ametaj,* *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Uterine involution and resumption of ovarian cyclicity are good indicators of uterine status and reproductive performance of postpartum dairy cows. The objective of this study was to investigate the effect of intravaginal probiotics on uterine involution and resumption of ovarian cyclicity in postpartum dairy cows. 154 pregnant Holstein cows were randomly assigned (based on parity and BCS) to 3 groups 2 wk before the expected day of calving. Cows received intravaginally a mixture of lactic acid bacteria (LAB) or carrier (skim milk) once a wk at −2, −1 and +1 wk relative to calving as following: treatment 1 (TRT1) - 2 consecutive LAB and 1 carrier dose; treatment 2(TRT2) - 3 consecutive LAB doses; and control (CTR) - 3 consecutive carrier doses. LAB used in this study were a mixture of 3 bacteria: *Lactobacillus sakei* FUA3089, *Pediococcus acidilactici* FUA3138, and FUA3140 and infused at a dose of 10^8-10^9 cfu per dose. Uterine involution was evaluated by rectal ultrasonography using a Sonosite ultrasound fitted with a 7.5MHz probe once a wk at +2, +3, +5, +7 wk to obtain images of the cervix, uterine body and horns, follicles, and corpus luteum. Data were analyzed with the mixed procedure of SAS including treatment, parity, and wk. Results showed differences among treatments in terms of the cross-sectional areas of gravid horn and uterine body. TRT1 had smaller cross-sectional areas of the gravid horn than TRT2 (3.98 ± 0.13 vs. 4.48 ± 0.14 cm^2; $P < 0.01$) and CTR (3.98 ± 0.13 vs. 4.23 ± 0.12 cm^2; $P > 0.05$). The cross-sectional areas of uterine body were smaller in TRT1 compared with TRT2 (5.41 ± 0.16 vs. 5.90 ± 0.17 cm^2; $P < 0.05$) and CTR (5.41 ± 0.16 vs. 5.95 ± 0.15 cm^2; $P < 0.01$). Multiparous cows had larger gravid horn cross-sectional areas than primiparous cows (4.57 vs. 3.90 cm^2; $P < 0.001$). Parity also affected cervix and uterine body cross-section areas ($P < 0.05$). Week had an effect on the cross-sectional areas of gravid horn, cervix, and uterine body ($P < 0.001$). Based on the presence of corpus luteum, data showed that the number of cows that had resumed their cyclic activity by wk +7 were 57%, 67%, and 55% ($P = 0.08$) in TRT1, TRT2, and CTR, respectively. Overall, intravaginal LAB treatment expedited involution of the uterine gravid horn and body, and had a tendency to hasten the resumption of ovarian cyclicity in postparturient dairy cows.

Key Words: dairy cows, lactic acid bacteria, uterine involution

T17 Plane of nutrition during the pre- and post-weaned periods influences the innate immune activity of Holstein calves. B. S. Obeidat[1], C. J. Cobb[1], M. D. Sellers[1], A. R. Pepper-Yowell[1], D. L. Hanson[1], T. J. Earleywine[2], and M. A. Ballou*[1], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock,* [2]*Land O'Lakes, Animal Milk Products Co., Shoreview, MN.*

Objective was to determine the influence of plane of nutrition during the pre- and post-weaned periods on the performance and innate immune activity of Holstein calves. Thirty 9 (2 ± 1 d old) calves were randomly assigned to 2 treatments. Treatments were a low (LPN; n = 18) and high plane of nutrition (HPN; n = 21). Calves in LPN treatment were fed 409 g/d dry matter (DM) of a 20% CP/20% fat milk replacer; whereas calves in HPN treatment were fed 756 and 910 g/d DM of a 28% CP/20% fat during the 1st wk and wk 2–6, respectively. Weaning was initiated during the 7th wk by removing the PM feeding and calves were completely weaned when they were consuming 800 g DM of calf starter after d 53. Calves were fed their respective calf starter until the end of the study at 91 d. Peripheral blood samples were collected on d 3, 10, 21, 45, 47, 53, and 91 for ex vivo immunological and biochemical analyses. Data were analyzed by ANOVA with repeated measures. Metabolizable energy intake, crude protein intake, and average daily gain were greater ($P < 0.001$) for HPN calves compared with LPN calves. No difference between treatments was observed for secretion of tumor necrosis factor-α when whole blood was cocultured with lipopolysaccharide. On d 3 and 21 neutrophil L-selectin expression was greater ($P < 0.05$) in LPN than HPN. The percentage of neutrophils producing an oxidative burst when cocultured with *Escherichia coli* tended ($P = 0.06$) to be greater and was greater ($P < 0.05$) in LPN than HPN on d 10 and 21, respectively. In addition, neutrophils from LPN had greater ($P < 0.01$) oxidative burst intensity throughout the study. On d 3, 10, 21, and 45 plasma glucose concentrations were greater ($P < 0.02$) in calves fed the HPN. The innate immune responses of calves fed a LPN were more active during the pre-weaning period than calves fed a HPN; however, this response was not observed during the immediate post-weaned period. The exact mechanism underlying the more active innate immune responses of the LPN during the pre-weaned period is not known, but could be due to either increased immunogenic stimulation or decreased stress.

Key Words: calf, immune, plane of nutrition

T18 Pathophysiological response to an oral *Salmonella typhimurium* challenge is influenced by the inoculum dose in newborn colostrum-fed Jersey calves. A. R. Pepper-Yowell,* D. L. Hanson, M. D. Sellers, C. J. Cobb, B. S. Obeidat, and M. A. Ballou, *Texas Tech University, Lubbock.*

Objective was to determine how the pathophysiology of newborn Jersey calves changed over time at increasing doses of an oral *Salmonella typhimurium* (ATCC14028) challenge. Twenty Jersey bull calves (4 ± 1 d old) were orally inoculated with one of 5 doses (n = 4) of *Salmonella typhimurium*: saline, 1×10^4, 1×10^6, 1×10^8, or 1×10^{10} colony forming units. Peripheral blood samples were collected daily from −2 to 11 d and on d 14 relative to the challenge and analyzed for glucose, urea nitrogen, and haptoglobin. Indwelling rectal temperature probes collected hourly measurements throughout the study. Both 10^8 and 10^{10} were 100% lethal doses (LD_{100}) occurring between 2 and 8 d post challenge; whereas 10^6 was an LD_{50} occurring between 10 and 11 d post challenge. None of the 10^4 calves showed any visual signs of disease during the observation period. All values are expressed as differences from the mean of the saline at each time point. Time to reach nadir glucose values for 10^8 and 10^{10} was faster than 10^4 and 10^6 ($P < 0.01$; 3.5, 1.0, 9.0 and 7.8 ± 1.04 d). Average nadir glucose value for 10^8 was lower than 10^4 ($P < 0.05$; −44.9 and −28.6 ± 4.91 mg/dL). Time to peak urea nitrogen was faster for 10^{10} than 10^4, 10^6 and 10^8 ($P < 0.01$; 1.0, 6.0, 6.0, and 3.8 ± 0.94 d). Peak urea nitrogen was lower for 10^4 and 10^{10} than 10^6 and 10^8 ($P < 0.05$; 8.2, 5.8, 14.9 and 15.6 ± 2.12 mg/dL). Time to peak haptoglobin was faster for 10^8 and 10^{10} than 10^4 and 10^6 ($P < 0.01$; 1.8, 1.0, 4.0 and 4.0 ± 0.63 d). Time to peak rectal temperature was faster for 10^8 and 10^{10} than 10^4 and 10^6 ($P < 0.01$; 1.5, 1.0, 3.5 and 3.3 ± 0.33 d). There was no treatment effect on peak haptoglobin values and peak rectal temperature ($P = 0.22$ and $P = 0.13$). However, when the animals were classified by survivability the calves that died had higher average haptoglobin than calves that survived ($P < 0.01$; 3.5 and 1.8 ± 0.38 OD). Increasing the dose of *Salmonella typhimurium* in newborn Jersey calves shortened the timeframe that calves reached a peak immune reaction, and increased the magnitude of the reaction for metabolic parameters.

Key Words: bacteria challenge, calf, health

T19 Effect of dietary supplementation with *Curcuma longa* (turmeric) during *Eimeria maxima* and *Eimeria tenella* infection of chickens. D. K. Kim*[1], H. S. Lillehoj[1], S. H. Lee[1], S. I. Jang[1], M. S. Park[1], and D. Bravo[2], [1]*Animal Parasitic Diseases Laboratory, Animal and Natural Resources Institute, United States Department of Agriculture, Beltsville, MD,* [2]*Pancosma SA, Geneva, Switzerland.*

The effects of orally administered *Curcuma longa* (turmeric) on the classic criteria of coccidiosis in chicken was evaluated during experimental *Eimeria maxima* (EM) or *Eimeria tenella* (ET) infection and the modification of genome-wide profile was analyzed in uninfected condition. Broiler chickens continuously fed from hatch with *Curcuma Longa* supplemented diet and orally challenged with live EM or ET had increased body weight gain, greater antibody responses to microneme protein 2 from ET (EtMIC2) compared with chickens fed a non-supplemented diet. However, the chickens fed turmeric-supplemented diet shed significantly decreased fecal oocyst excretion only in ET infected chickens, not in EM infection group. Differences between groups were considered statistically significant at $P < 0.05$ by one-way ANOVA. Differential gene expression by microarray hybridization using a cutoff of >2.0-fold changes identified 601 transcripts whose levels were significantly altered in intestinal lymphocytes of turmeric-fed birds without *Eimeria* infection compared with non-supplemented controls (287 upregulated, 314 downregulated). Biological pathway analysis identified the most significant function belonging to the categories of "Disease and Disorder" as "Nutritional Diseases." The levels of local cytokine transcripts of IL-1β, IL-6, IL-15, and IFN-γ were consistently greater in the turmeric-fed no-infection group compared with the controls fed only the standard diet. These results suggest the immunologic and genomic changes that occur in chickens following dietary supplementation of turmeric that are relevant to protective immunity during avian coccidiosis.

Key Words: *Curcuma longa*, turmeric, coccidiosis

T20 Detection of neutralizing antibody titration against rabies virus in dogs. A. E. Gazi*[1] and S. Ak[2], [1]*Tarim Ilce Mudurlugu, Bozyazi, Turkey,* [2]*Istanbul University, Veteriner Fak. Microbiology, Istanbul, Turkey.*

The aim of this study was to determine the titers of neutralizing antibodies against rabies virus in 5 hundred vaccinated owned and stray dogs within the Istanbul province. The levels of the neutralizing antibody titration in the blood serum were evaluated by ELISA method. Sixty-five

(13%) of the dogs examined had adequate level (0.5 IU/ml and over) of antibody titration. In addition, the effects on the formation of the neutralizing antibody levels following the vaccination of some factors, such as being owned or stray, the number of repetition of vaccination, the age, living area, sex, interval between the last vaccination and sampling, have been evaluated. The statistical comparisons of the ages, number of repetition of vaccination, interval between the last vaccination and the sampling dates of the groups were analyzed by using one way ANOVA. *t*-test procedure was used to evaluate rest of the data. As a result of the statistical evaluations, it has been determined that interval between the last vaccination and sampling had an important effect on formation of the neutralizing antibody titration ($P < 0.001$). Moreover, the effect of the age of the dogs was also significant for the neutralizing antibody levels ($P < 0.05$). In contrast, being owned or stray, sex, living area and the number of repetition of the vaccination had no effects on the neutralizing antibody levels.

Key Words: rabies, vaccines, immunogenicity of rabies vaccine

T21 Dairy health records use and management by producers in Washington and Idaho.

J. R. Wenz*[1], D. A. Moore[1], R. A. Jussaume[1], S. Giebel[1], S. Poisson[1], and C. S. Schneider[2], [1]*Wasington State University, Pullman,* [2]*University of Idaho, Moscow.*

Nationally, more than 90% of large dairy herds use computerized records, making it possible to use epidemiologic techniques to evaluate management of the herd. However, accuracy and consistency of these data are often lacking. Dairy management software prescribes the way reproduction records are entered but health data entry is user-defined and highly variable within and between farms. Therefore, the ability to meaningfully summarize and evaluate health data are limited. The purpose of this study was to evaluate the use and perceived value of health data on dairies. Mail and online survey that focused on perception of health data utility and how health data were recorded was pre-tested and then provided to 951 dairy producers in Washington and Idaho. Comparisons of proportion of respondents to a question were made using a chi-squared test for homogeneity of proportions. A total of 242 (25.4%) surveys were returned. About 65% of producers used commercial dairy management software and just over half recorded some health events in the computer. Of the 116 that used commercial software and recorded some health events, 85% indicated that their disease and treatment records were most useful for making culling decisions for individual cows but were less confident about the ability of their computerized health records to track drug withdrawal times, monitor disease in the herd or evaluate the effectiveness of management practices for groups of cows. Of all the respondents, 45.6% (108) agreed that better guidelines on how to record disease and treatment records are needed while 16.5% (39) disagreed. Few respondents agreed that disease and treatment data are recorded the same way on most dairies (11.4%). A minority of respondents (16.5%) were dissatisfied with the quality of their records. A higher percentage of dissatisfied respondents agreed that better guidelines for recording health data were needed versus the need for better guidelines on reproduction data (90 vs 51%; $P < 0.001$). Most producers saw value to their health data but primarily for making individual cow decisions. Improvements in health data quality allowing epidemiological evaluation to inform herd-level decision making will require on-farm health data entry industry standards as currently exist for milk production and reproduction records. Such standards would be best implemented by a change from user-defined to prescribed data entry in dairy management software.

Key Words: dairy, health, records

T22 Effect of method of detection and uterine dimensions in the diagnosis of endometritis in lactating dairy cows.

R. L. A. Cerri*[1], D. M. Veira[2], A. M. Tabmasbi[3], A. M. L. Madureira[1], S. A. Balios[1], A. H. Souza[4], and J. L. M. Vasconcelos[5], [1]*University of British Columbia, Vancouver, BC, Canada,* [2]*Agriculture and Agri-Food Canada, Agassiz, BC, Canada,* [3]*Fedowsi University of Mashhad, Iran,* [4]*University of Wisconsin, Madison,* [5]*Sao Paulo State University, Botucatu, SP, Brazil.*

Objectives of this study were to 1) identify the agreement among different methods to detect endometritis and, 2) determine interactions among uterine measurements, parity, BCS and endometritis diagnosis. Three-hundred and forty-seven diagnoses were performed in lactating Holstein cows from the UBC Dairy Centre. Cows were diagnosed at 30 and 44 ± 3 d in milk by gloved hand (GH) and Metricheck (MC) exams based on vaginal discharge that were scored on a 1–5 scale (>3 considered positive), and ultrasonography (US) of the uterus (presence of ecogenic fluid in lumen) as the gold standard. Blood samples and BCS (Low <2.75 > Moderate) were collected on the same dates of uterine exams. Major US measures of the uterus were diameter of the endometrium in both horns (Small <18mm > Large), asymmetry between horns (Moderate <3mm > High), and diameter of the inner layer of cervix (Small <18mm > Large). Data was analyzed by logistic regression using SAS (significant if $P < 0.05$). Results show that endometritis was diagnosed in 10.6% of the time, whereas MC and GH were diagnosed in 15.7% and 13.4% of the time. Considering US as the reference method, agreement with MC and GH was 35.3% and 32.3%, respectively. A large uterine horn (22.8% vs. 12.8%), high asymmetry of uterine horns (16.3% vs. 6.2%) and a large cervix (15.5% vs. 5.8%) measured by US were more likely to be diagnosed with endometritis. When diagnosis was done with MC or GH, the high asymmetry between uterine horns proved significant (20.3% vs. 9.8%) to predict endometritis, but only in the GH a large cervix was more likely to predict endometritis (18.9% vs. 8.2%). Primiparous cows were also more likely to be diagnosed with endometritis based on vaginal discharge (20.2% vs. 12.6%) compared with multiparous cows. BCS had no influence in the diagnosis of endometritis. In conclusion, methods that used solely vaginal discharge to detect clinical cases of endometritis overestimated the number of endometritis cases and were inaccurate compared with US diagnosis. Methods using vaginal discharge are likely diagnosing vaginitis or cervicitis more accurately than endometritis.

Key Words: dairy cows, endometritis, ultrasound

T23 Effects of phytoncide supplementation on growth performance, nutrient digestibility, blood profiles, diarrhea score, and fecal microbial shedding in weaning pigs.

S. Zhang*[1], J. H. Jung[1], H. S. Kim[2], B. Y. Kim[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea,* [2]*Phylus Co. Ltd., Chungbuk, South Korea.*

A total of 140 weaning pigs [(Landrace × Yorkshire) × Duroc, BW = 6.47 ± 0.86 kg] were used in a 5-week growth trial to determine the effects of phytoncide supplementation on growth performance, apparent total tract digestibility (ATTD), blood profiles, diarrhea score, and fecal microbial shedding. Pigs were randomly assigned into 1 of 5 treatments. Dietary treatments were: NC, basal diet (without antibiotics); PC, NC + 0.05% tylosin; EO, NC + 0.1% essential oil; PP, NC + 0.2% PP (phytoncide with 2% citric acid), and PA, NC + 0.2% PA (phytoncide). Each treatment had 7 replicate pens with 4 pigs per pen. All pigs were housed in pens with a self-feeder and a nipple drinker, and allowed ad libitum access to feed and water throughout the experiment. Statistical analyses were conducted in accordance with mean separations performed by the Duncan multiple range test using the GLM procedure of the SAS statistical software package (1996). During 0–2 weeks, the gain to feed (G/f) ratio in EO and PP treatments were increased ($P < 0.05$) compared with PA treatments. During 2–5 weeks, PA treatment had the highest ($P < 0.05$) G/f among treatments. Pigs fed the PC and PP diets had higher ($P < 0.05$) ATTD of gross energy than those fed the NC and EO diets at 2 week. The ATTD of dry matter (DM) was improved ($P < 0.05$) in PC, PP and PA treatments compared with NC treatment at 5 week. The PP treatment increased ($P < 0.05$) the concentration of immunoglobulin G (IgG) in blood compared with NC, PC and EO treatments at 2 week. These pigs fed PP diet showed greater ($P < 0.05$) amounts of fecal *Lactobacillus* compared with NC treatment. However, no difference ($P > 0.05$) was observed in diarrhea score among treatments. In conclusion, dietary supplementation with 0.2% PP may improve nutrient digestibility, increase blood IgG concentration, and the amounts of fecal *Lactobacillus* in weaning pigs, which indicated that phytoncide with 2% citric acid could be used as an alternative for antibiotics in weaning pigs.

Key Words: blood profiles, phytoncide, weaning pigs

T24 Influence of tannins extract supplementation on feedlot performance of receiving bull-calves naturally infested with gastro intestinal parasites. R. Barajas*[1], B. J. Cervantes[2], M. A. Espino[1,3], A. Camacho[1], I. Enriquez[1], C. Barraza[1], L. R. Flores[1], J. J. Lomeli[1], and J. A. Romo[1], [1]*FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México*, [2]*Ganadera Los Migueles S.A. de C.V., Culiacán, Sinaloa, México*, [3]*Pronutrient Developers, León, Guanajuato, México.*

Sixty-five bull-calves 171 ± SE 2.77 kg were used to determine the influence of tannins extract supplementation on feedlot performance of receiving bull-calves naturally-infested with gastro intestinal parasites. Bull-calves were individually weighed, ear-tagged, and grouped in 4 blocks using initial weight criteria for reduction of social interaction, and allotted in 16 ground floor pens (6 × 12 m). Bull-calves were weighed d 1 and 28 when feces and blood samples were taken from each bull-calve to exploring the presence of gastro-intestinal parasites, blood parasites, and plasma urea nitrogen (PUN) determination. Inside each block, pens were randomly assigned to receive 1 of 2 treatments: 1) Feeding with a 70% concentrate ground sorghum-DDG-canola meal based diet (CTRL; n = 32); or 2) Diet similar to CTRL, added with 0.3% (dry matter basis) of tannins extract (TE; n = 33). Tannins extract was supplied as TMP-Protein Enhancer (Técnica Mineral Pecuaria; Mexico), a premix that contains 56% of a condensed (Quebracho tree) and soluble (Chesnutt) tannins-blend. Number of infested animals was compared using Chi-squared test. Number of parasites-eggs by gram of feces data (NEGF) was transformed to square-root before analyses. NEGF, PUN, final weight and Average daily gain were analyzed by ANOVA. No blood-parasites were found. Eggs of found parasites corresponded to: < i (85%), *Eimeria* sp. (72%), *Cooperia* sp. (71%), *Trichostrongylus* sp. (52%), and *Esophagostomus* sp. (32%). In d 1 and 28 the amount of infested-calves and the NEGF were similar ($P > 0.50$) between treatments. TE supplementation decreased ($P = 0.03$) 15.5% PUN concentration (14.06 vs. 11.88 mg/dL). Final weight was similar between treatments ($P = 0.51$). Average daily gain tended to be higher ($P = 0.07$) in bull-calves fed-TE (1.370 vs. 1.191 kg/day for TE and CTRL, respectively. It is concluded that tannins extract supplementation in dose near to 0.3% of dietary DM, did not produce changes on GI parasites population of receiving bull-calves.

Key Words: feedlot-calves, parasites, tannins

T25 Effects of different levels of fermented oat on growth performance, diarrhea score, fecal microbial shedding, and fecal noxious gas emission in weaning pigs. J. P. Wang,* J. P. Lee, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to investigate the effects of different levels of fermented oat on growth performance, diarrhea score, fecal microbial shedding, and fecal noxious gas emission in weaning pigs. A total of 125 weaning piglets [(Landrace × Yorkshire) × Duroc, BW = 7.31 ± 0.24 kg] weaned at 21 d of age were assigned to 5 treatments in randomized complete block designs based on the initial BW and sex. This experiment included 2 phases. In phase 1 (0–21 d), there were 5 treatments: T1, basal diet + 15% nature oat; T2, basal diet + 3.7% fermented oat + 11.3% nature oat; T3, basal diet + 7.5% fermented oat + 7.5% nature oat; T4, basal diet + 11.3% fermented oat + 3.7% nature oat, and T5, basal diet + 15% fermented oat. In phase 2 (21–35 d), it also included 5 diets, an half of dose in phase 1 were supplemented in phase 2. Pigs were allowed ad libitum access to feed and water and their BW and FI were measured by each phase for entire experiment. During the phase 1, the use of 7.5%, 11.3%, 15% fermented oat to replace nature oat improved ($P < 0.05$) ADG and G/f compared with T1 and T2 treatments. Use of fermented oat up to 7.5% replacing nature oat showed the highest ($P < 0.05$) ADG and G/f among dietary treatments. During the phase 2, pigs fed the 3.5%, 5.3%, and 7% fermented oat substituted diets showed higher ($P < 0.05$) ADG compared with those fed the basal diet. Overall, ADG and ADFI were higher ($P < 0.05$) in T3, T4 and T5 treatments compared with T1 and T2 treatments. Different levels of fermented oat had no effect ($P < 0.05$) on diarrhea score, nutrient digestibility, fecal microbial shedding, and fecal noxious gas emission. Collectively, we could conclude that supplementation with 50% fermented oat to replace nature oat is an appropriate dose to achieve a better growth performance in weaning pigs.

Key Words: fermented oat, growth performance, weaning pigs

T26 GPR109A mediates calcium mobilization induced by BHBA in isolated bovine monocytes. L. K. Mamedova*[1], E. C. Titgemeyer[1], G. M. Pighetti[2], J. Y. Lu[1], D. H. Hua[1], and B. J. Bradford[1], [1]*Kansas State University, Manhattan*, [2]*University of Tennessee, Knoxville.*

Ketosis is a common in early lactation dairy cows, and ketosis greatly elevates the risk of subsequent infections. In vitro administration of β-hydroxybutyric acid (BHBA) has inhibitory effects on the function of bovine neutrophils, monocytes, and lymphocytes. However, mechanisms linking BHBA to altered immune function remain unknown. Our objective was to evaluate the potential role of the BHBA receptor GPR109A in leukocytes. Blood was collected from 3 healthy Holstein cows in mid-lactation and peripheral blood mononuclear cells (monocytes) and polymorphonuclear neutrophils were isolated. Protein and RNA were extracted, mRNA abundance of GPR109A was determined by quantitative RT-PCR, and protein abundance was determined by Western blot. Results demonstrated strong expression of GPR109A at the mRNA (mean Ct = 22.7 ± 0.6) and protein levels in both cell types. Next, isolated monocytes and neutrophils were exposed to BHBA (1 mM) or niacin (10 μM), a potent agonist of GPR109A. Immediately after exposure to treatments, cytosolic calcium concentrations were monitored by fluorescence assay. Both BHBA and niacin elevated cytosolic calcium in both monocytes and neutrophils (all $P < 0.01$). Finally, RNA interference was used to knock down the protein before exposure to agonists. Isolated monocytes were transfected with siRNA (scrambled or GPR109A) and incubated for 24 h. Cells were then treated with 1 mM BHBA and calcium mobilization was assessed, or cells were harvested to determine knockdown efficiency. Although incubation time was short due to the limited viability of isolated monocytes, densitometry analysis of Western blot revealed that GPR109A protein was significantly knocked down by the siRNA treatment (36 ± 10% decrease, $P < 0.05$). As in the initial study, BHBA caused a significant increase in cytosolic calcium, and GPR109A siRNA decreased this response by 63 ± 3% ($P < 0.001$). Collectively, these results suggest that GPR109A at least partially mediates calcium mobilization responses to BHBA in bovine leukocytes. Further research is required to determine whether such mechanisms underlie the effects of BHBA on immune function.

Key Words: G protein coupled receptor, ketone, immunity

T27 Effects of bacteriophage as an alternative for antibiotics on egg performance, egg quality, fecal microbial shedding, and fecal moisture content in laying hens.

P. Y. Zhao,* B. R. Lee, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of two hundred forty 40-wk-old ISA-brown laying hens were used in a 6-week feeding trial to evaluate the effects of bacteriophage as an alternative for antibiotics on egg performance, egg quality, fecal microbial shedding, and fecal moisture content. Hens were allotted to 1 of 4 dietary treatments with 10 replications (6 adjacent cages per replication and 1 hen per cage) in a completely randomized design. Dietary treatments included: 1) CON, basal diet; 2) BPS1, CON + 0.020% bacteriophage; 3) BPS2, CON + 0.035% bacteriophage, and 4) BPS3, CON + 0.050% bacteriophage. Bacteriophage used in our study contains *Salmonella gallinarum*, *S. typhimurium*, *S. enteritidis*, *S. pullorum*, *Staphylococcus aureus*. The counts of bacteriophage are 10^8 pfu/gram. All diets were formulated to meet or exceed the NRC (1994) requirements for laying hens. Hens were provided with basal diet for a 7 d adjustment period before the beginning of the experiment. All hens were allowed ad libitum access to water and feed through nipple drinkers and feeders, respectively. The hens were housed in a windowless and environmentally controlled room that was maintained at 21°C, and had a daily lighting schedule of 16 h light and 8 h dark. During 0–6 weeks, no difference ($P > 0.05$) was observed in egg production and egg weight among dietary treatments. At 4 and 5 weeks, birds in BPS2 group had higher ($P < 0.05$) Haugh unit (HU) than those in CON group. HU in birds fed the BPS1 and BPS3 diets was greater ($P < 0.05$) than those fed the CON diet at 5 and 6 weeks. However, egg weight, egg shell color, yolk height, yolk color unit, egg shell strength, egg shell thickness, egg gravity, fecal microbial shedding, and fecal moisture content were not influenced ($P > 0.05$) by dietary treatments during the entire experimental period. In conclusion, bacteriophage supplementation in our study had beneficial effects on HU, which related to a higher egg albumen contents, thus led to fresher eggs in laying hens.

Key Words: bacteriophage, egg quality, laying hens

T28 Effects of bacteriophage as an alternative for antibiotics on growth performance, nutrient digestibility, blood profiles, fecal microbial shedding, diarrhea score, and fecal moisture content in growing pigs.

S. M. Hong,* H. Y. Baek, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 96 growing pigs [(Landrace × Yorkshire) × Duroc, BW = 28.85 ± 1.63 kg] were used in a 6-week feeding trial to investigate the effects of bacteriophage as an alternative for antibiotics on growth performance, apparent total tract digestibility (ATTD), blood profiles, fecal microbial shedding, diarrhea score, and fecal moisture content. Pigs were randomly allotted to 4 treatments with 6 replicate pens (4 pigs per pen) per treatment according to their initial BW. Dietary treatments were: 1) NC, negative control diet (without antibiotics); 2) PC, NC + 22ppm tylosin; 3) BP1, NC + 0.025% bacteriophage and 4) BP2, NC + 0.05% bacteriophage. Bacteriophage used in our study contains *E. coli* K88, *E. coli* K99, *Salmonella typhimurium*, *S. enteritidis*, *S. cholerasuis*, *Clostridium perfringens* type A & C, *Staphylococcus aureus*. The counts of bacteriophage are 10^8 pfu/gram. No difference ($P > 0.05$) was observed in growth performance and blood profiles among treatments throughout the experimental period. The ATTD of DM was higher ($P < 0.05$) in PC, BP1, and BP2 treatments than that in NC treatment. The ATTD of N was improved ($P < 0.05$) in bacteriophage treatments than that in NC treatment. The ATTD of energy was higher ($P < 0.05$) in PC treatment than that in NC treatment. Fecal *Lactobacillus* counts were increased ($P < 0.05$) in BP2 treatment compared with NC and PC treatments, whereas fecal *Escherichia coli* population was reduced ($P < 0.05$) in PC and BP2 treatments compared with NC treatment. No significant difference ($P > 0.05$) was noted in diarrhea score and fecal moisture content among treatments. In conclusion, supplementation with 0.05% bacteriophage in growing pig diet improved nutrient digestibility, benefited the fecal *Lactobacillus* population, and inhibited the growth of *Escherichia coli*, indicating bacteriophage can be used as an alternative for antibiotics in growing pigs.

Key Words: bacteriophage, nutrient digestibility, growing pig

T29 Effects of bacteriophage as an alternative for antibiotics on growth performance, nutrient digestibility, relative organ weight, blood profiles, and fecal microbial shedding in broilers.

X. Y. Guo,* J. H. Cho, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 720 1-d-old ROSS 308 broilers (BW = 44.2 ± 0.2 g) were used in a 32-d trial to investigate the effects of bacteriophage as an alternative for antibiotics on growth performance, apparent total tract nutrient digestibility, relative organ weight, blood profiles, and fecal microbial shedding. Broilers were randomly assigned to 1 of 4 treatments (12 replicate pens per treatment with 15 broilers per pen). Dietary treatments were: 1) NC, basal diet (without antibiotics); 2) PC, NC + 0.05% tylosin; 3) BP1, NC + 0.025% bacteriophage; 4) BP2, NC + 0.05% bacteriophage. Bacteriophage contains *Salmonella gallinarum*, *S. typhimurium*, *S. enteritidis*, *Clostridium perfringens* type A & C, and *Staphylococcus aureus*. The counts of bacteriophage are 10^8 pfu/gram. This trial was separated into starter phase (d 0–14) and finisher phase (d 15–32). Broilers were allowed *ad libitum* access to feed and water. The feed conversion ratio (FCR) decreased ($P < 0.05$) in BP2 treatment compared with NC treatment. No difference ($P > 0.05$) was found in BWG, FI and FCR among treatments during neither period nor overall period. The apparent total tract nutrient digestibility was unaffected ($P > 0.05$) by dietary treatments. The relative liver weight was higher ($P < 0.05$) in BP1 treatment than NC treatment. The meat quality and other relative organ weights were not affected ($P > 0.05$) by dietary treatments. There was no difference ($P > 0.05$) in blood profiles among treatments. The fecal *Lactobacillus* counts were increased ($P < 0.05$) in BP2 treatment compared with NC treatment. The fecal *E. coli* population was reduced ($P < 0.05$) in PC, BP1 and BP2 treatments compared with NC treatment. Collectively, the dietary bacteriophage supplementation at the level of 0.05% could benefit intestinal beneficial bacteria, and inhibit the growth of pernicious bacteria, thus maintained the intestinal health of broilers.

Key Words: bacteriophage, broilers, microbial shedding

T30 Changes in bacterial communities in bovine milk when comparing low and high somatic cell count quarters using culture independent analysis. S. M. Buttram*[1], K. M. Hunt[1], L. K. Fox[2], and M. A. McGuire[1], [1]*Department of Animal and Veterinary Science, University of Idaho, Moscow,* [2]*Department of Animal Science, Washington State University, Pullman.*

Many believe that bovine milk is sterile unless infectious mastitis is occurring. However recent reports indicate the presence of microbial communities in milk of healthy mammary glands, but little is known about these communities when there is an increase in somatic cell count (SCC). The objective of this study was to characterize the microbial communities in bovine milk, to determine if sampling type affected bacterial diversity, and to compare how communities changed with an increase in SCC. Milk was collected once from 6 Holstein cows that had at least one high SCC (≥400,000 cells/ml) quarter and one low SCC quarter using 4 sampling techniques: fore strip, needle aspirate of foremilk, residual strip, and needle aspirate of residual milk. To characterize the microbial communities, culture independent pyrosequencing of the 16S ribosomal RNA gene was used to determine percentage relative abundance. Results (mean ± SEM) demonstrated that the most abundant bacterial genera in low SCC milk included: *Clostridium* (29.6 ± 4%), *Sporacetigenium* (11.6 ± 1.7%), *Pelomonas* (10.9 ± 2.4%), *Turicibacter* (5.8 ± 1.0%), and *Staphylococcus* (5.1 ± 1.7%). The most abundant genera in high SCC milk included: *Staphylococcus* (63 ± 7.3%), *Peptoniphilus* (7.9 ± 3.7%), *Enterococcus* (6.1 ± 4.2%), *Arcanobacterium* (4.5 ± 2.1%), and *Sporacetigenium* (2.8 ± 1.0). Milk collected from high SCC quarters displayed increased *Staphylococcus* and reduced bacterial diversity (number of genera above 5% relative abundance). This occurred across all sample types. These results suggest that bovine milk is not sterile and contains diverse microbial communities when SCC is low. When an increase in SCC occurs, these bacterial communities are altered as bacterial diversity is diminished.

Key Words: microbial communities, somatic cell count, bovine milk

T31 Group housed Holstein bull calves have suppressed innate immune function compared to individually housed calves during weaning. L. E. Hulbert*[1], M. S. Calvo[1], M. A. Ballou[2], K. C. Klasing[1], and F. M. Mitloehner[1], [1]*Department of Animal Science, University of California-Davis, Davis,* [2]*Animal and Food Sciences, Texas Tech University, Lubbock.*

Objectives were to (1) determine if housing calves in groups of 3 (Group; n = 9 pens) or individually (Indv; n = 18) influences the innate immune responses of Holstein calves during weaning and (2) determine whether the response of grouped calves is influenced by their ADG ranking within a pen (Low = 0.80 ± 0.116; Mid = 1.27 ± 0.116; or High = 1.68 ± 0.116 kg/d). Calves were fed 227 g of milk replacer (MR) twice-daily until weaning and offered ad libitum calf-starter throughout the experiment. Weaning was initiated at age 53 d by removal of pm MR and was completed at age 64 d by removal of am MR. Peripheral whole blood (WB) samples were collected before the am MR at age 53, 57, 64, 67 and 71 d. In all calves, plasma cortisol and urea nitrogen (UN) increased at 67 d from pre-weaning concentrations ($P \leq 0.05$). Indv-housed calves had greater haptoglobin at 67 d ($P \leq 0.05$). Overall, neutrophil oxidative burst (OB) and phagocytosis (PG) to heat-killed *E. coli* was lower in Group calves compared with Indv-calves ($P \leq 0.05$). In addition, Group-calves had lower ($P \leq 0.05$). Tumor Necrosis Factor (TNF)-α concentrations from WB stimulated with endotoxin than Indv-calves at pre-weaning ($P \leq 0.05$). Indv-calves also had greater WB killing (WBK) of *E. coli* than Group-calves at 64 d of age ($P \leq 0.05$). Within Group, Low-ranked calves had the least glucose ($P \leq 0.05$), greatest UN ($P \leq 0.05$), and least OB and PG ($P \leq 0.05$) than other Group-calves. Mid-ranked calves had increased TNF-α responses at 67 and 71 d ($P \leq 0.05$). In addition, secretion Interferon-γ by WB stimulated with phytohemagglutinin was greater among Mid-ranked calves at 57 and 64 d ($P \leq 0.05$). Lastly, High-ranked calves had greater WBK at 57 and 64 d than other Group-calves ($P \leq 0.05$). Weaning may have a more negative effect on innate immune function for group-housed calves than individually housed calves, especially the lowest performing calves.

Key Words: bovine, commingle, immunity

T32 Effects of dietary herb supplementation on growth performance, and appearance of diarrhea in weaning-growing pigs. J. P. Wang,* X. Y. Guo, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea.*

A total of 200 weaning pigs [(Landrace × Yorkshire) × Duroc, BW = 7.00 ± 0.86 kg] were used in a 10-week feeding experiment to determine the effects of dietary supplementation of herb extract on growth performance, and appearance of diarrhea in weaning-growing pigs. Pigs were randomly allocated into 1 of 5 treatments with 2 replicate pens per treatment and 20 pigs per pen. Dietary treatments were: 1) CON, basal diet; 2) A, CON + 0.1% anti-diarrhea herb seed; 3) B, CON + 0.05% (*Lonicera japonica* + *Japanese atractylodes*); 4) C, CON + 0.1% (*Scutellaria baicalensis* + *Houttuynia cordata*); 5) D, CON + 0.1% anti-diarrhea herb extract. All pigs were housed in pens with a self-feeder and a nipple drinker to allow *ad libitum* access to feed and water throughout the experimental period. The experiment included weaning phase (0–5 weeks) and growing phase (5–10 weeks). In each phase, body weight and feed consumption were recorded to calculate ADG, ADFI, and G/f. Diarrhea pig number was recorded daily from d 0 to 6 in each phase. During 0–5 weeks, ADG and G/f were higher ($P < 0.05$) in B, C and D treatments than those in CON and A treatments. ADFI was increased ($P < 0.05$) in D treatment compared with CON and A treatments. During 5–10 week, pigs fed the B, C and D diets had a greater ($P < 0.05$) ADG and ADFI than those pigs fed the CON and A diets. Overall, pigs fed the B, C and D diets had a higher ($P < 0.05$) ADG than those fed the CON and A diets. From d 2 to 6 in weaning phase and d 1 to 6 in growing phase, the number of diarrhea pigs was decreased ($P < 0.05$) by the application of herbs. In conclusion, dietary supplementation of 0.05% (*Lonicera japonica* + *Japanese atractylodes*), 0.1% (*Scutellaria baicalensis* + *Houttuynia cordata*), and 0.1% anti-diarrhea herb extract could improve the growth performance, and decrease the diarrhea rate in weaning-growing pigs.

Key Words: growth performance, herb, weaning-growing pigs

T33 Efficacy of a yeast cell wall-derived mycotoxin adsorbent on excretion of aflatoxin B_2 in rats. B. Walters,* T. Smith, and M. Crump, *University of Guelph, Guelph, Ontario, Canada.*

Mycotoxins are natural contaminants of livestock feeds and impair production efficiency. One method to reduce exposure of animals to mycotoxins is by using specialized feed additives known as mycotoxin adsorbents (MA). These use nonspecific binding to sequester mycotoxins preventing them from being absorbed into the bloodstream. Current research has shown that MA can reduce symptoms of mycotoxicoses but quantitative evidence of reduced exposure has yet to be demonstrated. The current study sought to quantify the adsorptive capabilities of a yeast cell wall-derived MA (GMA). In the first experiment, male Sprague-Dawley rats were randomly placed in groups of 10 and were fed either a control diet or a diet containing 1, 3 or 5% w/w GMA (Integral, Alltech Inc., Nicholasville, KY). Rats were fed this diet for 7 d and then exposed by oral gavage to a tracer dose of ^{3}H-8,9-aflatoxin B_2. Feces and urine were collected 24 h after dosing. The rats were sacrificed by CO_2. The dose collected in each sample was compared between groups using SAS and no significant difference was observed between any GMA group and the control. Due to the kinetics of the digestive pathway, it was thought that total excretion after a set time did not provide as much information as excretion over time. In the second experiment, rats were grouped as before using only the 5% GMA and control diets. Feces and urine were collected for 6, 12, 18, 24, 48 and 72 h after dosing. The amount of excreted dose was higher among the GMA-treated rats compared with the control during the first 18 h after the initial dosing. After 18 h, excretion of dose in both groups was lower. Using ANOVA with a factorial design indicated a significant interaction between diet and time ($P < 0.05$). The natural logarithm of the excreted dose was used for linear regression analysis and showed that the excretion rate in the GMA-treated rats ($r^2 = 0.88$) was faster than the control ($r^2 = 0.80$). Based on this model, it was concluded that GMA reduces transit time of aflatoxin and reduces exposure in rats.

Key Words: aflatoxin, adsorbent, glucomannan

T34 Biotransformation approaches to alleviate the toxic effects induced by Fusarium toxins in swine. B. Grenier*[1,3], A. P. Loureiro-Bracarense[2], J. Lucioli[2], A. M. Cossalter[1], W. D. Moll[3], G. Schatzmayr[3], and I. P. Oswald[1], *[1]Institut National de la Recherche Agronomique-ToxAlim, Immuno-Mycotoxicology, Toulouse, France, [2]Universidade Estadual de Londrina, Lab Patologia Animal, Londrina, Brazil, [3]Biomin Research Center, Tulln, Austria.*

Mycotoxins are secondary metabolites of fungi that can cause serious health problems in animals, and may result in severe economic losses. Therefore, development of control strategies is necessary. Based on enzymatic reactions, we evaluated the efficiency of detoxifying agents into the gastrointestinal tract of piglets fed a co-contaminated diet with low doses of deoxynivalenol (DON) and fumonisins (FUMO). Four diets were formulated and given to piglets for 5 weeks; a control diet with or without the detoxifying agents (DA), and a co-contaminated diet with both Fusarium toxins (3 mg DON/kg, 6 mg FUMO/kg of feed) with or without DA. At d 4 and 16, the animals were subcutaneously immunized with ovalbumin (OVA) to assess the specific immune response. A decreased proportion of blood neutrophils was observed in the animals fed DON+FUMO diet ($P = 0.04$), and by contrast animals fed this diet with DA were not affected. Microscopical lesions (mild to moderate) were recorded in liver and lungs of piglets exposed to mycotoxins. Addition of the DA did not significantly reduce the hepatic lesion score, but significantly counteracted the effects on the proliferation index of hepatocytes ($P < 0.01$). Similarly, in lung, occurrence and extent of lesions were strongly reduced after inclusion of DA in the co-contaminated diet ($P = 0.01$). Assessment of the specific immune response at d 35 showed a restoration of immune parameters in presence of DA in contaminated feed. Indeed, the ability of lymphocytes to proliferate upon OVA stimulation was significantly enhanced in the DON+FUMO+DA diet (by 2.2 fold, $P = 0.05$). The concentration of IgG anti-OVA was partially increased in plasma of animals fed the co-contaminated with DA (+33%, $P = 0.28$). In spleen, the profile of cytokines expression (IL-1β, IL-6, IL-8 and IL-12p40) in the group containing both toxins with DA was similar in comparison to both control groups, whereas the association of the mycotoxins significantly depressed the mRNA levels ($P < 0.05$). In conclusion, the adverse effects induced by the ingestion of both DON and FUMO in piglets were partially to totally counteract in presence of DA in this diet.

Key Words: Fusarium toxins, biotransformation, immune response

T35 Impact of cow genetics regarding the osteopontin gene for the immune response to MAP infection. C. Thibault[1], P.-L. Dudemaine[2,1], and N. Bissonnette*[1,2], *[1]Agricultre and Agri-Food Canada, Dairy and Swine Research and Development Center, Sherbrooke, Quebec, Canada, [2]Université de Sherbrooke, Sherbrooke, Quebec, Canada.*

Bovine paratuberculosis is a pandemic infection that affects much of the world′s ruminant population. The causative pathogen is *Mycobacterium avium* ssp. *paratuberculosis* (MAP). The goal of this study was to measure the effect of cow genetics regarding the osteopontin (OPN) gene for the immune response to MAP infection. The importance of gaining insight into the unique interactions between host macrophages and mycobacteria is explained. MAP evades host immune responses and is able to persist and multiply in macrophages which generate granuloma formation. Granulomas are characterized by a mononuclear cell infiltration of macrophages and lymphocytes, by the formation of giant cells and epithelioid cells, and by fibrosis, sometimes with calcification. Previous investigations observed that OPN, an early T-cell activating factor, is more abundant in granulomas. In addition, studies confirmed the increased susceptibility of OPN-null mice to intracellular mycobacteria. MAP is believed to grow and survive in macrophages. Thus, the role of OPN in the mycobacteria–macrophage relationship is of considerable interest. In a previous study, our team found that OPN was correlated with bovine mastitis susceptibility and that expression of the OPN gene was correlated with the genotypes (i.e., gene haplotypes). We have undertaken a study of gene expression changes after ex vivo MAP infection using macrophage from different bovine genotypes (SPP1 haplotypes). Four reference genes were also measured; UXT and PPIA were selected by BestKeeper. The qRT-PCR results were analyzed according to the relative quantification method ($2^{-\Delta\Delta Ct}$). Results show that MAP induces a marked increase in cytokines, including interleukin (IL)-1β, −6, −8, −10, and −23 and TNF-α (but not IL-12, SPP1, NOD-2, and SLC11A1 also known as NRAMP1). SPP1 genotype has an effect on IL-6 at 6 h, −8, −10, and −23 gene expression at 24 h ($P < 0.05$) with a tendency for IL-1β at 24 h ($P = 0.09$). The strategy of identifying host genes altered by infection whose expression is linked to animal genetics can provide valuable information for targeting improved disease resistance in genetic selection.

Key Words: bovine paratuberculosis, osteopontin, macrophage

T36 Polymorphisms in the osteopontin gene are associated with *Mycobacterium avium* ssp. *paratuberculosis* infection status.

C. Thibault[1], P.-L. Dudemaine[2], G. Fecteau[3], G. Côté[4,2], O. Labrecque[5], and N. Bissonnette*[1,2], *[1]Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Center, Sherbrooke, QC, Canada, [2]Université de Sherbrooke, Sherbrooke, Québec, Canada, [3]Faculté de médecine vétérinaire de l'Université de Montréal, Saint-Hyacinthe, QC, Canada, [4]Ministère de l'Agriculture, des pêcheries et de l'Alimentation, Québec, QC, Canada, [5]Laboratoire d'épidémiosurveillance animale du Québec, Saint-Hyacinthe, QC, Canada.*

The Canadian dairy industry is aware of the importance of considering resistance to bovine paratuberculosis as a target trait for improvement. The objective of the study was to detect and assess whether DNA polymorphisms in the bovine candidate gene, osteopontin (OPN), are associated with susceptibility to paratuberculosis in dairy cattle. Johne′s disease (JD) is a debilitating and chronic enteritis in ruminants caused by an intracellular pathogen called *Mycobacterium avium* ssp. *paratuberculosis* (MAP). JD and bovine paratuberculosis causes significant economic losses to the Canadian dairy industry. Because of the limited sensitivity, diagnosis of paratuberculosis is difficult because animals remain asymptomatic for years. Variability in the susceptibility of cattle to MAP infection is evident. To detect genetic variations (single nucleotide polymorphisms (SNP), the 10-kilobase DNA fragment carrying the encoding OPN gene has been sequenced using 108 Holstein cows from the same group of age. The MAP status of the cows was determined using serum or milk ELISA combined to fecal culture assays. Fifty-seven cows were positive to both tests and considered infected. Fifty-one cows tested negative over a 6-mo period (2 consecutive tests) and were declared negative). Logistic regression was used to determine the association of SNPs and reconstructed haplotypes with MAP infection status. A total of 9 informative SNPs were identified. The SNPs *SPP1c. 1301G>A* and *SPP1c. 1251C>T* (numbering according to GenBank no. AY878328) genotypes were confirmed and found tightly linked ($P = 0.0007$, Chi-Square) with MAP infection status. In our previous study, these SNPs were associated with the mammary health status of lactating cows. As OPN is now recognized as an important proinflammatory cytokine with pleiotropic beneficial functions, including intracellular pathogen clearance, the presence of genetic variations and their association with infection status confirms the importance of this candidate gene in JD disease. It may be possible to use OPN gene in selective breeding strategies to enhance health status including resistance to MAP infection.

Key Words: bovine paratuberculosis, osteopontin, susceptibility/resistance

T37 Phytonutrients affect the integrity of the mucus layer and susceptibility to enteric pathogens.

M. Wlodarska[1], B. B. Finlay[1], and D. Bravo*[2], *[1]University of British Columbia, Vancouver, British Columbia, Canada, [2]Pancosma, Geneva, Switzerland.*

Plant extracts, also known as phytonutrients, are gaining interest for their use as health promoting feed additives in animal production. Their mechanism of action, however, is still unknown. We hypothesize that phytonutrients may function by acting on the large intestine to alter the microbial ecosystem, strengthen mucosal defenses, and stimulate innate immunity. Mucus secretion and thickness is thought to play a major role in both health and disease by providing a protective yet permeable barrier between intestinal contents and host tissue. The mucus layer in the large intestine consists of 2 stratified layers, mainly composed of the secreted mucin, Muc2. The inner layer is of dense composition and devoid of commensal bacteria, while the outer layer is built as a loose matrix housing commensal bacteria. Six phytonutrients: anethol, capsicum oleoresin, carvacrol, cinnamaldehyde, eugenol, and garlicon40, with known antimicrobial and anti-inflammatory properties were evaluated in C57Bl/6 mice for their effect on the mucus layer, microbial composition, and colitis induced by the natural mouse pathogen, *Citrobacter rodentium* (*C. rodentium*). Each phytonutrient was given to mice through their drinking water for 7 d. Of the 6 phytonutrients tested, eugenol-fed mice were found to have increased Muc2 expression ($P = 0.06$) and a significantly thicker inner mucus layer ($^*P = 0.02$) in the large intestine compared with untreated mice. Eugenol-fed mice were less susceptible to *C. rodentium*-induced goblet cell depletion in the large intestine ($^{***}P = 0.0004$) and showed a decrease in systemic pro-inflammatory cytokines, TNF-α ($^*P = 0.02$), IFN-gamma and MCP-1, 6 d post infection. These results suggest that eugenol acts to strengthen the mucosal barrier by increasing the thickness of the inner mucus layer, which protects against invading pathogens and intestinal inflammation.

Key Words: phytonutrient, mucus, pathogen

Breeding and Genetics: Applications and Methods in Animal Breeding

T38 Effect of diet and sex on growth of cattle evaluated with non-linear mixed effects models. A. Dufek*[1,2] and E. Vacatko[1,2], [1]*Research Institute for Cattle Breeding, Ltd., Rapotin, Czech Republic,* [2]*Agriresearch Rapotin Ltd., Vikyrovice, Czech Republic.*

Accurate statistical model is a reliable basis for testing hypothesis especially in cases of non-linear relationship between variables. The aim of this study was to analyze mass growth pattern in beef cattle in the *R* software. We used the Gompertz and logistic function to describe the mass vs. age relationship and to test differences in growth patterns among groups of 2x2 experimental design (heifers, bulls vs. intensive fattening system: IF = maize silage in feedlot, extensive fattening system: EF = grazing, finishing on brewer's grains). Repeated measures growth data (8 measures per animal, n = 76) were evaluated in the package *nlme* (3.1–92) in the *R* (2.9.1). The Gompertz [y = A*exp(-exp(-K*(x-Ti))] and logistic [y = A/(1+exp(-K*(x-Ti)))] functions were parameterized in the *R* where A = a response (body mass [kg]) that approaches a horizontal asymptote as $x \to \infty$, exp = exponential function, K = a rate constant, x = age, Ti = the inflection point representing age with the highest growth rate. The values of the parameters for the basic models including all animals were A = 613, K = 0.004, Ti = 240 for Gompertz and A = 565, K = 0.006, Ti = 299 for logistic function. Based on the lower residual sum of square, the logistic function was selected to build the mixed model with one random effect: animal, 2 fixed effects: sex, fattening system and one covariate: the day of birth of an animal in a suckler herd representing the effect of season. Significance of the effects was determined using likelihood ratio test. The effects of sex, diet and interaction on the A and Ti were significant on the level $P < 0.001$; the A-values were 897, 470, 703, 372 and the Ti were 348, 278, 345, 205 for IF bulls, EF bulls, IF heifers, EF heifers, respectively. The date of birth had no effect on the A ($P = 0.67$) or Ti ($P = 0.12$). Analysis of residual variability showed differences between groups of sex ($P < 0.001$) and diet ($P < 0.001$): the standard error for the heifers was 49% of that for the bulls and for the IF group was 68% of that for the EF group. The results revealed that fattening system and sex affected both growing pattern and its variability. The *nlme* in the *R* is very effective tool for non-linear analyses.

Key Words: growth, nonlinear, mixed

T39 The effect of the ancestor on inbreeding depression in milk yield during the first lactation. J. Bezdicek*[1], L. Stadnik[2], F. Louda[3], and O. Latal[1], [1]*Agrovyzkum Rapotin Ltd., Vikyrovice, Czech Republic,* [2]*Czech University of Life Sciences Prague, Prague, Czech Republic,* [3]*Research Institute for Cattle Breeding, Ltd., Vikyrovice, Czech Republic.*

The objective of this study was to examine the effect of ancestor on inbreeding depression in milk yield (in kg) in Holstein cows. In total we evaluated differences in 9 ancestors. The database included Holstein cows (215,000) calved in the Czech Republic in the years 1995–2006. For proper comparison, each inbred cow was assigned an outbred equal. Inbred cows were matched with their outbred equals on characteristics such as identical sire, first calving on the same farm, in the same year and period (±2 mo) and dam reaching the same breeding value of milk production (±5%). In each group of ancestors, the goal to create pairs of inbred and outbred cows equivalent in terms of origin (the same sire, dam with similar breeding value) and which would also produce in the same environment. The PROC GLM of SAS® with fixed effects (F_X, ancestor, age at first calving, year of birth, milk production, breeding values of the sire and dam) was applied to all data. For evaluation of F_X level we used the software B-calc. The level of inbreeding was between F_X = 3.125–6.25%. Differences in the inbreeding depression of the 9 ancestors with the following number of inbred daughters (144; 107; 24; 48; 40; 25; 21; 20; 20) were evaluated. The total group of inbred cows (n = 449 cows) showed a significant decrease in milk production (−269 kg; $P < 0.001$) compared with their outbred equals (n = 449). A decrease in milk production was also found after dividing the studied group according to the 9 ancestors. The decrease was in the range −151 to −466 kg. These differences were significant within groups 1 and 9 ($P < 0.05$) and non significant within other groups. An effect of ancestor and breeding value of dam and sire as well was found to be highly significant ($P < 0.001$). Coefficients of determination varied within different groups of ancestors rating from 0.1552 to 0.5601 (total group 0.3514). The correlation coefficient (negative) between milk production and calculated coefficient F_X was significant (r = −0.09; $P < 0.01$). This study showed an inbreeding level F_X = 3.125–6.25% depression effect on milk production. There was also a significant effect of ancestor found.

Key Words: ancestor, inbreeding, milk production

T40 Association between milk production and Holstein fraction of upgraded dairy cattle in the Thai tropics. S. Koonawootrittriron[1], P. Yodklaew[1], M. A. Elzo*[2], and T. Suwanasopee[1], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville.*

Upgrading local dairy cattle to Holstein (H) has been used as a strategy to increase milk production in many tropical countries. The expectation is that milk production will increase alongside increments in H fraction of upgraded animals. However, lack of adaptation of high percent H cattle to tropical conditions may prevent them from achieving their expected production potential. The aim of this study was to evaluate the association between milk production and H fraction of high percent upgraded cattle in Central Thailand using 305-d milk production (MY) of 3,222 first lactation cows from 304 farms. Data were gathered between 1990 and 2011. Eight high H fraction groups were defined: BG1 ($H < 0.625$), BG2 ($0.625 \le H < 0.6875$), BG3 ($0.6875 \le H < 0.75$), BG4 ($0.75 \le H < 0.8125$), BG5 ($0.8125 \le H < 0.875$), BG6 ($0.875 \le H < 0.9375$), BG7 ($0.9375 \le H < 1$) and BG8 (H). The model included herd-year-season subclass, calving age (month) and breed group as fixed effects, and residual as a random effect. Least squares means (LSM) of MY were estimated for each breed group and then used to fit a second degree polynomial function to explain the change in MY for every 0.0625 H fraction in cows 62.5% H and above. The average milk production of all cows in this study was 4,145 kg (SD = 1,115 kg). Milk production differed across herd-year-seasons, calving ages, and breed group subclasses ($P < 0.01$). Cows with H fraction from 0.8125 to less than 0.875 had the highest MY of all breed groups. The LSM of MY tended to increase as H fraction increased from BG1 (4,075 ± 109 kg) to BG5 (4,285 ± 47 kg) and then it decreased toward BG8 (4,120 ± 76 kg). This association between MY and H fraction can be explained with a second degree polynomial equation: MY = 2,055 + 5,082(H fraction) - 2,957(H fraction)^2 ($R^2 = 0.61$). The quadratic association between MY and H fraction found in Central Thailand stressed the limitations of upgrading adapted local dairy cattle to H as a means of increasing milk production under tropical conditions.

Key Words: milk production, tropics, upgrading

T41 Genetic analysis of longevity traits in a Holstein cattle population near Benghazi, Libya.

E. Abdalla*[1], S. A. M. Bozrayda[2], and I. A. S. Al-Drussi[2], [1]*Department of Animal Sciences, University of Wisconsin-Madison, Madison,* [2]*Department of Animal Production, University of Benghazi, Benghazi, Libya.*

The aim of this study was to estimate the longevity of 2196 German Holstein Frisian cows under Libyan conditions. Three different longevity measurements were used to estimate the effect of inbreeding and management on the survival of those cows. True herd life (THL), which is the period in days from birth of an animal until culling, productive life (PL), which is the period in days from birth an animal until culling and number of lactations were used as measurements of longevity. Cows were distributed in 6 generations in the period from 1989 to 2004. In 1996, Libyan dairy cattle producers faced some difficulties in importing semen from foreign countries so they started using local sires. The analysis was performed using linear animal model. Origin of sire, generation, age at first calving, level of milk production, year and month of calving were considered as fixed effects. Additive animal effect was the only random effect in the model and days open was included as a covariate. All factors included in the model showed a highly significant effect ($P < 0.001$) on THL, PL, number of lactations and 305-d milk yield with the exception of true herd life, which was independent of age at first calving and month of calving. Daughters of local sires compared with daughters of North American and European sires, had a shorter THL and PL ($P < 0.01$). They also had less number of lactations and lower 305-d milk yield at the same significant level. Heritability estimates of longevity traits and 305-d milk yield were low because the effect of inbreeding in the last 3 generations. Effect of inbreeding was also clear on longevity traits. Very high genetic and phenotypic correlations were found between longevity traits. Genetically, 305-d milk yield was moderately correlated with longevity traits.

Key Words: longevity, heritability, genetic correlations

T42 Ranking of Brown Swiss cattle based on genetic evaluation and grades in judgment at the show ring.

R. Ramírez-Valverde,* R. Núñez-Domínguez, M. Hernández-León, and M. A. Pablo-Altunar, *Universidad Autónoma Chapingo, Chapingo, Mexico, Mexico.*

The objective was to determine the association between ranking of animals based on grades of conformation in judgment of cattle (JUD) at the show ring and their predicted transmitted abilities (PTA), for registered Brown Swiss cattle in Mexico. Ranking values obtained in JUD were transformed using the rankit transformation, assigning the highest rankit to the first place. Correlation analyses were performed between JUD and PTA. Records of JUD were used for the total of 735 animals; by sex (454 males and 194 females), in 6 years of livestock national show ring competitions (2003, 2004, 2005, 2006, 2009 and 2010) and 3 categories (adult, youth and calf). PTA values came from the most recent national genetic evaluation (2009) for milk yield adjusted to 210 d. Additionally, averages of the PTA and percentage of animals with positive PTA from those used in JUD were estimated. Using the complete data set, correlation between JUD and PTA was different from zero (0.17, $P < 0.05$). This result suggests a low association between both ways to evaluate animals. The correlation between JUD and PTA of adult animals was higher than using those of young animals and calves, which indicates a better association for adults. Correlations by sex and category varied throughout the years; this could indicate differences in the ability to judge animals by evaluators. Averages of the animals′ PTA were positive and the percentages of animals with positive PTA fluctuated between 67 and 86%, indicating just a tendency of Brown Swiss breeders to use animals genetically superior in the JUD.

Key Words: breeding value, judgment of cattle, Brown Swiss

T43 Genetic evaluation of mobility for Brown Swiss dairy cattle.

G. R. Wiggans[1], J. R. Wright*[1], C. J. Muenzenberger[2], and R. R. Neitzel[2], [1]*Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD,* [2]*Brown Swiss Cattle Breeders Association of the USA, Beloit, WI.*

Genetic parameters were estimated for mobility score and 16 current linear type traits for Brown Swiss dairy cattle. Mobility is defined as a composite trait measuring the cow's ability to move as well as the structure of her feet, pasterns, and legs. Scores from 50 to 99 were assigned by appraisers for the Brown Swiss Cattle Breeders Association beginning in June 2007. Only scores made before 69 mo of age were used. After edits, 32,710 records were available for 19,472 cows in 819 herds. The model included fixed effects for the interaction of herd and appraisal date (2109 groups); appraisal age within parity (46 groups); lactation stage within parity (21 groups), as well as random effects for animal, permanent environment and residual error. A multitrait analysis was run using canonical transformation, multiple diagonalization, and a decelerated expectation-maximization REML algorithm. Resulting heritability was 0.21 for mobility, and ranged from 0.06 to 0.37 for the other 16 type traits. The traits with the highest genetic correlation with mobility were final score (0.78), rear legs rear view (0.74), rear udder width (0.52) and foot angle (0.51). Predicted transmitting ability (PTA) for mobility was calculated using the current Brown Swiss multitrait type evaluation system, but using only appraisals where all traits were scored. For 1868 bulls evaluated, PTA mobility ranged from 1.6 to −1.8, standard deviation 0.5, and was most highly correlated with the PTA for final score (0.88), rear legs rear view (0.77), rear udder height (0.70) and rear udder width (0.69), similar to the trait correlations as was expected. When matched with official evaluations from August 2011, PTA mobility had moderately high correlations with PTA of milk, fat, protein, and productive life (0.31 to 0.41). The mobility trait may increase accuracy and timeliness of predictions of productive life by increasing the accuracy of the foot and leg composite.

Key Words: mobility, type trait, genetic evaluation

T405 Covariance functions, genetic parameters and breeding values for longitudinal ultrasound measures of ribeye area in a Colombian multibreed cattle population.

C. A. Martinez[1], M. A. Elzo*[2], A. Jimenez[3], C. Manrique[1], and G. Hu[2], [1]*Universidad Nacional de Colombia, Bogota, Colombia,* [2]*University of Florida, Gainesville,* [3]*Colombian Association of Zebu Cattle Breeders, Bogota, Colombia.*

The objective of this research was to obtain restricted maximum likelihood estimates of covariance functions and predictions of breeding values for longitudinal records of ribeye area measured by ultrasound in a Colombian multibreed cattle population. The data set contained 708 records from 340 calves progeny of 37 sires from 9 breeds (Gray Brahman, Red Brahman, Guzerat, Blanco Orejinegro, Romosinuano, Braunvieh, Normand, Limousine and Simmental) mated to Gray Brahman Cows. The model was a random regression model that used Legendre polynomials (LP) of order 1 to 3. Fixed effects were age of animal, dam parity, contemporary group (herd-year-season-sex), breed additive genetic and heterosis, whereas direct and maternal additive genetic and maternal permanent environment were random effects.

Residual variances were modeled as constant or changing across the growth trajectory. Models were compared with the corrected Akaike's information criterion and the Schwarz's Bayesian information criterion. The best model had first order LP and constant residual variance. This model was used to obtain genetic parameters and breeding values. Direct additive genetic variance decreased until 156 d of age and increased afterward. Maternal additive genetic and maternal permanent environment variances increased with age. Direct heritability estimates for REA at 4 mo, weaning, 12 and 15 mo (taken as target ages) were 0.004, 0.01, 0.03 and 0.06, respectively. Maternal heritabilities for the same ages were 0.32, 0.35, 0.37 and 0.38. Direct additive correlations ranged from −0.7 to 1. Maternal additive genetic and permanent environmental correlations were close to unity across the entire range of ages. According to these results selection for maternal ability appeared to be feasible in this multibreed population and maternal effects showed an important influence on REA pre and postweaning. Validation of these results with larger multigenerational multibreed populations is required.

Key Words: carcass composition, covariance functions, crossbred cattle

T44 Considerations in using residual feed intake to define feed efficiency in dairy cattle.

M. VandeHaar*[1], D. M. Spurlock[2], L. Armentano[3], R. Tempelman[1], K. Weigel[3], and R. Veerkamp[4], [1]*Michigan State University, East Lansing,* [2]*Iowa State University, Ames,* [3]*University of Wisconsin, Madison,* [4]*Wageningen UR, Wageningen, the Netherlands.*

With the advent of genomic selection, the dairy industry will soon be able to focus more directly on selection for feed efficiency. Thus, it is important that geneticists and nutritionists agree on how best to define and measure feed efficiency. The objective of this study is to quantify relationships among factors that affect feed efficiency in dairy cattle. Residual feed intake (RFI) is a measure of actual versus predicted intake for an individual. Predicted intake can be determined from nutritional models, or it can be determined statistically as the deviation from average intake of cohorts, after adjustment for differences in production, body weight (BW), and/or BW changes. A cow with negative RFI is more efficient than her cohorts because she has lower maintenance requirements, digests feed more efficiently, or uses digested feed more efficiently for maintenance, gain, or milk. Decisions about whether and how to adjust for differences in BW or BW change are critical to selection strategies focused on improving feed efficiency. Inappropriate adjustment for BW and body energy change may cause inadvertent bias toward cows that are larger, lose body condition to support milk output, or gain body condition when fed a high energy diet. Moreover, adjustment for BW change requires accurate measures of BW that are not unduly influenced by gut fill. Daily feed intake and milk production, and weekly body weight and milk composition data were recorded on 500 cows for 8 wk starting at approximately 70 DIM. RFI was calculated as the deviation from average intake of cohorts, after appropriate adjustments. Metabolic BW was a significant contributor to variation in intake. However, it accounted for only 10% of the variation whereas milk energy output accounted for 60%. BW change accounted for even less variation in intake, but its consideration likely is essential to ensure improvement in feed efficiency does not occur at the expense of health and fertility. Careful consideration of all factors affecting feed efficiency, including RFI, maintenance requirements, and production, will be necessary to achieve continued improvement of feed efficiency.

Key Words: genomic selection, feed efficiency, residual feed intake

T45 Contribution of heredity, nutrition and management to milk yield improvement in Shanghai from 1998 to 2010.

G. L. Liu*[1,2], L. M. Huang[2], C. G. Zhang[1], X. L. Tang[2], and F. S. Fu[2], [1]*State Key Laboratory of Dairy Biotechnology, Shanghai Bright Holstan Co. Ltd., Shanghai, China,* [2]*Shanghai Dairy Breeding Center Co. Ltd., Shanghai, China.*

Milk yield of Chinese Holstein cow is influenced by a variety of factors, including management, genetic effect, nutritional status, disease and environment. The purpose of this work was to establish the contribution of heredity, nutrition and management to milk yield improvement in Shanghai area. Milk yield changes were analyzed with total 68,138 milk yield records of 17,034 cows in 10 dairy farms from Shanghai Dairy Herd Improvement Project (from 1998 to 2010). The nutritional statuses of the 10 dairy farms were evaluated through 120 TMR diet samples assays. The management statuses were quantified through Brightdairy Thousand Points Evaluation. The hereditary effects were analyzed with breeding value of sires and maternal grandsires of the 17,034 cows. Hereditary effect, nutritional status and management status were defined as independent variables, and milk yield change as dependent variable. The results indicated that average 305-d milk yield increased from 7,418 kg in 1998 to 8,356 kg in 2010. Hereditary effect, nutritional status and management status were the significant factors ($P < 0.05$) affecting milk yield improvement. The results of path analysis revealed that management status (cumulative effect was 0.3324) had the highest positive relationship with milk yield improvement followed by hereditary effect (0.2816) and nutritional status (0.2086).

Key Words: heredity, nutrition, management

T46 Multiple trait analysis for milk yield and milking time of Holstein Cows.

L. El Faro*[1], J. P. Pereira[2], C. C. P. Paz[1], D. A. C. Cruz[3], V. L. Cardoso[1], and A. B. Bignardi[4], [1]*APTA/SAA, Ribeirao Preto, Sao Paulo, Brazil,* [2]*UNESP, Jaboticabal, Sao Paulo, Brazil,* [3]*Instituto de Zootecnia, Nova Odessa, Sao Paulo, Brazil,* [4]*Federal University of Mato Grosso, Rondonopolis, Mato Grosso, Brazil.*

Test-day milk yields and milking time of 2,175 first lactation Holstein cows of one herd of southeast region of Brazil, calving from 1997 to 2005 were analyzed by standard multiple trait model (MT), principal components (PC) and by random regression models (RRM). Cows were milked 3 times a day, by electronic machines, totalizing 18,666 records. The reduced rank analysis adjusted the first 2, 3, or 4 genetic principal components. RRM fitted Legendre polynomials (LP) for random additive genetic and permanent environmental trends, respectively with 4 and 5 coefficients. For all models, fixed effects included contemporary groups (year-month of test), linear and quadratic effects of age of cow at calving, and management group. For RRM only, the average trend of milk yield and milking time were fitted by a third order LP and residual variances by step functions considering 4 heterogeneous classes. Comparing MT and PC models, a PC with 2 genetic principal components (PC2), with 220 parameters, was enough to fit the data. Heritability estimates for milk yields ranged from 0.10 to 0.32 and from 0.07 to 0.29 for milking time, considering PC2. For RRM the estimates ranged from 0.17 to 0.35 for milk and from 0.23 to 0.33 for milking time. Both models estimated higher heritability at the end of lactation. The RRM was less parameterized (105 parameters) and produced higher heritability estimates than PC2, but unexpected negative genetic correlation between some milk yields were estimated by RRM, differently from those estimated by PC2 model. Genetic correlation for PC2 were all positive and higher estimates were found among closer test-days, ranging from 0.38 to 0.99 for milk yields and from 0.33 to 0.99 for milking time. The genetic correlations of milk yields and milking time at the same test-days were negative

between records of the first half of lactation (−0.38 to 0.99) and positive on the second half (0.06 to 0.61), but the association was stronger for the first 5 mo. The negative genetic correlation at the first half of lactation is in desirable direction, suggesting that greater production is associated with smaller milking time or higher milk flow. This could be related to a scaling factor because the milk yield is higher during early lactation

Key Words: dairy cattle, functional traits, longitudinal data

T47 Milk fat:protein ratio in lactating dairy cows: Effects on conception at first postpartum AI. A. H. Souza*[1], L. F. Ferraretto[1], P. D. Carvalho[1], A. R. Dresch[1], L. M. Vieira[1,2], R. A. Cerri[3], M. C. Wiltbank[1], and R. D. Shaver[1], *[1]University of Wisconsin-Madison, Madison, [2]University of Sao Paulo-VRA, SP 05508, Brazil, [3]University of British Columbia, BC, Canada.*

Objectives of this retrospective study were to use information of milk composition from the first 5 DHIA milk test results to predict conception at 1st postpartum AI (CRAI1) in lactating Holstein cows. Specific interest was to study if milk fat:protein ratio (FPR) was associated with CRAI1. Edits in the data set were: Holstein herds only, herd size ≥ 100 lactating cows only, herds with CRAI1 between 20 to 60% only, DIM at 1st AI between 30 to 200d, only confirmed pregnancy outcomes included, lactation number 1 to 6 only, 305ME ≥ 20.000, %protein between 2.0 to 4.5, and %fat between 1 to 8. After edits, data from 207.506 1st postpartum breedings performed in 648 herds in Midwest-USA from July/2009 to July/2010 were included in the analysis. A scoring system based on FPR in a scale from 0 to 5 was as follows: FPRS0, cows with zero milk tests with FPR within 1 to 1.4 included; FPRS1, cows with only 1 out of first 5 milk tests with FPR within 1 to 1.4 included; FPRS2, cows with 2 out of 5 milk tests with FPR within 1 to 1.4; so forth. The procedure Glimmix of SAS using cow within herd and herd as random effects was used. The software Weka was used to find thresholds of milk composition and CRAI1. At first test, only about 50% of the cows had their FPR within 1 to 1.4, but this percentage increased to ~70% at 2nd through 5th tests. Most cows not 1–1.4 FPR were above (~45% of the cows at 1st test), and only minority (~5% at 1st test) below these thresholds. At 5th test % of cows above 1.4 FPR decreased to only ~10%; but, % of cows below 1.0 FPR increased to ~18%. This pattern did not ($P > 0.10$) seem to change throughout different seasons. In addition, FPRS5 cows presented significantly ($P < 0.01$) greater CRAI1, followed by FPRS4, and cows with FPRS0 to 3 did not differ in terms of conception at 1st AI (FPRS5 = 38.8%a, FPRS4 = 36.8%b; FPRS3 = 35.2%c; FPRS2 = 34.4%c, FPRS1 = 34.7c; FPRS0 = 34.2%c). Interestingly, an interaction between FPRS and season was found in which cows with FPRS5 had essentially same CRAI1 across all seasons; however, FPRS ≤ 3 had considerably lower CRAI1 in warmer months compared with cooler months of the year. In conclusion, cows presenting 4 or more out of the first 5 postpartum milk tests within FPR range of 1 to 1.4 seem to have improved fertility after 1st postpartum AI. Possible underlying reasons for this lower fertility in cows deviating from 1 to 1.4 FPR at beginning of lactation need to be further investigated through manipulative studies. Supported by AgSource Cooperative Services, USDA Grant 2010–85122–20612.

Key Words: milk composition, fertility, dairy cow

T48 Prediction of milk and fat production and estimation of breeding values in Holstein dairy cows using neuro-fuzzy and artificial neural networks. S. Shahinfar*[1], H. Mehrabani-Yeganeh[1], C. Lucas[2], A. Kalhor[2], A. Kazemian[2], and K. A. Weigel[3], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Center of Excellence: Control and Intelligent Processing, Faculty of Electrical and Computer Engineering, Tehran, Iran, [3]Department of Dairy Science, University of Wisconsin-Madison, Madison.*

New computational techniques enable for rapid data analysis and fast decision making on dairy farms. The goals of such techniques are to detect short-term management changes and adjust the breeding strategies in real time. The objective of this study was to investigate the potential of 2 types of intelligent learning methods, artificial neural networks (ANN) and neuro-fuzzy systems (NFS), for computing the estimating breeding values (EBV) and production potential of Iranian dairy cattle. The back propagation algorithm was used to build ANN that could predict breeding values from the performance data of selection candidates. Subsequently, fuzzy logic was incorporated into the ANN to form a NFS that was also used to predict the breeding values and performance records. Explanatory variables included age at first calving, days in milk, ambient temperature, ambient humidity, length of the photoperiod, raw and adjusted (ME) milk and fat production and average production of contemporaries, and milk and fat EBV of parents. Correlations of 0.7 and 0.8 were achieved between predicted and actual values for milk and fat production, respectively. Correlations between EBV for milk yield and predictions from the ANN and NFS learning method were 0.917 and 0.926, respectively, whereas for fat yield correlation were 0.926 and 0.932, respectively. Finally, correlations between multi-trait predictions of BLUP EBV for milk and fat yield and corresponding predictions from a multi-trait implementation of ANN were 0.925 and 0.930, respectively; correlations with predictions from a multi-trait implementation of NFS were 0.935 and 0.949, respectively for milk and fat yield.

Key Words: artificial neural networks, neuro-fuzzy systems, machine learning

T49 New software for sparse matrix factorization and inversion using the supernodal techniques. Y. Masuda* and M. Suzuki, *Obihiro University of A & VM, Obihiro, Japan.*

We developed a set of subroutines for various sparse matrix operations including symbolic and numerical factorization, solution, and sparse inversion by using some modern sparse algorithms. Some programs for ordering or symbolic operations were imported from public domain packages. Ordering routines (AMD, QAMD, and AMF) were extracted from the MUMPS package. Symbolic factorization was performed by SMBFCT from the public domain version of SPARSPAK with some modifications. Supernodal left-looking approach for factorization and inverse-multifrontal method for sparse inversion were implemented. They relied on Basic Linear Algebra Subprograms (BLAS). When a highly optimized BLAS library was used, supernodal algorithms for factorization and inversion were 5 and 10 times faster than traditional approaches for a coefficient matrix of order 1 million or more from an animal model with random regressions. The time-efficiency was more improved as increasing the order. For solution of mixed model equations, estimation of genetic parameters by restricted maximum likelihood, and calculation of reliabilities, computing time would be greatly reduced. All programs were written in standard Fortran 95 and packaged into several modules. The source codes are available by requests to the first author for the academic and noncommercial purposes.

Key Words: computation, algorithms, mixed model equations

T50 Genotype × climate interaction in the genetic evaluation for growing traits in Braunvieh cattle.

L. A. Saavedra-Jiménez[1], R. Ramírez-Valverde[1], R. Núñez-Domínguez*[1], N. López-Villalobos[2], A. Ruíz-Flores[1], and J. G. García-Muñiz[1], [1]*Universidad Autónoma Chapingo, Chapingo, México,* [2]*Massey University, Palmerston North, New Zealand.*

The presence of genotype × environment interaction causes changes in ranking of breeding values (BV) of sires from one environment to another, which affects genetic progress. The objective was to determine the magnitude of genotype × climate interaction (G×C) for growth traits in the genetic evaluation of Braunvieh cattle. Traits studied were weaning weight (WW) and yearling weight (YW). Records provided by the Asociación Mexicana de Criadores de Ganado Suizo de Registro, were grouped based on the meteorological variables recorded nearest to the herd by the National Weather System. The CLUSTER procedure in SAS was used to classify herds into 3 climates: dry tropic (DT), wet tropic (WT) and temperate (TE). Records of WW were 5348, 4501 and 2515 in DT, WT and TE, respectively, with 25173 animals in the pedigree. For YW, there were 3811, 2652 and 1528 records in DT, WT and TE, respectively, with 18072 animals in the pedigree. An animal model with ASReml software was used to estimate genetic parameters and to predict BVs. Bivariate analyses were carried out for pairwise combinations of climates for each growth trait. The criteria to evaluate G×C were: 1) genetic correlations (r_g) in bivariate analyses, and 2) frequencies of coincidence (FC) in the ranking of top 25 sires. Estimates of r_g between DT and WT, DT and TE, and WT and TE were −0.36, 0.84 and 0.72 for WW, and 0.23, 0.99 and 0.23 for YW, respectively. The FC between DT and WT, DT and TE, and WT and TE were 0.16, 0.92 and 0.76 for WW, and 0.60, 1.00 and 0.64 for YW, respectively. The size of r_g and FC imply the presence of G×C when compared WT with DT or TE, suggesting that genetic evaluations should be carried out separately for animals performing under wet tropical conditions.

Key Words: genotype by environment, weaning weight, Braunvieh cattle

T51 Relationships among visual scores with feedlot performance and feed efficiency in *Bos indicus* cattle.

P. H. Cancian*[1], S. L. Silva[1], A. C. Ianni[1], F. R. Manicardi[1], R. C. Gomes[2], and J. B. S. Ferraz[1], [1]*Faculdade de Zootecnia e Engenharia de Alimentos / Universidade de São Paulo (FZEA/USP), Pirassununga, São Paulo, Brazil,* [2]*Departamento de Zootecnia / Universidade Estadual de Londrina (UEL), Londrina, Paraná, Brazil.*

Visual evaluation of live beef cattle have been largely used to identify more adequate animals for meat production and, in Brazil, even as selection criteria in breeding programs. However, the relationship of these evaluations with feed efficiency traits in feedlot are unknown. The objective of this work was to evaluate phenotypic correlations of visual scores of conformation (C), precocity (P) and muscularity (M) with feedlot performance. Forty 3 bulls and 43 steers of Nellore were visually evaluated by an experienced technician twice. In the first evaluation (VS16), cattle (16-mo old, 313 ± 25 kg BW) was grazing in *Brachiaria* spp. pastures. At 22-mo of age, they were fed ad libitum for 84 d for individual dry matter intake (DMI) and average daily gain (ADG) records. A second evaluation of visual scores (VS22) were carried out on d 21 of the 84-d period. The body weight (BW) was measured each 28 d to calculate average daily gain (ADG) and gain to feed ratio (G:F). The visual were assigned to each animal in a within-gender comparison and the relationship among traits was evaluated by Pearson correlation. Visual scores showed moderate to high correlations with BW in both evaluations. The correlations between BW and C were 0.75 and 0.35 in VS16 and VS22, whereas with P the correlations coefficients were 0.46 and 0.29, respectively. For muscularity, the correlation with BW was 0.5 in both evaluations. Conformation score was positively correlated with DMI and ADG in both VS16 (0.47 and 0.27) and VS22 (0.33 and 0.13) and negatively with G:F in both evaluations (−0.15 and −0.19). Correlation of P with DMI was low and positive (0.25) in VS16 and nonsignificant ($P > 0.05$) with the rest of traits in both evaluations. Visual evaluation of M had nonsignificant correlations with all efficiency traits in both evaluations, except with DMI in VS22 (0.25; $P < 0.05$).The visual score of conformation may be an indication that animals with larger frame sizes, can ingest more food than the others. Visual assessments for precocity and musculature appeared as features of low accuracy to select efficient cattle.

Key Words: conformation, precocity, muscularity

T52 Genetic parameters for carcass traits and weaning weight of composite beef cattle in Brazil.

J. Ramírez-Díaz[1], T. A. Oliveira[1], A. Zampar[1], S. F. N. Pertile[1], M. A. Elzo[3], J. B. S. Ferraz[2], and G. B. Mourão*[1], [1]*University of São Paulo - ESALQ, Piracicaba, São Paulo, Brazil,* [2]*University of São Paulo - FZEA, Pirassununga, São Paulo, Brazil,* [3]*University of Florida, Gainesville.*

Heritability and genetic correlations for weaning weight (WW; n = 328,326) and real-time ultrasound measurements of ribeye area (REA), subcutaneous fat thickness (BF) and rump fat (RF) from 863 calves were estimated using data from the Montana Tropical composite beef cattle population in Brazil. Images of carcass traits were obtained for ultrasound scanning (Aloka, SSD 500, with linear transducer of 3.5 megahertz and 172 mm long and acoustic guide attached) and analyzed using LINCE software. Calves were weaned at 6 m (205 d). of age, and ultrasounds were collected at 21 m (639 d) of age. Single-trait and multi-trait analyses with direct additive effects only were considered. The maternal additive effects was considered only for WW. Models included contemporary group (herd of birth-herd of weaning-herd of measurement-year of birth-season of birth-sex of animal) as a fixed effect, and age of dam, individual and maternal heterozygosity, and age at measurement as covariates for single trait analyses. Two-trait analyses excluded the covariate for age of dam. Random effects were animal and residual. The A^{-1} matrix contained 536,120 animals. Variance and covariance components were estimated using REML methodology and ASREML software. Heritabilities (h^2) and standard error (in parenthesis) for WW, BF and RF were 0.31(0.0104), 0.13(0.1320), 0.10(0.1278) respectively. The h^2 for REA was close to zero. Maternal (h^2) was 0.1940(0.0066) for WW. The genetic correlation between WW and BF was near zero (0.038), low and negative between WW and RF (−0.26), and positive between WW and REA (0.20) with standard errors of 0.23, 0.27 and 0.24. The low heritability estimates for ultrasound traits indicated that selection for these traits at this age would be rather ineffective. Selection for WW may reduce RF. In the 2-trait analysis, the h^2 were 0.36 (0.0047) and 0.14 (0.1322) for WW and BF, 0.36 (0.0047) and 0.12 (0.1322) for WW and RF and 0.36 (0.0047) and 0.01 (0.0829) for WW and REA. These results should be considered with caution because of the small number of observations for ultrasound carcass traits.

Key Words: beef cattle, tropical composite, ultrasound traits

T53 Influence of maternal genetic effect on the estimation of genetic parameters in post-weaning traits. G. A. Oliveira Júnior*[1], F. M. Rezende[1], J. B. S. Ferraz[1], J. P. Eler[1], and G. B. Mourão[2], [1]*Faculdade de Zootecnia e Engenharia de Alimentos - Universidade de São Paulo, Pirassununga, São Paulo, Brazil,* [2]*Escola Superior de Agricultura Luiz de Queiroz - Universidade de São Paulo, Piracicaba, São Paulo, Brazil.*

The maternal genetic effect may interfere with the performance of the animal's post-weaning traits in beef cattle. The aim of this study was to estimate the importance of maternal effects on genetic analyses of post-weaning traits in Nellore cattle. The database used for estimation of (co)variance components contained information from 115,922 animals corresponding to 176,679 animals in the pedigree, with 80,581 different dams. The traits analyzed were scrotal circumference (SC), visual score of muscling (MUSC) and post weaning weight gain (PWGAIN), measured around 18 mo of age. (Co)variance components and direct breeding value estimates were predicted using restricted maximum likelihood and univariate animal model analyses as implemented in the MTDFREML software. Two models were evaluated for each trait: one including only the direct animal effect, and the other including a maternal effect. Contemporary group, the age of animals at the measurement and the age of dam at delivery (AOD), considered as a covariate with quadratic effects, were considered as fixed effects. The AOD was not used for MUSC. The management group at weaning was fitted as a random effect for all analyzed traits. Basic edits involved the exclusion of all information out of the interval between −3.5 and 3.5 standard deviations for each trait, data from contemporary groups including fewer than 20 animals, and data from progeny of sires or dams with only one offspring in the data set. Likelihood ratio tests and Pearson and Spearman correlations were used to compare models. The likelihood ratio test showed that the inclusion of the maternal genetic effect was statistically significant ($P < 0.01$) in the prediction of (co) variance components for all post weaning traits analyzed. However, the rank of the animals did not change, indicating that there is no gain from including genetic maternal effects in the model. The results of the estimates of direct additive heritabilities with no maternal effect were 0.23, 0.21, and 0.55 for PWGAIN, MUSC and SC respectively. When we added the maternal additive effect in the analyses, these results didn't vary significantly (PWGAIN = 0.22, MUSC = 0.23), except for SC, with 0.44 for heritability. The maternal additive heritabilities were lower than the direct additive heritabilities for all traits considered, that was expected. The estimates for maternal additive heritabilities were 0.05 for PWGAIN, 0.01 for MUSC and 0.10 for SC. The prediction of maternal additive genetic merit can be an indicator of maternal effect, mainly on the post weaning weight gain and scrotal circumference traits. However, due to the low value of maternal heritability of these traits, the value of accuracy of these predictions might be low as well and they must be used carefully.

Key Words: *Bos indicus* cattle, genetic parameters, variance components

T54 Selection for resistance to *Haemonchus contortus* in Santa Ines hair sheep: Comparisons of methods of animal evaluation at countryside and in the laboratory. P. S. Oliveira,* J. B. S. Ferraz, J. P. Eler, L. S. Oliveira, C. T. Moncau, M. D. Poleti, B. Silva, F. M. Rezende, G. A. Oliveira Júnior, J. Daniel, and E. C. Mattos, *Faculdade de Zootecnia e Engenharia de Alimentos - Universidade de São Paulo, Pirassununga, São Paulo, Brazil.*

The use of new tools to assist selection resistant or susceptible animals to gastrointestinal parasites, associated with the fecal egg counts (FEC), have been developed and applied to Santa Ines hair sheep to distinguish between resistant and susceptible individuals, without the need for laboratory tests. Distinguishment is needed to identify animals to be used in a DNA marker association study that is being developed. Thus, this study aimed to evaluate possible correlations between traits evaluated at countryside in the animals (Conjunctival Mucous Color (FAMACHA) and body score (BS) and in the laboratory (the Fecal Egg Counts (FEC), Hemoglobin (HGB) and Packed Cell volume (PCV)) in 503 sheep from Santa Ines, from 4 herds located in 3 different states of Brazil. For the laboratory analysis were collected individual samples of blood for the determination of HGB and PCV, and feces for FEC. FAMACHA test consisted in the visual evaluation of the color the ocular mucosa (scale from 1 to 5), where the higher value meant more anemic animals. The assessment of BS was performed by palpation in the lumbar region, where 0 meant cachectic animals and 5 meant obese animals. Subsequently, simple correlation coefficients between all variables were obtained by SAS PROC CORR. The correlations of greater magnitude ($P < 0.0001$) were found for FAMACHA with HGB and PCV ($r = -0.63$ and -0.64 respectively) and BS with HGB and PCV ($r = 0.68$ and 0.65 respectively). Lower magnitude correlations were found for FEC with FAMACHA, BS, HGB and PCV ($r = 0.21$, 0.25, -0.30 and -0.29 respectively) and between BS and FAMACHA ($r = -0.44$). Analyzing the study it can be concluded that the association of the method FAMACHA with BS can be considered an efficient method to diagnosis of anemia in Santa Ines sheep at countryside. Furthermore, increase in FEC also reduces levels HGB and PCV, however, this can't be considered as the only cause of anemia in sheep.

Key Words: FAMACHA, body score, packed cell volume

T55 Test-day model for milk yield of dairy buffaloes in Colombia. N. Hurtado Lugo*[1,2], G. M. F. de Camargo[1], R. Aspilcuelta[1], S. Gutiérrez[2], E. Taccari[1], F. M. M. Gil[1], L. G. Albuquerque[1], M. Cerón[2], and H. Tonhati[1], [1]*State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil,* [2]*University of Antioquia, Medellín, Ant, Colombia.*

The test-day model is the preferred method for genetic evaluations in dairy cattle. The aim of this study was to estimate the genetic parameters for the milk yield at the Test-Day (TD) in dairy buffalo in Colombia. Test-day records were collected from 7 dairy herds, members of the Colombian Buffalo Breeders Association (ACB). The TDs were separated in 9 classes of 30 d each, for total of 9 test-day controls (TD, 1 to 9). For this study, 28372 TDs records of 1220 lactations from 1997 to 2009 were used. Single and multiple trait analyses were used and variance components were estimated by Restricted Maximum Likelihood. The (co)variance components were estimated with the MTDFREML software. The model used in the TDs analysis included the additive genetic, permanent environment and residual as random effects; and the contemporary group (herd, year, and season of calving) as fixed effect. The buffalo age at calving was considered as covariate (linear and quadratic). The calving seasons were January–April, May–July, August–October, and November–December. The TDs varied from 4.84 to 3.2 kg/day. The heritability estimations for TD varied from 0.07 ± 0.087 to 0.16 ± 0.11 for single-trait analyses and from 0.31 ± 0.098 to 0.45 ± 0.198 for the multiple-trait analyses. The genetic correlations for single and tetra-trait TD models were high, bigger and varied from 0.36 to 0.96 and from 0.41 to 0.99, respectively. Correlations among TD increased as time between observations decreased for single- and multiple-trait models. In conclusion, the results of this study suggest that selection of buffaloes in Colombia should use breeding values obtained in a multi-trait test-day model, because of their high heritability.

Key Words: buffalo, genetic correlation, yield

T56 Random regression models for test-day milk production for first lactation in Colombian buffaloes.

N. Hurtado-Lugo*[1,2], M. Cerón[2], R. Aspilcuelta[1], S. Gutierrez[2], L. Albuquerque[1], F. R. Araujo Neto[1], G. M. F. de Camargo[1], and H. Tonhati[1], [1]*Faculty of Agriculture and Veterinary Sciences, State University of São Paulo, Jaboticabal, São Paulo, Brazil,* [2]*Faculty of Agriculture Sciences, University of Antioquia, Medellín, Colombia.*

The Random regression models for genetic evaluation in dairy cattle consider individual lactation curves using ordinary polynomials of linear functions. Alternative models to understand the genetic variability for milk yield along the lactation curve are required for genetic evaluations of the buffalo population in Colombia. The knowledge of the lactation curve may be of interest for production and management requirements of this specie. This study has the aim to estimate the genetic parameters using RRM for the milk yield at the Test-Day in Colombian buffalo dairy. A total of 9432 milk yield records were analyzed, corresponding to 1,746 first lactations of crossbred buffalo cows. The fixed effects were: contemporary group that was composed by farm, month and station of parity and milking days and age of the cow at calving (linear effect) as fixed effects and the random effects were the direct genetic and the permanent environment. The variance components were estimated using the statistical package WOMBAT. The residual variances were heterogeneous, modeled by a step function (LRT), containing 4 classes of variances. Results from different models of analyses were compared by the Restricted Maximum Likelihood (REML) form of the Akaike information criterion (AIC), the Schwarz Bayesian information criterion (BIC) and by inspecting the variance component and genetic parameter estimates. The most appropriate model was the one using a Legendre's polynomial function of 4rd order for the genetic effect and 5th order for the permanent environmental effect (4,5,4). The phenotypic mean for test-day was 3,6 ± 1,42 kg. The heritabilities for all models test ranged from 0.38 to 0.01. For the best model (4,5,4) the heritabilities ranged from 0.38 to 0.12. The highest values were observed between the 2 and 5 test day. For genetic and phenotypic correlation estimates ranged from 0.39 to 0.96 and from 0.42 to 0.91, respectively. Genetic correlations were higher than phenotypic ones. The results of this study indicate the necessity to consider the heterogeneity of residual variances to model changes in the variations for days in milk.

Key Words: animal model, Legendre polynomial, heritability

T57 Genetic parameters for growth curves in free range chickens.

G. A. Rovadoscki, F. L. Silva, T. A. Oliveira, A. Zampar, V. J. M. Savino, A. A. D. Coelho, J. Ramírez-Díaz, G. B. Mourão, R. S. Bueno, and G. A. Oliveira Junior,* *University of São Paulo, Piracicaba, São Paulo, Brazil.*

Nonlinear models have been used to describe growth in different species. These models feature parameters of biological meaning, and they have proven quite effective, especially in research related to animal breeding programs. The estimation of genetic parameters for growth curves fitted by nonlinear models provides the identification of animals that were more suitable for certain purposes of selection, for example, the optimum age of slaughter. Growth models usually have 2 parameters with biological meaning. The asymptotic weight (A) estimates the adult weight, whereas mature rate (k) is an indicator of the rate at which the animal approaches the adult body weight. The objective of this study was to estimate the genetic variance for the parameters A and k of the growth curves in free-range chickens by univariate and bivariate models. For this experiment we used an experimental lineage called 7P. Data from 11 weights of 934 chickens, being 470 males and 464 females, collected from birth to 84 d of age, totaling 5183 observations. The growth curve was estimated by nonlinear logistic model by OLS. The (co) variances were estimated using the methodology REML by ASREML® software. The coefficients of heritability (h^2) for A were 0.1816(0.0618) and 0.1888(0.630) and for k were 0.1571(0.0569) and 0.1567(0.0568), for the univariate and bivariate, respectively, with little difference between the values obtained for the models. The correlation between A and k, found for the bivariate model was −0.77, indicating that animals that grow faster have lower adult weight.

Key Words: variance components, heritability, performance

T58 Comparative analyses of proximate and chemical characteristics of eggs from six indigenous bird species.

O. T. F. Abanikannda,* A. O. Leigh, and H. Y. Ogungbo, *Lagos State University, Ojo, Lagos, Nigeria.*

Birds are raised mainly for their meat, eggs or feathers. Egg is a common food and the cheapest per unit source of animal protein and serves as a good source of vitamins and minerals. However, despite its nutritional value some health issues may arise as a result of its consumption. This study was aimed at assessing the inter specie differences in the physical characteristic, proximate composition and chemical constituents of eggs from 6 species (Chicken, Duck, Guinea Fowl, Pigeon, Quail and Turkey) of extensively managed indigenous birds. A total of 240 eggs comprising 40 eggs from each of the 6 species were sampled. The eggs were cleaned, labeled and measured with digital weighing scale and vernier calipers for its physical characteristics (egg weight, length, width, vertical, and horizontal circumferences). Proximate composition (moisture content, dry matter, total ash, crude protein, crude fat and carbohydrate) of the eggs along with mineral analyses (calcium, magnesium, manganese, iron, zinc and cobalt) were conducted using standard laboratory procedures for proximate and mineral assay procedures. All statistical analyses (descriptive and model fitting) were conducted using the JMP software. The one way ANOVA procedure for each of the response variable investigated was fitted by the model $Y_{ij} = \mu + a_i + e_{ij}$, while species was the sole predictor variable. Further comparison of the means was done after a significant ANOVA using the Tukey's post-hoc method. Specie was a significant ($P < 0.001$) source of variation in all the 5 physical characteristics accounting for over 90% of the variation, while its effect was significant ($P < 0.001$) and moderate to high on proximate composition with the exception of crude fat ($P > 0.05$). In the same vein species was a significant ($P < 0.001$) source of variation on mineral content except ($P > 0.05$) for magnesium and zinc. The nutritive value of Quail eggs are quite promising considering its proximate and mineral content mix which makes it a safer and healthier dietary source of nutrients and minerals when compared with Pigeon eggs.

Table 1. Means of proximate composition and mineral content of eggs

Species	N	DM (%)	Crude ash (%)	CP (%)	Carbohydrate (%)	Ca (%)	Fe (ppm)	Co (ppm)	Mn (%)
Chicken	40	26.59^{b}	5.50^{ab}	6.51^{c}	33.12^{c}	0.050^{b}	25.71^{b}	0.375^{b}	21.67^{b}
Duck	40	34.40^{a}	4.00^{bc}	8.14^{b}	42.35^{abc}	0.049^{b}	30.00^{ab}	0.350^{b}	27.50^{b}
Guinea Fowl	40	29.93^{ab}	6.00^{a}	6.15^{c}	34.78^{bc}	0.053^{b}	22.50^{b}	0.400^{b}	18.75^{b}
Pigeon	40	20.25^{c}	3.14^{c}	13.01^{a}	46.50^{a}	0.053^{b}	41.43^{a}	0.543^{a}	68.57^{a}
Quail	40	30.00^{ab}	3.25^{c}	8.72^{b}	48.35^{a}	0.120^{a}	20.00^{b}	0.400^{b}	24.00^{b}
Turkey	40	33.87^{a}	3.88^{c}	7.04^{c}	45.40^{ab}	0.048^{b}	30.00^{ab}	0.400^{b}	23.75^{b}

Key Words: species, proximate composition, mineral content

T59 Statistical classification of six indigenous bird species based on external and internal qualities of their eggs. O. T. F. Abanikannda,* A. O. Leigh, and O. I. Adekanbi, *Lagos State University, Ojo - Lagos, Nigeria.*

Classification is a method of categorizing organism into different groups based on their biological similarities and differences, and it is a systematic grouping of organisms into categories on the basis of evolutionary or structural relationships between them. Conventionally, such classifications could be traditional, phenetic or cladistic but the objective of this study is to employ statistical techniques to discriminate among the different species based on the external and internal measurements of the birds' eggs. A total of 210 eggs comprising 35 each from 6 free ranging indigenous species (chicken, duck, guinea fowl, pigeon, quail and turkey) were sampled. Five external characteristics (egg weight, egg length, egg width, vertical and horizontal circumference), 3 internal qualities (yolk, albumen and shell weights) were measured and 6 indices (shape index, egg surface area, egg volume, surface area to volume ratio, yolk to albumen ratio and egg density) were computed. All weights were measured with a digital scale sensitive up to 0.00g and linear measures were with digital vernier caliper (0.00mm) and flex tape for the circumferences. The distribution and fit model procedures of JMP statistical software were used to analyze the data and further mean separation after a significant effect was done using the Tukey's method. The model for each of the 14 variables studied is given by $Y_{ij} = \mu + \alpha_i + e_{ij}$. Complete method of hierarchical clustering of JMP was used for classification of the species. Specie was a highly significant ($P < 0.001$) and the largest source of variation in all the parameters studied, accounting mostly for over 95 percent of variation observed except in shape index (31%) and yolk to albumen ratio (36%). Three primary clusters of 2 species each were formed comprising chicken and guinea fowl, duck and turkey, and pigeon and quail, respectively, with the duck and turkey cluster been intermediate in distance between the other 2 clusters. The dendrogram from this clustering is similar to the classification from traditional methods which are used in taxonomy to classify the birds. The result revealed that statistical classification is a reliable and veritable method for specie identification and constellation.

Table 1. Hierarchical clustering history of the 6 species of birds1

Number of Clusters	Distance	Leader	Joiner
5	2.081991550	Pigeon	Quail
4	2.765695694	Duck	Turkey
3	3.539278540	Chicken	Guinea Fowl
2	5.216181164	Chicken	Duck
1	9.632125371	Chicken	Pigeon

Dairy Foods: Cheese and Dairy Products

T60 Prediction of process cheese functionality using dielectric spectroscopy. J. K. Amamcharla* and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

Process cheese (PC) is manufactured by blending and heating of natural cheese, emulsifying agents, sodium chloride, acidifying agents, water and other optional ingredients. The selection ingredients used in PC formulations play a crucial role in the functionality of the finished product. There is a need to develop a rapid method to predict the functional properties of PC. The objective of the study was to predict the functional properties of PC using dielectric spectroscopy. Dielectric properties of the PC were collected over the frequency range 0.2–3.2 GHz at a constant temperature (25°C). Dielectric spectra were collected using an open-ended high temperature dielectric probe (Agilent Technologies, Englewood, CO) connected to a vector network analyzer (Agilent Technologies). Dielectric spectra were collected in triplicate at 4 different locations in each sample. Twenty-four PCs were manufactured using a 3 × 2 × 2 factorial design using Intact casein content (ICC; levels: 14, 15.5, and 17%), cooking temperature (CT; 170 and 190°F), and cooking mixer speed (CMS; 100 and 350rpm) as independent variables. Partial least square regression (PLSR) and neural network (NN) models were developed using the dielectric spectra of PCs to predict the hardness (gf), melting point (°C) and modified Schreiber melt diameter (mm) of PC. Penetrometer, dynamic stress rheometry (DSR), and modified Schreiber melt (MSM) test were used as the reference methods, respectively. The PLSR and NN models were validated using the full cross-validation method. Root mean square error of crossvalidation (RMSECV) for PLS was found to be 2.5°C, 1.96mm, and 15.2gf for DSR melt point, MSM diameter, and hardness of PC, respectively. Similarly, RMSECV for NN was found to be 2.7°C, 2.1 mm, and 22gf for DSR melt point, MSM diameter, and hardness of PC, respectively. Practical utility of the calibration models were evaluated using the ratio of prediction error to deviation (RPD). The RPD was found to be > 2 for the 3 functional properties, indicting a good practical utility of the models.

Key Words: dielectric spectroscopy, process cheese, functional properties

T61 The impact of cation substitution on the flavor of reduced sodium full fat Cheddar cheese. E. Kang*[1], M. Kim[1], D. J. McMahon[2], and M. A. Drake[1], [1]*North Carolina State University, Raleigh,* [2]*Utah State University, Logan.*

Sodium reduction is a key issue in the dairy industry as salt plays a crucial role in flavor and ripening of Cheddar cheese. Previous research showed that more than 30% sodium reduction negatively affected flavor development and consumer acceptance. Substitution of potassium chloride and small amounts of magnesium and calcium chlorides may maintain salty taste while minimizing sodium in cheese. The objective of this study was to evaluate the effect of partial salt substitution on flavor and flavor chemistry of full fat Cheddar cheese. Seven full fat Cheddar cheeses with the molar salt contents equivalent to 1.7% (wt/wt) sodium chloride (NaCl) but different ratios of sodium, potassium, calcium and magnesium cations were manufactured. Cheeses made using only NaCl at 1.7% (wt/wt) (C) served as positive controls while cheeses made using 0.7% (wt/wt) NaCl (LC) served as negative controls (LC). The experiment was replicated 3 times. Cheeses were ripened at 6°C and sampled for sensory, organic acids, and volatile compound analyses through 9 mo of aging. Trained sensory panelists documented flavor attributes. Organic acids and volatile compounds were extracted and separated by high performance liquid chromatography or by solids phase microextraction with gas chromatography mass spectrometry, respectively. Consumer acceptance tests were performed after 6 mo. Salty taste intensity was consistent among cheeses except for the LC cheese, but other aromatic and basic taste differences were documented and these differences (bitter taste, sulfur and brothy flavors) increased with increased sodium cation substitution (>25%) or decreased salt (LC). Citric and lactic acids were higher in LC compared with other cheeses. Volatile compound differences were noted when more than 25% sodium was replaced. No differences in consumer liking were observed with up to 50% replacement of potassium with sodium ($P > 0.05$), and consumers on sodium restricted diets scored low sodium cheeses higher than those on unrestricted diets ($P < 0.05$). These results demonstrate that flavor and taste differences due to different cation salts will not affect consumer liking up to 50% sodium replacement.

Key Words: sodium, cheese, salt replacement

T62 A novel approach to produce low fat Cheddar cheese. I. Amelia*[1], D. M. Barbano[1], and M. A. Drake[2], [1]*Cornell University, Ithaca, NY,* [2]*North Carolina State University, Raleigh.*

Our objective was to develop a new process to make low fat Cheddar cheese (LFCC) and compare its composition and properties to commercial full fat Cheddar cheese (FFCC) and commercial 50% and 75% reduced fat Cheddar cheese (RFCC). A RFCC (53% reduction) was produced using a fat removal process (Nelson and Barbano, JDS 2004) and then combined with dry micellar casein concentrate (MCC), water, and salt to achieve 6% fat, 28% protein, 1.2% salt in LFCC. The 6% fat target (83% fat reduction) was used to comply with the FDA low fat labeling regulation. The pH of the LFCC formulation was adjusted to 5.3 with lactic acid. Rennet was added, followed by pressing and packaging in 40 min total time. The cheese texture was conceptualized as a filled-gel model of protein matrix and filler (100% minus %protein). The filler volumes for FFCC, 50% RFCC, 75% RFCC, and LFCC were 75.8, 70.6, 67.4, and 70.3%, respectively, while the moistures were 35.7, 49.2, 52.5, and 58.1%, respectively. The RFCC had the hardest texture. The texture of the LFCC was more similar to the FFCC than either of the RFCC, even though the filler volume of the LFCC was similar to the 50% RFCC. The soft texture of our LFCC was because the original matrix structure of the starting FFCC was broken by blending. A new matrix structure was formed by the interaction of added rennet with the MCC resulting in a softer texture that was more similar to FFCC. Descriptive flavor scores were used to construct a PCA biplot to visualize flavor profile differences among cheeses. Both RFCC and LFCC were missing typical aged full-fat Cheddar flavor characters (nutty, brothy, catty, milkfat). The 50% RFCC and 75% RFCC were characterized by strong whey and cooked flavors while LFCC had bitter and grape-tortilla flavor which was thought to originate from the dry MCC. The sulfur flavor in LFCC was closer to FFCC, than both RFCC. The LFCC flavor produced by this method could be manipulated by adding flavoring ingredients (e.g., enzyme modified cheese) that could boost typical flavors of FFCC. Progress was made in development of a new LFCC making process that achieves a texture similar to FFCC, but the LFCC still needed improvement in Cheddar flavor characteristics.

Key Words: cheese, low fat, micellar casein

T63 Effect of grazing on Caciocavallo cheese quality produced in Alta Irpinia. G. Esposito*[1,3], A. Di Francia[1], F. Napolitano[2], M. L. Varricchio[1], A. Braghieri[2], and F. Masucci[1], [1]*Dipartimento di Scienze del Suolo, della Pianta, dell'Ambiente e delle Produzioni Animali,Universitá degli Studi di Napoli Federico II, Portici (Napoli), Italy,* [2]*Dipartimento di Scienze delle Produzioni animali, Universitá degli Studi della Basilicata, Potenza, Italy,* [3]*Department of Production Animal Studies, Faculty of Veterinary Science, University of Pretoria, Pretoria, South Africa.*

Dairy system in Alta Irpinia (Campania, southern Italy) is characterized by semi-extensive farms where cow feeding is based on grazing pasture in spring, and on hays and concentrates in winter. Milk is used to make a typical cheese named Caciocavallo. The aim of the study was to evaluate the effect of grazing on fatty acid (FA) profile, sensory properties and consumer liking of Caciocavallo made in Alta Irpinia. The study was conducted in 3 farms (A, B, C) and in 2 periods: spring (10 wk) and winter (10 wk). Pasture, feedstuff samples, milk and corresponding Caciocavallo cheeses were collected every 2 wk. Data on milk and cheese composition, cheese sensory properties and consumer acceptability were analyzed by GLM procedure, with season effect, farm and their interaction. To assess the FA transfer from milk to cheese, data of both FA profiles were compared by one-way ANOVA. Spring milk had higher contents of C18:0 (SEM 0.65; $P = 0.011$), C18:1t11 (SEM 0.03; $P < 0.001$), C18:3 (SEM 0.059; $P < 0.001$), CLA c9-t11 (SEM 0.087; $P < 0.001$). The cheese FA profile reflected the one of raw milk with few differences due to the aging process. Higher contents of C18:0 (SEM 1.17; $P = 0.01$), C18:3n-3 (SEM 0.01; $P = 0.007$), and CLAc9-t11 (SEM 0.21; $P = 0.004$) were observed in spring compared with winter cheeses. Sensory profile of spring cheese markedly differed across the 3 farms and the 2 periods. In particular, sensory profile of spring cheese produced from milk of cows fed natural pasture (farm A) differed from cheeses of cows fed sown pasture (farms B and C). A higher color intensity (yellowness) was observed in spring products (SEM 1.95; $P < 0.001$) due to the transfer of pigments (e.g., β-carotene) from fresh plants to the cheeses. Consumers expressed no preference for cheeses produced in different farms or seasons. This may be a consequence of the high temperatures (70–80°C) reached during the cheese making process possibly flattening the differences perceivable by untrained consumers. Overall, it is concluded that our work allowed the characterization and differentiation of Caciocavallo cheese produced in Alta Irpinia by different cattle feeding system.

Key Words: CLA, pasture, sensory properties and cheese quality

T64 Sensory and instrumental measure of temporal volatile release from cheese. S. White,* R. E. Miracle, E. A. Foegeding, and M. A. Drake, *North Carolina State University, Raleigh.*

Understanding what consumers experience during consumption of a food product is of great concern to manufacturers. This not only includes overall flavor and texture profiles, but the temporal duration and intensity of these attributes. Volatile compound and rheological tools have been extensively and successfully related to sensory perception. However, matching temporal changes by sensory and instrumental analyses remains a challenge. The objective of this study was to develop and validate an apparatus to measure dynamic volatile compound release from cheese and to verify this instrument with sensory analysis. Two provolone cheeses, made from the same lot of milk, were selected for their differences in free fatty acid flavor intensity. The free fatty acid profiles of the cheeses were analyzed by descriptive sensory analysis, solid phase microextraction gas chromatography (SPME-GCMS) and sensory time intensity. Additionally, a Seward Stomacher 80 Biomaster lab system was modified to measure dynamic volatile release from these samples. The temporal volatile release (TVR) apparatus was designed to allow N_2 gas flow in the stomacher over the sample and through an outlet equipped for SPME fiber exposure. Volatiles were extracted after 10, 20 and 30 s of compression then quantified by GCMS. All experiments were conducted in triplicate. Statistical differences were analyzed using one-way ANOVA. Both sensory time intensity (TI) of free fatty acid flavor and the TVR showed differences ($P < 0.05$) between the cheeses not observed with traditional SPME-GCMS or by descriptive sensory analysis. The TVR volatile measurements were correlated with the sensory TI results ($r^2 = 0.88$, $P < 0.05$); and the TVR apparatus was able to measure differences in the relative volatile compound intensity of free fatty acids as well as the temporal release of these compounds. When used in conjunction with established sensory and flavor chemistry tools, this instrument can help food scientists understand what volatiles contribute to temporal perception of flavor.

Key Words: cheese flavor, time intensity, flavor release

T65 Light backscatter–Shedding new light on milk coagulation. R. Miller, A. Villarroel, B. Krahn, and L. Goddik,* *Oregon State University, Corvallis.*

The objective of this project was to evaluate the application of light backscatter technology to analyze the influences of somatic cell level, breed, parity, age of milk, and lactation stage on milk coagulation rate. Milk collected from individual cows (n = 31) was centrifuged to equalize fat composition and was tested during chymosin-induced coagulation. Coagulation rate was determined using diffuse reflectance to monitor changes in protein aggregation. Only breed and days in milk were significant with respect to milk coagulation rate. A student *t*-test was performed to evaluate differences in mean coagulation time between Holstein and Jersey milk. Coagulation of Jersey milk was significantly faster than Holstein milk. There was no evidence to suggest that somatic cell level affected coagulation rate. Initial pH of the milk was a significant indicator of SCC level, but was not a significant predictor of milk coagulation rate after the pH was equalized for all of the milks tested, suggesting that discrepancies in pH and not SCC level are what affect milk coagulation rate. The influence of milk age was also considered, using individual cow milk samples (n = 6) held for zero to 5 d. Coagulation rate did not vary significantly over the 5 d period. Overall, the results of this study indicate that only breed and days in milk significantly affect milk coagulation rate as measured by diffuse reflectance. The study also demonstrated that diffuse reflectance can be utilized to monitor milk coagulation rate.

Key Words: coagulation, SCC, quality

T66 Selection criteria for lactic cultures in reduced fat Cheddar cheese. A. C. Biswas,* A. N. Hassan, and L. E. Metzger, *Dairy Science Department, South Dakota State University, Brookings.*

The objective of this research was to screen several commercially available ropy strains of lactic acid bacteria for suitability in making reduced fat cheese with improved textural characteristics. Exopolysaccharide (EPS)-producing lactic cultures have been used to improve texture and meltability of reduced fat Cheddar and process cheeses. In our previous studies, among numerous cultures tested, the most successful strain in making reduced fat cheese was a highly ropy *Lactococcus lactis* ssp. *cremoris* (JFR) isolated from commercial buttermilk. Several single and mixed cultures of *Streptococcus thermophilus*, *Lactococcus lactis*, and *Lactobacillus delbrueckii* ssp. *bulgaricus* were obtained from commercial sources and tested in this study. Cultures were screened for ropiness, and 5 highly ropy strains were selected. Selected strains were then evaluated against 2 control cultures: JFR and an EPS-negative culture. Rehydrated skim milk (11% w/w) steamed (95°C) for 15min. was inoculated with the test culture and fermented at the appropriate temperature (37°C for thermophiles and 32°C for mesophiles) to a pH value of 4.6. After overnight cooling at 4°C, fermented milk was tested for shear and heat stability, viscosity, water-holding capacity (WHC), and flow and viscoelastic properties. Milk fermented with JFR had the highest WHC, yield stress, consistency coefficient, ropiness, viscoelastic moduli, and shear stability. Water holding capacity determines moisture retention in cheese. The increase in viscoelastic moduli in the presence of EPS would indicate EPS-protein interactions which lead to stronger bodied, less pasty cheese, and lower whey viscosity (due to retention of EPS within the protein matrix). High heat and shear stability of EPS are important attributes in process cheese making. No direct relationship was found between ropiness and any of the tested traits. In conclusion, ropy cultures producing high water holding capacity, shear stability, consistency coefficient, yield stress, and viscoelastic moduli in fermented milk would produce reduced fat cheese with improved textural and melting properties.

Key Words: starter cultures, reduced fat cheese, exopolysaccharides

T67 Influence of salt levels, rate of salting and potassium chloride on whey syneresis from Cheddar cheese curd.

Y. Lu* and D. J. McMahon, *Western Dairy Center, Utah State University, Logan.*

There is interest in lowering the sodium content of cheese by either reducing the amount of added salt or by replacing some of the sodium with potassium. Such changes have the potential to affect whey expulsion from cheese curd and subsequent mechanical handling of the curd after salting. Our objective was to determine effects on cheese curd syneresis of salting time intervals, salting levels, and 33% KCl molar substitution of NaCl. Four sets of unsalted fresh Cheddar curds were obtained and salted with different methods, with 3 replicates of each set on separate days.. Set A was salted with 3.0% (wt/wt) NaCl over 3 applications either 5 or 10 min apart. Set B was salted with 3.0, 2.5, and 2.0% NaCl over 3 applications 5 min apart. Set C was salted with 2.0% NaCl using 1, 2, or 3 applications. Set D received salt consisting of a 2:1 molar ratio of NaCl and KCl over 3 applications 5 min apart. Whey was collected every 5 or 10 min until 30 or 40 min after the start of salting. Salted curds were pressed for 3 h. In general, whey expulsion started after the second salt addition, and with rapidly after the third application. Using 10-min salting intervals delayed whey syneresis but after pressing there was no significant influence on final cheese composition. Lowering salting levels significantly reduced the amount of whey expelled before pressing from a mean of 25 g/kg with 3.0% salt to 13 and 4 g/kg with 2.5 and 2.0% salting, respectively. This resulted in corresponding cheeses with higher moisture (35.6, 35.9, 37.0%) and slightly lower pH (5.3, 5.3, 5.2), respectively. In Set C cheese, adding 2.0% salt over one, 2, or 3 applications did not significantly affect cheese composition, with mean whey expulsion being ≤7 g/kg. Partial substitution with KCl did not affect amount of whey expelled or cheese moisture composition, although there was a slightly faster whey expulsion when using the NaCl/KCl mixture.

Key Words: cheese, salting, sodium

T68 Effect of different gums supplementation on textural properties of goat milk yogurts.

Y. W. Park*[1], J. Oglesby[1], S. A. Hayek[2], R. Gyawali[2], and S. Ibrahim[2], [1]*Fort Valley State University, Fort Valley, GA,* [2]*North Carolina A&T State University, Greensboro.*

Texture plays a significant role in sensory quality and consumer acceptability of fermented dairy foods. Casein gels are responsible for various rheological and textural properties of dairy products, such as yogurt and cheese. A study was conducted to evaluate the differences in textural properties of caprine milk yogurts fortified with 7 different kinds of gums during 4 weeks refrigerated storage. The experimental caprine yogurts were manufactured using goat milk produced at the Georgia Small Ruminant Research and Extension Center, Fort Valley State University, Fort Valley, with 0.2% addition of 7 different gums to pasteurized milk (w/v), which were: (1) xanthum, (2) modified food starch with agar pectin, (3) carrageenan, (4) locust bean, (5) carrageenan, maltodextrin, and dextrose, (6) guar, (7) modified food starch with gums 3, 4 and 5, and the yogurts were stored for 0, 2, and 4 wk at 4°C. Textural characteristics of all yogurts were determined using a texture analyzer (model TA.XT2i, Texture Technology Corp., Scarsdale, NY). Viscosity of the yogurts was measured by firmness (g force) and consistency, and adhesiveness or stickiness was measured by cohesiveness (g force) and index of viscosity. Firmness of control and 1 to 7 different gum added yogurts for the 0 and 4 wk storage were: 19.1, 23.0; 41.8, 63.7; 20.6, 22.2; 19.7, 20.9; 50.2, 64.7; 18.9, 19.7; 20.0, 20.8; 19.3, 21.1, respectively, indicating firmness of xanthum and locust bean fortified yogurts had significantly higher than control and the other gum treated groups. Locust bean showed the highest textural integrity among all tested gums. Viscosity, cohesiveness, and adhesiveness of #1 and #4 gums added yogurts were also significantly higher than the other yogurts. It was concluded that locust bean and xanthum were choice of gums for the best textural quality of caprine milk yogurt.

Key Words: goat milk yogurt, gums, texture

T69 The role of different sweeteners on WPI flavor contributions in acidic protein beverages.

S. White* and M. A. Drake, *North Carolina State University, Raleigh.*

The modern consumer demands that food products have high nutritional value without sacrificing flavor. Among these products are high protein beverages that may contain low calorie sweeteners. Previous research has documented that processing steps in protein beverage manufacture may increase off flavors in the finished product. This objective of this study was to determine if different sweeteners affected WPI flavor contributions in WPI beverages after acidification and pasteurization. Duplicate lots of WPI were rehydrated to 10% solids (w/v) and sweetened with fructose, sucralose, or stevia followed by acidification to pH 3.2 and heat treatment at 85C for 30 s. The experimental controls included unsweetened WPI, as well as deionized water sweetened with fructose, sucralose and stevia; all processed in the same manner. All treatments were evaluated by descriptive sensory analysis, solid phase microextraction gas chromatography mass spectrometry and gas chromatography-olfactometry. The experiment was repeated in triplicate and statistical differences were analyzed using one-way ANOVA and principal component analysis. WPI with different sweeteners were distinct in sensory and volatile profiles ($P < 0.05$). After acidification and heating, model beverages made with sucralose and stevia had higher soapy flavors than those sweetened with fructose; beverages with sucralose were also metallic. WPI model beverages with fructose had higher cabbage flavor, and higher dimethyl trisulfide concentrations after processing. However, other sensory differences were not confirmed by volatile analysis suggesting additional cognitive effects on sensory perception. A comparison of sweetened water and sweetened WPI indicated that processing effects (heat and acidification) on the sweetener alone did not impart unique flavors. Sweeteners influenced sweet taste quality and temporality and enhanced soapy or cabbage flavors contributed by WPI. These results demonstrate that sweetener type influences sensory properties (aromatics and basic tastes) of whey protein beverages.

Key Words: WPI, protein beverages, sweeteners

T70 Concentrations of IGF-1 and IGFBP-3 in several Korean commercial dairy products by immunoradiometric assay. S. H. Kang,* D. W. Kim, K. H. Kim, K. S. Kim, and S. C. Baick, *Seoul Dairy Cooperative R&D Center, Shingil-dong, Ansan-si, Kyunggi-do, Republic of Korea.*

Insulin-like growth factor-1(IGF-1) is a mitogenic polypeptide with a molecular structure similar to that of insulin which stimulates growth, differentiation and metabolism in a variety of cell types by acting through IGF-1 receptors. Milk-derived growth factors may also mediate the growth of tissues not directly associated with the GI tract and may have greater implications for overall growth and development of the neonate. The objectives of this study were to determine the change of insulin-like growth factor-1(IGF-1) and of insulin-like growth factor binding protein-3(IGFBP-3) content in commercial dairy products marketed in Korea. IGF-1 content was determined by immunoradiometric assay (IRMA). All the experiments were triplicated and the data were analyzed by the SAS system using a procedure of ANOVA. There were no significant differences in IGF-1 content by different pasteurization methods between HTST and UHT heat treatment. The mean IGF-1 content of commercial market milk, plain yogurt, skim milk powder, infant formula and sweet cheese whey powder was 2.3 ± 0.6, 8.7 ± 0.8, 4.8 ± 0.1, 4.1 ± 0.4 and 7.8 ± 0.2 ng/mL, respectively. However, the concentrations of IGFBP-3 in all the dairy products could not be measured by using commercially available human IGFBP-3 IRMA kits (<1.0 ng/mL), because the kits were generated against human IGFBP-3 epitopes and failed to recognize bovine milk IGFBP-3. The IGF-1 content in unprocessed milk has been reported in the range of 1.27 - 8.10 ng/mL. It was concluded that the concentration of IGF-1 in the examined milk products was not altered by homogenization, conventional heat treatment or spray drying.

Key Words: IGF-1, IGFBP-3, immunoradiometric assay

T71 The fatty acid composition of butter and cultured butter with lactobacillus acidophilus added to starter. O. Tsisaryk*[1], L. Musij[1], and O. Golubets[2], [1]*Lviv National University of Veterinary Medicine and Biotechnologies, Lviv, Ukraine,* [2]*Ukrainian State Research and Production Centre for Standardization, Metrology, Certification and Consumer Rights Production, Kiev, Ukraine.*

Our purpose was to create butter which would combine functional properties probiotics and increase the content of CLA. Some fermented dairy products contain higher levels of CLA than non-fermented, and the yield of CLA was dependent on the species of lactic acid bacteria inoculated. Some studies have shown that among lactic cultures inoculation of L. acidophilus into milk was most effective in promotion c-9,t-11-CLA formation. The objective of the study was to determine the fatty acid composition of sweet butter and cultured butter when a L. acidophilus was added to the starter. Control butter was churned from sweet cream (SB) and cultured butter (CB) from fermented cream. The cream was fermented by the starter Flora Danica Chr. Hansen (*Lac. lactis*, *Lac. cremoris*, *Leu. cremoris*, *Lac. diacetylactis*) at 20°C (CB1); Flora Danica and *L. acidophilus* La-5 (1:1) at 20°C (CB2); and Flora Danica and *L. acidophilus* La-5 (1:1) at 30°C – a more comfortable temperature for *L. acidophilus* (CB3). The experiment was replicated 3 times. Butter samples were stored at –20°C until the fatty acid analysis by GLC. The FAME were separated on a column (100 m × 0.25 mm × 0.2 µm [HP-88] 88%-cyanopropyl aryl-polysilixane, Agilent Technologies) in a chromatograph (Hewlett Packard 6890). All samples of butter contained similar concentrations of total trans-isomers, transvaccenic acid (4.0%) and c-9,t-11-CLA (1.9%). The content of butyric acid increased from 4.0 in SB to 4.3–4.4% in CB ($P < 0.05$). The sum of branched-chain fatty acids decreased from 2.6 in SB to 1.8% in CB; the percentage anteiso-C14:0 was 0.8% in SB, but it was not detected in CB. The content of C14:1 was 1.74% in cultured samples, but only 0.9% in SB. The sum of unpaired fatty acids was the same in all samples. The percentage of the sum of medium-chain saturated fatty acids (C12-C16) decreased from 40.8 in SB, CB1, and CB2 to 40.5% in CB3 ($P < 0.05$). It was concluded that there were not significant differences in fatty acid composition between the samples of cultured butter, but there were some differences between sweet and cultured butter in content of short- and branched-chain fatty acids.

Key Words: butter, cultured butter, fatty acids

T72 Effect of sodium reduction on the survival of *Listeria monocytogenes* and *Bacillus anthracis* in Cheddar cheese. E. Hystead,* F. Diez-Gonzalez, and T. C. Schoenfuss, *University of Minnesota, St. Paul.*

Reduction in sodium intake is a public health priority. Cheddar cheese is a targeted food for sodium reduction efforts because of its relatively high salt content. One of the roles of salt in cheese is the inhibition of spoilage and pathogenic microorganisms. Additionally, a bioterrorism attack on the milk supply with an agent that survives pasteurization, such as *Bacillus anthracis*, could be used against cheese. The objective of this study was to determine the ability of *Listeria monocytogenes* and *Bacillus anthracis* to survive in Cheddar cheese at reduced and low sodium levels. Stirred curd Cheddar cheese was manufactured separately with 2 different starter cultures, and 5 salting treatments: full sodium, 25%, and 55% reduced sodium with and without potassium chloride (KCl) addition. Shredded cheese from each treatment was inoculated with 5 strains of *L. monocytogenes* or 2 strains of *B. anthracis*, and stored at 4° and 12°C. Enumeration of pathogens, and aerobic count, and lactic acid bacteria was performed at regular intervals over 30 to 60 d. Water activity, pH and moisture were also monitored. *L. monocytogenes* count declined by 4 log cfu/g in all treatments after 60 d at 4°C. Results from subsequent experiments with higher inocula and higher pH, showed no more than 1 log cfu/g decrease in counts in all treatments. Furthermore, the 55% reduced sodium treatment had no reduction at all. The populations of *L. monocytogenes* (at 12°C), *B. anthracis*, aerobic count, and lactic acid bacteria survived consistently at 5, 6, 5.5, and 8.5 log cfu/g respectively, at any temperature or salting treatment. Survival of *L. monocytogenes*, and *B. anthracis* appeared to be due to an increase in pH of stored Cheddar cheese from averages of 4.7 to 5.4 over 6 mo. These results indicate that pathogens were able to survive in Cheddar cheese, regardless of sodium reduction level, but this survival was dependent on pH. In the event of an accidental or intentional contamination, reduction of sodium may increase the risk of pathogen survival if the pH of Cheddar cheese is not sufficiently low.

Key Words: Cheddar cheese, sodium reduction, food safety

T73 Effects of acidification of milk by glucono-δ-lactone (GDL) on the solubility of milk protein concentrate powder. H. Eshpari*[1,2], M. Corredig[1], and P. Tong[2], [1]*University of Guelph, Guelph, Ontario, Canada,* [2]*California Polytechnic State University, San Luis Obispo.*

A limiting factor in using milk protein concentrates (MPC) as a high quality protein source for different food applications is their poor reconstitution properties. It is known that in native casein micelles, there is an optimal balance of hydrophobic and electrostatic interactions; however, acid-induced changes of casein micelles have disruptive effects on the attractive and repulsive forces in casein micelle structure. Depending on the extent of disruption, different structures of acid modified micelles are obtained, that may result in different solubility and functional properties of casein micelles. The main objective of this study was to investigate the effects of acidification of milk by glucono-δ-lactone (GDL) before ultrafiltration on the reconstitutability of MPC powders. Milk protein concentrate 80 powders were manufactured in duplicate by ultrafiltration, diafiltration, and spray-dying using milk (~pH 6.6) and GDL-treated milk (pH 6.0). Powder samples were tested in duplicate for reconstitutability, particle size and microstructure. It was observed that acidification of milk to pH 6 significantly increased ($P < 0.001$) the mean solubility of milk protein concentrate from 79.81 to 90%. Particle size analysis and scanning electron microscopy (SEM) observations showed no significant difference in the mean particle size distribution and microstructure of the powder due to the effect of milk acidification. Mineral content and casein micelle structure of the powders need to be investigated to better understand the beneficial effect of milk acidification on solubility. Overall, this study demonstrates the importance of milk acidification and pH in determining the solubility of milk protein concentrate.

Key Words: acidification, milk protein concentrate, solubility

T74 Influence of ethanol on some characteristics of stirred yogurt. B. Mena*[1,2] and K. Aryana[2,1], [1]*Louisiana State University,* [2]*Louisiana State University Agricultural Center.*

Alcohol is used in manufacture of some products such as egg nog. The objective was to study the effect of ethanol on the growth of yogurt culture bacteria and the physico-chemical characteristics of stirred yogurt. The treatments were 0% (control), 2.5%, 5% and 7.5% v/v of ethanol. The ethanol was incorporated by stirring it into one day old plain yogurt. Product characteristics were studied weekly for 4 weeks of refrigerated (4°C) storage. Data were analyzed using Proc Mixed model of Statistical Analysis System. The ethanol*storage time interaction effect was significant for *Lactobacillus bulgaricus* counts. The storage time effect was significant for *Streptococcus thermophilus*, *Lactobacillus bulgaricus*, pH and titratable acidity (TA). Ethanol incorporation in yogurt did not influence the counts of *Streptococcus thermophilus*, *Lactobacillus bulgaricus* nor the viscosity of the yogurts. Ethanol incorporation in yogurt significantly influenced pH and TA of the yogurts. The pH of the control yogurts were significantly lower than yogurt with 7.5% ethanol, while there were no differences between the control and yogurts with 2.5 and 5% ethanol. Control yogurts had significantly the highest TA followed by yogurts with 2.5% ethanol while yogurts with 5 and 7.5% ethanol had significantly the lowest TA values not different form each other. Yogurts with ethanol can successfully be manufactured without adversely influencing counts of its culture bacteria over product shelf life.

Key Words: yogurt, ethanol, culture

Extension Education

T75 Water use efficiency on small-scale irrigated dairy farms in the Mexicali Valley, México. L. Avendaño-Reyes*[1], F. D. Alavarez-Valenzuela[1], U. Macías-Cruz[1], A. López-López[1], P. H. Robinson[2], and A. Correa[1], *[1]Universidad Autónoma de Baja California, Valle de Mexicali, Baja California, México, [2]University of California, Davis.*

The Mexicali Valley is contiguous to the Imperial Valley in the US state of California and has over 200,000 ha of irrigated land. Under a 1944 water treaty with the United States, Mexicali is guaranteed an annual quantity of 1,850,234,000 m^3 of water to be deliver from the Colorado River. Agriculture depends primarily on this annual quota of irrigation water. The dairy sector is predominantly small-scale and generates income to sustain most agricultural households. However, a proposed concrete lining in the United States on the All-American Channel would cut off billions of leaked gallons of water, which is used to irrigate several crops and livestock use in Mexicali Valley. The aim of this study was to use a survey method to investigate key factors that influence water use efficiency (WUE) in small-holders of the Mexicali Valley, Baja California, México. Descriptive statistics and regression analysis were performed. In the last 5 years there has a been a reduction in the number of dairy small holders because due to economic issues in the Mexicali Valley. Most of the small holder dairy producers are mature to old males (~55 years old), with a low level of education and with about 25 years dairying experience. The general management of the cows is supervised by professionals in less than 50% of the small dairy producers, but almost all participate in the government Brucella surveys. However, largely due to lack of milk management equipment, hygiene of milk is poor and this may lead to disease in the rural population that consumes their milk. Irrigation systems for grazing lands are deficient and a large amount of irrigation water is wasted or poorly managed. Water use efficiency is not associated with milk production or herd size, but it increased with an increase in total irrigated land area. Small dairy producers in the Mexicali Valley require more external support if they are to survive in the current and likely future economic climate, and to avoid other social problems such as migration to the USA to seek out ways to improve their families lifestyle.

Key Words: milk production, irrigation water, grazing dairy cattle

T76 Complexity graphics for complex issues in animal science. M. Boggess,* *USDA-ARS, Beltsville, MD.*

Modern scientific challenges to food animal production are increasingly complex making them difficult to visualize for academics as well as industry stakeholders. Scientists are evolving research models to tackle these complex challenges through larger comprehensive collaborations that feature interdisciplinary approaches to project management and scientific experimentation. Public funding agencies are following suit, requiring larger collaborative programs that feature funding line items for research, education and extension. Administering these programs requires superior leadership, communication and project management. Better tools are also needed to accomplish these goals. “Complexity graphics” are proposed as an innovative tool to visually convey the primary and secondary factors affecting a particular trait, concept or production challenge. Examples include animal production sustainability; sow lifetime productivity; maternal reproduction, bovine viral diarrhea and pork quality, although virtually any complex trait or concept could be illustrated. Sophistication ranges from s simple graphic to serial animation with multiple points of emphasis. These tools have proven to be beneficial with varied animal science and industry audiences to convey and illustrate the factors and relationships influencing complex traits. These tools have also proven beneficial to scientific teams attempting to visualize an interdisciplinary approach to a specific research project in the animal sciences.

Key Words: education, extension, collaboration

T77 Factors limiting productive efficiency in small dairies of central Mexico (Aguascalientes State). R. R. Lozano-Dominguez,* C. F. Arechiga, R. M. Rincon, and L. M. Escareno-Sanchez, *Universidad Autonoma de Zacatecas, Zacatecas, Mexico.*

Objective of present study was to identify the main factors compromising productive efficiency in small and familiar dairy productive systems typical of central Mexico at Aguascalientes state. Data from small dairies (n = 183) was collected including social, agricultural and animal productivity aspects. Such information was analyzed by ANOVA in which main independent variables were location and land property type. Thus, 64% of small familiar dairies are considered as “ejido” properties (communal-type property; $P < 0.01$). Labor is mainly a family responsibility (89.1%). Ejidal-type properties has a reduced number of hectares) compared with private properties (8.1 ± 1.9 vs. 15.9 ± 2.6 ha; $P < 0.01$). Forage corn is the main crop either at irrigated soils (4.0 ± 1.0 ha) as well as a seasonal crop during the rainy season at non-irrigated soils (6.3 ± 1.1 ha) in both property types (i.e., communal or ejido type vs. private property type; $P > 0.05$). Alfalfa is the second most important crop (2.4 ha); However, 79.2% of small-familiar dairies did not produced their own forage crops. Average number of dairy cows on milking line was 15.8 ± 1.4 with an average daily milk yield of 16.2 ± 1.04 kg. Showing differences within location and type of land property ($P < 0.05$). Culling (12.3%) and abortions (8.8%) rates were similar within locations ($P > 0.05$). Milk selling price was of 3.9 ± 0.46 Mexican pesos (MP); generating a daily income for milk sales of $951.50 MP per production unit (around US$75). Therefore, a negative profitability was obtained (-$0.28 cents) per liter of milk sold. Despite the fact, of being small dairy production units with reduced milk yields, when we consider a weekly labor payment for the dairy producer, profitability incomes become negatives. Nevertheless, in most cases such income represents the main and single income for the small and familiar-type diaries of central Mexico.

Key Words: small dairies, milk yield, Mexico

T78 Evaluation of on-farm forage dry matter determined by near infrared spectroscopy. M. S. Akins*[1], M. Dobberstein[2], and R. D. Shaver[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, [2]Dinamica Generale US, DeKalb, IL.*

The objective of this study was to evaluate the use of near infrared spectroscopy (NIRS; Dinamica Generale, Mantova, Italy) for on-farm measurement of forage dry matter (DM) content. The NIRS also measured protein, NDF, ADF, starch, ash and fat, but only DM content was evaluated. To calibrate the NIRS to forages at the University of Wisconsin-Madison Emmons Blaine Dairy Center (Arlington, WI), 10 samples of corn silage (CS) and alfalfa silage (AS) were analyzed using the NIRS to obtain a spectral analysis, then sent to a commercial laboratory (Dairyland Laboratories, Inc., Arcadia, WI) for DM analysis using a 2 step method (microwave drying to 90–95% DM, then use

NIRS to measure total DM content). Spectral and DM analysis data were used to update calibration equations for each forage. Samples of CS and AS were obtained twice weekly on Monday and Thursday for 11 wk. A total of 94 CS samples from 6 silo bags and 2 bunker silos, and 20 AS samples from one bunker silo were analyzed for DM content on-farm using the NIRS. Samples (60–100 g) were put in the scanning tray, compressed, and scanned by moving the tray in the scanning chamber for 10 s. The sample was removed from the tray and the entire sample was dried in an oven at 60°C for 48 h to measure DM content. Bias was calculated for each sample as the difference between oven and NIRS DM. The DM contents using the oven and NIRS were 38.1 ± 4.2% and 37.2 ± 3.9% for CS, and 43.4 ± 3.8% and 41.8 ± 4.4% for AS, respectively. The minimum and maximum DM contents of CS were 27.3% and 47.1% DM using the oven, and 26.5% and 46.7% using the NIRS, respectively. The minimum and maximum DM contents of AS were 31.6% and 47.7% using the oven, and 27.7% and 45.8% using the NIRS, respectively. For CS, the regression equation developed was NIRS DM% = (0.867 × Oven DM%) + 4.23; $R^2 = 0.85$, and the AS regression equation was NIRS DM% = (1.1395 × Oven DM%) − 7.7; $R^2 = 0.95$. The NIRS accurately (bias = 0.8% units) but less precisely (standard deviation of bias = 1.6% units) measured DM content of CS, and consistently measured lower DM content of AS (bias = 1.6 ± 1.1% units). Overall, the on-farm NIRS measured DM content comparable to the oven method.

Key Words: forage dry matter, NIRS

T79 Compliance of small and medium-sized farms in adopting recommendations for improved farm productivity and nutrient utilization.

L. D. Baker,* R. J. Munson, Z. Dou, D. T. Galligan, J. D. Ferguson, C. F. Ramberg, D. W. Remsburg, and Z. Wu, *University of Pennsylvania, Kennett Square.*

Ten dairy farms with less than 200 cows were identified from the Chesapeake Bay watershed in Pennsylvania to participate in an integrated nutrient management program in collaboration with herd veterinarians, nutritionists, agronomists and farm economists to improve farm profitability and to reduce nutrient and phosphorus excretion. Farms were visited quarterly for 2 years by project members to evaluate nutrition and management practices. DHIA records were analyzed monthly to monitor milk production and components, milk urea nitrogen, reproductive performance, and culling practices. Four farms substantially improved their financial situation during the study by making changes in their feeding program when they changed nutritionists, some of them longstanding relationships. Nutrient efficiency was improved on these farms as well. Recommendations by project leaders and collaborators for improvement of feeding and farm management practices were not adopted by all farms. On several farms (6 of 10) small amounts of forages with varying quality were produced and frequent forage changes prevented farms from having a balanced ration for extended periods of time. Conflicts in recommendations between project members and field nutritionists confused producers and resulted in less compliance toward project goals. For example, high quality forage was fed on one farm, but the nutritionist was reluctant to reduce the amount of supplemental grains, therefore increasing feed expense and nutrient excretion for this farm. On another farm the nutritionist was resistant to removing phosphorus from the top dress, resulting in high fecal phosphorus. Agronomists had positive effect on most of the farms, instituting cover crops and manure and soil testing for appropriate application rates and fertilization. There were 2 farms that did not comply with agronomic or project member recommendations, basing their actions on emotions rather than on sound decision making to improve profits. In general veterinarians supported systematic breeding programs recommended by project members with many farms having a positive improvement in pregnancy rate. Partially supported by National Fish and Wildlife Foundation.

Key Words: small farms, dairy farm management, nutrient management

T80 A collaborative bovine artificial insemination course for students attending a Caribbean veterinary school.

J. C. Dalton*[1], J. Q. Robinson[2], and J. M. DeJarnette[3], [1]*University of Idaho, Caldwell,* [2]*Ross University School of Veterinary Medicine, Basseterre, St. Kitts,* [3]*Select Sires Inc., Plain City, OH.*

Artificial insemination (AI) is a critical career skill for food animal veterinarians. Consequently, Ross University School of Veterinary Medicine Student Chapter of the American Association of Bovine Practitioners (SCAABP), Select Sires, and University of Idaho Extension have partnered to offer an intensive 2-d course to provide AI training to students attending the Caribbean veterinary school. The program consisted of 7 h of classroom teaching followed by 10 h of live animal experience. Topics included reproductive anatomy and physiology, semen handling, estrous detection, AI technique, estrous and ovulation synchronization protocols, sexed semen, and a virtual AI stud tour. A registration fee of $EC350.00 ($US130.00) included the cost of handouts, and breakfast and lunch on each day. The AI course was held twice in 2010 and 3 times in 2011. A 25-question test was given to participants (n = 83) at the beginning and conclusion of each AI course. The overall mean test score for the pre-test was 77.7%, while the mean for the post-test was 96.2%. The mean difference was 18.5%. Eighty-one students (81/83; 98%) received a certificate of completion by demonstrating sufficient skill at semen handling and AI technique. The course has developed into a high-demand educational program in which priority is given to SCAABP members based on 1) points earned through participation in other chapter events, 2) semester of enrollment at Ross University, and 3) participation in at least 1 chapter-sponsored bovine palpation trip to a local ranch. This collaborative effort ensures students attending the geographically remote veterinary school receive the educational opportunity to increase their knowledge and develop the skill of performing AI in cattle.

Key Words: artificial insemination, cattle, veterinary school

T81 Repro money: A farmer-directed team-based extension program to improve reproductive performance in Wisconsin dairy herds.

M. C. Cordoba,* P. M. Fricke, P. L. Ruegg, R. D. Shaver, K. A. Weigel, and V. E. Cabrera, *University of Wisconsin-Madison.*

Poor reproduction in dairy cattle is a multifactorial problem that includes aspects of physiology, genetics, management, health, and nutrition. Thus, improving reproductive performance requires an integrated approach among farm personnel and consultants that deal with reproduction. Our objective is to improve the reproductive efficiency and profitability of the dairy enterprise through implementation of farmer-directed team-based program called Repro Money. Each farm that enrolls in the Repro Money program agrees to conduct 4 meetings during a 6 to 8 mo period. Before the first meeting, the farm owner selects team members (e.g., veterinarian, nutritionist, AI technician, county extension agent, herd manager) and designates a team leader. At the first meeting, the team leader uses a data gathering and survey tool to analyze and identify farm-specific critical control points for successful reproductive management including: pregnancy rate, insemination risk, conception risk, detection of estrus, male and female fertility, transition cow management, synchronization protocols, and nutrition and heifer management. Based on results from this tool, the team sets goals, develops an action plan, assigns responsibilities, and determines appropriate evaluation strategies for individual team members. Meetings 2 and 3 are structured to ensure that team goals identified at the first meeting are on track. During the fourth and final meeting, the team reassesses the reproductive performance of the dairy using the same tool as the first meeting thereby documenting change. We are now in the process of enrolling farms into the Repro Money program. One of the early adopters of Repro Money increased their 21-d pregnancy rate from 18 to 24% resulting in an estimated $39,000 per year profit increase after implementing management changes identified during the program. With this farmer-directed team-based approach, dairy farmers can best utilize their personnel and advisers in a coordinated way to improve reproductive performance. Supported by AFRI Competitive Grant no. 2010–85122–20612

Key Words: reproduction, dairy cattle, team-based

T82 Calf-ETERIA: Using calf health and productivity as a template for extension and translation of research information for agriculture. V. Bielmann*[1], K. Leslie[1], T. Wright[2], and T. DeVries[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph, Ontario, Canada.*

There is increasing evidence from research that calf and heifer management is extremely important for long-term health, production and survival of dairy cattle. In addition, several key risk factors affecting these effects, and management programs for improvement of the situation, have been identified and refined. General adoption of these programs could be improved, and if so, would yield significant financial savings for the dairy industry. Nevertheless, leading producers, extension educators, dairy researchers and veterinarians have been largely unsuccessful in making noteworthy improvements on an industry-wide basis. The Calf-ETERIA Knowledge Translation and Transfer (KTT) project is an extension effort aimed at addressing this dilemma. A key objective of this project was to survey Ontario dairy producers on their calf and heifer management practices. The benefits of benchmarking these practices include using these levels to assess progress over the duration of the project in terms of animal well-being and financial benefit. In total, 3,145 surveys were mailed to Ontario dairy producers who were clients of the CanWest Dairy Herd Improvement program. Once the completed surveys were returned, data was entered into an Access database. The response rate for the survey was 30% (963/3,145). Survey results indicate that navel dipping is no longer routine practice on dairy farms, with only 38% of respondents implementing this practice. Thirty percent of producers indicated that colostrum quality is assessed on farm. However, of this 30%, 91% said the method of assessing quality was by visual inspection (color, consistency or volume), not by using a tool such as a colostrometer. The time of weaning on Ontario dairy farms is primarily decided by the age of the calf, with the majority of calves being weaned at 8 or 11 weeks of age (36% and 31%, respectively). The age at which fresh water is first offered to calves varied with 23% of producers offering water within 5 d of birth, 29% offering water 5–10 d after birth, 30% waited until the calves were older than 10 d of age, and the remaining 17% of producers do not offer water until after weaning. When asked what the cost of raising a heifer was, 58% of producers answered $1500-$2000, while 32% answered $1000-$1500. The remaining 10% answered $1000 (5%), $2500-$3000 (4%) and greater than $3000 (1%). This survey is the most comprehensive data set for calf and heifer management in Ontario since the 1980s and will be the first to evaluate the effect of different KTT approaches intended to positively affect change on dairy farms in Ontario. It is clear from the survey results that there are some areas of calf raising in which management practices vary widely across farms and can be improved upon.

Key Words: calf, heifer, management practices

T83 Comparison of out-of-season estrus synchronization protocols in meat goats. N. C. Whitley[1], K. Moulton*[1], R. A. Franco[1], A. E. Cooper[1], and T. J. Conrad-Acuna[2], *[1]Cooperative Extension Program, North Carolina A&T State University, Greensboro, [2]North Carolina State University Cooperative Extension, Richmond County, Rockingham.*

The objective was to demonstrate different methods for estrus synchronization for out of season breeding in meat goats on a producer-owned farm. The farm owner noted repeated failure of previous spring breeding attempts without hormone use. For this study, 33 mature Boer does were used in April 2011, with 10 receiving CIDR vaginal inserts (CIDR), 10 receiving CIDR inserts along with 400 IU PMSG and 200 IU hCG (5 mL PG600 sc; CP treatment group) and 13 receiving no treatment (CON; buck effect only). Does averaged 3.2 ± 0.2 years of age and were assigned to treatments such that 3 to 5 does from each treatment were represented in each of 3 single-sire mating groups. All males were kept away from sight and smell of the females for at least 3 weeks before the study. The CIDRs were inserted on d 0 and removed on d 13 for 20 does with 10 does receiving PG600 at CIDR removal. Mature Boer bucks were placed with does on d 13 and removed on d 27. On d 66, blood samples were collected via jugular vein puncture to determine pregnancy status (bioPRYN; BioTracking, LLC). Pregnancy and kidding rates were not influenced by treatment or mating group based on Fisher Exact Test analysis. Number of kids born was analyzed using Proc GLM of SAS. Pregnancy rates for CON, CIDR, and CP respectively were 69%, 90%, and 50% and kidding rates for CON, CIDR, and CP were 67, 89, and 40%, respectively. Kidding rates were 60% for 2 mating groups and 73% for the other. Number of kids born per doe kidding was not influenced by treatment, averaging 1.9 ± 0.3, 2.1 ± 0.3 and 2.5 ± 0.4 for CON, CIDR and CP, respectively. Number of kids born per doe exposed tended ($P < 0.10$) to be influenced by treatment, averaging 1.3 ± 0.3, 1.9 ± 0.4 and 1.0 ± 0.4 for CON, CIDR and CP, respectively. For this farm with small sample sizes, the use of the buck effect alone was just as effective as hormonal treatments for inducing out-of-season breeding in meat goat does, though CIDR alone tended to result in more kids born per doe exposed. More research is needed; however, based on these results, the farm owner intends to use CIDRs for out of season breeding this spring.

Key Words: CIDR, estrus synchronization, goat

T84 Using soil moisture monitoring to improve irrigation in dairy pastures. T. W. Downing,* *Oregon State University, Corvallis.*

Irrigating pastures on the Oregon coast has not been emphasized in the past because of the high seasonal rainfall and low return for the investment. As feed costs have risen, more emphasis has been placed on increasing the productivity of coastal pastures and this has stimulated a new interest in improving irrigation. Monitoring soil moisture tension or soil moisture content can help identify problems in irrigation water management that affect pasture yield or water use. Problems include excessive intervals between irrigations, inadequate wetting, too-frequent irrigations and differences in soil moisture type extraction patterns. This project was designed to monitor irrigation effectiveness of 2 types of irrigation systems on 4 dairies over 2 growing seasons. Watermark soil moisture probes were installed in 2 pastures on each dairy and soil moisture tension was recorded every 2 h at 15, 30, 45 and 60 cm deep for 2 years. Irrigation was done with either a traveling big gun irrigator or pod irrigation system. Year 1 dairy operators were asked to irrigate as they normally would and performance was recorded. In year 2 we demonstrated how to use the soil moisture monitoring system for management and reviewed the first years performance. Irrigation dates and volumes were also recorded in year 2. Irrigations done with big gun irrigators applied 4 irrigations averaging 66.25 ± 13.25mm and irrigations made with pod irrigation systems averaged 6 irrigations averaging 40.75 ± 14.87mm. Soil moisture tension measured in ranged from 0 to 97 centibars for the big gun irrigators and soil moisture from pod irrigators ranged from 10 to 62 centibars throughout the second year. Soil moisture monitoring has shown it was extremely beneficial in making decisions in dairy pastures and irrigating effectively was challenging for big gun equipment. Dairies irrigating with pods were over irrigating initially and reduced irrigations by 15% when they used soil moisture data.

Key Words: soil moisture monitoring, irrigating pastures

Food Safety: Food Safety Advances

T85 Occurrence of several antibiotic residues in raw milk in ten provinces of China. R. W. Han[1,2], J. Q. Wang*[1], N. Zheng[1], X. M. Xu[1], Y. P. Zhen[1], X. Y. Qu[1], P. Sun[1], and Z. N. Yu[3], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Food Science and Engineering, Qingdao Agricultural University, Qingdao, Shandong, China,* [3]*Haidu College, Qingdao Agricultural University, Laiyang, Shandong, China.*

The objective of this study was to investigate the occurrence of antibiotic residues in raw milk in China. A total of 199 raw milk samples from 10 provinces of China were examined for β-lactams, tetracyclines, sulfonamides and quinolones. SNAP Beta-Lactam Test kit (Idexx) was used for qualitative detection of β-lactam antibiotics, and sample was positive with the ratio 1.06 or higher. The limits of detection (LOD) of R-Biopharm test kits (Ridascreen) which used for quantitative detection of tetracyclines, sulfonamides and quinolones were 1.5μg/kg, 5.0μg/kg, and 0.25μg/kg, respectively, which were far below the maximum residue limits (MRL, regulated by EU, CAC, and China).Only one positive sample from Beijing for β-lactams was found with a ratio of 1.39. No sample was positive for tetracyclines, while 47.23% samples for quinolones and 20.1% samples for sulfonamides were positive. Sulfonamides and quinolones were positive in all provinces. Shanghai (detection rate 5%) was lowest for quinolones and Hebei (detection rate 80%) was highest. Beijing (detection rate 10%) was lowest for sulfonamides and Shanghai (detection rate 80%) was highest. The maximums detected for sulfonamides and quinolones were 16.28μg/kg (Guangdong) and 23.25μg/kg (Tianjin), respectively. All samples for tetracyclines, sulfonamides and quinolones were under their MRL. In general, the residue levels of the 4 major antibiotics in raw milk in China are safe for people. But stringent measures still needed to control antibiotic residues in raw milk because of the high detection rate of some antibiotics.

Key Words: antibiotic residues, raw milk, China

T86 Occurrence of aflatoxin M1 in raw milk and UHT milk in China. N. Zheng, J. Q. Wang,* R. W. Han, X. M. Xu, Y. P. Zhen, X. Y. Qu, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Aflatoxin M1 (AFM1) can cause teratogenic and mutagenic effects, and has been classified as a secondary group of carcinogenic compounds by the International Agency for Research on Cancer of World Health Organization. AFM1 is the only mycotoxin that has a legal limit in milk worldwide. The limits of 50 ng/L by the European Union and 500 ng/L by the USA have been adopted by many countries and international organization. The objective of the present study was to investigate the occurrence of AFM1 in raw milk and UHT milk in China. 360 raw milk samples and 153 UHT milk samples were collected from primary milk producing regions in China, including Beijing, Hebei, Shanxi, Shanghai, Guangdong provinces. The AFM1 was examined using a competitive enzyme immunoassay kit (R1111, R-Biopharm AG, Darmstadt, Germany), with the limits of detection of 5 ng/L. The data was statistically analyzed using the SPSS version 11.5 (SPSS, Inc., Chicago, IL). 78.1% of raw milk samples and 54.9% of UHT milk samples contained AFM1. It showing that the occurrence of AFM1 in raw milk were higher than that in UHT milk. The concentration of AFM1 in positive raw milk samples and UHT milk samples were in the range of 5 to 123 ng/L and 6 to 160 ng/L, respectively. However, the content of AFM1 between positive raw milk samples and positive UHT milk samples had no significent ($P > 0.05$) difference. AFM1 contents in all positive samples were far below the China and the US legal limit of 500 ng/L, but 10% of the raw milk samples and 20.3% of the UHT milk samples exceeded the EU legal limit of 50 ng/L. Therefore, the potential for contamination of AFM1 in milk in China should be considered, and effective measures should be applied to decrease the contaminant of milk with AFM1.

Key Words: aflatoxin M1, milk, China

T87 Purple prairie clover condensed tannins inhibit *Escherichia coli* through disruption of outer and inner membranes. X. L. Liu*[1,2], L. Jin[1], Z. Xu[1], Y. Q. Hao[2], T. A. McAllister[1], and Y. Wang[1], [1]*AAFC, Lethbridge, AB, Canada,* [2]*Inner Mongolia Agricultural University, China.*

It has been suggested that feeding condensed tannin (CT)-containing forage could be a strategy to mitigate pathogens such as *Escherichia coli* O157:H7 in ruminants. Although antimicrobial activity of CT against G^+ bacteria is well documented, few of them possess activity against G^- bacteria, including *E. coli*. Our previous research revealed that CT isolated from purple prairie clover (PPC; *Dalea purpurea* Vent.) possesses a broad-spectrum of anti- *E. coli* and *E. coli* O157:H7 activity, which was bacterostatic up to the concentration of 400 μg/mL, through an unknown mechanism. The objective of this study was to evaluate the effect of PPC CT on cell aggregation, cell membrane permeability and integrity. *E. coli* (ATCC25922) was aerobically cultured in M9 media containing 0 or a sub-lethal concentration (MIC = 12 μg/mL) of 10 μg/mL of CT at 37°C for 10 h. The bacteria were separated from the media and re-suspended in phosphate buffer (adjusted to $OD_{420} = 1.0$). Inner membrane (IM) permeabilization was determined by measuring cytoplasmic β-galactosidase activity and outer membrane (OM) disruption by fluorescence measurement of the uptake of 1-N-phenylnaphthylamine (NPN) by the cell membrane. Cell aggregation was assessed using fluorescence spectrophotometry and fluorescence microscopy and cell wall integrity was examined by transmission electron microscopy (TEM). All determinations except for TEM were done 3 times over 2-wk period with 4 replicates for each time. *E. coli* cultured with 10 μg/ml CT had higher ($P < 0.01$) extracellular β-galactosidase activity than those cultured without CT, indicating an increase in the IM permeability by CT. The NPN uptake by OM was increased ($P < 0.001$) by culturing *E. coli* with 10 μg/ml of CT. Fluorescence microscopy showed that *E. coli* cells aggregated immediately after CT was added to the cell suspension and this was accompanied by a reduction ($P < 0.01$) in fluorescence. Examination by TEM revealed that the OM structure was also disrupted. These observations suggest that PPC CT inhibit *E. coli* growth through disruption of cell membrane structure and function. Whether inhibition of *E. coli* O157:H7 by PPC CT involves the similar mechanism needs to be further studied.

Key Words: condensed tannin, *E. coli*, cell membrane permeability

T88 Antimicrobial resistance of *Salmonella enterica* isolated from bulk tank milk and milk filters in the United States. J. S. Van Kessel*[1], J. Sonnier[1], S. Zhao[2], and J. S. Karns[1], [1]*Environmental Microbial and Food Safety Laboratory, USDA-ARS, Beltsville, MD,* [2]*Center for Veterinary Medicine, US FDA, Laurel, MD.*

Non-typhoid *Salmonella* is frequently associated with dairy cattle and their environment. Despite well-developed milking hygiene protocols, fecal contamination of the bulk milk can still occur; *Salmonella* has often been isolated from bulk milk. The prevalence of *Salmonella* in US bulk tank milk was determined as part of the NAHMS Dairy Surveys in 2002 and 2007. In-line milk filters were also tested in the 2007 survey. The objective of this study was to determine the level of antimicrobial susceptibilities in *Salmonella* isolated from bulk milk and milk filters in the NAHMS surveys. Susceptibilities to 15 antibiotics were determined for 176 *Salmonella* isolates, representing 26 serotypes, using a Sensititer automated antimicrobial susceptibility system. Resistant isolates were screened by PCR for the presence of the bla_{CMY} gene and class I integrons, and further characterized by pulsed-field gel electrophoresis (PFGE). Thirty isolates (17.0%) including 6 serotypes [Newport (14/14), Dublin (7/7), Typhimurium (3/5), Kentucky (4/22), Anatum (1/13), and Infantis (1/2)] exhibited resistance to at least one antimicrobial agent. Twenty isolates (11.4%) including all 14 *Salmonella* Newport, 2 *Salmonella* Dublin, 2 *Salmonella* Typhimurium and 1 *Salmonella* Infantis displayed the typical MDR-AmpC phenotype, which showed resistance to ampicillin, chloramphenicol, streptomycin, sulfonamide, tetracycline (ACSSuT), plus resistance to amoxicillin/clavulanic acid, cefoxitin, ceftiofur and ceftriaxone. All MDR-AmpC isolates carried the bla_{CMY} gene and 5 resistant isolates contained class I integrons (2.8%). Two-enzyme (*Xba*I and *Bln*I) PFGE discerned clades within serotypes, although it did not discriminate isolates based on year, antibiotic resistance profile, or geographic location. Testing raw milk and milk filters may be a useful means of surveying dairy farms for the presence of antimicrobial resistant *Salmonella*. These data suggest that there is a low but notable presence of antimicrobial resistance in salmonellae from raw milk.

Key Words: antimicrobial resistance, raw milk, *Salmonella*

T89 The effects of tetracycline analogue on prevalence of resistance genes encoded by *Escherichia coli* isolated from feedlot cattle. X. Jin[1,2], T. A. McAllister[1], Q. Li[2], and T. W. Alexander*[1], [1]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

The effects of administering feedlot cattle subtherapeutic levels of chlortetracycline (CT) or CT and therapeutic levels of oxytetracycline (CT-OX) on resistance genotype in *Escherichia coli* were investigated. Fecal samples were collected from cattle that had been housed in commercial feedlots for greater than 60 d and had a documented history of antimicrobial use. Isolates were tested for susceptibility to tetracycline, chlortetracycline, and oxytetracycline using disk diffusion or broth microdilution. Detection of *tet*(A), *tet*(B), and *tet*(C) genes encoded by tetracycline-resistant isolates (n = 176) was performed by multiplex PCR. All isolates encoded at least one or a combination of 2 resistance genes. Prevalence of *tet*(A) was similar between groups of *E. coli*, however prevalence of *tet*(B) was lower (18% versus 34%; $P < 0.05$) and *tet*(C) was greater (46% versus 28%; $P < 0.05$) in CT isolates. The nature of the *tet* determinants was further assessed in a group of intermediately tetracycline-resistant isolates (n = 52). The *tet*(C) gene was present in 92% of these isolates. Minimum inhibitory concentrations showed that susceptibility was dependent on tetracycline analog and the type of resistance determinant. Copies of *tet*(C) transcripts, analyzed by real-time PCR, indicated that upregulation did not occur in tetracycline-resistant isolates when compared with intermediately-resistant isolates. However, sequence analysis of the *tet*(C) gene revealed a T→G substitution at position 1063 in intermediately-resistant isolates that may have affected phenotype. These data provide insight into the relationship between the type of tetracycline analog administered to cattle and the prevalence of resistance genes in *E. coli*.

Key Words: *Escherichia coli*, antimicrobial resistance, tetracyclines

T90 Cranberry juice and cranberry fiber are accepted by newly weaned pigs. S. D. Eicher*[1], B. T. Richert[2], and M. H. Rostagno[1], [1]*USDA-ARS, West Lafayette, IN,* [2]*Purdue University, West Lafayette, IN.*

Cranberry products offer a novel mechanism to control the ability of pathogens to colonize their host. However, it is not known how well pigs will consume juice or feed with cranberry fiber incorporated. The objective of this experiment was to determine if cranberry liquid or fiber products were palatable to newly weaned pigs. Pigs were weaned onto a pelleted diet for 3 d before starting this experiment. In a randomized complete block design, 60 4 recently weaned pigs (22 d of age) were blocked by weight into 8 pens with 4 pens/preference test (pen = experimental unit). Pigs were assigned to treatments to test for preferences of cranberry juice (0, 1, or 10% of 7.5 Brix) or a control dry feed versus dry feed supplemented with 4% cranberry fiber (both cranberry products were from Marshall Ingredients, NY). Control dry feed was provided to pigs on the liquid preference test, and water was provided for those on the dry feed preference test. Liquid choices were added as needed and weighed back every 3-d period. Dry feeds were also added as needed and weighed back every 3 d. Occurrences of eating or drinking of the test liquids and feeds were taken for 2 h from 0900 to 1100 and 1400 to 1600 for the first 3-d period by 1-min duration scan samples every 10 min. Cranberry juice (10%) was consumed more readily than water or than the 1% cranberry juice ($P = 0.01$) during the last 2 periods. Behavior tended to support the consumption of 10% cranberry juice, particularly in the morning observations, but overall was not different among liquid treatments ($P = 0.15$). Although the cranberry supplemented dry feed was eaten more on the first observation period, the treatments were preferred similarly over the remainder of the observations; and overall, the dry feeds were consumed relatively equally, 163 vs. 135 g/d for control and cranberry feeds respectively ($P > 0.10$). Results of this study support the use of cranberry products as a liquid (10%) or as fiber (4%) added to dry feed. Consequently, cranberry products will be used in follow-up research to determine its efficiency as microbial and immune modulators in young pigs.

T91 Evaluation of hygienic and sanitary quality of jerked beef commercialized in Salvador city, Bahia, Brazil. L. Pereira, M. Silva, W. Costa, and R. Matoso,* *UFBA, Salvador, Bahia, Brazil.*

The objective of this study was to assess the sanitary quality of jerked beef sold in the city of Salvador, Bahia. We collected 30 samples of dried beef in retail markets located in different neighborhoods of the city. These samples were collected in the form of presentation available to consumers, observing their physical integrity. Each sample was subjected to processing and then plated in liquid and specific solid media to investigate aerobic mesophilic heterotrophic bacteria, coagulase-positive *Staphylococcus*, yeasts and molds. The plates for detection of aerobic heterotrophic bacterial mesophilic and *Staphylococcus* coagulase-positive were incubated at 35°C for 48 h while the plates for the detection of yeasts and molds were incubated at 28°C for 5 d. Afterward colonies were read and counted, in addition to the complementary tests (smear stained by Gram's method, the catalase and coagulase test). It was observed that 100% of samples had counts of aerobic mesophilic microorganisms ranging from 1.2×10^6 to 9.3×10^6 cfu/g, higher than acceptable levels for other meat products contained in Resolution RDC No. 12 of Ministry of Health. Although the counts of molds and yeasts were lower, ranging from 2×10^2 to 8.3×10 cfu/g. When correlating the results with those previously described in literature, it is possible to verify that the samples were in low hygiene conditions. Finally, the presence of *Staphylococcus* coagulase positive in 100% of the samples indicates that there was poor handling of the food product. It is extremely necessary to establish more rigorous standards for the microbiological quality of jerked beef to determine the quality of these products intended for human consumption. These standards should guarantee foods with good hygiene conditions what would increase product lifetime, avoid economic losses and prevent risks to public health.

Key Words: meat products, public health, microbiological quality

Forage and Pastures II

T92 Productive response of finishing young bulls to tannins supplementation. M. Velázquez-Martínez[1], O. Hernández-Mendo[1], S. Pérez-Elizalde[1], E. López-Pérez[2], and G. Aranda-Osorio*[2], *[1]Colegio de Postgraduados, Montecillos, Texcoco, México, [2]Universidad Autónoma Chapingo, Chapingo, Texcoco, México.*

The aim of this study was to evaluate the productive performance of finishing bullocks when adding tannins into their diet. Twenty-seven crossbred (*B. taurus* × *B. indicus*) bullocks, with initial liveweight of 412.3 ± 22.19 kg, were used. They were allocated into 3 groups of 9 animals each, and then distributed, at random, to one of following treatments: T1) control (experimental diet), T2) control + 2,500 IU of vitamin E/animal/day, and T3) control + 4% (kg of DM) of condensed tannins. Quebracho extract (*Schinopsis balansae*, Indunor S.A.C.F.I.F.), was used as source of tannins. Dry matter intake (DMI), average daily gain (ADG), feed conversion (FC), feed efficiency (FE) and hot carcass yield (HCY), were evaluated. Animals were slaughtered at 518.65 ± 33.51 kg of liveweight on average. The variables were analyzed in a completely randomized design with Proc GLM of SAS/STAT. There were no differences ($P \geq 0.05$) among treatments, with averages for DMI, ADG, FC, FE, and HCY, of 10.85 kg, 1.98 kg, 5.60 kg, 183.6 g/kg DM and 57.74%, respectively, which agrees with those results reported by other authors. This study provides evidence that 4% of condensed tannins from Quebracho tree in diets for finishing bullocks did not affect animal performance. However, future studies should take into consideration its effect on ruminal variables, anti-gastrointestinal parasites, and antioxidant effect on meat quality, before its use under commercial conditions.

Key Words: beef cattle, tannins, performance

T93 Pelibuey sheep productive response to different sources of tannins from forage trees. M. Velázquez-Martínez[1], O. Hernández-Mendo[1], S. Pérez-Elizalde[1], E. López-Pérez[2], and G. Aranda-Osorio*[2], *[1]Colegio de Postgraduados, Montecillos, Texcoco, México, [2]Universidad Autónoma Chapingo, Chapingo, Texcoco, México.*

The objective of this study was to evaluate the effect of supplementing tannins from different forage tree species on growth performance and carcass yield of Pelibuey sheep. Thirty-six Pelibuey male sheep were used, with initial liveweight of 23.74 ± 4.57 kg and 5–6 mo of age, on average. The animals were distributed homogeneously into 4 groups of 3 each, with 3 replicates per group, and then randomly assigned to each of the following treatments: T1) control (experimental diet), T2) *Gliricidia sepium* (GS) diet, T3) *Guazuma ulmifolia* (GU) diet, and T4) Quebracho extract (*Schinopsis balansae*, Indunor S.A.C.F.I.F.) diet (QE). All diets were formulated to fulfill the animal requirements (15.4% CP, 33.8% NDF, 2.8 Mcal of ME, 0.92 Ca and 0.32 P, on average). The variables evaluated were dry matter intake (DMI), average daily gain (ADG), feed conversion (FC), feed efficiency (FE), hot carcass yield (HCY) and cold carcass yield (CCY). Animals were slaughtered with an average liveweight of 40.23 ± 4.24 kg. The data were analyzed by using the Proc Mixed from SAS/STAT, and a means comparison with *t*-test (PDIFF). The T3GU had the lowest ($P \leq 0.05$) DMI (1.18 kg) compared with the other treatments, which averaged 1.27 kg. The ADG was not different ($P \geq 0.05$) among treatments (268 g on average). The FC was higher ($P \leq 0.05$) for T2GS (5.22 kg) compared with the other treatments, which averaged 4.60 kg. The T2GS had the lowest ($P \leq 0.05$) FE (195 g/kg) compared with the other treatments, which averaged 220.6 g/kg. The HCY and CCY was higher ($P \leq 0.05$) for T3GU with 52.61 and 50.86% respectively. The results suggest that the use of fodder tree is an alternative for feeding Pelibuey sheep because they do not alter finishing performance and, at the same time, their use may decrease feeding costs. It is important to explore their effects on meat quality.

Key Words: sheep, tannins, performance

T94 Effects of tannin deactivation by alkaline chemicals on in vitro dry matter and organic matter digestibility in sainfoin (*Onobrychis vicifolia*). H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Nutritive value of forages for ruminant animals is inherently variable and depends on many factors including antinutritional factors. Sainfoin is a temperate legume forage, with medium to high concentrations of condensed tannins (CT). The objective of present study was to examine the effectiveness of tannin deactivation on nutrient availability from sainfoin. Second cut forage was shade dried and chopped (3 –5 cm length). Forage samples (1 kg, in 3 replicates) were exposed to $KMnO_4$ (0.03 M) and NaOH (0.05 M) solutions and water with forage to reagent ratio of 1:4 (wt/vol). The pH of solutions were determined (12.28 and 12.04 for NaOH and $KMnO_4$, respectively). All of the treatments were carried out in triplicate, in 25°C temperature, for 20 min, with hand shaking. Treated forages were then exposed to 40°C temperature in a forced air oven, for 48 h. All forage samples were ground to pass 0.5 mm screen size (ball mill) for determination of CT concentration using Butanol-HCl reagent. Also grinding with 1 mm laboratory mill was done for in vitro digestibility trial. The in vitro digestion technique used was that of Tilley and Terry (1963) as modified by Wilkins (1966) in triplicates. Rumen liquor was withdrawn from 2 rumen-fistulated Holstein cows fed a balanced diet, exceeded maintenance requirements (CNCPS) in 2 equal meals. Rumen fluids were mixed and then squeezed through 4 layers of cheesecloth. Completely randomized design, GLM PROC of SAS and Duncan's test were used for data analysis ($P \leq 0.05$). Untreated forage have CT concentration of 21.3+0.4 g/kg dry matter, but both the chemicals and water reduced CT levels more than 90 percent. In contrast, treatments were failed to significantly affecting dry matter and organic matter digestibility. It seems that in vitro digestibility (Tilley and Terry) overestimates OM digestibility of untreated tanniferous forages. This effect was explained by rapid passing of phenols through filter paper that entered the digestible fraction. In vitro gas production technique may be a suitable substitute.

Table 1. Effect of treatments on CT content and in vitro digestibility of DM and OM (means ± SD, g/100 g)

Treatment	CT	DMD	OMD
Control	$2.13^a \pm 0.041$	75.6 ± 0.83	68.9 ± 1.24
NaOH	$0.13^c \pm 0.001$	75.7 ± 2.43	69.8 ± 1.53
$KMnO_4$	$0.16^b \pm 0.011$	75.2 ± 2.06	69.9 ± 2.02
Water	$0.17^b \pm 0.012$	76.7 ± 1.98	69.8 ± 2.74

T95 Different rumen environments can cause different degradation profile of dry matter from tanniferous forages.

H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Conventional in situ degradability methods have some problems in the case of tanniferous feeds because of small sample weight in nylon bags and dilution of antinutrients in rumen fluid. Thus we use another method to assess tannin effects on DM degradability in sainfoin. Second-cut sainfoin was dried and chopped (3–5cm length). Polyethylene glycol (PEG) solution in distilled water [6000 MW, 5% (wt/vol), volume to forage weight ratio of 1:1] and distilled water (volume to forage weight ratio of 4:1) were used to treat forage samples. Treatments were carried out at an ambient temperature for 20 min with hand shaking for water and overnight for PEG. Extractable condensed tannin content was determined using butanol-HCl reagent. An in situ experiment was done in 3 × 3 change-over design. Three ruminally fistulated Holstein cows (multiparous, 680 ± 20kg of BW) were used with 10 d for adaptation and 7 d for nylon bag incubation, each period. Forages were fed as sole diet (equals at 0800 and 1600) along with mineral/vitamins to meet 110% of the animal's maintenance requirements. CT content of untrated forage was 21.3, which water and PEG decreased it to 1.7 and 0.3 g/kg DM, respectively. Untreated Forage samples were ground to pass 2 mm screen (Wiley mill) and sieved to remove particles <50 µm. Five gram of samples weighed into nylon bags (10 × 20cm, 50 µm pore size) with sample size:surface area of 12.5 mg/cm^2. Duplicates were incubated for 4, 8, 12, 24, 48, 72 and 96h in ventral rumen. Degradation profiles were calculated by the nonlinear model of Ørskov and McDonald (1979). The effective degradability (ED) was calculated using NEWAY package. PROC MIXED of SAS 9.1 (2002) was used to statistical analysis at 0.05 probability level. Degradation rate increased from 0.0626^{b} (control) to 0.0751^{b} and 0.0961^{a} h^{-1} and lag time decreased from 2.4^{a} h (control) to 1.33^{b} and 0.8 ^{b} h for water and PEG, respectively (^{a} and ^{b} indicate statistical differences between treatments). PEG significantly increased ED from 52.43 to 55.9 and from 47.93 to 51.60 in outflow rates of 0.05 and 0.08 respectively (relative to control). We concluded that PEG and water treatments diminished phenolic compound effects on rumen environment and can increase nutrient availability in situ due to increased microbial activity and nutrient availability.

Key Words: sainfoin, degradability, tannin

T96 Comparisons of metabolizable energy estimates for sainfoin (*Onobrychis viciifolia*) from different in vitro and in vivo methods.

H. Khalilvandi-Behroozyar*[1,2], K. Rezayazdi[1], and M. Dehghan-Banadaki[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Sainfoin (*Onobrychis viciifolia* is a non-bloating member of the Fabaceae family. Limitations in nutrient availability data, limited the inclusion of sainfoin in balanced rations. The aim of the present study was to determine and compare the ME content of sainfoin with different methods. Forages were taken from farms (6 farms, 4 samples from each) in Isfahan, Iran. Shade dried, baled and representative samples were obtained and cut into 30–50mm lengths. Chemical analysis were done according to AOAC standard methods. Condensed tannin content was determined by butanol-HCl reagent (21.3 g/kg DM). Hay samples were milled through 2 and 1mm sieves for gas production and Tilley and Terry, respectively. Forages were incubated with rumen fluid in glass syringes following the procedures of Menke et al. Twenty-four hour gas value (34.9 ± 1·03 mL) was used for ME determination using equation 1, ME = 2.2 + 0.1357 GP$_{24}$ + 0.0057 CP (g/kg DM) + 0.0002859 EE^2(g/kg DM) ; equation 2, ME = 2.2 + 0.136 GP$_{24}$ + 0.057 CP (g/100 g DM) + 0.0029 CP^2 (g/100 g DM) and indirectly by equations 3, OMD = 14.88 + 0.8893 GP$_{24}$ + 0.448 CP (g/100 g DM) + 0.0651ash (g/100 g DM) and 4,ME = 0.0157 × DOMD. The in vitro digestion technique used was that of Tilley and Terry (1963) as modified by Wilkins (1966) in triplicates. Three ruminally fistulated Holstein cows (multiparous, 680 ± 20 kg) were used in in vivo trial with 10 d for adaptation and 7 d for sample collection. Forages were used as the sole diet along with mineral/vitamins to achieve 10% more than maintenance energy requirements (NRC, 2001). Total fecal collection, acid insoluble ash (AIA) and chromium oxide were used for determination of OM digestibility. A comparison of means were undertaken using GLM procedure of SAS using a CRD design ($P \leq 0.05$). Organic matter digestibility was 59.23, 59.36, 60.41 and 68.90 for total fecal, Cr2O3, AIA and Tilley and Terry, respectively. The content of digestible organic matter (DOM) was 643.7 g/kg DM, and estimated ME, from Tilley and Terry trial was 10.11 MJ/kg DM. Gas production gave mean estimates of 7.19 MJ/kg DM and the mean of in vivo measurements was 8.75 MJ/kg DM (table1). The OM digestibility in Tilley and Terry method was higher than values determined by in vivo and gas production profiles. Higher OM digestibilities determined by a filtration-based method such as Tilley and Terry for high tanniferous materials, was explained by rapid passing of phenols through filter paper that entered the digestible fraction. Low sample size especially in tanniferous plants can affect gas production results. It seems that in vivo methods are the best for ME estimation in the case of forages with antinutrients.

Table 1. Organic matter digestibility and metabolizable energy estimates of sainfoin with different in vitro and in vivo methods

	Gas production			Tilley and Terry	Total fecal collection	Chromium oxide	AIA	SEM	Error df
	(Eq. 1)	(Eq. 2)	(Eq. 3 & 4)						
ME (MJ/kg DM)	7.87^{c}	8.04^{c}	7.59^{c}	10.11^{a}	8.69^{b}	8.71^{b}	8.86^{b}	0.222	12

T97 Deactivation of tannins by chemical materials affect ruminal degradability kinetics and metabolizable protein profiles of sainfoin (*Onobrychis vicifolia*).

H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Sainfoin (*Onobrychis viciifolia* Scop.) is tanniferous legume forage. There are few reports about effects of tannin destructive or binding matter on metabolizable protein profile of sainfoin. Second cut forage was shade dried and chopped (3 –5 cm length), and then exposed to solutions of KMnO$_4$ (0.03 M, pH 12.04), NaOH (0.05 M, pH 12.28) and water with forage to reagent volume ratio of 1:4 (wt/vol). All of above treatments were carried out in triplicates, in 25°C temperature, for 20 min, with hand shaking. Treated forages were then exposed to 40°C temperature in a forced air oven, for 48 h. All forage samples were ground to pass 0.5 mm screen size (ball mill) for determinations of condensed (CT) concentrations using Butanol-HCl reagent. Also grinding with 2 mm laboratory mill was done for in situ trial. Crude protein degradability was determined using 3 ruminally fistulated Holstein cows. Samples (5 g) were weighed into nylon bags and duplicates were incubated for

4,8,12,24,48,72 and 96 in the ventral rumen. Effective degradability (ED) was calculated with NEWAY package. Degradation parameters then used to calculate QDP, SDP, RDP, ERDP, DUP, UDP and MP according to formula were presented by AFRC. GLM PROC of SAS and Duncan's Test were used for statistical analysis ($P \leq 0.05$). Control forage had CT concentration of 21.3+0.4 g/kg DM. Sodium hydroxide, KMnO4 and water decreased it by 93.79, 92.41, and 92.06%, respectively. Treatments increased degradability of sainfoin in all of the rumen incubation times (data not shown). Rapid degradable fraction increased with all of treatments. Slowly degradable fraction was not affected by treatments, but rate of degradation of this fraction significantly increased by water and NaOH. Also, treatments significantly improved effective degradability in different rumen outflow rates. All of the treatments improved protein metabolizability of sainfoin. Also, DUP (Digestible undegradable protein) /UDP (undegradable protein) ratio improved by water and $KMnO_4$. Despite that NaOH significantly reduced condensed tannins and improved degradability profiles, cannot increase metabolizable protein. This can be attributed to post ruminal behavior of NaOH treated proteins that reduced digestibility of undegraded protein content. Water as farm available material with no environmental hazard, greatly improved protein metabolism characteristics of sainfoin.

Table 1. Effects of tannin deactivation on MP fractions of sainfoin (g/100 g CP)

	QDP	SDP	RDP	ERDP	UDP	DUP	MP	DUP/ UDP (%)
Control	17.06^{d}	21.15^{b}	38.21^{c}	34.80^{c}	61.79^{a}	27.78^{b}	49.97^{b}	44.96^{b}

T98 Correlations between condensed tannins and CNCPS protein fractions of sainfoin. H. Khalilvandi-Behroozyar*[1,2], K. Rezayazdi[1], and M. Dehghan-Banadaki[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Cornell Net Carbohydrate and Protein System (CNCPS) is a growing feed evaluation and ration balancing system in the world but there are few reports about sainfoin. In this study we examine the effects of chemical tannin deactivation methods on CNCPS protein fractions of sainfoin. Also, correlations between condensed tannin (CT) content, acid detergent insoluble nitrogen, neutral detergent insoluble nitrogen, crude protein content, etc. were calculated. Samples of forage were chopped 3–5 cm length, and then treated with solutions of $KMnO_4$ (0.03 M), NaOH (0.05 M), sodium bicarbonate (0.1 M), wood ash (180 g/L) and water with forage to reagent volume ratio of 1:4 (wt/vol). Five percent solution of PEG (6000 MW) was sprayed to forage with 1:1 ratio. Treatment with urea (20 g/100 mL/1 kg of DM) was done using adhesive rubber to create anaerobic conditions for 1 week. All forage samples were ground to pass 0.5 mm screen size. Determinations of CT content of treated and control forages were done using butanol-HCl reagent. The CNCPS protein fractions of sainfoin, determined according to standardized procedure where the A fraction (non-protein N) was determined using TCA solution. Results are presented as percentage of CP. Data was analyzed by SAS using GLM procedure for a completely randomized design ($P \leq 0.05$). In untreated forage a large portion of crude protein was in the C fraction, which is unavailable for animal. This can be due to condensed tannin- protein complexes. Treatments were improved nutritional availability of protein by decreasing the C and increasing the A and B3 fractions. Reduction of antinutritional factors greatly changed protein fractions of sainfoin. For exampleb treatment with water was resulted in 34.2, 1.3, 37.2, 17.1 and 10.2 percentage for A, B_1, B_2, B_3 and C sections, respectively. These values for untreated and PEG treated forage were 16.8, 9.7, 28.6, 13.9, 30.9 and 16.6, 6.7, 52.4, 13.6, 10.6, respectively (other data not shown). Protein content of C fraction had highly positive correlation with CT, ADIN, and NDIN. Conversely, A fraction had negative correlation with this fractions. Correlation coefficients in Table 1 showed that we can attribute increasing in A fraction and reduction of C fraction in treated forages to reduction of CT.

Table 1. Correlation coefficients between CNCPS protein fractions and antinutritional factors in sainfoin

T99 Local equations to predict relative feed value for alfalfa in northern Mexico. C. Arzola*[1], F. Carrera[1], R. Copado[1], J. Salinas[2], C. Rodriguez[1], O. Ruiz[1], H. Gaytan[1], and A. Corral[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico, [2]Universidad Autonoma de Tamaulipas, Cd. Victoria, Tamaulipas, Mexico.*

Knowing the chemical makeup of alfalfa in the field allows dairy producers to pick up the best time to harvest and determine the price of the crop. The use of wet chemistry is time-consuming, so alternative methods such as the predictive equations of alfalfa quality (PEAQ) have been used. Using samples of alfalfa of 15 farms located in the region of Delicias, Chihuahua, Mexico, planted with either one of 2 varieties of alfalfa (excellent or multileaf excellent), local equations (LE) were developed, on the assumption that such equations should reflect more accurately the relationship of ADF and NDF composition to stem length and phenologic stage than equations from PEAQ. Sampling was conducted during one year of alfalfa production on 113 locations, starting at the end of February and ending in late October. Those equations were calculated for each variety and for the whole group (Table 1). Relative feed values (RFV) were calculated with ADF and NDF values obtained with laboratory analyses (LV), LE equations (both varieties and whole group) and PEAQ equations. No additional advantage in terms of accuracy ($P < 0.05$) was obtained when comparing values from equations for separate varieties or the whole group. Calculated values for both ADF and NDF using those obtained with LE were more accurate than those of PEAQ as compared with the laboratory values (LV), but RFV was better estimated with PEAQ than with LE (203, 196 and 198 for LV, LE and PEAQ respectively). Such contradictory response is due to the fact that LE equations rendered lower values for ADF than LV values (21.92 vs 22.03) whereas PEAQ rendered higher values than ¨true¨ values (LV) (24.58 vs 22.03). A general conclusion is that the use of LE does not have advantage over PEAQ

Table 1. Local predictive equations of alfalfa quality

	Whole Group	R^2
ADF	Y =7.095+(0.23*SL)+(0.843*PS)	0.4783
NDF	Y = 11.887+(.276*SL)+(3.290 *PS)	0.5369
	Excellent Variety	
ADF	Y = 7.84+(O.217*SL)+(0.851*PS)	0.4597
NDF	Y = 12.908+(0.268*SL)+(3.081*PS)	0.4947
	Multileaf Excellent Variety	
ADF	Y = 2.162+(0.315*SL)+(0.264*PS)	0.6226
NDF	Y = 5.653+(0.353*SL)+(3.841*PS)	0.8235

SL = stem length in cm; PS = phenologic stage.

T100 A simplified procedure for measuring NDF within in situ Dacron bags for corn plant components ground to 6 mm. L. J. Nuzback, W. M. Rutherford, and F. N. Owens,* *Pioneer Hi-Bred International, a DuPont Company, Johnston, IA.*

Direct assays of NDF within in situ bags could simplify measurement of in situ NDF disappearance by avoiding re-grinding, compositing, and repackaging of in situ residues for NDF analysis. We compared estimates of NDF using samples ground to 6 mm in 50 micron bags (ONDF) with measured aNDF (samples ground at 1 mm in F-57 bags) using 2 sample sets — 288 samples (whole corn plants plus plant parts) and 90 whole plant corn samples (11 hybrids harvested between 22 and 50% DM). For ONDF analysis, 4 replicate 0.5 g samples of each feedstuff ground to 6 mm in 50 micron Dacron bags (5 by 5 cm) were extracted using automated aNDF procedures (Ankom Technology, Macedon, NY). Residue weights were compared with aNDF values from a lab certified by the NFTA. For the first sample set, ONDF closely matched aNDF ($\text{ONDF} = 1.089 \pm 0.19 \times \text{aNDF} - 5.77 \pm 1.17$; $R^2 = 0.92$; root MSE 4.0) but deviations from regression ($P < 0.05$) were detected in 2 cases. For corn cobs, ONDF exceeded aNDF by 4.4%, presumably reflecting wash loss of finely ground particles. For whole plant samples, ONDF exceeded aNDF by 3.6 and 4.2% in the 2 sample sets. This difference was negatively ($P < 0.001$) related to hemicellulose content of samples and may reflect either particle loss from finely ground samples or incomplete NDF extraction from coarsely ground samples. Though the absolute values differed slightly, correlations between ONDF and aNDF values were sufficiently high ($R^2 > 0.91$) to reliably rank samples and detect differences in NDF content of samples. Direct comparison of 48 h ruminal disappearance with 4 corn silage samples (54 to 68% in situ NDF disappearance) revealed similar means (56.7% in situ ONDF versus 56.4 in situ aNDF) and a high correlation ($R^2 = 0.87$). Through avoiding the needs for sample transfer, compiling multiple residues, and grinding, this modified procedure can simplify measurement of in situ NDF disappearance.

Key Words: NDF, in situ, digestibility

T101 Digestibility and fecal output prediction using acid-detergent lignin, alkaline-peroxide lignin, and acid-detergent insoluble ash in cattle offered bermudagrass hays of varying quality. J. Kanani*[1], D. Philipp[1], K. P. Coffey[1], E. B. Kegley[1], C. P. West[1], S. Gadberry[2], J. Jennings[2], A. Young[1], and R. Rhein[1], *[1]University of Arkansas, Division of Agriculture, Fayetteville, [2]University of Arkansas, Division of Agriculture, Little Rock.*

The potential of acid-detergent insoluble ash (ADIA), alkaline-peroxide lignin (APL), and ADL to predict DM digestibility (DMD) and fecal output (FO) by cattle offered bermudagrass [*Cynodon dactylon* (L.) Pers.] hay of different qualities was evaluated. Eight ruminally cannulated cows (594 ± 100.3 kg) were allocated randomly to 4 bermudagrass hay diets categorized by their low (L), medium low (ML), medium high (MH), or high (H) CP concentrations (7.9, 11.0, 13.0, and 16.4% DM, respectively). Diets were offered in 3 periods to provide 2 replicates per diet per period ($n = 24$). Cows were individually offered hay at a total of 2% of BW in equal feedings at 0800 and 1700 for a 10-d adaptation followed by a 5-d total fecal collection (TC) each period. Hay, orts, and feces were analyzed for ADL, APL, and ADIA concentrations. Actual DMI, DMD, and FO were determined based on hay offered, orts, and feces excreted. Recovery of APL, ADL, and ADIA were expressed as the ratio of the quantity of marker excreted per unit of marker consumed on percentage basis. Data for in vivo DMI, DMD, and FO were analyzed as a replicated 4 × 4 Latin square with one period missing using PROC GLM of SAS, with effects of cow, diet, and period in the model. Data for ADL, APL, and ADIA recovery and marker-based estimates of DMD and FO were analyzed using PROC GLM of SAS, where diet, marker, and the diet by marker interaction were included in the model. Diet affected actual DMI ($P = 0.02$), but not FO ($P = 0.16$), or apparent DMD ($P = 0.23$). Average ADL recovery differed from 100% ($P < 0.05$), and that of APL tended to differ ($P = 0.08$) from 100%, but ADIA recovery was not different from 100% ($P = 0.41$). Estimates of DMD and FO derived using APL and ADIA were not different ($P \geq 0.32$) from TC while those using ADL differed ($P < 0.05$) from that of TC. Therefore, ADIA and APL are potential internal markers to predict DMD and FO of bermudagrass of various qualities fed to cattle.

Key Words: acid-detergent insoluble ash, alkaline-peroxide lignin, bermudagrass digestibility

T102 Diurnal variation in fecal concentrations of indigestible-acid detergent fiber, acid-detergent insoluble ash, and alkaline-peroxide lignin from cattle offered bermudagrass hays of varying quality. J. Kanani*[1], D. Philipp[1], K. P. Coffey[1], E. B. Kegley[1], C. P. West[1], S. Gadberry[2], J. Jennings[2], A. Young[1], and R. Rhein[1], *[1]University of Arkansas, Division of Agriculture, Fayetteville, [2]University of Arkansas, Division of Agriculture, Little Rock.*

The effect of time of fecal sampling on the accuracy of indigestible acid-detergent fiber (IADF), acid-detergent insoluble ash (ADIA), and alkaline-peroxide lignin (APL) for the prediction of fecal output (FO) in cattle fed bermudagrass was evaluated. Eight ruminally cannulated cows (594 ± 100.3 kg) were allocated randomly to 4 bermudagrass hay diets having a wide range of nutritional value (CP content of 7.9 to 16.4% DM) providing 2 replicates per diet for 3 periods ($n = 24$). Cows were individually fed their respective hay at a total of 2% of BW in equal feedings at 0800 and 1700 for a 10-d adaptation period followed by a 5-d total fecal collection (TC) period in 2.7 × 4.3-m pens fitted with rubber mats. Fecal grab samples were taken each day of the fecal collection period at 0600, 1200, 1800, and 2400 either directly from the rectum or from fresh feces, and were composited by cow and time. Duplicate samples of each hay, ort, and fecal sample were incubated for 144 h in the rumen of 2 cows for each period ($n = 6$ cows), followed by a sequential analysis of NDF and ADF to obtain IADF. Additionally, forage, ort, and fecal samples were analyzed for concentrations of APL and ADIA. Time of sampling affected the concentration of IADF ($P < 0.01$) while ADIA and APL concentrations in fecal grab samples were not different ($P \geq 0.24$) across sampling times or from that in total feces. Estimates of DMD by a representative sample from TC and that from all grab sampling times and their different combinations were not different ($P \geq 0.46$) from actual DMD regardless of which internal marker was used. Also, FO estimated by in vivo, samples from TC, or samples from different sampling times, and all different combinations of sampling time were not different ($P \geq 0.22$) across internal markers. Therefore, there is little variation in concentrations of ADIA and APL in daily fecal excretion and a minimum of 2 fecal grab samplings daily can be used in the prediction of DMD and FO.

Key Words: bermudagrass digestibility, fecal sampling time, internal markers
